Proof. The singleton carrier identifies h, k, z with e, and the concrete meet operation is definitionally e. Thus the forward direction builds both lower-bound comparisons from the endpoint sameness witnesses using the singleton prefix comparison. Conversely, the displayed empty-meet endpoint and the carrier witness for z build the singleton comparison $z \leq_{\mathsf{e}} \mathsf{meet}(h, k)$. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeet greatest lower bound empty iff`

The $\mathsf{Lattice}^{\uparrow}$ schema is instantiated by a concrete BHist carrier and operations, so Lean can target $\mathsf{BEDC.Derived.LatticeUp}$ as a BHist-anchored certificate rather than an abstract operator schema.

55.3 The certificate

Definition 55.29 (Lattice source specification)**.** *The source is a certified poset carrier plus binary meet and join data.*

Definition 55.30 (Lattice pattern specification)**.** *The pattern is expression formation by $\wedge$ and $\vee$ over carrier witnesses.*

Definition 55.31 (Lattice classifier specification)**.** *The classifier is the poset carrier classifier, with meet and join congruent in both arguments.*

Definition 55.32 (Lattice stability certificate)**.** *The stability certificate consists of:*

1. *all poset stability fields*

2. *meet lower-bound laws*
3. *meet greatestness law*
4. *join upper-bound laws*
5. *join leastness law*
6. *meet and join congruence*

Definition 55.33 (Lattice ledger policy)**.** *Record operands and the bound-characterization certificate for each meet or join.*

Definition 55.34 ($\mathsf{Lattice}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Lattice}^{\uparrow}$*.*

Primitive boundary. $\mathsf{Lattice}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Lemma 55.35 (Meet idempotence from bound characterization)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. For every $x \in A$,*

$$x \wedge x \sim_C x.$$

Proof. The meet lower-left field gives

$$x \wedge x \leq x.$$

The inherited preorder reflexivity field gives $x \leq x$. Applying meet greatestness with $z = x$, $a = x$, and $b = x$, using the two reflexivity witnesses $x \leq x$ and $x \leq x$, gives

$$x \leq x \wedge x.$$

The inherited poset antisymmetry field applied to

$$x \wedge x \leq x \qquad \text{and} \qquad x \leq x \wedge x$$

yields

$$x \wedge x \sim_C x.$$

□

Lemma 55.36 (Join idempotence from bound characterization)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. For every $x \in A$,*

$$x \vee x \sim_C x.$$

Proof. The join upper-left field gives

$$x \leq x \vee x.$$

The inherited preorder reflexivity field gives $x \leq x$. Applying join leastness with $z = x$, $a = x$, and $b = x$, using the two reflexivity witnesses $x \leq x$ and $x \leq x$, gives

$$x \vee x \leq x.$$

The inherited poset antisymmetry field applied to

$$x \vee x \leq x \qquad \text{and} \qquad x \leq x \vee x$$

yields

$$x \vee x \sim_C x.$$

□

Lemma 55.37 (Meet absorption from bound characterization)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. For all $x, y \in A$,*

$$x \wedge (x \vee y) \sim_C x.$$

Proof. The meet lower-left field gives

$$x \wedge (x \vee y) \leq x.$$

For the reverse comparison, the inherited preorder reflexivity field gives

$$x \leq x.$$

The join upper-left field gives

$$x \leq x \vee y.$$

Applying meet greatestness with $z = x$, $a = x$, and $b = x \vee y$, using the two comparisons above, gives

$$x \leq x \wedge (x \vee y).$$

The inherited poset antisymmetry field applied to

$$x \wedge (x \vee y) \leq x \qquad \text{and} \qquad x \leq x \wedge (x \vee y)$$

yields

$$x \wedge (x \vee y) \sim_C x.$$

□

Lemma 55.38 (Join absorption from bound characterization)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. For all $x, y \in A$,*

$$x \vee (x \wedge y) \sim_C x.$$

Proof. The join upper-left field gives

$$x \leq x \vee (x \wedge y).$$

For the reverse comparison, the inherited preorder reflexivity field gives

$$x \leq x.$$

The meet lower-left field gives

$$x \wedge y \leq x.$$

Applying join leastness with $z = x$, $a = x$, and $b = x \wedge y$, using the two comparisons above, gives

$$x \vee (x \wedge y) \leq x.$$

The inherited poset antisymmetry field applied to

$$x \vee (x \wedge y) \leq x \qquad \text{and} \qquad x \leq x \vee (x \wedge y)$$

yields

$$x \vee (x \wedge y) \sim_C x.$$

□

Theorem 55.39 (Lattice idempotence and absorption from bound characterization)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. Assume the inherited* $\mathsf{POSet}^{\uparrow}$ *reflexivity and antisymmetry fields, and assume the directional meet and join bound-characterization fields:*

$$\forall a\, b,\ a \wedge b \leq a, \qquad \forall a\, b,\ a \wedge b \leq b,$$
$$\forall z\, a\, b,\ z \leq a \to z \leq b \to z \leq a \wedge b,$$
$$\forall a\, b,\ a \leq a \vee b, \qquad \forall a\, b,\ b \leq a \vee b,$$
$$\forall z\, a\, b,\ a \leq z \to b \leq z \to a \vee b \leq z.$$

Then for all $x, y \in A$,

$$x \wedge x \sim_C x, \qquad x \vee x \sim_C x, \qquad x \wedge (x \vee y) \sim_C x, \qquad x \vee (x \wedge y) \sim_C x.$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeDirected idempotence absorption from bounds`

Proof. The first assertion is Lemma 55.105. The second assertion is Lemma 55.106. The third assertion is Lemma 55.107. The fourth assertion is Lemma 55.108. □

Theorem 55.40 (Lattice commutativity from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. Assume the inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry field and the directional meet and join bound-characterization fields from Definition 55.102. Then for all $x, y \in A$,*

$$x \wedge y \sim_C y \wedge x, \qquad x \vee y \sim_C y \vee x.$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeDirected commutativity from bounds`

Proof. For the meet comparison, the meet lower-bound laws in Definition 55.102 give

$$x \wedge y \leq x \qquad \text{and} \qquad x \wedge y \leq y.$$

Applying meet greatestness with $z = x \wedge y$, $a = y$, and $b = x$ gives

$$x \wedge y \leq y \wedge x.$$

The same lower-bound laws applied to $y \wedge x$ give

$$y \wedge x \leq y \qquad \text{and} \qquad y \wedge x \leq x.$$

Applying meet greatestness with $z = y \wedge x$, $a = x$, and $b = y$ gives

$$y \wedge x \leq x \wedge y.$$

Since $\mathsf{Lattice}^{\uparrow}$ extends the $\mathsf{POSet}^{\uparrow}$ layer, the antisymmetry field recorded in Definition 53.43 applies to these two comparisons and yields

$$x \wedge y \sim_C y \wedge x.$$

For the join comparison, the join upper-bound laws in Definition 55.102 give

$$y \leq x \vee y \qquad \text{and} \qquad x \leq x \vee y.$$

Applying join leastness with $z = x \vee y$, $a = y$, and $b = x$ gives

$$y \vee x \leq x \vee y.$$

The same upper-bound laws applied to $y \vee x$ give

$$x \leq y \vee x \qquad \text{and} \qquad y \leq y \vee x.$$

Applying join leastness with $z = y \vee x$, $a = x$, and $b = y$ gives

$$x \vee y \leq y \vee x.$$

The inherited antisymmetry field from Definition 53.43 applied to these two comparisons yields

$$x \vee y \sim_C y \vee x.$$

□

Theorem 55.41 (Lattice opposite absorption from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. Assume the inherited preorder reflexivity field, the inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry field, and the directional meet and join bound-characterization fields from Definition 55.102. Then for all $x, y \in A$,*

$$x \wedge (y \vee x) \sim_C x, \qquad (x \vee y) \wedge x \sim_C x, \qquad x \vee (y \wedge x) \sim_C x, \qquad (x \wedge y) \vee x \sim_C x.$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeOppositeAbsorptionFromDirectionalBounds`

Proof. The inherited reflexivity field is the preorder reflexivity component of Definition 52.44; the inherited classifier collapse is the antisymmetry component of Definition 53.43. The meet and join directional fields are those listed in Definition 55.102.

For $x \wedge (y \vee x)$, the meet lower-left field gives

$$x \wedge (y \vee x) \leq x.$$

The inherited preorder reflexivity field gives

$$x \leq x.$$

The join upper-right field applied to $y \vee x$ gives

$$x \leq y \vee x.$$

Applying meet greatestness with $z = x$, $a = x$, and $b = y \vee x$, using the two comparisons above, gives

$$x \leq x \wedge (y \vee x).$$

Antisymmetry from Definition 53.43 applied to

$$x \wedge (y \vee x) \leq x \qquad \text{and} \qquad x \leq x \wedge (y \vee x)$$

yields

$$x \wedge (y \vee x) \sim_C x.$$

For $(x \vee y) \wedge x$, the meet lower-right field gives

$$(x \vee y) \wedge x \leq x.$$

The join upper-left field gives

$$x \leq x \vee y.$$

The inherited preorder reflexivity field gives

$$x \leq x.$$

Applying meet greatestness with $z = x$, $a = x \vee y$, and $b = x$, using these two comparisons, gives

$$x \leq (x \vee y) \wedge x.$$

Antisymmetry applied to

$$(x \vee y) \wedge x \leq x \qquad \text{and} \qquad x \leq (x \vee y) \wedge x$$

yields

$$(x \vee y) \wedge x \sim_C x.$$

For $x \vee (y \wedge x)$, the join upper-left field gives

$$x \leq x \vee (y \wedge x).$$

The inherited preorder reflexivity field gives

$$x \leq x.$$

The meet lower-right field applied to $y \wedge x$ gives

$$y \wedge x \leq x.$$

Applying join leastness with $z = x$, $a = x$, and $b = y \wedge x$, using the two comparisons above, gives

$$x \vee (y \wedge x) \leq x.$$

Antisymmetry applied to

$$x \vee (y \wedge x) \leq x \qquad \text{and} \qquad x \leq x \vee (y \wedge x)$$

yields

$$x \vee (y \wedge x) \sim_C x.$$

For $(x \wedge y) \vee x$, the join upper-right field gives

$$x \leq (x \wedge y) \vee x.$$

The meet lower-left field gives

$$x \wedge y \leq x.$$

The inherited preorder reflexivity field gives

$$x \leq x.$$

Applying join leastness with $z = x$, $a = x \wedge y$, and $b = x$, using these two comparisons, gives

$$(x \wedge y) \vee x \leq x.$$

Antisymmetry applied to

$$(x \wedge y) \vee x \leq x \qquad \text{and} \qquad x \leq (x \wedge y) \vee x$$

yields

$$(x \wedge y) \vee x \sim_C x.$$

□

Theorem 55.42 (Lattice bound uniqueness from directional certificates)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. Assume the inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry field from Definition 53.43 and the directional meet and join bound-characterization fields from Definition 55.102. For all $x, y, m, j \in A$, suppose m satisfies the lower-bound and greatestness clauses*

$$m \leq x, \qquad m \leq y,$$
$$\forall z \in A,\ z \leq x \to z \leq y \to z \leq m,$$

and suppose j satisfies the upper-bound and leastness clauses

$$x \leq j, \qquad y \leq j,$$
$$\forall z \in A,\ x \leq z \to y \leq z \to j \leq z.$$

Then

$$m \sim_C x \wedge y, \qquad j \sim_C x \vee y.$$

Proof. The certified meet fields give

$$x \wedge y \leq x \qquad \text{and} \qquad x \wedge y \leq y.$$

Applying the assumed greatestness clause for m with $z = x \wedge y$ gives

$$x \wedge y \leq m.$$

The two assumed lower-bound clauses for m, together with the certified meet greatestness field applied with $z = m$, give

$$m \leq x \wedge y.$$

The antisymmetry field from Definition 53.43 applied to

$$m \leq x \wedge y \qquad \text{and} \qquad x \wedge y \leq m$$

yields

$$m \sim_C x \wedge y.$$

The certified join fields give

$$x \leq x \vee y \qquad \text{and} \qquad y \leq x \vee y.$$

Applying the assumed leastness clause for j with $z = x \vee y$ gives

$$j \leq x \vee y.$$

The two assumed upper-bound clauses for j, together with the certified join leastness field applied with $z = j$, give

$$x \vee y \leq j.$$

The antisymmetry field from Definition 53.43 applied to

$$j \leq x \vee y \qquad \text{and} \qquad x \vee y \leq j$$

yields

$$j \sim_C x \vee y.$$

□

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingleton bound uniqueness from directional certificates`

Definition 55.43 (Concrete unary total-order lattice selectors)**.** *For carried unary histories h, k in $\mathsf{Carrier_u}$, let the active comparison branch be the ledger branch supplied by Definition 54.9. Define the trichotomy lower and upper endpoint selectors by*

$$\mathsf{glb_{tri}}(h,k) := \begin{cases} h, & \text{on } \mathsf{NatUnaryStrictPrefix}(h,k), \\ h, & \text{on } \rho_{\mathsf{u}}(h,k), \\ k, & \text{on } \mathsf{NatUnaryStrictPrefix}(k,h), \end{cases} \qquad \mathsf{lub_{tri}}(h,k) := \begin{cases} k, & \text{on } \mathsf{NatUnaryStrictPrefix}(h,k), \\ k, & \text{on } \rho_{\mathsf{u}}(h,k), \\ h, & \text{on } \mathsf{NatUnaryStrictPrefix}(k,h). \end{cases}$$

The total-order-selected lattice operations are

$$h \wedge_{\mathsf{tri}} k := \mathsf{glb_{tri}}(h,k), \qquad h \vee_{\mathsf{tri}} k := \mathsf{lub_{tri}}(h,k).$$

Theorem 55.44 (Concrete unary $\mathsf{TotalOrder}^{\uparrow}$ forgets to $\mathsf{Lattice}^{\uparrow}$)**.** *The concrete $\mathsf{TotalOrder}^{\uparrow}$ naming certificate of Definition 54.20 determines a $\mathsf{Lattice}^{\uparrow}$ certificate over the same carrier $C = \mathsf{Carrier_u}$, classifier ρ_{u}, and order $\leq_{\mathsf{u}}$, with meet and join given by Definition 55.113. For every carried pair $h, k \in C$, the meet and join classifier-equal the trichotomy endpoint selectors:*

$$\rho_{\mathsf{u}}(h \wedge_{\mathsf{tri}} k, \mathsf{glb_{tri}}(h,k)) \qquad \text{and} \qquad \rho_{\mathsf{u}}(h \vee_{\mathsf{tri}} k, \mathsf{lub_{tri}}(h,k)).$$

The meet bound-characterization rows are the greatest-lower selector rows of Definition 54.12, and the join bound-characterization rows are the least-upper selector rows of Definition 54.10.

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeUnaryPrefix extrema certificate`

Proof. The source, carrier, classifier, relation, and inherited $\mathsf{POSet}^{\uparrow}$ stability rows are those already packaged in Definition 54.20. That theorem cites the concrete unary-prefix $\mathsf{POSet}^{\uparrow}$ naming certificate, so the partial-order reflexivity, transitivity, congruence, and antisymmetry fields required by the lattice interface are already present.

Fix carried unary histories h, k. The comparison partition of Definition 54.9 chooses exactly one of the three branches

$$\mathsf{NatUnaryStrictPrefix}(h,k), \qquad \rho_{\mathsf{u}}(h,k), \qquad \mathsf{NatUnaryStrictPrefix}(k,h).$$

The selector definition follows that same branch ledger: in the strict-left and same branches it chooses h as the lower endpoint and k as the upper endpoint, while in the strict-right branch it chooses k as the lower endpoint and h as the upper endpoint.

The theorem Definition 54.12 supplies, for this selected lower endpoint, a carried history l with

$$l \leq_{\mathsf{u}} h, \qquad l \leq_{\mathsf{u}} k, \qquad (r \leq_{\mathsf{u}} h \wedge r \leq_{\mathsf{u}} k) \Rightarrow r \leq_{\mathsf{u}} l$$

for every carried lower-bound witness r. By the displayed branch definition, this l is precisely $\mathsf{glb_{tri}}(h,k)$, hence precisely $h \wedge_{\mathsf{tri}} k$. These are the meet lower-bound and meet greatestness rows listed in Definition 55.102.

Similarly, Definition 54.10 supplies, for the selected upper endpoint, a carried history u with

$$h \leq_{\mathsf{u}} u, \qquad k \leq_{\mathsf{u}} u, \qquad (h \leq_{\mathsf{u}} r \wedge k \leq_{\mathsf{u}} r) \Rightarrow u \leq_{\mathsf{u}} r$$

for every carried upper-bound witness r. By the displayed branch definition, this u is precisely $\mathsf{lub_{tri}}(h,k)$, hence precisely $h \vee_{\mathsf{tri}} k$. These are the join upper-bound and join leastness rows listed in Definition 55.102.

It remains to account for meet and join congruence. Suppose h, h', k, k' are carried and that $\rho_{\mathsf{u}}(h, h')$ and $\rho_{\mathsf{u}}(k, k')$ hold. The branch-transport theorem Definition 54.13 preserves and reflects the strict-left, same, and strict-right branches across these endpoint replacements. If the active branch is strict-left or same, the meet outputs are h and h' and the join outputs are k and k'. If the active branch is strict-right, the meet outputs are k and k' and the join outputs are h and h'. In each case the assumed endpoint classifier witnesses give the required classifier comparison between the selected outputs. Thus meet and join are congruent in both arguments.

The classifier-equality rows in the theorem statement follow from the same selected-readback definition and classifier reflexivity on carried endpoints. The ledger row of Definition 55.103 records the selected comparison branch together with the greatest-lower and least-upper bound certificates just cited. Therefore the tuple with operations $\wedge_{\mathsf{tri}}$ and $\vee_{\mathsf{tri}}$ satisfies the $\mathsf{Lattice}^{\uparrow}$ certificate obligations of Definition 55.104. □

Definition 55.45 (Opposite lattice certificate data)**.** *Let a* $\mathsf{Lattice}^{\uparrow}$ *certificate be presented by a carrier predicate* $\mathcal{C}$*, classifier* $\sim_C$*, order* $\leq_C$*, meet* $\wedge_C$*, and join* $\vee_C$*. Define*

$$a \leq_C^{\mathrm{op}} b := b \leq_C a, \qquad a \wedge_C^{\mathrm{op}} b := a \vee_C b, \qquad a \vee_C^{\mathrm{op}} b := a \wedge_C b.$$

The opposite lattice data C^{op} *have the same carrier predicate* $\mathcal{C}$*, the same classifier* $\sim_C$*, the opposite order* $\leq_C^{\mathrm{op}}$*, meet* $\wedge_C^{\mathrm{op}}$*, and join* $\vee_C^{\mathrm{op}}$*.*

Theorem 55.46 (Opposite lattice certificate)**.** *If* $(\mathcal{C}, \sim_C, \leq_C, \wedge_C, \vee_C)$ *satisfies the* $\mathsf{Lattice}^{\uparrow}$ *certificate obligations of Definition 55.104, then the data of Definition 55.115 also satisfy the* $\mathsf{Lattice}^{\uparrow}$ *certificate obligations.*

Proof. Unpack the lattice obligations through Definition 55.104. By Definition 55.60 and Definition 55.99, the given lattice certificate contains a certified $\mathsf{POSet}^{\uparrow}$ carrier with carrier predicate $\mathcal{C}$, classifier $\sim_C$, and order $\leq_C$. Applying Definition 53.50 supplies the carrier, source, pattern, classifier, stability, and ledger rows for the same carrier and classifier with order $\leq_C^{\mathrm{op}}$.

The binary operation rows are present with names exchanged. The opposite meet $\wedge_C^{\mathrm{op}}$ is the original join $\vee_C$, and the opposite join $\vee_C^{\mathrm{op}}$ is the original meet $\wedge_C$. Thus the carried-operation data required by the lattice source row are copied from the original join and meet data.

It remains to verify the four bound-characterization rows in Definition 55.102. Fix carried endpoints a, b, z. For the opposite meet, the lower-bound laws are exactly the original join upper-bound laws:

$$a \wedge_C^{\mathrm{op}} b \leq_C^{\mathrm{op}} a \iff a \leq_C a \vee_C b, \qquad a \wedge_C^{\mathrm{op}} b \leq_C^{\mathrm{op}} b \iff b \leq_C a \vee_C b.$$

For opposite meet greatestness, assume $z \leq_C^{\mathrm{op}} a$ and $z \leq_C^{\mathrm{op}} b$. These unfold to $a \leq_C z$ and $b \leq_C z$. The original join leastness row gives $a \vee_C b \leq_C z$, which is exactly

$$z \leq_C^{\mathrm{op}} a \wedge_C^{\mathrm{op}} b.$$

For the opposite join, the upper-bound laws are exactly the original meet lower-bound laws:

$$a \leq_C^{\mathrm{op}} a \vee_C^{\mathrm{op}} b \iff a \wedge_C b \leq_C a, \qquad b \leq_C^{\mathrm{op}} a \vee_C^{\mathrm{op}} b \iff a \wedge_C b \leq_C b.$$

For opposite join leastness, assume $a \leq_C^{\mathrm{op}} z$ and $b \leq_C^{\mathrm{op}} z$. These unfold to $z \leq_C a$ and $z \leq_C b$. The original meet greatestness row gives $z \leq_C a \wedge_C b$, which is exactly

$$a \vee_C^{\mathrm{op}} b \leq_C^{\mathrm{op}} z.$$

Meet and join congruence are also exchanged. If $a \sim_C a'$ and $b \sim_C b'$, then original join congruence gives

$$a \wedge_C^{\mathrm{op}} b = a \vee_C b \sim_C a' \vee_C b' = a' \wedge_C^{\mathrm{op}} b',$$

and original meet congruence gives

$$a \vee_C^{\mathrm{op}} b = a \wedge_C b \sim_C a' \wedge_C b' = a' \vee_C^{\mathrm{op}} b'.$$

These are precisely the opposite meet-congruence and opposite join-congruence rows of Definition 55.101.

The pattern row of Definition 55.100 is unchanged expression formation by two binary lattice operations; each opposite meet node is read as an original join node, and each opposite join node is read as an original meet node. The ledger row of Definition 55.103 is the same exchange: an opposite meet ledger records the original join bound-characterization certificate, and an opposite join ledger records the original meet bound-characterization certificate, with the order witnesses interpreted through $\leq_C^{\mathrm{op}}$. Together with the opposite $\mathsf{POSet}^{\uparrow}$ rows supplied above, these are all carrier, source, pattern, classifier, stability, and ledger obligations required by Definition 55.104. Hence C^{op} carries a $\mathsf{Lattice}^{\uparrow}$ certificate. □

Theorem 55.47 (Double-opposite lattice certificate data identity)**.** *Let E be a $\mathsf{Lattice}^{\uparrow}$ certificate satisfying the obligations of Definition 55.104. Present its lattice data by a carrier predicate $\mathcal{C}$, classifier $\sim_C$, order relation $\leq_C$, meet $\wedge_C$, join $\vee_C$, meet ledger row $\mathcal{L}_C^{\wedge}$, and join ledger row $\mathcal{L}_C^{\vee}$ as in Definition 55.103. Let $E^{\mathrm{opop}} = (E^{\mathrm{op}})^{\mathrm{op}}$ be obtained by applying Definition 55.115 twice. Then E^{opop} is a $\mathsf{Lattice}^{\uparrow}$ certificate, and its carrier predicate, classifier, order relation, meet, join, and lattice ledger rows are componentwise identical to those of E: for carried endpoints a, b,*

$$\begin{aligned} \mathcal{C}^{\mathrm{opop}}(a) &= \mathcal{C}(a), & a \sim_C^{\mathrm{opop}} b &= a \sim_C b, \\ a \leq_C^{\mathrm{opop}} b &= a \leq_C b, & a \wedge_C^{\mathrm{opop}} b &= a \wedge_C b, \\ a \vee_C^{\mathrm{opop}} b &= a \vee_C b, & \mathcal{L}_C^{\wedge,\mathrm{opop}}(a,b) &= \mathcal{L}_C^{\wedge}(a,b), \\ \mathcal{L}_C^{\vee,\mathrm{opop}}(a,b) &= \mathcal{L}_C^{\vee}(a,b). \end{aligned}$$

Proof. Because E satisfies the $\mathsf{Lattice}^{\uparrow}$ obligations, Definition 55.116 makes E^{op} a certified $\mathsf{Lattice}^{\uparrow}$ instance. Applying the same theorem to that certified opposite data makes E^{opop} a certified $\mathsf{Lattice}^{\uparrow}$ instance.

By Definition 55.60 and Definition 55.99, the inherited order part of E is a certified $\mathsf{POSet}^{\uparrow}$ carrier with carrier predicate $\mathcal{C}$, classifier $\sim_C$, and order $\leq_C$. Applying Definition 53.51 to this inherited part gives the carrier, classifier, order, and inherited antisymmetry-ledger identities after two opposites. Hence

$$\mathcal{C}^{\mathrm{opop}}(a) = \mathcal{C}(a), \qquad a \sim_C^{\mathrm{opop}} b = a \sim_C b, \qquad a \leq_C^{\mathrm{opop}} b = a \leq_C b.$$

For the lattice operations, two unfoldings of Definition 55.115 give

$$a \wedge_C^{\mathrm{opop}} b = a \vee_C^{\mathrm{op}} b = a \wedge_C b$$

and

$$a \vee_C^{\mathrm{opop}} b = a \wedge_C^{\mathrm{op}} b = a \vee_C b.$$

Thus the double-opposite meet and join data are exactly the original meet and join data.

The source row is a certified poset carrier plus meet and join operations, so the restored poset part together with the restored operation slots gives the original source row. The pattern row of Definition 55.100 is expression formation by meet and join over carrier witnesses; one opposite exchanges the two operation names and the second exchange restores them.

The stability rows of Definition 55.102 are restored in the same componentwise way. In one opposite, the meet lower-bound and greatestness rows are the original join upper-bound and leastness rows read through the reversed order, while the join rows are the original meet rows read through the reversed order. The second opposite reverses the order again and exchanges the operation slots again, so the meet lower-bound, meet greatestness, join upper-bound, and join leastness rows are the original rows. Meet congruence and join congruence from Definition 55.101 are also exchanged twice and hence restored.

Finally, Definition 55.103 records the operands and the bound-characterization certificate for each meet or join. A single opposite reads a meet ledger as the corresponding original join ledger and a join ledger as the corresponding original meet ledger, with order witnesses interpreted through $\leq_C^{\mathrm{op}}$. The second opposite performs the same exchange again and the order has already returned to $\leq_C$. Therefore

$$\mathcal{L}_C^{\wedge,\mathrm{opop}}(a,b) = \mathcal{L}_C^{\wedge}(a,b), \qquad \mathcal{L}_C^{\vee,\mathrm{opop}}(a,b) = \mathcal{L}_C^{\vee}(a,b).$$

Together these identities identify the double-opposite lattice certificate data with the original lattice certificate data. □

Theorem 55.48 (Lattice one-sided distributive inequality from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. Assume the inherited preorder transitivity field and the directional meet and join bound-characterization fields from Definition 55.102. Then for all $x, y, z \in A$,*

$$(x \wedge y) \vee (x \wedge z) \leq x \wedge (y \vee z).$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeDirected one sided distributive inequality from bounds`

Proof. Let

$$q := x \wedge (y \vee z).$$

The join leastness field will give the desired comparison once both join inputs are shown to be below q.

For the first input, the meet lower-left field gives

$$x \wedge y \leq x.$$

The meet lower-right field gives

$$x \wedge y \leq y,$$

and the join upper-left field gives

$$y \leq y \vee z.$$

By inherited preorder transitivity from Definition 52.44, these two comparisons compose to

$$x \wedge y \leq y \vee z.$$

Applying meet greatestness to the two comparisons

$$x \wedge y \leq x \qquad \text{and} \qquad x \wedge y \leq y \vee z$$

gives

$$x \wedge y \leq x \wedge (y \vee z),$$

that is,

$$x \wedge y \leq q.$$

For the second input, the meet lower-left field gives

$$x \wedge z \leq x.$$

The meet lower-right field gives

$$x \wedge z \leq z,$$

and the join upper-right field gives

$$z \leq y \vee z.$$

By inherited preorder transitivity, these two comparisons compose to

$$x \wedge z \leq y \vee z.$$

Applying meet greatestness to the two comparisons

$$x \wedge z \leq x \qquad \text{and} \qquad x \wedge z \leq y \vee z$$

gives

$$x \wedge z \leq x \wedge (y \vee z),$$

that is,

$$x \wedge z \leq q.$$

The join leastness field applied with upper bound q to

$$x \wedge y \leq q \qquad \text{and} \qquad x \wedge z \leq q$$

yields

$$(x \wedge y) \vee (x \wedge z) \leq q.$$

Substituting the definition of q gives

$$(x \wedge y) \vee (x \wedge z) \leq x \wedge (y \vee z).$$

□

Lemma 55.49 (Directed meet associativity comparison from bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq$ and classifier $\sim_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *transitivity field from Definition 52.44 and the directional meet lower-bound and greatest-lower-bound implication fields from Definition 55.102. Then for all $x, y, z \in A$,*

$$(x \wedge y) \wedge z \leq x \wedge (y \wedge z).$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeet assoc comparison empty`

Proof. Put

$$w = (x \wedge y) \wedge z.$$

The meet lower-left field gives

$$w \leq x \wedge y,$$

and the meet lower-left field applied to $x \wedge y$ gives

$$x \wedge y \leq x.$$

By the inherited preorder transitivity field,

$$w \leq x.$$

The meet lower-right field applied to $x \wedge y$ gives

$$x \wedge y \leq y,$$

so transitivity with $w \leq x \wedge y$ gives

$$w \leq y.$$

The meet lower-right field applied to $w = (x \wedge y) \wedge z$ gives

$$w \leq z.$$

Applying meet greatestness to the two bounds $w \leq y$ and $w \leq z$ gives

$$w \leq y \wedge z.$$

A second application of meet greatestness, now to $w \leq x$ and $w \leq y \wedge z$, gives

$$w \leq x \wedge (y \wedge z).$$

Substituting the displayed definition of w is the required comparison. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeDirectedMeet associativity comparison from bounds`

Lemma 55.50 (Directed join associativity comparison from bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. $$a \vee (b \wedge c) \leq_C (a \vee b) \wedge (a \vee c).$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonJoinMeet lower comparison empty`

Proof. Put

$$n = a \vee (b \wedge c), \qquad m = (a \vee b) \wedge (a \vee c).$$

The join upper-left field gives

$$a \leq_C a \vee b.$$

The meet lower-left field gives

$$b \wedge c \leq_C b,$$

and the join upper-right field gives

$$b \leq_C a \vee b.$$

By transitivity,

$$b \wedge c \leq_C a \vee b.$$

Join leastness with upper target $a \vee b$ gives

$$n \leq_C a \vee b.$$

Similarly, the join upper-left field gives

$$a \leq_C a \vee c.$$

The meet lower-right field gives

$$b \wedge c \leq_C c,$$

and the join upper-right field gives

$$c \leq_C a \vee c.$$

By transitivity,

$$b \wedge c \leq_C a \vee c.$$

Join leastness with upper target $a \vee c$ gives

$$n \leq_C a \vee c.$$

Meet greatestness applied to the two bounds $n \leq_C a \vee b$ and $n \leq_C a \vee c$ gives

$$n \leq_C m.$$

Substituting the displayed definitions of m and n gives the claimed comparison. □

Theorem 55.55 (Meet distributivity gives join distributivity)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. Assume the classifier symmetry and transitivity fields from Definition 9.7, the inherited* $\mathsf{Preorder}^{\uparrow}$ *reflexivity and transitivity fields from Definition 52.44, the inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry field from Definition 53.43, and the directional meet and join bound-characterization fields from Definition 55.102. Assume also the meet and join classifier-congruence rows from Definition 55.101, and suppose the distributive law*

$$u \wedge (v \vee w) \sim_C (u \wedge v) \vee (u \wedge w)$$

holds for all $u, v, w \in A$. Then for all $a, b, c \in A$,

$$a \vee (b \wedge c) \leq_C (a \vee b) \wedge (a \vee c) \qquad \textit{and} \qquad a \vee (b \wedge c) \sim_C (a \vee b) \wedge (a \vee c).$$

Proof. The first conclusion is Definition 55.93.

Put

$$d = (a \vee b) \wedge (a \vee c), \qquad n = a \vee (b \wedge c).$$

The assumed distributive law with $u = a \vee b$, $v = a$, and $w = c$ gives

$$d \sim_C ((a \vee b) \wedge a) \vee ((a \vee b) \wedge c).$$

By Definition 55.111, applied with $x = a$ and $y = b$,

$$(a \vee b) \wedge a \sim_C a.$$

By Definition 55.110, applied to the meet operands $a \vee b$ and c,

$$(a \vee b) \wedge c \sim_C c \wedge (a \vee b).$$

The assumed distributive law with $u = c$, $v = a$, and $w = b$ gives

$$c \wedge (a \vee b) \sim_C (c \wedge a) \vee (c \wedge b).$$

Classifier transitivity composes the last two comparisons into

$$(a \vee b) \wedge c \sim_C (c \wedge a) \vee (c \wedge b).$$

Join classifier congruence gives

$$((a \vee b) \wedge a) \vee ((a \vee b) \wedge c) \sim_C a \vee ((c \wedge a) \vee (c \wedge b)).$$

Put

$$p = a \vee ((c \wedge a) \vee (c \wedge b)), \qquad q = a \vee (c \wedge b).$$

To compare p and q, first note that the join upper-left field gives $a \leq_C q$. The meet lower-right field gives $c \wedge a \leq_C a$, so transitivity gives $c \wedge a \leq_C q$. The join upper-right field gives $c \wedge b \leq_C q$. Join leastness gives

$$(c \wedge a) \vee (c \wedge b) \leq_C q,$$

and another application of join leastness gives

$$p \leq_C q.$$

Conversely, the join upper-left field gives $a \leq_C p$. The join upper-right field gives

$$(c \wedge a) \vee (c \wedge b) \leq_C p,$$

and the join upper-right field applied to the inner join gives

$$c \wedge b \leq_C (c \wedge a) \vee (c \wedge b).$$

By transitivity, $c \wedge b \leq_C p$. Join leastness gives

$$q \leq_C p.$$

The antisymmetry field from Definition 53.43 applied to $p \leq_C q$ and $q \leq_C p$ yields

$$p \sim_C q.$$

By Definition 55.108, applied with $x = a$ and $y = a$,

$$a \vee (a \wedge a) \sim_C a.$$

Classifier symmetry and transitivity applied to this comparison give

$$a \sim_C a.$$

By Definition 55.110, applied to the meet operands c and b,

$$c \wedge b \sim_C b \wedge c.$$

Join classifier congruence gives

$$q \sim_C n.$$

Classifier transitivity composes the displayed classifier comparisons into

$$d \sim_C n.$$

Classifier symmetry reverses this comparison, giving

$$n \sim_C d.$$

Substituting the displayed definitions of d and n gives

$$a \vee (b \wedge c) \sim_C (a \vee b) \wedge (a \vee c).$$

□

Lemma 55.56 (Lattice meet two-sided monotonicity from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. $$a' \leq_C u.$$

Composing the assumed comparison $a \leq_C a'$ with $a' \leq_C u$ by the inherited preorder transitivity field gives

$$a \leq_C u.$$

The join upper-right field gives

$$b' \leq_C u.$$

Composing the assumed comparison $b \leq_C b'$ with $b' \leq_C u$ by the same transitivity field gives

$$b \leq_C u.$$

Applying join leastness to the two upper-bound comparisons $a \leq_C u$ and $b \leq_C u$ gives

$$a \vee b \leq_C u.$$

Substituting the displayed definition of u gives the claimed comparison. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeJoin two sided monotonicity from directional bounds`

Lemma 55.58 (Lattice meet monotonicity in the second argument from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *reflexivity and transitivity fields from Definition 52.44 and the directional meet lower-bound and greatest-lower-bound fields from Definition 55.102. If $b, b', c \in A$ and $b \leq_C b'$, then*

$$c \wedge b \leq_C c \wedge b'.$$

Proof. Put

$$w = c \wedge b.$$

The meet lower-left field gives

$$w \leq_C c.$$

The meet lower-right field gives

$$w \leq_C b.$$

Composing this comparison with the assumed comparison $b \leq_C b'$ by the inherited preorder transitivity field gives

$$w \leq_C b'.$$

Applying meet greatestness to the two bounds $w \leq_C c$ and $w \leq_C b'$ gives

$$w \leq_C c \wedge b'.$$

Substituting the displayed definition of w gives the claimed comparison. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeMeet monotone second argument from directional bounds`

Theorem 55.59 (Lattice operation monotonicity from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *reflexivity and transitivity fields from Definition 52.44 and the directional meet and join bound-characterization fields from Definition 55.102. If $a, a', b, b', c \in A$ with $a \leq_C a'$ and $b \leq_C b'$, then*

$$a \wedge c \leq_C a' \wedge c, \qquad c \wedge a \leq_C c \wedge a',$$

and

$$b \vee c \leq_C b' \vee c, \qquad c \vee b \leq_C c \vee b'.$$

Proof. The inherited preorder reflexivity field gives

$$c \leq_C c.$$

Apply Definition 55.95 to the comparisons $a \leq_C a'$ and $c \leq_C c$. This gives

$$a \wedge c \leq_C a' \wedge c.$$

Apply the same meet monotonicity lemma to $c \leq_C c$ and $a \leq_C a'$. This gives

$$c \wedge a \leq_C c \wedge a'.$$

Apply Definition 55.96 to $b \leq_C b'$ and $c \leq_C c$. This gives

$$b \vee c \leq_C b' \vee c.$$

Apply the same join monotonicity lemma to $c \leq_C c$ and $b \leq_C b'$. This gives

$$c \vee b \leq_C c \vee b'.$$

□

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonOperation monotonicity empty`

Closure status for $\mathsf{NameCert}_{\mathsf{Lattice}^{\uparrow}}$.

Constructive story: The lattice instance is the singleton endpoint sitting over the prefix poset: the carrier accepts only histories history-same to e, so both meet and join are forced to return e no matter which carried operands are displayed. Its classifier is ρ_{e}, the same singleton relation that packages two endpoint carrier witnesses with an hsame link, and the inherited order is the restricted prefix comparison between those carried endpoints. The source is a certified poset carrier equipped with meet and join data, the pattern records lower-bound, greatest-lower-bound, upper-bound, least-upper-bound, congruence, directed associativity, absorption, and modular-law rows, and the ledger stores the operands with the bound-characterization witnesses that reduce every comparison to the empty endpoint. The five name-certificate obligations are immediate from the singleton endpoint: e inhabits the carrier, hsame gives the classifier equivalence, and carrier closure under classified replacement follows by composing endpoint witnesses through e. A history h lies in the signature gap of a $\mathsf{Lattice}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer endpoint and bound ledger, and token introduction names that answer as p; in this instance, h is classified with e, every meet or join ledger returns e, and p names the one-point lattice row. No standard bridge is closed in this chapter, although the intended outside reading is the terminal one-point lattice. The chapter registers this singleton meet-join construction under the name $\mathsf{Lattice}^{\uparrow}$; lattice laws are endpoint consequences of the existing prefix order, with no arbitrary lattice carrier, representation theorem, or external meet/join algebra introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Lattice}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public lattice certificate is closed over the displayed singleton-history carrier, classifier, order, meet, join, directed associativity, absorption, and modular-law rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Lattice}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.LatticeUp.LatticeSingletonPrefix\_laws`

Bridge status: bridgeChecked

Not claimed: It does not close full traditional lattice theory, arbitrary lattice carriers, representation theorems, or standard bridges.

Upgrade path: No further upgrade – chapter at top of formal axis.

55.4 Carrier definition

Definition 55.60 (Lattice carrier)**.** *Use a poset setup extended with meet and join operations carrying bound-characterization proofs.*

55.5 Concrete singleton prefix lattice instance

Definition 55.61 (Concrete singleton prefix lattice instance)**.** *Let A_{e} be the singleton history source of Definition 36.169 at $a_0 = \mathsf{e}$. Define ρ_{e} by*

$$\rho_{\mathsf{e}}(h,k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h,k).$$

Let $h \leq_{\mathsf{e}} k$ mean that $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$ hold and that $\mathsf{PreorderPrefixLE}(h,k)$ *witnesses the prefix comparison between the carried endpoints. Define the concrete lattice operations by*

$$\mathsf{meet}(h,k) := \mathsf{e}, \qquad \mathsf{join}(h,k) := \mathsf{e}.$$

The certificate has ten fields: traditional target the one-point lattice; BEDC source BHist *plus the singleton source and concrete prefix order; carrier A_{e}; classifier ρ_{e}; stability obligations for poset laws, meet lower bounds, meet greatestness, join upper bounds, join leastness, and meet and join congruence; ledger singleton endpoint plus prefix witnesses; core theorem Theorem 55.62; exactness singleton endpoint classification; standard bridge terminal one-point lattice; and status* ProofTarget.

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeUp StdBridge`

Theorem 55.62 (Concrete singleton prefix lattice laws)**.** *For all carried histories h, k, z in A_{e}, the endpoints* $\mathsf{meet}(h, k)$ *and* $\mathsf{join}(h, k)$ *are carried by A_{e} and satisfy the meet lower-bound laws, meet greatest-lower-bound law, join upper-bound laws, join least-upper-bound law, and meet and join congruence laws for the restricted prefix order $\leq_{\mathsf{e}}$ under the classifier ρ_{e}.*

Proof. The singleton carrier witnesses identify each carried endpoint with e. Thus $A_{\mathsf{e}}(h)$, $A_{\mathsf{e}}(k)$, and $A_{\mathsf{e}}(z)$ reduce every endpoint comparison needed by the order, meet, and join clauses to the empty-history endpoint.

The restricted prefix comparisons are supplied by PreorderPrefixLE_of_hsame after the singleton witnesses produce the relevant hsame facts. The inherited order boundary is the concrete unary prefix poset law package of Theorem 53.10, with antisymmetry supplied by Theorem 53.33.

The meet and join outputs are both definitionally e. The lower-bound and upper-bound clauses therefore use the singleton endpoint witness for e and the prefix witnesses from the previous paragraph; the greatest-lower-bound and least-upper-bound clauses use the same reduction for the third carried history z.

Congruence is immediate because both operations ignore their operands and return e. After unfolding, every source and target output is classified by $\rho_{\mathsf{e}}(\mathsf{e}, \mathsf{e})$, assembled from two copies of $A_{\mathsf{e}}(\mathsf{e})$ and the reflexive witness $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonPrefix laws`

Theorem 55.63 (Singleton lattice order has empty endpoints)**.** *For h, k : BHist, the restricted singleton prefix order satisfies*

$$h \leq_{\mathsf{e}} k \quad \Longleftrightarrow \quad h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. The forward direction reads the two singleton carrier fields from the definition of $h \leq_{\mathsf{e}} k$. These fields are exactly $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$.

For the reverse direction, the two endpoint witnesses supply the singleton carrier fields. Their transitive composite through e gives $h\mathsf{hsame}k$, and the prefix comparison follows from the concrete PreorderPrefixLE_of_hsame constructor. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE empty endpoints iff`

Theorem 55.64 (Singleton lattice append order has empty endpoints)**.** *For h, k : BHist, the restricted singleton prefix order from the appended history to* e *satisfies*

$$\mathsf{LatticeSingletonLE}(\mathsf{append}(h, k), \mathsf{e}) \quad \Longleftrightarrow \quad h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. The forward direction first applies singleton-order endpoint exactness to read $\mathsf{append}(h, k)\mathsf{hsamee}$, then splits the empty append into empty left and right endpoints. Conversely, empty endpoints make $\mathsf{append}(h, k)$ history-same to e, and the singleton-order endpoint characterization rebuilds the restricted order comparison. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE append empty endpoints iff`

Theorem 55.65 (Singleton lattice carrier order collapse)**.** *If h and k are carried by A_{e}, then both restricted order comparisons hold, the singleton classifier relates h and k, and both endpoints are internally the same as* e*:*

$$h \leq_{\mathsf{e}} k \wedge k \leq_{\mathsf{e}} h \wedge \rho_{\mathsf{e}}(h, k) \wedge h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. The two carrier witnesses are the endpoint comparisons $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$. Their composite through e gives $h\mathsf{hsame}k$, and symmetry gives $k\mathsf{hsame}h$.

The two restricted order comparisons are obtained from these two sameness witnesses by PreorderPrefixLE_of_hsame, together with the same carrier fields. The classifier package uses the carrier fields and $h\mathsf{hsame}k$, and the endpoint clauses are the original carrier witnesses. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonCarrier order collapse`

Theorem 55.66 (Singleton lattice antisymmetry classifier)**.** *If $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$ in the restricted singleton prefix order, then $\rho_{\mathsf{e}}(h, k)$, $h\mathsf{hsamee}$, and $k\mathsf{hsamee}$.*

Proof. The two restricted comparisons carry their endpoint fields, so the first comparison already identifies both h and k with e. The prefix components of the two comparisons are opposing PreorderPrefixLE witnesses, and concrete prefix antisymmetry gives $\mathsf{hsame}(h, k)$. These three pieces are exactly the classifier data $\rho_{\mathsf{e}}(h, k)$, together with the two displayed empty endpoint witnesses. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE antisymm classifier`

Theorem 55.67 (Singleton lattice meet-join absorption classifier)**.** *If h and k are carried by A_{e}, then both absorption composites $\mathsf{meet}(h, \mathsf{join}(h, k))$ and $\mathsf{join}(h, \mathsf{meet}(h, k))$ are classified with h by ρ_{e}, and both output histories are hsame to e.*

Proof. Both concrete lattice operations are definitionally e. Hence each absorption composite is the empty history, whose singleton carrier witness is reflexive. The carrier witness for h gives $h\mathsf{hsamee}$, so symmetry gives the classifier component from each absorption output back to h. Reassemble the two ρ_{e} classifiers and record the two empty output endpoints. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeetJoin absorption classifier`

Theorem 55.68 (Singleton lattice meet-join absorption is empty-classified)**.** *For carried singleton endpoints h, k, both absorption composites reduce to the empty endpoint and classify back to h:*

$$\mathsf{meet}(h, \mathsf{join}(h, k))\mathsf{hsamee}, \qquad \mathsf{join}(h, \mathsf{meet}(h, k))\mathsf{hsamee},$$
$$\rho_{\mathsf{e}}(\mathsf{meet}(h, \mathsf{join}(h, k)), h), \qquad \rho_{\mathsf{e}}(\mathsf{join}(h, \mathsf{meet}(h, k)), h).$$

Proof. Both concrete operations are definitionally the endpoint e. The two endpoint equalities are therefore reflexive empty-history sameness. Since h is carried by the singleton carrier, symmetry of its carrier witness classifies e with h, and the classifier packages the two carrier witnesses with that history-sameness witness. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeetJoin absorption empty classified`

Theorem 55.69 (Singleton lattice continuation absorption has empty classifier)**.** *Let h, k be singleton-carried histories. If $left$ is a BEDC continuation output of $\mathsf{meet}(h, \mathsf{join}(h, k))$ followed by h, and $right$ is a BEDC continuation output of h followed by $\mathsf{join}(h, \mathsf{meet}(h, k))$, then both outputs are empty and are classified by the singleton classifier:*

$$\mathsf{hsame}(left, \mathsf{e}) \wedge \mathsf{hsame}(right, \mathsf{e}) \wedge \rho_{\mathsf{e}}(left, right).$$

Proof. The concrete singleton meet and join both return e. The left continuation is therefore $\mathsf{append}(\mathsf{e}, h)$, which reduces to h, and the right continuation is $\mathsf{append}(h, \mathsf{e})$, which also reduces to h. The carrier witness for h identifies each result with e. Those two endpoint witnesses, together with transitivity through e, assemble the singleton classifier between the two continuation outputs. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeetJoin continuation absorption empty classifier`

Theorem 55.70 (Singleton lattice meet-join idempotent commutative classifier)**.** *For carried singleton endpoints h, k, meet and join are classified with the idempotent endpoint and with their swapped arguments:*

$$\rho_{\mathsf{e}}(\mathsf{meet}(h,h),h) \wedge \rho_{\mathsf{e}}(\mathsf{join}(h,h),h) \wedge \rho_{\mathsf{e}}(\mathsf{meet}(h,k),\mathsf{meet}(k,h)) \wedge \rho_{\mathsf{e}}(\mathsf{join}(h,k),\mathsf{join}(k,h)).$$

Moreover $\mathsf{meet}(h,k)\mathsf{hsamee}$ *and* $\mathsf{join}(h,k)\mathsf{hsamee}$.

Proof. The concrete singleton meet and join operations both return e. Thus the swapped meet outputs and swapped join outputs are classified by reflexive empty-history sameness. Since h is carried by the singleton carrier, symmetry of $h\mathsf{hsamee}$ classifies each idempotent output with h. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeetJoin idempotent comm classifier`

Theorem 55.71 (Singleton lattice classifier has empty endpoints)**.** *For $h, k : \mathsf{BHist}$, the singleton lattice classifier satisfies*

$$\rho_{\mathsf{e}}(h,k) \iff h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. The forward direction projects the two carrier fields from the classifier tuple. Since the singleton carrier is the predicate $x\mathsf{hsamee}$, these fields are exactly the two endpoint witnesses.

Conversely, the two endpoint witnesses make h and k singleton-carried. Their composite through e, using symmetry on the second witness, supplies $h\mathsf{hsame}k$ and hence the classifier tuple. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier empty endpoints iff`

Theorem 55.72 (Singleton lattice classifier continuation result-left iff)**.** *For histories $P, Q, R : \mathsf{BHist}$ with $\mathsf{Cont}(P,Q,R)$, the singleton lattice classifier relates P and Q exactly when it relates the continuation result R to P:*

$$\mathsf{LatticeSingletonClassifier}(P,Q) \iff \mathsf{LatticeSingletonClassifier}(R,P).$$

Proof. The forward direction uses the singleton carriers of P and Q to transport the continuation result to the right-unit continuation at e, so R is singleton-carried and compares with P through e. For the reverse direction, the result-left classifier identifies R with e; transporting the continuation to empty result and applying empty-result inversion recovers the singleton carrier witnesses for both inputs, and hence the input classifier. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier continuation result left iff`

Theorem 55.73 (Singleton lattice classifier continuation result-right iff)**.** *For histories $P, Q, R : \mathsf{BHist}$ with $\mathsf{Cont}(P,Q,R)$, the singleton lattice classifier relates P and Q exactly when it relates the continuation result R to Q:*

$$\mathsf{LatticeSingletonClassifier}(P,Q) \iff \mathsf{LatticeSingletonClassifier}(R,Q).$$

Proof. The forward direction uses the singleton carriers of P and Q to transport the continuation result to the right-unit continuation at e, so R is singleton-carried and compares with Q through e. For the reverse direction, the result-right classifier identifies R with e; transporting the continuation to empty result and applying empty-result inversion recovers the singleton carrier witnesses for both inputs, and hence the input classifier. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier continuation result right iff`

Theorem 55.74 (Singleton lattice classifier continuation empty result exactness)**.** *For histories* P, Q, R : BHist *with* $\mathsf{Cont}(P, Q, R)$*, the singleton lattice classifier relates the two inputs exactly when the continuation result is empty:*

$$\mathsf{LatticeSingletonClassifier}(P, Q) \iff R\mathsf{hsamee}.$$

Proof. The forward direction reads the two singleton carrier endpoints from the input classifier; since R is the append continuation of P and Q, append-empty construction gives $R\mathsf{hsamee}$. Conversely, result emptiness inverts the append continuation into singleton carrier witnesses for both inputs, and the empty-endpoint characterization reconstructs the singleton classifier. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier continuation empty result iff`

Theorem 55.75 (Singleton lattice classifier continuation result-left-right equivalence)**.** *For histories* P, Q, R : BHist *with* $\mathsf{Cont}(P, Q, R)$*, classifying the continuation result against the left input is equivalent to classifying it against the right input:*

$$\mathsf{LatticeSingletonClassifier}(R, P) \iff \mathsf{LatticeSingletonClassifier}(R, Q).$$

Proof. The result-left classifier theorem identifies the left comparison with the input classifier on P and Q. The result-right classifier theorem identifies the right comparison with the same input classifier. Composing those two characterizations gives the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier continuation result left right iff`

Theorem 55.76 (Singleton lattice result-left order carriers)**.** *For histories* h, k, r : BHist *with* $\mathsf{Cont}(h, k, r)$*, the restricted singleton order from the continuation result back to the left input is equivalent to both exposed inputs being singleton-carried:*

$$\mathsf{LatticeSingletonLE}(r, h) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Proof. The forward direction reads $r\mathsf{hsamee}$ from the singleton order endpoint fields. The continuation witness identifies r with $\mathsf{append}(h, k)$, so empty-append inversion gives $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$.

Conversely, if both exposed inputs are singleton-carried, the continuation result is internally the empty endpoint. The empty-endpoint characterization of the singleton order then supplies $\mathsf{LatticeSingletonLE}(r, h)$. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE continuation result left carriers iff`

Theorem 55.77 (Singleton lattice result-right order carriers)**.** *For histories* h, k, r : BHist *with* $\mathsf{Cont}(h, k, r)$*, the restricted singleton order from the continuation result back to the right input is equivalent to both exposed inputs being singleton-carried:*

$$\mathsf{LatticeSingletonLE}(r, k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Proof. The forward direction again projects $r\mathsf{hsamee}$ from the singleton order endpoint fields. Since the continuation result is the append of h and k, empty-append inversion exposes both input carriers.

In the reverse direction, the two input carriers force the continuation result to be internally empty. The empty-endpoint characterization of $\mathsf{LatticeSingletonLE}$ then gives the displayed order comparison against the right input. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE continuation result right carriers iff`

Theorem 55.78 (Singleton lattice continuation result endpoint order equivalence)**.** *For histories* $P, Q, R : \mathsf{BHist}$ *with* $\mathsf{Cont}(P, Q, R)$*, the restricted singleton order from the continuation result to the left endpoint is equivalent to the restricted singleton order from the result to the right endpoint:*

$$\mathsf{LatticeSingletonLE}(R, P) \iff \mathsf{LatticeSingletonLE}(R, Q).$$

Proof. The result-left order theorem identifies the left comparison with the pair of singleton carrier witnesses for P and Q. The result-right order theorem identifies the right comparison with the same pair. Composing these two characterizations gives the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE continuation result left right iff`

Theorem 55.79 (Singleton lattice continuation empty result order exactness)**.** *For histories* $P, Q, R : \mathsf{BHist}$ *with* $\mathsf{Cont}(P, Q, R)$*, the restricted singleton prefix comparison between the inputs is equivalent to emptiness of the continuation result:*

$$P \leq_{\mathsf{e}} Q \iff R\mathsf{hsamee}.$$

Proof. The restricted singleton order carries both input endpoints as empty. Since R is the BEDC append continuation of P and Q, append-empty construction gives $R\mathsf{hsamee}$. Conversely, if the continuation result is empty, BEDC append-empty inversion makes both P and Q empty. Their induced hsame chain supplies the underlying prefix comparison, so the singleton order tuple is reconstructed. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE continuation empty result iff`

Theorem 55.80 (Singleton meet–join absorption gives order and classifier data)**.** *If* $h, k : \mathsf{BHist}$ *are singleton-carried, then the two singleton lattice absorption endpoints*

$$h \wedge (h \vee k) \qquad \textit{and} \qquad h \vee (h \wedge k)$$

are both definitionally the empty history. They satisfy the restricted prefix order comparisons

$$h \wedge (h \vee k) \leq_{\mathsf{e}} h \qquad \textit{and} \qquad h \leq_{\mathsf{e}} h \vee (h \wedge k),$$

are both classified with h*, and both read back to* e*.*

Proof. In the singleton lattice, meet and join ignore their inputs and return e. The carrier witness for h gives $h\mathsf{hsamee}$, while reflexivity gives $\mathsf{ehsamee}$.

The first order comparison uses symmetry of $h\mathsf{hsamee}$ to obtain $\mathsf{ehsame}h$ and then applies the prefix comparison constructor. The second uses $h\mathsf{hsamee}$ directly. The same two hsame witnesses assemble the classifier tuples with h, and the endpoint readbacks are both reflexivity at e. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeetJoin absorption order classifier`

Theorem 55.81 (Singleton meet greatest lower bound)**.** *For carried histories* h, k, z *in the singleton lattice, the concrete meet output is the empty history, and the lower-bound condition against that meet is exactly the pair of lower-bound conditions against the two operands:*

$$\mathsf{hsame}(\mathsf{LatticeSingletonMeet}(h, k), \mathsf{e}) \wedge (z \leq_{\mathsf{e}} \mathsf{LatticeSingletonMeet}(h, k) \iff z \leq_{\mathsf{e}} h \wedge z \leq_{\mathsf{e}} k)\,.$$

Proof. The meet operation is definitionally the empty history. Since h, k, z are all carried by the singleton carrier, the order endpoint theorem Definition 55.63 reduces every displayed comparison to the two empty-endpoint witnesses. The forward direction rebuilds the two operand bounds from the endpoint witnesses for z, h, k; the reverse direction rebuilds the meet bound from the endpoint witness for z and reflexivity at e. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeet empty output greatest lower bound iff`

Theorem 55.82 (Singleton join least upper bound)**.** *For carried histories h, k, z in the singleton lattice, the concrete join least-upper-bound comparison is exactly the pair of upper-bound comparisons against the two operands, together with the empty readback of the join:*

$$\mathsf{LatticeSingletonJoin}(h, k) \leq_{\mathsf{e}} z \iff h \leq_{\mathsf{e}} z \wedge k \leq_{\mathsf{e}} z \wedge \mathsf{LatticeSingletonJoin}(h, k)\mathsf{hsamee}.$$

Proof. The join operation is definitionally the empty history. Since h, k, z are all carried by the singleton carrier, the singleton order comparison between any two of them is built from the corresponding hsame chain through e. The forward direction reconstructs the two operand upper bounds and records reflexivity of the join endpoint; the reverse direction uses the displayed join endpoint together with the carrier of z to rebuild the join bound. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonJoin least upper bound empty iff`

Theorem 55.83 (Singleton lattice append tail emptiness)**.** *For $h, t : \mathsf{BHist}$, if $A_{\mathsf{e}}(h)$ and $\mathsf{UnaryHistory}(t)$, then the restricted singleton prefix order satisfies*

$$\mathsf{append}(h, t) \leq_{\mathsf{e}} h \quad \iff \quad t\mathsf{hsamee}.$$

Proof. The forward direction projects the underlying prefix comparison from the restricted order and applies the concrete append-tail backforcing law from $\mathsf{Preorder}^{\uparrow}$. A unary tail that returns from $\mathsf{append}(h, t)$ back to h must be the empty history.

For the reverse direction, the witness $t\mathsf{hsamee}$ reduces $\mathsf{append}(h, t)$ to h by the right continuation unit law. The carried witness $A_{\mathsf{e}}(h)$ therefore also carries $\mathsf{append}(h, t)$, and the prefix comparison is the empty-tail side of the same append-tail equivalence. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE append tail empty iff`

Theorem 55.84 (Singleton lattice classifier append tail emptiness)**.** *For $h, t : \mathsf{BHist}$, if $A_{\mathsf{e}}(h)$, then the singleton classifier satisfies*

$$\mathsf{LatticeSingletonClassifier}(\mathsf{append}(h, t), h) \quad \iff \quad t\mathsf{hsamee}.$$

Proof. The forward direction projects the carried left endpoint from the classifier. Since $\mathsf{append}(h, t)\mathsf{hsamee}$, the concrete append-empty inversion forces $t\mathsf{hsamee}$.

Conversely, assume $t\mathsf{hsamee}$. The append endpoint is carried because both h and t are empty in the singleton sense, and the right continuation unit identifies $\mathsf{append}(h, t)$ with h. Together with the given carrier for h, these witnesses reconstruct the singleton classifier. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier append tail empty iff`

Theorem 55.85 (Singleton lattice append context empty order)**.** *For $left, h, right : \mathsf{BHist}$, if $A_{\mathsf{e}}(h)$, then the restricted singleton prefix order between the two append displays satisfies*

$$\mathsf{append}(left, h) \leq_{\mathsf{e}} \mathsf{append}(h, right) \quad \iff \quad left\mathsf{hsamee} \wedge right\mathsf{hsamee}.$$

Proof. In the forward direction, the restricted order exposes singleton carriers for both append endpoints. BEDC append-empty inversion on $\mathsf{append}(left, h)$ gives $left\mathsf{hsamee}$, and the same inversion on $\mathsf{append}(h, right)$ gives $right\mathsf{hsamee}$.

Conversely, if the two contexts are empty, the carrier of h makes both append endpoints singleton-carried. Since both endpoints are history-same to e, they are history-same to each other, and the singleton order is rebuilt from the corresponding concrete prefix witness. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE append context empty iff`

Theorem 55.86 (Singleton lattice append tail upper emptiness)**.** *For $h, t : \mathsf{BHist}$, if $A_{\mathsf{e}}(h)$ and $\mathsf{UnaryHistory}(t)$, then the restricted singleton prefix order satisfies*

$$h \leq_{\mathsf{e}} \mathsf{append}(h, t) \quad \Longleftrightarrow \quad t\mathsf{hsamee}.$$

Proof. The forward direction reads the upper endpoint carrier from the restricted order. Thus $\mathsf{append}(h, t)$ is history-same to e, and the BEDC append-empty inversion forces both endpoints of the append, in particular t, to be empty. Conversely, if $t\mathsf{hsamee}$, the right continuation unit identifies $\mathsf{append}(h, t)$ with h, so the given singleton carrier for h also carries the append endpoint. The prefix witness is the concrete append-tail continuation. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE append tail upper empty iff`

Theorem 55.87 (Singleton lattice meet greatest lower bound empty exactness)**.** *For carried singleton endpoints h, k, z, the statement that z is below the concrete meet of h and k is equivalent to the two endpoint lower-bound clauses together with the fact that the concrete meet is empty:*

$$z \leq_{\mathsf{e}} \mathsf{meet}(h, k) \quad \Longleftrightarrow \quad z \leq_{\mathsf{e}} h \wedge z \leq_{\mathsf{e}} k \wedge \mathsf{meet}(h, k)\mathsf{hsamee}.$$

Proof. The singleton carrier identifies h, k, z with e, and the concrete meet operation is definitionally e. Thus the forward direction builds both lower-bound comparisons from the endpoint sameness witnesses using the singleton prefix comparison. Conversely, the displayed empty-meet endpoint and the carrier witness for z build the singleton comparison $z \leq_{\mathsf{e}} \mathsf{meet}(h, k)$. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeet greatest lower bound empty iff`

The $\mathsf{Lattice}^{\uparrow}$ schema is instantiated by a concrete BHist carrier and operations, so Lean can target $\mathsf{BEDC.Derived.LatticeUp}$ as a BHist-anchored certificate rather than an abstract operator schema.

Lemma 55.88 (Directed meet associativity comparison from bounds)**.** *Let A be a $\mathsf{Lattice}^{\uparrow}$ carrier with order $\leq$ and classifier $\sim_C$. Assume the inherited $\mathsf{Preorder}^{\uparrow}$ transitivity field from Definition 52.44 and the directional meet lower-bound and greatest-lower-bound implication fields from Definition 55.102. Then for all $x, y, z \in A$,*

$$(x \wedge y) \wedge z \leq x \wedge (y \wedge z).$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeet assoc comparison empty`

Proof. Put

$$w = (x \wedge y) \wedge z.$$

The meet lower-left field gives

$$w \leq x \wedge y,$$

and the meet lower-left field applied to $x \wedge y$ gives

$$x \wedge y \leq x.$$

By the inherited preorder transitivity field,

$$w \leq x.$$

The meet lower-right field applied to $x \wedge y$ gives

$$x \wedge y \leq y,$$

so transitivity with $w \leq x \wedge y$ gives

$$w \leq y.$$

The meet lower-right field applied to $w = (x \wedge y) \wedge z$ gives

$$w \leq z.$$

Applying meet greatestness to the two bounds $w \leq y$ and $w \leq z$ gives

$$w \leq y \wedge z.$$

A second application of meet greatestness, now to $w \leq x$ and $w \leq y \wedge z$, gives

$$w \leq x \wedge (y \wedge z).$$

Substituting the displayed definition of w is the required comparison. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeDirectedMeet associativity comparison from bounds`

Lemma 55.89 (Directed join associativity comparison from bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *transitivity field from Definition 52.44 and the directional join upper-bound and least-upper-bound implication fields from Definition 55.102. Then for all $x, y, z \in A$, $(x \vee y) \vee z \leq_C x \vee (y \vee z)$.*

Proof. Put $w = x \vee (y \vee z)$. The join upper-left field gives $x \leq_C w$. The join upper-left field applied to $y \vee z$ gives $y \leq_C y \vee z$, and the join upper-right field applied to $w = x \vee (y \vee z)$ gives $y \vee z \leq_C w$. By the inherited preorder transitivity field, $y \leq_C w$. Applying join leastness to the two bounds $x \leq_C w$ and $y \leq_C w$ gives $x \vee y \leq_C w$. The join upper-right field applied to $y \vee z$ gives $z \leq_C y \vee z$, and transitivity with $y \vee z \leq_C w$ gives $z \leq_C w$. A second application of join leastness, now to $x \vee y \leq_C w$ and $z \leq_C w$, gives $(x \vee y) \vee z \leq_C w$. Substituting the definition of w gives $(x \vee y) \vee z \leq_C x \vee (y \vee z)$. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonJoin directed assoc comparison from bounds`

Lemma 55.90 (Meet absorbs a smaller ordered endpoint)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *reflexivity field from Definition 52.44, the inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry field from Definition 53.43, and the directional meet lower-bound and greatest-lower-bound fields from Definition 55.102. If $x, z \in A$ and $x \leq_C z$, then*

$$z \wedge x \sim_C x.$$

Proof. The meet lower-right field gives

$$z \wedge x \leq_C x.$$

The inherited preorder reflexivity field gives

$$x \leq_C x.$$

Together with the assumed comparison $x \leq_C z$, meet greatestness applied with witness endpoint x and operands z and x gives

$$x \leq_C z \wedge x.$$

The antisymmetry field from Definition 53.43 applied to these two comparisons yields

$$z \wedge x \sim_C x.$$

□

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeMeet absorbs smaller ordered endpoint from bounds`

Lemma 55.91 (Modular lower comparison from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *transitivity field from Definition 52.44 and the directional meet lower-bound, meet greatestness, join upper-bound, and join leastness fields from Definition 55.102. If $x, y, z \in A$ and $x \leq_C z$, then*

$$x \vee (y \wedge z) \leq_C (x \vee y) \wedge z.$$

Proof. Put

$$n = x \vee (y \wedge z), \qquad m = (x \vee y) \wedge z.$$

The join upper-left field gives

$$x \leq_C x \vee y.$$

The meet lower-left field gives

$$y \wedge z \leq_C y,$$

and the join upper-right field gives

$$y \leq_C x \vee y.$$

By transitivity,

$$y \wedge z \leq_C x \vee y.$$

Join leastness with upper target $x \vee y$ gives

$$n \leq_C x \vee y.$$

The assumption gives $x \leq_C z$, and the meet lower-right field gives

$$y \wedge z \leq_C z.$$

Join leastness with upper target z gives

$$n \leq_C z.$$

Meet greatestness applied to the two bounds $n \leq_C x \vee y$ and $n \leq_C z$ gives

$$n \leq_C m.$$

Substituting the displayed definitions of m and n gives the claimed comparison. □

Lean4 ✓ BEDC.Derived.LatticeUp.LatticeModular lower comparison from directional bounds

Theorem 55.92 (Distributivity gives the modular law)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. Assume the classifier symmetry and transitivity fields from Definition 9.7, the inherited* $\mathsf{Preorder}^{\uparrow}$ *reflexivity and transitivity fields from Definition 52.44, the inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry field from Definition 53.43, and the directional meet and join bound-characterization fields from Definition 55.102. Assume also the join classifier-congruence field from Definition 55.101, and suppose the distributive law*

$$a \wedge (b \vee c) \sim_C (a \wedge b) \vee (a \wedge c)$$

holds for all $a, b, c \in A$. If $x, y, z \in A$ and $x \leq_C z$, then

$$x \vee (y \wedge z) \leq_C (x \vee y) \wedge z \qquad \textit{and} \qquad x \vee (y \wedge z) \sim_C (x \vee y) \wedge z.$$

Lean4 ✓ BEDC.Derived.LatticeUp.LatticeSingleton distributivity modular law

Proof. The first conclusion is Definition 55.91.

Put

$$m = (x \vee y) \wedge z, \qquad n = x \vee (y \wedge z).$$

By Definition 55.110, applied to the meet operands $x \vee y$ and z,

$$m \sim_C z \wedge (x \vee y).$$

The assumed distributive law with $a = z$, $b = x$, and $c = y$ gives

$$z \wedge (x \vee y) \sim_C (z \wedge x) \vee (z \wedge y).$$

By Definition 55.90 and the assumption $x \leq_C z$,

$$z \wedge x \sim_C x.$$

By Definition 55.110, applied to the meet operands z and y,

$$z \wedge y \sim_C y \wedge z.$$

Join classifier congruence applied to the last two classifier comparisons gives

$$(z \wedge x) \vee (z \wedge y) \sim_C x \vee (y \wedge z).$$

Classifier transitivity composes the three displayed classifier comparisons into

$$m \sim_C n.$$

Classifier symmetry reverses this comparison, giving

$$n \sim_C m.$$

Substituting the displayed definitions of m and n gives

$$x \vee (y \wedge z) \sim_C (x \vee y) \wedge z.$$

□

Lemma 55.93 (Join-meet lower comparison from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *transitivity field from Definition 52.44 and the directional meet lower-bound, meet greatestness, join upper-bound, and join leastness fields from Definition 55.102. Then for all $a, b, c \in A$,*

$$a \vee (b \wedge c) \leq_C (a \vee b) \wedge (a \vee c).$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonJoinMeet lower comparison empty`

Proof. Put

$$n = a \vee (b \wedge c), \qquad m = (a \vee b) \wedge (a \vee c).$$

The join upper-left field gives

$$a \leq_C a \vee b.$$

The meet lower-left field gives

$$b \wedge c \leq_C b,$$

and the join upper-right field gives

$$b \leq_C a \vee b.$$

By transitivity,

$$b \wedge c \leq_C a \vee b.$$

Join leastness with upper target $a \vee b$ gives

$$n \leq_C a \vee b.$$

Similarly, the join upper-left field gives

$$a \leq_C a \vee c.$$

The meet lower-right field gives

$$b \wedge c \leq_C c,$$

and the join upper-right field gives

$$c \leq_C a \vee c.$$

By transitivity,

$$b \wedge c \leq_C a \vee c.$$

Join leastness with upper target $a \vee c$ gives

$$n \leq_C a \vee c.$$

Meet greatestness applied to the two bounds $n \leq_C a \vee b$ and $n \leq_C a \vee c$ gives

$$n \leq_C m.$$

Substituting the displayed definitions of m and n gives the claimed comparison. □

Theorem 55.94 (Meet distributivity gives join distributivity)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. Assume the classifier symmetry and transitivity fields from Definition 9.7, the inherited* $\mathsf{Preorder}^{\uparrow}$ *reflexivity and transitivity fields from Definition 52.44, the inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry field from Definition 53.43, and the directional meet and join bound-characterization fields from Definition 55.102. Assume also the meet and join classifier-congruence rows from Definition 55.101, and suppose the distributive law*

$$u \wedge (v \vee w) \sim_C (u \wedge v) \vee (u \wedge w)$$

holds for all $u, v, w \in A$. Then for all $a, b, c \in A$,

$$a \vee (b \wedge c) \leq_C (a \vee b) \wedge (a \vee c) \qquad \textit{and} \qquad a \vee (b \wedge c) \sim_C (a \vee b) \wedge (a \vee c).$$

Proof. The first conclusion is Definition 55.93.

Put

$$d = (a \vee b) \wedge (a \vee c), \qquad n = a \vee (b \wedge c).$$

The assumed distributive law with $u = a \vee b$, $v = a$, and $w = c$ gives

$$d \sim_C ((a \vee b) \wedge a) \vee ((a \vee b) \wedge c).$$

By Definition 55.111, applied with $x = a$ and $y = b$,

$$(a \vee b) \wedge a \sim_C a.$$

By Definition 55.110, applied to the meet operands $a \vee b$ and c,

$$(a \vee b) \wedge c \sim_C c \wedge (a \vee b).$$

The assumed distributive law with $u = c$, $v = a$, and $w = b$ gives

$$c \wedge (a \vee b) \sim_C (c \wedge a) \vee (c \wedge b).$$

Classifier transitivity composes the last two comparisons into

$$(a \vee b) \wedge c \sim_C (c \wedge a) \vee (c \wedge b).$$

Join classifier congruence gives

$$((a \vee b) \wedge a) \vee ((a \vee b) \wedge c) \sim_C a \vee ((c \wedge a) \vee (c \wedge b)).$$

Put

$$p = a \vee ((c \wedge a) \vee (c \wedge b)), \qquad q = a \vee (c \wedge b).$$

To compare p and q, first note that the join upper-left field gives $a \leq_C q$. The meet lower-right field gives $c \wedge a \leq_C a$, so transitivity gives $c \wedge a \leq_C q$. The join upper-right field gives $c \wedge b \leq_C q$. Join leastness gives

$$(c \wedge a) \vee (c \wedge b) \leq_C q,$$

and another application of join leastness gives

$$p \leq_C q.$$

Conversely, the join upper-left field gives $a \leq_C p$. The join upper-right field gives

$$(c \wedge a) \vee (c \wedge b) \leq_C p,$$

and the join upper-right field applied to the inner join gives

$$c \wedge b \leq_C (c \wedge a) \vee (c \wedge b).$$

By transitivity, $c \wedge b \leq_C p$. Join leastness gives

$$q \leq_C p.$$

The antisymmetry field from Definition 53.43 applied to $p \leq_C q$ and $q \leq_C p$ yields

$$p \sim_C q.$$

By Definition 55.108, applied with $x = a$ and $y = a$,

$$a \vee (a \wedge a) \sim_C a.$$

Classifier symmetry and transitivity applied to this comparison give

$$a \sim_C a.$$

By Definition 55.110, applied to the meet operands c and b,

$$c \wedge b \sim_C b \wedge c.$$

Join classifier congruence gives

$$q \sim_C n.$$

Classifier transitivity composes the displayed classifier comparisons into

$$d \sim_C n.$$

Classifier symmetry reverses this comparison, giving

$$n \sim_C d.$$

Substituting the displayed definitions of d and n gives

$$a \vee (b \wedge c) \sim_C (a \vee b) \wedge (a \vee c).$$

□

Lemma 55.95 (Lattice meet two-sided monotonicity from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *transitivity field from Definition 52.44 and the directional meet lower-bound and greatest-lower-bound fields from Definition 55.102. If $a, a', b, b' \in A$ with $a \leq_C a'$ and $b \leq_C b'$, then*

$$a \wedge b \leq_C a' \wedge b'.$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeet monotone empty`

Proof. Put

$$w = a \wedge b.$$

The meet lower-left field gives

$$w \leq_C a.$$

Composing this comparison with the assumed comparison $a \leq_C a'$ by the inherited preorder transitivity field gives

$$w \leq_C a'.$$

The meet lower-right field gives

$$w \leq_C b.$$

Composing this comparison with the assumed comparison $b \leq_C b'$ gives

$$w \leq_C b'.$$

Applying meet greatestness to the two bounds $w \leq_C a'$ and $w \leq_C b'$ gives

$$w \leq_C a' \wedge b'.$$

Substituting the displayed definition of w gives the claimed comparison. □

Lemma 55.96 (Join is monotone in both ordered endpoints)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *transitivity field from Definition 52.44 and the directional join upper-bound and least-upper-bound fields from Definition 55.102. If $a, b, a', b' \in A$ with $a \leq_C a'$ and $b \leq_C b'$, then*

$$a \vee b \leq_C a' \vee b'.$$

Proof. Put

$$u = a' \vee b'.$$

The join upper-left field gives

$$a' \leq_C u.$$

Composing the assumed comparison $a \leq_C a'$ with $a' \leq_C u$ by the inherited preorder transitivity field gives

$$a \leq_C u.$$

The join upper-right field gives

$$b' \leq_C u.$$

Composing the assumed comparison $b \leq_C b'$ with $b' \leq_C u$ by the same transitivity field gives

$$b \leq_C u.$$

Applying join leastness to the two upper-bound comparisons $a \leq_C u$ and $b \leq_C u$ gives

$$a \vee b \leq_C u.$$

Substituting the displayed definition of u gives the claimed comparison. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeJoin two sided monotonicity from directional bounds`

Lemma 55.97 (Lattice meet monotonicity in the second argument from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *reflexivity and transitivity fields from Definition 52.44 and the directional meet lower-bound and greatest-lower-bound fields from Definition 55.102. If $b, b', c \in A$ and $b \leq_C b'$, then*

$$c \wedge b \leq_C c \wedge b'.$$

Proof. Put

$$w = c \wedge b.$$

The meet lower-left field gives

$$w \leq_C c.$$

The meet lower-right field gives

$$w \leq_C b.$$

Composing this comparison with the assumed comparison $b \leq_C b'$ by the inherited preorder transitivity field gives

$$w \leq_C b'.$$

Applying meet greatestness to the two bounds $w \leq_C c$ and $w \leq_C b'$ gives

$$w \leq_C c \wedge b'.$$

Substituting the displayed definition of w gives the claimed comparison. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeMeet monotone second argument from directional bounds`

Theorem 55.98 (Lattice operation monotonicity from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with order $\leq_C$ and classifier $\sim_C$. Assume the inherited* $\mathsf{Preorder}^{\uparrow}$ *reflexivity and transitivity fields from Definition 52.44 and the directional meet and join bound-characterization fields from Definition 55.102. If $a, a', b, b', c \in A$ with $a \leq_C a'$ and $b \leq_C b'$, then*

$$a \wedge c \leq_C a' \wedge c, \qquad c \wedge a \leq_C c \wedge a',$$

and

$$b \vee c \leq_C b' \vee c, \qquad c \vee b \leq_C c \vee b'.$$

Proof. The inherited preorder reflexivity field gives

$$c \leq_C c.$$

Apply Definition 55.95 to the comparisons $a \leq_C a'$ and $c \leq_C c$. This gives

$$a \wedge c \leq_C a' \wedge c.$$

Apply the same meet monotonicity lemma to $c \leq_C c$ and $a \leq_C a'$. This gives

$$c \wedge a \leq_C c \wedge a'.$$

Apply Definition 55.96 to $b \leq_C b'$ and $c \leq_C c$. This gives

$$b \vee c \leq_C b' \vee c.$$

Apply the same join monotonicity lemma to $c \leq_C c$ and $b \leq_C b'$. This gives

$$c \vee b \leq_C c \vee b'.$$

Proof. The join upper-left field gives

$$x \leq x \vee (x \wedge y).$$

For the reverse comparison, the inherited preorder reflexivity field gives

$$x \leq x.$$

The meet lower-left field gives

$$x \wedge y \leq x.$$

Applying join leastness with $z = x$, $a = x$, and $b = x \wedge y$, using the two comparisons above, gives

$$x \vee (x \wedge y) \leq x.$$

The inherited poset antisymmetry field applied to

$$x \vee (x \wedge y) \leq x \qquad \text{and} \qquad x \leq x \vee (x \wedge y)$$

yields

$$x \vee (x \wedge y) \sim_C x.$$

□

Theorem 55.109 (Lattice idempotence and absorption from bound characterization)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. Assume the inherited* $\mathsf{POSet}^{\uparrow}$ *reflexivity and antisymmetry fields, and assume the directional meet and join bound-characterization fields:*

$$\begin{gathered}
\forall a\, b,\ a \wedge b \leq a, \qquad \forall a\, b,\ a \wedge b \leq b, \\
\forall z\, a\, b,\ z \leq a \to z \leq b \to z \leq a \wedge b, \\
\forall a\, b,\ a \leq a \vee b, \qquad \forall a\, b,\ b \leq a \vee b, \\
\forall z\, a\, b,\ a \leq z \to b \leq z \to a \vee b \leq z.
\end{gathered}$$

Then for all $x, y \in A$,

$$x \wedge x \sim_C x, \qquad x \vee x \sim_C x, \qquad x \wedge (x \vee y) \sim_C x, \qquad x \vee (x \wedge y) \sim_C x.$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeDirected idempotence absorption from bounds`

Proof. The first assertion is Lemma 55.105. The second assertion is Lemma 55.106. The third assertion is Lemma 55.107. The fourth assertion is Lemma 55.108. □

Theorem 55.110 (Lattice commutativity from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. Assume the inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry field and the directional meet and join bound-characterization fields from Definition 55.102. Then for all $x, y \in A$,*

$$x \wedge y \sim_C y \wedge x, \qquad x \vee y \sim_C y \vee x.$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeDirected commutativity from bounds`

Proof. For the meet comparison, the meet lower-bound laws in Definition 55.102 give

$$x \wedge y \leq x \qquad \text{and} \qquad x \wedge y \leq y.$$

Applying meet greatestness with $z = x \wedge y$, $a = y$, and $b = x$ gives

$$x \wedge y \leq y \wedge x.$$

The same lower-bound laws applied to $y \wedge x$ give

$$y \wedge x \leq y \qquad \text{and} \qquad y \wedge x \leq x.$$

Applying meet greatestness with $z = y \wedge x$, $a = x$, and $b = y$ gives

$$y \wedge x \leq x \wedge y.$$

Since $\mathsf{Lattice}^{\uparrow}$ extends the $\mathsf{POSet}^{\uparrow}$ layer, the antisymmetry field recorded in Definition 53.43 applies to these two comparisons and yields

$$x \wedge y \sim_C y \wedge x.$$

For the join comparison, the join upper-bound laws in Definition 55.102 give

$$y \leq x \vee y \qquad \text{and} \qquad x \leq x \vee y.$$

Applying join leastness with $z = x \vee y$, $a = y$, and $b = x$ gives

$$y \vee x \leq x \vee y.$$

The same upper-bound laws applied to $y \vee x$ give

$$x \leq y \vee x \qquad \text{and} \qquad y \leq y \vee x.$$

Applying join leastness with $z = y \vee x$, $a = x$, and $b = y$ gives

$$x \vee y \leq y \vee x.$$

The inherited antisymmetry field from Definition 53.43 applied to these two comparisons yields

$$x \vee y \sim_C y \vee x.$$

□

Theorem 55.111 (Lattice opposite absorption from directional bounds)**.** *Let A be a $\mathsf{Lattice}^{\uparrow}$ carrier with classifier $\sim_C$. Assume the inherited preorder reflexivity field, the inherited $\mathsf{POSet}^{\uparrow}$ antisymmetry field, and the directional meet and join bound-characterization fields from Definition 55.102. Then for all $x, y \in A$,*

$$x \wedge (y \vee x) \sim_C x, \qquad (x \vee y) \wedge x \sim_C x, \qquad x \vee (y \wedge x) \sim_C x, \qquad (x \wedge y) \vee x \sim_C x.$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeOppositeAbsorptionFromDirectionalBounds`

Proof. The inherited reflexivity field is the preorder reflexivity component of Definition 52.44; the inherited classifier collapse is the antisymmetry component of Definition 53.43. The meet and join directional fields are those listed in Definition 55.102.

For $x \wedge (y \vee x)$, the meet lower-left field gives

$$x \wedge (y \vee x) \leq x.$$

The inherited preorder reflexivity field gives

$$x \leq x.$$

The join upper-right field applied to $y \vee x$ gives

$$x \leq y \vee x.$$

Applying meet greatestness with $z = x$, $a = x$, and $b = y \vee x$, using the two comparisons above, gives

$$x \leq x \wedge (y \vee x).$$

Antisymmetry from Definition 53.43 applied to

$$x \wedge (y \vee x) \leq x \qquad \text{and} \qquad x \leq x \wedge (y \vee x)$$

yields

$$x \wedge (y \vee x) \sim_C x.$$

For $(x \vee y) \wedge x$, the meet lower-right field gives

$$(x \vee y) \wedge x \leq x.$$

The join upper-left field gives

$$x \leq x \vee y.$$

The inherited preorder reflexivity field gives

$$x \leq x.$$

Applying meet greatestness with $z = x$, $a = x \vee y$, and $b = x$, using these two comparisons, gives

$$x \leq (x \vee y) \wedge x.$$

Antisymmetry applied to

$$(x \vee y) \wedge x \leq x \qquad \text{and} \qquad x \leq (x \vee y) \wedge x$$

yields

$$(x \vee y) \wedge x \sim_C x.$$

For $x \vee (y \wedge x)$, the join upper-left field gives

$$x \leq x \vee (y \wedge x).$$

The inherited preorder reflexivity field gives

$$x \leq x.$$

The meet lower-right field applied to $y \wedge x$ gives

$$y \wedge x \leq x.$$

Applying join leastness with $z = x$, $a = x$, and $b = y \wedge x$, using the two comparisons above, gives

$$x \vee (y \wedge x) \leq x.$$

Antisymmetry applied to

$$x \vee (y \wedge x) \leq x \qquad \text{and} \qquad x \leq x \vee (y \wedge x)$$

yields

$$x \vee (y \wedge x) \sim_C x.$$

For $(x \wedge y) \vee x$, the join upper-right field gives

$$x \leq (x \wedge y) \vee x.$$

The meet lower-left field gives

$$x \wedge y \leq x.$$

The inherited preorder reflexivity field gives

$$x \leq x.$$

Applying join leastness with $z = x$, $a = x \wedge y$, and $b = x$, using these two comparisons, gives

$$(x \wedge y) \vee x \leq x.$$

Antisymmetry applied to

$$(x \wedge y) \vee x \leq x \qquad \text{and} \qquad x \leq (x \wedge y) \vee x$$

yields

$$(x \wedge y) \vee x \sim_C x.$$

□

Theorem 55.112 (Lattice bound uniqueness from directional certificates)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. Assume the inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry field from Definition 53.43 and the directional meet and join bound-characterization fields from Definition 55.102. For all $x, y, m, j \in A$, suppose m satisfies the lower-bound and greatestness clauses*

$$m \leq x, \qquad m \leq y,$$
$$\forall z \in A,\ z \leq x \to z \leq y \to z \leq m,$$

and suppose j satisfies the upper-bound and leastness clauses

$$x \leq j, \qquad y \leq j,$$
$$\forall z \in A,\ x \leq z \to y \leq z \to j \leq z.$$

Then

$$m \sim_C x \wedge y, \qquad j \sim_C x \vee y.$$

Proof. The certified meet fields give

$$x \wedge y \leq x \qquad \text{and} \qquad x \wedge y \leq y.$$

Applying the assumed greatestness clause for m with $z = x \wedge y$ gives

$$x \wedge y \leq m.$$

The two assumed lower-bound clauses for m, together with the certified meet greatestness field applied with $z = m$, give

$$m \leq x \wedge y.$$

The antisymmetry field from Definition 53.43 applied to

$$m \leq x \wedge y \qquad \text{and} \qquad x \wedge y \leq m$$

yields

$$m \sim_C x \wedge y.$$

The certified join fields give

$$x \leq x \vee y \qquad \text{and} \qquad y \leq x \vee y.$$

Applying the assumed leastness clause for j with $z = x \vee y$ gives

$$j \leq x \vee y.$$

The two assumed upper-bound clauses for j, together with the certified join leastness field applied with $z = j$, give

$$x \vee y \leq j.$$

The antisymmetry field from Definition 53.43 applied to

$$j \leq x \vee y \qquad \text{and} \qquad x \vee y \leq j$$

yields

$$j \sim_C x \vee y.$$

□

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingleton bound uniqueness from directional certificates`

Definition 55.113 (Concrete unary total-order lattice selectors)**.** *For carried unary histories h, k in $\mathsf{Carrier_u}$, let the active comparison branch be the ledger branch supplied by Definition 54.9. Define the trichotomy lower and upper endpoint selectors by*

$$\mathsf{glb_{tri}}(h,k) := \begin{cases} h, & \textit{on } \mathsf{NatUnaryStrictPrefix}(h,k), \\ h, & \textit{on } \rho_{\mathsf{u}}(h,k), \\ k, & \textit{on } \mathsf{NatUnaryStrictPrefix}(k,h), \end{cases} \qquad \mathsf{lub_{tri}}(h,k) := \begin{cases} k, & \textit{on } \mathsf{NatUnaryStrictPrefix}(h,k), \\ k, & \textit{on } \rho_{\mathsf{u}}(h,k), \\ h, & \textit{on } \mathsf{NatUnaryStrictPrefix}(k,h). \end{cases}$$

The total-order-selected lattice operations are

$$h \wedge_{\mathsf{tri}} k := \mathsf{glb_{tri}}(h,k), \qquad h \vee_{\mathsf{tri}} k := \mathsf{lub_{tri}}(h,k).$$

Theorem 55.114 (Concrete unary $\mathsf{TotalOrder}^{\uparrow}$ forgets to $\mathsf{Lattice}^{\uparrow}$)**.** *The concrete* $\mathsf{TotalOrder}^{\uparrow}$ *naming certificate of Definition 54.20 determines a* $\mathsf{Lattice}^{\uparrow}$ *certificate over the same carrier* $C = \mathsf{Carrier}_{\mathsf{u}}$*, classifier* ρ_{u}*, and order* $\leq_{\mathsf{u}}$*, with meet and join given by Definition 55.113. For every carried pair* $h, k \in C$*, the meet and join classifier-equal the trichotomy endpoint selectors:*

$$\rho_{\mathsf{u}}(h \wedge_{\mathsf{tri}} k, \mathsf{glb}_{\mathsf{tri}}(h,k)) \qquad \textit{and} \qquad \rho_{\mathsf{u}}(h \vee_{\mathsf{tri}} k, \mathsf{lub}_{\mathsf{tri}}(h,k)).$$

The meet bound-characterization rows are the greatest-lower selector rows of Definition 54.12, and the join bound-characterization rows are the least-upper selector rows of Definition 54.10.

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeUnaryPrefix extrema certificate`

Proof. The source, carrier, classifier, relation, and inherited $\mathsf{POSet}^{\uparrow}$ stability rows are those already packaged in Definition 54.20. That theorem cites the concrete unary-prefix $\mathsf{POSet}^{\uparrow}$ naming certificate, so the partial-order reflexivity, transitivity, congruence, and antisymmetry fields required by the lattice interface are already present.

Fix carried unary histories h, k. The comparison partition of Definition 54.9 chooses exactly one of the three branches

$$\mathsf{NatUnaryStrictPrefix}(h,k), \qquad \rho_{\mathsf{u}}(h,k), \qquad \mathsf{NatUnaryStrictPrefix}(k,h).$$

The selector definition follows that same branch ledger: in the strict-left and same branches it chooses h as the lower endpoint and k as the upper endpoint, while in the strict-right branch it chooses k as the lower endpoint and h as the upper endpoint.

The theorem Definition 54.12 supplies, for this selected lower endpoint, a carried history l with

$$l \leq_{\mathsf{u}} h, \qquad l \leq_{\mathsf{u}} k, \qquad (r \leq_{\mathsf{u}} h \wedge r \leq_{\mathsf{u}} k) \Rightarrow r \leq_{\mathsf{u}} l$$

for every carried lower-bound witness r. By the displayed branch definition, this l is precisely $\mathsf{glb}_{\mathsf{tri}}(h,k)$, hence precisely $h \wedge_{\mathsf{tri}} k$. These are the meet lower-bound and meet greatestness rows listed in Definition 55.102.

Similarly, Definition 54.10 supplies, for the selected upper endpoint, a carried history u with

$$h \leq_{\mathsf{u}} u, \qquad k \leq_{\mathsf{u}} u, \qquad (h \leq_{\mathsf{u}} r \wedge k \leq_{\mathsf{u}} r) \Rightarrow u \leq_{\mathsf{u}} r$$

for every carried upper-bound witness r. By the displayed branch definition, this u is precisely $\mathsf{lub}_{\mathsf{tri}}(h,k)$, hence precisely $h \vee_{\mathsf{tri}} k$. These are the join upper-bound and join leastness rows listed in Definition 55.102.

It remains to account for meet and join congruence. Suppose h, h', k, k' are carried and that $\rho_{\mathsf{u}}(h,h')$ and $\rho_{\mathsf{u}}(k,k')$ hold. The branch-transport theorem Definition 54.13 preserves and reflects the strict-left, same, and strict-right branches across these endpoint replacements. If the active branch is strict-left or same, the meet outputs are h and h' and the join outputs are k and k'. If the active branch is strict-right, the meet outputs are k and k' and the join outputs are h and h'. In each case the assumed endpoint classifier witnesses give the required classifier comparison between the selected outputs. Thus meet and join are congruent in both arguments.

The classifier-equality rows in the theorem statement follow from the same selected-readback definition and classifier reflexivity on carried endpoints. The ledger row of Definition 55.103 records the selected comparison branch together with the greatest-lower and least-upper bound certificates just cited. Therefore the tuple with operations $\wedge_{\mathsf{tri}}$ and $\vee_{\mathsf{tri}}$ satisfies the $\mathsf{Lattice}^{\uparrow}$ certificate obligations of Definition 55.104. □

Definition 55.115 (Opposite lattice certificate data)**.** *Let a* $\mathsf{Lattice}^{\uparrow}$ *certificate be presented by a carrier predicate* $\mathcal{C}$*, classifier* $\sim_C$*, order* $\leq_C$*, meet* $\wedge_C$*, and join* $\vee_C$*. Define*

$$a \leq_C^{\mathrm{op}} b := b \leq_C a, \qquad a \wedge_C^{\mathrm{op}} b := a \vee_C b, \qquad a \vee_C^{\mathrm{op}} b := a \wedge_C b.$$

The opposite lattice data C^{op} *have the same carrier predicate* $\mathcal{C}$*, the same classifier* $\sim_C$*, the opposite order* $\leq_C^{\mathrm{op}}$*, meet* $\wedge_C^{\mathrm{op}}$*, and join* $\vee_C^{\mathrm{op}}$*.*

Theorem 55.116 (Opposite lattice certificate)**.** *If* $(\mathcal{C}, \sim_C, \leq_C, \wedge_C, \vee_C)$ *satisfies the* $\mathsf{Lattice}^{\uparrow}$ *certificate obligations of Definition 55.104, then the data of Definition 55.115 also satisfy the* $\mathsf{Lattice}^{\uparrow}$ *certificate obligations.*

Proof. Unpack the lattice obligations through Definition 55.104. By Definition 55.60 and Definition 55.99, the given lattice certificate contains a certified $\mathsf{POSet}^{\uparrow}$ carrier with carrier predicate $\mathcal{C}$, classifier $\sim_C$, and order $\leq_C$. Applying Definition 53.50 supplies the carrier, source, pattern, classifier, stability, and ledger rows for the same carrier and classifier with order $\leq_C^{\mathrm{op}}$.

The binary operation rows are present with names exchanged. The opposite meet $\wedge_C^{\mathrm{op}}$ is the original join $\vee_C$, and the opposite join $\vee_C^{\mathrm{op}}$ is the original meet $\wedge_C$. Thus the carried-operation data required by the lattice source row are copied from the original join and meet data.

It remains to verify the four bound-characterization rows in Definition 55.102. Fix carried endpoints a, b, z. For the opposite meet, the lower-bound laws are exactly the original join upper-bound laws:

$$a \wedge_C^{\mathrm{op}} b \leq_C^{\mathrm{op}} a \iff a \leq_C a \vee_C b, \qquad a \wedge_C^{\mathrm{op}} b \leq_C^{\mathrm{op}} b \iff b \leq_C a \vee_C b.$$

For opposite meet greatestness, assume $z \leq_C^{\mathrm{op}} a$ and $z \leq_C^{\mathrm{op}} b$. These unfold to $a \leq_C z$ and $b \leq_C z$. The original join leastness row gives $a \vee_C b \leq_C z$, which is exactly

$$z \leq_C^{\mathrm{op}} a \wedge_C^{\mathrm{op}} b.$$

For the opposite join, the upper-bound laws are exactly the original meet lower-bound laws:

$$a \leq_C^{\mathrm{op}} a \vee_C^{\mathrm{op}} b \iff a \wedge_C b \leq_C a, \qquad b \leq_C^{\mathrm{op}} a \vee_C^{\mathrm{op}} b \iff a \wedge_C b \leq_C b.$$

For opposite join leastness, assume $a \leq_C^{\mathrm{op}} z$ and $b \leq_C^{\mathrm{op}} z$. These unfold to $z \leq_C a$ and $z \leq_C b$. The original meet greatestness row gives $z \leq_C a \wedge_C b$, which is exactly

$$a \vee_C^{\mathrm{op}} b \leq_C^{\mathrm{op}} z.$$

Meet and join congruence are also exchanged. If $a \sim_C a'$ and $b \sim_C b'$, then original join congruence gives

$$a \wedge_C^{\mathrm{op}} b = a \vee_C b \sim_C a' \vee_C b' = a' \wedge_C^{\mathrm{op}} b',$$

and original meet congruence gives

$$a \vee_C^{\mathrm{op}} b = a \wedge_C b \sim_C a' \wedge_C b' = a' \vee_C^{\mathrm{op}} b'.$$

These are precisely the opposite meet-congruence and opposite join-congruence rows of Definition 55.101.

The pattern row of Definition 55.100 is unchanged expression formation by two binary lattice operations; each opposite meet node is read as an original join node, and each opposite join node is read as an original meet node. The ledger row of Definition 55.103 is the same exchange: an

opposite meet ledger records the original join bound-characterization certificate, and an opposite join ledger records the original meet bound-characterization certificate, with the order witnesses interpreted through $\leq_C^{\mathrm{op}}$. Together with the opposite $\mathsf{POSet}^{\uparrow}$ rows supplied above, these are all carrier, source, pattern, classifier, stability, and ledger obligations required by Definition 55.104. Hence C^{op} carries a $\mathsf{Lattice}^{\uparrow}$ certificate. □

Theorem 55.117 (Double-opposite lattice certificate data identity)**.** *Let E be a $\mathsf{Lattice}^{\uparrow}$ certificate satisfying the obligations of Definition 55.104. Present its lattice data by a carrier predicate $\mathcal{C}$, classifier $\sim_C$, order relation $\leq_C$, meet $\wedge_C$, join $\vee_C$, meet ledger row $\mathcal{L}_C^{\wedge}$, and join ledger row $\mathcal{L}_C^{\vee}$ as in Definition 55.103. Let $E^{\mathrm{opop}} = (E^{\mathrm{op}})^{\mathrm{op}}$ be obtained by applying Definition 55.115 twice. Then E^{opop} is a $\mathsf{Lattice}^{\uparrow}$ certificate, and its carrier predicate, classifier, order relation, meet, join, and lattice ledger rows are componentwise identical to those of E: for carried endpoints a, b,*

$$\begin{aligned} \mathcal{C}^{\mathrm{opop}}(a) &= \mathcal{C}(a), & a \sim_C^{\mathrm{opop}} b &= a \sim_C b, \\ a \leq_C^{\mathrm{opop}} b &= a \leq_C b, & a \wedge_C^{\mathrm{opop}} b &= a \wedge_C b, \\ a \vee_C^{\mathrm{opop}} b &= a \vee_C b, & \mathcal{L}_C^{\wedge,\mathrm{opop}}(a,b) &= \mathcal{L}_C^{\wedge}(a,b), \\ \mathcal{L}_C^{\vee,\mathrm{opop}}(a,b) &= \mathcal{L}_C^{\vee}(a,b). \end{aligned}$$

Proof. Because E satisfies the $\mathsf{Lattice}^{\uparrow}$ obligations, Definition 55.116 makes E^{op} a certified $\mathsf{Lattice}^{\uparrow}$ instance. Applying the same theorem to that certified opposite data makes E^{opop} a certified $\mathsf{Lattice}^{\uparrow}$ instance.

By Definition 55.60 and Definition 55.99, the inherited order part of E is a certified $\mathsf{POSet}^{\uparrow}$ carrier with carrier predicate $\mathcal{C}$, classifier $\sim_C$, and order $\leq_C$. Applying Definition 53.51 to this inherited part gives the carrier, classifier, order, and inherited antisymmetry-ledger identities after two opposites. Hence

$$\mathcal{C}^{\mathrm{opop}}(a) = \mathcal{C}(a), \qquad a \sim_C^{\mathrm{opop}} b = a \sim_C b, \qquad a \leq_C^{\mathrm{opop}} b = a \leq_C b.$$

For the lattice operations, two unfoldings of Definition 55.115 give

$$a \wedge_C^{\mathrm{opop}} b = a \vee_C^{\mathrm{op}} b = a \wedge_C b$$

and

$$a \vee_C^{\mathrm{opop}} b = a \wedge_C^{\mathrm{op}} b = a \vee_C b.$$

Thus the double-opposite meet and join data are exactly the original meet and join data.

The source row is a certified poset carrier plus meet and join operations, so the restored poset part together with the restored operation slots gives the original source row. The pattern row of Definition 55.100 is expression formation by meet and join over carrier witnesses; one opposite exchanges the two operation names and the second exchange restores them.

The stability rows of Definition 55.102 are restored in the same componentwise way. In one opposite, the meet lower-bound and greatestness rows are the original join upper-bound and leastness rows read through the reversed order, while the join rows are the original meet rows read through the reversed order. The second opposite reverses the order again and exchanges the operation slots again, so the meet lower-bound, meet greatestness, join upper-bound, and join leastness rows are the original rows. Meet congruence and join congruence from Definition 55.101 are also exchanged twice and hence restored.

Finally, Definition 55.103 records the operands and the bound-characterization certificate for each meet or join. A single opposite reads a meet ledger as the corresponding original join ledger

and a join ledger as the corresponding original meet ledger, with order witnesses interpreted through $\leq_C^{\mathrm{op}}$. The second opposite performs the same exchange again and the order has already returned to $\leq_C$. Therefore

$$\mathcal{L}_C^{\wedge,\mathrm{opop}}(a,b) = \mathcal{L}_C^{\wedge}(a,b), \qquad \mathcal{L}_C^{\vee,\mathrm{opop}}(a,b) = \mathcal{L}_C^{\vee}(a,b).$$

Together these identities identify the double-opposite lattice certificate data with the original lattice certificate data. □

Theorem 55.118 (Lattice one-sided distributive inequality from directional bounds)**.** *Let A be a* $\mathsf{Lattice}^{\uparrow}$ *carrier with classifier $\sim_C$. Assume the inherited preorder transitivity field and the directional meet and join bound-characterization fields from Definition 55.102. Then for all $x, y, z \in A$,*

$$(x \wedge y) \vee (x \wedge z) \leq x \wedge (y \vee z).$$

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeDirected one sided distributive inequality from bounds`

Proof. Let

$$q := x \wedge (y \vee z).$$

The join leastness field will give the desired comparison once both join inputs are shown to be below q.

For the first input, the meet lower-left field gives

$$x \wedge y \leq x.$$

The meet lower-right field gives

$$x \wedge y \leq y,$$

and the join upper-left field gives

$$y \leq y \vee z.$$

By inherited preorder transitivity from Definition 52.44, these two comparisons compose to

$$x \wedge y \leq y \vee z.$$

Applying meet greatestness to the two comparisons

$$x \wedge y \leq x \qquad \text{and} \qquad x \wedge y \leq y \vee z$$

gives

$$x \wedge y \leq x \wedge (y \vee z),$$

that is,

$$x \wedge y \leq q.$$

For the second input, the meet lower-left field gives

$$x \wedge z \leq x.$$

The meet lower-right field gives

$$x \wedge z \leq z,$$

and the join upper-right field gives

$$z \leq y \vee z.$$

By inherited preorder transitivity, these two comparisons compose to

$$x \wedge z \leq y \vee z.$$

Applying meet greatestness to the two comparisons

$$x \wedge z \leq x \qquad \text{and} \qquad x \wedge z \leq y \vee z$$

gives

$$x \wedge z \leq x \wedge (y \vee z),$$

that is,

$$x \wedge z \leq q.$$

The join leastness field applied with upper bound q to

$$x \wedge y \leq q \qquad \text{and} \qquad x \wedge z \leq q$$

yields

$$(x \wedge y) \vee (x \wedge z) \leq q.$$

Substituting the definition of q gives

$$(x \wedge y) \vee (x \wedge z) \leq x \wedge (y \vee z).$$

□

Chapter 56

A Concrete Naming Certificate for $\mathsf{Interval}^{\uparrow}$

The unit interval interface $\mathsf{Interval}^{\uparrow}$ is licensed over Bishop reals from chapter 38 as the predicate "$0 \leq x$ and $x \leq 1$" interpreted constructively (with explicit moduli for the inequalities). The classifier is real sameness restricted to interval witnesses. It is not a primitive geometric object; it is licensed only as a derived sub-carrier of $\mathsf{Real}^{\uparrow}$.

Remark 56.1 (Interval certificate scope)**.** *This chapter records the interval licensing target as a bounded subcarrier with classifier transport inherited from internal history sameness.*

56.1 Carrier definition

Definition 56.2 (Interval carrier)**.** *Use real witnesses $x : \mathsf{Real}^{\uparrow}$ paired with constructive proofs $0 \leq x$ and $x \leq 1$.*

Theorem 56.3 (Interval empty boundary)**.** *If a history h is internally the same as e, then h inhabits the interval carrier whose lower boundary is $\mathsf{hsame}(\mathsf{e}, -)$ and whose upper boundary is $\mathsf{hsame}(-, \mathsf{e})$.*

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalCarrier empty boundary of hsame`

Proof. Transport the unary empty history across the symmetry of the given $\mathsf{hsame}(h, \mathsf{e})$ witness. The lower boundary uses the symmetric witness, and the upper boundary uses the original witness. □

Theorem 56.4 (Interval empty-boundary carrier iff endpoint)**.** *For the interval carrier whose lower boundary is $\mathsf{hsame}(\mathsf{e}, -)$ and whose upper boundary is $\mathsf{hsame}(-, \mathsf{e})$, carrier membership of h is equivalent to the endpoint witness $\mathsf{hsame}(h, \mathsf{e})$.*

Proof. In the forward direction, eliminate the concrete interval-carrier conjunction and project the upper-boundary witness. In the reverse direction, apply the empty-boundary carrier constructor to the endpoint witness. □

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalCarrier empty boundary iff hsame empty`

Theorem 56.5 (Interval empty boundary hsame transport)**.** *For the interval carrier whose lower boundary is $\mathsf{hsame}(\mathsf{e}, -)$ and whose upper boundary is $\mathsf{hsame}(-, \mathsf{e})$, internal sameness transports carrier membership.*

Proof. Unpack the interval carrier into unary membership and the two boundary witnesses. Unary membership transports along the given hsame witness. The lower boundary composes $\mathsf{hsame}(\mathsf{e}, h)$ with $\mathsf{hsame}(h, k)$, and the upper boundary composes the symmetric witness $\mathsf{hsame}(k, h)$ with $\mathsf{hsame}(h, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalCarrier empty boundary hsame transport`

Definition 56.6 (Interval empty-boundary ledger policy)**.** *The empty-boundary interval ledger records a raw endpoint in the concrete carrier whose lower boundary is* $\mathsf{hsame}(\mathsf{e}, -)$ *and whose upper boundary is* $\mathsf{hsame}(-, \mathsf{e})$*, together with an internal history-sameness link from the raw endpoint to the visible endpoint.*

Lean4 (definition) `BEDC.Derived.IntervalUp.IntervalEmptyBoundaryLedgerPolicy`

Theorem 56.7 (Interval empty-boundary ledger visible carrier)**.** *If an empty-boundary interval ledger relates a raw endpoint to a visible endpoint, then the visible endpoint remains in the same concrete empty-boundary interval carrier.*

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalEmptyBoundaryLedgerPolicy visible carrier`

Proof. Unpack the ledger into raw carrier evidence and the raw-visible hsame link. The empty-boundary carrier transport theorem carries the raw carrier evidence across that link to the visible endpoint. □

Theorem 56.8 (Interval empty-boundary ledger visible no zero endpoint)**.** *No visible endpoint of an empty-boundary interval ledger can have the form* $\mathsf{e0}(t)$*.*

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalEmptyBoundaryLedgerPolicy visible no e0`

Proof. The visible-carrier theorem exposes the transported empty-boundary carrier at $\mathsf{e0}(t)$. Its upper boundary is an $\mathsf{hsame}(\mathsf{e0}(t), \mathsf{e})$ witness, contradicting BEDC history no-confusion. □

Theorem 56.9 (Interval empty-boundary ledger raw-visible classifier)**.** *If an empty-boundary interval ledger relates a raw endpoint to a visible endpoint, then those endpoints satisfy the restricted empty-boundary interval classifier.*

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalEmptyBoundaryLedgerPolicy raw visible classifier`

Proof. Unpack the ledger into raw carrier evidence and the raw-visible hsame link. The visible carrier theorem supplies the visible endpoint carrier, and the two carrier witnesses with the stored link rebuild the interval classifier. □

Theorem 56.10 (Interval empty-boundary ledger classifier endpoint equivalence)**.** *If* IntervalEmptyBoundaryLedger *holds, then every target history w is classified from ρ exactly when it is classified from v by the empty-boundary interval classifier:*

$$\mathsf{IntervalClassifierSpec}_{\mathsf{e}}(\rho, w) \leftrightarrow \mathsf{IntervalClassifierSpec}_{\mathsf{e}}(v, w).$$

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalEmptyBoundaryLedgerPolicy classifier endpoint equivalence`

Proof. The ledger supplies the raw-visible empty-boundary interval classifier. For the raw-to-visible direction, reverse that classifier by symmetry and compose it with the raw-target classifier by transitivity. For the visible-to-raw direction, compose the raw-visible classifier with the visible-target classifier. □

Theorem 56.11 (Interval empty boundary carrier uniqueness)**.** *For the interval carrier whose lower boundary is* $\mathsf{hsame}(\mathsf{e}, -)$ *and whose upper boundary is* $\mathsf{hsame}(-, \mathsf{e})$*, any two carrier inhabitants are internally the same history.*

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalCarrier empty boundary unique`

Proof. Unpack the two carrier witnesses and read their upper-bound witnesses $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$. Compose the first with the symmetry of the second to obtain $\mathsf{hsame}(h, k)$. □

Theorem 56.12 (Interval empty-boundary classifier)**.** *If h and k are both internally the same as* e*, then they satisfy the interval classifier whose lower boundary is* $\mathsf{hsame}(\mathsf{e}, -)$ *and whose upper boundary is* $\mathsf{hsame}(-, \mathsf{e})$*.*

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalClassifierSpec empty boundary of hsame`

Proof. Apply the empty-boundary carrier theorem to h and to k. The classifier relation is $\mathsf{hsame}(h, k)$, obtained by composing $\mathsf{hsame}(h, \mathsf{e})$ with the symmetry of $\mathsf{hsame}(k, \mathsf{e})$. □

Theorem 56.13 (Interval empty-boundary classifier characterization)**.** *For the interval classifier whose lower boundary is* $\mathsf{hsame}(\mathsf{e}, -)$ *and whose upper boundary is* $\mathsf{hsame}(-, \mathsf{e})$*, a pair h, k is classified exactly when both endpoint histories are internally the same as* e*.*

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalClassifierSpec empty boundary iff`

Proof. In the forward direction, eliminate the restricted classifier witness and read the two upper-bound witnesses from the carrier data. In the reverse direction, apply the empty-boundary classifier theorem to the two endpoint witnesses. □

Theorem 56.14 (Interval empty-boundary classifier iff endpoints)**.** *For the interval classifier whose lower boundary is* $\mathsf{hsame}(\mathsf{e}, -)$ *and whose upper boundary is* $\mathsf{hsame}(-, \mathsf{e})$*, a classifier witness between h and k is equivalent to endpoint witnesses* $\mathsf{hsame}(h, \mathsf{e})$ *and* $\mathsf{hsame}(k, \mathsf{e})$*.*

Proof. In one direction, eliminate the restricted classifier witness and project the upper-boundary fields from the two interval carriers. In the other direction, apply the empty-boundary classifier constructor to the two endpoint witnesses. □

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalClassifierSpec empty boundary iff endpoints`

Theorem 56.15 (Interval empty boundary excludes left zero-extension)**.** *For the interval classifier whose lower boundary is* $\mathsf{hsame}(\mathsf{e}, -)$ *and whose upper boundary is* $\mathsf{hsame}(-, \mathsf{e})$*, no classifier witness can have left endpoint* $\mathsf{E0}(t)$*.*

Proof. Eliminate the classifier witness and read the upper-boundary field of the left carrier. It gives $\mathsf{hsame}(\mathsf{E0}(t), \mathsf{e})$, contradicting BEDC history no-confusion for zero-extension versus the empty history. □

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalClassifierSpec empty boundary no e0 left`

56.2 The certificate

Definition 56.16 (Interval source specification)**.** *The source is the Bishop real source restricted to the closed unit interval predicate.*

Definition 56.17 (Interval pattern specification)**.** *The pattern is subcarrier formation by attaching lower and upper bound witnesses to a real.*

Definition 56.18 (Interval classifier specification)**.** *The classifier is* $\mathsf{Real}^{\uparrow}$ *sameness restricted to interval witnesses.*

Theorem 56.19 (Interval classifier transitivity)**.** *If interval classifier witnesses relate h to k and k to r, then they determine an interval classifier witness from h to r.*

Proof. Eliminate both restricted classifier witnesses. The first left carrier and the second right carrier become the endpoint data for the composite classifier, and the underlying history link is the transitive composite of the two hsame witnesses. □

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalClassifierSpec trans`

Theorem 56.20 (Interval classifier symmetry)**.** *If interval classifier witnesses relate h to k, then they determine an interval classifier witness from k to h.*

Proof. Eliminate the restricted classifier witness. The endpoint interval-carrier witnesses are exchanged, and the stored history-sameness link is reversed by symmetry of hsame. □

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalClassifierSpec symm`

Definition 56.21 (Interval stability certificate)**.** *The stability certificate consists of:*

1. *real classifier reflexivity and transitivity*
2. *lower-bound preservation under real sameness*
3. *upper-bound preservation under real sameness*
4. *closure of endpoints* 0 *and* 1
5. *closure of interval operations explicitly proved to preserve bounds*

Definition 56.22 (Interval ledger policy)**.** *Record the real ledger and both inequality moduli.*

Definition 56.23 ($\mathsf{Interval}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Interval}^{\uparrow}$*.*

Theorem 56.24 (Concrete $\mathsf{Interval}^{\uparrow}$ naming certificate)**.** *The bounded-real subcarrier tuple forms a valid NameCert for* $\mathsf{Interval}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.IntervalUp.interval name certificate`

Primitive boundary. $\mathsf{Interval}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 56.25 (Zero-axiom encoding note)**.** *Uses constructive inequality witnesses with moduli rather than classical order trichotomy.*

Closure status for $\mathsf{NameCert}_{\mathsf{Interval}^{\uparrow}}$**.**

Constructive story: An interval endpoint is admitted by taking an existing real-style history surface and attaching lower and upper boundary predicates; in the checked empty-boundary instance, both predicates force the same endpoint, so the carried histories are exactly those history-same to e. The classifier is real or history sameness restricted to histories that satisfy the two boundary witnesses, and in the empty-boundary specialization it is equivalent to both endpoints being classified with e. The source is the bounded-real subcarrier, the pattern records subcarrier formation by lower and upper bounds together with boundary weakening and no-zero-extension rows, and the ledger stores the raw endpoint, the visible endpoint, and the hsame link that transports both boundary witnesses. Because the empty endpoint inhabits the carrier, restricted hsame is reflexive, symmetric, and transitive, and carrier membership transports along history-sameness while preserving both boundaries, the five name-certificate obligations close inside the same history layer. A history h lies in the signature gap of an $\mathsf{Interval}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer endpoint and boundary ledger, and token introduction names that answer as p; unfolded here, h is a bounded endpoint whose lower and upper witnesses match the token, and in the empty-boundary row this collapses to $h$hsamee. Boundary weakening maps may move from a stronger interval predicate to a weaker one by explicit pointwise maps, but no standard bridge to external real intervals is claimed. The chapter registers this bounded-subcarrier construction under the name $\mathsf{Interval}^{\uparrow}$; the interval is not a primitive geometric object, and interval arithmetic, compactness, completeness, and Heine–Borel data are not introduced.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Interval}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The scoped interval certificate binds the bounded-real subcarrier, lower and upper boundary predicates, restricted interval classifier, empty-boundary ledger policy, boundary weakening maps, BHist, and hsame transport.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Interval}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.IntervalUp.interval\_name\_certificate`

Bridge status: paperBridge

Not claimed: General interval arithmetic, compactness of $[0, 1]$, metric completeness, Heine-Borel, and any standard bridge to external real intervals are not closed here.

Upgrade path: No further paper theory-axis upgrade is recorded here; bridge verification remains a separate formal-axis matter.

Theorem 56.26 (Interval carrier boundary weakening)**.** *Let* $\ell_1, \ell_2, u_1, u_2 : \mathsf{BHist} \to \mathsf{Prop}$ *be interval boundary predicates. Suppose that for every history* $h : \mathsf{BHist}$ *there are pointwise boundary maps*

$$\lambda_h : \ell_2(h) \to \ell_1(h), \qquad \upsilon_h : u_2(h) \to u_1(h).$$

Then every inhabitant of the inner interval carrier is an inhabitant of the outer interval carrier:

$$\mathsf{IntervalCarrier}_{\ell_2,u_2}(h) \to \mathsf{IntervalCarrier}_{\ell_1,u_1}(h).$$

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalCarrier boundary weakening`

Proof. By Definition 56.2, an inner carrier witness consists of unary membership for h, a lower-bound witness in $\ell_2(h)$, and an upper-bound witness in $u_2(h)$. Keep the unary membership witness unchanged. Apply the pointwise lower-bound map λ_h to the lower witness, and apply the pointwise upper-bound map υ_h to the upper witness. These three witnesses reconstruct $\mathsf{IntervalCarrier}_{\ell_1,u_1}(h)$ by Definition 56.2. □

Theorem 56.27 (Interval classifier boundary weakening)**.** *Let* $\ell_1, \ell_2, u_1, u_2 : \mathsf{BHist} \to \mathsf{Prop}$ *be interval boundary predicates. Suppose that for every history* $x : \mathsf{BHist}$ *there are pointwise boundary maps*

$$\lambda_x : \ell_2(x) \to \ell_1(x), \qquad \upsilon_x : u_2(x) \to u_1(x).$$

Then for all histories $h, k : \mathsf{BHist}$,

$$\mathsf{IntervalClassifierSpec}_{\ell_2,u_2}(h,k) \to \mathsf{IntervalClassifierSpec}_{\ell_1,u_1}(h,k).$$

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalClassifierSpec boundary weakening`

Proof. Eliminate the inner classifier witness using Definition 56.18. It consists of an $\mathsf{IntervalCarrier}_{\ell_2,u_2}(h)$ witness, an $\mathsf{IntervalCarrier}_{\ell_2,u_2}(k)$ witness, and the stored $\mathsf{hsame}(h,k)$ link. Apply Definition 56.26 at h to obtain $\mathsf{IntervalCarrier}_{\ell_1,u_1}(h)$, and apply the same theorem at k to obtain $\mathsf{IntervalCarrier}_{\ell_1,u_1}(k)$. Rebuild the restricted classifier from these two carrier witnesses and the unchanged stored $\mathsf{hsame}(h,k)$ witness by Definition 56.18. □

Proposition 56.28 (Interval nesting requires boundary eliminators)**.** *There is a finite one-history interpretation of the interval carrier and classifier clauses in which bare symbolic lower- and upper-nesting assumptions hold, the inner interval classifier holds at the unique endpoint, and the outer interval classifier fails at the pair of unique endpoints. Hence the classifier weakening*

$$\mathsf{IntervalClassifierSpec}_{\ell_{\mathrm{in}},u_{\mathrm{in}}}(h,k) \to \mathsf{IntervalClassifierSpec}_{\ell_{\mathrm{out}},u_{\mathrm{out}}}(h,k)$$

is not forced by symbolic nesting data unless that data eliminates to pointwise boundary maps

$$\forall x : \mathsf{BHist},\ \ell_{\mathrm{in}}(x) \to \ell_{\mathrm{out}}(x) \qquad \textit{and} \qquad \forall x : \mathsf{BHist},\ u_{\mathrm{in}}(x) \to u_{\mathrm{out}}(x),$$

as required by Definition 56.27. In the naming-certificate template of Definition 9.6, a classifier-facing nesting field must therefore supply those maps, or data from which those maps are obtained.

Lean4 ✓ `BEDC.Derived.IntervalUp.IntervalClassifierSpec boundary eliminator counterexample`

Proof. Interpret BHist by the singleton set $H = \{\star\}$. Let the unary-history predicate hold at $\star$, and let $\mathsf{hsame}(\star,\star)$ hold. Define the inner and outer boundaries by

$$\ell_{\mathrm{in}}(\star) = \top, \qquad u_{\mathrm{in}}(\star) = \top, \qquad \ell_{\mathrm{out}}(\star) = \bot, \qquad u_{\mathrm{out}}(\star) = \bot.$$

Let the bare symbolic lower-nesting and upper-nesting assumptions be two atomic propositions σ_ℓ and σ_u, both interpreted by $\top$.

By Definition 56.2, $\mathsf{IntervalCarrier}_{\ell_{\mathrm{in}},u_{\mathrm{in}}}(\star)$ holds: its witnesses are the unary-history witness, the true inner lower-bound witness, and the true inner upper-bound witness. Together with $\mathsf{hsame}(\star,\star)$, Definition 56.18 gives

$$\mathsf{IntervalClassifierSpec}_{\ell_{\mathrm{in}},u_{\mathrm{in}}}(\star,\star).$$

If the outer classifier held, Definition 56.18 would expose an outer carrier witness at the left endpoint. Eliminating that carrier by Definition 56.2 would give a witness of $\ell_{\mathrm{out}}(\star)$ and a witness of $u_{\mathrm{out}}(\star)$. These are witnesses of $\bot$, so the outer classifier fails.

A lower-bound eliminator in this interpretation is exactly a map $\top \to \bot$, obtained by evaluating $\forall x : H,\ \ell_{\mathrm{in}}(x) \to \ell_{\mathrm{out}}(x)$ at $\star$. Applying such a map to the true inner lower-bound witness would produce a contradiction. The upper-bound eliminator has the same form after evaluating $\forall x : H,\ u_{\mathrm{in}}(x) \to u_{\mathrm{out}}(x)$ at $\star$. Thus the true symbolic tokens σ_ℓ and σ_u do not determine carrier inclusion; only boundary eliminators, or structure that yields them, can support interval classifier weakening. □

The child file `parts/concrete_instances/metric/l10_sibling_dependency_route.tex` records the structural $\mathsf{Met}^{\uparrow}$ L10 sibling route through chapter 38, chapter 126, chapter 301, and chapter 291.

Chapter 57

A Concrete Naming Certificate for $\mathsf{Met}^{\uparrow}$

57.1 Carrier definition

Definition 57.1 (MetricSpace BHist distance carrier)**.** *A* $\mathsf{Met}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(x, y, d;\ w, c, \pi, \rho, \nu)$$

where x and y are endpoint histories, w is a displayed $\mathsf{MetricDistanceWitness}(x, y, d)$*, c is the componentwise* hsame *transport surface for endpoints and result histories, π is the visible* Cont *provenance of the distance row, ρ is the* Pkg *provenance connecting the packet to the concrete source, and ν is the local* NameCert *ledger for the carrier rows. The value read as a real distance is not an independent host function $C \times C \to \mathsf{Real}^{\uparrow}$; it is the public* $\mathsf{Real}^{\uparrow}$ *distance component exposed through the existing real-distance interface of Definition 57.311.*

The carrier exposes only the displayed finite rows. It contains no ambient host metric, quotient distance, completion operator, or $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricTasteGate single carrier alignment`

57.2 The certificate

Definition 57.2 (MetricSpace source specification)**.** *The source is the finite endpoint packet (x, y) together with its displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *support.*

Lean4 (definition) `BEDC.Derived.MetricUp.MetricSourceSpecification`

Definition 57.3 (MetricSpace pattern specification)**.** *The pattern is metric judgment formation from endpoint histories to displayed* $\mathsf{MetricDistanceWitness}(x, y, d)$ *rows, with the public* $\mathsf{Real}^{\uparrow}$ *distance read only through the real-distance interface.*

Lean4 (definition) `BEDC.Derived.MetricUp.MetricPatternSpecification`

Definition 57.4 (MetricSpace classifier specification)**.** *The classifier is componentwise* hsame *transport on the two endpoint histories and the result history. Distance-witness rows are stable under this transport because the transported packet carries the same* Cont*,* Pkg*, and* NameCert *provenance.*

Lean4 (definition) `BEDC.Derived.MetricUp.MetricClassifierSpecification`
Lean4 ✓ `BEDC.Derived.MetricUp.MetricClassifierSpecification component transport`

Definition 57.5 (MetricSpace stability certificate)**.** *The stability certificate consists of:*

1. *carrier admission for finite endpoint histories and a displayed* MetricDistanceWitness *row;*
2. *componentwise classifier transport for endpoints, result histories, and the visible distance witness;*
3. *symmetry and triangle visibility through the checked* MetricDistanceWitness *rows;*
4. *positive-distance handoff through the scoped* $\mathsf{RealAlgOrder}^{\uparrow}$ *interface;*
5. *ledger exactness excluding host metrics, quotient distances, completion data, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricStabilityCertificate packet rows`

Theorem 57.6 (MetricSpace BHist distance NameCert obligations)**.** *For every* $\mathsf{Met}^{\uparrow}$ *packet of Definition 57.1, the local* NameCert *ledger is accepted exactly when it supplies the following five rows:*

1. *carrier admission for the finite* BHist *endpoint packet* $(x, y, d;\ w, c, \pi, \rho, \nu)$*;*
2. *distance-witness classifier transport along componentwise* hsame*;*
3. *symmetry and triangle visibility by the existing* MetricDistanceWitness *symmetry, visible-context, and triangle boundary rows;*
4. *positive-distance handoff through the scoped* $\mathsf{RealAlgOrder}^{\uparrow}$ *public interface;*
5. *ledger exactness stating that the accepted packet has no host metric, quotient distance, completion coordinate, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Conversely, these five rows repack as the $\mathsf{Met}^{\uparrow}$ *carrier certificate and expose the real-distance value only through the public interface of Definition 57.311.*

Proof. For carrier admission, read the source as the finite endpoint packet of Definition 57.1. Its displayed MetricDistanceWitness row and the local NameCert ledger provide the concrete carrier row, while Pkg records the source provenance.

For classifier transport, use the componentwise hsame rows on the two endpoints and the result history. The visible-context transport theorems for MetricDistanceWitness keep the same Cont and provenance rows, so the transported distance witness remains in the packet.

For symmetry and triangle visibility, apply Definition 57.9, Definition 57.13, and Definition 57.134. These rows expose only finite histories and visible continuation ledgers.

For the positive-distance side, use Definition 57.324 and the public real-distance carrier interface. The handoff reads the same endpoint histories, transport rows, Cont routes, Pkg provenance, and local NameCert rows.

The exactness row is then a direct inventory comparison. Every accepted field has already been listed among BHist, hsame, Cont, Pkg, NameCert, MetricDistanceWitness, and the public $\mathsf{Real}^{\uparrow}$-distance interface, so there is no coordinate through which a host metric, quotient distance, completion object, or $\mathsf{Real}^{\uparrow}$ completeness principle can enter. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricBHistDistance namecert obligations`

The generic MetricDistanceWitness surface is consumed by the $\mathsf{RealMetric}^{\uparrow}$ concrete distance packet in chapter 1638. There the $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAbs}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows supply the displayed distance value before the $\mathsf{Met}^{\uparrow}$ laws are read.

Theorem 57.7 (Metric empty distance witness exactness)**.** *For histories x, y, a concrete distance witness with empty distance ledger is equivalent to both endpoint histories being empty up to the history classifier:*

$$\mathsf{MetricDistanceWitness}(x, y, \mathsf{e}) \iff \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).$$

Proof. In the forward direction, unpack the concrete distance witness. Its continuation field is $\mathsf{Cont}(x, y, \mathsf{e})$, and empty-result inversion for continuation forces both endpoint histories to be empty.

Conversely, case analysis on the two endpoint sameness witnesses reduces the claim to the empty history. The empty endpoint, empty target, and empty distance are unary, and the continuation ledger is the reflexive empty concatenation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty distance iff`

Theorem 57.8 (Metric distance witness depth additivity)**.** *Let* MetricDistanceDepth *be the structural depth of a BEDC history, counting each visible constructor above* e*. For histories x, y, d, every concrete metric distance witness carries exactly the append-depth ledger:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \implies \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(x) + \mathsf{MetricDistanceDepth}(y).$$

Proof. Unpack the concrete witness. Its continuation field is precisely the BEDC append ledger $d = x \cdot y$. The structural-depth equation follows by induction on the right history y, with the empty case reflexive and both visible constructor cases obtained by applying successor congruence to the induction hypothesis. □

Lean4 (definition) `BEDC.Derived.MetricUp.MetricDistanceDepth`
Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness depth add`

Theorem 57.9 (Metric distance witness symmetric classifier)**.** *For unary endpoint histories x, y, if d_{xy} is witnessed by the continuation ledger from x to y and d_{yx} is witnessed by the reversed ledger from y to x, then the two distance histories classify together by* hsame*:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \implies \mathsf{MetricDistanceWitness}(y, x, d_{yx}) \implies \mathsf{hsame}(d_{xy}, d_{yx}).$$

Proof. Unpack the two concrete distance witnesses. The endpoint histories are unary in both directions, and the two displayed continuations are precisely the forward and reversed unary continuation ledgers. Unary continuation commutativity gives $\mathsf{hsame}(d_{xy}, d_{yx})$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness symmetric classifier`

Theorem 57.10 (Metric distance witness prefix closure)**.** *For unary histories p, x, y, d, a unary visible prefix on the first endpoint and the distance ledger preserves the concrete metric distance witness:*

$$\mathsf{UnaryHistory}(p) \implies \mathsf{MetricDistanceWitness}(x, y, d) \implies \mathsf{MetricDistanceWitness}(p \cdot x, y, p \cdot d).$$

Proof. Unpack the witness into unary endpoint and distance histories together with the continuation ledger $d = x \cdot y$. Unary append closure gives unary histories for $p \cdot x$ and $p \cdot d$. The prefixed continuation ledger is exactly the associativity equality $(p \cdot x) \cdot y = p \cdot (x \cdot y)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix closed`

Theorem 57.11 (Metric distance witness prefix iff)**.** *For histories p, x, y, d, a prefixed source and distance witness is equivalent to unary evidence for the prefix together with the unprefixed distance witness:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y, p \cdot d) \iff \mathsf{UnaryHistory}(p) \ \wedge \ \mathsf{MetricDistanceWitness}(x, y, d).$$

Proof. From the prefixed witness, unary append factorization recovers unary evidence for p, x, and d, and continuation prefix cancellation recovers $\mathsf{Cont}(x, y, d)$.

Conversely, unary append closure builds the prefixed source and distance histories, and continuation associativity transports the original ledger $d = x \cdot y$ to $p \cdot d = (p \cdot x) \cdot y$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix iff`

Theorem 57.12 (Metric distance witness suffix iff)**.** *For histories p, x, y, d, a common right suffix on the target and distance is equivalent to unary evidence for the suffix together with the unextended distance witness:*

$$\mathsf{MetricDistanceWitness}(x, y \cdot p, d \cdot p) \iff \mathsf{UnaryHistory}(p) \ \wedge \ \mathsf{MetricDistanceWitness}(x, y, d).$$

Proof. From the suffixed witness, unary append factorization recovers unary evidence for y, p, and d. Reassociation exposes a common right suffix p, and right append cancellation recovers the base continuation $\mathsf{Cont}(x, y, d)$.

Conversely, unary append closure builds the suffixed target and distance histories, and associativity transports the original ledger $d = x \cdot y$ to $d \cdot p = x \cdot (y \cdot p)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness suffix iff`

Theorem 57.13 (Metric distance witness visible-context exactness)**.** *For histories p, q, x, y, d, simultaneous visible ledgers on the source side and target side are exactly equivalent to unary evidence for the two ledgers together with the central distance witness:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{MetricDistanceWitness}(x, y, d).$$

Proof. In the forward direction, apply Definition 57.12 with source $p \cdot x$, target y, distance $p \cdot d$, and suffix q. This recovers $\mathsf{UnaryHistory}(q)$ together with $\mathsf{MetricDistanceWitness}(p{\cdot}x, y, p{\cdot}d)$. Then apply Definition 57.11 to the remaining witness to recover $\mathsf{UnaryHistory}(p)$ and $\mathsf{MetricDistanceWitness}(x, y, d)$.

Conversely, assume unary evidence for p and q together with the central distance witness. Apply Definition 57.11 from right to left to build $\mathsf{MetricDistanceWitness}(p \cdot x, y, p \cdot d)$. Then apply Definition 57.12 from right to left with suffix q to append the visible target ledger and obtain $\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context iff`

Theorem 57.14 (Metric distance witness visible-context empty distance exactness)**.** *For histories p, q, x, y, a visible-context distance witness whose central distance ledger is empty is exactly unary evidence for the visible prefix and suffix together with empty classification of both central endpoints:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}\mathsf{e}){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).$$

Proof. Apply visible-context exactness to peel off the prefix and suffix. The central witness is then $\mathsf{MetricDistanceWitness}(x, y, \mathsf{e})$, which empty-distance exactness identifies with $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$. Conversely, the two empty endpoint classifiers build the central empty-distance witness, and visible-context exactness reattaches the same prefix and suffix. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance iff`

Theorem 57.15 (Metric visible-context empty-distance continuation splice)**.** *For histories p, q, x, y, l, r, m, o, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

and continuations $\mathsf{Cont}(l, x, m)$ and $\mathsf{Cont}(m, r, o)$ hold. Then the empty central endpoint exposed by the witness splices the continuation directly:

$$\mathsf{Cont}(l, r, o).$$

Proof. Apply visible-context empty-distance exactness to the witness. This gives $\mathsf{hsame}(x, \mathsf{e})$. Substitute the empty central endpoint into $\mathsf{Cont}(l, x, m)$, so the first continuation identifies m with l. The second continuation $\mathsf{Cont}(m, r, o)$ is therefore the desired direct continuation $\mathsf{Cont}(l, r, o)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance continuation splice`

Theorem 57.16 (Metric visible-context empty-distance continuation splice determinacy)**.** *For histories $p, q, x, y, l, r, m, o, o'$, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

and continuations $\mathsf{Cont}(l, x, m)$, $\mathsf{Cont}(m, r, o)$, and $\mathsf{Cont}(l, r, o')$ hold. Then the spliced result is determined by the displayed direct continuation:

$$\mathsf{hsame}(o, o').$$

Proof. The visible-context empty-distance continuation splice turns the first two continuations into $\mathsf{Cont}(l, r, o)$. BEDC continuation determinacy compares this spliced continuation with the displayed continuation $\mathsf{Cont}(l, r, o')$, giving $\mathsf{hsame}(o, o')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance continuation splice hsame`

Theorem 57.17 (Metric visible-context empty-distance continuation result determinacy)**.** *For histories p, q, x, y, l, m, n, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

and continuations $\mathsf{Cont}(l, x, m)$ and $\mathsf{Cont}(l, y, n)$ hold. Then the two continuation results are classified together:

$$\mathsf{hsame}(m, n).$$

Proof. Apply visible-context empty-distance exactness to the metric witness. This identifies both central endpoints x and y with e. After substituting these endpoint classifiers, the two displayed continuations have the same left source and the same empty right endpoint. BEDC continuation determinacy therefore compares their results and gives $\mathsf{hsame}(m, n)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance continuation results hsame`

Theorem 57.18 (Metric visible-context empty-distance append unit laws)**.** *For histories* p, q, x, y, l, r*, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q).$$

Then the central endpoints act as append units:

$$x \cdot r = r \quad \wedge \quad l \cdot y = l.$$

Proof. Apply visible-context empty-distance exactness to the witness. This exposes $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$. Substituting these empty endpoints turns the two displayed append equations into the BEDC left and right append unit laws. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance append unit laws`

Theorem 57.19 (Metric visible-context empty-distance endpoint continuation units)**.** *For histories* $p, q, x, y, l, r, o_L, o_R$*, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

and continuations $\mathsf{Cont}(l, x, o_L)$ *and* $\mathsf{Cont}(y, r, o_R)$ *hold. Then both displayed endpoint continuations reduce to unit continuations:*

$$\mathsf{hsame}(o_L, l) \wedge \mathsf{hsame}(o_R, r).$$

Proof. Visible-context empty-distance exactness exposes $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$. After substituting these central endpoints, $\mathsf{Cont}(l, x, o_L)$ is a right-unit continuation and $\mathsf{Cont}(y, r, o_R)$ is a left-unit continuation. The BEDC continuation unit laws therefore give $\mathsf{hsame}(o_L, l)$ and $\mathsf{hsame}(o_R, r)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance endpoint continuation units`

Theorem 57.20 (Metric visible-context empty-distance witness splice)**.** *For histories* p, q, x, y, l, r, m, o*, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

and unary endpoint evidence for l *and* r *hold. If* $\mathsf{Cont}(l, x, m)$ *and* $\mathsf{Cont}(m, r, o)$ *hold, then the spliced continuation is a metric distance witness:*

$$\mathsf{MetricDistanceWitness}(l, r, o).$$

Proof. The visible-context empty-distance continuation splice supplies $\mathsf{Cont}(l, r, o)$. Together with the unary endpoint hypotheses, unary continuation closure gives the unary carrier for o. These three fields are exactly the concrete metric distance witness from l to r with output o. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance witness splice`

Theorem 57.21 (Metric visible-context empty-distance continuation witness depth package)**.** *For histories* $p, q, x, y, l, r, m, o : \mathsf{BHist}$*, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

holds together with $\mathsf{UnaryHistory}(l)$*,* $\mathsf{UnaryHistory}(r)$*,* $\mathsf{Cont}(l, x, m)$*, and* $\mathsf{Cont}(m, r, o)$*. Then the direct continuation carries a metric witness whose depth is induced by the two visible endpoints:*

$$\mathsf{MetricDistanceWitness}(l, r, o) \wedge \mathsf{MetricDistanceDepth}(o) = \mathsf{MetricDistanceDepth}(l) + \mathsf{MetricDistanceDepth}(r).$$

Proof. Apply the visible-context empty-distance continuation splice to the distance witness and the two continuation ledgers. This gives the direct continuation $\mathsf{Cont}(l, r, o)$.

The unary carriers for l and r then close the continuation under the metric distance witness constructor, so the direct continuation packages as $\mathsf{MetricDistanceWitness}(l, r, o)$.

Finally, metric witness depth additivity applied to this witness gives $\mathsf{MetricDistanceDepth}(o) = \mathsf{MetricDistanceDepth}(l) + \mathsf{MetricDistanceDepth}(r)$. Pairing the witness with that displayed equation is the required conjunction. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance continuation witness depth`

Theorem 57.22 (Metric visible-context empty-distance two-sided endpoint witness transport)**.** *For histories* $p, q, x, y, l, r, m, n, o : \mathsf{BHist}$*, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

holds together with $\mathsf{UnaryHistory}(l)$*,* $\mathsf{UnaryHistory}(r)$*,* $\mathsf{Cont}(l, x, m)$*,* $\mathsf{Cont}(y, r, n)$*, and* $\mathsf{Cont}(l, r, o)$*. Then the two reduced endpoint continuations carry the same metric distance witness:*

$$\mathsf{MetricDistanceWitness}(m, n, o).$$

Proof. Apply Definition 57.394 to the visible-context empty-distance witness and the two endpoint continuation ledgers. This gives $\mathsf{hsame}(m, l)$ and $\mathsf{hsame}(n, r)$.

The unary endpoint hypotheses for l and r, together with the direct continuation ledger $\mathsf{Cont}(l, r, o)$, build the concrete direct metric witness $\mathsf{MetricDistanceWitness}(l, r, o)$.

Now use Definition 57.347. Transport the first endpoint along the symmetry of $\mathsf{hsame}(m, l)$, the second endpoint along the symmetry of $\mathsf{hsame}(n, r)$, and the result endpoint along reflexivity of $\mathsf{hsame}(o, o)$. The continuation ledger transports with the same three relations, so the transported fields package as $\mathsf{MetricDistanceWitness}(m, n, o)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance two sided endpoint witness transport`

The ten-field fit is: traditional target visible-context zero-distance splice; BEDC source MetricDistanceWitness plus Cont; carrier MetricDistanceWitness; classifier hsame; stability obligations the two unary carriers and the two continuation ledgers; ledger the hidden empty central distance; core theorem this package; exactness the displayed witness-plus-depth conjunction; standard bridge deferred; and status ProofTarget.

Theorem 57.23 (Metric distance witness visible-context depth additivity)**.** *For histories* p, q, x, y, d*, a visible-context distance witness determines the same central depth equation as the central witness:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(x) + \mathsf{MetricDistanceDep}$$

Proof. Apply Definition 57.13 to recover the central witness $\mathsf{MetricDistanceWitness}(x, y, d)$, then apply Definition 57.8. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context depth add`

Theorem 57.24 (Metric distance witness visible-context result determinacy)**.** *For histories p, q, x, y, d, d', if the same visible endpoint histories carry two visible distance ledgers with central parts d and d', then those central parts classify together:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d'){\cdot}q) \Longrightarrow \mathsf{hsame}(d, d').$$

Proof. Apply Definition 57.13 to the first visible witness. This recovers $\mathsf{MetricDistanceWitness}(x, y, d)$ together with unary evidence for the visible prefix and suffix.

Apply the same visible-context exactness theorem to the second visible witness. This recovers $\mathsf{MetricDistanceWitness}(x, y, d')$ over the same central endpoints.

Unpack the two central witnesses. Their continuation ledgers have the same source endpoint x and target endpoint y, namely $\mathsf{Cont}(x, y, d)$ and $\mathsf{Cont}(x, y, d')$. By continuation determinacy Definition 18.16, their results classify together, giving $\mathsf{hsame}(d, d')$.

The per-object template is as follows. The traditional target is visible metric distance readback. The BEDC source is BHist with Cont and UnaryHistory. The carrier is MetricDistanceWitness and the classifier is hsame. The ledger is the visible prefix and suffix context around the central endpoints. The core theorem is central-result determinacy, exactness is uniqueness of the central distance, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context result deterministic`

Theorem 57.25 (Metric distance witness visible-context prefix-independent result determinacy)**.** *For histories p, q, p', q', x, y, d, e, if two visible distance ledgers have the same central endpoints x and y but possibly different visible prefix and suffix contexts, then their central distance histories classify together:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{MetricDistanceWitness}(p'{\cdot}x, y{\cdot}q', (p'{\cdot}e){\cdot}q') \Longrightarrow \mathsf{hsame}(d, e).$$

Proof. Apply Definition 57.13 to each visible ledger. The first application recovers the central witness $\mathsf{MetricDistanceWitness}(x, y, d)$, while the second recovers $\mathsf{MetricDistanceWitness}(x, y, e)$, independently of the visible prefix and suffix histories. Their continuation fields share the same source and target endpoints, so continuation determinacy gives $\mathsf{hsame}(d, e)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context prefix independent result deterministic`

Theorem 57.26 (Metric distance witness endpoint-hsame result determinacy)**.** *For histories x, x', y, y', d, d', if x classifies with x' and y classifies with y', then two metric distance witnesses over those classified endpoints have classified results:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{MetricDistanceWitness}(x', y', d') \Longrightarrow \mathsf{hsame}(d,$$

Proof. Case-reduce the two endpoint hsame witnesses. The two distance witnesses then display continuation ledgers with the same source and target endpoints. Apply continuation result determinacy to the two continuation fields. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness hsame result deterministic`

Theorem 57.27 (Metric distance witness visible-context endpoint-hsame result determinacy)**.** *For histories $p, q, x, x', y, y', d, d'$, classified central endpoints determine classified central distance results under the same visible prefix and suffix:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{MetricDistanceWitness}(p{\cdot}x', y'{\cdot}q, (p{\cdot}d$$

Proof. Apply Definition 57.13 to both visible ledgers. The first application recovers $\mathsf{MetricDistanceWitness}(x, y, d)$, and the second recovers $\mathsf{MetricDistanceWitness}(x', y', d')$.

The supplied endpoint classifications $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(y, y')$ now match the hypotheses of Definition 57.26, which gives $\mathsf{hsame}(d, d')$ for the central distance histories. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context endpoint hsame result deterministic`

Theorem 57.28 (Metric distance witness visible-context source determinacy)**.** *For histories p, q, x, x', y, d, if two visible distance ledgers share the same visible target endpoint and the same contextual distance result, then their central source endpoints classify together:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{MetricDistanceWitness}(p{\cdot}x', y{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{hsame}(x, x').$$

Proof. Apply Definition 57.13 to both visible ledgers. The first application recovers the central continuation $\mathsf{Cont}(x, y, d)$, and the second recovers $\mathsf{Cont}(x', y, d)$. Continuation right cancellation over the common right endpoint y and common result d gives $\mathsf{hsame}(x, x')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context source deterministic`

Theorem 57.29 (Metric distance witness visible-context target determinacy)**.** *For histories p, q, x, y, y', d, if two visible distance ledgers share the same visible source endpoint and the same contextual distance result, then their central target endpoints classify together:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{MetricDistanceWitness}(p{\cdot}x, y'{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{hsame}(y, y').$$

Proof. Apply Definition 57.13 to both visible ledgers. The first application recovers the central continuation $\mathsf{Cont}(x, y, d)$, and the second recovers $\mathsf{Cont}(x, y', d)$. Continuation left cancellation over the common left endpoint x and common result d gives $\mathsf{hsame}(y, y')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context target deterministic`

Theorem 57.30 (Metric distance witness continuation hsame transport)**.** *For histories x, x', y, y', d, d' : BHist, history-sameness of the two endpoints and of the distance result transports the continuation field exposed by a metric distance witness:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{Cont}(x', y', d').$$

Proof. Case-reduce the three supplied hsame witnesses. The transported endpoints and result are then definitionally the endpoints and result of the original metric distance witness. Project its continuation field $\mathsf{Cont}(x, y, d)$, which is the required transported continuation ledger. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness cont hsame transport`

Theorem 57.31 (Metric distance witness hsame field transport)**.** *For histories x, x', y, y', d, d' : BHist, history-sameness of the two endpoints and of the distance result transports all exposed fields of a metric distance witness:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{UnaryHistory}(x') \wedge \mathsf{UnaryHisto}$$

Proof. Case-reduce the three supplied hsame witnesses. The transported source, target, and distance histories are then definitionally the original fields. Project the three unary carrier fields and the continuation ledger from the metric distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness hsame fields transport`

Theorem 57.32 (Metric distance witness hsame transport depth add)**.** *For histories* x, x', y, y', d, d' : BHist*, history-sameness of the two endpoints and of the distance result transports the continuation field and preserves the append-depth ledger:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{Cont}(x', y', d') \wedge \mathsf{MetricDistanc}$$

Proof. Case-reduce the three supplied hsame witnesses. The transported histories are then the source, target, and distance of the original metric witness. Project its continuation field and apply the metric distance depth-add theorem to the same witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness hsame transport cont depth add`

Theorem 57.33 (Metric distance witness hsame source determinacy)**.** *For histories* x, x', y, y', d, d' : BHist*, if the target and distance ledgers classify by* hsame *and the two concrete metric distance witnesses hold,*

$$\mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{MetricDistanceWitness}(x', y', d'),$$

then the witnesses expose both continuation fields and determine the source:

$$\mathsf{Cont}(x, y, d) \wedge \mathsf{Cont}(x', y', d') \wedge \mathsf{hsame}(x, x').$$

Proof. Project the continuation fields from the two metric distance witnesses. After case-reducing the target and distance hsame witnesses, the continuations share the same right context and result. Continuation right cancellation then identifies the two sources. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness hsame source deterministic`

Theorem 57.34 (Metric distance witness hsame target determinacy)**.** *For histories* x, x', y, y', d, d' : BHist*, if the source and distance ledgers classify by* hsame *and the two concrete metric distance witnesses hold,*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{MetricDistanceWitness}(x', y', d'),$$

then the witnesses expose both continuation fields and determine the target:

$$\mathsf{Cont}(x, y, d) \wedge \mathsf{Cont}(x', y', d') \wedge \mathsf{hsame}(y, y').$$

Proof. Project the continuation fields from the two metric distance witnesses. After case-reducing the source and distance hsame witnesses, the continuations share the same left context and result. Continuation left cancellation then identifies the two targets. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness hsame target deterministic`

Theorem 57.35 (Metric distance witness visible-context hsame source determinacy)**.** *For histories* $p, q, p', q', x, x', y, y', d, d'$: BHist*, if the visible targets and visible distances have the same central target and distance under* hsame*, then the central sources are determined:*

$$\mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(p' \cdot x', y' \cdot q', (p' \cdot d') \cdot q') \Longrightarrow \mathsf{hsame}(x, x').$$

Proof. Apply Definition 57.13 to both visible-context witnesses. This exposes central witnesses $\mathsf{MetricDistanceWitness}(x, y, d)$ and $\mathsf{MetricDistanceWitness}(x', y', d')$. The supplied hsame relations on y, y' and d, d' then fit Definition 57.349, whose source component is the displayed $\mathsf{hsame}(x, x')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context hsame source deterministic`

Theorem 57.36 (Metric distance witness visible-context hsame target determinacy)**.** *For histories* $p, q, p', q', x, x', y, y', d, d' : \mathsf{BHist}$*, if the visible sources and visible distances have the same central source and distance under* hsame*, then the central targets are determined:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(p' \cdot x', y' \cdot q', (p' \cdot d') \cdot q') \Longrightarrow \mathsf{hsame}(y, y').$$

Proof. Apply Definition 57.13 to both visible-context witnesses. This exposes central witnesses $\mathsf{MetricDistanceWitness}(x, y, d)$ and $\mathsf{MetricDistanceWitness}(x', y', d')$. The supplied hsame relations on x, x' and d, d' then fit Definition 57.350, whose target component is the displayed $\mathsf{hsame}(y, y')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context hsame target deterministic`

Theorem 57.37 (Metric distance witness prefix-independent endpoint-hsame result determinacy)**.** *For histories* $p, q, p', q', x, x', y, y', d, e : \mathsf{BHist}$*, if the central endpoints classify by* hsame *while the visible prefixes and suffixes may differ, then the exposed central distance results classify together:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(p' \cdot x', y' \cdot q', (p' \cdot e) \cdot q') \Longrightarrow \mathsf{hsame}(d, e).$$

Proof. Apply visible-context exactness to both metric witnesses. This removes the prefix and suffix contexts and exposes central witnesses $\mathsf{MetricDistanceWitness}(x, y, d)$ and $\mathsf{MetricDistanceWitness}(x', y', e)$. The supplied endpoint classifications then fit the endpoint-hsame result determinacy theorem, giving the displayed $\mathsf{hsame}(d, e)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context prefix independent endpoint hsame result deterministic`

Theorem 57.38 (Metric distance witness visible right tail determinacy)**.** *For histories* $p, q, p', q', x, y, d, d' : \mathsf{BHist}$*, if two visible-context metric witnesses share the central source and the right endpoint* $\mathsf{E1}(y)$*, and their displayed distance results are respectively* $\mathsf{E1}(d)$ *and* $\mathsf{E1}(d')$ *inside their visible contexts, then the distance tails classify together:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, \mathsf{E1}(y) \cdot q, (p \cdot \mathsf{E1}(d)) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(p' \cdot x, \mathsf{E1}(y) \cdot q', (p' \cdot \mathsf{E1}(d')) \cdot q') \Longrightarrow \mathsf{hsame}(d, d').$$

Proof. Visible-context exactness removes the outer prefixes and suffixes, exposing two central metric witnesses with right endpoint $\mathsf{E1}(y)$ and results $\mathsf{E1}(d)$ and $\mathsf{E1}(d')$. Right-$\mathsf{E1}$ result exactness descends both witnesses to their tails, after which continuation determinism identifies the tail distance results. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context right e1 result tail deterministic`

Theorem 57.39 (Metric distance witness visible-context semantic name certificate)**.** *For unary visible contexts p, q and unary central endpoints x, y, the contextual distance predicate $d \mapsto \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q)$ carries a semantic naming certificate with classifier* hsame*:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{UnaryHistory}(x) \Longrightarrow \mathsf{UnaryHistory}(y) \Longrightarrow \mathsf{SemanticNameCert}(d \mapsto \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q))(d \mapsto \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d)$$

Proof. The inhabited carrier is the central distance $x \cdot y$, lifted through visible-context exactness. The classifier is hsame, so its equivalence laws are the kernel history-sameness laws. Transport along the classifier is by case analysis on the history-sameness witness, after which the contextual distance predicate is unchanged. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context semanticNameCert`

Theorem 57.40 (Metric distance witness empty-left exactness)**.** *For histories y, d, a concrete distance witness whose left endpoint is empty is exactly unary evidence for the right endpoint together with the boundary classification of the distance as that endpoint:*

$$\mathsf{MetricDistanceWitness}(\mathsf{e}, y, d) \Longleftrightarrow \mathsf{UnaryHistory}(y) \ \wedge \ \mathsf{hsame}(d, y).$$

Proof. Unpack the distance witness. The continuation ledger has empty left endpoint, so left-unit exactness gives $\mathsf{hsame}(d, y)$, while the witness already contains the unary evidence for y.

Conversely, from unary evidence for y and $\mathsf{hsame}(d, y)$, transport unary evidence from y to d and use the left-unit continuation equivalence to build the concrete distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty left iff`

Theorem 57.41 (Metric distance witness empty-source visible-distance target exactness)**.** *For histories $target, d$, a concrete distance witness from the empty source whose distance ledger is visibly one-headed identifies the target with that same one-headed ledger and exposes unary evidence for the ledger tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{e}, target, \mathsf{E1}(d)) \Longrightarrow target = \mathsf{E1}(d) \wedge \mathsf{UnaryHistory}(d).$$

Proof. Apply empty-left exactness to obtain unary evidence for *target* and the classifier $\mathsf{hsame}(\mathsf{E1}(d), target)$. One-constructor inversion on this classifier presents *target* as $\mathsf{E1}(d)$ up to the exposed tail equality. Substitution into the unary target witness and unary one-step inversion give $\mathsf{UnaryHistory}(d)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty source e1 distance target exactness`

Theorem 57.42 (Metric distance witness empty-target visible-distance source exactness)**.** *For histories $source, d$, a concrete distance witness into the empty target whose distance ledger is visibly one-headed identifies the source with that same one-headed ledger and exposes unary evidence for the ledger tail:*

$$\mathsf{MetricDistanceWitness}(source, \mathsf{e}, \mathsf{E1}(d)) \Longrightarrow source = \mathsf{E1}(d) \wedge \mathsf{UnaryHistory}(d).$$

Proof. Apply empty-right exactness to obtain unary evidence for *source* and the classifier $\mathsf{hsame}(\mathsf{E1}(d), source)$. One-constructor inversion on this classifier presents *source* as $\mathsf{E1}(d)$ up to the exposed tail equality. Substitution into the unary source witness and unary one-step inversion give $\mathsf{UnaryHistory}(d)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty target e1 distance source exactness`

Theorem 57.43 (Metric nonempty distance has a nonempty endpoint)**.** *For histories* x, y, d : BHist*, if* MetricDistanceWitness(x, y, d) *holds and* d *is not history-same as* e*, then at least one endpoint is not history-same as* e*:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to (d\mathsf{hsamee} \to \mathsf{False}) \to ((x\mathsf{hsamee} \to \mathsf{False}) \vee (y\mathsf{hsamee} \to \mathsf{False})).$$

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness nonempty distance endpoint nonempty`

Proof. Case-split the two endpoint histories. A visible endpoint constructor is immediately disjoint from e, giving the required side of the disjunction. In the remaining empty/empty case, the continuation field of the metric witness identifies the distance result with e, contradicting the assumed nonempty distance. □

Theorem 57.44 (Metric nonempty distance endpoint positive depth)**.** *For histories* x, y, d : BHist*, if* MetricDistanceWitness(x, y, d) *holds and* d *is not history-same as* e*, then at least one endpoint has positive structural metric depth:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to (d\mathsf{hsamee} \to \mathsf{False}) \to (0 < \mathsf{MetricDistanceDepth}(x) \vee 0 < \mathsf{MetricDistanceDepth}(y))$$

Proof. Apply the nonempty-distance endpoint theorem to obtain a nonempty endpoint. The positive-depth classifier for metric histories converts that endpoint nonemptiness into positive structural depth on the corresponding side of the disjunction. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness nonempty distance endpoint positive depth`

Theorem 57.45 (Metric positive distance e-one shape)**.** *For histories* x, y, d : BHist*, if* MetricDistanceWitness$(x, y,$ *holds and the structural depth of* d *is not zero, then* d *is visibly one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to (\mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{False}) \to \exists tail,\ d = \mathsf{E1}(tail) \wedge \mathsf{UnaryHistory}(tail).$$

Proof. Unpack the metric distance witness to obtain the unary carrier for the distance history d. Case analysis on d rules out e by the positive depth hypothesis and rules out an E0 head by unary-history inversion. The remaining E1 case exposes its tail, and one-step unary inversion gives the unary tail witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness positive distance e1 shape`

Theorem 57.46 (Metric nonempty distance endpoint e-one cases)**.** *For histories* x, y, d : BHist*, if* MetricDistanceWitness(x, y, d) *holds and the distance endpoint is not history-same as* e*, then at least one endpoint is visibly one-headed with a unary tail:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(x, y, d) \to (d\mathsf{hsamee} \to \mathsf{False}) \to \\ &\quad (\exists x_0,\ x = \mathsf{E1}(x_0) \wedge \mathsf{UnaryHistory}(x_0)) \vee (\exists y_0,\ y = \mathsf{E1}(y_0) \wedge \mathsf{UnaryHistory}(y_0)).\end{aligned}$$

Proof. First apply the endpoint non-emptiness theorem to the metric witness and the nonempty distance assumption. On whichever side is nonempty, use the endpoint's unary-history carrier from the metric witness and apply unary nonempty one-tail readback. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness nonempty distance endpoint e1 cases`

Theorem 57.47 (Metric empty-source nonempty distance target e-one cases)**.** *For histories* $target, dist$: BHist*, if a concrete metric distance witness starts at the empty source and its distance endpoint is not history-same as* e*, then the target endpoint is visibly one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{e}, target, dist) \to (dist\mathsf{hsamee} \to \mathsf{False}) \to \exists targetTail,\ target = \mathsf{E1}(targetTail) \wedge \mathsf{UnaryHist}$$

Proof. Apply the nonempty-distance endpoint e-one cases theorem. The source-side visible branch would identify e with a one-headed history, which is impossible by constructor disjointness. The remaining branch is exactly the target e-one readback. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty source nonempty distance target e1 cases`

Theorem 57.48 (Metric empty-target nonempty distance source e-one cases)**.** *For histories* $source, dist$: BHist*, if a concrete metric distance witness ends at the empty target and its distance endpoint is not history-same as* e*, then the source endpoint is visibly one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(source, \mathsf{e}, dist) \to (dist\mathsf{hsamee} \to \mathsf{False}) \to \exists sourceTail,\ source = \mathsf{E1}(sourceTail) \wedge \mathsf{UnaryH}$$

Proof. Apply the nonempty-distance endpoint e-one cases theorem. The target-side visible branch would identify e with a one-headed history, which is impossible by constructor disjointness. The remaining branch is exactly the source e-one readback. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty target nonempty distance source e1 cases`

Theorem 57.49 (Metric empty-boundary nonempty distance positive endpoint depth)**.** *For histories* $source, target, dist$: BHist*, a concrete metric distance witness with exactly one empty boundary and a nonempty distance endpoint forces positive structural depth on the other endpoint:*

$$(\mathsf{MetricDistanceWitness}(\mathsf{e}, target, dist) \to (dist\mathsf{hsamee} \to \mathsf{False}) \to 0 < \mathsf{MetricDistanceDepth}(target)) \wedge$$
$$(\mathsf{MetricDistanceWitness}(source, \mathsf{e}, dist) \to (dist\mathsf{hsamee} \to \mathsf{False}) \to 0 < \mathsf{MetricDistanceDepth}(source)).$$

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary nonempty distance positive endpoint depth`

Proof. For the empty-source implication, apply Theorem 57.217 to the displayed witness and the nonempty distance hypothesis. The result expresses $target$ as $\mathsf{E1}(targetTail)$ with a unary tail, so the structural metric depth of $target$ is a successor and is therefore positive.

For the empty-target implication, apply Theorem 57.218 in the same way. The source endpoint is read back as $\mathsf{E1}(sourceTail)$ with a unary tail, and the one-headed shape gives positive structural metric depth for $source$. □

The ten-field fit is: traditional target paired empty-boundary nonzero-distance endpoint depth; BEDC source MetricDistanceWitness over BHist; carrier the surviving boundary endpoint; classifier hsame; stability unary one-headed readback and depth positivity; ledger the nonempty distance endpoint; core theorem Theorem 57.219; exactness positive depth on the nonempty boundary endpoint; standard bridge finite unary metric boundary readback; status ProofTarget.

Theorem 57.50 (Metric visible-boundary positive-depth endpoint readback)**.** *For histories* $p, q, source, target, dis$ BHist*, a visible-context metric distance witness with exactly one empty central boundary and positive central distance depth reads back the nonempty central endpoint as one-headed and positive-depth:*

$$(\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, target \cdot q, (p \cdot dist) \cdot q) \to (\mathsf{MetricDistanceDepth}(dist) = 0 \to \mathsf{False}) \to$$
$$\exists targetTail,\ target = \mathsf{E1}(targetTail) \wedge \mathsf{UnaryHistory}(targetTail) \wedge 0 < \mathsf{MetricDistanceDepth}(target)) \wedge$$
$$(\mathsf{MetricDistanceWitness}(p \cdot source, \mathsf{e} \cdot q, (p \cdot dist) \cdot q) \to (\mathsf{MetricDistanceDepth}(dist) = 0 \to \mathsf{False}) \to$$
$$\exists sourceTail,\ source = \mathsf{E1}(sourceTail) \wedge \mathsf{UnaryHistory}(sourceTail) \wedge 0 < \mathsf{MetricDistanceDepth}(source)).$$

Proof. For the empty central source implication, apply Definition 57.13 to peel the visible prefix p and suffix q from the displayed witness. This recovers the central witness $\mathsf{MetricDistanceWitness}(\mathsf{e}, target, dist)$.

The positive-depth hypothesis rules out $\mathsf{MetricDistanceDepth}(dist) = 0$. By Definition 57.253, this is the same nonempty-distance input required by the empty-source e-one cases theorem. Apply Definition 57.217 to obtain $target = \mathsf{E1}(targetTail)$ with unary $targetTail$. The one-headed displayed endpoint has successor structural metric depth, so $0 < \mathsf{MetricDistanceDepth}(target)$.

For the empty central target implication, the same visible-context peeling recovers $\mathsf{MetricDistanceWitness}(source$ The same zero-depth equivalence converts positive depth of $dist$ into the nonempty-distance input, and Definition 57.218 gives $source = \mathsf{E1}(sourceTail)$ with unary $sourceTail$. The displayed one-headed source again has positive structural metric depth. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible boundary positive depth endpoint readback`

Theorem 57.51 (Metric distance witness zero-headed component impossibility)**.** *For histories $x, y, d : \mathsf{BHist}$, no concrete metric distance witness has a zero-headed source, target, or distance component:*

$$(\mathsf{MetricDistanceWitness}(\mathsf{E0}(x), y, d) \to \mathsf{False}) \wedge (\mathsf{MetricDistanceWitness}(x, \mathsf{E0}(y), d) \to \mathsf{False}) \wedge (\mathsf{MetricDistanceWit}$$

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e0 component absurd`

Proof. Unpack the concrete witness. Its three component fields are unary-history evidence for the source, target, and distance histories. BEDC unary histories are generated only from e by $\mathsf{E1}$, so each displayed $\mathsf{E0}$ component contradicts unary no-zero-extension. □

Theorem 57.52 (Metric empty distance visible endpoint impossibility)**.** *For histories x, y, d, tx, ty, if a metric distance witness has a result history-same as e, then neither endpoint can be history-same as a visible one-headed history:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(x, y, d) \to \mathsf{hsame}(d, \mathsf{e}) \to \\ &\quad (\mathsf{hsame}(x, \mathsf{E1}(tx)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y, \mathsf{E1}(ty)) \to \mathsf{False}).\end{aligned}$$

Proof. Transport the continuation result of the metric witness along the displayed distance classifier, obtaining an empty-distance witness over the same endpoints. Empty-distance exactness identifies both endpoints with e. Composing either endpoint comparison with a visible one-headed classifier contradicts the empty/e-one no-confusion theorem. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty distance visible endpoint absurd`

Theorem 57.53 (Metric empty-distance composite endpoint collapse)**.** *For histories x, y, z, d_{xy}, d_{yz}, if $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$ and $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$ both have distance histories classified as e, then all three endpoints classify together:*

$$d_{xy}\mathsf{hsamee} \to d_{yz}\mathsf{hsamee} \to \mathsf{hsame}(x, y) \wedge \mathsf{hsame}(y, z) \wedge \mathsf{hsame}(x, z).$$

Proof. Transport each distance witness to the empty-distance case. Empty-distance exactness identifies the corresponding endpoint pair with e, and transitivity through e gives the three endpoint comparisons. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty distance composite endpoint collapse`

Theorem 57.54 (Metric e1-pair empty-distance impossibility)**.** *For histories x, y : BHist,*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{e}) \to \mathsf{False}.$$

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e1 pair empty distance absurd`

Proof. Apply empty-distance exactness to the displayed metric witness. It forces the left endpoint $\mathsf{E1}(x)$ to be history-same as e, contradicting the disjointness of visible one-headed histories from the empty history. □

Theorem 57.55 (Metric e1 endpoints force e1 distance)**.** *For histories x, y, d : BHist, a metric distance witness between two one-headed endpoints forces the distance history itself to be one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), d) \Longrightarrow \exists d_0 : \mathsf{BHist},\ d = \mathsf{E1}(d_0) \wedge \mathsf{UnaryHistory}(d_0).$$

Proof. Case-analyze the distance history. The empty case contradicts Definition 57.224; the zero-headed case contradicts the unary carrier field of the witness. The one-headed case exposes the displayed tail, and unary inversion supplies its carrier proof. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e1 endpoints distance e1 shape`

Theorem 57.56 (Metric right-boundary visible context distance source)**.** *For histories p, q, x, d : BHist, a visible-context distance witness with empty central right endpoint identifies the central distance with the visible source and gives the same structural depth:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{hsame}(d, x) \wedge \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(x).$$

Proof. Right-boundary visible-context exactness extracts the central classifier $\mathsf{hsame}(d, x)$. Case analysis on that classifier identifies the two histories, and the metric-depth equality follows by reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right boundary visible context distance source`

Theorem 57.57 (Metric right-boundary visible context positive-depth source shape)**.** *For histories p, q, x, d : BHist, a visible-context distance witness with empty central right endpoint and positive central distance depth forces the central source to be visibly one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow (\mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{False}) \Longrightarrow \exists x_0 : \mathsf{BHist},\ x = \mathsf{E1}(x_0) \wedge \mathsf{Ur}$$

Proof. Apply right-boundary visible-context exactness. It exposes unary evidence for the central source and the classifier $\mathsf{hsame}(d, x)$. If x classified as e, transitivity would classify d as e, and the zero-depth classifier would contradict the positive-depth hypothesis. Thus x is a nonempty unary history, so unary nonempty e-one tail readback supplies the required x_0. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right boundary visible context positive depth source e1 shape`

Theorem 57.58 (Metric left-boundary visible-context distance target)**.** *For histories p, q, y, d, a visible-context distance witness whose central left endpoint is empty identifies the central distance with the target and aligns their structural depths:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, y{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{hsame}(d, y) \wedge \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(y).$$

Proof. Apply left-boundary visible-context exactness to peel the visible prefix and suffix. The central empty-left witness gives $\mathsf{hsame}(d, y)$. Case analysis on that classifier reduces the displayed depth equation to reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left boundary visible context distance target`

Theorem 57.59 (Metric distance witness empty-right exactness)**.** *For histories x, d, a concrete distance witness whose right endpoint is empty is exactly unary evidence for the left endpoint together with the boundary classification of the distance as that endpoint:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{e}, d) \iff \mathsf{UnaryHistory}(x) \ \wedge \ \mathsf{hsame}(d, x).$$

Proof. Unpack the distance witness. The witness contains unary evidence for x, and the continuation ledger has empty right endpoint. Right-unit exactness for continuations gives the boundary classifier $\mathsf{hsame}(d, x)$.

Conversely, assume unary evidence for x and $\mathsf{hsame}(d, x)$. Transport unary evidence from x to d along this classifier, then use the right-unit continuation equivalence to build the continuation ledger with right endpoint e. Repacking the unary data and this ledger gives $\mathsf{MetricDistanceWitness}(x, \mathsf{e}, d)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty right iff`

Theorem 57.60 (Metric distance witness left e1 result cases)**.** *For histories x, y, d, a distance witness from a visible left endpoint to a visible result has only the empty middle case or a visible middle tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow (y = \mathsf{e} \wedge \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, d)) \vee (\exists y_1 : \mathsf{BHist}.\ y = \mathsf{E1}(y_1) \wedge \mathsf{Metric}$$

Proof. Unpack the distance witness and invert the continuation ledger with visible result $\mathsf{E1}(d)$. If the middle endpoint is empty, the continuation reduces the visible equality to $\mathsf{hsame}(x, d)$ and the witness supplies unary evidence for x. The zero-tagged middle case contradicts constructor no-confusion. In the visible middle case, strip one $\mathsf{E1}$ constructor from the continuation ledger and repack the remaining unary evidence as the tail distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result cases`

Theorem 57.61 (Metric distance witness left e1 result iff)**.** *For histories x, y, d, a distance witness from a visible left endpoint to a visible result is equivalent to the empty middle case or to a visible middle tail carrying the remaining witness:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \iff (y = \mathsf{e} \wedge \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, d)) \vee (\exists y_1 : \mathsf{BHist}.\ y = \mathsf{E1}(y_1) \wedge \mathsf{Metric}$$

Proof. The forward direction is the visible-result case split. For the reverse direction, the empty middle branch rebuilds the witness from unary closure under $\mathsf{E1}$ and the right-unit continuation law. The visible middle branch adds one visible constructor back to the middle endpoint and result ledger by the one-step continuation rule. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result iff`

Theorem 57.62 (Metric distance witness left e1 result depth addition)**.** *For histories x, y, d, every visible-result distance witness*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d))$$

descends the metric depth identity to the visible tails:

$$\mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(x) + \mathsf{MetricDistanceDepth}(y).$$

Proof. Apply metric-distance depth addition to the displayed witness. The resulting identity has a visible constructor on the source side and on the result side. Normalize the natural-number expression with successor addition, then cancel the shared successor. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result depth add`

Theorem 57.63 (Metric distance witness left e1 result empty target iff)**.** *For histories x, y, d, a metric distance witness from $\mathsf{E1}(x)$ to target y with visible result $\mathsf{E1}(d)$ identifies y with the empty history exactly when the exposed source tail is unary and agrees with the result tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow (\mathsf{hsame}(y, \mathsf{e}) \Longleftrightarrow \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, d)).$$

Proof. Split the target shape. The empty target branch is the right-unit continuation case and reads back the unary source tail and the tail equality. The $e0$ target contradicts the unary target carrier. The visible target branch cannot also have $x\mathsf{hsame}d$: transporting the result to $\mathsf{E1}(x)$ would make $\mathsf{Cont}(\mathsf{E1}(x), \mathsf{E1}(y_1), \mathsf{E1}(x))$, so right-unit uniqueness would identify $\mathsf{E1}(y_1)$ with e, contradicting constructor disjointness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result empty target iff`

Theorem 57.64 (Metric distance witness left e1 result hsame source)**.** *For histories x, x', y, d, a distance witness from $\mathsf{E1}(x)$ to a visible result keeps the same empty-or-visible alternative after transporting the displayed source payload along $\mathsf{hsame}(x, x')$:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow \mathsf{hsame}(x, x') \Longrightarrow (y = \mathsf{e} \wedge \mathsf{UnaryHistory}(x') \wedge \mathsf{hsame}(x', d)) \vee (\exists y_1 : \mathsf{BHist}.$$

Proof. Case-reduce the source hsame witness. The transported payload is then definitionally the original payload, and the established visible-result split gives the displayed empty target or visible target branch. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result hsame source`

Theorem 57.65 (Metric distance witness left e1 result hsame target)**.** *For histories x, y, y', d, a distance witness from a visible left endpoint to a visible result keeps the same empty-or-visible target alternative after transporting the target presentation along $\mathsf{hsame}(y, y')$:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow (y' = \mathsf{e} \wedge \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, d)) \vee (\exists y_1 : \mathsf{BHist}. y$$

Proof. Apply the visible-result case split. In the empty branch, empty-history inversion transports the displayed target to e. In the visible branch, one-constructor inversion of $\mathsf{hsame}(\mathsf{E1}(y_0), y')$ exposes $y' = \mathsf{E1}(y_1)$ and $y_0\mathsf{hsame}y_1$; unary and continuation transport carry the tail metric witness to the displayed target tail. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result hsame target`

Theorem 57.66 (Metric distance witness left e1 result hsame result)**.** *For histories x, y, d, d', a distance witness from a visible left endpoint to a visible result keeps the same empty-or-visible target alternative after transporting the displayed result tail along* $\mathsf{hsame}(d, d')$*:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow (y = \mathsf{e} \wedge \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, d')) \vee (\exists y_1 : \mathsf{BHist}.\ y$$

Proof. First lift the result-tail agreement through the visible constructor, obtaining $\mathsf{hsame}(\mathsf{E1}(d), \mathsf{E1}(d'))$. The metric hsame transport field is then applied with reflexive source and target transports, so the original witness repacks as $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d'))$.

Apply Theorem 57.286 to this transported witness. The empty target branch gives $\mathsf{UnaryHistory}(x)$ and $\mathsf{hsame}(x, d')$; the visible target branch gives a tail y_1 with $y = \mathsf{E1}(y_1)$ and $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y_1, d')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result hsame result`

Theorem 57.67 (Metric distance witness left e1 result tail determinism)**.** *For histories x, y, d, d', two visible-result distance witnesses with the same visible left endpoint and target determine the same result tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d')) \Longrightarrow \mathsf{hsame}(d, d').$$

Proof. Unpack the two distance witnesses only to their continuation ledgers. BEDC continuation determinacy gives $\mathsf{hsame}(\mathsf{E1}(d), \mathsf{E1}(d'))$ for the two visible results. One-constructor inversion for $\mathsf{E1}$ then descends this classifier to $\mathsf{hsame}(d, d')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result tail deterministic`

Theorem 57.68 (Metric distance witness left e1 result shape)**.** *For histories x, y, d, every distance witness from* $\mathsf{E1}(x)$ *has a visible result shape:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d) \Longrightarrow \exists k : \mathsf{BHist}.\ \mathsf{hsame}(d, \mathsf{E1}(k)) \wedge \Big((y = \mathsf{e} \wedge \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, k)) \vee \exists y_1 : \mathsf{B}$$

Proof. Decompose the result history. An empty result is incompatible with a visible left endpoint and the continuation equation; an $\mathsf{E0}$ result is incompatible with the unary distance carrier. In the $\mathsf{E1}(k)$ case, the established visible-result split gives either the empty target boundary or the visible target tail witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result shape`

Theorem 57.69 (Metric distance witness one-headed left empty-target exactness)**.** *For histories x, d, a distance witness from a visible left endpoint to an empty right endpoint with visible result exposes the unary tail and identifies the result tail with the left tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{e}, \mathsf{E1}(d)) \Longrightarrow \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(d, x).$$

Proof. Unpack the distance witness. Unary inversion removes the visible constructor from the left endpoint carrier. The continuation ledger has empty right endpoint, so right-unit exactness identifies $\mathsf{E1}(d)$ with $\mathsf{E1}(x)$; then one-constructor cancellation yields $\mathsf{hsame}(d, x)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 empty target exactness`

Theorem 57.70 (Metric distance witness left e1 visible target exactness)**.** *For histories x, y, d, y_1, a distance witness whose left endpoint and result are visible descends across a visible presentation of the target endpoint:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow \mathsf{hsame}(y, \mathsf{E1}(y_1)) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y_1, d).$$

Proof. Apply the left visible-result case split. The empty-middle branch contradicts the displayed visible presentation of y. In the visible-middle branch, strip the $\mathsf{E1}$ constructor from that presentation and transport the recovered tail witness along the resulting hsame equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target exactness`

Theorem 57.71 (Metric distance witness left e1 visible target step)**.** *For histories x, y, d, a distance witness from $\mathsf{E1}(x)$ to y with result d remains a distance witness after placing the target and result under one visible $\mathsf{E1}$ constructor:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d)).$$

Proof. Unpack the witness into unary carriers and the continuation ledger. Unary closure supplies carriers for $\mathsf{E1}(y)$ and $\mathsf{E1}(d)$, and the continuation step rule lifts the same ledger from target y and result d to target $\mathsf{E1}(y)$ and result $\mathsf{E1}(d)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target step`

Theorem 57.72 (Metric distance witness left e1 visible target result shape)**.** *For histories x, y, d, any distance witness from $\mathsf{E1}(x)$ to $\mathsf{E1}(y)$ has a visible result tail, and that tail is again the distance witness from $\mathsf{E1}(x)$ to y:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), d) \Longrightarrow \exists k.\ \mathsf{hsame}(d, \mathsf{E1}(k)) \wedge \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, k).$$

Proof. Apply the left visible-result shape split to the displayed witness. The empty-target branch would identify $\mathsf{E1}(y)$ with e, contradicting constructor no-confusion. The remaining visible branch supplies the result tail k and the descended witness with target y. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target result shape`

Theorem 57.73 (Metric distance witness left e1 visible target result tail exactness)**.** *For histories x, y, d, k, if a distance witness from $\mathsf{E1}(x)$ to $\mathsf{E1}(y)$ has displayed result history-same as $\mathsf{E1}(k)$, then k is the descended distance result from $\mathsf{E1}(x)$ to y:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), d) \Longrightarrow \mathsf{hsame}(d, \mathsf{E1}(k)) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, k).$$

Proof. Apply the visible-target result shape theorem to expose a result tail k_0, a displayed comparison $\mathsf{hsame}(d, \mathsf{E1}(k_0))$, and the descended witness. Composing this comparison with the assumed comparison to $\mathsf{E1}(k)$ gives a one-headed history-sameness relation between $\mathsf{E1}(k_0)$ and $\mathsf{E1}(k)$. Constructor inversion descends it to $\mathsf{hsame}(k_0, k)$, and tail transport returns the displayed witness at k. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target result tail hsame exact`

Theorem 57.74 (Metric distance witness left e1 visible target result-source absurd)**.** *For histories x, y, d, a distance witness from $\mathsf{E1}(x)$ to $\mathsf{E1}(y)$ with visible result $\mathsf{E1}(d)$ cannot also identify the descended result d with the visible source $\mathsf{E1}(x)$ when the target tail is nonempty:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d)) \Longrightarrow (\mathsf{hsame}(y, \mathsf{e}) \Rightarrow \bot) \Longrightarrow \mathsf{hsame}(d, \mathsf{E1}(x)) \Longrightarrow \bot.$$

Proof. Right-visible result exactness descends the witness to $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d)$. Transporting its continuation result across $\mathsf{hsame}(d, \mathsf{E1}(x))$ makes y a right-unit continuation at $\mathsf{E1}(x)$, so right-unit uniqueness gives $\mathsf{hsame}(y, \mathsf{e})$, contradicting the displayed nonempty target-tail hypothesis. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target result source absurd`

Theorem 57.75 (Metric distance witness left e1 source step)**.** *For histories x, y, d, a distance witness from x to y with result d remains a distance witness after placing the source and result under one visible $\mathsf{E1}$ constructor:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)).$$

Proof. Unpack the witness into unary carriers and the continuation ledger $d = x \cdot y$. Unary closure supplies the new source and result carriers. Since y is unary, the append law rewrites $\mathsf{E1}(x) \cdot y$ as $\mathsf{E1}(x \cdot y)$, so the lifted result $\mathsf{E1}(d)$ satisfies the required continuation equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 source step`

Theorem 57.76 (Metric distance witness left e1 source iff)**.** *For histories x, y, d, placing the source and result under one visible $\mathsf{E1}$ constructor is reversible:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longleftrightarrow \mathsf{MetricDistanceWitness}(x, y, d).$$

Proof. The reverse direction is Theorem 57.298. For the forward direction, split on the target history. The empty target case is the right empty-boundary exactness of the metric witness. A zero-headed target contradicts the unary target carrier recorded in the witness. In the one-headed target case, the result equation descends through the visible constructor, and unary append commutes the visible source constructor across the unary target tail, giving the original continuation ledger. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 source iff`

Theorem 57.77 (Metric distance witness left e1 source result iff)**.** *For histories x, y, d, placing both the source and result under one visible $\mathsf{E1}$ constructor is reversible:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longleftrightarrow \mathsf{MetricDistanceWitness}(x, y, d).$$

Proof. For the forward direction, unpack the displayed witness. Unary inversion on the source and result gives unary carriers for x and d. The continuation ledger identifies $\mathsf{E1}(d)$ with $\mathsf{E1}(x) \cdot y$, and the unary append law for the target rewrites the right side to $\mathsf{E1}(x \cdot y)$; constructor inversion exposes the descended continuation ledger $d = x \cdot y$.

For the reverse direction, apply Definition 57.298. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 source result iff`

Theorem 57.78 (Metric distance witness left e1 visible target iff)**.** *For histories x, y, d, placing both the target and result under one visible* E1 *constructor is reversible for a visible left endpoint:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d)) \iff \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d).$$

Proof. For the forward direction, apply Theorem 57.70 to the displayed witness with the reflexive presentation $\mathsf{hsame}(\mathsf{E1}(y), \mathsf{E1}(y))$. This strips the visible target presentation and returns the tail witness with target y and result d.

For the reverse direction, apply Theorem 57.294. The visible target constructor and matching visible result constructor are restored by the continuation step rule. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target iff`

The ten-field fit is: traditional target visible unary metric descent/extension; BEDC source BHist with UnaryHistory and Cont; carrier MetricDistanceWitness; classifier hsame; ledger one visible target constructor; core theorem Theorem 57.301; exactness reversible target-step readback; status ProofTarget.

Theorem 57.79 (Metric distance witness right e1 result exactness)**.** *For histories x, y, d, a distance witness with right endpoint and result both under one visible constructor descends to the tail witness:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d).$$

Proof. Unpack the distance witness into unary carrier fields and the continuation ledger. Unary inversion removes the visible constructor from the right endpoint and result carriers. The continuation step-rule inversion removes the same right-side constructor from the continuation ledger, and the four fields repack as $\mathsf{MetricDistanceWitness}(x, y, d)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result exactness`

Theorem 57.80 (Metric distance witness right e1 result shape)**.** *For histories x, y, d, every concrete metric distance witness whose right endpoint is visibly one-headed has a visibly one-headed distance ledger, and the exposed distance tail is again the metric witness for the exposed right endpoint:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), d) \Longrightarrow \exists k : \mathsf{BHist}.\ \mathsf{hsame}(d, \mathsf{E1}(k)) \wedge \mathsf{MetricDistanceWitness}(x, y, k).$$

Proof. Unpack the distance witness into unary carrier fields and the continuation ledger. The continuation result has the form $d = x \cdot \mathsf{E1}(y)$, which is definitionally $\mathsf{E1}(x \cdot y)$. Choose $k = x \cdot y$. Unary inversion on the visible right endpoint gives the carrier for y, unary append closure gives the carrier for k, and the canonical append equality gives the descended continuation ledger. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result shape`

Theorem 57.81 (Metric distance witness right e1 result not empty)**.** *For histories x, y, d, no concrete metric distance witness whose right endpoint is visibly one-headed can have a distance result history-same to* e*:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), d) \Longrightarrow \mathsf{hsame}(d, \mathsf{e}) \Longrightarrow \bot.$$

Proof. Apply the right e-one result shape theorem to expose a tail k with $\mathsf{hsame}(d, \mathsf{E1}(k))$. Composing this with $\mathsf{hsame}(d, \mathsf{e})$ gives $\mathsf{hsame}(\mathsf{E1}(k), \mathsf{e})$, contradicting constructor disjointness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result not empty`

Theorem 57.82 (Metric distance witness right e1 result e0 absurd)**.** *For histories x, y, d, no concrete metric distance witness can have a visibly one-headed right endpoint while its distance result is visibly zero-headed:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E0}(d)) \Longrightarrow \bot.$$

Proof. Apply the right e-one result shape theorem to the witness. It exposes a tail k with $\mathsf{hsame}(\mathsf{E0}(d), \mathsf{E1}(k))$. Constructor no-confusion for generated history sameness rejects this zero-headed versus one-headed comparison. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result e0 absurd`

Theorem 57.83 (Metric distance witness right e1 result tail exactness)**.** *For histories x, y, d, k, if a distance witness has a visibly one-headed right endpoint and its displayed result is history-same as $\mathsf{E1}(k)$, then k is the exact descended distance tail:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), d) \Longrightarrow \mathsf{hsame}(d, \mathsf{E1}(k)) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, k).$$

Proof. Apply right e-one result shape to expose an intermediate tail k_0 together with $\mathsf{hsame}(d, \mathsf{E1}(k_0))$ and the descended metric witness. Compose this classifier with the displayed result classifier, invert the resulting one-headed hsame comparison, and transport the tail witness along the exposed tail equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result tail hsame exact`

Theorem 57.84 (Metric distance witness right e1 result tail determinism)**.** *For histories x, y, d, d', two metric distance witnesses with the same source, the same visible right endpoint, and visible results determine the same result tail:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \Longrightarrow \mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d')) \Longrightarrow \mathsf{hsame}(d, d').$$

Proof. Project the continuation ledgers from the two metric witnesses. Continuation determinacy identifies the visible results $\mathsf{hsame}(\mathsf{E1}(d), \mathsf{E1}(d'))$, and one-constructor inversion descends this classifier to the tail relation $\mathsf{hsame}(d, d')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result tail deterministic`

Theorem 57.85 (Metric distance witness right e1 source shape)**.** *For histories x, y, d, every concrete metric distance witness whose right endpoint is visibly one-headed exposes a visible distance tail and the matching empty-or-visible source alternative:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), d) \Longrightarrow \exists k : \mathsf{BHist}.\ \mathsf{hsame}(d, \mathsf{E1}(k)) \wedge \Big((x = \mathsf{e} \wedge \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(k, y)) \vee \exists x_1 : \mathsf{E}$$

Proof. Apply Definition 57.330 to the given witness. This produces a history k, a displayed result comparison $\mathsf{hsame}(d, \mathsf{E1}(k))$, and the descended witness $\mathsf{MetricDistanceWitness}(x, y, k)$.

We next rebuild the displayed-result witness with result $\mathsf{E1}(k)$. Keep the original source and right endpoint carriers, close the descended tail carrier under $\mathsf{E1}$, and transport the original continuation field along $\mathsf{hsame}(d, \mathsf{E1}(k))$.

Apply Definition 57.94 to this displayed-result witness. In the empty branch, keep the same k and record $x = \mathsf{e}$, the unary carrier for y, and $\mathsf{hsame}(k, y)$. In the visible branch, keep the same k and the exposed x_1, together with $x = \mathsf{E1}(x_1)$ and the descended metric witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 source shape`

Theorem 57.86 (Metric distance witness right e1 result iff)**.** *For histories x, y, d, a distance witness whose right endpoint and result both carry one visible constructor is equivalent to the descended tail witness:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \Longleftrightarrow \mathsf{MetricDistanceWitness}(x, y, d).$$

Proof. The forward direction is right one-headed result exactness. For the reverse direction, keep the source unary carrier, close the right endpoint and result carriers under $\mathsf{E1}$, and lift the continuation ledger by the one-step continuation rule. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result iff`

Theorem 57.87 (Metric distance witness right e1 result hsame source)**.** *For histories x, x', y, d, a distance witness whose right endpoint and result both carry one visible constructor has the same empty-or-visible source readback after source transport:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \wedge \mathsf{hsame}(x, x') \Longrightarrow (x' = \mathsf{e} \wedge \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(d, y))$$

or there exists $x_1 : \mathsf{BHist}$ such that

$$x' = \mathsf{E1}(x_1) \wedge \mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y, d).$$

Proof. Apply the right one-headed source case split before transport. In the empty branch, empty hsame inversion identifies x' with e. In the visible branch, visible hsame inversion exposes the transported tail, and unary and continuation transport rebuild the descended metric witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result hsame source`

Theorem 57.88 (Metric distance witness right e1 result hsame target)**.** *For histories x, y, y', d, a distance witness whose right endpoint and result both carry one visible constructor has the same empty-or-visible source readback after target-tail transport:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \wedge \mathsf{hsame}(y, y') \Longrightarrow (x = \mathsf{e} \wedge \mathsf{UnaryHistory}(y') \wedge \mathsf{hsame}(d, y'))$$

or there exists $x_1 : \mathsf{BHist}$ such that

$$x = \mathsf{E1}(x_1) \wedge \mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y', d).$$

Proof. Apply the right one-headed source case split before target transport. In the empty-source branch, transport the unary carrier and compose the displayed result-tail comparison with $\mathsf{hsame}(y, y')$. In the visible-source branch, keep the exposed source tail and transport the target carrier and continuation ledger across the target-tail classifier, leaving the source and result endpoints fixed. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result hsame target`

Theorem 57.89 (Metric right e-one result two-sided endpoint transport)**.** *For histories x, x', y, y', d, simultaneous source and target-tail transport preserves the empty-or-visible readback of a right e-one metric result:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \wedge \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \Longrightarrow (x' = \mathsf{e} \wedge \mathsf{UnaryHistory}(y') \wedge \mathsf{hsame}(d, y'))$$

or there exists $x_1 : \mathsf{BHist}$ such that

$$x' = \mathsf{E1}(x_1) \wedge \mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y', d).$$

Proof. First apply Definition 57.337 to the displayed witness and the supplied $\mathsf{hsame}(x, x')$. This gives the transported source readback with target tail y still fixed.

In the empty-source branch, keep $x' = \mathsf{e}$. Transport the unary carrier from y to y' along $\mathsf{hsame}(y, y')$, and compose the displayed comparison $\mathsf{hsame}(d, y)$ with $\mathsf{hsame}(y, y')$ to obtain $\mathsf{hsame}(d, y')$.

In the visible-source branch, keep the exposed x_1 and the equality $x' = \mathsf{E1}(x_1)$. The descended witness $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y, d)$ supplies the source, target, and result carriers; unary transport moves the target carrier from y to y', while metric continuation transport carries the continuation ledger across the same target-tail classifier with source and result fixed. Repacking these fields gives $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y', d)$.

Ten-field fit: traditional target two-sided visible endpoint transport; BEDC source BHist, hsame, and MetricDistanceWitness; carrier unary metric endpoints; classifier hsame; stability source and target-tail transport; ledger exposed right e-one distance tail; core theorem Definition 57.339; exactness simultaneous transported source readback; standard bridge finite unary metric endpoint transport; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result two sided endpoint transport`

Theorem 57.90 (Metric e-one pair result tail readback)**.** *For histories x, y, d, a metric distance witness whose source, target, and result are all visibly one-headed exposes unary source and target tails and the tail continuation ledger:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d)) \Longrightarrow \mathsf{UnaryHistory}(x) \wedge \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(d, \mathsf{E1}(x) \cdot y).$$

Proof. Apply right e-one result exactness to descend the target and result to $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d)$. Unary inversion on the source carrier gives unary evidence for x, the descended witness carries unary evidence for y, and its continuation ledger is exactly $d\mathsf{hsameE1}(x) \cdot y$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e1 pair result tail readback`

Theorem 57.91 (Metric e-one pair result tail exactness iff)**.** *For histories x, y, d, a metric distance witness whose source, target, and result are all visibly one-headed is equivalent to unary tail data together with the exposed continuation ledger:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d)) \Longleftrightarrow \mathsf{UnaryHistory}(x) \wedge \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(d, \mathsf{E1}(x) \cdot y).$$

Proof. For the forward direction, apply Theorem 57.340. It descends the visible target and result constructors and returns exactly the two unary tail carriers and the displayed continuation ledger.

For the reverse direction, start from the unary tail carriers and the hsame ledger. Unary closure builds the source carrier $\mathsf{UnaryHistory}(\mathsf{E1}(x))$, and the continuation ledger transports the append result so that d is the concrete distance from $\mathsf{E1}(x)$ to y. This gives the central witness $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d)$.

Apply Theorem 57.294 to this central witness. The visible target constructor and the matching visible result constructor are restored, producing $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d))$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e1 pair result iff`
Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e1 pair result tail exactness iff`

The ten-field fit is: traditional target one-headed metric tail exactness; BEDC source BHist, UnaryHistory, Cont, and MetricDistanceWitness; carrier concrete metric distance witnesses; classifier hsame; stability visible-constructor closure and continuation transport; ledger exposed tail distance; core theorem Theorem 57.341; exactness bidirectional tail data; standard bridge finite metric endpoint readback; status ProofTarget.

Theorem 57.92 (Metric distance witness right e1 visible source exactness)**.** *For histories x, y, d, x_1, a distance witness whose right endpoint and result are visibly tagged descends to the tail while respecting a visible presentation of the source endpoint:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \Longrightarrow \mathsf{hsame}(x, \mathsf{E1}(x_1)) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y, d).$$

Proof. First apply right one-headed result exactness to remove the matching visible constructors from the right endpoint and result. The displayed hsame source presentation then rewrites the descended source to $\mathsf{E1}(x_1)$, preserving the concrete distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 visible source exactness`

Theorem 57.93 (Metric distance witness right e1 empty-source exactness)**.** *For histories y, d, a distance witness from the empty source to a visible right endpoint with visible result is exactly unary evidence for the endpoint and sameness of the descended distance:*

$$\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{E1}(y), \mathsf{E1}(d)) \Longrightarrow \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(d, y).$$

Proof. First descend the right endpoint and visible result to $\mathsf{MetricDistanceWitness}(\mathsf{e}, y, d)$. The empty-left exactness theorem then gives the unary endpoint carrier and $\mathsf{hsame}(d, y)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 empty source exactness`

Theorem 57.94 (Metric distance witness right one-headed source cases)**.** *For histories x, y, d, a distance witness with right endpoint and result both under one visible constructor either starts at the empty source boundary or starts from a one-headed source whose tail still carries the descended distance witness:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \Longrightarrow \big(x = \mathsf{e} \wedge \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(d, y)\big)$$

or there exists $x_1 : \mathsf{BHist}$ such that

$$x = \mathsf{E1}(x_1) \wedge \mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y, d).$$

Proof. First descend the right endpoint and result with the right one-headed result exactness theorem. Classify the unary source endpoint. The empty-source case is the empty-left exactness theorem for the descended witness, giving the target carrier and the distance-target sameness. A zero-headed source contradicts the unary source carrier. A one-headed source keeps the descended witness itself with the displayed source equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 source cases`

Theorem 57.95 (Metric distance witness right-boundary visible-context exactness)**.** *For histories p, q, x, d, a visible-context distance witness whose central right endpoint is empty is exactly unary evidence for the visible ledgers and the central left endpoint, together with the right-boundary classifier:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longleftrightarrow \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(d, x).$$

Proof. In the forward direction, apply Definition 57.13 with central right endpoint e. This recovers unary evidence for p and q together with $\mathsf{MetricDistanceWitness}(x, \mathsf{e}, d)$. Apply Definition 57.59 to that central witness to obtain $\mathsf{UnaryHistory}(x)$ and $\mathsf{hsame}(d, x)$.

Conversely, assume unary evidence for p, q, and x, together with $\mathsf{hsame}(d, x)$. By Definition 57.59 from right to left, these central data build $\mathsf{MetricDistanceWitness}(x, \mathsf{e}, d)$. Applying Definition 57.13 from right to left with prefix p and suffix q gives the displayed visible-context witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right boundary visible context iff`

Theorem 57.96 (Metric distance witness left-boundary visible-context exactness)**.** *For histories p, q, y, d, a visible-context distance witness whose central left endpoint is empty is exactly unary evidence for the visible ledgers and the central right endpoint, together with the left-boundary classifier:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, y{\cdot}q, (p{\cdot}d){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(d, y).$$

Proof. In the forward direction, apply Definition 57.13 with central left endpoint e. This recovers unary evidence for p and q together with $\mathsf{MetricDistanceWitness}(\mathsf{e}, y, d)$. Apply Definition 57.40 to that central witness to obtain $\mathsf{UnaryHistory}(y)$ and $\mathsf{hsame}(d, y)$.

Conversely, assume unary evidence for p, q, and y, together with $\mathsf{hsame}(d, y)$. By Definition 57.40 from right to left, these central data build $\mathsf{MetricDistanceWitness}(\mathsf{e}, y, d)$. Applying Definition 57.13 from right to left with prefix p and suffix q gives the displayed visible-context witness.

The per-object template is as follows. The traditional target is visible metric left-boundary readback. The BEDC source is BHist with Cont and $\mathsf{UnaryHistory}$. The carrier is $\mathsf{MetricDistanceWitness}$ and the classifier is hsame. The ledger is the visible prefix and suffix context. The core theorem is left-boundary exactness, exactness is the displayed equivalence, the standard bridge is metric boundary readback, and the status is $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left boundary visible context iff`

Theorem 57.97 (Metric distance witness empty-boundary visible-context exactness)**.** *For histories p, q, d, a visible-context distance witness whose central left and right endpoints are both empty is exactly unary evidence for the visible ledgers together with the empty-distance classifier:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \iff \mathsf{UnaryHistory}(p) \ \wedge \ \mathsf{UnaryHistory}(q) \ \wedge \ \mathsf{hsame}(d, \mathsf{e}).$$

Proof. Apply Definition 57.13 to remove the visible prefix and suffix. The central witness is $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d)$. Applying Definition 57.40 identifies it with the empty-boundary classifier $\mathsf{hsame}(d, \mathsf{e})$, while the visible-context theorem records exactly the unary histories for p and q.

Conversely, unary histories for p and q and the classifier $\mathsf{hsame}(d, \mathsf{e})$ build the central witness by Definition 57.40. Reattaching the same visible prefix and suffix by Definition 57.13 gives the displayed visible-context witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context iff`

Theorem 57.98 (Metric distance witness empty-boundary visible-context depth zero)**.** *For histories p, q, d, a visible-context distance witness whose central left and right endpoints are both empty forces the central distance depth to be zero:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{MetricDistanceDepth}(d) = 0.$$

Proof. Apply Definition 57.13 to remove the visible prefix and suffix. The central witness is then $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d)$. Applying Definition 57.40 gives $\mathsf{hsame}(d, \mathsf{e})$. Case analysis on this history classifier reduces the displayed depth equation to reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context depth zero`

Theorem 57.99 (Metric depth-zero distance has empty endpoints)**.** *For histories x, y, d, a concrete distance witness whose distance ledger has structural depth zero has empty endpoints:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to \mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).$$

Proof. Classify the displayed distance history. The empty distance case is exactly the empty-distance witness exactness theorem. A zero-headed or one-headed distance has successor depth, contradicting the displayed zero-depth equation by constructor no-confusion for natural numbers. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness depth zero empty endpoints`

Theorem 57.100 (Metric empty endpoints have depth-zero distance)**.** *For histories x, y, d, a concrete distance witness whose endpoints are both history-same to* e *has structural distance depth zero:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to \mathsf{hsame}(x, \mathsf{e}) \to \mathsf{hsame}(y, \mathsf{e}) \to \mathsf{MetricDistanceDepth}(d) = 0.$$

Proof. Eliminate the two endpoint sameness witnesses, reducing both endpoints to e. The continuation ledger inside the distance witness then reduces the distance history itself to e, and the depth definition evaluates to zero. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty endpoints depth zero`

Theorem 57.101 (Metric distance depth zero iff empty)**.** *For a history d, structural metric distance depth is zero exactly when d classifies with the empty history:*

$$\mathsf{MetricDistanceDepth}(d) = 0 \iff \mathsf{hsame}(d, \mathsf{e}).$$

Proof. Case-analyze the history d. The empty case is reflexive. A zero-headed or one-headed history has successor depth, so it cannot satisfy the zero-depth equation. Conversely, a history-sameness proof with e reduces the depth equation to the empty reflexive case. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth zero iff empty`

Theorem 57.102 (Metric distance positive depth iff nonempty)**.** *For a history d, positive structural metric distance depth is equivalent to not being history-same as* e*:*

$$0 < \mathsf{MetricDistanceDepth}(d) \iff (d\mathsf{hsamee} \to \mathsf{False}).$$

Proof. Case-analyze d. The empty case has depth zero and cannot satisfy the nonempty predicate. A zero-headed or one-headed history has successor depth, and constructor separation rules out history-sameness with e. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth positive iff nonempty`

Theorem 57.103 (Metric distance append positive depth iff)**.** *For histories p and d, an appended distance ledger has positive structural depth exactly when one of its two factors has positive structural depth:*

$$0 < \mathsf{MetricDistanceDepth}(p \cdot d) \iff 0 < \mathsf{MetricDistanceDepth}(p) \vee 0 < \mathsf{MetricDistanceDepth}(d).$$

Proof. Use the positive-depth classifier to replace positive depth by internal nonemptiness. Kernel append nonemptiness then splits the appended history into the left or right nonempty factor. The converse applies the same two classifiers in reverse and rebuilds nonemptiness of the appended history from the displayed nonempty factor. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth append positive iff`

Theorem 57.104 (Metric distance positive depth shape cases)**.** *For a history d, positive structural metric distance depth exposes one of the two visible history constructors:*

$$(\mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{False}) \implies (\exists z : \mathsf{BHist}.\ d = \mathsf{E0}(z)) \vee (\exists z : \mathsf{BHist}.\ d = \mathsf{E1}(z)).$$

Proof. Case-analyze d. The empty branch contradicts the displayed positive-depth hypothesis because the structural depth of e is zero. The two visible branches return the exposed payload under $\mathsf{E0}$ or $\mathsf{E1}$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth positive shape cases`

Theorem 57.105 (Metric distance depth append-left equality emptiness)**.** *For histories p and d, appending p on the left preserves structural metric distance depth exactly when p is the empty history:*

$$\mathsf{MetricDistanceDepth}(p \cdot d) = \mathsf{MetricDistanceDepth}(d) \iff \mathsf{hsame}(p, \mathsf{e}).$$

Proof. Induct on the displayed tail d. The empty tail is precisely Definition 57.253. A zero-headed or one-headed tail reduces the equality through successor injectivity, and the reverse direction rebuilds the same successor equality after the left prefix is identified with e. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth append left eq iff empty`

Theorem 57.106 (Metric distance depth append-left cancellation)**.** *For histories $p, d, e : \mathsf{BHist}$, equality of structural metric distance depths after appending the same left prefix cancels that prefix:*

$$\mathsf{MetricDistanceDepth}(p{\cdot}d) = \mathsf{MetricDistanceDepth}(p{\cdot}e) \implies \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(e).$$

Proof. The structural depth of a left append decomposes as the depth of the common prefix plus the depth of the tail. Rewriting both displayed sides by this depth-add equation reduces the claim to left cancellation for addition in $\mathbb{N}$, yielding equality of the two tail depths. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth append left cancel`

Theorem 57.107 (Metric strict prefix depth decomposition)**.** *For histories $h, k : \mathsf{BHist}$, a strict unary prefix witness from h to k exposes a nonempty unary tail whose continuation reconstructs k, and the metric depth of k splits as the depth of h plus the depth of that tail:*

$$\mathsf{NatUnaryStrictPrefix}(h, k) \implies \exists tail : \mathsf{BHist}.\ \mathsf{UnaryHistory}(tail) \wedge (tail = \mathsf{e} \to \mathsf{False}) \wedge \mathsf{Cont}(h, tail, k) \wedge \mathsf{MetricDistance}$$

Proof. Unpack the strict-prefix witness. It already supplies a unary nonempty tail and a continuation ledger from h through that tail to k. Inverting the continuation identifies k with $h \cdot tail$. Induction on the concrete tail then proves the structural depth equation for append, giving the displayed sum formula. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth strict prefix decomposes`

Theorem 57.108 (Metric distance depth visible-context cancellation)**.** *For histories p, q, d, e : BHist, equality of structural depths after a common visible prefix and suffix cancels both contexts:*

$$\mathsf{MetricDistanceDepth}((p{\cdot}d){\cdot}q) = \mathsf{MetricDistanceDepth}((p{\cdot}e){\cdot}q) \Longrightarrow \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(e$$

Proof. Induct on the visible suffix q. The empty suffix is exactly Definition 57.258. In the two visible constructor cases, both displayed depths have a common successor head, so successor injectivity removes the suffix constructor and the induction hypothesis cancels the remaining visible context. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth visible context cancel`

Theorem 57.109 (Metric distance depth append-right cancellation iff)**.** *For histories p, d, e : BHist, appending the same right suffix preserves and reflects equality of structural metric distance depth:*

$$\mathsf{MetricDistanceDepth}(d{\cdot}p) = \mathsf{MetricDistanceDepth}(e{\cdot}p) \Longleftrightarrow \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(e).$$

Proof. Induct on the common suffix p. The empty suffix is immediate. In the two visible constructor cases, both appended depths carry the same successor head; successor injectivity gives the forward implication, and congruence of successor rebuilds the appended equality in the reverse implication. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth append right cancel iff`

Theorem 57.110 (Metric distance depth append-right equality emptiness)**.** *For histories p and d, appending p on the right preserves structural metric distance depth exactly when p is the empty history:*

$$\mathsf{MetricDistanceDepth}(d \cdot p) = \mathsf{MetricDistanceDepth}(d) \Longleftrightarrow \mathsf{hsame}(p, \mathsf{e}).$$

Proof. The structural depth of a right append decomposes as the depth of d plus the depth of p. If the appended depth equals the original depth, cancellation by $\mathbb{N}$-addition forces the depth of p to be zero, hence Definition 57.253 identifies p with e. Conversely, substituting $p = \mathsf{e}$ makes the right append definitionally equal to d. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth append right eq iff empty`

Theorem 57.111 (Metric distance same-source continuation result cancellation)**.** *For unary histories x, y, z and continuation rows $\mathsf{Cont}(x, y, d)$ and $\mathsf{Cont}(x, z, e)$, equality of the two result depths cancels the common source depth:*

$$\mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(e) \Longrightarrow \mathsf{MetricDistanceDepth}(y) = \mathsf{MetricDistanceDepth}(z).$$

Proof. Package the two continuation rows as metric-distance witnesses. Depth additivity gives $\mathsf{depth}(d) = \mathsf{depth}(x) + \mathsf{depth}(y)$ and $\mathsf{depth}(e) = \mathsf{depth}(x) + \mathsf{depth}(z)$. The displayed result depth equality therefore has a common left summand, and natural-number cancellation identifies the two target depths. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth same source cont result cancel`

Theorem 57.112 (Metric distance depth visible-context equality emptiness)**.** *For histories p, q, d, adding visible context on both sides preserves the central structural metric distance depth exactly when both visible contexts are empty:*

$$\mathsf{MetricDistanceDepth}((p \cdot d) \cdot q) = \mathsf{MetricDistanceDepth}(d) \iff \mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(q, \mathsf{e}).$$

Proof. Expand structural depth over the two append contexts. The resulting natural number equation has the form $(\mathsf{depth}(p) + \mathsf{depth}(d)) + \mathsf{depth}(q) = \mathsf{depth}(d)$, so associativity and commutativity of addition reduce it to a zero-sum constraint on the two context depths. Then Definition 57.253 identifies both contexts with e. The reverse direction substitutes the two empty-context identifications and applies the one-sided append equality theorems above. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth visible context eq iff empty`

Theorem 57.113 (Metric visible-context zero depth iff empty components)**.** *For histories p, q, d, the full visible-context ledger has structural metric depth zero exactly when the prefix, central distance, and suffix are all empty:*

$$\mathsf{MetricDistanceDepth}((p \cdot d) \cdot q) = 0 \iff \mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(d, \mathsf{e}) \wedge \mathsf{hsame}(q, \mathsf{e}).$$

Proof. The zero-depth classifier first identifies the whole visible ledger with e. BEDC append-empty inversion splits the outer append into $(p \cdot d)\mathsf{hsamee}$ and $q\mathsf{hsamee}$, and a second inversion splits $p \cdot d$. Conversely, substituting the three empty components makes the displayed depth definition evaluate to zero. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth visible context zero iff`

Theorem 57.114 (Metric visible-context total zero components)**.** *For histories p, q, x, y, d, a visible-context distance witness whose full result ledger has structural depth zero exposes empty prefix, source, target, suffix, and central distance components:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \to \\ &\quad \mathsf{MetricDistanceDepth}((p \cdot d) \cdot q) = 0 \to \\ &\quad \mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(q, \mathsf{e}) \wedge \mathsf{hsame}(d, \mathsf{e}).\end{aligned}$$

Proof. Zero depth classifies the full result ledger with e, and two append-empty inversions expose the empty prefix, central distance, and suffix. Transport the witness continuation along the same empty result classifier. The empty-result continuation inversion then classifies the visible source $p \cdot x$ and target $y \cdot q$ with e, and append-empty inversion splits these endpoint histories into their displayed components. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context total zero components`

Theorem 57.115 (Metric visible-context depth-zero collapse)**.** *For histories p, q, x, y, d, a visible-context distance witness whose central distance has structural depth zero collapses the central distance and both central endpoints to the empty history:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d){\cdot}q) \to \mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{hsame}(d, \mathsf{e}) \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).$$

Proof. Apply visible-context exactness to peel away the prefix p and suffix q, recovering the central witness $\mathsf{MetricDistanceWitness}(x, y, d)$. The depth-zero endpoint theorem gives $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$, while the depth-zero classifier theorem gives $\mathsf{hsame}(d, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context depth zero collapse`

Theorem 57.116 (Metric empty-boundary visible-context continuation left unit)**.** *For histories p, q, d, r, out, an empty-boundary visible-context distance witness and a continuation out of the central distance identify the continuation result with its right input:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \to \mathsf{Cont}(d, r, out) \to \mathsf{hsame}(out, r).$$

Proof. Apply empty-boundary visible-context exactness to read back $\mathsf{hsame}(d, \mathsf{e})$. Case analysis on this classifier reduces the continuation to an empty-left continuation, whose result is the right input by the left-unit law for Cont. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation left unit result`

Theorem 57.117 (Metric empty-boundary visible-context continuation left unit iff)**.** *For histories p, q, d, r, out, an empty-boundary visible-context distance witness turns continuation from the central distance into exactly the left-unit continuation classifier:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \to \big(\mathsf{Cont}(d, r, out) \leftrightarrow \mathsf{hsame}(out, r)\big).$$

Proof. The visible-context empty-boundary theorem gives $\mathsf{hsame}(d, \mathsf{e})$. Case analysis on this classifier reduces the displayed continuation predicate to $\mathsf{Cont}(\mathsf{e}, r, out)$, which is characterized by the BEDC left-unit equivalence. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation left unit iff`

Theorem 57.118 (Metric empty-boundary visible-context continuation right unit iff)**.** *For histories p, q, d, l, out, an empty-boundary visible-context distance witness turns continuation into the central distance into exactly the right-unit continuation classifier:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \to \big(\mathsf{Cont}(l, d, out) \leftrightarrow \mathsf{hsame}(out, l)\big).$$

Proof. Again the visible-context empty-boundary theorem gives $\mathsf{hsame}(d, \mathsf{e})$. After case analysis, the displayed continuation predicate is $\mathsf{Cont}(l, \mathsf{e}, out)$, which is characterized by the BEDC right-unit equivalence. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation right unit iff`

Theorem 57.119 (Metric empty-boundary continuation splice)**.** *For histories p, q, d, l, r, mid, out, an empty-boundary visible-context distance witness makes a continuation through the central distance splice to the continuation that skips that empty central boundary:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \to \mathsf{Cont}(l, d, mid) \to \mathsf{Cont}(mid, r, out) \to \mathsf{Cont}(l, r, out).$$

Proof. The empty-boundary visible-context theorem gives $\mathsf{hsame}(d, \mathsf{e})$. After case analysis on this classifier, the left continuation is $\mathsf{Cont}(l, \mathsf{e}, mid)$, so its unit law identifies mid with l. The right continuation is therefore the desired $\mathsf{Cont}(l, r, out)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation splice`

Theorem 57.120 (Metric empty-boundary visible-context witness splice)**.** *For histories p, q, d, l, r, mid, out, an empty-boundary visible-context distance witness upgrades a two-step continuation through the central distance into a metric distance witness for the visible endpoints:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \to \mathsf{UnaryHistory}(l) \to \mathsf{UnaryHistory}(r) \to \mathsf{Cont}(l, d, mid) \to \mathsf{Cont}(mid, r, out) \to \mathsf{MetricDistanceWitness}(l, r, out).$$

Proof. The empty-boundary continuation-splice theorem gives the concrete continuation $\mathsf{Cont}(l, r, out)$ from the visible-context witness and the two displayed continuation rows. Together with the displayed unary carriers for l and r, the BEDC unary-continuation closure theorem supplies $\mathsf{UnaryHistory}(out)$. These four rows are precisely the fields of $\mathsf{MetricDistanceWitness}(l, r, out)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context witness splice`

Theorem 57.121 (Metric empty-boundary continuation splice determinacy)**.** *For histories $p, q, d, l, r, mid, out, out$ an empty-boundary visible-context distance witness makes the spliced continuation result match any displayed direct continuation result:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \to \mathsf{Cont}(l, d, mid) \to \mathsf{Cont}(mid, r, out) \to \mathsf{Cont}(l, r, out') \to \mathsf{hsame}(out, out')$$

Proof. The continuation-splice theorem supplies $\mathsf{Cont}(l, r, out)$ from the empty-boundary visible-context witness and the two displayed continuation rows. BEDC continuation determinacy compares this spliced continuation with the displayed $\mathsf{Cont}(l, r, out')$, giving $\mathsf{hsame}(out, out')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation splice hsame`

Theorem 57.122 (Metric visible-context positive central depth has a nonempty endpoint)**.** *For histories p, q, x, y, d, a visible-context distance witness whose central distance has positive structural depth exposes a nonempty central endpoint:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d){\cdot}q) \to (\mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{False}) \to ((\mathsf{hsame}(x, \mathsf{e}) \to \mathsf{False}) \vee (\mathsf{hsame}$$

Proof. Apply visible-context exactness to peel away the displayed prefix p and suffix q, obtaining the central witness $\mathsf{MetricDistanceWitness}(x, y, d)$.

It remains to convert positive structural depth into nonempty-distance input. If $\mathsf{hsame}(d, \mathsf{e})$ held, the depth-zero classifier theorem would give $\mathsf{MetricDistanceDepth}(d) = 0$, contradicting the positive-depth hypothesis.

Apply the nonempty-distance endpoint theorem to the central witness and this derived nonempty-distance contradiction. The result is exactly the displayed disjunction: either the left central endpoint is not history-same to e, or the right central endpoint is not history-same to e. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context positive depth nonempty endpoint`

Theorem 57.123 (Metric visible-context positive central depth e-one endpoint cases)**.** *For histories p, q, x, y, d : BHist, positive central distance depth in a visible MetricUp ledger exposes an e-one constructor at one central endpoint with a unary tail:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \to \\ &\quad (\mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{False}) \to \\ &\quad (\exists x_0,\ x = \mathsf{E1}(x_0) \wedge \mathsf{UnaryHistory}(x_0)) \vee (\exists y_0,\ y = \mathsf{E1}(y_0) \wedge \mathsf{UnaryHistory}(y_0)).\end{aligned}$$

Here the BEDC source is MetricDistanceWitness*, the carrier objects are* UnaryHistory *histories, the classifier is* hsame*, and the obligation is constructor readback under visible prefix and suffix ledgers.*

Proof. Apply visible-context exactness to remove the prefix p and suffix q from the displayed ledger. This recovers the central witness $\mathsf{MetricDistanceWitness}(x, y, d)$.

Next convert positive central depth into the nonempty-distance input required by the constructor readback theorem. If $d$hsamee held, then Definition 57.253 would give $\mathsf{MetricDistanceDepth}(d) = 0$, contradicting the positive-depth hypothesis.

Apply Definition 57.216 to the recovered central witness and this nonempty-distance contradiction. The result is exactly the displayed disjunction of e-one endpoint witnesses with unary tails. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context positive depth e1 endpoint cases`

Theorem 57.124 (Metric distance witness visible-context symmetric classifier)**.** *For histories $p, q, x, y, d_{xy}, d_{yx}$, symmetric distance witnesses remain classified by* hsame *after the same visible source and target contexts are peeled away:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p \cdot y, x \cdot q, (p \cdot d_{yx}) \cdot q) \Longrightarrow \mathsf{hsame}(d_{xy}, d_{yx}).\end{aligned}$$

Proof. Apply Definition 57.13 to each contextual witness. The first application recovers $\mathsf{MetricDistanceWitness}(x, y,$ and the second recovers $\mathsf{MetricDistanceWitness}(y, x, d_{yx})$. The central witnesses are then classified by Definition 57.9. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context symmetric classifier`

Theorem 57.125 (Metric distance witness prefix-independent symmetric classifier)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, symmetric metric distance witnesses with independent visible contexts still determine the same central distance classifier:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \Longrightarrow \mathsf{hsame}(d_{xy}, d_{yx}).\end{aligned}$$

Proof. Apply Definition 57.13 to both visible-context witnesses. This recovers central witnesses $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$ and $\mathsf{MetricDistanceWitness}(y, x, d_{yx})$. The central symmetric classifier then gives $\mathsf{hsame}(d_{xy}, d_{yx})$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context prefix independent symmetric classifier`

Theorem 57.126 (Metric distance witness prefix-independent symmetric zero-depth collapse)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, symmetric visible-context distance witnesses with independent contexts and a zero-depth forward distance collapse the two central distances and both central endpoints:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xy}) = 0 \Longrightarrow \\ &\mathsf{hsame}(d_{xy}, d_{yx}) \wedge \mathsf{MetricDistanceDepth}(d_{yx}) = 0 \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).\end{aligned}$$

Proof. Apply Definition 57.303 to the two visible-context witnesses. This gives $\mathsf{hsame}(d_{xy}, d_{yx})$.

Apply Definition 57.267 to the first visible-context witness and the zero-depth hypothesis for d_{xy}. This gives the empty endpoint classifiers $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$.

Finally peel the second visible-context witness with Definition 57.13. The recovered central witness $\mathsf{MetricDistanceWitness}(y, x, d_{yx})$, together with the two empty endpoint classifiers in reversed order, is the input required by Definition 57.252; hence $\mathsf{MetricDistanceDepth}(d_{yx}) = 0$. Combining these three pieces gives the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context prefix independent symmetric zero depth collapse`
Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth collapse`

Theorem 57.127 (Metric prefix-independent symmetric zero-depth reverse empty-boundary)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, symmetric visible-context distance witnesses with independent contexts and a zero-depth forward distance also package the reverse context as its own empty-boundary distance witness:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xy}) = 0 \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p' \cdot \mathsf{e}, \mathsf{e} \cdot q', (p' \cdot \mathsf{e}) \cdot q').\end{aligned}$$

Proof. Peel the reverse visible-context witness with Definition 57.13. This recovers the unary context data for p' and q' together with the central reverse witness $\mathsf{MetricDistanceWitness}(y, x, d_{yx})$.

Apply Definition 57.304 to the two displayed visible-context witnesses and the zero-depth forward distance. The resulting endpoint classifiers include $\mathsf{hsame}(y, \mathsf{e})$ and $\mathsf{hsame}(x, \mathsf{e})$.

Finally use Definition 57.389 in the reverse context. The recovered carriers for p' and q', together with the empty endpoint classifiers in reverse order, rebuild exactly $\mathsf{MetricDistanceWitness}(p' \cdot \mathsf{e}, \mathsf{e} \cdot q', (p' \cdot \mathsf{e}) \cdot q')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth reverse empty boundary package`

Theorem 57.128 (Metric prefix-independent symmetric zero-depth two-sided empty-boundary package)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, symmetric visible-context distance witnesses with independent contexts and a zero-depth forward distance package both contextual empty-boundary witnesses together with the reverse zero-depth row and the central endpoint classifiers:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xy}) = 0 \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot \mathsf{e}) \cdot q) \wedge \\ &\mathsf{MetricDistanceWitness}(p' \cdot \mathsf{e}, \mathsf{e} \cdot q', (p' \cdot \mathsf{e}) \cdot q') \wedge \mathsf{MetricDistanceDepth}(d_{yx}) = 0 \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).\end{aligned}$$

Proof. Apply Definition 57.304 to the two visible-context witnesses and the zero-depth forward distance. This gives the same-distance classifier, the reverse zero-depth row, and the two central endpoint classifiers $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$.

Peel the forward visible-context witness with Definition 57.13 to recover the unary carrier rows for p and q. These carriers, together with the endpoint classifiers from the collapse theorem, are exactly the right-hand data in Definition 57.389; hence they build $\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot \mathsf{e}) \cdot q)$.

Apply Definition 57.305 to the same hypotheses to obtain the reverse contextual empty-boundary witness. Conjoining the forward package, the reverse package, the reverse zero-depth row, and the two endpoint classifiers gives the displayed conclusion. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth two sided empty boundary package`

The ten-field fit is: traditional target metric zero-depth symmetric boundary packaging; BEDC source BHist with MetricDistanceWitness and MetricDistanceDepth; carrier MetricDistanceWitness; classifier hsame; stability zero-depth endpoint collapse; ledger the two symmetric visible contexts; core theorem Theorem 57.306; exactness two-sided empty-boundary packaging; standard bridge none claimed; status ProofTarget.

Theorem 57.129 (Metric prefix-independent symmetric zero-depth continuation splice)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}, l, r, mid, out$, symmetric visible-context distance witnesses with independent contexts and zero-depth forward distance make any continuation through the reverse central distance splice across the empty boundary:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \to \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \to \mathsf{MetricDistance}$$
$$\mathsf{Cont}(l, d_{yx}, mid) \to \mathsf{Cont}(mid, r, out) \to \mathsf{Cont}(l, r, out).$$

Proof. The symmetric zero-depth collapse theorem gives $\mathsf{MetricDistanceDepth}(d_{yx}) = 0$. The depth-zero classifier theorem converts this to $\mathsf{hsame}(d_{yx}, \mathsf{e})$. Case analysis reduces the left continuation to the right-unit case, identifying mid with l, and the remaining continuation is exactly the displayed splice result. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth continuation splice`

Theorem 57.130 (Metric prefix-independent symmetric zero-depth witness splice)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}, l, r, mid, out$, symmetric visible-context distance witnesses with independent contexts and zero-depth forward distance turn any unary continuation through the reverse central distance into a metric distance witness:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \to \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \to \mathsf{MetricDistance}$$
$$\mathsf{UnaryHistory}(l) \to \mathsf{UnaryHistory}(r) \to \mathsf{Cont}(l, d_{yx}, mid) \to \mathsf{Cont}(mid, r, out) \to \mathsf{MetricDistanceWitness}(l, r, out).$$

Proof. The continuation-splice theorem gives $\mathsf{Cont}(l, r, out)$ from the two visible-context witnesses, the zero-depth row, and the two displayed continuation ledgers through d_{yx}. The supplied unary histories for l and r, together with unary continuation closure, give the unary carrier row for out. These three carrier rows and the spliced continuation are exactly the metric distance witness package. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth witness splice`

Theorem 57.131 (Metric symmetric zero-depth distance continuation result)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$ symmetric visible-context distance witnesses with independent contexts and zero-depth forward distance make any two-step continuation through the two central distances return to the original left endpoint:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \to \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \to \mathsf{MetricDistance}$$
$$\mathsf{Cont}(l, d_{xy}, mid) \to \mathsf{Cont}(mid, d_{yx}, out) \to \mathsf{hsame}(out, l).$$

Proof. The forward zero-depth hypothesis converts d_{xy} to the empty history by the depth-zero classifier theorem. The symmetric zero-depth collapse theorem also gives zero depth for d_{yx}, hence $d_{yx}\mathsf{hsamee}$. Case analysis on these two empty-distance classifiers reduces both continuations to right-unit continuations, first identifying mid with l and then out with mid. Transitivity gives the displayed $\mathsf{hsame}(out, l)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth distance continuation result`

Theorem 57.132 (Metric symmetric zero-depth reverse distance continuation result)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}, l, mid, out$, symmetric visible-context distance witnesses with independent contexts and zero-depth forward distance also make the reverse-ordered two-step continuation return to the original left endpoint:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \to \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \to \mathsf{MetricDistance}$$
$$\mathsf{Cont}(l, d_{yx}, mid) \to \mathsf{Cont}(mid, d_{xy}, out) \to \mathsf{hsame}(out, l).$$

Proof. Apply Definition 57.304 to the two visible-context witnesses and the zero-depth hypothesis for d_{xy}. This gives $\mathsf{MetricDistanceDepth}(d_{yx}) = 0$.

Now apply Definition 57.309 with the two visible contexts swapped: p', q', y, x, d_{yx} play the forward roles and p, q, x, y, d_{xy} play the reverse roles. The recovered zero-depth row for d_{yx} is the forward depth hypothesis in that swapped instance, and the displayed ledgers are exactly $\mathsf{Cont}(l, d_{yx}, mid)$ followed by $\mathsf{Cont}(mid, d_{xy}, out)$.

Thus the swapped distance-continuation result returns $\mathsf{hsame}(out, l)$. The fit records traditional target zero-distance round trip, BEDC source BHist with Cont and MetricDistanceWitness, carrier the visible-context witness pair, classifier hsame, stability from zero-depth collapse and continuation unit laws, ledger the two central distance histories, core theorem this reverse-order round trip, exactness boundary-unit cancellation, standard bridge zero metric distance as identity path, and status ProofTarget. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth reverse distance continuation result`

Theorem 57.133 (Metric distance witness visible-context determinacy)**.** *For histories p, q, x, y, d, e, two contextual distance ledgers for the same visible endpoints determine the same central distance:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot e) \cdot q) \Longrightarrow \mathsf{hsame}(d, e).$$

Proof. Apply Definition 57.13 to the first contextual witness to recover the central witness $\mathsf{MetricDistanceWitness}(x,$ Apply the same theorem to the second contextual witness to recover $\mathsf{MetricDistanceWitness}(x, y, e)$.

Unpack the two central distance witnesses. They provide continuation ledgers $\mathsf{Cont}(x, y, d)$ and $\mathsf{Cont}(x, y, e)$ over the same source and target histories; continuation determinacy, Theorem 18.16, yields $\mathsf{hsame}(d, e)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context determinacy`

Theorem 57.134 (MetricSpace visible-context triangle boundary)**.** *For unary visible contexts p, q and central witnesses* $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$ *and* $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$*, a displayed append or continuation row for the composite distance d_{xyz} yields* $\mathsf{MetricDistanceWitness}(p \cdot x, z \cdot q, (p \cdot d_{xyz}) \cdot q)$*. Every source and result read is confined to* BHist*,* UnaryHistory*,* Cont*, and* hsame*.*

The boundary introduces no host metric, real inequality, completion, or quotient distance.

Proof. Apply the central triangle append closure to the two middle witnesses and the displayed composite row. This produces the central witness $\mathsf{MetricDistanceWitness}(x, z, d_{xyz})$ over the same BHist and continuation coordinates.

Transport that central witness through the visible prefix and suffix contexts using the existing visible-context exactness lemmas. Determinacy then identifies the distance row seen after peeling the contexts with the central row d_{xyz}.

The construction mentions only the unary histories, continuation ledgers, and hsame transports used by those lemmas. Hence no ambient metric, inequality, completion, or quotient coordinate is added. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceVisibleContextTriangleBoundary`

Theorem 57.135 (MetricSpace LocatedReal distance source boundary)**.** *Let L_x and L_y be accepted* $\mathsf{LocatedReal}^{\uparrow}$ *packets whose* $\mathsf{StreamName}^{\uparrow}$ *schedules admit a common finite observation window. Suppose their* DyadicRatCore *endpoint ledgers and radius ledgers are transported to that window by the displayed* hsame *and* Cont *rows, and suppose a contextual metric row* $\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q)$ *is displayed for the two projected endpoints.*

Then any $\mathsf{Met}^{\uparrow}$ *consumer reads the distance-source boundary exactly through the finite rows named by Definition 309.11 together with the metric visible-context rows: the* $\mathsf{RegSeqRat}^{\uparrow}$ *source windows, the* DyadicRatCore *endpoint and radius rows, the* $\mathsf{StreamName}^{\uparrow}$ *schedule rows, the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance, and the* hsame *classifier on the central distance row d.*

Conversely, any packet carrying precisely those rows repacks as the metric distance-source row for the two located packets. No quotient real, host real equality, trichotomy principle, open-cover compactness datum, or metric completion object is part of this boundary.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness locatedreal distance source boundary`

Proof. This boundary is the $\mathsf{Met}^{\uparrow}$ consumer of the located-real carrier of **??**; the cited sibling supplies the two accepted $\mathsf{LocatedReal}^{\uparrow}$ packets and their endpoint rows, while this theorem supplies the visible-context distance read.

Project L_x and L_y with Definition 309.11. This leaves only the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source windows, the common $\mathsf{StreamName}^{\uparrow}$ schedule, the transported DyadicRatCore endpoint and radius ledgers, the enclosure classifier rows, and the visible BHist, hsame, Cont, Pkg, and NameCert provenance.

Next apply Definition 57.13 to the contextual metric row. The visible prefix and suffix rows are peeled away, leaving the central witness $\mathsf{MetricDistanceWitness}(x, y, d)$ over the two projected located endpoints.

For uniqueness of the central distance read, apply Definition 57.133. Any second packet with the same displayed source windows, endpoint ledgers, schedule rows, provenance rows, and contextual metric witness has a central distance classifier $\mathsf{hsame}(d, e)$, so the metric consumer cannot distinguish a hidden distance coordinate.

The converse direction repacks exactly the displayed rows: the located packets come from the handoff surface, the contextual distance row supplies the metric visible context, and the central hsame classifier is the only distance classifier retained. Since each coordinate in this construction is one of the listed finite rows, no excluded real-number, compactness, or completion principle is introduced. □

Theorem 57.136 (Metric distance witness triangle append closure)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, a distance witness from x to y, a distance witness from y to z, and a distance witness from d_{xy} to z close the appended triangle ledger:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{xyz}, x \cdot d_{yz}).$$

Proof. Unpack the three distance witnesses to their continuation fields. The three continuations identify d_{xy} with $x \cdot y$, d_{yz} with $y \cdot z$, and d_{xyz} with $(x \cdot y) \cdot z$. Associativity of history append classifies this last ledger with $x \cdot (y \cdot z)$, hence with $x \cdot d_{yz}$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append closed`

Theorem 57.137 (Metric distance witness unary append commutation package)**.** *For unary histories x and y, the appended endpoints $x \cdot y$ and $y \cdot x$ carry the canonical metric distance witness $(x \cdot y) \cdot (y \cdot x)$, and the endpoints are* hsame*:*

$$\mathsf{MetricDistanceWitness}(x \cdot y, y \cdot x, (x \cdot y) \cdot (y \cdot x)) \wedge \mathsf{hsame}(x \cdot y, y \cdot x).$$

Proof. Unary append closure supplies the two endpoint carriers and the displayed distance carrier. The distance ledger is the canonical continuation from $x \cdot y$ to $y \cdot x$, and unary append commutativity gives the endpoint classifier. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness unary append comm package`

Theorem 57.138 (Metric distance witness composite endpoint append result)**.** *For histories $x, x', y, y', z, z', d_{xy}, d_{xyz}$, endpoint comparisons $x\mathsf{hsame}x'$, $y\mathsf{hsame}y'$, and $z\mathsf{hsame}z'$ transport the composite distance ledger to the endpoint-normal append result:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{xyz}, x' \cdot (y' \cdot z')).$$

Proof. Transport along the three endpoint hsame comparisons and unpack the two distance witnesses to their continuation fields. Constructor analysis of the two continuation ledgers reduces the displayed result comparison to associativity of history append. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness composite endpoint hsame append result`

Theorem 57.139 (Metric distance witness triangle continuation middle closure)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, a distance witness from x to y, a distance witness from y to z, and a continuation ledger $\mathsf{Cont}(d_{xy}, z, d_{xyz})$ close the middle-composite distance witness:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{Cont}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(x, d_{yz}, d_{xyz}).$$

Proof. The two distance witnesses expose the continuation ledgers $\mathsf{Cont}(x, y, d_{xy})$ and $\mathsf{Cont}(y, z, d_{yz})$. Together with the displayed ledger $\mathsf{Cont}(d_{xy}, z, d_{xyz})$, constructor analysis reduces the resulting source-to-middle continuation to associativity of history append. The unary carrier for d_{xyz} follows from unary continuation closure applied to d_{xy} and z. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle cont middle closed`

Theorem 57.140 (Metric distance witness visible-context triangle continuation middle closure)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, a visible-context witness for the left triangle edge, a central witness from y to z, and a continuation ledger from d_{xy} by z close the central middle-composite distance witness:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{Cont}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(x, d_{yz}, d_{xyz}).$$

Proof. Apply Definition 57.13 to the visible-context witness. This recovers the central edge witness $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$. The recovered edge witness, the given y-to-z witness, and the displayed continuation ledger are exactly the inputs of Definition 57.359, which returns the displayed middle-composite distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context triangle cont middle closed`

Theorem 57.141 (Metric distance witness triangle middle result determinacy)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, displayed, if the witnesses from x to y and from y to z are given, and $\mathsf{Cont}(d_{xy}, z, d_{xyz})$ displays the middle composite, then any distance witness from x to d_{yz} has the same result:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{Cont}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(x, d_{yz}, displayed) \Longrightarrow \mathsf{hsame}(d_{xyz}, displayed).$$

Proof. Triangle continuation middle closure constructs the canonical witness $\mathsf{MetricDistanceWitness}(x, d_{yz}, d_{xyz})$ from the two edge witnesses and the displayed middle continuation. The displayed witness has the same source and target histories as this canonical witness, so continuation determinacy applied to their distance ledgers identifies the two result histories. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle cont middle result deterministic`

Theorem 57.142 (Metric distance witness triangle append depth add)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, three triangle distance witnesses identify the displayed ledger with $x \cdot d_{yz}$ and compute its structural depth as the sum of the left endpoint depth and the middle-to-right distance depth:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{xyz}, x \cdot d_{yz}) \wedge \mathsf{MetricDistanceDepth}(d_{xyz}) = \mathsf{MetricDistanceDepth}(x$$

Proof. Triangle append closure supplies the equality $\mathsf{hsame}(d_{xyz}, x \cdot d_{yz})$. Together with the unary carrier fields already present in the three distance witnesses, this equality is a concrete distance witness from x to d_{yz} with result d_{xyz}. The metric depth addition law applied to that central witness gives the displayed depth equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append depth add`

Theorem 57.143 (Metric distance witness continuation depth add)**.** *For histories x, y, z, d_{xy}, d_{xyz}, a distance witness from x to y and a displayed continuation from d_{xy} by z compute the final structural distance depth:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{UnaryHistory}(z) \Longrightarrow \mathsf{Cont}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xyz}) = \mathsf{Metri}$$

Proof. The first witness supplies the unary carrier of d_{xy}. Together with the unary carrier of z and the displayed continuation ledger, this forms a second distance witness from d_{xy} to z with result d_{xyz}. Apply the depth additivity theorem to the first and second witnesses, then associate addition. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness cont depth add`

Theorem 57.144 (Metric distance witness triangle depth-zero collapse)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if three triangle distance witnesses have a final ledger of structural depth zero, then the triangle append equality holds and every displayed endpoint and intermediate distance collapses to* e*:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xyz}) = 0 \Longrightarrow \\ &\mathsf{hsame}(d_{xyz}, x \cdot d_{yz}) \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xy}, \mathsf{e}) \wedge \mathsf{hsame}(d_{yz}, \mathsf{e}).\end{aligned}$$

Proof. Triangle append closure forms the central witness from x to d_{yz} with result d_{xyz}. The depth-zero endpoint theorem for this central witness forces x and d_{yz} to be empty. Empty-distance exactness for the witness from y to z then forces y and z to be empty, and the continuation field in the witness from x to y forces d_{xy} to be empty. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle depth zero collapse`

Theorem 57.145 (Metric triangle left distance empty collapse)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the left distance in a metric triangle is history-same to* e*, then its endpoints collapse and the remaining two displayed distances are exactly the right endpoint:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \\ &\mathsf{hsame}(d_{xy}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(d_{xyz}, z) \wedge \mathsf{hsame}(d_{yz}, z).\end{aligned}$$

Proof. Empty-distance exactness for the witness from x to y gives $x\mathsf{hsame}\mathsf{e}$ and $y\mathsf{hsame}\mathsf{e}$. With d_{xy} collapsed, empty-left exactness for the outer witness gives $d_{xyz}\mathsf{hsame}z$. Collapsing y in the second witness and applying the same empty-left exactness gives $d_{yz}\mathsf{hsame}z$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle left distance empty collapse`

Theorem 57.146 (Metric triangle depth-zero iff empty spine)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, three concrete metric distance witnesses identify final structural depth zero exactly with emptiness of the three endpoints and the two displayed edge distances:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \\ &\mathsf{MetricDistanceDepth}(d_{xyz}) = 0 \Longleftrightarrow \\ &\mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xy}, \mathsf{e}) \wedge \mathsf{hsame}(d_{yz}, \mathsf{e}).\end{aligned}$$

Proof. For the forward direction, apply Definition 57.364 to the three triangle witnesses and the displayed zero-depth equation. The theorem returns a larger conjunction containing the append equality as its first component; discard that component and retain precisely the five empty-spine classifiers.

For the reverse direction, assume the five displayed classifiers. Apply Definition 57.252 to the first edge witness, using $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$, to get $\mathsf{MetricDistanceDepth}(d_{xy}) = 0$. Then use Definition 57.253 to recover $\mathsf{hsame}(d_{xy}, \mathsf{e})$ as the certified empty left endpoint for the outer witness. Finally apply Definition 57.252 to $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$, together with $\mathsf{hsame}(d_{xy}, \mathsf{e})$ and $\mathsf{hsame}(z, \mathsf{e})$, to obtain $\mathsf{MetricDistanceDepth}(d_{xyz}) = 0$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle depth zero iff empty spine`

Fit: traditional target triangle degeneracy criterion; BEDC source $BHist$ metric distance witnesses; carrier the three witnessed edges; classifier hsame; stability supplied by existing depth-zero and empty-endpoint lemmas; ledger the two edge distances; core theorem this iff; exactness zero-depth iff empty spine; standard bridge none claimed; status ProofTarget.

Theorem 57.147 (Metric distance witness visible-context triangle depth-zero collapse)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the first triangle edge is displayed through visible source and target ledgers and the final triangle distance has structural depth zero, then the triangle append equality holds and every central endpoint and intermediate distance collapses to* e*:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, p \cdot d_{xy} \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xyz}) = 0 \Longrightarrow \\ &\mathsf{hsame}(d_{xyz}, x \cdot d_{yz}) \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xy}, \mathsf{e}) \wedge \mathsf{hsame}(d_{yz}, \mathsf{e}).\end{aligned}$$

Proof. Apply Definition 57.13 to the contextual first edge. This recovers the central witness $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$ while leaving the two remaining triangle witnesses unchanged.

Apply Definition 57.364 to the central witness, the witness from y to z, the witness from d_{xy} to z, and the depth-zero hypothesis. The resulting conjunction is exactly the stated visible-context collapse conclusion. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context triangle depth zero collapse`

Theorem 57.148 (Metric distance witness visible-context triangle depth-zero iff empty spine)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, visible source and target ledgers around the first edge preserve the exact zero-depth triangle criterion:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, p \cdot d_{xy} \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \\ &\mathsf{MetricDistanceDepth}(d_{xyz}) = 0 \Longleftrightarrow \\ &\mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xy}, \mathsf{e}) \wedge \mathsf{hsame}(d_{yz}, \mathsf{e}).\end{aligned}$$

Proof. Apply Definition 57.13 to the contextual first edge. This recovers the central witness $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$, so the three hypotheses now have the same shape as the central triangle criterion.

For the forward direction, apply Definition 57.366 to the central witness, the witness from y to z, and the witness from d_{xy} to z. The forward half turns the displayed zero-depth equation into the five empty-spine classifiers.

For the reverse direction, use the same central iff theorem with the recovered central witness and the two unchanged triangle witnesses. Its reverse half turns the five displayed empty-spine classifiers into $\mathsf{MetricDistanceDepth}(d_{xyz}) = 0$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context triangle depth zero iff empty spine`

Theorem 57.149 (Metric triangle nonempty distance has a nonempty endpoint)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the three triangle distance witnesses hold and the final triangle distance is not history-same as* e*, then at least one endpoint of the triangle is not history-same as* e*:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow ($$

Proof. Apply metric nonempty-distance endpoint exactness to the outer witness $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$ If the nonempty endpoint is z, the conclusion follows directly. If it is d_{xy}, apply the same exactness theorem to $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$, yielding a nonempty x or y endpoint. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle nonempty endpoint nonempty`

Theorem 57.150 (Metric triangle nonempty spine one-headed endpoint cases)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the three triangle distance witnesses hold and the final triangle distance is not history-same as* e*, then at least one triangle endpoint is visibly one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow (d_{xyz}\mathsf{hsamee} \to \mathsf{False}) \Longrightarrow$$
$$(\exists x_0,\ x = \mathsf{E1}(x_0) \wedge \mathsf{UnaryHistory}(x_0)) \vee (\exists y_0,\ y = \mathsf{E1}(y_0) \wedge \mathsf{UnaryHistory}(y_0)) \vee (\exists z_0,\ z = \mathsf{E1}(z_0) \wedge \mathsf{UnaryHistory}($$

Proof. Apply the nonempty endpoint theorem for metric triangles. In each endpoint case, the corresponding unary carrier is a field of one of the triangle distance witnesses. Unary nonempty one-tail readback turns that nonempty carrier into the displayed $\mathsf{E1}$ endpoint with a unary tail. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle nonempty spine e1 endpoint cases`

Theorem 57.151 (Metric triangle nonempty spine iff nonempty distance)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, the same three triangle distance witnesses identify nonemptiness of the final triangle distance exactly with nonemptiness of at least one point of the triangle spine:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow$$
$$(d_{xyz}\mathsf{hsamee} \to \mathsf{False}) \Longleftrightarrow$$
$$((x\mathsf{hsamee} \to \mathsf{False}) \vee (y\mathsf{hsamee} \to \mathsf{False}) \vee (z\mathsf{hsamee} \to \mathsf{False}) \vee (d_{xy}\mathsf{hsamee} \to \mathsf{False}) \vee (d_{yz}\mathsf{hsamee} \to \mathsf{False})).$$

Proof. For the forward direction, apply Definition 57.369 to the three triangle witnesses and the displayed nonempty-distance hypothesis. The resulting endpoint disjunction is injected into the five-way spine disjunction by choosing the corresponding x, y, or z summand.

For the reverse direction, assume the five-way spine disjunction and suppose $d_{xyz}\mathsf{hsamee}$. By Definition 57.253, this gives $\mathsf{MetricDistanceDepth}(d_{xyz}) = 0$. Applying Definition 57.366 to the three triangle witnesses then yields $\mathsf{hsame}(x, \mathsf{e})$, $\mathsf{hsame}(y, \mathsf{e})$, $\mathsf{hsame}(z, \mathsf{e})$, $\mathsf{hsame}(d_{xy}, \mathsf{e})$, and $\mathsf{hsame}(d_{yz}, \mathsf{e})$.

Case-analyze the five-way spine disjunction. In each case, the selected nonempty spine component is a function from the corresponding empty classifier to False, so applying it to the matching classifier from the empty-spine conjunction gives the desired contradiction. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle nonempty spine iff nonempty distance`

Theorem 57.152 (Metric distance witness visible-context triangle nonempty spine iff nonempty distance)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, a triangle whose first edge is displayed through visible contexts has the same exact nonempty-spine criterion as the central triangle:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow$$
$$(d_{xyz}\mathsf{hsamee} \to \mathsf{False}) \Longleftrightarrow$$
$$((x\mathsf{hsamee} \to \mathsf{False}) \vee (y\mathsf{hsamee} \to \mathsf{False}) \vee (z\mathsf{hsamee} \to \mathsf{False}) \vee (d_{xy}\mathsf{hsamee} \to \mathsf{False}) \vee (d_{yz}\mathsf{hsamee} \to \mathsf{False})).$$

Proof. Apply Definition 57.13 to the displayed first-edge witness. Its forward direction recovers the central witness $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$, while the unary evidence for p and q is not needed by the remaining argument.

Now apply Definition 57.371 to this recovered central witness and to the two unchanged witnesses $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$ and $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$. The result is exactly the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context triangle nonempty spine iff nonempty distance`

Theorem 57.153 (Metric distance witness triangle append context closure)**.** *If p and q are supplied as unary visible contexts, distance witnesses from x to y, from y to z, and from d_{xy} to z produce a distance witness from $p \cdot x$ to $d_{yz} \cdot q$ whose result is $p \cdot d_{xyz} \cdot q$:*

$$\begin{aligned}&\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, d_{yz} \cdot q, p \cdot d_{xyz} \cdot q).\end{aligned}$$

Proof. The triangle append closure identifies the central result with $x \cdot d_{yz}$. Together with the carrier fields already present in the three distance witnesses, this gives the central witness from x to d_{yz} with result d_{xyz}. Visible-context closure then appends the unary contexts p and q on the outside. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context closed`

Theorem 57.154 (Metric distance witness visible-context triangle append closure)**.** *If the distance witness from x to y is displayed through visible contexts p, q, and the two remaining triangle witnesses are present, then the triangle append result is unchanged at the central layer:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, p{\cdot}d_{xy}{\cdot}q) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}$$

Proof. Visible-context exactness recovers the central distance witness $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$ from the displayed contextual witness. The ordinary triangle append closure applied to this recovered witness and the two remaining triangle witnesses gives $d_{xyz}\mathsf{hsame}x \cdot d_{yz}$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context triangle append closed`

Theorem 57.155 (Metric distance witness triangle append context result determinacy)**.** *For unary visible contexts p, q, if the three triangle distance witnesses from x to y, from y to z, and from d_{xy} to z are given, then any displayed distance witness from $p \cdot x$ to $d_{yz} \cdot q$ has the same result as the canonical contextual triangle result:*

$$\begin{aligned}&\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, d_{yz} \cdot q, displayed) \Longrightarrow \mathsf{hsame}(displayed, p \cdot d_x\end{aligned}$$

Proof. Triangle append context closure constructs the canonical witness from $p \cdot x$ to $d_{yz} \cdot q$ with result $p \cdot d_{xyz} \cdot q$. The displayed witness and this canonical witness have the same source and target histories, so continuation determinacy for their distance ledgers identifies their result histories. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context result deterministic`

Theorem 57.156 (Metric distance witness triangle append context source determinacy)**.** *For unary visible contexts p, q, if the three triangle distance witnesses from x to y, from y to z, and from d_{xy} to z are given, then any displayed witness with the canonical contextual result and target $d_{yz} \cdot q$ determines the exposed source:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x', d_{yz} \cdot q, (p \cdot d_{xyz}) \cdot q) \Longrightarrow \mathsf{hsame}(x, x').$$

Proof. Triangle append context closure constructs the canonical contextual witness from $p \cdot x$ to $d_{yz} \cdot q$ with result $(p \cdot d_{xyz}) \cdot q$. Visible-context source determinacy then compares this canonical witness with the displayed witness, using the shared target $d_{yz} \cdot q$ and shared central distance d_{xyz}, and recovers $\mathsf{hsame}(x, x')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context source deterministic`

Theorem 57.157 (Metric distance witness triangle append context endpoint determinacy)**.** *For unary visible contexts p, q, if the three triangle distance witnesses from x to y, from y to z, and from d_{xy} to z are given, then the canonical contextual triangle result $(p \cdot d_{xyz}) \cdot q$ determines both exposed endpoints:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \left(\begin{array}{l} (\mathsf{MetricDistanceWitness}(p \cdot x', d_{yz} \cdot q, (p \cdot d_{xyz}) \cdot q) \Longrightarrow \mathsf{hsame}(x, x')) \\ \wedge \\ (\mathsf{MetricDistanceWitness}(p \cdot x, e \cdot q, (p \cdot d_{xyz}) \cdot q) \Longrightarrow \mathsf{hsame}(d_{yz}, e)) \end{array} \right)$$

Proof. Triangle append context closure first constructs the canonical contextual witness $\mathsf{MetricDistanceWitness}(p \cdot x, d_{yz} \cdot q, (p \cdot d_{xyz}) \cdot q)$ from the three triangle witnesses and the unary context hypotheses.

For the displayed witness with source $p \cdot x'$ and target $d_{yz} \cdot q$, visible-context source determinacy compares it with the canonical contextual witness and recovers $\mathsf{hsame}(x, x')$ at the exposed source.

For the displayed witness with source $p \cdot x$ and target $e \cdot q$, visible-context target determinacy compares it with the same canonical contextual witness and recovers $\mathsf{hsame}(d_{yz}, e)$ at the exposed middle target. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context endpoint deterministic`

Theorem 57.158 (Metric distance witness triangle append context endpoint transport)**.** *For unary visible contexts p, q, if the three triangle distance witnesses from x to y, from y to z, and from d_{xy} to z are given, then endpoint comparisons on the exposed source and middle target transport the canonical contextual triangle witness:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(d_{yz}, e) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x', e \cdot q, (p \cdot d_{xyz}) \cdot q).$$

Proof. Triangle append context closure first constructs the canonical contextual witness $\mathsf{MetricDistanceWitness}(p \cdot x, d_{yz} \cdot q, (p \cdot d_{xyz}) \cdot q)$ from the three triangle witnesses and the unary context hypotheses.

The source comparison $\mathsf{hsame}(x, x')$ gives the contextual comparison $\mathsf{hsame}(p \cdot x, p \cdot x')$ by constructor reduction of the BEDC append context. The middle-target comparison $\mathsf{hsame}(d_{yz}, e)$ similarly gives $\mathsf{hsame}(d_{yz} \cdot q, e \cdot q)$. The result history is unchanged.

Apply the metric witness field transport theorem to these two endpoint comparisons and the reflexive result comparison. It transports the unary endpoint fields and the continuation ledger of the canonical contextual witness, which is exactly the displayed transported witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context endpoint transport`

Theorem 57.159 (Metric distance witness triangle append context endpoint iff)**.** *For unary visible contexts p, q, if the three triangle distance witnesses from x to y, from y to z, and from d_{xy} to z are given, then the canonical contextual triangle result classifies exactly the exposed source and middle target:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \Big(\mathsf{MetricDistanceWitness}(p \cdot x', e \cdot q, (p \cdot d_{xyz}) \cdot q) \Longleftrightarrow \mathsf{hsame}(x, x') \wedge \mathsf{hsame}$$

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context endpoint iff`

Proof. For the forward direction, apply Definition 57.377 to the displayed witness after visible-context exactness has placed it in the canonical contextual form. The source projection gives $\mathsf{hsame}(x, x')$, while the target projection gives $\mathsf{hsame}(d_{yz}, e)$; together these are the two components of the displayed conjunction.

For the reverse direction, assume $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(d_{yz}, e)$. Apply Definition 57.373 to the two unary contexts and the three triangle witnesses. This gives the canonical witness

$$\mathsf{MetricDistanceWitness}(p \cdot x, d_{yz} \cdot q, (p \cdot d_{xyz}) \cdot q).$$

Append congruence transports $\mathsf{hsame}(x, x')$ to $\mathsf{hsame}(p \cdot x, p \cdot x')$ and transports $\mathsf{hsame}(d_{yz}, e)$ to $\mathsf{hsame}(d_{yz} \cdot q, e \cdot q)$. Unary transport preserves the endpoint carriers across these classifiers, and Definition 57.346 transports the continuation ledger while keeping the contextual result fixed. Repacking the transported carriers with this ledger gives the displayed witness $\mathsf{MetricDistanceWitness}(p \cdot x', e \cdot q, (p \cdot d_{xyz}) \cdot q)$. □

Theorem 57.160 (Metric triangle right distance empty collapse)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the right distance in a metric triangle is history-same to e, then the shared endpoint and right endpoint collapse and the remaining displayed distances read back to the left endpoint:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xy}, x) \wedge \mathsf{hsame}(d_{xyz}, x).$$

Proof. Empty-distance exactness for the witness from y to z gives $y\mathsf{hsame}\mathsf{e}$ and $z\mathsf{hsame}\mathsf{e}$. Collapsing y in the first witness and using empty-right exactness identifies d_{xy} with x. Collapsing z in the outer witness identifies d_{xyz} with d_{xy}, and transitivity composes this with the previous readback to obtain $d_{xyz}\mathsf{hsame}x$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle right distance empty collapse`

Theorem 57.161 (Metric triangle left distance empty visible-context closure)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the left distance in a metric triangle is history-same to e, then the triangle closes through the visible context with empty central source:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{xy}, \mathsf{e}) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, z \cdot q, (p \cdot d_{xyz}) \cdot q).$$

Proof. The left-distance empty collapse identifies the left endpoints with e and reads d_{xyz} back to z. Empty-left exactness therefore builds the central witness $\mathsf{MetricDistanceWitness}(\mathsf{e}, z, d_{xyz})$. The visible-context iff then appends the certified unary ledgers p and q around this central witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle left distance empty visible context closed`

Theorem 57.162 (Metric triangle right distance empty visible-context closure)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the right distance in a metric triangle is history-same to* e*, then the triangle closes through the visible context with empty central target:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, \mathsf{e} \cdot q, (p \cdot d_{xyz}) \cdot q).$$

Proof. The right-distance empty collapse identifies the shared and right endpoints with e and reads d_{xyz} back to x. Empty-right exactness therefore builds the central witness $\mathsf{MetricDistanceWitness}(x, \mathsf{e}, d_{xyz})$. The visible-context iff then appends the certified unary ledgers p and q around this central witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle right distance empty visible context closed`

Theorem 57.163 (Metric triangle right distance empty spine witness)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the right distance in a metric triangle is history-same to* e*, then the outer displayed distance itself is a metric witness from x to the empty endpoint:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow \mathsf{MetricDistanceWitness}(x, \mathsf{e}, d_{xyz}).$$

Proof. The right-distance empty collapse identifies d_{xyz} with x and the first metric witness supplies unary membership of x. Empty-right metric exactness then packages this endpoint readback as a metric witness from x to e with displayed distance d_{xyz}. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle right distance empty spine witness`

Theorem 57.164 (Metric triangle right empty boundary witness)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if* $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$*,* $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$*, and* $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$ *form a metric triangle and* $d_{yz}\mathsf{hsame}\mathsf{e}$*, then the outer result is itself a distance witness from x to the empty boundary:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{e}, d_{xyz}).$$

Proof. By Definition 57.380, the right empty distance identifies d_{xyz} with x. The canonical right-empty witness $\mathsf{MetricDistanceWitness}(x, \mathsf{e}, x)$ uses the source carrier of the first edge, the empty unary carrier, and the right unit continuation $x \cdot \mathsf{e} = x$. Transporting the result field along $d_{xyz}\mathsf{hsame}x$ gives the displayed witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle right empty boundary witness`

Theorem 57.165 (Metric triangle bilateral empty edge collapse)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if both displayed edge distances in a metric triangle are history-same to* e*, then all three endpoints, the outer displayed distance, the final structural depth, and the empty-to-empty outer witness collapse to the empty case:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{xy}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xyz}, \mathsf{e}) \wedge \mathsf{MetricDistanceDepth}(d_{xyz}) = 0 \wedge \mathsf{MetricDistanceWitness}$$

Proof. Apply Definition 57.365 to the three triangle witnesses and the classifier $\mathsf{hsame}(d_{xy}, \mathsf{e})$. This gives the empty classifiers for x and y, and reads d_{xyz} and d_{yz} back to the right endpoint z.

Apply Definition 57.380 to the same three witnesses and the classifier $\mathsf{hsame}(d_{yz}, \mathsf{e})$. This gives the empty classifiers for y and z, and reads d_{xy} and d_{xyz} back to the left endpoint x.

The endpoint classifiers give the first three conjuncts. For the outer distance, compose the left-collapse readback $\mathsf{hsame}(d_{xyz}, z)$ with $\mathsf{hsame}(z, \mathsf{e})$ by transitivity of hsame. Apply Definition 57.253 to this empty final-distance classifier to obtain $\mathsf{MetricDistanceDepth}(d_{xyz}) = 0$.

The empty-boundary metric witness $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, \mathsf{e})$ is the exact empty-distance case. Transporting its result field along $d_{xyz}\mathsf{hsamee}$ yields $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d_{xyz})$. Conjoining these rows gives the displayed package. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle bilateral empty edge collapse`

Fit: traditional target degenerate triangle normalization; BEDC source $BHist$ metric distance witnesses; carrier the three witnessed edges; classifier hsame; stability from the two empty-edge collapse lemmas and depth-zero readback; ledger the two displayed edge distances; core theorem this block; exactness the endpoint and final-distance collapse; standard bridge none claimed; status $\mathsf{ProofTarget}$.

Theorem 57.166 (Metric triangle two-sided empty boundary package)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the two edge distances in a metric triangle are both history-same to e, then every displayed endpoint and the outer displayed distance collapse to the empty boundary, and the outer result is itself an empty-to-empty distance witness:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow$$
$$\mathsf{hsame}(d_{xy}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow$$
$$\mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xyz}, \mathsf{e}) \wedge \mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d_{xyz}).$$

Proof. Apply Definition 57.365 to the same triangle and the hypothesis $d_{xy}\mathsf{hsamee}$. This gives $x\mathsf{hsamee}$, $y\mathsf{hsamee}$, $d_{xyz}\mathsf{hsame}z$, and $d_{yz}\mathsf{hsame}z$.

Apply Definition 57.380 to the same triangle and the hypothesis $d_{yz}\mathsf{hsamee}$. This gives $y\mathsf{hsamee}$, $z\mathsf{hsamee}$, $d_{xy}\mathsf{hsame}x$, and $d_{xyz}\mathsf{hsame}x$.

The endpoint conclusions package the three empty endpoint readbacks. Symmetry and transitivity of hsame compose $d_{xyz}\mathsf{hsame}z$ with $z\mathsf{hsamee}$, so $d_{xyz}\mathsf{hsamee}$.

Finally, the empty-boundary metric witness $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, \mathsf{e})$ is the exact empty-distance case. Transporting its result field along $d_{xyz}\mathsf{hsamee}$ yields $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d_{xyz})$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness two sided empty triangle boundary package`

Theorem 57.167 (Metric triangle left empty boundary witness)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$, $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$, and $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$ form a metric triangle and $d_{xy}\mathsf{hsamee}$, then the outer result is itself a distance witness from the empty boundary to z:*

$$\mathsf{MetricDistanceWitness}(\mathsf{e}, z, d_{xyz}).$$

Proof. By Definition 57.365, the left empty distance identifies d_{xyz} with z.

The second edge supplies the unary carrier for z. Apply Definition 57.40 with this carrier and the displayed classifier $d_{xyz}\mathsf{hsame}z$ to package the canonical witness from e to z with displayed distance d_{xyz}. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle left empty boundary witness`

Theorem 57.168 (Metric triangle two-sided empty witness exactness)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if* $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$, $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$, *and* $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$ *form a metric triangle and both displayed edge distances are history-same to* e, *then the outer result simultaneously carries every empty-boundary witness row needed by the triangle:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow$$
$$\mathsf{hsame}(d_{xy}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow$$
$$\mathsf{hsame}(d_{xyz}, \mathsf{e}) \wedge \mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d_{xyz}) \wedge \mathsf{MetricDistanceWitness}(\mathsf{e}, z, d_{xyz}) \wedge \mathsf{MetricDistanceWitness}(x, \mathsf{e},$$

Proof. First apply Definition 57.385 to the three triangle witnesses and the two classifiers $\mathsf{hsame}(d_{xy}, \mathsf{e})$ and $\mathsf{hsame}(d_{yz}, \mathsf{e})$. This gives $\mathsf{hsame}(d_{xyz}, \mathsf{e})$ together with the empty-to-empty witness $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d$

Next apply Definition 57.387 to the same triangle and $\mathsf{hsame}(d_{xy}, \mathsf{e})$. This supplies the boundary row $\mathsf{MetricDistanceWitness}(\mathsf{e}, z, d_{xyz})$.

Finally apply Definition 57.384 to the same triangle and $\mathsf{hsame}(d_{yz}, \mathsf{e})$. This supplies $\mathsf{MetricDistanceWitness}(x, \mathsf{e},$ and the four rows assemble into the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness two sided empty triangle witness exactness`

Theorem 57.169 (Metric RealAlgOrder apartness distance scope)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints carried by the* RealAlgOrder *constant boundary, the finite packet supplied by Definition 38.46 and read by Definition 304.5 and Definition 304.8 is exactly the* $\mathsf{Met}^{\uparrow}$ *positive-separation distance scope.*

The scope consists of the two endpoint histories, the positive $\mathsf{DyadicRatCore}^{\uparrow}$ *radius or apartness row, the* hsame *transports, the* Cont *routes, the visible* Pkg *provenance, and the* NameCert *ledger tying the endpoints to their constant-rational source. Repacked as a metric consumer row, these data form the positive-separation side of a* MetricDistanceWitness *boundary and expose no trichotomy, completion, quotient-real equality, open-cover compactness, or host real equality.*

Proof. Project the constant carrier, classifier, algebra, order, and apartness rows from the RealAlgOrder constant boundary. By Definition 38.46, the consumer sees only the two $\mathsf{Real}^{\uparrow}$ endpoint histories, their rational source witnesses, the positive dyadic or apartness row, and the displayed hsame, Cont, Pkg, and NameCert provenance.

Apply the scoped certificate Definition 38.43. It keeps the endpoint histories inside the constant-rational boundary and prevents any additional real-order coordinate from being read by the downstream consumer.

Next apply Definition 304.5 and Definition 304.8. These two rows identify the same finite packet as apartness data consumable by metric or order constructions, with the positive row and endpoint readbacks still tied to the same BHist, hsame, Cont, Pkg, and NameCert ledger.

Finally repack the resulting finite separation row as the positive-separation side of the $\mathsf{Met}^{\uparrow}$ distance consumer boundary. The metric visible-context and boundary exactness rows are used only to keep the BEDC ledger stable under contextual prefixes and empty-boundary readback; they do not add a coordinate for trichotomy, completion, quotient-real equality, open-cover compactness, or host real equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderApartnessDistanceScope`

Theorem 57.170 (Metric RealAlgOrder apartness positive reflection)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints, any finite packet satisfying Definition 57.324 and the* $\mathsf{ApartnessReal}^{\uparrow}$ *metric consumer boundary determines exactly the positive-separation component of the* $\mathsf{Met}^{\uparrow}$ *distance witness. Every metric consumer may read the same positive dyadic or apartness row, endpoint histories,* hsame

transports, Cont *routes,* Pkg *provenance, and* NameCert *provenance supplied by the scoped packet. The reflection exports no converse trichotomy, quotient-real equality, completion, or host equality.*

Proof. Start with the constant-rational handoff Definition 38.46. Its packet gives the endpoint histories, the rational source rows, and the positive dyadic or apartness row that can be consumed without reading an additional real-order coordinate.

Apply Definition 38.43. The certificate keeps those rows inside the constant-rational RealAlgOrder surface and records the displayed hsame, Cont, Pkg, and NameCert provenance.

Use Definition 304.5 together with Definition 304.8. These results identify the same positive row as the separation data that an ApartnessReal$^{\uparrow}$ metric consumer may read.

Finally apply Definition 57.324 and project the positive side of the resulting MetricDistanceWitness boundary. This is only a repacking of the displayed finite rows, so the metric consumer gains no coordinate for converse trichotomy, quotient-real equality, completion, or host equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderApartnessPositiveReflection`

Theorem 57.171 (Metric RealAlgOrder positive-radius distance boundary)**.** *For constant-rational* Real$^{\uparrow}$ *endpoints carried by the scoped* RealAlgOrder$^{\uparrow}$ *boundary, the positive* DyadicRatCore$^{\uparrow}$ *radius or apartness row, the two endpoint* BHist *rows, the displayed* hsame *transports, the* Cont *routes, visible* Pkg *provenance, and the local* NameCert *rows are exactly the positive-distance boundary of the* MetricDistanceWitness *consumed by* Met$^{\uparrow}$*. Thus the concrete dyadic-or-apartness row named by the* RealAlgOrder$^{\uparrow}$ *packet is the positive-distance component read by the metric witness, and every such metric witness component recovers the same finite positive-radius row.*

The boundary is local to the displayed BEDC rows. It contains no trichotomy, quotient-real equality, completion, open-cover compactness, host metric-space structure, or host real equality.

Proof. For the forward direction, start with the scoped constant-rational RealAlgOrder$^{\uparrow}$ packet. Apply Definition 38.46 to expose exactly the two endpoint histories, their rational source rows, the positive dyadic or apartness row, the hsame transports, the Cont routes, visible Pkg provenance, and the local NameCert ledger. Then apply Definition 304.5 and Definition 57.325. These rows identify the same finite packet as the positive component of the MetricDistanceWitness boundary read by Met$^{\uparrow}$.

For the reverse direction, begin with a positive-distance boundary of the MetricDistanceWitness whose endpoints are the same constant-rational Real$^{\uparrow}$ rows. Use Definition 57.312 to read the positive-radius budget through the scoped RealAlgOrder$^{\uparrow}$ certificate, and then use Definition 57.315 to identify the public positive-distance component with the finite apartness packet of the same endpoint histories, transports, routes, package provenance, and name-certificate rows.

Both directions therefore name the same concrete positive row. The repacking steps only move between the RealAlgOrder, ApartnessReal, and MetricSpace consumer surfaces; they do not introduce a branch for trichotomy, a quotient-real equality, a completion principle, an open-cover compactness principle, a host metric-space structure, or a host real equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderPositiveRadiusDistanceBoundary`
↪ variant `BEDC.Derived.MetricUp.MetricRealAlgOrder positive radius distance boundary`

Theorem 57.172 (RealAlgOrder apartness metric symmetric separation)**.** *For constant-rational* Real$^{\uparrow}$ *endpoints carried by the* RealAlgOrder *constant boundary, the positive-separation packet identified by Definition 57.325 remains a valid positive-separation component of the* Met$^{\uparrow}$ *distance witness after the two endpoint histories are swapped. The swapped orientation keeps the same positive* DyadicRatCore$^{\uparrow}$ *radius or apartness row, the same finite separation ledger, and the same displayed*

hsame, Cont, Pkg, *and* NameCert *provenance; only the left and right endpoint histories are read in the reverse order.*

This is a metric-facing consequence of apartness symmetry. It gives the symmetric endpoint orientation required by a distance witness, but it does not add trichotomy, quotient-real equality, completion, or host real equality.

Proof. Start with the constant-rational handoff Definition 38.46. It supplies the two endpoint histories, rational source rows, positive dyadic or apartness row, and visible hsame, Cont, Pkg, and NameCert provenance.

Apply the scoped certificate Definition 38.43. The certificate keeps both endpoint histories inside the same constant-rational RealAlgOrder boundary and does not introduce any additional real-order coordinate.

Use Definition 304.4 to exchange the two endpoint histories and endpoint readbacks. The apartness row, positive radius or separation ledger, and all displayed transport and provenance rows are preserved componentwise.

Finally apply Definition 57.325 to the swapped packet. Since the positive-separation component is the same finite row read in the opposite endpoint order, it is again a valid positive component of the $\mathsf{Met}^{\uparrow}$ distance witness, with no added equality, completion, or trichotomy principle. □

Lean4 ✓ `BEDC.Derived.MetricUp.RealAlgOrderApartnessMetricSymmetricSeparation`

Theorem 57.173 (Metric RealAlgOrder apartness triangle budget)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints* x, y, z *carried by the* RealAlgOrder *constant boundary, two adjacent finite apartness packets for* (x, y) *and* (y, z) *supply the exact visible rows required by the* $\mathsf{Met}^{\uparrow}$ *triangle-budget consumer for the outer pair* (x, z) *after endpoint orientation is normalized. The consumer may read only the three endpoint histories, the two positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius or apartness rows, the finite adjacent separation ledgers, the induced outer-pair* BHist *row, the displayed* hsame *transports, the* Cont *routes, the visible* Pkg *provenance, and the local* NameCert *rows attached to the constant-rational sources.*

The statement is a local RealAlgOrder-to-MetricSpace budget law. It exports no trichotomy, quotient-real equality, completion, open-cover compactness, or host metric-space structure.

Proof. Begin with the two adjacent apartness packets. Apply Definition 57.325 to each packet; this exposes exactly the positive-separation rows, endpoint histories, hsame transports, Cont routes, Pkg provenance, and NameCert rows already present in the constant-rational boundary.

If one adjacent packet is presented in the reverse endpoint order, use Definition 57.327 to swap only the endpoint histories. The positive row and finite ledger are unchanged, so the two adjacent packets now share the middle endpoint history y in the orientation read by the triangle consumer.

With the adjacent rows normalized, invoke the $\mathsf{Met}^{\uparrow}$ visible-context triangle boundary and the public law package. These rows concatenate the two finite positive-separation ledgers into the outer-pair triangle budget while preserving the displayed BHist, hsame, Cont, Pkg, and NameCert provenance.

No excluded principle is used in the repacking step. Trichotomy, quotient-real equality, completion, open-cover compactness, and a host metric-space structure are not coordinates of the adjacent RealAlgOrder packets or of the visible triangle-budget consumer surface. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderApartness triangle budget`

Theorem 57.174 (RealAlgOrder apartness metric NameCert route)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints carried by the scoped* $\mathsf{RealAlgOrder}^{\uparrow}$ *boundary, the carrier and classifier rows of Definition 38.43, the finite apartness-to-metric handoff of Definition 38.46, the* $\mathsf{ApartnessReal}^{\uparrow}$ *metric handoff of Definition 304.5, the positive-separation reflection of Definition 57.325, the symmetric endpoint separation of Definition 57.327, and the triangle-budget rows of Definition 57.328 assemble into the exact finite* NameCert *route consumable by* $\mathsf{Met}^{\uparrow}$ *and by the* $\mathsf{S}^{1\uparrow}$ *boundary reader.*

The route consists only of endpoint BHist *rows, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius or apartness rows, the displayed* hsame *transports, the* Cont *routes, the* Pkg *provenance, and the local* NameCert *rows attached to the constant-rational sources and metric consumers. It exports no trichotomy, quotient-real equality, completion, open-cover compactness, or host equality.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderApartnessMetricNameCertRoute`

Proof. First read the two endpoint rows through Definition 38.43. This fixes the scoped $\mathsf{RealAlgOrder}^{\uparrow}$ carrier and classifier surface and keeps the endpoint histories tied to their constant-rational source rows.

Next apply Definition 38.46 and Definition 304.5. These two handoffs present the same finite apartness row as metric-facing positive-separation data, with the visible BHist, hsame, Cont, Pkg, and NameCert provenance unchanged.

Now use Definition 57.325 to package the positive row as the positive component of the $\mathsf{Met}^{\uparrow}$ distance witness, and use Definition 57.327 when the consumer requests the opposite endpoint orientation.

Finally apply Definition 57.328. The triangle route concatenates only the displayed adjacent separation ledgers and therefore gives exactly the finite NameCert route needed by metric and circle-boundary consumers, without adding any excluded host-order, quotient, completion, compactness, or equality principle. □

Definition 57.175 (MetricSpace real-distance carrier)**.** *The* $\mathsf{Met}^{\uparrow}$ *real-distance carrier for the open Real Algebra and Geometry phase is the finite unary endpoint packet*

$$(x, y, d, r;\ w, b, c, p, a)$$

where x *and* y *are unary* BHist *endpoint histories,* w *is the displayed row* $\mathsf{MetricDistanceWitness}(x, y, d)$*,* b *is the closed ball-budget row* $\mathsf{MetricBallBudget}_d(x, y; r)$*,* c *is the classifier row* hsame *on endpoint and result histories,* p *is the visible* Cont *provenance for the distance witness, and* a *is the* RealAlgOrder *budget packet consisting of the constant-rational endpoint rows, positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *or apartness row, ordered-real comparison, addition, transitivity, and addition-monotonicity rows used by the budget predicate.*

The carrier exposes exactly these rows. It does not contain an ambient host metric space, a quotient-real equality, a completeness principle, an open-cover compactness principle, or a topology generator separate from the displayed distance packet.

Lean4 (definition) `BEDC.Derived.MetricUp.MetricspaceRealDistanceCarrier`

Theorem 57.176 (MetricSpace RealAlgOrder positive-radius budget interface)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints in the carrier of Definition 57.311, the* a*-coordinate supplies exactly the ordered-real fields required by Definition 57.232 and consumed by Definition 57.233: ordered-real comparison, addition, transitivity, and two-sided addition-monotonicity. The interface is read through the scoped* $\mathsf{RealAlgOrder}^{\uparrow}$ *certificate and the apartness distance scope of Definition 57.324,*

so the positive-radius row is the same finite order-or-apartness row exposed to the metric budget consumer.

This interface exports no trichotomy branch, quotient-real equality, completeness principle, open-cover compactness, or host metric-space row.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderPositiveRadiusBudgetInterface`

Proof. Project the a-coordinate from Definition 57.311. By construction this coordinate is the RealAlgOrder budget packet attached to the same endpoint histories, distance witness, classifier, continuation, and provenance rows as the metric carrier.

Apply Definition 766.2. Its order stability and ledger-exactness rows identify the comparison, addition, transitivity, and addition-monotonicity data as finite displayed order rows, while Definition 766.7 prevents any trichotomy, quotient-real equality, host real carrier, or completeness coordinate from being read through the order or apartness side.

Next use Definition 57.324 together with Definition 57.315. These theorems identify the metric-facing positive row with the same endpoint BHist histories, positive DyadicRatCore$^{\uparrow}$ radius or apartness row, hsame transports, Cont routes, Pkg provenance, and NameCert ledger supplied by the scoped RealAlgOrder$^{\uparrow}$ packet.

Finally compare this inventory with Definition 57.232. The predicate asks only for ordered-real comparison, addition, budget transitivity, and two-sided budget-addition monotonicity, and Definition 57.233 consumes only those displayed fields. Therefore the a-coordinate is precisely the positive-radius budget interface used by the composition theorem, with none of the excluded host principles added. □

Theorem 57.177 (MetricSpace public law package)**.** *The real-distance carrier of Definition 57.311 supports the public* Met$^{\uparrow}$ *distance laws needed by the open phase:*

1. *symmetry, by transporting the endpoint order through* MetricDistanceWitness *symmetry and the RealAlgOrder apartness symmetric-separation row;*
2. *identity boundary, by the empty-distance row and the empty-boundary visible-context rows;*
3. *triangle-budget composition, by the visible-context triangle boundary and the* MetricBallBudget *composition row;*
4. *carrier transport, by* hsame *transport of endpoints and result histories together with the displayed* Cont *provenance.*

These laws are public laws of the finite BEDC packet only. They do not assert an arbitrary host metric, completeness, compactness, or a hidden equality on real distances.

Proof. For symmetry, read the distance row through Definition 57.9. The positive real-distance side is kept in the same packet by Definition 57.327, so swapping the endpoints changes only the orientation of the unary endpoint histories.

For the identity boundary, apply Definition 57.7. The visible-context empty-boundary rows then show that a zero public distance read is exactly the empty endpoint boundary up to hsame, with no quotient-real equality added.

For triangle-budget composition, use Definition 57.134 to form the composite witness over the same endpoint and continuation rows. Then apply Definition 57.233 to compose the two displayed budget rows.

For carrier transport, use the endpoint and result hsame rows already contained in Definition 57.311. The visible Cont provenance identifies the transported witness with the same public distance packet, so every exported law remains inside the carrier. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealDistanceCarrier public law package`

Theorem 57.178 (MetricSpace open-phase consumer interface)**.** *Every* $\mathsf{S}^{1\uparrow}$ *consumer and every later L10 consumer in the open Real Algebra and Geometry phase reads* $\mathsf{Met}^{\uparrow}$ *real-distance data only through the carrier of Definition 57.311 and the law package of Definition 57.313. The consumer surface is the RealAlgOrder apartness distance scope together with the existing visible-context consumer surface; it exposes no additional host metric-space coordinate, no completion row, and no open-cover compactness row.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceOpenPhaseConsumerInterface`

Proof. Start with Definition 57.324. It identifies the constant-rational endpoint histories, positive apartness or dyadic radius, and visible hsame, Cont, Pkg, and NameCert provenance available to a metric-facing real-distance consumer.

Next apply Definition 57.237. That consumer theorem restricts $\mathsf{S}^{1\uparrow}$ and the named downstream metric consumers to the visible-context distance witness, ball-budget, classifier, and finite provenance rows.

The L10 consumers in the open phase can only compose with the same RealAlgOrder apartness scope and the same visible-context public surface. Therefore their readable interface is exactly Definition 57.311 equipped with Definition 57.313, and no host metric, completion, or open-cover compactness coordinate is exported. □

Theorem 57.179 (MetricSpace RealAlgOrder positive-distance public correspondence)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints, the positive component of the* $\mathsf{Met}^{\uparrow}$ *real-distance carrier of Definition 57.311 is equivalent to the finite apartness packet isolated by Definition 57.324 and Definition 57.325. Concretely, to read a positive public distance row is to read the two endpoint* BHist *histories, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius or apartness row, the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and* NameCert *ledger supplied by the* RealAlgOrder *constant-rational boundary; conversely, those same rows repack as the positive component of the carrier.*

Endpoint reversal is supplied by Definition 57.327. The correspondence introduces no trichotomy, completion, quotient-real equality, open-cover compactness, or host equality.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderPositiveDistancePublicCorrespondence`

Proof. Project the carrier of Definition 57.311. Its positive side is not a separate host metric object; it is the displayed RealAlgOrder budget packet attached to the distance witness, classifier, continuation, package, and name-certificate rows.

For the forward direction, read that budget packet through Definition 57.324. Then apply Definition 57.325 to identify the positive public distance row with the finite apartness data available to a metric-facing consumer.

For the reverse direction, start with the finite apartness packet named by the same two theorems. The rows already match the carrier fields: endpoint histories, positive dyadic or apartness data, hsame transports, Cont routes, Pkg provenance, and the NameCert ledger. Repacking these rows with the carrier's displayed distance witness gives the positive component of the public real-distance carrier.

Finally use Definition 57.327 for endpoint reversal. Symmetry changes only the orientation of the two endpoint histories, so the same finite packet remains the public positive-distance witness and no trichotomy, completion, quotient-real equality, open-cover compactness, or host equality is added. □

Theorem 57.180 (MetricSpace apartness positive-distance triangle boundary)**.** *Let x, y, and z be constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints read through the* $\mathsf{Met}^{\uparrow}$ *real-distance public surface. Suppose the adjacent positive distance reads for (x, y) and (y, z) are represented by the finite* RealAlgOrder *apartness packets isolated in Definition 57.315. Then the triangle-boundary consumer read for the outer pair (x, z) factors through exactly those endpoint* BHist *histories, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *or apartness rows, the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and the metric triangle ledger of Definition 57.313.*

The resulting consumer row exports only this visible finite boundary. It does not export trichotomy, open-cover compactness, completed-real equality, or a host metric-space structure.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceApartnessPositiveDistanceTriangleBoundary`

Proof. Apply Definition 57.315 to the adjacent packets (x, y) and (y, z). Each read gives the same kind of finite public data: endpoint histories, positive dyadic or apartness rows, displayed hsame transports, continuation routes, package provenance, and local name-certificate rows.

Use Definition 57.327 whenever an adjacent endpoint orientation must be read from the opposite side. This changes only the order in which the two endpoint histories are presented; it does not add trichotomy, completed-real equality, compactness, or host metric structure.

Finally apply Definition 57.313. Its triangle row is already a visible-context ledger over the public distance witness, so the two adjacent positive packets repack as the outer triangle-boundary consumer read for (x, z). The repacking uses only the displayed BHist, hsame, Cont, Pkg, NameCert, and metric-law rows listed in the statement. □

Theorem 57.181 (MetricSpace SOne RealAlgOrder consumer factorization)**.** *Every* $\mathsf{S}^{1\uparrow}$ *metric consumer read whose two real coordinates are read through the constant-rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *boundary factors through the finite rows of Definition 57.311. The only readable rows are the endpoint* BHist *rows of the two coordinates, the displayed* MetricDistanceWitness *row, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *or apartness rows supplied by the* $\mathsf{RealAlgOrder}^{\uparrow}$ *boundary, the* hsame *transport rows,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and the triangle ledger of Definition 57.313.*

Thus the $\mathsf{Met}^{\uparrow}$ *consumer surface seen from* $\mathsf{S}^{1\uparrow}$ *and* $\mathsf{RealAlgOrder}^{\uparrow}$ *is a finite BEDC packet. It does not include trichotomy, completed-real equality, open-cover compactness, or a host metric-space structure.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceSoneRealalgorderConsumerFactorization`
↪ variant `BEDC.Derived.MetricUp.MetricspaceS1RealalgorderConsumerFactorization`

Proof. Project the admitted circle point through Definition 58.59. The public bridge exposes only the two $\mathsf{Real}^{\uparrow}$ component rows, their product ledger, the unit-equation row, and the displayed hsame, Cont, Pkg, and NameCert rows.

Apply Definition 57.315 to each constant-rational component read. This replaces every positive metric-distance demand by the visible $\mathsf{RealAlgOrder}^{\uparrow}$ apartness packet, with endpoint histories, positive dyadic or apartness data, and the same transport and package rows as in the carrier.

Next use Definition 57.316. Its triangle-boundary row is exactly the finite metric-law ledger over the positive packets, so the $\mathsf{S}^{1\uparrow}$ metric consumer has no additional distance coordinate beyond the carrier and public-law rows.

Finally compare with Definition 58.61. The observation boundary already prevents quotient-circle, angle, compactness, connectedness, and metric-completeness rows from entering the read. Since the $\mathsf{RealAlgOrder}^{\uparrow}$ correspondence contributes no trichotomy or completed-real equality and

the $\mathsf{Met}^{\uparrow}$ law package contributes no host metric space, the resulting consumer factors through exactly the finite packet listed in the statement. □

Theorem 57.182 (MetricSpace real-distance scoped certificate)**.** *The finite* $\mathsf{Met}^{\uparrow}$ *scoped certificate for the open real-algebra and geometry phase consists exactly of the real-distance carrier of Definition 57.311, the public law package of Definition 57.313, the open-phase consumer interface of Definition 57.314, the* RealAlgOrder *positive-distance correspondence of Definition 57.315, and the apartness triangle boundary of Definition 57.316.*

Its rows are only the displayed BHist *endpoint histories,* hsame *transport rows,* Cont *routes,* Pkg *provenance, local* NameCert *registrations, the public metric-law rows, and the displayed* RealAlgOrder *positive-distance budget rows. The certificate exports no host metric-space primitive, quotient-real equality, completion, open-cover compactness, or trichotomy.*

Proof. Begin with the carrier of Definition 57.311. It supplies the endpoint histories, the displayed distance witness, the transport and continuation routes, package provenance, and the local name-certificate row.

Attach the public law package of Definition 57.313 and read it through Definition 57.314. This gives the open phase only the finite law rows for symmetry, separation, and triangle composition over the same carrier fields.

Next insert the RealAlgOrder side by Definition 57.315. That theorem identifies the positive-distance consumer row with the displayed apartness budget packet, so no second positivity primitive or completed-real coordinate is introduced.

Finally compose with Definition 57.316. The triangle-boundary read uses the same endpoint histories, positive-distance budget rows, hsame, Cont, Pkg, and NameCert data already listed above. Since none of the cited components contains a host metric, quotient-real equality, completion, open-cover compactness, or trichotomy row, the assembled scoped certificate has no coordinate from which such data could be exported. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealDistanceScopedCertificate`

Theorem 57.183 (MetricSpace RealAlgOrder triangle consumer exhaustion)**.** *Every* $\mathsf{Met}^{\uparrow}$ *triangle-consumer read whose endpoints are constant rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *endpoints and whose distance data are read through the real-distance carrier of Definition 57.311 is exhausted by the finite rows already displayed in that carrier, the public law package of Definition 57.313, the positive-distance correspondence of Definition 57.315, and the apartness triangle boundary of Definition 57.316.*

Equivalently, a triangle consumer over endpoints (x, y, z) *can read only the three endpoint* BHist *histories, the two adjacent positive* $\mathsf{RealAlgOrder}^{\uparrow}$ *packets, the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and the finite metric-law triangle ledger. It has no coordinate for trichotomy, quotient-real equality, completion, open-cover compactness, or an ambient host metric-space structure.*

Proof. Project the adjacent positive-distance reads for (x, y) and (y, z) through Definition 57.315. The projection exposes only endpoint histories, positive dyadic or apartness rows, transport rows, continuation routes, package provenance, and local name-certificate data.

Orient the two adjacent endpoint packets by Definition 57.327. Endpoint reversal changes only the order of the displayed unary histories, so it cannot introduce trichotomy, quotient-real equality, completion, compactness, or a host metric-space coordinate.

Compose the oriented packets through Definition 57.316. That boundary theorem is the public triangle read of Definition 57.313, hence the outer consumer is formed from the same two adjacent positive packets and the same finite triangle ledger.

Finally compare the assembled read with Definition 57.318. The scoped certificate lists every exported coordinate of the real-distance public surface. Since the triangle construction above uses only those rows, no additional coordinate remains for a mature metric-space primitive or completed real equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderTriangleConsumerExhaustion`

Theorem 57.184 (MetricSpace RealAlgOrder SOne distance route exhaustion)**.** *For any accepted* $\mathsf{S}^{1\uparrow}$ *metric consumer whose coordinates are read through constant-rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *endpoints and whose distance request uses the carrier of Definition 57.311, the public read is exhausted by the finite route consisting of the two* $\mathsf{S}^{1\uparrow}$ *coordinate histories, the* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness or positive dyadic rows, the* MetricDistanceWitness *rows, endpoint and result* hsame *transports,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and the* $\mathsf{Met}^{\uparrow}$ *triangle ledger.*

This route exports no angle parametrization, quotient-circle equality, completed-real equality, open-cover compactness, trichotomy, or host metric-space primitive.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderSoneDistanceRouteExhaustion`

Proof. First apply Definition 57.317. It reduces the accepted $\mathsf{S}^{1\uparrow}$ metric read to the real-distance carrier of Definition 57.311, so the only available coordinate histories are the two visible $\mathsf{S}^{1\uparrow}$ histories and their constant-rational endpoint rows.

Next use Definition 57.315 on the distance request. The positive component of the carrier is exactly the visible $\mathsf{RealAlgOrder}^{\uparrow}$ apartness or positive dyadic packet, together with the same hsame, Cont, Pkg, and local NameCert rows.

For triangle-facing consumers, compose with Definition 57.316 and Definition 57.319. These results identify the remaining public metric-law data with the finite $\mathsf{Met}^{\uparrow}$ triangle ledger over the displayed distance witnesses and endpoint transports.

Finally compare with the $\mathsf{S}^{1\uparrow}$ observation boundary used in Definition 57.317. That boundary excludes angle parametrization, quotient-circle equality, completed real equality, open-cover compactness, trichotomy, and host metric-space primitives from the consumer surface, so the finite route listed in the statement is exhaustive. □

Theorem 57.185 (Metric RealAlgOrder SOne equation-distance factorization)**.** *Every accepted* $\mathsf{S}^{1\uparrow}$ *equation-distance consumer whose component reads pass through* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness or positive dyadic rows and whose metric request uses Definition 57.311 factors through exactly the finite rows listed in Definition 57.320. The same route supplies the equation-consumer boundary and excludes angle parametrization, quotient-circle equality, completed-real equality, trichotomy, open-cover compactness, and host metric primitives.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderSoneEquationDistanceFactorization`

Proof. First apply Definition 57.317. It places the accepted $\mathsf{S}^{1\uparrow}$ equation-distance read on the real-distance carrier, so the visible component histories are the two displayed circle coordinates and their constant-rational $\mathsf{RealAlgOrder}^{\uparrow}$ endpoint rows.

Next use Definition 57.315. The positive-distance component is read only through apartness or positive dyadic rows, the distance witness, endpoint transports, continuation routes, package provenance, and local naming certificates.

For metric-law consumers, compose with Definition 57.319. This keeps the triangle-facing read on the same distance witnesses and the same finite $\mathsf{Met}^{\uparrow}$ ledger.

Finally compare the resulting packet with Definition 57.320. Its displayed BHist, hsame, Cont, Pkg, and NameCert rows already list every coordinate available to the equation consumer, leaving no coordinate for angle parameters, quotient or completed equality, trichotomy, open-cover compactness, or host metric primitives. □

Theorem 57.186 (Metric RealAlgOrder SOne equation-distance symmetry)**.** *Let an accepted* $\mathsf{S}^{1\uparrow}$ *equation-distance consumer factor through constant-rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *coordinate endpoints and the* $\mathsf{Met}^{\uparrow}$ *real-distance carrier of Definition 57.311. Then the coordinate-swapped equation-distance read factors through the same finite route after coordinate-pair determinacy,* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness metric symmetric separation, and* $\mathsf{Met}^{\uparrow}$ *route exhaustion. The swapped read introduces no angle parametrization, quotient-circle equality, completed-real equality, trichotomy, open-cover compactness, or host metric primitive.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderSoneEquationDistanceSymmetry`

Proof. Start with the original accepted equation-distance consumer and apply Definition 57.321. The factorization exposes only the two $\mathsf{S}^{1\uparrow}$ coordinate histories, their constant-rational $\mathsf{RealAlgOrder}^{\uparrow}$ endpoint rows, the real-distance witness, endpoint transports, continuation routes, package provenance, and local name-certificate rows.

For the coordinate swap, use Definition 58.25. The determinacy statement identifies the swapped pair as the same two circle coordinate histories with their order reversed, so no angle parameter or quotient-circle equality is added to the read.

Apply Definition 57.327 to the endpoint rows. This reverses the apartness or positive dyadic separation packet inside $\mathsf{RealAlgOrder}^{\uparrow}$ while preserving the same endpoint histories, the same hsame transports, and the same finite package and certificate data.

Finally compare the swapped packet with Definition 57.320. That exhaustion theorem already lists the complete $\mathsf{Met}^{\uparrow}$ route available to the equation-distance carrier. Hence the coordinate-swapped read stays on the same finite route and leaves no coordinate for completed-real equality, trichotomy, open-cover compactness, or host metric primitives. □

Theorem 57.187 (MetricSpace RealAlgOrder SOne positive-boundary equivalence)**.** *Let constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints be accepted by the* $\mathsf{S}^{1\uparrow}$ *component-and-equation consumer through the* $\mathsf{Met}^{\uparrow}$ *real-distance carrier of Definition 57.311. Then the* $\mathsf{RealAlgOrder}^{\uparrow}$ *positive-boundary row, the* $\mathsf{Met}^{\uparrow}$ *positive-distance row, and the* $\mathsf{S}^{1\uparrow}$ *equation-separation row are equivalent finite BEDC readings of the same packet. The shared packet consists exactly of endpoint* BHist *rows, a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *or apartness row,* hsame *transports,* Cont *routes,* Pkg *provenance, local* NameCert *rows, the metric distance witness, and the* $\mathsf{S}^{1\uparrow}$ *component and unit-equation rows. It does not include trichotomy, quotient-real equality, angle quotient, completed-real equality, open-cover compactness, connectedness, or host metric primitives.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderSonePositiveBoundaryEquivalence`

Proof. First apply Definition 57.315. This identifies the $\mathsf{RealAlgOrder}^{\uparrow}$ positive-boundary read with the $\mathsf{Met}^{\uparrow}$ positive-distance row through the visible endpoint histories, apartness or positive dyadic data, transport rows, continuation routes, package provenance, local naming certificates, and the metric distance witness.

Next apply Definition 57.317. The $\mathsf{S}^{1\uparrow}$ component-and-equation consumer can only enter through that real-distance public interface, so its component rows and unit-equation rows read the same endpoints and distance witness rather than a separate angle or quotient-circle carrier.

The route is exhaustive by Definition 57.320. Hence any consumer claiming one of the three boundary views must use the displayed BHist, hsame, Cont, Pkg, NameCert, distance, component, and unit-equation rows.

Finally compare with Definition 38.65 and Definition 58.67. These two boundary theorems give the reverse readings from the $\mathsf{RealAlgOrder}^{\uparrow}$–$\mathsf{Met}^{\uparrow}$ side and from the $\mathsf{S}^{1\uparrow}$ equation consumer side. Together they show that the positive-boundary, positive-distance, and equation-separation rows are three readings of one finite certificate packet, with no remaining coordinate for trichotomy, quotient-real equality, angle quotient, completed-real equality, open-cover compactness, connectedness, or host metric primitives. □

Theorem 57.188 (MetricSpace SOne distance source boundary)**.** *Every accepted* $\mathsf{S}^{1\uparrow}$ *packet over the* $\mathsf{Real}^{\uparrow}$ *product carrier reads* $\mathsf{Met}^{\uparrow}$ *distance data only through the finite rows of Definition 57.311 and the public law package of Definition 57.313. Its circle-side source is constrained by Definition 58.59, Definition 58.61, and Definition 58.62. Its* $\mathsf{RealAlgOrder}^{\uparrow}$ *side is constrained by Definition 57.324 and Definition 38.63.*

Thus a $\mathsf{S}^{1\uparrow}$ *consumer of real-distance data can read only the two* $\mathsf{Real}^{\uparrow}$ *component rows, the product-carrier ledger, the unit-equation row, componentwise* hsame *classifiers, equation transport, finite-window* RegSeqRat *stream-name and real-seal rows, the displayed* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness budget rows, the metric endpoint histories,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and the public metric-law rows. The boundary exports no angle quotient, covering-space quotient, host metric function, completion row, compactness row, connectedness row, or topology generator.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceSoneDistanceSourceBoundary`
↪ variant `BEDC.Derived.MetricUp.MetricspaceSOneDistanceSourceBoundary`

Proof. Project the accepted $\mathsf{S}^{1\uparrow}$ packet through Definition 58.59. This exposes the two $\mathsf{Real}^{\uparrow}$ component rows, the product carrier, the unit-equation witness, the componentwise classifier rows, and equation transport, and excludes the circle-specific quotient and topology rows named in the statement.

Refine the two real components through Definition 58.61 and Definition 58.62. The metric-facing source rows are then finite-window RegSeqRat and real-seal observations attached to the same public certificate, rather than an ambient circle metric or a hidden completion object.

Pass the real-algebra side through Definition 57.324 and Definition 38.63. These two boundaries keep the apartness and unit-equation reads tied to the displayed $\mathsf{RealAlgOrder}^{\uparrow}$ endpoint and budget rows, so the metric source has no trichotomy, quotient-real equality, host metric, or Real completeness coordinate.

Repack the resulting endpoint rows, budget rows, transport rows, continuation routes, provenance rows, and local certificate rows as the carrier of Definition 57.311. Attach Definition 57.313 and read the package through Definition 57.314. The open real-algebra and geometry phase therefore consumes exactly the finite real-distance carrier and its public law rows, with no additional metric, topology, compactness, connectedness, completion, angle, or covering quotient data. □

Theorem 57.189 (Metric distance witness semantic name certificate)**.** *For unary endpoint histories* x, y*, the concrete distance-witness predicate* $d \mapsto \mathsf{MetricDistanceWitness}(x, y, d)$ *carries a semantic naming certificate whose source, pattern, and ledger predicates are the same concrete witness predicate and whose classifier is* hsame*.*

Proof. The carrier witness is the concrete distance history $x \cdot y$. Unary append closure supplies its unary carrier witness, and the continuation field is the reflexive ledger $\mathsf{Cont}(x, y, x \cdot y)$. The

classifier fields are the reflexive, symmetric, and transitive laws for hsame. Carrier transport is history-sameness transport of the concrete distance witness. □

Definition 57.190 (MetricSpace ledger policy)**.** *Record carrier witnesses and the real ledger of each distance value.*

Lean4 (definition) BEDC.Derived.MetricUp.MetricLedgerPolicy
Lean4 ✓ BEDC.Derived.MetricUp.MetricLedgerPolicy rows

Definition 57.191 ($\mathsf{Met}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Met}^{\uparrow}$*.*

Lean4 (definition) BEDC.Derived.MetricUp.MetricCertificateObligations

Definition 57.192 (Metric ball budget predicate)**.** *For a certified* $\mathsf{Met}^{\uparrow}$ *setup on a carrier* X *with distance* $d : X \times X \to \mathsf{Real}^{\uparrow}$*, a ball-budget structure supplies an ordered-real comparison* $\leq_{\mathsf{R}}$ *on* $\mathsf{Real}^{\uparrow}$*, an addition operation* $+$ *on* $\mathsf{Real}^{\uparrow}$*, a transitivity field for* $\leq_{\mathsf{R}}$*, and a two-sided addition-monotonicity field saying that* $a \leq_{\mathsf{R}} a'$ *and* $b \leq_{\mathsf{R}} b'$ *entail* $a + b \leq_{\mathsf{R}} a' + b'$*. Relative to this chosen budget structure, the closed ball-budget predicate is*

$$\mathsf{MetricBallBudget}_d(x, y; r) :\Longleftrightarrow d(x, y) \leq_{\mathsf{R}} r.$$

Lean4 (definition) BEDC.Derived.MetricUp.MetricBallBudget

Theorem 57.193 (Metric ball budget composition)**.** *Let* X *be a carrier equipped with the* $\mathsf{Met}^{\uparrow}$ *certificate obligations of Definition 57.231, and let* $d : X \times X \to \mathsf{Real}^{\uparrow}$ *be its certified distance. Assume also the ball-budget ordered-real fields of Definition 57.232: the comparison* $\leq_{\mathsf{R}}$*, addition* $+$*, budget-transitivity, and two-sided budget-addition-monotonicity. For* $x, y, z : X$ *and budgets* $r, s : \mathsf{Real}^{\uparrow}$*,*

$$\mathsf{MetricBallBudget}_d(x, y; r) \Longrightarrow \mathsf{MetricBallBudget}_d(y, z; s) \Longrightarrow \mathsf{MetricBallBudget}_d(x, z; r + s).$$

Equivalently,

$$d(x, y) \leq_{\mathsf{R}} r \Longrightarrow d(y, z) \leq_{\mathsf{R}} s \Longrightarrow d(x, z) \leq_{\mathsf{R}} r + s.$$

Proof. Unfold Definition 57.232. The two premises are the budget comparisons $d(x, y) \leq_{\mathsf{R}} r$ and $d(y, z) \leq_{\mathsf{R}} s$. The triangle-inequality field of Definition 57.5 gives

$$d(x, z) \leq_{\mathsf{R}} d(x, y) + d(y, z).$$

Apply the supplied two-sided budget-addition-monotonicity field to the two budget premises. This gives

$$d(x, y) + d(y, z) \leq_{\mathsf{R}} r + s.$$

Apply the supplied budget-transitivity field to the triangle inequality and the displayed budget bound. This yields $d(x, z) \leq_{\mathsf{R}} r + s$. Refolding Definition 57.232 gives the closed ball-budget conclusion. □

Lean4 ✓ BEDC.Derived.MetricUp.MetricBallBudget composition

Theorem 57.194 (Metric distance witness standard bridge)**.** *For the public* $\mathsf{Met}^{\uparrow}$ *distance-witness surface over unary* BHist *endpoints* x, y*, there is a conservative standard interpretation whose BEDC carrier is*

$$\{\, d \mid \mathsf{MetricDistanceWitness}(x, y, d) \,\},$$

whose classifier is hsame*, whose forward row reads such a witness as the finite append-distance presentation between the two unary endpoints, and whose reverse row reconstructs the BEDC witness from that finite append presentation. The bridge is only for this generated distance-witness surface; it does not assert arbitrary host real metrics.*

Proof. The carrier and classifier come from Definition 57.229: the public BEDC objects are exactly the d satisfying $\mathsf{MetricDistanceWitness}(x, y, d)$, and the classifier is hsame.

For the forward row, apply Definition 57.13 to read the visible unary context as the finite append-distance presentation between the endpoints. Definition 57.133 ensures that this presentation is determined by the visible context, while Definition 57.9 transports the same presentation across the symmetric endpoint order.

For the reverse row, read the finite append-distance presentation back through Definition 57.13. The resulting BEDC witness is classified by the same hsame row, and Definition 57.233 supplies the budget-compatible composition law needed by the public distance-witness surface.

Thus the two rows form a conservative paper-side standard bridge for the generated MetricDistanceWitness surface only. No completeness, compactness, topology, or arbitrary host-real metric structure is introduced. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricUp StdBridge`

Definition 57.195 (MetricSpaceUp public distance surface)**.** *The* $\mathsf{Met}^{\uparrow}$ *public distance surface is the finite* BHist *surface whose carrier rows are the unary endpoint histories* x, y*, the displayed* $\mathsf{MetricDistanceWitness}(x, y, d)$ *row, the ball-budget row* $\mathsf{MetricBallBudget}_d(x, y; r)$*, the classifier row* hsame*, the finite* Cont *provenance row, and the* $\mathsf{Real}^{\uparrow}$ *budget rows used by Definition 57.232. A public distance read of* $\mathsf{Met}^{\uparrow}$ *is a projection of this surface and no larger host metric-space object.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspacePublicDistanceSurface hsame transport`

Theorem 57.196 (MetricSpaceUp public distance surface exhaustion)**.** *Every public distance read of* $\mathsf{Met}^{\uparrow}$ *projects exactly to the* BHist *endpoint rows, the* MetricDistanceWitness *row, the* MetricBallBudget *row, the* hsame *classifier row, the finite* Cont *provenance row, and the* $\mathsf{Real}^{\uparrow}$ *budget rows of Definition 57.235. Conversely, any such finite family repacks as the same public distance surface.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspacePublicDistanceSurface exhaustion`

Proof. Project a public read through the distance-witness semantic certificate of Definition 57.229. This fixes the BHist endpoints, the concrete $\mathsf{MetricDistanceWitness}(x, y, d)$ row, and the hsame classifier row.

Next apply Definition 57.233. The only budget rows available to the public read are the displayed $\mathsf{Real}^{\uparrow}$ comparison, addition, transitivity, and monotonicity fields used to compose ball-budget witnesses.

Finally use Definition 57.234 and Definition 57.133. The bridge reads the same finite witness surface in the standard direction, and visible context determinacy prevents an additional host distance row from entering the packet. Repacking the projected rows gives exactly Definition 57.235. □

Theorem 57.197 (MetricSpaceUp visible-context distance consumer surface)**.** *The named visible-context consumers* $\mathsf{TotallyBounded}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*, and* $\mathsf{S}^{1\uparrow}$ *may read a* $\mathsf{Met}^{\uparrow}$ *distance only through the visible-context distance witness, ball-budget, and classifier rows of Definition 57.235. Their public use of the metric interface does not add a host metric carrier, a separate topology generator, or an analytic completeness or compactness row.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspacePublicDistanceSurface visible context consumer surface`

Proof. Start with the public surface of Definition 57.235. The only exported distance data are the $\mathsf{MetricDistanceWitness}$ row, the ball-budget row, the hsame classifier, and the finite Cont provenance over the displayed $\mathsf{Real}^{\uparrow}$ budget rows.

Apply Definition 57.133. Any visible-context consumer that reads a distance witness receives the determined finite witness row rather than an external host distance function.

Use Definition 57.233 for all budget propagation and Definition 57.234 for the standard distance-facing reading. These two rows exhaust the consumer-facing surface, so the listed downstream chapters can consume only the visible-context witness, budget, and classifier rows. □

Theorem 57.198 (MetricSpace visible-context public certificate)**.** *The public* $\mathsf{Met}^{\uparrow}$ *certificate is exactly the finite* BHist *endpoint rows, the* $\mathsf{MetricDistanceWitness}$ *row, the* $\mathsf{MetricBallBudget}$ *row, the* hsame *classifier row, the finite* Cont *provenance row, and the* $\mathsf{Real}^{\uparrow}$ *budget rows of Definition 57.235. Every downstream read by* $\mathsf{TotallyBounded}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*, and* $\mathsf{S}^{1\uparrow}$ *factors through the visible-context consumer surface of Definition 57.237, so the certificate exports no host metric-space carrier, no separate topology generator, and no analytic completeness or compactness row.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspacePublicDistanceSurface visible context public certificate`

Proof. First project the visible distance read through Definition 57.229. This fixes the endpoint BHist rows, the displayed $\mathsf{MetricDistanceWitness}$ row, and the hsame classifier that names the distance witness.

Next compose the budget rows by Definition 57.233. The only available comparison, addition, transitivity, and monotonicity data are the displayed $\mathsf{Real}^{\uparrow}$ budget rows already present in Definition 57.235.

Then read the standard-facing side through Definition 57.234. The bridge has the same finite witness surface, so it does not introduce a host metric function or an ambient metric-space object.

Finally apply Definition 57.237. The listed downstream chapters read the metric interface only through this visible-context surface. Combining these rows gives exactly the public $\mathsf{Met}^{\uparrow}$ certificate and no larger object. □

Primitive boundary. $\mathsf{Met}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Theorem 57.199 (Metric distance witness empty-boundary visible-context distance empty)**.** *For histories* p, q, d*, a visible-context distance witness whose central left and right endpoints are both empty identifies the central distance with the empty history and gives zero central distance depth:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{hsame}(d, \mathsf{e}) \wedge \mathsf{MetricDistanceDepth}(d) = 0.$$

Proof. Apply Definition 57.13 to peel away the visible prefix and suffix. The remaining central witness is $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d)$. The empty-left boundary theorem identifies d with e; case analysis on that classifier gives the zero depth equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context distance empty`

Theorem 57.200 (Metric prefix-independent symmetric zero-depth empty-boundary forward)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, suppose the two symmetric visible-context distance witnesses*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q), \qquad \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q')$$

hold. If $\mathsf{MetricDistanceDepth}(d_{xy}) = 0$*, then the original visible context carries the empty-boundary witness*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot \mathsf{e}) \cdot q).$$

Proof. Peel both visible-context witnesses to their central witnesses. Symmetric classification compares d_{xy} and d_{yx}. Case analysis on the zero-depth central distance leaves only $d_{xy} = \mathsf{e}$; the empty-distance visible-context readback then identifies the two central endpoints as empty. Reattaching the original prefix and suffix gives the displayed empty-boundary witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth empty boundary forward`

Theorem 57.201 (Metric empty-boundary visible context append unit laws)**.** *For histories p, q, d, l, r, a visible-context distance witness whose central endpoints are both empty makes the central distance act as a left and right append unit:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{append}(d, r) = r \ \wedge \ \mathsf{append}(l, d) = l.$$

Proof. The empty-boundary distance theorem identifies d with e. Case analysis on that classifier reduces the two displayed equations to the left and right unit laws for finite-kernel append. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context append unit laws`

Theorem 57.202 (Metric empty-boundary visible context unit splice commute)**.** *For histories $p, q, d, l, r, out_L, out_R$, an empty-boundary visible-context distance witness makes left and right continuation through the central distance commute after one ordinary append splice:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{Cont}(l, d, out_L) \Longrightarrow \mathsf{Cont}(d, r, out_R) \Longrightarrow \mathsf{hsame}(out_L{\cdot}r, l{\cdot}out_R).$$

Proof. The empty-boundary distance theorem identifies d with e. The left continuation then has right-unit result $out_L \mathsf{hsame} l$, and the right continuation has left-unit result $out_R \mathsf{hsame} r$. Substituting these two unit identifications reduces the displayed splice comparison to reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context unit splice commute`

Theorem 57.203 (Metric visible-context empty-distance unit splice commute)**.** *For histories $p, q, x, y, l, r, out_L, out_R$, a visible-context empty-distance witness makes left continuation through x and right continuation through y commute after one ordinary append splice:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}\mathsf{e}){\cdot}q) \Longrightarrow \mathsf{Cont}(l, x, out_L) \Longrightarrow \mathsf{Cont}(y, r, out_R) \Longrightarrow \mathsf{hsame}(out_L{\cdot}r, l{\cdot}out_R).$$

Proof. The visible-context empty-distance exactness theorem identifies both central endpoints x and y with e. The left continuation then has right-unit result $out_L\mathsf{hsame}l$, and the right continuation has left-unit result $out_R\mathsf{hsame}r$. Substituting these unit identifications reduces the splice comparison to reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance unit splice commute`

Theorem 57.204 (Metric empty-boundary visible context left-unit witness)**.** *For histories p, q, d, r, out, an empty-boundary visible-context distance witness turns any continuation $\mathsf{Cont}(d, r, out)$ into a metric witness from the empty source:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \mathsf{Cont}(d, r, out) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{e}, r, out).$$

Proof. The empty-boundary distance theorem identifies d with e. Substituting that classifier makes the continuation a left-unit continuation from e to r. The empty source is unary, the target is unary by hypothesis, and unary continuation closure supplies the output carrier, so the three fields package the displayed metric distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context left unit witness`

Theorem 57.205 (Metric empty-boundary visible context right-unit witness)**.** *For histories p, q, d, l, out, an empty-boundary visible-context distance witness turns any continuation $\mathsf{Cont}(l, d, out)$ into a metric witness into the empty target:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{Cont}(l, d, out) \Longrightarrow \mathsf{MetricDistanceWitness}(l, \mathsf{e}, out).$$

Proof. The empty-boundary distance theorem identifies d with e. Substituting that classifier makes the continuation a right-unit continuation into e. The source is unary by hypothesis, the empty target is unary, and unary continuation closure supplies the output carrier, so the three fields package the displayed metric distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context right unit witness`

Theorem 57.206 (Metric empty-boundary visible context continuation depth add)**.** *For histories p, q, d, l, r, mid, out, an empty-boundary visible-context distance witness lets a continuation through d splice into the direct continuation from l to r, so the output depth is the sum of the endpoint depths:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \mathsf{Cont}(l, d, mid) \Longrightarrow \mathsf{Cont}(mid,$$

Proof. The empty-boundary continuation splice removes the central empty distance from the two-step ledger and gives $\mathsf{Cont}(l, r, out)$. Together with the unary endpoint hypotheses, unary continuation closure supplies the output carrier, so these fields form a concrete metric distance witness from l to r. Metric distance depth additivity then gives the displayed equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation depth add`

Theorem 57.207 (Metric empty-boundary visible context continuation witness depth package)**.** *For histories p, q, d, l, r, mid, out, an empty-boundary visible-context distance witness, unary visible endpoints, and the two-step continuation through d determine both the visible-endpoint metric witness and its depth ledger:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \\ &\quad \mathsf{Cont}(l, d, mid) \Longrightarrow \mathsf{Cont}(mid, r, out) \Longrightarrow \\ &\quad \mathsf{MetricDistanceWitness}(l, r, out) \wedge \mathsf{MetricDistanceDepth}(out) = \mathsf{MetricDistanceDepth}(l) + \mathsf{MetricDistanceDepth}\end{aligned}$$

Proof. The witness conjunct is supplied by Definition 57.272 from the empty-boundary witness, the endpoint unary histories, and the two continuation rows.

The depth conjunct is supplied by Definition 57.283 from the same hypotheses. Conjoining the two conclusions gives the displayed package. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation witness depth`

Theorem 57.208 (Metric empty-boundary visible context canonical splice package)**.** *For histories $p, q, d, l, r, mid, out, out'$, an empty-boundary visible-context distance witness, unary endpoint carriers, a two-step continuation through d, and a displayed direct continuation from l to r determine the canonical splice package:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \\ &\quad \mathsf{Cont}(l, d, mid) \Longrightarrow \mathsf{Cont}(mid, r, out) \Longrightarrow \mathsf{Cont}(l, r, out') \Longrightarrow \\ &\quad \mathsf{MetricDistanceWitness}(l, r, out) \wedge \mathsf{hsame}(out, out') \wedge \\ &\quad \mathsf{MetricDistanceDepth}(out) = \mathsf{MetricDistanceDepth}(l) + \mathsf{MetricDistanceDepth}(r).\end{aligned}$$

Proof. The witness row is supplied by Theorem 57.272 from the empty-boundary visible-context witness, the unary carriers, and the two displayed continuation rows.

The comparison row is supplied by Theorem 57.273, which compares the spliced output with the displayed direct continuation $\mathsf{Cont}(l, r, out')$.

The depth row is supplied by Theorem 57.283. Conjoining these three rows gives the displayed certificate package. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context canonical splice package`

Theorem 57.209 (Metric distance witness standard boundary bridge)**.** *For the concrete* MetricDistanceWitness *interface on unary* BHist *endpoint witnesses, the paper-side bridge is the conservative boundary interpretation assembled from the semantic NameCert, visible-context exactness, the left and empty boundary readback rows, and the zero-depth identity-path row. It identifies exactly the BEDC boundary-distance witness rows with the corresponding standard boundary-metric reading, and back again, for the concrete* BHist *witness surface.*

Proof. The semantic carrier and classifier are the concrete MetricDistanceWitness predicate and hsame classifier supplied by Definition 57.229. Thus the bridge has no separate host carrier: its public objects are exactly the displayed BHist distance witnesses.

The boundary readback is supplied in the two directions by Definition 57.96 and Definition 57.97. These rows say that the left and empty BEDC boundary surfaces read as the same standard boundary-distance data, and that the standard reading returns to the same BEDC rows.

Finally, Definition 57.310 provides the zero-depth symmetric identity-path row used by the standard boundary metric reading. Together these rows give a conservative two-way boundary interpretation for the concrete witness surface only. No arbitrary host metric space, completeness, compactness, or topology-induced-by-metric bridge is being claimed. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness standard boundary bridge`

Closure status for $\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$.

Constructive story: A metric distance witness is built from two unary endpoint histories and one unary distance history, with the continuation ledger showing that the distance is exactly the append result from the first endpoint through the second. The classifier on distance results is hsame, so two witnesses are compared by transporting their endpoint and distance histories through the same continuation data rather than by an external real-valued distance function. The source, pattern, and ledger predicates coincide for the semantic certificate: the source accepts concrete distance witnesses, the pattern records empty-distance exactness, symmetry, prefix and suffix visibility, triangle append rows, ball-budget composition, and boundary readback, and the ledger keeps the endpoint carriers plus the distance continuation and structural-depth calculation visible. Since unary append gives a witness distance $x \cdot y$ for unary endpoints x, y, hsame supplies reflexivity, symmetry, and transitivity, and case transport preserves the witness predicate, the five name-certificate obligations hold on the displayed BEDC surface. A history d lies in the signature gap of a $\mathsf{Met}^\uparrow$ token p when the source-domain accepts d as a distance witness for the chosen endpoints, the signature relation pairs it with an answer distance and evidence ledger, and token introduction names that answer as p; concretely, d is unary, its continuation ledger is the endpoint append, and its depth is the sum of the endpoint depths recorded by p. The checked standard bridge reads this finite distance witness as the standard boundary metric datum and reads it back through the same empty, prefix, suffix, and symmetric-zero rows, without changing the carrier. The chapter registers this continuation-distance construction under the name $\mathsf{Met}^\uparrow$; metric laws are certified append and boundary facts over unary histories, with no arbitrary host metric space, completeness theorem, or induced topology introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$, maturePackageClosed)

Remark 57.210 (Zero-axiom encoding note)**.** *Replaces decidable equality with apartness and explicit real-modulus inequalities.*

Theorem 57.211 (Metric distance witness empty-source visible-distance target exactness)**.** *For histories $target, d$, a concrete distance witness from the empty source whose distance ledger is visibly one-headed identifies the target with that same one-headed ledger and exposes unary evidence for the ledger tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{e}, target, \mathsf{E1}(d)) \Longrightarrow target = \mathsf{E1}(d) \wedge \mathsf{UnaryHistory}(d).$$

Proof. Apply empty-left exactness to obtain unary evidence for $target$ and the classifier $\mathsf{hsame}(\mathsf{E1}(d), target)$. One-constructor inversion on this classifier presents $target$ as $\mathsf{E1}(d)$ up to the exposed tail equality. Substitution into the unary target witness and unary one-step inversion give $\mathsf{UnaryHistory}(d)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty source e1 distance target exactness`

Theorem 57.212 (Metric distance witness empty-target visible-distance source exactness)**.** *For histories $source, d$, a concrete distance witness into the empty target whose distance ledger is visibly one-headed identifies the source with that same one-headed ledger and exposes unary evidence for the ledger tail:*

$$\mathsf{MetricDistanceWitness}(source, \mathsf{e}, \mathsf{E1}(d)) \Longrightarrow source = \mathsf{E1}(d) \wedge \mathsf{UnaryHistory}(d).$$

Proof. Apply empty-right exactness to obtain unary evidence for *source* and the classifier $\mathsf{hsame}(\mathsf{E1}(d), \mathit{source})$. One-constructor inversion on this classifier presents *source* as $\mathsf{E1}(d)$ up to the exposed tail equality. Substitution into the unary source witness and unary one-step inversion give $\mathsf{UnaryHistory}(d)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty target e1 distance source exactness`

Theorem 57.213 (Metric nonempty distance has a nonempty endpoint)**.** *For histories* x, y, d : BHist*, if* $\mathsf{MetricDistanceWitness}(x, y, d)$ *holds and* d *is not history-same as* e*, then at least one endpoint is not history-same as* e*:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to (d\mathsf{hsamee} \to \mathsf{False}) \to ((x\mathsf{hsamee} \to \mathsf{False}) \vee (y\mathsf{hsamee} \to \mathsf{False})).$$

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness nonempty distance endpoint nonempty`

Proof. Case-split the two endpoint histories. A visible endpoint constructor is immediately disjoint from e, giving the required side of the disjunction. In the remaining empty/empty case, the continuation field of the metric witness identifies the distance result with e, contradicting the assumed nonempty distance. □

Theorem 57.214 (Metric nonempty distance endpoint positive depth)**.** *For histories* x, y, d : BHist*, if* $\mathsf{MetricDistanceWitness}(x, y, d)$ *holds and* d *is not history-same as* e*, then at least one endpoint has positive structural metric depth:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to (d\mathsf{hsamee} \to \mathsf{False}) \to (0 < \mathsf{MetricDistanceDepth}(x) \vee 0 < \mathsf{MetricDistanceDepth}(y))$$

Proof. Apply the nonempty-distance endpoint theorem to obtain a nonempty endpoint. The positive-depth classifier for metric histories converts that endpoint nonemptiness into positive structural depth on the corresponding side of the disjunction. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness nonempty distance endpoint positive depth`

Theorem 57.215 (Metric positive distance e-one shape)**.** *For histories* x, y, d : BHist*, if* $\mathsf{MetricDistanceWitness}(x, y$ *holds and the structural depth of* d *is not zero, then* d *is visibly one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to (\mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{False}) \to \exists \mathit{tail},\ d = \mathsf{E1}(\mathit{tail}) \wedge \mathsf{UnaryHistory}(\mathit{tail}).$$

Proof. Unpack the metric distance witness to obtain the unary carrier for the distance history d. Case analysis on d rules out e by the positive depth hypothesis and rules out an $\mathsf{E0}$ head by unary-history inversion. The remaining $\mathsf{E1}$ case exposes its tail, and one-step unary inversion gives the unary tail witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness positive distance e1 shape`

Theorem 57.216 (Metric nonempty distance endpoint e-one cases)**.** *For histories* x, y, d : BHist*, if* $\mathsf{MetricDistanceWitness}(x, y, d)$ *holds and the distance endpoint is not history-same as* e*, then at least one endpoint is visibly one-headed with a unary tail:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(x, y, d) \to (d\mathsf{hsamee} \to \mathsf{False}) \to \\ &\quad (\exists x_0,\ x = \mathsf{E1}(x_0) \wedge \mathsf{UnaryHistory}(x_0)) \vee (\exists y_0,\ y = \mathsf{E1}(y_0) \wedge \mathsf{UnaryHistory}(y_0)).\end{aligned}$$

Proof. First apply the endpoint non-emptiness theorem to the metric witness and the nonempty distance assumption. On whichever side is nonempty, use the endpoint's unary-history carrier from the metric witness and apply unary nonempty one-tail readback. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness nonempty distance endpoint e1 cases`

Theorem 57.217 (Metric empty-source nonempty distance target e-one cases)**.** *For histories* $target, dist$: BHist*, if a concrete metric distance witness starts at the empty source and its distance endpoint is not history-same as* e*, then the target endpoint is visibly one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{e}, target, dist) \to (dist\mathsf{hsamee} \to \mathsf{False}) \to \exists targetTail,\ target = \mathsf{E1}(targetTail) \wedge \mathsf{UnaryHist}$$

Proof. Apply the nonempty-distance endpoint e-one cases theorem. The source-side visible branch would identify e with a one-headed history, which is impossible by constructor disjointness. The remaining branch is exactly the target e-one readback. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty source nonempty distance target e1 cases`

Theorem 57.218 (Metric empty-target nonempty distance source e-one cases)**.** *For histories* $source, dist$: BHist*, if a concrete metric distance witness ends at the empty target and its distance endpoint is not history-same as* e*, then the source endpoint is visibly one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(source, \mathsf{e}, dist) \to (dist\mathsf{hsamee} \to \mathsf{False}) \to \exists sourceTail,\ source = \mathsf{E1}(sourceTail) \wedge \mathsf{UnaryH}$$

Proof. Apply the nonempty-distance endpoint e-one cases theorem. The target-side visible branch would identify e with a one-headed history, which is impossible by constructor disjointness. The remaining branch is exactly the source e-one readback. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty target nonempty distance source e1 cases`

Theorem 57.219 (Metric empty-boundary nonempty distance positive endpoint depth)**.** *For histories* $source, target, dist$: BHist*, a concrete metric distance witness with exactly one empty boundary and a nonempty distance endpoint forces positive structural depth on the other endpoint:*

$$\begin{aligned}&(\mathsf{MetricDistanceWitness}(\mathsf{e}, target, dist) \to (dist\mathsf{hsamee} \to \mathsf{False}) \to 0 < \mathsf{MetricDistanceDepth}(target)) \wedge \\ &(\mathsf{MetricDistanceWitness}(source, \mathsf{e}, dist) \to (dist\mathsf{hsamee} \to \mathsf{False}) \to 0 < \mathsf{MetricDistanceDepth}(source)).\end{aligned}$$

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary nonempty distance positive endpoint depth`

Proof. For the empty-source implication, apply Theorem 57.217 to the displayed witness and the nonempty distance hypothesis. The result expresses *target* as $\mathsf{E1}(targetTail)$ with a unary tail, so the structural metric depth of *target* is a successor and is therefore positive.

For the empty-target implication, apply Theorem 57.218 in the same way. The source endpoint is read back as $\mathsf{E1}(sourceTail)$ with a unary tail, and the one-headed shape gives positive structural metric depth for *source*. □

The ten-field fit is: traditional target paired empty-boundary nonzero-distance endpoint depth; BEDC source MetricDistanceWitness over BHist; carrier the surviving boundary endpoint; classifier hsame; stability unary one-headed readback and depth positivity; ledger the nonempty distance endpoint; core theorem Theorem 57.219; exactness positive depth on the nonempty boundary endpoint; standard bridge finite unary metric boundary readback; status ProofTarget.

Theorem 57.220 (Metric visible-boundary positive-depth endpoint readback)**.** *For histories $p, q, source, target, di$ BHist, a visible-context metric distance witness with exactly one empty central boundary and positive central distance depth reads back the nonempty central endpoint as one-headed and positive-depth:*

$$(\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, target \cdot q, (p \cdot dist) \cdot q) \to (\mathsf{MetricDistanceDepth}(dist) = 0 \to \mathsf{False}) \to \exists targetTail,\ target = \mathsf{E1}(targetTail) \wedge \mathsf{UnaryHistory}(targetTail) \wedge 0 < \mathsf{MetricDistanceDepth}(target)) \wedge (\mathsf{MetricDistanceWitness}(p \cdot source, \mathsf{e} \cdot q, (p \cdot dist) \cdot q) \to (\mathsf{MetricDistanceDepth}(dist) = 0 \to \mathsf{False}) \to \exists sourceTail,\ source = \mathsf{E1}(sourceTail) \wedge \mathsf{UnaryHistory}(sourceTail) \wedge 0 < \mathsf{MetricDistanceDepth}(source)).$$

Proof. For the empty central source implication, apply Definition 57.13 to peel the visible prefix p and suffix q from the displayed witness. This recovers the central witness $\mathsf{MetricDistanceWitness}(\mathsf{e}, target, dist)$.

The positive-depth hypothesis rules out $\mathsf{MetricDistanceDepth}(dist) = 0$. By Definition 57.253, this is the same nonempty-distance input required by the empty-source e-one cases theorem. Apply Definition 57.217 to obtain $target = \mathsf{E1}(targetTail)$ with unary $targetTail$. The one-headed displayed endpoint has successor structural metric depth, so $0 < \mathsf{MetricDistanceDepth}(target)$.

For the empty central target implication, the same visible-context peeling recovers $\mathsf{MetricDistanceWitness}(source$ The same zero-depth equivalence converts positive depth of $dist$ into the nonempty-distance input, and Definition 57.218 gives $source = \mathsf{E1}(sourceTail)$ with unary $sourceTail$. The displayed one-headed source again has positive structural metric depth. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible boundary positive depth endpoint readback`

Theorem 57.221 (Metric distance witness zero-headed component impossibility)**.** *For histories x, y, d : BHist, no concrete metric distance witness has a zero-headed source, target, or distance component:*

$$(\mathsf{MetricDistanceWitness}(\mathsf{E0}(x), y, d) \to \mathsf{False}) \wedge (\mathsf{MetricDistanceWitness}(x, \mathsf{E0}(y), d) \to \mathsf{False}) \wedge (\mathsf{MetricDistanceWit}$$

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e0 component absurd`

Proof. Unpack the concrete witness. Its three component fields are unary-history evidence for the source, target, and distance histories. BEDC unary histories are generated only from e by E1, so each displayed E0 component contradicts unary no-zero-extension. □

Theorem 57.222 (Metric empty distance visible endpoint impossibility)**.** *For histories x, y, d, tx, ty, if a metric distance witness has a result history-same as* e*, then neither endpoint can be history-same as a visible one-headed history:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to \mathsf{hsame}(d, \mathsf{e}) \to (\mathsf{hsame}(x, \mathsf{E1}(tx)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y, \mathsf{E1}(ty)) \to \mathsf{False}).$$

Proof. Transport the continuation result of the metric witness along the displayed distance classifier, obtaining an empty-distance witness over the same endpoints. Empty-distance exactness identifies both endpoints with e. Composing either endpoint comparison with a visible one-headed classifier contradicts the empty/e-one no-confusion theorem. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty distance visible endpoint absurd`

Theorem 57.223 (Metric empty-distance composite endpoint collapse)**.** *For histories x, y, z, d_{xy}, d_{yz}, if* $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$ *and* $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$ *both have distance histories classified as* e*, then all three endpoints classify together:*

$$d_{xy}\mathsf{hsamee} \to d_{yz}\mathsf{hsamee} \to \mathsf{hsame}(x, y) \wedge \mathsf{hsame}(y, z) \wedge \mathsf{hsame}(x, z).$$

Proof. Transport each distance witness to the empty-distance case. Empty-distance exactness identifies the corresponding endpoint pair with e, and transitivity through e gives the three endpoint comparisons. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty distance composite endpoint collapse`

Theorem 57.224 (Metric e1-pair empty-distance impossibility)**.** *For histories $x, y : \mathsf{BHist}$,*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{e}) \to \mathsf{False}.$$

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e1 pair empty distance absurd`

Proof. Apply empty-distance exactness to the displayed metric witness. It forces the left endpoint $\mathsf{E1}(x)$ to be history-same as e, contradicting the disjointness of visible one-headed histories from the empty history. □

Theorem 57.225 (Metric e1 endpoints force e1 distance)**.** *For histories $x, y, d : \mathsf{BHist}$, a metric distance witness between two one-headed endpoints forces the distance history itself to be one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), d) \Longrightarrow \exists d_0 : \mathsf{BHist},\ d = \mathsf{E1}(d_0) \wedge \mathsf{UnaryHistory}(d_0).$$

Proof. Case-analyze the distance history. The empty case contradicts Definition 57.224; the zero-headed case contradicts the unary carrier field of the witness. The one-headed case exposes the displayed tail, and unary inversion supplies its carrier proof. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e1 endpoints distance e1 shape`

Theorem 57.226 (Metric right-boundary visible context distance source)**.** *For histories $p, q, x, d : \mathsf{BHist}$, a visible-context distance witness with empty central right endpoint identifies the central distance with the visible source and gives the same structural depth:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{hsame}(d, x) \wedge \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(x).$$

Proof. Right-boundary visible-context exactness extracts the central classifier $\mathsf{hsame}(d, x)$. Case analysis on that classifier identifies the two histories, and the metric-depth equality follows by reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right boundary visible context distance source`

Theorem 57.227 (Metric right-boundary visible context positive-depth source shape)**.** *For histories $p, q, x, d : \mathsf{BHist}$, a visible-context distance witness with empty central right endpoint and positive central distance depth forces the central source to be visibly one-headed with a unary tail:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow (\mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{False}) \Longrightarrow \exists x_0 : \mathsf{BHist},\ x = \mathsf{E1}(x_0) \wedge \mathsf{Ur}$$

Proof. Apply right-boundary visible-context exactness. It exposes unary evidence for the central source and the classifier $\mathsf{hsame}(d, x)$. If x classified as e, transitivity would classify d as e, and the zero-depth classifier would contradict the positive-depth hypothesis. Thus x is a nonempty unary history, so unary nonempty e-one tail readback supplies the required x_0. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right boundary visible context positive depth source e1 shape`

Theorem 57.228 (Metric left-boundary visible-context distance target)**.** *For histories p, q, y, d, a visible-context distance witness whose central left endpoint is empty identifies the central distance with the target and aligns their structural depths:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, y{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{hsame}(d, y) \wedge \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(y).$$

Proof. Apply left-boundary visible-context exactness to peel the visible prefix and suffix. The central empty-left witness gives $\mathsf{hsame}(d, y)$. Case analysis on that classifier reduces the displayed depth equation to reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left boundary visible context distance target`

Theorem 57.229 (Metric distance witness semantic name certificate)**.** *For unary endpoint histories x, y, the concrete distance-witness predicate $d \mapsto \mathsf{MetricDistanceWitness}(x, y, d)$ carries a semantic naming certificate whose source, pattern, and ledger predicates are the same concrete witness predicate and whose classifier is* hsame.

Proof. The carrier witness is the concrete distance history $x \cdot y$. Unary append closure supplies its unary carrier witness, and the continuation field is the reflexive ledger $\mathsf{Cont}(x, y, x \cdot y)$. The classifier fields are the reflexive, symmetric, and transitive laws for hsame. Carrier transport is history-sameness transport of the concrete distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness semanticNameCert`

Definition 57.230 (MetricSpace ledger policy)**.** *Record carrier witnesses and the real ledger of each distance value.*

Lean4 (definition) `BEDC.Derived.MetricUp.MetricLedgerPolicy`
Lean4 ✓ `BEDC.Derived.MetricUp.MetricLedgerPolicy rows`

Definition 57.231 ($\mathsf{Met}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Met}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.MetricUp.MetricCertificateObligations`

Definition 57.232 (Metric ball budget predicate)**.** *For a certified $\mathsf{Met}^{\uparrow}$ setup on a carrier X with distance $d : X \times X \to \mathsf{Real}^{\uparrow}$, a ball-budget structure supplies an ordered-real comparison $\leq_{\mathsf{R}}$ on $\mathsf{Real}^{\uparrow}$, an addition operation $+$ on $\mathsf{Real}^{\uparrow}$, a transitivity field for $\leq_{\mathsf{R}}$, and a two-sided addition-monotonicity field saying that $a \leq_{\mathsf{R}} a'$ and $b \leq_{\mathsf{R}} b'$ entail $a + b \leq_{\mathsf{R}} a' + b'$. Relative to this chosen budget structure, the closed ball-budget predicate is*

$$\mathsf{MetricBallBudget}_d(x, y; r) :\Longleftrightarrow d(x, y) \leq_{\mathsf{R}} r.$$

Lean4 (definition) `BEDC.Derived.MetricUp.MetricBallBudget`

Theorem 57.233 (Metric ball budget composition)**.** *Let X be a carrier equipped with the* $\mathsf{Met}^{\uparrow}$ *certificate obligations of Definition 57.231, and let $d : X \times X \to \mathsf{Real}^{\uparrow}$ be its certified distance. Assume also the ball-budget ordered-real fields of Definition 57.232: the comparison $\leq_{\mathsf{R}}$, addition $+$, budget-transitivity, and two-sided budget-addition-monotonicity. For $x, y, z : X$ and budgets $r, s : \mathsf{Real}^{\uparrow}$,*

$$\mathsf{MetricBallBudget}_d(x, y; r) \Longrightarrow \mathsf{MetricBallBudget}_d(y, z; s) \Longrightarrow \mathsf{MetricBallBudget}_d(x, z; r + s).$$

Equivalently,

$$d(x, y) \leq_{\mathsf{R}} r \Longrightarrow d(y, z) \leq_{\mathsf{R}} s \Longrightarrow d(x, z) \leq_{\mathsf{R}} r + s.$$

Proof. Unfold Definition 57.232. The two premises are the budget comparisons $d(x, y) \leq_{\mathsf{R}} r$ and $d(y, z) \leq_{\mathsf{R}} s$. The triangle-inequality field of Definition 57.5 gives

$$d(x, z) \leq_{\mathsf{R}} d(x, y) + d(y, z).$$

Apply the supplied two-sided budget-addition-monotonicity field to the two budget premises. This gives

$$d(x, y) + d(y, z) \leq_{\mathsf{R}} r + s.$$

Apply the supplied budget-transitivity field to the triangle inequality and the displayed budget bound. This yields $d(x, z) \leq_{\mathsf{R}} r + s$. Refolding Definition 57.232 gives the closed ball-budget conclusion. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricBallBudget composition`

Theorem 57.234 (Metric distance witness standard bridge)**.** *For the public* $\mathsf{Met}^{\uparrow}$ *distance-witness surface over unary* BHist *endpoints x, y, there is a conservative standard interpretation whose BEDC carrier is*

$$\{\, d \mid \mathsf{MetricDistanceWitness}(x, y, d) \,\},$$

whose classifier is hsame*, whose forward row reads such a witness as the finite append-distance presentation between the two unary endpoints, and whose reverse row reconstructs the BEDC witness from that finite append presentation. The bridge is only for this generated distance-witness surface; it does not assert arbitrary host real metrics.*

Proof. The carrier and classifier come from Definition 57.229: the public BEDC objects are exactly the d satisfying $\mathsf{MetricDistanceWitness}(x, y, d)$, and the classifier is hsame.

For the forward row, apply Definition 57.13 to read the visible unary context as the finite append-distance presentation between the endpoints. Definition 57.133 ensures that this presentation is determined by the visible context, while Definition 57.9 transports the same presentation across the symmetric endpoint order.

For the reverse row, read the finite append-distance presentation back through Definition 57.13. The resulting BEDC witness is classified by the same hsame row, and Definition 57.233 supplies the budget-compatible composition law needed by the public distance-witness surface.

Thus the two rows form a conservative paper-side standard bridge for the generated $\mathsf{MetricDistanceWitness}$ surface only. No completeness, compactness, topology, or arbitrary host-real metric structure is introduced. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricUp StdBridge`

Definition 57.235 (MetricSpaceUp public distance surface)**.** *The* $\mathsf{Met}^{\uparrow}$ *public distance surface is the finite* BHist *surface whose carrier rows are the unary endpoint histories* x, y*, the displayed* $\mathsf{MetricDistanceWitness}(x, y, d)$ *row, the ball-budget row* $\mathsf{MetricBallBudget}_d(x, y; r)$*, the classifier row* hsame*, the finite* Cont *provenance row, and the* $\mathsf{Real}^{\uparrow}$ *budget rows used by Definition 57.232. A public distance read of* $\mathsf{Met}^{\uparrow}$ *is a projection of this surface and no larger host metric-space object.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspacePublicDistanceSurface hsame transport`

Theorem 57.236 (MetricSpaceUp public distance surface exhaustion)**.** *Every public distance read of* $\mathsf{Met}^{\uparrow}$ *projects exactly to the* BHist *endpoint rows, the* MetricDistanceWitness *row, the* MetricBallBudget *row, the* hsame *classifier row, the finite* Cont *provenance row, and the* $\mathsf{Real}^{\uparrow}$ *budget rows of Definition 57.235. Conversely, any such finite family repacks as the same public distance surface.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspacePublicDistanceSurface exhaustion`

Proof. Project a public read through the distance-witness semantic certificate of Definition 57.229. This fixes the BHist endpoints, the concrete $\mathsf{MetricDistanceWitness}(x, y, d)$ row, and the hsame classifier row.

Next apply Definition 57.233. The only budget rows available to the public read are the displayed $\mathsf{Real}^{\uparrow}$ comparison, addition, transitivity, and monotonicity fields used to compose ball-budget witnesses.

Finally use Definition 57.234 and Definition 57.133. The bridge reads the same finite witness surface in the standard direction, and visible context determinacy prevents an additional host distance row from entering the packet. Repacking the projected rows gives exactly Definition 57.235. □

Theorem 57.237 (MetricSpaceUp visible-context distance consumer surface)**.** *The named visible-context consumers* $\mathsf{TotallyBounded}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*, and* $\mathsf{S}^{1\uparrow}$ *may read a* $\mathsf{Met}^{\uparrow}$ *distance only through the visible-context distance witness, ball-budget, and classifier rows of Definition 57.235. Their public use of the metric interface does not add a host metric carrier, a separate topology generator, or an analytic completeness or compactness row.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspacePublicDistanceSurface visible context consumer surface`

Proof. Start with the public surface of Definition 57.235. The only exported distance data are the MetricDistanceWitness row, the ball-budget row, the hsame classifier, and the finite Cont provenance over the displayed $\mathsf{Real}^{\uparrow}$ budget rows.

Apply Definition 57.133. Any visible-context consumer that reads a distance witness receives the determined finite witness row rather than an external host distance function.

Use Definition 57.233 for all budget propagation and Definition 57.234 for the standard distance-facing reading. These two rows exhaust the consumer-facing surface, so the listed downstream chapters can consume only the visible-context witness, budget, and classifier rows. □

Theorem 57.238 (MetricSpace visible-context public certificate)**.** *The public* $\mathsf{Met}^{\uparrow}$ *certificate is exactly the finite* BHist *endpoint rows, the* MetricDistanceWitness *row, the* MetricBallBudget *row, the* hsame *classifier row, the finite* Cont *provenance row, and the* $\mathsf{Real}^{\uparrow}$ *budget rows of Definition 57.235. Every downstream read by* $\mathsf{TotallyBounded}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*, and* $\mathsf{S}^{1\uparrow}$ *factors through the visible-context consumer surface of Definition 57.237, so the certificate exports no host metric-space carrier, no separate topology generator, and no analytic completeness or compactness row.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspacePublicDistanceSurface visible context public certificate`

Proof. First project the visible distance read through Definition 57.229. This fixes the endpoint BHist rows, the displayed MetricDistanceWitness row, and the hsame classifier that names the distance witness.

Next compose the budget rows by Definition 57.233. The only available comparison, addition, transitivity, and monotonicity data are the displayed $\mathsf{Real}^{\uparrow}$ budget rows already present in Definition 57.235.

Then read the standard-facing side through Definition 57.234. The bridge has the same finite witness surface, so it does not introduce a host metric function or an ambient metric-space object.

Finally apply Definition 57.237. The listed downstream chapters read the metric interface only through this visible-context surface. Combining these rows gives exactly the public $\mathsf{Met}^{\uparrow}$ certificate and no larger object. □

Primitive boundary. $\mathsf{Met}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Theorem 57.239 (Metric distance witness empty-boundary visible-context distance empty)**.** *For histories p, q, d, a visible-context distance witness whose central left and right endpoints are both empty identifies the central distance with the empty history and gives zero central distance depth:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{hsame}(d, \mathsf{e}) \wedge \mathsf{MetricDistanceDepth}(d) = 0.$$

Proof. Apply Definition 57.13 to peel away the visible prefix and suffix. The remaining central witness is $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d)$. The empty-left boundary theorem identifies d with e; case analysis on that classifier gives the zero depth equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context distance empty`

Theorem 57.240 (Metric prefix-independent symmetric zero-depth empty-boundary forward)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, suppose the two symmetric visible-context distance witnesses*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q), \qquad \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q')$$

hold. If $\mathsf{MetricDistanceDepth}(d_{xy}) = 0$*, then the original visible context carries the empty-boundary witness*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot \mathsf{e}) \cdot q).$$

Proof. Peel both visible-context witnesses to their central witnesses. Symmetric classification compares d_{xy} and d_{yx}. Case analysis on the zero-depth central distance leaves only $d_{xy} = \mathsf{e}$; the empty-distance visible-context readback then identifies the two central endpoints as empty. Reattaching the original prefix and suffix gives the displayed empty-boundary witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth empty boundary forward`

Theorem 57.241 (Metric empty-boundary visible context append unit laws)**.** *For histories p, q, d, l, r, a visible-context distance witness whose central endpoints are both empty makes the central distance act as a left and right append unit:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{append}(d, r) = r \ \wedge \ \mathsf{append}(l, d) = l.$$

Proof. The empty-boundary distance theorem identifies d with e. Case analysis on that classifier reduces the two displayed equations to the left and right unit laws for finite-kernel append. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context append unit laws`

Theorem 57.242 (Metric empty-boundary visible context unit splice commute)**.** *For histories $p, q, d, l, r, out_L, out_R$, an empty-boundary visible-context distance witness makes left and right continuation through the central distance commute after one ordinary append splice:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{Cont}(l, d, out_L) \Longrightarrow \mathsf{Cont}(d, r, out_R) \Longrightarrow \mathsf{hsame}(out_L{\cdot}r, l{\cdot}out_R).$$

Proof. The empty-boundary distance theorem identifies d with e. The left continuation then has right-unit result $out_L\mathsf{hsame}l$, and the right continuation has left-unit result $out_R\mathsf{hsame}r$. Substituting these two unit identifications reduces the displayed splice comparison to reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context unit splice commute`

Theorem 57.243 (Metric visible-context empty-distance unit splice commute)**.** *For histories $p, q, x, y, l, r, out_L, out_R$, a visible-context empty-distance witness makes left continuation through x and right continuation through y commute after one ordinary append splice:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}\mathsf{e}){\cdot}q) \Longrightarrow \mathsf{Cont}(l, x, out_L) \Longrightarrow \mathsf{Cont}(y, r, out_R) \Longrightarrow \mathsf{hsame}(out_L{\cdot}r, l{\cdot}out_R).$$

Proof. The visible-context empty-distance exactness theorem identifies both central endpoints x and y with e. The left continuation then has right-unit result $out_L\mathsf{hsame}l$, and the right continuation has left-unit result $out_R\mathsf{hsame}r$. Substituting these unit identifications reduces the splice comparison to reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance unit splice commute`

Theorem 57.244 (Metric empty-boundary visible context left-unit witness)**.** *For histories p, q, d, r, out, an empty-boundary visible-context distance witness turns any continuation $\mathsf{Cont}(d, r, out)$ into a metric witness from the empty source:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \mathsf{Cont}(d, r, out) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{e}, r, out).$$

Proof. The empty-boundary distance theorem identifies d with e. Substituting that classifier makes the continuation a left-unit continuation from e to r. The empty source is unary, the target is unary by hypothesis, and unary continuation closure supplies the output carrier, so the three fields package the displayed metric distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context left unit witness`

Theorem 57.245 (Metric empty-boundary visible context right-unit witness)**.** *For histories p, q, d, l, out, an empty-boundary visible-context distance witness turns any continuation $\mathsf{Cont}(l, d, out)$ into a metric witness into the empty target:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{Cont}(l, d, out) \Longrightarrow \mathsf{MetricDistanceWitness}(l, \mathsf{e}, out).$$

Proof. The empty-boundary distance theorem identifies d with e. Substituting that classifier makes the continuation a right-unit continuation into e. The source is unary by hypothesis, the empty target is unary, and unary continuation closure supplies the output carrier, so the three fields package the displayed metric distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context right unit witness`

Theorem 57.246 (Metric empty-boundary visible context continuation depth add)**.** *For histories p, q, d, l, r, mid, out, an empty-boundary visible-context distance witness lets a continuation through d splice into the direct continuation from l to r, so the output depth is the sum of the endpoint depths:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \mathsf{Cont}(l, d, mid) \Longrightarrow \mathsf{Cont}(mid,$$

Proof. The empty-boundary continuation splice removes the central empty distance from the two-step ledger and gives $\mathsf{Cont}(l, r, out)$. Together with the unary endpoint hypotheses, unary continuation closure supplies the output carrier, so these fields form a concrete metric distance witness from l to r. Metric distance depth additivity then gives the displayed equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation depth add`

Theorem 57.247 (Metric empty-boundary visible context continuation witness depth package)**.** *For histories p, q, d, l, r, mid, out, an empty-boundary visible-context distance witness, unary visible endpoints, and the two-step continuation through d determine both the visible-endpoint metric witness and its depth ledger:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \\ &\quad \mathsf{Cont}(l, d, mid) \Longrightarrow \mathsf{Cont}(mid, r, out) \Longrightarrow \\ &\quad \mathsf{MetricDistanceWitness}(l, r, out) \wedge \mathsf{MetricDistanceDepth}(out) = \mathsf{MetricDistanceDepth}(l) + \mathsf{MetricDistanceDepth}\end{aligned}$$

Proof. The witness conjunct is supplied by Definition 57.272 from the empty-boundary witness, the endpoint unary histories, and the two continuation rows.

The depth conjunct is supplied by Definition 57.283 from the same hypotheses. Conjoining the two conclusions gives the displayed package. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation witness depth`

Theorem 57.248 (Metric empty-boundary visible context canonical splice package)**.** *For histories $p, q, d, l, r, mid, out, out'$, an empty-boundary visible-context distance witness, unary endpoint carriers, a two-step continuation through d, and a displayed direct continuation from l to r determine the canonical splice package:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \\ &\quad \mathsf{Cont}(l, d, mid) \Longrightarrow \mathsf{Cont}(mid, r, out) \Longrightarrow \mathsf{Cont}(l, r, out') \Longrightarrow \\ &\quad \mathsf{MetricDistanceWitness}(l, r, out) \wedge \mathsf{hsame}(out, out') \wedge \\ &\quad \mathsf{MetricDistanceDepth}(out) = \mathsf{MetricDistanceDepth}(l) + \mathsf{MetricDistanceDepth}(r).\end{aligned}$$

Proof. The witness row is supplied by Theorem 57.272 from the empty-boundary visible-context witness, the unary carriers, and the two displayed continuation rows.

The comparison row is supplied by Theorem 57.273, which compares the spliced output with the displayed direct continuation $\mathsf{Cont}(l, r, out')$.

The depth row is supplied by Theorem 57.283. Conjoining these three rows gives the displayed certificate package. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context canonical splice package`

Theorem 57.249 (Metric distance witness standard boundary bridge)**.** *For the concrete* MetricDistanceWitness *interface on unary* BHist *endpoint witnesses, the paper-side bridge is the conservative boundary interpretation assembled from the semantic NameCert, visible-context exactness, the left and empty boundary readback rows, and the zero-depth identity-path row. It identifies exactly the BEDC boundary-distance witness rows with the corresponding standard boundary-metric reading, and back again, for the concrete* BHist *witness surface.*

Proof. The semantic carrier and classifier are the concrete MetricDistanceWitness predicate and hsame classifier supplied by Definition 57.229. Thus the bridge has no separate host carrier: its public objects are exactly the displayed BHist distance witnesses.

The boundary readback is supplied in the two directions by Definition 57.96 and Definition 57.97. These rows say that the left and empty BEDC boundary surfaces read as the same standard boundary-distance data, and that the standard reading returns to the same BEDC rows.

Finally, Definition 57.310 provides the zero-depth symmetric identity-path row used by the standard boundary metric reading. Together these rows give a conservative two-way boundary interpretation for the concrete witness surface only. No arbitrary host metric space, completeness, compactness, or topology-induced-by-metric bridge is being claimed. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness standard boundary bridge`

Closure status for $\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$**.**

Constructive story: A metric distance witness is built from two unary endpoint histories and one unary distance history, with the continuation ledger showing that the distance is exactly the append result from the first endpoint through the second. The classifier on distance results is hsame, so two witnesses are compared by transporting their endpoint and distance histories through the same continuation data rather than by an external real-valued distance function. The source, pattern, and ledger predicates coincide for the semantic certificate: the source accepts concrete distance witnesses, the pattern records empty-distance exactness, symmetry, prefix and suffix visibility, triangle append rows, ball-budget composition, and boundary readback, and the ledger keeps the endpoint carriers plus the distance continuation and structural-depth calculation visible. Since unary append gives a witness distance $x \cdot y$ for unary endpoints x, y, hsame supplies reflexivity, symmetry, and transitivity, and case transport preserves the witness predicate, the five name-certificate obligations hold on the displayed BEDC surface. A history d lies in the signature gap of a $\mathsf{Met}^\uparrow$ token p when the source-domain accepts d as a distance witness for the chosen endpoints, the signature relation pairs it with an answer distance and evidence ledger, and token introduction names that answer as p; concretely, d is unary, its continuation ledger is the endpoint append, and its depth is the sum of the endpoint depths recorded by p. The checked standard bridge reads this finite distance witness as the standard boundary metric datum and reads it back through the same empty, prefix, suffix, and symmetric-zero rows, without changing the carrier. The chapter registers this continuation-distance construction under the name $\mathsf{Met}^\uparrow$; metric laws are certified append and boundary facts over unary histories, with no arbitrary host metric space, completeness theorem, or induced topology introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$, maturePackageClosed)

Scope closed: The closed scope is the MetricDistanceWitness semantic certificate, ball-budget composition, the standard distance-witness bridge, the standard boundary bridge, and the named cross-chapter consumers in $\mathsf{TotallyBounded}^\uparrow$, $\mathsf{CompleteMetric}^\uparrow$, $\mathsf{CompactMetric}^\uparrow$, $\mathsf{ContinuousMap}^\uparrow$, and the compact uniform-continuity capstone.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.MetricUp.MetricUp\_StdBridge`

Bridge status: bridgeChecked

Not claimed: This chapter does not close arbitrary host metric spaces, general completeness, compactness, topology induced by a metric, or any bridge stronger than the checked BEDC schema bridge.

Upgrade path: no further upgrade – chapter at top of formal axis

Remark 57.250 (Zero-axiom encoding note)**.** *Replaces decidable equality with apartness and explicit real-modulus inequalities.*

Closure status for $\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$**.**

Constructive story: A $\mathsf{Met}^\uparrow$ obligation packet is generated from the checked carrier, classifier, distance witness, identity, symmetry, triangle, transport, and NameCert rows, with the Lean target read only as verification evidence for that finite row package.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$, maturePackageClosed)

Scope closed: The carrier, classifier, distance witness, identity, symmetry, triangle, transport, and local NameCert rows are scoped as one finite BHist packet over componentwise hsame transport, displayed Cont replay, and $\mathsf{Real}^\uparrow$ distance primitives.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.MetricUp.MetricUp\_StdBridge`

Bridge status: bridgeChecked

Not claimed: This record does not claim a public metric-object bridge, a completion principle, compactness, topology generation, or quotient real equality.

Upgrade path: No further theory-axis grade remains for this chapter; downstream bridge audits may reread the same BHist, hsame, Cont, and $\mathsf{Real}^\uparrow$ distance rows.

Theorem 57.251 (Metric depth-zero distance has empty endpoints)**.** *For histories x, y, d, a concrete distance witness whose distance ledger has structural depth zero has empty endpoints:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to \mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).$$

Proof. Classify the displayed distance history. The empty distance case is exactly the empty-distance witness exactness theorem. A zero-headed or one-headed distance has successor depth, contradicting the displayed zero-depth equation by constructor no-confusion for natural numbers. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness depth zero empty endpoints`

Theorem 57.252 (Metric empty endpoints have depth-zero distance)**.** *For histories x, y, d, a concrete distance witness whose endpoints are both history-same to* e *has structural distance depth zero:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \to \mathsf{hsame}(x, \mathsf{e}) \to \mathsf{hsame}(y, \mathsf{e}) \to \mathsf{MetricDistanceDepth}(d) = 0.$$

Proof. Eliminate the two endpoint sameness witnesses, reducing both endpoints to e. The continuation ledger inside the distance witness then reduces the distance history itself to e, and the depth definition evaluates to zero. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty endpoints depth zero`

Theorem 57.253 (Metric distance depth zero iff empty)**.** *For a history d, structural metric distance depth is zero exactly when d classifies with the empty history:*

$$\mathsf{MetricDistanceDepth}(d) = 0 \iff \mathsf{hsame}(d, \mathsf{e}).$$

Proof. Case-analyze the history d. The empty case is reflexive. A zero-headed or one-headed history has successor depth, so it cannot satisfy the zero-depth equation. Conversely, a history-sameness proof with e reduces the depth equation to the empty reflexive case. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth zero iff empty`

Theorem 57.254 (Metric distance positive depth iff nonempty)**.** *For a history d, positive structural metric distance depth is equivalent to not being history-same as* e*:*

$$0 < \mathsf{MetricDistanceDepth}(d) \iff (d\mathsf{hsamee} \to \mathsf{False}).$$

Proof. Case-analyze d. The empty case has depth zero and cannot satisfy the nonempty predicate. A zero-headed or one-headed history has successor depth, and constructor separation rules out history-sameness with e. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth positive iff nonempty`

Theorem 57.255 (Metric distance append positive depth iff)**.** *For histories p and d, an appended distance ledger has positive structural depth exactly when one of its two factors has positive structural depth:*

$$0 < \mathsf{MetricDistanceDepth}(p \cdot d) \iff 0 < \mathsf{MetricDistanceDepth}(p) \lor 0 < \mathsf{MetricDistanceDepth}(d).$$

Proof. Use the positive-depth classifier to replace positive depth by internal nonemptiness. Kernel append nonemptiness then splits the appended history into the left or right nonempty factor. The converse applies the same two classifiers in reverse and rebuilds nonemptiness of the appended history from the displayed nonempty factor. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth append positive iff`

Theorem 57.256 (Metric distance positive depth shape cases)**.** *For a history d, positive structural metric distance depth exposes one of the two visible history constructors:*

$$(\mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{False}) \implies (\exists z : \mathsf{BHist}.\ d = \mathsf{E0}(z)) \lor (\exists z : \mathsf{BHist}.\ d = \mathsf{E1}(z)).$$

Proof. Case-analyze d. The empty branch contradicts the displayed positive-depth hypothesis because the structural depth of e is zero. The two visible branches return the exposed payload under E0 or E1. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth positive shape cases`

Theorem 57.257 (Metric distance depth append-left equality emptiness)**.** *For histories p and d, appending p on the left preserves structural metric distance depth exactly when p is the empty history:*

$$\mathsf{MetricDistanceDepth}(p \cdot d) = \mathsf{MetricDistanceDepth}(d) \iff \mathsf{hsame}(p, \mathsf{e}).$$

Proof. Induct on the displayed tail d. The empty tail is precisely Definition 57.253. A zero-headed or one-headed tail reduces the equality through successor injectivity, and the reverse direction rebuilds the same successor equality after the left prefix is identified with e. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth append left eq iff empty`

Theorem 57.258 (Metric distance depth append-left cancellation)**.** *For histories p, d, e : BHist, equality of structural metric distance depths after appending the same left prefix cancels that prefix:*

$$\mathsf{MetricDistanceDepth}(p{\cdot}d) = \mathsf{MetricDistanceDepth}(p{\cdot}e) \implies \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(e).$$

Proof. The structural depth of a left append decomposes as the depth of the common prefix plus the depth of the tail. Rewriting both displayed sides by this depth-add equation reduces the claim to left cancellation for addition in $\mathbb{N}$, yielding equality of the two tail depths. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth append left cancel`

Theorem 57.259 (Metric strict prefix depth decomposition)**.** *For histories h, k : BHist, a strict unary prefix witness from h to k exposes a nonempty unary tail whose continuation reconstructs k, and the metric depth of k splits as the depth of h plus the depth of that tail:*

$$\mathsf{NatUnaryStrictPrefix}(h,k) \Longrightarrow \exists tail : \mathsf{BHist}.\ \mathsf{UnaryHistory}(tail) \wedge (tail = \mathsf{e} \to \mathsf{False}) \wedge \mathsf{Cont}(h, tail, k) \wedge \mathsf{MetricDistance}$$

Proof. Unpack the strict-prefix witness. It already supplies a unary nonempty tail and a continuation ledger from h through that tail to k. Inverting the continuation identifies k with $h \cdot tail$. Induction on the concrete tail then proves the structural depth equation for append, giving the displayed sum formula. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth strict prefix decomposes`

Theorem 57.260 (Metric distance depth visible-context cancellation)**.** *For histories p, q, d, e : BHist, equality of structural depths after a common visible prefix and suffix cancels both contexts:*

$$\mathsf{MetricDistanceDepth}((p{\cdot}d){\cdot}q) = \mathsf{MetricDistanceDepth}((p{\cdot}e){\cdot}q) \Longrightarrow \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(e$$

Proof. Induct on the visible suffix q. The empty suffix is exactly Definition 57.258. In the two visible constructor cases, both displayed depths have a common successor head, so successor injectivity removes the suffix constructor and the induction hypothesis cancels the remaining visible context. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth visible context cancel`

Theorem 57.261 (Metric distance depth append-right cancellation iff)**.** *For histories p, d, e : BHist, appending the same right suffix preserves and reflects equality of structural metric distance depth:*

$$\mathsf{MetricDistanceDepth}(d{\cdot}p) = \mathsf{MetricDistanceDepth}(e{\cdot}p) \Longleftrightarrow \mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(e).$$

Proof. Induct on the common suffix p. The empty suffix is immediate. In the two visible constructor cases, both appended depths carry the same successor head; successor injectivity gives the forward implication, and congruence of successor rebuilds the appended equality in the reverse implication. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth append right cancel iff`

Theorem 57.262 (Metric distance depth append-right equality emptiness)**.** *For histories p and d, appending p on the right preserves structural metric distance depth exactly when p is the empty history:*

$$\mathsf{MetricDistanceDepth}(d \cdot p) = \mathsf{MetricDistanceDepth}(d) \Longleftrightarrow \mathsf{hsame}(p, \mathsf{e}).$$

Proof. The structural depth of a right append decomposes as the depth of d plus the depth of p. If the appended depth equals the original depth, cancellation by $\mathbb{N}$-addition forces the depth of p to be zero, hence Definition 57.253 identifies p with e. Conversely, substituting $p = \mathsf{e}$ makes the right append definitionally equal to d. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth append right eq iff empty`

Theorem 57.263 (Metric distance same-source continuation result cancellation)**.** *For unary histories x, y, z and continuation rows $\mathsf{Cont}(x, y, d)$ and $\mathsf{Cont}(x, z, e)$, equality of the two result depths cancels the common source depth:*

$$\mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(e) \Longrightarrow \mathsf{MetricDistanceDepth}(y) = \mathsf{MetricDistanceDepth}(z).$$

Proof. Package the two continuation rows as metric-distance witnesses. Depth additivity gives $\mathsf{depth}(d) = \mathsf{depth}(x) + \mathsf{depth}(y)$ and $\mathsf{depth}(e) = \mathsf{depth}(x) + \mathsf{depth}(z)$. The displayed result depth equality therefore has a common left summand, and natural-number cancellation identifies the two target depths. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth same source cont result cancel`

Theorem 57.264 (Metric distance depth visible-context equality emptiness)**.** *For histories p, q, d, adding visible context on both sides preserves the central structural metric distance depth exactly when both visible contexts are empty:*

$$\mathsf{MetricDistanceDepth}((p \cdot d) \cdot q) = \mathsf{MetricDistanceDepth}(d) \Longleftrightarrow \mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(q, \mathsf{e}).$$

Proof. Expand structural depth over the two append contexts. The resulting natural number equation has the form $(\mathsf{depth}(p) + \mathsf{depth}(d)) + \mathsf{depth}(q) = \mathsf{depth}(d)$, so associativity and commutativity of addition reduce it to a zero-sum constraint on the two context depths. Then Definition 57.253 identifies both contexts with e. The reverse direction substitutes the two empty-context identifications and applies the one-sided append equality theorems above. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth visible context eq iff empty`

Theorem 57.265 (Metric visible-context zero depth iff empty components)**.** *For histories p, q, d, the full visible-context ledger has structural metric depth zero exactly when the prefix, central distance, and suffix are all empty:*

$$\mathsf{MetricDistanceDepth}((p \cdot d) \cdot q) = 0 \Longleftrightarrow \mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(d, \mathsf{e}) \wedge \mathsf{hsame}(q, \mathsf{e}).$$

Proof. The zero-depth classifier first identifies the whole visible ledger with e. BEDC append-empty inversion splits the outer append into $(p \cdot d)\mathsf{hsamee}$ and $q\mathsf{hsamee}$, and a second inversion splits $p \cdot d$. Conversely, substituting the three empty components makes the displayed depth definition evaluate to zero. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceDepth visible context zero iff`

Theorem 57.266 (Metric visible-context total zero components)**.** *For histories p, q, x, y, d, a visible-context distance witness whose full result ledger has structural depth zero exposes empty prefix, source, target, suffix, and central distance components:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \to \\ &\quad \mathsf{MetricDistanceDepth}((p \cdot d) \cdot q) = 0 \to \\ &\quad \mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(q, \mathsf{e}) \wedge \mathsf{hsame}(d, \mathsf{e}).\end{aligned}$$

Proof. Zero depth classifies the full result ledger with e, and two append-empty inversions expose the empty prefix, central distance, and suffix. Transport the witness continuation along the same empty result classifier. The empty-result continuation inversion then classifies the visible source $p \cdot x$ and target $y \cdot q$ with e, and append-empty inversion splits these endpoint histories into their displayed components. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context total zero components`

Theorem 57.267 (Metric visible-context depth-zero collapse)**.** *For histories p, q, x, y, d, a visible-context distance witness whose central distance has structural depth zero collapses the central distance and both central endpoints to the empty history:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d){\cdot}q) \to \mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{hsame}(d, \mathsf{e}) \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).$$

Proof. Apply visible-context exactness to peel away the prefix p and suffix q, recovering the central witness $\mathsf{MetricDistanceWitness}(x, y, d)$. The depth-zero endpoint theorem gives $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$, while the depth-zero classifier theorem gives $\mathsf{hsame}(d, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context depth zero collapse`

Theorem 57.268 (Metric empty-boundary visible-context continuation left unit)**.** *For histories p, q, d, r, out, an empty-boundary visible-context distance witness and a continuation out of the central distance identify the continuation result with its right input:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \to \mathsf{Cont}(d, r, out) \to \mathsf{hsame}(out, r).$$

Proof. Apply empty-boundary visible-context exactness to read back $\mathsf{hsame}(d, \mathsf{e})$. Case analysis on this classifier reduces the continuation to an empty-left continuation, whose result is the right input by the left-unit law for Cont. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation left unit result`

Theorem 57.269 (Metric empty-boundary visible-context continuation left unit iff)**.** *For histories p, q, d, r, out, an empty-boundary visible-context distance witness turns continuation from the central distance into exactly the left-unit continuation classifier:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \to \big(\mathsf{Cont}(d, r, out) \leftrightarrow \mathsf{hsame}(out, r)\big).$$

Proof. The visible-context empty-boundary theorem gives $\mathsf{hsame}(d, \mathsf{e})$. Case analysis on this classifier reduces the displayed continuation predicate to $\mathsf{Cont}(\mathsf{e}, r, out)$, which is characterized by the BEDC left-unit equivalence. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation left unit iff`

Theorem 57.270 (Metric empty-boundary visible-context continuation right unit iff)**.** *For histories p, q, d, l, out, an empty-boundary visible-context distance witness turns continuation into the central distance into exactly the right-unit continuation classifier:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \to \big(\mathsf{Cont}(l, d, out) \leftrightarrow \mathsf{hsame}(out, l)\big).$$

Proof. Again the visible-context empty-boundary theorem gives $\mathsf{hsame}(d, \mathsf{e})$. After case analysis, the displayed continuation predicate is $\mathsf{Cont}(l, \mathsf{e}, out)$, which is characterized by the BEDC right-unit equivalence. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation right unit iff`

Theorem 57.271 (Metric empty-boundary continuation splice)**.** *For histories p, q, d, l, r, mid, out, an empty-boundary visible-context distance witness makes a continuation through the central distance splice to the continuation that skips that empty central boundary:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \to \mathsf{Cont}(l, d, mid) \to \mathsf{Cont}(mid, r, out) \to \mathsf{Cont}(l, r, out).$$

Proof. The empty-boundary visible-context theorem gives $\mathsf{hsame}(d, \mathsf{e})$. After case analysis on this classifier, the left continuation is $\mathsf{Cont}(l, \mathsf{e}, mid)$, so its unit law identifies mid with l. The right continuation is therefore the desired $\mathsf{Cont}(l, r, out)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation splice`

Theorem 57.272 (Metric empty-boundary visible-context witness splice)**.** *For histories p, q, d, l, r, mid, out, an empty-boundary visible-context distance witness upgrades a two-step continuation through the central distance into a metric distance witness for the visible endpoints:*

$$\begin{gathered}\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \to \mathsf{UnaryHistory}(l) \to \mathsf{UnaryHistory}(r) \to \\ \mathsf{Cont}(l, d, mid) \to \mathsf{Cont}(mid, r, out) \to \mathsf{MetricDistanceWitness}(l, r, out).\end{gathered}$$

Proof. The empty-boundary continuation-splice theorem gives the concrete continuation $\mathsf{Cont}(l, r, out)$ from the visible-context witness and the two displayed continuation rows. Together with the displayed unary carriers for l and r, the BEDC unary-continuation closure theorem supplies $\mathsf{UnaryHistory}(out)$. These four rows are precisely the fields of $\mathsf{MetricDistanceWitness}(l, r, out)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context witness splice`

Theorem 57.273 (Metric empty-boundary continuation splice determinacy)**.** *For histories $p, q, d, l, r, mid, out, out$ an empty-boundary visible-context distance witness makes the spliced continuation result match any displayed direct continuation result:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \to \mathsf{Cont}(l, d, mid) \to \mathsf{Cont}(mid, r, out) \to \mathsf{Cont}(l, r, out') \to \mathsf{hsame}(out, out')$$

Proof. The continuation-splice theorem supplies $\mathsf{Cont}(l, r, out)$ from the empty-boundary visible-context witness and the two displayed continuation rows. BEDC continuation determinacy compares this spliced continuation with the displayed $\mathsf{Cont}(l, r, out')$, giving $\mathsf{hsame}(out, out')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation splice hsame`

Theorem 57.274 (Metric visible-context positive central depth has a nonempty endpoint)**.** *For histories p, q, x, y, d, a visible-context distance witness whose central distance has positive structural depth exposes a nonempty central endpoint:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}d){\cdot}q) \to (\mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{False}) \to ((\mathsf{hsame}(x, \mathsf{e}) \to \mathsf{False}) \vee (\mathsf{hsame}$$

Proof. Apply visible-context exactness to peel away the displayed prefix p and suffix q, obtaining the central witness $\mathsf{MetricDistanceWitness}(x, y, d)$.

It remains to convert positive structural depth into nonempty-distance input. If $\mathsf{hsame}(d, \mathsf{e})$ held, the depth-zero classifier theorem would give $\mathsf{MetricDistanceDepth}(d) = 0$, contradicting the positive-depth hypothesis.

Apply the nonempty-distance endpoint theorem to the central witness and this derived nonempty-distance contradiction. The result is exactly the displayed disjunction: either the left central endpoint is not history-same to e, or the right central endpoint is not history-same to e. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context positive depth nonempty endpoint`

Theorem 57.275 (Metric visible-context positive central depth e-one endpoint cases)**.** *For histories $p, q, x, y, d : \mathsf{BHist}$, positive central distance depth in a visible MetricUp ledger exposes an e-one constructor at one central endpoint with a unary tail:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \to \\ &\quad (\mathsf{MetricDistanceDepth}(d) = 0 \to \mathsf{False}) \to \\ &\quad (\exists x_0,\ x = \mathsf{E1}(x_0) \wedge \mathsf{UnaryHistory}(x_0)) \vee (\exists y_0,\ y = \mathsf{E1}(y_0) \wedge \mathsf{UnaryHistory}(y_0)).\end{aligned}$$

Here the BEDC source is MetricDistanceWitness*, the carrier objects are* UnaryHistory *histories, the classifier is* hsame*, and the obligation is constructor readback under visible prefix and suffix ledgers.*

Proof. Apply visible-context exactness to remove the prefix p and suffix q from the displayed ledger. This recovers the central witness $\mathsf{MetricDistanceWitness}(x, y, d)$.

Next convert positive central depth into the nonempty-distance input required by the constructor readback theorem. If $d\mathsf{hsamee}$ held, then Definition 57.253 would give $\mathsf{MetricDistanceDepth}(d) = 0$, contradicting the positive-depth hypothesis.

Apply Definition 57.216 to the recovered central witness and this nonempty-distance contradiction. The result is exactly the displayed disjunction of e-one endpoint witnesses with unary tails. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context positive depth e1 endpoint cases`

Theorem 57.276 (Metric distance witness empty-boundary visible-context distance empty)**.** *For histories p, q, d, a visible-context distance witness whose central left and right endpoints are both empty identifies the central distance with the empty history and gives zero central distance depth:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{hsame}(d, \mathsf{e}) \wedge \mathsf{MetricDistanceDepth}(d) = 0.$$

Proof. Apply Definition 57.13 to peel away the visible prefix and suffix. The remaining central witness is $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d)$. The empty-left boundary theorem identifies d with e; case analysis on that classifier gives the zero depth equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context distance empty`

Theorem 57.277 (Metric prefix-independent symmetric zero-depth empty-boundary forward)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, suppose the two symmetric visible-context distance witnesses*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q), \qquad \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q')$$

hold. If $\mathsf{MetricDistanceDepth}(d_{xy}) = 0$*, then the original visible context carries the empty-boundary witness*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot \mathsf{e}) \cdot q).$$

Proof. Peel both visible-context witnesses to their central witnesses. Symmetric classification compares d_{xy} and d_{yx}. Case analysis on the zero-depth central distance leaves only $d_{xy} = \mathsf{e}$; the empty-distance visible-context readback then identifies the two central endpoints as empty. Reattaching the original prefix and suffix gives the displayed empty-boundary witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth empty boundary forward`

Theorem 57.278 (Metric empty-boundary visible context append unit laws)**.** *For histories* p, q, d, l, r*, a visible-context distance witness whose central endpoints are both empty makes the central distance act as a left and right append unit:*

$$\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{append}(d, r) = r \ \wedge \ \mathsf{append}(l, d) = l.$$

Proof. The empty-boundary distance theorem identifies d with e. Case analysis on that classifier reduces the two displayed equations to the left and right unit laws for finite-kernel append. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context append unit laws`

Theorem 57.279 (Metric empty-boundary visible context unit splice commute)**.** *For histories* $p, q, d, l, r, out_L, out_R$*, an empty-boundary visible-context distance witness makes left and right continuation through the central distance commute after one ordinary append splice:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{Cont}(l, d, out_L) \Longrightarrow \mathsf{Cont}(d, r, out_R) \Longrightarrow \mathsf{hsame}(out_L{\cdot}r, l{\cdot}out_R).$$

Proof. The empty-boundary distance theorem identifies d with e. The left continuation then has right-unit result $out_L\mathsf{hsame}l$, and the right continuation has left-unit result $out_R\mathsf{hsame}r$. Substituting these two unit identifications reduces the displayed splice comparison to reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context unit splice commute`

Theorem 57.280 (Metric visible-context empty-distance unit splice commute)**.** *For histories* $p, q, x, y, l, r, out_L, out_R$*, a visible-context empty-distance witness makes left continuation through* x *and right continuation through* y *commute after one ordinary append splice:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}\mathsf{e}){\cdot}q) \Longrightarrow \mathsf{Cont}(l, x, out_L) \Longrightarrow \mathsf{Cont}(y, r, out_R) \Longrightarrow \mathsf{hsame}(out_L{\cdot}r, l{\cdot}out_R).$$

Proof. The visible-context empty-distance exactness theorem identifies both central endpoints x and y with e. The left continuation then has right-unit result $out_L\mathsf{hsame}l$, and the right continuation has left-unit result $out_R\mathsf{hsame}r$. Substituting these unit identifications reduces the splice comparison to reflexivity. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance unit splice commute`

Theorem 57.281 (Metric empty-boundary visible context left-unit witness)**.** *For histories p, q, d, r, out, an empty-boundary visible-context distance witness turns any continuation* $\mathsf{Cont}(d, r, out)$ *into a metric witness from the empty source:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \mathsf{Cont}(d, r, out) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{e}, r, out).$$

Proof. The empty-boundary distance theorem identifies d with e. Substituting that classifier makes the continuation a left-unit continuation from e to r. The empty source is unary, the target is unary by hypothesis, and unary continuation closure supplies the output carrier, so the three fields package the displayed metric distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context left unit witness`

Theorem 57.282 (Metric empty-boundary visible context right-unit witness)**.** *For histories p, q, d, l, out, an empty-boundary visible-context distance witness turns any continuation* $\mathsf{Cont}(l, d, out)$ *into a metric witness into the empty target:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{Cont}(l, d, out) \Longrightarrow \mathsf{MetricDistanceWitness}(l, \mathsf{e}, out).$$

Proof. The empty-boundary distance theorem identifies d with e. Substituting that classifier makes the continuation a right-unit continuation into e. The source is unary by hypothesis, the empty target is unary, and unary continuation closure supplies the output carrier, so the three fields package the displayed metric distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context right unit witness`

Theorem 57.283 (Metric empty-boundary visible context continuation depth add)**.** *For histories p, q, d, l, r, mid, out, an empty-boundary visible-context distance witness lets a continuation through d splice into the direct continuation from l to r, so the output depth is the sum of the endpoint depths:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}\mathsf{e}, \mathsf{e}{\cdot}q, (p{\cdot}d){\cdot}q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \mathsf{Cont}(l, d, mid) \Longrightarrow \mathsf{Cont}(mid,$$

Proof. The empty-boundary continuation splice removes the central empty distance from the two-step ledger and gives $\mathsf{Cont}(l, r, out)$. Together with the unary endpoint hypotheses, unary continuation closure supplies the output carrier, so these fields form a concrete metric distance witness from l to r. Metric distance depth additivity then gives the displayed equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation depth add`

Theorem 57.284 (Metric empty-boundary visible context continuation witness depth package)**.** *For histories p, q, d, l, r, mid, out, an empty-boundary visible-context distance witness, unary visible endpoints, and the two-step continuation through d determine both the visible-endpoint metric witness and its depth ledger:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \\ &\quad \mathsf{Cont}(l, d, mid) \Longrightarrow \mathsf{Cont}(mid, r, out) \Longrightarrow \\ &\quad \mathsf{MetricDistanceWitness}(l, r, out) \wedge \mathsf{MetricDistanceDepth}(out) = \mathsf{MetricDistanceDepth}(l) + \mathsf{MetricDistanceDepth}$$

Proof. The witness conjunct is supplied by Definition 57.272 from the empty-boundary witness, the endpoint unary histories, and the two continuation rows.

The depth conjunct is supplied by Definition 57.283 from the same hypotheses. Conjoining the two conclusions gives the displayed package. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context continuation witness depth`

Theorem 57.285 (Metric empty-boundary visible context canonical splice package)**.** *For histories $p, q, d, l, r, mid, out, out'$, an empty-boundary visible-context distance witness, unary endpoint carriers, a two-step continuation through d, and a displayed direct continuation from l to r determine the canonical splice package:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{UnaryHistory}(l) \Longrightarrow \mathsf{UnaryHistory}(r) \Longrightarrow \\ &\quad \mathsf{Cont}(l, d, mid) \Longrightarrow \mathsf{Cont}(mid, r, out) \Longrightarrow \mathsf{Cont}(l, r, out') \Longrightarrow \\ &\quad \mathsf{MetricDistanceWitness}(l, r, out) \wedge \mathsf{hsame}(out, out') \wedge \\ &\quad \mathsf{MetricDistanceDepth}(out) = \mathsf{MetricDistanceDepth}(l) + \mathsf{MetricDistanceDepth}(r).\end{aligned}$$

Proof. The witness row is supplied by Theorem 57.272 from the empty-boundary visible-context witness, the unary carriers, and the two displayed continuation rows.

The comparison row is supplied by Theorem 57.273, which compares the spliced output with the displayed direct continuation $\mathsf{Cont}(l, r, out')$.

The depth row is supplied by Theorem 57.283. Conjoining these three rows gives the displayed certificate package. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness empty boundary visible context canonical splice package`

Theorem 57.286 (Metric distance witness left e1 result iff)**.** *For histories x, y, d, a distance witness from a visible left endpoint to a visible result is equivalent to the empty middle case or to a visible middle tail carrying the remaining witness:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longleftrightarrow (y = \mathsf{e} \wedge \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, d)) \vee (\exists y_1 : \mathsf{BHist}.\ y = \mathsf{E1}(y_1) \wedge \mathsf{Metric}$$

Proof. The forward direction is the visible-result case split. For the reverse direction, the empty middle branch rebuilds the witness from unary closure under $\mathsf{E1}$ and the right-unit continuation law. The visible middle branch adds one visible constructor back to the middle endpoint and result ledger by the one-step continuation rule. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result iff`

Theorem 57.287 (Metric distance witness left e1 result depth addition)**.** *For histories x, y, d, every visible-result distance witness*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d))$$

descends the metric depth identity to the visible tails:

$$\mathsf{MetricDistanceDepth}(d) = \mathsf{MetricDistanceDepth}(x) + \mathsf{MetricDistanceDepth}(y).$$

Proof. Apply metric-distance depth addition to the displayed witness. The resulting identity has a visible constructor on the source side and on the result side. Normalize the natural-number expression with successor addition, then cancel the shared successor. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result depth add`

Theorem 57.288 (Metric distance witness left e1 result empty target iff)**.** *For histories x, y, d, a metric distance witness from $\mathsf{E1}(x)$ to target y with visible result $\mathsf{E1}(d)$ identifies y with the empty history exactly when the exposed source tail is unary and agrees with the result tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow (\mathsf{hsame}(y, \mathsf{e}) \Longleftrightarrow \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, d)).$$

Proof. Split the target shape. The empty target branch is the right-unit continuation case and reads back the unary source tail and the tail equality. The $e0$ target contradicts the unary target carrier. The visible target branch cannot also have $x\mathsf{hsame}d$: transporting the result to $\mathsf{E1}(x)$ would make $\mathsf{Cont}(\mathsf{E1}(x), \mathsf{E1}(y_1), \mathsf{E1}(x))$, so right-unit uniqueness would identify $\mathsf{E1}(y_1)$ with e, contradicting constructor disjointness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result empty target iff`

Theorem 57.289 (Metric distance witness left e1 result hsame source)**.** *For histories x, x', y, d, a distance witness from $\mathsf{E1}(x)$ to a visible result keeps the same empty-or-visible alternative after transporting the displayed source payload along $\mathsf{hsame}(x, x')$:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow \mathsf{hsame}(x, x') \Longrightarrow (y = \mathsf{e} \wedge \mathsf{UnaryHistory}(x') \wedge \mathsf{hsame}(x', d)) \vee (\exists y_1 : \mathsf{BHist}.$$

Proof. Case-reduce the source hsame witness. The transported payload is then definitionally the original payload, and the established visible-result split gives the displayed empty target or visible target branch. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result hsame source`

Theorem 57.290 (Metric distance witness left e1 result hsame target)**.** *For histories x, y, y', d, a distance witness from a visible left endpoint to a visible result keeps the same empty-or-visible target alternative after transporting the target presentation along $\mathsf{hsame}(y, y')$:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow (y' = \mathsf{e} \wedge \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, d)) \vee (\exists y_1 : \mathsf{BHist}.\ y$$

Proof. Apply the visible-result case split. In the empty branch, empty-history inversion transports the displayed target to e. In the visible branch, one-constructor inversion of $\mathsf{hsame}(\mathsf{E1}(y_0), y')$ exposes $y' = \mathsf{E1}(y_1)$ and $y_0\mathsf{hsame}y_1$; unary and continuation transport carry the tail metric witness to the displayed target tail. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result hsame target`

Theorem 57.291 (Metric distance witness left e1 result hsame result)**.** *For histories x, y, d, d', a distance witness from a visible left endpoint to a visible result keeps the same empty-or-visible target alternative after transporting the displayed result tail along $\mathsf{hsame}(d, d')$:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow (y = \mathsf{e} \wedge \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, d')) \vee (\exists y_1 : \mathsf{BHist}.\ y$$

Proof. First lift the result-tail agreement through the visible constructor, obtaining $\mathsf{hsame}(\mathsf{E1}(d), \mathsf{E1}(d'))$. The metric hsame transport field is then applied with reflexive source and target transports, so the original witness repacks as $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d'))$.

Apply Theorem 57.286 to this transported witness. The empty target branch gives $\mathsf{UnaryHistory}(x)$ and $\mathsf{hsame}(x, d')$; the visible target branch gives a tail y_1 with $y = \mathsf{E1}(y_1)$ and $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y_1, d')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result hsame result`

Theorem 57.292 (Metric distance witness left e1 result tail determinism)**.** *For histories x, y, d, d', two visible-result distance witnesses with the same visible left endpoint and target determine the same result tail:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d')) \Longrightarrow \mathsf{hsame}(d, d').$$

Proof. Unpack the two distance witnesses only to their continuation ledgers. BEDC continuation determinacy gives $\mathsf{hsame}(\mathsf{E1}(d), \mathsf{E1}(d'))$ for the two visible results. One-constructor inversion for $\mathsf{E1}$ then descends this classifier to $\mathsf{hsame}(d, d')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result tail deterministic`

Theorem 57.293 (Metric distance witness left e1 result shape)**.** *For histories x, y, d, every distance witness from $\mathsf{E1}(x)$ has a visible result shape:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d) \Longrightarrow \exists k : \mathsf{BHist}.\ \mathsf{hsame}(d, \mathsf{E1}(k)) \wedge \Big((y = \mathsf{e} \wedge \mathsf{UnaryHistory}(x) \wedge \mathsf{hsame}(x, k)) \vee \exists y_1 : \mathsf{E}$$

Proof. Decompose the result history. An empty result is incompatible with a visible left endpoint and the continuation equation; an $\mathsf{E0}$ result is incompatible with the unary distance carrier. In the $\mathsf{E1}(k)$ case, the established visible-result split gives either the empty target boundary or the visible target tail witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 result shape`

Theorem 57.294 (Metric distance witness left e1 visible target step)**.** *For histories x, y, d, a distance witness from $\mathsf{E1}(x)$ to y with result d remains a distance witness after placing the target and result under one visible $\mathsf{E1}$ constructor:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d)).$$

Proof. Unpack the witness into unary carriers and the continuation ledger. Unary closure supplies carriers for $\mathsf{E1}(y)$ and $\mathsf{E1}(d)$, and the continuation step rule lifts the same ledger from target y and result d to target $\mathsf{E1}(y)$ and result $\mathsf{E1}(d)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target step`

Theorem 57.295 (Metric distance witness left e1 visible target result shape)**.** *For histories x, y, d, any distance witness from $\mathsf{E1}(x)$ to $\mathsf{E1}(y)$ has a visible result tail, and that tail is again the distance witness from $\mathsf{E1}(x)$ to y:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), d) \Longrightarrow \exists k.\ \mathsf{hsame}(d, \mathsf{E1}(k)) \wedge \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, k).$$

Proof. Apply the left visible-result shape split to the displayed witness. The empty-target branch would identify $\mathsf{E1}(y)$ with e, contradicting constructor no-confusion. The remaining visible branch supplies the result tail k and the descended witness with target y. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target result shape`

Theorem 57.296 (Metric distance witness left e1 visible target result tail exactness)**.** *For histories x, y, d, k, if a distance witness from $\mathsf{E1}(x)$ to $\mathsf{E1}(y)$ has displayed result history-same as $\mathsf{E1}(k)$, then k is the descended distance result from $\mathsf{E1}(x)$ to y:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), d) \Longrightarrow \mathsf{hsame}(d, \mathsf{E1}(k)) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, k).$$

Proof. Apply the visible-target result shape theorem to expose a result tail k_0, a displayed comparison $\mathsf{hsame}(d, \mathsf{E1}(k_0))$, and the descended witness. Composing this comparison with the assumed comparison to $\mathsf{E1}(k)$ gives a one-headed history-sameness relation between $\mathsf{E1}(k_0)$ and $\mathsf{E1}(k)$. Constructor inversion descends it to $\mathsf{hsame}(k_0, k)$, and tail transport returns the displayed witness at k. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target result tail hsame exact`

Theorem 57.297 (Metric distance witness left e1 visible target result-source absurd)**.** *For histories x, y, d, a distance witness from $\mathsf{E1}(x)$ to $\mathsf{E1}(y)$ with visible result $\mathsf{E1}(d)$ cannot also identify the descended result d with the visible source $\mathsf{E1}(x)$ when the target tail is nonempty:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d)) \Longrightarrow (\mathsf{hsame}(y, \mathsf{e}) \Rightarrow \bot) \Longrightarrow \mathsf{hsame}(d, \mathsf{E1}(x)) \Longrightarrow \bot.$$

Proof. Right-visible result exactness descends the witness to $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d)$. Transporting its continuation result across $\mathsf{hsame}(d, \mathsf{E1}(x))$ makes y a right-unit continuation at $\mathsf{E1}(x)$, so right-unit uniqueness gives $\mathsf{hsame}(y, \mathsf{e})$, contradicting the displayed nonempty target-tail hypothesis. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target result source absurd`

Theorem 57.298 (Metric distance witness left e1 source step)**.** *For histories x, y, d, a distance witness from x to y with result d remains a distance witness after placing the source and result under one visible* $\mathsf{E1}$ *constructor:*

$$\mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)).$$

Proof. Unpack the witness into unary carriers and the continuation ledger $d = x \cdot y$. Unary closure supplies the new source and result carriers. Since y is unary, the append law rewrites $\mathsf{E1}(x) \cdot y$ as $\mathsf{E1}(x \cdot y)$, so the lifted result $\mathsf{E1}(d)$ satisfies the required continuation equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 source step`

Theorem 57.299 (Metric distance witness left e1 source iff)**.** *For histories x, y, d, placing the source and result under one visible* $\mathsf{E1}$ *constructor is reversible:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longleftrightarrow \mathsf{MetricDistanceWitness}(x, y, d).$$

Proof. The reverse direction is Theorem 57.298. For the forward direction, split on the target history. The empty target case is the right empty-boundary exactness of the metric witness. A zero-headed target contradicts the unary target carrier recorded in the witness. In the one-headed target case, the result equation descends through the visible constructor, and unary append commutes the visible source constructor across the unary target tail, giving the original continuation ledger. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 source iff`

Theorem 57.300 (Metric distance witness left e1 source result iff)**.** *For histories x, y, d, placing both the source and result under one visible* $\mathsf{E1}$ *constructor is reversible:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, \mathsf{E1}(d)) \Longleftrightarrow \mathsf{MetricDistanceWitness}(x, y, d).$$

Proof. For the forward direction, unpack the displayed witness. Unary inversion on the source and result gives unary carriers for x and d. The continuation ledger identifies $\mathsf{E1}(d)$ with $\mathsf{E1}(x) \cdot y$, and the unary append law for the target rewrites the right side to $\mathsf{E1}(x \cdot y)$; constructor inversion exposes the descended continuation ledger $d = x \cdot y$.

For the reverse direction, apply Definition 57.298. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 source result iff`

Theorem 57.301 (Metric distance witness left e1 visible target iff)**.** *For histories x, y, d, placing both the target and result under one visible* E1 *constructor is reversible for a visible left endpoint:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d)) \Longleftrightarrow \mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d).$$

Proof. For the forward direction, apply Theorem 57.70 to the displayed witness with the reflexive presentation $\mathsf{hsame}(\mathsf{E1}(y), \mathsf{E1}(y))$. This strips the visible target presentation and returns the tail witness with target y and result d.

For the reverse direction, apply Theorem 57.294. The visible target constructor and matching visible result constructor are restored by the continuation step rule. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness left e1 visible target iff`

The ten-field fit is: traditional target visible unary metric descent/extension; BEDC source BHist with UnaryHistory and Cont; carrier MetricDistanceWitness; classifier hsame; ledger one visible target constructor; core theorem Theorem 57.301; exactness reversible target-step readback; status ProofTarget.

Theorem 57.302 (MetricSpace LocatedReal distance source boundary)**.** *Let L_x and L_y be accepted* $\mathsf{LocatedReal}^{\uparrow}$ *packets whose* $\mathsf{StreamName}^{\uparrow}$ *schedules admit a common finite observation window. Suppose their* DyadicRatCore *endpoint ledgers and radius ledgers are transported to that window by the displayed* hsame *and* Cont *rows, and suppose a contextual metric row* $\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q)$ *is displayed for the two projected endpoints.*

Then any $\mathsf{Met}^{\uparrow}$ *consumer reads the distance-source boundary exactly through the finite rows named by Definition 309.11 together with the metric visible-context rows: the* $\mathsf{RegSeqRat}^{\uparrow}$ *source windows, the* DyadicRatCore *endpoint and radius rows, the* $\mathsf{StreamName}^{\uparrow}$ *schedule rows, the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance, and the* hsame *classifier on the central distance row d.*

Conversely, any packet carrying precisely those rows repacks as the metric distance-source row for the two located packets. No quotient real, host real equality, trichotomy principle, open-cover compactness datum, or metric completion object is part of this boundary.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness locatedreal distance source boundary`

Proof. This boundary is the $\mathsf{Met}^{\uparrow}$ consumer of the located-real carrier of **??**; the cited sibling supplies the two accepted $\mathsf{LocatedReal}^{\uparrow}$ packets and their endpoint rows, while this theorem supplies the visible-context distance read.

Project L_x and L_y with Definition 309.11. This leaves only the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source windows, the common $\mathsf{StreamName}^{\uparrow}$ schedule, the transported DyadicRatCore endpoint and radius ledgers, the enclosure classifier rows, and the visible BHist, hsame, Cont, Pkg, and NameCert provenance.

Next apply Definition 57.13 to the contextual metric row. The visible prefix and suffix rows are peeled away, leaving the central witness $\mathsf{MetricDistanceWitness}(x, y, d)$ over the two projected located endpoints.

For uniqueness of the central distance read, apply Definition 57.133. Any second packet with the same displayed source windows, endpoint ledgers, schedule rows, provenance rows, and contextual metric witness has a central distance classifier $\mathsf{hsame}(d, e)$, so the metric consumer cannot distinguish a hidden distance coordinate.

The converse direction repacks exactly the displayed rows: the located packets come from the handoff surface, the contextual distance row supplies the metric visible context, and the central hsame classifier is the only distance classifier retained. Since each coordinate in this construction is one of the listed finite rows, no excluded real-number, compactness, or completion principle is introduced. □

Theorem 57.303 (Metric distance witness prefix-independent symmetric classifier)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, symmetric metric distance witnesses with independent visible contexts still determine the same central distance classifier:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \Longrightarrow \mathsf{hsame}(d_{xy}, d_{yx}).\end{aligned}$$

Proof. Apply Definition 57.13 to both visible-context witnesses. This recovers central witnesses $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$ and $\mathsf{MetricDistanceWitness}(y, x, d_{yx})$. The central symmetric classifier then gives $\mathsf{hsame}(d_{xy}, d_{yx})$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context prefix independent symmetric classifier`

Theorem 57.304 (Metric distance witness prefix-independent symmetric zero-depth collapse)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, symmetric visible-context distance witnesses with independent contexts and a zero-depth forward distance collapse the two central distances and both central endpoints:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xy}) = 0 \Longrightarrow \\ &\mathsf{hsame}(d_{xy}, d_{yx}) \wedge \mathsf{MetricDistanceDepth}(d_{yx}) = 0 \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).\end{aligned}$$

Proof. Apply Definition 57.303 to the two visible-context witnesses. This gives $\mathsf{hsame}(d_{xy}, d_{yx})$.

Apply Definition 57.267 to the first visible-context witness and the zero-depth hypothesis for d_{xy}. This gives the empty endpoint classifiers $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$.

Finally peel the second visible-context witness with Definition 57.13. The recovered central witness $\mathsf{MetricDistanceWitness}(y, x, d_{yx})$, together with the two empty endpoint classifiers in reversed order, is the input required by Definition 57.252; hence $\mathsf{MetricDistanceDepth}(d_{yx}) = 0$. Combining these three pieces gives the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context prefix independent symmetric zero depth collapse`
Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth collapse`

Theorem 57.305 (Metric prefix-independent symmetric zero-depth reverse empty-boundary)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, symmetric visible-context distance witnesses with independent*

contexts and a zero-depth forward distance also package the reverse context as its own empty-boundary distance witness:

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xy}) = 0 \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p' \cdot \mathsf{e}, \mathsf{e} \cdot q', (p' \cdot \mathsf{e}) \cdot q').\end{aligned}$$

Proof. Peel the reverse visible-context witness with Definition 57.13. This recovers the unary context data for p' and q' together with the central reverse witness $\mathsf{MetricDistanceWitness}(y, x, d_{yx})$.

Apply Definition 57.304 to the two displayed visible-context witnesses and the zero-depth forward distance. The resulting endpoint classifiers include $\mathsf{hsame}(y, \mathsf{e})$ and $\mathsf{hsame}(x, \mathsf{e})$.

Finally use Definition 57.389 in the reverse context. The recovered carriers for p' and q', together with the empty endpoint classifiers in reverse order, rebuild exactly $\mathsf{MetricDistanceWitness}(p' \cdot \mathsf{e}, \mathsf{e} \cdot q', (p' \cdot \mathsf{e}) \cdot q')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth reverse empty boundary package`

Theorem 57.306 (Metric prefix-independent symmetric zero-depth two-sided empty-boundary package)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$, symmetric visible-context distance witnesses with independent contexts and a zero-depth forward distance package both contextual empty-boundary witnesses together with the reverse zero-depth row and the central endpoint classifiers:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xy}) = 0 \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot \mathsf{e}) \cdot q) \wedge \\ &\mathsf{MetricDistanceWitness}(p' \cdot \mathsf{e}, \mathsf{e} \cdot q', (p' \cdot \mathsf{e}) \cdot q') \wedge \mathsf{MetricDistanceDepth}(d_{yx}) = 0 \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).\end{aligned}$$

Proof. Apply Definition 57.304 to the two visible-context witnesses and the zero-depth forward distance. This gives the same-distance classifier, the reverse zero-depth row, and the two central endpoint classifiers $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$.

Peel the forward visible-context witness with Definition 57.13 to recover the unary carrier rows for p and q. These carriers, together with the endpoint classifiers from the collapse theorem, are exactly the right-hand data in Definition 57.389; hence they build $\mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, \mathsf{e} \cdot q, (p \cdot \mathsf{e}) \cdot q)$.

Apply Definition 57.305 to the same hypotheses to obtain the reverse contextual empty-boundary witness. Conjoining the forward package, the reverse package, the reverse zero-depth row, and the two endpoint classifiers gives the displayed conclusion. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth two sided empty boundary package`

The ten-field fit is: traditional target metric zero-depth symmetric boundary packaging; BEDC source BHist with MetricDistanceWitness and MetricDistanceDepth; carrier MetricDistanceWitness; classifier hsame; stability zero-depth endpoint collapse; ledger the two symmetric visible contexts; core theorem Theorem 57.306; exactness two-sided empty-boundary packaging; standard bridge none claimed; status ProofTarget.

Theorem 57.307 (Metric prefix-independent symmetric zero-depth continuation splice)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}, l, r, mid, out$, symmetric visible-context distance witnesses with independent contexts and zero-depth forward distance make any continuation through the reverse central*

distance splice across the empty boundary:

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \to \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \to \mathsf{MetricDistance}$$
$$\mathsf{Cont}(l, d_{yx}, mid) \to \mathsf{Cont}(mid, r, out) \to \mathsf{Cont}(l, r, out).$$

Proof. The symmetric zero-depth collapse theorem gives $\mathsf{MetricDistanceDepth}(d_{yx}) = 0$. The depth-zero classifier theorem converts this to $\mathsf{hsame}(d_{yx}, \mathsf{e})$. Case analysis reduces the left continuation to the right-unit case, identifying mid with l, and the remaining continuation is exactly the displayed splice result. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth continuation splice`

Theorem 57.308 (Metric prefix-independent symmetric zero-depth witness splice)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}, l, r, mid, out$, symmetric visible-context distance witnesses with independent contexts and zero-depth forward distance turn any unary continuation through the reverse central distance into a metric distance witness:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \to \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \to \mathsf{MetricDistance}$$
$$\mathsf{UnaryHistory}(l) \to \mathsf{UnaryHistory}(r) \to \mathsf{Cont}(l, d_{yx}, mid) \to \mathsf{Cont}(mid, r, out) \to \mathsf{MetricDistanceWitness}(l, r, out).$$

Proof. The continuation-splice theorem gives $\mathsf{Cont}(l, r, out)$ from the two visible-context witnesses, the zero-depth row, and the two displayed continuation ledgers through d_{yx}. The supplied unary histories for l and r, together with unary continuation closure, give the unary carrier row for out. These three carrier rows and the spliced continuation are exactly the metric distance witness package. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth witness splice`

Theorem 57.309 (Metric symmetric zero-depth distance continuation result)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}$ symmetric visible-context distance witnesses with independent contexts and zero-depth forward distance make any two-step continuation through the two central distances return to the original left endpoint:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \to \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \to \mathsf{MetricDistance}$$
$$\mathsf{Cont}(l, d_{xy}, mid) \to \mathsf{Cont}(mid, d_{yx}, out) \to \mathsf{hsame}(out, l).$$

Proof. The forward zero-depth hypothesis converts d_{xy} to the empty history by the depth-zero classifier theorem. The symmetric zero-depth collapse theorem also gives zero depth for d_{yx}, hence $d_{yx}\mathsf{hsamee}$. Case analysis on these two empty-distance classifiers reduces both continuations to right-unit continuations, first identifying mid with l and then out with mid. Transitivity gives the displayed $\mathsf{hsame}(out, l)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth distance continuation result`

Theorem 57.310 (Metric symmetric zero-depth reverse distance continuation result)**.** *For histories $p, q, p', q', x, y, d_{xy}, d_{yx}, l, mid, out$, symmetric visible-context distance witnesses with independent contexts and zero-depth forward distance also make the reverse-ordered two-step continuation return to the original left endpoint:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \to \mathsf{MetricDistanceWitness}(p' \cdot y, x \cdot q', (p' \cdot d_{yx}) \cdot q') \to \mathsf{MetricDistance}$$
$$\mathsf{Cont}(l, d_{yx}, mid) \to \mathsf{Cont}(mid, d_{xy}, out) \to \mathsf{hsame}(out, l).$$

Proof. Apply Definition 57.304 to the two visible-context witnesses and the zero-depth hypothesis for d_{xy}. This gives $\mathsf{MetricDistanceDepth}(d_{yx}) = 0$.

Now apply Definition 57.309 with the two visible contexts swapped: p', q', y, x, d_{yx} play the forward roles and p, q, x, y, d_{xy} play the reverse roles. The recovered zero-depth row for d_{yx} is the forward depth hypothesis in that swapped instance, and the displayed ledgers are exactly $\mathsf{Cont}(l, d_{yx}, mid)$ followed by $\mathsf{Cont}(mid, d_{xy}, out)$.

Thus the swapped distance-continuation result returns $\mathsf{hsame}(out, l)$. The fit records traditional target zero-distance round trip, BEDC source BHist with Cont and MetricDistanceWitness, carrier the visible-context witness pair, classifier hsame, stability from zero-depth collapse and continuation unit laws, ledger the two central distance histories, core theorem this reverse-order round trip, exactness boundary-unit cancellation, standard bridge zero metric distance as identity path, and status ProofTarget. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness prefix independent symmetric zero depth reverse distance continuation result`

Definition 57.311 (MetricSpace real-distance carrier)**.** *The* $\mathsf{Met}^{\uparrow}$ *real-distance carrier for the open Real Algebra and Geometry phase is the finite unary endpoint packet*

$$(x, y, d, r;\ w, b, c, p, a)$$

where x and y are unary BHist *endpoint histories, w is the displayed row* $\mathsf{MetricDistanceWitness}(x, y, d)$*, b is the closed ball-budget row* $\mathsf{MetricBallBudget}_d(x, y; r)$*, c is the classifier row* hsame *on endpoint and result histories, p is the visible* Cont *provenance for the distance witness, and a is the* RealAlgOrder *budget packet consisting of the constant-rational endpoint rows, positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *or apartness row, ordered-real comparison, addition, transitivity, and addition-monotonicity rows used by the budget predicate.*

The carrier exposes exactly these rows. It does not contain an ambient host metric space, a quotient-real equality, a completeness principle, an open-cover compactness principle, or a topology generator separate from the displayed distance packet.

Lean4 (definition) `BEDC.Derived.MetricUp.MetricspaceRealDistanceCarrier`

Theorem 57.312 (MetricSpace RealAlgOrder positive-radius budget interface)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints in the carrier of Definition 57.311, the a-coordinate supplies exactly the ordered-real fields required by Definition 57.232 and consumed by Definition 57.233: ordered-real comparison, addition, transitivity, and two-sided addition-monotonicity. The interface is read through the scoped* $\mathsf{RealAlgOrder}^{\uparrow}$ *certificate and the apartness distance scope of Definition 57.324, so the positive-radius row is the same finite order-or-apartness row exposed to the metric budget consumer.*

This interface exports no trichotomy branch, quotient-real equality, completeness principle, open-cover compactness, or host metric-space row.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderPositiveRadiusBudgetInterface`

Proof. Project the a-coordinate from Definition 57.311. By construction this coordinate is the RealAlgOrder budget packet attached to the same endpoint histories, distance witness, classifier, continuation, and provenance rows as the metric carrier.

Apply Definition 766.2. Its order stability and ledger-exactness rows identify the comparison, addition, transitivity, and addition-monotonicity data as finite displayed order rows, while Definition 766.7 prevents any trichotomy, quotient-real equality, host real carrier, or completeness coordinate from being read through the order or apartness side.

Next use Definition 57.324 together with Definition 57.315. These theorems identify the metric-facing positive row with the same endpoint BHist histories, positive $\mathsf{DyadicRatCore}^{\uparrow}$ radius or apartness row, hsame transports, Cont routes, Pkg provenance, and NameCert ledger supplied by the scoped $\mathsf{RealAlgOrder}^{\uparrow}$ packet.

Finally compare this inventory with Definition 57.232. The predicate asks only for ordered-real comparison, addition, budget transitivity, and two-sided budget-addition monotonicity, and Definition 57.233 consumes only those displayed fields. Therefore the a-coordinate is precisely the positive-radius budget interface used by the composition theorem, with none of the excluded host principles added. □

Theorem 57.313 (MetricSpace public law package)**.** *The real-distance carrier of Definition 57.311 supports the public* $\mathsf{Met}^{\uparrow}$ *distance laws needed by the open phase:*

1. *symmetry, by transporting the endpoint order through* MetricDistanceWitness *symmetry and the RealAlgOrder apartness symmetric-separation row;*
2. *identity boundary, by the empty-distance row and the empty-boundary visible-context rows;*
3. *triangle-budget composition, by the visible-context triangle boundary and the* MetricBallBudget *composition row;*
4. *carrier transport, by* hsame *transport of endpoints and result histories together with the displayed* Cont *provenance.*

These laws are public laws of the finite BEDC packet only. They do not assert an arbitrary host metric, completeness, compactness, or a hidden equality on real distances.

Proof. For symmetry, read the distance row through Definition 57.9. The positive real-distance side is kept in the same packet by Definition 57.327, so swapping the endpoints changes only the orientation of the unary endpoint histories.

For the identity boundary, apply Definition 57.7. The visible-context empty-boundary rows then show that a zero public distance read is exactly the empty endpoint boundary up to hsame, with no quotient-real equality added.

For triangle-budget composition, use Definition 57.134 to form the composite witness over the same endpoint and continuation rows. Then apply Definition 57.233 to compose the two displayed budget rows.

For carrier transport, use the endpoint and result hsame rows already contained in Definition 57.311. The visible Cont provenance identifies the transported witness with the same public distance packet, so every exported law remains inside the carrier. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealDistanceCarrier public law package`

Theorem 57.314 (MetricSpace open-phase consumer interface)**.** *Every* $\mathsf{S}^{1\uparrow}$ *consumer and every later L10 consumer in the open Real Algebra and Geometry phase reads* $\mathsf{Met}^{\uparrow}$ *real-distance data only through the carrier of Definition 57.311 and the law package of Definition 57.313. The consumer surface is the RealAlgOrder apartness distance scope together with the existing visible-context consumer surface; it exposes no additional host metric-space coordinate, no completion row, and no open-cover compactness row.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceOpenPhaseConsumerInterface`

Proof. Start with Definition 57.324. It identifies the constant-rational endpoint histories, positive apartness or dyadic radius, and visible hsame, Cont, Pkg, and NameCert provenance available to a metric-facing real-distance consumer.

Next apply Definition 57.237. That consumer theorem restricts $\mathsf{S}^{1\uparrow}$ and the named downstream metric consumers to the visible-context distance witness, ball-budget, classifier, and finite provenance rows.

The L10 consumers in the open phase can only compose with the same RealAlgOrder apartness scope and the same visible-context public surface. Therefore their readable interface is exactly Definition 57.311 equipped with Definition 57.313, and no host metric, completion, or open-cover compactness coordinate is exported. □

Theorem 57.315 (MetricSpace RealAlgOrder positive-distance public correspondence)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints, the positive component of the* $\mathsf{Met}^{\uparrow}$ *real-distance carrier of Definition 57.311 is equivalent to the finite apartness packet isolated by Definition 57.324 and Definition 57.325. Concretely, to read a positive public distance row is to read the two endpoint* BHist *histories, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius or apartness row, the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and* NameCert *ledger supplied by the* RealAlgOrder *constant-rational boundary; conversely, those same rows repack as the positive component of the carrier.*

Endpoint reversal is supplied by Definition 57.327. The correspondence introduces no trichotomy, completion, quotient-real equality, open-cover compactness, or host equality.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderPositiveDistancePublicCorrespondence`

Proof. Project the carrier of Definition 57.311. Its positive side is not a separate host metric object; it is the displayed RealAlgOrder budget packet attached to the distance witness, classifier, continuation, package, and name-certificate rows.

For the forward direction, read that budget packet through Definition 57.324. Then apply Definition 57.325 to identify the positive public distance row with the finite apartness data available to a metric-facing consumer.

For the reverse direction, start with the finite apartness packet named by the same two theorems. The rows already match the carrier fields: endpoint histories, positive dyadic or apartness data, hsame transports, Cont routes, Pkg provenance, and the NameCert ledger. Repacking these rows with the carrier's displayed distance witness gives the positive component of the public real-distance carrier.

Finally use Definition 57.327 for endpoint reversal. Symmetry changes only the orientation of the two endpoint histories, so the same finite packet remains the public positive-distance witness and no trichotomy, completion, quotient-real equality, open-cover compactness, or host equality is added. □

Theorem 57.316 (MetricSpace apartness positive-distance triangle boundary)**.** *Let x, y, and z be constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints read through the* $\mathsf{Met}^{\uparrow}$ *real-distance public surface. Suppose the adjacent positive distance reads for (x, y) and (y, z) are represented by the finite* RealAlgOrder *apartness packets isolated in Definition 57.315. Then the triangle-boundary consumer read for the outer pair (x, z) factors through exactly those endpoint* BHist *histories, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *or apartness rows, the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and the metric triangle ledger of Definition 57.313.*

The resulting consumer row exports only this visible finite boundary. It does not export trichotomy, open-cover compactness, completed-real equality, or a host metric-space structure.

Lean4 ✓ BEDC.Derived.MetricUp.MetricspaceApartnessPositiveDistanceTriangleBoundary

Proof. Apply Definition 57.315 to the adjacent packets (x, y) and (y, z). Each read gives the same kind of finite public data: endpoint histories, positive dyadic or apartness rows, displayed hsame transports, continuation routes, package provenance, and local name-certificate rows.

Use Definition 57.327 whenever an adjacent endpoint orientation must be read from the opposite side. This changes only the order in which the two endpoint histories are presented; it does not add trichotomy, completed-real equality, compactness, or host metric structure.

Finally apply Definition 57.313. Its triangle row is already a visible-context ledger over the public distance witness, so the two adjacent positive packets repack as the outer triangle-boundary consumer read for (x, z). The repacking uses only the displayed BHist, hsame, Cont, Pkg, NameCert, and metric-law rows listed in the statement. □

Theorem 57.317 (MetricSpace SOne RealAlgOrder consumer factorization)**.** *Every* $\mathsf{S}^{1\uparrow}$ *metric consumer read whose two real coordinates are read through the constant-rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *boundary factors through the finite rows of Definition 57.311. The only readable rows are the endpoint* BHist *rows of the two coordinates, the displayed* MetricDistanceWitness *row, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *or apartness rows supplied by the* $\mathsf{RealAlgOrder}^{\uparrow}$ *boundary, the* hsame *transport rows,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and the triangle ledger of Definition 57.313.*

Thus the $\mathsf{Met}^{\uparrow}$ *consumer surface seen from* $\mathsf{S}^{1\uparrow}$ *and* $\mathsf{RealAlgOrder}^{\uparrow}$ *is a finite BEDC packet. It does not include trichotomy, completed-real equality, open-cover compactness, or a host metric-space structure.*

Lean4 ✓ BEDC.Derived.MetricUp.MetricspaceSoneRealalgorderConsumerFactorization
↪ variant BEDC.Derived.MetricUp.MetricspaceS1RealalgorderConsumerFactorization

Proof. Project the admitted circle point through Definition 58.59. The public bridge exposes only the two $\mathsf{Real}^{\uparrow}$ component rows, their product ledger, the unit-equation row, and the displayed hsame, Cont, Pkg, and NameCert rows.

Apply Definition 57.315 to each constant-rational component read. This replaces every positive metric-distance demand by the visible $\mathsf{RealAlgOrder}^{\uparrow}$ apartness packet, with endpoint histories, positive dyadic or apartness data, and the same transport and package rows as in the carrier.

Next use Definition 57.316. Its triangle-boundary row is exactly the finite metric-law ledger over the positive packets, so the $\mathsf{S}^{1\uparrow}$ metric consumer has no additional distance coordinate beyond the carrier and public-law rows.

Finally compare with Definition 58.61. The observation boundary already prevents quotient-circle, angle, compactness, connectedness, and metric-completeness rows from entering the read. Since the $\mathsf{RealAlgOrder}^{\uparrow}$ correspondence contributes no trichotomy or completed-real equality and the $\mathsf{Met}^{\uparrow}$ law package contributes no host metric space, the resulting consumer factors through exactly the finite packet listed in the statement. □

Theorem 57.318 (MetricSpace real-distance scoped certificate)**.** *The finite* $\mathsf{Met}^{\uparrow}$ *scoped certificate for the open real-algebra and geometry phase consists exactly of the real-distance carrier of Definition 57.311, the public law package of Definition 57.313, the open-phase consumer interface of Definition 57.314, the* RealAlgOrder *positive-distance correspondence of Definition 57.315, and the apartness triangle boundary of Definition 57.316.*

Its rows are only the displayed BHist *endpoint histories,* hsame *transport rows,* Cont *routes,* Pkg *provenance, local* NameCert *registrations, the public metric-law rows, and the displayed* RealAlgOrder

positive-distance budget rows. The certificate exports no host metric-space primitive, quotient-real equality, completion, open-cover compactness, or trichotomy.

Proof. Begin with the carrier of Definition 57.311. It supplies the endpoint histories, the displayed distance witness, the transport and continuation routes, package provenance, and the local name-certificate row.

Attach the public law package of Definition 57.313 and read it through Definition 57.314. This gives the open phase only the finite law rows for symmetry, separation, and triangle composition over the same carrier fields.

Next insert the RealAlgOrder side by Definition 57.315. That theorem identifies the positive-distance consumer row with the displayed apartness budget packet, so no second positivity primitive or completed-real coordinate is introduced.

Finally compose with Definition 57.316. The triangle-boundary read uses the same endpoint histories, positive-distance budget rows, hsame, Cont, Pkg, and NameCert data already listed above. Since none of the cited components contains a host metric, quotient-real equality, completion, open-cover compactness, or trichotomy row, the assembled scoped certificate has no coordinate from which such data could be exported. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealDistanceScopedCertificate`

Theorem 57.319 (MetricSpace RealAlgOrder triangle consumer exhaustion)**.** *Every* $\mathsf{Met}^{\uparrow}$ *triangle-consumer read whose endpoints are constant rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *endpoints and whose distance data are read through the real-distance carrier of Definition 57.311 is exhausted by the finite rows already displayed in that carrier, the public law package of Definition 57.313, the positive-distance correspondence of Definition 57.315, and the apartness triangle boundary of Definition 57.316.*

Equivalently, a triangle consumer over endpoints (x, y, z) *can read only the three endpoint* BHist *histories, the two adjacent positive* $\mathsf{RealAlgOrder}^{\uparrow}$ *packets, the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and the finite metric-law triangle ledger. It has no coordinate for trichotomy, quotient-real equality, completion, open-cover compactness, or an ambient host metric-space structure.*

Proof. Project the adjacent positive-distance reads for (x, y) and (y, z) through Definition 57.315. The projection exposes only endpoint histories, positive dyadic or apartness rows, transport rows, continuation routes, package provenance, and local name-certificate data.

Orient the two adjacent endpoint packets by Definition 57.327. Endpoint reversal changes only the order of the displayed unary histories, so it cannot introduce trichotomy, quotient-real equality, completion, compactness, or a host metric-space coordinate.

Compose the oriented packets through Definition 57.316. That boundary theorem is the public triangle read of Definition 57.313, hence the outer consumer is formed from the same two adjacent positive packets and the same finite triangle ledger.

Finally compare the assembled read with Definition 57.318. The scoped certificate lists every exported coordinate of the real-distance public surface. Since the triangle construction above uses only those rows, no additional coordinate remains for a mature metric-space primitive or completed real equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderTriangleConsumerExhaustion`

Theorem 57.320 (MetricSpace RealAlgOrder SOne distance route exhaustion)**.** *For any accepted* $\mathsf{S}^{1\uparrow}$ *metric consumer whose coordinates are read through constant-rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *endpoints and whose distance request uses the carrier of Definition 57.311, the public read is exhausted by the*

finite route consisting of the two $\mathsf{S}^{1\uparrow}$ *coordinate histories, the* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness or positive dyadic rows, the* MetricDistanceWitness *rows, endpoint and result* hsame *transports,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and the* $\mathsf{Met}^{\uparrow}$ *triangle ledger.*

This route exports no angle parametrization, quotient-circle equality, completed-real equality, open-cover compactness, trichotomy, or host metric-space primitive.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderSoneDistanceRouteExhaustion`

Proof. First apply Definition 57.317. It reduces the accepted $\mathsf{S}^{1\uparrow}$ metric read to the real-distance carrier of Definition 57.311, so the only available coordinate histories are the two visible $\mathsf{S}^{1\uparrow}$ histories and their constant-rational endpoint rows.

Next use Definition 57.315 on the distance request. The positive component of the carrier is exactly the visible $\mathsf{RealAlgOrder}^{\uparrow}$ apartness or positive dyadic packet, together with the same hsame, Cont, Pkg, and local NameCert rows.

For triangle-facing consumers, compose with Definition 57.316 and Definition 57.319. These results identify the remaining public metric-law data with the finite $\mathsf{Met}^{\uparrow}$ triangle ledger over the displayed distance witnesses and endpoint transports.

Finally compare with the $\mathsf{S}^{1\uparrow}$ observation boundary used in Definition 57.317. That boundary excludes angle parametrization, quotient-circle equality, completed real equality, open-cover compactness, trichotomy, and host metric-space primitives from the consumer surface, so the finite route listed in the statement is exhaustive. □

Theorem 57.321 (Metric RealAlgOrder SOne equation-distance factorization)**.** *Every accepted* $\mathsf{S}^{1\uparrow}$ *equation-distance consumer whose component reads pass through* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness or positive dyadic rows and whose metric request uses Definition 57.311 factors through exactly the finite rows listed in Definition 57.320. The same route supplies the equation-consumer boundary and excludes angle parametrization, quotient-circle equality, completed-real equality, trichotomy, open-cover compactness, and host metric primitives.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderSoneEquationDistanceFactorization`

Proof. First apply Definition 57.317. It places the accepted $\mathsf{S}^{1\uparrow}$ equation-distance read on the real-distance carrier, so the visible component histories are the two displayed circle coordinates and their constant-rational $\mathsf{RealAlgOrder}^{\uparrow}$ endpoint rows.

Next use Definition 57.315. The positive-distance component is read only through apartness or positive dyadic rows, the distance witness, endpoint transports, continuation routes, package provenance, and local naming certificates.

For metric-law consumers, compose with Definition 57.319. This keeps the triangle-facing read on the same distance witnesses and the same finite $\mathsf{Met}^{\uparrow}$ ledger.

Finally compare the resulting packet with Definition 57.320. Its displayed BHist, hsame, Cont, Pkg, and NameCert rows already list every coordinate available to the equation consumer, leaving no coordinate for angle parameters, quotient or completed equality, trichotomy, open-cover compactness, or host metric primitives. □

Theorem 57.322 (Metric RealAlgOrder SOne equation-distance symmetry)**.** *Let an accepted* $\mathsf{S}^{1\uparrow}$ *equation-distance consumer factor through constant-rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *coordinate endpoints and the* $\mathsf{Met}^{\uparrow}$ *real-distance carrier of Definition 57.311. Then the coordinate-swapped equation-distance read factors through the same finite route after coordinate-pair determinacy,* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness metric symmetric separation, and* $\mathsf{Met}^{\uparrow}$ *route exhaustion. The swapped read introduces*

no angle parametrization, quotient-circle equality, completed-real equality, trichotomy, open-cover compactness, or host metric primitive.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderSoneEquationDistanceSymmetry`

Proof. Start with the original accepted equation-distance consumer and apply Definition 57.321. The factorization exposes only the two $\mathsf{S}^{1\uparrow}$ coordinate histories, their constant-rational $\mathsf{RealAlgOrder}^{\uparrow}$ endpoint rows, the real-distance witness, endpoint transports, continuation routes, package provenance, and local name-certificate rows.

For the coordinate swap, use Definition 58.25. The determinacy statement identifies the swapped pair as the same two circle coordinate histories with their order reversed, so no angle parameter or quotient-circle equality is added to the read.

Apply Definition 57.327 to the endpoint rows. This reverses the apartness or positive dyadic separation packet inside $\mathsf{RealAlgOrder}^{\uparrow}$ while preserving the same endpoint histories, the same hsame transports, and the same finite package and certificate data.

Finally compare the swapped packet with Definition 57.320. That exhaustion theorem already lists the complete $\mathsf{Met}^{\uparrow}$ route available to the equation-distance carrier. Hence the coordinate-swapped read stays on the same finite route and leaves no coordinate for completed-real equality, trichotomy, open-cover compactness, or host metric primitives. □

Theorem 57.323 (MetricSpace RealAlgOrder SOne positive-boundary equivalence)**.** *Let constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints be accepted by the* $\mathsf{S}^{1\uparrow}$ *component-and-equation consumer through the* $\mathsf{Met}^{\uparrow}$ *real-distance carrier of Definition 57.311. Then the* $\mathsf{RealAlgOrder}^{\uparrow}$ *positive-boundary row, the* $\mathsf{Met}^{\uparrow}$ *positive-distance row, and the* $\mathsf{S}^{1\uparrow}$ *equation-separation row are equivalent finite BEDC readings of the same packet. The shared packet consists exactly of endpoint* BHist *rows, a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *or apartness row,* hsame *transports,* Cont *routes,* Pkg *provenance, local* $\mathsf{NameCert}$ *rows, the metric distance witness, and the* $\mathsf{S}^{1\uparrow}$ *component and unit-equation rows. It does not include trichotomy, quotient-real equality, angle quotient, completed-real equality, open-cover compactness, connectedness, or host metric primitives.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderSonePositiveBoundaryEquivalence`

Proof. First apply Definition 57.315. This identifies the $\mathsf{RealAlgOrder}^{\uparrow}$ positive-boundary read with the $\mathsf{Met}^{\uparrow}$ positive-distance row through the visible endpoint histories, apartness or positive dyadic data, transport rows, continuation routes, package provenance, local naming certificates, and the metric distance witness.

Next apply Definition 57.317. The $\mathsf{S}^{1\uparrow}$ component-and-equation consumer can only enter through that real-distance public interface, so its component rows and unit-equation rows read the same endpoints and distance witness rather than a separate angle or quotient-circle carrier.

The route is exhaustive by Definition 57.320. Hence any consumer claiming one of the three boundary views must use the displayed BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, distance, component, and unit-equation rows.

Finally compare with Definition 38.65 and Definition 58.67. These two boundary theorems give the reverse readings from the $\mathsf{RealAlgOrder}^{\uparrow}$–$\mathsf{Met}^{\uparrow}$ side and from the $\mathsf{S}^{1\uparrow}$ equation consumer side. Together they show that the positive-boundary, positive-distance, and equation-separation rows are three readings of one finite certificate packet, with no remaining coordinate for trichotomy, quotient-real equality, angle quotient, completed-real equality, open-cover compactness, connectedness, or host metric primitives. □

Theorem 57.324 (Metric RealAlgOrder apartness distance scope)**.** *For constant-rational* Real$^{\uparrow}$ *endpoints carried by the* RealAlgOrder *constant boundary, the finite packet supplied by Definition 38.46 and read by Definition 304.5 and Definition 304.8 is exactly the* Met$^{\uparrow}$ *positive-separation distance scope.*

The scope consists of the two endpoint histories, the positive DyadicRatCore$^{\uparrow}$ *radius or apartness row, the* hsame *transports, the* Cont *routes, the visible* Pkg *provenance, and the* NameCert *ledger tying the endpoints to their constant-rational source. Repacked as a metric consumer row, these data form the positive-separation side of a* MetricDistanceWitness *boundary and expose no trichotomy, completion, quotient-real equality, open-cover compactness, or host real equality.*

Proof. Project the constant carrier, classifier, algebra, order, and apartness rows from the RealAlgOrder constant boundary. By Definition 38.46, the consumer sees only the two Real$^{\uparrow}$ endpoint histories, their rational source witnesses, the positive dyadic or apartness row, and the displayed hsame, Cont, Pkg, and NameCert provenance.

Apply the scoped certificate Definition 38.43. It keeps the endpoint histories inside the constant-rational boundary and prevents any additional real-order coordinate from being read by the downstream consumer.

Next apply Definition 304.5 and Definition 304.8. These two rows identify the same finite packet as apartness data consumable by metric or order constructions, with the positive row and endpoint readbacks still tied to the same BHist, hsame, Cont, Pkg, and NameCert ledger.

Finally repack the resulting finite separation row as the positive-separation side of the Met$^{\uparrow}$ distance consumer boundary. The metric visible-context and boundary exactness rows are used only to keep the BEDC ledger stable under contextual prefixes and empty-boundary readback; they do not add a coordinate for trichotomy, completion, quotient-real equality, open-cover compactness, or host real equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderApartnessDistanceScope`

Theorem 57.325 (Metric RealAlgOrder apartness positive reflection)**.** *For constant-rational* Real$^{\uparrow}$ *endpoints, any finite packet satisfying Definition 57.324 and the* ApartnessReal$^{\uparrow}$ *metric consumer boundary determines exactly the positive-separation component of the* Met$^{\uparrow}$ *distance witness. Every metric consumer may read the same positive dyadic or apartness row, endpoint histories,* hsame *transports,* Cont *routes,* Pkg *provenance, and* NameCert *provenance supplied by the scoped packet. The reflection exports no converse trichotomy, quotient-real equality, completion, or host equality.*

Proof. Start with the constant-rational handoff Definition 38.46. Its packet gives the endpoint histories, the rational source rows, and the positive dyadic or apartness row that can be consumed without reading an additional real-order coordinate.

Apply Definition 38.43. The certificate keeps those rows inside the constant-rational RealAlgOrder surface and records the displayed hsame, Cont, Pkg, and NameCert provenance.

Use Definition 304.5 together with Definition 304.8. These results identify the same positive row as the separation data that an ApartnessReal$^{\uparrow}$ metric consumer may read.

Finally apply Definition 57.324 and project the positive side of the resulting MetricDistanceWitness boundary. This is only a repacking of the displayed finite rows, so the metric consumer gains no coordinate for converse trichotomy, quotient-real equality, completion, or host equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderApartnessPositiveReflection`

Theorem 57.326 (Metric RealAlgOrder positive-radius distance boundary)**.** *For constant-rational* Real$^{\uparrow}$ *endpoints carried by the scoped* RealAlgOrder$^{\uparrow}$ *boundary, the positive* DyadicRatCore$^{\uparrow}$ *radius*

or apartness row, the two endpoint BHist *rows, the displayed* hsame *transports, the* Cont *routes, visible* Pkg *provenance, and the local* NameCert *rows are exactly the positive-distance boundary of the* MetricDistanceWitness *consumed by* $\mathsf{Met}^{\uparrow}$*. Thus the concrete dyadic-or-apartness row named by the* $\mathsf{RealAlgOrder}^{\uparrow}$ *packet is the positive-distance component read by the metric witness, and every such metric witness component recovers the same finite positive-radius row.*

The boundary is local to the displayed BEDC rows. It contains no trichotomy, quotient-real equality, completion, open-cover compactness, host metric-space structure, or host real equality.

Proof. For the forward direction, start with the scoped constant-rational $\mathsf{RealAlgOrder}^{\uparrow}$ packet. Apply Definition 38.46 to expose exactly the two endpoint histories, their rational source rows, the positive dyadic or apartness row, the hsame transports, the Cont routes, visible Pkg provenance, and the local NameCert ledger. Then apply Definition 304.5 and Definition 57.325. These rows identify the same finite packet as the positive component of the MetricDistanceWitness boundary read by $\mathsf{Met}^{\uparrow}$.

For the reverse direction, begin with a positive-distance boundary of the MetricDistanceWitness whose endpoints are the same constant-rational $\mathsf{Real}^{\uparrow}$ rows. Use Definition 57.312 to read the positive-radius budget through the scoped $\mathsf{RealAlgOrder}^{\uparrow}$ certificate, and then use Definition 57.315 to identify the public positive-distance component with the finite apartness packet of the same endpoint histories, transports, routes, package provenance, and name-certificate rows.

Both directions therefore name the same concrete positive row. The repacking steps only move between the RealAlgOrder, ApartnessReal, and MetricSpace consumer surfaces; they do not introduce a branch for trichotomy, a quotient-real equality, a completion principle, an open-cover compactness principle, a host metric-space structure, or a host real equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderPositiveRadiusDistanceBoundary`
↪ variant `BEDC.Derived.MetricUp.MetricRealAlgOrder positive radius distance boundary`

Theorem 57.327 (RealAlgOrder apartness metric symmetric separation)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints carried by the* RealAlgOrder *constant boundary, the positive-separation packet identified by Definition 57.325 remains a valid positive-separation component of the* $\mathsf{Met}^{\uparrow}$ *distance witness after the two endpoint histories are swapped. The swapped orientation keeps the same positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius or apartness row, the same finite separation ledger, and the same displayed* hsame*,* Cont*,* Pkg*, and* NameCert *provenance; only the left and right endpoint histories are read in the reverse order.*

This is a metric-facing consequence of apartness symmetry. It gives the symmetric endpoint orientation required by a distance witness, but it does not add trichotomy, quotient-real equality, completion, or host real equality.

Proof. Start with the constant-rational handoff Definition 38.46. It supplies the two endpoint histories, rational source rows, positive dyadic or apartness row, and visible hsame, Cont, Pkg, and NameCert provenance.

Apply the scoped certificate Definition 38.43. The certificate keeps both endpoint histories inside the same constant-rational RealAlgOrder boundary and does not introduce any additional real-order coordinate.

Use Definition 304.4 to exchange the two endpoint histories and endpoint readbacks. The apartness row, positive radius or separation ledger, and all displayed transport and provenance rows are preserved componentwise.

Finally apply Definition 57.325 to the swapped packet. Since the positive-separation component is the same finite row read in the opposite endpoint order, it is again a valid positive component of the $\mathsf{Met}^{\uparrow}$ distance witness, with no added equality, completion, or trichotomy principle. □

Lean4 ✓ `BEDC.Derived.MetricUp.RealAlgOrderApartnessMetricSymmetricSeparation`

Theorem 57.328 (Metric RealAlgOrder apartness triangle budget)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints* x, y, z *carried by the* RealAlgOrder *constant boundary, two adjacent finite apartness packets for* (x, y) *and* (y, z) *supply the exact visible rows required by the* $\mathsf{Met}^{\uparrow}$ *triangle-budget consumer for the outer pair* (x, z) *after endpoint orientation is normalized. The consumer may read only the three endpoint histories, the two positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius or apartness rows, the finite adjacent separation ledgers, the induced outer-pair* BHist *row, the displayed* hsame *transports, the* Cont *routes, the visible* Pkg *provenance, and the local* NameCert *rows attached to the constant-rational sources.*

The statement is a local RealAlgOrder-to-MetricSpace budget law. It exports no trichotomy, quotient-real equality, completion, open-cover compactness, or host metric-space structure.

Proof. Begin with the two adjacent apartness packets. Apply Definition 57.325 to each packet; this exposes exactly the positive-separation rows, endpoint histories, hsame transports, Cont routes, Pkg provenance, and NameCert rows already present in the constant-rational boundary.

If one adjacent packet is presented in the reverse endpoint order, use Definition 57.327 to swap only the endpoint histories. The positive row and finite ledger are unchanged, so the two adjacent packets now share the middle endpoint history y in the orientation read by the triangle consumer.

With the adjacent rows normalized, invoke the $\mathsf{Met}^{\uparrow}$ visible-context triangle boundary and the public law package. These rows concatenate the two finite positive-separation ledgers into the outer-pair triangle budget while preserving the displayed BHist, hsame, Cont, Pkg, and NameCert provenance.

No excluded principle is used in the repacking step. Trichotomy, quotient-real equality, completion, open-cover compactness, and a host metric-space structure are not coordinates of the adjacent RealAlgOrder packets or of the visible triangle-budget consumer surface. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricRealalgorderApartness triangle budget`

Theorem 57.329 (RealAlgOrder apartness metric NameCert route)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints carried by the scoped* $\mathsf{RealAlgOrder}^{\uparrow}$ *boundary, the carrier and classifier rows of Definition 38.43, the finite apartness-to-metric handoff of Definition 38.46, the* $\mathsf{ApartnessReal}^{\uparrow}$ *metric handoff of Definition 304.5, the positive-separation reflection of Definition 57.325, the symmetric endpoint separation of Definition 57.327, and the triangle-budget rows of Definition 57.328 assemble into the exact finite* NameCert *route consumable by* $\mathsf{Met}^{\uparrow}$ *and by the* $\mathsf{S}^{1\uparrow}$ *boundary reader.*

The route consists only of endpoint BHist *rows, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius or apartness rows, the displayed* hsame *transports, the* Cont *routes, the* Pkg *provenance, and the local* NameCert *rows attached to the constant-rational sources and metric consumers. It exports no trichotomy, quotient-real equality, completion, open-cover compactness, or host equality.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceRealalgorderApartnessMetricNameCertRoute`

Proof. First read the two endpoint rows through Definition 38.43. This fixes the scoped $\mathsf{RealAlgOrder}^{\uparrow}$ carrier and classifier surface and keeps the endpoint histories tied to their constant-rational source rows.

Next apply Definition 38.46 and Definition 304.5. These two handoffs present the same finite apartness row as metric-facing positive-separation data, with the visible BHist, hsame, Cont, Pkg, and NameCert provenance unchanged.

Now use Definition 57.325 to package the positive row as the positive component of the $\mathsf{Met}^{\uparrow}$ distance witness, and use Definition 57.327 when the consumer requests the opposite endpoint orientation.

Finally apply Definition 57.328. The triangle route concatenates only the displayed adjacent separation ledgers and therefore gives exactly the finite NameCert route needed by metric and circle-boundary consumers, without adding any excluded host-order, quotient, completion, compactness, or equality principle. □

Theorem 57.330 (Metric distance witness right e1 result shape)**.** *For histories x, y, d, every concrete metric distance witness whose right endpoint is visibly one-headed has a visibly one-headed distance ledger, and the exposed distance tail is again the metric witness for the exposed right endpoint:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), d) \Longrightarrow \exists k : \mathsf{BHist}.\ \mathsf{hsame}(d, \mathsf{E1}(k)) \wedge \mathsf{MetricDistanceWitness}(x, y, k).$$

Proof. Unpack the distance witness into unary carrier fields and the continuation ledger. The continuation result has the form $d = x \cdot \mathsf{E1}(y)$, which is definitionally $\mathsf{E1}(x \cdot y)$. Choose $k = x \cdot y$. Unary inversion on the visible right endpoint gives the carrier for y, unary append closure gives the carrier for k, and the canonical append equality gives the descended continuation ledger. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result shape`

Theorem 57.331 (Metric distance witness right e1 result not empty)**.** *For histories x, y, d, no concrete metric distance witness whose right endpoint is visibly one-headed can have a distance result history-same to* e*:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), d) \Longrightarrow \mathsf{hsame}(d, \mathsf{e}) \Longrightarrow \bot.$$

Proof. Apply the right e-one result shape theorem to expose a tail k with $\mathsf{hsame}(d, \mathsf{E1}(k))$. Composing this with $\mathsf{hsame}(d, \mathsf{e})$ gives $\mathsf{hsame}(\mathsf{E1}(k), \mathsf{e})$, contradicting constructor disjointness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result not empty`

Theorem 57.332 (Metric distance witness right e1 result e0 absurd)**.** *For histories x, y, d, no concrete metric distance witness can have a visibly one-headed right endpoint while its distance result is visibly zero-headed:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E0}(d)) \Longrightarrow \bot.$$

Proof. Apply the right e-one result shape theorem to the witness. It exposes a tail k with $\mathsf{hsame}(\mathsf{E0}(d), \mathsf{E1}(k))$. Constructor no-confusion for generated history sameness rejects this zero-headed versus one-headed comparison. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result e0 absurd`

Theorem 57.333 (Metric distance witness right e1 result tail exactness)**.** *For histories x, y, d, k, if a distance witness has a visibly one-headed right endpoint and its displayed result is history-same as $\mathsf{E1}(k)$, then k is the exact descended distance tail:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), d) \Longrightarrow \mathsf{hsame}(d, \mathsf{E1}(k)) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, k).$$

Proof. Apply right e-one result shape to expose an intermediate tail k_0 together with $\mathsf{hsame}(d, \mathsf{E1}(k_0))$ and the descended metric witness. Compose this classifier with the displayed result classifier, invert the resulting one-headed hsame comparison, and transport the tail witness along the exposed tail equality. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result tail hsame exact`

Theorem 57.334 (Metric distance witness right e1 result tail determinism)**.** *For histories x, y, d, d', two metric distance witnesses with the same source, the same visible right endpoint, and visible results determine the same result tail:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \Longrightarrow \mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d')) \Longrightarrow \mathsf{hsame}(d, d').$$

Proof. Project the continuation ledgers from the two metric witnesses. Continuation determinacy identifies the visible results $\mathsf{hsame}(\mathsf{E1}(d), \mathsf{E1}(d'))$, and one-constructor inversion descends this classifier to the tail relation $\mathsf{hsame}(d, d')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result tail deterministic`

Theorem 57.335 (Metric distance witness right e1 source shape)**.** *For histories x, y, d, every concrete metric distance witness whose right endpoint is visibly one-headed exposes a visible distance tail and the matching empty-or-visible source alternative:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), d) \Longrightarrow \exists k : \mathsf{BHist}.\ \mathsf{hsame}(d, \mathsf{E1}(k)) \wedge \Big((x = \mathsf{e} \wedge \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(k, y)) \vee \exists x_1 : \mathsf{E}$$

Proof. Apply Definition 57.330 to the given witness. This produces a history k, a displayed result comparison $\mathsf{hsame}(d, \mathsf{E1}(k))$, and the descended witness $\mathsf{MetricDistanceWitness}(x, y, k)$.

We next rebuild the displayed-result witness with result $\mathsf{E1}(k)$. Keep the original source and right endpoint carriers, close the descended tail carrier under $\mathsf{E1}$, and transport the original continuation field along $\mathsf{hsame}(d, \mathsf{E1}(k))$.

Apply Definition 57.94 to this displayed-result witness. In the empty branch, keep the same k and record $x = \mathsf{e}$, the unary carrier for y, and $\mathsf{hsame}(k, y)$. In the visible branch, keep the same k and the exposed x_1, together with $x = \mathsf{E1}(x_1)$ and the descended metric witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 source shape`

Theorem 57.336 (Metric distance witness right e1 result iff)**.** *For histories x, y, d, a distance witness whose right endpoint and result both carry one visible constructor is equivalent to the descended tail witness:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \Longleftrightarrow \mathsf{MetricDistanceWitness}(x, y, d).$$

Proof. The forward direction is right one-headed result exactness. For the reverse direction, keep the source unary carrier, close the right endpoint and result carriers under $\mathsf{E1}$, and lift the continuation ledger by the one-step continuation rule. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result iff`

Theorem 57.337 (Metric distance witness right e1 result hsame source)**.** *For histories x, x', y, d, a distance witness whose right endpoint and result both carry one visible constructor has the same empty-or-visible source readback after source transport:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \wedge \mathsf{hsame}(x, x') \Longrightarrow (x' = \mathsf{e} \wedge \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(d, y))$$

or there exists $x_1 : \mathsf{BHist}$ *such that*

$$x' = \mathsf{E1}(x_1) \wedge \mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y, d).$$

Proof. Apply the right one-headed source case split before transport. In the empty branch, empty hsame inversion identifies x' with e. In the visible branch, visible hsame inversion exposes the transported tail, and unary and continuation transport rebuild the descended metric witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result hsame source`

Theorem 57.338 (Metric distance witness right e1 result hsame target)**.** *For histories x, y, y', d, a distance witness whose right endpoint and result both carry one visible constructor has the same empty-or-visible source readback after target-tail transport:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \wedge \mathsf{hsame}(y, y') \Longrightarrow (x = \mathsf{e} \wedge \mathsf{UnaryHistory}(y') \wedge \mathsf{hsame}(d, y'))$$

or there exists $x_1 : \mathsf{BHist}$ *such that*

$$x = \mathsf{E1}(x_1) \wedge \mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y', d).$$

Proof. Apply the right one-headed source case split before target transport. In the empty-source branch, transport the unary carrier and compose the displayed result-tail comparison with $\mathsf{hsame}(y, y')$. In the visible-source branch, keep the exposed source tail and transport the target carrier and continuation ledger across the target-tail classifier, leaving the source and result endpoints fixed. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result hsame target`

Theorem 57.339 (Metric right e-one result two-sided endpoint transport)**.** *For histories x, x', y, y', d, simultaneous source and target-tail transport preserves the empty-or-visible readback of a right e-one metric result:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{E1}(y), \mathsf{E1}(d)) \wedge \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \Longrightarrow (x' = \mathsf{e} \wedge \mathsf{UnaryHistory}(y') \wedge \mathsf{hsame}(d, y'))$$

or there exists $x_1 : \mathsf{BHist}$ *such that*

$$x' = \mathsf{E1}(x_1) \wedge \mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y', d).$$

Proof. First apply Definition 57.337 to the displayed witness and the supplied $\mathsf{hsame}(x, x')$. This gives the transported source readback with target tail y still fixed.

In the empty-source branch, keep $x' = \mathsf{e}$. Transport the unary carrier from y to y' along $\mathsf{hsame}(y, y')$, and compose the displayed comparison $\mathsf{hsame}(d, y)$ with $\mathsf{hsame}(y, y')$ to obtain $\mathsf{hsame}(d, y')$.

In the visible-source branch, keep the exposed x_1 and the equality $x' = \mathsf{E1}(x_1)$. The descended witness $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y, d)$ supplies the source, target, and result carriers; unary transport moves the target carrier from y to y', while metric continuation transport carries the

continuation ledger across the same target-tail classifier with source and result fixed. Repacking these fields gives $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x_1), y', d)$.

Ten-field fit: traditional target two-sided visible endpoint transport; BEDC source BHist, hsame, and MetricDistanceWitness; carrier unary metric endpoints; classifier hsame; stability source and target-tail transport; ledger exposed right e-one distance tail; core theorem Definition 57.339; exactness simultaneous transported source readback; standard bridge finite unary metric endpoint transport; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness right e1 result two sided endpoint transport`

Theorem 57.340 (Metric e-one pair result tail readback)**.** *For histories x, y, d, a metric distance witness whose source, target, and result are all visibly one-headed exposes unary source and target tails and the tail continuation ledger:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d)) \Longrightarrow \mathsf{UnaryHistory}(x) \wedge \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(d, \mathsf{E1}(x) \cdot y).$$

Proof. Apply right e-one result exactness to descend the target and result to $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d)$. Unary inversion on the source carrier gives unary evidence for x, the descended witness carries unary evidence for y, and its continuation ledger is exactly $d\mathsf{hsameE1}(x) \cdot y$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e1 pair result tail readback`

Theorem 57.341 (Metric e-one pair result tail exactness iff)**.** *For histories x, y, d, a metric distance witness whose source, target, and result are all visibly one-headed is equivalent to unary tail data together with the exposed continuation ledger:*

$$\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d)) \Longleftrightarrow \mathsf{UnaryHistory}(x) \wedge \mathsf{UnaryHistory}(y) \wedge \mathsf{hsame}(d, \mathsf{E1}(x) \cdot y).$$

Proof. For the forward direction, apply Theorem 57.340. It descends the visible target and result constructors and returns exactly the two unary tail carriers and the displayed continuation ledger.

For the reverse direction, start from the unary tail carriers and the hsame ledger. Unary closure builds the source carrier $\mathsf{UnaryHistory}(\mathsf{E1}(x))$, and the continuation ledger transports the append result so that d is the concrete distance from $\mathsf{E1}(x)$ to y. This gives the central witness $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), y, d)$.

Apply Theorem 57.294 to this central witness. The visible target constructor and the matching visible result constructor are restored, producing $\mathsf{MetricDistanceWitness}(\mathsf{E1}(x), \mathsf{E1}(y), \mathsf{E1}(d))$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e1 pair result iff`
Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness e1 pair result tail exactness iff`

The ten-field fit is: traditional target one-headed metric tail exactness; BEDC source BHist, UnaryHistory, Cont, and MetricDistanceWitness; carrier concrete metric distance witnesses; classifier hsame; stability visible-constructor closure and continuation transport; ledger exposed tail distance; core theorem Theorem 57.341; exactness bidirectional tail data; standard bridge finite metric endpoint readback; status ProofTarget.

Theorem 57.342 (MetricSpace SOne distance source boundary)**.** *Every accepted $\mathsf{S}^{1\uparrow}$ packet over the $\mathsf{Real}^{\uparrow}$ product carrier reads $\mathsf{Met}^{\uparrow}$ distance data only through the finite rows of Definition 57.311 and the public law package of Definition 57.313. Its circle-side source is constrained by Definition 58.59, Definition 58.61, and Definition 58.62. Its $\mathsf{RealAlgOrder}^{\uparrow}$ side is constrained by Definition 57.324 and Definition 38.63.*

Thus a $\mathsf{S}^{1\uparrow}$ *consumer of real-distance data can read only the two* $\mathsf{Real}^{\uparrow}$ *component rows, the product-carrier ledger, the unit-equation row, componentwise* hsame *classifiers, equation transport, finite-window* RegSeqRat *stream-name and real-seal rows, the displayed* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness budget rows, the metric endpoint histories,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and the public metric-law rows. The boundary exports no angle quotient, covering-space quotient, host metric function, completion row, compactness row, connectedness row, or topology generator.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceSoneDistanceSourceBoundary`
↪ variant `BEDC.Derived.MetricUp.MetricspaceSOneDistanceSourceBoundary`

Proof. Project the accepted $\mathsf{S}^{1\uparrow}$ packet through Definition 58.59. This exposes the two $\mathsf{Real}^{\uparrow}$ component rows, the product carrier, the unit-equation witness, the componentwise classifier rows, and equation transport, and excludes the circle-specific quotient and topology rows named in the statement.

Refine the two real components through Definition 58.61 and Definition 58.62. The metric-facing source rows are then finite-window RegSeqRat and real-seal observations attached to the same public certificate, rather than an ambient circle metric or a hidden completion object.

Pass the real-algebra side through Definition 57.324 and Definition 38.63. These two boundaries keep the apartness and unit-equation reads tied to the displayed $\mathsf{RealAlgOrder}^{\uparrow}$ endpoint and budget rows, so the metric source has no trichotomy, quotient-real equality, host metric, or Real completeness coordinate.

Repack the resulting endpoint rows, budget rows, transport rows, continuation routes, provenance rows, and local certificate rows as the carrier of Definition 57.311. Attach Definition 57.313 and read the package through Definition 57.314. The open real-algebra and geometry phase therefore consumes exactly the finite real-distance carrier and its public law rows, with no additional metric, topology, compactness, connectedness, completion, angle, or covering quotient data. □

Theorem 57.343 (Metric seed closure surface)**.** *The* $\mathsf{Met}^{\uparrow}$ *seed closure surface is the finite public package assembled from the metric carrier of Definition 57.1, the boundary exactness rows of Definition 57.211 and Definition 57.212, the real-distance public interface of Definition 57.311, the triangle continuation rows of Definition 57.356, and the transport surface of Definition 57.347. A seed consumer of* $\mathsf{Met}^{\uparrow}$ *can read only these carrier, boundary, distance, triangle, and transport rows together with their* hsame*,* Cont*,* Pkg*, and local* NameCert *provenance.*

Proof. Project the metric carrier first. The carrier fixes the endpoint histories, distance witness rows, classifier, continuation, provenance, and local naming coordinates available to any public metric read.

Boundary exactness then identifies the endpoint and empty-boundary cases already named by the carrier. The real-distance public interface supplies the displayed ordered-real budget rows used by downstream consumers.

The triangle surface is the visible continuation package: triangle append closure and the associated middle-continuation rows keep composite distance reads inside the same finite witness family. Transport then moves endpoints, witnesses, budgets, and provenance componentwise through the displayed hsame and Cont rows.

No additional host metric, topology generator, compactness principle, completeness row, or quotient real equality appears in these referenced surfaces. Hence the named carrier, boundary, distance, triangle, and transport files form the seed closure surface for $\mathsf{Met}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricSeedClosureSurface public package`

The $\mathsf{Met}^{\uparrow}$ seed surface is the carrier, distance witness, boundary exactness, real-distance interface, triangle continuation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row described by Definition 57.343. Its binding closure registration is recorded in the obligation-status child file, where the same checked Lean target is read independently from the paper-side closure grade.

Theorem 57.344 (MetricSpace L10 sibling lattice route)**.** *Every* $\mathsf{Met}^{\uparrow}$ *real-distance consumer used by the current L10 Real and Completion route factors through the finite sibling surfaces already present in the metric child files:* **??**, *chapter 58, chapter 38, chapter 126, chapter 301, and chapter 291. The lattice route is the displayed finite read through LocatedReal endpoints, SOne component routes, the Real public-distance certificate, StreamName finite windows, RegSeqRat regular-source rows, and DyadicRatCore endpoint and budget ledgers.*

The route introduces no host metric function, quotient real equality, selected limit, open-cover compactness, or metric-completion datum.

Lean4 ✓ `BEDC.Derived.MetricUp.MetricspaceL10SiblingLatticeRoute finite packet`

Proof. First place the located-real side on its finite source boundary. Apply Definition 57.302. The distance consumer is then read only through accepted $\mathsf{LocatedReal}^{\uparrow}$ packets, their $\mathsf{StreamName}^{\uparrow}$ schedules, $\mathsf{RegSeqRat}^{\uparrow}$ source windows, and DyadicRatCore endpoint and radius ledgers, together with visible BHist, hsame, Cont, Pkg, and NameCert rows.

Next place the circle-side metric consumer on its finite component route. Apply Definition 57.342. This keeps the $\mathsf{S}^{1\uparrow}$ read on the two $\mathsf{Real}^{\uparrow}$ component rows, the unit-equation row, componentwise classifiers, finite-window stream and regular-source rows, and the same visible provenance surface.

Now attach the Real-facing certificate by Definition 57.318. Its certificate is exactly the real-distance carrier, the public metric laws, the RealAlgOrder positive-distance correspondence, and the apartness triangle boundary. Therefore the metric consumer reaches the L10 Real face through the same finite packet rather than through a separate real equality or completion coordinate.

Finally apply Definition 57.313. The exported metric laws are symmetry, identity boundary, triangle-budget composition, and carrier transport over the displayed packet. Since the LocatedReal and SOne source boundaries already factor through the named Real, StreamName, RegSeqRat, and DyadicRatCore sibling faces, the assembled L10 route is the finite sibling lattice listed in the statement. None of the cited rows contains a host metric function, quotient real equality, selected limit, open-cover compactness, or metric-completion datum, so none is introduced by the factorization. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricSpaceL10SiblingLatticeRoute`

Lemma 57.345 (Metric L10 sibling dependency route)**.** *Every* $\mathsf{Met}^{\uparrow}$ *consumer in the L10 route reads distance rows through the finite sibling dependency surface already named by the metric packet:* $\mathsf{Real}^{\uparrow}$ *distance endpoints from chapter 38,* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison rows or apartness rows when positive distance is inspected,* $\mathsf{S}^{1\uparrow}$ *rows where circle distances are consumed through chapter 58, and* $\mathsf{ContinuousMap}^{\uparrow}$ *rows where modulus transport is needed through chapter 130. The route is a finite displayed dependency route, not a host metric space, completed distance function, quotient real equality, or ambient continuity theorem.*

Lean4 ✓ `BEDC.Derived.MetricUp.MetricL10SiblingDependencyRoute surface`

Theorem 57.346 (Metric distance witness continuation hsame transport)**.** *For histories* x, x', y, y', d, d' : BHist*, history-sameness of the two endpoints and of the distance result transports the continuation field exposed by a metric distance witness:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{Cont}(x', y', d').$$

Proof. Case-reduce the three supplied hsame witnesses. The transported endpoints and result are then definitionally the endpoints and result of the original metric distance witness. Project its continuation field $\mathsf{Cont}(x, y, d)$, which is the required transported continuation ledger. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness cont hsame transport`

Theorem 57.347 (Metric distance witness hsame field transport)**.** *For histories* x, x', y, y', d, d' : BHist*, history-sameness of the two endpoints and of the distance result transports all exposed fields of a metric distance witness:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{UnaryHistory}(x') \wedge \mathsf{UnaryHisto}$$

Proof. Case-reduce the three supplied hsame witnesses. The transported source, target, and distance histories are then definitionally the original fields. Project the three unary carrier fields and the continuation ledger from the metric distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness hsame fields transport`

Theorem 57.348 (Metric distance witness hsame transport depth add)**.** *For histories* x, x', y, y', d, d' : BHist*, history-sameness of the two endpoints and of the distance result transports the continuation field and preserves the append-depth ledger:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{Cont}(x', y', d') \wedge \mathsf{MetricDistanc}$$

Proof. Case-reduce the three supplied hsame witnesses. The transported histories are then the source, target, and distance of the original metric witness. Project its continuation field and apply the metric distance depth-add theorem to the same witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness hsame transport cont depth add`

Theorem 57.349 (Metric distance witness hsame source determinacy)**.** *For histories* x, x', y, y', d, d' : BHist*, if the target and distance ledgers classify by* hsame *and the two concrete metric distance witnesses hold,*

$$\mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{MetricDistanceWitness}(x', y', d'),$$

then the witnesses expose both continuation fields and determine the source:

$$\mathsf{Cont}(x, y, d) \wedge \mathsf{Cont}(x', y', d') \wedge \mathsf{hsame}(x, x').$$

Proof. Project the continuation fields from the two metric distance witnesses. After case-reducing the target and distance hsame witnesses, the continuations share the same right context and result. Continuation right cancellation then identifies the two sources. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness hsame source deterministic`

Theorem 57.350 (Metric distance witness hsame target determinacy)**.** *For histories* x, x', y, y', d, d' : BHist*, if the source and distance ledgers classify by* hsame *and the two concrete metric distance witnesses hold,*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d) \Longrightarrow \mathsf{MetricDistanceWitness}(x', y', d'),$$

then the witnesses expose both continuation fields and determine the target:

$$\mathsf{Cont}(x, y, d) \wedge \mathsf{Cont}(x', y', d') \wedge \mathsf{hsame}(y, y').$$

Proof. Project the continuation fields from the two metric distance witnesses. After case-reducing the source and distance hsame witnesses, the continuations share the same left context and result. Continuation left cancellation then identifies the two targets. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness hsame target deterministic`

Theorem 57.351 (Metric distance witness visible-context hsame source determinacy)**.** *For histories* $p, q, p', q', x, x', y, y', d, d'$: BHist*, if the visible targets and visible distances have the same central target and distance under* hsame*, then the central sources are determined:*

$$\mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(p' \cdot x', y' \cdot q', (p' \cdot d') \cdot q') \Longrightarrow \mathsf{hsame}(x, x').$$

Proof. Apply Definition 57.13 to both visible-context witnesses. This exposes central witnesses $\mathsf{MetricDistanceWitness}(x, y, d)$ and $\mathsf{MetricDistanceWitness}(x', y', d')$. The supplied hsame relations on y, y' and d, d' then fit Definition 57.349, whose source component is the displayed $\mathsf{hsame}(x, x')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context hsame source deterministic`

Theorem 57.352 (Metric distance witness visible-context hsame target determinacy)**.** *For histories* $p, q, p', q', x, x', y, y', d, d'$: BHist*, if the visible sources and visible distances have the same central source and distance under* hsame*, then the central targets are determined:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(d, d') \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(p' \cdot x', y' \cdot q', (p' \cdot d') \cdot q') \Longrightarrow \mathsf{hsame}(y, y').$$

Proof. Apply Definition 57.13 to both visible-context witnesses. This exposes central witnesses $\mathsf{MetricDistanceWitness}(x, y, d)$ and $\mathsf{MetricDistanceWitness}(x', y', d')$. The supplied hsame relations on x, x' and d, d' then fit Definition 57.350, whose target component is the displayed $\mathsf{hsame}(y, y')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context hsame target deterministic`

Theorem 57.353 (Metric distance witness prefix-independent endpoint-hsame result determinacy)**.** *For histories* $p, q, p', q', x, x', y, y', d, e$: BHist*, if the central endpoints classify by* hsame *while the visible prefixes and suffixes may differ, then the exposed central distance results classify together:*

$$\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(p' \cdot x', y' \cdot q', (p' \cdot e) \cdot q') \Longrightarrow \mathsf{hsame}(d, e).$$

Proof. Apply visible-context exactness to both metric witnesses. This removes the prefix and suffix contexts and exposes central witnesses $\mathsf{MetricDistanceWitness}(x, y, d)$ and $\mathsf{MetricDistanceWitness}(x', y', e)$. The supplied endpoint classifications then fit the endpoint-hsame result determinacy theorem, giving the displayed $\mathsf{hsame}(d, e)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context prefix independent endpoint hsame result deterministic`

Theorem 57.354 (Metric distance witness visible right tail determinacy)**.** *For histories $p, q, p', q', x, y, d, d'$: BHist, if two visible-context metric witnesses share the central source and the right endpoint $\mathsf{E1}(y)$, and their displayed distance results are respectively $\mathsf{E1}(d)$ and $\mathsf{E1}(d')$ inside their visible contexts, then the distance tails classify together:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, \mathsf{E1}(y) \cdot q, (p \cdot \mathsf{E1}(d)) \cdot q) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(p' \cdot x, \mathsf{E1}(y) \cdot q', (p' \cdot \mathsf{E1}(d')) \cdot q') \Longrightarrow \mathsf{hsame}(d, d').$$

Proof. Visible-context exactness removes the outer prefixes and suffixes, exposing two central metric witnesses with right endpoint $\mathsf{E1}(y)$ and results $\mathsf{E1}(d)$ and $\mathsf{E1}(d')$. Right-$\mathsf{E1}$ result exactness descends both witnesses to their tails, after which continuation determinism identifies the tail distance results. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context right e1 result tail deterministic`

Theorem 57.355 (Metric distance witness visible-context semantic name certificate)**.** *For unary visible contexts p, q and unary central endpoints x, y, the contextual distance predicate $d \mapsto \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q)$ carries a semantic naming certificate with classifier hsame:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{UnaryHistory}(x) \Longrightarrow \mathsf{UnaryHistory}(y) \Longrightarrow$$
$$\mathsf{SemanticNameCert}(d \mapsto \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d) \cdot q))\,(d \mapsto \mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d$$

Proof. The inhabited carrier is the central distance $x \cdot y$, lifted through visible-context exactness. The classifier is hsame, so its equivalence laws are the kernel history-sameness laws. Transport along the classifier is by case analysis on the history-sameness witness, after which the contextual distance predicate is unchanged. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context semanticNameCert`

Theorem 57.356 (Metric distance witness triangle append closure)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, a distance witness from x to y, a distance witness from y to z, and a distance witness from d_{xy} to z close the appended triangle ledger:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{xyz}, x \cdot d_{yz}).$$

Proof. Unpack the three distance witnesses to their continuation fields. The three continuations identify d_{xy} with $x \cdot y$, d_{yz} with $y \cdot z$, and d_{xyz} with $(x \cdot y) \cdot z$. Associativity of history append classifies this last ledger with $x \cdot (y \cdot z)$, hence with $x \cdot d_{yz}$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append closed`

Theorem 57.357 (Metric distance witness unary append commutation package)**.** *For unary histories x and y, the appended endpoints $x \cdot y$ and $y \cdot x$ carry the canonical metric distance witness $(x \cdot y) \cdot (y \cdot x)$, and the endpoints are hsame:*

$$\mathsf{MetricDistanceWitness}(x \cdot y, y \cdot x, (x \cdot y) \cdot (y \cdot x)) \wedge \mathsf{hsame}(x \cdot y, y \cdot x).$$

Proof. Unary append closure supplies the two endpoint carriers and the displayed distance carrier. The distance ledger is the canonical continuation from $x \cdot y$ to $y \cdot x$, and unary append commutativity gives the endpoint classifier. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness unary append comm package`

Theorem 57.358 (Metric distance witness composite endpoint append result)**.** *For histories $x, x', y, y', z, z', d_{xy}, d_{xyz}$, endpoint comparisons $x\mathsf{hsame}x'$, $y\mathsf{hsame}y'$, and $z\mathsf{hsame}z'$ transport the composite distance ledger to the endpoint-normal append result:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{xyz}, x' \cdot (y' \cdot z')).$$

Proof. Transport along the three endpoint hsame comparisons and unpack the two distance witnesses to their continuation fields. Constructor analysis of the two continuation ledgers reduces the displayed result comparison to associativity of history append. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness composite endpoint hsame append result`

Theorem 57.359 (Metric distance witness triangle continuation middle closure)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, a distance witness from x to y, a distance witness from y to z, and a continuation ledger $\mathsf{Cont}(d_{xy}, z, d_{xyz})$ close the middle-composite distance witness:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{Cont}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(x, d_{yz}, d_{xyz}).$$

Proof. The two distance witnesses expose the continuation ledgers $\mathsf{Cont}(x, y, d_{xy})$ and $\mathsf{Cont}(y, z, d_{yz})$. Together with the displayed ledger $\mathsf{Cont}(d_{xy}, z, d_{xyz})$, constructor analysis reduces the resulting source-to-middle continuation to associativity of history append. The unary carrier for d_{xyz} follows from unary continuation closure applied to d_{xy} and z. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle cont middle closed`

Theorem 57.360 (Metric distance witness visible-context triangle continuation middle closure)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, a visible-context witness for the left triangle edge, a central witness from y to z, and a continuation ledger from d_{xy} by z close the central middle-composite distance witness:*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{Cont}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(x, d_{yz}, d_{xyz}).$$

Proof. Apply Definition 57.13 to the visible-context witness. This recovers the central edge witness $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$. The recovered edge witness, the given y-to-z witness, and the displayed continuation ledger are exactly the inputs of Definition 57.359, which returns the displayed middle-composite distance witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context triangle cont middle closed`

Theorem 57.361 (Metric distance witness triangle middle result determinacy)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}, displayed$, if the witnesses from x to y and from y to z are given, and $\mathsf{Cont}(d_{xy}, z, d_{xyz})$ displays the middle composite, then any distance witness from x to d_{yz} has the same result:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{Cont}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(x, d_{yz}, displayed) \Longrightarrow \mathsf{hsame}(d_{xyz}, displayed).$$

Proof. Triangle continuation middle closure constructs the canonical witness $\mathsf{MetricDistanceWitness}(x, d_{yz}, d_{xyz})$ from the two edge witnesses and the displayed middle continuation. The displayed witness has the same source and target histories as this canonical witness, so continuation determinacy applied to their distance ledgers identifies the two result histories. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle cont middle result deterministic`

Theorem 57.362 (Metric distance witness triangle append depth add)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, three triangle distance witnesses identify the displayed ledger with $x \cdot d_{yz}$ and compute its structural depth as the sum of the left endpoint depth and the middle-to-right distance depth:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{xyz}, x \cdot d_{yz}) \wedge \mathsf{MetricDistanceDepth}(d_{xyz}) = \mathsf{MetricDistanceDepth}(x$$

Proof. Triangle append closure supplies the equality $\mathsf{hsame}(d_{xyz}, x \cdot d_{yz})$. Together with the unary carrier fields already present in the three distance witnesses, this equality is a concrete distance witness from x to d_{yz} with result d_{xyz}. The metric depth addition law applied to that central witness gives the displayed depth equation. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append depth add`

Theorem 57.363 (Metric distance witness continuation depth add)**.** *For histories x, y, z, d_{xy}, d_{xyz}, a distance witness from x to y and a displayed continuation from d_{xy} by z compute the final structural distance depth:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{UnaryHistory}(z) \Longrightarrow \mathsf{Cont}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xyz}) = \mathsf{Metri}$$

Proof. The first witness supplies the unary carrier of d_{xy}. Together with the unary carrier of z and the displayed continuation ledger, this forms a second distance witness from d_{xy} to z with result d_{xyz}. Apply the depth additivity theorem to the first and second witnesses, then associate addition. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness cont depth add`

Theorem 57.364 (Metric distance witness triangle depth-zero collapse)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if three triangle distance witnesses have a final ledger of structural depth zero, then the triangle append equality holds and every displayed endpoint and intermediate distance collapses to* e*:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xyz}) = 0 \Longrightarrow$$
$$\mathsf{hsame}(d_{xyz}, x \cdot d_{yz}) \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xy}, \mathsf{e}) \wedge \mathsf{hsame}(d_{yz}, \mathsf{e}).$$

Proof. Triangle append closure forms the central witness from x to d_{yz} with result d_{xyz}. The depth-zero endpoint theorem for this central witness forces x and d_{yz} to be empty. Empty-distance exactness for the witness from y to z then forces y and z to be empty, and the continuation field in the witness from x to y forces d_{xy} to be empty. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle depth zero collapse`

Theorem 57.365 (Metric triangle left distance empty collapse)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the left distance in a metric triangle is history-same to* e*, then its endpoints collapse and the remaining two displayed distances are exactly the right endpoint:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow$$
$$\mathsf{hsame}(d_{xy}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(d_{xyz}, z) \wedge \mathsf{hsame}(d_{yz}, z).$$

Proof. Empty-distance exactness for the witness from x to y gives $x\mathsf{hsamee}$ and $y\mathsf{hsamee}$. With d_{xy} collapsed, empty-left exactness for the outer witness gives $d_{xyz}\mathsf{hsame}z$. Collapsing y in the second witness and applying the same empty-left exactness gives $d_{yz}\mathsf{hsame}z$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle left distance empty collapse`

Theorem 57.366 (Metric triangle depth-zero iff empty spine)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, three concrete metric distance witnesses identify final structural depth zero exactly with emptiness of the three endpoints and the two displayed edge distances:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \\ &\mathsf{MetricDistanceDepth}(d_{xyz}) = 0 \Longleftrightarrow \\ &\mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xy}, \mathsf{e}) \wedge \mathsf{hsame}(d_{yz}, \mathsf{e}).\end{aligned}$$

Proof. For the forward direction, apply Definition 57.364 to the three triangle witnesses and the displayed zero-depth equation. The theorem returns a larger conjunction containing the append equality as its first component; discard that component and retain precisely the five empty-spine classifiers.

For the reverse direction, assume the five displayed classifiers. Apply Definition 57.252 to the first edge witness, using $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$, to get $\mathsf{MetricDistanceDepth}(d_{xy}) = 0$. Then use Definition 57.253 to recover $\mathsf{hsame}(d_{xy}, \mathsf{e})$ as the certified empty left endpoint for the outer witness. Finally apply Definition 57.252 to $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$, together with $\mathsf{hsame}(d_{xy}, \mathsf{e})$ and $\mathsf{hsame}(z, \mathsf{e})$, to obtain $\mathsf{MetricDistanceDepth}(d_{xyz}) = 0$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle depth zero iff empty spine`

Fit: traditional target triangle degeneracy criterion; BEDC source $BHist$ metric distance witnesses; carrier the three witnessed edges; classifier hsame; stability supplied by existing depth-zero and empty-endpoint lemmas; ledger the two edge distances; core theorem this iff; exactness zero-depth iff empty spine; standard bridge none claimed; status ProofTarget.

Theorem 57.367 (Metric distance witness visible-context triangle depth-zero collapse)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the first triangle edge is displayed through visible source and target ledgers and the final triangle distance has structural depth zero, then the triangle append equality holds and every central endpoint and intermediate distance collapses to* e*:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, p \cdot d_{xy} \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceDepth}(d_{xyz}) = 0 \Longrightarrow \\ &\mathsf{hsame}(d_{xyz}, x \cdot d_{yz}) \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xy}, \mathsf{e}) \wedge \mathsf{hsame}(d_{yz}, \mathsf{e}).\end{aligned}$$

Proof. Apply Definition 57.13 to the contextual first edge. This recovers the central witness $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$ while leaving the two remaining triangle witnesses unchanged.

Apply Definition 57.364 to the central witness, the witness from y to z, the witness from d_{xy} to z, and the depth-zero hypothesis. The resulting conjunction is exactly the stated visible-context collapse conclusion. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context triangle depth zero collapse`

Theorem 57.368 (Metric distance witness visible-context triangle depth-zero iff empty spine)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, visible source and target ledgers around the first edge preserve the exact zero-depth triangle criterion:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, p \cdot d_{xy} \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \\ &\mathsf{MetricDistanceDepth}(d_{xyz}) = 0 \Longleftrightarrow \\ &\mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xy}, \mathsf{e}) \wedge \mathsf{hsame}(d_{yz}, \mathsf{e}).\end{aligned}$$

Proof. Apply Definition 57.13 to the contextual first edge. This recovers the central witness $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$, so the three hypotheses now have the same shape as the central triangle criterion.

For the forward direction, apply Definition 57.366 to the central witness, the witness from y to z, and the witness from d_{xy} to z. The forward half turns the displayed zero-depth equation into the five empty-spine classifiers.

For the reverse direction, use the same central iff theorem with the recovered central witness and the two unchanged triangle witnesses. Its reverse half turns the five displayed empty-spine classifiers into $\mathsf{MetricDistanceDepth}(d_{xyz}) = 0$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context triangle depth zero iff empty spine`

Theorem 57.369 (Metric triangle nonempty distance has a nonempty endpoint)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the three triangle distance witnesses hold and the final triangle distance is not history-same as* e*, then at least one endpoint of the triangle is not history-same as* e*:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow ($$

Proof. Apply metric nonempty-distance endpoint exactness to the outer witness $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$ If the nonempty endpoint is z, the conclusion follows directly. If it is d_{xy}, apply the same exactness theorem to $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$, yielding a nonempty x or y endpoint. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle nonempty endpoint nonempty`

Theorem 57.370 (Metric triangle nonempty spine one-headed endpoint cases)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the three triangle distance witnesses hold and the final triangle distance is not history-same as* e*, then at least one triangle endpoint is visibly one-headed with a unary tail:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow (d_{xyz}\mathsf{hsamee} \to \mathsf{False}) \Longrightarrow \\ &(\exists x_0,\ x = \mathsf{E1}(x_0) \wedge \mathsf{UnaryHistory}(x_0)) \vee (\exists y_0,\ y = \mathsf{E1}(y_0) \wedge \mathsf{UnaryHistory}(y_0)) \vee (\exists z_0,\ z = \mathsf{E1}(z_0) \wedge \mathsf{UnaryHistory}($$

Proof. Apply the nonempty endpoint theorem for metric triangles. In each endpoint case, the corresponding unary carrier is a field of one of the triangle distance witnesses. Unary nonempty one-tail readback turns that nonempty carrier into the displayed $\mathsf{E1}$ endpoint with a unary tail. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle nonempty spine e1 endpoint cases`

Theorem 57.371 (Metric triangle nonempty spine iff nonempty distance)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, the same three triangle distance witnesses identify nonemptiness of the final triangle distance exactly with nonemptiness of at least one point of the triangle spine:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \\ &(d_{xyz}\mathsf{hsamee} \to \mathsf{False}) \Longleftrightarrow \\ &((x\mathsf{hsamee} \to \mathsf{False}) \vee (y\mathsf{hsamee} \to \mathsf{False}) \vee (z\mathsf{hsamee} \to \mathsf{False}) \vee (d_{xy}\mathsf{hsamee} \to \mathsf{False}) \vee (d_{yz}\mathsf{hsamee} \to \mathsf{False})).\end{aligned}$$

Proof. For the forward direction, apply Definition 57.369 to the three triangle witnesses and the displayed nonempty-distance hypothesis. The resulting endpoint disjunction is injected into the five-way spine disjunction by choosing the corresponding x, y, or z summand.

For the reverse direction, assume the five-way spine disjunction and suppose $d_{xyz}\mathsf{hsamee}$. By Definition 57.253, this gives $\mathsf{MetricDistanceDepth}(d_{xyz}) = 0$. Applying Definition 57.366 to the three triangle witnesses then yields $\mathsf{hsame}(x, \mathsf{e})$, $\mathsf{hsame}(y, \mathsf{e})$, $\mathsf{hsame}(z, \mathsf{e})$, $\mathsf{hsame}(d_{xy}, \mathsf{e})$, and $\mathsf{hsame}(d_{yz}, \mathsf{e})$.

Case-analyze the five-way spine disjunction. In each case, the selected nonempty spine component is a function from the corresponding empty classifier to False, so applying it to the matching classifier from the empty-spine conjunction gives the desired contradiction. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle nonempty spine iff nonempty distance`

Theorem 57.372 (Metric distance witness visible-context triangle nonempty spine iff nonempty distance)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, a triangle whose first edge is displayed through visible contexts has the same exact nonempty-spine criterion as the central triangle:*

$$\begin{aligned}&\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot d_{xy}) \cdot q) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \\ &(d_{xyz}\mathsf{hsamee} \to \mathsf{False}) \Longleftrightarrow \\ &((x\mathsf{hsamee} \to \mathsf{False}) \vee (y\mathsf{hsamee} \to \mathsf{False}) \vee (z\mathsf{hsamee} \to \mathsf{False}) \vee (d_{xy}\mathsf{hsamee} \to \mathsf{False}) \vee (d_{yz}\mathsf{hsamee} \to \mathsf{False})).\end{aligned}$$

Proof. Apply Definition 57.13 to the displayed first-edge witness. Its forward direction recovers the central witness $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$, while the unary evidence for p and q is not needed by the remaining argument.

Now apply Definition 57.371 to this recovered central witness and to the two unchanged witnesses $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$ and $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$. The result is exactly the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context triangle nonempty spine iff nonempty distance`

Theorem 57.373 (Metric distance witness triangle append context closure)**.** *If p and q are supplied as unary visible contexts, distance witnesses from x to y, from y to z, and from d_{xy} to z produce a distance witness from $p \cdot x$ to $d_{yz} \cdot q$ whose result is $p \cdot d_{xyz} \cdot q$:*

$$\begin{aligned}&\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \\ &\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, d_{yz} \cdot q, p \cdot d_{xyz} \cdot q).\end{aligned}$$

Proof. The triangle append closure identifies the central result with $x \cdot d_{yz}$. Together with the carrier fields already present in the three distance witnesses, this gives the central witness from x to d_{yz} with result d_{xyz}. Visible-context closure then appends the unary contexts p and q on the outside. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context closed`

Theorem 57.374 (Metric distance witness visible-context triangle append closure)**.** *If the distance witness from x to y is displayed through visible contexts p, q, and the two remaining triangle witnesses are present, then the triangle append result is unchanged at the central layer:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, p{\cdot}d_{xy}{\cdot}q) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}$$

Proof. Visible-context exactness recovers the central distance witness $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$ from the displayed contextual witness. The ordinary triangle append closure applied to this recovered witness and the two remaining triangle witnesses gives $d_{xyz}\mathsf{hsame}x \cdot d_{yz}$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context triangle append closed`

Theorem 57.375 (Metric distance witness triangle append context result determinacy)**.** *For unary visible contexts p, q, if the three triangle distance witnesses from x to y, from y to z, and from d_{xy} to z are given, then any displayed distance witness from $p \cdot x$ to $d_{yz} \cdot q$ has the same result as the canonical contextual triangle result:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, d_{yz} \cdot q, displayed) \Longrightarrow \mathsf{hsame}(displayed, p \cdot d_x$$

Proof. Triangle append context closure constructs the canonical witness from $p \cdot x$ to $d_{yz} \cdot q$ with result $p \cdot d_{xyz} \cdot q$. The displayed witness and this canonical witness have the same source and target histories, so continuation determinacy for their distance ledgers identifies their result histories. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context result deterministic`

Theorem 57.376 (Metric distance witness triangle append context source determinacy)**.** *For unary visible contexts p, q, if the three triangle distance witnesses from x to y, from y to z, and from d_{xy} to z are given, then any displayed witness with the canonical contextual result and target $d_{yz} \cdot q$ determines the exposed source:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x', d_{yz} \cdot q, (p \cdot d_{xyz}) \cdot q) \Longrightarrow \mathsf{hsame}(x, x').$$

Proof. Triangle append context closure constructs the canonical contextual witness from $p \cdot x$ to $d_{yz} \cdot q$ with result $(p \cdot d_{xyz}) \cdot q$. Visible-context source determinacy then compares this canonical witness with the displayed witness, using the shared target $d_{yz} \cdot q$ and shared central distance d_{xyz}, and recovers $\mathsf{hsame}(x, x')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context source deterministic`

Theorem 57.377 (Metric distance witness triangle append context endpoint determinacy)**.** *For unary visible contexts p, q, if the three triangle distance witnesses from x to y, from y to z, and from d_{xy} to z are given, then the canonical contextual triangle result $(p \cdot d_{xyz}) \cdot q$ determines both exposed endpoints:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow$$
$$\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \left(\begin{array}{l} (\mathsf{MetricDistanceWitness}(p \cdot x', d_{yz} \cdot q, (p \cdot d_{xyz}) \cdot q) \Longrightarrow \mathsf{hsame}(x, x')) \\ \wedge \\ (\mathsf{MetricDistanceWitness}(p \cdot x, e \cdot q, (p \cdot d_{xyz}) \cdot q) \Longrightarrow \mathsf{hsame}(d_{yz}, e)) \end{array} \right)$$

Proof. Triangle append context closure first constructs the canonical contextual witness $\mathsf{MetricDistanceWitness}(p \cdot x, d_{yz} \cdot q, (p \cdot d_{xyz}) \cdot q)$ from the three triangle witnesses and the unary context hypotheses.

For the displayed witness with source $p \cdot x'$ and target $d_{yz} \cdot q$, visible-context source determinacy compares it with the canonical contextual witness and recovers $\mathsf{hsame}(x, x')$ at the exposed source.

For the displayed witness with source $p \cdot x$ and target $e \cdot q$, visible-context target determinacy compares it with the same canonical contextual witness and recovers $\mathsf{hsame}(d_{yz}, e)$ at the exposed middle target. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context endpoint deterministic`

Theorem 57.378 (Metric distance witness triangle append context endpoint transport)**.** *For unary visible contexts p, q, if the three triangle distance witnesses from x to y, from y to z, and from d_{xy} to z are given, then endpoint comparisons on the exposed source and middle target transport the canonical contextual triangle witness:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(d_{yz}, e) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x', e \cdot q, (p \cdot d_{xyz}) \cdot q).$$

Proof. Triangle append context closure first constructs the canonical contextual witness $\mathsf{MetricDistanceWitness}(p \cdot x, d_{yz} \cdot q, (p \cdot d_{xyz}) \cdot q)$ from the three triangle witnesses and the unary context hypotheses.

The source comparison $\mathsf{hsame}(x, x')$ gives the contextual comparison $\mathsf{hsame}(p \cdot x, p \cdot x')$ by constructor reduction of the BEDC append context. The middle-target comparison $\mathsf{hsame}(d_{yz}, e)$ similarly gives $\mathsf{hsame}(d_{yz} \cdot q, e \cdot q)$. The result history is unchanged.

Apply the metric witness field transport theorem to these two endpoint comparisons and the reflexive result comparison. It transports the unary endpoint fields and the continuation ledger of the canonical contextual witness, which is exactly the displayed transported witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context endpoint transport`

Theorem 57.379 (Metric distance witness triangle append context endpoint iff)**.** *For unary visible contexts p, q, if the three triangle distance witnesses from x to y, from y to z, and from d_{xy} to z are given, then the canonical contextual triangle result classifies exactly the exposed source and middle target:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \Big(\mathsf{MetricDistanceWitness}(p \cdot x', e \cdot q, (p \cdot d_{xyz}) \cdot q) \Longleftrightarrow \mathsf{hsame}(x, x') \wedge \mathsf{hsame}$$

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle append context endpoint iff`

Proof. For the forward direction, apply Definition 57.377 to the displayed witness after visible-context exactness has placed it in the canonical contextual form. The source projection gives $\mathsf{hsame}(x, x')$, while the target projection gives $\mathsf{hsame}(d_{yz}, e)$; together these are the two components of the displayed conjunction.

For the reverse direction, assume $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(d_{yz}, e)$. Apply Definition 57.373 to the two unary contexts and the three triangle witnesses. This gives the canonical witness

$$\mathsf{MetricDistanceWitness}(p \cdot x, d_{yz} \cdot q, (p \cdot d_{xyz}) \cdot q).$$

Append congruence transports $\mathsf{hsame}(x, x')$ to $\mathsf{hsame}(p \cdot x, p \cdot x')$ and transports $\mathsf{hsame}(d_{yz}, e)$ to $\mathsf{hsame}(d_{yz} \cdot q, e \cdot q)$. Unary transport preserves the endpoint carriers across these classifiers, and Definition 57.346 transports the continuation ledger while keeping the contextual result fixed. Repacking the transported carriers with this ledger gives the displayed witness $\mathsf{MetricDistanceWitness}(p \cdot x', e \cdot q, (p \cdot d_{xyz}) \cdot q)$. □

Theorem 57.380 (Metric triangle right distance empty collapse)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the right distance in a metric triangle is history-same to* e*, then the shared endpoint and right endpoint collapse and the remaining displayed distances read back to the left endpoint:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xy}, x) \wedge \mathsf{hsame}(d_{xyz}, x).$$

Proof. Empty-distance exactness for the witness from y to z gives $y\mathsf{hsamee}$ and $z\mathsf{hsamee}$. Collapsing y in the first witness and using empty-right exactness identifies d_{xy} with x. Collapsing z in the outer witness identifies d_{xyz} with d_{xy}, and transitivity composes this with the previous readback to obtain $d_{xyz}\mathsf{hsame}x$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle right distance empty collapse`

Theorem 57.381 (Metric triangle left distance empty visible-context closure)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the left distance in a metric triangle is history-same to* e*, then the triangle closes through the visible context with empty central source:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{xy}, \mathsf{e}) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot \mathsf{e}, z \cdot q, (p \cdot d_{xyz}) \cdot q).$$

Proof. The left-distance empty collapse identifies the left endpoints with e and reads d_{xyz} back to z. Empty-left exactness therefore builds the central witness $\mathsf{MetricDistanceWitness}(\mathsf{e}, z, d_{xyz})$. The visible-context iff then appends the certified unary ledgers p and q around this central witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle left distance empty visible context closed`

Theorem 57.382 (Metric triangle right distance empty visible-context closure)**.** *For histories $p, q, x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the right distance in a metric triangle is history-same to* e*, then the triangle closes through the visible context with empty central target:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow \mathsf{MetricDistanceWitness}(p \cdot x, \mathsf{e} \cdot q, (p \cdot d_{xyz}) \cdot q).$$

Proof. The right-distance empty collapse identifies the shared and right endpoints with e and reads d_{xyz} back to x. Empty-right exactness therefore builds the central witness $\mathsf{MetricDistanceWitness}(x, \mathsf{e}, d_{xyz})$. The visible-context iff then appends the certified unary ledgers p and q around this central witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle right distance empty visible context closed`

Theorem 57.383 (Metric triangle right distance empty spine witness)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the right distance in a metric triangle is history-same to* e*, then the outer displayed distance itself is a metric witness from x to the empty endpoint:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow \mathsf{MetricDistanceWitness}(x, \mathsf{e}, d_{xyz}).$$

Proof. The right-distance empty collapse identifies d_{xyz} with x and the first metric witness supplies unary membership of x. Empty-right metric exactness then packages this endpoint readback as a metric witness from x to e with displayed distance d_{xyz}. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle right distance empty spine witness`

Theorem 57.384 (Metric triangle right empty boundary witness)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if* $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$*,* $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$*, and* $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$ *form a metric triangle and $d_{yz}\mathsf{hsame}\mathsf{e}$, then the outer result is itself a distance witness from x to the empty boundary:*

$$\mathsf{MetricDistanceWitness}(x, \mathsf{e}, d_{xyz}).$$

Proof. By Definition 57.380, the right empty distance identifies d_{xyz} with x. The canonical right-empty witness $\mathsf{MetricDistanceWitness}(x, \mathsf{e}, x)$ uses the source carrier of the first edge, the empty unary carrier, and the right unit continuation $x \cdot \mathsf{e} = x$. Transporting the result field along $d_{xyz}\mathsf{hsame}x$ gives the displayed witness. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle right empty boundary witness`

Theorem 57.385 (Metric triangle bilateral empty edge collapse)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if both displayed edge distances in a metric triangle are history-same to* e*, then all three endpoints, the outer displayed distance, the final structural depth, and the empty-to-empty outer witness collapse to the empty case:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow \mathsf{hsame}(d_{xy}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow$$
$$\mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xyz}, \mathsf{e}) \wedge \mathsf{MetricDistanceDepth}(d_{xyz}) = 0 \wedge \mathsf{MetricDistanceWitness}$$

Proof. Apply Definition 57.365 to the three triangle witnesses and the classifier $\mathsf{hsame}(d_{xy}, \mathsf{e})$. This gives the empty classifiers for x and y, and reads d_{xyz} and d_{yz} back to the right endpoint z.

Apply Definition 57.380 to the same three witnesses and the classifier $\mathsf{hsame}(d_{yz}, \mathsf{e})$. This gives the empty classifiers for y and z, and reads d_{xy} and d_{xyz} back to the left endpoint x.

The endpoint classifiers give the first three conjuncts. For the outer distance, compose the left-collapse readback $\mathsf{hsame}(d_{xyz}, z)$ with $\mathsf{hsame}(z, \mathsf{e})$ by transitivity of hsame. Apply Definition 57.253 to this empty final-distance classifier to obtain $\mathsf{MetricDistanceDepth}(d_{xyz}) = 0$.

The empty-boundary metric witness $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, \mathsf{e})$ is the exact empty-distance case. Transporting its result field along $d_{xyz}\mathsf{hsame}\mathsf{e}$ yields $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d_{xyz})$. Conjoining these rows gives the displayed package. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle bilateral empty edge collapse`

Fit: traditional target degenerate triangle normalization; BEDC source $BHist$ metric distance witnesses; carrier the three witnessed edges; classifier hsame; stability from the two empty-edge collapse lemmas and depth-zero readback; ledger the two displayed edge distances; core theorem this block; exactness the endpoint and final-distance collapse; standard bridge none claimed; status $\mathsf{ProofTarget}$.

Theorem 57.386 (Metric triangle two-sided empty boundary package)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if the two edge distances in a metric triangle are both history-same to* e*, then every displayed endpoint and the outer displayed distance collapse to the empty boundary, and the outer result is itself an empty-to-empty distance witness:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow$$
$$\mathsf{hsame}(d_{xy}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow$$
$$\mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}) \wedge \mathsf{hsame}(z, \mathsf{e}) \wedge \mathsf{hsame}(d_{xyz}, \mathsf{e}) \wedge \mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d_{xyz}).$$

Proof. Apply Definition 57.365 to the same triangle and the hypothesis $d_{xy}\mathsf{hsame}\mathsf{e}$. This gives $x\mathsf{hsame}\mathsf{e}$, $y\mathsf{hsame}\mathsf{e}$, $d_{xyz}\mathsf{hsame}z$, and $d_{yz}\mathsf{hsame}z$.

Apply Definition 57.380 to the same triangle and the hypothesis $d_{yz}\mathsf{hsame}\mathsf{e}$. This gives $y\mathsf{hsame}\mathsf{e}$, $z\mathsf{hsame}\mathsf{e}$, $d_{xy}\mathsf{hsame}x$, and $d_{xyz}\mathsf{hsame}x$.

The endpoint conclusions package the three empty endpoint readbacks. Symmetry and transitivity of hsame compose $d_{xyz}\mathsf{hsame}z$ with $z\mathsf{hsame}\mathsf{e}$, so $d_{xyz}\mathsf{hsame}\mathsf{e}$.

Finally, the empty-boundary metric witness $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, \mathsf{e})$ is the exact empty-distance case. Transporting its result field along $d_{xyz}\mathsf{hsame}\mathsf{e}$ yields $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d_{xyz})$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness two sided empty triangle boundary package`

Theorem 57.387 (Metric triangle left empty boundary witness)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if* $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$*,* $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$*, and* $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$ *form a metric triangle and* $d_{xy}\mathsf{hsame}\mathsf{e}$*, then the outer result is itself a distance witness from the empty boundary to z:*

$$\mathsf{MetricDistanceWitness}(\mathsf{e}, z, d_{xyz}).$$

Proof. By Definition 57.365, the left empty distance identifies d_{xyz} with z.

The second edge supplies the unary carrier for z. Apply Definition 57.40 with this carrier and the displayed classifier $d_{xyz}\mathsf{hsame}z$ to package the canonical witness from e to z with displayed distance d_{xyz}. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness triangle left empty boundary witness`

Theorem 57.388 (Metric triangle two-sided empty witness exactness)**.** *For histories $x, y, z, d_{xy}, d_{yz}, d_{xyz}$, if* $\mathsf{MetricDistanceWitness}(x, y, d_{xy})$*,* $\mathsf{MetricDistanceWitness}(y, z, d_{yz})$*, and* $\mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz})$ *form a metric triangle and both displayed edge distances are history-same to* e*, then the outer result simultaneously carries every empty-boundary witness row needed by the triangle:*

$$\mathsf{MetricDistanceWitness}(x, y, d_{xy}) \Longrightarrow \mathsf{MetricDistanceWitness}(y, z, d_{yz}) \Longrightarrow \mathsf{MetricDistanceWitness}(d_{xy}, z, d_{xyz}) \Longrightarrow$$
$$\mathsf{hsame}(d_{xy}, \mathsf{e}) \Longrightarrow \mathsf{hsame}(d_{yz}, \mathsf{e}) \Longrightarrow$$
$$\mathsf{hsame}(d_{xyz}, \mathsf{e}) \wedge \mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d_{xyz}) \wedge \mathsf{MetricDistanceWitness}(\mathsf{e}, z, d_{xyz}) \wedge \mathsf{MetricDistanceWitness}(x, \mathsf{e},$$

Proof. First apply Definition 57.385 to the three triangle witnesses and the two classifiers $\mathsf{hsame}(d_{xy}, \mathsf{e})$ and $\mathsf{hsame}(d_{yz}, \mathsf{e})$. This gives $\mathsf{hsame}(d_{xyz}, \mathsf{e})$ together with the empty-to-empty witness $\mathsf{MetricDistanceWitness}(\mathsf{e}, \mathsf{e}, d$

Next apply Definition 57.387 to the same triangle and $\mathsf{hsame}(d_{xy}, \mathsf{e})$. This supplies the boundary row $\mathsf{MetricDistanceWitness}(\mathsf{e}, z, d_{xyz})$.

Finally apply Definition 57.384 to the same triangle and $\mathsf{hsame}(d_{yz}, \mathsf{e})$. This supplies $\mathsf{MetricDistanceWitness}(x, \mathsf{e},$ and the four rows assemble into the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness two sided empty triangle witness exactness`

Theorem 57.389 (Metric distance witness visible-context empty distance exactness)**.** *For histories p, q, x, y, a visible-context distance witness whose central distance ledger is empty is exactly unary evidence for the visible prefix and suffix together with empty classification of both central endpoints:*

$$\mathsf{MetricDistanceWitness}(p{\cdot}x, y{\cdot}q, (p{\cdot}\mathsf{e}){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{hsame}(x, \mathsf{e}) \wedge \mathsf{hsame}(y, \mathsf{e}).$$

Proof. Apply visible-context exactness to peel off the prefix and suffix. The central witness is then $\mathsf{MetricDistanceWitness}(x, y, \mathsf{e})$, which empty-distance exactness identifies with $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$. Conversely, the two empty endpoint classifiers build the central empty-distance witness, and visible-context exactness reattaches the same prefix and suffix. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance iff`

Theorem 57.390 (Metric visible-context empty-distance continuation splice)**.** *For histories p, q, x, y, l, r, m, o, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

and continuations $\mathsf{Cont}(l, x, m)$ and $\mathsf{Cont}(m, r, o)$ hold. Then the empty central endpoint exposed by the witness splices the continuation directly:

$$\mathsf{Cont}(l, r, o).$$

Proof. Apply visible-context empty-distance exactness to the witness. This gives $\mathsf{hsame}(x, \mathsf{e})$. Substitute the empty central endpoint into $\mathsf{Cont}(l, x, m)$, so the first continuation identifies m with l. The second continuation $\mathsf{Cont}(m, r, o)$ is therefore the desired direct continuation $\mathsf{Cont}(l, r, o)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance continuation splice`

Theorem 57.391 (Metric visible-context empty-distance continuation splice determinacy)**.** *For histories $p, q, x, y, l, r, m, o, o'$, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

and continuations $\mathsf{Cont}(l, x, m)$, $\mathsf{Cont}(m, r, o)$, and $\mathsf{Cont}(l, r, o')$ hold. Then the spliced result is determined by the displayed direct continuation:

$$\mathsf{hsame}(o, o').$$

Proof. The visible-context empty-distance continuation splice turns the first two continuations into $\mathsf{Cont}(l, r, o)$. BEDC continuation determinacy compares this spliced continuation with the displayed continuation $\mathsf{Cont}(l, r, o')$, giving $\mathsf{hsame}(o, o')$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance continuation splice hsame`

Theorem 57.392 (Metric visible-context empty-distance continuation result determinacy)**.** *For histories p, q, x, y, l, m, n, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

and continuations $\mathsf{Cont}(l, x, m)$ and $\mathsf{Cont}(l, y, n)$ hold. Then the two continuation results are classified together:

$$\mathsf{hsame}(m, n).$$

Proof. Apply visible-context empty-distance exactness to the metric witness. This identifies both central endpoints x and y with e. After substituting these endpoint classifiers, the two displayed continuations have the same left source and the same empty right endpoint. BEDC continuation determinacy therefore compares their results and gives $\mathsf{hsame}(m, n)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance continuation results hsame`

Theorem 57.393 (Metric visible-context empty-distance append unit laws)**.** *For histories p, q, x, y, l, r, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q).$$

Then the central endpoints act as append units:

$$x \cdot r = r \quad \wedge \quad l \cdot y = l.$$

Proof. Apply visible-context empty-distance exactness to the witness. This exposes $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$. Substituting these empty endpoints turns the two displayed append equations into the BEDC left and right append unit laws. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance append unit laws`

Theorem 57.394 (Metric visible-context empty-distance endpoint continuation units)**.** *For histories $p, q, x, y, l, r, o_L, o_R$, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

and continuations $\mathsf{Cont}(l, x, o_L)$ and $\mathsf{Cont}(y, r, o_R)$ hold. Then both displayed endpoint continuations reduce to unit continuations:

$$\mathsf{hsame}(o_L, l) \wedge \mathsf{hsame}(o_R, r).$$

Proof. Visible-context empty-distance exactness exposes $\mathsf{hsame}(x, \mathsf{e})$ and $\mathsf{hsame}(y, \mathsf{e})$. After substituting these central endpoints, $\mathsf{Cont}(l, x, o_L)$ is a right-unit continuation and $\mathsf{Cont}(y, r, o_R)$ is a left-unit continuation. The BEDC continuation unit laws therefore give $\mathsf{hsame}(o_L, l)$ and $\mathsf{hsame}(o_R, r)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance endpoint continuation units`

Theorem 57.395 (Metric visible-context empty-distance witness splice)**.** *For histories p, q, x, y, l, r, m, o, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

and unary endpoint evidence for l and r hold. If $\mathsf{Cont}(l, x, m)$ and $\mathsf{Cont}(m, r, o)$ hold, then the spliced continuation is a metric distance witness:

$$\mathsf{MetricDistanceWitness}(l, r, o).$$

Proof. The visible-context empty-distance continuation splice supplies $\mathsf{Cont}(l, r, o)$. Together with the unary endpoint hypotheses, unary continuation closure gives the unary carrier for o. These three fields are exactly the concrete metric distance witness from l to r with output o. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance witness splice`

Theorem 57.396 (Metric visible-context empty-distance continuation witness depth package)**.** *For histories* $p, q, x, y, l, r, m, o : \mathsf{BHist}$*, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

holds together with $\mathsf{UnaryHistory}(l)$*,* $\mathsf{UnaryHistory}(r)$*,* $\mathsf{Cont}(l, x, m)$*, and* $\mathsf{Cont}(m, r, o)$*. Then the direct continuation carries a metric witness whose depth is induced by the two visible endpoints:*

$$\mathsf{MetricDistanceWitness}(l, r, o) \wedge \mathsf{MetricDistanceDepth}(o) = \mathsf{MetricDistanceDepth}(l) + \mathsf{MetricDistanceDepth}(r).$$

Proof. Apply the visible-context empty-distance continuation splice to the distance witness and the two continuation ledgers. This gives the direct continuation $\mathsf{Cont}(l, r, o)$.

The unary carriers for l and r then close the continuation under the metric distance witness constructor, so the direct continuation packages as $\mathsf{MetricDistanceWitness}(l, r, o)$.

Finally, metric witness depth additivity applied to this witness gives $\mathsf{MetricDistanceDepth}(o) = \mathsf{MetricDistanceDepth}(l) + \mathsf{MetricDistanceDepth}(r)$. Pairing the witness with that displayed equation is the required conjunction. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance continuation witness depth`

Theorem 57.397 (Metric visible-context empty-distance two-sided endpoint witness transport)**.** *For histories* $p, q, x, y, l, r, m, n, o : \mathsf{BHist}$*, suppose*

$$\mathsf{MetricDistanceWitness}(p \cdot x, y \cdot q, (p \cdot \mathsf{e}) \cdot q)$$

holds together with $\mathsf{UnaryHistory}(l)$*,* $\mathsf{UnaryHistory}(r)$*,* $\mathsf{Cont}(l, x, m)$*,* $\mathsf{Cont}(y, r, n)$*, and* $\mathsf{Cont}(l, r, o)$*. Then the two reduced endpoint continuations carry the same metric distance witness:*

$$\mathsf{MetricDistanceWitness}(m, n, o).$$

Proof. Apply Definition 57.394 to the visible-context empty-distance witness and the two endpoint continuation ledgers. This gives $\mathsf{hsame}(m, l)$ and $\mathsf{hsame}(n, r)$.

The unary endpoint hypotheses for l and r, together with the direct continuation ledger $\mathsf{Cont}(l, r, o)$, build the concrete direct metric witness $\mathsf{MetricDistanceWitness}(l, r, o)$.

Now use Definition 57.347. Transport the first endpoint along the symmetry of $\mathsf{hsame}(m, l)$, the second endpoint along the symmetry of $\mathsf{hsame}(n, r)$, and the result endpoint along reflexivity of $\mathsf{hsame}(o, o)$. The continuation ledger transports with the same three relations, so the transported fields package as $\mathsf{MetricDistanceWitness}(m, n, o)$. □

Lean4 ✓ `BEDC.Derived.MetricUp.MetricDistanceWitness visible context empty distance two sided endpoint witness transport`

The ten-field fit is: traditional target visible-context zero-distance splice; BEDC source MetricDistanceWitness plus Cont; carrier MetricDistanceWitness; classifier hsame; stability obligations the two unary carriers and the two continuation ledgers; ledger the hidden empty central distance; core theorem this package; exactness the displayed witness-plus-depth conjunction; standard bridge deferred; and status ProofTarget.

Chapter 58

A Concrete Naming Certificate for $\mathsf{S}^{1\uparrow}$

The circle interface $\mathsf{S}^{1\uparrow}$ is a certificate-obligation schema over the product carrier $\mathsf{Real}^{\uparrow} \times \mathsf{Real}^{\uparrow}$ from chapter 38. Its carrier is the unit-circle subspace: pairs (x, y) equipped with a certified equation witness that $x^2 + y^2$ is classified as the real unit. The interface is not a primitive topological space; it is admitted only when the product real witnesses, equation witness, componentwise classifier, and equation transport data are supplied. The metric-observation and standard topological bridge boundaries consume the metric carrier discipline of chapter 57 and the compact-source discipline of chapter 129 only as downstream finite rows, not as angle, covering, compactness, or connectedness claims.

58.1 Carrier obligation surface

Definition 58.1 (SOne carrier)**.** *Use pairs (x, y) of Bishop real witnesses with a certified unit equation witness $x^2 + y^2 \approx 1$ under* RealClassifier*.*

Lean4 (definition) `BEDC.Derived.S1Up.SOneUnitHistory`
Lean4 (definition) `BEDC.Derived.S1Up.SOneProductHistoryCarrier`
Lean4 (definition) `BEDC.Derived.S1Up.SOneHistoryCarrier`

Theorem 58.2 (S1Up root obligation surface)**.** *An accepted $\mathsf{S}^{1\uparrow}$ carrier over* BHist *consists of two $\mathsf{Real}^{\uparrow}$ coordinate rows, the product-source row inherited from $\mathsf{Prod}^{\uparrow}$, the $\mathsf{Real}^{\uparrow}$ classifier transports for both coordinates, a displayed radius row asserting that $x^2 + y^2$ is classified with the $\mathsf{Real}^{\uparrow}$ unit, and a* NameCert *ledger recording the $\mathsf{Real}^{\uparrow}$ and product witnesses.*

The radius row is a classifier obligation over the displayed real-coordinate data. It is not a host equality and it does not add a primitive circle carrier outside the real/product source rows.

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier root obligation surface`

Proof. Unpack the two $\mathsf{Real}^{\uparrow}$ coordinate certificates. They supply the two BHist component rows and the componentwise classifier transports used by the circle carrier.

Use the $\mathsf{Prod}^{\uparrow}$ product carrier to pair those rows into one source packet. The resulting packet records the real-coordinate witnesses and the product source row in the same BHist ledger.

Finally record the radius condition $x^2 + y^2$ against the $\mathsf{Real}^{\uparrow}$ unit as a displayed classifier obligation. Since the condition is stored as a row in the NameCert ledger, the carrier exposes only the real, product, radius, and ledger witnesses described above. □

Theorem 58.3 (SOne history carrier rational components)**.** *For every history h, the concrete $\mathsf{S}^{1\uparrow}$ product-history carrier exposes product components x, y and rational denominator tails d_x, d_y such that both components are displayed as real constants and the BEDC continuation ledger composes the two components into h:*

$$\mathsf{SOneProductHistoryCarrier}(h) \Longrightarrow \exists x, y, d_x, d_y.\ \mathsf{hsame}(x, \mathsf{E1}(d_x)) \wedge \mathsf{RatHistoryCarrier}(d_x) \wedge \mathsf{hsame}(y, \mathsf{E1}(d_y)) \wedge \mathsf{RatHisto}$$

Proof. Unpack the $\mathsf{S}^{1\uparrow}$ carrier as the $\mathsf{Prod}^{\uparrow}$ carrier over two real-constant history carriers. The product carrier supplies the two component histories and their continuation ledger into h. Each real-constant carrier then exposes a rational denominator tail together with the displayed $\mathsf{E1}$ presentation of that component. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier rational components`

Theorem 58.4 (SOne history carrier real-pair carrier)**.** *For histories x, y, e, p, the concrete $\mathsf{S}^{1\uparrow}$ history carrier determines the underlying product-real pair carrier:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{ProdHistoryCarrier}(\mathsf{RealConstantHistoryCarrier}, \mathsf{RealConstantHistoryCarrier}, p).$$

Proof. Unpack the circle carrier. Its first two fields are real-constant carrier witnesses for x and y, and its continuation field records $\mathsf{Cont}(x, y, p)$. These three data are precisely the product-history carrier introduction rule for the two real-constant component predicates. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier real pair`

Theorem 58.5 (SOne point ledger determinacy)**.** *For histories x, y, e, e', p, p', two concrete $\mathsf{S}^{1\uparrow}$ history-carrier witnesses with the same component histories determine the point ledger up to the BEDC history classifier:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{SOneHistoryCarrier}(x, y, e', p') \Longrightarrow \mathsf{hsame}(p, p').$$

Proof. Unpack the two circle-carrier witnesses only as far as their point-continuation ledgers. Both ledgers have the same source component x and the same right component y. Continuation determinacy therefore identifies their continuation results, giving $\mathsf{hsame}(p, p')$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier point deterministic`

Theorem 58.6 (SOne history carrier e-zero point exclusion)**.** *For histories x, y, e, t, a concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness cannot have an $\mathsf{E0}$-headed point ledger:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, \mathsf{E0}(t)) \Longrightarrow \bot.$$

Proof. Unpack the circle carrier to the second real-constant component and the continuation ledger. The second component displays y as $\mathsf{E1}(d)$ for a rational history d. Transporting the continuation ledger along that display makes the point ledger an $\mathsf{E1}$-headed append result, contradicting the displayed $\mathsf{E0}$ head. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier point e0 absurd`

Theorem 58.7 (SOne history carrier empty point exclusion)**.** *For histories x, y, e, a concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness cannot have the empty point ledger:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, \mathsf{e}) \Longrightarrow \bot.$$

Proof. Unpack the circle carrier to the second real-constant component and the continuation ledger. The second component displays y as $\mathsf{E1}(d)$ for a rational history d. Transporting the continuation along that display makes the point ledger an $\mathsf{E1}$-headed append result, contradicting the empty endpoint. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier point empty absurd`

Theorem 58.8 (SOne history carrier empty point exclusion)**.** *For histories x, y, e, a concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness cannot have an empty point ledger:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, \mathsf{e}) \Longrightarrow \bot.$$

Proof. Unpack the circle carrier to the first real-constant component and the continuation ledger. The empty-result continuation inversion forces the first component to be empty, while the real-constant carrier displays it as an $\mathsf{E1}$-headed rational history. Constructor no-confusion gives the contradiction. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier empty point absurd`

Theorem 58.9 (SOne history carrier e-one point shape)**.** *For histories x, y, e, p, every concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness exposes the point ledger as an $\mathsf{E1}$-headed history:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \exists t : \mathsf{BHist}.\ p = \mathsf{E1}(t).$$

Proof. Unpack the carrier to the second real-constant component and the continuation ledger. The second component displays y as $\mathsf{E1}(d)$ for a rational history d. Substituting that display into the continuation equation makes the point ledger p the append result with an $\mathsf{E1}$-headed right component, hence $p = \mathsf{E1}(\mathsf{append}(x, d))$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier point e1 shape`

Theorem 58.10 (SOne history carrier rational unit components)**.** *For histories x, y, e, p, the concrete $\mathsf{S}^{1\uparrow}$ history carrier exposes rational denominator tails for both real components while preserving the unit equation classifier and the continuation ledger:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \exists d_x, d_y.\ \mathsf{hsame}(x, \mathsf{E1}(d_x)) \wedge \mathsf{RatHistoryCarrier}(d_x) \wedge \mathsf{hsame}(y, \mathsf{E1}(d_y)) \wedge \mathsf{RatHistoryCar}$$

Proof. Unpack the $\mathsf{S}^{1\uparrow}$ history carrier. Its first two fields are real-constant carrier witnesses, so each component supplies a rational denominator tail and the corresponding $\mathsf{E1}$ presentation. The remaining fields are exactly the unit-equation classifier and the BEDC continuation ledger. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier rational unit components`

Theorem 58.11 (SOne history carrier point-tail readback)**.** *For histories x, y, e, t, a concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness whose point ledger is visibly one-tagged exposes the rational component tails and reads the visible point tail as the continuation of the first coordinate by the second coordinate tail:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, \mathsf{E1}(t)) \Longrightarrow \exists d_x, d_y : \mathsf{BHist}.\ \mathsf{hsame}(x, \mathsf{E1}(d_x)) \wedge \mathsf{RatHistoryCarrier}(d_x) \wedge \mathsf{hsame}(y, \mathsf{E1}(d_y)) \wedge \mathsf{Ra}$$

Proof. Apply Definition 58.10. This exposes rational tails d_x, d_y, presentations $\mathsf{hsame}(x, \mathsf{E1}(d_x))$ and $\mathsf{hsame}(y, \mathsf{E1}(d_y))$, and the continuation ledger $\mathsf{Cont}(x, y, \mathsf{E1}(t))$.

Using the presentation $\mathsf{hsame}(y, \mathsf{E1}(d_y))$, the continuation result has the form $\mathsf{E1}(t) = \mathsf{E1}(x \cdot d_y)$. Constructor inversion for $\mathsf{E1}$ gives $\mathsf{hsame}(t, x \cdot d_y)$. Package this with the two exposed rational carrier witnesses. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier point tail readback`

Theorem 58.12 (SOne y endpoint reads the point tail)**.** *For histories x, y, e, t, d_y, a concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness with point ledger $\mathsf{E1}(t)$ and second coordinate presented as $\mathsf{E1}(d_y)$ reads back the point tail as the continuation of x by d_y:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, \mathsf{E1}(t)) \to \mathsf{hsame}(y, \mathsf{E1}(d_y)) \to \mathsf{hsame}(t, x \cdot d_y).$$

Proof. Unpack only the point-continuation field of the circle carrier. Transport the displayed second endpoint along $\mathsf{hsame}(y, \mathsf{E1}(d_y))$. The continuation result then has the visible form $\mathsf{E1}(t) = \mathsf{E1}(x \cdot d_y)$, and one-constructor inversion gives the displayed tail classifier. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier y e1 point tail hsame`

Theorem 58.13 (SOne endpoints read the e-one point tail)**.** *For histories x, y, e, t, d_x, d_y, a concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness with point ledger $\mathsf{E1}(t)$ and coordinate presentations $\mathsf{hsame}(x, \mathsf{E1}(d_x))$ and $\mathsf{hsame}(y, \mathsf{E1}(d_y))$ reads the point tail as*

$$\mathsf{hsame}(t, \mathsf{E1}(d_x) \cdot d_y).$$

Proof. The second coordinate presentation gives the point-tail readback $t \sim x \cdot d_y$. Transporting the first coordinate presentation $x \sim \mathsf{E1}(d_x)$ through the same continuation tail identifies this with $\mathsf{E1}(d_x) \cdot d_y$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier x y e1 point tail hsame`

Theorem 58.14 (SOne e-one components read point tail)**.** *For histories d_x, d_y, e, t, a concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness whose coordinates and point ledger are all one-headed exposes rational coordinate tails and reads the point tail from the BEDC continuation:*

$$\mathsf{SOneHistoryCarrier}(\mathsf{E1}(d_x), \mathsf{E1}(d_y), e, \mathsf{E1}(t)) \Longrightarrow \mathsf{RatHistoryCarrier}(d_x) \wedge \mathsf{RatHistoryCarrier}(d_y) \wedge \mathsf{hsame}(t, \mathsf{E1}(d_x) \cdot d_y).$$

Proof. The first two carrier fields are real-constant carriers on one-headed histories, hence the real-constant e-one exactness theorem gives rational carriers for d_x and d_y. The displayed second coordinate presentation is reflexive, so the point-tail readback theorem gives $\mathsf{hsame}(t, \mathsf{E1}(d_x) \cdot d_y)$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier e1 components tail`

Theorem 58.15 (SOne e-one components unit tail readback)**.** *For histories d_x, d_y, e, t, a concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness whose coordinates and point ledger are all one-headed exposes the two rational coordinate tails, identifies the equation endpoint with the circle unit history, and reads the point tail as the displayed continuation:*

$$\mathsf{SOneHistoryCarrier}(\mathsf{E1}(d_x), \mathsf{E1}(d_y), e, \mathsf{E1}(t)) \Longrightarrow \mathsf{RatHistoryCarrier}(d_x) \wedge \mathsf{RatHistoryCarrier}(d_y) \wedge \mathsf{hsame}(e, \mathsf{SOneUnitHis}$$

Proof. The e-one component tail theorem supplies the two rational coordinate carriers and the equality $t\mathsf{hsameE1}(d_x) \cdot d_y$. The equation-unit readback identifies e with $\mathsf{SOneUnitHistory}$. Reading the displayed tail equality as a BEDC continuation gives $\mathsf{Cont}(\mathsf{E1}(d_x), d_y, t)$, and these four fields form the claimed package. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier e1 components unit tail readback`

Theorem 58.16 (SOne e-one components unit equation classifier)**.** *For histories d_x, d_y, e, t, a concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness whose coordinates, equation endpoint, and point ledger are one-headed exposes the two rational coordinate tails, the rational classifier from the equation tail to the unit tail, and the displayed point continuation:*

$$\mathsf{SOneHistoryCarrier}(\mathsf{E1}(d_x), \mathsf{E1}(d_y), \mathsf{E1}(e), \mathsf{E1}(t)) \Longrightarrow \mathsf{RatHistoryCarrier}(d_x) \wedge \mathsf{RatHistoryCarrier}(d_y) \wedge \mathsf{RatHistoryClassifi}$$

Proof. The unit-tail readback supplies the two rational coordinate carriers and the displayed point continuation. The stored real-constant classifier on the one-headed equation endpoint has target $\mathsf{SOneUnitHistory} = \mathsf{E1}(\mathsf{E1}(\mathsf{e}))$, so the real-constant e-one exactness theorem reads it as the rational classifier between the equation tail and $\mathsf{E1}(\mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier e1 components unit equation classifier`

Theorem 58.17 (SOne e-one components carrier exactness)**.** *For histories d_x, d_y, e, t, the one-headed presentation of a concrete $\mathsf{S}^{1\uparrow}$ history carrier is exact: it is present precisely when the two coordinate tails are rational carriers, the equation tail classifies the one-headed empty tail, and the point tail is the displayed continuation:*

$$\mathsf{SOneHistoryCarrier}(\mathsf{E1}(d_x), \mathsf{E1}(d_y), \mathsf{E1}(e), \mathsf{E1}(t)) \Longleftrightarrow \mathsf{RatHistoryCarrier}(d_x) \wedge \mathsf{RatHistoryCarrier}(d_y) \wedge \mathsf{RatHistoryClassif}$$

Proof. The forward direction is exactly the e-one unit-equation classifier readback: apply Definition 58.16 to the given $\mathsf{S}^{1\uparrow}$ carrier witness.

For the reverse direction, start from the four displayed fields. The two rational carrier fields repack as the real-constant carrier witnesses for $\mathsf{E1}(d_x)$ and $\mathsf{E1}(d_y)$. The rational classifier $\mathsf{RatHistoryClassifier}(e, \mathsf{E1}($ lifts along the real-constant e-one classifier exactness theorem to the required classifier from $\mathsf{E1}(e)$ to $\mathsf{SOneUnitHistory}$.

It remains to supply the point-continuation field. The hypothesis $\mathsf{Cont}(\mathsf{E1}(d_x), d_y, t)$ is exactly the statement that the one-headed point ledger $\mathsf{E1}(t)$ carries the append continuation determined by $\mathsf{E1}(d_x)$ and d_y. With these four fields repacked, the constructor for $\mathsf{SOneHistoryCarrier}$ gives the desired carrier witness. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier e1 components carrier exactness`

Theorem 58.18 (SOne history carrier y e-one point shape)**.** *For histories x, y, e, p, d_y, if a concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness presents the second coordinate as $\mathsf{E1}(d_y)$, then the point ledger is visibly one-headed and its exposed tail is the continuation of x by d_y:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{hsame}(y, \mathsf{E1}(d_y)) \Longrightarrow \exists t : \mathsf{BHist}.\ \mathsf{hsame}(p, \mathsf{E1}(t)) \wedge \mathsf{Cont}(x, d_y, t).$$

Proof. Unpack the circle carrier only to its point-continuation field. Replacing the second coordinate by its $\mathsf{E1}(d_y)$ presentation makes the point ledger definitionally $\mathsf{E1}(x \cdot d_y)$. Choose the exposed payload $t = x \cdot d_y$; the remaining continuation statement is the canonical append ledger. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier y e1 point shape`

Theorem 58.19 (SOne unit equation determinacy)**.** *For histories x, y, e, p, every concrete $\mathsf{S}^{1\uparrow}$ history-carrier witness determines that its stored equation endpoint is the unit history:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{hsame}(e, \mathsf{SOneUnitHistory}).$$

Proof. Unpack the SOneHistoryCarrier witness and keep the RealConstantHistoryClassifier$(e, \mathsf{SOneUnitHistory})$ field. This classifier exposes rational tails for both endpoints. Its rational payload classifier identifies the tails, and constructor congruence lifts that equality through E1. Composing this equality with the stored endpoint presentations gives hsame$(e, \mathsf{SOneUnitHistory})$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier unit equation deterministic`

Theorem 58.20 (SOne history carrier equation-pair determinacy)**.** *For histories $x, y, e, p, x', y', e', p'$, any two concrete $\mathsf{S}^{1\uparrow}$ history-carrier witnesses determine history-same equation ledgers:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{SOneHistoryCarrier}(x', y', e', p') \Longrightarrow \mathsf{hsame}(e, e').$$

Proof. Apply the unit-equation determinacy theorem to each carrier witness. The first witness identifies e with SOneUnitHistory, and the second identifies e' with the same endpoint. Transitivity through that endpoint gives hsame(e, e'). □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier equation pair deterministic`

Theorem 58.21 (SOne equation unit readback)**.** *For histories x, y, e, p, the concrete $\mathsf{S}^{1\uparrow}$ history carrier determines that its equation witness is the BEDC unit history:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{hsame}(e, \mathsf{SOneUnitHistory}).$$

Proof. Unpack the circle carrier to its equation-classifier field RealConstantHistoryClassifier$(e, \mathsf{SOneUnitHistory})$. That field displays e and SOneUnitHistory as E1-sealed rational histories, with a rational classifier between the displayed tails. The rational classifier contains an hsame witness between those tails; one-constructor congruence lifts it to the sealed endpoints, and transitivity with the two endpoint displays identifies e with SOneUnitHistory. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier equation unit`

Theorem 58.22 (SOne history carrier public readback)**.** *For histories x, y, e, p, the concrete $\mathsf{S}^{1\uparrow}$ history carrier exposes the product carrier, identifies the equation endpoint with the BEDC unit history, and reads back rational tails for both real components:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{SOneProductHistoryCarrier}(p) \wedge \mathsf{hsame}(e, \mathsf{SOneUnitHistory}) \wedge \exists d_x, d_y.\ \mathsf{hsame}(x, \mathsf{E1}(d$$

Proof. The product carrier is obtained by repacking the two real-constant component carriers with the continuation ledger. Equation-unit determinacy identifies the stored equation endpoint with SOneUnitHistory. Finally, the rational unit component readback exposes the two rational tails and the same continuation ledger, while its equation classifier field is no longer needed. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier public readback`

Theorem 58.23 (SOne component classifier ledger determinacy)**.** *For histories $x, y, e, p, x', y', e', p'$, componentwise BEDC history classification of two concrete $\mathsf{S}^{1\uparrow}$ carrier witnesses determines both hidden ledgers:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{SOneHistoryCarrier}(x', y', e', p') \Longrightarrow \mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(e, e')$$

Proof. Unpack the two circle-carrier witnesses into their four fields. The first gives the real-constant component carriers for x and y, the equation classifier $\mathsf{RealConstantHistoryClassifier}(e, \mathsf{SOneUnitHistory})$, and the continuation ledger $\mathsf{Cont}(x, y, p)$. The second gives the corresponding fields for x', y', e', and p'.

For the equation ledger, unpack the two $\mathsf{RealConstantHistoryClassifier}(-, \mathsf{SOneUnitHistory})$ witnesses. Each contains a $\mathsf{RatHistoryClassifier}$ tail against the fixed $\mathsf{SOneUnitHistory}$ endpoint. Constructor inversion for the one-constructor rational history spine exposes the same rational tail on both sides. The hsame symmetry and transitivity rules then connect e to e', and rebuilding the history classifier witness yields $\mathsf{hsame}(e, e')$.

For the point ledger, apply continuation hsame-respect to the two ContR ledgers using the supplied component witnesses $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(y, y')$. Continuation determinacy identifies the resulting point histories, giving $\mathsf{hsame}(p, p')$.

Pair the two conclusions. The certificate fit is the traditional target unit-circle classifier determinacy; the BEDC source BHist with $\mathsf{RealConstantHistoryClassifier}$ and ContR; the carrier $\mathsf{SOneHistoryCarrier}$; the classifier hsame on exposed components; the ledger equation proof and point continuation; the core theorem this determinacy statement; the exactness claim hidden-ledger uniqueness; the standard bridge deferred outside this theorem; and the status $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier component classifier ledger determinacy`

Theorem 58.24 (SOne scoped carrier package)**.** *An accepted* $\mathsf{S}^{1\uparrow}$ *carrier exports exactly the scoped carrier rows consumed by* $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readers: the two* $\mathsf{Real}^{\uparrow}$ *component rows, the inherited product ledger, the unit-equation witness, the public point readback, component-classifier determinacy, coordinate transport, and the finite-window consumer boundary. The same carrier exports no compactness row, connectedness row, angle row, winding row, quotient-circle row, host equality row, or metric-completeness row.*

Proof. The public carrier rows are supplied by Definition 58.22: the two real-coordinate component rows, the product ledger, and the public point ledger are all read from the displayed BHist, hsame, and Cont data.

The ledger exactness rows are the checked local rows. Apply Definition 58.23 for the hidden point and equation-ledger determinacy, and apply Definition 58.21 for the fixed unit-equation witness. Apply Definition 58.25 for coordinate transport.

Finally, Definition 58.27 gives the finite-window consumer boundary: any shared-point read factors through the same component rows and point ledger. The listed negative rows are absent because none of the displayed constructor, classifier, continuation, package, or naming rows carries compactness, connectedness, angle, winding, quotient-circle, host equality, or metric-completeness data. □

Theorem 58.25 (SOne history carrier coordinate-pair determinacy)**.** *For histories* x, x', y, y', e, e', p, *two concrete* $\mathsf{S}^{1\uparrow}$ *carrier witnesses with the same point ledger and history-same second coordinate determine the first coordinate and the equation witness:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{SOneHistoryCarrier}(x', y', e', p) \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(e, e').$$

Proof. Unpack the two circle-carrier witnesses. The shared point ledger gives $\mathsf{Cont}(x, y, p)$ and $\mathsf{Cont}(x', y', p)$; after transporting along $\mathsf{hsame}(y, y')$, continuation right-cancellation identifies x with x'. The equation components are both classified against the fixed $\mathsf{SOneUnitHistory}$ endpoint, so the unit-equation determinacy readback identifies each equation witness with that endpoint, and transitivity gives $\mathsf{hsame}(e, e')$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier coordinate pair deterministic`

Theorem 58.26 (SOne history carrier coordinate-pair right determinacy)**.** *For histories x, x', y, y', e, e', p, two concrete $\mathsf{S}^{1\uparrow}$ carrier witnesses with the same point ledger and history-same first coordinate determine the second coordinate and the equation witness:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{SOneHistoryCarrier}(x', y', e', p) \Longrightarrow \mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \wedge \mathsf{hsame}(e, e').$$

Proof. Unpack the two circle-carrier witnesses. The shared point ledger gives $\mathsf{Cont}(x, y, p)$ and $\mathsf{Cont}(x', y', p)$; after transporting along $\mathsf{hsame}(x, x')$, continuation left-cancellation identifies y with y'. The equation components are both classified against the fixed $\mathsf{SOneUnitHistory}$ endpoint, so unit-equation determinacy identifies each equation witness with that endpoint, and transitivity gives $\mathsf{hsame}(e, e')$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier coordinate pair right deterministic`

Theorem 58.27 (SOne shared-point component equivalence)**.** *For histories x, x', y, y', e, e', p, two concrete $\mathsf{S}^{1\uparrow}$ carrier witnesses over the same displayed point ledger have the following shared-point component equivalence:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{SOneHistoryCarrier}(x', y', e', p) \Longrightarrow (\mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \wedge \mathsf{hsame}(e, e')) \wedge ($$

Proof. Assume the two displayed carrier witnesses $\mathsf{SOneHistoryCarrier}(x, y, e, p)$ and $\mathsf{SOneHistoryCarrier}(x', y', e', p)$.

For the first branch, suppose $\mathsf{hsame}(x, x')$. Apply Definition 58.26 to the two carrier witnesses and the first-coordinate equality. The hypotheses use the same displayed point ledger p, so right determinacy recovers both $\mathsf{hsame}(y, y')$ and $\mathsf{hsame}(e, e')$; the equation component is recovered against the fixed $\mathsf{SOneUnitHistory}$ ledger exposed by the carrier.

For the second branch, suppose $\mathsf{hsame}(y, y')$. Apply Definition 58.25 to the same two carrier witnesses and the second-coordinate equality. The shared displayed point ledger is again p, so coordinate-pair determinacy recovers $\mathsf{hsame}(x, x')$ and the same equation-ledger comparison $\mathsf{hsame}(e, e')$ against $\mathsf{SOneUnitHistory}$.

Pair the two implications. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier shared point component iff`

Definition 58.28 (SOne displayed completion readback)**.** *Let α be a displayed BEDC source map on* BHist*. A row*

$$\mathsf{SOneDisplayedCompletionReadback}_\alpha(a, x, y, e, p, c)$$

means that the source row a is read through a concrete $\mathsf{S}^{1\uparrow}$ carrier and that the $\mathsf{Completion}^\uparrow$ endpoint is represented by the same visible point ledger:

$$\mathsf{SOneDisplayedCompletionReadback}_\alpha(a, x, y, e, p, c) :\Longleftrightarrow \mathsf{SOneHistoryCarrier}(x, y, e, p) \wedge \mathsf{hsame}(\alpha(a), p) \wedge \mathsf{hsame}(c, p).$$

The predicate has no field for a host quotient representative: the only completion readback data are the displayed point ledger p and the two hsame *comparisons tying p to the source image and to the public endpoint.*

Lean4 (definition) `BEDC.Derived.S1Up.SOneDisplayedCompletionReadback`

Proposition 58.29 (SOne completion readback preserves source separation)**.** *Let α be a displayed BEDC source map on* BHist *whose additive and cancellation rows supply the injectivity judgment*

$$\forall u, v : \mathsf{BHist}.\ \mathsf{hsame}(\alpha(u), \alpha(v)) \Longrightarrow \mathsf{hsame}(u, v).$$

Then displayed $\mathsf{S}^{1\uparrow}$-$\mathsf{Completion}^{\uparrow}$ *readback is injective on source rows and therefore preserves source separation:*

$$\mathsf{SOneDisplayedCompletionReadback}_{\alpha}(a, x, y, e, p, c) \wedge \mathsf{SOneDisplayedCompletionReadback}_{\alpha}(a', x', y', e', p', c')$$
$$\Longrightarrow (\mathsf{hsame}(c, c') \Longrightarrow \mathsf{hsame}(a, a')) \wedge ((\mathsf{hsame}(a, a') \Longrightarrow \bot) \Longrightarrow (\mathsf{hsame}(c, c') \Longrightarrow \bot)).$$

Lean4 ✓ `BEDC.Derived.S1Up.SOneDisplayedCompletionReadback source separation`

Proof. Unpack the two displayed completion-readback rows of Definition 58.28. The first row gives $\mathsf{SOneHistoryCarrier}(x, y, e, p)$, $\mathsf{hsame}(\alpha(a), p)$, and $\mathsf{hsame}(c, p)$. The second gives $\mathsf{SOneHistoryCarrier}(x', y', e', p')$, $\mathsf{hsame}(\alpha(a'), p')$, and $\mathsf{hsame}(c', p')$.

By Definition 58.1 and Definition 58.22, the ledgers p and p' are the public point histories exposed by concrete $\mathsf{S}^{1\uparrow}$ carriers: each is read from the displayed real-coordinate carrier, the unit-equation ledger, and the BEDC continuation row. Thus the endpoint comparisons above are comparisons with visible BHist representatives, not comparisons inside an external completion quotient.

Assume $\mathsf{hsame}(c, c')$. Compose the displayed comparisons by symmetry and transitivity of hsame:

$$\alpha(a)\ \mathsf{hsame}\ p\ \mathsf{hsame}\ c\ \mathsf{hsame}\ c'\ \mathsf{hsame}\ p'\ \mathsf{hsame}\ \alpha(a').$$

This gives $\mathsf{hsame}(\alpha(a), \alpha(a'))$. Applying the injectivity judgment for α gives $\mathsf{hsame}(a, a')$, proving the readback-injectivity clause.

For source separation, suppose $\mathsf{hsame}(a, a') \Longrightarrow \bot$ and suppose $\mathsf{hsame}(c, c')$. The injectivity clause just proved yields $\mathsf{hsame}(a, a')$, which contradicts the displayed source-separation hypothesis. Hence $\mathsf{hsame}(c, c') \Longrightarrow \bot$. The argument uses only the concrete $\mathsf{S}^{1\uparrow}$ carrier readback, hsame symmetry and transitivity, and the source-map injectivity row supplied by additive cancellation. □

Definition 58.30 (SOne visible finite-rank and prime-support ledgers)**.** *Fix a concrete* $\mathsf{S}^{1\uparrow}$ *history-carrier witness* $\mathsf{SOneHistoryCarrier}(x, y, e, p)$*. A* visible $\mathsf{S}^{1\uparrow}$ bridge ledger *is the BEDC ledger surface obtained from the carrier fields of Definition 58.2: the two* $\mathsf{Real}^{\uparrow}$ *coordinate rows, the* $\mathsf{Prod}^{\uparrow}$ *product row, the unit-equation classifier row, and the displayed point-continuation row for p.*

A bounded-rank certificate *on this visible ledger is a pair $(b, R_{\leq b})$ where b is a displayed BEDC rank row and $R_{\leq b}$ asserts that every prime-support row read from the visible bridge ledger factors through rank at most b.*

A cofinal prime-support evidence row *on the same visible ledger is a predicate C_{prime} such that, for every displayed BEDC rank row b, there is a visible prime-support row q_b in the point-continuation ledger of p whose support does not factor through rank at most b.*

A finite-rank host homologization certificate admitted through the $\mathsf{S}^{1\uparrow}$ carrier/readback bridge *is a host-side finite-rank homologization claim whose theorem-preservation and no-host-leak fields translate its public* $\mathsf{S}^{1\uparrow}$ *consequence to a bounded-rank certificate on the visible ledger, rather than to a host equality or an unrecorded host quotient.*

Lemma 58.31 (SOne finite-rank host certificate induces bounded visible rank)**.** *For a concrete carrier witness* $\mathsf{SOneHistoryCarrier}(x, y, e, p)$*, every finite-rank host homologization certificate admitted through the* $\mathsf{S}^{1\uparrow}$ *carrier/readback bridge induces a bounded-rank certificate on the visible* $\mathsf{S}^{1\uparrow}$ *bridge ledger of Definition 58.30.*

Proof. The carrier surface is fixed by Definition 58.2: the visible data are the two real-coordinate rows, the product row, the unit row, and the point-continuation ledger. The public readback theorem Definition 58.22 exposes exactly these BEDC-side rows and no additional host carrier.

An admitted host homologization certificate can therefore reach the public $\mathsf{S}^{1\uparrow}$ surface only through the standard bridge discipline: its preserved host claim must be listed in the theorem-preservation field, and the no-host-leak field of Definition 9204.5 forbids the host's finite-rank object, host quotient, or host equality from becoming a BEDC export. Hence the finite-rank content has only one BEDC-visible form: an explicit displayed rank bound b together with a ledger assertion that all prime-support rows visible in the $\mathsf{S}^{1\uparrow}$ point ledger factor through rank at most b. This is precisely a bounded-rank certificate on the visible bridge ledger. □

Theorem 58.32 (SOne finite-rank host homologization obstruction)**.** *Let* $\mathsf{SOneHistoryCarrier}(x, y, e, p)$ *be a concrete* $\mathsf{S}^{1\uparrow}$ *history-carrier witness. If the visible* $\mathsf{S}^{1\uparrow}$ *bridge ledger carries cofinal prime-support evidence in the sense of Definition 58.30, then no finite-rank host homologization certificate can be admitted through the* $\mathsf{S}^{1\uparrow}$ *carrier/readback bridge for that ledger.*

Proof. Suppose that such a finite-rank host homologization certificate were admitted. By Definition 58.31, it induces a bounded-rank certificate $(b, R_{\leq b})$ on the visible $\mathsf{S}^{1\uparrow}$ bridge ledger. Thus every visible prime-support row in the point-continuation ledger of p must factor through rank at most b.

Apply the cofinal prime-support evidence to this same displayed bound b. It provides a visible prime-support row q_b in the point-continuation ledger of p whose support does not factor through rank at most b.

The row q_b is visible in the same ledger to which $R_{\leq b}$ applies, so $R_{\leq b}$ says that q_b factors through rank at most b. Cofinality says that the same row does not factor through rank at most b. This contradiction blocks the induced bounded-rank certificate, and therefore blocks the admitted finite-rank host homologization certificate that would induce it. □

58.2 The certificate

Definition 58.33 (SOne source specification)**.** *The source is the* $\mathsf{Prod}^{\uparrow}$ *pair of two* $\mathsf{Real}^{\uparrow}$ *witnesses together with the real-algebra data needed to form* $x^2 + y^2$ *and the displayed unit witness.*

Lean4 (definition) `BEDC.Derived.S1Up.SOneSourceSpec`

Lean4 ✓ `BEDC.Derived.S1Up.SOneSourceSpec history carrier fields`

Definition 58.34 (SOne pattern specification)**.** *The pattern is unit-circle formation from a real pair and a certified proof object for the equation* $x^2 + y^2 \approx 1$.

Definition 58.35 (SOne classifier specification)**.** *The concrete* BHist *classifier relates two* $\mathsf{SOneHistoryCarrier}$ *witnesses* (x, y, e, p) *and* (x', y', e', p') *exactly when* $\mathsf{hsame}(x, x')$ *and* $\mathsf{hsame}(y, y')$ *hold component-wise. Under those component witnesses, the equation and point ledgers are determined by Definition 58.23, and they are transported by Definition 58.43 and Definition 58.44.*

Definition 58.36 (SOne component classifier relation)**.** *For histories* $x, y, e, p, x', y', e', p'$*, the concrete relation* $\mathsf{SOneComponentClassifier}((x, y, e, p), (x', y', e', p'))$ *means the conjunction:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \wedge \mathsf{SOneHistoryCarrier}(x', y', e', p') \wedge \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y').$$

Thus the classifier exposes exactly the two real component comparisons. The equation ledger and the point ledger are not classifier fields; they are recovered by Definition 58.23.

Lean4 (definition) `BEDC.Derived.S1Up.SOneComponentClassifier`

Theorem 58.37 (SOne component classifier stability)**.** *On the carrier* SOneHistoryCarrier*, the relation* SOneComponentClassifier *supplies the stability row required by the semantic* NameCert *for* $\mathsf{S}^{1\uparrow}$*. Concretely:*

1. *it is reflexive, symmetric, and transitive by the equivalence theorem for* hsame *on the two exposed real components;*
2. *any classifier witness projects the two carrier rows and determines* $\mathsf{hsame}(e, e')$ *and* $\mathsf{hsame}(p, p')$ *from its exposed component comparisons;*
3. *the carrier transports from* (x, y, e, p) *to* (x', y', e', p') *along the resulting four coordinate* hsame *witnesses.*

Lean4 ✓ `BEDC.Derived.S1Up.SOneComponentClassifier stability`

Proof. Reflexivity, symmetry, and transitivity are inherited componentwise from Definition 3.8. Reflexivity uses the two diagonal component witnesses; symmetry reverses both exposed witnesses; transitivity composes the two exposed witnesses through the middle carrier.

For the hidden ledgers, unpack the classifier witness into four fields: the source carrier row $\mathsf{SOneHistoryCarrier}(x, y, e, p)$, the target carrier row $\mathsf{SOneHistoryCarrier}(x', y', e', p')$, and the exposed component witnesses $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(y, y')$. Apply Definition 58.23 to these four fields; it returns exactly the equation witness $\mathsf{hsame}(e, e')$ and the point witness $\mathsf{hsame}(p, p')$.

The equation ledger is stable by Definition 58.43. With the component ledgers and the determined point ledger, Definition 58.44 then transports the whole carrier from (x, y, e, p) to (x', y', e', p').

The certificate fit has ten fields: the traditional target is unit-circle component classification; the BEDC source is BHist with RealConstantHistoryCarrier, RealConstantHistoryClassifier, $\mathsf{Prod}^{\uparrow}$, and Cont; the carrier is SOneHistoryCarrier; the classifier is SOneComponentClassifier; the stability obligations are equivalence plus carrier transport; the ledger data are the equation and point witnesses; the core theorem is this stability theorem; exactness is hidden-ledger determinacy; the standard bridge is deferred; and the status is ProofTarget. □

Theorem 58.38 (SOne carrier-classifier ledger obligation surface)**.** *For* $\mathsf{S}^{1\uparrow}$ *over* BHist*, the carrier-classifier ledger obligation surface consists of the* $\mathsf{Real}^{\uparrow}$ *component carrier rows, the* $\mathsf{Prod}^{\uparrow}$ *product readback row, the* Cont *point ledger, the componentwise* hsame *classifier rows, and the* $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ *ledger rows displayed by Definition 58.33, Definition 58.35, Definition 58.36, and Definition 58.37. These obligations do not claim connectedness, compactness, angle parametrisation, or a standard topological circle bridge.*

Lean4 ✓ `BEDC.Derived.S1Up.SOneComponentClassifier ledger obligation surface`

Proof. The carrier part is the concrete $\mathsf{SOneHistoryCarrier}(x, y, e, p)$ row over BHist. Its visible payload names two $\mathsf{Real}^{\uparrow}$ component histories, the displayed product history, and the continuation ledger $\mathsf{Cont}(x, y, p)$.

The classifier part is $\mathsf{SOneComponentClassifier}((x, y, e, p), (x', y', e', p'))$. By Definition 58.36, it contains exactly the two carrier rows and the two exposed component comparisons $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(y, y')$.

The ledger part is recovered by Definition 58.37. Its proof invokes Definition 58.23 to determine the hidden equation and point rows, then uses the carrier transport surface to keep the certificate inside the same $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ obligations.

No argument in these rows reads a topological circle. The surface is confined to BHist, $\mathsf{Real}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, Cont, hsame, and $\mathsf{NameCert}$ data, so connectedness, compactness, angle parametrisation, and standard topological bridges remain outside the obligation list. □

Theorem 58.39 (SOne equation transport obligation surface)**.** *For* $\mathsf{S}^{1\uparrow}$ *over* BHist*, the equation transport obligation surface is the* $\mathsf{Real}^{\uparrow}$ *equation witness row, the fixed unit-history classifier row, the componentwise* hsame *rows, the* Cont *ledger, and the* $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ *carrier row transported by Definition 58.43 and Definition 58.44. It excludes connectedness, compactness, angle parametrisation, and standard topological circle bridges.*

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier equation transport obligation surface`

Proof. Begin with the equation row inside $\mathsf{SOneHistoryCarrier}(x, y, e, p)$. The row is a $\mathsf{Real}^{\uparrow}$-typed witness that the displayed equation history is classified against $\mathsf{SOneUnitHistory}$, while the same carrier also records the two real component histories and the point ledger.

Definition 58.43 gives the isolated equation replacement obligation. It changes only the displayed equation witness along $\mathsf{hsame}(e, e')$ and leaves the component carriers and Cont ledger unchanged.

Definition 58.44 gives the full coordinate transport obligation. It combines the two component hsame rows, the equation hsame row, and the point hsame row to produce the transported $\mathsf{SOneHistoryCarrier}(x', y', e', p')$.

These two transport theorems enumerate exactly the equation-facing $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ obligations. They do not provide any connectedness, compactness, angle parametrisation, or standard topological circle bridge row. □

Theorem 58.40 (SOne product-real ledger obligation surface)**.** *For* $\mathsf{S}^{1\uparrow}$ *over* BHist*, the product-real ledger obligation surface is the public readback of the* $\mathsf{Prod}^{\uparrow}$ *point history, the two* $\mathsf{Real}^{\uparrow}$ *component histories, the* Cont *ledger, the transported* hsame *rows, and the* $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ *readback ledger supplied by Definition 58.22, Definition 58.45, and Definition 58.46. It does not claim connectedness, compactness, angle parametrisation, or any standard topological circle bridge.*

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier product real ledger obligation surface`

Proof. Definition 58.22 reads a concrete carrier as a product carrier at p, the fixed unit-equation history, two rational witnesses for the real component histories, and the continuation ledger $\mathsf{Cont}(x, y, p)$. This is the public product-real ledger for the source tuple.

Definition 58.45 applies the coordinate transport surface before taking the same readback at (x', y', e', p'). The product row, the real component rows, the equation row, and the continuation ledger remain inside the transported $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ carrier.

Definition 58.46 shows that a component classifier witness already contains enough carrier and hidden-ledger data to recover the transported public package. Thus the product-real ledger surface is exactly the readback, transport, and classifier-readback trio.

The trio is still a BEDC history certificate surface. It records no connectedness, no compactness, no angle parametrisation, and no standard topological circle bridge. □

Theorem 58.41 (SOneUp public NameCert obligation assembly)**.** *For* $\mathsf{S}^{1\uparrow}$ *over* BHist*, the carrier-classifier ledger surface, equation-transport surface, product-real ledger surface, source specification, classifier specification, and component-classifier stability assemble into the public* $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ *obligation surface. The public fields are exactly the two* $\mathsf{Real}^{\uparrow}$ *component rows, the* $\mathsf{Prod}^{\uparrow}$ *product row, the unit-equation witness, componentwise* hsame*, the* Cont *point ledger, and the* $\mathsf{NameCert}$ *ledger*

rows supplied by Definition 58.38, Definition 58.39, Definition 58.40, Definition 58.33, Definition 58.36, and Definition 58.37. It excludes connectedness, compactness, angle parametrisation, and standard topological circle bridges.

Proof. First project the public carrier and classifier rows from Definition 58.38. This gives the two real component histories, the source-side classifier rows, the hidden equation ledger, and the point ledger over BHist.

Next use Definition 58.39 and Definition 58.40. The equation theorem supplies the unit-equation witness and its hsame transport, while the product-real theorem exposes the $\mathsf{Prod}^{\uparrow}$ point row, the two $\mathsf{Real}^{\uparrow}$ component rows, and the public readback ledger.

Finally apply Definition 58.37. Its component classifier stability transports the exposed component comparisons and determines the hidden ledger rows, so the projected carrier, equation, product, Cont, and $\mathsf{NameCert}$ rows repack as the public $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ obligation surface. Since every projected row is one of these BEDC rows, no connectedness, compactness, angle parametrisation, or standard topological-circle bridge is introduced. □

Definition 58.42 (SOne stability certificate)**.** *The stability certificate consists of:*

1. *reflexivity from reflexivity of the two real components and identity transport of the equation witness*
2. *symmetry by symmetry of the two real components and reverse transport of the equation witness*
3. *transitivity by transitivity of the two real components and composition of equation transport*
4. *compatibility with the* $\mathsf{Prod}^{\uparrow}$ *classifier over* $\mathsf{Real}^{\uparrow} \times \mathsf{Real}^{\uparrow}$
5. *preservation of the certified equation* $x^2 + y^2 \approx 1$

Theorem 58.43 (SOne equation-witness transport)**.** *For histories* x, y, e, e', p*, the concrete* $\mathsf{S}^{1\uparrow}$ *history carrier is stable under replacement of the displayed unit-equation witness along the equation ledger:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{hsame}(e, e') \Longrightarrow \mathsf{SOneHistoryCarrier}(x, y, e', p).$$

Proof. Unpack $\mathsf{SOneHistoryCarrier}(x, y, e, p)$ into the two $\mathsf{RealConstantHistoryCarrier}$ component fields, the $\mathsf{RealConstantHistoryClassifier}(e, \mathsf{SOneUnitHistory})$ field, and the continuation witness $\mathsf{Cont}(x, y, p)$.

The equation ledger gives $\mathsf{hsame}(e, e')$. Combine it with $\mathsf{hsame}(\mathsf{SOneUnitHistory}, \mathsf{SOneUnitHistory})$ by reflexivity and apply the endpoint-transport theorem for the real-constant history classifier. This produces $\mathsf{RealConstantHistoryClassifier}(e', \mathsf{SOneUnitHistory})$ while the two component carriers and the continuation ledger remain unchanged.

Repack the four fields into $\mathsf{SOneHistoryCarrier}(x, y, e', p)$. The certificate fit is the traditional target unit-circle equation transport; the BEDC source BHist with $\mathsf{RealConstantHistoryClassifier}$; the carrier $\mathsf{SOneHistoryCarrier}$; the classifier hsame on the equation ledger; the stability obligation equation-witness transport; the ledger transported unit-equation proof; the core theorem equation-witness replacement; the exactness claim that the same $\mathsf{S}^{1\uparrow}$ carrier is preserved; the standard bridge deferred outside this theorem; and the status $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier equation witness transport`

Theorem 58.44 (SOne carrier hsame transport)**.** *For histories* $x, y, e, p, x', y', e', p'$*, the concrete* $\mathsf{S}^{1\uparrow}$ *history carrier is stable under componentwise* hsame *transport on all exposed carrier coordinates:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(e, e') \Longrightarrow \mathsf{hsame}(p, p') \Longrightarrow \mathsf{SOneHistoryC}$$

Proof. Unpack $\mathsf{SOneHistoryCarrier}(x, y, e, p)$ into the two $\mathsf{RealConstantHistoryCarrier}$ component fields, the $\mathsf{RealConstantHistoryClassifier}(e, \mathsf{SOneUnitHistory})$ field, and the continuation witness $\mathsf{Cont}(x, y, p)$.

Transport the first and second real-constant carrier fields along $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(y, y')$. Each step composes the exposed endpoint equality of the real-constant carrier with the supplied history equality, so the same real-constant carrier predicate is obtained at x' and at y'.

Transport the equation classifier by applying $\mathsf{RealConstantHistoryClassifier_endpoint_transport}$ to $\mathsf{hsame}(e, e')$ and the reflexive witness $\mathsf{hsame}(\mathsf{SOneUnitHistory}, \mathsf{SOneUnitHistory})$. This gives $\mathsf{RealConstantHistoryClassifier}(e', \mathsf{SOneUnitHistory})$.

Transport the continuation ledger by the kernel continuation hsame transport theorem, using the component witnesses for x, y, and p. The result is $\mathsf{Cont}(x', y', p')$.

Repack the two transported real-constant carriers, the transported equation classifier, and the transported continuation ledger into $\mathsf{SOneHistoryCarrier}(x', y', e', p')$. The certificate fit is the traditional target unit-circle carrier transport; the BEDC source BHist with real-constant carrier, real-constant classifier, and Cont; the carrier $\mathsf{SOneHistoryCarrier}$; the classifier hsame on the exposed coordinates; the stability obligation carrier transport; the ledger transported endpoints and equation proof; the core theorem this carrier-transport statement; the exactness claim that the same carrier predicate is preserved; the standard bridge deferred outside this theorem; and the status $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier coordinate transport`

Theorem 58.45 (SOne transported public readback)**.** *For histories $x, y, e, p, x', y', e', p'$, a concrete $\mathsf{S}^{1\uparrow}$ history carrier and componentwise transported BEDC history data expose the public readback at the transported tuple:*

$$\mathsf{SOneHistoryCarrier}(x, y, e, p) \Longrightarrow \mathsf{hsame}(x, x') \Longrightarrow \mathsf{hsame}(y, y') \Longrightarrow \mathsf{hsame}(e, e') \Longrightarrow \mathsf{hsame}(p, p') \Longrightarrow \mathsf{SOneProductH}$$

Proof. First apply Definition 58.44 to the displayed carrier and the four supplied hsame witnesses. This produces the transported carrier $\mathsf{SOneHistoryCarrier}(x', y', e', p')$.

Next apply Definition 58.22 to that transported carrier. Its conclusion is exactly the product carrier at p', the unit-equation readback for e', the two rational component witnesses for x' and y', and the transported continuation ledger.

The ten-field fit is: traditional target transported unit-circle public readback; BEDC source $\mathsf{S}^{1\uparrow}$ over BHist, $\mathsf{Real}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, and Cont; carrier $\mathsf{SOneHistoryCarrier}$; classifier coordinate hsame; stability coordinate transport; ledger transported equation and point witnesses; core theorem this readback; exactness public carrier and unit-equation exposure; standard bridge deferred; status $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier public readback transport`

Theorem 58.46 (SOne component classifier public readback)**.** *For histories $x, y, e, p, x', y', e', p'$, a component-classifier witness carries the two concrete $\mathsf{S}^{1\uparrow}$ history carrier rows and exposes the public readback at the transported tuple:*

$$\mathsf{SOneComponentClassifier}((x, y, e, p), (x', y', e', p')) \Longrightarrow \mathsf{SOneProductHistoryCarrier}(p') \wedge \mathsf{hsame}(e', \mathsf{SOneUnitHistory}) \wedge$$

Lean4 ✓ `BEDC.Derived.S1Up.SOneComponentClassifier public readback`

Proof. Unpack the component classifier. By Definition 58.36, its data are the source carrier row $\mathsf{SOneHistoryCarrier}(x, y, e, p)$, the target carrier row $\mathsf{SOneHistoryCarrier}(x', y', e', p')$, and the component witnesses $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(y, y')$.

Apply Definition 58.23 to the two projected carriers and the two component witnesses. This determines the hidden equation ledger $\mathsf{hsame}(e, e')$ and the hidden point ledger $\mathsf{hsame}(p, p')$.

With the two public component witnesses and the two determined hidden ledgers, Definition 58.44 transports $\mathsf{SOneHistoryCarrier}(x, y, e, p)$ to $\mathsf{SOneHistoryCarrier}(x', y', e', p')$.

Finally apply Definition 58.22 to the transported carrier. The conclusion is precisely the product carrier at p', the unit-equation readback for e', the rational component witnesses for x' and y', and the continuation ledger $\mathsf{Cont}(x', y', p')$. □

Theorem 58.47 (SOne component classifier full readback package)**.** *For histories $x, y, e, p, x', y', e', p'$, a component-classifier witness packages the public readback at the source tuple, the hidden equation and point ledgers, and the public readback at the transported tuple:*

$$\mathsf{SOneComponentClassifier}((x, y, e, p), (x', y', e', p')) \Longrightarrow \Big(\mathsf{SOneProductHistoryCarrier}(p) \wedge \mathsf{hsame}(e, \mathsf{SOneUnitHistory}) \wedge$$

Proof. Unpack the component classifier through Definition 58.36. This gives the source carrier row $\mathsf{SOneHistoryCarrier}(x, y, e, p)$, the target carrier row $\mathsf{SOneHistoryCarrier}(x', y', e', p')$, and the exposed component witnesses $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(y, y')$.

Apply Definition 58.22 to the source carrier. It produces the first displayed public package: the product carrier at p, the unit-equation readback at e, the two rational component witnesses for x and y, and the continuation ledger $\mathsf{Cont}(x, y, p)$.

Next apply Definition 58.23 to the two carrier rows and the two exposed component comparisons. This returns the hidden equation ledger $\mathsf{hsame}(e, e')$ and the hidden point ledger $\mathsf{hsame}(p, p')$.

For the transported public package, either apply Definition 58.46 directly to the original classifier witness, or apply Definition 58.22 to the target carrier row. The resulting fields are exactly the product carrier at p', the unit-equation readback at e', the rational component witnesses for x' and y', and the continuation ledger $\mathsf{Cont}(x', y', p')$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneComponentClassifier full readback package`

Theorem 58.48 (SOne component classifier visible source unit-equation package)**.** *For histories $d_x, d_y, e_t, t, x', y', e', p'$, a component-classifier witness whose source tuple is visibly one-headed packages the rational source data, the hidden ledger transport, and the public target readback:*

$$\mathsf{SOneComponentClassifier}((\mathsf{E1}(d_x), \mathsf{E1}(d_y), \mathsf{E1}(e_t), \mathsf{E1}(t)), (x', y', e', p')) \Longrightarrow \Big(\mathsf{RatHistoryCarrier}(d_x) \wedge \mathsf{RatHistoryCarrie}$$

Proof. Unpack the component classifier through Definition 58.36. Its source row is $\mathsf{SOneHistoryCarrier}(\mathsf{E1}(d_x), \mathsf{E1}(d_y$ with a target carrier row at (x', y', e', p') and exposed component witnesses from $\mathsf{E1}(d_x)$ to x' and from $\mathsf{E1}(d_y)$ to y'.

Apply Definition 58.16 to the visible source row. This gives the two rational coordinate carriers, the rational unit-equation classifier $\mathsf{RatHistoryClassifier}(e_t, \mathsf{E1}(\mathsf{e}))$, and the source continuation ledger $\mathsf{Cont}(\mathsf{E1}(d_x), d_y, t)$.

Next apply Definition 58.23 to the source and target carrier rows together with the exposed component witnesses. The hidden equation and point ledgers are exactly $\mathsf{hsame}(\mathsf{E1}(e_t), e')$ and $\mathsf{hsame}(\mathsf{E1}(t), p')$.

Finally apply Definition 58.46 to the original classifier witness. Its conclusion is the target public readback package: the product carrier at p', the unit-equation readback at e', two rational witnesses for x' and y', and the continuation ledger $\mathsf{Cont}(x', y', p')$. Repack these three packages in the displayed order. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneComponentClassifier visible source unit equation package`

Definition 58.49 (SOne ledger policy)**.** *Record both real witnesses, the componentwise real-classifier witnesses used in classifier derivations, and the transported unit equation proof.*

Lean4 (definition) `BEDC.Derived.S1Up.SOneLedgerPolicy`

Lean4 ✓ `BEDC.Derived.S1Up.SOneLedgerPolicy component readback`

Definition 58.50 ($\mathsf{S}^{1\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{S}^{1\uparrow}$*.*

Theorem 58.51 (SOne semantic NameCert field assembly)**.** *The concrete carrier* $\mathsf{SOneHistoryCarrier}$*, the component classifier relation of Definition 58.36, the source and pattern specifications of Definition 58.33 and Definition 58.34, the stability certificate of Definition 58.42, and the ledger policy of Definition 58.49 supply the five semantic certificate rows needed for the* $\mathsf{S}^{1\uparrow}$ $\mathsf{NameCert}$*: carrier and public readback, hidden equation/point ledger determinacy, equation replacement, full coordinate carrier transport, and transported public readback.*

Proof. The carrier and public-readback row is Definition 58.22. It reads a concrete $\mathsf{SOneHistoryCarrier}(x, y, e, p)$ as a product carrier, the fixed unit-equation history, rational witnesses for x and y, and the continuation ledger at p.

For the classifier row, unpack Definition 58.36. A classifier witness supplies the source carrier row, the target carrier row, and the two component witnesses $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(y, y')$. Applying Definition 58.23 to these four projected fields determines the hidden ledgers $\mathsf{hsame}(e, e')$ and $\mathsf{hsame}(p, p')$.

The stability row first replaces the equation witness through Definition 58.43. With the two public component witnesses and the two hidden ledgers now in hand, Definition 58.44 transports the full concrete carrier from (x, y, e, p) to (x', y', e', p').

The final readback row is Definition 58.45. It applies the transported carrier to expose the product carrier at p', the transported unit-equation witness, the rational component witnesses at x' and y', and the continuation ledger $\mathsf{Cont}(x', y', p')$. These five rows are exactly the semantic payload required by the concrete $\mathsf{NameCert}$ data for $\mathsf{S}^{1\uparrow}$. □

Lean4 ✓ `BEDC.Derived.S1Up.SOne semantic namecert field assembly`

Lean4 ✓ `BEDC.Derived.S1Up.SOne semantic name certificate fields`

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier semanticNameCert field assembly`

Lean4 ✓ `BEDC.Derived.S1Up.SOneComponentClassifier semantic name certificate fields`

Theorem 58.52 (Semantic SOneUp history certificate)**.** *The concrete data* $\mathsf{SOneHistoryCarrier}$*, Definition 58.33, Definition 58.34, Definition 58.35, Definition 58.42, and Definition 58.49 assemble a semantic* $\mathsf{NameCert}$ *for* $\mathsf{S}^{1\uparrow}$ *over* BHist*.*

Proof. Definition 58.51 supplies the fieldwise semantic payload for the displayed carrier, classifier, source, pattern, stability, and ledger data. Packing those rows under the obligations named in Definition 58.50 gives the semantic $\mathsf{NameCert}$ for $\mathsf{S}^{1\uparrow}$ over BHist. □

Lean4 ✓ `BEDC.Derived.S1Up.sone history semantic name certificate`

Definition 58.53 (SOne public constructor packet)**.** *A public constructor packet for* $\mathsf{S}^{1\uparrow}$ *is a finite* BHist *packet whose displayed rows are exactly two* $\mathsf{Real}^{\uparrow}$ *component histories* x *and* y*, the* $\mathsf{Prod}^{\uparrow}$ *point row* p *for the ordered pair, the unit-equation witness row* e *certifying* $x^2 + y^2 \approx 1$*, the componentwise* $\mathsf{hsame}(x, x')$ *and* $\mathsf{hsame}(y, y')$ *transport rows used by the classifier, the* Cont *ledger carrying the point and equation endpoints, and the* $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ *provenance row. The packet has no field for an angle parameter, quotient representative, connectedness witness, compactness witness, or standard circle bridge.*

Theorem 58.54 (SOne public constructor scope)**.** *Every accepted public constructor packet of Definition 58.53 reads only the two* $\mathsf{Real}^{\uparrow}$ *component rows, the* $\mathsf{Prod}^{\uparrow}$ *point row, the unit-equation witness, the componentwise* hsame *classifier rows, the* Cont *continuation ledger, and the* $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ *provenance row. Conversely, those displayed rows repack into the same public constructor surface whenever the carrier and equation transport obligations of Definition 58.52 are present.*

Proof. Project the packet to its displayed rows. The definition lists only the two real components, the product point, the equation witness, the componentwise classifier transports, the continuation ledger, and the certificate provenance.

For the repacking direction, first use Definition 58.41 to align the displayed rows with the public $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ fields. Then apply Definition 58.52 to supply the carrier, classifier, stability, and ledger envelope.

The packet has no row for angle parametrisation, quotient representatives, connectedness, compactness, or a standard bridge. A public read therefore cannot leave the displayed BEDC rows, and the same rows reconstruct the public constructor surface. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier public constructor scope`
Lean4 ✓ `BEDC.Derived.S1Up.SOnePublicConstructorPacket scope`

Theorem 58.55 (SOne public endpoint exactness)**.** *Let P and P' be accepted public constructor packets for* $\mathsf{S}^{1\uparrow}$*. If their two real component rows are related componentwise by* hsame*, then the unit-equation witness rows and product-point ledger rows exposed by P and P' are the same public* $\mathsf{S}^{1\uparrow}$ *endpoints under the classifier of Definition 58.36. No hidden angle, quotient, or host-circle endpoint can distinguish the two accepted packets.*

Lean4 ✓ `BEDC.Derived.S1Up.SOneComponentClassifier public endpoint exactness`

Proof. Read both packets through Definition 58.54. The only classifier data available are the two component rows and their componentwise hsame witnesses.

Apply Definition 58.23. The component classifier determines the equation ledger and the point ledger from those two real-component comparisons.

Finally transport the carrier with Definition 58.43 and Definition 58.44. The transported equation witness and product point are exactly the public endpoints read by the two packets, and no undisplayed host-circle row remains available to separate them. □

Theorem 58.56 (SOne public constructor compatibility)**.** *Every public* $\mathsf{S}^{1\uparrow}$ *constructor row built from two* $\mathsf{Real}^{\uparrow}$ *component rows, the* $\mathsf{Prod}^{\uparrow}$ *point readback, the unit-equation witness, componentwise* hsame*, and the* Cont *point ledger repacks into the same public* $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ *surface. Conversely, every public constructor read from* $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ *exposes only those component, product, equation, transport, continuation, and provenance rows. It exposes no connectedness, compactness, angle parametrisation, or standard circle bridge.*

Proof. Start with the displayed public constructor row. Apply Definition 58.41 to identify the public $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ fields as the two $\mathsf{Real}^{\uparrow}$ component rows, the $\mathsf{Prod}^{\uparrow}$ point row, the unit-equation witness, componentwise hsame, and the Cont point ledger.

The semantic certificate is then supplied by Definition 58.52. Its carrier, classifier, source, stability, and ledger rows give the certificate envelope into which the public constructor fields repack.

For the reverse read, project the public surface through Definition 58.40, Definition 58.39, and Definition 58.46. These results recover exactly the product readback, equation transport, component comparisons, and continuation ledgers available to a public constructor.

No further row is present in the carrier or in the semantic certificate. Therefore the public constructor interface is compatible with the unit-circle equation and exposes only the listed BEDC history rows, while connectedness, compactness, angle parametrisation, and standard circle bridges remain outside the exported surface. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneHistoryCarrier public constructor compatibility`

Primitive boundary. $\mathsf{S}^{1\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 58.57 (Zero-axiom encoding note)**.** *The interface records explicit component witnesses and equation transport, with no quotient-type representative and no use of* Quot.sound*.*

Theorem 58.58 (SOne public constructor standard bridge boundary)**.** *Any standard-circle comparison admitted by this chapter consumes exactly the public constructor packet rows of Definition 58.53: two* $\mathsf{Real}^{\uparrow}$ *component histories, the* $\mathsf{Prod}^{\uparrow}$ *point row, the unit-equation witness, componentwise* hsame *transports, the continuation ledger, and certificate provenance. Conversely, those rows supply the BEDC side of a standard-circle bridge. The consumable surface excludes angle quotients, trigonometric libraries, covering-space data, winding-number data, and topological-group structure.*

Lean4 ✓ `BEDC.Derived.S1Up.SOneUp StdBridge`

Proof. First project an admitted standard-circle comparison to the public constructor surface. By Definition 58.53, its exported rows are exactly the two real component histories, product point row, unit-equation witness, componentwise transports, continuation ledger, and provenance fields.

Next apply Definition 58.56 and Definition 58.52. These identify the displayed rows with the public $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ carrier, classifier, stability, and ledger envelope. Conversely, the public readback and constructor interface of Definition 58.22, Definition 58.45, and Definition 58.46 repacks them as the BEDC side of a standard-circle comparison.

The cited projections never manufacture angle representatives, trigonometric operations, covering-space lifts, winding-number ledgers, or a topological-group law. Those structures remain outside the bridge boundary. □

Theorem 58.59 (SOne Real metric bridge boundary)**.** *The public* $\mathsf{S}^{1\uparrow}$ *bridge boundary over the* $\mathsf{Real}^{\uparrow}$ *product carrier consists only of the two* $\mathsf{Real}^{\uparrow}$ *component rows, the product carrier ledger, the unit-equation witness, the componentwise classifier, and equation transport. It does not expose angle parametrisation, winding data, covering quotients, compactness, or connectedness.*

Lean4 ✓ `BEDC.Derived.S1Up.SOneRealMetricBridgeBoundary public rows`

Proof. Read the carrier through the child file section 58.1. The carrier readbacks expose the two real component histories, the product-history row, the continuation ledger, and the displayed unit-equation witness.

Read the certificate through the child file certificate surface. The component classifier exposes only hsame on the two real coordinates, while the hidden equation and point ledgers are determined and transported by the equation transport and carrier transport rows.

Repack those rows as the public bridge boundary. Every exported field is one of the RealUp component, product carrier, unit-equation, component classifier, or equation-transport rows already displayed in this chapter, so no angle, winding, covering, compactness, or connectedness datum is part of the boundary. □

Theorem 58.60 (SOne real metric coordinate boundary)**.** *The standard topological bridge boundary of an admitted* $\mathsf{S}^{1\uparrow}$ *packet exposes exactly two* $\mathsf{Real}^{\uparrow}$ *component rows, their rational component witnesses, the product carrier row, the unit-equation row, a unary bridge ledger, and the endpoint equation* $\mathsf{hsame}(\mathsf{bridge}, \mathsf{append}(\mathsf{point}, \mathsf{equation}))$*. It exposes no angle parametrisation, winding datum, quotient presentation, compactness, connectedness, or metric-completeness row.*

Lean4 ✓ `BEDC.Derived.S1Up.SOneStandardTopologicalBridgeBoundary component rows`

Proof. Combine Definition 58.59 with the component readback rows in section 58.1. The bridge boundary already limits the public circle read to the Real component rows, product carrier ledger, unit-equation witness, componentwise classifier, and equation transport.

The component readbacks supply the rational witnesses for the two Real rows, the unary bridge ledger, and the displayed endpoint equation. The checked Lean row packages exactly those component fields, so no angle parametrisation, winding datum, quotient presentation, compactness, connectedness, or metric-completeness row is exported. □

Theorem 58.61 (SOne RegSeqRat metric observation boundary)**.** *An admitted* $\mathsf{S}^{1\uparrow}$ *point over the* $\mathsf{Real}^{\uparrow}$ *product carrier exposes to any metric-observation consumer only the two component* $\mathsf{Real}^{\uparrow}$ *finite-window read surfaces, the* $\mathsf{RegSeqRat}$ *stream-name and real-seal rows attached to those components, the product carrier ledger, the unit-equation witness, the componentwise* hsame *classifier rows, and equation transport. Compactness, connectedness, angle parametrisation, winding data, quotient-circle presentation, and metric-completeness rows are not exported by this boundary.*

Proof. Start from the public $\mathsf{S}^{1\uparrow}$ bridge boundary in Definition 58.59. It already restricts the circle read to the two real component rows, the product carrier ledger, the unit-equation witness, the componentwise classifier, and equation transport.

Now read each real component through Definition 38.342. The component access there is a finite-window read surface, so a metric-observation consumer sees only the selected real rows rather than an ambient metric-complete real line.

For the regular-sequence presentation, use Definition 38.276 for the stream-name rows and Definition 38.278 for the finite-window real-seal rows. These are attached componentwise to the two $\mathsf{Real}^{\uparrow}$ reads and do not add a new circle-level carrier.

Combining the three component readings with the $\mathsf{S}^{1\uparrow}$ bridge boundary gives exactly the listed consumer surface. Since no cited surface exports compactness, connectedness, angle data, winding data, quotient-circle presentation, or metric-completeness rows, none of those rows is available through the admitted $\mathsf{S}^{1\uparrow}$ observation boundary. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneRegSeqRatMetricObservationBoundary public rows`

Theorem 58.62 (SOne public certificate boundary)**.** *The public* $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ *boundary is exactly the* $\mathsf{Real}^{\uparrow}$ *pair carrier, product ledger, unit-equation witness, componentwise* hsame *classifier, equation transport, and finite-window* $\mathsf{RegSeqRat}$ *read surfaces isolated by the* $\mathsf{S}^{1\uparrow}$ *bridge and metric-observation boundaries. No compactness, connectedness, angle, quotient, or completeness row is part of the public certificate boundary.*

Lean4 ✓ `BEDC.Derived.S1Up.SOne public namecert obligation assembly`

Proof. Apply Definition 58.59. It identifies the public circle boundary with the two $\mathsf{Real}^{\uparrow}$ component rows, product carrier ledger, unit-equation witness, componentwise classifier, and equation transport.

Apply Definition 58.61. It refines the component access to the finite-window RegSeqRat stream-name and real-seal read surfaces while preserving the same product, equation, classifier, and transport rows.

The public $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$ can therefore export only the intersection of those already isolated rows. Since the first boundary excludes angle data, winding data, covering quotients, compactness, and connectedness, and the second also excludes quotient-circle presentation and metric-completeness rows, the certificate has exactly the displayed RealUp-pair, equation, classifier, transport, and finite-window read surface. □

Theorem 58.63 (SOne componentwise classifier equation transport)**.** *Let P and Q be accepted public $\mathsf{S}^{1\uparrow}$ packets over* BHist*. Suppose the two* $\mathsf{Real}^{\uparrow}$ *component rows of P and Q are related by the componentwise* hsame *classifier of Definition 58.36. Then the unit-equation witness row, product point ledger row, and both* RegSeqRat *finite-window read surfaces of P transport to the corresponding public rows of Q. This consumer reads no angle, quotient-circle, winding, compactness, or connectedness datum.*

Lean4 ✓ `BEDC.Derived.S1Up.SOneComponentClassifier equation transport`

Proof. Apply Definition 58.59. It restricts the public circle packet to the two $\mathsf{Real}^{\uparrow}$ component rows, the product ledger, the unit-equation witness, the componentwise classifier, and the equation-transport row.

Use Definition 58.36 to compare the two accepted packets component by component. Hidden-ledger determinacy in that definition identifies the product-point continuation and the unit-equation witness once the two displayed $\mathsf{Real}^{\uparrow}$ component rows are related by hsame.

Apply Definition 58.61. The same two component comparisons refine to the finite-window RegSeqRat stream-name and real-seal read surfaces on both coordinates, without adding a circle-level carrier.

Finally use Definition 58.62. The public certificate contains exactly those RealUp, product, equation, classifier, and finite-window rows, so the componentwise classifier comparison is sufficient to transport the whole public finite-window circle boundary while leaving all topological circle data unread. □

Theorem 58.64 (SOne standard topological bridge boundary)**.** *Any standard topological-circle bridge for $\mathsf{S}^{1\uparrow}$ may read only the two $\mathsf{Real}^{\uparrow}$ component finite-window surfaces, the product ledger, the unit-equation witness, the componentwise classifier, and equation transport. Compactness, connectedness, angle parametrisation, winding data, quotient-circle presentation, and metric-completeness rows remain outside the bridge.*

↪ variant `BEDC.Derived.S1Up.SOneStandardTopologicalBridgeBoundary component rows`

Proof. Begin with Definition 58.59. It confines a public circle bridge to the two real component rows, product carrier ledger, unit-equation witness, componentwise classifier, and equation transport.

Refine the two component reads through Definition 58.61. The real components may be consumed through their finite-window RegSeqRat read surfaces, but that refinement still does not expose compactness, connectedness, angle data, winding data, quotient presentation, or metric-completeness rows.

Finally apply Definition 58.62. It identifies the public certificate boundary with the same RealUp-pair, product, equation, classifier, transport, and finite-window read rows. Therefore the

standard topological bridge boundary has exactly those readable rows and no topology data outside the displayed certificate surface. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneStandardTopologicalBridgeBoundary public rows`

Theorem 58.65 (SOne standard topological circle acceptance factorization)**.** *Every accepted standard topological-circle bridge row for* $\mathsf{S}^{1\uparrow}$ *factors through exactly the* $\mathsf{Real}^{\uparrow}$*-pair carrier, finite-window* RegSeqRat *component reads, product ledger, unit-equation witness, componentwise classifier, and equation transport isolated by Definition 58.59, Definition 58.61, and Definition 58.62. No compactness, connectedness, angle, winding, quotient-circle, or metric-completeness row can enter the bridge unless supplied by a later certificate.*

Lean4 ✓ `BEDC.Derived.S1Up.SOneStandardTopologicalCircleAcceptance factorization public rows`

Proof. Project the accepted bridge row through Definition 58.64. The projection leaves only the two $\mathsf{Real}^{\uparrow}$ component rows, product ledger, unit-equation witness, componentwise classifier, and equation transport.

Refine those component rows with Definition 58.61. Each real component is read by a finite-window RegSeqRat stream-name and real-seal surface, and the refinement preserves the same product, equation, classifier, and transport rows.

Finally use Definition 58.62. It shows that the public certificate has no additional readable coordinate beyond the RealUp-pair carrier, finite-window reads, product ledger, unit-equation witness, componentwise classifier, and equation transport. Hence topology-specific compactness, connectedness, angle, winding, quotient-circle, and metric-completeness rows are absent unless a later certificate supplies them. □

Theorem 58.66 (SOne standard bridge componentwise transport stability)**.** *Let P and Q be accepted public* $\mathsf{S}^{1\uparrow}$ *packets. Suppose their two* $\mathsf{Real}^{\uparrow}$ *component rows are related by Definition 58.36. If P admits a standard topological-circle bridge row, then Q admits a standard topological-circle bridge row with the same readable* $\mathsf{Real}^{\uparrow}$ *component finite-window surfaces, product ledger, unit-equation witness, componentwise classifier, and equation transport. Compactness, connectedness, angle, winding, quotient-circle, and metric-completeness rows remain unavailable.*

↪ variant `BEDC.Derived.S1Up.SOneStandardBridgeComponentwiseTransport stability`

↪ variant `BEDC.Derived.S1Up.SOneStandardTopologicalBridgeBoundary componentwise transport stability`

Proof. Apply Definition 58.63. The componentwise classifier relation transports the product ledger, unit-equation witness, equation-transport row, and the two finite-window RegSeqRat read surfaces from P to Q.

Next apply Definition 58.64. The standard bridge row for P has no readable coordinate outside those component, product, equation, classifier, transport, and finite-window rows, so the transported data already identify the public bridge boundary available to Q.

Finally use Definition 58.65. The transported boundary repacks as the same public standard topological-circle bridge surface for Q, while compactness, connectedness, angle, winding, quotient-circle, and metric-completeness data remain absent from the bridge. □

Lean4 ✓ `BEDC.Derived.S1Up.SOneStandardBridge componentwise transport stability`

Theorem 58.67 (SOne RealAlgOrder equation consumer boundary)**.** *Every* $\mathsf{RealAlgOrder}^{\uparrow}$*-facing equation consumer of an accepted* $\mathsf{S}^{1\uparrow}$ *packet factors through the two* $\mathsf{Real}^{\uparrow}$ *component rows, the*

product ledger, the unit-equation witness, the componentwise classifier, equation transport, finite-window RegSeqRat *reads, and the visible* BHist, hsame, Cont, Pkg, *and* NameCert *rows. Such a consumer can read the circle equation only through this displayed component-and-equation surface.*

It cannot read compactness, connectedness, angle, winding, quotient-circle data, metric-completeness data, or host real extensionality as an alternate equation source.

Proof. First project the accepted packet through Definition 58.59. The only real-facing rows left available are the two $\mathsf{Real}^{\uparrow}$ components, the product ledger, the unit-equation witness, the componentwise classifier, and equation transport.

Next refine the component reads by Definition 58.61. This replaces any metric-facing component observation by finite-window RegSeqRat reads and the visible BHist, hsame, Cont, Pkg, and NameCert ledger rows.

Apply Definition 58.62. It exhausts the public certificate by the same carrier, component, product, equation, classifier, transport, and finite-window rows, so no hidden host-real row remains for an equation consumer.

Finally use Definition 58.65. The standard acceptance surface repacks those rows without adding compactness, connectedness, angle, winding, quotient-circle, metric-completeness, or host real extensionality data. Hence the $\mathsf{RealAlgOrder}^{\uparrow}$ equation consumer boundary is exactly the displayed component-and-equation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{S}^1\uparrow}$**.**

Constructive story: A circle point is generated by placing two $\mathsf{Real}^{\uparrow}$ constant histories side by side, using the product continuation ledger to assemble the point history p, and carrying a separate equation history e that certifies x^2+y^2 against the real unit; empty points, zero-headed points, and pairs without that unit-equation witness are outside the carrier. The classifier deliberately exposes only the two component comparisons $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(y, y')$: once those are present, the hidden equation ledger and point ledger are determined and transported, so the construction never quotients by angles or by a host $\mathbb{R}/\mathbb{Z}$ presentation. The source specification is the product of two real witnesses together with the real-algebra rows needed to form the unit equation, the pattern specification is unit-circle formation from that pair and its certified equation object, and the ledger keeps the rational tails of the two real constants, the product continuation, the equation witness, and the transported component rows visible. The five name-certificate obligations reduce to componentwise history-equality: an admitted pair with its unit equation inhabits the carrier, reflexivity, symmetry, and transitivity are inherited from the two real components, and full carrier transport works because the hidden equation and point witnesses can be recovered from those component comparisons. A point history h lies in the signature gap of a $\mathsf{S}^{1\uparrow}$ token p when the source-domain accepts h as such a real pair with unit-equation ledger, the signature relation pairs it with an answer circle point and evidence ledger, and the token-introduction relation names that answer as p; unfolded, the two real components and their equation witness match the point encoded by p. The chapter registers this component-and-equation construction under the name $\mathsf{S}^{1\uparrow}$ and records a paper-level standard topological bridge over exactly the component, product, equation, classifier, transport, and finite-window rows; it introduces no trigonometric library, winding theory, covering-space quotient, or topological-group structure.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{S}^1\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: The public scope is the RealUp-pair carrier, product ledger, unit-equation witness, componentwise classifier, equation transport, and finite-window read surface displayed in this chapter.

Definition 58.71 (ContinuousMap stability certificate)**.** *The stability certificate consists of:*

1. *continuous-map classifier reflexivity*
2. *continuous-map classifier symmetry*
3. *continuous-map classifier transitivity*
4. *modulus validity for uniform continuity*
5. *graph and modulus replacement under the continuous-map classifier*
6. *closure under identity*
7. *closure under composition by composing moduli*

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier stability certificate fields`

Theorem 58.72 (Continuous modulus chain factorization)**.** *For histories s, δ_1, δ_2, t, assume the two-link chain*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t).$$

Then there is a history m such that both one-step links are certified:

$$\mathsf{ContinuousModulusWitness}(s, \delta_1, m) \quad \textit{and} \quad \mathsf{ContinuousModulusWitness}(m, \delta_2, t).$$

Proof. Unpack the chain into unary data for s, δ_1, δ_2, and t, together with a middle history m and continuation ledgers $s \cdot \delta_1 = m$ and $m \cdot \delta_2 = t$.

The first ledger and the unary source and modulus data assemble

$$\mathsf{ContinuousModulusWitness}(s, \delta_1, m).$$

Unary continuation closure then makes the middle history unary. The second ledger and the unary δ_2 and target data assemble

$$\mathsf{ContinuousModulusWitness}(m, \delta_2, t).$$

Taking this middle history as the existential witness gives the displayed factorization of the chain into its two certified one-step modulus witnesses. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain factorizes`

Theorem 58.73 (Continuous modulus chain middle deterministic factorization)**.** *For histories s, δ_1, δ_2, t, a continuous modulus chain determines a middle history m such that the two one-step modulus witnesses factor the chain, and every other first-leg middle endpoint is the same BEDC history:*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow \exists m.\ \mathsf{ContinuousModulusWitness}(s, \delta_1, m) \wedge \mathsf{ContinuousModulusWitness}(m, \delta$$

$$\wedge\ \forall m'.\ \mathsf{Cont}(s, \delta_1, m') \Longrightarrow \mathsf{Cont}(m', \delta_2, t) \Longrightarrow \mathsf{hsame}(m, m').$$

Proof. Unpack the chain into unary data and a displayed middle history m with continuation ledgers $s \cdot \delta_1 = m$ and $m \cdot \delta_2 = t$. As in Theorem 59.96, the first ledger gives the first witness and unary continuation closure supplies unary data for m, so the second ledger gives the second witness. If another m' satisfies the same first continuation ledger, Cont determinacy for $s \cdot \delta_1$ yields $\mathsf{hsame}(m, m')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain middle deterministic factorization`

Theorem 58.74 (Continuous modulus chain target determinacy)**.** *For histories $source, first, second, target, targe$ two modulus-chain witnesses with the same source and the same two modulus histories determine the same target up to* hsame*:*

$$\mathsf{ContinuousModulusChain}(source, first, second, target) \Longrightarrow \mathsf{ContinuousModulusChain}(source, first, second, target')$$

Proof. Unpack both chains. The first continuation ledgers share *source* and $first$, so continuation determinacy identifies the two middle histories up to hsame. Transport the second continuation comparison along this middle sameness, keeping the common *second* history fixed; continuation respect for hsame then gives $\mathsf{hsame}(target, target')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain target deterministic`

Theorem 58.75 (Continuous modulus chain append-suffix target determinacy)**.** *For histories $q, source, first, second, target, target'$, two modulus chains with the same source and moduli whose targets share the right suffix q determine the unsuffixed targets up to* hsame*.*

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain append suffix target deterministic`

Proof. Target determinacy identifies $\mathsf{append}(target, q)$ with $\mathsf{append}(target', q)$. Cancel the common right suffix. □

Theorem 58.76 (Continuous modulus chain result determinacy)**.** *For histories $s, \delta_1, \delta_2, t, t'$, two continuous modulus chains with the same source and modulus ledgers determine the same target history:*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t') \Longrightarrow \mathsf{hsame}(t, t').$$

Proof. Unpack the two chains into middle histories m and m' with first ledgers $s \cdot \delta_1 = m$ and $s \cdot \delta_1 = m'$, and second ledgers $m \cdot \delta_2 = t$ and $m' \cdot \delta_2 = t'$. Determinacy of the first continuation gives $\mathsf{hsame}(m, m')$. Continuation compatibility with this middle history equality and reflexivity of δ_2 transports the two second ledgers to obtain $\mathsf{hsame}(t, t')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain result deterministic`

Theorem 58.77 (Continuous modulus chain source determinacy)**.** *For histories $source, source', first, second, tar$ two modulus-chain witnesses with the same two modulus histories and the same target determine the same source up to* hsame*:*

$$\mathsf{ContinuousModulusChain}(source, first, second, target) \Longrightarrow \mathsf{ContinuousModulusChain}(source', first, second, target)$$

Proof. Unpack both chains into middle histories and continuation ledgers. The second continuation ledgers have common suffix *second* and common target, so right cancellation identifies the two middle histories. The first continuation ledgers then have common suffix $first$ and endpoints identified by that middle sameness; common-suffix cancellation gives $\mathsf{hsame}(source, source')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain source deterministic`

Theorem 58.78 (Continuous modulus chain append-suffix source determinacy)**.** *For histories $q, source, source', first, second, target$, two modulus chains with the same moduli and target whose sources share the right suffix q determine the unsuffixed sources up to* hsame*.*

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain append suffix source deterministic`

Proof. Source determinacy identifies $\mathsf{append}(source, q)$ with $\mathsf{append}(source', q)$. Cancel the common right suffix. □

Theorem 58.79 (Continuous modulus chain first determinacy)**.** *For histories $source, first, first', second, target$, two modulus-chain witnesses with the same source, second modulus, and target determine the same first modulus up to* hsame*:*

$$\mathsf{ContinuousModulusChain}(source, first, second, target) \Longrightarrow \mathsf{ContinuousModulusChain}(source, first', second, target)$$

Proof. Unpack both chains. Right cancellation on the two second-leg continuation ledgers identifies the middle histories. Transport the second first-leg ledger along this middle sameness so that both first-leg ledgers have the same source and the same middle endpoint. Left cancellation of continuation then gives $\mathsf{hsame}(first, first')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain first deterministic`

Theorem 58.80 (Continuous modulus chain second determinacy)**.** *For histories $source, first, second, second', tar$ two modulus-chain witnesses with the same source, first modulus, and target determine the same second modulus up to* hsame*:*

$$\mathsf{ContinuousModulusChain}(source, first, second, target) \Longrightarrow \mathsf{ContinuousModulusChain}(source, first, second', target)$$

Proof. Unpack both chains into their middle histories. Determinacy of $\mathsf{Cont}(source, first, -)$ identifies those middle histories. After transporting across this middle equality, the second-leg ledgers have common left endpoint and common target, so continuation left cancellation gives $\mathsf{hsame}(second, second')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain second deterministic`

Theorem 58.81 (Continuous modulus chain composite closure)**.** *For unary histories s, δ_1, δ_2, t, a two-link modulus chain from s through δ_1 and δ_2 to t, together with a continuation ledger composing δ_1 and δ_2 into δ, determines a single continuous modulus witness from s to t using δ:*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow \mathsf{Cont}(\delta_1, \delta_2, \delta) \Longrightarrow \mathsf{ContinuousModulusWitness}(s, \delta, t).$$

Proof. Unpack the chain into unary endpoint and modulus data plus a middle history with ledgers $m = s \cdot \delta_1$ and $t = m \cdot \delta_2$. The composite modulus is unary by closure of unary continuation. The source-to-target continuation is the associativity equality $(s \cdot \delta_1) \cdot \delta_2 = s \cdot (\delta_1 \cdot \delta_2)$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain composite closed`

Theorem 58.82 (Continuous modulus chain endpoint cycle empties moduli)**.** *If* $\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2,$ *and* $\mathsf{hsame}(s, t)$*, then*

$$\mathsf{hsame}(\delta_1, \mathsf{e}) \wedge \mathsf{hsame}(\delta_2, \mathsf{e}).$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain endpoint cycle moduli empty`

Proof. Unpack the chain as $\mathsf{Cont}(s, \delta_1, m)$ and $\mathsf{Cont}(m, \delta_2, t)$. Transport the second ledger across $\mathsf{hsame}(s, t)$ and apply mutual-extension tail cancellation. □

Theorem 58.83 (Continuous modulus witness composite public readback)**.** *For histories source, first, second, mi two certified one-step modulus witnesses*

$$\mathsf{ContinuousModulusWitness}(source, first, middle)$$

and

$$\mathsf{ContinuousModulusWitness}(middle, second, target)$$

together with $\mathsf{Cont}(first, second, composite)$ *determine the composite witness*

$$\mathsf{ContinuousModulusWitness}(source, composite, target).$$

Any displayed witness from source through the same composite has target history hsame *to target.*

Proof. The two one-step witnesses supply the source, modulus, middle, and target carriers plus the two continuation ledgers, hence assemble a $\mathsf{ContinuousModulusChain}(source, first, second, target)$. Composite closure turns this chain and the displayed modulus composition into the one-step composite witness. If another target is displayed for the same source and composite modulus, target determinacy for continuous modulus witnesses identifies it with *target*. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness composite public readback`

Theorem 58.84 (Continuous function carrier modulus-chain replacement)**.** *For histories source, map, target, oldM assume an existing continuous-function carrier, a two-step modulus chain from the same target history to a certificate history, and a continuation ledger composing the two modulus steps:*

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, map, target, oldMod, oldCert),\\ &\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert),\\ &\mathsf{Cont}(\delta_1, \delta_2, \delta).\end{aligned}$$

Then the carrier admits the composite modulus and the chain certificate:

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, \delta, cert).$$

Proof. Unpack the given carrier into unary data for $source$, map, $target$, $oldMod$, and $oldCert$. Keep the graph ledger $\mathsf{Cont}(source, map, target)$; the old modulus and certificate are used only to expose the source, map, and target carrier data.

Apply Theorem 59.105 to the chain $\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert)$ and the composition ledger $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. This yields the replacement modulus witness

$$\mathsf{ContinuousModulusWitness}(target, \delta, cert).$$

Unpack this witness to obtain unary data for δ and $cert$, together with the modulus-certificate ledger $\mathsf{Cont}(target, \delta, cert)$. Reassemble $\mathsf{ContinuousFunctionCarrier}(source, map, target, \delta, cert)$ from the preserved source, map, and target data, the preserved graph ledger, and this new modulus witness.

The ten-field certificate fit is the following. The traditional target is uniform-continuity data whose modulus certificate may be recomputed through a two-link modulus chain. The BEDC source is $BHist$ equipped with Cont. The carrier is $\mathsf{ContinuousFunctionCarrier}$ and the classifier is hsame. The stability obligation is carrier preservation under modulus-chain replacement. The ledger consists of source, map, target, old modulus, old certificate, two modulus steps, the composite modulus, and the terminal certificate. The core theorem is this carrier-level replacement, exactness is the displayed carrier conclusion, the standard bridge is deferred, and the status is $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier modulus chain replacement`

Theorem 58.85 (Prefixed continuous function carrier graph-chain closure)**.** *For histories $p, source, map, target, \delta_1$ unary source, map, target, and visible-prefix histories, a graph continuation ledger, a two-step modulus chain from the target history to a certificate history, and a continuation ledger composing the two modulus steps determine the prefixed graph carrier with the composite modulus certificate:*

$$\begin{aligned}&\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(source) \Longrightarrow \\ &\mathsf{UnaryHistory}(target) \Longrightarrow \mathsf{UnaryHistory}(map) \Longrightarrow \\ &\mathsf{Cont}(source, map, target) \Longrightarrow \mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert) \Longrightarrow \mathsf{Cont}(\delta_1, \delta_2, \delta) \Longrightarrow \\ &\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert).\end{aligned}$$

Proof. First apply Theorem 59.113 to the prefix p, the chain $\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert)$, and the composition ledger $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. This gives the modulus witness

$$\mathsf{ContinuousModulusWitness}(p \cdot target, \delta, p \cdot cert).$$

Unpack this witness into unary data for $p \cdot target$, the composite modulus δ, and $p \cdot cert$, together with the certificate ledger $\mathsf{Cont}(p \cdot target, \delta, p \cdot cert)$.

The graph ledger is prefixed directly from $\mathsf{Cont}(source, map, target)$. Associativity of history append gives

$$(p \cdot source) \cdot map = p \cdot (source \cdot map) = p \cdot target.$$

Unary append closure applied to p and $source$ supplies the unary source history $p \cdot source$. The unary map hypothesis is reused, and the prefixed target, composite modulus, and prefixed certificate data come from the modulus witness. These fields assemble $\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert)$.

The ten-field certificate fit is the following. The traditional target is uniformly continuous map composition under visible finite-prefix evidence. The BEDC source is $BHist$ equipped with Cont. The carrier is $\mathsf{ContinuousFunctionCarrier}$ and the classifier is hsame. The stability obligation is carrier preservation from graph data and a prefixed two-link modulus chain. The ledger consists of source, map, target, two modulus steps, the composite modulus, the terminal certificate, and the visible prefix. The core theorem is this carrier-level closure, exactness is the displayed carrier conclusion, the standard bridge is deferred, and the status is $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain closed`

Theorem 58.86 (Prefixed continuous function carrier graph-chain public readback)**.** *For histories $p, source, map, target, target', \delta_1, \delta_2, \delta, cert, cert'$, assume unary histories p, source, target, and map, a graph ledger $\mathsf{Cont}(source, map, target)$, a two-link modulus chain $\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cer$ and a composition ledger $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. If a displayed prefixed continuous-function carrier has target $p \cdot target'$ and certificate $p \cdot cert'$,*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target', \delta, p \cdot cert'),$$

then the public target and certificate are determined:

$$\mathsf{hsame}(target, target') \quad \textit{and} \quad \mathsf{hsame}(cert, cert').$$

Proof. The graph ledger and the modulus chain first build the canonical prefixed continuous-function carrier with target $p \cdot target$ and certificate $p \cdot cert$. Carrier target-certificate determinacy compares this canonical carrier with the displayed carrier, giving equality of the two prefixed targets and equality of the two prefixed certificates. Left cancellation of the shared prefix p yields the displayed public readback equalities. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain public readback`

Theorem 58.87 (Prefixed continuous function carrier graph-chain second determinacy)**.** *For histories $p, source, map, target, \delta_1, \delta_2, \delta_2', \delta, \delta', cert$, assume δ_1, δ_2, and δ_2' are unary histories, with continuation ledgers*

$$\mathsf{Cont}(\delta_1, \delta_2, \delta), \qquad \mathsf{Cont}(\delta_1, \delta_2', \delta').$$

If the two composite moduli support the same prefixed continuous function carrier,

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta', p \cdot cert),$$

then the second modulus components are history-same:

$$\mathsf{hsame}(\delta_2, \delta_2').$$

Proof. Unpack the two continuous function carriers and compare their terminal certificate ledgers. Since both ledgers start at $p \cdot target$ and end at $p \cdot cert$, continuation left cancellation identifies the composite moduli δ and δ'. Transport to a common composite modulus, then apply left cancellation to the two ledgers out of δ_1 to obtain $\mathsf{hsame}(\delta_2, \delta_2')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain second deterministic`

Theorem 58.88 (Prefixed continuous function carrier graph-chain first determinacy)**.** *For histories $p, source, map, target, \delta_1, \delta_1', \delta_2, \delta, \delta', cert$, assume δ_1, δ_1', and δ_2 are unary histories, with continuation ledgers*

$$\mathsf{Cont}(\delta_1, \delta_2, \delta), \qquad \mathsf{Cont}(\delta_1', \delta_2, \delta').$$

If the two composite moduli support the same prefixed continuous function carrier,

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta', p \cdot cert),$$

then the first modulus components are history-same:

$$\mathsf{hsame}(\delta_1, \delta_1').$$

Proof. Unpack the two continuous function carriers and compare their terminal certificate ledgers. Since both ledgers start at $p \cdot target$ and end at $p \cdot cert$, continuation left cancellation identifies the composite moduli δ and δ'. Common-suffix cancellation on the two composite modulus ledgers, using the shared suffix δ_2, then yields $\mathsf{hsame}(\delta_1, \delta_1')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain first deterministic`

Theorem 58.89 (Prefixed continuous modulus composite closure)**.** *For unary histories $p, s, \delta_1, \delta_2, t, \delta$, a unary prefix p, a two-link modulus chain from s through δ_1 and δ_2 to t, and a continuation ledger composing δ_1 and δ_2 into δ determine a prefixed continuous modulus witness:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow$$
$$\mathsf{Cont}(\delta_1, \delta_2, \delta) \Longrightarrow \mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t).$$

Proof. Unpack the chain into unary endpoint and modulus histories, together with the continuation ledgers from s to the middle history and from the middle history to t.

The prefixed source and target histories are unary by unary append closure applied to p with s and t. The composite modulus history is unary by unary continuation closure applied to the two modulus histories and their composition ledger.

The remaining continuation ledger is obtained by associating the concatenation spine:

$$(p \cdot s) \cdot \delta = p \cdot (s \cdot \delta) = p \cdot t.$$

Thus the prefixed endpoints and the same composite modulus satisfy the public continuous modulus witness predicate. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite closed`

Theorem 58.90 (Continuous modulus witness prefixed composite factorization)**.** *For histories $p, s, \delta_1, \delta_2, \delta, t$, if δ_1 and δ_2 are unary histories, $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ holds, and*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t)$$

holds, then there is a middle history m such that

$$\mathsf{ContinuousModulusWitness}(s, \delta_1, m) \quad \wedge \quad \mathsf{ContinuousModulusWitness}(m, \delta_2, t).$$

Proof. First remove the common prefix from the displayed continuous modulus witness using Theorem 59.21. This leaves a witness from s through the composite modulus δ to t.

Choose $m = s \cdot \delta_1$. The first witness is immediate from $\mathsf{Cont}(s, \delta_1, s \cdot \delta_1)$ and unary append closure. For the second witness, case-analyze the two continuation ledgers $\mathsf{Cont}(s, \delta, t)$ and $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. Associativity identifies $(s \cdot \delta_1) \cdot \delta_2$ with $s \cdot (\delta_1 \cdot \delta_2)$, hence with t. This supplies the required continuation ledger from m through δ_2 to t. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite factorizes`

Theorem 58.91 (Continuous prefixed composite middle deterministic factorization)**.** *For histories $p, s, \delta_1, \delta_2, \delta, t$, if δ_1 and δ_2 are unary histories, $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ holds, and*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t)$$

holds, then there is a middle history m such that

$$\mathsf{ContinuousModulusWitness}(s, \delta_1, m) \quad \wedge \quad \mathsf{ContinuousModulusWitness}(m, \delta_2, t),$$

and every other middle history carrying the same two witness legs is hsame *to m.*

Proof. First apply the prefixed composite factorization theorem to expose a middle history and the two one-step continuous modulus witnesses. If another middle history carries a witness from s through δ_1, both first legs have the same source and modulus; one-step target determinacy therefore identifies the two middle histories by hsame. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite middle deterministic factorization`

Theorem 58.92 (Continuous prefixed composite first deterministic)**.** *For histories $p, s, \delta_1, \delta_1', \delta_2, \delta, \delta', t$, assume δ_1, δ_1', and δ_2 are unary, $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ and $\mathsf{Cont}(\delta_1', \delta_2, \delta')$ hold, and both*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t) \quad \textit{and} \quad \mathsf{ContinuousModulusWitness}(p \cdot s, \delta', p \cdot t)$$

hold. Then $\mathsf{hsame}(\delta_1, \delta_1')$.

Proof. Factor both prefixed composite witnesses. The second legs share the same target t and the same second modulus δ_2, so one-step source determinacy identifies their middle histories. The first legs then share the same source s and hsame target histories, so one-step modulus determinacy identifies δ_1 and δ_1'. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite first deterministic`

Theorem 58.93 (Continuous modulus witness prefixed composite source determinacy)**.** *For histories $p, s, s', \delta_1, \delta_2, \delta, t$, assume δ_1 and δ_2 are unary histories and $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. If two prefixed composite modulus witnesses share the same composite modulus and the same prefixed target,*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t) \quad \textit{and} \quad \mathsf{ContinuousModulusWitness}(p \cdot s', \delta, p \cdot t),$$

then their unprefixed sources are history-same:

$$\mathsf{hsame}(s, s').$$

Proof. Factor both prefixed composite witnesses into two one-step modulus witnesses. The second legs share the modulus δ_2 and target t, so one-step source determinacy identifies the two recovered middle histories. The first legs then share the modulus δ_1 and have history-same middle targets, so one-step source determinacy gives $\mathsf{hsame}(s, s')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite source deterministic`

Theorem 58.94 (Continuous prefixed composite second deterministic)**.** *For histories $p, s, \delta_1, \delta_2, \delta_2', \delta, \delta', t$, assume δ_1, δ_2, and δ_2' are unary, $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ and $\mathsf{Cont}(\delta_1, \delta_2', \delta')$ hold, and both*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t) \quad \textit{and} \quad \mathsf{ContinuousModulusWitness}(p \cdot s, \delta', p \cdot t)$$

hold. Then $\mathsf{hsame}(\delta_2, \delta_2')$.

Proof. Factor both prefixed composite witnesses. The first legs share the same source s and first modulus δ_1, so one-step target determinacy identifies the two middle histories. The second legs then have hsame source histories and the same target t, so one-step modulus determinacy identifies δ_2 and δ_2'. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite second deterministic`

Theorem 58.95 (Continuous modulus chain prefix closure)**.** *For histories $p, s, \delta_1, \delta_2, t$, a unary prefix on the source and target preserves a two-link continuous modulus chain:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow \mathsf{ContinuousModulusChain}(p{\cdot}s, \delta_1, \delta_2, p{\cdot}t).$$

Proof. Unpack the chain into unary endpoint data and a middle history m with continuations $m = s \cdot \delta_1$ and $t = m \cdot \delta_2$. Use $p \cdot m$ as the middle history for the prefixed chain. Unary append closure supplies the prefixed endpoints, and continuation associativity prefixes both ledger equalities. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain prefix closed`

Theorem 58.96 (Continuous modulus chain prefix exactness)**.** *For histories $p, s, \delta_1, \delta_2, t$, prefixing both endpoints of a two-link continuous modulus chain is exact:*

$$\mathsf{ContinuousModulusChain}(p{\cdot}s, \delta_1, \delta_2, p{\cdot}t) \Longleftrightarrow \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t).$$

The traditional target is prefix-stable uniform-modulus data. The BEDC source is BHist with Cont*, the carrier is* $\mathsf{ContinuousModulusChain}$*, and the classifier is* hsame*. The stability obligation is prefix exactness. The ledger records source, two precision histories, middle, and target continuations. The core theorem is this exactness statement, the exactness predicate is the displayed iff, the standard bridge is deferred, and the status is* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, unpack the prefixed chain. Unary append factorization gives unary p and unary s. Let the unprefixed middle be $s \cdot \delta_1$.

The first continuation ledger, together with associativity, identifies the prefixed middle as $p \cdot (s \cdot \delta_1)$. The second continuation ledger then has a common visible prefix p on both sides. Associativity and left cancellation recover the unprefixed second continuation from $s \cdot \delta_1$ through δ_2 to t. These data assemble $\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t)$, paired with unary p.

For the reverse direction, take unary p together with the unprefixed chain and apply Theorem 59.119. This gives the prefixed chain from $p \cdot s$ through the same two precision histories to $p \cdot t$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain prefix iff`

Theorem 58.97 (Continuous modulus chain suffix exactness)**.** *For histories $p, s, \delta_1, \delta_2, t$, suffixing the second modulus and the target of a two-link continuous modulus chain is exact:*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2 \cdot p, t \cdot p) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t).$$

Proof. For the forward direction, unpack the suffixed chain and derive the unary middle history from the first continuation. The second continuation is a continuous modulus witness from the middle history through $\delta_2 \cdot p$ to $t \cdot p$. Apply Theorem 59.22 to remove the common right suffix from that second leg, then rebuild the original two-link chain.

For the reverse direction, apply Theorem 59.22 to the second leg of the chain and reuse the same middle history and first continuation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain suffix iff`

Definition 58.98 (ContinuousMap ledger policy)**.** *Record the graph relation, source and target metric ledgers, the totally bounded subset witness, the unary precision ledger, and the modulus ledger.*

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier ledger policy fields`

Definition 58.99 ($\mathsf{ContinuousMap}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{ContinuousMap}^{\uparrow}$.

↪ variant `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier certificate semanticNameCert`
Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousUp StdBridge`

Primitive boundary. $\mathsf{ContinuousMap}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 58.100 (Zero-axiom encoding note)**.** *The encoding avoids extensional equality of maps and host* `Nat` *by using graph classifier sameness and unary precision histories. The modulus object is a certified relation between precision histories, so no host-level numeric modulus is exposed at the certificate boundary.*

Proposition 58.101 (Uniform modulus restriction along subset containment)**.** *Let Y and Z be certified* $\mathsf{Met}^{\uparrow}$ *objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, and let $i : U \subseteq T$ be a certified inclusion. For a graph witness $f : T \to Z$, let $f \restriction_U$ be the same graph relation read with the source classifier restricted along i. If a unary precision ledger δ satisfies the modulus-validity field of Definition 59.161 for f over T, then the same δ satisfies that modulus-validity field for $f \restriction_U$ over U.*

Proof. Fix a target precision request and two source histories admitted by U. The certified inclusion sends their source-membership ledgers to membership ledgers for T:

$$u_j \in U \Longrightarrow i(\nu_j) \in T \qquad (j = 0, 1).$$

The graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger are the same ledgers as in the witness over T, as specified by Definition 59.93 and Definition 59.122.

Apply the modulus-validity field over T to the two transported source memberships. It returns the codomain metric conclusion at the requested target precision for the two graph outputs. The metric judgments are well formed and stable under classifier replacement by Definition 57.4 and Definition 57.5.

The restricted witness over U asks for exactly the same codomain conclusion, with only the source-admission hypotheses narrowed from T to U. The totality and single-valuedness clauses from Definition 59.1 license the same graph outputs, while no precision or modulus ledger is changed. □

↪ variant `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction public readback`

Closure status for $\mathsf{NameCert}_{\mathsf{Continuous}\uparrow}$.

Constructive story: A continuous map is carried by a graph-and-modulus history packet: source, target, map code, modulus, and certificate histories are unary, the graph ledger continues the source through the map to the target, and the modulus ledger continues the target through the modulus to the certificate. Two such witnesses are classified by the graph outputs agreeing under the target classifier for classified source inputs and by their unary modulus ledgers mutually refining each requested precision; on the checked carrier rows this is enforced through hsame determinacy of the displayed continuation fields. The source consists of certified metric spaces and the totally bounded source discipline, the pattern records graph-with-modulus formation, identity, composition, prefix and restriction examples, terminal-modulus extension, and modulus-chain exactness, and the ledger keeps the graph relation, metric ledgers, precision history, modulus history, and certificate history visible. The five name-certificate obligations close because the identity map uses the empty map code with a one-step modulus witness, hsame supplies reflexive, symmetric, and transitive comparison of the displayed histories, and carrier transport follows by moving each continuation ledger across history-sameness. A carrier row lies in the signature gap of a $\mathsf{Continuous}^{\uparrow}$ token p when the source-domain accepts the graph-and-modulus packet, the signature relation pairs it with an answer packet and evidence ledger, and token introduction names that answer as p; unfolded, the graph sends each accepted source history to the encoded target history and the modulus ledger supplies the precision conversion recorded by p. The checked standard bridge reads the same relation-plus-ledger data as a continuous-map boundary and reads it back without host-level function extensionality or a numeric modulus object. The chapter registers this graph-modulus construction under the name $\mathsf{Continuous}^{\uparrow}$; continuity is an explicit BEDC certificate surface, not a host function space, completeness theorem, or external map equality principle.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Continuous}\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: The mature paper scope binds the ContinuousFunctionCarrier semantic certificate, modulus-witness determinacy and exactness rows, identity, composition, prefix, and restriction examples, and the ContinuousMapUp consumer surface cited by the chapter.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Continuous}\uparrow}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier\_certificate\_semanticNameCert`

Theorem 58.102 (Continuous modulus chain prefix closure)**.** *For histories $p, s, \delta_1, \delta_2, t$, a unary prefix on the source and target preserves a two-link continuous modulus chain:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow \mathsf{ContinuousModulusChain}(p{\cdot}s, \delta_1, \delta_2, p{\cdot}t).$$

Proof. Unpack the chain into unary endpoint data and a middle history m with continuations $m = s \cdot \delta_1$ and $t = m \cdot \delta_2$. Use $p \cdot m$ as the middle history for the prefixed chain. Unary append closure supplies the prefixed endpoints, and continuation associativity prefixes both ledger equalities. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain prefix closed`

Theorem 58.103 (Continuous modulus chain prefix exactness)**.** *For histories $p, s, \delta_1, \delta_2, t$, prefixing both endpoints of a two-link continuous modulus chain is exact:*

$$\mathsf{ContinuousModulusChain}(p{\cdot}s, \delta_1, \delta_2, p{\cdot}t) \Longleftrightarrow \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t).$$

The traditional target is prefix-stable uniform-modulus data. The BEDC source is BHist with Cont*, the carrier is* ContinuousModulusChain*, and the classifier is* hsame*. The stability obligation is prefix exactness. The ledger records source, two precision histories, middle, and target continuations. The core theorem is this exactness statement, the exactness predicate is the displayed iff, the standard bridge is deferred, and the status is* ProofTarget*.*

Proof. For the forward direction, unpack the prefixed chain. Unary append factorization gives unary p and unary s. Let the unprefixed middle be $s \cdot \delta_1$.

The first continuation ledger, together with associativity, identifies the prefixed middle as $p \cdot (s \cdot \delta_1)$. The second continuation ledger then has a common visible prefix p on both sides. Associativity and left cancellation recover the unprefixed second continuation from $s \cdot \delta_1$ through δ_2 to t. These data assemble $\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t)$, paired with unary p.

For the reverse direction, take unary p together with the unprefixed chain and apply Theorem 59.119. This gives the prefixed chain from $p \cdot s$ through the same two precision histories to $p \cdot t$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain prefix iff`

Theorem 58.104 (Continuous modulus chain suffix exactness)**.** *For histories $p, s, \delta_1, \delta_2, t$, suffixing the second modulus and the target of a two-link continuous modulus chain is exact:*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2 \cdot p, t \cdot p) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t).$$

Proof. For the forward direction, unpack the suffixed chain and derive the unary middle history from the first continuation. The second continuation is a continuous modulus witness from the middle history through $\delta_2 \cdot p$ to $t \cdot p$. Apply Theorem 59.22 to remove the common right suffix from that second leg, then rebuild the original two-link chain.

For the reverse direction, apply Theorem 59.22 to the second leg of the chain and reuse the same middle history and first continuation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain suffix iff`

Proposition 58.105 (Uniform modulus restriction along subset containment)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, and let $i : U \subseteq T$ be a certified inclusion. For a graph witness $f : T \to Z$, let $f \restriction_U$ be the same graph relation read with the source classifier restricted along i. If a unary precision ledger δ satisfies the modulus-validity field of Definition 59.161 for f over T, then the same δ satisfies that modulus-validity field for $f \restriction_U$ over U.*

Proof. Fix a target precision request and two source histories admitted by U. The certified inclusion sends their source-membership ledgers to membership ledgers for T:

$$u_j \in U \Longrightarrow i(\nu_j) \in T \qquad (j = 0, 1).$$

The graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger are the same ledgers as in the witness over T, as specified by Definition 59.93 and Definition 59.122. Apply the modulus-validity field over T to the two transported source memberships. It returns the codomain metric conclusion at the requested target precision for the two graph outputs. The metric judgments are well formed and stable under classifier replacement by Definition 57.4 and Definition 57.5.

The restricted witness over U asks for exactly the same codomain conclusion, with only the source-admission hypotheses narrowed from T to U. The totality and single-valuedness clauses from Definition 59.1 license the same graph outputs, while no precision or modulus ledger is changed. □

↪ variant BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction public readback

Proposition 58.106 (Uniform continuity modulus restriction along subset inclusion)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, and let*

$$i : U \subseteq T$$

be a certified inclusion, meaning that each membership ledger $\nu : U(u)$ is transported to a membership ledger $i(\nu) : T(u)$. Let $f : T \to Z$ be a certified graph witness with totality and single-valuedness as in Definition 59.1, and let $f \restriction_U$ be the same graph relation read with the source classifier restricted through i. If a unary precision ledger δ satisfies the modulus-validity field of Definition 59.161 for f on T, then the same δ satisfies the modulus-validity field for $f \restriction_U$ on U.

Proof. Fix a target precision request n and the source precision returned by the unary ledger δ. To verify the restricted modulus field, take source histories u_0, u_1 admitted by U, graph outputs z_0, z_1 for $f \restriction_U$, and the source closeness judgment required at the returned source precision.

The inclusion certificate transports the two source-admission ledgers:

$$\nu_j : U(u_j) \Longrightarrow i(\nu_j) : T(u_j) \qquad (j = 0, 1).$$

By Definition 59.93 and Definition 59.122, restricting the source subset does not alter the graph relation, the codomain classifier ledger, the precision ledger, or the modulus ledger. Thus the graph witnesses for $f \restriction_U$ are the same graph witnesses for f after the source admissions are read in T.

Apply the modulus-validity field for f on T to the transported memberships, the same source closeness judgment, and the same two graph outputs. It yields the target metric closeness conclusion at precision n. The well-formedness and representative stability of this conclusion are exactly the classifier and stability data of Definition 57.4 and Definition 57.5.

This is the entire obligation for the restricted witness: only the source-admission hypotheses have been narrowed from T to U, and those hypotheses enter the original modulus field through the certified inclusion. The precision ledger δ is unchanged. □

Lean4 ✓ BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction modulus chain

Theorem 58.107 (Continuous empty-source restriction public package)**.** *Let restricted, source, map, target, target′,* BHist *be histories. Assume*

$$\mathsf{Cont}(\mathit{restricted}, \mathsf{e}, \mathit{source}),$$

$$\mathsf{ContinuousFunctionCarrier}(\mathit{source}, \mathit{map}, \mathit{target}, \mathit{oldMod}, \mathit{oldCert}),$$

$$\mathsf{ContinuousModulusChain}(\mathit{target}, \delta_1, \delta_2, \mathit{cert}),$$

$$\mathsf{Cont}(\delta_1, \delta_2, \delta),$$

and a displayed restricted carrier

$$\mathsf{ContinuousFunctionCarrier}(\mathit{restricted}, \mathit{map}, \mathit{target}', \delta, \mathit{cert}').$$

Then the empty-source restriction has the public package

$$\mathsf{ContinuousFunctionCarrier}(\mathit{restricted}, \mathit{map}, \mathit{target}, \delta, \mathit{cert}),$$

$$\mathsf{ContinuousModulusWitness}(\mathit{target}, \delta, \mathit{cert}),$$

and

$$\mathsf{hsame}(\mathit{target}, \mathit{target}') \wedge \mathsf{hsame}(\mathit{cert}, \mathit{cert}').$$

Proof. Apply the preceding checked empty-source restriction-chain theorem to the source restriction, the original carrier, the modulus chain, and the composite modulus relation. This produces the restricted ContinuousFunctionCarrier over $(\mathit{restricted}, \mathit{map}, \mathit{target}, \delta, \mathit{cert})$ and the ContinuousModulusWitness over $(\mathit{target}, \delta, \mathit{cert})$.

It remains to read back the displayed public target and certificate. The Lean-side theorem BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier_empty_source_restriction_public_readback applies to the same hypotheses together with the displayed restricted carrier, and returns $\mathsf{hsame}(\mathit{target}, \mathit{target}') \wedge \mathsf{hsame}(\mathit{cert}, \mathit{cert}')$.

Ten-field fit: traditional target restriction of uniformly continuous maps along an empty-source inclusion; BEDC source BHist, Cont, ContinuousFunctionCarrier, and ContinuousModulusChain; carrier the restricted ContinuousFunctionCarrier; classifier hsame on target and certificate histories; stability hsame transport and modulus-chain composition; ledger unchanged graph with replaced modulus/certificate chain; core theorem this public package; exactness the target/certificate readback; standard bridge ordinary restricted-map readback; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction public readback`

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction public package`

Theorem 58.108 (Uniform continuity modulus restriction is transitive)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let V, U, and T be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusions*

$$j : V \subseteq U$$

and

$$i : U \subseteq T.$$

For a certified graph witness $f : T \to Z$, let $f \restriction_U$ be the restriction along i, let $(f \restriction_U) \restriction_V$ be the successive restriction along j, and let $f \restriction_V$ be the direct restriction along the composite inclusion $i \circ j : V \subseteq T$. The composite inclusion carries the same history-level graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger as the successive restriction. If a unary precision ledger δ satisfies the modulus-validity field of Definition 59.161 for f over T, then δ satisfies that field for both $f \restriction_V$ and $(f \restriction_U) \restriction_V$, and the two restricted witnesses are related by the $\mathsf{ContinuousMap}^{\uparrow}$ classifier of Definition 59.94.

Proof. Apply Proposition 59.80 first to $i : U \subseteq T$. This transports the modulus-validity field for f over T to the restriction $f \restriction_U$ over U, with the graph relation and all precision data left unchanged.

Apply the same proposition to $j : V \subseteq U$ and the already restricted witness $f \restriction_U$. The result is the modulus-validity field for $(f \restriction_U) \restriction_V$ over V, with the same history-level graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger.

Apply Proposition 59.80 once more to the composite inclusion $i \circ j : V \subseteq T$. This gives the direct restricted witness $f \restriction_V$ and its modulus-validity field over V using the original witness f and the same unary precision ledger δ.

It remains to compare the direct and successive restrictions. By Definition 59.93, restriction changes only the source-admission reading of the graph; by Definition 59.122, the graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger are recorded as the same ledgers. Thus the direct and successive witnesses present the same carrier data to the classifier, and Definition 59.94 relates them as $\mathsf{ContinuousMap}^{\uparrow}$ witnesses.

Ten-field fit: traditional target functorial restriction of uniformly continuous maps; BEDC source BHist with certified source predicates and ContinuousFunctionCarrier; carrier restricted graph witness; classifier ContinuousMap classifier; stability nested source-admission transport; ledger unchanged graph/modulus ledgers; core theorem this block; exactness direct-versus-successive restriction agreement; standard bridge restriction functoriality for uniformly continuous maps; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction transitive package`

Theorem 58.109 (Uniform continuity restriction functorial action)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T, U, and V be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92. Let*

$$e_T : T \subseteq T$$

be the identity inclusion, and let

$$i : U \subseteq T$$

and

$$j : V \subseteq U$$

be certified inclusions. Let $f : T \to Z$ be a certified graph witness whose unary precision ledger δ satisfies the modulus-validity field of Definition 59.161 over T. Then restriction along e_T preserves δ and is related to f by the $\mathsf{ContinuousMap}^{\uparrow}$ classifier of Definition 59.94. Moreover, the successive restriction $(f \restriction_U) \restriction_V$ and the direct restriction along the certified composite inclusion $i \circ j : V \subseteq T$ are related by the same classifier and preserve the same graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger.

Proof. For the identity clause, apply Proposition 59.80 to the certified inclusion $e_T : T \subseteq T$. The source-admission transport is the identity transport on the T ledger, so the restricted witness reads the same histories as f.

The unchanged ledger clauses of Definition 59.93 and Definition 59.122 keep the graph relation, codomain classifier ledger, unary precision ledger δ, and modulus ledger fixed. Hence the two witnesses present the same carrier data, and Definition 59.94 relates the identity restriction to f as $\mathsf{ContinuousMap}^{\uparrow}$ representatives.

For the composition clause, apply Theorem 59.82 to the inclusions $j : V \subseteq U$ and $i : U \subseteq T$. It gives the modulus-validity field for both the successive and direct restrictions with the same unary precision ledger δ.

The same theorem also identifies the direct and successive restrictions at the level of the $\mathsf{ContinuousMap}^{\uparrow}$ classifier. Its comparison uses exactly the shared graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger supplied by the restriction policy.

Ten-field fit: traditional target restriction action of uniformly continuous maps; BEDC source BHist source predicates plus ContinuousFunctionCarrier; carrier restricted graph witness; classifier ContinuousMapUp; stability identity and composite source-admission transport; ledger unchanged graph/modulus data; core theorem this action law; exactness identity and composition agreement; standard bridge restriction of uniformly continuous maps; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction functorial action`

Theorem 58.110 (Uniform continuity restriction commutes with terminal modulus extension)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusion $i : U \subseteq T$. Let $f : T \to Z$ be a certified graph witness, and let*

$$source, map, target, modulus, cert, extra, modulus', cert' : \mathsf{BHist}$$

be the BEDC histories recording the source ledger for T, the graph ledger of f, the codomain classifier ledger, the original unary modulus, the terminal certificate, the additional terminal modulus, the composite modulus, and the terminal certificate after composition. Assume that f satisfies the ContinuousMap carrier, totality, single-valuedness, and modulus-validity fields of Definition 59.1 and Definition 59.161 over T, and assume

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert),\\&\mathsf{ContinuousModulusWitness}(cert, extra, cert'),\\&\mathsf{Cont}(modulus, extra, modulus').\end{aligned}$$

Then the $\mathsf{ContinuousMap}^{\uparrow}$ witness obtained by restricting f along i and then applying terminal modulus extension with extra, $modulus'$, and $cert'$ is related by the classifier of Definition 59.94 to the witness obtained by first applying terminal modulus extension over T and then restricting along i. Both witnesses present the restricted graph $f\restriction_U$, the source-admission transport through i, the codomain classifier ledger for Z, the composite modulus ledger $modulus'$, and the terminal certificate ledger $cert'$.

Proof. Apply Theorem 59.162 to the displayed carrier, the terminal modulus witness, and the composite continuation ledger. This gives a continuous-function carrier over T with histories $source, map, target, modulus', cert'$.

Restrict this extended carrier along $i : U \subseteq T$. Proposition 59.80 transports the modulus-validity field to U, while Definition 59.93 and Definition 59.122 keep the graph relation, target classifier, precision ledger, and modulus ledger fixed.

For the other route, first apply Proposition 59.80 to the original witness f. The restricted witness over U carries the same graph ledger map, the same target ledger $target$, and the same modulus and certificate ledgers $modulus, cert$, with only the source-admission hypotheses narrowed through i.

Now apply Theorem 59.162 to this restricted carrier using the same $\mathsf{ContinuousModulusWitness}(cert, extra, cert')$ and the same $\mathsf{Cont}(modulus, extra, modulus')$. The resulting restricted-then-extended witness has composite modulus $modulus'$ and terminal certificate $cert'$.

It remains to compare the two route results. Their graph relation is the same relation read on U, source histories admitted by U are transported to T by the same inclusion certificate, the codomain classifier ledger is the same Z ledger, and the composite modulus and terminal certificate

ledgers are the same displayed histories. Therefore Definition 59.94 relates the two witnesses as $\mathsf{ContinuousMap}^{\uparrow}$ representatives.

Ten-field fit: traditional target commutation of source restriction with terminal modulus extension; BEDC source BHist with certified source predicates, Cont, and ContinuousModulusWitness; carrier ContinuousFunctionCarrier with restricted graph witness; classifier ContinuousMap classifier; stability source-admission transport plus terminal modulus preservation; ledger unchanged graph relation, codomain classifier ledger, composite modulus ledger, and terminal certificate ledger; core theorem this block; exactness equality of the two route witnesses under Definition 59.94; standard bridge restriction and modulus-normalization order independence for uniformly continuous maps; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction terminal modulus package`
Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction terminal modulus commutes`

Theorem 58.111 (Uniform continuity restriction commutes with iterated terminal modulus extension)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusion $i : U \subseteq T$. Let $f : T \to Z$ be a certified graph witness, and let*

$$source, map, target, modulus, cert, extra_0, modulus_0, cert_0, extra_1, modulus_1, cert_1 : \mathsf{BHist}$$

be the BEDC histories recording the source ledger for T, the graph ledger of f, the codomain classifier ledger, the initial unary modulus, the initial terminal certificate, the first added terminal modulus, the first composite modulus, the first terminal certificate after composition, the second added terminal modulus, the second composite modulus, and the final terminal certificate. Assume that f satisfies the ContinuousMap carrier, totality, single-valuedness, and modulus-validity fields of Definition 59.1 and Definition 59.161 over T, and assume

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert),\\
&\mathsf{ContinuousModulusWitness}(cert, extra_0, cert_0), \quad \mathsf{Cont}(modulus, extra_0, modulus_0),\\
&\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1), \quad \mathsf{Cont}(modulus_0, extra_1, modulus_1).
\end{aligned}$$

Then the $\mathsf{ContinuousMap}^{\uparrow}$ witness obtained by restricting f along i and then applying the two terminal modulus extensions with final histories $modulus_1, cert_1$ is related by the classifier of Definition 59.94 to the witness obtained by applying the two terminal modulus extensions over T and then restricting along i. Both routes expose the restricted graph ledger map, the transported source-admission ledger through i, the same target classifier ledger $target$, and final histories $modulus_1, cert_1$.

Proof. Apply Theorem 59.84 to the initial carrier, the witness $\mathsf{ContinuousModulusWitness}(cert, extra_0, cert_0)$, and the continuation ledger $\mathsf{Cont}(modulus, extra_0, modulus_0)$. This relates the route that restricts first and then performs the first terminal extension to the route that performs the first terminal extension over T and then restricts. Both resulting representatives carry restricted graph ledger map, transported source-admission through i, target ledger $target$, and histories $modulus_0, cert_0$.

Apply Theorem 59.162 to the initial carrier and the first terminal data. It keeps the carrier over T live after the first extension, now with histories $source, map, target, modulus_0, cert_0$. Applying the same theorem to the restricted representative supplied by the first commutation keeps the restricted carrier live with the same graph and target ledgers and with histories $modulus_0, cert_0$.

Now apply Theorem 59.84 to these first-extended carriers, using $\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1)$ and $\mathsf{Cont}(modulus_0, extra_1, modulus_1)$. This relates the route that restricts before the second terminal extension to the route that performs the second terminal extension over T before restriction. The two representatives therefore expose the same restricted graph ledger, source-admission transport, target classifier ledger, and final histories $modulus_1, cert_1$.

The first commutation gives a classifier relation between the two intermediate representatives, and the second commutation gives a classifier relation between the two final representatives built from those intermediates. By the transitivity clause in Definition 59.94, the endpoints are related as $\mathsf{ContinuousMap}^{\uparrow}$ witnesses: restricting first and applying both terminal extensions is classified together with extending twice over T and then restricting to U.

Ten-field fit: traditional target finite terminal-modulus normalization under source restriction; BEDC source BHist with certified source predicates, Cont, and two $\mathsf{ContinuousModulusWitness}$ ledgers; carrier $\mathsf{ContinuousFunctionCarrier}$ preserved through two terminal extensions; classifier ContinuousMap classifier with transitivity; stability transported source admission plus preserved modulus-validity fields; ledger restricted graph ledger, target classifier ledger, and final histories $modulus_1, cert_1$; core theorem this block; exactness equality of the two finite route endpoints under Definition 59.94; standard bridge finite modulus-normalization stability for uniformly continuous maps; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction iterated terminal modulus commutes`

Theorem 58.112 (Uniform continuity restriction commutes with visible terminal modulus extension)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusion $i : U \subseteq T$. Let*

$$p, q, source, map, target, modulus, cert, extra, modulus', cert' : \mathsf{BHist}$$

be histories, and assume the visible continuous-function carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q),$$

the terminal modulus witness

$$\mathsf{ContinuousModulusWitness}(cert, extra, cert'),$$

and the terminal modulus composition ledger

$$\mathsf{Cont}(modulus, extra, modulus').$$

Then the $\mathsf{ContinuousMap}^{\uparrow}$ witness obtained by restricting the visible carrier along i and then applying visible terminal modulus extension with $extra$, $modulus'$, and $cert'$ is related by the classifier of Definition 59.94 to the witness obtained by first applying visible terminal modulus extension and then restricting along i. Both routes expose the restricted graph ledger map, the same source-admission transport through i, the visible target ledger $p \cdot target$, the composite modulus ledger $modulus' \cdot q$, and the terminal certificate ledger $(p \cdot cert') \cdot q$.

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction visible terminal modulus commutes`

Proof. Peel the visible carrier by Theorem 59.169. This recovers unary context histories for p and q together with the central carrier

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert).$$

Apply Theorem 59.84 to this central carrier, the source inclusion $i : U \subseteq T$, the witness $\mathsf{ContinuousModulusWitness}(cert, extra, cert')$, and the ledger $\mathsf{Cont}(modulus, extra, modulus')$. The central endpoints are classified together: one restricts first and then extends the terminal modulus, and the other extends over T first and then restricts.

Reattach the visible prefix and suffix to the two central endpoints. Theorem 59.163 supplies the visible terminal extension on the route whose extension is performed after the visible carrier is restricted, and the reverse use of Theorem 59.169 repacks the same unary histories around the endpoint obtained by extending first.

The visible-context exactness theorem identifies the exposed public ledgers on both routes. The graph ledger is the restricted reading of *map*, the source-admission hypotheses are transported through the same inclusion certificate i, the target ledger is $p \cdot target$, and the final ledgers are $modulus' \cdot q$ and $(p \cdot cert') \cdot q$. Therefore the classifier of Definition 59.94 relates the two visible witnesses as $\mathsf{ContinuousMap}^{\uparrow}$ representatives.

Ten-field fit: traditional target commutation of source restriction with visible terminal modulus extension; BEDC source BHist with visible contexts, certified source predicates, Cont, and ContinuousModulusWitness; carrier visible ContinuousFunctionCarrier with restricted graph witness; classifier ContinuousMap classifier; stability source-admission transport plus visible terminal modulus preservation; ledger restricted graph relation, visible target ledger, composite modulus ledger, and visible terminal certificate ledger; core theorem this block; exactness equality of the two visible route endpoints under Definition 59.94; standard bridge restriction and visible modulus-normalization order independence for uniformly continuous maps; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible source restriction terminal modulus commutes`
Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible empty source restriction terminal modulus commutes`

Theorem 58.113 (Uniform continuity visible restriction commutes with modulus chains)**.** *Let*

$$p, q, restricted, source, map, target, target', oldMod, oldCert, \delta_1, \delta_2, \delta, cert, cert' : \mathsf{BHist}$$

be histories. Assume the source restriction ledger

$$\mathsf{Cont}(restricted, \mathsf{e}, source),$$

the visible continuous-function carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, oldMod \cdot q, (p \cdot oldCert) \cdot q),$$

the two-link modulus chain

$$\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert),$$

the composite modulus ledger

$$\mathsf{Cont}(\delta_1, \delta_2, \delta),$$

and a displayed restricted carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot \mathit{restricted}, \mathit{map}, p \cdot \mathit{target}', \delta \cdot q, (p \cdot \mathit{cert}') \cdot q).$$

Then the canonical visible restricted carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot \mathit{restricted}, \mathit{map}, p \cdot \mathit{target}, \delta \cdot q, (p \cdot \mathit{cert}) \cdot q),$$

the central witness

$$\mathsf{ContinuousModulusWitness}(\mathit{target}, \delta, \mathit{cert}),$$

and the readback

$$\mathsf{hsame}(\mathit{target}, \mathit{target}') \wedge \mathsf{hsame}(\mathit{cert}, \mathit{cert}')$$

hold.

Proof. Peel the displayed visible carrier by Theorem 59.169. This exposes the central carrier over $(\mathit{source}, \mathit{map}, \mathit{target}, \mathit{oldMod}, \mathit{oldCert})$ while retaining the same visible prefix p and suffix q.

Apply the checked central chain theorem recorded above, namely BEDC.Derived.ContinuousUp.ContinuousFunctio to the exposed carrier, the source restriction ledger, the displayed modulus chain, and the composite ledger $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. It yields the central restricted carrier

$$\mathsf{ContinuousFunctionCarrier}(\mathit{restricted}, \mathit{map}, \mathit{target}, \delta, \mathit{cert})$$

and the witness $\mathsf{ContinuousModulusWitness}(\mathit{target}, \delta, \mathit{cert})$.

Reattach the visible prefix and suffix with the reverse direction of Theorem 59.169. The resulting public carrier is exactly

$$\mathsf{ContinuousFunctionCarrier}(p \cdot \mathit{restricted}, \mathit{map}, p \cdot \mathit{target}, \delta \cdot q, (p \cdot \mathit{cert}) \cdot q).$$

It remains to compare this canonical carrier with the displayed restricted carrier. The visible-context target-certificate determinacy theorem applies to the two carriers with the same visible source, graph, modulus, prefix, and suffix data, so it returns $\mathsf{hsame}(\mathit{target}, \mathit{target}') \wedge \mathsf{hsame}(\mathit{cert}, \mathit{cert}')$.

Ten-field fit: traditional target commutation of visible source restriction with finite modulus-chain normalization; BEDC source BHist with Cont, visible contexts, and ContinuousModulusChain; carrier visible ContinuousFunctionCarrier with restricted source; classifier hsame on target and certificate histories; stability central chain witness plus visible-context transport; ledger composite modulus δ with unchanged graph ledger; core theorem this visible chain replacement law; exactness target-certificate readback against any displayed restricted carrier; standard bridge visible uniformly continuous restriction under modulus-chain normalization; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible source restriction modulus chain commutes`

Theorem 58.114 (Uniform continuity restriction commutes with three-step terminal modulus reassociation)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusion $i : U \subseteq T$. Let $f : T \to Z$ be a certified graph witness, and let*

$$\mathit{source}, \mathit{map}, \mathit{target}, \mathit{modulus}_0, \mathit{cert}_0, \mathit{extra}_1, \mathit{modulus}_1, \mathit{cert}_1, \mathit{extra}_2, \mathit{modulus}_2, \mathit{cert}_2, \mathit{extra}_3, \mathit{modulus}_3, \mathit{cert}_3, \mathit{ext}$$

be the BEDC histories recording the source ledger for T, the graph ledger of f, the codomain classifier ledger, the initial unary modulus and terminal certificate, the three terminal additions with their sequential output moduli and certificates, and the binary and ternary composite terminal ledgers. Assume that f satisfies the ContinuousMap carrier, totality, single-valuedness, and modulus-validity fields of Definition 59.1 and Definition 59.161 over T, and assume

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus_0, cert_0),\\
&\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1), \quad \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2), \quad \mathsf{ContinuousM}\\
&\mathsf{Cont}(modulus_0, extra_1, modulus_1), \quad \mathsf{Cont}(modulus_1, extra_2, modulus_2), \quad \mathsf{Cont}(modulus_2, extra_3, modulus_3),\\
&\mathsf{Cont}(extra_1, extra_2, extra_{12}), \quad \mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}),\\
&\mathsf{Cont}(extra_{12}, extra_3, extra_{123}), \quad \mathsf{Cont}(modulus_0, extra_{123}, modulus_{123}).
\end{aligned}$$

Then the $\mathsf{ContinuousMap}^{\uparrow}$ *witness obtained by restricting f along i and applying the three terminal modulus extensions with final public histories $map, target, modulus_3, cert_3$ is related by the classifier of Definition 59.94 to the witness obtained by first reassociating the three terminal extensions over T and then restricting along i with final public histories $map, target, modulus_{123}, cert_3$. The comparison includes the terminal-modulus equality* $\mathsf{hsame}(modulus_3, modulus_{123})$*, and both classified endpoints expose the restricted graph ledger map, the source-admission transport through i, the same target ledger target, and the same terminal certificate ledger $cert_3$.*

Proof. First apply Theorem 59.85 to the initial carrier and the first two terminal extensions. This relates the route that restricts before the first two extensions to the route that performs those two extensions over T before restriction. Both intermediate representatives expose the restricted graph ledger *map*, the transported source-admission through i, the target ledger *target*, and terminal data $modulus_2, cert_2$.

Next keep the third extension live on both sides. Apply Theorem 59.84 to the two-step carrier over T using $\mathsf{ContinuousModulusWitness}(cert_2, extra_3, cert_3)$ and $\mathsf{Cont}(modulus_2, extra_3, modulus_3)$. This classifies the endpoint obtained by restricting first and then applying all three terminal extensions with the endpoint obtained by applying the sequential three-step extension over T and then restricting.

Now identify the sequential and reassociated terminal moduli over the unreduced source. Theorem 59.168, with the empty visible prefix and suffix, supplies the carrier with final data $modulus_3, cert_3$, the carrier with final data $modulus_{123}, cert_3$, and the comparison $\mathsf{hsame}(modulus_3, modulus_{123})$.

Restrict the reassociated carrier along $i : U \subseteq T$. Proposition 59.80 transports the modulus-validity field to U, and the ledger policy keeps the graph relation *map*, the target classifier ledger *target*, and the terminal certificate ledger $cert_3$ fixed.

Finally use classifier transitivity in Definition 59.94. The sequential endpoint is classified with the extend-over-T sequential endpoint by the preceding commutation steps, the terminal chapter identifies that endpoint with the reassociated carrier through $\mathsf{hsame}(modulus_3, modulus_{123})$, and restriction of the reassociated carrier gives the displayed final representative. Target and certificate determinacy keep the exposed target and terminal certificate ledgers equal, so the two restricted endpoints are $\mathsf{ContinuousMap}^{\uparrow}$ representatives of the same public certificate.

Ten-field fit: traditional target finite three-step terminal-modulus normalization under source restriction; BEDC source BHist with certified source predicates, Cont, and three ContinuousModulusWitness ledgers; carrier ContinuousFunctionCarrier preserved through sequential and reassociated terminal extensions; classifier ContinuousMap classifier with transitivity; stability transported source admission plus preserved modulus-validity fields; ledger restricted graph ledger, target classifier ledger, final sequential and reassociated modulus ledgers, and terminal certificate ledger; core theorem this block; exactness equality of the two route endpoints plus $\mathsf{hsame}(modulus_3, modulus_{123})$; standard

bridge finite modulus-normalization coherence for uniformly continuous maps; status ProofTarget. □

Theorem 58.115 (Uniform continuity visible restriction commutes with three-step terminal modulus reassociation)**.** *Let Y and Z be certified* $\mathsf{Met}^{\uparrow}$ *objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusion $i : U \subseteq T$. Let $f : T \to Z$ be a certified graph witness, and let*

$$p, q, source, map, target, modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, modulus_2, cert_2, extra_3, modulus_3, cert_3$$

be the visible context histories, the source, graph, and target ledgers for f, the initial visible unary modulus and terminal certificate, the three terminal additions with their sequential output moduli and certificates, and the binary and ternary composite terminal ledgers. Assume that f satisfies the ContinuousMap carrier, totality, single-valuedness, and modulus-validity fields of Definition 59.1 and Definition 59.161 over T, and assume

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_0 \cdot q, (p \cdot cert_0) \cdot q),$$

the three terminal modulus witnesses

$$\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1), \quad \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2), \quad \mathsf{ContinuousM}$$

and the sequential and reassociated terminal modulus ledgers

$$\begin{aligned}&\mathsf{Cont}(modulus_0, extra_1, modulus_1), \quad \mathsf{Cont}(modulus_1, extra_2, modulus_2), \quad \mathsf{Cont}(modulus_2, extra_3, modulus_3),\\ &\mathsf{Cont}(extra_1, extra_2, extra_{12}), \quad \mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}),\\ &\mathsf{Cont}(extra_{12}, extra_3, extra_{123}), \quad \mathsf{Cont}(modulus_0, extra_{123}, modulus_{123}).\end{aligned}$$

Then the $\mathsf{ContinuousMap}^{\uparrow}$ *witness obtained by restricting the visible carrier along i and applying the three visible terminal modulus extensions with exposed public histories $map, p \cdot target, modulus_3 \cdot q, (p \cdot cert_3) \cdot q$ is related by the classifier of Definition 59.94 to the witness obtained by first reassociating the three terminal extensions over the central carrier and then restricting along i with exposed public histories $map, p \cdot target, modulus_{123} \cdot q, (p \cdot cert_3) \cdot q$. The comparison includes the central readback* $\mathsf{hsame}(modulus_3, modulus_{123})$*, and both visible endpoints carry the same source-admission transport through i, the same graph ledger map, the same visible target ledger $p \cdot target$, and the same visible terminal certificate ledger $(p \cdot cert_3) \cdot q$.*

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible source restriction terminal modulus reassociation`

Proof. Peel the visible carrier by Theorem 59.169. This exposes the central carrier

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus_0, cert_0)$$

under the same certified source inclusion $i : U \subseteq T$, while retaining the visible prefix p and suffix q for later reattachment.

Apply Theorem 59.88 to the central carrier, the three ContinuousModulusWitness rows, and the sequential and reassociated Cont rows. The central route that restricts first and then applies the three terminal extensions is classified with the route that first reassociates the three terminal extensions over T and then restricts, and the same step records $\mathsf{hsame}(modulus_3, modulus_{123})$.

Reattach the common visible prefix and suffix to the two central endpoints. The visible terminal-extension theorem supplies the route whose terminal extensions are performed after restriction, and the reverse direction of Theorem 59.169 repacks the endpoint obtained from the reassociated central carrier.

The visible-context exactness theorems identify the public ledgers after reattachment. The sequential endpoint exposes $p \cdot target$, $modulus_3 \cdot q$, and $(p \cdot cert_3) \cdot q$, while the reassociated endpoint exposes $p \cdot target$, $modulus_{123} \cdot q$, and the same visible terminal certificate $(p \cdot cert_3) \cdot q$.

Finally use classifier transitivity from Definition 59.94. The peeled central comparison, the two visible reattachments, and the visible exactness readbacks compose into a $\mathsf{ContinuousMap}^{\uparrow}$ classifier relation between the displayed public endpoints, with the central modulus comparison $\mathsf{hsame}(modulus_3, modulus_{123})$ carried along.

Ten-field fit: traditional target visible source restriction under three-step terminal-modulus reassociation; BEDC source BHist with visible contexts, certified source predicates, Cont, and three ContinuousModulusWitness rows; carrier visible ContinuousFunctionCarrier with restricted source admission; classifier ContinuousMap classifier with transitivity; stability visible-context peeling, central restriction reassociation, and visible reattachment; ledger restricted graph ledger, visible target ledger, sequential and reassociated visible modulus ledgers, and visible terminal certificate ledger; core theorem this visible reassociation statement; exactness public readback with $\mathsf{hsame}(modulus_3, modulus_{123})$; standard bridge public visible uniformly continuous restriction under three terminal modulus extensions; status ProofTarget. □

Theorem 58.116 (Uniform continuity visible restriction three-step terminal modulus normal form)**.** *Let*

$$p, q, restricted, source, map, target, target', modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, modulus_2, cert_2, extra$$

be histories. Assume the source restriction ledger

$$\mathsf{Cont}(restricted, \mathsf{e}, source),$$

the visible continuous-function carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_0 \cdot q, (p \cdot cert_0) \cdot q),$$

the three terminal modulus witnesses

$$\begin{gathered}\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1),\\ \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2),\\ \mathsf{ContinuousModulusWitness}(cert_2, extra_3, cert_3),\end{gathered}$$

the sequential and reassociated terminal modulus ledgers

$$\begin{gathered}\mathsf{Cont}(modulus_0, extra_1, modulus_1), \quad \mathsf{Cont}(modulus_1, extra_2, modulus_2), \quad \mathsf{Cont}(modulus_2, extra_3, modulus_3),\\ \mathsf{Cont}(extra_1, extra_2, extra_{12}), \quad \mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}),\\ \mathsf{Cont}(extra_{12}, extra_3, extra_{123}), \quad \mathsf{Cont}(modulus_0, extra_{123}, modulus_{123}),\end{gathered}$$

and the displayed restricted sequential carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot restricted, map, p \cdot target', modulus_3 \cdot q, (p \cdot cert') \cdot q).$$

Then the visible restricted carrier has the three-step terminal modulus normal form

$$\mathsf{ContinuousFunctionCarrier}(p \cdot restricted, map, p \cdot target, modulus_{123} \cdot q, (p \cdot cert_3) \cdot q),$$

and the displayed sequential endpoint reads back to the same public data:

$$\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert_3, cert') \wedge \mathsf{hsame}(modulus_3, modulus_{123}).$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible source restriction terminal modulus normal form`

Proof. First apply Theorem 59.168 to the unreduced visible carrier, the three terminal witness rows, and the displayed sequential and reassociated Cont ledgers. It supplies the visible sequential carrier with final data $modulus_3, cert_3$, the visible reassociated carrier with final data $modulus_{123}, cert_3$, and the modulus comparison $\mathsf{hsame}(modulus_3, modulus_{123})$.

Restrict the reassociated carrier along the same source ledger $\mathsf{Cont}(restricted, \mathsf{e}, source)$. Proposition 59.80 transports the source-admission field, while the visible context and ledger policies preserve the graph ledger map, target ledger $p \cdot target$, reassociated modulus ledger $modulus_{123} \cdot q$, and certificate ledger $(p \cdot cert_3) \cdot q$.

Next compare the sequential and reassociated routes through Theorem 59.88, applied to the central histories under the same source restriction and terminal ledgers. This identifies the restricted sequential endpoint with the restricted reassociated endpoint and records the same terminal-modulus readback $\mathsf{hsame}(modulus_3, modulus_{123})$.

Finally apply Theorem 59.174 to the canonical restricted sequential carrier and the displayed restricted sequential carrier. They share the visible source $p \cdot restricted$, the graph ledger map, the visible modulus $modulus_3 \cdot q$, and the same visible prefix and suffix, so determinacy gives $\mathsf{hsame}(target, target')$ and $\mathsf{hsame}(cert_3, cert')$. Combining these with the modulus comparison yields the stated normal-form readback.

Ten-field fit: traditional target visible source restriction followed by three terminal modulus extensions; BEDC source BHist with visible contexts, source restriction ledger, Cont, and three ContinuousModulusWitness rows; carrier visible ContinuousFunctionCarrier with restricted source; classifier hsame target, certificate, and modulus readback; stability source-admission restriction plus terminal modulus reassociation; ledger restricted graph ledger, visible target ledger, sequential and reassociated modulus ledgers, and terminal certificate ledger; core theorem this normal-form statement; exactness comparison against any displayed restricted sequential carrier; standard bridge visible uniformly continuous restriction under three terminal modulus extensions; status ProofTarget. □

Theorem 58.117 (Continuous restriction visible modulus-chain functorial normal form)**.** *Let T, U, V, and W be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusions*

$$k : W \subseteq V, \qquad j : V \subseteq U, \qquad i : U \subseteq T.$$

Let

$$p, q, source_T, source_U, source_V, source_W, map, target, target_d, target_s, oldMod, oldCert, \delta_1, \delta_2, \delta, cert, cert_d, cert_s :$$

be histories. Assume the visible carrier over T

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source_T, map, p \cdot target, oldMod \cdot q, (p \cdot oldCert) \cdot q),$$

the source-restriction ledgers

$$\mathsf{Cont}(source_U, \mathsf{e}, source_T), \qquad \mathsf{Cont}(source_V, \mathsf{e}, source_U), \qquad \mathsf{Cont}(source_W, \mathsf{e}, source_V), \qquad \mathsf{Cont}(source_W, \mathsf{e}, s$$

the two-link visible modulus chain

$$\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert),$$

the composite modulus ledger

$$\mathsf{Cont}(\delta_1, \delta_2, \delta),$$

the displayed direct restricted carrier over W

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source_W, map, p \cdot target_d, \delta \cdot q, (p \cdot cert_d) \cdot q),$$

and the displayed successive restricted carrier over W

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source_W, map, p \cdot target_s, \delta \cdot q, (p \cdot cert_s) \cdot q).$$

Then the route that restricts directly from T to W and the route that restricts successively

$$T \longrightarrow U \longrightarrow V \longrightarrow W$$

before applying the same visible modulus-chain replacement have the common public normal form

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source_W, map, p \cdot target, \delta \cdot q, (p \cdot cert) \cdot q),$$

and their displayed target and certificate readbacks agree:

$$\mathsf{hsame}(target, target_d) \wedge \mathsf{hsame}(cert, cert_d) \wedge \mathsf{hsame}(target, target_s) \wedge \mathsf{hsame}(cert, cert_s).$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible source restriction modulus chain functorial normal form`

Proof. First collapse the nested source restrictions. Apply Theorem 59.83 to $i : U \subseteq T$ and $j : V \subseteq U$ to compare the direct restriction from T to V with the successive route through U.

Apply Theorem 59.83 again to the composite inclusion $V \subseteq T$ and $k : W \subseteq V$. This identifies the direct restriction from T to W with the three-step route through U and V at the $\mathsf{ContinuousMap}^{\uparrow}$ classifier, while preserving the graph ledger map, the visible target ledger $p{\cdot}target$, and the source ledger $p \cdot source_W$.

Next normalize the visible modulus data on the direct representative. Theorem 59.87, applied to the direct source ledger $\mathsf{Cont}(source_W, \mathsf{e}, source_T)$ and the chain $\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert)$, supplies the canonical visible carrier over W with public histories map, $p{\cdot}target$, $\delta{\cdot}q$, and $(p{\cdot}cert){\cdot}q$.

It remains to read back the two displayed endpoints. The direct displayed carrier has the same restricted source, graph ledger, visible modulus ledger, and visible prefix and suffix as the canonical direct carrier, so Theorem 59.87 gives $\mathsf{hsame}(target, target_d)$ and $\mathsf{hsame}(cert, cert_d)$.

Transport the same canonical carrier across the classifier comparison supplied by the functorial restriction step. Target and certificate determinacy for visible modulus contexts then applies to the successive displayed carrier, giving $\mathsf{hsame}(target, target_s)$ and $\mathsf{hsame}(cert, cert_s)$. Combining the four readbacks yields the stated common normal form for the direct and successive routes.

Ten-field fit: traditional target nested restriction of uniformly continuous maps followed by a visible two-link modulus-chain replacement; BEDC source BHist with visible contexts, certified source-restriction ledgers, Cont, and ContinuousModulusChain; carrier visible ContinuousFunctionCarrier over the final source W; classifier ContinuousMap classifier plus hsame target and certificate readback; stability identity and composite source-admission transport with modulus-chain preservation; ledger common graph ledger, visible target ledger, composite modulus ledger, and visible certificate ledger; core theorem this normal form; exactness direct-versus-successive route agreement after the same chain replacement; standard bridge functorial source restriction with visible modulus-chain normalization for uniformly continuous maps; status ProofTarget. □

Chapter 59

A Concrete Naming Certificate for $\mathsf{ContinuousMap}^{\uparrow}$

The continuous-map interface $\mathsf{ContinuousMap}^{\uparrow}$ has certificate obligations between two metric spaces from chapter 57. The carrier is a BEDC graph witness between certified source and target point histories, together with a unary precision-indexed modulus relation. Totality over classifier-admitted source histories and single-valuedness up to the target classifier are certificate fields, so the public object is a relation-plus-ledger certificate rather than a host-level map or host-level numeric modulus.

59.1 Carrier definition

Definition 59.1 (ContinuousMap carrier)**.** *Use a graph relation between source point histories and target point histories, equipped with source and target metric ledgers, a totally bounded source witness, a unary precision ledger, and a modulus ledger relating requested source precision to target precision. The carrier includes totality for every source history accepted by the source classifier and single-valuedness up to the target classifier for any two target histories related to the same classifier-admitted source history.*

Lean4 (definition) `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier`

Definition 59.2 (Continuous modulus witness)**.** *For histories source, modulus, and cert,* ContinuousModulusWitn *records the four components*

$$\mathsf{UnaryHistory}(source), \quad \mathsf{UnaryHistory}(modulus), \quad \mathsf{UnaryHistory}(cert), \quad \mathsf{Cont}(source, modulus, cert).$$

Lean4 (definition) `BEDC.Derived.ContinuousUp.ContinuousModulusWitness`

Definition 59.3 (Continuous modulus chain)**.** *For histories source*, $first$, *second*, $target$, ContinuousModulusChain *consists of unary histories for source,* $first$*, second, and* $target$*, plus a middle history* m *with*

$$\mathsf{Cont}(source, first, m) \quad \textit{and} \quad \mathsf{Cont}(m, second, target).$$

Lean4 (definition) `BEDC.Derived.ContinuousUp.ContinuousModulusChain`

Theorem 59.4 (Continuous modulus witness empty-source exactness)**.** *For histories modulus and* $target$*, a one-step modulus witness whose source is empty is exactly a unary target together with classifier equality between the modulus and the target:*

$$\mathsf{ContinuousModulusWitness}(\mathsf{e}, modulus, target) \iff \mathsf{UnaryHistory}(target) \wedge \mathsf{hsame}(modulus, target).$$

Proof. Unpack the witness. The continuation ledger is $\mathsf{Cont}(\mathsf{e}, modulus, target)$, so the left-unit continuation theorem identifies the target with the modulus. This gives the forward classifier equality after symmetry, while the target unary field is one of the witness fields.

Conversely, transport the target unary field across the classifier equality to obtain a unary modulus. The source is unary by the empty-history constructor, and the left-unit continuation equivalence rebuilds $\mathsf{Cont}(\mathsf{e}, modulus, target)$ from the same classifier equality. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness empty source iff`

Theorem 59.5 (Continuous modulus witness empty-modulus exactness)**.** *For histories source and target, a one-step modulus witness whose modulus is empty is exactly unary source evidence, unary target evidence, and classifier equality between the source and the target:*

$$\mathsf{ContinuousModulusWitness}(source, \mathsf{e}, target) \iff \mathsf{UnaryHistory}(source) \wedge \mathsf{UnaryHistory}(target) \wedge \mathsf{hsame}(source, targ$$

Proof. Unpack the witness. Its continuation ledger is $\mathsf{Cont}(source, \mathsf{e}, target)$, so the right-unit continuation theorem identifies *target* with *source*. Symmetry gives the displayed endpoint classifier, and the source and target unary fields are already present in the witness.

Conversely, use the empty-history unary constructor for the modulus. The supplied endpoint classifier, after symmetry, is exactly the right-unit continuation equivalence needed to rebuild $\mathsf{Cont}(source, \mathsf{e}, target)$. Together with the two unary endpoint fields, this reassembles the witness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness empty modulus iff`

Theorem 59.6 (Continuous modulus witness endpoint cycle modulus empty)**.** *For histories source, modulus, target, a one-step continuous modulus witness whose source and target are history-same has empty modulus:*

$$\mathsf{ContinuousModulusWitness}(source, modulus, target) \Longrightarrow \mathsf{hsame}(source, target) \Longrightarrow \mathsf{hsame}(modulus, \mathsf{e}).$$

Proof. The witness contains the continuation ledger $\mathsf{Cont}(source, modulus, target)$. Transport that ledger across the endpoint cycle to get a self-extension of *source*, and apply right-unit uniqueness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness endpoint cycle modulus empty`

Theorem 59.7 (Continuous function carrier composition closure)**.** *If f carries a source history to a middle history with modulus $modF$, and g carries the middle history to a target history with modulus $modG$, then a continuation composite fg with modulus composite $modFG$ carries the source history to the target history.*

Proof. The two carrier witnesses give unary histories for the source, target, maps, and moduli, plus continuation ledgers for the source-to-middle and middle-to-target maps. Unary continuation closure gives unary histories for the composite map and composite modulus. Case analysis on the continuation constructors reduces the source-to-target continuation to associativity of history append, while the supplied target-to-certificate ledger records the composite modulus certificate. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier comp closed`

Theorem 59.8 (Continuous function carrier composition endpoint hsame transport)**.** *For histories* $source, source', middle, target, target', f, g, fg, fg', modF, modG, modFG, modFG', certF, certG, cert, cert'$*, composition of two continuous-function carriers is stable under endpoint, composite map, composite modulus, and certificate history sameness:*

$$\mathsf{hsame}(source, source') \Longrightarrow \mathsf{hsame}(target, target') \Longrightarrow \mathsf{hsame}(fg, fg') \Longrightarrow \mathsf{hsame}(modFG, modFG') \Longrightarrow \mathsf{hsame}(c$$
$$\mathsf{ContinuousFunctionCarrier}(source, f, middle, modF, certF) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(middle, g, target, modG$$
$$\mathsf{Cont}(f, g, fg) \Longrightarrow \mathsf{Cont}(modF, modG, modFG) \Longrightarrow \mathsf{Cont}(target, modFG, cert) \Longrightarrow$$
$$\mathsf{ContinuousFunctionCarrier}(source', fg', target', modFG', cert').$$

Proof. Composition closure first builds the carrier at the displayed composite graph, composite modulus, target, and certificate. Case analysis on the five hsame witnesses transports those histories to the stated endpoint presentation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier comp endpoint hsame transport`

Theorem 59.9 (Continuous modulus chain composite endpoint hsame transport)**.** *For histories* $source, source', first, second, target, target', composite, composite'$*, endpoint and composite history sameness transports the composite closure witness:*

$$\mathsf{hsame}(source, source') \Longrightarrow \mathsf{hsame}(target, target') \Longrightarrow \mathsf{hsame}(composite, composite') \Longrightarrow$$
$$\mathsf{ContinuousModulusChain}(source, first, second, target) \Longrightarrow \mathsf{Cont}(first, second, composite) \Longrightarrow$$
$$\mathsf{ContinuousModulusWitness}(source', composite', target').$$

Proof. First compose the two-link modulus chain with the displayed continuation ledger. The three hsame witnesses identify the source, target, and composite histories with their transported presentations, so the resulting continuous modulus witness has the transported endpoints. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain composite endpoint hsame transport`

Theorem 59.10 (Continuous modulus chain composite public readback)**.** *For histories* $source, first, second, targe$ *a two-link modulus chain and a public composite modulus ledger give the chain-level readback:*

$$\mathsf{ContinuousModulusChain}(source, first, second, target) \Longrightarrow \mathsf{Cont}(first, second, composite) \Longrightarrow$$
$$\mathsf{ContinuousModulusWitness}(source, composite, target) \wedge$$
$$\forall target'.\ \mathsf{ContinuousModulusWitness}(source, composite, target') \Longrightarrow \mathsf{hsame}(target, target').$$

Proof. Apply Theorem 59.105 to the chain and composite ledger to obtain $\mathsf{ContinuousModulusWitness}(source, comp$

For any competing $target'$, apply Theorem 59.127 to this witness, the competing witness, reflexivity of the shared source, and the shared composite modulus. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain composite public readback`

Theorem 59.11 (Continuous function carrier composition through modulus chain)**.** *If two continuous-function carriers compose through* fg*, and their moduli form a concrete modulus chain over the target certificate, then the composite modulus ledger yields the composite continuous-function carrier:*

$$\mathsf{ContinuousFunctionCarrier}(source, f, middle, modF, certF) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(middle, g, target, modG$$
$$\mathsf{Cont}(f, g, fg) \Longrightarrow \mathsf{ContinuousModulusChain}(target, modF, modG, cert) \Longrightarrow \mathsf{Cont}(modF, modG, modFG) \Longrightarrow$$
$$\mathsf{ContinuousFunctionCarrier}(source, fg, target, modFG, cert).$$

Proof. The modulus chain and the displayed modulus continuation produce a concrete modulus witness from *target* through *modFG* to *cert*. Its continuation field is the target-certificate ledger required by continuous-function composition closure. Feeding that ledger together with the two function carriers, the graph continuation, and the modulus continuation gives the composite carrier. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier comp modulus chain closed`

Theorem 59.12 (Continuous function carrier empty-map identity)**.** *For histories source, modulus, and cert, a certified modulus witness over the source ledger determines the identity continuous-function carrier:*

$$\mathsf{ContinuousModulusWitness}(source, modulus, cert) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(source, \mathsf{e}, source, modulus, cert)$$

Proof. Unpack the modulus witness. It supplies unary histories for *source*, *modulus*, and *cert*, together with the supplied certificate continuation $\mathsf{Cont}(source, modulus, cert)$.

The empty map ledger is unary by the empty-history constructor. The graph part of the identity carrier is the right-unit continuation $\mathsf{Cont}(source, \mathsf{e}, source)$.

Reassemble ContinuousFunctionCarrier from the unary source ledger used for both source and target slots, the unary empty map ledger, the unary modulus ledger, the right-unit graph continuation, and the supplied certificate continuation.

The ten-field certificate fit is the following. The traditional target is the identity uniformly continuous graph. The BEDC source is $BHist$ with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is identity closure. The ledger consists of source, empty map, modulus, and certificate histories. The core theorem is this identity carrier, exactness is the displayed carrier, the standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty map identity`

Theorem 59.13 (Continuous function carrier empty-map exactness)**.** *For histories source, target, modulus, and cert, the empty graph map inside* ContinuousFunctionCarrier *is exact:*

$$\mathsf{ContinuousFunctionCarrier}(source, \mathsf{e}, target, modulus, cert) \Longleftrightarrow \mathsf{hsame}(target, source) \wedge \mathsf{ContinuousModulusWitness}$$

Proof. In the forward direction, unpack the carrier. The graph ledger is $\mathsf{Cont}(source, \mathsf{e}, target)$, so the continuation right-unit theorem gives $\mathsf{hsame}(target, source)$. The target-modulus certificate ledger supplies $\mathsf{Cont}(target, modulus, cert)$, and unary continuation closure supplies the unary certificate history. Together with the target and modulus unary fields, these assemble the displayed modulus witness.

Conversely, assume the target-source classifier and the modulus witness over *target*. Transport the target unary ledger across $\mathsf{hsame}(target, source)$ to obtain the source unary ledger. The empty map is unary, the graph ledger is the right-unit continuation read from $\mathsf{hsame}(target, source)$, and the supplied modulus witness gives the target, modulus, certificate, and certificate-ledger fields of the carrier. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty map iff`

Theorem 59.14 (Continuous function carrier hsame transport)**.** *For histories* $source, map, target, modulus, cert$ *and displayed histories* $source', map', target', modulus', cert'$*, if each displayed history is* hsame*-equivalent to the corresponding carrier field, then the carrier transports across those five endpoint identifications:*

$$\mathsf{hsame}(source, source') \wedge \mathsf{hsame}(map, map') \wedge \mathsf{hsame}(target, target') \wedge \mathsf{hsame}(modulus, modulus') \wedge \mathsf{hsame}(cert, c$$
$$\Longrightarrow \mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(source', map', t$$

Proof. Unpack the concrete carrier witness into its four unary ledgers and two continuation ledgers. Case analysis on the five hsame witnesses identifies the displayed source, map, target, modulus, and certificate histories with the original fields. The same unary and continuation ledgers then reassemble the displayed ContinuousFunctionCarrier. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier hsame transport`

Theorem 59.15 (Continuous function carrier target-certificate determinacy)**.** *For histories source, map, target, ta if* ContinuousFunctionCarrier$(source, map, target, modulus, cert)$ *and* ContinuousFunctionCarrier$(source, map, targe$ *then both the target ledger and the certificate ledger are determined up to the history classifier:*

$$\mathsf{hsame}(target, target') \quad \textit{and} \quad \mathsf{hsame}(cert, cert').$$

Proof. Unpack the two carrier witnesses. The first carrier supplies the graph ledger Cont$(source, map, target)$ and the certificate ledger Cont$(target, modulus, cert)$; the second supplies Cont$(source, map, target')$ and Cont$(target', modulus, cert')$.

Continuation determinacy applied to the two graph ledgers gives hsame$(target, target')$. This is the target part of the displayed conclusion.

For the certificate part, keep the common modulus ledger fixed and transport the first certificate continuation across the recovered target sameness. The transported ledger and the second certificate ledger now have the same source history up to hsame and the same modulus history, so continuation respect for hsame gives hsame$(cert, cert')$.

The ten-field certificate fit is the following. The traditional target is single-valued graph-with-modulus evidence. The BEDC source is $BHist$ equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is target and certificate determinacy. The ledger is source, map, target, modulus, and certificate histories. The core theorem is this determinacy result. The exactness predicate is the pair of displayed hsame conclusions. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier target cert deterministic`

Theorem 59.16 (Continuous function carrier composite public readback)**.** *If two continuous-function carriers compose through fg and $modFG$, and a displayed carrier uses the same source, composite map, and composite modulus, then the displayed target and certificate are determined by the canonical composite target and certificate:*

$$\mathsf{hsame}(target, target') \quad \textit{and} \quad \mathsf{hsame}(cert, cert').$$

Proof. Continuous-function composition closure constructs the canonical composite carrier from the two input carriers and the supplied continuation ledgers for fg, $modFG$, and $cert$. Target-certificate determinacy compares this canonical carrier with the displayed carrier over the same source, map, and modulus, yielding the two public readback equalities. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier comp public readback`

Theorem 59.17 (Continuous function carrier map determinacy)**.** *For histories source, map, map′, target, modulus if two continuous-function carrier witnesses share the same source, target, modulus, and certificate, then their graph maps are determined up to* hsame*:*

ContinuousFunctionCarrier$(source, map, target, modulus, cert) \Longrightarrow$ ContinuousFunctionCarrier$(source, map', target,$

Proof. Unpack both carrier witnesses. Their graph ledgers are $\mathsf{Cont}(source, map, target)$ and $\mathsf{Cont}(source, map', target)$. Continuation left cancellation with the common source history and common target history yields $\mathsf{hsame}(map, map')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier map deterministic`

Theorem 59.18 (Continuous function carrier source determinacy)**.** *For histories $source, source', map, target, mod$ if two continuous-function carrier witnesses share the same graph map, target, modulus, and certificate, then their source histories are determined up to* hsame*:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(source', map, target,$$

Proof. Unpack both carrier witnesses. Their graph ledgers are $\mathsf{Cont}(source, map, target)$ and $\mathsf{Cont}(source', map, target)$. Continuation right cancellation with the common map history and common target history yields $\mathsf{hsame}(source, source')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier source deterministic`

Theorem 59.19 (Continuous function carrier modulus determinacy)**.** *For histories $source, map, target, modulus,$ if two continuous-function carrier witnesses share the same graph target and terminal certificate, then their modulus histories are determined up to* hsame*:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(source, map, target,$$

Proof. Unpack both carrier witnesses. Their certificate ledgers are $\mathsf{Cont}(target, modulus, cert)$ and $\mathsf{Cont}(target, modulus', cert)$. Continuation left cancellation with the common target history and common certificate history yields $\mathsf{hsame}(modulus, modulus')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier modulus deterministic`

Theorem 59.20 (Continuous function carrier prefix closure)**.** *For histories p, source, map, $targetHist$, modulus, and $certHist$, a visible unary prefix on the source, target, and certificate ledgers preserves the full continuous-function carrier:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(source, map, targetHist, modulus, certHist) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot targetHist, modulus, p \cdot certHist).$$

Proof. Unpack the carrier into unary histories for the source, target, map, and modulus, together with continuations $targetHist = source \cdot map$ and $certHist = targetHist \cdot modulus$.

Unary append closure supplies the prefixed source and target histories $p \cdot source$ and $p \cdot targetHist$. The map and modulus histories are kept unchanged, so their unary witnesses are reused directly.

The graph ledger for the prefixed carrier follows by applying the prefix p to the continuation and reassociating append:

$$(p \cdot source) \cdot map = p \cdot (source \cdot map) = p \cdot targetHist.$$

The modulus-certificate ledger is transported in the same way:

$$(p \cdot targetHist) \cdot modulus = p \cdot (targetHist \cdot modulus) = p \cdot certHist.$$

The ten-field certificate fit is the following. The traditional target is prefix-stable continuous graph evidence. The BEDC source is $BHist$ equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is prefix closure of the graph and modulus-certificate ledgers. The ledger consists of source, map, target, modulus, and certificate histories. The core theorem is this prefix closure, exactness is the displayed carrier witness, the standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefix closed`

Theorem 59.21 (Continuous modulus witness prefix exactness)**.** *For histories p, s, δ, t, a common visible unary prefix on the source and target ledgers is exactly the same as unary evidence for the prefix together with the unprefixed one-step modulus witness:*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousModulusWitness}(s, \delta, t).$$

Proof. For the forward direction, unpack the prefixed witness into unary histories for $p \cdot s$, δ, and $p \cdot t$, together with the continuation ledger

$$(p \cdot s) \cdot \delta = p \cdot t.$$

Unary append factorization on $p \cdot s$ recovers $\mathsf{UnaryHistory}(p)$ and $\mathsf{UnaryHistory}(s)$. The same factorization on $p \cdot t$ recovers $\mathsf{UnaryHistory}(t)$. Associativity rewrites the displayed continuation ledger as $p \cdot (s \cdot \delta) = p \cdot t$, and left cancellation on the continuation ledger recovers $s \cdot \delta = t$. These data reassemble $\mathsf{ContinuousModulusWitness}(s, \delta, t)$.

For the reverse direction, project $\mathsf{UnaryHistory}(p)$ and the unprefixed witness from the conjunction. Unpacking the witness supplies unary histories for s, δ, and t, and the continuation ledger $s \cdot \delta = t$.

Unary append closure gives unary histories for $p \cdot s$ and $p \cdot t$. Prefixed continuation associativity transports the unprefixed ledger to $(p \cdot s) \cdot \delta = p \cdot t$, so the prefixed witness is reconstructed.

The ten-field certificate fit is the following. The traditional target is one-step modulus readback. The BEDC source is $BHist$ equipped with Cont. The carrier is ContinuousModulusWitness and the classifier is hsame. The stability obligation is prefix exactness. The ledger consists of source, modulus, target, and prefix histories. The core theorem is this iff, exactness is the displayed iff, the standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefix iff`

Theorem 59.22 (Continuous modulus witness suffix exactness)**.** *For histories p, s, δ, t, a common visible unary suffix on the modulus and target ledgers is exactly the same as unary evidence for the suffix together with the unsuffixed one-step modulus witness:*

$$\mathsf{ContinuousModulusWitness}(s, \delta \cdot p, t \cdot p) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousModulusWitness}(s, \delta, t).$$

Proof. For the forward direction, unpack the suffixed witness. Unary append factorization on $\delta \cdot p$ gives unary δ and unary p, while factorization on $t \cdot p$ gives unary t. The continuation ledger has the common right suffix p after associativity, so right cancellation recovers $t = s \cdot \delta$. These fields reassemble the unsuffixed witness.

For the reverse direction, unary closure appends the unary suffix to both the modulus and target histories. Associativity transports the unsuffixed continuation ledger to the suffixed continuation ledger. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness suffix iff`

Theorem 59.23 (Continuous modulus witness visible context exactness)**.** *For histories p, q, s, δ, t, simultaneous visible context on the source, modulus, and target ledgers is exactly the pair of unary context witnesses together with the base one-step modulus witness:*

$$\mathsf{ContinuousModulusWitness}(p{\cdot}s, \delta{\cdot}q, (p{\cdot}t){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{ContinuousModulusWitness}(s, \delta, t$$

Proof. Peel the right suffix from the modulus and target ledgers by suffix exactness. The remaining witness has the common left prefix on source and target, so prefix exactness recovers the unary prefix and the central witness. Conversely, rebuild the prefixed central witness first, then reattach the right suffix. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness visible context iff`

Theorem 59.24 (Continuous function carrier visible modulus context exactness)**.** *For histories $p, q, source, map, target, modulus, cert$, a visible prefix on the source, target, and certificate ledgers together with a visible suffix on the modulus and certificate ledgers is exactly unary evidence for the two context histories together with the central continuous-function carrier:*

$$\mathsf{ContinuousFunctionCarrier}(p{\cdot}source, map, p{\cdot}target, modulus{\cdot}q, (p{\cdot}cert){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{Co}$$

Proof. Peel the right suffix from the modulus and certificate ledgers by modulus suffix exactness. The remaining carrier has the common left prefix on source, target, and certificate, so carrier prefix exactness recovers the unary prefix and the central carrier. Conversely, rebuild the prefixed carrier first, then reattach the modulus suffix. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context iff`

Theorem 59.25 (Continuous function carrier visible-context empty-map exactness)**.** *For histories $p, q, source, target, modulus, cert$, the empty graph map remains exact under visible prefix and suffix ledgers:*

$$\mathsf{ContinuousFunctionCarrier}(p{\cdot}source, \mathsf{e}, p{\cdot}target, modulus{\cdot}q, (p{\cdot}cert){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{hsame}$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context empty map exactness`

Proof. For the forward direction, apply Theorem 59.169 to strip the visible prefix from source, target, and certificate and the visible suffix from modulus and certificate. The exposed central carrier has empty map, so Theorem 59.13 gives $\mathsf{hsame}(target, source)$ and the central modulus witness.

For the reverse direction, start from unary context evidence, the *target–source* classifier, and the central modulus witness. Use Theorem 59.13 to rebuild the central empty-map carrier, then apply Theorem 59.169 to restore the visible prefix and suffix ledgers.

The ten-field certificate fit is the identity uniformly continuous graph readback over the $BHist/\mathsf{Cont}$ source, with ContinuousFunctionCarrier as carrier, hsame as classifier, visible prefix/suffix stability as the context law, the empty graph map as the readback field, central modulus witness exactness as the certificate content, source and target ledgers classified by hsame, modulus and certificate ledgers preserved by the suffix, and ContinuousMapUp identity-map use downstream. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context empty map iff`

↪ variant `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context empty map exactness`

Theorem 59.26 (Continuous modulus chain visible context exactness)**.** *For histories $p, q, source, first, second, tar$ a visible prefix on the source and target together with a visible suffix on the second modulus and target is exactly unary evidence for the two contexts together with the central two-link chain:*

$$\mathsf{ContinuousModulusChain}(p{\cdot}source, first, second{\cdot}q, (p{\cdot}target){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{Continuousl}$$

Proof. Peel the right suffix from the second modulus and target by chain suffix exactness. The remaining chain has the common left prefix on source and target, so chain prefix exactness exposes unary p and the central chain. Conversely, rebuild the prefixed chain first, then reattach the suffix. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain visible context iff`

Theorem 59.27 (Continuous modulus chain visible context second determinacy)**.** *For histories $p, q, source, first, second, second', target$, if two visible-context two-link modulus chains share the same visible source, first modulus, and visible target,*

$$\mathsf{ContinuousModulusChain}(p{\cdot}source, first, second{\cdot}q, (p{\cdot}target){\cdot}q) \quad \textit{and} \quad \mathsf{ContinuousModulusChain}(p{\cdot}source, first, s$$

then secondhsame*second'*.

Proof. Apply the visible-context exactness statement to both chains. This removes the common prefix and suffix contexts and exposes two central chains with the same source, first modulus, and target. The ordinary second-modulus determinacy theorem identifies the two central second moduli. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain visible context second deterministic`

Theorem 59.28 (Continuous function carrier visible-context field determinacy)**.** *For histories $p, q, source, source', map, map', target, target', modulus, modulus', cert, cert'$, visible-modulus-context continuous-function carriers determine each central public field as follows.*

1. *Same visible source, target, modulus, and certificate determine the map:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(p$$

2. *Same visible map, target, modulus, and certificate determine the source:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(p$$

3. *Same visible source, map, target, and certificate determine the modulus:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(p$$

4. *Same visible source, map, and modulus determine the target and certificate:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(p$$

Proof. 1. In the map clause, apply Theorem 59.169 to the two displayed visible carriers. The exposed central carriers share source, target, modulus, and certificate, so Theorem 59.17 gives $\mathsf{hsame}(map, map')$.

2. In the source clause, apply the same exactness theorem to the two displayed visible carriers. The exposed central carriers share map, target, modulus, and certificate, so Theorem 59.18 gives $\mathsf{hsame}(source, source')$.

3. In the modulus clause, apply the same exactness theorem to the two displayed visible carriers. The exposed central carriers share source, map, target, and certificate, so Theorem 59.19 gives $\mathsf{hsame}(modulus, modulus')$.

4. In the target-certificate clause, apply the same exactness theorem to the two displayed visible carriers. The exposed central carriers share source, map, and modulus, so Theorem 59.15 gives $\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert, cert')$.

□

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context field determinacy`

Theorem 59.29 (Continuous function carrier visible-context target-certificate determinacy)**.** *For histories $p, q, source, map, target, target', modulus, cert, cert'$, if both visible-modulus-context carrier presentations*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target', modulus \cdot q, (p \cdot cert') \cdot q)$$

hold, then the public target and certificate ledgers are determined by the central presentation:

$$\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert, cert').$$

Proof. Apply Theorem 59.169 to the first visible carrier. This recovers the unary context histories $\mathsf{UnaryHistory}(p)$ and $\mathsf{UnaryHistory}(q)$ together with the central witness $\mathsf{ContinuousFunctionCarrier}(source, map, targe$

Apply the same exactness theorem to the second visible carrier. The common visible prefix and suffix are peeled in the same way, producing the central witness $\mathsf{ContinuousFunctionCarrier}(source, map, target', moc$

Now apply Theorem 59.15 to the two central carrier witnesses. It gives the displayed $\mathsf{hsame}(target, target')$ and $\mathsf{hsame}(cert, cert')$ conclusions, which are already the public target and certificate comparisons required here.

The ten-field certificate fit is the following. The traditional target is public target-certificate determinacy for visible continuous-function carrier presentations. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is visible-context public readback. The ledger is source, map, target, modulus, and certificate histories together with the visible prefix and suffix contexts. The core theorem is this result. The exactness predicate is the displayed pair of hsame conclusions. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context target cert deterministic`

Theorem 59.30 (Continuous function carrier visible-context map determinacy)**.** *For histories* $p, q, source, map, map', target, modulus, cert$*, if both visible-modulus-context carrier presentations*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map', p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q)$$

hold, then the public graph map ledger is determined by the central presentation:

$$\mathsf{hsame}(map, map').$$

Proof. Apply Theorem 59.169 to the first visible carrier. This removes the shared visible prefix and suffix contexts and exposes the central witness $\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert)$.

Apply the same visible-context exactness theorem to the second carrier. The same source, target, modulus, and certificate ledgers remain, producing $\mathsf{ContinuousFunctionCarrier}(source, map', target, modulus, ce$

Now apply Theorem 59.17 to the two central carrier witnesses. It gives the displayed $\mathsf{hsame}(map, map')$ comparison, which is already the public visible-context map readback required here.

The ten-field certificate fit is the following. The traditional target is visible map-ledger uniqueness. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is visible-context map readback. The ledger is source, map, target, modulus, and certificate histories together with the visible prefix and suffix contexts. The core theorem is this result. The exactness predicate is the displayed hsame conclusion. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context map deterministic`

Theorem 59.31 (Continuous function carrier visible-context graph-modulus determinacy)**.** *For histories* $p, q, source, map, map', target, modulus, modulus', cert$*, if both visible-modulus-context carrier presentations*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map', p \cdot target, modulus' \cdot q, (p \cdot cert) \cdot q)$$

hold, then the public graph and modulus ledgers are simultaneously determined:

$$\mathsf{hsame}(map, map') \wedge \mathsf{hsame}(modulus, modulus').$$

Proof. Apply Theorem 59.169 to both visible carrier hypotheses. The common displayed prefix and suffix are peeled away, leaving central carriers over $(source, map, target, modulus, cert)$ and $(source, map', target, modulus', cert)$.

Apply Theorem 59.139 to the two central carriers. This exposes graph ledgers $\mathsf{Cont}(source, map, target)$ and $\mathsf{Cont}(source, map', target)$, and certificate ledgers $\mathsf{Cont}(target, modulus, cert)$ and $\mathsf{Cont}(target, modulus', cert)$

Continuation left cancellation on the two graph ledgers gives $\mathsf{hsame}(map, map')$. The same cancellation principle on the two target-certificate ledgers gives $\mathsf{hsame}(modulus, modulus')$, and the two comparisons are paired as the displayed conclusion.

The ten-field certificate fit is: traditional target visible continuous-function determinacy; BEDC source BHist with Cont; carrier ContinuousFunctionCarrier; classifier hsame; stability obligation visible-context public readback; ledger source, map, target, modulus, certificate, prefix, and suffix; core theorem this statement; exactness the displayed pair of hsame conclusions; standard bridge deferred; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context graph modulus deterministic`

Theorem 59.32 (Continuous function carrier visible-context cycle tails empty)**.** *For histories $p, q, source, map, target, modulus, cert$, a visible-context continuous-function carrier whose central source and certificate are history-same has empty central graph and modulus tails:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q) \Longrightarrow \mathsf{hsame}(source, cert) \Longrightarrow \mathsf{hsame}$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context cycle tails empty`

Proof. Apply Theorem 59.169 to the displayed visible carrier. This recovers unary witnesses for the visible prefix p and suffix q, and it exposes the central carrier $\mathsf{ContinuousFunctionCarrier}(source, map, target, modulu$

Apply Theorem 59.140 to the central carrier and the displayed $\mathsf{hsame}(source, cert)$ cycle. The endpoint-certificate cycle cancellation theorem gives exactly $\mathsf{hsame}(map, \mathsf{e}) \wedge \mathsf{hsame}(modulus, \mathsf{e})$.

The ten-field certificate fit is the following. The traditional target is visible cycle-tail pruning. The BEDC source is BHist with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is visible-context central readback. The ledger is source, map, target, modulus, certificate, prefix, and suffix histories. The core theorem is this statement. The exactness predicate is the displayed pair of empty-tail conclusions. The standard bridge is deferred, and the status is ProofTarget. □

Theorem 59.33 (Continuous function carrier visible-context composition closure)**.** *For histories $p, q, source, middle, target, f, g, fg, modF, modG, modFG, certF, certG, cert$, suppose the two contextualized carriers*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, f, p \cdot middle, modF \cdot q, (p \cdot certF) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot middle, g, p \cdot target, modG \cdot q, (p \cdot certG) \cdot q)$$

hold. If the graph, modulus, and target-certificate ledgers

$$\mathsf{Cont}(f, g, fg), \quad \mathsf{Cont}(modF, modG, modFG), \quad \mathsf{Cont}(target, modFG, cert)$$

hold, then the composite carrier remains inside the same visible context:

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, fg, p \cdot target, modFG \cdot q, (p \cdot cert) \cdot q).$$

Proof. Apply Theorem 59.169 to the first contextualized carrier. This recovers unary witnesses for the visible prefix p and suffix q, together with the central carrier $\mathsf{ContinuousFunctionCarrier}(source, f, middle, modF,$

Apply the same visible-context exactness theorem to the second contextualized carrier. The common contexts are peeled away, exposing $\mathsf{ContinuousFunctionCarrier}(middle, g, target, modG, certG)$ over the same central middle and target histories.

Apply Theorem 59.7 to these two central carriers with the displayed graph, modulus, and target-certificate ledgers. The result is the central composite carrier $\mathsf{ContinuousFunctionCarrier}(source, fg, target, modFG,$

Finally use Theorem 59.169 in the reverse direction, with the recovered unary witnesses for p and q, to reattach the visible prefix and suffix. This yields the displayed composite carrier in the same visible context.

The ten-field certificate fit is the following. The traditional target is composition closure for contextual continuous-function carriers. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is contextual composition closure with fixed visible prefix and suffix. The ledger consists of source, middle, target, graph map, modulus, certificate, visible prefix, and visible suffix histories. The core theorem is this visible-context closure statement. The exactness claim is the reverse use of visible-context exactness after central composition closure. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context comp central package`

Theorem 59.34 (Continuous function carrier visible-context composition public readback)**.** *For histories* $p, q, source, middle, target, target', f, g, fg, modF, modG, modFG, certF, certG, cert, cert'$*, suppose the two contextualized carriers*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, f, p \cdot middle, modF \cdot q, (p \cdot certF) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot middle, g, p \cdot target, modG \cdot q, (p \cdot certG) \cdot q)$$

hold, together with the graph, modulus, and target-certificate ledgers

$$\mathsf{Cont}(f, g, fg), \quad \mathsf{Cont}(modF, modG, modFG), \quad \mathsf{Cont}(target, modFG, cert).$$

If a displayed visible composite carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, fg, p \cdot target', modFG \cdot q, (p \cdot cert') \cdot q)$$

also holds, then the public composite target and certificate read back to the canonical central pair:

$$\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert, cert').$$

Proof. Apply Theorem 59.169 to the first contextualized carrier. This peels the common visible prefix and suffix, and it exposes the central carrier $\mathsf{ContinuousFunctionCarrier}(source, f, middle, modF, certF)$.

Apply the same visible-context exactness theorem to the second contextualized carrier. The central carrier $\mathsf{ContinuousFunctionCarrier}(middle, g, target, modG, certG)$ is recovered over the same middle history and canonical target history.

Apply the visible-context exactness theorem once more to the displayed composite carrier. This removes the displayed visible context and gives the central displayed carrier $\mathsf{ContinuousFunctionCarrier}(source, fg, ta$

Now apply Theorem 59.16 to the two central input carriers, the three displayed continuation ledgers, and the central displayed composite carrier. The central public readback theorem gives exactly $\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert, cert')$.

The ten-field certificate fit is the following. The traditional target is public readback for contextual continuous-function composition. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is contextual composite target and certificate readback. The ledger consists of source, middle, target, displayed target, graph map, modulus, certificate, displayed certificate, visible prefix, and visible suffix histories. The core theorem is this visible-context readback statement. The exactness claim is the central target-certificate pair returned after peeling visible context. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context composition public readback`

Theorem 59.35 (Continuous function carrier visible-context composite ledger determinacy)**.** *For histories* $p, q, source, middle, target, f, g, fg, fg', modF, modG, modFG, modFG', certF, certG, cert, cert'$*, suppose the two visible-context input carriers*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, f, p \cdot middle, modF \cdot q, (p \cdot certF) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot middle, g, p \cdot target, modG \cdot q, (p \cdot certG) \cdot q)$$

hold. If both composite ledger triples

$$\begin{array}{lll} \mathsf{Cont}(f, g, fg), & \mathsf{Cont}(modF, modG, modFG), & \mathsf{Cont}(target, modFG, cert), \\ \mathsf{Cont}(f, g, fg'), & \mathsf{Cont}(modF, modG, modFG'), & \mathsf{Cont}(target, modFG', cert') \end{array}$$

hold, then the public composite graph, composite modulus, and composite certificate ledgers are independent of the chosen admissible triple:

$$\mathsf{hsame}(fg, fg') \wedge \mathsf{hsame}(modFG, modFG') \wedge \mathsf{hsame}(cert, cert').$$

Proof. Apply Theorem 59.178 to the two input carriers and the first composite ledger triple. This builds the visible composite carrier over $(fg, modFG, cert)$. Apply the same closure theorem to the same input carriers and the second composite ledger triple, giving the visible composite carrier over $(fg', modFG', cert')$.

Apply continuation determinacy, Theorem 18.16, to the two graph ledgers $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f, g, fg')$. Apply the same determinacy theorem to the two modulus ledgers $\mathsf{Cont}(modF, modG, modFG)$ and $\mathsf{Cont}(modF, modG, modFG')$. These give $\mathsf{hsame}(fg, fg')$ and $\mathsf{hsame}(modFG, modFG')$.

Use Theorem 59.169 to peel the visible prefix and suffix from the two composite carriers. Then use Theorem 59.14 to place the two central composite carriers over a common graph and modulus representative while leaving the target fixed.

Now Theorem 59.15 applies to the aligned central carriers. Its certificate conclusion gives $\mathsf{hsame}(cert, cert')$, which combines with the graph and modulus comparisons above to give the displayed triple classifier.

The ten-field certificate fit is the following. The traditional target is composite-ledger well-definedness for continuous maps. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is composite ledger independence. The ledger consists of source, middle, target, map, modulus, certificate, prefix, and suffix histories. The core theorem is this determinacy result. The exactness claim is the displayed triple classifier. The downstream consumer is ContinuousMapUp composition well-definedness. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context composite ledger determinacy`
Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context composite ledger deterministic`

Theorem 59.36 (Continuous function carrier visible fourfold left-right synchronization)**.** *For BHist histories* $p, q, source, mid_1, mid_2, mid_3, target, f, g, h, k, fg, fgh, hk, ghk, map_L, map_R, mod_F, mod_G, mod_H,$ *suppose the four visible-context one-step carriers*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, f, p \cdot mid_1, mod_F \cdot q, (p \cdot cert_F) \cdot q),\\
&\mathsf{ContinuousFunctionCarrier}(p \cdot mid_1, g, p \cdot mid_2, mod_G \cdot q, (p \cdot cert_G) \cdot q),\\
&\mathsf{ContinuousFunctionCarrier}(p \cdot mid_2, h, p \cdot mid_3, mod_H \cdot q, (p \cdot cert_H) \cdot q),\\
&\mathsf{ContinuousFunctionCarrier}(p \cdot mid_3, k, p \cdot target, mod_K \cdot q, (p \cdot cert_K) \cdot q)
\end{aligned}$$

hold. Suppose also that the left-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}),\\
\mathsf{Cont}(fg, h, fgh), & \mathsf{Cont}(mod_{FG}, mod_H, mod_{FGH}), & \mathsf{Cont}(mid_3, mod_{FGH}, cert_{FGH}),\\
\mathsf{Cont}(fgh, k, map_L), & \mathsf{Cont}(mod_{FGH}, mod_K, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)
\end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(h, k, hk), & \mathsf{Cont}(mod_H, mod_K, mod_{HK}), & \mathsf{Cont}(target, mod_{HK}, cert_{HK}),\\
\mathsf{Cont}(g, hk, ghk), & \mathsf{Cont}(mod_G, mod_{HK}, mod_{GHK}), & \mathsf{Cont}(target, mod_{GHK}, cert_{GHK}),\\
\mathsf{Cont}(f, ghk, map_R), & \mathsf{Cont}(mod_F, mod_{GHK}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)
\end{array}$$

hold. Then the two visible-context composite carriers exist and their public graph, modulus, and certificate histories agree:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map_L, p \cdot target, mod_L \cdot q, (p \cdot cert_L) \cdot q) \wedge\\
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map_R, p \cdot target, mod_R \cdot q, (p \cdot cert_R) \cdot q) \wedge\\
&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).
\end{aligned}$$

Proof. Apply Theorem 59.169 to each of the four displayed visible-context one-step carriers. This peels the common visible prefix p from source, target, and certificate ledgers and the common visible suffix q from modulus and certificate ledgers. The result is unary evidence for the two context histories together with the four central carriers from *source* through *target*.

Apply Theorem 59.156 to those four central carriers and to the displayed left-deep and right-deep ledger arrays. The central theorem constructs the left-deep carrier $\mathsf{ContinuousFunctionCarrier}(source, map_L, ta$ the right-deep carrier $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$, and the three public synchronizations $\mathsf{hsame}(map_L, map_R)$, $\mathsf{hsame}(mod_L, mod_R)$, and $\mathsf{hsame}(cert_L, cert_R)$.

Use Theorem 59.169 in the reverse direction with the recovered unary witnesses for p and q to reattach the visible context to the left-deep central carrier. Use the same reverse implication for the right-deep central carrier. These two applications give exactly the two displayed visible-context composite carriers.

The ten-field certificate fit is the following. The traditional target is fourfold contextual continuous composition coherence. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The ledger data are the source, intermediate, target, graph, modulus, certificate, visible prefix, and visible suffix histories displayed above. The stability field is visible-context left-right bracketing synchronization. The core theorem is this visible fourfold statement. The exactness field is the pair of reattached visible carriers together with the three hsame conclusions. The downstream consumer is ContinuousMapUp associativity coherence, the standard bridge is deferred, and the status is ProofTarget. □

Theorem 59.37 (Continuous modulus witness visible context source determinacy)**.** *For histories p, q, s, s', δ, t, two visible-context one-step modulus witnesses with the same visible modulus and visible target contexts determine the same central source history:*

$$\mathsf{ContinuousModulusWitness}(p{\cdot}s, \delta{\cdot}q, (p{\cdot}t){\cdot}q) \Longrightarrow \mathsf{ContinuousModulusWitness}(p{\cdot}s', \delta{\cdot}q, (p{\cdot}t){\cdot}q) \Longrightarrow \mathsf{hsame}(s, s').$$

Proof. Apply visible-context exactness to both witnesses. The recovered central witnesses share the modulus δ and target t, so one-step source determinacy gives $\mathsf{hsame}(s, s')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness visible context source deterministic`

Theorem 59.38 (Continuous modulus witness visible context modulus determinacy)**.** *For histories $p, q, s, \delta, \delta', t$, two visible-context one-step modulus witnesses with the same visible source and target contexts determine the same central modulus history:*

$$\mathsf{ContinuousModulusWitness}(p{\cdot}s, \delta{\cdot}q, (p{\cdot}t){\cdot}q) \Longrightarrow \mathsf{ContinuousModulusWitness}(p{\cdot}s, \delta'{\cdot}q, (p{\cdot}t){\cdot}q) \Longrightarrow \mathsf{hsame}(\delta, \delta').$$

Proof. Apply visible-context exactness to both witnesses. The recovered central witnesses have the same source s and target t, so one-step modulus determinacy identifies δ and δ'. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness visible context modulus deterministic`

Theorem 59.39 (Continuous modulus witness visible context target determinacy)**.** *For histories p, q, s, δ, t, t', two visible-context one-step modulus witnesses with the same visible source and modulus contexts determine the same central target history:*

$$\mathsf{ContinuousModulusWitness}(p{\cdot}s, \delta{\cdot}q, (p{\cdot}t){\cdot}q) \Longrightarrow \mathsf{ContinuousModulusWitness}(p{\cdot}s, \delta{\cdot}q, (p{\cdot}t'){\cdot}q) \Longrightarrow \mathsf{hsame}(t, t').$$

Proof. Apply visible-context exactness to both witnesses. The recovered central witnesses share source s and modulus δ, so one-step target determinacy gives $\mathsf{hsame}(t, t')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness visible context target deterministic`

Theorem 59.40 (Continuous modulus witness zero-headed component impossibility)**.** *For histories $source, modulus, target$: BHist, no concrete one-step modulus witness has a zero-headed source, modulus, or target component:*

$$(\mathsf{ContinuousModulusWitness}(\mathsf{E0}(source), modulus, target) \to \mathsf{False}) \wedge (\mathsf{ContinuousModulusWitness}(source, \mathsf{E0}(mod$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness e0 component absurd`

Proof. The witness definition records unary-history evidence for its source, modulus, and target components. Each displayed $\mathsf{E0}$ component contradicts the unary no-zero-extension theorem, since unary histories are generated only by the empty history and one-headed extension. □

Theorem 59.41 (Continuous modulus witness left e1 result cases)**.** *For histories $source, modulus, target$, a one-step modulus witness from a visible source endpoint to a visible target endpoint has only the empty modulus case or a visible modulus tail:*

$$\mathsf{ContinuousModulusWitness}(\mathsf{E1}(source), modulus, \mathsf{E1}(target)) \Longrightarrow (modulus = \mathsf{e} \wedge \mathsf{UnaryHistory}(source) \wedge \mathsf{hsame}(sou$$

Proof. Unpack the modulus witness and invert the continuation ledger with visible result $\mathsf{E1}(target)$. The empty modulus case strips the outer visible constructor from the source-target equality and keeps the unary source evidence. The zero-tagged modulus case is ruled out by constructor no-confusion. In the visible modulus case, remove one $\mathsf{E1}$ constructor from the continuation ledger and repack the remaining fields as the tail witness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness left e1 result cases`

Theorem 59.42 (Continuous modulus witness right e1 result exactness)**.** *For histories source, modulus, target, a modulus witness whose modulus and target histories are both visibly tagged has an exact untagged tail:*

$$\mathsf{ContinuousModulusWitness}(source, \mathsf{E1}(modulus), \mathsf{E1}(target)) \Longrightarrow \mathsf{ContinuousModulusWitness}(source, modulus, tar$$

Proof. Unpack the source, modulus, target unary witnesses and the continuation ledger. Unary inversion removes the visible constructor from the modulus and target carriers. The right $\mathsf{E1}$ continuation inversion removes the same constructor from the continuation ledger, yielding the exact untagged modulus witness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness right e1 result exactness`

Theorem 59.43 (Continuous modulus witness right e1 visible source exactness)**.** *For histories source, modulus, target, sourceTail, a modulus witness whose modulus and target histories are both visibly tagged descends to the tail while respecting a visible presentation of the source endpoint:*

$$\mathsf{ContinuousModulusWitness}(source, \mathsf{E1}(modulus), \mathsf{E1}(target)) \Longrightarrow \mathsf{hsame}(source, \mathsf{E1}(sourceTail)) \Longrightarrow \mathsf{ContinuousM}$$

Proof. Apply right one-headed result exactness to strip the visible constructor from the modulus and target components of the witness. The displayed hsame presentation of the source endpoint then transports the descended witness to the concrete visible source $\mathsf{E1}(sourceTail)$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness right e1 visible source exactness`

Theorem 59.44 (Continuous modulus witness right e1 source cases)**.** *For histories source, modulus, target, a modulus witness whose modulus and target histories are both visibly tagged has only the empty source case or a visible source tail:*

$$\mathsf{ContinuousModulusWitness}(source, \mathsf{E1}(modulus), \mathsf{E1}(target)) \Longrightarrow (source = \mathsf{e} \wedge \mathsf{UnaryHistory}(modulus) \wedge \mathsf{hsame}(tar$$

Proof. First descend the witness by stripping the common visible constructor from the modulus and target histories. The descended source carrier is unary, so it is either empty or visibly tagged. In the empty case, the continuation ledger is a left-unit ledger and gives $\mathsf{hsame}(target, modulus)$. In the visible case, constructor equality identifies the source with $\mathsf{E1}(sourceTail)$ and the descended witness is repacked with that source presentation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness right e1 source cases`

Theorem 59.45 (Continuous function carrier terminal modulus extension)**.** *For histories source, map, target, mod a continuous-function carrier remains a continuous-function carrier after the terminal certificate is extended by one more modulus witness and the modulus ledger is composed:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert, extra, cert') =$$

Proof. Unpack the given carrier. This exposes the graph ledger $\mathsf{Cont}(source, map, target)$ and the terminal modulus-certificate ledger $\mathsf{Cont}(target, modulus, cert)$, together with the unary carrier data for the displayed histories.

Unpack the additional modulus witness $\mathsf{ContinuousModulusWitness}(cert, extra, cert')$. It supplies $\mathsf{Cont}(cert, extra, cert')$, so the two ledgers $\mathsf{Cont}(target, modulus, cert)$ and $\mathsf{Cont}(cert, extra, cert')$ assemble the chain $\mathsf{ContinuousModulusChain}(target, modulus, extra, cert')$ with middle history $cert$.

Apply Theorem 59.108 to the original carrier, this chain, and the displayed composition ledger $\mathsf{Cont}(modulus, extra, modulus')$. The replacement theorem repacks the preserved graph data with the composite terminal modulus certificate, giving the displayed carrier conclusion.

The ten-field certificate fit is the following. The traditional target is terminal modulus extension for continuous maps. The BEDC source is BHist with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is preservation under one terminal modulus extension. The ledger is source, map, target, original modulus and certificate, extra modulus, composite modulus, and terminal certificate. The core theorem is this closure, exactness is the displayed carrier conclusion, the standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier terminal modulus extension`

Theorem 59.46 (Continuous function carrier visible terminal modulus extension)**.** *For histories $p, q, source, map, target, modulus, cert, extra, modulus', cert'$, visible continuous-function carrier data remain carrier data after the central terminal certificate is extended and the terminal modulus ledger is composed:*

$$\mathsf{ContinuousFunctionCarrier}(p{\cdot}source, map, p{\cdot}target, modulus{\cdot}q, (p{\cdot}cert){\cdot}q) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert, extr$$

Proof. Peel the visible presentation by Theorem 59.169. This recovers the unary context histories $\mathsf{UnaryHistory}(p)$ and $\mathsf{UnaryHistory}(q)$ together with the central carrier $\mathsf{ContinuousFunctionCarrier}(source, map, target$

Apply Theorem 59.162 to the central carrier, the witness $\mathsf{ContinuousModulusWitness}(cert, extra, cert')$, and the composition ledger $\mathsf{Cont}(modulus, extra, modulus')$. The conclusion is the central carrier $\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus', cert')$.

Use the reverse direction of Theorem 59.169 with the recovered unary histories. It repacks the same prefix p and suffix q around the central carrier, producing the displayed visible carrier conclusion. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus extension`

Theorem 59.47 (Continuous function carrier visible terminal modulus extension output determinacy)**.** *For histories $p, q, source, map, target, target', modulus, cert, extra, modulus', cert', cert''$, suppose*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q)$$

holds, together with $\mathsf{ContinuousModulusWitness}(cert, extra, cert')$ *and* $\mathsf{Cont}(modulus, extra, modulus')$*. If the post-extension visible carrier*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target', modulus' \cdot q, (p \cdot cert'') \cdot q)$$

also holds, then the visible target and terminal certificate are determined:

$$\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert', cert'').$$

Proof. Apply Theorem 59.163 to the original visible carrier, the central witness $\mathsf{ContinuousModulusWitness}(cert, ext$ and the terminal modulus ledger $\mathsf{Cont}(modulus, extra, modulus')$. This constructs the canonical post-extension visible carrier with target *target* and terminal certificate $cert'$.

Compare that canonical carrier with the independently displayed post-extension carrier by Theorem 59.174. The two carrier presentations share p, q, *source*, *map*, and $modulus'$, so the determinacy theorem returns exactly $\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert', cert'')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus extension output determinacy`

Theorem 59.48 (Continuous function carrier visible terminal modulus extension transitive)**.** *For histories* $p, q, source, map, target, modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, modulus_2, cert_2$, *visible continuous-function carrier data remain carrier data after two consecutive terminal certificate extensions and their two terminal modulus ledgers:*

$$\mathsf{ContinuousFunctionCarrier}(p{\cdot}source, map, p{\cdot}target, modulus_0{\cdot}q, (p{\cdot}cert_0){\cdot}q) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert_0, e$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus extension transitive`

Proof. Apply Theorem 59.163 to the displayed visible carrier, the witness $\mathsf{ContinuousModulusWitness}(cert_0, extra_1,$ and the first composition ledger $\mathsf{Cont}(modulus_0, extra_1, modulus_1)$. This gives the visible carrier with terminal modulus $modulus_1$ and terminal certificate $cert_1$.

Apply the same theorem again to that intermediate carrier, the witness $\mathsf{ContinuousModulusWitness}(cert_1, extra_2$ and the second composition ledger $\mathsf{Cont}(modulus_1, extra_2, modulus_2)$. The result is the visible carrier whose terminal modulus is $modulus_2$ and whose terminal certificate is $cert_2$, which is the displayed conclusion.

The ten-field certificate fit is the following. The traditional target is two-step terminal modulus extension for continuous maps. The BEDC source is BHist with Cont, ContinuousModulusWitness, and ContinuousFunctionCarrier. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is preservation under two consecutive terminal modulus extensions. The ledger is the two extra modulus witnesses and the two composite modulus rows. The core theorem is this closure, exactness is the displayed carrier conclusion, the standard bridge is deferred, and the status is ProofTarget. □

Theorem 59.49 (Continuous function carrier visible terminal modulus reassociation)**.** *For histories* $p, q, source, map, target, modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, extra_{12}, modulus_2, modulus_{12}, cert_2$ *sequential two-step terminal extension and the corresponding composite one-step terminal extension produce the same visible terminal modulus data:*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_0 \cdot q, (p \cdot cert_0) \cdot q) \Longrightarrow \\
&\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2) \Longrightarrow \\
&\mathsf{Cont}(modulus_0, extra_1, modulus_1) \Longrightarrow \mathsf{Cont}(modulus_1, extra_2, modulus_2) \Longrightarrow \\
&\mathsf{Cont}(extra_1, extra_2, extra_{12}) \Longrightarrow \mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}) \Longrightarrow \\
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_2 \cdot q, (p \cdot cert_2) \cdot q) \wedge \\
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_{12} \cdot q, (p \cdot cert_2) \cdot q) \wedge \\
&\mathsf{hsame}(modulus_2, modulus_{12}).
\end{aligned}$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus reassociation`

Proof. Apply Theorem 59.165 to the displayed visible carrier, the two certificate-extension witnesses, and the two sequential terminal modulus ledgers. This constructs the sequential visible carrier with terminal data $(modulus_2, cert_2)$.

Next assemble the certificate witnesses $\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1)$ and ContinuousModulusW into $\mathsf{ContinuousModulusChain}(cert_0, extra_1, extra_2, cert_2)$ with middle history $cert_1$. By Theorem 59.105 and the ledger $\mathsf{Cont}(extra_1, extra_2, extra_{12})$, this gives the composite witness ContinuousModulusWitness

Apply Theorem 59.163 to the original visible carrier, this composite witness, and $\mathsf{Cont}(modulus_0, extra_{12}, modu$ The result is the composite one-step visible carrier with terminal data $(modulus_{12}, cert_2)$.

Finally use Theorem 4.56 on $\mathsf{Cont}(modulus_0, extra_1, modulus_1)$, $\mathsf{Cont}(modulus_1, extra_2, modulus_2)$, $\mathsf{Cont}(extra_1, extra_2, extra_{12})$, and $\mathsf{Cont}(modulus_0, extra_{12}, modulus_{12})$. It identifies the sequential and composite terminal moduli, giving $\mathsf{hsame}(modulus_2, modulus_{12})$, and the three displayed conclusions are then packed together. □

↪ variant BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus reassociation

Theorem 59.50 (Continuous function carrier visible terminal modulus reassociation output determinacy)**.** *For histories $p, q, source, map, target, target', modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, extra_{12}, n$ the displayed composite visible output is determined by the reassociated terminal modulus construction:*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_0 \cdot q, (p \cdot cert_0) \cdot q) \Longrightarrow \\
&\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2) \Longrightarrow \\
&\mathsf{Cont}(modulus_0, extra_1, modulus_1) \Longrightarrow \mathsf{Cont}(modulus_1, extra_2, modulus_2) \Longrightarrow \\
&\mathsf{Cont}(extra_1, extra_2, extra_{12}) \Longrightarrow \mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}) \Longrightarrow \\
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target', modulus_{12} \cdot q, (p \cdot cert'') \cdot q) \Longrightarrow \\
&\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert_2, cert'') \wedge \mathsf{hsame}(modulus_2, modulus_{12}).
\end{aligned}$$

Lean4 ✓ BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus reassociation output determinacy

Proof. First apply Theorem 59.166 to the original visible carrier, the two certificate-extension witnesses, and the four terminal modulus ledgers. This supplies the canonical composite visible carrier $\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_{12} \cdot q, (p \cdot cert_2) \cdot q)$ together with $\mathsf{hsame}(modulus_2, modulus_{12})$.

Next compare that canonical composite carrier with the independently displayed composite carrier $\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target', modulus_{12} \cdot q, (p \cdot cert'') \cdot q)$. By Theorem 59.174, the common visible source, map, and terminal modulus determine the public target and certificate, giving $\mathsf{hsame}(target, target')$ and $\mathsf{hsame}(cert_2, cert'')$.

Finally package those two target-certificate comparisons with the modulus comparison obtained from reassociation. The result is the displayed triple $\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert_2, cert'') \wedge \mathsf{hsame}(modulus_2, modulus_{12})$. □

Theorem 59.51 (Continuous function carrier visible terminal modulus three-step reassociation)**.** *For histories $p, q, source, map, target, modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, modulus_2, cert_2, extra_3, mo$ sequential three-step terminal extension and the corresponding composite one-step terminal exten-*

sion produce the same visible terminal modulus data:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_0 \cdot q, (p \cdot cert_0) \cdot q) \Longrightarrow \\
&\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2) \Longrightarrow \\
&\mathsf{ContinuousModulusWitness}(cert_2, extra_3, cert_3) \Longrightarrow \\
&\mathsf{Cont}(modulus_0, extra_1, modulus_1) \Longrightarrow \mathsf{Cont}(modulus_1, extra_2, modulus_2) \Longrightarrow \\
&\mathsf{Cont}(modulus_2, extra_3, modulus_3) \Longrightarrow \mathsf{Cont}(extra_1, extra_2, extra_{12}) \Longrightarrow \\
&\mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}) \Longrightarrow \mathsf{Cont}(extra_{12}, extra_3, extra_{123}) \Longrightarrow \\
&\mathsf{Cont}(modulus_0, extra_{123}, modulus_{123}) \Longrightarrow \\
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_3 \cdot q, (p \cdot cert_3) \cdot q) \wedge \\
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_{123} \cdot q, (p \cdot cert_3) \cdot q) \wedge \\
&\mathsf{hsame}(modulus_3, modulus_{123}).
\end{aligned}$$

Proof. Apply Theorem 59.165 to the displayed visible carrier, the first two certificate-extension witnesses, and the first two sequential terminal modulus ledgers. This gives the visible carrier with terminal data $(modulus_2, cert_2)$. Apply Theorem 59.163 to that carrier, the third certificate-extension witness, and $\mathsf{Cont}(modulus_2, extra_3, modulus_3)$. The sequential visible carrier with terminal data $(modulus_3, cert_3)$ follows.

Next compose the first two certificate witnesses. They form the chain $\mathsf{ContinuousModulusChain}(cert_0, extra_1, ext$ with middle history $cert_1$, so Theorem 59.105 and $\mathsf{Cont}(extra_1, extra_2, extra_{12})$ supply $\mathsf{ContinuousModulusWitness}($

Compose that witness with the third one. The chain $\mathsf{ContinuousModulusChain}(cert_0, extra_{12}, extra_3, cert_3)$ with middle history $cert_2$, together with $\mathsf{Cont}(extra_{12}, extra_3, extra_{123})$, gives $\mathsf{ContinuousModulusWitness}(cert_0, ext$ by the same composite-closure theorem.

Apply Theorem 59.163 to the original visible carrier, the composite witness just constructed, and $\mathsf{Cont}(modulus_0, extra_{123}, modulus_{123})$. This produces the composite one-step visible carrier with terminal data $(modulus_{123}, cert_3)$.

It remains to identify the two terminal moduli. First use Theorem 4.56 on $\mathsf{Cont}(modulus_0, extra_1, modulus_1)$, $\mathsf{Cont}(modulus_1, extra_2, modulus_2)$, $\mathsf{Cont}(extra_1, extra_2, extra_{12})$, and $\mathsf{Cont}(modulus_0, extra_{12}, modulus_{12})$, obtaining $\mathsf{hsame}(modulus_2, modulus_{12})$.

Transport the third terminal continuation along that comparison, carrying $\mathsf{Cont}(modulus_2, extra_3, modulus_3)$ to the row $\mathsf{Cont}(modulus_{12}, extra_3, modulus_3)$. Then apply Theorem 4.56 to $\mathsf{Cont}(modulus_0, extra_{12}, modulus_{12})$, the transported row, $\mathsf{Cont}(extra_{12}, extra_3, extra_{123})$, and $\mathsf{Cont}(modulus_0, extra_{123}, modulus_{123})$. The resulting comparison is $\mathsf{hsame}(modulus_3, modulus_{123})$, and the two visible carriers and this comparison form the displayed triple. □

Theorem 59.52 (Continuous modulus witness modulus determinacy)**.** *If two one-step modulus witnesses have* hsame *source histories and* hsame *target histories, then their modulus histories are* hsame*:*

$$\mathsf{hsame}(modulus, modulus').$$

Proof. Unpack both witnesses, identify the source and target endpoints by hsame, and apply continuation left cancellation to the two modulus ledgers. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness modulus hsame deterministic`

Theorem 59.53 (Continuous modulus witness target determinacy)**.** *If two one-step modulus witnesses have* hsame *source histories and the same modulus history, then their target histories are* hsame*:*

$$\mathsf{hsame}(target, target').$$

Proof. Unpack both witnesses, identify the source endpoint by hsame, and apply continuation result determinacy to the two continuation ledgers with the shared source and modulus. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness target hsame deterministic`

Theorem 59.54 (Continuous modulus witness source determinacy)**.** *If two one-step modulus witnesses have* hsame *target histories and the same modulus history, then their source histories are* hsame*:*

$$\mathsf{hsame}(source, source').$$

Proof. Unpack both witnesses, identify the target endpoint by hsame, and apply continuation right cancellation to the two ledgers with the shared modulus and target. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness source hsame deterministic`

Theorem 59.55 (Continuous modulus witness empty target exactness)**.** *For histories source and modulus, a one-step continuous modulus witness with empty target is exactly the conjunction that both source and modulus are empty histories:*

$$\mathsf{ContinuousModulusWitness}(source, modulus, \mathsf{e}) \iff \mathsf{hsame}(source, \mathsf{e}) \wedge \mathsf{hsame}(modulus, \mathsf{e}).$$

Proof. Unpack the witness into unary carriers and the continuation ledger $\mathsf{Cont}(source, modulus, \mathsf{e})$. Empty-result inversion for continuation gives the two endpoint equalities. Conversely, if both endpoints are empty, the empty unary carrier and the canonical empty continuation rebuild the witness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness empty target iff`

Theorem 59.56 (Continuous empty-source nonempty modulus shape)**.** *For histories target, modulus, an empty-source continuous modulus witness with nonempty modulus has exactly one visible unary payload:*

$$\mathsf{ContinuousModulusWitness}(\mathsf{e}, modulus, target) \wedge \neg\mathsf{hsame}(modulus, \mathsf{e}) \iff \exists r : \mathsf{BHist}.\ target = \mathsf{E1}(r) \wedge modulus = \mathsf{E}$$

Proof. Empty-source modulus exactness identifies *modulus* with *target* and gives unary membership of *target*. Nonemptiness excludes the empty target, unary membership excludes zero-headed targets, and the visible case strips one E1 constructor to expose the unary payload. The reverse direction rebuilds the witness from the visible unary target and reflexive sameness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness empty source nonempty modulus shape iff`

Theorem 59.57 (Continuous modulus chain empty target exactness)**.** *For histories source, first, second, a two-link continuous modulus chain ending at* e *is exactly the conjunction that all three displayed histories are empty:*

$$\mathsf{ContinuousModulusChain}(source, first, second, \mathsf{e}) \iff \mathsf{hsame}(source, \mathsf{e}) \wedge \mathsf{hsame}(first, \mathsf{e}) \wedge \mathsf{hsame}(second, \mathsf{e}).$$

Proof. Unpack the middle history and the two continuation ledgers. Empty-result inversion on the second leg identifies the middle history and *second* with e; after replacing the middle endpoint, empty-result inversion on the first leg identifies *source* and *first* with e. The reverse direction uses the empty middle history and the two right-unit continuations at e. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain empty target iff`

Theorem 59.58 (Continuous modulus chain empty moduli exactness)**.** *For histories source, target, a two-link continuous modulus chain with both moduli empty is exactly the conjunction that the endpoints are unary and the target is history-same to the source:*

$$\mathsf{ContinuousModulusChain}(source, \mathsf{e}, \mathsf{e}, target) \iff \mathsf{UnaryHistory}(source) \wedge \mathsf{UnaryHistory}(target) \wedge \mathsf{hsame}(target, sourc$$

Proof. Unpack the middle history and the two continuation ledgers. Each empty-modulus leg is a right-unit continuation, so the middle endpoint is history-same to the source and the target endpoint is history-same to the middle endpoint. Transitivity gives $\mathsf{hsame}(target, source)$. Conversely, choose *source* as the middle history, use the canonical right-unit continuation for the first leg, and use the displayed endpoint sameness to build the second right-unit continuation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain empty moduli iff`

Theorem 59.59 (Continuous modulus chain empty second witness)**.** *For histories source, first, second, target, if a two-link continuous modulus chain has second*hsamee*, then the first link directly witnesses* $\mathsf{ContinuousModulusWitness}(source, first, target)$*.*

Proof. Unpack the middle history and the two continuation ledgers. The second ledger, transported across *second*hsamee, is compared with the right-unit continuation at the middle endpoint, so the target is history-same to the middle endpoint. Transporting the first continuation result along this endpoint sameness gives the displayed one-step witness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain empty second witness`

Theorem 59.60 (Continuous modulus chain empty first witness)**.** *For histories source, first, second, target, if a two-link continuous modulus chain has first*hsamee*, then the second link directly witnesses* $\mathsf{ContinuousModulusWitness}(source, second, target)$*.*

Proof. Unpack the middle history and the two continuation ledgers. The first ledger, transported across *first*hsamee, is compared with the right-unit continuation at the source endpoint, so the middle endpoint is history-same to the source. Transporting the second continuation source along this endpoint sameness gives the displayed one-step witness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain empty first witness`

Theorem 59.61 (Continuous function carrier empty certificate exactness)**.** *For histories source, map, target, modu a continuous-function carrier with empty certificate is exactly the conjunction that its graph and modulus histories are all empty:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, \mathsf{e}) \iff \mathsf{hsame}(source, \mathsf{e}) \wedge \mathsf{hsame}(map, \mathsf{e}) \wedge \mathsf{hsame}(target, \mathsf{e})$$

Proof. Unpack the graph continuation and the target-to-certificate continuation. Empty-result inversion on the certificate leg identifies *target* and *modulus* with e; after replacing the target endpoint, empty-result inversion on the graph leg identifies *source* and *map* with e. Conversely, when all four histories are empty, the empty unary carrier and the two right-unit continuations rebuild the carrier. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty cert iff`

Theorem 59.62 (Continuous function carrier empty-modulus exactness)**.** *For histories source, map, target, cert, a continuous-function carrier with empty modulus is exactly the graph carrier data together with the statement that the certificate is history-same to the target:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, \mathsf{e}, cert) \iff \mathsf{UnaryHistory}(source) \wedge \mathsf{UnaryHistory}(target) \wedge \mathsf{UnaryHist}$$

Proof. Unpack the continuous-function carrier. The graph fields already supply the three displayed unary histories and the graph continuation ledger. The target-to-certificate leg has empty modulus, so the right-unit continuation law identifies *cert* with *target*. Conversely, the displayed graph data, the empty unary carrier, and the right-unit continuation rebuilt from $\mathsf{hsame}(cert, target)$ reassemble the continuous-function carrier. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty modulus iff`

Theorem 59.63 (Continuous function carrier empty-target exactness)**.** *For histories source, map, modulus, cert, the empty target case of* ContinuousFunctionCarrier *is exact:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, \mathsf{e}, modulus, cert) \iff \mathsf{hsame}(source, \mathsf{e}) \wedge \mathsf{hsame}(map, \mathsf{e}) \wedge \mathsf{UnaryHistory}(mod$$

Proof. In the forward direction, empty-result inversion on the graph ledger identifies the source and map histories with e. The certificate ledger is then a left-unit continuation from e through *modulus*, so the certificate is history-same to the modulus; unary continuation closure supplies the certificate carrier.

Conversely, the displayed empty source and map rebuild the graph ledger by the right-unit continuation at e. The displayed certificate-modulus sameness rebuilds the certificate ledger by the left-unit continuation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty target iff`

Theorem 59.64 (Continuous function carrier empty-source exactness)**.** *For histories map, target, modulus, and cert, the empty source case of* ContinuousFunctionCarrier *is exact:*

$$\mathsf{ContinuousFunctionCarrier}(\mathsf{e}, map, target, modulus, cert) \iff \mathsf{UnaryHistory}(map) \wedge \mathsf{ContinuousModulusWitness}(map$$

Proof. In the forward direction, unpack the carrier. The graph ledger is $\mathsf{Cont}(\mathsf{e}, map, target)$, so the continuation left-unit theorem identifies *target* with *map*. The target-modulus continuation then becomes a modulus witness over *map*, and unary continuation closure supplies the certificate carrier.

Conversely, the displayed modulus witness supplies the map, modulus, certificate, and certificate-continuation fields. The empty source is unary, the target is identified with the map by the displayed hsame, and the graph ledger is the left-unit continuation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source iff`

Theorem 59.65 (Continuous function carrier graph-modulus readback)**.** *For histories source, map, target, modulu every continuous-function carrier directly exposes its graph continuation ledger, its modulus-certificate continuation ledger, and the two corresponding one-step modulus witnesses:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \Longrightarrow \mathsf{Cont}(source, map, target) \wedge \mathsf{Cont}(target, modu$$
$$\wedge\ \mathsf{ContinuousModulusWitness}(source, map, target) \wedge \mathsf{ContinuousModulusWitness}(target, modulus, cert).$$

Proof. Unpack the continuous-function carrier into unary data for *source*, *target*, *map*, and *modulus*, together with the two continuation ledgers. The graph ledger and the first three unary fields form $\mathsf{ContinuousModulusWitness}(source, map, target)$. Unary closure along the target-modulus ledger supplies the carrier for *cert*, and this packages the second witness $\mathsf{ContinuousModulusWitness}(target,$ □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier graph modulus cont readback`

Theorem 59.66 (Continuous function carrier endpoint-certificate cycle tails)**.** *For histories source, map, target, m a continuous-function carrier whose source is history-same to its certificate has empty graph tail and empty modulus tail:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \Longrightarrow \mathsf{hsame}(source, cert) \Longrightarrow \mathsf{hsame}(map, \mathsf{e}) \wedge \mathsf{hsame}($$

Proof. Unpack the carrier into its graph ledger $\mathsf{Cont}(source, map, target)$ and certificate ledger $\mathsf{Cont}(target, modulus, cert)$. Transport the certificate ledger across $\mathsf{hsame}(source, cert)$, obtaining $\mathsf{Cont}(target, modulus, source)$. The two ledgers form a continuation cycle, so mutual-extension cancellation forces both tails, *map* and *modulus*, to be history-same to e. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier endpoint cert cycle tails empty`

Theorem 59.67 (Continuous function carrier endpoint-certificate cycle exactness)**.** *For histories source, map, target, modulus, cert, if a continuous-function carrier closes its public source against its endpoint certificate, then the carrier is an identity presentation at that endpoint:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \Longrightarrow \mathsf{hsame}(source, cert) \Longrightarrow \mathsf{hsame}(map, \mathsf{e}) \wedge \mathsf{hsame}(modulus, \mathsf{e}) \wedge \mathsf{hsame}(target, source) \wedge \mathsf{hsame}(cert, source).$$

Proof. Apply Definition 59.140 to the carrier and the displayed endpoint certificate equality. This gives $\mathsf{hsame}(map, \mathsf{e})$ and $\mathsf{hsame}(modulus, \mathsf{e})$.

Unpack the graph ledger $\mathsf{Cont}(source, map, target)$ from the carrier. Transport that ledger across $\mathsf{hsame}(map, \mathsf{e})$ to obtain $\mathsf{Cont}(source, \mathsf{e}, target)$. The right-unit clause of Definition 21.12 supplies $\mathsf{Cont}(source, \mathsf{e}, source)$, and continuation determinacy from Definition 21.7 identifies *target* with *source*.

Finally, symmetry in Definition 3.8 turns the displayed $\mathsf{hsame}(source, cert)$ into $\mathsf{hsame}(cert, source)$, and the four pieces assemble the stated conjunction. □

The ten-field fit is: traditional target, identity-cycle exactness for continuous-function carriers; BEDC kernel, $BHist$; ledger relation, Cont; carrier, ContinuousFunctionCarrier; classifier, hsame; ledger fields, *source*, *map*, *target*, *modulus*, *cert*; core theorem, Definition 59.141; exactness, the four displayed hsame rows; standard bridge, deferred; downstream consumer, ContinuousMapUp identity and category normalization.

Theorem 59.68 (Continuous function carrier composite endpoint-certificate cycle exactness)**.** *For histories source, middle, target, f, g, fg, modF, modG, modFG, certF, certG, cert, closed composition of continuous-function carriers inherits endpoint-certificate cycle collapse:*

$$\mathsf{ContinuousFunctionCarrier}(source, f, middle, modF, certF) \wedge \mathsf{ContinuousFunctionCarrier}(middle, g, target, modG, c$$
$$\mathsf{Cont}(f, g, fg) \wedge \mathsf{Cont}(modF, modG, modFG) \wedge \mathsf{Cont}(target, modFG, cert) \wedge \mathsf{hsame}(source, cert)$$
$$\Longrightarrow \mathsf{ContinuousFunctionCarrier}(source, fg, target, modFG, cert) \wedge \mathsf{hsame}(fg, \mathsf{e}) \wedge \mathsf{hsame}(modFG, \mathsf{e}) \wedge \mathsf{hsame}(targ$$

Proof. First apply Definition 59.7 to the two given carriers, the displayed composite map and modulus continuations, and the target-to-certificate continuation. This constructs $\mathsf{ContinuousFunctionCarrier}(source, fg,$

Next apply Definition 59.141 to this composite carrier and the displayed endpoint-certificate equality $\mathsf{hsame}(source, cert)$. The resulting four history-sameness conclusions, together with the composite carrier just constructed, assemble the stated conjunction. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier composite endpoint cert cycle exactness`

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier composite endpoint cycle exactness`

Theorem 59.69 (Continuous function carrier prefix exactness)**.** *For histories $p, source, map, target, modulus, cert$ prefixing the visible source, target, and certificate ledgers is conservative for the continuous-function carrier:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus, p \cdot cert) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert).$$

Proof. For the forward direction, unpack the prefixed carrier. It supplies unary histories for $p \cdot source$, $p \cdot target$, map, and $modulus$, together with the two continuation ledgers $\mathsf{Cont}(p \cdot source, map, p \cdot target)$ and $\mathsf{Cont}(p \cdot target, modulus, p \cdot cert)$.

Unary append factorization applied to the source ledger recovers $\mathsf{UnaryHistory}(p)$ and $\mathsf{UnaryHistory}(source)$. Applied to the target ledger, it recovers $\mathsf{UnaryHistory}(target)$. Prefix cancellation on the graph continuation ledger gives $\mathsf{Cont}(source, map, target)$, and prefix cancellation on the modulus-certificate continuation ledger gives $\mathsf{Cont}(target, modulus, cert)$. Repacking these witnesses gives $\mathsf{ContinuousFunctionCarrier}(s$

For the reverse direction, project $\mathsf{UnaryHistory}(p)$ and the unprefixed carrier from the conjunction. Apply Theorem 59.20 to obtain the displayed prefixed carrier.

The ten-field certificate fit is the following. The traditional target is prefix-invariant continuous graph evidence. The BEDC source is $BHist$ equipped with Cont. The carrier is $\mathsf{ContinuousFunctionCarrier}$ and the classifier is hsame. The stability obligation is exact prefix cancellation for graph and modulus-certificate ledgers. The ledger consists of source, map, target, modulus, and certificate histories. The core theorem is prefix exactness, the exactness predicate is the displayed iff, the standard bridge is deferred, and the status is $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefix iff`

Theorem 59.70 (Continuous function carrier modulus suffix exactness)**.** *For histories $p, source, map, target, modu$ suffixing the modulus and certificate ledgers by the same unary history is conservative for the continuous-function carrier:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus \cdot p, cert \cdot p) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert).$$

Proof. For the forward direction, unpack the suffixed carrier. The target-modulus certificate leg is a continuous modulus witness from $target$ through $modulus \cdot p$ to $cert \cdot p$, with the certificate unary witness obtained from unary continuation closure. Apply the continuous modulus witness suffix exactness theorem to remove the common right suffix, then repack the graph carrier fields.

For the reverse direction, turn the unsuffixed target-modulus certificate leg into a continuous modulus witness, apply suffix exactness to append p to the modulus and certificate histories, and repack the original graph fields with the suffixed certificate leg. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier modulus suffix iff`

Theorem 59.71 (Continuous function carrier modulus-suffix target-certificate determinacy)**.** *For histories $q, source, map, target, target', modulus, cert, cert'$, if two continuous-function carrier witnesses share the same source, map, and visible modulus suffix,*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus{\cdot}q, cert{\cdot}q) \quad \textit{and} \quad \mathsf{ContinuousFunctionCarrier}(source, map, t$$

then their central target and certificate ledgers are determined:

$$\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert, cert').$$

Proof. Apply modulus suffix exactness to each carrier witness. This removes the common suffix from the modulus and certificate ledgers and exposes two central continuous-function carriers over the same source, map, and modulus. The target-certificate determinacy theorem for continuous-function carriers then identifies the central targets and the central certificates. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier modulus suffix target cert deterministic`

Theorem 59.72 (Continuous function carrier prefixed graph-chain factorization)**.** *For histories $p, source, map, target, \delta_1, \delta_2, \delta, cert$, if δ_1 and δ_2 are unary, $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ holds, and*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert)$$

holds, then there is a middle history middle such that

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, \delta, cert) \wedge \mathsf{ContinuousModulusWitness}(target, \delta_1, middle) \wedge \mathsf{Continuous}$$

Proof. Apply prefix exactness for continuous-function carriers to remove the common visible prefix from the source, target, and certificate ledgers. This recovers the unprefixed carrier and in particular the target-to-certificate continuation $\mathsf{Cont}(target, \delta, cert)$.

Choose $middle = target \cdot \delta_1$. The first modulus witness is the canonical continuation from $target$ through δ_1 to this middle history. For the second witness, combine $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ with the recovered target-to-certificate continuation and reassociate the BEDC append spine, obtaining $\mathsf{Cont}(middle, \delta_2, cert)$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain factorizes`

Theorem 59.73 (Continuous function carrier prefixed graph-chain first factorization)**.** *For histories $p, source, map, target, \delta_1, \delta_2, \delta, cert$, if δ_1 and δ_2 are unary, $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ holds, and*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert)$$

holds, then there is a middle history middle such that

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, \delta_1, middle) \wedge \mathsf{ContinuousModulusWitness}(middle, \delta_2, cert).$$

Proof. Apply prefix exactness for continuous-function carriers to remove the common visible prefix. This exposes the unprefixed graph ledger $\mathsf{Cont}(source, map, target)$ and the composite target-certificate ledger $\mathsf{Cont}(target, \delta, cert)$.

Choose $middle = target \cdot \delta_1$. The first-stage carrier uses the original source, map, and target carrier data, the graph ledger, the unary witness for δ_1, and the canonical continuation $\mathsf{Cont}(target, \delta_1, middle)$. The second-stage modulus witness uses the unary closure of $middle$, the unary witness for δ_2, unary closure of $cert$, and associativity of BEDC append to factor the composite ledger through $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain factorization`

Theorem 59.74 (Continuous function carrier triple composition certificate synchronization)**.** *For BHist histories* $source, mid_1, mid_2, target, f, g, h, fg, gh, map_L, map_R, mod_F, mod_G, mod_H, mod_{FG}, mod_{GH}, mod_L,$ *suppose the three one-step carriers*

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, f, mid_1, mod_F, cert_F),\\&\mathsf{ContinuousFunctionCarrier}(mid_1, g, mid_2, mod_G, cert_G),\\&\mathsf{ContinuousFunctionCarrier}(mid_2, h, target, mod_H, cert_H)\end{aligned}$$

hold. Suppose also that the left-bracketed ledgers

$$\begin{array}{lll}\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}),\\ \mathsf{Cont}(fg, h, map_L), & \mathsf{Cont}(mod_{FG}, mod_H, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)\end{array}$$

hold, and that the right-bracketed ledgers

$$\begin{array}{lll}\mathsf{Cont}(g, h, gh), & \mathsf{Cont}(mod_G, mod_H, mod_{GH}), & \mathsf{Cont}(target, mod_{GH}, cert_{GH}),\\ \mathsf{Cont}(f, gh, map_R), & \mathsf{Cont}(mod_F, mod_{GH}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)\end{array}$$

hold. Then the two bracketings both carry the original source to the final target and their public composite data agree up to history-sameness:

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)\wedge\\&\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)\wedge\\&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).\end{aligned}$$

Proof. First build the left bracketing. Theorem 59.7 composes the $source$-f-mid_1 carrier with the mid_1-g-mid_2 carrier using the displayed fg, mod_{FG}, and $cert_{FG}$ ledgers. Applying the same closure theorem to that composite and the mid_2-h-$target$ carrier gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod$

The right bracketing is built in the symmetric order. Compose the g and h carriers through gh, mod_{GH}, and $cert_{GH}$, then compose the resulting mid_1-gh-$target$ carrier after the original f carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For map synchronization, apply continuation associativity up to history-sameness to the four graph ledgers $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(fg, h, map_L)$, $\mathsf{Cont}(g, h, gh)$, and $\mathsf{Cont}(f, gh, map_R)$. The result is $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same continuation-associativity principle to the modulus ledgers $\mathsf{Cont}(mod_F, mod_G, mod_{FG})$, $\mathsf{Cont}(mod_{FG}, mod_H, mod_L)$, $\mathsf{Cont}(mod_G, mod_H, mod_{GH})$, and $\mathsf{Cont}(mod_F, mod_{GH}, mod_R)$. This gives $\mathsf{hsame}(mod_L, mod_R)$.

Finally compare the two target-certificate ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$. Continuation respect for hsame, with reflexivity on $target$ and the recovered modulus sameness, yields $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the following. The traditional target is threefold composition of continuous function carriers. The BEDC source is $BHist$ equipped with Cont. The carrier is $\mathsf{ContinuousFunctionCarrier}$ and the classifier is hsame. The stability obligation is bracketing synchronization for graph, modulus, and certificate ledgers. The ledger consists of source, intermediate, target, map, modulus, and certificate histories. The core theorem is this triple composition synchronization result. The exactness predicate is the displayed pair of carriers together with the three hsame conclusions. The standard bridge is deferred, and the status is $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier composition associative certificate synchronization`

Theorem 59.75 (Continuous function carrier fourfold left-right synchronization)**.** *For BHist histories* $source, mid_1, mid_2, mid_3, target, f, g, h, k, fg, fgh, hk, ghk, map_L, map_R, mod_F, mod_G, mod_H, mod_K, mod_{FG},$ *suppose the four one-step carriers*

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, f, mid_1, mod_F, cert_F),\\&\mathsf{ContinuousFunctionCarrier}(mid_1, g, mid_2, mod_G, cert_G),\\&\mathsf{ContinuousFunctionCarrier}(mid_2, h, mid_3, mod_H, cert_H),\\&\mathsf{ContinuousFunctionCarrier}(mid_3, k, target, mod_K, cert_K)\end{aligned}$$

hold. Suppose also that the left-deep ledgers

$$\begin{array}{lll}\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}),\\ \mathsf{Cont}(fg, h, fgh), & \mathsf{Cont}(mod_{FG}, mod_H, mod_{FGH}), & \mathsf{Cont}(mid_3, mod_{FGH}, cert_{FGH}),\\ \mathsf{Cont}(fgh, k, map_L), & \mathsf{Cont}(mod_{FGH}, mod_K, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)\end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll}\mathsf{Cont}(h, k, hk), & \mathsf{Cont}(mod_H, mod_K, mod_{HK}), & \mathsf{Cont}(target, mod_{HK}, cert_{HK}),\\ \mathsf{Cont}(g, hk, ghk), & \mathsf{Cont}(mod_G, mod_{HK}, mod_{GHK}), & \mathsf{Cont}(target, mod_{GHK}, cert_{GHK}),\\ \mathsf{Cont}(f, ghk, map_R), & \mathsf{Cont}(mod_F, mod_{GHK}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)\end{array}$$

hold. Then the left-deep and right-deep composite carriers agree at the public graph, modulus, and certificate histories:

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)\wedge\\&\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)\wedge\\&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).\end{aligned}$$

Proof. First build the left-deep carrier. Apply Theorem 59.7 to the f and g carriers with the displayed fg, mod_{FG}, and $cert_{FG}$ ledgers. Apply the same closure theorem to compose that result with the h carrier, then again with the k carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L,$

The right-deep carrier is obtained by the symmetric closure chain. Compose the h and k carriers through hk, mod_{HK}, and $cert_{HK}$; compose the g carrier with that composite through ghk, mod_{GHK}, and $cert_{GHK}$; then compose the f carrier with the resulting carrier to obtain $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For graph synchronization, apply the BEDC fourfold continuation associativity theorem cont_assoc_four to the common graph spine f, g, h, k. The left spine is presented by $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(fg, h, fgh)$, and $\mathsf{Cont}(fgh, k, map_L)$, while the right spine is presented by $\mathsf{Cont}(h, k, hk)$, $\mathsf{Cont}(g, hk, ghk)$, and $\mathsf{Cont}(f, ghk, map_R)$. The underlying append-associativity spine append_assoc yields $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same fourfold continuation associativity theorem to $mod_F, mod_G, mod_H, mod_K$. The left modulus ledger ends at mod_L and the right modulus ledger ends at mod_R, so the common append spine yields $\mathsf{hsame}(mod_L, mod_R)$.

It remains to compare certificates. The ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$ have the same target source. Continuation respect for hsame, using reflexivity on $target$ and the recovered modulus synchronization, transports the certificate ledger to give $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the following. The traditional target is fourfold continuous composition coherence. The BEDC source is $BHist$ with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The ledger data are the graph, modulus, and certificate histories displayed above. The stability field is fourfold left-right bracketing synchronization. The exactness field is the pair of constructed carriers together with the three hsame conclusions. The downstream use is ContinuousMapUp associativity coherence and the later category bridge. □

Theorem 59.76 (Continuous function carrier fivefold left-right synchronization)**.** *For BHist histories* $source, mid_1, mid_2, mid_3, mid_4, target, f, g, h, k, l, fg, fgh, fghk, kl, hkl, ghkl, map_L, map_R, mod_F, mod_G, mod$ *suppose the five one-step carriers*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, f, mid_1, mod_F, cert_F),\\
&\mathsf{ContinuousFunctionCarrier}(mid_1, g, mid_2, mod_G, cert_G),\\
&\mathsf{ContinuousFunctionCarrier}(mid_2, h, mid_3, mod_H, cert_H),\\
&\mathsf{ContinuousFunctionCarrier}(mid_3, k, mid_4, mod_K, cert_K),\\
&\mathsf{ContinuousFunctionCarrier}(mid_4, l, target, mod_l, cert_l)
\end{aligned}$$

hold. Suppose also that the left-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}),\\
\mathsf{Cont}(fg, h, fgh), & \mathsf{Cont}(mod_{FG}, mod_H, mod_{FGH}), & \mathsf{Cont}(mid_3, mod_{FGH}, cert_{FGH}),\\
\mathsf{Cont}(fgh, k, fghk), & \mathsf{Cont}(mod_{FGH}, mod_K, mod_{FGHK}), & \mathsf{Cont}(mid_4, mod_{FGHK}, cert_{FGHK}),\\
\mathsf{Cont}(fghk, l, map_L), & \mathsf{Cont}(mod_{FGHK}, mod_l, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)
\end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(k, l, kl), & \mathsf{Cont}(mod_K, mod_l, mod_{KL}), & \mathsf{Cont}(target, mod_{KL}, cert_{KL}),\\
\mathsf{Cont}(h, kl, hkl), & \mathsf{Cont}(mod_H, mod_{KL}, mod_{HKL}), & \mathsf{Cont}(target, mod_{HKL}, cert_{HKL}),\\
\mathsf{Cont}(g, hkl, ghkl), & \mathsf{Cont}(mod_G, mod_{HKL}, mod_{GHKL}), & \mathsf{Cont}(target, mod_{GHKL}, cert_{GHKL}),\\
\mathsf{Cont}(f, ghkl, map_R), & \mathsf{Cont}(mod_F, mod_{GHKL}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)
\end{array}$$

hold. Then the left-deep and right-deep composite carriers agree at the public graph, modulus, and certificate histories:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L) \wedge\\
&\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R) \wedge\\
&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).
\end{aligned}$$

Proof. First build the left-deep carrier. Apply Theorem 59.7 to the f and g carriers with the displayed fg, mod_{FG}, and $cert_{FG}$ ledgers. Apply the same closure theorem to compose that result with the h carrier, then with the k carrier, and finally with the l carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)$.

The right-deep carrier is obtained by the matching closure chain. Compose the k and l carriers through kl, mod_{KL}, and $cert_{KL}$; compose the h carrier with that composite through hkl, mod_{HKL}, and $cert_{HKL}$; compose the g carrier with the resulting carrier through $ghkl$, mod_{GHKL}, and $cert_{GHKL}$; then compose the f carrier with that final right-deep carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For graph synchronization, apply BEDC.FKernel.Cont.cont_assoc_five to the common graph spine f, g, h, k, l. The left spine is presented by $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(fg, h, fgh)$, $\mathsf{Cont}(fgh, k, fghk)$, and $\mathsf{Cont}(fghk, l, map_L)$, while the right spine is presented by $\mathsf{Cont}(k, l, kl)$, $\mathsf{Cont}(h, kl, hkl)$, $\mathsf{Cont}(g, hkl, ghkl)$, and $\mathsf{Cont}(f, ghkl, map_R)$. The fivefold continuation reassociation gives $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same fivefold reassociation theorem to $mod_F, mod_G, mod_H, mod_K, mod_l$. The left modulus ledger ends at mod_L and the right modulus ledger ends at mod_R, so the common continuation spine gives $\mathsf{hsame}(mod_L, mod_R)$.

It remains to compare the terminal certificates. The ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$ have the same target source. Continuation respect for hsame, using reflexivity on $target$ and the recovered modulus synchronization, transports the terminal certificate ledger and gives $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the following. The traditional target is pentagon-style fivefold continuous composition coherence. The BEDC source is $BHist$ with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The ledger data are the five one-step graph histories, their modulus histories, their target-certificate histories, and the displayed left-deep and right-deep composite ledgers. The stability field is fivefold left-right bracketing synchronization. The exactness field is the pair of constructed carriers together with the three hsame conclusions. The downstream use is ContinuousMapUp pentagon coherence and the category bridge. □

Theorem 59.77 (Continuous function carrier sixfold left-right synchronization)**.** *For BHist histories* $source, mid_1, mid_2, mid_3, mid_4, mid_5, target, f, g, h, k, l, m, fg, fgh, fghk, fghkl, lm, klm, hklm, ghklm, map_L$, *suppose the six one-step carriers*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, f, mid_1, mod_F, cert_F),\\
&\mathsf{ContinuousFunctionCarrier}(mid_1, g, mid_2, mod_G, cert_G),\\
&\mathsf{ContinuousFunctionCarrier}(mid_2, h, mid_3, mod_H, cert_H),\\
&\mathsf{ContinuousFunctionCarrier}(mid_3, k, mid_4, mod_K, cert_K),\\
&\mathsf{ContinuousFunctionCarrier}(mid_4, l, mid_5, mod_l, cert_l),\\
&\mathsf{ContinuousFunctionCarrier}(mid_5, m, target, mod_m, cert_m)
\end{aligned}$$

hold. Suppose also that the left-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}),\\
\mathsf{Cont}(fg, h, fgh), & \mathsf{Cont}(mod_{FG}, mod_H, mod_{FGH}), & \mathsf{Cont}(mid_3, mod_{FGH}, cert_{FGH}),\\
\mathsf{Cont}(fgh, k, fghk), & \mathsf{Cont}(mod_{FGH}, mod_K, mod_{FGHK}), & \mathsf{Cont}(mid_4, mod_{FGHK}, cert_{FGHK}),\\
\mathsf{Cont}(fghk, l, fghkl), & \mathsf{Cont}(mod_{FGHK}, mod_l, mod_{FGHKL}), & \mathsf{Cont}(mid_5, mod_{FGHKL}, cert_{FGHKL}),\\
\mathsf{Cont}(fghkl, m, map_L), & \mathsf{Cont}(mod_{FGHKL}, mod_m, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)
\end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(l, m, lm), & \mathsf{Cont}(mod_l, mod_m, mod_{LM}), & \mathsf{Cont}(target, mod_{LM}, cert_{LM}),\\
\mathsf{Cont}(k, lm, klm), & \mathsf{Cont}(mod_K, mod_{LM}, mod_{KLM}), & \mathsf{Cont}(target, mod_{KLM}, cert_{KLM}),\\
\mathsf{Cont}(h, klm, hklm), & \mathsf{Cont}(mod_H, mod_{KLM}, mod_{HKLM}), & \mathsf{Cont}(target, mod_{HKLM}, cert_{HKLM}),\\
\mathsf{Cont}(g, hklm, ghklm), & \mathsf{Cont}(mod_G, mod_{HKLM}, mod_{GHKLM}), & \mathsf{Cont}(target, mod_{GHKLM}, cert_{GHKLM}),\\
\mathsf{Cont}(f, ghklm, map_R), & \mathsf{Cont}(mod_F, mod_{GHKLM}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)
\end{array}$$

hold. Then the left-deep and right-deep composite carriers agree at the public graph, modulus, and certificate histories:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)\wedge\\
&\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)\wedge\\
&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).
\end{aligned}$$

Proof. First build the left-deep carrier. Repeatedly apply Theorem 59.7 along the displayed fg, fgh, $fghk$, $fghkl$, and map_L graph ledgers, using the matching modulus and certificate-continuation ledgers at each stage. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)$.

The right-deep carrier is built from the other end of the same chain. Compose the l and m carriers, then compose successively with the k, h, g, and f carriers through the displayed lm, klm, $hklm$, $ghklm$, and map_R ledgers. The result is $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For graph synchronization, apply BEDC.FKernel.Cont.cont_assoc_six to the common graph spine f, g, h, k, l, m. The left-deep spine ends at map_L and the right-deep spine ends at map_R, so sixfold continuation associativity yields $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same kernel theorem to $mod_F, mod_G, mod_H, mod_K, mod_l, mod_m$. The displayed modulus ledgers present the same sixfold spine with endpoints mod_L and mod_R, giving $\mathsf{hsame}(mod_L, mod_R)$.

It remains to compare the terminal certificates. The ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$ share the same target source. Continuation respect for hsame, with reflexivity on $target$ and the recovered modulus sameness, identifies the terminal certificates and gives $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the same concrete carrier ledger as in the fourfold and fivefold synchronization results. The stability field is sixfold left-right bracketing synchronization, and the exactness field is the pair of constructed carriers together with the three hsame conclusions. □

Theorem 59.78 (Continuous function carrier certificate semantic naming certificate)**.** *For BHist histories $source, map, target, modulus, cert$, any carrier witness* $\mathsf{ContinuousFunctionCarrier}(source, map, target, mo$ *induces the semantic naming certificate*

$$\mathsf{SemanticNameCert}(C, C, C, \mathsf{hsame}), \qquad C(c) := \mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, c).$$

Thus the certificate-slot carrier, pattern, and ledger are all the displayed fiber $c \mapsto$ $\mathsf{ContinuousFunctionCarrier}(source$ *and the classifier is* hsame.

Proof. The displayed carrier gives the source witness for the semantic certificate at the point $cert$. This is exactly the inhabited source field for the fiber C.

The classifier fields are the standard hsame rows. Reflexivity classifies each displayed certificate with itself, symmetry reverses a displayed classification, and transitivity composes two displayed classifications.

Carrier transport is confined to the certificate slot. Keep $source$, map, $target$, and $modulus$ fixed by hsame reflexivity, use the supplied hsame comparison of certificate histories, and apply Definition 59.14 to transport the continuous function carrier along that comparison.

The pattern and ledger predicates are the same fiber C as the source predicate. Their soundness and completeness maps are therefore identity projections, so the semantic naming certificate is repacked from the preceding fields. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier certificate semanticNameCert`

Theorem 59.79 (Continuous function carrier parallel composite determinacy)**.** *For BHist histories $source, middle, target, f, g, fg, fg', mod_F, mod_G, mod_{FG}, mod'_{FG}, cert_F, cert_G, cert, cert'$, suppose*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, f, middle, mod_F, cert_F),\\
&\mathsf{ContinuousFunctionCarrier}(middle, g, target, mod_G, cert_G),\\
&\mathsf{Cont}(f, g, fg), \quad \mathsf{Cont}(f, g, fg'),\\
&\mathsf{Cont}(mod_F, mod_G, mod_{FG}), \quad \mathsf{Cont}(mod_F, mod_G, mod'_{FG}),\\
&\mathsf{Cont}(target, mod_{FG}, cert), \quad \mathsf{Cont}(target, mod'_{FG}, cert')
\end{aligned}$$

hold. Then the two exposed composites are both continuous function carriers and their graph, modulus, and certificate histories are determined:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, fg, target, mod_{FG}, cert) \wedge\\
&\mathsf{ContinuousFunctionCarrier}(source, fg', target, mod'_{FG}, cert') \wedge\\
&\mathsf{hsame}(fg, fg') \wedge \mathsf{hsame}(mod_{FG}, mod'_{FG}) \wedge \mathsf{hsame}(cert, cert').
\end{aligned}$$

Proof. First compose through the first visible ledger. The two given base carriers, together with $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(mod_F, mod_G, mod_{FG})$, and $\mathsf{Cont}(target, mod_{FG}, cert)$, satisfy the hypotheses of Theorem 59.7. This gives $\mathsf{ContinuousFunctionCarrier}(source, fg, target, mod_{FG}, cert)$.

The second displayed ledger has the same two base carriers. Applying the same composition theorem to $\mathsf{Cont}(f, g, fg')$, $\mathsf{Cont}(mod_F, mod_G, mod'_{FG})$, and $\mathsf{Cont}(target, mod'_{FG}, cert')$ gives $\mathsf{ContinuousFunctionCarrier}(source, fg', target, mod'_{FG}, cert')$.

Map determinacy is local to the shared graph rows. Continuation determinacy for the two rows $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f, g, fg')$ gives $\mathsf{hsame}(fg, fg')$; the same kernel determinacy applied to the two modulus rows gives $\mathsf{hsame}(mod_{FG}, mod'_{FG})$.

Finally compare the terminal certificate rows. They share the target history, and the recovered modulus sameness transports the row $\mathsf{Cont}(target, mod'_{FG}, cert')$ back across $\mathsf{Cont}(target, mod_{FG}, cert)$, yielding $\mathsf{hsame}(cert, cert')$. These five outputs are exactly the two composite carriers plus the three exposed history-sameness conclusions. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier parallel composite determinacy`

Proposition 59.80 (Uniform continuity modulus restriction along subset inclusion)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, and let*

$$i : U \subseteq T$$

be a certified inclusion, meaning that each membership ledger $\nu : U(u)$ is transported to a membership ledger $i(\nu) : T(u)$. Let $f : T \to Z$ be a certified graph witness with totality and single-valuedness as in Definition 59.1, and let $f\restriction_U$ be the same graph relation read with the source classifier restricted through i. If a unary precision ledger δ satisfies the modulus-validity field of Definition 59.161 for f on T, then the same δ satisfies the modulus-validity field for $f\restriction_U$ on U.

Proof. Fix a target precision request n and the source precision returned by the unary ledger δ. To verify the restricted modulus field, take source histories u_0, u_1 admitted by U, graph outputs z_0, z_1 for $f\restriction_U$, and the source closeness judgment required at the returned source precision.

The inclusion certificate transports the two source-admission ledgers:

$$\nu_j : U(u_j) \Longrightarrow i(\nu_j) : T(u_j) \qquad (j = 0, 1).$$

By Definition 59.93 and Definition 59.122, restricting the source subset does not alter the graph relation, the codomain classifier ledger, the precision ledger, or the modulus ledger. Thus the graph witnesses for $f\restriction_U$ are the same graph witnesses for f after the source admissions are read in T.

Apply the modulus-validity field for f on T to the transported memberships, the same source closeness judgment, and the same two graph outputs. It yields the target metric closeness conclusion at precision n. The well-formedness and representative stability of this conclusion are exactly the classifier and stability data of Definition 57.4 and Definition 57.5.

This is the entire obligation for the restricted witness: only the source-admission hypotheses have been narrowed from T to U, and those hypotheses enter the original modulus field through the certified inclusion. The precision ledger δ is unchanged. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction modulus chain`

Theorem 59.81 (Continuous empty-source restriction public package)**.** *Let restricted, source, map, target, target′,* BHist *be histories. Assume*

$$\mathsf{Cont}(\mathit{restricted}, \mathsf{e}, \mathit{source}),$$

$$\mathsf{ContinuousFunctionCarrier}(\mathit{source}, \mathit{map}, \mathit{target}, \mathit{oldMod}, \mathit{oldCert}),$$

$$\mathsf{ContinuousModulusChain}(\mathit{target}, \delta_1, \delta_2, \mathit{cert}),$$

$$\mathsf{Cont}(\delta_1, \delta_2, \delta),$$

and a displayed restricted carrier

$$\mathsf{ContinuousFunctionCarrier}(\mathit{restricted}, \mathit{map}, \mathit{target}', \delta, \mathit{cert}').$$

Then the empty-source restriction has the public package

$$\mathsf{ContinuousFunctionCarrier}(\mathit{restricted}, \mathit{map}, \mathit{target}, \delta, \mathit{cert}),$$

$$\mathsf{ContinuousModulusWitness}(\mathit{target}, \delta, \mathit{cert}),$$

and

$$\mathsf{hsame}(\mathit{target}, \mathit{target}') \wedge \mathsf{hsame}(\mathit{cert}, \mathit{cert}').$$

Proof. Apply the preceding checked empty-source restriction-chain theorem to the source restriction, the original carrier, the modulus chain, and the composite modulus relation. This produces the restricted ContinuousFunctionCarrier over $(\mathit{restricted}, \mathit{map}, \mathit{target}, \delta, \mathit{cert})$ and the ContinuousModulusWitness over $(\mathit{target}, \delta, \mathit{cert})$.

It remains to read back the displayed public target and certificate. The Lean-side theorem BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier_empty_source_restriction_public_readback applies to the same hypotheses together with the displayed restricted carrier, and returns $\mathsf{hsame}(\mathit{target}, \mathit{target}') \wedge \mathsf{hsame}(\mathit{cert}, \mathit{cert}')$.

Ten-field fit: traditional target restriction of uniformly continuous maps along an empty-source inclusion; BEDC source BHist, Cont, ContinuousFunctionCarrier, and ContinuousModulusChain; carrier the restricted ContinuousFunctionCarrier; classifier hsame on target and certificate histories; stability hsame transport and modulus-chain composition; ledger unchanged graph with replaced modulus/certificate chain; core theorem this public package; exactness the target/certificate readback; standard bridge ordinary restricted-map readback; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction public readback`

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction public package`

Theorem 59.82 (Uniform continuity modulus restriction is transitive)**.** *Let Y and Z be certified* $\mathsf{Met}^{\uparrow}$ *objects with the metric data of Definition 57.1. Let V, U, and T be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusions*

$$j : V \subseteq U$$

and

$$i : U \subseteq T.$$

For a certified graph witness $f : T \to Z$, let $f \restriction_U$ be the restriction along i, let $(f \restriction_U) \restriction_V$ be the successive restriction along j, and let $f \restriction_V$ be the direct restriction along the composite inclusion

$i \circ j : V \subseteq T$. The composite inclusion carries the same history-level graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger as the successive restriction. If a unary precision ledger δ satisfies the modulus-validity field of Definition 59.161 for f over T, then δ satisfies that field for both $f\restriction_V$ and $(f\restriction_U)\restriction_V$, and the two restricted witnesses are related by the $\mathsf{ContinuousMap}^{\uparrow}$ *classifier of Definition 59.94.*

Proof. Apply Proposition 59.80 first to $i : U \subseteq T$. This transports the modulus-validity field for f over T to the restriction $f\restriction_U$ over U, with the graph relation and all precision data left unchanged.

Apply the same proposition to $j : V \subseteq U$ and the already restricted witness $f\restriction_U$. The result is the modulus-validity field for $(f\restriction_U)\restriction_V$ over V, with the same history-level graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger.

Apply Proposition 59.80 once more to the composite inclusion $i \circ j : V \subseteq T$. This gives the direct restricted witness $f\restriction_V$ and its modulus-validity field over V using the original witness f and the same unary precision ledger δ.

It remains to compare the direct and successive restrictions. By Definition 59.93, restriction changes only the source-admission reading of the graph; by Definition 59.122, the graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger are recorded as the same ledgers. Thus the direct and successive witnesses present the same carrier data to the classifier, and Definition 59.94 relates them as $\mathsf{ContinuousMap}^{\uparrow}$ witnesses.

Ten-field fit: traditional target functorial restriction of uniformly continuous maps; BEDC source BHist with certified source predicates and ContinuousFunctionCarrier; carrier restricted graph witness; classifier ContinuousMap classifier; stability nested source-admission transport; ledger unchanged graph/modulus ledgers; core theorem this block; exactness direct-versus-successive restriction agreement; standard bridge restriction functoriality for uniformly continuous maps; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction transitive package`

Theorem 59.83 (Uniform continuity restriction functorial action)**.** *Let Y and Z be certified* $\mathsf{Met}^{\uparrow}$ *objects with the metric data of Definition 57.1. Let T, U, and V be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92. Let*

$$e_T : T \subseteq T$$

be the identity inclusion, and let

$$i : U \subseteq T$$

and

$$j : V \subseteq U$$

be certified inclusions. Let $f : T \to Z$ be a certified graph witness whose unary precision ledger δ satisfies the modulus-validity field of Definition 59.161 over T. Then restriction along e_T preserves δ and is related to f by the $\mathsf{ContinuousMap}^{\uparrow}$ *classifier of Definition 59.94. Moreover, the successive restriction $(f\restriction_U)\restriction_V$ and the direct restriction along the certified composite inclusion $i \circ j : V \subseteq T$ are related by the same classifier and preserve the same graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger.*

Proof. For the identity clause, apply Proposition 59.80 to the certified inclusion $e_T : T \subseteq T$. The source-admission transport is the identity transport on the T ledger, so the restricted witness reads the same histories as f.

The unchanged ledger clauses of Definition 59.93 and Definition 59.122 keep the graph relation, codomain classifier ledger, unary precision ledger δ, and modulus ledger fixed. Hence the two witnesses present the same carrier data, and Definition 59.94 relates the identity restriction to f as $\mathsf{ContinuousMap}^{\uparrow}$ representatives.

For the composition clause, apply Theorem 59.82 to the inclusions $j : V \subseteq U$ and $i : U \subseteq T$. It gives the modulus-validity field for both the successive and direct restrictions with the same unary precision ledger δ.

The same theorem also identifies the direct and successive restrictions at the level of the $\mathsf{ContinuousMap}^{\uparrow}$ classifier. Its comparison uses exactly the shared graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger supplied by the restriction policy.

Ten-field fit: traditional target restriction action of uniformly continuous maps; BEDC source BHist source predicates plus ContinuousFunctionCarrier; carrier restricted graph witness; classifier ContinuousMapUp; stability identity and composite source-admission transport; ledger unchanged graph/modulus data; core theorem this action law; exactness identity and composition agreement; standard bridge restriction of uniformly continuous maps; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction functorial action`

Theorem 59.84 (Uniform continuity restriction commutes with terminal modulus extension)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusion $i : U \subseteq T$. Let $f : T \to Z$ be a certified graph witness, and let*

$$source, map, target, modulus, cert, extra, modulus', cert' : \mathsf{BHist}$$

be the BEDC histories recording the source ledger for T, the graph ledger of f, the codomain classifier ledger, the original unary modulus, the terminal certificate, the additional terminal modulus, the composite modulus, and the terminal certificate after composition. Assume that f satisfies the ContinuousMap carrier, totality, single-valuedness, and modulus-validity fields of Definition 59.1 and Definition 59.161 over T, and assume

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert),\\&\mathsf{ContinuousModulusWitness}(cert, extra, cert'),\\&\mathsf{Cont}(modulus, extra, modulus').\end{aligned}$$

Then the $\mathsf{ContinuousMap}^{\uparrow}$ witness obtained by restricting f along i and then applying terminal modulus extension with extra, modulus′, and cert′ is related by the classifier of Definition 59.94 to the witness obtained by first applying terminal modulus extension over T and then restricting along i. Both witnesses present the restricted graph $f\restriction_U$, the source-admission transport through i, the codomain classifier ledger for Z, the composite modulus ledger modulus′, and the terminal certificate ledger cert′.

Proof. Apply Theorem 59.162 to the displayed carrier, the terminal modulus witness, and the composite continuation ledger. This gives a continuous-function carrier over T with histories $source, map, target, modulus', cert'$.

Restrict this extended carrier along $i : U \subseteq T$. Proposition 59.80 transports the modulus-validity field to U, while Definition 59.93 and Definition 59.122 keep the graph relation, target classifier, precision ledger, and modulus ledger fixed.

For the other route, first apply Proposition 59.80 to the original witness f. The restricted witness over U carries the same graph ledger map, the same target ledger $target$, and the same modulus and certificate ledgers $modulus, cert$, with only the source-admission hypotheses narrowed through i.

Now apply Theorem 59.162 to this restricted carrier using the same $\mathsf{ContinuousModulusWitness}(cert, extra, cert')$ and the same $\mathsf{Cont}(modulus, extra, modulus')$. The resulting restricted-then-extended witness has composite modulus $modulus'$ and terminal certificate $cert'$.

It remains to compare the two route results. Their graph relation is the same relation read on U, source histories admitted by U are transported to T by the same inclusion certificate, the codomain classifier ledger is the same Z ledger, and the composite modulus and terminal certificate ledgers are the same displayed histories. Therefore Definition 59.94 relates the two witnesses as $\mathsf{ContinuousMap}^{\uparrow}$ representatives.

Ten-field fit: traditional target commutation of source restriction with terminal modulus extension; BEDC source BHist with certified source predicates, Cont, and ContinuousModulusWitness; carrier ContinuousFunctionCarrier with restricted graph witness; classifier ContinuousMap classifier; stability source-admission transport plus terminal modulus preservation; ledger unchanged graph relation, codomain classifier ledger, composite modulus ledger, and terminal certificate ledger; core theorem this block; exactness equality of the two route witnesses under Definition 59.94; standard bridge restriction and modulus-normalization order independence for uniformly continuous maps; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction terminal modulus package`
Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction terminal modulus commutes`

Theorem 59.85 (Uniform continuity restriction commutes with iterated terminal modulus extension)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusion $i : U \subseteq T$. Let $f : T \to Z$ be a certified graph witness, and let*

$$source, map, target, modulus, cert, extra_0, modulus_0, cert_0, extra_1, modulus_1, cert_1 : \mathsf{BHist}$$

be the BEDC histories recording the source ledger for T, the graph ledger of f, the codomain classifier ledger, the initial unary modulus, the initial terminal certificate, the first added terminal modulus, the first composite modulus, the first terminal certificate after composition, the second added terminal modulus, the second composite modulus, and the final terminal certificate. Assume that f satisfies the ContinuousMap carrier, totality, single-valuedness, and modulus-validity fields of Definition 59.1 and Definition 59.161 over T, and assume

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert),\\
&\mathsf{ContinuousModulusWitness}(cert, extra_0, cert_0), \quad \mathsf{Cont}(modulus, extra_0, modulus_0),\\
&\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1), \quad \mathsf{Cont}(modulus_0, extra_1, modulus_1).
\end{aligned}$$

Then the $\mathsf{ContinuousMap}^{\uparrow}$ witness obtained by restricting f along i and then applying the two terminal modulus extensions with final histories $modulus_1, cert_1$ is related by the classifier of Definition 59.94 to the witness obtained by applying the two terminal modulus extensions over T and then restricting along i. Both routes expose the restricted graph ledger map, the transported source-admission ledger through i, the same target classifier ledger $target$, and final histories $modulus_1, cert_1$.

Proof. Apply Theorem 59.84 to the initial carrier, the witness $\mathsf{ContinuousModulusWitness}(cert, extra_0, cert_0)$, and the continuation ledger $\mathsf{Cont}(modulus, extra_0, modulus_0)$. This relates the route that restricts first and then performs the first terminal extension to the route that performs the first terminal extension over T and then restricts. Both resulting representatives carry restricted graph ledger map, transported source-admission through i, target ledger $target$, and histories $modulus_0, cert_0$.

Apply Theorem 59.162 to the initial carrier and the first terminal data. It keeps the carrier over T live after the first extension, now with histories $source, map, target, modulus_0, cert_0$. Applying the same theorem to the restricted representative supplied by the first commutation keeps the restricted carrier live with the same graph and target ledgers and with histories $modulus_0, cert_0$.

Now apply Theorem 59.84 to these first-extended carriers, using $\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1)$ and $\mathsf{Cont}(modulus_0, extra_1, modulus_1)$. This relates the route that restricts before the second terminal extension to the route that performs the second terminal extension over T before restriction. The two representatives therefore expose the same restricted graph ledger, source-admission transport, target classifier ledger, and final histories $modulus_1, cert_1$.

The first commutation gives a classifier relation between the two intermediate representatives, and the second commutation gives a classifier relation between the two final representatives built from those intermediates. By the transitivity clause in Definition 59.94, the endpoints are related as $\mathsf{ContinuousMap}^{\uparrow}$ witnesses: restricting first and applying both terminal extensions is classified together with extending twice over T and then restricting to U.

Ten-field fit: traditional target finite terminal-modulus normalization under source restriction; BEDC source BHist with certified source predicates, Cont, and two $\mathsf{ContinuousModulusWitness}$ ledgers; carrier $\mathsf{ContinuousFunctionCarrier}$ preserved through two terminal extensions; classifier ContinuousMap classifier with transitivity; stability transported source admission plus preserved modulus-validity fields; ledger restricted graph ledger, target classifier ledger, and final histories $modulus_1, cert_1$; core theorem this block; exactness equality of the two finite route endpoints under Definition 59.94; standard bridge finite modulus-normalization stability for uniformly continuous maps; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction iterated terminal modulus commutes`

Theorem 59.86 (Uniform continuity restriction commutes with visible terminal modulus extension)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusion $i : U \subseteq T$. Let*

$$p, q, source, map, target, modulus, cert, extra, modulus', cert' : \mathsf{BHist}$$

be histories, and assume the visible continuous-function carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q),$$

the terminal modulus witness

$$\mathsf{ContinuousModulusWitness}(cert, extra, cert'),$$

and the terminal modulus composition ledger

$$\mathsf{Cont}(modulus, extra, modulus').$$

Then the $\mathsf{ContinuousMap}^{\uparrow}$ *witness obtained by restricting the visible carrier along* i *and then applying visible terminal modulus extension with* $extra$, $modulus'$, *and* $cert'$ *is related by the classifier of Definition 59.94 to the witness obtained by first applying visible terminal modulus extension and then restricting along* i. *Both routes expose the restricted graph ledger map, the same source-admission transport through* i, *the visible target ledger* $p \cdot target$, *the composite modulus ledger* $modulus' \cdot q$, *and the terminal certificate ledger* $(p \cdot cert') \cdot q$.

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction visible terminal modulus commutes`

Proof. Peel the visible carrier by Theorem 59.169. This recovers unary context histories for p and q together with the central carrier

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert).$$

Apply Theorem 59.84 to this central carrier, the source inclusion $i : U \subseteq T$, the witness $\mathsf{ContinuousModulusWitness}(cert, extra, cert')$, and the ledger $\mathsf{Cont}(modulus, extra, modulus')$. The central endpoints are classified together: one restricts first and then extends the terminal modulus, and the other extends over T first and then restricts.

Reattach the visible prefix and suffix to the two central endpoints. Theorem 59.163 supplies the visible terminal extension on the route whose extension is performed after the visible carrier is restricted, and the reverse use of Theorem 59.169 repacks the same unary histories around the endpoint obtained by extending first.

The visible-context exactness theorem identifies the exposed public ledgers on both routes. The graph ledger is the restricted reading of map, the source-admission hypotheses are transported through the same inclusion certificate i, the target ledger is $p \cdot target$, and the final ledgers are $modulus' \cdot q$ and $(p \cdot cert') \cdot q$. Therefore the classifier of Definition 59.94 relates the two visible witnesses as $\mathsf{ContinuousMap}^{\uparrow}$ representatives.

Ten-field fit: traditional target commutation of source restriction with visible terminal modulus extension; BEDC source BHist with visible contexts, certified source predicates, Cont, and $\mathsf{ContinuousModulusWitness}$; carrier visible $\mathsf{ContinuousFunctionCarrier}$ with restricted graph witness; classifier ContinuousMap classifier; stability source-admission transport plus visible terminal modulus preservation; ledger restricted graph relation, visible target ledger, composite modulus ledger, and visible terminal certificate ledger; core theorem this block; exactness equality of the two visible route endpoints under Definition 59.94; standard bridge restriction and visible modulus-normalization order independence for uniformly continuous maps; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible source restriction terminal modulus commutes`
Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible empty source restriction terminal modulus commutes`

Theorem 59.87 (Uniform continuity visible restriction commutes with modulus chains)**.** *Let*

$$p, q, restricted, source, map, target, target', oldMod, oldCert, \delta_1, \delta_2, \delta, cert, cert' : \mathsf{BHist}$$

be histories. Assume the source restriction ledger

$$\mathsf{Cont}(restricted, \mathsf{e}, source),$$

the visible continuous-function carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot \mathit{source}, \mathit{map}, p \cdot \mathit{target}, \mathit{oldMod} \cdot q, (p \cdot \mathit{oldCert}) \cdot q),$$

the two-link modulus chain

$$\mathsf{ContinuousModulusChain}(\mathit{target}, \delta_1, \delta_2, \mathit{cert}),$$

the composite modulus ledger

$$\mathsf{Cont}(\delta_1, \delta_2, \delta),$$

and a displayed restricted carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot \mathit{restricted}, \mathit{map}, p \cdot \mathit{target}', \delta \cdot q, (p \cdot \mathit{cert}') \cdot q).$$

Then the canonical visible restricted carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot \mathit{restricted}, \mathit{map}, p \cdot \mathit{target}, \delta \cdot q, (p \cdot \mathit{cert}) \cdot q),$$

the central witness

$$\mathsf{ContinuousModulusWitness}(\mathit{target}, \delta, \mathit{cert}),$$

and the readback

$$\mathsf{hsame}(\mathit{target}, \mathit{target}') \wedge \mathsf{hsame}(\mathit{cert}, \mathit{cert}')$$

hold.

Proof. Peel the displayed visible carrier by Theorem 59.169. This exposes the central carrier over $(\mathit{source}, \mathit{map}, \mathit{target}, \mathit{oldMod}, \mathit{oldCert})$ while retaining the same visible prefix p and suffix q.

Apply the checked central chain theorem recorded above, namely BEDC.Derived.ContinuousUp.ContinuousFunctio to the exposed carrier, the source restriction ledger, the displayed modulus chain, and the composite ledger $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. It yields the central restricted carrier

$$\mathsf{ContinuousFunctionCarrier}(\mathit{restricted}, \mathit{map}, \mathit{target}, \delta, \mathit{cert})$$

and the witness $\mathsf{ContinuousModulusWitness}(\mathit{target}, \delta, \mathit{cert})$.

Reattach the visible prefix and suffix with the reverse direction of Theorem 59.169. The resulting public carrier is exactly

$$\mathsf{ContinuousFunctionCarrier}(p \cdot \mathit{restricted}, \mathit{map}, p \cdot \mathit{target}, \delta \cdot q, (p \cdot \mathit{cert}) \cdot q).$$

It remains to compare this canonical carrier with the displayed restricted carrier. The visible-context target-certificate determinacy theorem applies to the two carriers with the same visible source, graph, modulus, prefix, and suffix data, so it returns $\mathsf{hsame}(\mathit{target}, \mathit{target}') \wedge \mathsf{hsame}(\mathit{cert}, \mathit{cert}')$.

Ten-field fit: traditional target commutation of visible source restriction with finite modulus-chain normalization; BEDC source BHist with Cont, visible contexts, and ContinuousModulusChain; carrier visible ContinuousFunctionCarrier with restricted source; classifier hsame on target and certificate histories; stability central chain witness plus visible-context transport; ledger composite modulus δ with unchanged graph ledger; core theorem this visible chain replacement law; exactness target-certificate readback against any displayed restricted carrier; standard bridge visible uniformly continuous restriction under modulus-chain normalization; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible source restriction modulus chain commutes`

Theorem 59.88 (Uniform continuity restriction commutes with three-step terminal modulus reassociation)**.** *Let Y and Z be certified* $\mathsf{Met}^{\uparrow}$ *objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusion $i : U \subseteq T$. Let $f : T \to Z$ be a certified graph witness, and let*

$$source, map, target, modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, modulus_2, cert_2, extra_3, modulus_3, cert_3, ext$$

be the BEDC histories recording the source ledger for T, the graph ledger of f, the codomain classifier ledger, the initial unary modulus and terminal certificate, the three terminal additions with their sequential output moduli and certificates, and the binary and ternary composite terminal ledgers. Assume that f satisfies the ContinuousMap carrier, totality, single-valuedness, and modulus-validity fields of Definition 59.1 and Definition 59.161 over T, and assume

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus_0, cert_0),\\
&\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1), \quad \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2), \quad \mathsf{ContinuousM}\\
&\mathsf{Cont}(modulus_0, extra_1, modulus_1), \quad \mathsf{Cont}(modulus_1, extra_2, modulus_2), \quad \mathsf{Cont}(modulus_2, extra_3, modulus_3),\\
&\mathsf{Cont}(extra_1, extra_2, extra_{12}), \quad \mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}),\\
&\mathsf{Cont}(extra_{12}, extra_3, extra_{123}), \quad \mathsf{Cont}(modulus_0, extra_{123}, modulus_{123}).
\end{aligned}$$

Then the $\mathsf{ContinuousMap}^{\uparrow}$ *witness obtained by restricting f along i and applying the three terminal modulus extensions with final public histories $map, target, modulus_3, cert_3$ is related by the classifier of Definition 59.94 to the witness obtained by first reassociating the three terminal extensions over T and then restricting along i with final public histories $map, target, modulus_{123}, cert_3$. The comparison includes the terminal-modulus equality* $\mathsf{hsame}(modulus_3, modulus_{123})$*, and both classified endpoints expose the restricted graph ledger map, the source-admission transport through i, the same target ledger target, and the same terminal certificate ledger $cert_3$.*

Proof. First apply Theorem 59.85 to the initial carrier and the first two terminal extensions. This relates the route that restricts before the first two extensions to the route that performs those two extensions over T before restriction. Both intermediate representatives expose the restricted graph ledger *map*, the transported source-admission through i, the target ledger *target*, and terminal data $modulus_2, cert_2$.

Next keep the third extension live on both sides. Apply Theorem 59.84 to the two-step carrier over T using $\mathsf{ContinuousModulusWitness}(cert_2, extra_3, cert_3)$ and $\mathsf{Cont}(modulus_2, extra_3, modulus_3)$. This classifies the endpoint obtained by restricting first and then applying all three terminal extensions with the endpoint obtained by applying the sequential three-step extension over T and then restricting.

Now identify the sequential and reassociated terminal moduli over the unreduced source. Theorem 59.168, with the empty visible prefix and suffix, supplies the carrier with final data $modulus_3, cert_3$, the carrier with final data $modulus_{123}, cert_3$, and the comparison $\mathsf{hsame}(modulus_3, modulus_{123})$.

Restrict the reassociated carrier along $i : U \subseteq T$. Proposition 59.80 transports the modulus-validity field to U, and the ledger policy keeps the graph relation *map*, the target classifier ledger *target*, and the terminal certificate ledger $cert_3$ fixed.

Finally use classifier transitivity in Definition 59.94. The sequential endpoint is classified with the extend-over-T sequential endpoint by the preceding commutation steps, the terminal chapter

identifies that endpoint with the reassociated carrier through $\mathsf{hsame}(modulus_3, modulus_{123})$, and restriction of the reassociated carrier gives the displayed final representative. Target and certificate determinacy keep the exposed target and terminal certificate ledgers equal, so the two restricted endpoints are $\mathsf{ContinuousMap}^{\uparrow}$ representatives of the same public certificate.

Ten-field fit: traditional target finite three-step terminal-modulus normalization under source restriction; BEDC source BHist with certified source predicates, Cont, and three ContinuousModulusWitness ledgers; carrier ContinuousFunctionCarrier preserved through sequential and reassociated terminal extensions; classifier ContinuousMap classifier with transitivity; stability transported source admission plus preserved modulus-validity fields; ledger restricted graph ledger, target classifier ledger, final sequential and reassociated modulus ledgers, and terminal certificate ledger; core theorem this block; exactness equality of the two route endpoints plus $\mathsf{hsame}(modulus_3, modulus_{123})$; standard bridge finite modulus-normalization coherence for uniformly continuous maps; status ProofTarget. □

Theorem 59.89 (Uniform continuity visible restriction commutes with three-step terminal modulus reassociation)**.** *Let Y and Z be certified $\mathsf{Met}^{\uparrow}$ objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusion $i : U \subseteq T$. Let $f : T \to Z$ be a certified graph witness, and let*

$$p, q, source, map, target, modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, modulus_2, cert_2, extra_3, modulus_3, cert_3$$

be the visible context histories, the source, graph, and target ledgers for f, the initial visible unary modulus and terminal certificate, the three terminal additions with their sequential output moduli and certificates, and the binary and ternary composite terminal ledgers. Assume that f satisfies the ContinuousMap carrier, totality, single-valuedness, and modulus-validity fields of Definition 59.1 and Definition 59.161 over T, and assume

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_0 \cdot q, (p \cdot cert_0) \cdot q),$$

the three terminal modulus witnesses

$$\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1), \quad \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2), \quad \mathsf{ContinuousM}$$

and the sequential and reassociated terminal modulus ledgers

$$\mathsf{Cont}(modulus_0, extra_1, modulus_1), \quad \mathsf{Cont}(modulus_1, extra_2, modulus_2), \quad \mathsf{Cont}(modulus_2, extra_3, modulus_3),$$
$$\mathsf{Cont}(extra_1, extra_2, extra_{12}), \quad \mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}),$$
$$\mathsf{Cont}(extra_{12}, extra_3, extra_{123}), \quad \mathsf{Cont}(modulus_0, extra_{123}, modulus_{123}).$$

Then the $\mathsf{ContinuousMap}^{\uparrow}$ witness obtained by restricting the visible carrier along i and applying the three visible terminal modulus extensions with exposed public histories $map, p \cdot target, modulus_3 \cdot q, (p \cdot cert_3) \cdot q$ is related by the classifier of Definition 59.94 to the witness obtained by first reassociating the three terminal extensions over the central carrier and then restricting along i with exposed public histories $map, p \cdot target, modulus_{123} \cdot q, (p \cdot cert_3) \cdot q$. The comparison includes the central readback $\mathsf{hsame}(modulus_3, modulus_{123})$, and both visible endpoints carry the same source-admission transport through i, the same graph ledger map, the same visible target ledger $p \cdot target$, and the same visible terminal certificate ledger $(p \cdot cert_3) \cdot q$.

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible source restriction terminal modulus reassociation`

Proof. Peel the visible carrier by Theorem 59.169. This exposes the central carrier

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus_0, cert_0)$$

under the same certified source inclusion $i : U \subseteq T$, while retaining the visible prefix p and suffix q for later reattachment.

Apply Theorem 59.88 to the central carrier, the three $\mathsf{ContinuousModulusWitness}$ rows, and the sequential and reassociated Cont rows. The central route that restricts first and then applies the three terminal extensions is classified with the route that first reassociates the three terminal extensions over T and then restricts, and the same step records $\mathsf{hsame}(modulus_3, modulus_{123})$.

Reattach the common visible prefix and suffix to the two central endpoints. The visible terminal-extension theorem supplies the route whose terminal extensions are performed after restriction, and the reverse direction of Theorem 59.169 repacks the endpoint obtained from the reassociated central carrier.

The visible-context exactness theorems identify the public ledgers after reattachment. The sequential endpoint exposes $p \cdot target$, $modulus_3 \cdot q$, and $(p \cdot cert_3) \cdot q$, while the reassociated endpoint exposes $p \cdot target$, $modulus_{123} \cdot q$, and the same visible terminal certificate $(p \cdot cert_3) \cdot q$.

Finally use classifier transitivity from Definition 59.94. The peeled central comparison, the two visible reattachments, and the visible exactness readbacks compose into a $\mathsf{ContinuousMap}^{\uparrow}$ classifier relation between the displayed public endpoints, with the central modulus comparison $\mathsf{hsame}(modulus_3, modulus_{123})$ carried along.

Ten-field fit: traditional target visible source restriction under three-step terminal-modulus reassociation; BEDC source BHist with visible contexts, certified source predicates, Cont, and three $\mathsf{ContinuousModulusWitness}$ rows; carrier visible $\mathsf{ContinuousFunctionCarrier}$ with restricted source admission; classifier ContinuousMap classifier with transitivity; stability visible-context peeling, central restriction reassociation, and visible reattachment; ledger restricted graph ledger, visible target ledger, sequential and reassociated visible modulus ledgers, and visible terminal certificate ledger; core theorem this visible reassociation statement; exactness public readback with $\mathsf{hsame}(modulus_3, modulus_{123})$; standard bridge public visible uniformly continuous restriction under three terminal modulus extensions; status ProofTarget. □

Theorem 59.90 (Uniform continuity visible restriction three-step terminal modulus normal form)**.** *Let*

$$p, q, restricted, source, map, target, target', modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, modulus_2, cert_2, extra$$

be histories. Assume the source restriction ledger

$$\mathsf{Cont}(restricted, \mathsf{e}, source),$$

the visible continuous-function carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_0 \cdot q, (p \cdot cert_0) \cdot q),$$

the three terminal modulus witnesses

$$\begin{aligned}&\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1),\\ &\mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2),\\ &\mathsf{ContinuousModulusWitness}(cert_2, extra_3, cert_3),\end{aligned}$$

the sequential and reassociated terminal modulus ledgers

$$\mathsf{Cont}(modulus_0, extra_1, modulus_1), \quad \mathsf{Cont}(modulus_1, extra_2, modulus_2), \quad \mathsf{Cont}(modulus_2, extra_3, modulus_3),$$
$$\mathsf{Cont}(extra_1, extra_2, extra_{12}), \quad \mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}),$$
$$\mathsf{Cont}(extra_{12}, extra_3, extra_{123}), \quad \mathsf{Cont}(modulus_0, extra_{123}, modulus_{123}),$$

and the displayed restricted sequential carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot restricted, map, p \cdot target', modulus_3 \cdot q, (p \cdot cert') \cdot q).$$

Then the visible restricted carrier has the three-step terminal modulus normal form

$$\mathsf{ContinuousFunctionCarrier}(p \cdot restricted, map, p \cdot target, modulus_{123} \cdot q, (p \cdot cert_3) \cdot q),$$

and the displayed sequential endpoint reads back to the same public data:

$$\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert_3, cert') \wedge \mathsf{hsame}(modulus_3, modulus_{123}).$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible source restriction terminal modulus normal form`

Proof. First apply Theorem 59.168 to the unreduced visible carrier, the three terminal witness rows, and the displayed sequential and reassociated Cont ledgers. It supplies the visible sequential carrier with final data $modulus_3, cert_3$, the visible reassociated carrier with final data $modulus_{123}, cert_3$, and the modulus comparison $\mathsf{hsame}(modulus_3, modulus_{123})$.

Restrict the reassociated carrier along the same source ledger $\mathsf{Cont}(restricted, \mathsf{e}, source)$. Proposition 59.80 transports the source-admission field, while the visible context and ledger policies preserve the graph ledger map, target ledger $p \cdot target$, reassociated modulus ledger $modulus_{123} \cdot q$, and certificate ledger $(p \cdot cert_3) \cdot q$.

Next compare the sequential and reassociated routes through Theorem 59.88, applied to the central histories under the same source restriction and terminal ledgers. This identifies the restricted sequential endpoint with the restricted reassociated endpoint and records the same terminal-modulus readback $\mathsf{hsame}(modulus_3, modulus_{123})$.

Finally apply Theorem 59.174 to the canonical restricted sequential carrier and the displayed restricted sequential carrier. They share the visible source $p \cdot restricted$, the graph ledger map, the visible modulus $modulus_3 \cdot q$, and the same visible prefix and suffix, so determinacy gives $\mathsf{hsame}(target, target')$ and $\mathsf{hsame}(cert_3, cert')$. Combining these with the modulus comparison yields the stated normal-form readback.

Ten-field fit: traditional target visible source restriction followed by three terminal modulus extensions; BEDC source BHist with visible contexts, source restriction ledger, Cont, and three $\mathsf{ContinuousModulusWitness}$ rows; carrier visible $\mathsf{ContinuousFunctionCarrier}$ with restricted source; classifier hsame target, certificate, and modulus readback; stability source-admission restriction plus terminal modulus reassociation; ledger restricted graph ledger, visible target ledger, sequential and reassociated modulus ledgers, and terminal certificate ledger; core theorem this normal-form statement; exactness comparison against any displayed restricted sequential carrier; standard bridge visible uniformly continuous restriction under three terminal modulus extensions; status ProofTarget. □

Theorem 59.91 (Continuous restriction visible modulus-chain functorial normal form)**.** *Let T, U, V, and W be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, with certified inclusions*

$$k : W \subseteq V, \qquad j : V \subseteq U, \qquad i : U \subseteq T.$$

Let

$$p, q, source_T, source_U, source_V, source_W, map, target, target_d, target_s, oldMod, oldCert, \delta_1, \delta_2, \delta, cert, cert_d, cert_s :$$

be histories. Assume the visible carrier over T

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source_T, map, p \cdot target, oldMod \cdot q, (p \cdot oldCert) \cdot q),$$

the source-restriction ledgers

$$\mathsf{Cont}(source_U, \mathsf{e}, source_T), \qquad \mathsf{Cont}(source_V, \mathsf{e}, source_U), \qquad \mathsf{Cont}(source_W, \mathsf{e}, source_V), \qquad \mathsf{Cont}(source_W, \mathsf{e}, s$$

the two-link visible modulus chain

$$\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert),$$

the composite modulus ledger

$$\mathsf{Cont}(\delta_1, \delta_2, \delta),$$

the displayed direct restricted carrier over W

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source_W, map, p \cdot target_d, \delta \cdot q, (p \cdot cert_d) \cdot q),$$

and the displayed successive restricted carrier over W

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source_W, map, p \cdot target_s, \delta \cdot q, (p \cdot cert_s) \cdot q).$$

Then the route that restricts directly from T to W and the route that restricts successively

$$T \longrightarrow U \longrightarrow V \longrightarrow W$$

before applying the same visible modulus-chain replacement have the common public normal form

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source_W, map, p \cdot target, \delta \cdot q, (p \cdot cert) \cdot q),$$

and their displayed target and certificate readbacks agree:

$$\mathsf{hsame}(target, target_d) \wedge \mathsf{hsame}(cert, cert_d) \wedge \mathsf{hsame}(target, target_s) \wedge \mathsf{hsame}(cert, cert_s).$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible source restriction modulus chain functorial normal form`

Proof. First collapse the nested source restrictions. Apply Theorem 59.83 to $i : U \subseteq T$ and $j : V \subseteq U$ to compare the direct restriction from T to V with the successive route through U.

Apply Theorem 59.83 again to the composite inclusion $V \subseteq T$ and $k : W \subseteq V$. This identifies the direct restriction from T to W with the three-step route through U and V at the $\mathsf{ContinuousMap}^{\uparrow}$ classifier, while preserving the graph ledger map, the visible target ledger $p \cdot target$, and the source ledger $p \cdot source_W$.

Next normalize the visible modulus data on the direct representative. Theorem 59.87, applied to the direct source ledger $\mathsf{Cont}(source_W, \mathsf{e}, source_T)$ and the chain $\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert)$, supplies the canonical visible carrier over W with public histories map, $p{\cdot}target$, $\delta{\cdot}q$, and $(p{\cdot}cert){\cdot}q$.

It remains to read back the two displayed endpoints. The direct displayed carrier has the same restricted source, graph ledger, visible modulus ledger, and visible prefix and suffix as the canonical direct carrier, so Theorem 59.87 gives $\mathsf{hsame}(target, target_d)$ and $\mathsf{hsame}(cert, cert_d)$.

Transport the same canonical carrier across the classifier comparison supplied by the functorial restriction step. Target and certificate determinacy for visible modulus contexts then applies to the successive displayed carrier, giving $\mathsf{hsame}(target, target_s)$ and $\mathsf{hsame}(cert, cert_s)$. Combining the four readbacks yields the stated common normal form for the direct and successive routes.

Ten-field fit: traditional target nested restriction of uniformly continuous maps followed by a visible two-link modulus-chain replacement; BEDC source BHist with visible contexts, certified source-restriction ledgers, Cont, and ContinuousModulusChain; carrier visible ContinuousFunctionCarrier over the final source W; classifier ContinuousMap classifier plus hsame target and certificate readback; stability identity and composite source-admission transport with modulus-chain preservation; ledger common graph ledger, visible target ledger, composite modulus ledger, and visible certificate ledger; core theorem this normal form; exactness direct-versus-successive route agreement after the same chain replacement; standard bridge functorial source restriction with visible modulus-chain normalization for uniformly continuous maps; status ProofTarget. □

Definition 59.95 (ContinuousMap stability certificate)**.** *The stability certificate consists of:*

1. *continuous-map classifier reflexivity*
2. *continuous-map classifier symmetry*
3. *continuous-map classifier transitivity*
4. *modulus validity for uniform continuity*

5. *graph and modulus replacement under the continuous-map classifier*
6. *closure under identity*
7. *closure under composition by composing moduli*

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier stability certificate fields`

Theorem 59.96 (Continuous modulus chain factorization)**.** *For histories s, δ_1, δ_2, t, assume the two-link chain*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t).$$

Then there is a history m such that both one-step links are certified:

$$\mathsf{ContinuousModulusWitness}(s, \delta_1, m) \quad \textit{and} \quad \mathsf{ContinuousModulusWitness}(m, \delta_2, t).$$

Proof. Unpack the chain into unary data for s, δ_1, δ_2, and t, together with a middle history m and continuation ledgers $s \cdot \delta_1 = m$ and $m \cdot \delta_2 = t$.

The first ledger and the unary source and modulus data assemble

$$\mathsf{ContinuousModulusWitness}(s, \delta_1, m).$$

Unary continuation closure then makes the middle history unary. The second ledger and the unary δ_2 and target data assemble

$$\mathsf{ContinuousModulusWitness}(m, \delta_2, t).$$

Taking this middle history as the existential witness gives the displayed factorization of the chain into its two certified one-step modulus witnesses. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain factorizes`

Theorem 59.97 (Continuous modulus chain middle deterministic factorization)**.** *For histories s, δ_1, δ_2, t, a continuous modulus chain determines a middle history m such that the two one-step modulus witnesses factor the chain, and every other first-leg middle endpoint is the same BEDC history:*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow \exists m.\ \mathsf{ContinuousModulusWitness}(s, \delta_1, m) \wedge \mathsf{ContinuousModulusWitness}(m, \delta$$

$$\wedge\ \forall m'.\ \mathsf{Cont}(s, \delta_1, m') \Longrightarrow \mathsf{Cont}(m', \delta_2, t) \Longrightarrow \mathsf{hsame}(m, m').$$

Proof. Unpack the chain into unary data and a displayed middle history m with continuation ledgers $s \cdot \delta_1 = m$ and $m \cdot \delta_2 = t$. As in Theorem 59.96, the first ledger gives the first witness and unary continuation closure supplies unary data for m, so the second ledger gives the second witness. If another m' satisfies the same first continuation ledger, Cont determinacy for $s \cdot \delta_1$ yields $\mathsf{hsame}(m, m')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain middle deterministic factorization`

Theorem 59.98 (Continuous modulus chain target determinacy)**.** *For histories $source, first, second, target, targe$ two modulus-chain witnesses with the same source and the same two modulus histories determine the same target up to* hsame*:*

$$\mathsf{ContinuousModulusChain}(source, first, second, target) \Longrightarrow \mathsf{ContinuousModulusChain}(source, first, second, target')$$

Proof. Unpack both chains. The first continuation ledgers share *source* and $first$, so continuation determinacy identifies the two middle histories up to hsame. Transport the second continuation comparison along this middle sameness, keeping the common *second* history fixed; continuation respect for hsame then gives $\mathsf{hsame}(target, target')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain target deterministic`

Theorem 59.99 (Continuous modulus chain append-suffix target determinacy)**.** *For histories $q, source, first, second, target, target'$, two modulus chains with the same source and moduli whose targets share the right suffix q determine the unsuffixed targets up to* hsame*.*

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain append suffix target deterministic`

Proof. Target determinacy identifies $\mathsf{append}(target, q)$ with $\mathsf{append}(target', q)$. Cancel the common right suffix. □

Theorem 59.100 (Continuous modulus chain result determinacy)**.** *For histories $s, \delta_1, \delta_2, t, t'$, two continuous modulus chains with the same source and modulus ledgers determine the same target history:*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t') \Longrightarrow \mathsf{hsame}(t, t').$$

Proof. Unpack the two chains into middle histories m and m' with first ledgers $s \cdot \delta_1 = m$ and $s \cdot \delta_1 = m'$, and second ledgers $m \cdot \delta_2 = t$ and $m' \cdot \delta_2 = t'$. Determinacy of the first continuation gives $\mathsf{hsame}(m, m')$. Continuation compatibility with this middle history equality and reflexivity of δ_2 transports the two second ledgers to obtain $\mathsf{hsame}(t, t')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain result deterministic`

Theorem 59.101 (Continuous modulus chain source determinacy)**.** *For histories $source, source', first, second, ta$ two modulus-chain witnesses with the same two modulus histories and the same target determine the same source up to* hsame*:*

$$\mathsf{ContinuousModulusChain}(source, first, second, target) \Longrightarrow \mathsf{ContinuousModulusChain}(source', first, second, target$$

Proof. Unpack both chains into middle histories and continuation ledgers. The second continuation ledgers have common suffix *second* and common target, so right cancellation identifies the two middle histories. The first continuation ledgers then have common suffix $first$ and endpoints identified by that middle sameness; common-suffix cancellation gives $\mathsf{hsame}(source, source')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain source deterministic`

Theorem 59.102 (Continuous modulus chain append-suffix source determinacy)**.** *For histories $q, source, source', first, second, target$, two modulus chains with the same moduli and target whose sources share the right suffix q determine the unsuffixed sources up to* hsame*.*

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain append suffix source deterministic`

Proof. Source determinacy identifies $\mathsf{append}(source, q)$ with $\mathsf{append}(source', q)$. Cancel the common right suffix. □

Theorem 59.103 (Continuous modulus chain first determinacy)**.** *For histories source, first, first′, second, target two modulus-chain witnesses with the same source, second modulus, and target determine the same first modulus up to* hsame*:*

$$\mathsf{ContinuousModulusChain}(source, first, second, target) \Longrightarrow \mathsf{ContinuousModulusChain}(source, first', second, target)$$

Proof. Unpack both chains. Right cancellation on the two second-leg continuation ledgers identifies the middle histories. Transport the second first-leg ledger along this middle sameness so that both first-leg ledgers have the same source and the same middle endpoint. Left cancellation of continuation then gives $\mathsf{hsame}(first, first')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain first deterministic`

Theorem 59.104 (Continuous modulus chain second determinacy)**.** *For histories source, first, second, second′, ta two modulus-chain witnesses with the same source, first modulus, and target determine the same second modulus up to* hsame*:*

$$\mathsf{ContinuousModulusChain}(source, first, second, target) \Longrightarrow \mathsf{ContinuousModulusChain}(source, first, second', target)$$

Proof. Unpack both chains into their middle histories. Determinacy of $\mathsf{Cont}(source, first, -)$ identifies those middle histories. After transporting across this middle equality, the second-leg ledgers have common left endpoint and common target, so continuation left cancellation gives $\mathsf{hsame}(second, second')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain second deterministic`

Theorem 59.105 (Continuous modulus chain composite closure)**.** *For unary histories s, δ_1, δ_2, t, a two-link modulus chain from s through δ_1 and δ_2 to t, together with a continuation ledger composing δ_1 and δ_2 into δ, determines a single continuous modulus witness from s to t using δ:*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow \mathsf{Cont}(\delta_1, \delta_2, \delta) \Longrightarrow \mathsf{ContinuousModulusWitness}(s, \delta, t).$$

Proof. Unpack the chain into unary endpoint and modulus data plus a middle history with ledgers $m = s \cdot \delta_1$ and $t = m \cdot \delta_2$. The composite modulus is unary by closure of unary continuation. The source-to-target continuation is the associativity equality $(s \cdot \delta_1) \cdot \delta_2 = s \cdot (\delta_1 \cdot \delta_2)$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain composite closed`

Theorem 59.106 (Continuous modulus chain endpoint cycle empties moduli)**.** *If* $\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2$ *and* $\mathsf{hsame}(s, t)$*, then*

$$\mathsf{hsame}(\delta_1, \mathsf{e}) \wedge \mathsf{hsame}(\delta_2, \mathsf{e}).$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain endpoint cycle moduli empty`

Proof. Unpack the chain as $\mathsf{Cont}(s, \delta_1, m)$ and $\mathsf{Cont}(m, \delta_2, t)$. Transport the second ledger across $\mathsf{hsame}(s, t)$ and apply mutual-extension tail cancellation. □

Theorem 59.107 (Continuous modulus witness composite public readback)**.** *For histories source, first, second, m two certified one-step modulus witnesses*

$$\mathsf{ContinuousModulusWitness}(source, first, middle)$$

and

$$\mathsf{ContinuousModulusWitness}(middle, second, target)$$

together with $\mathsf{Cont}(first, second, composite)$ *determine the composite witness*

$$\mathsf{ContinuousModulusWitness}(source, composite, target).$$

Any displayed witness from source through the same composite has target history hsame *to target.*

Proof. The two one-step witnesses supply the source, modulus, middle, and target carriers plus the two continuation ledgers, hence assemble a $\mathsf{ContinuousModulusChain}(source, first, second, target)$. Composite closure turns this chain and the displayed modulus composition into the one-step composite witness. If another target is displayed for the same source and composite modulus, target determinacy for continuous modulus witnesses identifies it with $target$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness composite public readback`

Theorem 59.108 (Continuous function carrier modulus-chain replacement)**.** *For histories* $source, map, target, old$ *assume an existing continuous-function carrier, a two-step modulus chain from the same target history to a certificate history, and a continuation ledger composing the two modulus steps:*

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, map, target, oldMod, oldCert),\\&\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert),\\&\mathsf{Cont}(\delta_1, \delta_2, \delta).\end{aligned}$$

Then the carrier admits the composite modulus and the chain certificate:

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, \delta, cert).$$

Proof. Unpack the given carrier into unary data for $source$, map, $target$, $oldMod$, and $oldCert$. Keep the graph ledger $\mathsf{Cont}(source, map, target)$; the old modulus and certificate are used only to expose the source, map, and target carrier data.

Apply Theorem 59.105 to the chain $\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert)$ and the composition ledger $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. This yields the replacement modulus witness

$$\mathsf{ContinuousModulusWitness}(target, \delta, cert).$$

Unpack this witness to obtain unary data for δ and $cert$, together with the modulus-certificate ledger $\mathsf{Cont}(target, \delta, cert)$. Reassemble $\mathsf{ContinuousFunctionCarrier}(source, map, target, \delta, cert)$ from the preserved source, map, and target data, the preserved graph ledger, and this new modulus witness.

The ten-field certificate fit is the following. The traditional target is uniform-continuity data whose modulus certificate may be recomputed through a two-link modulus chain. The BEDC source is $BHist$ equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is carrier preservation under modulus-chain replacement. The ledger consists of source, map, target, old modulus, old certificate, two modulus steps, the composite modulus, and the terminal certificate. The core theorem is this carrier-level replacement, exactness is the displayed carrier conclusion, the standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier modulus chain replacement`

Theorem 59.109 (Prefixed continuous function carrier graph-chain closure)**.** *For histories $p, source, map, target, \delta$ unary source, map, target, and visible-prefix histories, a graph continuation ledger, a two-step modulus chain from the target history to a certificate history, and a continuation ledger composing the two modulus steps determine the prefixed graph carrier with the composite modulus certificate:*

$$\begin{aligned}&\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{UnaryHistory}(source) \Longrightarrow \\ &\mathsf{UnaryHistory}(target) \Longrightarrow \mathsf{UnaryHistory}(map) \Longrightarrow \\ &\mathsf{Cont}(source, map, target) \Longrightarrow \mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert) \Longrightarrow \mathsf{Cont}(\delta_1, \delta_2, \delta) \Longrightarrow \\ &\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert).\end{aligned}$$

Proof. First apply Theorem 59.113 to the prefix p, the chain $\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2, cert)$, and the composition ledger $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. This gives the modulus witness

$$\mathsf{ContinuousModulusWitness}(p \cdot target, \delta, p \cdot cert).$$

Unpack this witness into unary data for $p \cdot target$, the composite modulus δ, and $p \cdot cert$, together with the certificate ledger $\mathsf{Cont}(p \cdot target, \delta, p \cdot cert)$.

The graph ledger is prefixed directly from $\mathsf{Cont}(source, map, target)$. Associativity of history append gives

$$(p \cdot source) \cdot map = p \cdot (source \cdot map) = p \cdot target.$$

Unary append closure applied to p and $source$ supplies the unary source history $p \cdot source$. The unary map hypothesis is reused, and the prefixed target, composite modulus, and prefixed certificate data come from the modulus witness. These fields assemble $\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert)$.

The ten-field certificate fit is the following. The traditional target is uniformly continuous map composition under visible finite-prefix evidence. The BEDC source is $BHist$ equipped with Cont. The carrier is $\mathsf{ContinuousFunctionCarrier}$ and the classifier is hsame. The stability obligation is carrier preservation from graph data and a prefixed two-link modulus chain. The ledger consists of source, map, target, two modulus steps, the composite modulus, the terminal certificate, and the visible prefix. The core theorem is this carrier-level closure, exactness is the displayed carrier conclusion, the standard bridge is deferred, and the status is $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain closed`

Theorem 59.110 (Prefixed continuous function carrier graph-chain public readback)**.** *For histories $p, source, map, target, target', \delta_1, \delta_2, \delta, cert, cert'$, assume unary histories p, source, target, and map, a graph ledger $\mathsf{Cont}(source, map, target)$, a two-link modulus chain $\mathsf{ContinuousModulusChain}(target, \delta_1, \delta_2$ and a composition ledger $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. If a displayed prefixed continuous-function carrier has target $p \cdot target'$ and certificate $p \cdot cert'$,*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target', \delta, p \cdot cert'),$$

then the public target and certificate are determined:

$$\mathsf{hsame}(target, target') \quad \textit{and} \quad \mathsf{hsame}(cert, cert').$$

Proof. The graph ledger and the modulus chain first build the canonical prefixed continuous-function carrier with target $p \cdot target$ and certificate $p \cdot cert$. Carrier target-certificate determinacy compares this canonical carrier with the displayed carrier, giving equality of the two prefixed targets and equality of the two prefixed certificates. Left cancellation of the shared prefix p yields the displayed public readback equalities. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain public readback`

Theorem 59.111 (Prefixed continuous function carrier graph-chain second determinacy)**.** *For histories $p, source, map, target, \delta_1, \delta_2, \delta_2', \delta, \delta', cert$, assume δ_1, δ_2, and δ_2' are unary histories, with continuation ledgers*

$$\mathsf{Cont}(\delta_1, \delta_2, \delta), \qquad \mathsf{Cont}(\delta_1, \delta_2', \delta').$$

If the two composite moduli support the same prefixed continuous function carrier,

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta', p \cdot cert),$$

then the second modulus components are history-same:

$$\mathsf{hsame}(\delta_2, \delta_2').$$

Proof. Unpack the two continuous function carriers and compare their terminal certificate ledgers. Since both ledgers start at $p \cdot target$ and end at $p \cdot cert$, continuation left cancellation identifies the composite moduli δ and δ'. Transport to a common composite modulus, then apply left cancellation to the two ledgers out of δ_1 to obtain $\mathsf{hsame}(\delta_2, \delta_2')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain second deterministic`

Theorem 59.112 (Prefixed continuous function carrier graph-chain first determinacy)**.** *For histories $p, source, map, target, \delta_1, \delta_1', \delta_2, \delta, \delta', cert$, assume δ_1, δ_1', and δ_2 are unary histories, with continuation ledgers*

$$\mathsf{Cont}(\delta_1, \delta_2, \delta), \qquad \mathsf{Cont}(\delta_1', \delta_2, \delta').$$

If the two composite moduli support the same prefixed continuous function carrier,

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta', p \cdot cert),$$

then the first modulus components are history-same:

$$\mathsf{hsame}(\delta_1, \delta_1').$$

Proof. Unpack the two continuous function carriers and compare their terminal certificate ledgers. Since both ledgers start at $p \cdot target$ and end at $p \cdot cert$, continuation left cancellation identifies the composite moduli δ and δ'. Common-suffix cancellation on the two composite modulus ledgers, using the shared suffix δ_2, then yields $\mathsf{hsame}(\delta_1, \delta_1')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain first deterministic`

Theorem 59.113 (Prefixed continuous modulus composite closure)**.** *For unary histories $p, s, \delta_1, \delta_2, t, \delta$, a unary prefix p, a two-link modulus chain from s through δ_1 and δ_2 to t, and a continuation ledger composing δ_1 and δ_2 into δ determine a prefixed continuous modulus witness:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow \\ \mathsf{Cont}(\delta_1, \delta_2, \delta) \Longrightarrow \mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t).$$

Proof. Unpack the chain into unary endpoint and modulus histories, together with the continuation ledgers from s to the middle history and from the middle history to t.

The prefixed source and target histories are unary by unary append closure applied to p with s and t. The composite modulus history is unary by unary continuation closure applied to the two modulus histories and their composition ledger.

The remaining continuation ledger is obtained by associating the concatenation spine:

$$(p \cdot s) \cdot \delta = p \cdot (s \cdot \delta) = p \cdot t.$$

Thus the prefixed endpoints and the same composite modulus satisfy the public continuous modulus witness predicate. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite closed`

Theorem 59.114 (Continuous modulus witness prefixed composite factorization)**.** *For histories $p, s, \delta_1, \delta_2, \delta, t$, if δ_1 and δ_2 are unary histories, $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ holds, and*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t)$$

holds, then there is a middle history m such that

$$\mathsf{ContinuousModulusWitness}(s, \delta_1, m) \quad \wedge \quad \mathsf{ContinuousModulusWitness}(m, \delta_2, t).$$

Proof. First remove the common prefix from the displayed continuous modulus witness using Theorem 59.21. This leaves a witness from s through the composite modulus δ to t.

Choose $m = s \cdot \delta_1$. The first witness is immediate from $\mathsf{Cont}(s, \delta_1, s \cdot \delta_1)$ and unary append closure. For the second witness, case-analyze the two continuation ledgers $\mathsf{Cont}(s, \delta, t)$ and $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. Associativity identifies $(s \cdot \delta_1) \cdot \delta_2$ with $s \cdot (\delta_1 \cdot \delta_2)$, hence with t. This supplies the required continuation ledger from m through δ_2 to t. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite factorizes`

Theorem 59.115 (Continuous prefixed composite middle deterministic factorization)**.** *For histories $p, s, \delta_1, \delta_2, \delta, t$, if δ_1 and δ_2 are unary histories, $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ holds, and*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t)$$

holds, then there is a middle history m such that

$$\mathsf{ContinuousModulusWitness}(s, \delta_1, m) \quad \wedge \quad \mathsf{ContinuousModulusWitness}(m, \delta_2, t),$$

and every other middle history carrying the same two witness legs is hsame *to m.*

Proof. First apply the prefixed composite factorization theorem to expose a middle history and the two one-step continuous modulus witnesses. If another middle history carries a witness from s through δ_1, both first legs have the same source and modulus; one-step target determinacy therefore identifies the two middle histories by hsame. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite middle deterministic factorization`

Theorem 59.116 (Continuous prefixed composite first deterministic)**.** *For histories $p, s, \delta_1, \delta_1', \delta_2, \delta, \delta', t$, assume δ_1, δ_1', and δ_2 are unary,* $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ *and* $\mathsf{Cont}(\delta_1', \delta_2, \delta')$ *hold, and both*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t) \quad \textit{and} \quad \mathsf{ContinuousModulusWitness}(p \cdot s, \delta', p \cdot t)$$

hold. Then $\mathsf{hsame}(\delta_1, \delta_1')$*.*

Proof. Factor both prefixed composite witnesses. The second legs share the same target t and the same second modulus δ_2, so one-step source determinacy identifies their middle histories. The first legs then share the same source s and hsame target histories, so one-step modulus determinacy identifies δ_1 and δ_1'. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite first deterministic`

Theorem 59.117 (Continuous modulus witness prefixed composite source determinacy)**.** *For histories $p, s, s', \delta_1, \delta_2, \delta, t$, assume δ_1 and δ_2 are unary histories and* $\mathsf{Cont}(\delta_1, \delta_2, \delta)$*. If two prefixed composite modulus witnesses share the same composite modulus and the same prefixed target,*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t) \quad \textit{and} \quad \mathsf{ContinuousModulusWitness}(p \cdot s', \delta, p \cdot t),$$

then their unprefixed sources are history-same:

$$\mathsf{hsame}(s, s').$$

Proof. Factor both prefixed composite witnesses into two one-step modulus witnesses. The second legs share the modulus δ_2 and target t, so one-step source determinacy identifies the two recovered middle histories. The first legs then share the modulus δ_1 and have history-same middle targets, so one-step source determinacy gives $\mathsf{hsame}(s, s')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite source deterministic`

Theorem 59.118 (Continuous prefixed composite second deterministic)**.** *For histories $p, s, \delta_1, \delta_2, \delta_2', \delta, \delta', t$, assume δ_1, δ_2, and δ_2' are unary,* $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ *and* $\mathsf{Cont}(\delta_1, \delta_2', \delta')$ *hold, and both*

$$\mathsf{ContinuousModulusWitness}(p \cdot s, \delta, p \cdot t) \quad \textit{and} \quad \mathsf{ContinuousModulusWitness}(p \cdot s, \delta', p \cdot t)$$

hold. Then $\mathsf{hsame}(\delta_2, \delta_2')$*.*

Proof. Factor both prefixed composite witnesses. The first legs share the same source s and first modulus δ_1, so one-step target determinacy identifies the two middle histories. The second legs then have hsame source histories and the same target t, so one-step modulus determinacy identifies δ_2 and δ_2'. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness prefixed composite second deterministic`

Theorem 59.119 (Continuous modulus chain prefix closure)**.** *For histories $p, s, \delta_1, \delta_2, t$, a unary prefix on the source and target preserves a two-link continuous modulus chain:*

$$\mathsf{UnaryHistory}(p) \Longrightarrow \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t) \Longrightarrow \mathsf{ContinuousModulusChain}(p{\cdot}s, \delta_1, \delta_2, p{\cdot}t).$$

Proof. Unpack the chain into unary endpoint data and a middle history m with continuations $m = s \cdot \delta_1$ and $t = m \cdot \delta_2$. Use $p \cdot m$ as the middle history for the prefixed chain. Unary append closure supplies the prefixed endpoints, and continuation associativity prefixes both ledger equalities. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain prefix closed`

Theorem 59.120 (Continuous modulus chain prefix exactness)**.** *For histories $p, s, \delta_1, \delta_2, t$, prefixing both endpoints of a two-link continuous modulus chain is exact:*

$$\mathsf{ContinuousModulusChain}(p \cdot s, \delta_1, \delta_2, p \cdot t) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t).$$

The traditional target is prefix-stable uniform-modulus data. The BEDC source is BHist with Cont*, the carrier is* ContinuousModulusChain*, and the classifier is* hsame*. The stability obligation is prefix exactness. The ledger records source, two precision histories, middle, and target continuations. The core theorem is this exactness statement, the exactness predicate is the displayed iff, the standard bridge is deferred, and the status is* ProofTarget*.*

Proof. For the forward direction, unpack the prefixed chain. Unary append factorization gives unary p and unary s. Let the unprefixed middle be $s \cdot \delta_1$.

The first continuation ledger, together with associativity, identifies the prefixed middle as $p \cdot (s \cdot \delta_1)$. The second continuation ledger then has a common visible prefix p on both sides. Associativity and left cancellation recover the unprefixed second continuation from $s \cdot \delta_1$ through δ_2 to t. These data assemble $\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t)$, paired with unary p.

For the reverse direction, take unary p together with the unprefixed chain and apply Theorem 59.119. This gives the prefixed chain from $p \cdot s$ through the same two precision histories to $p \cdot t$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain prefix iff`

Theorem 59.121 (Continuous modulus chain suffix exactness)**.** *For histories $p, s, \delta_1, \delta_2, t$, suffixing the second modulus and the target of a two-link continuous modulus chain is exact:*

$$\mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2 \cdot p, t \cdot p) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousModulusChain}(s, \delta_1, \delta_2, t).$$

Proof. For the forward direction, unpack the suffixed chain and derive the unary middle history from the first continuation. The second continuation is a continuous modulus witness from the middle history through $\delta_2 \cdot p$ to $t \cdot p$. Apply Theorem 59.22 to remove the common right suffix from that second leg, then rebuild the original two-link chain.

For the reverse direction, apply Theorem 59.22 to the second leg of the chain and reuse the same middle history and first continuation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain suffix iff`

Definition 59.122 (ContinuousMap ledger policy)**.** *Record the graph relation, source and target metric ledgers, the totally bounded subset witness, the unary precision ledger, and the modulus ledger.*

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier ledger policy fields`

Definition 59.123 ($\mathsf{ContinuousMap}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{ContinuousMap}^{\uparrow}$*.*

↪ variant `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier certificate semanticNameCert`

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousUp StdBridge`

Primitive boundary. $\mathsf{ContinuousMap}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 59.124 (Zero-axiom encoding note)**.** *The encoding avoids extensional equality of maps and host* `Nat` *by using graph classifier sameness and unary precision histories. The modulus object is a certified relation between precision histories, so no host-level numeric modulus is exposed at the certificate boundary.*

Proposition 59.125 (Uniform modulus restriction along subset containment)**.** *Let Y and Z be certified* $\mathsf{Met}^{\uparrow}$ *objects with the metric data of Definition 57.1. Let T and U be certified source-subset witnesses in the totally bounded domain discipline of Definition 59.92, and let $i : U \subseteq T$ be a certified inclusion. For a graph witness $f : T \to Z$, let $f\restriction_U$ be the same graph relation read with the source classifier restricted along i. If a unary precision ledger δ satisfies the modulus-validity field of Definition 59.161 for f over T, then the same δ satisfies that modulus-validity field for $f\restriction_U$ over U.*

Proof. Fix a target precision request and two source histories admitted by U. The certified inclusion sends their source-membership ledgers to membership ledgers for T:

$$u_j \in U \Longrightarrow i(\nu_j) \in T \qquad (j = 0, 1).$$

The graph relation, codomain classifier ledger, unary precision ledger, and modulus ledger are the same ledgers as in the witness over T, as specified by Definition 59.93 and Definition 59.122. Apply the modulus-validity field over T to the two transported source memberships. It returns the codomain metric conclusion at the requested target precision for the two graph outputs. The metric judgments are well formed and stable under classifier replacement by Definition 57.4 and Definition 57.5.

The restricted witness over U asks for exactly the same codomain conclusion, with only the source-admission hypotheses narrowed from T to U. The totality and single-valuedness clauses from Definition 59.1 license the same graph outputs, while no precision or modulus ledger is changed. □

↪ variant `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source restriction public readback`

Closure status for $\mathsf{NameCert}_{\mathsf{Continuous}^{\uparrow}}$**.**

Constructive story: A continuous map is carried by a graph-and-modulus history packet: source, target, map code, modulus, and certificate histories are unary, the graph ledger continues the source through the map to the target, and the modulus ledger continues the target through the modulus to the certificate. Two such witnesses are classified by the graph outputs agreeing under the target classifier for classified source inputs and by their unary modulus ledgers mutually refining each requested precision; on the checked carrier rows this is enforced through hsame determinacy of the displayed continuation fields. The source consists of certified metric spaces and the totally bounded source discipline, the pattern records graph-with-modulus formation, identity, composition, prefix and restriction examples, terminal-modulus extension, and modulus-chain exactness, and the ledger keeps the graph relation, metric ledgers, precision history, modulus history, and certificate history visible. The five name-certificate obligations close because the identity map uses the empty map code with a one-step modulus witness, hsame supplies reflexive, symmetric, and transitive comparison of the displayed histories, and carrier transport follows by moving each continuation ledger across history-sameness. A carrier row lies in the signature gap of a $\mathsf{Continuous}^{\uparrow}$ token p when the source-domain accepts the graph-and-modulus packet, the signature relation pairs it with an answer packet and evidence ledger, and token introduction names that answer as p; unfolded, the graph sends each accepted source history to the encoded target history and the modulus ledger supplies the precision conversion recorded by p. The checked standard bridge reads the same relation-plus-ledger data as a continuous-map boundary and reads it back without host-level function extensionality or a numeric modulus object. The chapter registers this graph-modulus construction under the name $\mathsf{Continuous}^{\uparrow}$; continuity is an explicit BEDC certificate surface, not a host function space, completeness theorem, or external map equality principle.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Continuous}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature paper scope binds the ContinuousFunctionCarrier semantic certificate, modulus-witness determinacy and exactness rows, identity, composition, prefix, and restriction examples, and the ContinuousMapUp consumer surface cited by the chapter.
Formal verification: FormalStatus(NameCert$_{\text{Continuous}\uparrow}$, bridgeChecked)
Lean target: `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier\_certificate\_semanticNameCert`
Bridge status: bridgeChecked
Not claimed: The chapter does not close host functions, host function spaces, or standard-model completeness.
Upgrade path: no further upgrade – chapter at top of formal axis

Theorem 59.126 (Continuous modulus witness modulus determinacy)**.** *If two one-step modulus witnesses have* hsame *source histories and* hsame *target histories, then their modulus histories are* hsame*:*

$$\mathsf{hsame}(modulus, modulus').$$

Proof. Unpack both witnesses, identify the source and target endpoints by hsame, and apply continuation left cancellation to the two modulus ledgers. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness modulus hsame deterministic`

Theorem 59.127 (Continuous modulus witness target determinacy)**.** *If two one-step modulus witnesses have* hsame *source histories and the same modulus history, then their target histories are* hsame*:*

$$\mathsf{hsame}(target, target').$$

Proof. Unpack both witnesses, identify the source endpoint by hsame, and apply continuation result determinacy to the two continuation ledgers with the shared source and modulus. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness target hsame deterministic`

Theorem 59.128 (Continuous modulus witness source determinacy)**.** *If two one-step modulus witnesses have* hsame *target histories and the same modulus history, then their source histories are* hsame*:*

$$\mathsf{hsame}(source, source').$$

Proof. Unpack both witnesses, identify the target endpoint by hsame, and apply continuation right cancellation to the two ledgers with the shared modulus and target. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness source hsame deterministic`

Theorem 59.129 (Continuous modulus witness empty target exactness)**.** *For histories source and modulus, a one-step continuous modulus witness with empty target is exactly the conjunction that both source and modulus are empty histories:*

$$\mathsf{ContinuousModulusWitness}(source, modulus, \mathsf{e}) \iff \mathsf{hsame}(source, \mathsf{e}) \wedge \mathsf{hsame}(modulus, \mathsf{e}).$$

Proof. Unpack the witness into unary carriers and the continuation ledger $\mathsf{Cont}(source, modulus, \mathsf{e})$. Empty-result inversion for continuation gives the two endpoint equalities. Conversely, if both endpoints are empty, the empty unary carrier and the canonical empty continuation rebuild the witness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness empty target iff`

Theorem 59.130 (Continuous empty-source nonempty modulus shape)**.** *For histories target, modulus, an empty-source continuous modulus witness with nonempty modulus has exactly one visible unary payload:*

$$\mathsf{ContinuousModulusWitness}(\mathsf{e}, modulus, target) \wedge \neg \mathsf{hsame}(modulus, \mathsf{e}) \iff \exists r : \mathsf{BHist}.\ target = \mathsf{E1}(r) \wedge modulus = \mathsf{E}$$

Proof. Empty-source modulus exactness identifies *modulus* with *target* and gives unary membership of *target*. Nonemptiness excludes the empty target, unary membership excludes zero-headed targets, and the visible case strips one E1 constructor to expose the unary payload. The reverse direction rebuilds the witness from the visible unary target and reflexive sameness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness empty source nonempty modulus shape iff`

Theorem 59.131 (Continuous modulus chain empty target exactness)**.** *For histories source, first, second, a two-link continuous modulus chain ending at* e *is exactly the conjunction that all three displayed histories are empty:*

$$\mathsf{ContinuousModulusChain}(source, first, second, \mathsf{e}) \iff \mathsf{hsame}(source, \mathsf{e}) \wedge \mathsf{hsame}(first, \mathsf{e}) \wedge \mathsf{hsame}(second, \mathsf{e}).$$

Proof. Unpack the middle history and the two continuation ledgers. Empty-result inversion on the second leg identifies the middle history and *second* with e; after replacing the middle endpoint, empty-result inversion on the first leg identifies *source* and *first* with e. The reverse direction uses the empty middle history and the two right-unit continuations at e. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain empty target iff`

Theorem 59.132 (Continuous modulus chain empty moduli exactness)**.** *For histories source, target, a two-link continuous modulus chain with both moduli empty is exactly the conjunction that the endpoints are unary and the target is history-same to the source:*

$$\mathsf{ContinuousModulusChain}(source, \mathsf{e}, \mathsf{e}, target) \iff \mathsf{UnaryHistory}(source) \wedge \mathsf{UnaryHistory}(target) \wedge \mathsf{hsame}(target, sour$$

Proof. Unpack the middle history and the two continuation ledgers. Each empty-modulus leg is a right-unit continuation, so the middle endpoint is history-same to the source and the target endpoint is history-same to the middle endpoint. Transitivity gives $\mathsf{hsame}(target, source)$. Conversely, choose *source* as the middle history, use the canonical right-unit continuation for the first leg, and use the displayed endpoint sameness to build the second right-unit continuation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain empty moduli iff`

Theorem 59.133 (Continuous modulus chain empty second witness)**.** *For histories source, first, second, target, if a two-link continuous modulus chain has second*hsamee*, then the first link directly witnesses* $\mathsf{ContinuousModulusWitness}(source, first, target)$*.*

Proof. Unpack the middle history and the two continuation ledgers. The second ledger, transported across *second*hsamee, is compared with the right-unit continuation at the middle endpoint, so the target is history-same to the middle endpoint. Transporting the first continuation result along this endpoint sameness gives the displayed one-step witness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain empty second witness`

Theorem 59.134 (Continuous modulus chain empty first witness)**.** *For histories source*, *first*, *second*, *target, if a two-link continuous modulus chain has first*hsamee*, then the second link directly witnesses* ContinuousModulusWitness(*source*, *second*, *target*)*.*

Proof. Unpack the middle history and the two continuation ledgers. The first ledger, transported across *first*hsamee, is compared with the right-unit continuation at the source endpoint, so the middle endpoint is history-same to the source. Transporting the second continuation source along this endpoint sameness gives the displayed one-step witness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain empty first witness`

Theorem 59.135 (Continuous function carrier empty certificate exactness)**.** *For histories source*, *map*, *target*, *mod a continuous-function carrier with empty certificate is exactly the conjunction that its graph and modulus histories are all empty:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, \mathsf{e}) \iff \mathsf{hsame}(source, \mathsf{e}) \wedge \mathsf{hsame}(map, \mathsf{e}) \wedge \mathsf{hsame}(target, \mathsf{e})$$

Proof. Unpack the graph continuation and the target-to-certificate continuation. Empty-result inversion on the certificate leg identifies *target* and *modulus* with e; after replacing the target endpoint, empty-result inversion on the graph leg identifies *source* and *map* with e. Conversely, when all four histories are empty, the empty unary carrier and the two right-unit continuations rebuild the carrier. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty cert iff`

Theorem 59.136 (Continuous function carrier empty-modulus exactness)**.** *For histories source*, *map*, *target*, *cert, a continuous-function carrier with empty modulus is exactly the graph carrier data together with the statement that the certificate is history-same to the target:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, \mathsf{e}, cert) \iff \mathsf{UnaryHistory}(source) \wedge \mathsf{UnaryHistory}(target) \wedge \mathsf{UnaryHist}$$

Proof. Unpack the continuous-function carrier. The graph fields already supply the three displayed unary histories and the graph continuation ledger. The target-to-certificate leg has empty modulus, so the right-unit continuation law identifies *cert* with *target*. Conversely, the displayed graph data, the empty unary carrier, and the right-unit continuation rebuilt from hsame(*cert*, *target*) reassemble the continuous-function carrier. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty modulus iff`

Theorem 59.137 (Continuous function carrier empty-target exactness)**.** *For histories source*, *map*, *modulus*, *cert, the empty target case of* ContinuousFunctionCarrier *is exact:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, \mathsf{e}, modulus, cert) \iff \mathsf{hsame}(source, \mathsf{e}) \wedge \mathsf{hsame}(map, \mathsf{e}) \wedge \mathsf{UnaryHistory}(mod$$

Proof. In the forward direction, empty-result inversion on the graph ledger identifies the source and map histories with e. The certificate ledger is then a left-unit continuation from e through *modulus*, so the certificate is history-same to the modulus; unary continuation closure supplies the certificate carrier.

Conversely, the displayed empty source and map rebuild the graph ledger by the right-unit continuation at e. The displayed certificate-modulus sameness rebuilds the certificate ledger by the left-unit continuation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty target iff`

Theorem 59.138 (Continuous function carrier empty-source exactness)**.** *For histories map, target, modulus, and cert, the empty source case of* ContinuousFunctionCarrier *is exact:*

$$\mathsf{ContinuousFunctionCarrier}(\mathsf{e}, map, target, modulus, cert) \iff \mathsf{UnaryHistory}(map) \wedge \mathsf{ContinuousModulusWitness}(map$$

Proof. In the forward direction, unpack the carrier. The graph ledger is $\mathsf{Cont}(\mathsf{e}, map, target)$, so the continuation left-unit theorem identifies *target* with *map*. The target-modulus continuation then becomes a modulus witness over *map*, and unary continuation closure supplies the certificate carrier.

Conversely, the displayed modulus witness supplies the map, modulus, certificate, and certificate-continuation fields. The empty source is unary, the target is identified with the map by the displayed hsame, and the graph ledger is the left-unit continuation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier empty source iff`

Theorem 59.139 (Continuous function carrier graph-modulus readback)**.** *For histories source, map, target, modu every continuous-function carrier directly exposes its graph continuation ledger, its modulus-certificate continuation ledger, and the two corresponding one-step modulus witnesses:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \implies \mathsf{Cont}(source, map, target) \wedge \mathsf{Cont}(target, modu$$
$$\wedge\ \mathsf{ContinuousModulusWitness}(source, map, target) \wedge \mathsf{ContinuousModulusWitness}(target, modulus, cert).$$

Proof. Unpack the continuous-function carrier into unary data for *source*, *target*, *map*, and *modulus*, together with the two continuation ledgers. The graph ledger and the first three unary fields form $\mathsf{ContinuousModulusWitness}(source, map, target)$. Unary closure along the target-modulus ledger supplies the carrier for *cert*, and this packages the second witness $\mathsf{ContinuousModulusWitness}(target,$ □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier graph modulus cont readback`

Theorem 59.140 (Continuous function carrier endpoint-certificate cycle tails)**.** *For histories source, map, target, modulus, cert, a continuous-function carrier whose source is history-same to its certificate has empty graph tail and empty modulus tail:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \implies \mathsf{hsame}(source, cert) \implies \mathsf{hsame}(map, \mathsf{e}) \wedge \mathsf{hsame}($$

Proof. Unpack the carrier into its graph ledger $\mathsf{Cont}(source, map, target)$ and certificate ledger $\mathsf{Cont}(target, modulus, cert)$. Transport the certificate ledger across $\mathsf{hsame}(source, cert)$, obtaining $\mathsf{Cont}(target, modulus, source)$. The two ledgers form a continuation cycle, so mutual-extension cancellation forces both tails, *map* and *modulus*, to be history-same to e. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier endpoint cert cycle tails empty`

Theorem 59.141 (Continuous function carrier endpoint-certificate cycle exactness)**.** *For histories source, map, target, modulus, cert, if a continuous-function carrier closes its public source against its endpoint certificate, then the carrier is an identity presentation at that endpoint:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \implies \mathsf{hsame}(source, cert) \implies$$
$$\mathsf{hsame}(map, \mathsf{e}) \wedge \mathsf{hsame}(modulus, \mathsf{e}) \wedge \mathsf{hsame}(target, source) \wedge \mathsf{hsame}(cert, source).$$

Proof. Apply Definition 59.140 to the carrier and the displayed endpoint certificate equality. This gives $\mathsf{hsame}(map, \mathsf{e})$ and $\mathsf{hsame}(modulus, \mathsf{e})$.

Unpack the graph ledger $\mathsf{Cont}(source, map, target)$ from the carrier. Transport that ledger across $\mathsf{hsame}(map, \mathsf{e})$ to obtain $\mathsf{Cont}(source, \mathsf{e}, target)$. The right-unit clause of Definition 21.12 supplies $\mathsf{Cont}(source, \mathsf{e}, source)$, and continuation determinacy from Definition 21.7 identifies $target$ with $source$.

Finally, symmetry in Definition 3.8 turns the displayed $\mathsf{hsame}(source, cert)$ into $\mathsf{hsame}(cert, source)$, and the four pieces assemble the stated conjunction. □

The ten-field fit is: traditional target, identity-cycle exactness for continuous-function carriers; BEDC kernel, $BHist$; ledger relation, Cont; carrier, $\mathsf{ContinuousFunctionCarrier}$; classifier, hsame; ledger fields, $source, map, target, modulus, cert$; core theorem, Definition 59.141; exactness, the four displayed hsame rows; standard bridge, deferred; downstream consumer, $\mathsf{ContinuousMapUp}$ identity and category normalization.

Theorem 59.142 (Continuous function carrier composite endpoint-certificate cycle exactness)**.** *For histories $source, middle, target, f, g, fg, modF, modG, modFG, certF, certG, cert$, closed composition of continuous-function carriers inherits endpoint-certificate cycle collapse:*

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, f, middle, modF, certF) \wedge \mathsf{ContinuousFunctionCarrier}(middle, g, target, modG, c\\ &\mathsf{Cont}(f, g, fg) \wedge \mathsf{Cont}(modF, modG, modFG) \wedge \mathsf{Cont}(target, modFG, cert) \wedge \mathsf{hsame}(source, cert)\\ &\Longrightarrow \mathsf{ContinuousFunctionCarrier}(source, fg, target, modFG, cert) \wedge \mathsf{hsame}(fg, \mathsf{e}) \wedge \mathsf{hsame}(modFG, \mathsf{e}) \wedge \mathsf{hsame}(targ\end{aligned}$$

Proof. First apply Definition 59.7 to the two given carriers, the displayed composite map and modulus continuations, and the target-to-certificate continuation. This constructs $\mathsf{ContinuousFunctionCarrier}(source, fg,$

Next apply Definition 59.141 to this composite carrier and the displayed endpoint-certificate equality $\mathsf{hsame}(source, cert)$. The resulting four history-sameness conclusions, together with the composite carrier just constructed, assemble the stated conjunction. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier composite endpoint cert cycle exactness`

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier composite endpoint cycle exactness`

Theorem 59.143 (Continuous function carrier prefix exactness)**.** *For histories $p, source, map, target, modulus, cer$ prefixing the visible source, target, and certificate ledgers is conservative for the continuous-function carrier:*

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus, p \cdot cert) \Longleftrightarrow\\ &\mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert).\end{aligned}$$

Proof. For the forward direction, unpack the prefixed carrier. It supplies unary histories for $p \cdot source$, $p \cdot target$, map, and $modulus$, together with the two continuation ledgers $\mathsf{Cont}(p \cdot source, map, p \cdot target)$ and $\mathsf{Cont}(p \cdot target, modulus, p \cdot cert)$.

Unary append factorization applied to the source ledger recovers $\mathsf{UnaryHistory}(p)$ and $\mathsf{UnaryHistory}(source)$. Applied to the target ledger, it recovers $\mathsf{UnaryHistory}(target)$. Prefix cancellation on the graph continuation ledger gives $\mathsf{Cont}(source, map, target)$, and prefix cancellation on the modulus-certificate continuation ledger gives $\mathsf{Cont}(target, modulus, cert)$. Repacking these witnesses gives $\mathsf{ContinuousFunctionCarrier}(s$

For the reverse direction, project $\mathsf{UnaryHistory}(p)$ and the unprefixed carrier from the conjunction. Apply Theorem 59.20 to obtain the displayed prefixed carrier.

The ten-field certificate fit is the following. The traditional target is prefix-invariant continuous graph evidence. The BEDC source is $BHist$ equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is exact prefix cancellation for graph and modulus-certificate ledgers. The ledger consists of source, map, target, modulus, and certificate histories. The core theorem is prefix exactness, the exactness predicate is the displayed iff, the standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefix iff`

Theorem 59.144 (Continuous function carrier modulus suffix exactness)**.** *For histories $p, source, map, target, mod$ suffixing the modulus and certificate ledgers by the same unary history is conservative for the continuous-function carrier:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus \cdot p, cert \cdot p) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert).$$

Proof. For the forward direction, unpack the suffixed carrier. The target-modulus certificate leg is a continuous modulus witness from $target$ through $modulus \cdot p$ to $cert \cdot p$, with the certificate unary witness obtained from unary continuation closure. Apply the continuous modulus witness suffix exactness theorem to remove the common right suffix, then repack the graph carrier fields.

For the reverse direction, turn the unsuffixed target-modulus certificate leg into a continuous modulus witness, apply suffix exactness to append p to the modulus and certificate histories, and repack the original graph fields with the suffixed certificate leg. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier modulus suffix iff`

Theorem 59.145 (Continuous function carrier modulus-suffix target-certificate determinacy)**.** *For histories $q, source, map, target, target', modulus, cert, cert'$, if two continuous-function carrier witnesses share the same source, map, and visible modulus suffix,*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus{\cdot}q, cert{\cdot}q) \quad \textit{and} \quad \mathsf{ContinuousFunctionCarrier}(source, map, t$$

then their central target and certificate ledgers are determined:

$$\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert, cert').$$

Proof. Apply modulus suffix exactness to each carrier witness. This removes the common suffix from the modulus and certificate ledgers and exposes two central continuous-function carriers over the same source, map, and modulus. The target-certificate determinacy theorem for continuous-function carriers then identifies the central targets and the central certificates. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier modulus suffix target cert deterministic`

Theorem 59.146 (Continuous function carrier prefixed graph-chain factorization)**.** *For histories $p, source, map, target, \delta_1, \delta_2, \delta, cert$, if δ_1 and δ_2 are unary,* $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ *holds, and*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert)$$

holds, then there is a middle history middle such that

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, \delta, cert) \wedge \mathsf{ContinuousModulusWitness}(target, \delta_1, middle) \wedge \mathsf{Continuous}$$

Proof. Apply prefix exactness for continuous-function carriers to remove the common visible prefix from the source, target, and certificate ledgers. This recovers the unprefixed carrier and in particular the target-to-certificate continuation $\mathsf{Cont}(target, \delta, cert)$.

Choose $middle = target \cdot \delta_1$. The first modulus witness is the canonical continuation from $target$ through δ_1 to this middle history. For the second witness, combine $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ with the recovered target-to-certificate continuation and reassociate the BEDC append spine, obtaining $\mathsf{Cont}(middle, \delta_2, cert)$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain factorizes`

Theorem 59.147 (Continuous function carrier prefixed graph-chain first factorization)**.** *For histories $p, source, map, target, \delta_1, \delta_2, \delta, cert$, if δ_1 and δ_2 are unary, $\mathsf{Cont}(\delta_1, \delta_2, \delta)$ holds, and*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, \delta, p \cdot cert)$$

holds, then there is a middle history middle such that

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, \delta_1, middle) \wedge \mathsf{ContinuousModulusWitness}(middle, \delta_2, cert).$$

Proof. Apply prefix exactness for continuous-function carriers to remove the common visible prefix. This exposes the unprefixed graph ledger $\mathsf{Cont}(source, map, target)$ and the composite target-certificate ledger $\mathsf{Cont}(target, \delta, cert)$.

Choose $middle = target \cdot \delta_1$. The first-stage carrier uses the original source, map, and target carrier data, the graph ledger, the unary witness for δ_1, and the canonical continuation $\mathsf{Cont}(target, \delta_1, middle)$. The second-stage modulus witness uses the unary closure of $middle$, the unary witness for δ_2, unary closure of $cert$, and associativity of BEDC append to factor the composite ledger through $\mathsf{Cont}(\delta_1, \delta_2, \delta)$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier prefixed graph chain factorization`

Theorem 59.148 (Continuous function carrier triple composition certificate synchronization)**.** *For BHist histories $source, mid_1, mid_2, target, f, g, h, fg, gh, map_L, map_R, mod_F, mod_G, mod_H, mod_{FG}, mod_{GH}, mod_L$, suppose the three one-step carriers*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, f, mid_1, mod_F, cert_F),\\
&\mathsf{ContinuousFunctionCarrier}(mid_1, g, mid_2, mod_G, cert_G),\\
&\mathsf{ContinuousFunctionCarrier}(mid_2, h, target, mod_H, cert_H)
\end{aligned}$$

hold. Suppose also that the left-bracketed ledgers

$$\begin{array}{lll}
\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}),\\
\mathsf{Cont}(fg, h, map_L), & \mathsf{Cont}(mod_{FG}, mod_H, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)
\end{array}$$

hold, and that the right-bracketed ledgers

$$\begin{array}{lll}
\mathsf{Cont}(g, h, gh), & \mathsf{Cont}(mod_G, mod_H, mod_{GH}), & \mathsf{Cont}(target, mod_{GH}, cert_{GH}),\\
\mathsf{Cont}(f, gh, map_R), & \mathsf{Cont}(mod_F, mod_{GH}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)
\end{array}$$

hold. Then the two bracketings both carry the original source to the final target and their public composite data agree up to history-sameness:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L) \wedge\\
&\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R) \wedge\\
&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).
\end{aligned}$$

Proof. First build the left bracketing. Theorem 59.7 composes the $source$-f-mid_1 carrier with the mid_1-g-mid_2 carrier using the displayed fg, mod_{FG}, and $cert_{FG}$ ledgers. Applying the same closure theorem to that composite and the mid_2-h-$target$ carrier gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod$

The right bracketing is built in the symmetric order. Compose the g and h carriers through gh, mod_{GH}, and $cert_{GH}$, then compose the resulting mid_1-gh-$target$ carrier after the original f carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For map synchronization, apply continuation associativity up to history-sameness to the four graph ledgers $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(fg, h, map_L)$, $\mathsf{Cont}(g, h, gh)$, and $\mathsf{Cont}(f, gh, map_R)$. The result is $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same continuation-associativity principle to the modulus ledgers $\mathsf{Cont}(mod_F, mod_G, mod_{FG})$, $\mathsf{Cont}(mod_{FG}, mod_H, mod_L)$, $\mathsf{Cont}(mod_G, mod_H, mod_{GH})$, and $\mathsf{Cont}(mod_F, mod_{GH}, mod_R)$. This gives $\mathsf{hsame}(mod_L, mod_R)$.

Finally compare the two target-certificate ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$. Continuation respect for hsame, with reflexivity on $target$ and the recovered modulus sameness, yields $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the following. The traditional target is threefold composition of continuous function carriers. The BEDC source is $BHist$ equipped with Cont. The carrier is $\mathsf{ContinuousFunctionCarrier}$ and the classifier is hsame. The stability obligation is bracketing synchronization for graph, modulus, and certificate ledgers. The ledger consists of source, intermediate, target, map, modulus, and certificate histories. The core theorem is this triple composition synchronization result. The exactness predicate is the displayed pair of carriers together with the three hsame conclusions. The standard bridge is deferred, and the status is $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier composition associative certificate synchronization`

Theorem 59.149 (Continuous function carrier fourfold left-right synchronization)**.** *For BHist histories* $source, mid_1, mid_2, mid_3, target, f, g, h, k, fg, fgh, hk, ghk, map_L, map_R, mod_F, mod_G, mod_H, mod_K, mod_{FG}$ *suppose the four one-step carriers*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, f, mid_1, mod_F, cert_F),\\
&\mathsf{ContinuousFunctionCarrier}(mid_1, g, mid_2, mod_G, cert_G),\\
&\mathsf{ContinuousFunctionCarrier}(mid_2, h, mid_3, mod_H, cert_H),\\
&\mathsf{ContinuousFunctionCarrier}(mid_3, k, target, mod_K, cert_K)
\end{aligned}$$

hold. Suppose also that the left-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}),\\
\mathsf{Cont}(fg, h, fgh), & \mathsf{Cont}(mod_{FG}, mod_H, mod_{FGH}), & \mathsf{Cont}(mid_3, mod_{FGH}, cert_{FGH}),\\
\mathsf{Cont}(fgh, k, map_L), & \mathsf{Cont}(mod_{FGH}, mod_K, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)
\end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(h, k, hk), & \mathsf{Cont}(mod_H, mod_K, mod_{HK}), & \mathsf{Cont}(target, mod_{HK}, cert_{HK}),\\
\mathsf{Cont}(g, hk, ghk), & \mathsf{Cont}(mod_G, mod_{HK}, mod_{GHK}), & \mathsf{Cont}(target, mod_{GHK}, cert_{GHK}),\\
\mathsf{Cont}(f, ghk, map_R), & \mathsf{Cont}(mod_F, mod_{GHK}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)
\end{array}$$

hold. Then the left-deep and right-deep composite carriers agree at the public graph, modulus, and certificate histories:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)\wedge\\
&\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)\wedge\\
&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).
\end{aligned}$$

Proof. First build the left-deep carrier. Apply Theorem 59.7 to the f and g carriers with the displayed fg, mod_{FG}, and $cert_{FG}$ ledgers. Apply the same closure theorem to compose that result with the h carrier, then again with the k carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, c$

The right-deep carrier is obtained by the symmetric closure chain. Compose the h and k carriers through hk, mod_{HK}, and $cert_{HK}$; compose the g carrier with that composite through ghk, mod_{GHK}, and $cert_{GHK}$; then compose the f carrier with the resulting carrier to obtain $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For graph synchronization, apply the BEDC fourfold continuation associativity theorem cont_assoc_four to the common graph spine f, g, h, k. The left spine is presented by $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(fg, h, fgh)$, and $\mathsf{Cont}(fgh, k, map_L)$, while the right spine is presented by $\mathsf{Cont}(h, k, hk)$, $\mathsf{Cont}(g, hk, ghk)$, and $\mathsf{Cont}(f, ghk, map_R)$. The underlying append-associativity spine append_assoc yields $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same fourfold continuation associativity theorem to $mod_F, mod_G, mod_H, mod_K$. The left modulus ledger ends at mod_L and the right modulus ledger ends at mod_R, so the common append spine yields $\mathsf{hsame}(mod_L, mod_R)$.

It remains to compare certificates. The ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$ have the same target source. Continuation respect for hsame, using reflexivity on $target$ and the recovered modulus synchronization, transports the certificate ledger to give $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the following. The traditional target is fourfold continuous composition coherence. The BEDC source is $BHist$ with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The ledger data are the graph, modulus, and certificate histories displayed above. The stability field is fourfold left-right bracketing synchronization. The exactness field is the pair of constructed carriers together with the three hsame conclusions. The downstream use is ContinuousMapUp associativity coherence and the later category bridge. □

Theorem 59.150 (Continuous function carrier fivefold left-right synchronization)**.** *For BHist histories* $source, mid_1, mid_2, mid_3, mid_4, target, f, g, h, k, l, fg, fgh, fghk, kl, hkl, ghkl, map_L, map_R, mod_F, mod_G, mo$ *suppose the five one-step carriers*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, f, mid_1, mod_F, cert_F),\\
&\mathsf{ContinuousFunctionCarrier}(mid_1, g, mid_2, mod_G, cert_G),\\
&\mathsf{ContinuousFunctionCarrier}(mid_2, h, mid_3, mod_H, cert_H),\\
&\mathsf{ContinuousFunctionCarrier}(mid_3, k, mid_4, mod_K, cert_K),\\
&\mathsf{ContinuousFunctionCarrier}(mid_4, l, target, mod_l, cert_l)
\end{aligned}$$

hold. Suppose also that the left-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}),\\
\mathsf{Cont}(fg, h, fgh), & \mathsf{Cont}(mod_{FG}, mod_H, mod_{FGH}), & \mathsf{Cont}(mid_3, mod_{FGH}, cert_{FGH}),\\
\mathsf{Cont}(fgh, k, fghk), & \mathsf{Cont}(mod_{FGH}, mod_K, mod_{FGHK}), & \mathsf{Cont}(mid_4, mod_{FGHK}, cert_{FGHK}),\\
\mathsf{Cont}(fghk, l, map_L), & \mathsf{Cont}(mod_{FGHK}, mod_l, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)
\end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(k, l, kl), & \mathsf{Cont}(mod_K, mod_l, mod_{KL}), & \mathsf{Cont}(target, mod_{KL}, cert_{KL}),\\
\mathsf{Cont}(h, kl, hkl), & \mathsf{Cont}(mod_H, mod_{KL}, mod_{HKL}), & \mathsf{Cont}(target, mod_{HKL}, cert_{HKL}),\\
\mathsf{Cont}(g, hkl, ghkl), & \mathsf{Cont}(mod_G, mod_{HKL}, mod_{GHKL}), & \mathsf{Cont}(target, mod_{GHKL}, cert_{GHKL}),\\
\mathsf{Cont}(f, ghkl, map_R), & \mathsf{Cont}(mod_F, mod_{GHKL}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)
\end{array}$$

hold. Then the left-deep and right-deep composite carriers agree at the public graph, modulus, and certificate histories:

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)\wedge\\&\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)\wedge\\&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).\end{aligned}$$

Proof. First build the left-deep carrier. Apply Theorem 59.7 to the f and g carriers with the displayed fg, mod_{FG}, and $cert_{FG}$ ledgers. Apply the same closure theorem to compose that result with the h carrier, then with the k carrier, and finally with the l carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)$.

The right-deep carrier is obtained by the matching closure chain. Compose the k and l carriers through kl, mod_{KL}, and $cert_{KL}$; compose the h carrier with that composite through hkl, mod_{HKL}, and $cert_{HKL}$; compose the g carrier with the resulting carrier through $ghkl$, mod_{GHKL}, and $cert_{GHKL}$; then compose the f carrier with that final right-deep carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For graph synchronization, apply BEDC.FKernel.Cont.cont_assoc_five to the common graph spine f, g, h, k, l. The left spine is presented by $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(fg, h, fgh)$, $\mathsf{Cont}(fgh, k, fghk)$, and $\mathsf{Cont}(fghk, l, map_L)$, while the right spine is presented by $\mathsf{Cont}(k, l, kl)$, $\mathsf{Cont}(h, kl, hkl)$, $\mathsf{Cont}(g, hkl, ghkl)$, and $\mathsf{Cont}(f, ghkl, map_R)$. The fivefold continuation reassociation gives $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same fivefold reassociation theorem to $mod_F, mod_G, mod_H, mod_K, mod_l$ The left modulus ledger ends at mod_L and the right modulus ledger ends at mod_R, so the common continuation spine gives $\mathsf{hsame}(mod_L, mod_R)$.

It remains to compare the terminal certificates. The ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$ have the same target source. Continuation respect for hsame, using reflexivity on $target$ and the recovered modulus synchronization, transports the terminal certificate ledger and gives $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the following. The traditional target is pentagon-style fivefold continuous composition coherence. The BEDC source is $BHist$ with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The ledger data are the five one-step graph histories, their modulus histories, their target-certificate histories, and the displayed left-deep and right-deep composite ledgers. The stability field is fivefold left-right bracketing synchronization. The exactness field is the pair of constructed carriers together with the three hsame conclusions. The downstream use is ContinuousMapUp pentagon coherence and the category bridge. □

Theorem 59.151 (Continuous function carrier sixfold left-right synchronization)**.** *For BHist histories* $source, mid_1, mid_2, mid_3, mid_4, mid_5, target, f, g, h, k, l, m, fg, fgh, fghk, fghkl, lm, klm, hklm, ghklm, map_L,$ *suppose the six one-step carriers*

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(source, f, mid_1, mod_F, cert_F),\\&\mathsf{ContinuousFunctionCarrier}(mid_1, g, mid_2, mod_G, cert_G),\\&\mathsf{ContinuousFunctionCarrier}(mid_2, h, mid_3, mod_H, cert_H),\\&\mathsf{ContinuousFunctionCarrier}(mid_3, k, mid_4, mod_K, cert_K),\\&\mathsf{ContinuousFunctionCarrier}(mid_4, l, mid_5, mod_l, cert_l),\\&\mathsf{ContinuousFunctionCarrier}(mid_5, m, target, mod_m, cert_m)\end{aligned}$$

hold. Suppose also that the left-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}), \\
\mathsf{Cont}(fg, h, fgh), & \mathsf{Cont}(mod_{FG}, mod_H, mod_{FGH}), & \mathsf{Cont}(mid_3, mod_{FGH}, cert_{FGH}), \\
\mathsf{Cont}(fgh, k, fghk), & \mathsf{Cont}(mod_{FGH}, mod_K, mod_{FGHK}), & \mathsf{Cont}(mid_4, mod_{FGHK}, cert_{FGHK}), \\
\mathsf{Cont}(fghk, l, fghkl), & \mathsf{Cont}(mod_{FGHK}, mod_l, mod_{FGHKL}), & \mathsf{Cont}(mid_5, mod_{FGHKL}, cert_{FGHKL}), \\
\mathsf{Cont}(fghkl, m, map_L), & \mathsf{Cont}(mod_{FGHKL}, mod_m, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)
\end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(l, m, lm), & \mathsf{Cont}(mod_l, mod_m, mod_{LM}), & \mathsf{Cont}(target, mod_{LM}, cert_{LM}), \\
\mathsf{Cont}(k, lm, klm), & \mathsf{Cont}(mod_K, mod_{LM}, mod_{KLM}), & \mathsf{Cont}(target, mod_{KLM}, cert_{KLM}), \\
\mathsf{Cont}(h, klm, hklm), & \mathsf{Cont}(mod_H, mod_{KLM}, mod_{HKLM}), & \mathsf{Cont}(target, mod_{HKLM}, cert_{HKLM}), \\
\mathsf{Cont}(g, hklm, ghklm), & \mathsf{Cont}(mod_G, mod_{HKLM}, mod_{GHKLM}), & \mathsf{Cont}(target, mod_{GHKLM}, cert_{GHKLM}), \\
\mathsf{Cont}(f, ghklm, map_R), & \mathsf{Cont}(mod_F, mod_{GHKLM}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)
\end{array}$$

hold. Then the left-deep and right-deep composite carriers agree at the public graph, modulus, and certificate histories:

$$\begin{array}{l}
\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L) \wedge \\
\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R) \wedge \\
\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).
\end{array}$$

Proof. First build the left-deep carrier. Repeatedly apply Theorem 59.7 along the displayed fg, fgh, $fghk$, $fghkl$, and map_L graph ledgers, using the matching modulus and certificate-continuation ledgers at each stage. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)$.

The right-deep carrier is built from the other end of the same chain. Compose the l and m carriers, then compose successively with the k, h, g, and f carriers through the displayed lm, klm, $hklm$, $ghklm$, and map_R ledgers. The result is $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For graph synchronization, apply BEDC.FKernel.Cont.cont_assoc_six to the common graph spine f, g, h, k, l, m. The left-deep spine ends at map_L and the right-deep spine ends at map_R, so sixfold continuation associativity yields $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same kernel theorem to $mod_F, mod_G, mod_H, mod_K, mod_l, mod_m$. The displayed modulus ledgers present the same sixfold spine with endpoints mod_L and mod_R, giving $\mathsf{hsame}(mod_L, mod_R)$.

It remains to compare the terminal certificates. The ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$ share the same target source. Continuation respect for hsame, with reflexivity on $target$ and the recovered modulus sameness, identifies the terminal certificates and gives $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the same concrete carrier ledger as in the fourfold and fivefold synchronization results. The stability field is sixfold left-right bracketing synchronization, and the exactness field is the pair of constructed carriers together with the three hsame conclusions. □

Theorem 59.152 (Continuous function carrier certificate semantic naming certificate)**.** *For BHist histories $source, map, target, modulus, cert$, any carrier witness* $\mathsf{ContinuousFunctionCarrier}(source, map, target, mo$ *induces the semantic naming certificate*

$$\mathsf{SemanticNameCert}(C, C, C, \mathsf{hsame}), \qquad C(c) := \mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, c).$$

Thus the certificate-slot carrier, pattern, and ledger are all the displayed fiber $c \mapsto$ $\mathsf{ContinuousFunctionCarrier}(source$ *and the classifier is* hsame*.*

Proof. The displayed carrier gives the source witness for the semantic certificate at the point *cert*. This is exactly the inhabited source field for the fiber C.

The classifier fields are the standard hsame rows. Reflexivity classifies each displayed certificate with itself, symmetry reverses a displayed classification, and transitivity composes two displayed classifications.

Carrier transport is confined to the certificate slot. Keep *source*, *map*, *target*, and *modulus* fixed by hsame reflexivity, use the supplied hsame comparison of certificate histories, and apply Definition 59.14 to transport the continuous function carrier along that comparison.

The pattern and ledger predicates are the same fiber C as the source predicate. Their soundness and completeness maps are therefore identity projections, so the semantic naming certificate is repacked from the preceding fields. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier certificate semanticNameCert`

Theorem 59.153 (Continuous function carrier parallel composite determinacy)**.** *For BHist histories* $source, middle, target, f, g, fg, fg', mod_F, mod_G, mod_{FG}, mod'_{FG}, cert_F, cert_G, cert, cert'$*, suppose*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, f, middle, mod_F, cert_F),\\
&\mathsf{ContinuousFunctionCarrier}(middle, g, target, mod_G, cert_G),\\
&\mathsf{Cont}(f, g, fg), \quad \mathsf{Cont}(f, g, fg'),\\
&\mathsf{Cont}(mod_F, mod_G, mod_{FG}), \quad \mathsf{Cont}(mod_F, mod_G, mod'_{FG}),\\
&\mathsf{Cont}(target, mod_{FG}, cert), \quad \mathsf{Cont}(target, mod'_{FG}, cert')
\end{aligned}$$

hold. Then the two exposed composites are both continuous function carriers and their graph, modulus, and certificate histories are determined:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, fg, target, mod_{FG}, cert) \wedge\\
&\mathsf{ContinuousFunctionCarrier}(source, fg', target, mod'_{FG}, cert') \wedge\\
&\mathsf{hsame}(fg, fg') \wedge \mathsf{hsame}(mod_{FG}, mod'_{FG}) \wedge \mathsf{hsame}(cert, cert').
\end{aligned}$$

Proof. First compose through the first visible ledger. The two given base carriers, together with $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(mod_F, mod_G, mod_{FG})$, and $\mathsf{Cont}(target, mod_{FG}, cert)$, satisfy the hypotheses of Theorem 59.7. This gives $\mathsf{ContinuousFunctionCarrier}(source, fg, target, mod_{FG}, cert)$.

The second displayed ledger has the same two base carriers. Applying the same composition theorem to $\mathsf{Cont}(f, g, fg')$, $\mathsf{Cont}(mod_F, mod_G, mod'_{FG})$, and $\mathsf{Cont}(target, mod'_{FG}, cert')$ gives $\mathsf{ContinuousFunctionCarrier}(source, fg', target, mod'_{FG}, cert')$.

Map determinacy is local to the shared graph rows. Continuation determinacy for the two rows $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f, g, fg')$ gives $\mathsf{hsame}(fg, fg')$; the same kernel determinacy applied to the two modulus rows gives $\mathsf{hsame}(mod_{FG}, mod'_{FG})$.

Finally compare the terminal certificate rows. They share the target history, and the recovered modulus sameness transports the row $\mathsf{Cont}(target, mod'_{FG}, cert')$ back across $\mathsf{Cont}(target, mod_{FG}, cert)$, yielding $\mathsf{hsame}(cert, cert')$. These five outputs are exactly the two composite carriers plus the three exposed history-sameness conclusions. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier parallel composite determinacy`

Theorem 59.154 (Continuous function carrier certificate semantic naming certificate)**.** *For BHist histories* $source, map, target, modulus, cert$*, any carrier witness* $\mathsf{ContinuousFunctionCarrier}(source, map, target, mo$ *induces the semantic naming certificate*

$$\mathsf{SemanticNameCert}(C, C, C, \mathsf{hsame}), \qquad C(c) := \mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, c).$$

Thus the certificate-slot carrier, pattern, and ledger are all the displayed fiber $c \mapsto \mathsf{ContinuousFunctionCarrier}(source$ *and the classifier is* hsame.

Proof. The displayed carrier gives the source witness for the semantic certificate at the point *cert*. This is exactly the inhabited source field for the fiber C.

The classifier fields are the standard hsame rows. Reflexivity classifies each displayed certificate with itself, symmetry reverses a displayed classification, and transitivity composes two displayed classifications.

Carrier transport is confined to the certificate slot. Keep *source*, *map*, *target*, and *modulus* fixed by hsame reflexivity, use the supplied hsame comparison of certificate histories, and apply Definition 59.14 to transport the continuous function carrier along that comparison.

The pattern and ledger predicates are the same fiber C as the source predicate. Their soundness and completeness maps are therefore identity projections, so the semantic naming certificate is repacked from the preceding fields. □

\mathsf{Cont}(fghkl, m, map_L), & \mathsf{Cont}(mod_{FGHKL}, mod_m, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)
\end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(l, m, lm), & \mathsf{Cont}(mod_l, mod_m, mod_{LM}), & \mathsf{Cont}(target, mod_{LM}, cert_{LM}),\\
\mathsf{Cont}(k, lm, klm), & \mathsf{Cont}(mod_K, mod_{LM}, mod_{KLM}), & \mathsf{Cont}(target, mod_{KLM}, cert_{KLM}),\\
\mathsf{Cont}(h, klm, hklm), & \mathsf{Cont}(mod_H, mod_{KLM}, mod_{HKLM}), & \mathsf{Cont}(target, mod_{HKLM}, cert_{HKLM}),\\
\mathsf{Cont}(g, hklm, ghklm), & \mathsf{Cont}(mod_G, mod_{HKLM}, mod_{GHKLM}), & \mathsf{Cont}(target, mod_{GHKLM}, cert_{GHKLM}),\\
\mathsf{Cont}(f, ghklm, map_R), & \mathsf{Cont}(mod_F, mod_{GHKLM}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)
\end{array}$$

hold. Then the left-deep and right-deep composite carriers agree at the public graph, modulus, and certificate histories:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L) \wedge\\
&\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R) \wedge\\
&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).
\end{aligned}$$

Proof. First build the left-deep carrier. Repeatedly apply Theorem 59.7 along the displayed fg, fgh, $fghk$, $fghkl$, and map_L graph ledgers, using the matching modulus and certificate-continuation ledgers at each stage. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)$.

The right-deep carrier is built from the other end of the same chain. Compose the l and m carriers, then compose successively with the k, h, g, and f carriers through the displayed lm, klm, $hklm$, $ghklm$, and map_R ledgers. The result is $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For graph synchronization, apply BEDC.FKernel.Cont.cont_assoc_six to the common graph spine f, g, h, k, l, m. The left-deep spine ends at map_L and the right-deep spine ends at map_R, so sixfold continuation associativity yields $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same kernel theorem to $mod_F, mod_G, mod_H, mod_K, mod_l, mod_m$. The displayed modulus ledgers present the same sixfold spine with endpoints mod_L and mod_R, giving $\mathsf{hsame}(mod_L, mod_R)$.

It remains to compare the terminal certificates. The ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$ share the same target source. Continuation respect for hsame, with reflexivity on $target$ and the recovered modulus sameness, identifies the terminal certificates and gives $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the same concrete carrier ledger as in the fourfold and fivefold synchronization results. The stability field is sixfold left-right bracketing synchronization, and the exactness field is the pair of constructed carriers together with the three hsame conclusions. □

Theorem 59.156 (Continuous function carrier fourfold left-right synchronization)**.** *For BHist histories* $source, mid_1, mid_2, mid_3, target, f, g, h, k, fg, fgh, hk, ghk, map_L, map_R, mod_F, mod_G, mod_H, mod_K, mod_{FG}$ *suppose the four one-step carriers*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, f, mid_1, mod_F, cert_F),\\
&\mathsf{ContinuousFunctionCarrier}(mid_1, g, mid_2, mod_G, cert_G),\\
&\mathsf{ContinuousFunctionCarrier}(mid_2, h, mid_3, mod_H, cert_H),\\
&\mathsf{ContinuousFunctionCarrier}(mid_3, k, target, mod_K, cert_K)
\end{aligned}$$

hold. Suppose also that the left-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}),\\
\mathsf{Cont}(fg, h, fgh), & \mathsf{Cont}(mod_{FG}, mod_H, mod_{FGH}), & \mathsf{Cont}(mid_3, mod_{FGH}, cert_{FGH}),\\
\mathsf{Cont}(fgh, k, map_L), & \mathsf{Cont}(mod_{FGH}, mod_K, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)
\end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(h, k, hk), & \mathsf{Cont}(mod_H, mod_K, mod_{HK}), & \mathsf{Cont}(target, mod_{HK}, cert_{HK}),\\
\mathsf{Cont}(g, hk, ghk), & \mathsf{Cont}(mod_G, mod_{HK}, mod_{GHK}), & \mathsf{Cont}(target, mod_{GHK}, cert_{GHK}),\\
\mathsf{Cont}(f, ghk, map_R), & \mathsf{Cont}(mod_F, mod_{GHK}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)
\end{array}$$

hold. Then the left-deep and right-deep composite carriers agree at the public graph, modulus, and certificate histories:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L) \wedge\\
&\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R) \wedge\\
&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).
\end{aligned}$$

Proof. First build the left-deep carrier. Apply Theorem 59.7 to the f and g carriers with the displayed fg, mod_{FG}, and $cert_{FG}$ ledgers. Apply the same closure theorem to compose that result with the h carrier, then again with the k carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L,$

The right-deep carrier is obtained by the symmetric closure chain. Compose the h and k carriers through hk, mod_{HK}, and $cert_{HK}$; compose the g carrier with that composite through ghk, mod_{GHK}, and $cert_{GHK}$; then compose the f carrier with the resulting carrier to obtain $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For graph synchronization, apply the BEDC fourfold continuation associativity theorem cont_assoc_four to the common graph spine f, g, h, k. The left spine is presented by $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(fg, h, fgh)$, and $\mathsf{Cont}(fgh, k, map_L)$, while the right spine is presented by $\mathsf{Cont}(h, k, hk)$, $\mathsf{Cont}(g, hk, ghk)$, and $\mathsf{Cont}(f, ghk, map_R)$. The underlying append-associativity spine append_assoc yields $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same fourfold continuation associativity theorem to $mod_F, mod_G, mod_H, mod_K$. The left modulus ledger ends at mod_L and the right modulus ledger ends at mod_R, so the common append spine yields $\mathsf{hsame}(mod_L, mod_R)$.

It remains to compare certificates. The ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$ have the same target source. Continuation respect for hsame, using reflexivity on $target$ and the recovered modulus synchronization, transports the certificate ledger to give $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the following. The traditional target is fourfold continuous composition coherence. The BEDC source is $BHist$ with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The ledger data are the graph, modulus, and certificate histories displayed above. The stability field is fourfold left-right bracketing synchronization. The exactness field is the pair of constructed carriers together with the three hsame conclusions. The downstream use is ContinuousMapUp associativity coherence and the later category bridge. □

Theorem 59.157 (Continuous function carrier fivefold left-right synchronization)**.** *For BHist histories* $source, mid_1, mid_2, mid_3, mid_4, target, f, g, h, k, l, fg, fgh, fghk, kl, hkl, ghkl, map_L, map_R, mod_F, mod_G, mo$ *suppose the five one-step carriers*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, f, mid_1, mod_F, cert_F),\\

&\mathsf{ContinuousFunctionCarrier}(mid_2, h, mid_3, mod_H, cert_H),\\
&\mathsf{ContinuousFunctionCarrier}(mid_3, k, mid_4, mod_K, cert_K),\\
&\mathsf{ContinuousFunctionCarrier}(mid_4, l, target, mod_l, cert_l)
\end{aligned}$$

hold. Suppose also that the left-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}),\\
\mathsf{Cont}(fg, h, fgh), & \mathsf{Cont}(mod_{FG}, mod_H, mod_{FGH}), & \mathsf{Cont}(mid_3, mod_{FGH}, cert_{FGH}),\\
\mathsf{Cont}(fgh, k, fghk), & \mathsf{Cont}(mod_{FGH}, mod_K, mod_{FGHK}), & \mathsf{Cont}(mid_4, mod_{FGHK}, cert_{FGHK}),\\
\mathsf{Cont}(fghk, l, map_L), & \mathsf{Cont}(mod_{FGHK}, mod_l, mod_L), & \mathsf{Cont}(target, mod_L, cert_L)
\end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll}
\mathsf{Cont}(k, l, kl), & \mathsf{Cont}(mod_K, mod_l, mod_{KL}), & \mathsf{Cont}(target, mod_{KL}, cert_{KL}),\\
\mathsf{Cont}(h, kl, hkl), & \mathsf{Cont}(mod_H, mod_{KL}, mod_{HKL}), & \mathsf{Cont}(target, mod_{HKL}, cert_{HKL}),\\
\mathsf{Cont}(g, hkl, ghkl), & \mathsf{Cont}(mod_G, mod_{HKL}, mod_{GHKL}), & \mathsf{Cont}(target, mod_{GHKL}, cert_{GHKL}),\\
\mathsf{Cont}(f, ghkl, map_R), & \mathsf{Cont}(mod_F, mod_{GHKL}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R)
\end{array}$$

hold. Then the left-deep and right-deep composite carriers agree at the public graph, modulus, and certificate histories:

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L) \wedge\\
&\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R) \wedge\\
&\mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R).
\end{aligned}$$

Proof. First build the left-deep carrier. Apply Theorem 59.7 to the f and g carriers with the displayed fg, mod_{FG}, and $cert_{FG}$ ledgers. Apply the same closure theorem to compose that result with the h carrier, then with the k carrier, and finally with the l carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_L, target, mod_L, cert_L)$.

The right-deep carrier is obtained by the matching closure chain. Compose the k and l carriers through kl, mod_{KL}, and $cert_{KL}$; compose the h carrier with that composite through hkl, mod_{HKL}, and $cert_{HKL}$; compose the g carrier with the resulting carrier through $ghkl$, mod_{GHKL}, and $cert_{GHKL}$; then compose the f carrier with that final right-deep carrier. This gives $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$.

For graph synchronization, apply BEDC.FKernel.Cont.cont_assoc_five to the common graph spine f, g, h, k, l. The left spine is presented by $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(fg, h, fgh)$, $\mathsf{Cont}(fgh, k, fghk)$, and $\mathsf{Cont}(fghk, l, map_L)$, while the right spine is presented by $\mathsf{Cont}(k, l, kl)$, $\mathsf{Cont}(h, kl, hkl)$, $\mathsf{Cont}(g, hkl, ghkl)$, and $\mathsf{Cont}(f, ghkl, map_R)$. The fivefold continuation reassociation gives $\mathsf{hsame}(map_L, map_R)$.

For modulus synchronization, apply the same fivefold reassociation theorem to $mod_F, mod_G, mod_H, mod_K, mod_l$ The left modulus ledger ends at mod_L and the right modulus ledger ends at mod_R, so the common continuation spine gives $\mathsf{hsame}(mod_L, mod_R)$.

It remains to compare the terminal certificates. The ledgers $\mathsf{Cont}(target, mod_L, cert_L)$ and $\mathsf{Cont}(target, mod_R, cert_R)$ have the same target source. Continuation respect for hsame, using reflexivity on $target$ and the recovered modulus synchronization, transports the terminal certificate ledger and gives $\mathsf{hsame}(cert_L, cert_R)$.

The ten-field certificate fit is the following. The traditional target is pentagon-style fivefold continuous composition coherence. The BEDC source is $BHist$ with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The ledger data are the five one-step graph histories, their modulus histories, their target-certificate histories, and the displayed left-deep and right-deep composite ledgers. The stability field is fivefold left-right bracketing synchronization. The exactness field is the pair of constructed carriers together with the three hsame conclusions. The downstream use is ContinuousMapUp pentagon coherence and the category bridge. □

Theorem 59.158 (Continuous modulus witness right e1 result exactness)**.** *For histories $source, modulus, target$, a modulus witness whose modulus and target histories are both visibly tagged has an exact untagged tail:*

$$\mathsf{ContinuousModulusWitness}(source, \mathsf{E1}(modulus), \mathsf{E1}(target)) \Longrightarrow \mathsf{ContinuousModulusWitness}(source, modulus, tar$$

Proof. Unpack the source, modulus, target unary witnesses and the continuation ledger. Unary inversion removes the visible constructor from the modulus and target carriers. The right E1 continuation inversion removes the same constructor from the continuation ledger, yielding the exact untagged modulus witness. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness right e1 result exactness`

Theorem 59.159 (Continuous modulus witness right e1 visible source exactness)**.** *For histories $source, modulus, target, sourceTail$, a modulus witness whose modulus and target histories are both visibly tagged descends to the tail while respecting a visible presentation of the source endpoint:*

$$\mathsf{ContinuousModulusWitness}(source, \mathsf{E1}(modulus), \mathsf{E1}(target)) \Longrightarrow \mathsf{hsame}(source, \mathsf{E1}(sourceTail)) \Longrightarrow \mathsf{ContinuousM}$$

Proof. Apply right one-headed result exactness to strip the visible constructor from the modulus and target components of the witness. The displayed hsame presentation of the source endpoint then transports the descended witness to the concrete visible source $\mathsf{E1}(sourceTail)$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness right e1 visible source exactness`

Theorem 59.160 (Continuous modulus witness right e1 source cases)**.** *For histories source, modulus, target, a modulus witness whose modulus and target histories are both visibly tagged has only the empty source case or a visible source tail:*

$$\mathsf{ContinuousModulusWitness}(source, \mathsf{E1}(modulus), \mathsf{E1}(target)) \Longrightarrow (source = \mathsf{e} \wedge \mathsf{UnaryHistory}(modulus) \wedge \mathsf{hsame}(tar$$

Proof. First descend the witness by stripping the common visible constructor from the modulus and target histories. The descended source carrier is unary, so it is either empty or visibly tagged. In the empty case, the continuation ledger is a left-unit ledger and gives $\mathsf{hsame}(target, modulus)$. In the visible case, constructor equality identifies the source with $\mathsf{E1}(sourceTail)$ and the descended witness is repacked with that source presentation. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusWitness right e1 source cases`

Definition 59.161 (ContinuousMap stability certificate)**.** *The stability certificate consists of:*

1. *continuous-map classifier reflexivity*
2. *continuous-map classifier symmetry*
3. *continuous-map classifier transitivity*
4. *modulus validity for uniform continuity*
5. *graph and modulus replacement under the continuous-map classifier*
6. *closure under identity*
7. *closure under composition by composing moduli*

Theorem 59.162 (Continuous function carrier terminal modulus extension)**.** *For histories source, map, target, mo a continuous-function carrier remains a continuous-function carrier after the terminal certificate is extended by one more modulus witness and the modulus ledger is composed:*

$$\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert, extra, cert') =$$

Proof. Unpack the given carrier. This exposes the graph ledger $\mathsf{Cont}(source, map, target)$ and the terminal modulus-certificate ledger $\mathsf{Cont}(target, modulus, cert)$, together with the unary carrier data for the displayed histories.

Unpack the additional modulus witness $\mathsf{ContinuousModulusWitness}(cert, extra, cert')$. It supplies $\mathsf{Cont}(cert, extra, cert')$, so the two ledgers $\mathsf{Cont}(target, modulus, cert)$ and $\mathsf{Cont}(cert, extra, cert')$ assemble the chain $\mathsf{ContinuousModulusChain}(target, modulus, extra, cert')$ with middle history $cert$.

Apply Theorem 59.108 to the original carrier, this chain, and the displayed composition ledger $\mathsf{Cont}(modulus, extra, modulus')$. The replacement theorem repacks the preserved graph data with the composite terminal modulus certificate, giving the displayed carrier conclusion.

The ten-field certificate fit is the following. The traditional target is terminal modulus extension for continuous maps. The BEDC source is BHist with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is preservation under one terminal modulus extension. The ledger is source, map, target, original modulus and certificate, extra modulus, composite modulus, and terminal certificate. The core theorem is this closure, exactness is the displayed carrier conclusion, the standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier terminal modulus extension`

Theorem 59.163 (Continuous function carrier visible terminal modulus extension)**.** *For histories $p, q, source, map, target, modulus, cert, extra, modulus', cert'$, visible continuous-function carrier data remain carrier data after the central terminal certificate is extended and the terminal modulus ledger is composed:*

$$\mathsf{ContinuousFunctionCarrier}(p{\cdot}source, map, p{\cdot}target, modulus{\cdot}q, (p{\cdot}cert){\cdot}q) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert, extr$$

Proof. Peel the visible presentation by Theorem 59.169. This recovers the unary context histories $\mathsf{UnaryHistory}(p)$ and $\mathsf{UnaryHistory}(q)$ together with the central carrier $\mathsf{ContinuousFunctionCarrier}(source, map, target$

Apply Theorem 59.162 to the central carrier, the witness $\mathsf{ContinuousModulusWitness}(cert, extra, cert')$, and the composition ledger $\mathsf{Cont}(modulus, extra, modulus')$. The conclusion is the central carrier $\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus', cert')$.

Use the reverse direction of Theorem 59.169 with the recovered unary histories. It repacks the same prefix p and suffix q around the central carrier, producing the displayed visible carrier conclusion. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus extension`

Theorem 59.164 (Continuous function carrier visible terminal modulus extension output determinacy)**.** *For histories $p, q, source, map, target, target', modulus, cert, extra, modulus', cert', cert''$, suppose*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q)$$

holds, together with $\mathsf{ContinuousModulusWitness}(cert, extra, cert')$ *and* $\mathsf{Cont}(modulus, extra, modulus')$*. If the post-extension visible carrier*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target', modulus' \cdot q, (p \cdot cert'') \cdot q)$$

also holds, then the visible target and terminal certificate are determined:

$$\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert', cert'').$$

Proof. Apply Theorem 59.163 to the original visible carrier, the central witness $\mathsf{ContinuousModulusWitness}(cert, ext$ and the terminal modulus ledger $\mathsf{Cont}(modulus, extra, modulus')$. This constructs the canonical post-extension visible carrier with target $target$ and terminal certificate $cert'$.

Compare that canonical carrier with the independently displayed post-extension carrier by Theorem 59.174. The two carrier presentations share p, q, $source$, map, and $modulus'$, so the determinacy theorem returns exactly $\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert', cert'')$. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus extension output determinacy`

Theorem 59.165 (Continuous function carrier visible terminal modulus extension transitive)**.** *For histories $p, q, source, map, target, modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, modulus_2, cert_2$, visible continuous-function carrier data remain carrier data after two consecutive terminal certificate extensions and their two terminal modulus ledgers:*

$$\mathsf{ContinuousFunctionCarrier}(p{\cdot}source, map, p{\cdot}target, modulus_0{\cdot}q, (p{\cdot}cert_0){\cdot}q) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert_0, e$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus extension transitive`

Proof. Apply Theorem 59.163 to the displayed visible carrier, the witness $\mathsf{ContinuousModulusWitness}(cert_0, extra_1,$ and the first composition ledger $\mathsf{Cont}(modulus_0, extra_1, modulus_1)$. This gives the visible carrier with terminal modulus $modulus_1$ and terminal certificate $cert_1$.

Apply the same theorem again to that intermediate carrier, the witness $\mathsf{ContinuousModulusWitness}(cert_1, extra_2$ and the second composition ledger $\mathsf{Cont}(modulus_1, extra_2, modulus_2)$. The result is the visible carrier whose terminal modulus is $modulus_2$ and whose terminal certificate is $cert_2$, which is the displayed conclusion.

The ten-field certificate fit is the following. The traditional target is two-step terminal modulus extension for continuous maps. The BEDC source is BHist with Cont, ContinuousModulusWitness, and ContinuousFunctionCarrier. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is preservation under two consecutive terminal modulus extensions. The ledger is the two extra modulus witnesses and the two composite modulus rows. The core theorem is this closure, exactness is the displayed carrier conclusion, the standard bridge is deferred, and the status is ProofTarget. □

Theorem 59.166 (Continuous function carrier visible terminal modulus reassociation)**.** *For histories* $p, q, source, map, target, modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, extra_{12}, modulus_2, modulus_{12}, cert_2$ *sequential two-step terminal extension and the corresponding composite one-step terminal extension produce the same visible terminal modulus data:*

$$\begin{aligned}
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_0 \cdot q, (p \cdot cert_0) \cdot q) \Longrightarrow \\
&\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2) \Longrightarrow \\
&\mathsf{Cont}(modulus_0, extra_1, modulus_1) \Longrightarrow \mathsf{Cont}(modulus_1, extra_2, modulus_2) \Longrightarrow \\
&\mathsf{Cont}(extra_1, extra_2, extra_{12}) \Longrightarrow \mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}) \Longrightarrow \\
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_2 \cdot q, (p \cdot cert_2) \cdot q) \wedge \\
&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_{12} \cdot q, (p \cdot cert_2) \cdot q) \wedge \\
&\mathsf{hsame}(modulus_2, modulus_{12}).
\end{aligned}$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus reassociation`

Proof. Apply Theorem 59.165 to the displayed visible carrier, the two certificate-extension witnesses, and the two sequential terminal modulus ledgers. This constructs the sequential visible carrier with terminal data $(modulus_2, cert_2)$.

Next assemble the certificate witnesses $\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1)$ and ContinuousModulusW into $\mathsf{ContinuousModulusChain}(cert_0, extra_1, extra_2, cert_2)$ with middle history $cert_1$. By Theorem 59.105 and the ledger $\mathsf{Cont}(extra_1, extra_2, extra_{12})$, this gives the composite witness ContinuousModulusWitness

Apply Theorem 59.163 to the original visible carrier, this composite witness, and $\mathsf{Cont}(modulus_0, extra_{12}, modu$ The result is the composite one-step visible carrier with terminal data $(modulus_{12}, cert_2)$.

Finally use Theorem 4.56 on $\mathsf{Cont}(modulus_0, extra_1, modulus_1)$, $\mathsf{Cont}(modulus_1, extra_2, modulus_2)$, $\mathsf{Cont}(extra_1, extra_2, extra_{12})$, and $\mathsf{Cont}(modulus_0, extra_{12}, modulus_{12})$. It identifies the sequential and composite terminal moduli, giving $\mathsf{hsame}(modulus_2, modulus_{12})$, and the three displayed conclusions are then packed together. □

↪ variant `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus reassociation`

Theorem 59.167 (Continuous function carrier visible terminal modulus reassociation output determinacy)**.** *For histories* $p, q, source, map, target, target', modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, extra_1$

the displayed composite visible output is determined by the reassociated terminal modulus construction:

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_0 \cdot q, (p \cdot cert_0) \cdot q) \Longrightarrow \\ &\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2) \Longrightarrow \\ &\mathsf{Cont}(modulus_0, extra_1, modulus_1) \Longrightarrow \mathsf{Cont}(modulus_1, extra_2, modulus_2) \Longrightarrow \\ &\mathsf{Cont}(extra_1, extra_2, extra_{12}) \Longrightarrow \mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}) \Longrightarrow \\ &\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target', modulus_{12} \cdot q, (p \cdot cert'') \cdot q) \Longrightarrow \\ &\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert_2, cert'') \wedge \mathsf{hsame}(modulus_2, modulus_{12}).\end{aligned}$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible terminal modulus reassociation output determinacy`

Proof. First apply Theorem 59.166 to the original visible carrier, the two certificate-extension witnesses, and the four terminal modulus ledgers. This supplies the canonical composite visible carrier $\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_{12} \cdot q, (p \cdot cert_2) \cdot q)$ together with $\mathsf{hsame}(modulus_2, modulus_{12})$.

Next compare that canonical composite carrier with the independently displayed composite carrier $\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target', modulus_{12} \cdot q, (p \cdot cert'') \cdot q)$. By Theorem 59.174, the common visible source, map, and terminal modulus determine the public target and certificate, giving $\mathsf{hsame}(target, target')$ and $\mathsf{hsame}(cert_2, cert'')$.

Finally package those two target-certificate comparisons with the modulus comparison obtained from reassociation. The result is the displayed triple $\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert_2, cert'') \wedge \mathsf{hsame}(modulus_2, modulus_{12})$. □

Theorem 59.168 (Continuous function carrier visible terminal modulus three-step reassociation)**.** *For histories $p, q, source, map, target, modulus_0, cert_0, extra_1, modulus_1, cert_1, extra_2, modulus_2, cert_2, extra_3, mo$ sequential three-step terminal extension and the corresponding composite one-step terminal extension produce the same visible terminal modulus data:*

$$\begin{aligned}&\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_0 \cdot q, (p \cdot cert_0) \cdot q) \Longrightarrow \\ &\mathsf{ContinuousModulusWitness}(cert_0, extra_1, cert_1) \Longrightarrow \mathsf{ContinuousModulusWitness}(cert_1, extra_2, cert_2) \Longrightarrow \\ &\mathsf{ContinuousModulusWitness}(cert_2, extra_3, cert_3) \Longrightarrow \\ &\mathsf{Cont}(modulus_0, extra_1, modulus_1) \Longrightarrow \mathsf{Cont}(modulus_1, extra_2, modulus_2) \Longrightarrow \\ &\mathsf{Cont}(modulus_2, extra_3, modulus_3) \Longrightarrow \mathsf{Cont}(extra_1, extra_2, extra_{12}) \Longrightarrow \\ &\mathsf{Cont}(modulus_0, extra_{12}, modulus_{12}) \Longrightarrow \mathsf{Cont}(extra_{12}, extra_3, extra_{123}) \Longrightarrow \\ &\mathsf{Cont}(modulus_0, extra_{123}, modulus_{123}) \Longrightarrow \\ &\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_3 \cdot q, (p \cdot cert_3) \cdot q) \wedge \\ &\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus_{123} \cdot q, (p \cdot cert_3) \cdot q) \wedge \\ &\mathsf{hsame}(modulus_3, modulus_{123}).\end{aligned}$$

Proof. Apply Theorem 59.165 to the displayed visible carrier, the first two certificate-extension witnesses, and the first two sequential terminal modulus ledgers. This gives the visible carrier with terminal data $(modulus_2, cert_2)$. Apply Theorem 59.163 to that carrier, the third certificate-extension witness, and $\mathsf{Cont}(modulus_2, extra_3, modulus_3)$. The sequential visible carrier with terminal data $(modulus_3, cert_3)$ follows.

Next compose the first two certificate witnesses. They form the chain $\mathsf{ContinuousModulusChain}(cert_0, extra_1, ext$ with middle history $cert_1$, so Theorem 59.105 and $\mathsf{Cont}(extra_1, extra_2, extra_{12})$ supply $\mathsf{ContinuousModulusWitness}($

Compose that witness with the third one. The chain $\mathsf{ContinuousModulusChain}(cert_0, extra_{12}, extra_3, cert_3)$ with middle history $cert_2$, together with $\mathsf{Cont}(extra_{12}, extra_3, extra_{123})$, gives $\mathsf{ContinuousModulusWitness}(cert_0, ext$ by the same composite-closure theorem.

Apply Theorem 59.163 to the original visible carrier, the composite witness just constructed, and $\mathsf{Cont}(modulus_0, extra_{123}, modulus_{123})$. This produces the composite one-step visible carrier with terminal data $(modulus_{123}, cert_3)$.

It remains to identify the two terminal moduli. First use Theorem 4.56 on $\mathsf{Cont}(modulus_0, extra_1, modulus_1)$, $\mathsf{Cont}(modulus_1, extra_2, modulus_2)$, $\mathsf{Cont}(extra_1, extra_2, extra_{12})$, and $\mathsf{Cont}(modulus_0, extra_{12}, modulus_{12})$, obtaining $\mathsf{hsame}(modulus_2, modulus_{12})$.

Transport the third terminal continuation along that comparison, carrying $\mathsf{Cont}(modulus_2, extra_3, modulus_3)$ to the row $\mathsf{Cont}(modulus_{12}, extra_3, modulus_3)$. Then apply Theorem 4.56 to $\mathsf{Cont}(modulus_0, extra_{12}, modulus_{12})$, the transported row, $\mathsf{Cont}(extra_{12}, extra_3, extra_{123})$, and $\mathsf{Cont}(modulus_0, extra_{123}, modulus_{123})$. The resulting comparison is $\mathsf{hsame}(modulus_3, modulus_{123})$, and the two visible carriers and this comparison form the displayed triple. □

Theorem 59.169 (Continuous function carrier visible modulus context exactness)**.** *For histories $p, q, source, map, target, modulus, cert$, a visible prefix on the source, target, and certificate ledgers together with a visible suffix on the modulus and certificate ledgers is exactly unary evidence for the two context histories together with the central continuous-function carrier:*

$$\mathsf{ContinuousFunctionCarrier}(p{\cdot}source, map, p{\cdot}target, modulus{\cdot}q, (p{\cdot}cert){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{Co}$$

Proof. Peel the right suffix from the modulus and certificate ledgers by modulus suffix exactness. The remaining carrier has the common left prefix on source, target, and certificate, so carrier prefix exactness recovers the unary prefix and the central carrier. Conversely, rebuild the prefixed carrier first, then reattach the modulus suffix. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context iff`

Theorem 59.170 (Continuous function carrier visible-context empty-map exactness)**.** *For histories $p, q, source, target, modulus, cert$, the empty graph map remains exact under visible prefix and suffix ledgers:*

$$\mathsf{ContinuousFunctionCarrier}(p{\cdot}source, \mathsf{e}, p{\cdot}target, modulus{\cdot}q, (p{\cdot}cert){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{hsame}$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context empty map exactness`

Proof. For the forward direction, apply Theorem 59.169 to strip the visible prefix from source, target, and certificate and the visible suffix from modulus and certificate. The exposed central carrier has empty map, so Theorem 59.13 gives $\mathsf{hsame}(target, source)$ and the central modulus witness.

For the reverse direction, start from unary context evidence, the *target–source* classifier, and the central modulus witness. Use Theorem 59.13 to rebuild the central empty-map carrier, then apply Theorem 59.169 to restore the visible prefix and suffix ledgers.

The ten-field certificate fit is the identity uniformly continuous graph readback over the $BHist/\mathsf{Cont}$ source, with ContinuousFunctionCarrier as carrier, hsame as classifier, visible prefix/suffix stability as the context law, the empty graph map as the readback field, central modulus witness exactness as the certificate content, source and target ledgers classified by hsame, modulus and certificate ledgers preserved by the suffix, and ContinuousMapUp identity-map use downstream. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context empty map iff`

↪ variant `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context empty map exactness`

Theorem 59.171 (Continuous modulus chain visible context exactness)**.** *For histories $p, q, source, first, second, t$ a visible prefix on the source and target together with a visible suffix on the second modulus and target is exactly unary evidence for the two contexts together with the central two-link chain:*

$$\mathsf{ContinuousModulusChain}(p{\cdot}source, first, second{\cdot}q, (p{\cdot}target){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{Continuous}$$

Proof. Peel the right suffix from the second modulus and target by chain suffix exactness. The remaining chain has the common left prefix on source and target, so chain prefix exactness exposes unary p and the central chain. Conversely, rebuild the prefixed chain first, then reattach the suffix. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain visible context iff`

Theorem 59.172 (Continuous modulus chain visible context second determinacy)**.** *For histories $p, q, source, first, second, second', target$, if two visible-context two-link modulus chains share the same visible source, first modulus, and visible target,*

$$\mathsf{ContinuousModulusChain}(p{\cdot}source, first, second{\cdot}q, (p{\cdot}target){\cdot}q) \quad \textit{and} \quad \mathsf{ContinuousModulusChain}(p{\cdot}source, first, s$$

then secondhsame*second'*.

Proof. Apply the visible-context exactness statement to both chains. This removes the common prefix and suffix contexts and exposes two central chains with the same source, first modulus, and target. The ordinary second-modulus determinacy theorem identifies the two central second moduli. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousModulusChain visible context second deterministic`

Theorem 59.173 (Continuous function carrier visible-context field determinacy)**.** *For histories $p, q, source, source', map, map', target, target', modulus, modulus', cert, cert'$, visible-modulus-context continuous-function carriers determine each central public field as follows.*

1. *Same visible source, target, modulus, and certificate determine the map:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(p$$

2. *Same visible map, target, modulus, and certificate determine the source:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(p$$

3. *Same visible source, map, target, and certificate determine the modulus:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(p$$

4. *Same visible source, map, and modulus determine the target and certificate:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q) \Longrightarrow \mathsf{ContinuousFunctionCarrier}(p$$

Proof. 1. In the map clause, apply Theorem 59.169 to the two displayed visible carriers. The exposed central carriers share source, target, modulus, and certificate, so Theorem 59.17 gives $\mathsf{hsame}(map, map')$.

2. In the source clause, apply the same exactness theorem to the two displayed visible carriers. The exposed central carriers share map, target, modulus, and certificate, so Theorem 59.18 gives $\mathsf{hsame}(source, source')$.
3. In the modulus clause, apply the same exactness theorem to the two displayed visible carriers. The exposed central carriers share source, map, target, and certificate, so Theorem 59.19 gives $\mathsf{hsame}(modulus, modulus')$.
4. In the target-certificate clause, apply the same exactness theorem to the two displayed visible carriers. The exposed central carriers share source, map, and modulus, so Theorem 59.15 gives $\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert, cert')$.

□

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context field determinacy`

Theorem 59.174 (Continuous function carrier visible-context target-certificate determinacy)**.** *For histories $p, q, source, map, target, target', modulus, cert, cert'$, if both visible-modulus-context carrier presentations*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target', modulus \cdot q, (p \cdot cert') \cdot q)$$

hold, then the public target and certificate ledgers are determined by the central presentation:

$$\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert, cert').$$

Proof. Apply Theorem 59.169 to the first visible carrier. This recovers the unary context histories $\mathsf{UnaryHistory}(p)$ and $\mathsf{UnaryHistory}(q)$ together with the central witness $\mathsf{ContinuousFunctionCarrier}(source, map, targe$

Apply the same exactness theorem to the second visible carrier. The common visible prefix and suffix are peeled in the same way, producing the central witness $\mathsf{ContinuousFunctionCarrier}(source, map, target', mod$

Now apply Theorem 59.15 to the two central carrier witnesses. It gives the displayed $\mathsf{hsame}(target, target')$ and $\mathsf{hsame}(cert, cert')$ conclusions, which are already the public target and certificate comparisons required here.

The ten-field certificate fit is the following. The traditional target is public target-certificate determinacy for visible continuous-function carrier presentations. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is visible-context public readback. The ledger is source, map, target, modulus, and certificate histories together with the visible prefix and suffix contexts. The core theorem is this result. The exactness predicate is the displayed pair of hsame conclusions. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context target cert deterministic`

Theorem 59.175 (Continuous function carrier visible-context map determinacy)**.** *For histories $p, q, source, map, map', target, modulus, cert$, if both visible-modulus-context carrier presentations*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map', p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q)$$

hold, then the public graph map ledger is determined by the central presentation:

$$\mathsf{hsame}(map, map').$$

Proof. Apply Theorem 59.169 to the first visible carrier. This removes the shared visible prefix and suffix contexts and exposes the central witness $\mathsf{ContinuousFunctionCarrier}(source, map, target, modulus, cert)$.

Apply the same visible-context exactness theorem to the second carrier. The same source, target, modulus, and certificate ledgers remain, producing $\mathsf{ContinuousFunctionCarrier}(source, map', target, modulus, ce$

Now apply Theorem 59.17 to the two central carrier witnesses. It gives the displayed $\mathsf{hsame}(map, map')$ comparison, which is already the public visible-context map readback required here.

The ten-field certificate fit is the following. The traditional target is visible map-ledger uniqueness. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is visible-context map readback. The ledger is source, map, target, modulus, and certificate histories together with the visible prefix and suffix contexts. The core theorem is this result. The exactness predicate is the displayed hsame conclusion. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context map deterministic`

Theorem 59.176 (Continuous function carrier visible-context graph-modulus determinacy)**.** *For histories $p, q, source, map, map', target, modulus, modulus', cert$, if both visible-modulus-context carrier presentations*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map', p \cdot target, modulus' \cdot q, (p \cdot cert) \cdot q)$$

hold, then the public graph and modulus ledgers are simultaneously determined:

$$\mathsf{hsame}(map, map') \wedge \mathsf{hsame}(modulus, modulus').$$

Proof. Apply Theorem 59.169 to both visible carrier hypotheses. The common displayed prefix and suffix are peeled away, leaving central carriers over $(source, map, target, modulus, cert)$ and $(source, map', target, modulus', cert)$.

Apply Theorem 59.139 to the two central carriers. This exposes graph ledgers $\mathsf{Cont}(source, map, target)$ and $\mathsf{Cont}(source, map', target)$, and certificate ledgers $\mathsf{Cont}(target, modulus, cert)$ and $\mathsf{Cont}(target, modulus', cert)$

Continuation left cancellation on the two graph ledgers gives $\mathsf{hsame}(map, map')$. The same cancellation principle on the two target-certificate ledgers gives $\mathsf{hsame}(modulus, modulus')$, and the two comparisons are paired as the displayed conclusion.

The ten-field certificate fit is: traditional target visible continuous-function determinacy; BEDC source BHist with Cont; carrier ContinuousFunctionCarrier; classifier hsame; stability obligation visible-context public readback; ledger source, map, target, modulus, certificate, prefix, and suffix; core theorem this statement; exactness the displayed pair of hsame conclusions; standard bridge deferred; status ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context graph modulus deterministic`

Theorem 59.177 (Continuous function carrier visible-context cycle tails empty)**.** *For histories $p, q, source, map, target, modulus, cert$, a visible-context continuous-function carrier whose central source and certificate are history-same has empty central graph and modulus tails:*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, map, p \cdot target, modulus \cdot q, (p \cdot cert) \cdot q) \Longrightarrow \mathsf{hsame}(source, cert) \Longrightarrow \mathsf{hsame}$$

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context cycle tails empty`

Proof. Apply Theorem 59.169 to the displayed visible carrier. This recovers unary witnesses for the visible prefix p and suffix q, and it exposes the central carrier $\mathsf{ContinuousFunctionCarrier}(source, map, target, modulu$

Apply Theorem 59.140 to the central carrier and the displayed $\mathsf{hsame}(source, cert)$ cycle. The endpoint-certificate cycle cancellation theorem gives exactly $\mathsf{hsame}(map, \mathsf{e}) \wedge \mathsf{hsame}(modulus, \mathsf{e})$.

The ten-field certificate fit is the following. The traditional target is visible cycle-tail pruning. The BEDC source is BHist with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is visible-context central readback. The ledger is source, map, target, modulus, certificate, prefix, and suffix histories. The core theorem is this statement. The exactness predicate is the displayed pair of empty-tail conclusions. The standard bridge is deferred, and the status is ProofTarget. □

Theorem 59.178 (Continuous function carrier visible-context composition closure)**.** *For histories $p, q, source, middle, target, f, g, fg, modF, modG, modFG, certF, certG, cert$, suppose the two contextualized carriers*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, f, p \cdot middle, modF \cdot q, (p \cdot certF) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot middle, g, p \cdot target, modG \cdot q, (p \cdot certG) \cdot q)$$

hold. If the graph, modulus, and target-certificate ledgers

$$\mathsf{Cont}(f, g, fg), \quad \mathsf{Cont}(modF, modG, modFG), \quad \mathsf{Cont}(target, modFG, cert)$$

hold, then the composite carrier remains inside the same visible context:

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, fg, p \cdot target, modFG \cdot q, (p \cdot cert) \cdot q).$$

Proof. Apply Theorem 59.169 to the first contextualized carrier. This recovers unary witnesses for the visible prefix p and suffix q, together with the central carrier $\mathsf{ContinuousFunctionCarrier}(source, f, middle, modF,$

Apply the same visible-context exactness theorem to the second contextualized carrier. The common contexts are peeled away, exposing $\mathsf{ContinuousFunctionCarrier}(middle, g, target, modG, certG)$ over the same central middle and target histories.

Apply Theorem 59.7 to these two central carriers with the displayed graph, modulus, and target-certificate ledgers. The result is the central composite carrier $\mathsf{ContinuousFunctionCarrier}(source, fg, target, modFG,$

Finally use Theorem 59.169 in the reverse direction, with the recovered unary witnesses for p and q, to reattach the visible prefix and suffix. This yields the displayed composite carrier in the same visible context.

The ten-field certificate fit is the following. The traditional target is composition closure for contextual continuous-function carriers. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is contextual composition closure with fixed visible prefix and suffix. The ledger consists of source, middle,

target, graph map, modulus, certificate, visible prefix, and visible suffix histories. The core theorem is this visible-context closure statement. The exactness claim is the reverse use of visible-context exactness after central composition closure. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context comp central package`

Theorem 59.179 (Continuous function carrier visible-context composition public readback)**.** *For histories* $p, q, source, middle, target, target', f, g, fg, modF, modG, modFG, certF, certG, cert, cert'$*, suppose the two contextualized carriers*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, f, p \cdot middle, modF \cdot q, (p \cdot certF) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot middle, g, p \cdot target, modG \cdot q, (p \cdot certG) \cdot q)$$

hold, together with the graph, modulus, and target-certificate ledgers

$$\mathsf{Cont}(f, g, fg), \quad \mathsf{Cont}(modF, modG, modFG), \quad \mathsf{Cont}(target, modFG, cert).$$

If a displayed visible composite carrier

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, fg, p \cdot target', modFG \cdot q, (p \cdot cert') \cdot q)$$

also holds, then the public composite target and certificate read back to the canonical central pair:

$$\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert, cert').$$

Proof. Apply Theorem 59.169 to the first contextualized carrier. This peels the common visible prefix and suffix, and it exposes the central carrier $\mathsf{ContinuousFunctionCarrier}(source, f, middle, modF, certF)$.

Apply the same visible-context exactness theorem to the second contextualized carrier. The central carrier $\mathsf{ContinuousFunctionCarrier}(middle, g, target, modG, certG)$ is recovered over the same middle history and canonical target history.

Apply the visible-context exactness theorem once more to the displayed composite carrier. This removes the displayed visible context and gives the central displayed carrier $\mathsf{ContinuousFunctionCarrier}(source, fg, ta$

Now apply Theorem 59.16 to the two central input carriers, the three displayed continuation ledgers, and the central displayed composite carrier. The central public readback theorem gives exactly $\mathsf{hsame}(target, target') \wedge \mathsf{hsame}(cert, cert')$.

The ten-field certificate fit is the following. The traditional target is public readback for contextual continuous-function composition. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is contextual composite target and certificate readback. The ledger consists of source, middle, target, displayed target, graph map, modulus, certificate, displayed certificate, visible prefix, and visible suffix histories. The core theorem is this visible-context readback statement. The exactness claim is the central target-certificate pair returned after peeling visible context. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context composition public readback`

Theorem 59.180 (Continuous function carrier visible-context composite ledger determinacy)**.** *For histories* $p, q, source, middle, target, f, g, fg, fg', modF, modG, modFG, modFG', certF, certG, cert, cert'$*, suppose the two visible-context input carriers*

$$\mathsf{ContinuousFunctionCarrier}(p \cdot source, f, p \cdot middle, modF \cdot q, (p \cdot certF) \cdot q)$$

and

$$\mathsf{ContinuousFunctionCarrier}(p \cdot middle, g, p \cdot target, modG \cdot q, (p \cdot certG) \cdot q)$$

hold. If both composite ledger triples

$$\begin{array}{lll} \mathsf{Cont}(f, g, fg), & \mathsf{Cont}(modF, modG, modFG), & \mathsf{Cont}(target, modFG, cert), \\ \mathsf{Cont}(f, g, fg'), & \mathsf{Cont}(modF, modG, modFG'), & \mathsf{Cont}(target, modFG', cert') \end{array}$$

hold, then the public composite graph, composite modulus, and composite certificate ledgers are independent of the chosen admissible triple:

$$\mathsf{hsame}(fg, fg') \wedge \mathsf{hsame}(modFG, modFG') \wedge \mathsf{hsame}(cert, cert').$$

Proof. Apply Theorem 59.178 to the two input carriers and the first composite ledger triple. This builds the visible composite carrier over $(fg, modFG, cert)$. Apply the same closure theorem to the same input carriers and the second composite ledger triple, giving the visible composite carrier over $(fg', modFG', cert')$.

Apply continuation determinacy, Theorem 18.16, to the two graph ledgers $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f, g, fg')$. Apply the same determinacy theorem to the two modulus ledgers $\mathsf{Cont}(modF, modG, modFG)$ and $\mathsf{Cont}(modF, modG, modFG')$. These give $\mathsf{hsame}(fg, fg')$ and $\mathsf{hsame}(modFG, modFG')$.

Use Theorem 59.169 to peel the visible prefix and suffix from the two composite carriers. Then use Theorem 59.14 to place the two central composite carriers over a common graph and modulus representative while leaving the target fixed.

Now Theorem 59.15 applies to the aligned central carriers. Its certificate conclusion gives $\mathsf{hsame}(cert, cert')$, which combines with the graph and modulus comparisons above to give the displayed triple classifier.

The ten-field certificate fit is the following. The traditional target is composite-ledger well-definedness for continuous maps. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The stability obligation is composite ledger independence. The ledger consists of source, middle, target, map, modulus, certificate, prefix, and suffix histories. The core theorem is this determinacy result. The exactness claim is the displayed triple classifier. The downstream consumer is ContinuousMapUp composition well-definedness. The standard bridge is deferred, and the status is ProofTarget. □

Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context composite ledger determinacy`
Lean4 ✓ `BEDC.Derived.ContinuousUp.ContinuousFunctionCarrier visible modulus context composite ledger deterministic`

Theorem 59.181 (Continuous function carrier visible fourfold left-right synchronization)**.** *For BHist histories* $p, q, source, mid_1, mid_2, mid_3, target, f, g, h, k, fg, fgh, hk, ghk, map_L, map_R, mod_F, mod_G, mod_H,$ *suppose the four visible-context one-step carriers*

$$\begin{array}{l} \mathsf{ContinuousFunctionCarrier}(p \cdot source, f, p \cdot mid_1, mod_F \cdot q, (p \cdot cert_F) \cdot q), \\ \mathsf{ContinuousFunctionCarrier}(p \cdot mid_1, g, p \cdot mid_2, mod_G \cdot q, (p \cdot cert_G) \cdot q), \\ \mathsf{ContinuousFunctionCarrier}(p \cdot mid_2, h, p \cdot mid_3, mod_H \cdot q, (p \cdot cert_H) \cdot q), \\ \mathsf{ContinuousFunctionCarrier}(p \cdot mid_3, k, p \cdot target, mod_K \cdot q, (p \cdot cert_K) \cdot q) \end{array}$$

hold. Suppose also that the left-deep ledgers

$$\begin{array}{lll} \mathsf{Cont}(f, g, fg), & \mathsf{Cont}(mod_F, mod_G, mod_{FG}), & \mathsf{Cont}(mid_2, mod_{FG}, cert_{FG}), \\ \mathsf{Cont}(fg, h, fgh), & \mathsf{Cont}(mod_{FG}, mod_H, mod_{FGH}), & \mathsf{Cont}(mid_3, mod_{FGH}, cert_{FGH}), \\ \mathsf{Cont}(fgh, k, map_L), & \mathsf{Cont}(mod_{FGH}, mod_K, mod_L), & \mathsf{Cont}(target, mod_L, cert_L) \end{array}$$

hold, and that the right-deep ledgers

$$\begin{array}{lll} \mathsf{Cont}(h, k, hk), & \mathsf{Cont}(mod_H, mod_K, mod_{HK}), & \mathsf{Cont}(target, mod_{HK}, cert_{HK}), \\ \mathsf{Cont}(g, hk, ghk), & \mathsf{Cont}(mod_G, mod_{HK}, mod_{GHK}), & \mathsf{Cont}(target, mod_{GHK}, cert_{GHK}), \\ \mathsf{Cont}(f, ghk, map_R), & \mathsf{Cont}(mod_F, mod_{GHK}, mod_R), & \mathsf{Cont}(target, mod_R, cert_R) \end{array}$$

hold. Then the two visible-context composite carriers exist and their public graph, modulus, and certificate histories agree:

$$\begin{array}{l} \mathsf{ContinuousFunctionCarrier}(p \cdot source, map_L, p \cdot target, mod_L \cdot q, (p \cdot cert_L) \cdot q) \wedge \\ \mathsf{ContinuousFunctionCarrier}(p \cdot source, map_R, p \cdot target, mod_R \cdot q, (p \cdot cert_R) \cdot q) \wedge \\ \mathsf{hsame}(map_L, map_R) \wedge \mathsf{hsame}(mod_L, mod_R) \wedge \mathsf{hsame}(cert_L, cert_R). \end{array}$$

Proof. Apply Theorem 59.169 to each of the four displayed visible-context one-step carriers. This peels the common visible prefix p from source, target, and certificate ledgers and the common visible suffix q from modulus and certificate ledgers. The result is unary evidence for the two context histories together with the four central carriers from *source* through *target*.

Apply Theorem 59.156 to those four central carriers and to the displayed left-deep and right-deep ledger arrays. The central theorem constructs the left-deep carrier $\mathsf{ContinuousFunctionCarrier}(source, map_L, ta$ the right-deep carrier $\mathsf{ContinuousFunctionCarrier}(source, map_R, target, mod_R, cert_R)$, and the three public synchronizations $\mathsf{hsame}(map_L, map_R)$, $\mathsf{hsame}(mod_L, mod_R)$, and $\mathsf{hsame}(cert_L, cert_R)$.

Use Theorem 59.169 in the reverse direction with the recovered unary witnesses for p and q to reattach the visible context to the left-deep central carrier. Use the same reverse implication for the right-deep central carrier. These two applications give exactly the two displayed visible-context composite carriers.

The ten-field certificate fit is the following. The traditional target is fourfold contextual continuous composition coherence. The BEDC source is BHist equipped with Cont. The carrier is ContinuousFunctionCarrier and the classifier is hsame. The ledger data are the source, intermediate, target, graph, modulus, certificate, visible prefix, and visible suffix histories displayed above. The stability field is visible-context left-right bracketing synchronization. The core theorem is this visible fourfold statement. The exactness field is the pair of reattached visible carriers together with the three hsame conclusions. The downstream consumer is ContinuousMapUp associativity coherence, the standard bridge is deferred, and the status is ProofTarget. □

Chapter 60

A Concrete Naming Certificate for $\mathsf{Compact}^{\uparrow}$

The compactness interface $\mathsf{Compact}^{\uparrow}$ has certificate obligations for subsets of metric spaces from chapter 57. The BEDC-licensed carrier is a subset predicate equipped with explicit locatedness witnesses and finite-net witnesses: locatedness gives, for any point and rational ϵ, a decision whether the point is within ϵ of the subset; finite-net data gives, for any rational ϵ, a finite ϵ-net.

60.1 Carrier definition

Definition 60.1 (Compact carrier)**.** *Use a metric-space subset predicate equipped with locatedness and total-boundedness witness functions.*

Lean4 (definition) `BEDC.Derived.CompactUp.CompactWitnessCarrier`

Theorem 60.2 (Compact witness carrier finite extension closure)**.** *If a compact witness carrier records unary subset, locatedness, and finite-net histories through locatedness and compactness ledgers, then appending a unary finite-net refinement preserves the same witness shape.*

Proof. The existing carrier supplies unary histories for the subset, locatedness, and finite-net ledgers together with continuations through the located and compact witnesses. Unary continuation closure gives the refined finite-net carrier. Continuation associativity combines the old compactness ledger with the refinement ledger, and determinism identifies the associated witness with the named refined finite-net history. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier finite extension closed`

Definition 60.3 (Compact finite refinement chain)**.** *The compact finite refinement chain relation is written*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact).$$

It is the inductive BEDC relation on paired finite-net and compactness ledgers generated by the following constructors:

1. *the base constructor relates* $(finite, compact)$ *to itself;*
2. *the step constructor says that, from a prior chain to* (f, c)*,* $\mathsf{UnaryHistory}(e)$*,* $\mathsf{Cont}(f, e, f')$*, and* $\mathsf{Cont}(c, e, c')$*, one obtains a chain to* (f', c')*.*

Lean4 (definition) `BEDC.Derived.CompactUp.CompactFiniteRefinementChain`

Theorem 60.4 (Compact finite refinement chain transitivity)**.** *For finite-net ledgers $finite$, $midFinite$, and $finalFinite$ and compactness ledgers $compact$, $midCompact$, and $finalCompact$, if*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, midFinite, midCompact)$$

and

$$\mathsf{CompactFiniteRefinementChain}(midFinite, midCompact, finalFinite, finalCompact),$$

then

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact).$$

Proof. Induct on the second compact finite refinement chain.

In the base case, the second chain ends at its starting pair $(midFinite, midCompact)$. The desired chain is exactly the first chain.

In the step case, the second chain is obtained from a prior pair (f, c) by a unary refinement history e together with witnesses $\mathsf{UnaryHistory}(e)$, $\mathsf{Cont}(f, e, f')$, and $\mathsf{Cont}(c, e, c')$. Apply the induction hypothesis to compose the first chain with the prior second-chain segment, producing a chain from $(finite, compact)$ to (f, c).

Apply the step constructor of Definition 60.3 to that composed chain and the displayed unary-history and continuation witnesses. This gives the required chain from $(finite, compact)$ to (f', c'), which is the final pair in the step case. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain transitivity`

Theorem 60.5 (Compact finite refinement chain prefix closure)**.** *For a prefix ledger p and finite-net and compactness ledgers $finite, compact, finalFinite, finalCompact$, if*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact),$$

then

$$\mathsf{CompactFiniteRefinementChain}(p \cdot finite, p \cdot compact, p \cdot finalFinite, p \cdot finalCompact).$$

Proof. Induct on the compact finite refinement chain. The base constructor is stable under prefixing because both endpoints remain identical pairs. In the step case, apply the induction hypothesis to the prior chain and rebuild the step constructor. The two continuation witnesses are obtained by applying the prefix operation to the original continuation equalities and reassociating append. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain prefix closed`

Theorem 60.6 (Compact finite refinement chain final endpoints unary)**.** *If*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact),$$

and the starting finite-net and compactness ledgers are unary histories, then the final finite-net and compactness ledgers are unary histories:

$$\mathsf{UnaryHistory}(finite) \wedge \mathsf{UnaryHistory}(compact) \Longrightarrow \mathsf{UnaryHistory}(finalFinite) \wedge \mathsf{UnaryHistory}(finalCompact).$$

Proof. Induct on the compact finite refinement chain. In the base case, the final endpoints are the starting endpoints, so the supplied unary-history witnesses are the desired witnesses. In the step case, the induction hypothesis gives unary-history witnesses for the prior finite-net and compactness ledgers. The step constructor supplies a unary refinement history and two continuation witnesses. Closure of unary histories under continuation gives unary histories for both final ledgers. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain final endpoints unary`

Theorem 60.7 (Compact finite refinement chain initial endpoints unary)**.** *If*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact),$$

and the final finite-net and compactness ledgers are unary histories, then the initial finite-net and compactness ledgers are unary histories:

$$\mathsf{UnaryHistory}(finalFinite) \wedge \mathsf{UnaryHistory}(finalCompact) \Longrightarrow \mathsf{UnaryHistory}(finite) \wedge \mathsf{UnaryHistory}(compact).$$

Proof. Induct on the compact finite refinement chain. The base case is immediate. In the step case, factor the final unary-history witnesses through the two continuation witnesses by unary left-factor closure, then apply the induction hypothesis to the prior chain. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain initial endpoints unary`

Theorem 60.8 (Compact finite refinement chain endpoint hsame)**.** *If*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact)$$

and $\mathsf{hsame}(finite, compact)$*, then* $\mathsf{hsame}(finalFinite, finalCompact)$*.*

Proof. Induct on the compact finite refinement chain. The base case is the supplied starting endpoint equality. In the step case, the induction hypothesis gives equality of the current finite and compact endpoints; the common unary refinement tail and the two continuation witnesses transport that equality to the next endpoints by continuation respect for hsame. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain endpoint hsame`

Theorem 60.9 (Compact finite refinement chain endpoint hsame reflects)**.** *If*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact)$$

and $\mathsf{hsame}(finalFinite, finalCompact)$*, then* $\mathsf{hsame}(finite, compact)$*.*

Proof. Induct on the compact finite refinement chain. The base case is the supplied final endpoint equality. In the step case, both endpoints were extended by the same refinement tail. Common-suffix cancellation for the two continuation witnesses reflects hsame from the final endpoints to the preceding endpoints, and the induction hypothesis reflects it to the starting endpoints. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain endpoint hsame reflects`

Theorem 60.10 (Compact finite refinement chain endpoint hsame iff)**.** *If*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact)$$

holds, then

$$\mathsf{hsame}(finalFinite, finalCompact) \Longleftrightarrow \mathsf{hsame}(finite, compact).$$

Proof. Use the forward endpoint-transport theorem for one implication and the endpoint reflection theorem for the other. The same finite refinement chain supplies the common continuation structure needed by both directions. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain endpoint hsame iff`

Theorem 60.11 (Compact finite refinement chain empty final reflects empty initial)**.** *If a compact finite refinement chain ends with both final ledgers empty, then both initial ledgers are empty:*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact) \wedge \mathsf{hsame}(finalFinite, \mathsf{e}) \wedge \mathsf{hsame}(final$$

Proof. Induct on the refinement chain. In a step, transport the final empty equality back across each displayed continuation, use empty-result inversion to identify the prior ledger with e, and apply the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain empty final reflects empty initial`

Theorem 60.12 (Compact finite refinement chain nonempty forward)**.** *If a compact finite refinement chain starts from a finite-net ledger apart from* e*, then its final finite-net ledger is apart from* e*:*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact) \wedge ((finite\mathsf{hsamee}) \to \bot) \Longrightarrow ((finalF$$

Proof. Induct on the refinement chain. The base case is the starting apartness predicate. In a step, a collapse of the final finite ledger to e identifies the appended prior finite ledger and refinement tail with e. Empty-append inversion gives a collapse of the prior finite ledger, contradicting the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain nonempty forward`

Theorem 60.13 (Compact finite refinement chain compact nonempty forward)**.** *If a compact finite refinement chain starts from a compact ledger apart from* e*, then its final compact ledger is apart from* e*:*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact) \wedge ((compact\mathsf{hsamee}) \to \bot) \Longrightarrow ((fina$$

Proof. Induct on the refinement chain. The base case is the starting compact apartness predicate. In a step, a collapse of the final compact ledger to e makes the appended prior compact ledger empty, and empty-append inversion gives the contradiction by the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain compact nonempty forward`

Theorem 60.14 (Compact finite refinement chain continuation witness)**.** *If*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact)$$

holds, then there is a unary refinement history extra that realizes both final endpoints as continuations from their corresponding starts:

$$\mathsf{UnaryHistory}(extra) \wedge \mathsf{Cont}(finite, extra, finalFinite) \wedge \mathsf{Cont}(compact, extra, finalCompact).$$

Proof. Induct on the finite refinement chain. The base case uses the empty history as the common continuation tail and the right-unit continuation law on both endpoints. In the step case, the induction hypothesis supplies a common accumulated tail. Associate that tail with the step refinement on the finite side and on the compact side. Continuation determinism identifies the two associated tails, unary continuation closure proves the accumulated tail unary, and the associated continuations give the two displayed endpoint ledgers. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain continuation witness`

Theorem 60.15 (Compact witness carrier finite refinement chain closure)**.** *If*

$$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact)$$

and

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact),$$

then

$$\mathsf{CompactWitnessCarrier}(subset, located, finalFinite, intermediate, finalCompact).$$

Proof. Induct on the given compact finite refinement chain.

In the base case, the final finite-net ledger and final compactness ledger are the original ledgers $finite$ and $compact$. The desired carrier is exactly the given compact witness carrier.

In the step case, the induction hypothesis gives the carrier at the prior pair (f, c). Apply Theorem 60.2 to that carrier, the unary refinement history e, and the continuations $\mathsf{Cont}(f, e, f')$ and $\mathsf{Cont}(c, e, c')$. The result is the required compact witness carrier at (f', c'). □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier finite refinement chain closed`

Theorem 60.16 (Compact witness carrier empty final refinement reflects empty initial)**.** *For a compact witness carrier, if a finite refinement chain sends the finite and compact ledgers to empty final ledgers, then all five carrier ledgers are empty:*

$$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact) \wedge \mathsf{CompactFiniteRefinementChain}(finite, c$$
$$\wedge\ \mathsf{hsame}(finalFinite, \mathsf{e}) \wedge \mathsf{hsame}(finalCompact, \mathsf{e}) \Longrightarrow \mathsf{hsame}(subset, \mathsf{e}) \wedge \mathsf{hsame}(located, \mathsf{e}) \wedge \mathsf{hsame}(finite, \mathsf{e}) \wedge$$

Proof. First apply the finite-chain empty reflection theorem to the refinement chain. Then use empty-result inversion on the compactness continuation $\mathsf{Cont}(intermediate, finite, compact)$ and on the locatedness continuation $\mathsf{Cont}(subset, located, intermediate)$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier empty final refinement reflects empty initial`

Theorem 60.17 (Compact witness carrier finite refinement chain endpoints unary)**.** *If*

$$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact)$$

and

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact),$$

then the final finite-net and compactness ledgers are unary histories:

$$\mathsf{UnaryHistory}(finalFinite) \wedge \mathsf{UnaryHistory}(finalCompact).$$

Proof. The compact witness carrier supplies a unary finite-net ledger. Its subset and located unary witnesses, together with the first continuation ledger, give a unary intermediate ledger; combining that with the finite-net unary witness and the second continuation ledger gives a unary compactness ledger. Applying the finite refinement chain endpoint theorem to these two starting endpoints gives the displayed final endpoint unary witnesses. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier finite refinement chain endpoints unary`

Theorem 60.18 (Compact witness carrier finite refinement endpoint package)**.** *If*

$$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact)$$

and

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact)$$

hold, then both final endpoints are unary and the endpoint classifier relation is reflected exactly:

$$\begin{aligned}&\mathsf{UnaryHistory}(finalFinite) \wedge \mathsf{UnaryHistory}(finalCompact)\\ &\wedge\ (\mathsf{hsame}(finalFinite, finalCompact) \iff \mathsf{hsame}(finite, compact)).\end{aligned}$$

Proof. Apply Theorem 60.17 to the compact witness carrier and the finite refinement chain. This gives the unary witnesses for the final finite-net and compactness endpoints.

Apply Theorem 60.10 to the same finite refinement chain. It gives the displayed classifier equivalence, and conjoining it with the endpoint unary witnesses gives the package. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier finite refinement endpoint package`

Theorem 60.19 (Compact witness carrier iterated finite refinement closure)**.** *For histories subset, located, $finite$, $extra_0$, $extra_1$, intermediate, compact, $finite_0$, $compact_0$, $finite_1$, and $compact_1$, assume:*

1. $$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact);$$
2. $\mathsf{UnaryHistory}(extra_0)$ *and* $\mathsf{UnaryHistory}(extra_1)$*;*
3. $\mathsf{Cont}(finite, extra_0, finite_0)$ *and* $\mathsf{Cont}(compact, extra_0, compact_0)$*;*
4. $\mathsf{Cont}(finite_0, extra_1, finite_1)$ *and* $\mathsf{Cont}(compact_0, extra_1, compact_1)$*.*

Then

$$\mathsf{CompactWitnessCarrier}(subset, located, finite_1, intermediate, compact_1)$$

Proof. First apply Theorem 60.2 to the carrier with finite-net ledger $finite$ and compactness ledger $compact$, using $extra_0$ as the unary refinement history. This produces the intermediate carrier.

$$\mathsf{CompactWitnessCarrier}(subset, located, finite_0, intermediate, compact_0)$$

Apply the same theorem again to that intermediate carrier, now using $extra_1$ as the unary refinement history and the continuations from $finite_0$ to $finite_1$ and from $compact_0$ to $compact_1$. The resulting carrier is:

$$\mathsf{CompactWitnessCarrier}(subset, located, finite_1, intermediate, compact_1)$$

□

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier iterated finite refinement closed`

Theorem 60.20 (Compact witness carrier located extension closure)**.** *If a compact witness carrier records a subset through locatedness and finite-net histories, then appending a unary locatedness refinement preserves the compact witness shape after reassociating the subset ledger.*

Proof. The carrier supplies unary subset, locatedness, and finite-net histories, together with a continuation from the subset through the locatedness witness to the intermediate witness. Unary continuation closure makes the refined locatedness history unary. Continuation associativity shifts the subset ledger across the locatedness refinement, and determinism identifies the associated locatedness witness with the displayed refinement. The final finite-net ledger then gives the compact witness endpoint. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier located extension closed`

Definition 60.21 (Compact located refinement chain)**.** *The compact located refinement chain relation is written*

$$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, final$$

It is the inductive BEDC relation on locatedness, intermediate, and compactness ledgers with the finite-net ledger held fixed, generated by the following constructors:

1. *the base constructor relates* $(located, intermediate, compact)$ *to itself while keeping* $finite$ *fixed;*
2. *the step constructor says that, from a prior chain to* (l, i, c)*,* $\mathsf{UnaryHistory}(e)$*,* $\mathsf{Cont}(l, e, l')$*,* $\mathsf{Cont}(i, e, i')$*, and* $\mathsf{Cont}(i', finite, c')$*, one obtains a chain to* (l', i', c')*.*

Lean4 (definition) `BEDC.Derived.CompactUp.CompactLocatedRefinementChain`

Theorem 60.22 (Compact located refinement chain transitivity)**.** *For a fixed finite-net ledger* $finite$*, locatedness ledgers* $located$*,* $midLocated$*, and* $finalLocated$*, intermediate ledgers* $intermediate$*,* $midIntermediate$*, and* $finalIntermediate$*, and compactness ledgers* $compact$*,* $midCompact$*, and* $finalCompact$*, if*

$$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, midLocated, midIntermediate, midCom$$

and

$$\mathsf{CompactLocatedRefinementChain}(finite, midLocated, midIntermediate, midCompact, finalLocated, finalInterm$$

then

$$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, final$$

Proof. Induct on the second compact located refinement chain.

In the base case, the second chain ends at its starting triple $(midLocated, midIntermediate, midCompact)$. The desired chain is exactly the first chain.

In the step case, the second chain is obtained from a prior triple (l, i, c) by a unary refinement history e together with witnesses $\mathsf{UnaryHistory}(e)$, $\mathsf{Cont}(l, e, l')$, $\mathsf{Cont}(i, e, i')$, and $\mathsf{Cont}(i', finite, c')$. Apply the induction hypothesis to compose the first chain with the prior second-chain segment, producing a chain from $(located, intermediate, compact)$ to (l, i, c).

Apply the step constructor of Definition 60.21 to that composed chain and the displayed unary-history and continuation witnesses. This gives the required chain from $(located, intermediate, compact)$ to (l', i', c'), which is the final triple in the step case. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain transitivity`

Theorem 60.23 (Compact located refinement chain prefix closure)**.** *For a prefix ledger p, if*

$$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, finalC$$

then

$$\mathsf{CompactLocatedRefinementChain}(finite, p{\cdot}located, p{\cdot}intermediate, p{\cdot}compact, p{\cdot}finalLocated, p{\cdot}finalIntermedia$$

Proof. Induct on the compact located refinement chain. The base constructor is stable under prefixing because the locatedness, intermediate, and compactness endpoints remain the same triples after prefixing. In the step case, apply the induction hypothesis to the prior chain and rebuild the step constructor. The located, intermediate, and compact continuation witnesses are obtained by applying the prefix operation to the original continuation equalities and reassociating append. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain prefix closed`

Theorem 60.24 (Compact located refinement chain final endpoints unary)**.** *If*

$$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, finalC$$

and the fixed finite-net ledger plus the starting locatedness, intermediate, and compactness ledgers are unary histories, then the final locatedness, intermediate, and compactness ledgers are unary histories:

$$\mathsf{UnaryHistory}(finite) \wedge \mathsf{UnaryHistory}(located) \wedge \mathsf{UnaryHistory}(intermediate) \wedge \mathsf{UnaryHistory}(compact) \Longrightarrow \mathsf{UnaryHistory}$$

Proof. Induct on the compact located refinement chain. In the base case, the final endpoints are the starting locatedness, intermediate, and compactness ledgers. In the step case, the induction hypothesis gives unary-history witnesses for the prior locatedness and intermediate ledgers. The step constructor supplies a unary refinement history and continuation witnesses for the next locatedness and intermediate ledgers, so continuation closure gives unary histories for those two ledgers. The fixed finite-net unary-history witness and the final continuation witness then give the final compactness unary-history witness. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain final endpoints unary`

Theorem 60.25 (Compact located refinement chain initial endpoints unary)**.** *If*

$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, final($

and the final locatedness and intermediate ledgers are unary histories, then the initial locatedness and intermediate ledgers are unary histories:

$\mathsf{UnaryHistory}(finalLocated) \wedge \mathsf{UnaryHistory}(finalIntermediate) \Longrightarrow \mathsf{UnaryHistory}(located) \wedge \mathsf{UnaryHistory}(intermed$

Proof. Induct on the compact located refinement chain. The base case is immediate, because the final locatedness and intermediate ledgers are the starting ledgers. In the step case, factor the final unary-history witnesses through the locatedness and intermediate continuation witnesses by unary left-factor closure, then apply the induction hypothesis to the prior chain. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain initial endpoints unary`
↪ variant `BEDC.Derived.CompactUp.CompactLocatedRefinementChain initial located intermediate unary`

Theorem 60.26 (Compact located refinement chain endpoint hsame)**.** *If*

$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, final($

and $\mathsf{hsame}(located, intermediate)$*, then* $\mathsf{hsame}(finalLocated, finalIntermediate)$*.*

Proof. Induct on the compact located refinement chain. The base case is the supplied starting equality between locatedness and the intermediate ledger. In the step case, the induction hypothesis gives equality of the current located and intermediate endpoints; the shared refinement tail and the two displayed continuations transport it to the next located and intermediate endpoints. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain endpoint hsame`

Theorem 60.27 (Compact located refinement chain endpoint hsame reflects)**.** *If*

$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, final($

and $\mathsf{hsame}(finalLocated, finalIntermediate)$*, then* $\mathsf{hsame}(located, intermediate)$*.*

Proof. Induct on the compact located refinement chain. The base case is the supplied final equality. In the step case, located and intermediate endpoints are extended by the same refinement tail, so common-suffix cancellation reflects the final hsame witness to the preceding located and intermediate endpoints. The induction hypothesis then reflects that witness to the starting pair. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain endpoint hsame reflects`

Theorem 60.28 (Compact located refinement chain endpoint unary hsame iff)**.** *If a compact located refinement chain carries unary starting histories* $finite, located, intermediate, compact$*, then its final located, intermediate, and compact endpoints are unary, and* $\mathsf{hsame}(finalLocated, finalIntermediate)$ *holds exactly when* $\mathsf{hsame}(located, intermediate)$ *holds.*

Proof. Apply Definition 60.24 for the unary endpoints, and combine Definition 60.26 with Definition 60.27. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain endpoint unary hsame iff`

Theorem 60.29 (Compact located refinement chain continuation witness)**.** *If*

$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, final($

holds and $\mathsf{Cont}(intermediate, finite, compact)$ *is the starting compactness ledger, then there is a unary refinement history extra such that*

$\mathsf{UnaryHistory}(extra) \wedge \mathsf{Cont}(located, extra, finalLocated) \wedge \mathsf{Cont}(intermediate, extra, finalIntermediate) \wedge \mathsf{Cont}(fi$

Proof. Induct on the located refinement chain. The base case uses the empty history as the common locatedness and intermediate tail, together with the supplied starting compactness ledger. In the step case, the induction hypothesis supplies an accumulated tail for locatedness and the intermediate ledger. Associate that tail with the step refinement on both ledgers. Determinism identifies the two associated tails, unary continuation closure proves the accumulated tail unary, and the step compactness continuation gives the final compact endpoint ledger. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain continuation witness`

Theorem 60.30 (Compact located refinement chain final compact determinacy)**.** *If two compact located refinement chains share the same starting compactness ledger and the same final located and intermediate endpoints, then their final compact endpoints are* hsame*-equal.*

Proof. Apply the continuation witness theorem to both chains using the same starting compactness ledger. Both witnesses end in $\mathsf{Cont}(finalIntermediate, finite, -)$, so continuation determinism identifies the final compact endpoints. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain final compact deterministic`

Theorem 60.31 (Compact located refinement chain common-source final located determinacy)**.** *If two compact located refinement chains share the same starting compactness ledger and their final intermediate ledgers are* hsame*, then the first chain has a common located refinement witness and the two final located histories are* hsame*.*

Proof. Apply the located continuation-witness theorem to both chains using the same starting compactness ledger. The shared intermediate source and the equality of final intermediate ledgers cancel the refinement tails. Continuation determinism on the located ledgers then identifies the two final located histories, while the first witness supplies the displayed existential data. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain common source final located deterministic`

Theorem 60.32 (Compact located refinement chain common-source final located tail determinacy)**.** *If two compact located refinement chains share the same starting compactness ledger and their final located histories are* hsame*, then their final intermediate histories and final compact histories are* hsame*.*

Proof. Apply the located continuation-witness theorem to both chains using the same starting compactness ledger. The final located equality cancels the common located source and identifies the two refinement tails. Continuation determinism then identifies the final intermediate histories, and the resulting intermediate equality identifies the final compact histories through the fixed finite suffix. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain common source final located tail deterministic`

Theorem 60.33 (Compact located refinement chain common-source final intermediate tail determinacy)**.** *If two compact located refinement chains share the same starting compactness ledger and their final intermediate histories are* hsame*, then their final located histories and final compact histories are* hsame*.*

Proof. Apply the located continuation-witness theorem to both chains using the same starting compactness ledger. The final intermediate equality cancels the common intermediate source and identifies the refinement tails. Continuation determinism on the located ledgers identifies the final located histories, and continuation determinism over the fixed finite suffix identifies the final compact histories. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain common source final intermediate tail deterministic`

Theorem 60.34 (Compact located refinement chain common-source final compact tail determinacy)**.** *If two compact located refinement chains share the same starting compactness ledger and their final compact histories are* hsame*, then their final intermediate histories and final located histories are* hsame*.*

Proof. Apply the located continuation-witness theorem to both chains using the same starting compactness ledger. The final compact equality cancels the fixed finite suffix and identifies the final intermediate histories. That equality cancels the common intermediate source to identify the refinement tails, and continuation determinism on the located ledgers identifies the final located histories. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain common source final compact tail deterministic`

Theorem 60.35 (Compact located refinement chain empty final reflects empty initial)**.** *If a compact located refinement chain has empty final locatedness and intermediate ledgers, then its initial locatedness and intermediate ledgers are empty.*

Proof. Induct on the located refinement chain. In each step, transport the two final empty equalities across the displayed locatedness and intermediate continuations, use empty-result inversion, and apply the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain empty final reflects empty initial`

Theorem 60.36 (Compact located refinement chain located nonempty forward)**.** *If a compact located refinement chain starts from a locatedness ledger that is not history-same to* e*, then its final locatedness ledger is not history-same to* e*.*

Proof. Induct on the located refinement chain. The base case is the initial nonemptiness premise. In a step, an empty final locatedness endpoint transports across the displayed locatedness continuation; empty-result inversion then forces the prior locatedness endpoint to be empty, contradicting the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain located nonempty forward`

Theorem 60.37 (Compact located refinement chain intermediate nonempty forward)**.** *If a compact located refinement chain starts from an intermediate ledger that is not history-same to* e*, then its final intermediate ledger is not history-same to* e*.*

Proof. Induct on the located refinement chain. The base case is the initial nonemptiness premise. In a step, an empty final intermediate endpoint transports across the displayed intermediate continuation; empty-result inversion then forces the prior intermediate endpoint to be empty, contradicting the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain intermediate nonempty forward`

Theorem 60.38 (Compact witness carrier located empty final refinement reflects empty initial)**.** *For a compact witness carrier and a located refinement chain, if the final locatedness, intermediate, and compactness ledgers are empty, then all five initial carrier ledgers are empty.*

Proof. Use the located continuation witness to expose a common refinement tail. Empty-result inversion gives empty locatedness, intermediate, and finite ledgers; the carrier continuations then reflect emptiness to the subset and compactness ledgers. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier located empty final refinement reflects empty initial`

Theorem 60.39 (Compact witness carrier located finite empty final reflects empty initial)**.** *For a compact witness carrier, a located refinement chain, and a finite refinement chain starting from the located chain's final compact ledger, if the final locatedness, final intermediate, final finite, and final compact ledgers are all empty, then all five initial carrier ledgers are empty.*

Proof. First reflect the empty final finite and compact ledgers through the finite refinement chain to recover an empty final compact ledger for the located chain. Then apply the located empty-final reflection theorem to the compact witness carrier and located refinement chain. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier located finite empty final reflects empty initial`

Theorem 60.40 (Compact witness carrier located refinement chain closure)**.** *If* $\mathsf{CompactWitnessCarrier}(subset, loca$ *and* $\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, fi$ *then* $\mathsf{CompactWitnessCarrier}(subset, finalLocated, finite, finalIntermediate, finalCompact)$.

Proof. Induct on the compact located refinement chain. The base case is the supplied carrier. In the step case, apply Definition 60.20 to the carrier supplied by the induction hypothesis and the displayed locatedness, intermediate, and compactness continuations. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier located refinement chain closed`

Theorem 60.41 (Compact witness carrier located finite refinement chain closure)**.** *If*

$$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact),$$

and

$$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, finalC$$

and

$$\mathsf{CompactFiniteRefinementChain}(finite, finalCompact, finalFinite, finalCompact'),$$

then

$$\mathsf{CompactWitnessCarrier}(subset, finalLocated, finalFinite, finalIntermediate, finalCompact').$$

Proof. First apply Theorem 60.40 to the initial carrier and the located refinement chain. This gives

$$\mathsf{CompactWitnessCarrier}(subset, finalLocated, finite, finalIntermediate, finalCompact).$$

Then apply Theorem 60.15 to that carrier and the finite refinement chain from $(finite, finalCompact)$ to $(finalFinite, finalCompact')$. The result is the displayed compact witness carrier. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier located finite refinement chain closed`

Theorem 60.42 (Compact witness carrier located finite refinement chain final endpoints unary)**.** *Assume*

$$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact),$$

a located refinement chain from $(located, intermediate, compact)$ *to* $(finalLocated, finalIntermediate, finalComp$
over the same finite witness, and a finite refinement chain from $(finite, finalCompact)$ *to* $(finalFinite, finalCom$
Then

$$\mathsf{UnaryHistory}(finalLocated) \wedge \mathsf{UnaryHistory}(finalIntermediate) \wedge \mathsf{UnaryHistory}(finalFinite) \wedge \mathsf{UnaryHistory}(finalC$$

Proof. Unpack the compact witness carrier. The carrier provides unary witnesses for *subset*, *located*, and *finite* together with the continuation ledgers $\mathsf{Cont}(subset, located, intermediate)$ and $\mathsf{Cont}(intermediate, finite, compact)$. Closure of unary histories under Cont gives unary witnesses for *intermediate* and *compact*.

Apply the located-chain endpoint theorem to the located chain and these four initial endpoint witnesses. This gives unary witnesses for $finalLocated$, $finalIntermediate$, and $finalCompact$. Apply the finite-chain endpoint theorem to the finite chain, the original unary witness for $finite$, and the obtained unary witness for $finalCompact$. The result supplies unary witnesses for $finalFinite$ and $finalCompact'$, which together form the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier located finite refinement chain final endpoints unary`

Theorem 60.43 (Compact witness carrier located finite refinement certificate package)**.** *Assume*

$$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact),$$

a compact located refinement chain from $(finite, located, intermediate, compact)$ *to* $(finalLocated, finalIntermed$
and a compact finite refinement chain from $(finite, finalCompact)$ *to* $(finalFinite, finalCompact')$.
Then these data determine one refinement certificate with the following components:

1. *the refined carrier*

$$\mathsf{CompactWitnessCarrier}(subset, finalLocated, finalFinite, finalIntermediate, finalCompact');$$

2. *unary histories for* $finalLocated$, $finalIntermediate$, $finalFinite$, *and* $finalCompact'$;

3. *endpoint classifier equivalences*

$$finalLocated\mathsf{hsame}finalIntermediate \leftrightarrow located\mathsf{hsame}intermediate$$

and

$$finalFinite\mathsf{hsame}finalCompact' \leftrightarrow finite\mathsf{hsame}finalCompact;$$

4. *terminal empty reflection: if $finalLocated$, $finalIntermediate$, $finalFinite$, and $finalCompact'$ are each history-same to* e*, then subset, located, $finite$, intermediate, and compact are each history-same to* e*;*

5. *nonempty propagation from located to $finalLocated$, from intermediate to $finalIntermediate$, from $finite$ to $finalFinite$, and from $finalCompact$ to $finalCompact'$.*

Proof. First apply Theorem 60.41 to the initial carrier and the two refinement chains. This supplies the refined compact witness carrier.

Next apply Theorem 60.42 to the same inputs. The four endpoint unary witnesses are exactly the unary part of the certificate. The located endpoint classifier equivalence comes from the compact located refinement chain endpoint theorem, and the finite endpoint classifier equivalence comes from the compact finite refinement chain endpoint theorem.

The terminal empty-reflection component is Theorem 60.39. It takes the four empty terminal endpoints and reflects them back to the five initial carrier ledgers.

Finally, the nonempty propagation fields are supplied independently by Theorem 60.36, Theorem 60.37, the checked compact finite refinement chain nonempty-forward theorem, and the checked compact finite refinement chain compact-nonempty-forward theorem. Together these components form the advertised refinement certificate package. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier located finite refinement complete package`

Corollary 60.44 (Compact located refinement chain continuation determinacy)**.** *Fix the compact located refinement-chain rows*

$$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, final($$

and the starting compactness ledger $\mathsf{Cont}(intermediate, finite, compact)$*. Any consumer-facing continuation use accepted by this chapter factors through the following displayed rows and through no further coordinate: the located refinement tail from located to $finalLocated$, the intermediate refinement tail from intermediate to $finalIntermediate$, and the finite compactness suffix* $\mathsf{Cont}(finalIntermediate, finite, finalCompact)$*. Consequently, if a second accepted use has the same starting compactness ledger and the same named final located and intermediate ledgers, then it names the same finite route, the same normal-form endpoint, and the same exactness decision up to* hsame*; in particular, it cannot choose an alternate hidden coordinate or a duplicate classifier source.*

Proof. Apply Definition 60.29 to the accepted chain and the fixed starting compactness ledger. The witness exposes a unary refinement history *extra* together with exactly three continuation rows:

$$\mathsf{Cont}(located, extra, finalLocated), \quad \mathsf{Cont}(intermediate, extra, finalIntermediate), \quad \mathsf{Cont}(finalIntermediate,$$

These are the only route, transport, and readback rows made available by the continuation witness, so a consumer-facing use that is admitted by the compact located refinement-chain surface must

read its finite route from *extra*, its normal form from the two named endpoints, and its compact exactness decision from the displayed finite suffix.

Now compare with any second accepted use over the same starting compactness ledger and the same final located and intermediate ledgers. By Definition 60.31, the common source and final intermediate row identify the located endpoints and supply a common located refinement witness. With the located and intermediate rows fixed, Definition 60.30 identifies the final compact endpoints. Thus the two accepted uses have the same exposed refinement tail and the same compact suffix up to hsame. Any purported extra coordinate would have to change either the located endpoint, the intermediate endpoint, or the final compact endpoint; the cited determinacy rows identify all three, so no unlisted coordinate or second classifier source survives the comparison. □

Theorem 60.45 (Compact finite refinement common-source final finite determinacy)**.** *If two compact finite refinement chains start from the same finite and compact histories, and their final finite histories are* hsame*, then the first chain has a common continuation witness and the two final compact histories are* hsame*:*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact) \Longrightarrow \mathsf{CompactFiniteRefinementChain}($$

Proof. Apply the compact finite refinement continuation-witness theorem to both chains. The shared finite source and the equality of final finite ledgers cancel the two continuation tails. Transporting that tail equality through the compact continuation ledgers identifies the two final compact histories, while the first witness supplies the displayed existential data. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain common source final finite deterministic`

Theorem 60.46 (Compact finite refinement common-source final compact determinacy)**.** *If two compact finite refinement chains start from the same finite and compact histories, and their final compact histories are* hsame*, then the first chain has a common continuation witness and the two final finite histories are* hsame*:*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact) \Longrightarrow \mathsf{CompactFiniteRefinementChain}($$

Proof. Apply the compact finite refinement continuation-witness theorem to both chains. The shared compact source and the equality of final compact ledgers cancel the two continuation tails. Continuation determinism then identifies the two final finite histories, and the first witness supplies the displayed existential data. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain common source final compact deterministic`

Theorem 60.47 (Prefixed composite compact net refinement determinacy)**.** *For histories* $p, c, \epsilon, \eta, \eta', \theta, \theta', m$*, assume* ϵ*,* η*, and* η' *are unary histories, with continuation ledgers*

$$\mathsf{Cont}(\epsilon, \eta, \theta), \qquad \mathsf{Cont}(\epsilon, \eta', \theta').$$

If both composed precisions give compact net witnesses with the same prefixed center and the same prefixed refined net,

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m) \quad \textit{and} \quad \mathsf{CompactNetWitness}(p \cdot c, \theta', p \cdot m),$$

then the refinement precisions are history-same:

$$\mathsf{hsame}(\eta, \eta').$$

Proof. Unpack the two prefixed compact net witnesses. Their continuation ledgers have the same source $p \cdot c$ and the same result $p \cdot m$, so continuation left cancellation identifies the composed precisions θ and θ'. With the composed precision made common, the two ledgers out of ϵ have the same source and result, and another left-cancellation step yields $\mathsf{hsame}(\eta, \eta')$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefixed composite refinement deterministic`

Theorem 60.48 (Compact finite refinement flattening)**.** *Let subset, located, finite, intermediate, compact, midFinite, midCompact, finalFinite, and finalCompact be histories. Assume a compact witness carrier*

$$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact),$$

an outer finite refinement chain

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, midFinite, midCompact),$$

and a second finite refinement chain over the terminal finite-refinement pair

$$\mathsf{CompactFiniteRefinementChain}(midFinite, midCompact, finalFinite, finalCompact).$$

Then the two finite-refinement layers flatten to a single finite refinement chain with the same source:

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact).$$

Moreover the flattened endpoint keeps the original subset, locatedness, and intermediate classifier data:

$$\mathsf{CompactWitnessCarrier}(subset, located, finalFinite, intermediate, finalCompact).$$

Proof. Apply Theorem Definition 60.4 to the two displayed finite refinement chains. This gives the single chain from $(finite, compact)$ to $(finalFinite, finalCompact)$, so the source pair is the original source pair from the carrier.

Apply Theorem Definition 60.15 to the original compact witness carrier and this flattened chain. The closure theorem changes only the finite-net and compactness ledgers. Its conclusion has exactly the same *subset*, *located*, and *intermediate* arguments, so every locatedness classification witnessed by the original carrier is the same classification at the flattened endpoint. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain flattening located cont`

Corollary 60.49 (Prefixed composite compact net refinement readback determinacy)**.** *Fix histories $p, c, \epsilon, \eta, \eta', \theta, \theta', m$ and compact-refinement histories subset, located, finite, intermediate, compact, midFinite, midCompact, finalFinite, and finalCompact. Assume ϵ, η, and η' are unary histories and that the two prefixed composite compact-net uses expose exactly the continuation and witness rows*

$$\mathsf{Cont}(\epsilon, \eta, \theta), \qquad \mathsf{Cont}(\epsilon, \eta', \theta'),$$

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m), \qquad \mathsf{CompactNetWitness}(p \cdot c, \theta', p \cdot m).$$

Assume also that the finite compact-refinement packet exposes the carrier and two finite-refinement rows

$$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact),$$

$\mathsf{CompactFiniteRefinementChain}(finite, compact, midFinite, midCompact)$, $\mathsf{CompactFiniteRefinementChain}(mi$

Then every consumer-facing use admitted by these rows has the same displayed readback data: the prefixed composite refinement route is η up to hsame*, the finite route is the flattened chain*

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact),$$

the normal-form endpoint is the pair $(finalFinite, finalCompact)$, and the exactness decision is the carrier

$$\mathsf{CompactWitnessCarrier}(subset, located, finalFinite, intermediate, finalCompact).$$

Thus no accepted use can replace the refinement route by an alternate hidden coordinate or cite a duplicate classifier source for the finite endpoint.

Proof. The two prefixed composite compact-net uses have the same visible prefix p, center c, and final net m. Their only difference is the refinement continuation row out of the fixed first precision ϵ. Applying Definition 60.47 to the four displayed prefixed composite rows gives

$$\mathsf{hsame}(\eta, \eta').$$

Therefore any admitted composite readback that uses the second refinement row names the same refinement route as the first one, up to the chapter classifier hsame.

For the finite compact-refinement part, apply Definition 60.48 to the displayed carrier and the two displayed finite-refinement chains. The result is exactly the single finite route from $(finite, compact)$ to $(finalFinite, finalCompact)$, together with the carrier at the same final endpoint:

$$\mathsf{CompactFiniteRefinementChain}(finite, compact, finalFinite, finalCompact)$$

and

$$\mathsf{CompactWitnessCarrier}(subset, located, finalFinite, intermediate, finalCompact).$$

The flattening theorem changes only the finite-net and compactness ledgers and keeps the same *subset*, *located*, and *intermediate* classifier data. Hence the accepted use has no further coordinate from which to choose another route, normal form, or exactness source: the route is the flattened finite chain, the normal form is its displayed endpoint pair, and the exactness decision is the flattened carrier over that endpoint. Combining this with the prefixed composite determinacy proves the stated readback determinacy. □

Theorem 60.50 (Compact finite refinement chain final cases)**.** *Every compact finite refinement chain reaches its final endpoints in exactly one of the constructor-visible ways: either the chain is at the starting pair, with $finalFinite$hsame$finite$ and $finalCompact$hsame$compact$, or it has an immediate predecessor pair and a unary refinement history $extra$ with* $\mathsf{Cont}(currentFinite, extra, finalFinite)$ *and* $\mathsf{Cont}(currentCompact, extra, finalCompact)$*.*

Proof. Case-split on the chain constructor. The base constructor gives the two endpoint sameness proofs. The step constructor exposes the predecessor chain, the unary refinement history, and the two displayed continuation ledgers. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactFiniteRefinementChain final cases`

Theorem 60.51 (Compact located refinement chain final cases)**.** *Every compact located refinement chain reaches its final endpoints either at the starting triple, with all three final endpoints history-same to the starting ledgers, or by a final refinement step. In the step case there are current located, intermediate, and compact endpoints and a unary history extra such that the predecessor chain reaches the current endpoints,* $\mathsf{Cont}(currentLocated, extra, finalLocated)$*,* $\mathsf{Cont}(currentIntermediate, extra, fina$ *and* $\mathsf{Cont}(finalIntermediate, finite, finalCompact)$ *hold.*

Proof. Case-split on the located refinement-chain constructor. The base constructor returns the three endpoint sameness proofs. The step constructor supplies the predecessor chain, the unary refinement history, the located and intermediate continuation ledgers, and the final compactness continuation ledger. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactLocatedRefinementChain final cases`

Theorem 60.52 (Compact witness carrier located finite refinement endpoint package)**.** *Assume*

$$\mathsf{CompactWitnessCarrier}(subset, located, finite, intermediate, compact),$$

and

$$\mathsf{CompactLocatedRefinementChain}(finite, located, intermediate, compact, finalLocated, finalIntermediate, finalC$$

and

$$\mathsf{CompactFiniteRefinementChain}(finite, finalCompact, finalFinite, finalCompact').$$

Then one obtains

$$\mathsf{CompactWitnessCarrier}(subset, finalLocated, finalFinite, finalIntermediate, finalCompact'),$$

unary histories for $finalLocated$*,* $finalIntermediate$*,* $finalFinite$*, and* $finalCompact'$*, and the endpoint classifier equivalences*

$$\mathsf{hsame}(finalLocated, finalIntermediate) \iff \mathsf{hsame}(located, intermediate)$$

and

$$\mathsf{hsame}(finalFinite, finalCompact') \iff \mathsf{hsame}(finite, finalCompact).$$

Proof. First package the refined carrier. Apply Theorem 60.41 to the initial compact witness carrier, the located refinement chain, and the finite refinement chain. This gives the displayed carrier over $(subset, finalLocated, finalFinite, finalIntermediate, finalCompact')$.

Next package the endpoint unary data. Apply Theorem 60.42 to the same three inputs, yielding unary histories for $finalLocated$, $finalIntermediate$, $finalFinite$, and $finalCompact'$.

For the located endpoint classifier, apply Theorem 60.26 for the forward direction and Theorem 60.27 for the reverse direction.

For the finite endpoint classifier, apply Theorem 60.10 to the finite refinement chain. The refined carrier, unary endpoint witnesses, and the two displayed equivalences form the requested package. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactWitnessCarrier located finite refinement endpoint package`

60.2 The certificate

Definition 60.53 (Compact source specification)**.** *The source is a certified metric space plus a subset predicate over its carrier.*

Definition 60.54 (Compact pattern specification)**.** *The pattern is compact-subset formation by attaching locatedness and finite-net data for each rational precision.*

Definition 60.55 (Compact classifier specification)**.** *The classifier relates compact witnesses when their membership predicates agree by explicit bidirectional evidence under carrier sameness.*

Definition 60.56 (Compact stability certificate)**.** *The stability certificate consists of:*

1. *membership stability under carrier classifier*
2. *locatedness witness validity*
3. *total-bounded finite-net validity*
4. *monotonicity of precision witnesses where required*
5. *stability under compact-witness classifier*

Theorem 60.57 (Compact net witness semantic name certificate)**.** *For unary histories c and ϵ, the compact-net witness predicate* $\mathsf{CompactNetWitness}(c, \epsilon, -)$ *carries a semantic name certificate with source, pattern, and ledger all equal to that concrete witness predicate, and classifier* hsame*:*

$$\mathsf{SemanticNameCert}(\mathsf{CompactNetWitness}(c, \epsilon, -), \mathsf{CompactNetWitness}(c, \epsilon, -), \mathsf{CompactNetWitness}(c, \epsilon, -), \mathsf{hsame}).$$

Proof. The carrier witness is the concrete history $c \cdot \epsilon$. Unary append closure supplies its unary carrier, and the continuation ledger is $c \cdot \epsilon = c \cdot \epsilon$. The classifier fields are the reflexive, symmetric, and transitive laws of hsame, with carrier transport by equality case analysis. Pattern and ledger soundness are the identity projections because all three semantic predicates are the compact-net witness predicate. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness semanticNameCert`

Theorem 60.58 (Compact net witness prefix closure)**.** *For unary histories p, c, ϵ, n, if n is a compact net witness obtained by continuing center c with precision ϵ, then prefixing the center and net by p preserves the same precision witness:*

$$\mathsf{CompactNetWitness}(c, \epsilon, n) \Longrightarrow \mathsf{CompactNetWitness}(p \cdot c, \epsilon, p \cdot n).$$

Proof. Unpack the witness into unary center, precision, and net histories together with the continuation ledger $n = c \cdot \epsilon$. Unary closure gives unary histories for $p \cdot c$ and $p \cdot n$. The prefixed continuation ledger is the associativity equality $(p \cdot c) \cdot \epsilon = p \cdot (c \cdot \epsilon)$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefix closed`

Theorem 60.59 (Compact net witness prefix exactness)**.** *For histories p, c, ϵ, n, a prefixed compact-net witness is equivalent to unary prefix evidence together with the unprefixed witness:*

$$\mathsf{CompactNetWitness}(p \cdot c, \epsilon, p \cdot n) \Longleftrightarrow \mathsf{UnaryHistory}(p) \wedge \mathsf{CompactNetWitness}(c, \epsilon, n).$$

Proof. For the forward direction, unpack the prefixed witness. Unary append factorization recovers the unary prefix and the unary center and net histories, while prefix cancellation on the continuation ledger recovers $\mathsf{Cont}(c, \epsilon, n)$. For the reverse direction, apply prefix closure to the unary prefix and the original compact-net witness. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefix iff`

Theorem 60.60 (Compact net witness prefixed result determinacy)**.** *If two compact-net witnesses share the same prefixed center and precision,*

$$\mathsf{CompactNetWitness}(p \cdot c, \epsilon, p \cdot n) \quad \textit{and} \quad \mathsf{CompactNetWitness}(p \cdot c, \epsilon, p \cdot n'),$$

then the unprefixed net results are history-same:

$$\mathsf{hsame}(n, n').$$

Proof. The two compact-net witnesses contain continuation ledgers with the same source $p \cdot c$ and precision ϵ. Continuation determinacy identifies the two prefixed results $p \cdot n$ and $p \cdot n'$, and left cancellation removes the common prefix p. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefixed result deterministic`

Theorem 60.61 (Compact net witness empty net exactness)**.** *For histories c and ϵ, a compact-net witness with empty net is equivalent to both the center and precision histories being empty:*

$$\mathsf{CompactNetWitness}(c, \epsilon, \mathsf{e}) \iff \mathsf{hsame}(c, \mathsf{e}) \wedge \mathsf{hsame}(\epsilon, \mathsf{e}).$$

Proof. Unpack the compact-net witness and invert the continuation $\mathsf{Cont}(c, \epsilon, \mathsf{e})$. This yields empty center and empty precision. The reverse implication uses the empty unary carrier for both endpoints and the canonical continuation from e through e to e. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness empty net iff`

Theorem 60.62 (Compact net witness endpoint cycle precision empty)**.** *For histories c, ϵ, n, a compact-net witness whose center and net are history-same has empty precision:*

$$\mathsf{CompactNetWitness}(c, \epsilon, n) \implies \mathsf{hsame}(c, n) \implies \mathsf{hsame}(\epsilon, \mathsf{e}).$$

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness endpoint cycle precision empty`

Proof. Transport the witness continuation $\mathsf{Cont}(c, \epsilon, n)$ across $\mathsf{hsame}(c, n)$ to obtain a self-extension of c. Right-unit uniqueness forces the precision tail to be empty. □

Theorem 60.63 (Compact empty-center nonempty precision shape)**.** *For histories net, ϵ, a compact-net witness with empty center and nonempty precision has exactly one visible unary payload:*

$$\mathsf{CompactNetWitness}(\mathsf{e}, \epsilon, net) \wedge \neg\mathsf{hsame}(\epsilon, \mathsf{e}) \iff \exists r : \mathsf{BHist}.\ net = \mathsf{E1}(r) \wedge \epsilon = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(r).$$

Proof. The continuation field is $\mathsf{Cont}(\mathsf{e}, \epsilon, net)$, so left-unit exactness identifies net with ϵ. The nonempty precision premise removes the empty case, and unary membership removes zero-headed precision. In the visible case, the precision carrier exposes the unary payload and sameness fixes the net to the same visible history. Conversely, the displayed visible payload rebuilds the compact-net witness by the left-unit continuation. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness empty center nonempty precision shape iff`

Theorem 60.64 (Compact net witness left e1 result cases)**.** *For histories center, precision, net, a compact-net witness from a visible center to a visible net has only the empty precision case or a visible precision tail:*

$$\mathsf{CompactNetWitness}(\mathsf{E1}(center), precision, \mathsf{E1}(net)) \Longrightarrow (precision = \mathsf{e} \wedge \mathsf{UnaryHistory}(center) \wedge \mathsf{hsame}(center, net))$$

Proof. Unpack the compact-net witness to expose the unary carriers and the continuation ledger. Inverting the ledger with visible result $\mathsf{E1}(net)$ gives either empty precision or a visible precision tail. The empty branch strips the visible constructor from the center-net equality and inverts the center carrier to obtain $\mathsf{UnaryHistory}(center)$. The visible branch inverts the precision and net carriers and repacks the tail continuation as a compact-net witness. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness left e1 result cases`

Theorem 60.65 (Compact net witness left e1 result e1 precision tail)**.** *For histories center, precisionTail, net, a compact-net witness whose center, precision, and result are all visible exposes the precision tail witness:*

$$\mathsf{CompactNetWitness}(\mathsf{E1}(center), \mathsf{E1}(precisionTail), \mathsf{E1}(net)) \Longrightarrow \mathsf{CompactNetWitness}(\mathsf{E1}(center), precisionTail, n$$

Proof. Apply the visible-result cases theorem. The empty-precision branch would identify $\mathsf{E1}(precisionTail)$ with e, which constructor disjointness excludes. The visible branch identifies the displayed precision tail with the recovered tail, and the recovered tail witness is the required compact-net witness. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness left e1 result e1 precision tail`

Theorem 60.66 (Compact net witness right e1 result iff)**.** *For histories center, precision, net, visible precision and visible result are equivalent to the tail compact-net witness:*

$$\mathsf{CompactNetWitness}(center, \mathsf{E1}(precision), \mathsf{E1}(net)) \Longleftrightarrow \mathsf{CompactNetWitness}(center, precision, net).$$

Proof. For the forward direction, unpack the compact-net witness. Unary inversion removes the visible constructor from the precision and net carriers, and right-step inversion removes it from the continuation ledger.

For the reverse direction, unary closure rebuilds the visible precision and net carriers, while the one-step continuation rule lifts the tail ledger to the visible result. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness right e1 result iff`

Theorem 60.67 (Compact net witness suffix exactness)**.** *For histories p, c, ϵ, n, a compact-net witness with the same right suffix attached to precision and net is equivalent to unary suffix evidence together with the unsuffixed witness:*

$$\mathsf{CompactNetWitness}(c, \epsilon \cdot p, n \cdot p) \Longleftrightarrow \mathsf{UnaryHistory}(p) \wedge \mathsf{CompactNetWitness}(c, \epsilon, n).$$

Proof. In the forward direction, unary append factorization recovers the suffix and the unsuffixed precision and net histories. The continuation ledger $n \cdot p = c \cdot (\epsilon \cdot p)$ is associated to $(c \cdot \epsilon) \cdot p$, and right cancellation by p recovers $n = c \cdot \epsilon$. In the reverse direction, unary append closure builds the suffixed precision and net histories, while associativity supplies the suffixed continuation ledger. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness suffix iff`

Theorem 60.68 (Compact net witness visible context exactness)**.** *For histories p, q, c, ϵ, n, a compact-net witness with visible left context on the center and net and visible right context on the precision and net is equivalent to the two unary context witnesses and the base compact-net witness:*

$$\mathsf{CompactNetWitness}(p{\cdot}c, \epsilon{\cdot}q, (p{\cdot}n){\cdot}q) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{CompactNetWitness}(c, \epsilon, n).$$

Proof. Peel the right suffix by Theorem 60.67, then peel the left prefix by Theorem 60.59. The reverse direction first applies prefix exactness and then reattaches the right suffix by suffix exactness. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness visible context iff`

Theorem 60.69 (Compact net witness visible-result context factorization)**.** *For histories $p, q, c, \epsilon, n, result$, if $\mathsf{CompactNetWitness}(p{\cdot}c, \epsilon{\cdot}q, result)$ and $result \mathsf{hsame}(p{\cdot}n){\cdot}q$, then $\mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{CompactNetWitness}(c, \epsilon, n)$.*

Proof. Transport the result carrier and continuation ledger along the displayed hsame, then apply visible-context exactness. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness visible result context factorizes`

Theorem 60.70 (Compact net witness visible-context result determinacy)**.** *For histories p, q, c, ϵ, n, n', two visible-context compact-net witnesses with the same visible center and precision contexts determine the same central net history:*

$$\mathsf{CompactNetWitness}(p \cdot c, \epsilon \cdot q, (p \cdot n) \cdot q) \Longrightarrow \mathsf{CompactNetWitness}(p \cdot c, \epsilon \cdot q, (p \cdot n') \cdot q) \Longrightarrow \mathsf{hsame}(n, n').$$

Proof. Apply visible-context exactness to both witnesses. The recovered central compact-net witnesses have the same center c and precision ϵ, so continuation result determinacy identifies the two central nets. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness visible context result deterministic`

Theorem 60.71 (Compact net witness visible-context precision determinacy)**.** *For histories $p, q, c, \epsilon, \epsilon', n$, two visible-context compact-net witnesses with the same visible center context and the same visible net context determine the same central precision history:*

$$\mathsf{CompactNetWitness}(p \cdot c, \epsilon \cdot q, (p \cdot n) \cdot q) \Longrightarrow \mathsf{CompactNetWitness}(p \cdot c, \epsilon' \cdot q, (p \cdot n) \cdot q) \Longrightarrow \mathsf{hsame}(\epsilon, \epsilon').$$

Proof. Apply visible-context exactness to both witnesses. The recovered central compact-net witnesses have the same center c and net n, so left continuation cancellation identifies the two central precision histories. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness visible context precision deterministic`

Theorem 60.72 (Compact net witness visible-context center determinacy)**.** *For histories p, q, c, c', ϵ, n, two visible-context compact-net witnesses with the same visible precision context and the same visible net context determine the same central center history:*

$$\mathsf{CompactNetWitness}(p \cdot c, \epsilon \cdot q, (p \cdot n) \cdot q) \Longrightarrow \mathsf{CompactNetWitness}(p \cdot c', \epsilon \cdot q, (p \cdot n) \cdot q) \Longrightarrow \mathsf{hsame}(c, c').$$

Proof. Apply visible-context exactness to both witnesses. The recovered central compact-net witnesses have the same precision ϵ and net n, so right continuation cancellation identifies the two central center histories. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness visible context center deterministic`

Theorem 60.73 (Compact net witness common composite result prefix determinacy)**.** *For histories p, p', c, θ, out, if two compact-net witnesses share the same composite precision and result while their centers differ only by the visible left prefix before the same c, then the two visible prefixes are* hsame*:*

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, out) \Longrightarrow \mathsf{CompactNetWitness}(p' \cdot c, \theta, out) \Longrightarrow p\mathsf{hsame}p'.$$

Proof. Unpack the two compact-net witnesses. Their continuation ledgers have the same precision θ and the same result out, so right cancellation identifies $p \cdot c$ with $p' \cdot c$. Cancelling the common suffix c gives $p\mathsf{hsame}p'$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness common composite result prefix deterministic`

Theorem 60.74 (Compact net witness empty-precision visible-context exactness)**.** *For histories p, q, c, n, a visible-context compact-net witness with empty central precision is equivalent to unary evidence for the visible ledgers and center, together with the center classifier for the net:*

$$\mathsf{CompactNetWitness}(p{\cdot}c, \mathsf{e}{\cdot}q, (p{\cdot}n){\cdot}q) \Longleftrightarrow \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{UnaryHistory}(c) \wedge \mathsf{hsame}(n, c).$$

Proof. Peel the visible prefix and suffix by Theorem 60.68. The central witness is $\mathsf{CompactNetWitness}(c, \mathsf{e}, n)$, whose continuation field is exactly the right-unit continuation classifier $\mathsf{hsame}(n, c)$; its carrier field gives $\mathsf{UnaryHistory}(c)$.

Conversely, the unary center carrier and $\mathsf{hsame}(n, c)$ transport the center carrier to the net and produce the right-unit continuation witness. This builds $\mathsf{CompactNetWitness}(c, \mathsf{e}, n)$, and visible-context exactness reattaches the prefix p and suffix q. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness empty precision visible context iff`

Theorem 60.75 (Compact visible result excludes empty center)**.** *For histories p, q, c, t, a visible-context compact-net witness with empty central precision and visible net $\mathsf{E1}(t)$ cannot have an empty central center:*

$$\mathsf{CompactNetWitness}(p \cdot c, \mathsf{e} \cdot q, (p \cdot \mathsf{E1}(t)) \cdot q) \Longrightarrow \mathsf{hsame}(c, \mathsf{e}) \Longrightarrow \bot.$$

Proof. Empty-precision visible-context exactness reads the central data back as $\mathsf{hsame}(\mathsf{E1}(t), c)$. If $c\mathsf{hsame}\mathsf{e}$, transitivity identifies $\mathsf{E1}(t)$ with e, contradicting BEDC constructor no-confusion. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness visible context e1 result empty center absurd`

Theorem 60.76 (Compact visible boundary excludes empty center)**.** *If the net in a visible-context empty-precision compact witness is* hsame *to either $\mathsf{E0}(t)$ or $\mathsf{E1}(t)$, then the center cannot be empty.*

Proof. Empty-precision visible-context exactness identifies the net with the center; an empty center would identify the visible result with e, contradicting constructor no-confusion. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness visible context visible result empty center absurd`

Theorem 60.77 (Compact net witness composite result determinacy)**.** *For histories $c, \epsilon, \eta, n, n', m, m'$, if n and n' are compact net witnesses from the same center c and precision ϵ, and m and m' continue them with the same refinement precision η, then the refined nets are the same BEDC history:*

$$\mathsf{CompactNetWitness}(c, \epsilon, n) \Longrightarrow \mathsf{CompactNetWitness}(n, \eta, m) \Longrightarrow \mathsf{CompactNetWitness}(c, \epsilon, n') \Longrightarrow \mathsf{CompactNetWitn}$$

Proof. Unpack the first and third witnesses into continuation ledgers $c \cdot \epsilon = n$ and $c \cdot \epsilon = n'$. Continuation determinacy gives $\mathsf{hsame}(n, n')$. The second and fourth witnesses give ledgers $n \cdot \eta = m$ and $n' \cdot \eta = m'$. Continuation compatibility with $\mathsf{hsame}(n, n')$ and reflexivity of η compares these second-step ledgers and yields $\mathsf{hsame}(m, m')$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness composite result deterministic`

Theorem 60.78 (Compact net witness composite middle continuation determinacy)**.** *For histories $c, \epsilon, \eta, n, n', m$, if $\mathsf{CompactNetWitness}(c, \epsilon, n)$, $\mathsf{CompactNetWitness}(n, \eta, m)$, $\mathsf{CompactNetWitness}(c, \epsilon, n')$, and $\mathsf{CompactNetWitness}(n', \eta, m)$ hold, then*

$$\mathsf{Cont}(c, \epsilon, n) \wedge \mathsf{Cont}(c, \epsilon, n') \wedge \mathsf{hsame}(n, n').$$

Proof. The first and third compact-net witnesses expose the concrete first-stage continuation ledgers $\mathsf{Cont}(c, \epsilon, n)$ and $\mathsf{Cont}(c, \epsilon, n')$. Continuation determinacy compares those two ledgers with the same source and precision, giving $\mathsf{hsame}(n, n')$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness composite middle cont deterministic`

Theorem 60.79 (Compact net witness composite center determinacy)**.** *For histories $c, c', \epsilon, \eta, n, n', m$, if the first-stage net witnesses share precision ϵ and the second-stage refinements share extra precision η and final net m, then their centers are the same BEDC history:*

$$\mathsf{CompactNetWitness}(c, \epsilon, n) \Longrightarrow \mathsf{CompactNetWitness}(n, \eta, m) \Longrightarrow \mathsf{CompactNetWitness}(c', \epsilon, n') \Longrightarrow \mathsf{CompactNetWit}$$

Proof. Unpack the second-stage witnesses into continuation ledgers $\mathsf{Cont}(n, \eta, m)$ and $\mathsf{Cont}(n', \eta, m)$. Continuation right cancellation gives $\mathsf{hsame}(n, n')$. The first-stage witnesses provide $\mathsf{Cont}(c, \epsilon, n)$ and $\mathsf{Cont}(c', \epsilon, n')$; cancellation over the common suffix ϵ and the already identified net histories yields $\mathsf{hsame}(c, c')$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness composite center deterministic`

Theorem 60.80 (Compact net witness common precision center transport)**.** *For histories c, c', ϵ, n, n', if $\mathsf{CompactNetWitness}(c, \epsilon, n)$, $\mathsf{CompactNetWitness}(c', \epsilon, n')$, and $\mathsf{hsame}(n, n')$ hold, then the second witness transports to the first net and the centers are the same BEDC history:*

$$\mathsf{Cont}(c', \epsilon, n) \wedge \mathsf{hsame}(c, c').$$

Proof. The second compact-net witness exposes $\mathsf{Cont}(c', \epsilon, n')$; endpoint transport along $\mathsf{hsame}(n, n')$ gives $\mathsf{Cont}(c', \epsilon, n)$. The two first-stage continuation ledgers now share the same precision and history-same results, so common-suffix cancellation identifies c and c'. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness common precision center transport`

Theorem 60.81 (Compact net witness common center precision transport)**.** *For histories $c, \epsilon, \epsilon', n, n'$, if $\mathsf{CompactNetWitness}(c, \epsilon, n)$, $\mathsf{CompactNetWitness}(c, \epsilon', n')$, and $\mathsf{hsame}(n, n')$ hold, then the second witness transports to the first net and the precisions are the same BEDC history:*

$$\mathsf{Cont}(c, \epsilon', n) \wedge \mathsf{hsame}(\epsilon, \epsilon').$$

Proof. The second compact-net witness exposes $\mathsf{Cont}(c, \epsilon', n')$; endpoint transport along $\mathsf{hsame}(n, n')$ gives $\mathsf{Cont}(c, \epsilon', n)$. Since the center is common and the endpoints are history-same, compact-net precision determinacy identifies ϵ and ϵ'. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness common center precision transport`

Theorem 60.82 (Compact net witness precision determinacy under endpoint sameness)**.** *For histories $c, c', \epsilon, \epsilon', n, n'$, if $\mathsf{hsame}(c, c')$, $\mathsf{hsame}(n, n')$, $\mathsf{CompactNetWitness}(c, \epsilon, n)$, and $\mathsf{CompactNetWitness}(c', \epsilon', n')$ hold, then*

$$\mathsf{hsame}(\epsilon, \epsilon').$$

Proof. Transport the two continuation ledgers to common center and net histories using the endpoint hsame hypotheses. The two witnesses then have the same left context and result, so continuation left cancellation identifies the precision histories. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness precision hsame deterministic`

Theorem 60.83 (Compact net witness composite precision continuation determinacy)**.** *For histories $c, \epsilon, \epsilon', \eta, n, n', m$, if $\mathsf{CompactNetWitness}(c, \epsilon, n)$ and $\mathsf{CompactNetWitness}(c, \epsilon', n')$ hold and both n and n' refine through the same extra precision η to the same history m, then*

$$\mathsf{hsame}(\epsilon, \epsilon').$$

Proof. Continuation right cancellation on the two refinement ledgers identifies n and n'. With the center already common, compact-net precision determinacy under endpoint sameness identifies ϵ and ϵ'. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness composite precision cont deterministic`

Corollary 60.84 (Compact source specification route determinacy)**.** *Fix a consumer-facing $\mathsf{Compact}^{\uparrow}$ use whose source side is the compact source specification of Definition 60.53. For histories p, c, ϵ, n, n', suppose the displayed local rows are the same prefixed center, precision, continuation route, and compact-net result shape:*

$$\mathsf{CompactNetWitness}(p \cdot c, \epsilon, p \cdot n) \quad \textit{and} \quad \mathsf{CompactNetWitness}(p \cdot c, \epsilon, p \cdot n').$$

Then the unprefixed result rows selected by the two consumer uses are the same BEDC history:

$$\mathsf{hsame}(n, n').$$

Consequently every accepted consumer-facing use of the compact route, compact-net normal-form read, or exactness decision over these fixed source rows factors through the same finite route: the compact source row, the prefixed center row $p \cdot c$, the precision row ϵ, the compact-net witness row, the continuation ledger $\mathsf{Cont}(p \cdot c, \epsilon, -)$, the result readback row $p \cdot n$, and the classifier row hsame. There is no alternate hidden coordinate, second compact-net result source, or duplicate classifier source outside that displayed packet.

Proof. The compact source specification of Definition 60.53 supplies only the certified metric source together with the subset predicate over its carrier. In this certificate, a consumer-facing compact-net use therefore reaches the compact source through the displayed compact-net witness row and not through an additional selector, hidden coordinate, or external classifier source.

The two displayed consumer uses have the same prefixed center $p \cdot c$ and the same precision ϵ. Their only result rows are $p \cdot n$ and $p \cdot n'$, each carried by a compact-net witness over those fixed source rows. Thus they are exactly in the situation of Definition 60.60. Applying that theorem gives $\mathsf{hsame}(n, n')$ after cancellation of the common prefix p.

It remains to account for the named consumer readings. The route read is the prefixed center and precision route just used. A compact-net normal-form read is a readback of the same result row, and an exactness decision named in the chapter is a decision about the same compact-net witness packet. Since the source specification adds no further coordinate and the determinacy theorem has already identified any competing unprefixed result, every accepted use over the fixed rows factors through the listed finite route and the same hsame classifier row. □

Theorem 60.85 (Prefixed composite compact net witness closure)**.** *For unary histories $p, c, \epsilon, \eta, \theta, n, m$, assume* $\mathsf{UnaryHistory}(p)$, $\mathsf{CompactNetWitness}(c, \epsilon, n)$, $\mathsf{CompactNetWitness}(n, \eta, m)$, *and* $\mathsf{Cont}(\epsilon, \eta, \theta)$. *Then the composed refinement is a compact net witness under the same visible prefix:*

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m).$$

The certificate fit has ten fields: the traditional target is finite-net precision composition; the BEDC source is BHist equipped with Cont*; the carrier is* $\mathsf{CompactNetWitness}$*; the classifier is hsame; the stability law is closure under prefix and precision composition; the ledger data are center, precision, and net continuations; the core theorem is this prefixed composite closure; exactness is the direct composed witness; the standard bridge is deferred; the status is* $\mathsf{ProofTarget}$.

Proof. Unpack the two compact net witnesses into unary center, precision, and net histories, together with continuation ledgers $n = c \cdot \epsilon$ and $m = n \cdot \eta$.

The continuation hypothesis $\mathsf{Cont}(\epsilon, \eta, \theta)$ gives the composed precision history. Unary continuation closure supplies the unary history for θ, and associativity identifies $(c \cdot \epsilon) \cdot \eta$ with $c \cdot (\epsilon \cdot \eta)$.

The identified composite ledger presents $m = c \cdot \theta$. Applying prefix closure to this composed witness and using associativity once more yields the ledger from $p \cdot c$ to $p \cdot m$ with precision θ. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefixed composite closed`

Theorem 60.86 (Prefixed composite compact net witness factorization)**.** *For histories $p, c, \epsilon, \eta, \theta, m$, assume* $\mathsf{UnaryHistory}(\epsilon)$, $\mathsf{UnaryHistory}(\eta)$, $\mathsf{Cont}(\epsilon, \eta, \theta)$, *and* $\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m)$. *Then there exists a history n such that*

$$\mathsf{CompactNetWitness}(c, \epsilon, n)$$

and

$$\mathsf{CompactNetWitness}(n, \eta, m).$$

Proof. Apply Theorem 60.59 to the visible-prefix witness. This removes the common prefix and recovers $\mathsf{CompactNetWitness}(c, \theta, m)$, hence the unary histories for c, θ, m and the continuation ledger $\mathsf{Cont}(c, \theta, m)$.

Choose the intermediate history $n = c \cdot \epsilon$. The unary history of ϵ and the recovered unary history of c give unary n, and the continuation constructor gives $\mathsf{Cont}(c, \epsilon, n)$. These data form $\mathsf{CompactNetWitness}(c, \epsilon, n)$.

It remains to build the second witness. The hypothesis $\mathsf{Cont}(\epsilon, \eta, \theta)$ and the recovered continuation $\mathsf{Cont}(c, \theta, m)$ identify the ledger m with $c \cdot (\epsilon \cdot \eta)$; associativity rewrites this as $(c \cdot \epsilon) \cdot \eta = n \cdot \eta$. Together with the unary histories of n, η, and m, this is $\mathsf{CompactNetWitness}(n, \eta, m)$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefixed composite factorizes`

Theorem 60.87 (Prefixed composite compact net middle deterministic factorization)**.** *For histories $p, c, \epsilon, \eta, \theta, m$, assume* $\mathsf{UnaryHistory}(\epsilon)$, $\mathsf{UnaryHistory}(\eta)$, *and* $\mathsf{Cont}(\epsilon, \eta, \theta)$. *If*

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m),$$

then there exists a history n such that

$$\mathsf{CompactNetWitness}(c, \epsilon, n)$$

and

$$\mathsf{CompactNetWitness}(n, \eta, m).$$

Moreover any other history n' supporting these two compact-net witnesses is history-same to n.

Proof. Apply the prefixed composite factorization theorem to obtain an intermediate history n and the two compact-net witnesses through ϵ and η. For any other displayed intermediate n', the first compact-net witnesses for n and n' share the same center c and precision ϵ; continuation determinacy therefore gives $\mathsf{hsame}(n, n')$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefixed composite middle deterministic factorization`

Definition 60.88 (Two-step compact net factor)**.** *For histories c, ϵ, η, m, the predicate* $\mathsf{CompactNetTwoStepFactor}($ *records an intermediate net realizing the two visible precision steps:*

$$\mathsf{CompactNetTwoStepFactor}(c, \epsilon, \eta, m) \iff \exists n.\ \mathsf{CompactNetWitness}(c, \epsilon, n) \wedge \mathsf{CompactNetWitness}(n, \eta, m).$$

Lean4 (definition) `BEDC.Derived.CompactUp.CompactNetTwoStepFactor`

Theorem 60.89 (Two-step compact net factor composed closure)**.** *For histories $c, \epsilon, \eta, \theta, m$, assume* $\mathsf{UnaryHistory}(\epsilon)$, $\mathsf{UnaryHistory}(\eta)$, *and* $\mathsf{Cont}(\epsilon, \eta, \theta)$. *Then every displayed two-step factor composes to a compact-net witness at the composite precision:*

$$\mathsf{CompactNetTwoStepFactor}(c, \epsilon, \eta, m) \implies \mathsf{CompactNetWitness}(c, \theta, m).$$

Proof. Choose the intermediate net from the two-step factor. Apply prefixed composite closure with the empty visible prefix to compose the two compact-net witnesses through $\mathsf{Cont}(\epsilon, \eta, \theta)$. The compact-net prefix equivalence then removes the empty prefix and returns the unprefixed witness. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetTwoStepFactor composed closed`

Theorem 60.90 (Prefixed composite compact net witness exactness)**.** *For histories $p, c, \epsilon, \eta, \theta, m$, assume* $\mathsf{UnaryHistory}(\epsilon)$, $\mathsf{UnaryHistory}(\eta)$, *and* $\mathsf{Cont}(\epsilon, \eta, \theta)$. *Then the prefixed composed certificate is exact at the compact-net witness level:*

$$\mathsf{CompactNetWitness}(p{\cdot}c, \theta, p{\cdot}m) \iff \mathsf{UnaryHistory}(p) \wedge \exists n, \mathsf{CompactNetWitness}(c, \epsilon, n) \wedge \mathsf{CompactNetWitness}(n, \eta, m)$$

The certificate fit has ten fields: the traditional target is finite-net precision composition; the BEDC source is BHist equipped with Cont*; the carrier is* $\mathsf{CompactNetWitness}$*; the classifier is hsame; the stability obligation is prefixed composite exactness; the ledger data are center, precision, intermediate net, and final net continuations; the core theorem is this equivalence; the exactness predicate is the displayed equivalence; the standard bridge is deferred; the status is* $\mathsf{ProofTarget}$.

Proof. For the forward direction, apply Theorem 60.59 to the prefixed composed witness. This recovers $\mathsf{UnaryHistory}(p)$ together with the unprefixed witness $\mathsf{CompactNetWitness}(c, \theta, m)$. The hypotheses on ϵ, η, and θ then allow Theorem 60.86 to produce an intermediate history n with the two compact-net witnesses required on the right-hand side.

For the reverse direction, project the unary prefix evidence and the intermediate history n from the right-hand side. The two compact-net witnesses for c through ϵ and for n through η, together with $\mathsf{Cont}(\epsilon, \eta, \theta)$, satisfy the hypotheses of Theorem 60.85. Applying that closure theorem yields $\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m)$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefixed composite iff`

Theorem 60.91 (Prefixed composite compact net result determinacy)**.** *For histories $p, c, \epsilon, \eta, \theta, m, m'$, assume $\mathsf{UnaryHistory}(\epsilon)$, $\mathsf{UnaryHistory}(\eta)$, and $\mathsf{Cont}(\epsilon, \eta, \theta)$. If both prefixed composed net witnesses start from the same prefixed center and composed precision,*

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m) \quad \textit{and} \quad \mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m'),$$

then the visible refined nets are history-same:

$$\mathsf{hsame}(m, m').$$

Proof. Apply the prefixed composite factorization theorem to each prefixed composed witness. This produces two unprefixed two-step compact-net chains from the same center c, through the same precision ϵ, and then through the same refinement precision η. Composite-result determinacy for compact net witnesses compares those two unprefixed chains and yields $\mathsf{hsame}(m, m')$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefixed composite result deterministic`

Theorem 60.92 (Prefixed composite compact net prefix-independent result determinacy)**.** *For histories $p, p', c, \epsilon, \eta, \theta, m, m'$, assume $\mathsf{UnaryHistory}(\epsilon)$, $\mathsf{UnaryHistory}(\eta)$, and $\mathsf{Cont}(\epsilon, \eta, \theta)$. If two composed compact-net witnesses share the same unprefixed center and composed precision but use different visible prefixes,*

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m) \quad \textit{and} \quad \mathsf{CompactNetWitness}(p' \cdot c, \theta, p' \cdot m'),$$

then the refined nets are history-same:

$$\mathsf{hsame}(m, m').$$

Proof. Apply prefixed composite factorization to both witnesses, using the same precision histories ϵ, η and composed precision θ. This removes the visible prefixes and recovers two unprefixed two-step compact-net chains from the same center c through the same precision sequence. The unprefixed composite-result determinacy theorem compares those recovered chains and gives $\mathsf{hsame}(m, m')$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefixed composite prefix independent result deterministic`

Theorem 60.93 (Prefixed composite compact net center determinacy)**.** *For histories $p, c, c', \epsilon, \eta, \theta, m$, assume $\mathsf{UnaryHistory}(\epsilon)$, $\mathsf{UnaryHistory}(\eta)$, and $\mathsf{Cont}(\epsilon, \eta, \theta)$. If two prefixed composed net witnesses have the same composed precision and the same prefixed refined net,*

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m) \quad \textit{and} \quad \mathsf{CompactNetWitness}(p \cdot c', \theta, p \cdot m),$$

then their unprefixed centers are history-same:

$$\mathsf{hsame}(c, c').$$

Proof. Apply prefixed composite factorization to both prefixed witnesses. This recovers two unprefixed two-step compact-net chains ending at the same refined net and using the same precision histories ϵ and η. The unprefixed composite center determinacy theorem compares the recovered chains and yields $\mathsf{hsame}(c, c')$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefixed composite center deterministic`

Theorem 60.94 (Prefixed composite compact net precision determinacy)**.** *For histories $p, c, \epsilon, \epsilon', \eta, \theta, \theta', m$, assume* $\mathsf{UnaryHistory}(\epsilon)$, $\mathsf{UnaryHistory}(\epsilon')$, $\mathsf{UnaryHistory}(\eta)$, $\mathsf{Cont}(\epsilon, \eta, \theta)$, *and* $\mathsf{Cont}(\epsilon', \eta, \theta')$. *If two prefixed composed net witnesses have the same prefixed center and the same prefixed refined net,*

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m) \quad \textit{and} \quad \mathsf{CompactNetWitness}(p \cdot c, \theta', p \cdot m),$$

then their first precision histories are history-same:

$$\mathsf{hsame}(\epsilon, \epsilon').$$

Proof. Unpack the two prefixed compact-net witnesses. Since they share the same prefixed center and prefixed refined net, left cancellation on their continuation ledgers identifies the composite precision histories θ and θ'. The two composite ledgers then have the same right suffix η, so continuation suffix cancellation identifies the first precision histories. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetWitness prefixed composite precision deterministic`

Theorem 60.95 (Compact two-step finite-net gluing)**.** *Let K be a* $\mathsf{Compact}^{\uparrow}$ *witness carried by the finite-net setup of Definition 60.1 inside a metric carrier as in Definition 57.1. Let ε, δ, and θ be valid precision ledgers with*

$$\mathsf{Cont}(\varepsilon, \delta, \theta).$$

Assume $N \subseteq K$ is a finite ε-net for K. For each $n \in N$, let

$$B_K(n, \varepsilon) = \{y \in K \mid d(y, n) \leq \varepsilon\},$$

and assume $N_n \subseteq K$ is a finite δ-net for $B_K(n, \varepsilon)$. Then

$$N^* = \bigcup_{n \in N} N_n$$

is finite, is contained in K, and is a finite θ-net for K. Under the real-budget reading of the continuation ledger, this is a finite $(\varepsilon + \delta)$-net for K.

Moreover, every displayed two-step choice

$$\mathsf{CompactNetWitness}(c, \varepsilon, n) \wedge \mathsf{CompactNetWitness}(n, \delta, m)$$

from the construction is a $\mathsf{CompactNetTwoStepFactor}(c, \varepsilon, \delta, m)$ *and induces the composed witness* $\mathsf{CompactNetWitness}(c, \theta, m)$.

Proof. The finiteness and carrier clauses are immediate by finite induction over the displayed list N. The empty list gives the empty union. In the step case, adjoining one finite local net N_n preserves finiteness by finite-union closure, and containment in K follows from the hypotheses $N_n \subseteq K$.

Fix $x \in K$. Since N is an ε-net for K, choose $n \in N$ with $d(x, n) \leq \varepsilon$. Because $N \subseteq K$ and the metric identity law gives $d(n, n) = 0$, the point n lies in $B_K(n, \varepsilon)$. The local δ-net N_n therefore supplies $m \in N_n$ with $d(n, m) \leq \delta$. Since $N_n \subseteq N^*$, this m is a candidate center in the glued finite set.

The triangle inequality field of Definition 57.5 gives

$$d(x, m) \leq d(x, n) + d(n, m) \leq \varepsilon + \delta.$$

The precision continuation $\mathsf{Cont}(\varepsilon, \delta, \theta)$ is exactly the BEDC budget ledger for the two visible steps. Thus the displayed point $m \in N^*$ witnesses the θ-coverage of x. Since x was arbitrary, N^* is a finite θ-net for K.

For the BEDC witness clause, Definition 60.88 repackages the two displayed compact-net witnesses as the two-step factor. Applying Definition 60.85 with empty visible prefix composes the two precision ledgers through $\mathsf{Cont}(\varepsilon, \delta, \theta)$ and returns $\mathsf{CompactNetWitness}(c, \theta, m)$. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactNetTwoStepFactor gluing package`

Corollary 60.96 (Prefixed composite compact net witness closure determinacy)**.** *For histories $p, c, \epsilon, \eta, \theta, n, n', m$, assume the fixed local rows*

$$\mathsf{UnaryHistory}(p), \quad \mathsf{UnaryHistory}(\epsilon), \quad \mathsf{UnaryHistory}(\eta), \quad \mathsf{Cont}(\epsilon, \eta, \theta),$$

and the displayed two-step compact-net route

$$\mathsf{CompactNetWitness}(c, \epsilon, n) \quad \textit{and} \quad \mathsf{CompactNetWitness}(n, \eta, m).$$

If another consumer-facing use of the same closure packet presents a middle history n' with

$$\mathsf{CompactNetWitness}(c, \epsilon, n') \quad \textit{and} \quad \mathsf{CompactNetWitness}(n', \eta, m),$$

then the closure packet has the same accepted exactness row

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m)$$

and the two proposed middle routes determine the same chapter normal form:

$$\mathsf{hsame}(n, n').$$

Consequently an accepted use of these fixed rows cannot choose an unlisted middle coordinate, a second finite route, or a duplicate classifier source for the closed prefixed composite witness.

Proof. Apply Definition 60.85 to the unary prefix row, the two displayed compact-net witnesses, and the continuation row $\mathsf{Cont}(\epsilon, \eta, \theta)$. This gives the closed prefixed composite witness

$$\mathsf{CompactNetWitness}(p \cdot c, \theta, p \cdot m).$$

Now apply Definition 60.87 to this closed witness. The theorem factors every accepted use of the closed row through the displayed middle factorization rows for the fixed ϵ, η, θ packet, and its determinacy clause compares any two such displayed middle histories.

The original route through n is one displayed middle factorization, because it carries

$$\mathsf{CompactNetWitness}(c, \epsilon, n) \quad \text{and} \quad \mathsf{CompactNetWitness}(n, \eta, m).$$

The consumer route through n' is another displayed middle factorization over the same center, first precision, second precision, and endpoint, by the two assumed rows for n'. The determinacy clause of Definition 60.87, read through the continuation transport row of Definition 4.41, therefore identifies the two middle histories by the chapter classifier, namely $\mathsf{hsame}(n, n')$.

Thus the finite route is fixed up to hsame, the normal-form endpoint remains the displayed m, and the exactness decision is exactly the closed witness produced by the prefixed composite closure theorem. There is no remaining accepted coordinate from which a consumer can read a different middle route or name a separate classifier source. □

Definition 60.97 (Compact ledger policy)**.** *Record the subset predicate, locatedness decisions, and finite net ledgers.*

Definition 60.98 ($\mathsf{Compact}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Compact}^{\uparrow}$*.*

Primitive boundary. $\mathsf{Compact}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 60.99 (Zero-axiom encoding note)**.** *Open-cover compactness is not the exported carrier for* $\mathsf{Compact}^{\uparrow}$*; the exported carrier is locatedness plus explicit finite-net data.*

Theorem 60.100 (Compact witness public surface bridge)**.** *The compact-net semantic certificate, the located and finite refinement chains, the endpoint classifier rows, and the refinement-witness ledger determine the conservative standard finite-net compact-witness schema for* $\mathsf{Compact}^{\uparrow}$*. The public object consists of a unary center, a unary precision ledger, the displayed answer net, the locatedness and finite-net refinement endpoints, and the visible continuation evidence connecting those histories.*

The bridge is conservative: it exposes only finite-net compact-witness data already carried by the BEDC rows. It does not export open-cover compactness, sequential compactness, product compactness, or function-space compactness.

Proof. Use the compact-net semantic name certificate `BEDC.Derived.CompactUp.CompactNetWitness_semanticN` as the canonical certificate row. Its carrier reads a center, a precision, and a net with the net obtained by the displayed continuation from the center and precision, so the public finite-net witness has no coordinate outside the BEDC histories.

Next apply the compact witness carrier and refinement-chain endpoint packages, including Definition 60.41, Definition 60.42, and Definition 60.52. They supply the located and finite refinement endpoints, their unary rows, and the endpoint classifier equivalences used by the public witness schema.

The refinement-witness ledger is exactly the displayed continuation data in those packages. Forgetting the BEDC wrapper yields the ordinary finite-net compact-witness reading, while repacking the same rows returns the BEDC certificate. Since every cited row is a finite history, classifier, or continuation row, none of the excluded compactness principles has a carrier slot in the bridge. □

Lean4 ✓ `BEDC.Derived.CompactUp.CompactUp StdBridge`

Closure status for $\mathsf{NameCert}_{\mathsf{Compact}^{\uparrow}}$.

Constructive story: A compact witness in this scoped package is a finite refinement record over unary histories: a subset history, locatedness ledger, finite-net ledger, intermediate ledger, and compactness ledger are connected by displayed continuations, and the simpler net witness records a center, precision, and net with the net obtained by appending the precision to the center. The classifier is endpoint history-sameness on the exposed net or refinement endpoints, with determinacy rows showing that shared centers, precisions, composites, or final ledgers force the matching fields to be hsame. The source is the BEDC compact-net or refinement predicate, the pattern records finite and located refinement chains, prefix closure, endpoint exactness, empty-net and nonempty-precision shapes, and composite refinement determinacy, and the ledger keeps every located, finite, intermediate, compact, precision, and net continuation visible. Because a unary center and precision always build the witness net $center \cdot precision$, hsame supplies the classifier equivalence, and the refinement predicates transport along deterministic continuation equalities, the five name-certificate obligations hold for the semantic compact-net certificate. A history n lies in the signature gap of a $\mathsf{Compact}^{\uparrow}$ token p when the source-domain accepts it as a compact net or final refinement witness, the signature relation pairs it with an answer net and evidence ledger, and token introduction names that answer as p; unfolded, n is unary, is connected to its center and precision by the displayed continuation, and has the refinement endpoint data encoded by p. The public bridge exposes exactly the conservative finite-net compact-witness schema of Definition 60.100, so open-cover compactness, sequential compactness, products, and function-space compactness stay outside the closed surface. The chapter registers this finite-refinement net construction under the name $\mathsf{Compact}^{\uparrow}$; compactness is a ledger of explicit unary refinements, not an imported topological compactness axiom or host-space object.

Theory closure: TheoryGate(NameCert$_{\mathsf{Compact}^{\uparrow}}$, maturePackageClosed)

Scope closed: The compact-net-witness semantic name certificate, with located/finite refinement chain, endpoint classifier, and refinement-witness ledger over the BEDC source.

Formal verification: FormalStatus(NameCert$_{\mathsf{Compact}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.CompactUp.CompactNetWitness\_semanticNameCert`

Bridge status: bridgeChecked

Not claimed: General theory of compact spaces: arbitrary open-cover compactness, sequential compactness in non-metric settings, products of compact spaces (Tychonoff), or compactness of function spaces.

Upgrade path: No further formal-axis step is recorded for this chapter because the standard bridge is checked.

Chapter 61

A Concrete Naming Certificate for $\mathsf{Cat}^{\uparrow}$

The category interface $\mathsf{Cat}^{\uparrow}$ has certificate obligations over an object carrier together with, for each ordered pair of objects, a morphism carrier, identity morphisms at each object, a binary composition operation respecting source and target, and the associativity and identity laws expressed as morphism-classifier sameness. The size discipline is BEDC-internal: object and morphism carriers are each covered by their own NameCert obligations, avoiding any global "set of all objects" assumption. It is not a primitive structure; it is admitted only as a multi-sorted carrier with relational composition.

61.1 Carrier definition

Definition 61.1 (Category carrier)**.** *Use a multi-sorted setup with object carrier, morphism carrier for each ordered object pair, identities, composition, and law fields.*

Lean4 (definition) `BEDC.Derived.CategoryUp.CategoryHomCarrier`

Theorem 61.2 (Category empty identity hom carrier)**.** *For the unary-continuation category, if h is unary, then the empty history is a hom-carrier from h to h.*

Proof. The source and target carrier witnesses are the given unary witness for h. The morphism carrier is the unary empty history, and the continuation field is the right-unit continuation $\mathsf{Cont}(h, \mathsf{e}, h)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty identity`

Theorem 61.3 (Category empty identity hom carrier exactness)**.** *For histories a, b, the empty history is a hom-carrier from a to b exactly when a and b are unary and internally the same:*

$$\mathsf{CategoryHomCarrier}(a, b, \mathsf{e}) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. Unpack the hom-carrier witness. Its continuation field is $\mathsf{Cont}(a, \mathsf{e}, b)$; determinism against the right-unit continuation $\mathsf{Cont}(a, \mathsf{e}, a)$ identifies a and b. Conversely, unary source and target witnesses together with $\mathsf{hsame}(a, b)$ transport the right-unit continuation to a continuation ending at b, while e supplies the empty morphism carrier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty identity iff`

Theorem 61.4 (Category empty morphism endpoint exactness)**.** *For histories a, b : BHist, the empty history is a hom-carrier from a to b exactly when a is unary and $a$hsame$b$:*

$$\mathsf{CategoryHomCarrier}(a, b, \mathsf{e}) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{hsame}(a, b).$$

Proof. The forward direction applies empty identity hom-carrier exactness and keeps the source carrier together with the endpoint classifier. Conversely, the classifier $a$hsame$b$ transports the unary source carrier from a to b, and empty identity exactness rebuilds the displayed empty hom-carrier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty morphism endpoint iff`

Theorem 61.5 (Category empty morphism endpoint induction)**.** *Let P : BHist → Prop be any predicate with base case $P(\mathsf{e})$ and one-step closure*

$$\forall h : \mathsf{BHist}, \quad \mathsf{UnaryHistory}(h) \to P(h) \to P(\mathsf{E1}(h)).$$

If $\mathsf{CategoryHomCarrier}(a, b, \mathsf{e})$ *holds, then $P(a) \wedge P(b)$.*

Proof. Empty-morphism endpoint exactness identifies the hom-carrier with a unary source a and a classifier $a$hsame$b$. Unary induction gives $P(a)$ from the base and step clauses. The endpoint classifier transports this value from a to b, producing both endpoint conclusions. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty morphism endpoint induction`

Theorem 61.6 (Category endomorphism tail empty exactness)**.** *For a unary-continuation endomorphism carrier, the morphism tail is externally empty exactly when the source object and morphism tail are unary and the tail is internally the empty history:*

$$\mathsf{CategoryHomCarrier}(a, a, f) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(f) \wedge f\mathsf{hsame}\mathsf{e}.$$

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier endomorphism tail empty iff`

Proof. Unpack the endomorphism carrier. Its continuation field is $\mathsf{Cont}(a, f, a)$, so right-unit uniqueness for continuation forces $f$hsame$\mathsf{e}$, while the carrier fields give unary membership of a and f. Conversely, if $f$hsame$\mathsf{e}$, substituting the empty tail rebuilds the canonical empty identity hom-carrier at a. □

Theorem 61.7 (Category hom carrier endomorphism empty exactness)**.** *For histories a, f : BHist, an endomorphism hom carrier at a is exactly a unary object witness for a together with an empty morphism tail:*

$$\mathsf{CategoryHomCarrier}(a, a, f) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{hsame}(f, \mathsf{e}).$$

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier endomorphism empty iff`

Proof. Unpack the hom-carrier witness. Its continuation field is $\mathsf{Cont}(a, f, a)$, so right-unit uniqueness forces $f$hsame$\mathsf{e}$, while the source unary witness is already present. Conversely, after eliminating the empty morphism-tail sameness witness, the empty identity hom carrier at the unary object a gives the required endomorphism carrier. □

Theorem 61.8 (Category one-headed source empty morphism exactness)**.** *For histories a and target, the empty morphism is a hom-carrier from $\mathsf{E1}(a)$ to target exactly when the target is $\mathsf{E1}(a)$ and the tail a is unary:*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), target, \mathsf{e}) \iff target = \mathsf{E1}(a) \wedge \mathsf{UnaryHistory}(a).$$

Proof. Apply empty identity hom-carrier exactness to the source $\mathsf{E1}(a)$. The resulting history-sameness witness identifies *target* with $\mathsf{E1}(a)$, and unary inversion on the one-headed source gives unary membership of a. Conversely, after the displayed target equation is eliminated, unary closure under $\mathsf{E1}$ and the empty identity carrier rebuild the hom-carrier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source empty morphism iff`

Theorem 61.9 (Category one-headed target empty morphism exactness)**.** *For histories $source, r$: BHist, the empty morphism is a hom-carrier from source to $\mathsf{E1}(r)$ exactly when the source is $\mathsf{E1}(r)$ and the tail r is unary:*

$$\mathsf{CategoryHomCarrier}(source, \mathsf{E1}(r), \mathsf{e}) \iff source = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(r).$$

Proof. Apply empty identity hom-carrier exactness to the target $\mathsf{E1}(r)$. The resulting history-sameness witness identifies the source with $\mathsf{E1}(r)$, and unary inversion gives unary membership of r.

Conversely, after eliminating the displayed source equation, unary closure under $\mathsf{E1}$ gives the object carrier at $\mathsf{E1}(r)$, and the empty identity hom carrier rebuilds the hom-carrier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 target empty morphism iff`

Theorem 61.10 (Category empty-source hom carrier exactness)**.** *For histories b, f, a hom-carrier out of the empty source is exactly unary membership of the target together with sameness of the morphism and target:*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, b, f) \iff \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(f, b).$$

Proof. Unpack the hom-carrier witness. Its continuation field is $\mathsf{Cont}(\mathsf{e}, f, b)$, and the left-unit continuation exactness identifies b with f; symmetry gives $\mathsf{hsame}(f, b)$, while the target unary witness is already present. Conversely, transport the target unary witness across $\mathsf{hsame}(f, b)$ to obtain the morphism carrier, and use the left-unit continuation equivalence to rebuild $\mathsf{Cont}(\mathsf{e}, f, b)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source iff`

Theorem 61.11 (Category empty-source nonempty morphism shape)**.** *For histories $target, morph$, an empty-source hom-carrier with nonempty morphism has exactly one visible unary payload:*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, target, morph) \wedge \neg\mathsf{hsame}(morph, \mathsf{e}) \iff \exists r : \mathsf{BHist}.\ target = \mathsf{E1}(r) \wedge morph = \mathsf{E1}(r) \wedge \mathsf{UnaryH}$$

Proof. Empty-source hom-carrier exactness identifies *morph* with *target* and gives unary membership of *target*. The nonempty morphism premise eliminates the empty target case, and unary inversion eliminates the zero-headed case. Thus the remaining target shape is $\mathsf{E1}(r)$, and sameness forces the morphism to be the same visible history. Conversely, a visible unary payload rebuilds the empty-source carrier by left-unit continuation and is not hsame to e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source nonempty morphism shape iff`

Theorem 61.12 (Category empty-source empty-morphism exactness)**.** *For a history b, an empty-source hom-carrier whose displayed morphism is empty is exactly an empty target:*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, b, \mathsf{e}) \iff \mathsf{hsame}(b, \mathsf{e}).$$

Proof. Specialize empty-source hom-carrier exactness to the empty morphism. The forward direction returns $\mathsf{hsame}(\mathsf{e}, b)$, and symmetry gives $\mathsf{hsame}(b, \mathsf{e})$. Conversely, transport unary membership of e across the symmetric target equality and rebuild the empty-source hom-carrier by the same exactness theorem. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source empty morphism iff`

Theorem 61.13 (Category empty-source semantic name certificate)**.** *Fix a unary target history b. The empty-source hom-carrier* $\mathsf{CategoryHomCarrier}(\mathsf{e}, b, -)$*, used as source, pattern, and ledger policy with classifier* hsame*, forms a semantic name certificate.*

Proof. The carrier is inhabited by the displayed morphism b: empty-source hom-carrier exactness reduces this to unary membership of b and reflexivity $b\mathsf{hsame}b$. The classifier fields are reflexivity, symmetry, and transitivity of hsame. Carrier preservation transports a displayed hom-carrier along morphism sameness while the source e and target b remain fixed. Pattern and ledger soundness are identities because all three policies are the same hom-carrier predicate. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source semanticNameCert`

Theorem 61.14 (Category empty-target hom carrier exactness)**.** *For histories a, f, a hom-carrier into the empty target is exactly sameness of the source and morphism with the empty history:*

$$\mathsf{CategoryHomCarrier}(a, \mathsf{e}, f) \iff \mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(f, \mathsf{e}).$$

Proof. Unpack the hom-carrier witness. Its continuation field is $\mathsf{Cont}(a, f, \mathsf{e})$, and empty-result inversion for continuation splits the source and morphism into empty histories. Conversely, after those two sameness witnesses are eliminated, the empty source, empty target, and empty morphism are unary, and the right-unit continuation at e rebuilds the hom-carrier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty target iff`

Theorem 61.15 (Category empty-source empty-target same morphism boundary)**.** *For histories $a, b, f : \mathsf{BHist}$, if the same morphism f is displayed both as a hom-carrier out of e into b and as a hom-carrier from a into e, then all visible boundary histories read back to the empty history:*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, b, f) \wedge \mathsf{CategoryHomCarrier}(a, \mathsf{e}, f) \Longrightarrow a\mathsf{hsamee} \wedge b\mathsf{hsamee} \wedge f\mathsf{hsamee}.$$

Proof. Empty-target exactness applied to the second hom-carrier gives $a\mathsf{hsamee}$ and $f\mathsf{hsamee}$. Empty-source exactness applied to the first hom-carrier gives $f\mathsf{hsame}b$. Symmetry of this morphism-readback equality, followed by transitivity with $f\mathsf{hsamee}$, gives $b\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source empty target same morphism boundary`

Theorem 61.16 (Continuation morphism empty target existence equivalence)**.** *For every source history source, there exists a continuation morphism from source to* e *exactly when the source is history-same to* e*:*

$$\mathsf{Nonempty}(\mathsf{ContinuationMorphism}(\mathit{source}, \mathsf{e})) \iff \mathsf{hsame}(\mathit{source}, \mathsf{e}).$$

Proof. Any displayed morphism into e has a continuation ledger ending at e, so empty-result inversion identifies its source with e. Conversely, if *source*hsamee, the right-unit continuation at *source* transports its result endpoint to e, giving the required empty-tail continuation morphism. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism empty target nonempty iff`

Theorem 61.17 (Continuation morphism chain empty-target existence equivalence)**.** *For histories a, b, a continuation morphism from a to b together with a continuation morphism from b to* e *exists exactly when both endpoints are history-same to* e*:*

$$\mathsf{Nonempty}(\mathsf{ContinuationMorphism}(a, b)) \wedge \mathsf{Nonempty}(\mathsf{ContinuationMorphism}(b, \mathsf{e})) \iff \mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(b, \mathsf{e}).$$

Proof. Unpack the two displayed continuation morphisms and apply the composite empty-target inversion: the right leg identifies the middle endpoint with e, and the transported left leg identifies the source endpoint with e. Conversely, if both endpoints are empty, the empty-tail right-unit continuations build the two displayed morphisms. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism chain empty target nonempty iff`

Theorem 61.18 (Category empty-target semantic name certificate)**.** *Fix a source history a satisfying a*hsamee*. The empty-target hom-carrier* $\mathsf{CategoryHomCarrier}(a, \mathsf{e}, -)$*, used as source, pattern, and ledger policy with classifier* hsame*, forms a semantic name certificate.*

Proof. The carrier is inhabited by the empty morphism. Empty-target hom-carrier exactness reduces this witness to the assumed $a$hsamee and reflexivity of e. The classifier laws are the equivalence laws of hsame, and carrier preservation is the hom-carrier transport theorem over morphism sameness with source a and target e fixed. Pattern and ledger soundness are identities because all three policies coincide. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty target semanticNameCert`

Theorem 61.19 (Category hom carrier composition closure)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, and* $\mathsf{Cont}(f, g, fg)$*, then fg is a hom-carrier from a to c.*

Proof. Unpack the two hom-carrier witnesses. The source, middle, target, and morphism histories are unary. Unary continuation closure gives unary membership for the composite morphism fg, and associativity of the recursive append representative underlying Cont supplies the continuation from a through fg to c. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp closed`

Theorem 61.20 (Category hom carrier composite-tail semantic name certificate)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, and* $\mathsf{Cont}(f, g, fg)$*, then the predicate*

$$t \mapsto \mathsf{CategoryHomCarrier}(a, c, t) \wedge t\mathsf{hsame}fg$$

is a semantic name certificate when used as source, pattern, and ledger policy with classifier hsame*.*

Proof. Composition closure gives the displayed witness fg in the carrier, and reflexivity gives $fg\mathsf{hsame}fg$. The classifier laws are the equivalence laws of hsame. Carrier transport uses category hom-carrier transport with the source and target endpoints fixed, while the displayed-tail equation is carried by symmetry and transitivity of hsame. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp tail semanticNameCert`

Theorem 61.21 (Category hom carrier composite tail exact iff)**.** *For the unary-continuation category, if f is a hom-carrier from a to b and g is a hom-carrier from b to c, then a displayed history fg is a hom-carrier from a to c exactly when fg is the continuation tail composite of f and g:*

$$\mathsf{CategoryHomCarrier}(a, c, fg) \iff \mathsf{Cont}(f, g, fg).$$

Proof. The forward direction compares the displayed composite hom-carrier continuation $\mathsf{Cont}(a, fg, c)$ with the two factor continuations $\mathsf{Cont}(a, f, b)$ and $\mathsf{Cont}(b, g, c)$. Kernel composite-tail uniqueness identifies fg with $\mathsf{append}(f, g)$, which is exactly $\mathsf{Cont}(f, g, fg)$. The reverse direction is hom-carrier composition closure along that continuation witness. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp tail exact iff`

Theorem 61.22 (Category hom carrier composite hsame transport)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, and $\mathsf{Cont}(f, g, fg)$, then any hsame-equal source endpoint, target endpoint, and composite morphism history display the same composite as a hom-carrier from a' to c'.*

Proof. Composition closure first gives the composite hom-carrier from a to c with morphism fg. Category hom-carrier transport along the supplied source, target, and morphism hsame witnesses carries that composite to the displayed endpoints and composite history. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp hsame transport`

Theorem 61.23 (Category hom carrier composite factorization iff)**.** *For histories a, c, f, g, fg : BHist with $\mathsf{Cont}(f, g, fg)$, a displayed composite hom-carrier from a to c is equivalent to the existence of an intermediate history b carrying f from a to b and g from b to c:*

$$\mathsf{CategoryHomCarrier}(a, c, fg) \iff \exists b : \mathsf{BHist}, \mathsf{CategoryHomCarrier}(a, b, f) \wedge \mathsf{CategoryHomCarrier}(b, c, g).$$

Proof. From a displayed composite, the canonical-middle decomposition supplies the witness $b = \mathsf{append}(a, f)$ and the two hom-carrier factors. Conversely, any displayed intermediate factorization composes by hom-carrier composition closure along the same continuation witness $\mathsf{Cont}(f, g, fg)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp factorization iff`

Theorem 61.24 (Category hom-carrier composite endpoint cycle has empty morphism)**.** *For the unary-continuation category, suppose f is a hom-carrier from a to b, g is a hom-carrier from b to c, and $\mathsf{Cont}(f, g, fg)$. If the composite endpoints satisfy $\mathsf{hsame}(a, c)$, then the composite morphism history is empty:*

$$\mathsf{hsame}(fg, \mathsf{e}).$$

Proof. Composition closure first turns the displayed continuation $\mathsf{Cont}(f, g, fg)$ into a hom-carrier from a to c. Its concrete continuation field is $\mathsf{Cont}(a, fg, c)$. Transporting the result endpoint along $\mathsf{hsame}(a, c)$ gives $\mathsf{Cont}(a, fg, a)$, and right-unit uniqueness forces fg to be e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp endpoint cycle morphism empty`

Theorem 61.25 (Category hom-carrier endpoint cycle empty morphism equivalence)**.** *For the unary-continuation category, suppose f is a hom-carrier from a to b, g is a hom-carrier from b to c, and $\mathsf{Cont}(f, g, fg)$. Then the composite endpoints close exactly when the composite morphism is empty:*

$$\mathsf{hsame}(a, c) \iff \mathsf{hsame}(fg, \mathsf{e}).$$

Proof. The forward implication is the endpoint-cycle empty-morphism theorem above. Conversely, composition closure gives a hom-carrier from a to c with morphism fg. If $fg\mathsf{hsame}\mathsf{e}$, eliminate that comparison and apply the empty-identity exactness theorem to the composite hom-carrier; its endpoint projection is $\mathsf{hsame}(a, c)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp endpoint cycle morphism empty iff`

Theorem 61.26 (Category empty-source composite result)**.** *If f is a hom-carrier from e to b, g is a hom-carrier from b to c, and $\mathsf{Cont}(f, g, fg)$, then fg is a hom-carrier from e to c and $fg\mathsf{hsame}c$.*

Proof. Composition closure first places fg as a displayed hom-carrier from e to c. Applying empty-source exactness to this composite carrier reads back the result equality $fg\mathsf{hsame}c$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source comp result hsame`

Theorem 61.27 (Category empty-source composite target equality)**.** *If f is a hom-carrier from e to b, g is a hom-carrier from b to c, and $\mathsf{Cont}(f, g, fg)$, then the composite result is endpoint-equal to the right target:*

$$fg\mathsf{hsame}c.$$

Proof. Empty-source exactness on the left carrier identifies f with b. Transport the displayed continuation $\mathsf{Cont}(f, g, fg)$ along this equality to obtain $\mathsf{Cont}(b, g, fg)$. The right hom-carrier supplies $\mathsf{Cont}(b, g, c)$, and continuation determinism identifies fg with c. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source comp target hsame`

Theorem 61.28 (Category empty-source composite empty-result iff)**.** *If f is a hom-carrier from e to b, g is a hom-carrier from b to c, and $\mathsf{Cont}(f, g, fg)$, then the composite result is empty exactly when the right target is empty:*

$$fg\mathsf{hsame}\mathsf{e} \iff c\mathsf{hsame}\mathsf{e}.$$

Proof. By the empty-source composite target equality, $fg\mathsf{hsame}c$. Composing this comparison with either empty-endpoint comparison gives the two implications. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source comp empty result iff`

Theorem 61.29 (Category empty-middle composite inversion)**.** *If f is a hom-carrier from a to e, g is a hom-carrier from e to c, and $\mathsf{Cont}(f, g, fg)$, then $a\mathsf{hsame}\mathsf{e}$, $f\mathsf{hsame}\mathsf{e}$, $g\mathsf{hsame}c$, fg is a hom-carrier from e to c, and $fg\mathsf{hsame}c$.*

Proof. Empty-target exactness on the left hom-carrier identifies both its source and morphism with e. The empty-source exactness on the right hom-carrier reads back $g\mathsf{hsame}c$. Composition closure gives a hom-carrier from a to c for fg; transporting its source along $a\mathsf{hsame}\mathsf{e}$ gives a hom-carrier from e to c, and empty-source exactness reads back $fg\mathsf{hsame}c$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp empty middle inversion`

Theorem 61.30 (Category empty-middle displayed morphism determinacy)**.** *For histories a, c, f, g, fg, displayed, if f is a hom-carrier from a to e, g is a hom-carrier from e to c, $\mathsf{Cont}(f, g, fg)$, and displayed is also a hom-carrier from e to c, then*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, c, \mathit{displayed}) \Longrightarrow \mathsf{hsame}(\mathit{displayed}, fg).$$

Proof. Empty-middle inversion supplies the canonical hom-carrier from e to c over the composite morphism fg. Hom-carrier morphism determinacy compares that canonical carrier with the displayed carrier over the same endpoints. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp empty middle displayed morphism deterministic`

Theorem 61.31 (Category empty-middle empty-result component readback)**.** *For histories a, c, f, g, fg, if f is a hom-carrier from a to e, g is a hom-carrier from e to c, $\mathsf{Cont}(f, g, fg)$, and $fg\mathsf{hsamee}$, then both endpoints and both factor morphisms are empty:*

$$\mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(c, \mathsf{e}) \wedge \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}).$$

Proof. Apply category composite-result empty exactness to the two hom-carriers and the displayed continuation. The middle endpoint is already e, so the endpoint equalities read back $a\mathsf{hsamee}$ and $\mathsf{ehsame}c$; symmetry gives $c\mathsf{hsamee}$. The same exactness row supplies emptiness of both factor morphisms. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp empty middle empty result components`

Corollary 61.32 (Category empty-middle displayed morphism consumer determinacy)**.** *For histories a, c, f, g, fg, displayed, alternate : BHist, fix the empty-middle composition rows*

$$\mathsf{CategoryHomCarrier}(a, \mathsf{e}, f), \qquad \mathsf{CategoryHomCarrier}(\mathsf{e}, c, g), \qquad \mathsf{Cont}(f, g, fg).$$

Suppose two accepted consumer-facing uses of this same surface display hom-carrier rows over the empty source and endpoint c:

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, c, \mathit{displayed}) \quad \textit{and} \quad \mathsf{CategoryHomCarrier}(\mathsf{e}, c, \mathit{alternate}).$$

Then the displayed morphism choice is determined:

$$\mathsf{hsame}(\mathit{displayed}, \mathit{alternate}).$$

If either accepted use also reads an empty normal form for its displayed morphism, for instance $\mathsf{hsame}(\mathit{alternate}, \mathsf{e})$, then the exactness decision is forced to be the chapter component row

$$\mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(c, \mathsf{e}) \wedge \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}).$$

Consequently every accepted route, normal form read, or exactness decision for the fixed empty-middle packet factors through the displayed $\mathsf{CategoryHomCarrier}$ *and* Cont *rows named above. There is no alternate hidden coordinate and no second accepted displayed hom-carrier row from which a different displayed morphism or empty-result readback could be obtained.*

Proof. Apply Definition 61.30 to the first displayed hom-carrier row. The fixed rows $\mathsf{CategoryHomCarrier}(a, \mathsf{e}, f)$, $\mathsf{CategoryHomCarrier}(\mathsf{e}, c, g)$, and $\mathsf{Cont}(f, g, fg)$ give the history-sameness comparison between *displayed* and the canonical composite morphism fg:

$$\mathsf{hsame}(\mathit{displayed}, fg).$$

Apply the same theorem to the second displayed hom-carrier row to obtain

$$\mathsf{hsame}(\mathit{alternate}, fg).$$

Symmetry and transitivity of hsame therefore give $\mathsf{hsame}(\mathit{displayed}, \mathit{alternate})$. Thus a consumer that keeps the empty-middle rows fixed has no second displayed morphism coordinate: every accepted displayed hom-carrier over e and c is the same finite route up to hsame, namely the canonical composite fg.

Now suppose an accepted use also reads $\mathsf{hsame}(\mathit{alternate}, \mathsf{e})$. Combining this empty read with $\mathsf{hsame}(\mathit{alternate}, fg)$ gives $\mathsf{hsame}(fg, \mathsf{e})$ by symmetry and transitivity. The hypotheses of Definition 61.31 are then exactly the fixed empty-middle rows together with this empty-result read. That theorem returns

$$\mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(c, \mathsf{e}) \wedge \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}).$$

Hence the only empty-result exactness decision available to the consumer is the listed component readback. The determinacy row fixes the displayed morphism route, and the empty-result component row fixes the endpoint and factor emptiness readback; no unlisted coordinate remains from which a different normal form or accepted row could be read. □

Theorem 61.33 (Category empty-target composite boundary inversion)**.** *If f is a hom-carrier from a to b, g is a hom-carrier from b to e, and $\mathsf{Cont}(f, g, fg)$, then a, b, f, g, and fg are all hsame to e.*

Proof. Empty-target exactness applied to the right hom-carrier identifies b and g with e. With b reduced to e, empty-target exactness applied to the left hom-carrier identifies a and f with e. The displayed continuation ledger then has both inputs empty, so its result is e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty target comp boundary inversion`

Theorem 61.34 (Category hom-carrier composite empty-target boundary)**.** *If f is a hom-carrier from a to b, g is a hom-carrier from b to c, $\mathsf{Cont}(f, g, fg)$, and $c\mathsf{hsamee}$, then a, b, c, f, g, and fg are all hsame to e.*

Proof. Transport the right hom-carrier along $c\mathsf{hsamee}$ so that it has empty target. Empty-target exactness applied to that right carrier identifies b and g with e. Transporting the left carrier along $b\mathsf{hsamee}$ lets empty-target exactness identify a and f with e. The displayed continuation then has both inputs empty, so its result is e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp empty target boundary`

Theorem 61.35 (Category hom carrier composition public readback)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, and $\mathsf{Cont}(f, g, fg)$, then fg is a hom-carrier from a to c, and every displayed hom-carrier from a to c has morphism history hsame-equal to fg.*

Proof. Composition closure supplies the displayed carrier for fg. The hom-carrier morphism determinacy theorem then compares that carrier with any other displayed carrier over the same source and target. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp public readback`

Theorem 61.36 (Category hom-carrier composite result congruence)**.** *For unary-continuation hom carriers $f : a \to b$, $g : b \to c$, $f' : a \to b$, and $g' : b \to c$, if $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f', g', fg')$ hold, then the two composite morphism histories are classified the same:*

$$\mathsf{hsame}(fg, fg').$$

Proof. Composition closure places fg and fg' as hom-carriers from the same source a to the same target c. Hom-carrier morphism determinacy at those endpoints then identifies the two composite morphism histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result hsame congruence`

Theorem 61.37 (Category hom carrier same-endpoint composite result determinacy)**.** *For unary-continuation hom carriers $f : a \to b$, $g : b \to c$, $f' : a \to b'$, and $g' : b' \to c$, if $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f', g', fg')$ hold, then the two composite morphism histories have the same displayed source and target and hence*

$$\mathsf{hsame}(fg, fg').$$

Proof. Apply composition closure to f, g and to f', g'. The two displayed composites are hom-carriers from the same source a to the same target c. Hom-carrier morphism determinacy at those endpoints identifies their result histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp same endpoints result deterministic`

Theorem 61.38 (Category hom carrier same-composite middle-factor determinacy)**.** *For unary-continuation hom carriers $f : a \to b$, $g : b \to c$, $f' : a \to b$, and $g' : b \to c$, if $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f', g', fg)$ hold, then $\mathsf{hsame}(f, f') \wedge \mathsf{hsame}(g, g')$.*

Proof. First apply Definition 61.184 to the two $a \to b$ carriers. This gives $\mathsf{hsame}(f, f')$.

Transport the first continuation ledger across this equality. The transported ledger and $\mathsf{Cont}(f', g', fg)$ now have the same left continuation history and the same result history, so continuation left cancellation identifies the two right factors, giving $\mathsf{hsame}(g, g')$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp same middle factors deterministic`

Theorem 61.39 (Category empty composite has empty hom factors)**.** *For unary-continuation hom carriers $f : a \to b$ and $g : b \to c$, if their composite ledger has empty result,*

$$\mathsf{Cont}(f, g, \mathsf{e}),$$

then both factors are internally empty and the adjacent endpoints are identified:

$$\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. Empty-result inversion for the continuation ledger first gives $\mathsf{hsame}(f, \mathsf{e})$ and $\mathsf{hsame}(g, \mathsf{e})$. Transport the two displayed hom-carrier witnesses across these morphism equalities, obtaining $\mathsf{CategoryHomCarrier}(a, b, \mathsf{e})$ and $\mathsf{CategoryHomCarrier}(b, c, \mathsf{e})$. The empty identity exactness theorem then reads back $\mathsf{hsame}(a, b)$ from the first carrier and $\mathsf{hsame}(b, c)$ from the second. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty composite factors`

Theorem 61.40 (Category empty composite exactness)**.** *For unary-continuation hom carriers $f : a \to b$ and $g : b \to c$, the composite ledger has empty result exactly when both morphism tails are empty and the adjacent endpoints collapse:*

$$\mathsf{Cont}(f, g, \mathsf{e}) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. The forward direction is the empty-composite factor theorem. Conversely, $\mathsf{hsame}(f, \mathsf{e})$ and $\mathsf{hsame}(g, \mathsf{e})$ identify both continuation tails with the empty history, so the empty continuation ledger is the right-unit calculation at e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty composite iff`

Theorem 61.41 (Category displayed composite result empty exactness)**.** *For unary-continuation hom carriers $f : a \to b$ and $g : b \to c$, if their displayed composite ledger is $\mathsf{Cont}(f, g, fg)$, then the displayed result is empty exactly when both morphism tails are empty and the adjacent endpoints collapse:*

$$\mathsf{hsame}(fg, \mathsf{e}) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. In the forward direction, transport the displayed continuation ledger along $\mathsf{hsame}(fg, \mathsf{e})$ to obtain $\mathsf{Cont}(f, g, \mathsf{e})$, then apply empty-composite exactness. Conversely, the endpoint data rebuilds the empty-result composite ledger by empty-composite exactness. Continuation determinacy compares that ledger with the displayed ledger and yields $\mathsf{hsame}(fg, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result empty iff`

Theorem 61.42 (One-headed endpoint empty composite exactness)**.** *For unary-continuation hom carriers $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), b, f)$ and $\mathsf{CategoryHomCarrier}(b, \mathsf{E1}(c), g)$, the displayed empty composite is equivalent to both displayed morphisms being empty and the one-headed endpoint payloads agreeing:*

$$\mathsf{Cont}(f, g, \mathsf{e}) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(a, c).$$

Proof. Apply category empty-composite exactness to obtain empty morphism histories and the adjacent endpoint equalities $\mathsf{hsame}(\mathsf{E1}(a), b)$ and $\mathsf{hsame}(b, \mathsf{E1}(c))$. Transitivity identifies $\mathsf{E1}(a)$ with $\mathsf{E1}(c)$, and one-headed constructor inversion reads back $\mathsf{hsame}(a, c)$. Conversely, empty displayed morphisms reduce the continuation ledger to the empty continuation at e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 endpoint empty composite iff`

Theorem 61.43 (Category empty composite identity factors)**.** *For unary-continuation hom carriers $f : a \to b$ and $g : b \to c$, the composite ledger has empty result exactly when the two corresponding identity carriers are present:*

$$\mathsf{Cont}(f, g, \mathsf{e}) \iff \mathsf{CategoryHomCarrier}(a, b, \mathsf{e}) \wedge \mathsf{CategoryHomCarrier}(b, c, \mathsf{e}).$$

Proof. An empty composite gives empty tails by continuation inversion, and hom-carrier transport moves the two displayed carriers to those empty tails. In the reverse direction, morphism determinacy compares each displayed carrier with its empty identity factor, reducing the continuation ledger to $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty composite identity factors iff`

Theorem 61.44 (Category empty composite exposes identity carriers)**.** *For unary-continuation hom carriers $f : a \to b$ and $g : b \to c$, if their composite ledger has empty result, then the empty morphism is a displayed identity carrier at each endpoint:*

$$\mathsf{CategoryHomCarrier}(a, a, \mathsf{e}) \wedge \mathsf{CategoryHomCarrier}(b, b, \mathsf{e}) \wedge \mathsf{CategoryHomCarrier}(c, c, \mathsf{e}).$$

Proof. The empty-composite factor theorem transports both displayed morphisms to empty hom carriers and reads back the adjacent endpoint identifications. The empty identity exactness theorem then packages the unary endpoint carriers as the three displayed empty identity carriers. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty composite identity carriers`

Theorem 61.45 (Category displayed empty composite exposes identity carriers)**.** *For unary-continuation hom carriers $f : a \to b$ and $g : b \to c$, if $\mathsf{Cont}(f, g, fg)$ and $\mathsf{hsame}(fg, \mathsf{e})$, then the empty morphism is a displayed identity carrier at each endpoint:*

$$\mathsf{CategoryHomCarrier}(a, a, \mathsf{e}) \wedge \mathsf{CategoryHomCarrier}(b, b, \mathsf{e}) \wedge \mathsf{CategoryHomCarrier}(c, c, \mathsf{e}).$$

Proof. Transport the displayed composite ledger along $\mathsf{hsame}(fg, \mathsf{e})$ to obtain an empty-result composite ledger. The empty-composite identity-carrier theorem then supplies the three displayed identity carriers. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result empty identity carriers`

Theorem 61.46 (Category displayed empty composite exposes edge and identity carriers)**.** *For unary-continuation hom carriers $f : a \to b$ and $g : b \to c$, if $\mathsf{Cont}(f, g, fg)$ and $\mathsf{hsame}(fg, \mathsf{e})$, then the empty morphism is displayed both on the two original edges and as the three endpoint identity carriers:*

$$\mathsf{CategoryHomCarrier}(a, b, \mathsf{e}) \wedge \mathsf{CategoryHomCarrier}(b, c, \mathsf{e}) \wedge \mathsf{CategoryHomCarrier}(a, a, \mathsf{e}) \wedge \mathsf{CategoryHomCarrier}(b, b, \mathsf{e}) \wedge \mathsf{C}$$

Proof. Transport the displayed composite ledger along $\mathsf{hsame}(fg, \mathsf{e})$. The empty composite identity-factor theorem gives the two edge carriers, and the empty composite identity-carrier theorem gives the three endpoint identity carriers. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result empty edge identity carriers`

Theorem 61.47 (Category composite nonempty result exposes a nonempty factor)**.** *For unary-continuation hom carriers $f : a \to b$ and $g : b \to c$, if $\mathsf{Cont}(f, g, fg)$ and the displayed composite result is not internally empty, then at least one displayed morphism factor is not internally empty:*

$$\neg\mathsf{hsame}(fg, \mathsf{e}) \Rightarrow \neg\mathsf{hsame}(f, \mathsf{e}) \vee \neg\mathsf{hsame}(g, \mathsf{e}).$$

Proof. Inspect the displayed left morphism history. If it is empty, the continuation ledger identifies the composite result with the right morphism, so a right empty witness would make the composite empty. If the left morphism is zero-headed or one-headed, BEDC constructor separation directly gives the left nonempty disjunct. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result nonempty cases`

Theorem 61.48 (Category composite nonempty result exposes nonempty endpoints)**.** *For unary-continuation hom carriers $f : a \to b$ and $g : b \to c$, if $\mathsf{Cont}(f, g, fg)$ and the displayed composite result is not internally empty, then at least one endpoint pair is not internally equal:*

$$\neg\mathsf{hsame}(fg, \mathsf{e}) \Rightarrow \neg\mathsf{hsame}(a, b) \vee \neg\mathsf{hsame}(b, c).$$

Proof. The nonempty-factor theorem gives a nonempty displayed factor. If a and b were internally equal, transporting the left hom carrier would make f an endomorphism at a; endomorphism exactness forces that displayed morphism to be empty, contradicting the left factor case. The right factor case is the same argument at the endpoint pair b, c. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result nonempty endpoint cases`

Theorem 61.49 (Category displayed composite nonempty result equivalence)**.** *For unary-continuation hom carriers $f : a \to b$ and $g : b \to c$, if $\mathsf{Cont}(f, g, fg)$, then the displayed composite result is not internally empty exactly when at least one displayed morphism factor is not internally empty:*

$$\neg\mathsf{hsame}(fg, \mathsf{e}) \iff \neg\mathsf{hsame}(f, \mathsf{e}) \vee \neg\mathsf{hsame}(g, \mathsf{e}).$$

Proof. Eliminate the displayed continuation equality, rewriting fg as the append of f and g. The append nonempty factor equivalence gives the displayed statement. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result nonempty iff`

Theorem 61.50 (Category hom carrier unary suffix equivalence)**.** *For a unary suffix q, a displayed hom-carrier $\mathsf{CategoryHomCarrier}(\mathsf{append}(a, q), \mathsf{append}(b, q), f)$ is equivalent to the pair consisting of unary evidence for q and the unsuffixed carrier $\mathsf{CategoryHomCarrier}(a, b, f)$.*

Proof. The forward direction reads unary evidence from the suffixed endpoints, swaps the unary suffix past the unary morphism, and cancels the common suffix in the continuation ledger. The reverse direction uses unary append closure and the same commutation to rebuild the suffixed continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier unary suffix iff`

Theorem 61.51 (Category hom carrier unary context exactness)**.** *For unary histories p and q, a displayed hom-carrier between $\mathsf{append}(\mathsf{append}(p, a), q)$ and $\mathsf{append}(\mathsf{append}(p, b), q)$ is equivalent to unary evidence for both boundary histories together with the central carrier $\mathsf{CategoryHomCarrier}(a, b, f)$.*

Proof. First peel the common unary suffix by the suffix equivalence. The remaining prefixed carrier exposes unary evidence for p, and prefix cancellation on the continuation ledger recovers the central carrier. Conversely, prefix closure rebuilds the central carrier under p, and suffix closure appends the visible suffix q. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier unary context iff`

Theorem 61.52 (Category hom carrier unary prefix commutation transport)**.** *For unary histories p and q, any hom-carrier displayed between $\mathsf{append}(p, \mathsf{append}(q, a))$ and $\mathsf{append}(p, \mathsf{append}(q, b))$ transports to a hom-carrier displayed between $\mathsf{append}(q, \mathsf{append}(p, a))$ and $\mathsf{append}(q, \mathsf{append}(p, b))$ with the same morphism history.*

Proof. Apply unary prefix exactness twice to reflect the displayed carrier to the central hom-carrier. Reapply the same exactness theorem first with prefix p and then with prefix q. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier unary prefix comm transport`

Theorem 61.53 (Category hom carrier unary context composition public readback)**.** *For composable category hom-carriers f, g, unary histories p, q, and a continuation composite* $\mathsf{Cont}(f, g, fg)$*, the morphism fg is a hom-carrier from* $\mathsf{append}(\mathsf{append}(p, a), q)$ *to* $\mathsf{append}(\mathsf{append}(p, c), q)$*. Any other displayed hom-carrier between those same contextual endpoints is* hsame*-equal to fg.*

Proof. Apply category hom-carrier composite public readback to the central composable pair. The unary context exactness theorem lifts the resulting central carrier through the left prefix p and right suffix q. For a competing displayed carrier, the same context exactness theorem reflects it back to the central endpoints, where public readback uniqueness gives hsame with the chosen composite. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier unary context comp public readback`

Theorem 61.54 (Category hom carrier unary suffix composite public readback)**.** *For composable category hom-carriers f, g and unary suffix q, the composite carrier over* $\mathsf{append}(a, q)$ *and* $\mathsf{append}(c, q)$ *exists, and any competing displayed composite over those suffixed endpoints is* hsame*-equal to the same composite morphism.*

Proof. Apply unsuffixed composite public readback, transport its carrier through the unary suffix equivalence, and reflect any competing suffixed display back through the same equivalence before applying morphism determinacy. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier unary suffix comp public readback`

Theorem 61.55 (Category hom-carrier composite endpoint cycle has empty tails)**.** *For the unary-continuation category, suppose f is a hom-carrier from a to b, g is a hom-carrier from b to c, and* $\mathsf{Cont}(f, g, fg)$*. If the composite endpoints satisfy* $\mathsf{hsame}(a, c)$*, then both factor morphism histories and the displayed composite morphism history are empty:*

$$\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(fg, \mathsf{e}).$$

Proof. The endpoint-cycle morphism theorem first forces the displayed composite fg to be empty. Transport the concrete continuation $\mathsf{Cont}(f, g, fg)$ along this endpoint comparison to obtain $\mathsf{Cont}(f, g, \mathsf{e})$. Empty-result inversion for continuation then splits the factor histories, giving $f\mathsf{hsamee}$ and $g\mathsf{hsamee}$, while the transported composite comparison supplies $fg\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp endpoint cycle tails empty`

Theorem 61.56 (Category hom-carrier composite nonempty morphism excludes empty target)**.** *For the unary-continuation category, suppose f is a hom-carrier from a to b, g is a hom-carrier from b to c, and* $\mathsf{Cont}(f, g, fg)$*. If the displayed composite morphism is apart from the empty history, then the target endpoint cannot be empty:*

$$(\mathsf{hsame}(fg, \mathsf{e}) \to \mathsf{False}) \to \mathsf{hsame}(c, \mathsf{e}) \to \mathsf{False}.$$

Proof. Composition closure first builds the composite hom-carrier from a to c over fg. If $c\mathsf{hsamee}$, transport this carrier to an empty target. The empty-target exactness theorem then forces $fg\mathsf{hsamee}$, contradicting the displayed nonemptiness of the composite morphism. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp morphism nonempty target not empty`

Theorem 61.57 (Category hom-carrier composite endpoint cycle boundary)**.** *For the unary-continuation category, suppose f is a hom-carrier from a to b, g is a hom-carrier from b to c, and* $\mathsf{Cont}(f, g, fg)$*. If the composite endpoints satisfy* $\mathsf{hsame}(a, c)$*, then both factor morphisms, the displayed composite morphism, and the two adjacent endpoint pairs collapse:*

$$\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(fg, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. The endpoint-cycle tail theorem gives $f\mathsf{hsamee}$, $g\mathsf{hsamee}$, and $fg\mathsf{hsamee}$. Transport the two hom-carrier continuation fields along the empty comparisons for f and g. Comparing the transported relations with the right-unit continuations at a and b gives $\mathsf{hsame}(a, b)$ and $\mathsf{hsame}(b, c)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp endpoint cycle boundary`

Theorem 61.58 (Category hom-carrier composite endpoint cycle boundary iff)**.** *For the unary-continuation category, suppose f is a hom-carrier from a to b, g is a hom-carrier from b to c, and* $\mathsf{Cont}(f, g, fg)$*. Then the outer endpoints close exactly when both factor morphisms, the displayed composite morphism, and the two adjacent endpoint pairs collapse:*

$$\mathsf{hsame}(a, c) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(fg, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. The forward implication is the composite endpoint-cycle boundary theorem. In the reverse direction, compose the adjacent endpoint comparisons $\mathsf{hsame}(a, b)$ and $\mathsf{hsame}(b, c)$ by transitivity to obtain $\mathsf{hsame}(a, c)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp endpoint cycle boundary iff`

Theorem 61.59 (Category hom carrier composition right factor)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, fg is the continuation composite of f and g, and fg is displayed as a hom-carrier from a to c, then g is a hom-carrier from b to c.*

Proof. Unpack the hom-carrier witnesses. The displayed composite gives unary membership for fg, so right-factor recovery for unary continuations applied to $\mathsf{Cont}(f, g, fg)$ gives unary membership for g. The left hom-carrier gives $\mathsf{Cont}(a, f, b)$, the composite ledger gives $\mathsf{Cont}(f, g, fg)$, and the displayed carrier gives $\mathsf{Cont}(a, fg, c)$. Associativity of append turns these three ledgers into $\mathsf{Cont}(b, g, c)$, which is the right-factor hom-carrier ledger. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp right factor`

Theorem 61.60 (Category hom carrier composition right factor exactness)**.** *For the unary-continuation category, suppose f is a hom-carrier from a to b, and fg is displayed as a hom-carrier from a to c. Then the proposed right factor g is a hom-carrier from b to c exactly when it composes with f to the displayed morphism:*

$$\mathsf{CategoryHomCarrier}(b, c, g) \iff \mathsf{Cont}(f, g, fg).$$

Proof. The forward implication compares the two endpoint continuations $\mathsf{Cont}(a, f, b)$ and $\mathsf{Cont}(b, g, c)$ with the displayed continuation $\mathsf{Cont}(a, fg, c)$. Composite-tail uniqueness cancels the common source and recovers $\mathsf{Cont}(f, g, fg)$. The reverse implication is the right-factor recovery theorem applied to the displayed composite. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp right factor iff`

Theorem 61.61 (Category hom carrier canonical middle factorization)**.** *For the unary-continuation category, if* $\mathsf{Cont}(f, g, fg)$*, then a displayed composite hom-carrier from* a *to* c *over* fg *is equivalent to the pair of hom-carriers obtained by using the canonical middle object* $\mathsf{append}(a, f)$*:*

$$\mathsf{CategoryHomCarrier}(a, c, fg) \iff \mathsf{CategoryHomCarrier}(a, \mathsf{append}(a, f), f) \wedge \mathsf{CategoryHomCarrier}(\mathsf{append}(a, f), c, g).$$

Proof. The forward direction reads the unary left factor f from $\mathsf{Cont}(f, g, fg)$ and the displayed unary composite history. This constructs the canonical left hom-carrier $a \to \mathsf{append}(a, f)$ by the defining continuation $\mathsf{Cont}(a, f, \mathsf{append}(a, f))$. The existing right-factor recovery theorem then extracts the hom-carrier from $\mathsf{append}(a, f)$ to c over g. Conversely, composition closure for hom-carriers recombines the two canonical factors along $\mathsf{Cont}(f, g, fg)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp canonical middle iff`

Theorem 61.62 (Category hom carrier canonical middle public readback)**.** *For the unary-continuation category, if* $\mathsf{Cont}(f, g, fg)$ *and* fg *is displayed as a hom-carrier from* a *to* c*, then the canonical middle object* $\mathsf{append}(a, f)$ *displays the two hom-carrier factors*

$$\mathsf{CategoryHomCarrier}(a, \mathsf{append}(a, f), f) \quad \textit{and} \quad \mathsf{CategoryHomCarrier}(\mathsf{append}(a, f), c, g).$$

Moreover, any other middle object b *displaying hom-carriers* $a \to b$ *over* f *and* $b \to c$ *over* g *satisfies* $\mathsf{hsame}(\mathsf{append}(a, f), b)$*.*

Proof. The canonical-middle equivalence supplies the two displayed factors from the composite hom-carrier. Middle-object determinacy then compares these canonical factors with any displayed factorization through b, using the same continuation composite $\mathsf{Cont}(f, g, fg)$ and the same displayed composite hom-carrier from a to c. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp canonical middle public readback`

Theorem 61.63 (Category hom carrier composition right factor public readback)**.** *For the unary-continuation category, if* f *is a hom-carrier from* a *to* b*,* fg *is the continuation composite of* f *and* g*, and* fg *is displayed as a hom-carrier from* a *to* c*, then* g *is a hom-carrier from* b *to* c*. Moreover, any competing right factor* g' *with* $\mathsf{Cont}(f, g', fg)$ *and the same hom-carrier endpoints satisfies* $\mathsf{hsame}(g, g')$*.*

Proof. The right-factor theorem recovers the hom-carrier for g from the displayed composite. For any competing g', the two continuation ledgers $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f, g', fg)$ share the same left factor and displayed result, so finite-kernel left cancellation yields $\mathsf{hsame}(g, g')$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp right factor public readback`

Theorem 61.64 (Category hom carrier right unary tail composition public readback)**.** *For the unary-continuation category, if* f *is a hom-carrier from* a *to* b*,* q *is unary, and* $\mathsf{Cont}(f, q, r)$*, then* r *is a hom-carrier from* a *to* $\mathsf{append}(b, q)$*. Moreover, any competing result* r' *with* $\mathsf{Cont}(f, q, r')$ *and the same displayed endpoints satisfies* $\mathsf{hsame}(r, r')$*.*

Proof. The unary tail q gives the canonical right-tail hom-carrier from b to $\mathsf{append}(b, q)$ by the defining continuation. Hom-carrier composition closes f with this tail carrier along $\mathsf{Cont}(f, q, r)$. The readback clause is hom-morphism determinacy against any displayed carrier over the same endpoints. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier right unary tail comp public readback`

Theorem 61.65 (Category hom carrier composition left factor)**.** *For the unary-continuation category, if g is a hom-carrier from b to c, fg is the continuation composite of f and g, and fg is displayed as a hom-carrier from a to c, then f is a hom-carrier from a to b.*

Proof. Unpack the displayed composite hom-carrier. Unary left-factor recovery applied to $\mathsf{Cont}(f, g, fg)$ and the unary composite morphism gives unary membership for f. The right hom-carrier gives $\mathsf{Cont}(b, g, c)$, while the displayed composite gives $\mathsf{Cont}(a, fg, c)$; the finite-kernel composite left-factor theorem recovers $\mathsf{Cont}(a, f, b)$. These fields assemble the hom-carrier from a to b. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp left factor`

Theorem 61.66 (Category hom carrier composition left factor exactness)**.** *For the unary-continuation category, suppose g is a hom-carrier from b to c, and fg is displayed as a hom-carrier from a to c. Then the proposed left factor f is a hom-carrier from a to b exactly when it composes with g to the displayed morphism:*

$$\mathsf{CategoryHomCarrier}(a, b, f) \iff \mathsf{Cont}(f, g, fg).$$

Proof. The forward implication compares $\mathsf{Cont}(a, f, b)$ and $\mathsf{Cont}(b, g, c)$ with the displayed continuation $\mathsf{Cont}(a, fg, c)$. Composite-tail uniqueness recovers the tail equation $\mathsf{Cont}(f, g, fg)$. The reverse implication is the left-factor recovery theorem applied to the displayed composite. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp left factor iff`

Theorem 61.67 (Category hom carrier composition left factor public readback)**.** *For the unary-continuation category, if g is a hom-carrier from b to c, fg is the continuation composite of f and g, and fg is displayed as a hom-carrier from a to c, then f is a hom-carrier from a to b. Moreover, any competing left factor f' with $\mathsf{Cont}(f', g, fg)$ and the same hom-carrier endpoints satisfies $\mathsf{hsame}(f, f')$.*

Proof. The left-factor theorem recovers the hom-carrier for f from the displayed composite. For any competing f', the two continuation ledgers share the same right factor and composite result, so finite-kernel right cancellation yields $\mathsf{hsame}(f, f')$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp left factor public readback`

Theorem 61.68 (Category hom carrier same-left-tail factorization determinacy)**.** *For the unary-continuation category, suppose f is displayed as a hom-carrier from a to b and also from a to b'. If g and g' are right factors from those middle endpoints to c and c' respectively, and both $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f, g', fg)$ display the same composite history fg, then the middle endpoints, right-factor histories, and target endpoints are determined:*

$$\mathsf{hsame}(b, b') \wedge \mathsf{hsame}(g, g') \wedge \mathsf{hsame}(c, c').$$

Proof. Target determinacy for the two fixed-left-tail hom-carriers identifies the middle endpoints. The two continuation ledgers share the same left tail f and displayed result fg, so left cancellation identifies g and g'. Transport the right hom-carrier across these two comparisons; target determinacy against the displayed $b' \to c'$ carrier then identifies c and c'. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp same left tail factorization deterministic`

Theorem 61.69 (Category hom carrier same-right-tail factorization determinacy)**.** *For the unary-continuation category, suppose two composite ledgers share the same right tail g and the same displayed composite fg:*

$$\mathsf{CategoryHomCarrier}(a, b, f), \qquad \mathsf{CategoryHomCarrier}(b, c, g), \qquad \mathsf{Cont}(f, g, fg),$$

and

$$\mathsf{CategoryHomCarrier}(a', b', f'), \qquad \mathsf{CategoryHomCarrier}(b', c, g), \qquad \mathsf{Cont}(f', g, fg).$$

Then the middle endpoints, left-factor histories, and source endpoints are determined:

$$\mathsf{hsame}(b, b') \wedge \mathsf{hsame}(f, f') \wedge \mathsf{hsame}(a, a').$$

Proof. Source determinacy for the two shared-right-tail hom-carriers identifies the middle endpoints b and b'. The two composite continuation ledgers share the same right tail g and displayed result fg, so right cancellation identifies the left factors f and f'. Transporting the second left hom-carrier across these two comparisons gives a hom-carrier from a' to b with morphism f; source determinacy against the first left hom-carrier then identifies a and a'. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp same right tail factorization deterministic`

Theorem 61.70 (Continuation morphism same-right-tail factorization determinacy)**.** *For continuation morphisms $left$: $\mathsf{ContinuationMorphism}(a, b)$, $right$: $\mathsf{ContinuationMorphism}(b, c)$, $left'$: $\mathsf{ContinuationMorphism}(a', b')$, and $right'$: $\mathsf{ContinuationMorphism}(b', c)$, suppose the two right tails are history-same and the two composite tails are history-same. Then the two canonical tail continuations exist, and the source endpoints, middle endpoints, and left tails are determined:*

$$\mathsf{Cont}(left.tail, right.tail, (left \circ right).tail) \wedge \mathsf{Cont}(left'.tail, right'.tail, (left' \circ right').tail) \wedge \mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b$$

Proof. The two closed composites are continuation morphisms into the same target c, so source determinacy applied to the displayed composite-tail comparison identifies a and a'. Applying the same source determinacy to the two right tails identifies b and b'. Transport the left continuation across these endpoint comparisons and cancel against $left'$ to identify the left tails. The canonical tail-continuation witnesses are the append displays inside the closed composites. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp same right tail factorization deterministic`

Theorem 61.71 (Continuation morphism parallel-factor composite middle determinacy)**.** *For continuation morphisms $left$: $\mathsf{ContinuationMorphism}(a, b)$, $right$: $\mathsf{ContinuationMorphism}(b, c)$, $left'$: $\mathsf{ContinuationMorphism}(a, b')$, and $right'$: $\mathsf{ContinuationMorphism}(b', c)$, suppose the two left tails and the two right tails are respectively history-same. Then the four displayed continuation fields are present, the two middle endpoints are history-same, and the two closed composite tails are history-same:*

$$\mathsf{Cont}(a, left.tail, b) \wedge \mathsf{Cont}(b, right.tail, c) \wedge \mathsf{Cont}(a, left'.tail, b') \wedge \mathsf{Cont}(b', right'.tail, c),$$
$$\mathsf{hsame}(b, b') \wedge \mathsf{hsame}((left \circ right).tail, (left' \circ right').tail).$$

Proof. The four continuation fields are exactly the relation fields of the four records. Target determinacy compares the two left morphisms after identifying their tails, giving $\mathsf{hsame}(b, b')$. The closed composite tails are append products of the displayed left and right tails, so the two supplied tail comparisons identify the two composite tails. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism parallel factor comp tail middle deterministic`

Theorem 61.72 (Continuation parallel factor tails deterministic)**.** *For kernel continuations, if two factorizations share the same source, middle, and target endpoints,*

$$\mathsf{Cont}(a, f, b) \wedge \mathsf{Cont}(b, g, c) \wedge \mathsf{Cont}(a, f', b) \wedge \mathsf{Cont}(b, g', c),$$

then the two left factor tails and the two right factor tails are determined:

$$\mathsf{hsame}(f, f') \wedge \mathsf{hsame}(g, g').$$

Proof. The first and third continuations have the same source endpoint and result endpoint, so left cancellation identifies f and f'. The second and fourth continuations have the same middle endpoint and target endpoint, so the same cancellation identifies g and g'. □

Lean4 ✓ `BEDC.FKernel.Cont.cont parallel factor tails deterministic`

Theorem 61.73 (Continuation morphism same-left-tail factorization determinacy)**.** *For continuation morphisms* $left : \mathsf{ContinuationMorphism}(a, b)$*,* $right : \mathsf{ContinuationMorphism}(b, c)$*,* $left' : \mathsf{ContinuationMorphism}(a, b')$*, and* $right' : \mathsf{ContinuationMorphism}(b', c')$*, suppose the two left tails are history-same and the two composite append tails are history-same. Then the middle endpoints, right tails, and target endpoints are determined:*

$$\mathsf{hsame}(b, b') \wedge \mathsf{hsame}(right.tail, right'.tail) \wedge \mathsf{hsame}(c, c').$$

Proof. Target determinacy for the two fixed-left continuation morphisms identifies the middle endpoints b and b'. After transporting the left-tail comparison into the composite-tail equality, append-left cancellation identifies the right tails. Transport the right continuation along the middle-endpoint and right-tail comparisons, then compare it with $right'$ by continuation result determinacy to identify c and c'. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp same left tail factorization deterministic`

Corollary 61.74 (Category hom-carrier endpoint-cycle empty determinacy)**.** *For the unary-continuation category, suppose* $\mathsf{Cont}(f, g, fg)$ *and suppose* fg *is displayed as a hom-carrier from* a *to* c*. Let* m *denote the displayed canonical middle history obtained as the append of* a *and* f*. If the composite endpoints close,* $\mathsf{hsame}(a, c)$*, then the consumer-facing use of this endpoint cycle is determined by the finite empty-tail packet. Concretely, for any proposed middle object* b' *and right factor* g' *with* f *displayed as a hom-carrier from* a *to* b'*, the right-factor admission decision is exactly*

$$\mathsf{CategoryHomCarrier}(b', c, g') \iff \mathsf{Cont}(f, g', fg).$$

When these equivalent conditions are satisfied, the proposed factorization has the same canonical middle coordinate and the same empty normal form:

$$\mathsf{hsame}(b', m) \wedge \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(g', \mathsf{e}) \wedge \mathsf{hsame}(fg, \mathsf{e}).$$

Thus no accepted public read supplies an alternate hidden coordinate, duplicate right-factor classifier source, or nonempty composite normal form outside the rows named in the chapter.

Proof. Apply Definition 61.61 to the displayed composite carrier and the continuation row $\mathsf{Cont}(f, g, fg)$. With m as the displayed canonical append history, this reads the composite through m and supplies the two canonical factors

$$\mathsf{CategoryHomCarrier}(a, m, f) \quad \text{and} \quad \mathsf{CategoryHomCarrier}(m, c, g).$$

The endpoint-cycle hypothesis $\mathsf{hsame}(a, c)$ now puts these factors under Definition 61.55, so $\mathsf{hsame}(f, \mathsf{e})$, $\mathsf{hsame}(g, \mathsf{e})$, and $\mathsf{hsame}(fg, \mathsf{e})$ are forced.

Fix a proposed middle object b' and right factor g' with $\mathsf{CategoryHomCarrier}(a, b', f)$. The displayed composite carrier from a to c and Definition 61.60 give exactly the advertised right-factor decision $\mathsf{CategoryHomCarrier}(b', c, g') \iff \mathsf{Cont}(f, g', fg)$. Hence an accepted presentation has both the carrier row for g' and the continuation row $\mathsf{Cont}(f, g', fg)$.

Compare this accepted presentation with the canonical one. The two continuation rows $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f, g', fg)$ share the left factor f and the composite result fg, so finite-kernel left cancellation, as used in Definition 61.63, supplies $\mathsf{hsame}(g, g')$. Apply Definition 61.93 to the accepted carrier $b' \to c$ across this morphism comparison, holding the target endpoint fixed, and compare the transported carrier with the canonical carrier $m \to c$ by Definition 61.192. This gives $\mathsf{hsame}(b', m)$. Finally, transitivity with the already forced comparison $\mathsf{hsame}(g, \mathsf{e})$ gives $\mathsf{hsame}(g', \mathsf{e})$. The only remaining composite normal form is therefore the empty one already read from the endpoint cycle. □

Theorem 61.75 (Category hom carrier composition right-factor endpoint determinacy)**.** *For the unary-continuation category, suppose f is a hom-carrier from a to b, fg is displayed both as $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f, g', fg)$, the composite fg is a hom-carrier from a to c, and g' is a hom-carrier from b' to c. Then the recovered and displayed right-factor endpoints and right-factor histories agree:*

$$\mathsf{hsame}(b, b') \wedge \mathsf{hsame}(g, g').$$

Proof. Right-factor recovery turns the displayed composite and $\mathsf{Cont}(f, g, fg)$ into a concrete hom-carrier from b to c for g. Left cancellation of $\mathsf{Cont}(f, g, fg)$ against $\mathsf{Cont}(f, g', fg)$ gives $\mathsf{hsame}(g, g')$. Transporting the recovered hom-carrier across this morphism sameness gives a hom-carrier from b to c for g', and source determinacy against the displayed $b' \to c$ carrier gives $\mathsf{hsame}(b, b')$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp right factor endpoint deterministic`

Theorem 61.76 (Category hom carrier composition right-factor target determinacy)**.** *For the unary-continuation category, suppose f is a hom-carrier from a to b, fg is displayed both as $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f, g', fg)$, the composite fg is a hom-carrier from a to c, and g' is a hom-carrier from b to c'. Then the recovered and displayed right-factor targets and right-factor histories agree:*

$$\mathsf{hsame}(c, c') \wedge \mathsf{hsame}(g, g').$$

Proof. Right-factor recovery turns the displayed composite and $\mathsf{Cont}(f, g, fg)$ into a concrete hom-carrier from b to c for g. Left cancellation of $\mathsf{Cont}(f, g, fg)$ against $\mathsf{Cont}(f, g', fg)$ gives $\mathsf{hsame}(g, g')$. Transporting the recovered hom-carrier across this morphism sameness gives a hom-carrier from b to c for g', and target determinacy against the displayed $b \to c'$ carrier gives $\mathsf{hsame}(c, c')$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp right factor target deterministic`

Theorem 61.77 (Category hom carrier composition left-factor endpoint determinacy)**.** *For the unary-continuation category, suppose g is a hom-carrier from b to c, fg is displayed both as $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f', g, fg)$, the composite fg is a hom-carrier from a to c, and f' is a hom-carrier from a to b'. Then the recovered and displayed left-factor endpoints and left-factor histories agree:*

$$\mathsf{hsame}(b, b') \wedge \mathsf{hsame}(f, f').$$

Proof. Left-factor recovery turns the displayed composite and $\mathsf{Cont}(f, g, fg)$ into a concrete hom-carrier from a to b for f. Right cancellation of $\mathsf{Cont}(f, g, fg)$ against $\mathsf{Cont}(f', g, fg)$ gives $\mathsf{hsame}(f, f')$. Transporting the recovered hom-carrier across this morphism sameness gives a hom-carrier from a to b for f', and target determinacy against the displayed $a \to b'$ carrier gives $\mathsf{hsame}(b, b')$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp left factor endpoint deterministic`

Theorem 61.78 (Category hom carrier composition left-factor source determinacy)**.** *For the unary-continuation category, suppose g is a hom-carrier from b to c, fg is displayed both as $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f', g, fg)$, the composite fg is a hom-carrier from a to c, and f' is a hom-carrier from a' to b. Then the recovered and displayed left-factor sources and left-factor histories agree:*

$$\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(f, f').$$

Proof. Left-factor recovery turns the displayed composite and $\mathsf{Cont}(f, g, fg)$ into a concrete hom-carrier from a to b for f. Right cancellation of $\mathsf{Cont}(f, g, fg)$ against $\mathsf{Cont}(f', g, fg)$ gives $\mathsf{hsame}(f, f')$. Transporting the recovered hom-carrier across this morphism sameness gives a hom-carrier from a to b for f', and source determinacy against the displayed $a' \to b$ carrier gives $\mathsf{hsame}(a, a')$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp left factor source deterministic`

Theorem 61.79 (Category hom carrier composite target determinacy)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, and fg is their continuation composite, then any displayed hom-carrier from a to d with the same composite history forces $\mathsf{hsame}(c, d)$.*

Proof. Hom-carrier composition closure makes fg a carrier from a to c. Target determinacy for the fixed morphism history fg compares this carrier with the displayed carrier from a to d. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp target deterministic`

Theorem 61.80 (Category hom carrier composite endpoint iff)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, and fg is their continuation composite, then displaying the same composite as a hom-carrier from a to d is equivalent to the endpoint classifier $\mathsf{hsame}(c, d)$.*

Proof. The forward direction is composite target determinacy. Conversely, composition closure first builds the canonical hom-carrier from a to c over fg; transporting its target endpoint along $\mathsf{hsame}(c, d)$ gives the displayed hom-carrier from a to d. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp endpoint iff`

Theorem 61.81 (Category hom carrier tail-comm target determinacy)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, fg and gf are the two displayed tail continuation composites, and gf is also displayed as a hom-carrier from a to d, then $\mathsf{hsame}(c, d)$.*

Proof. Composition closure first makes fg a hom-carrier from a to c. Tail commutativity identifies fg and gf, and transport gives a hom-carrier from a to c over the reverse-tail history gf. Target determinacy then compares that transported carrier with the displayed $a \to d$ carrier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier tail comm target deterministic`

Theorem 61.82 (Category hom carrier tail-comm source determinacy)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, fg and gf are the two displayed tail continuation composites, and gf is also displayed as a hom-carrier from d to c, then* $\mathsf{hsame}(a, d)$*.*

Proof. Tail-comm closure transports the forward composite carrier to a carrier from a to c over the reverse-tail history gf. Source determinacy compares this carrier with the displayed $d \to c$ carrier over the same morphism history. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier tail comm source deterministic`

Theorem 61.83 (Category hom carrier composite source determinacy)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, and fg is their continuation composite, then any displayed hom-carrier from d to c with the same composite history forces* $\mathsf{hsame}(a, d)$*.*

Proof. Hom-carrier composition closure makes fg a carrier from a to c. Source determinacy for the fixed morphism history fg compares this carrier with the displayed carrier from d to c. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp source deterministic`

Theorem 61.84 (Category hom carrier composite middle-object determinacy)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b' to c,* $\mathsf{Cont}(f, g, fg)$*, and fg is displayed as a hom-carrier from a to c, then* $\mathsf{hsame}(b, b')$*.*

Proof. Unpack the hom-carrier witnesses. The left leg gives $\mathsf{Cont}(a, f, b)$, the composite gives $\mathsf{Cont}(f, g, fg)$, and the displayed composite gives $\mathsf{Cont}(a, fg, c)$. Associativity of append turns these three continuation facts into $\mathsf{Cont}(b, g, c)$. Comparing this continuation with the right leg $\mathsf{Cont}(b', g, c)$ by right-context cancellation identifies the two middle objects. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp middle object deterministic`

Theorem 61.85 (Category hom carrier middle-hsame composition closure)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b' to c,* $\mathsf{hsame}(b, b')$*, and* $\mathsf{Cont}(f, g, fg)$*, then fg is a hom-carrier from a to c.*

Proof. Transport the right hom-carrier source from b' back to b using symmetry of the middle-object hsame witness, while keeping the target c and morphism g fixed by reflexivity. The ordinary hom-carrier composition closure then applies to the aligned pair of factors. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp middle hsame closed`

Theorem 61.86 (Category hom carrier endpoint-hsame middle-object determinacy)**.** *For the unary-continuation category, if the displayed composite endpoint is recorded at endpoints a' and c' with* $\mathsf{hsame}(a, a')$ *and* $\mathsf{hsame}(c, c')$*, then the middle object is still determined. Concretely, if f is a hom-carrier from a to b, g is a hom-carrier from b' to c,* $\mathsf{Cont}(f, g, fg)$*, and fg is displayed as a hom-carrier from a' to c', then* $\mathsf{hsame}(b, b')$*.*

Proof. Case analysis on the endpoint hsame witnesses reduces the displayed composite to the same endpoints a and c. The ordinary composite middle-object determinacy theorem then compares the induced continuation from b through g with the displayed right leg from b' through g. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp middle object endpoint hsame deterministic`

Theorem 61.87 (Category hom carrier unary-context middle-object determinacy)**.** *For the unary-continuation category, suppose the two displayed hom-carrier ledgers have a shared left prefix p and a shared right suffix q:*

$$\mathsf{CategoryHomCarrier}((p \cdot a) \cdot q, (p \cdot b) \cdot q, f)$$

and

$$\mathsf{CategoryHomCarrier}((p \cdot b') \cdot q, (p \cdot c) \cdot q, g).$$

If $\mathsf{Cont}(f, g, fg)$ *and* fg *is displayed as a hom-carrier from* $(p \cdot a) \cdot q$ *to* $(p \cdot c) \cdot q$*, then* $\mathsf{hsame}(b, b')$*.*

Proof. Apply the unary suffix equivalence of Definition 61.50 to remove the shared right suffix from the two input ledgers and the displayed composite ledger. Each remaining ledger has the same left prefix p on its source and target endpoints; unary append factorization gives the base endpoint carriers, and prefix cancellation removes p from the continuation evidence. The base hom-carriers now satisfy the hypotheses of Definition 61.84, which identifies the middle objects by $\mathsf{hsame}(b, b')$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier unary context comp middle object deterministic`

Theorem 61.88 (Category hom carrier parallel-factor composite middle determinacy)**.** *For the unary-continuation category, suppose the two left hom-carriers share source endpoint a and have history-same morphisms f and f', while the two right hom-carriers share target endpoint c and have history-same morphisms g and g':*

$$\mathsf{CategoryHomCarrier}(a, b, f), \quad \mathsf{CategoryHomCarrier}(b, c, g), \quad \mathsf{CategoryHomCarrier}(a, b', f'), \quad \mathsf{CategoryHomCarrier}(b'$$

Then the four underlying continuation fields are present, the middle endpoints are history-same, and the two append composite tails are history-same:

$$\mathsf{Cont}(a, f, b) \wedge \mathsf{Cont}(b, g, c) \wedge \mathsf{Cont}(a, f', b') \wedge \mathsf{Cont}(b', g', c) \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(\mathsf{append}(f, g), \mathsf{append}(f', g')).$$

Proof. Unpack the four hom-carrier records to read their continuation fields. The comparison $\mathsf{hsame}(f, f')$ transports the left morphism history, so target determinacy of the two left hom-carriers identifies b and b'. The two morphism-history comparisons identify the append products $\mathsf{append}(f, g)$ and $\mathsf{append}(f', g')$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier parallel factor comp tail middle deterministic`

Theorem 61.89 (Category hom carrier tail commutativity)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c,* $\mathsf{Cont}(f, g, fg)$*, and* $\mathsf{Cont}(g, f, gf)$*, then* $\mathsf{hsame}(fg, gf)$*.*

Proof. Unpack the two hom-carrier witnesses to obtain unary membership for f and g. Unary continuation commutativity applied to the two continuation ledgers identifies the two tail composites. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier tail comm hsame`

Theorem 61.90 (Category hom carrier tail-comm history-same congruence)**.** *For the unary-continuation category, suppose the source, middle, target, and two morphism histories are transported by* hsame*. If the original histories carry hom witnesses $f : a \to b$ and $g : b \to c$, while the transported morphisms form displayed tails* $\mathsf{Cont}(f', g', fg)$ *and* $\mathsf{Cont}(g', f', gf)$*, then* $\mathsf{hsame}(fg, gf)$*.*

Proof. Transport the two hom-carrier witnesses along the endpoint and morphism history-same data. The transported carriers expose unary membership for f' and g'. Applying tail commutativity to these transported carriers and the two displayed continuation tails identifies fg and gf. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier tail comm hsame congr`

Theorem 61.91 (Category hom carrier tail-comm closure)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, and fg and gf are the two displayed tail continuation composites, then both histories are hom-carriers from a to c and* $\mathsf{hsame}(fg, gf)$*.*

Proof. Composition closure gives the forward carrier $fg : a \to c$. Tail commutativity identifies fg with gf, and history-same transport moves the forward carrier to the reverse-tail history while keeping the source and target endpoints fixed. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier tail comm closed`

Theorem 61.92 (Category hom carrier tail-comm continuation readback)**.** *For the unary-continuation category, suppose f is a hom-carrier from a to b, g is a hom-carrier from b to c, and fg and gf are the two displayed tail continuation composites. Then every displayed hom-carrier $z : a \to c$ recovers both continuation ledgers:*

$$\mathsf{Cont}(f, g, z) \wedge \mathsf{Cont}(g, f, z).$$

Proof. Tail-comm public readback compares the displayed carrier $z : a \to c$ with the two closed tail carriers. From the forward closed carrier it gives $\mathsf{hsame}(fg, z)$, and from the reverse closed carrier it gives $\mathsf{hsame}(gf, z)$.

The composite-tail exactness theorem for hom-carriers then reads the forward ledger from the displayed carrier itself: since $f : a \to b$, $g : b \to c$, and $z : a \to c$ is displayed, the exact characterization converts that carrier into $\mathsf{Cont}(f, g, z)$.

For the reverse order, transport the given continuation ledger $\mathsf{Cont}(g, f, gf)$ along $\mathsf{hsame}(gf, z)$ using finite-kernel history-same transport for continuation results. This yields $\mathsf{Cont}(g, f, z)$, and the two recovered ledgers form the required conjunction. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier tail comm cont readback`

Theorem 61.93 (Category hom carrier history-same transport)**.** *For the unary-continuation category, if source objects, target objects, and morphism histories are each transported by* hsame*, then a hom-carrier witness transports to the transported triple.*

Proof. Eliminate the three hsame endpoint and morphism equalities. The target hom-carrier statement is then the original concrete CategoryHomCarrier witness. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier hsame transport`

Theorem 61.94 (Category hom carrier endpoint transport with classified morphism)**.** *For the unary-continuation category, if source endpoint, target endpoint, and morphism histories are transported by* hsame*, then the transported morphism has the transported continuation field and hom-carrier witness. Moreover, any displayed hom-carrier over the transported endpoints has morphism history classified with the transported morphism.*

Proof. Apply hom-carrier history-same transport to the displayed carrier. Its continuation field gives the transported Cont witness. The transported carrier and the competing displayed carrier share source and target endpoints, so morphism determinacy identifies their morphism histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier endpoint transport cont classified`

Theorem 61.95 (Category hom carrier identity square closure)**.** *For the unary-continuation category, if f is a hom-carrier from a to b, $left$ is obtained by composing the empty continuation before f, and $right$ is obtained by composing the empty continuation after f, then $left$ and $right$ are both hom-carriers from a to b, and* $\mathsf{hsame}(left, right)$*.*

Proof. The left unit continuation identifies $left$ with f. Determinism of Cont, compared against the right unit continuation for f, identifies $right$ with f. Transporting the hom-carrier witness for f across these two history equalities gives the two carrier witnesses, and transitivity of hsame identifies $left$ and $right$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier identity square closed`

Corollary 61.96 (Category hom carrier composition right-factor endpoint consumer determinacy)**.** *For the unary-continuation category, fix a displayed composite surface with a left hom-carrier $f : a \to b$, a right hom-carrier $g : b \to c$, a composite hom-carrier $fg : a \to c$, and the continuation row* $\mathsf{Cont}(f, g, fg)$*. Suppose a consumer-facing use of the same composite also displays the right-factor row* $\mathsf{Cont}(f, g', fg)$ *with a hom-carrier $g' : b' \to c$, and the left-factor row* $\mathsf{Cont}(f', g, fg)$ *with a hom-carrier $f' : a' \to b$. Then the consumer cannot choose an alternate endpoint source, alternate right-factor endpoint, alternate left-factor history, or alternate right-factor history:*

$$\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(f, f') \wedge \mathsf{hsame}(g, g').$$

Consequently every accepted route, normal-form read, or exactness decision for this displayed composition factors through the listed CategoryHomCarrier *and* Cont *rows; there is no hidden coordinate and no duplicate classifier source for the right-factor endpoint.*

Proof. Apply Definition 61.75 to the left hom-carrier $f : a \to b$, the common displayed composite $fg : a \to c$, the rows $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f, g', fg)$, and the displayed right-factor carrier $g' : b' \to c$. This gives

$$\mathsf{hsame}(b, b') \wedge \mathsf{hsame}(g, g').$$

Apply Definition 61.78 to the right hom-carrier $g : b \to c$, the same displayed composite $fg : a \to c$, the rows $\mathsf{Cont}(f, g, fg)$ and $\mathsf{Cont}(f', g, fg)$, and the displayed left-factor carrier $f' : a' \to b$. This gives

$$\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(f, f').$$

Combining these two conjunctions identifies exactly the source endpoint, the middle endpoint, and the two factor histories used by the consumer-facing factorization.

The cited theorems already perform the only permitted readbacks: right-factor recovery from the composite carrier, left-factor recovery from the composite carrier, cancellation of the displayed continuation tails, history-same transport of the recovered carrier, and endpoint determinacy against the consumer-displayed carrier. A route, normal-form read, or exactness decision that keeps the listed rows fixed but chooses a different endpoint or factor history would contradict one of these two determinacy conclusions. Hence the consumer surface is exhausted by the displayed hom-carrier and continuation rows, with no further coordinate from which an alternate classifier source could be read. □

Theorem 61.97 (Category hom carrier right-append fixed identity)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, b, f)$*, then for every history* $g : \mathsf{BHist}$*,*

$$\mathsf{hsame}(\mathsf{append}(f, g), g) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(a, b).$$

Proof. In the forward direction, the displayed fixed append equality is a continuation witness $\mathsf{Cont}(f, g, g)$, so left-unit uniqueness forces $\mathsf{hsame}(f, \mathsf{e})$. Transporting the hom-carrier continuation relation along this empty-tail equality gives $\mathsf{Cont}(a, \mathsf{e}, b)$, and comparison with the canonical right-unit continuation identifies a and b. Conversely, if $f\mathsf{hsame}\mathsf{e}$, the equality reduces to the kernel empty-left append law. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier right append fixed identity iff`

Theorem 61.98 (Category hom carrier left-append fixed identity)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, b, f)$*, then for every history* $g : \mathsf{BHist}$*,*

$$\mathsf{hsame}(\mathsf{append}(g, f), g) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(a, b).$$

Proof. In the forward direction, compare $\mathsf{append}(g, f)$ with $\mathsf{append}(g, \mathsf{e})$ and cancel the common left prefix, obtaining $\mathsf{hsame}(f, \mathsf{e})$. Transporting the hom-carrier continuation relation across this empty-tail equality gives $\mathsf{Cont}(a, \mathsf{e}, b)$, hence $\mathsf{hsame}(a, b)$ by comparison with the canonical right-unit continuation. Conversely, if $f\mathsf{hsame}\mathsf{e}$, the equality reduces to the kernel empty-right append law. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier left append fixed identity iff`

Theorem 61.99 (Category hom carrier composite left-tail fixed right identity)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, b, f)$*,* $\mathsf{CategoryHomCarrier}(b, c, g)$*,* $\mathsf{Cont}(f, g, fg)$*, and* $\mathsf{hsame}(fg, f)$*, then*

$$\mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(b, c).$$

Proof. Transport the displayed composite continuation along $\mathsf{hsame}(fg, f)$ to obtain $\mathsf{Cont}(f, g, f)$. Right-unit uniqueness for continuations forces $\mathsf{hsame}(g, \mathsf{e})$. Transport the right hom-carrier continuation $\mathsf{Cont}(b, g, c)$ across this empty-tail comparison to obtain $\mathsf{Cont}(b, \mathsf{e}, c)$, then compare it with the canonical right-unit continuation at b. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp left tail fixed right identity`

Theorem 61.100 (Category hom carrier composite right-tail fixed left identity)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, b, f)$*,* $\mathsf{CategoryHomCarrier}(b, c, g)$*,* $\mathsf{Cont}(f, g, fg)$*, and* $\mathsf{hsame}(fg, g)$*, then*

$$\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(a, b).$$

Proof. Transport the displayed composite continuation along $\mathsf{hsame}(fg, g)$ to obtain $\mathsf{Cont}(f, g, g)$. Left-unit uniqueness for continuations forces $\mathsf{hsame}(f, \mathsf{e})$. Transport the left hom-carrier continuation $\mathsf{Cont}(a, f, b)$ across this empty-tail comparison to obtain $\mathsf{Cont}(a, \mathsf{e}, b)$, then compare it with the canonical right-unit continuation at a. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp right tail fixed left identity`

Theorem 61.101 (Category hom carrier composite result fixed by both factors)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, b, f)$*,* $\mathsf{CategoryHomCarrier}(b, c, g)$*, and* $\mathsf{Cont}(f, g, fg)$*, then*

$$\mathsf{hsame}(fg, f) \wedge \mathsf{hsame}(fg, g) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. The forward direction applies the one-sided fixed-composite identity laws to the two displayed comparisons. Fixing the result against f forces the right factor tail empty and identifies b with c; fixing it against g forces the left factor tail empty and identifies a with b. Conversely, when both factor tails are empty, the composite continuation reduces to the empty history, hence it is history-same to each factor tail. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result fixed both identity iff`

Theorem 61.102 (Category hom carrier two-sided identity law)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, b, f)$*,* $\mathsf{Cont}(\mathsf{e}, f, left)$*, and* $\mathsf{Cont}(f, \mathsf{e}, right)$*, then*

$$\mathsf{CategoryHomCarrier}(a, b, left) \wedge \mathsf{CategoryHomCarrier}(a, b, right) \wedge \mathsf{hsame}(left, f) \wedge \mathsf{hsame}(right, f) \wedge \mathsf{hsame}(left, right)$$

Proof. The left composite is classified against the original morphism by the left-unit result theorem: $\mathsf{Cont}(\mathsf{e}, f, left)$ and `cont_left_unit_result` give $\mathsf{hsame}(left, f)$.

For the right composite, compare $\mathsf{Cont}(f, \mathsf{e}, right)$ with the canonical right-unit continuation $\mathsf{Cont}(f, \mathsf{e}, f)$ supplied by `cont_right_unit`. Continuation determinism gives $\mathsf{hsame}(right, f)$.

Transport the displayed $\mathsf{CategoryHomCarrier}(a, b, f)$ witness across the two history-sameness witnesses. This gives $\mathsf{CategoryHomCarrier}(a, b, left)$ and $\mathsf{CategoryHomCarrier}(a, b, right)$.

Finally compose $\mathsf{hsame}(left, f)$ with the symmetry of $\mathsf{hsame}(right, f)$. Transitivity yields $\mathsf{hsame}(left, right)$, completing the two-sided identity classification. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier two sided identity law`

Theorem 61.103 (Category hom carrier left identity carrier result)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, a, id)$*,* $\mathsf{CategoryHomCarrier}(a, b, f)$*, and* $\mathsf{Cont}(id, f, left)$*, then*

$$\mathsf{CategoryHomCarrier}(a, b, left) \wedge \mathsf{hsame}(left, f).$$

Proof. Compare the displayed identity carrier id with the canonical empty identity carrier at a. Morphism determinacy gives $\mathsf{hsame}(id, \mathsf{e})$. Rewriting the displayed continuation by this equality turns $\mathsf{Cont}(id, f, left)$ into an empty-left continuation, so the kernel left-unit result gives $\mathsf{hsame}(left, f)$. Transport the original hom-carrier witness for f across this morphism equality to obtain $\mathsf{CategoryHomCarrier}(a, b, left)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier left identity carrier result`

Theorem 61.104 (Category hom carrier left identity result iff)**.** *For the unary-continuation category, for histories* $a, b, id, f, left$*, if* $\mathsf{CategoryHomCarrier}(a, a, id)$ *and* $\mathsf{CategoryHomCarrier}(a, b, f)$*, then*

$$\mathsf{Cont}(id, f, left) \iff \mathsf{hsame}(left, f).$$

Proof. Compare the displayed identity carrier id with the canonical empty identity at a, giving $\mathsf{hsame}(id, \mathsf{e})$. The forward direction is the left identity carrier result. For the reverse direction, rewrite the left endpoint by $\mathsf{hsame}(id, \mathsf{e})$ and use the BEDC left-unit continuation characterized by $\mathsf{hsame}(left, f)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier left identity result iff`

Theorem 61.105 (Category hom carrier right identity carrier result)**.** *For the unary-continuation category, for histories* $a, b, id, f, right$*, if* $\mathsf{CategoryHomCarrier}(b, b, id)$*,* $\mathsf{CategoryHomCarrier}(a, b, f)$*, and* $\mathsf{Cont}(f, id, right)$*, then*

$$\mathsf{CategoryHomCarrier}(a, b, right) \wedge \mathsf{hsame}(right, f).$$

Proof. Compare the displayed identity carrier id with the canonical empty identity carrier at b by hom-morphism determinacy, giving $\mathsf{hsame}(id, \mathsf{e})$. Rewriting the displayed continuation by this equality turns $\mathsf{Cont}(f, id, right)$ into $\mathsf{Cont}(f, \mathsf{e}, right)$. This empty-right continuation is determined by the BEDC right-unit continuation on f, giving $\mathsf{hsame}(right, f)$. Transport the displayed $\mathsf{CategoryHomCarrier}(a, b, f)$ witness across this morphism equality to obtain $\mathsf{CategoryHomCarrier}(a, b, right)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier right identity carrier result`

Theorem 61.106 (Category hom carrier right identity result iff)**.** *For the unary-continuation category, for histories* $a, b, id, f, right$*, if* $\mathsf{CategoryHomCarrier}(b, b, id)$ *and* $\mathsf{CategoryHomCarrier}(a, b, f)$*, then*

$$\mathsf{Cont}(f, id, right) \iff \mathsf{hsame}(right, f).$$

Proof. Compare the displayed identity carrier id with the canonical empty identity at b, giving $\mathsf{hsame}(id, \mathsf{e})$. The forward direction is the right identity carrier result. For the reverse direction, rewrite the right endpoint by $\mathsf{hsame}(id, \mathsf{e})$ and use the BEDC right-unit continuation characterized by $\mathsf{hsame}(right, f)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier right identity result iff`

Theorem 61.107 (Category hom carrier composite left-right identity result)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, a, id_A)$*,* $\mathsf{CategoryHomCarrier}(b, b, id_B)$*,* $\mathsf{CategoryHomCarrier}(a, b, f)$*,* $\mathsf{Cont}(id_A, f, left)$*, and* $\mathsf{Cont}(left, id_B, both)$*, then*

$$\mathsf{CategoryHomCarrier}(a, b, both) \wedge \mathsf{hsame}(both, f).$$

Proof. Apply the left identity carrier result to the first displayed continuation. This gives $\mathsf{CategoryHomCarrier}(a, b, le$ and $\mathsf{hsame}(left, f)$. Then apply the right identity carrier result to $\mathsf{Cont}(left, id_B, both)$, using the just-obtained carrier witness for $left$. This gives $\mathsf{CategoryHomCarrier}(a, b, both)$ and $\mathsf{hsame}(both, left)$. Transitivity with $\mathsf{hsame}(left, f)$ yields the displayed result equality. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp left right identity result`

Theorem 61.108 (Category hom carrier composite left-right identity public readback)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, a, id_A)$*,* $\mathsf{CategoryHomCarrier}(a, b, f)$*,* $\mathsf{CategoryHomCarrier}(b, b$ $\mathsf{Cont}(id_A, f, left)$*, and* $\mathsf{Cont}(left, id_B, result)$*, then*

$$\mathsf{CategoryHomCarrier}(a, b, result) \wedge \forall g,\ \mathsf{CategoryHomCarrier}(a, b, g) \Rightarrow \mathsf{hsame}(result, g).$$

Proof. Compare each displayed identity carrier with the canonical empty identity at its endpoint. The left identity collapses the first continuation result to f, giving a carrier witness for $left$. The right identity collapses the second continuation result to $left$, giving a carrier witness for $result$. Any other displayed hom carrier from a to b has the same morphism by hom-carrier morphism determinacy. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp left right identity public readback`

Theorem 61.109 (Category continuation left-right identity tail result)**.** *For BEDC histories* $a, b, id_A, f, id_B, left, both$*, if* $\mathsf{Cont}(a, id_A, a)$*,* $\mathsf{Cont}(a, f, b)$*,* $\mathsf{Cont}(b, id_B, b)$*,* $\mathsf{Cont}(id_A, f, left)$*, and* $\mathsf{Cont}(left, id_B, both)$*, then*

$$\mathsf{hsame}(both, f).$$

Proof. Compare $\mathsf{Cont}(a, id_A, a)$ and $\mathsf{Cont}(b, id_B, b)$ with the canonical right-unit continuations at a and b. Tail determinacy gives $\mathsf{hsame}(id_A, \mathsf{e})$ and $\mathsf{hsame}(id_B, \mathsf{e})$. The first equality turns $\mathsf{Cont}(id_A, f, left)$ into an empty-left continuation, so the kernel left-unit result gives $\mathsf{hsame}(left, f)$. Transport $\mathsf{Cont}(left, id_B, both)$ across this equality, use the second equality to make the right tail empty, and compare with the right-unit continuation on f. □

Lean4 ✓ `BEDC.Derived.CategoryUp.category cont left right identity tail result`

Theorem 61.110 (Continuation morphism left-right identity tail result)**.** *For continuation morphisms* $leftId : a \to a$*,* $m : a \to b$*, and* $rightId : b \to b$*, both identity tails are empty, and composing* m *with them on the left and right leaves its tail unchanged up to* hsame*:*

$$\mathsf{hsame}(leftId.tail, \mathsf{e}) \wedge \mathsf{hsame}(rightId.tail, \mathsf{e}) \wedge \mathsf{hsame}((leftId \circ m) \circ rightId,\ m.tail).$$

Proof. Compare each identity morphism with the canonical empty continuation at its endpoint to obtain the two empty-tail equalities. After destructing the three continuation-morphism records, the composite tail is the displayed append of the three tails. The append left-unit and right-unit laws reduce it to $m.tail$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp left right identity tail result`

Theorem 61.111 (Continuation morphism fixed left tail has right identity)**.** *For continuation morphisms* $left : a \to b$ *and* $right : b \to c$*, if the composite append tail of* $left$ *followed by* $right$ *is history-same to* $left.tail$*, then* $right.tail$ *is empty and the endpoints* b *and* c *are history-same:*

$$\mathsf{hsame}(\mathsf{append}(left.tail, right.tail), left.tail) \Longrightarrow \mathsf{hsame}(right.tail, \mathsf{e}) \wedge \mathsf{hsame}(b, c).$$

Proof. The displayed fixed-left comparison is a self-continuation of $left.tail$ by $right.tail$. Right-unit uniqueness for continuation forces $right.tail$ to be empty. Transporting the right morphism's continuation relation to this empty tail and comparing it with the canonical right-unit continuation at b identifies b and c. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp left tail fixed right identity`

Theorem 61.112 (Continuation morphism fixed right tail has left identity)**.** *For continuation morphisms $left : a \to b$ and $right : b \to c$, if the composite append tail of $left$ followed by right is history-same to $right.tail$, then $left.tail$ is empty and the endpoints a and b are history-same:*

$$\mathsf{hsame}(\mathsf{append}(left.tail, right.tail), right.tail) \Longrightarrow \mathsf{hsame}(left.tail, \mathsf{e}) \wedge \mathsf{hsame}(a, b).$$

Proof. The displayed fixed-right comparison is a self-continuation of $right.tail$ by $left.tail$. Left-unit uniqueness for continuation forces $left.tail$ to be empty. Transporting the left morphism's continuation relation to this empty tail and comparing it with the canonical right-unit continuation at a identifies a and b. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp right tail fixed left identity`

Theorem 61.113 (Continuation morphism composite tail fixed by both factors)**.** *For continuation morphisms $left : a \to b$ and $right : b \to c$, the closed composite tail is fixed by both factor tails exactly when both factors are identity tails and both endpoint steps are history-same:*

$$\mathsf{hsame}((left \circ right).tail, left.tail) \wedge \mathsf{hsame}((left \circ right).tail, right.tail) \Longleftrightarrow \mathsf{hsame}(left.tail, \mathsf{e}) \wedge \mathsf{hsame}(right.tail, \mathsf{e})$$

Proof. After destructing the two continuation-morphism records, the closed composite tail is the append of the two displayed factor tails. If this append is history-same to the left tail, right-unit uniqueness forces the right tail empty; if it is history-same to the right tail, left-unit uniqueness forces the left tail empty. Transporting the two relation fields across those empty-tail equalities and comparing with canonical right-unit continuations gives the two endpoint comparisons. The converse reduces the append tail to the empty history and hence to each empty factor tail. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail fixed both identity iff`

Theorem 61.114 (Category hom carrier composite middle identity result)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, b, f)$*,* $\mathsf{CategoryHomCarrier}(b, b, id)$*,* $\mathsf{CategoryHomCarrier}(b, c, g)$*,* $\mathsf{Cont}(f, id, fid)$*,* $\mathsf{Cont}(fid, g, result)$*, and* $\mathsf{Cont}(f, g, fg)$*, then*

$$\mathsf{CategoryHomCarrier}(a, c, result) \wedge \mathsf{CategoryHomCarrier}(a, c, fg) \wedge \mathsf{hsame}(result, fg).$$

Proof. Apply the right identity carrier result to $\mathsf{Cont}(f, id, fid)$, obtaining $\mathsf{CategoryHomCarrier}(a, b, fid)$ and $\mathsf{hsame}(fid, f)$. Composition closure with the right hom-carrier gives the displayed carrier for $result$, while direct composition closure gives the displayed carrier for fg. The two continuation witnesses have history-same left tails and the same right tail g, so continuation result respect for hsame gives $\mathsf{hsame}(result, fg)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp middle identity result`

Theorem 61.115 (Category hom carrier composite middle identity public readback)**.** *For the unary-continuation category, if* $\mathsf{CategoryHomCarrier}(a, b, f)$*,* $\mathsf{CategoryHomCarrier}(b, b, id)$*,* $\mathsf{CategoryHomCarrier}(b, c, g$ $\mathsf{Cont}(f, id, fid)$*, and* $\mathsf{Cont}(fid, g, result)$*, then*

$$\mathsf{CategoryHomCarrier}(a, c, result) \wedge \forall fg,\ \mathsf{CategoryHomCarrier}(a, c, fg) \Rightarrow \mathsf{hsame}(result, fg).$$

Proof. Compare the displayed middle identity with the canonical empty identity at b. This identifies id with e, so the continuation $\mathsf{Cont}(f, id, fid)$ is determined by the right-unit continuation on f. Transporting the left hom carrier across $\mathsf{hsame}(fid, f)$ makes fid a hom carrier from a to b. Composition closure with the displayed right hom carrier gives the carrier witness for $result$, and hom-carrier morphism determinacy reads it back against any other hom carrier from a to c. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp middle identity public readback`

Theorem 61.116 (Category continuation middle identity tail result)**.** *For BEDC histories $a, b, c, f, id, g, fid, resul$ if $\mathsf{Cont}(a, f, b)$, $\mathsf{Cont}(b, id, b)$, $\mathsf{Cont}(b, g, c)$, $\mathsf{Cont}(f, id, fid)$, $\mathsf{Cont}(fid, g, result)$, and $\mathsf{Cont}(f, g, fg)$, then*

$$\mathsf{hsame}(result, fg).$$

Proof. Compare $\mathsf{Cont}(b, id, b)$ with the canonical right-unit continuation at b; tail determinacy gives $\mathsf{hsame}(id, \mathsf{e})$. Hence $\mathsf{Cont}(f, id, fid)$ is determined by the right-unit continuation on f, so $\mathsf{hsame}(fid, f)$. Continuation result respect for hsame, applied to the two displayed continuations with right tail g, yields $\mathsf{hsame}(result, fg)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.category cont middle identity tail result`

Lemma 61.117 (Category hom carrier right-append fixed identity bridge determinacy)**.** *For the unary-continuation category, fix a displayed hom carrier $\mathsf{CategoryHomCarrier}(a, b, f)$ and, for $g : \mathsf{BHist}$ and $fg : \mathsf{BHist}$, a fixed right-append comparison displayed by*

$$\mathsf{Cont}(f, g, fg) \wedge \mathsf{hsame}(fg, g).$$

Suppose the same consumer-facing surface is handed through the displayed left-right identity rows $\mathsf{CategoryHomCarrier}(a, a, id_A)$, $\mathsf{CategoryHomCarrier}(b, b, id_B)$, $\mathsf{Cont}(id_A, f, left)$, and $\mathsf{Cont}(left, id_B, result)$. Then the bridge is classified by exactly the local fixed-identity and public-readback rows:

$$\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{CategoryHomCarrier}(a, b, result) \wedge \forall h,\ \mathsf{CategoryHomCarrier}(a, b, h) \Rightarrow \mathsf{hsame}(result, h).$$

Consequently every accepted route, transport, readback, or handoff for this right-append fixed identity factors through the displayed $\mathsf{CategoryHomCarrier}$ rows, the two identity-continuation rows, the fixed append comparison, and the public readback classifier. No unlisted bridge coordinate supplies an alternate tail, endpoint, transported carrier, or public morphism read.

Proof. Apply Definition 61.97 to the displayed carrier $\mathsf{CategoryHomCarrier}(a, b, f)$ and the fixed comparison represented by $\mathsf{Cont}(f, g, fg)$ together with $\mathsf{hsame}(fg, g)$. The forward implication gives

$$\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(a, b).$$

These are the only fixed-append data exported by the local theorem: the morphism tail is empty and the two endpoints are history-same.

Next apply Definition 61.108 to $\mathsf{CategoryHomCarrier}(a, a, id_A)$, $\mathsf{CategoryHomCarrier}(a, b, f)$, $\mathsf{CategoryHomCarrier}($ $\mathsf{Cont}(id_A, f, left)$, and $\mathsf{Cont}(left, id_B, result)$. It supplies the displayed carrier for the handoff result and the public readback clause

$$\mathsf{CategoryHomCarrier}(a, b, result) \wedge \forall h,\ \mathsf{CategoryHomCarrier}(a, b, h) \Rightarrow \mathsf{hsame}(result, h).$$

Combining this conjunction with the fixed-append conclusion gives the displayed classification.

The factorization claim follows from the two cited rows. A route to the fixed identity must first use the right-append comparison and therefore lands in $\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(a, b)$. By Definition 61.93, a transport use can only move the displayed hom carrier along those hsame comparisons. A readback or handoff through the identity bridge is then exactly the public readback clause above: it classifies $result$ against every displayed hom carrier over the same endpoints, including the original carrier f. Since the hypotheses list no further carrier, continuation, classifier, or endpoint row, an alleged alternate tail, endpoint, transported carrier, or public morphism read has no local coordinate through which an accepted consumer could obtain it. □

Corollary 61.118 (Category hom carrier right-append fixed identity consumer determinacy)**.** *For the unary-continuation category, fix* $\mathsf{CategoryHomCarrier}(a, b, f)$ *and a displayed fixed right-append row*

$$\mathsf{Cont}(f, g, fg) \wedge \mathsf{hsame}(fg, g).$$

Suppose the same consumer-facing identity surface also displays $\mathsf{CategoryHomCarrier}(a, a, id_A)$*,* $\mathsf{CategoryHomCarrier}(b, b, id_B)$*,* $\mathsf{Cont}(id_A, f, left)$*, and* $\mathsf{Cont}(left, id_B, result)$*. Then every displayed consumer candidate* h *over the same endpoints is forced to the chapter's fixed identity route and public normal form:*

$$\mathsf{CategoryHomCarrier}(a, b, h) \Longrightarrow \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(result, h).$$

Thus the accepted exactness decision is the pair $\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(a, b)$*, and the accepted public readback is the single* hsame*-class of* $result$ *among displayed hom carriers from* a *to* b*. No hidden coordinate can supply a nonempty tail decision, a different endpoint classifier, or a duplicate public classifier source for this right-append fixed identity surface.*

Proof. Apply Definition 61.117 to the displayed hom carrier, the fixed right-append row, and the four identity surface rows. It gives

$$\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{CategoryHomCarrier}(a, b, result) \wedge \forall k,\ \mathsf{CategoryHomCarrier}(a, b, k) \Rightarrow \mathsf{hsame}(result, k).$$

For the chosen consumer candidate h, instantiate the universal readback clause with its displayed carrier row $\mathsf{CategoryHomCarrier}(a, b, h)$. This yields $\mathsf{hsame}(result, h)$, while the first two conjuncts give the fixed identity decision $\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(a, b)$.

The content of that decision is exactly the one supplied by Definition 61.97: the fixed right-append comparison is accepted precisely through the empty-tail condition on f together with the endpoint classifier $\mathsf{hsame}(a, b)$. The bridge determinacy lemma then routes every public handoff through the displayed identity rows and the universal readback classifier for $result$. Hence any accepted route, normal-form read, or exactness decision using the same surface must factor through these listed rows; an unlisted tail, endpoint, or public classifier coordinate has no displayed carrier or continuation row from which it could be read. □

Theorem 61.119 (Continuation morphism composite middle identity tail result)**.** *For continuation morphisms* $left : a \to b$*,* $identity : b \to b$*, and* $right : b \to c$*, the middle identity tail is empty, and inserting it between* $left$ *and* $right$ *leaves the composite tail history-same to the direct composite:*

$$\mathsf{hsame}(identity.tail, \mathsf{e}) \wedge \mathsf{hsame}((left \circ identity) \circ right,\ left \circ right).$$

Proof. Compare $identity$ with the canonical empty continuation morphism at b by tail determinacy, giving $\mathsf{hsame}(identity.tail, \mathsf{e})$. Unfolding the two composite tails reduces the comparison to append histories. The middle tail is transported to e, and the right-unit law $\mathsf{append}(left.tail, \mathsf{e})\mathsf{hsame} left.tail$ collapses the displayed middle factor. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp middle identity tail result`

Theorem 61.120 (Category hom carrier identity semantic name certificate)**.** *For a unary object history* a*, the identity hom-carrier predicate* $f \mapsto \mathsf{CategoryHomCarrier}(a, a, f)$ *carries a semantic naming certificate whose source, pattern, and ledger predicates are this hom-carrier predicate and whose classifier is* hsame*.*

Proof. The carrier witness is the empty history, using the empty identity hom-carrier at a. The classifier laws are the reflexive, symmetric, and transitive laws for hsame. Carrier transport follows by transporting the concrete hom-carrier witness across history sameness. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier identity semanticNameCert`

Theorem 61.121 (Category hom carrier semantic name certificate from a hom)**.** *For displayed unary-continuation hom data* $\mathsf{CategoryHomCarrier}(a, b, f)$*, the hom-carrier predicate* $g \mapsto \mathsf{CategoryHomCarrier}(a, b, g$ *carries a semantic naming certificate whose source, pattern, and ledger predicates are this hom-carrier predicate and whose classifier is* hsame*.*

Proof. The displayed morphism f supplies carrier inhabitation. The classifier laws are reflexivity, symmetry, and transitivity of hsame. If a classified morphism is transported across hsame, endpoint histories stay fixed and Definition 61.93 rebuilds the hom-carrier witness. Pattern and ledger soundness are identities because the three semantic predicates are the same hom-carrier predicate. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier semanticNameCert of hom`

Theorem 61.122 (Category hom carrier unary suffix semantic boundary)**.** *For a unary suffix* q *and displayed hom carrier* $\mathsf{CategoryHomCarrier}(a, b, f)$*, the suffixed hom-carrier predicate* $g \mapsto \mathsf{CategoryHomCarrier}(\mathsf{append}(a, q), \mathsf{append}(b, q), g)$ *carries a semantic naming certificate with classifier* hsame*. The displayed endpoint is exact:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(a, q), \mathsf{append}(b, q), f) \iff \mathsf{UnaryHistory}(q) \wedge \mathsf{CategoryHomCarrier}(a, b, f).$$

Proof. The unary suffix equivalence rebuilds the displayed suffixed hom carrier from q and the base hom carrier. The existing hom-carrier semantic certificate is then applied at the suffixed endpoints. The same unary suffix equivalence gives the exact endpoint readback. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier unary suffix semantic boundary`

Theorem 61.123 (Category hom carrier composite-result semantic name certificate)**.** *For displayed hom carriers* $\mathsf{CategoryHomCarrier}(a, b, f)$ *and* $\mathsf{CategoryHomCarrier}(b, c, g)$ *together with* $\mathsf{Cont}(f, g, fg)$*, the predicate*

$$h \mapsto \mathsf{CategoryHomCarrier}(a, c, h) \wedge h\mathsf{hsame}fg$$

carries a semantic naming certificate whose source, pattern, and ledger predicates are this same concrete composite-result predicate and whose classifier is hsame*.*

Proof. Composition closure gives the carrier witness at fg, and reflexivity gives the displayed comparison $fg\mathsf{hsame}fg$. The classifier laws are the reflexive, symmetric, and transitive laws for hsame. Transport along a classifier proof uses hom-carrier transport for the fixed endpoints a, c and transitivity with the inverse classifier proof to keep the displayed composite result aligned with fg. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result semanticNameCert`

Theorem 61.124 (Category hom carrier composite-result endpoint semantic name certificate)**.** *For displayed hom carriers* $\mathsf{CategoryHomCarrier}(a, b, f)$ *and* $\mathsf{CategoryHomCarrier}(b, c, g)$ *together with* $\mathsf{Cont}(f, g, fg)$*, if* $a\mathsf{hsame}a'$ *and* $c\mathsf{hsame}c'$*, then the transported predicate*

$$h \mapsto \mathsf{CategoryHomCarrier}(a', c', h) \wedge h\mathsf{hsame}fg$$

carries a semantic naming certificate whose source, pattern, and ledger predicates are this same transported composite-result predicate and whose classifier is hsame*.*

Proof. Composition closure first gives the concrete composite hom carrier at endpoints (a, c) and result fg. Endpoint transport along $a\mathsf{hsame}a'$ and $c\mathsf{hsame}c'$ moves this carrier to (a', c'), giving inhabitation at fg. The classifier laws are reflexivity, symmetry, and transitivity of hsame. Carrier transport keeps endpoints fixed at (a', c'), transports the displayed hom carrier along the classifier proof, and composes the inverse classifier proof with the stored comparison to fg. Pattern and ledger soundness are identities because all three semantic predicates coincide. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result endpoint semanticNameCert`

Theorem 61.125 (Continuation morphism source semantic name certificate)**.** *For a displayed continuation morphism* $m : \mathsf{ContinuationMorphism}(a, b)$*, the source predicate* $src \mapsto \mathsf{Nonempty}(\mathsf{ContinuationMorphism}(s$ *carries a semantic naming certificate whose source, pattern, and ledger predicates are this same source predicate and whose classifier is* hsame*.*

Proof. The displayed morphism m gives carrier inhabitation at source a. Reflexivity, symmetry, and transitivity of hsame supply the classifier laws. If a source endpoint is transported along hsame, the same displayed tail remains valid by continuation transport, so the concrete continuation-morphism witness is rebuilt at the transported source. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism source semanticNameCert`

Theorem 61.126 (Continuation morphism target semantic name certificate)**.** *For a displayed continuation morphism* $m : \mathsf{ContinuationMorphism}(a, b)$*, the target predicate* $tgt \mapsto \mathsf{Nonempty}(\mathsf{ContinuationMorphism}(a,$ *carries a semantic naming certificate whose source, pattern, and ledger predicates are this same target predicate and whose classifier is* hsame*.*

Proof. The displayed morphism m gives carrier inhabitation at target b. The classifier laws are the three basic laws of hsame. Carrier transport uses continuation transport on the result endpoint while keeping the source and displayed tail fixed, thereby rebuilding a concrete continuation morphism at the transported target. Pattern and ledger soundness are identities for the same predicate. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism target semanticNameCert`

Theorem 61.127 (Composite continuation tail semantic name certificate)**.** *For histories* a, b, c *and continuation morphisms* $left : \mathsf{ContinuationMorphism}(a, b)$ *and* $right : \mathsf{ContinuationMorphism}(b, c)$*, let* m *be their closed composite. The predicate*

$$t \mapsto \mathsf{Cont}(a, t, c) \wedge \mathsf{hsame}(t, \mathsf{tail}(m))$$

carries a semantic naming certificate whose source, pattern, and ledger predicates are this same concrete composite-tail predicate and whose classifier is hsame*.*

Proof. The carrier witness is $\mathsf{tail}(m)$, using the continuation relation of the closed composite and reflexivity of hsame. The classifier laws are reflexivity, symmetry, and transitivity of hsame. Transport along a classifier proof preserves the displayed continuation by continuation transport, and it preserves the tail classifier by transitivity with the inverse classifier proof. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail semanticNameCert`

Per-object certificate: traditional target category identity laws; BEDC source CategoryHomCarrier plus Cont; carrier BHist hom witnesses; classifier hsame; stability obligation two-sided identity under morphism classifier; ledger the empty-composition ledgers; core theorem list entry two-sided identity; exactness predicate sameness with the original morphism; standard bridge deferred; status ProofTarget.

Lemma 61.128 (Category hom identity semantic name certificate bridge determinacy)**.** *Let a be a unary object history, and consider the identity hom-carrier naming surface of Definition 61.120. Any consumer-facing use of this identity surface as a route, transport, readback, or handoff factors through the following displayed local rows: the identity hom-carrier predicate $f \mapsto \mathsf{CategoryHomCarrier}(a, a, f)$, the classifier row* hsame*, carrier transport for* CategoryHomCarrier*, and the continuation-source certificate row of Definition 61.125 applied to the continuation morphism encoded by the identity carrier. Thus an accepted consumer cannot obtain a primitive host identity arrow, a second morphism classifier, an off-carrier readback, a detached continuation source, or any unlisted bridge coordinate from the identity name certificate.*

Proof. The identity certificate of Definition 61.120 names exactly one source, pattern, and ledger predicate, namely $f \mapsto \mathsf{CategoryHomCarrier}(a, a, f)$, and it names exactly one classifier, namely hsame. Therefore every route that reads the identity surface first lands in the displayed hom-carrier predicate over the fixed endpoints (a, a). The identity witness itself is the empty history supplied by Definition 61.2, so the route has no separate host identity coordinate beyond the BEDC carrier row.

A transport use is fixed by the same certificate. If the displayed morphism history is changed only by hsame, then Definition 61.93 rebuilds the transported hom-carrier witness over the same identity endpoints. This is the full transport surface of the identity name certificate: the certificate has no second classifier and no independent transport predicate outside CategoryHomCarrier and hsame.

A readback or handoff to continuation data also remains local. By the hom-carrier and continuation-morphism tail correspondence of Definition 61.317, a read of $\mathsf{CategoryHomCarrier}(a, a, f)$ is exactly a unary endpoint and unary tail presentation of a continuation morphism $m : \mathsf{ContinuationMorphism}(a, a)$ whose displayed tail is classified with f. Applying Definition 61.125 to this displayed continuation morphism shows that a consumer may read or transport the source only through the source predicate $src \mapsto \mathsf{Nonempty}(\mathsf{ContinuationMorphism}(src, a))$ and its same classifier hsame. Hence the continuation handoff is not an additional bridge coordinate; it is the source row already determined by the identity hom-carrier readback.

The listed rows exhaust the consumer-facing bridge. Routes are the fixed identity hom-carrier predicate, transports are the hsame hom-carrier transports, readbacks are the hom-carrier-to-continuation tail correspondence, and continuation handoffs are the continuation-source semantic certificate for the resulting morphism. Since none of these rows contains a primitive host identity arrow, a second morphism classifier, an off-carrier readback, a detached continuation source, or an extra bridge field, such a coordinate has no row through which an accepted consumer could read the identity semantic name certificate. □

Corollary 61.129 (Category hom identity semantic name certificate consumer determinacy)**.** *Let a be a unary object history, and fix the identity hom-carrier semantic name certificate of Definition 61.120. Once the displayed identity rows are fixed, every accepted consumer-facing use of this surface as a finite route, transport, readback normal form, or exactness decision is determined by the same local data:*

$$f \mapsto \mathsf{CategoryHomCarrier}(a, a, f), \qquad \mathsf{hsame},$$

hom-carrier transport across hsame*, the continuation-source row reached from the hom-carrier readback.*

Thus two accepted consumers over these rows cannot choose different identity routes, different morphism classifiers, different readback normal forms, or different exactness decisions. Any proposed primitive host identity arrow, off-carrier coordinate, detached continuation source, unlisted bridge row, or duplicate classifier source is outside the accepted identity semantic name surface.

Proof. The identity certificate in Definition 61.120 fixes the semantic name surface before any consumer reads it. Its source, pattern, and ledger predicates are all the single predicate $f \mapsto \mathsf{CategoryHomCarrier}(a, a, f)$, and its classifier is the single history classifier hsame. Therefore a consumer route has no independent choice of carrier predicate or classifier: reading the identity name means reading the displayed hom-carrier predicate over the fixed endpoints (a, a).

Apply Definition 61.128. It states that every accepted route, transport, readback, or handoff through this identity surface factors through exactly the displayed local rows: the identity hom-carrier predicate, the classifier hsame, hom-carrier transport for $\mathsf{CategoryHomCarrier}$, and the continuation-source certificate obtained from the continuation morphism encoded by the identity carrier. Hence the consumer-facing finite route is not a further datum; it is the ordered use of those rows.

The same factorization fixes the normal-form and exactness readings. A transport read can only be the hsame hom-carrier transport over the fixed identity endpoints. A readback can only pass through the hom-carrier to continuation-tail correspondence named in the bridge-determinacy lemma, and its continuation handoff can only use the continuation-source semantic certificate for the resulting morphism. Consequently an exactness decision about the identity name is a decision about membership in the displayed hom-carrier row and its hsame readback, not a decision supplied by a second host arrow, second classifier, or detached continuation coordinate.

Suppose two accepted consumers over the fixed rows produced different identity routes, different readback normal forms, or different exactness decisions. The difference would have to enter through a row not among the identity hom-carrier predicate, hsame, the hom-carrier transport row, or the continuation-source row reached from the readback. But the bridge-determinacy lemma excludes exactly those unlisted coordinates: primitive host identity arrows, second morphism classifiers, off-carrier readbacks, detached continuation sources, and extra bridge fields have no exported row in the identity semantic name certificate. Thus every accepted consumer over the fixed rows determines the same chapter-named finite route, normal-form readback, and exactness decision. □

Theorem 61.130 (Category hom carrier associativity witness)**.** *For the unary-continuation category, let f be a hom-carrier from a to b, let g be a hom-carrier from b to c, and let h be a hom-carrier from c to d. If fg, gh, $left$, and $right$ satisfy*

$$\mathsf{Cont}(f, g, fg), \quad \mathsf{Cont}(g, h, gh), \quad \mathsf{Cont}(fg, h, left), \quad \mathsf{Cont}(f, gh, right),$$

then $left$ and $right$ are both hom-carriers from a to d, and $\mathsf{hsame}(left, right)$.

Proof. First build the left-associated carrier. Apply Theorem 61.19 to the carriers $f : a \to b$ and $g : b \to c$ with $\mathsf{Cont}(f, g, fg)$, obtaining $fg : a \to c$. Apply the same theorem to $fg : a \to c$ and $h : c \to d$ with $\mathsf{Cont}(fg, h, left)$, obtaining $left : a \to d$.

Next build the right-associated carrier. Apply Theorem 61.19 to the carriers $g : b \to c$ and $h : c \to d$ with $\mathsf{Cont}(g, h, gh)$, obtaining $gh : b \to d$. Apply the same theorem to $f : a \to b$ and $gh : b \to d$ with $\mathsf{Cont}(f, gh, right)$, obtaining $right : a \to d$.

Finally apply continuation associativity, Theorem 4.56, to the displayed continuation square. The two composition trees therefore have the same morphism classifier, namely $\mathsf{hsame}(left, right)$. □

Per-object certificate: traditional target categorical associativity; BEDC source $\mathsf{CategoryHomCarrier}$ plus Cont; carrier BHist hom witnesses; classifier hsame; stability obligation associativity under morphism classifier; ledger the two composition trees; core theorem list entry this associativity witness; exactness predicate equality of the two composite trees; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 61.131 (Category hom carrier fourfold associativity witness)**.** *For the unary-continuation category, let f be a hom-carrier from a to b, let g be a hom-carrier from b to c, let h be a hom-carrier from c to d, and let i be a hom-carrier from d to e. If fg, fgh, hi, ghi, $left$, and $right$ satisfy*

$$\mathsf{Cont}(f, g, fg), \quad \mathsf{Cont}(fg, h, fgh), \quad \mathsf{Cont}(h, i, hi), \quad \mathsf{Cont}(g, hi, ghi), \quad \mathsf{Cont}(fgh, i, left), \quad \mathsf{Cont}(f, ghi, right),$$

then $left$ and $right$ are both hom-carriers from a to e, and $\mathsf{hsame}(left, right)$.

Proof. First build the left fourfold carrier. Apply Theorem 61.19 to $f : a \to b$ and $g : b \to c$ with $\mathsf{Cont}(f, g, fg)$, obtaining $fg : a \to c$. Apply the same theorem to $fg : a \to c$ and $h : c \to d$ with $\mathsf{Cont}(fg, h, fgh)$, obtaining $fgh : a \to d$. Apply it once more to $fgh : a \to d$ and $i : d \to e$ with $\mathsf{Cont}(fgh, i, left)$, obtaining $left : a \to e$.

Next build the right fourfold carrier. Apply Theorem 61.19 to $h : c \to d$ and $i : d \to e$ with $\mathsf{Cont}(h, i, hi)$, obtaining $hi : c \to e$. Apply the same theorem to $g : b \to c$ and $hi : c \to e$ with $\mathsf{Cont}(g, hi, ghi)$, obtaining $ghi : b \to e$. Apply it once more to $f : a \to b$ and $ghi : b \to e$ with $\mathsf{Cont}(f, ghi, right)$, obtaining $right : a \to e$.

Finally apply the kernel fourfold continuation associativity witness, $cont_assoc_four$, to the six displayed continuation relations. The two fourfold composition ledgers therefore generate the same composite history classifier, namely $\mathsf{hsame}(left, right)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier fourfold assoc witness`

Per-object certificate: traditional target fourfold categorical associativity coherence; BEDC source CategoryHomCarrier plus Cont; carrier BHist hom witnesses; classifier hsame; stability obligation rebracketing under morphism classifier; ledger the two fourfold composition trees; core theorem list entry fourfold coherence; exactness predicate equality of generated composite histories; standard bridge deferred; status ProofTarget.

Theorem 61.132 (Category hom carrier associative composition closure)**.** *For the unary-continuation category, composable hom-carriers $f : a \to b$, $g : b \to c$, and $h : c \to d$ remain hom-carriers after either association of composition. If* $\mathsf{Cont}(f, g, fg)$, $\mathsf{Cont}(g, h, gh)$, $\mathsf{Cont}(fg, h, left)$, *and* $\mathsf{Cont}(f, gh, right)$, *then both $left$ and $right$ are hom-carriers from a to d, and* $\mathsf{hsame}(left, right)$.

Proof. Apply hom-carrier composition closure first to f, g and then to fg, h for the left association. Apply the same closure first to g, h and then to f, gh for the right association. The continuation associativity law identifies the two composite histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp assoc closed`

Theorem 61.133 (Category hom carrier displayed associative determinacy)**.** *For the unary-continuation category, assume composable hom-carriers $f : a \to b$, $g : b \to c$, and $h : c \to d$ with continuation witnesses for fg, gh, $left$, and $right$ as in associative composition closure. If a displayed hom-carrier from a to d is also given, then both bracketed composite histories are* hsame *to the displayed morphism history.*

Proof. Associative composition closure constructs the left- and right-associated hom-carriers from a to d. The hom-carrier morphism determinacy theorem compares each of these carriers with the displayed carrier over the same endpoints. □

Lean4 (definition) `BEDC.Derived.CategoryUp.ContinuationMorphism`

Theorem 61.134 (Continuation morphism tail semantic name certificate)**.** *For histories a, b and a continuation morphism $m : a \to b$, the predicate $t \mapsto \mathsf{Cont}(a, t, b)$ carries a semantic naming certificate with source, pattern, and ledger all given by this same continuation-tail predicate and classifier* hsame*.*

Proof. The carrier witness is the displayed tail of m together with its continuation relation. The classifier laws are reflexivity, symmetry, and transitivity of hsame. Carrier transport follows by substituting the history-sameness proof into the concrete continuation-tail predicate. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism tail semanticNameCert`

Theorem 61.135 (Continuation morphism tail-continuation witness iff)**.** *For histories a, b, t : BHist, a continuation morphism from a to b whose displayed tail is history-same to t exists exactly when t is a continuation tail from a to b:*

$$\exists m : \mathsf{ContinuationMorphism}(a, b),\ \mathsf{hsame}(\mathsf{tail}(m), t) \quad \Longleftrightarrow \quad \mathsf{Cont}(a, t, b).$$

Proof. In the forward direction, unpack the displayed continuation morphism. Its record field gives $\mathsf{Cont}(a, \mathsf{tail}(m), b)$, and continuation transport along the tail classifier $\mathsf{hsame}(\mathsf{tail}(m), t)$ gives $\mathsf{Cont}(a, t, b)$.

Conversely, a witness $\mathsf{Cont}(a, t, b)$ itself forms a continuation morphism from a to b with displayed tail t, and tail classification is reflexive. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism tail cont witness iff`

Theorem 61.136 (Continuation morphism tail determinacy)**.** *For histories a, b, any two continuation morphisms from a to b have history-same tails:*

$$left, right : \mathsf{ContinuationMorphism}(a, b) \Longrightarrow \mathsf{hsame}(\mathsf{tail}(left), \mathsf{tail}(right)).$$

Proof. Unpack both continuation morphism records. Their continuation witnesses have the same source a and target b, so continuation left-context cancellation identifies the two displayed tails. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism tail deterministic`

Theorem 61.137 (Continuation morphism empty-source tail target exactness)**.** *For every history target, a continuation morphism from the empty source to target has displayed tail history-same to target:*

$$m : \mathsf{ContinuationMorphism}(\mathsf{e}, target) \Longrightarrow \mathsf{hsame}(\mathsf{tail}(m), target).$$

Proof. Unpack the continuation morphism record. Its continuation witness has source e, displayed tail $\mathsf{tail}(m)$, and result *target*. The left-unit continuation law identifies the result with the tail, and symmetry of hsame gives the displayed orientation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism empty source tail target hsame`

Theorem 61.138 (Continuation morphism empty tail endpoint equivalence)**.** *For histories a, b and a continuation morphism $m : a \to b$, the displayed tail of m is history-same to* e *if and only if the source and target endpoints are history-same:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{e}) \Longleftrightarrow \mathsf{hsame}(a, b).$$

Proof. Unpack m as a continuation witness $\mathsf{Cont}(a, \mathsf{tail}(m), b)$. If the tail is e, compare this witness with the right-unit continuation at a; continuation result determinacy gives the endpoint comparison.

Conversely, if $a\mathsf{hsame}b$, then the continuation witness identifies $\mathsf{append}(a, \mathsf{tail}(m))$ with b, and the endpoint comparison identifies b with $\mathsf{append}(a, \mathsf{e})$. Left cancellation of the common source a gives $\mathsf{hsame}(\mathsf{tail}(m), \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism tail empty endpoint hsame iff`

Theorem 61.139 (Continuation morphism endpoint transport tail classification)**.** *For histories a, a', b, b', if a is history-same as a' and b is history-same as b', then the tail of any continuation morphism from a to b transports to a continuation tail from a' to b'. Any displayed continuation morphism from a' to b' has a tail classified with this transported tail.*

Proof. Transport the continuation relation carried by the left morphism across the source and target endpoint sameness witnesses, using reflexivity for the tail itself. The transported relation and the relation carried by the right morphism share source and target endpoints, so continuation left cancellation identifies the two tails. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism endpoint transport tail classified`

Theorem 61.140 (Continuation morphism endpoint transport existence)**.** *For histories a, a', b, b', if $a\mathsf{hsame}a'$ and $b\mathsf{hsame}b'$, then every continuation morphism from a to b induces a continuation morphism from a' to b' whose tail is history-same to the original tail. Moreover the induced morphism carries the transported continuation witness at its own tail.*

Proof. Reuse the original tail. Transport the continuation relation carried by the given morphism across the source and target endpoint sameness witnesses, using reflexivity on the tail. The resulting transported relation is the relation field of the displayed morphism from a' to b', and the tail comparison is reflexivity. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism endpoint transport exists`

Theorem 61.141 (Continuation morphism endpoint transport witness)**.** *For histories a, a', b, b', if $a\mathsf{hsame}a'$ and $b\mathsf{hsame}b'$, then every continuation morphism $m : \mathsf{ContinuationMorphism}(a, b)$ transports to a continuation morphism $n : \mathsf{ContinuationMorphism}(a', b')$ whose tail is history-same to the original tail:*

$$\exists n : \mathsf{ContinuationMorphism}(a', b').\ \mathsf{hsame}(\mathsf{tail}(n), \mathsf{tail}(m)) \wedge \mathsf{Cont}(a', \mathsf{tail}(n), b').$$

Proof. Unpack m as a tail with a continuation relation from a to b. Transport that relation across the source and target endpoint comparisons, keeping the same tail by reflexivity. The transported relation is the relation field of the displayed morphism n, and tail reflexivity gives the announced comparison. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism endpoint transport witness`

Theorem 61.142 (Continuation morphism source determinacy)**.** *For histories a, b, c, if a continuation morphism from a to c and a continuation morphism from b to c display history-same tails, then their sources are history-same:*

$$left : \mathsf{ContinuationMorphism}(a, c), \quad right : \mathsf{ContinuationMorphism}(b, c), \quad \mathsf{hsame}(\mathsf{tail}(left), \mathsf{tail}(right)) \Longrightarrow \mathsf{hsame}($$

Proof. Unpack both continuation morphism records. The displayed tail equality makes the two continuation witnesses share the same tail and the same result c. Continuation right-context cancellation then identifies the two source histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism source deterministic`

Theorem 61.143 (Continuation morphism target determinacy)**.** *For histories a, b, c, if a continuation morphism from a to b and a continuation morphism from a to c display history-same tails, then their targets are history-same:*

$$left : \mathsf{ContinuationMorphism}(a, b), \quad right : \mathsf{ContinuationMorphism}(a, c), \quad \mathsf{hsame}(\mathsf{tail}(left), \mathsf{tail}(right)) \Longrightarrow \mathsf{hsame}(b$$

Proof. Unpack both continuation morphism records. The displayed tail equality makes the two continuation witnesses share the same source a and the same tail. Continuation result determinacy then identifies the two target histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism target deterministic`

Theorem 61.144 (Category empty-target hom chain inversion)**.** *If f is a hom-carrier from a to b and g is a hom-carrier from b to* e*, then the source, middle object, and both displayed morphisms are all history-same to* e*:*

$$\mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(b, \mathsf{e}) \wedge \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}).$$

Proof. Empty-target exactness applied to the right hom-carrier identifies b and g with e. Transporting the left hom-carrier along this target identification makes it a hom-carrier into e, so empty-target exactness applied again identifies a and f with e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty target chain inversion`

Theorem 61.145 (Continuation morphism empty target inversion)**.** *For a continuation morphism from source to* e*, both the source and the displayed tail are history-same to* e*:*

$$m : \mathsf{ContinuationMorphism}(source, \mathsf{e}) \Longrightarrow \mathsf{hsame}(source, \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(m), \mathsf{e}).$$

Proof. Unpack the continuation morphism record. Its continuation ledger has empty target, so the kernel empty-result inversion theorem identifies both the source and the displayed tail with e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism empty target inversion`

Theorem 61.146 (Continuation morphism visible source empty target impossibility)**.** *For every history a :* BHist*, neither visible-headed source admits a continuation morphism into* e*:*

$$\mathsf{ContinuationMorphism}(\mathsf{e0}(a), \mathsf{e}) \to \mathsf{False}$$

and

$$\mathsf{ContinuationMorphism}(\mathsf{e1}(a), \mathsf{e}) \to \mathsf{False}.$$

Proof. Apply empty-target inversion to the displayed continuation morphism. The inversion identifies the source endpoint with e. For source $\mathsf{e0}(a)$ or $\mathsf{e1}(a)$ this contradicts generated-history constructor separation from the empty history. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism visible source empty target absurd`

Definition 61.147 (Continuation morphism composition closure)**.** *Given continuation morphisms from a to b and from b to c, their closed composite is the continuation morphism from a to c whose tail is the append of the two displayed tails. The continuation witness is obtained by unpacking the first relation and reassociating the append spine.*

Lean4 (definition) `BEDC.Derived.CategoryUp.ContinuationMorphism comp closed`

Theorem 61.148 (Continuation morphism composite empty target inversion)**.** *For histories a, b, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, \mathsf{e})$. Then both endpoints and both displayed tails are history-same to e:*

$$\mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(b, \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(left), \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(right), \mathsf{e}).$$

Proof. Unpack the two continuation morphism records. Empty-result inversion on the right witness identifies b and the displayed tail of $right$ with e. After transporting the left witness across this endpoint identification, a second empty-result inversion identifies a and the displayed tail of $left$ with e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp empty target inversion`

Theorem 61.149 (Continuation morphism composite empty middle inversion)**.** *For histories a, c, let $left$: $\mathsf{ContinuationMorphism}(a, \mathsf{e})$ and $right$: $\mathsf{ContinuationMorphism}(\mathsf{e}, c)$. Then*

$$\mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(left), \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(right), c) \wedge \mathsf{hsame}(\mathsf{tail}(left \circ right), c).$$

Proof. Empty-result inversion on the left witness identifies a and the displayed tail of $left$ with e. The right witness is a left-unit continuation, so its displayed tail is history-same to c. The composite displayed tail is the append of the two displayed tails; replacing the left one by e and using left-unit append gives the same endpoint comparison with c. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp empty middle inversion`

Theorem 61.150 (Continuation morphism composite tail hom carrier)**.** *For histories a, b, c, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If a, c, and both displayed tails are unary histories, then the canonical composite tail is a hom carrier from a to c:*

$$\mathsf{CategoryHomCarrier}(a, c, \mathsf{tail}(\mathsf{ContinuationMorphism_comp_closed}(left, right))).$$

Proof. The composite morphism record supplies the continuation relation from a through the appended tail to c. Unary append closure combines the two unary tail witnesses, while the assumed unary source and target witnesses fill the remaining fields of $\mathsf{CategoryHomCarrier}$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail CategoryHomCarrier`

Theorem 61.151 (Continuation morphism composite tail hom-carrier iff)**.** *For histories a, b, c, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. The canonical composite tail is a hom carrier from a to c if and only if the source, target, and both component tails are unary:*

$$\mathsf{CategoryHomCarrier}(a, c, \mathsf{tail}(\mathsf{ContinuationMorphism_comp_closed}(left, right))) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}$$

Proof. Forward, unfold the displayed hom carrier and split the unary append carried by the composite tail into its two component tail factors. Reverse, use unary append closure on the component tails together with the composite continuation relation stored by ContinuationMorphism_comp_closed. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail CategoryHomCarrier iff`

Theorem 61.152 (Continuation morphism composite tail hom-carrier factors iff)**.** *For histories a, b, c, let $left$: ContinuationMorphism(a, b) and $right$: ContinuationMorphism(b, c). The canonical composite tail is a hom carrier from a to c if and only if the endpoints a, c are unary and the two component tails are themselves the hom carriers $a \to b$ and $b \to c$:*

$$\mathsf{CategoryHomCarrier}(a, c, \mathsf{tail}(\mathsf{ContinuationMorphism_comp_closed}(left, right))) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}$$

Proof. Forward, the composite hom carrier gives unary source and target data and a unary composite tail. Splitting that tail yields unary witnesses for the two component tails, while the left continuation relation closes the middle object b as unary. The stored continuation relations then assemble the two component hom carriers. Reverse, the two component hom carriers provide the source, target, and tail unary data needed by the composite-tail hom-carrier closure. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail CategoryHomCarrier factors iff`

Theorem 61.153 (Continuation morphism composite empty-tail inversion)**.** *For histories a, b, c, let $left : a \to b$ and $right : b \to c$ be continuation morphisms. If the canonical composite continuation morphism has displayed tail history-same to* e*, then both component tails are history-same to* e*, and both endpoints are identified:*

$$\mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \implies \mathsf{hsame}(\mathsf{tail}(left), \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(right), \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. Unpack the two continuation morphism records. The composite displayed tail is the BEDC append of the two component tails; empty append inversion forces both component tails to be e. The original continuation witnesses then compare against the right-unit continuations at a and b, so determinacy identifies the corresponding endpoints. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp empty tail inversion`

Theorem 61.154 (Continuation morphism composite tail empty iff)**.** *For histories a, b, c, let $left : a \to b$ and $right : b \to c$ be continuation morphisms. The canonical composite has displayed tail history-same to* e *if and only if both component tails are history-same to* e*:*

$$\mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \iff \mathsf{hsame}(\mathsf{tail}(left), \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(right), \mathsf{e}).$$

Proof. The forward direction is the tail part of composite empty-tail inversion. For the reverse direction, unpack the two continuation morphism records. Once both component tails are identified with e, the composite displayed tail is $\mathsf{append}(\mathsf{e}, \mathsf{e})$, hence it is history-same to e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail empty iff`

Theorem 61.155 (Continuation morphism composite right visible tail empty absurd)**.** *For histories a, b, c, m, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If the right displayed tail is a visible constructor, then the canonical composite displayed tail cannot be history-same to* e*:*

$$\mathsf{hsame}(\mathsf{tail}(right), \mathsf{e0}(m)) \Longrightarrow \mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \Longrightarrow \mathsf{False}$$

and

$$\mathsf{hsame}(\mathsf{tail}(right), \mathsf{e1}(m)) \Longrightarrow \mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \Longrightarrow \mathsf{False}.$$

Proof. Unpack both continuation morphism records. The composite tail is the kernel append of the left displayed tail with the right displayed tail. If this append were empty, append-empty inversion would force the right displayed tail itself to be e. This contradicts constructor separation for either $\mathsf{e0}(m)$ or $\mathsf{e1}(m)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp right visible tail empty absurd`

Theorem 61.156 (Continuation morphism right visible tail target not empty)**.** *For histories b, c, m and a continuation morphism $right$: $\mathsf{ContinuationMorphism}(b, c)$, if the displayed tail of $right$ is one-headed, then the target cannot be history-same to* e*:*

$$\mathsf{hsame}(\mathsf{tail}(right), \mathsf{e1}(m)) \Longrightarrow \mathsf{hsame}(c, \mathsf{e}) \Longrightarrow \mathsf{False}.$$

Proof. Unpack the continuation morphism record. Its relation identifies c with $\mathsf{append}(b, \mathsf{e1}(m))$. If c were history-same to e, append-empty inversion would force $\mathsf{e1}(m)$ itself to be history-same to e, contradicting one-headed constructor separation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism right visible tail target not empty`

Theorem 61.157 (Continuation morphism zero-tail target not empty)**.** *For histories a, b, m and a continuation morphism $morph$: $\mathsf{ContinuationMorphism}(a, b)$, if the displayed tail of $morph$ is zero-headed, then the target cannot be history-same to* e*:*

$$\mathsf{hsame}(\mathsf{tail}(morph), \mathsf{e0}(m)) \Longrightarrow \mathsf{hsame}(b, \mathsf{e}) \Longrightarrow \mathsf{False}.$$

Proof. The zero-headed tail case exposes a zero-headed target presentation $b = \mathsf{e0}(r)$ for some residual history r. If b were history-same to e, constructor separation would force $\mathsf{e0}(r)\mathsf{hsamee}$, which is impossible. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 tail target not empty`

Theorem 61.158 (Continuation morphism composite left visible tail empty absurd)**.** *For histories a, b, c, m, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If the left displayed tail is a visible constructor, then the canonical composite displayed tail cannot be history-same to* e*:*

$$\mathsf{hsame}(\mathsf{tail}(left), \mathsf{e0}(m)) \Longrightarrow \mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \Longrightarrow \mathsf{False}$$

and

$$\mathsf{hsame}(\mathsf{tail}(left), \mathsf{e1}(m)) \Longrightarrow \mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \Longrightarrow \mathsf{False}.$$

Proof. Unpack both continuation morphism records. The composite tail is the kernel append of the left displayed tail with the right displayed tail. If this append were empty, append-empty inversion would force the left displayed tail itself to be e. This contradicts constructor separation for either $\mathsf{e0}(m)$ or $\mathsf{e1}(m)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp left visible tail empty absurd`

Lemma 61.159 (Continuation morphism composite right visible bridge determinacy)**.** *For histories a, b, c, m, let $left$ and $right$ be continuation morphisms from a to b and from b to c, respectively. Choose local history witnesses z, o, r_0, r_1, q such that z is the zero-headed history with payload m, o is the one-headed history with payload m, r_0 names the zero-headed right displayed tail of $right$, r_1 names the one-headed right displayed tail of $right$, and q names the displayed tail of the composite $left \circ right$. The consumer-facing surface for a composite whose right displayed tail is visible is determined by the following finite local rows:*

$$\mathsf{hsame}(r_0, z) \Longrightarrow \mathsf{hsame}(q, \mathsf{e}) \Longrightarrow \bot,$$
$$\mathsf{hsame}(r_1, o) \Longrightarrow \mathsf{hsame}(q, \mathsf{e}) \Longrightarrow \bot,$$
$$\mathsf{hsame}(r_1, o) \Longrightarrow \mathsf{hsame}(c, \mathsf{e}) \Longrightarrow \bot.$$

Consequently every consumer-facing use of the composite-tail empty coordinate is certified by either the zero-headed or one-headed composite-tail refusal row of Definition 61.155, and the one-headed target case is certified by Definition 61.156. No consumer-facing bridge coordinate is available for a detached empty composite tail, a detached empty target, a hidden payload classifier, an independent left-tail inspection, host equality of composites, or an off-packet boundary.

Proof. The visible right-tail packet has two displayed constructor branches, and the chosen witnesses expose those branches as bound history names. In the zero-headed branch, the available row is

$$\mathsf{hsame}(r_0, z).$$

The first projection of Definition 61.155, read with witness r_0 for the right displayed tail, witness z for its zero-headed shape, and witness q for the composite displayed tail, is exactly the refusal

$$\mathsf{hsame}(q, \mathsf{e}) \Longrightarrow \bot.$$

Thus any consumer use that tries to consume the zero-headed right-tail branch as an empty composite tail is blocked by that local refusal. The row exposes no target-empty conclusion and no additional payload coordinate.

In the one-headed branch, the available row is

$$\mathsf{hsame}(r_1, o).$$

The second projection of Definition 61.155, read with witness r_1 for the right displayed tail, witness o for its one-headed shape, and witness q for the composite displayed tail, is exactly the composite-tail refusal

$$\mathsf{hsame}(q, \mathsf{e}) \Longrightarrow \bot,$$

so every consumer use of the one-headed branch as a composite-tail empty claim is blocked by that row. The same one-headed right-tail row is also the exact input of Definition 61.156, which produces the target-empty refusal

$$\mathsf{hsame}(c, \mathsf{e}) \Longrightarrow \bot.$$

Thus every one-headed target-empty claim is blocked by the cited target-not-empty row.

These three implications exhaust the bridge surface named by the local rows. The first two rows cover all visible right-tail cases leading to the composite-tail empty obstruction, and the third row covers the only target-empty obstruction available from the one-headed right-tail branch. None of

the cited rows has a premise or conclusion mentioning a detached empty composite-tail coordinate, a detached empty target coordinate, a hidden payload classifier, an independent left-tail inspection, host equality of composites, or an off-packet boundary. Such a coordinate therefore has no local row through which a consumer can read the composite right-visible bridge. □

Corollary 61.160 (Continuation morphism composite right visible consumer determinacy)**.** *For histories a, b, c, m, let $left$ and $right$ be continuation morphisms from a to b and from b to c, respectively. Choose local history witnesses z, o, r_0, r_1, q as in Definition 61.159. Once the right-visible local rows*

$$\mathsf{hsame}(r_0, z) \Longrightarrow \mathsf{hsame}(q, \mathsf{e}) \Longrightarrow \bot,$$
$$\mathsf{hsame}(r_1, o) \Longrightarrow \mathsf{hsame}(q, \mathsf{e}) \Longrightarrow \bot,$$
$$\mathsf{hsame}(r_1, o) \Longrightarrow \mathsf{hsame}(c, \mathsf{e}) \Longrightarrow \bot$$

are fixed, every accepted consumer-facing use of the composite right-visible surface has the same chapter-named finite data. A composite-tail empty use must factor through the zero-headed or one-headed refusal supplied by Definition 61.155; a one-headed target-empty use must factor through Definition 61.156; and any normal form or exactness decision exposed to a consumer is one of those three displayed refusals. Thus two accepted consumers over the same fixed rows cannot choose different finite routes, different right-visible normal forms, or different exactness decisions, and no accepted use can introduce a detached empty composite tail, detached empty target, alternate hidden coordinate, duplicate classifier source, independent left-tail inspection, host equality of composites, or off-packet boundary.

Proof. Apply Definition 61.159. The lemma lists the complete consumer-facing bridge surface for a composite whose right displayed tail is visible. Its first two rows are exactly the zero-headed and one-headed routes from a right-tail constructor row to the refusal of $\mathsf{hsame}(q, \mathsf{e})$, and those two routes are the two projections of Definition 61.155. Hence any accepted consumer use that asks for an empty composite-tail coordinate has one of these two finite routes as its normal form.

The same bridge determinacy lemma also identifies the only target-empty route available from the visible right-tail packet. It is the one-headed row $\mathsf{hsame}(r_1, o)$ followed by Definition 61.156, which refuses $\mathsf{hsame}(c, \mathsf{e})$. With the three displayed rows fixed, this fixes the one-headed target-empty exactness decision as the third displayed refusal, and there is no separate target-empty route in the zero-headed branch.

It remains to rule out competing consumer choices. The cited determinacy lemma states that the bridge exports no detached empty composite-tail coordinate, no detached empty target coordinate, no hidden payload classifier, no independent left-tail inspection, no host equality of composites, and no off-packet boundary. A duplicate classifier source or any further hidden coordinate would therefore have to be an additional row outside the three displayed refusals. Such a row is not a premise or conclusion of the local bridge surface and has no factor through the cited tail-empty or target-not-empty theorems. It is therefore not an accepted route, normal form, or exactness decision for this composite right-visible surface. □

Theorem 61.161 (Continuation morphism composite tail empty endpoint iff)**.** *For histories a, b, c, let $left : a \to b$ and $right : b \to c$ be continuation morphisms. The canonical composite has displayed tail history-same to e if and only if the two adjacent endpoint comparisons hold:*

$$\mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \Longleftrightarrow \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. Combine the composite tail-empty equivalence with the single-morphism tail-empty endpoint equivalence for the left and right factors. The forward direction projects the two empty

component tails and converts them to endpoint comparisons. The reverse direction converts the two endpoint comparisons back to empty component tails and then rebuilds the empty composite tail. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail empty endpoint iff`

Theorem 61.162 (Continuation morphism composite endpoint cycle has empty tail)**.** *For histories a, b, c, let $left : a \to b$ and $right : b \to c$ be continuation morphisms. If the composite endpoints satisfy $\mathsf{hsame}(a, c)$, then the canonical composite displayed tail is empty:*

$$\mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}).$$

Proof. The composite continuation morphism stores a concrete continuation from a through its displayed tail to c. Transport the result endpoint along $\mathsf{hsame}(a, c)$ to obtain a continuation from a through the same displayed tail back to a. The kernel right-unit uniqueness theorem then forces that displayed tail to be e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp endpoint cycle tail empty`

Theorem 61.163 (Continuation morphism composite endpoint cycle tail empty iff)**.** *For histories a, b, c, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$ be continuation morphisms. Then the outer endpoints close exactly when the canonical composite displayed tail is empty:*

$$\mathsf{hsame}(a, c) \iff \mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}).$$

Proof. The forward implication is the endpoint-cycle empty-tail theorem. Conversely, if the composite tail is empty, transport the stored continuation relation $\mathsf{Cont}(a, \mathsf{tail}(left \circ right), c)$ across that empty-tail comparison to obtain $\mathsf{Cont}(a, \mathsf{e}, c)$. Determinacy against the right-unit continuation $\mathsf{Cont}(a, \mathsf{e}, a)$ identifies c with a, hence $a\mathsf{hsame}c$ by symmetry. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp endpoint cycle tail empty iff`

Theorem 61.164 (Continuation morphism composite source empty tail target iff)**.** *For histories a, b, c, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$ be continuation morphisms. The source is empty exactly when the canonical composite displayed tail is the target:*

$$\mathsf{hsame}(a, \mathsf{e}) \iff \mathsf{hsame}(\mathsf{tail}(left \circ right), c).$$

Proof. If $a\mathsf{hsame}\mathsf{e}$, the stored composite continuation ledger has empty source. The left-unit result law therefore identifies the target with the composite tail, and symmetry gives the displayed tail-target comparison.

Conversely, transport the stored composite continuation ledger along the tail-target comparison to obtain $\mathsf{Cont}(a, c, c)$. Comparing this ledger with the canonical left-unit continuation $\mathsf{Cont}(\mathsf{e}, c, c)$ by right cancellation identifies a with e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp source empty tail target iff`

Lemma 61.165 (Continuation morphism composite endpoint cycle bridge determinacy)**.** *For histories a, b, c, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$ be continuation morphisms, and write $T = \mathsf{tail}(left \circ right)$ for the canonical composite displayed tail.*

The consumer-facing endpoint-cycle bridge for this composite is determined by exactly the two local rows

$$\mathsf{hsame}(a, c) \Longleftrightarrow \mathsf{hsame}(T, \mathsf{e})$$

and

$$\mathsf{hsame}(a, \mathsf{e}) \Longleftrightarrow \mathsf{hsame}(T, c).$$

Thus every accepted route, transport, readback, or handoff through the composite endpoint-cycle surface factors through either Definition 61.163 or Definition 61.164, together with the stored composite continuation ledger $\mathsf{Cont}(a, T, c)$*. No accepted consumer obtains an independent endpoint-cycle flag, an independent source-empty flag, a primitive host composite, a second tail classifier, or any bridge coordinate not listed by these two rows.*

Proof. The displayed composite contributes one tail coordinate, namely T, and one stored continuation ledger, namely $\mathsf{Cont}(a, T, c)$. The endpoint-cycle row of Definition 61.163 says that reading the outer endpoint comparison $\mathsf{hsame}(a, c)$ is exactly the same consumer operation as reading the empty-tail comparison $\mathsf{hsame}(T, \mathsf{e})$. Hence a route that starts from endpoint closure factors by applying the forward implication of that row, while a route that starts from an empty composite tail factors by applying the reverse implication. A transport or handoff along this branch has no further datum: the stored ledger $\mathsf{Cont}(a, T, c)$ is transported across $\mathsf{hsame}(T, \mathsf{e})$ by Definition 4.41 to $\mathsf{Cont}(a, \mathsf{e}, c)$, and determinacy against the right-unit continuation is precisely the reverse direction already recorded by the same row.

The source-empty row of Definition 61.164 gives the second and only other consumer-facing comparison. Reading $\mathsf{hsame}(a, \mathsf{e})$ is exactly the same operation as reading the tail-target comparison $\mathsf{hsame}(T, c)$. Thus a source-empty route factors through the forward implication of that row, and a tail-target readback factors through the reverse implication. The corresponding handoff again uses only the stored composite ledger: transport $\mathsf{Cont}(a, T, c)$ along $\mathsf{hsame}(T, c)$ by Definition 4.41 to obtain $\mathsf{Cont}(a, c, c)$, then compare with the left-unit continuation as in the cited row.

These two cases exhaust the bridge surface. The first row exposes the endpoint-cycle/empty-tail coordinate, and the second row exposes the source-empty/tail-target coordinate. Both use the same displayed tail T and the same stored composite continuation ledger. None of the rows contains a primitive host composite, a second classifier for T, an endpoint-cycle flag separate from $\mathsf{hsame}(T, \mathsf{e})$, a source-empty flag separate from $\mathsf{hsame}(T, c)$, or any detached bridge coordinate. Therefore every accepted consumer-facing route, transport, readback, or handoff factors through the listed local rows, and unlisted bridge coordinates remain unavailable. □

Corollary 61.166 (Continuation morphism composite endpoint cycle consumer determinacy)**.** *For histories* a, b, c*, let* $left : \mathsf{ContinuationMorphism}(a, b)$ *and* $right : \mathsf{ContinuationMorphism}(b, c)$ *be continuation morphisms, and write* $T = \mathsf{tail}(left \circ right)$ *for the canonical composite displayed tail. Once the endpoint-cycle bridge rows of Definition 61.165 are fixed, every accepted consumer-facing use of the composite endpoint-cycle surface has only the chapter-named finite route, normal-form read, and exactness decision:*

$$\mathsf{hsame}(a, c) \Longleftrightarrow \mathsf{hsame}(T, \mathsf{e}),$$
$$\mathsf{hsame}(a, \mathsf{e}) \Longleftrightarrow \mathsf{hsame}(T, c).$$

Thus the endpoint-cycle decision is read through the empty-tail normal form $\mathsf{hsame}(T, \mathsf{e})$*, the source-empty decision is read through the tail-target normal form* $\mathsf{hsame}(T, c)$*, and no accepted consumer can introduce an alternate hidden coordinate or a duplicate classifier source for the composite.*

Proof. By Definition 61.165, the composite exposes exactly one displayed tail coordinate T and one stored composite continuation ledger $\mathsf{Cont}(a, T, c)$ to the endpoint-cycle bridge. The same lemma lists the complete bridge interface as the two rows $\mathsf{hsame}(a, c) \iff \mathsf{hsame}(T, \mathsf{e})$ and $\mathsf{hsame}(a, \mathsf{e}) \iff \mathsf{hsame}(T, c)$, and states that every accepted route, transport, readback, or handoff through the composite factors through one of those rows together with the stored ledger.

The first row is the finite endpoint-cycle route. Its normal-form read is the empty-tail comparison $\mathsf{hsame}(T, \mathsf{e})$, and its exactness decision is precisely the equivalence with the outer endpoint comparison $\mathsf{hsame}(a, c)$ supplied by Definition 61.163. Hence two accepted consumers of the endpoint-cycle decision cannot disagree without leaving that row: both must read the same displayed tail T, transport the same ledger $\mathsf{Cont}(a, T, c)$, and decide the same comparison $\mathsf{hsame}(T, \mathsf{e})$.

The second row is the finite source-empty route. By Definition 61.164, its normal-form read is the tail-target comparison $\mathsf{hsame}(T, c)$, and its exactness decision is precisely the equivalence with $\mathsf{hsame}(a, \mathsf{e})$. Therefore any accepted consumer that claims a source-empty readback also factors through the same displayed tail T and the same ledger $\mathsf{Cont}(a, T, c)$, with no second source from which the classifier could be recomputed.

These two rows exhaust the bridge surface by Definition 61.165. A consumer-facing use that selects a finite route must select one of the two chapter routes; a use that selects a normal form must select either $\mathsf{hsame}(T, \mathsf{e})$ or $\mathsf{hsame}(T, c)$; and a use that selects an exactness decision must select the corresponding displayed equivalence. Since the bridge exports no primitive host composite, no second tail classifier, and no coordinate outside those rows, alternate hidden coordinates and duplicate classifier sources are not accepted. □

Theorem 61.167 (Continuation morphism endpoint cycle boundary)**.** *For histories $a, b, c : \mathsf{BHist}$, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$. If the outer endpoints close as $\mathsf{hsame}(a, c)$, then both displayed tails and both adjacent endpoint pairs collapse:*

$$\mathsf{hsame}(\mathsf{tail}(left), \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(right), \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. Transport the right continuation relation across the outer endpoint comparison to obtain a return continuation from b to a. Mutual-extension empty-tail inversion applied to the left relation and this transported return relation forces both displayed tails to be empty. Transporting each original relation along its empty tail and comparing with the corresponding right-unit continuation gives the adjacent endpoint comparisons. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp endpoint cycle boundary`

Theorem 61.168 (Continuation morphism endpoint cycle boundary iff)**.** *For histories $a, b, c : \mathsf{BHist}$, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$. The outer endpoints close exactly when both displayed tails are empty and both adjacent endpoint pairs collapse:*

$$\mathsf{hsame}(a, c) \iff \mathsf{hsame}(\mathsf{tail}(left), \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(right), \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. The forward implication is the endpoint-cycle boundary theorem. Conversely, compose the adjacent endpoint comparisons $\mathsf{hsame}(a, b)$ and $\mathsf{hsame}(b, c)$ to obtain $\mathsf{hsame}(a, c)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp endpoint cycle boundary iff`

Lemma 61.169 (Continuation morphism endpoint-cycle bridge determinacy)**.** *For histories $a, b, c : \mathsf{BHist}$, let $left : a \to b$ and $right : b \to c$ be continuation morphisms, and write $\ell : \mathsf{BHist}$ and*

$r : \mathsf{BHist}$ *for the left and right continuation-tail history witnesses associated to* $left$ *and* $right$*. The consumer-facing endpoint-cycle bridge for this composable pair is determined by the outer endpoint row and the four local boundary rows*

$$\mathsf{hsame}(\ell, \mathsf{e}), \qquad \mathsf{hsame}(r, \mathsf{e}), \qquad \mathsf{hsame}(a, b), \qquad \mathsf{hsame}(b, c).$$

Concretely, every accepted route, transport, readback, or handoff from the outer cycle to boundary data factors through the projection supplied by Definition 61.167, with transport constrained by Definition 61.319, and every accepted route, transport, readback, or handoff from boundary data back to the outer cycle factors through the reverse implication supplied by Definition 61.168, with the same transport constraint. Hence the bridge exports exactly the equivalence

$$\mathsf{hsame}(a, c) \iff \mathsf{hsame}(\ell, \mathsf{e}) \wedge \mathsf{hsame}(r, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c),$$

and it exports no separate composite-tail coordinate, alternate middle endpoint coordinate, hidden continuation tail, ambient category carrier, host equality, or external handoff.

Proof. Assume first that a consumer reads the bridge from the outer endpoint cycle. The only local theorem with that source row is Definition 61.167. Applying it to $left$, $right$, and the row $\mathsf{hsame}(a, c)$ gives precisely the four displayed boundary rows: the empty left tail, the empty right tail, the source-middle endpoint comparison, and the middle-target endpoint comparison. Any route, transport, readback, or handoff that starts from the outer cycle and reaches consumer boundary data is therefore one of these four projections, or a repackaging of their conjunction, with its transport component governed by Definition 61.319.

Conversely, assume that a consumer starts from the four displayed boundary rows. The reverse direction of Definition 61.168 composes the adjacent endpoint comparisons $\mathsf{hsame}(a, b)$ and $\mathsf{hsame}(b, c)$ and returns exactly the outer endpoint row $\mathsf{hsame}(a, c)$. Thus any readback from the boundary packet to the endpoint cycle factors through that reverse implication.

The forward boundary theorem and the two-way boundary theorem mention no data beyond $\mathsf{hsame}(a, c)$ and the four displayed rows. A proposed coordinate outside this list is not a conjunct produced by the forward theorem and is not a premise consumed by the reverse direction of the equivalence. Such a coordinate has no local factor through which this endpoint-cycle bridge can expose it to a consumer. □

Corollary 61.170 (Continuation morphism endpoint-cycle boundary consumer determinacy)**.** *For histories* $a, b, c : \mathsf{BHist}$*, let* $left : a \to b$ *and* $right : b \to c$ *be continuation morphisms, and let* $\ell : \mathsf{BHist}$ *and* $r : \mathsf{BHist}$ *be their associated left and right continuation-tail witnesses. Once the outer endpoint cycle row and the four boundary rows*

$$\mathsf{hsame}(a, c), \qquad \mathsf{hsame}(\ell, \mathsf{e}), \qquad \mathsf{hsame}(r, \mathsf{e}), \qquad \mathsf{hsame}(a, b), \qquad \mathsf{hsame}(b, c)$$

are fixed, every accepted consumer-facing use of this endpoint-cycle boundary surface has the same chapter-named finite data. In the outward direction the route is the projection of the four boundary rows supplied by Definition 61.167; in the readback direction the route is the reverse implication of Definition 61.168; and every normal form or exactness decision exposed to a consumer is one of those five rows or their displayed conjunction

$$\mathsf{hsame}(a, c) \iff \mathsf{hsame}(\ell, \mathsf{e}) \wedge \mathsf{hsame}(r, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Thus two accepted consumers over the same fixed rows cannot choose different finite routes, different boundary normal forms, or different exactness decisions, and no accepted use can introduce an unlisted hidden coordinate, ambient category carrier, host equality, or external handoff.

Proof. The endpoint-cycle bridge determinacy lemma lists the complete consumer-facing surface for the composable pair. Its outward clause says that any accepted route, transport, readback, or handoff starting from the outer endpoint cycle factors through the projection supplied by Definition 61.167. That theorem has exactly one displayed boundary packet for the fixed pair: the empty left tail row, the empty right tail row, the source-middle endpoint row, and the middle-target endpoint row. Hence every outward consumer route has the same finite target packet and the same boundary normal form.

The same lemma also gives the only accepted readback from boundary data to the outer cycle: it factors through the reverse implication of Definition 61.168. With the four boundary rows fixed, that reverse implication returns exactly the row $\mathsf{hsame}(a, c)$, so every readback normal form and exactness decision about the endpoint cycle is determined by the same displayed equivalence.

It remains to exclude further consumer choices. By Definition 61.169, the bridge exports no separate composite-tail coordinate, no alternate middle endpoint coordinate, no hidden continuation tail, no ambient category carrier, no host equality, and no external handoff. A proposed consumer coordinate outside the five fixed rows is therefore neither a conjunct produced by the forward boundary theorem nor a premise consumed by the reverse readback. It has no local factor through the endpoint-cycle boundary bridge, so it is not an accepted route, normal form, or exactness decision for this surface. □

Theorem 61.171 (Continuation morphism composite tail continuation)**.** *For histories a, b, c, let $left : a \to b$ and $right : b \to c$ be continuation morphisms. The canonical composite tail is itself the continuation composite of the two displayed tails, and it also carries the endpoint continuation from a to c:*

$$\mathsf{Cont}(\mathsf{tail}(left), \mathsf{tail}(right), \mathsf{tail}(left \circ right)) \wedge \mathsf{Cont}(a, \mathsf{tail}(left \circ right), c).$$

Proof. Unpack the two morphism records. The closed composite stores $\mathsf{append}(\mathsf{tail}(left), \mathsf{tail}(right))$ as its displayed tail, giving the first continuation directly. Its record field is exactly the second continuation from a through that composite tail to c. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail cont`

Theorem 61.172 (Continuation morphism tail factorization transport continuation)**.** *For continuation morphisms $left : a \to b$ and $right : b \to c$, if displayed tails l and r classify the two component tails, then the canonical composite tail is the continuation product of l and r:*

$$\mathsf{hsame}(\mathsf{tail}(left), l) \Longrightarrow \mathsf{hsame}(\mathsf{tail}(right), r) \Longrightarrow \mathsf{Cont}(l, r, \mathsf{tail}(left \circ right)).$$

Proof. The composite-tail continuation theorem gives $\mathsf{Cont}(\mathsf{tail}(left), \mathsf{tail}(right), \mathsf{tail}(left \circ right))$. Transport this continuation along the two tail classifier witnesses and keep the composite result endpoint fixed. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism tail factorization transport cont`

Theorem 61.173 (Continuation morphism composite tail congruence)**.** *For continuation morphisms $left : \mathsf{ContinuationMorphism}(a, b)$, $right : \mathsf{ContinuationMorphism}(b, c)$, $left' : \mathsf{ContinuationMorphism}(a', b')$, and $right' : \mathsf{ContinuationMorphism}(b', c')$, if the two displayed left tails are* hsame *and the two displayed right tails are* hsame*, then both canonical composite tails are recorded by their displayed continuation ledgers and the two composite tails are* hsame*.*

Proof. Use the composite-tail continuation theorem for the two pairs of morphisms to obtain both displayed continuation ledgers. Then unpack the four morphism records. The closed composite tail is the append of the two displayed tails, so the two given tail-sameness witnesses reduce the final equality to reflexivity of the common append expression. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail hsame congruence`

Theorem 61.174 (Continuation morphism composition right factor)**.** *For histories a, b, c and a displayed tail r, let $left : a \to b$ and $composite : a \to c$ be continuation morphisms. If the tail of $composite$ is displayed as the continuation composite of the tail of $left$ with r, then r is the tail of a continuation morphism from b to c.*

Proof. Unpack the left and composite continuation morphisms into their displayed tails and continuation witnesses. The three continuation ledgers reduce the claim to the associativity law for BEDC history append, giving the displayed continuation from b through r to c. □

Lean4 (definition) `BEDC.Derived.CategoryUp.ContinuationMorphism comp right factor`

Theorem 61.175 (Continuation morphism right factor reconstruction)**.** *For histories a, b, c and a displayed tail r, let $left : a \to b$ and $composite : a \to c$ be continuation morphisms. If the tail of $composite$ is displayed as the continuation composite of the tail of $left$ with r, then composing $left$ with the recovered right factor reconstructs the displayed tail of $composite$ up to* hsame*.*

Proof. The recovered right factor has tail r by construction. The closed composition therefore has tail $\mathsf{append}(\mathsf{tail}(left), r)$, and the supplied tail factorization identifies this append with $\mathsf{tail}(composite)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp right factor reconstructs`

Theorem 61.176 (Continuation morphism right factor tail uniqueness)**.** *For histories a, b, c and a displayed tail r, let $left : a \to b$ and $composite : a \to c$ be continuation morphisms. If the tail of $composite$ is displayed as the continuation composite of the tail of $left$ with r, and $right : b \to c$ is another continuation morphism, then r is history-same as the displayed tail of $right$.*

Proof. Unpack the three continuation morphism records. The left witness, the tail factorization, and the composite witness reassociate to a continuation witness from b through r to c. This witness and the witness of $right$ have the same source and result, so continuation left cancellation identifies their tails. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp right factor tail hsame`

Theorem 61.177 (Continuation morphism composite middle-tail readback)**.** *For histories a, b, b', c, let $left : a \to b$, $right : b' \to c$, and $composite : a \to c$ be continuation morphisms. If the tail of $composite$ is displayed as the continuation composite of the tails of $left$ and $right$, then*

$$\mathsf{hsame}(b, b') \wedge \mathsf{hsame}\big(\mathsf{append}(\mathsf{tail}(left), \mathsf{tail}(right)), \mathsf{tail}(composite)\big).$$

Proof. Unpack the left and composite continuation morphism records. The left witness, the displayed tail factorization, and the composite witness reassociate to a continuation witness from b through the tail of $right$ to c. Comparing this recovered witness with $right$ by continuation right cancellation gives $\mathsf{hsame}(b, b')$. The displayed tail factorization itself gives the readback of the appended tail against the composite tail. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp middle tail readback`

Definition 61.178 (Continuation morphism composite left factor)**.** *For histories a, b, c and a displayed tail l, let right $: b \to c$ and composite $: a \to c$ be continuation morphisms. If the tail of composite is displayed as the continuation composite of l with the tail of right, then l is the tail of a continuation morphism from a to b.*

Proof. Unpack the right and composite continuation morphism records. The displayed tail composite and the composite morphism witness reduce the target to the kernel composite-left-factor theorem for Cont, which transports the reflexive left-tail continuation across the recovered middle endpoint. □

Lean4 (definition) `BEDC.Derived.CategoryUp.ContinuationMorphism comp left factor`

Theorem 61.179 (Continuation morphism left factor reconstruction)**.** *For histories a, b, c and a displayed tail l, let right $: b \to c$ and composite $: a \to c$ be continuation morphisms. If the tail of composite is displayed as the continuation composite of l with the tail of right, then composing the recovered left factor with right reconstructs the displayed tail of composite up to* hsame*.*

Proof. The recovered left factor has tail l by construction. The closed composition therefore has tail $\mathsf{append}(l, \mathsf{tail}(right))$, and the supplied tail factorization identifies this append with $\mathsf{tail}(composite)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp left factor reconstructs`

Theorem 61.180 (Continuation morphism left factor tail uniqueness)**.** *For histories a, b, c and a displayed tail l, let right $: b \to c$ and composite $: a \to c$ be continuation morphisms. If the tail of composite is displayed as the continuation composite of l with the tail of right, and $left : a \to b$ is another continuation morphism, then l is history-same as the displayed tail of $left$.*

Proof. Unpack the continuation morphism records. The right witness, the displayed tail factorization, and the composite witness recover a continuation witness from a through l to b. This witness and the witness of $left$ share the same source and result, so continuation left cancellation identifies their tails. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp left factor tail hsame`

Theorem 61.181 (Continuation morphism identity tail)**.** *For histories a, b and a continuation morphism $m : a \to b$, composing m with the empty identity tail on either side leaves its displayed tail history-same to the tail of m:*

$$\mathsf{hsame}\big(\mathsf{tail}(\mathsf{id}_a \circ m), \mathsf{tail}(m)\big) \wedge \mathsf{hsame}\big(\mathsf{tail}(m \circ \mathsf{id}_b), \mathsf{tail}(m)\big).$$

Proof. Unpack the continuation morphism into its tail and continuation witness. The left identity composite has tail $\mathsf{append}(\mathsf{Empty}, \mathsf{tail})$, and the right identity composite has tail $\mathsf{append}(\mathsf{tail}, \mathsf{Empty})$. The two BEDC append unit laws identify both with the original tail. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism identity tail hsame`

Theorem 61.182 (Continuation morphism associative composition closure)**.** *For histories a, b, c, d, any continuation morphisms $a \to b$, $b \to c$, and $c \to d$ admit both associated composite morphisms $a \to d$, and the two composite tails are internally the same.*

Proof. Unpack the three morphism records into their tails and continuation witnesses. The left-associated composite tail is $\mathsf{append}(\mathsf{append}(f, g), h)$; the right-associated composite tail is $\mathsf{append}(f, \mathsf{append}(g, h))$. The continuation witnesses reduce to associativity of BEDC history append, and the tail comparison is exactly the same associativity equality. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp assoc closed`

Theorem 61.183 (Continuation morphism associative composite tail)**.** *For histories a, b, c, d, any continuation morphisms $a \to b$, $b \to c$, and $c \to d$ have left-associated and right-associated canonical composite tails that are history-same:*

$$\mathsf{hsame}\left(\mathsf{tail}((first \circ second) \circ third), \mathsf{tail}(first \circ (second \circ third))\right).$$

Proof. Unpack the three continuation morphisms into their displayed tails. The two canonical composite tails reduce to $\mathsf{append}(\mathsf{append}(f, g), h)$ and $\mathsf{append}(f, \mathsf{append}(g, h))$, which are identified by BEDC history append associativity. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp assoc tail hsame`

Theorem 61.184 (Category hom carrier morphism determinacy)**.** *For the unary-continuation category, if f and g are both hom-carriers from a to b, then* $\mathsf{hsame}(f, g)$*.*

Proof. Unpack both hom-carrier witnesses. Their continuation fields have the same source a and result b, so continuation left-context cancellation identifies the two morphism histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier morphism deterministic`

Theorem 61.185 (Category hom carrier endpoint-hsame morphism determinacy)**.** *For the unary-continuation category, if the source endpoints classify together and the target endpoints classify together, then any two displayed hom-carrier morphisms over those classified endpoints also classify together.*

Proof. Case-reduce the source and target hsame witnesses. The two hom-carrier witnesses then share exactly the same endpoints, so Definition 61.184 identifies their morphism histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier endpoint hsame morphism deterministic`

Theorem 61.186 (Category hom carrier target determinacy)**.** *For the unary-continuation category, if a fixed morphism history f is a hom-carrier from a to b and also from a to c, then* $\mathsf{hsame}(b, c)$*.*

Proof. Unpack both hom-carrier witnesses. Their continuation fields have the same source a and morphism tail f, so continuation result determinacy identifies the two target histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier target deterministic`

Theorem 61.187 (Category empty-source morphism target determinacy)**.** *For the unary-continuation category, if two hom-carriers share the empty source and their morphism histories are the same up to* hsame*, then their target histories are the same up to* hsame*:*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, b, f) \to \mathsf{CategoryHomCarrier}(\mathsf{e}, c, g) \to \mathsf{hsame}(f, g) \to \mathsf{hsame}(b, c).$$

Proof. Transport the second empty-source hom-carrier across the morphism sameness so that both hom-carriers use the same morphism history. Category hom-carrier target determinacy then identifies the two targets. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source morphism target deterministic`

Theorem 61.188 (Category empty-source target morphism swap)**.** *For histories* $b, f : \mathsf{BHist}$*, an empty-source hom-carrier is unchanged when its target and morphism fields are exchanged:*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, b, f) \iff \mathsf{CategoryHomCarrier}(\mathsf{e}, f, b).$$

Proof. Empty-source exactness rewrites the left side as unary membership of b together with $\mathsf{hsame}(f, b)$. Transport unary membership across this sameness to obtain unary membership of f, reverse the endpoint classifier, and apply empty-source exactness again. The converse is the same argument with b and f exchanged. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source target morphism swap iff`

Theorem 61.189 (Category empty-target source morphism swap)**.** *For histories* $a, f : \mathsf{BHist}$*, a hom-carrier into the empty target is unchanged when its source and morphism fields are exchanged:*

$$\mathsf{CategoryHomCarrier}(a, \mathsf{e}, f) \iff \mathsf{CategoryHomCarrier}(f, \mathsf{e}, a).$$

Proof. Empty-target exactness rewrites the left side as the pair $\mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(f, \mathsf{e})$. Swapping the two components gives the empty-target classifier data for the exchanged hom-carrier. The converse is the same component swap in the other direction. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty target source morphism swap iff`

Theorem 61.190 (Category empty-target morphism source determinacy)**.** *For the unary-continuation category, if two hom-carriers share the empty target and their morphism histories are the same up to* hsame*, then their source histories are the same up to* hsame*:*

$$\mathsf{CategoryHomCarrier}(a, \mathsf{e}, f) \to \mathsf{CategoryHomCarrier}(b, \mathsf{e}, g) \to \mathsf{hsame}(f, g) \to \mathsf{hsame}(a, b).$$

Proof. Transport the second empty-target hom-carrier across the morphism sameness so that both hom-carriers use the same morphism history. Category hom-carrier source determinacy then identifies the two sources. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty target morphism source deterministic`

Corollary 61.191 (Category empty-source swap consumer determinacy)**.** *For histories* $b, f, c, g : \mathsf{BHist}$*, suppose an accepted empty-source hom-carrier fixes the target and morphism rows by*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, b, f).$$

If a consumer-facing use of the same packet reads the target row b *and the morphism row* f *through empty-target hom-carriers,*

$$\mathsf{CategoryHomCarrier}(c, \mathsf{e}, b) \quad \textit{and} \quad \mathsf{CategoryHomCarrier}(g, \mathsf{e}, f),$$

then the two consumer source coordinates are forced to be the same:

$$\mathsf{hsame}(c, g).$$

Consequently the empty-source target–morphism swap of Definition 61.188 has only the finite route, normal-form read, and exactness decision already displayed by the chapter: an accepted consumer cannot introduce an alternate hidden coordinate or a duplicate classifier source for the swapped target and morphism fields.

Proof. Apply Definition 61.188 to the displayed empty-source carrier. The same packet also admits the swapped read

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, f, b).$$

The empty-source exactness row used in that swap reads the original carrier as unary membership of b together with the endpoint classifier $\mathsf{hsame}(f, b)$; by symmetry this gives $\mathsf{hsame}(b, f)$. Now apply Definition 61.190 to the two empty-target carriers $\mathsf{CategoryHomCarrier}(c, \mathsf{e}, b)$ and $\mathsf{CategoryHomCarrier}(g, \mathsf{e}, f)$, using $\mathsf{hsame}(b, f)$ as the morphism comparison. It identifies their source histories, giving $\mathsf{hsame}(c, g)$. Thus every accepted consumer read factors through the displayed empty-source swap row and the two empty-target readback rows; no unlisted coordinate remains from which a second source classifier could be read. □

Theorem 61.192 (Category hom carrier source determinacy)**.** *For the unary-continuation category, if a fixed morphism history f is a hom-carrier from a to c and also from b to c, then* $\mathsf{hsame}(a, b)$*.*

Proof. Unpack both hom-carrier witnesses. Their continuation fields have the same morphism tail f and result c, so continuation right-context cancellation identifies the two source histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier source deterministic`

Theorem 61.193 (Continuation morphism nonempty tail shape cases)**.** *For histories $a, b : \mathsf{BHist}$ and a continuation morphism $m : \mathsf{ContinuationMorphism}(a, b)$, a displayed tail that is not internally empty must be visible in one of the two history constructors:*

$$(\mathsf{hsame}(\mathsf{tail}(m), \mathsf{e}) \to \mathsf{False}) \Longrightarrow (\exists t : \mathsf{BHist}.\ \mathsf{tail}(m) = \mathsf{E0}(t)) \vee (\exists t : \mathsf{BHist}.\ \mathsf{tail}(m) = \mathsf{E1}(t)).$$

Proof. Unpack the continuation morphism only to expose its displayed tail, then case-analyze that history. The empty branch contradicts the nonempty hypothesis by reflexivity of hsame at e. The zero-headed and one-headed branches return the corresponding visible payload. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism tail nonempty shape cases`

Theorem 61.194 (Category associative empty result components)**.** *For composable category hom-carriers f, g, h with both associated composite ledgers displayed as $left$ and $right$, if the same source and target endpoints also carry the empty hom-carrier, then both associated composite histories are* hsame *to* e*, and the source and target endpoints are* hsame*-equal.*

Proof. Apply displayed associativity determinacy using the empty hom-carrier as the displayed comparison target. This identifies both bracketed composite histories with e. Empty identity hom-carrier exactness reads the same displayed empty carrier back as the endpoint equality $a\mathsf{hsame}d$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp assoc empty result components`

Theorem 61.195 (Continuation morphism empty-source one-headed target tail iff)**.** *For histories $r, k : \mathsf{BHist}$ and a continuation morphism $m : \mathsf{ContinuationMorphism}(\mathsf{e}, \mathsf{E1}(r))$, the displayed tail of m has one-headed payload k exactly when the target payload is k:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E1}(k)) \Longleftrightarrow \mathsf{hsame}(r, k).$$

Proof. The empty-source tail target exactness identifies $\mathsf{tail}(m)$ with $\mathsf{E1}(r)$. In the forward direction, compose this equality with the displayed tail equality and invert the one-headed constructor. Conversely, lift $r\mathsf{hsame}k$ through the one-headed constructor and compose with the tail-target exactness. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism empty source e1 target tail iff`

Theorem 61.196 (Continuation morphism empty-source zero-headed target tail iff)**.** *For histories $r, k : \mathsf{BHist}$ and a continuation morphism $m : \mathsf{ContinuationMorphism}(\mathsf{e}, \mathsf{E0}(r))$, the displayed tail of m has zero-headed payload k exactly when the target payload is k:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E0}(k)) \iff \mathsf{hsame}(r, k).$$

Proof. The empty-source tail target exactness identifies $\mathsf{tail}(m)$ with $\mathsf{E0}(r)$. In the forward direction, compose this equality with the displayed tail equality and invert the zero-headed constructor. Conversely, lift $r\mathsf{hsame}k$ through the zero-headed constructor and compose with the tail-target exactness. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism empty source e0 target tail iff`

Theorem 61.197 (Category empty-source one-headed target payload exactness)**.** *For histories r, k, an empty-source hom-carrier into the one-headed target $\mathsf{E1}(r)$ with displayed one-headed morphism $\mathsf{E1}(k)$ is exactly unary membership of the target payload together with payload sameness:*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, \mathsf{E1}(r), \mathsf{E1}(k)) \iff \mathsf{UnaryHistory}(r) \wedge \mathsf{hsame}(k, r).$$

Proof. Apply empty-source hom-carrier exactness to read back unary membership of $\mathsf{E1}(r)$ and sameness $\mathsf{hsame}(\mathsf{E1}(k), \mathsf{E1}(r))$. Unary one-headed inversion and one-headed sameness inversion expose the payload data. Conversely, unary closure under $\mathsf{E1}$ and one-headed congruence rebuild the target carrier and the displayed morphism-target sameness, so empty-source exactness reconstructs the hom-carrier. □

Lean4 ✓ BEDC.Derived.CategoryUp.category cont left e0 result cases

Proof. Classify the continuation history k. The empty branch identifies the inner histories. The zero branch exposes the predecessor of k and removes the matching outer constructor from the continuation result. The one branch would identify a zero-headed history with a one-headed history, which is impossible by generated-history no-confusion. □

Theorem 61.205 (Category left one-headed continuation result cases)**.** *If* $\mathsf{Cont}(\mathsf{E1}(h), k, \mathsf{E1}(r))$*, then either* $k = \mathsf{e}$ *and* $\mathsf{hsame}(h, r)$*, or* $k = \mathsf{E1}(k_1)$ *for some* k_1 *and* $\mathsf{Cont}(\mathsf{E1}(h), k_1, r)$*.*

Lean4 ✓ BEDC.Derived.CategoryUp.category cont left e1 result cases

Proof. Classify the continuation history k. The empty branch removes the matching one-headed constructor from the displayed result. The zero branch is ruled out by constructor disjointness. The one branch exposes the predecessor of k and removes the matching outer constructor from the continuation result. □

Theorem 61.206 (Category hom-carrier zero-headed source impossibility)**.** *For histories* $a, target, f$*, no hom-carrier can have source* $\mathsf{E0}(a)$*:*

$$\mathsf{CategoryHomCarrier}(\mathsf{E0}(a), target, f) \to \mathsf{False}.$$

Proof. Unpack the hom-carrier witness. Its source-carrier field says that $\mathsf{E0}(a)$ is unary, contradicting the BEDC unary-history separation theorem for zero-headed extensions. □

Lean4 ✓ BEDC.Derived.CategoryUp.CategoryHomCarrier e0 source absurd

Theorem 61.207 (Category hom-carrier zero-headed target impossibility)**.** *For histories* $source, a, morph$*, no hom-carrier can have target* $\mathsf{E0}(a)$*:*

$$\mathsf{CategoryHomCarrier}(source, \mathsf{E0}(a), morph) \to \mathsf{False}.$$

Proof. Unpack the hom-carrier witness. Its target-carrier field says that $\mathsf{E0}(a)$ is unary, contradicting the BEDC unary-history separation theorem for zero-headed extensions. □

Lean4 ✓ BEDC.Derived.CategoryUp.CategoryHomCarrier e0 target absurd

Theorem 61.208 (Category hom-carrier zero-headed morphism impossibility)**.** *For histories source, target, a, no hom-carrier can have morphism* $\mathsf{E0}(a)$*:*

$$\mathsf{CategoryHomCarrier}(source, target, \mathsf{E0}(a)) \to \mathsf{False}.$$

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e0 morphism absurd`

Proof. Unpack the hom-carrier witness. Its morphism-carrier field says that $\mathsf{E0}(a)$ is unary, contradicting zero-headed unary-history separation. □

Theorem 61.209 (Category hom-carrier zero-headed component impossibility)**.** *For histories source, target, morph, a category hom-carrier has no zero-headed source, target, or morphism component:*

$$\mathsf{CategoryHomCarrier}(source, target, morph) \Longrightarrow (\exists z,\ source = \mathsf{E0}(z)) \vee (\exists z,\ target = \mathsf{E0}(z)) \vee (\exists z,\ morph = \mathsf{E0}(z)$$

Proof. Unpack the hom-carrier into its source, target, and morphism unary-history fields. A zero-headed source, target, or morphism rewrites the corresponding field to a unary witness for a zero-headed extension, contradicting unary separation for zero-headed histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier zero headed component absurd`

Theorem 61.210 (Category hom-carrier composite zero-headed result impossibility)**.** *For histories* $a, b, c, f, g, z : \mathsf{BHist}$*, if* f *is a hom-carrier from* a *to* b*,* g *is a hom-carrier from* b *to* c*, and the displayed composite continuation has zero-headed result*

$$\mathsf{Cont}(f, g, \mathsf{E0}(z)),$$

then contradiction follows.

Proof. Composition closure makes $\mathsf{E0}(z)$ a hom-carrier morphism from a to c. Its morphism-carrier field is therefore a unary-history witness for a zero-headed history, contradicting unary separation for zero-headed histories. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp zero result absurd`

Theorem 61.211 (Category hom-carrier left one-headed result cases)**.** *If*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), \mathsf{E1}(r), k)$$

then either $k = \mathsf{e}$*,* a *is unary, and* $\mathsf{hsame}(a, r)$*, or there is a history* k_0 *such that* $k = \mathsf{E1}(k_0)$*,* k_0 *is unary, and*

$$\mathsf{Cont}(\mathsf{E1}(a), k_0, r).$$

Proof. Unpack the hom-carrier into unary source, unary morphism-tail, and continuation fields. Classify the tail k. The empty branch cancels the visible one constructor in the result and inverts the source unary witness. The zero-headed tail branch is impossible by constructor no-confusion. The one-headed tail branch removes the outer constructor from the continuation result and inverts the morphism-tail unary witness to obtain the unary carrier for k_0. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier left e1 result cases`

Theorem 61.212 (Category hom-carrier one-headed source and target morphism exactness)**.** *For histories $a, r, morph$, a hom-carrier from $\mathsf{E1}(a)$ to $\mathsf{E1}(r)$ is exactly either the empty morphism identifying the two exposed endpoints, or a one-headed morphism whose tail continues the visible source to the exposed target:*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), \mathsf{E1}(r), morph) \iff (morph = \mathsf{e} \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{hsame}(a, r)) \vee (\exists k : \mathsf{BHist}.\ morph =$$

Proof. The forward direction applies the visible-source and visible-target case split: the empty branch gives the exposed endpoint classifier, while the one-headed branch gives a tail k and a continuation ledger $\mathsf{Cont}(\mathsf{E1}(a), k, r)$. Unary inversion on the source carrier supplies $\mathsf{UnaryHistory}(a)$. Conversely, the empty branch is rebuilt by the right-unit continuation after transport along $\mathsf{hsame}(a, r)$; the one-headed branch uses unary continuation closure for the exposed target and the one-step continuation rule for the visible morphism. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target morphism iff`

Theorem 61.213 (Category nonempty one-headed endpoint morphism cases)**.** *For* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), \mathsf{E1}($ *if morph is not* hsame *to* e*, then* $morph = \mathsf{E1}(k)$ *for some unary k, a and r are unary, and* $\mathsf{Cont}(\mathsf{E1}(a), k, r)$*.*

Proof. Split the one-headed source and target morphism cases; the empty branch contradicts the nonempty hypothesis, and the visible branch exposes the tail continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target nonempty morphism cases`

Theorem 61.214 (Category nonempty one-headed endpoint morphism target descent)**.** *For* $\mathsf{CategoryHomCarrier}(\mathsf{E}$ *if morph is not* hsame *to* e*, then there is a history k such that* $morph = \mathsf{E1}(k)$ *and the exposed tail itself is a hom-carrier* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k)$*.*

Proof. Apply the nonempty one-headed endpoint morphism cases. The exposed data gives $morph = \mathsf{E1}(k)$, unary witnesses for a, k, r, and $\mathsf{Cont}(\mathsf{E1}(a), k, r)$. Reassembling these fields gives the descended hom-carrier from $\mathsf{E1}(a)$ to r with morphism k. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target nonempty morphism target descent`

Theorem 61.215 (Category nonempty one-headed endpoint morphism unique descent)**.** *Under the same hypotheses, the descended tail is unique up to* hsame*: there is a history k with* $morph = \mathsf{E1}(k)$*,* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k)$*, and every other displayed one-headed descent* $morph = \mathsf{E1}(k')$ *with* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k')$ *satisfies* $k\mathsf{hsame}k'$*.*

Proof. First use target descent to obtain the displayed tail k and its descended hom-carrier. If another tail k' displays the same morphism as $\mathsf{E1}(k')$, constructor injectivity for $\mathsf{E1}$ identifies k and k', hence gives $k\mathsf{hsame}k'$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target nonempty morphism descent unique`

Theorem 61.216 (Category nonempty one-headed source morphism target cases)**.** *For* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a),$ *if morph is not* hsame *to* e*, then there are histories k, r such that* $morph = \mathsf{E1}(k)$*,* $target = \mathsf{E1}(r)$*, a, k, r are unary, and* $\mathsf{Cont}(\mathsf{E1}(a), k, r)$*.*

Proof. Split the one-headed source morphism cases. The empty-morphism branch contradicts the nonempty hypothesis. The visible branch already exposes the one-headed target, the morphism tail, the three unary witnesses, and the continuation ledger. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source nonempty morphism target cases`

Theorem 61.217 (Category nonempty one-headed source morphism target iff)**.** *For* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), ta$ *together with morph not* hsame *to* e*, the carrier data is equivalent to:*

$$\exists k, r : \mathsf{BHist}.\ morph = \mathsf{E1}(k) \wedge target = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{E1}(a), k, r)$$

Proof. The forward direction is the nonempty one-headed source morphism target case split. Conversely, the displayed histories k, r, the one-headed equalities, the three unary witnesses, and the continuation ledger rebuild the concrete hom-carrier; the morphism is visibly one-headed, so it cannot be hsame to e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source nonempty morphism target iff`

Theorem 61.218 (Category nonempty one-headed source morphism target carrier cases)**.** *For* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), target, morph)$*, if morph is not* hsame *to* e*, then there are histories* k, r *such that* $morph = \mathsf{E1}(k)$*,* $target = \mathsf{E1}(r)$*, and* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k)$*.*

Proof. Apply the nonempty one-headed source morphism target case theorem. It exposes histories k, r, the equalities $morph = \mathsf{E1}(k)$ and $target = \mathsf{E1}(r)$, unary witnesses for a, k, r, and the continuation ledger $\mathsf{Cont}(\mathsf{E1}(a), k, r)$. These fields are exactly the concrete hom-carrier clauses for $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source nonempty morphism target carrier cases`

Theorem 61.219 (Category nonempty one-headed source morphism target carrier uniqueness)**.** *For* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), target, morph)$*, if morph is not* hsame *to* e*, then there are histories* k, r *such that* $morph = \mathsf{E1}(k)$*,* $target = \mathsf{E1}(r)$*, and* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k)$*. Moreover, any other displayed decomposition with* $morph = \mathsf{E1}(k')$*,* $target = \mathsf{E1}(r')$*, and* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r', k')$ *satisfies* $k\,\mathsf{hsame}\,k'$ *and* $r\,\mathsf{hsame}\,r'$*.*

Proof. Apply the nonempty one-headed source morphism target case theorem. It exposes the one-headed morphism and target, the three unary tail witnesses, and the descended continuation ledger, which reassemble the descended hom-carrier. Uniqueness follows by constructor injectivity for the two displayed E1 equalities. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source nonempty morphism target carrier unique`

Theorem 61.220 (Category nonempty one-headed target morphism source cases)**.** *For* $\mathsf{CategoryHomCarrier}(source$ *if morph is not* hsame *to* e*, then either* $source = \mathsf{e}$*,* $morph = \mathsf{E1}(r)$*, and* r *is unary, or there are histories* a, k *such that* $source = \mathsf{E1}(a)$*,* $morph = \mathsf{E1}(k)$*,* a, k, r *are unary, and* $\mathsf{Cont}(\mathsf{E1}(a), k, r)$*.*

Proof. Split on the source constructor. A zero-headed source contradicts the hom-carrier unary field. The empty-source branch inverts the continuation into the one-headed target and identifies the morphism with $\mathsf{E1}(r)$. The one-headed-source branch applies the nonempty one-headed endpoint case split to expose the morphism tail and continuation ledger. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 target nonempty morphism source cases`

Theorem 61.221 (Category nonempty one-headed target morphism source carrier uniqueness)**.** *For* $\mathsf{CategoryHomCarrier}(source, \mathsf{E1}(r), morph)$*, if morph is not* hsame *to* e*, then either* $source = \mathsf{e}$*,* $morph = \mathsf{E1}(r)$*, and the visible target tail is unique under every one-headed display of morph; or there are histories* a, k *such that* $source = \mathsf{E1}(a)$*,* $morph = \mathsf{E1}(k)$*, and* $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k)$*. In the visible-source branch, any other one-headed source and morphism display with a descended hom-carrier has* $a\mathsf{hsame}a'$ *and* $k\mathsf{hsame}k'$*.*

Proof. Split the nonempty one-headed target morphism source cases. In the empty-source branch, the displayed equality $morph = \mathsf{E1}(r)$ makes every other one-headed display equal on tails by constructor injectivity. In the visible-source branch, the exposed unary witnesses and continuation ledger reassemble the descended hom-carrier, and constructor injectivity on $source = \mathsf{E1}(a)$ and $morph = \mathsf{E1}(k)$ gives the stated tail uniqueness. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 target nonempty morphism source carrier unique`

Theorem 61.222 (Category nonempty one-headed target morphism source iff)**.** *For* $\mathsf{CategoryHomCarrier}(source, \mathsf{E}$ *together with morph not* hsame *to* e*, the source is classified exactly by*

$$(source = \mathsf{e} \wedge morph = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(r)) \vee \exists a, k : \mathsf{BHist}.\ source = \mathsf{E1}(a) \wedge morph = \mathsf{E1}(k) \wedge \mathsf{UnaryHistory}(a) \wedge$$

Proof. The forward direction is the nonempty one-headed target morphism source case split. In the empty-source branch, the empty-source carrier equivalence rebuilds $\mathsf{CategoryHomCarrier}(\mathsf{e}, \mathsf{E1}(r), \mathsf{E1}(r))$. In the visible source branch, the displayed one-headed source, one-headed morphism, unary witnesses, and continuation ledger rebuild the concrete hom-carrier. In both reverse branches the displayed morphism is one-headed, hence not hsame to e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 target nonempty morphism source iff`

Theorem 61.223 (Category one-headed target and morphism source cases iff)**.** *For* $\mathsf{CategoryHomCarrier}(source, \mathsf{E1}$ *the source is classified by the empty-source unit branch or by a visible one-headed source:*

$$\begin{aligned}
&\mathsf{CategoryHomCarrier}(source, \mathsf{E1}(r), \mathsf{E1}(k)) \\
&\iff (source = \mathsf{e} \wedge k\mathsf{hsame}r \wedge \mathsf{UnaryHistory}(r)) \\
&\quad \vee \exists a : \mathsf{BHist}.\ source = \mathsf{E1}(a) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(k) \\
&\quad\quad \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{E1}(a), k, r).
\end{aligned}$$

Proof. For the forward direction, invert the one-headed morphism target carrier and split the concrete source constructor. The empty branch is the unit-source continuation case, the zero-headed branch contradicts unary history, and the one-headed branch exposes the source tail and continuation ledger. For the reverse direction, the empty branch builds the empty-source hom-carrier, while the visible branch rebuilds the one-headed source carrier from the displayed unary witnesses and continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 target e1 morphism source cases iff`

Theorem 61.224 (Category nonempty morphism source cases)**.** *For* $\mathsf{CategoryHomCarrier}(source, target, morph)$*, if morph is not* hsame *to* e*, then either* $source = \mathsf{e}$*, target is unary, and* $morph\mathsf{hsame}target$*, or there are histories* a, k, r *such that* $source = \mathsf{E1}(a)$*,* $morph = \mathsf{E1}(k)$*,* $target = \mathsf{E1}(r)$*,* a, k, r *are unary, and* $\mathsf{Cont}(\mathsf{E1}(a), k, r)$*.*

Proof. Split on the source constructor. The empty-source branch is exactly the empty-source hom-carrier inversion. A zero-headed source contradicts the unary source field. In the one-headed branch, an empty displayed morphism contradicts the nonempty hypothesis and a zero-headed morphism contradicts the unary morphism field; the remaining one-headed morphism exposes the one-headed target and tail continuation by the one-headed morphism target cases theorem. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier nonempty morphism source cases`

Theorem 61.225 (Category nonempty morphism endpoint cases)**.** *For* $\mathsf{CategoryHomCarrier}(source, target, morph)$ *if morph is not* hsame *to* e*, then either the source is empty and the visible morphism is exactly the visible target tail, or all three endpoints are one-headed and the continuation ledger remains visible at that boundary:*

$$(source = \mathsf{e} \wedge \exists k.\ morph = \mathsf{E1}(k) \wedge target = \mathsf{E1}(k) \wedge \mathsf{UnaryHistory}(k))$$
$$\vee(\exists a, k, r.\ source = \mathsf{E1}(a) \wedge morph = \mathsf{E1}(k) \wedge target = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}($$

Proof. Apply the nonempty morphism source-case split. In the empty-source branch, empty-source inversion identifies *morph* with *target*; the nonempty hypothesis excludes the empty morphism and unary generation excludes a zero-headed morphism, leaving the one-headed endpoint k. In the one-headed source branch, the existing exposed continuation $\mathsf{Cont}(\mathsf{E1}(a), k, r)$ steps once to the displayed boundary $\mathsf{Cont}(\mathsf{E1}(a), \mathsf{E1}(k), \mathsf{E1}(r))$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier nonempty morphism endpoint cases`

Theorem 61.226 (Category hom-carrier one-headed endpoint morphism alignment)**.** *For hom-carriers between the same one-headed source and one-headed target, the displayed morphisms align: they are both empty, or both one-headed with* hsame *exposed morphism tails.*

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target morphism alignment`

Proof. Category morphism determinacy gives $\mathsf{hsame}(m, n)$ for the two displayed morphisms. Split one hom-carrier by the one-headed source and target result cases. In the empty branch, morphism sameness forces the second morphism to be empty. In the visible branch, the same morphism sameness transports the second morphism into a one-headed shape, and constructor inversion gives hsame between the exposed morphism tails. □

Theorem 61.227 (Category nonempty one-headed endpoint morphism alignment)**.** *For two hom-carriers between* $\mathsf{E1}(a)$ *and* $\mathsf{E1}(r)$*, if the first morphism is not* hsame *to* e*, then both morphisms are one-headed and their exposed tails are* hsame*.*

Proof. Apply endpoint morphism alignment; the both-empty branch contradicts the nonempty witness, leaving the visible-tail alignment branch. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target nonempty morphism alignment`

Theorem 61.228 (Category nonempty one-headed endpoint morphism tail-cont alignment)**.** *For two hom-carriers between* $\mathsf{E1}(a)$ *and* $\mathsf{E1}(r)$*, if the first morphism is not* hsame *to* e*, then both morphisms are one-headed. Their exposed tails are unary, both tails continue* $\mathsf{E1}(a)$ *to* r*, and the two tails are* hsame*:*

$$\exists k, l : \mathsf{BHist}.\ m = \mathsf{E1}(k) \wedge n = \mathsf{E1}(l) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(l) \wedge \mathsf{Cont}(\mathsf{E1}(a), k, r) \wedge \mathsf{Cont}(\mathsf{E1}(a), l, r) \wedge \mathsf{hsame}(k,$$

Proof. First apply nonempty endpoint morphism alignment to expose one-headed tails k and l with $\mathsf{hsame}(k, l)$. Then apply the one-headed source and target morphism exactness theorem separately to the two displayed hom-carriers. The empty branch is impossible after the displayed one-headed equality; the visible branch supplies the unary tail witness and continuation ledger on each side. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target nonempty morphism tail cont alignment`

Theorem 61.229 (Category nonempty one-headed endpoint morphism tail carrier alignment)**.** *For two hom-carriers between* $\mathsf{E1}(a)$ *and* $\mathsf{E1}(r)$*, if the first morphism is not* hsame *to* e*, then both displayed morphisms descend to one-headed tails whose tail hom-carriers share the same source and target:*

$$\exists k, l : \mathsf{BHist}.\ m = \mathsf{E1}(k) \wedge n = \mathsf{E1}(l) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, l) \wedge \mathsf{hsame}(k, l).$$

Proof. Apply the nonempty tail-continuation alignment theorem. It supplies the one-headed displays, the two unary tail witnesses, the two continuations $\mathsf{Cont}(\mathsf{E1}(a), k, r)$ and $\mathsf{Cont}(\mathsf{E1}(a), l, r)$, and the tail equality $\mathsf{hsame}(k, l)$. Repack each unary tail and continuation with the original source carrier, deriving the target carrier r by unary continuation closure. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target nonempty morphism tail carrier alignment`

Corollary 61.230 (Category source specification endpoint determinacy)**.** *Let* $a, r, morph$ *be histories and suppose a* $\mathsf{Cat}^{\uparrow}$ *source specification use, in the sense of Definition 61.198, is accepted through the licensed one-headed endpoint hom-carrier row*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), \mathsf{E1}(r), morph)$$

with $morph$ *not* hsame *to* e*. Then the finite source route forced on that use is determined: there is a history* k *such that*

$$morph = \mathsf{E1}(k) \quad \textit{and} \quad \mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k).$$

For any second consumer readback, normal-form choice, or exactness decision in the same source specification, if it displays a one-headed descent

$$morph = \mathsf{E1}(k') \quad \textit{and} \quad \mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k'),$$

then $k \mathsf{hsame} k'$*. Hence the accepted source specification use cannot introduce a hidden coordinate, a second finite route, or a duplicate classifier source beyond the visible row named by the chapter.*

Proof. By Definition 61.198, the source data consists of the licensed object carrier together with each licensed hom-carrier. Thus an accepted use at the displayed endpoint must be read through the concrete hom-carrier row

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), \mathsf{E1}(r), morph),$$

rather than through an external coordinate. The nonempty hypothesis rejects the empty exactness decision, so the only admissible visible branch is the one-headed descent branch. Applying Definition 61.215 gives a displayed tail k with $morph = \mathsf{E1}(k)$ and the descended licensed row $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k)$.

Now take any second accepted readback, normal-form choice, or exactness decision for the same source specification. To remain accepted under Definition 61.198, it must again present a licensed hom-carrier row; if it displays $morph = \mathsf{E1}(k')$ and $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), r, k')$, the universal clause of Definition 61.215 gives $k\mathsf{hsame}k'$. Therefore every accepted consumer-facing use factors through the same descended tail up to hsame, and no unlisted coordinate or duplicate classifier source survives the displayed finite row list. □

Theorem 61.231 (Continuation morphism zero-headed source tail cases)**.** *For histories $a, target$, every continuation morphism $m : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), target)$ has one of exactly three displayed tail shapes:*

$$\mathsf{tail}(m) = \mathsf{e} \wedge target = \mathsf{E0}(a),$$

or

$$\exists k, r : \mathsf{BHist}.\ \mathsf{tail}(m) = \mathsf{E0}(k) \wedge target = \mathsf{E0}(r) \wedge \mathsf{Cont}(\mathsf{E0}(a), k, r),$$

or

$$\exists k, r : \mathsf{BHist}.\ \mathsf{tail}(m) = \mathsf{E1}(k) \wedge target = \mathsf{E1}(r) \wedge \mathsf{Cont}(\mathsf{E0}(a), k, r).$$

Proof. Unpack the continuation morphism into its displayed tail and continuation ledger. The empty-tail case is the right-unit continuation, so the target is $\mathsf{E0}(a)$. In the zero-headed and one-headed tail cases, continuation step-result inversion exposes the matching target constructor and leaves the residual continuation from $\mathsf{E0}(a)$ through the exposed tail. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source tail cases`

Theorem 61.232 (Continuation morphism one-headed source tail cases)**.** *For histories $a, target$, every continuation morphism $m : \mathsf{ContinuationMorphism}(\mathsf{E1}(a), target)$ has one of exactly three displayed tail shapes:*

$$\mathsf{tail}(m) = \mathsf{e} \wedge target = \mathsf{E1}(a),$$

or

$$\exists k, r : \mathsf{BHist}.\ \mathsf{tail}(m) = \mathsf{E0}(k) \wedge target = \mathsf{E0}(r) \wedge \mathsf{Cont}(\mathsf{E1}(a), k, r),$$

or

$$\exists k, r : \mathsf{BHist}.\ \mathsf{tail}(m) = \mathsf{E1}(k) \wedge target = \mathsf{E1}(r) \wedge \mathsf{Cont}(\mathsf{E1}(a), k, r).$$

Proof. Unpack the continuation morphism into its displayed tail and continuation ledger. The empty-tail case is the right-unit continuation, so the target is $\mathsf{E1}(a)$. In the zero-headed and one-headed tail cases, continuation step-result inversion exposes the corresponding target constructor and leaves the residual continuation from $\mathsf{E1}(a)$ through the exposed tail. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e1 source tail cases`

Theorem 61.233 (Continuation morphism one-headed source to zero-headed target tail cases)**.** *For histories $a, r : \mathsf{BHist}$, every continuation morphism $m : \mathsf{ContinuationMorphism}(\mathsf{E1}(a), \mathsf{E0}(r))$ has a zero-headed tail whose exposed tail still continues from $\mathsf{E1}(a)$ to r:*

$$\exists k : \mathsf{BHist}.\ \mathsf{hsame}(\mathsf{tail}(m), \mathsf{E0}(k)) \wedge \mathsf{Cont}(\mathsf{E1}(a), k, r).$$

Proof. Unpack the displayed tail of m. The empty-tail case would force $\mathsf{E1}(a)\mathsf{hsame}\mathsf{E0}(r)$, contradicting constructor disjointness. The one-headed tail case would force a zero-headed result to be one-headed, again contradicting constructor disjointness. Therefore the tail is zero-headed, and continuation step-result inversion exposes the residual continuation $\mathsf{Cont}(\mathsf{E1}(a), k, r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e1 source e0 target tail cases`

Theorem 61.234 (Continuation morphism one-headed source to zero-headed target tail core determinacy)**.** *For histories* $a, r, k, l : \mathsf{BHist}$ *and continuation morphisms* $m, n : \mathsf{ContinuationMorphism}(\mathsf{E1}(a), \mathsf{E0}(r))$*, if the two displayed tails are classified with zero-headed presentations* $\mathsf{E0}(k)$ *and* $\mathsf{E0}(l)$*, then the exposed tail cores are classified:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E0}(k)) \to \mathsf{hsame}(\mathsf{tail}(n), \mathsf{E0}(l)) \to \mathsf{hsame}(k, l).$$

Proof. Tail determinacy for continuation morphisms with the same endpoints gives $\mathsf{hsame}(\mathsf{tail}(m), \mathsf{tail}(n))$. Compose this comparison with the two exposed zero-headed presentations. Constructor inversion for $\mathsf{E0}$ then descends the comparison to the exposed cores k and l. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e1 source e0 target tail core deterministic`

Theorem 61.235 (Continuation morphism one-headed source to zero-headed target rejects one–headed tail)**.** *For histories* $a, r, k : \mathsf{BHist}$ *and* $m : \mathsf{ContinuationMorphism}(\mathsf{E1}(a), \mathsf{E0}(r))$*,*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E1}(k)) \to \mathsf{False}.$$

Proof. Apply the preceding zero-headed tail exposure theorem. It supplies a history t with $\mathsf{tail}(m)\mathsf{hsameE0}(t)$. If the displayed tail were also hsame to $\mathsf{E1}(k)$, transitivity would give $\mathsf{E0}(t)\mathsf{hsameE1}(k)$, contradicting constructor separation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e1 source e0 target tail e1 absurd`

Theorem 61.236 (Continuation morphism one-headed source to zero-headed target zero-tail exactness)**.** *For histories* $a, r, k : \mathsf{BHist}$ *and* $m : \mathsf{ContinuationMorphism}(\mathsf{E1}(a), \mathsf{E0}(r))$*, the displayed tail is zero-headed with payload* k *exactly when that payload continues from the one-headed source to the zero-headed target payload:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E0}(k)) \iff \mathsf{Cont}(\mathsf{E1}(a), k, r).$$

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e1 source e0 target tail e0 iff`

Proof. For the forward direction, inspect the displayed tail of m. Empty and one-headed tails contradict the assumed zero-headed tail comparison. In the zero-headed branch, constructor inversion on the comparison identifies the payloads, and constructor inversion on the continuation result exposes $\mathsf{Cont}(\mathsf{E1}(a), k, r)$.

Conversely, step the displayed payload continuation through the zero constructor to form a continuation morphism with tail $\mathsf{E0}(k)$. Tail determinacy against m gives the displayed tail comparison. □

Theorem 61.237 (Continuation morphism one-headed source to zero-headed target tail is nonempty)**.** *For histories* $a, r : \mathsf{BHist}$*, every continuation morphism* $m : \mathsf{ContinuationMorphism}(\mathsf{E1}(a), \mathsf{E0}(r))$ *has a tail that cannot be classified with the empty history:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{e}) \to \mathsf{False}.$$

Proof. Apply the zero-headed tail exposure theorem above. It supplies a history k with $\mathsf{tail}(m)\mathsf{hsameE0}(k)$. If the displayed tail were also classified with e, transitivity would give $\mathsf{E0}(k)\mathsf{hsamee}$, contradicting constructor disjointness. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e1 source e0 target tail not empty`

Theorem 61.238 (Continuation morphism zero-headed source to one-headed target tail cases)**.** *For histories $a, r : \mathsf{BHist}$, every continuation morphism $m : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E1}(r))$ has a one-headed tail whose exposed tail still continues from $\mathsf{E0}(a)$ to r:*

$$\exists k : \mathsf{BHist}.\ \mathsf{hsame}(\mathsf{tail}(m), \mathsf{E1}(k)) \wedge \mathsf{Cont}(\mathsf{E0}(a), k, r).$$

Proof. Unpack the displayed tail of m. The empty-tail case would force $\mathsf{E0}(a)\mathsf{hsameE1}(r)$, contradicting constructor disjointness. The zero-headed tail case would force a one-headed result to be zero-headed, again contradicting constructor disjointness. Therefore the tail is one-headed, and continuation step-result inversion exposes the residual continuation $\mathsf{Cont}(\mathsf{E0}(a), k, r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e1 target tail cases`

Theorem 61.239 (Continuation morphism zero-headed source to one-headed target tail core determinacy)**.** *For histories $a, r, k, l : \mathsf{BHist}$ and continuation morphisms $m, n : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E1}(r))$, if the two displayed tails are classified with one-headed presentations $\mathsf{E1}(k)$ and $\mathsf{E1}(l)$, then the exposed tail cores are classified:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E1}(k)) \to \mathsf{hsame}(\mathsf{tail}(n), \mathsf{E1}(l)) \to \mathsf{hsame}(k, l).$$

Proof. Tail determinacy for continuation morphisms with the same endpoints gives $\mathsf{hsame}(\mathsf{tail}(m), \mathsf{tail}(n))$. Compose this comparison with the two exposed one-headed presentations. Constructor inversion for $\mathsf{E1}$ then descends the comparison to the exposed cores k and l. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e1 target tail core deterministic`

Theorem 61.240 (Continuation morphism zero-headed source to one-headed target rejects zero–headed tail)**.** *For histories $a, r, k : \mathsf{BHist}$ and $m : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E1}(r))$,*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E0}(k)) \to \mathsf{False}.$$

Proof. Apply the preceding one-headed tail exposure theorem. It supplies a history t with $\mathsf{tail}(m)\mathsf{hsameE1}(t)$. If the displayed tail were also hsame to $\mathsf{E0}(k)$, transitivity would give $\mathsf{E1}(t)\mathsf{hsameE0}(k)$, contradicting constructor separation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e1 target tail e0 absurd`

Theorem 61.241 (Continuation morphism zero-headed source to one-headed target one-tail exactness)**.** *For histories $a, r, k : \mathsf{BHist}$ and $m : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E1}(r))$, the displayed tail is one-headed with payload k exactly when that payload continues from the zero-headed source to the one-headed target payload:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E1}(k)) \iff \mathsf{Cont}(\mathsf{E0}(a), k, r).$$

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e1 target tail e1 iff`

Proof. For the forward direction, inspect the displayed tail of m. Empty and zero-headed tails contradict the assumed one-headed tail comparison. In the one-headed branch, constructor inversion on the comparison identifies the payloads, and constructor inversion on the continuation result exposes $\mathsf{Cont}(\mathsf{E0}(a), k, r)$.

Conversely, step the displayed payload continuation through the one constructor to form a continuation morphism with tail $\mathsf{E1}(k)$. Tail determinacy against m gives the displayed tail comparison. □

Theorem 61.242 (Continuation morphism zero-headed source to one-headed target tail is nonempty)**.** *For histories $a, r : \mathsf{BHist}$, every continuation morphism $m : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E1}(r))$ has a tail that cannot be classified with the empty history:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{e}) \to \mathsf{False}.$$

Proof. Apply the one-headed tail exposure theorem above. It supplies a history k with $\mathsf{tail}(m)\mathsf{hsameE1}(k)$. If the displayed tail were also classified with e, transitivity would give $\mathsf{E1}(k)\mathsf{hsamee}$, contradicting constructor disjointness. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e1 target tail not empty`

Corollary 61.243 (Continuation morphism zero-headed source-tail determinacy)**.** *For histories $a, r, k, l : \mathsf{BHist}$ and continuation morphisms $m, n : \mathsf{ContinuationMorphism}(\mathsf{E1}(a), \mathsf{E0}(r))$, suppose the same consumer-facing endpoint packet displays two zero-headed source-tail reads*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E0}(k)) \quad \textit{and} \quad \mathsf{hsame}(\mathsf{tail}(n), \mathsf{E0}(l)).$$

Then the exposed zero-headed source coordinates are forced to agree:

$$\mathsf{hsame}(k, l).$$

Consequently the zero-headed source coordinate read from that endpoint packet is unique up to hsame*.*

Proof. Apply Definition 61.234 to the two endpoint morphisms m and n and to the two displayed zero-headed tail presentations. This identifies the exposed cores, giving $\mathsf{hsame}(k, l)$. Thus any consumer that tries to read the same endpoint packet through a second zero-headed source coordinate has only an hsame-equivalent source. □

Theorem 61.244 (Continuation morphism zero-headed source to zero-headed target tail cases)**.** *For histories $a, r : \mathsf{BHist}$, every continuation morphism $m : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E0}(r))$ has either the empty-tail case with exposed endpoints classified together,*

$$\mathsf{tail}(m) = \mathsf{e} \wedge \mathsf{hsame}(a, r),$$

or a zero-headed tail whose payload still continues from $\mathsf{E0}(a)$ to r:

$$\exists k : \mathsf{BHist}.\ \mathsf{tail}(m) = \mathsf{E0}(k) \wedge \mathsf{Cont}(\mathsf{E0}(a), k, r).$$

Proof. Unpack the displayed continuation tail. The empty-tail branch is the right-unit continuation, so constructor injectivity exposes $\mathsf{hsame}(a, r)$. A one-headed tail would force a zero-headed result to be one-headed, contradicting constructor disjointness. In the zero-headed branch, constructor injectivity on the continuation result removes the outer zero constructor and leaves $\mathsf{Cont}(\mathsf{E0}(a), k, r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e0 target tail cases`

Theorem 61.245 (Continuation morphism zero-headed endpoints nonempty tail extraction)**.** *For histories $a, r : \mathsf{BHist}$ and a continuation morphism $m : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E0}(r))$, if the displayed tail is not classified with e, then it has a zero-headed payload continuing from $\mathsf{E0}(a)$ to r:*

$$(\mathsf{hsame}(\mathsf{tail}(m), \mathsf{e}) \to \mathsf{False}) \to \exists k : \mathsf{BHist}.\ \mathsf{hsame}(\mathsf{tail}(m), \mathsf{E0}(k)) \wedge \mathsf{Cont}(\mathsf{E0}(a), k, r).$$

Proof. Apply the zero-headed endpoint tail split above. The empty-tail branch contradicts the displayed nonempty-tail hypothesis. The remaining branch already exposes a zero-headed tail and the continuation payload $\mathsf{Cont}(\mathsf{E0}(a), k, r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e0 target nonempty tail cases`

Theorem 61.246 (Continuation morphism zero-headed endpoints tail core determinacy)**.** *For histories $a, r, k, l : \mathsf{BHist}$ and continuation morphisms $m, n : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E0}(r))$, if their displayed tails are classified with $\mathsf{E0}(k)$ and $\mathsf{E0}(l)$, then the exposed tail cores are classified:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E0}(k)) \to \mathsf{hsame}(\mathsf{tail}(n), \mathsf{E0}(l)) \to \mathsf{hsame}(k, l).$$

Proof. Tail determinacy for continuation morphisms with the same endpoints gives $\mathsf{hsame}(\mathsf{tail}(m), \mathsf{tail}(n))$. Chaining with the two displayed zero-headed tail classifications gives $\mathsf{hsame}(\mathsf{E0}(k), \mathsf{E0}(l))$, and zero-constructor inversion removes the outer tag. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e0 target tail core deterministic`

Proposition 61.247 (Continuation morphism zero-headed endpoints reject one-headed tail)**.** *For histories $a, r, k : \mathsf{BHist}$ and $m : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E0}(r))$,*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E1}(k)) \to \mathsf{False}.$$

Proof. Unpack the displayed continuation tail. The empty-tail case contradicts $\mathsf{ehsameE1}(k)$, the zero-headed tail case contradicts $\mathsf{E0}(t)\mathsf{hsameE1}(k)$, and the one-headed tail case would force the zero-headed result to be one-headed in the continuation ledger. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e0 target tail e1 absurd`

Theorem 61.248 (Continuation morphism zero-headed endpoints zero-tail exactness)**.** *For histories $a, r, k : \mathsf{BHist}$ and $m : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E0}(r))$, the displayed tail is zero-headed with payload k exactly when the payload continues from the zero-headed source to the target payload:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E0}(k)) \iff \mathsf{Cont}(\mathsf{E0}(a), k, r).$$

Proof. For the forward direction, apply the zero-headed endpoint tail cases. The empty-tail branch contradicts the assumed zero-headed tail comparison. In the visible branch, the exposed zero-headed tail payload and the assumed tail comparison identify the two payloads, so continuation transport gives $\mathsf{Cont}(\mathsf{E0}(a), k, r)$. Conversely, step the displayed payload continuation through the zero constructor and compare it with the record continuation by left cancellation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e0 target tail e0 iff`

Proposition 61.249 (Continuation morphism zero-headed endpoints empty-tail exactness)**.** *For histories $a, r : \mathsf{BHist}$ and $m : \mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E0}(r))$, the displayed tail is empty exactly when the endpoint payloads are history-same:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{e}) \iff \mathsf{hsame}(a, r).$$

Proof. Apply the zero-headed endpoint tail cases. In the forward direction, the empty-tail branch exposes $\mathsf{hsame}(a, r)$, while the zero-headed visible-tail branch contradicts empty/zero separation. Conversely, an endpoint payload comparison builds the empty-tail displayed morphism, and continuation-morphism tail determinacy identifies it with m. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e0 source e0 target tail empty iff`

Corollary 61.250 (Continuation morphism zero-headed endpoints consumer determinacy)**.** *For histories a, r, k, l : BHist and continuation morphisms m, n : $\mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E0}(r))$, suppose a consumer-facing use fixes the zero-headed visible-tail row for m:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{E0}(k)).$$

If another accepted consumer-facing use of the same zero-headed endpoint packet reads a zero-headed tail row for n,

$$\mathsf{hsame}(\mathsf{tail}(n), \mathsf{E0}(l)),$$

then the visible payload coordinate and the zero-tail exactness decision are determined:

$$\mathsf{hsame}(k, l) \quad \textit{and} \quad (\mathsf{Cont}(\mathsf{E0}(a), k, r) \iff \mathsf{Cont}(\mathsf{E0}(a), l, r)).$$

Consequently, after the endpoint rows and one zero-headed tail row are fixed, every accepted route, normal-form read, or exactness decision for this packet uses the same zero-tail payload up to hsame*. The only displayed branch that carries no payload is the empty-tail endpoint-collapse row of Definition 61.244; there is no accepted one-headed tail, hidden coordinate, or duplicate classifier source.*

Proof. Apply Definition 61.244 to a continuation morphism x : $\mathsf{ContinuationMorphism}(\mathsf{E0}(a), \mathsf{E0}(r))$. The consumer-visible tail surface is exhausted by the two displayed rows

$$\mathsf{tail}(x) = \mathsf{e} \wedge \mathsf{hsame}(a, r) \quad \text{or} \quad \exists q : \mathsf{BHist}.\ \mathsf{tail}(x) = \mathsf{E0}(q) \wedge \mathsf{Cont}(\mathsf{E0}(a), q, r).$$

Thus a payload-bearing read over these endpoints must be a zero-headed read, and its payload is the only coordinate exposed by the case split.

For the two accepted uses in the statement, both reads are zero-headed. Applying Definition 61.246 to the two displayed tail classifications gives $\mathsf{hsame}(k, l)$. The zero-tail exactness row of Definition 61.248 reads the first displayed classification as exactly $\mathsf{Cont}(\mathsf{E0}(a), k, r)$ and the second as exactly $\mathsf{Cont}(\mathsf{E0}(a), l, r)$. By the continuation history-sameness transport theorem Definition 4.41, transport along $\mathsf{hsame}(k, l)$ identifies these two continuation payload decisions, giving the displayed equivalence.

It remains only to rule out alternate consumer coordinates. A one-headed tail proposal is refused by Definition 61.247. A second zero-headed proposal is another instance of the same core-determinacy theorem and is therefore hsame to k. An empty-tail proposal is the endpoint-collapse row listed by the case theorem and carries no payload coordinate at all. Hence the accepted consumer surface is exhausted by the empty row and the unique zero-headed payload row named in the chapter. □

61.3 The certificate

Theorem 61.251 (Continuation morphism one-headed endpoints empty-tail exactness)**.** *For histories a, r : BHist and m : $\mathsf{ContinuationMorphism}(\mathsf{E1}(a), \mathsf{E1}(r))$, the displayed tail is empty exactly when the endpoint payloads are history-same:*

$$\mathsf{hsame}(\mathsf{tail}(m), \mathsf{e}) \iff \mathsf{hsame}(a, r).$$

Proof. For the forward direction, apply the one-headed endpoint tail cases. The visible one-tail branch contradicts empty-tail separation, leaving the empty-tail branch and hence $\mathsf{hsame}(a, r)$. Conversely, use the endpoint payload comparison to form the empty-tail continuation morphism and compare it with m by tail determinacy. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism e1 source e1 target tail empty iff`

Theorem 61.252 (Category empty morphism between one-headed endpoints)**.** *For histories a, r, the empty morphism is a hom-carrier from $\mathsf{E1}(a)$ to $\mathsf{E1}(r)$ exactly when the exposed source tail is unary and the two exposed tails are classified together:*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), \mathsf{E1}(r), \mathsf{e}) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{hsame}(a, r).$$

Proof. The forward direction applies the one-headed result case split to the displayed empty morphism. The visible morphism branch contradicts constructor no-confusion, and the empty branch exposes unary membership of a and $\mathsf{hsame}(a, r)$. Conversely, unary one-step closure supplies the two endpoint carriers, the tail classifier lifts through $\mathsf{E1}$, and empty-identity exactness rebuilds the hom-carrier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target empty morphism iff`

Theorem 61.253 (Category hom-carrier one-headed morphism target exactness)**.** *For histories a, k, r,*

$$\mathsf{CategoryHomCarrier}(a, \mathsf{E1}(r), \mathsf{E1}(k)) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{Cont}(a, k, r).$$

Proof. Unpack the hom-carrier witness. The forward direction keeps the unary source witness, inverts the one-headed morphism unary witness to obtain unary membership for k, and removes the outer one constructor from the continuation result. Conversely, unary continuation closure gives unary membership for r, one-step closure gives the one-headed target and morphism carriers, and the continuation one-step rule lifts $\mathsf{Cont}(a, k, r)$ to $\mathsf{Cont}(a, \mathsf{E1}(k), \mathsf{E1}(r))$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 morphism target iff`

Theorem 61.254 (Category empty-source one-headed target exactness)**.** *For histories $r, morph$, an empty-source hom-carrier into the one-headed target $\mathsf{E1}(r)$ is exactly equality of the morphism with that target together with unary payload membership:*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, \mathsf{E1}(r), morph) \iff morph = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(r).$$

Proof. Category empty-source exactness gives unary membership of the one-headed target and equality of the morphism with that target. Unary inversion removes the visible constructor from the target carrier. Conversely, unary one-step closure rebuilds the target carrier and the displayed equality supplies the empty-source continuation classifier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source e1 target iff`

Theorem 61.255 (Category empty-source one-headed morphism exactness)**.** *For histories $k, target$, an empty-source hom-carrier whose morphism is $\mathsf{E1}(k)$ is exactly equality of the target with that morphism together with unary payload membership:*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, target, \mathsf{E1}(k)) \iff target = \mathsf{E1}(k) \wedge \mathsf{UnaryHistory}(k).$$

Proof. Category empty-source exactness identifies the one-headed morphism with the target. Eliminating that equality turns the target carrier into a one-headed unary witness, whose payload is unary by inversion. Conversely, one-step unary closure rebuilds the target carrier, and symmetry of the displayed equality provides the required empty-source classifier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier empty source e1 morphism iff`

Theorem 61.256 (Category hom-carrier one-headed target morphism cases)**.** *For histories source, r, morph, a hom-carrier whose target is one-headed has only the empty morphism case or a one-headed morphism tail:*

$$\mathsf{CategoryHomCarrier}(source, \mathsf{E1}(r), morph) \Longrightarrow (morph = \mathsf{e} \wedge source = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(r))$$

or there exists a history k such that

$$morph = \mathsf{E1}(k) \wedge \mathsf{UnaryHistory}(source) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{Cont}(source, k, r).$$

Proof. Unpack the hom-carrier witness into unary source, target, and morphism fields and the continuation ledger. Classify the morphism history. In the empty morphism branch, the continuation right-unit shape identifies the source with $\mathsf{E1}(r)$, and unary inversion on the target gives the unary history for r. The zero-headed morphism branch contradicts unary-history separation for zero extensions. In the one-headed branch, unary inversion gives the tail carrier for k, and constructor inversion on the continuation ledger yields $\mathsf{Cont}(source, k, r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 target morphism cases`

Theorem 61.257 (Category hom-carrier one-headed target source and morphism cases)**.** *For histories source, r, morph, a hom-carrier whose target is* $\mathsf{E1}(r)$ *separates the empty source branch from the one-headed source branch:*

$$\mathsf{CategoryHomCarrier}(source, \mathsf{E1}(r), morph) \Longrightarrow (source = \mathsf{e} \wedge morph = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(r))$$

or there exists a history a such that

$$source = \mathsf{E1}(a) \wedge \mathsf{UnaryHistory}(a) \wedge ((morph = \mathsf{e} \wedge \mathsf{hsame}(a, r)) \vee \exists k,\ morph = \mathsf{E1}(k) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{Cont}(\mathsf{E1}($$

Proof. Classify the source endpoint. If it is empty, the continuation ledger and the one-headed target force the morphism to be $\mathsf{E1}(r)$, and target unary inversion gives $\mathsf{UnaryHistory}(r)$. If it is zero-headed, the source unary field contradicts zero-extension separation. If it is one-headed, apply the left-one-headed result case split: the empty morphism branch gives $\mathsf{hsame}(a, r)$, and the visible morphism branch exposes a tail k with $\mathsf{Cont}(\mathsf{E1}(a), k, r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 target source morphism cases`

Theorem 61.258 (Category hom-carrier one-headed morphism target cases)**.** *For histories a, target, k, a hom-carrier whose morphism endpoint is one-headed forces the target endpoint to be one-headed and descends the hom-carrier to the exposed target and morphism tails:*

$$\mathsf{CategoryHomCarrier}(a, target, \mathsf{E1}(k)) \Longrightarrow \exists r : \mathsf{BHist}.\ target = \mathsf{E1}(r) \wedge \mathsf{CategoryHomCarrier}(a, r, k).$$

Proof. Unpack the hom-carrier into its unary source, target, and morphism fields and its continuation ledger. The continuation step-result inversion for a one-headed right input exposes a target tail r with $target = \mathsf{E1}(r)$ and a tail continuation $\mathsf{Cont}(a, k, r)$. Unary inversion on the displayed target and morphism fields gives the two tail carriers, which repack with the source carrier and tail continuation as $\mathsf{CategoryHomCarrier}(a, r, k)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 morphism target cases`

Theorem 61.259 (Category hom-carrier one-headed morphism source and target cases)**.** *For histories $source, target, k$, a hom-carrier whose morphism endpoint is one-headed separates the empty source branch from the one-headed source branch:*

$$\mathsf{CategoryHomCarrier}(source, target, \mathsf{E1}(k)) \Longrightarrow (source = \mathsf{e} \wedge target = \mathsf{E1}(k) \wedge \mathsf{UnaryHistory}(k))$$

or there exist histories a, r such that

$$source = \mathsf{E1}(a) \wedge target = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{E1}(a), k, r).$$

Proof. Classify the source endpoint. If it is empty, empty-source one-headed morphism exactness identifies the target with $\mathsf{E1}(k)$ and exposes $\mathsf{UnaryHistory}(k)$. If it is zero-headed, the source unary field contradicts zero-extension separation. If it is one-headed, one-headed-source one-headed-morphism target exactness exposes the target tail r, the unary source and morphism tails, the unary target tail, and the continuation ledger $\mathsf{Cont}(\mathsf{E1}(a), k, r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 morphism source target cases`

Theorem 61.260 (Category composite one-headed morphism target factor)**.** *For composable category hom-carriers $f : a \to b$ and $g : b \to c$, if their continuation composite is the one-headed morphism $\mathsf{E1}(k)$, then the target object is one-headed and the right factor is already a hom-carrier into that displayed target:*

$$\begin{aligned}&\mathsf{CategoryHomCarrier}(a, b, f) \wedge \mathsf{CategoryHomCarrier}(b, c, g) \wedge \mathsf{Cont}(f, g, \mathsf{E1}(k))\\ &\quad\Longrightarrow \exists r : \mathsf{BHist}.\ c = \mathsf{E1}(r) \wedge \mathsf{CategoryHomCarrier}(a, r, k) \wedge \mathsf{CategoryHomCarrier}(b, \mathsf{E1}(r), g).\end{aligned}$$

Proof. First close composition to obtain a hom-carrier from a to c with morphism $\mathsf{E1}(k)$. The one-headed morphism target case theorem exposes a history r with $c = \mathsf{E1}(r)$ and a descended hom-carrier from a to r with morphism k. Substituting the displayed target equality transports the original right factor from target c to target $\mathsf{E1}(r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp e1 morphism target factor`

Theorem 61.261 (Category composite one-headed morphism right factor cases)**.** *For composable category hom-carriers $f : a \to b$ and $g : b \to c$, if their continuation composite is the one-headed morphism $\mathsf{E1}(k)$, then the right factor is either the empty identity case at the recovered target or a visible one-headed morphism into that target:*

$$\begin{aligned}&\mathsf{CategoryHomCarrier}(a, b, f) \wedge \mathsf{CategoryHomCarrier}(b, c, g) \wedge \mathsf{Cont}(f, g, \mathsf{E1}(k))\\ &\quad\Longrightarrow (g = \mathsf{e} \wedge c = b \wedge \mathsf{CategoryHomCarrier}(a, b, \mathsf{E1}(k)))\\ &\qquad\vee \exists l, r : \mathsf{BHist}.\ g = \mathsf{E1}(l) \wedge c = \mathsf{E1}(r) \wedge \mathsf{CategoryHomCarrier}(a, r, k) \wedge \mathsf{CategoryHomCarrier}(b, \mathsf{E1}(r), \mathsf{E1}(l)).\end{aligned}$$

Proof. Apply the one-headed composite target-factor theorem to recover r with $c = \mathsf{E1}(r)$, a descended left hom-carrier $\mathsf{CategoryHomCarrier}(a, r, k)$, and the original right hom-carrier $\mathsf{CategoryHomCarrier}(b, \mathsf{E1}(r)$ Split this right hom-carrier by the one-headed target morphism cases. In the empty branch, the source equality $b = \mathsf{E1}(r)$ identifies c with b, and the one-headed morphism target equivalence rebuilds $\mathsf{CategoryHomCarrier}(a, b, \mathsf{E1}(k))$ from the descended left carrier. In the visible branch, substitute $g = \mathsf{E1}(l)$ and keep the original right hom-carrier at the recovered target. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp e1 morphism right factor cases`

Theorem 61.262 (Category composite one-headed morphism left factor cases)**.** *For composable category hom-carriers $f : a \to b$ and $g : b \to c$, if their continuation composite is the one-headed morphism $\mathsf{E1}(k)$, then the left factor is either the empty identity case at the source boundary or a visible one-headed morphism whose target is one-headed:*

$$\begin{aligned}
&\mathsf{CategoryHomCarrier}(a, b, f) \wedge \mathsf{CategoryHomCarrier}(b, c, g) \wedge \mathsf{Cont}(f, g, \mathsf{E1}(k)) \\
&\quad \Longrightarrow (f = \mathsf{e} \wedge a = b \wedge \mathsf{CategoryHomCarrier}(b, c, \mathsf{E1}(k))) \\
&\qquad \vee \exists l, r : \mathsf{BHist}.\ f = \mathsf{E1}(l) \wedge b = \mathsf{E1}(r) \wedge \mathsf{CategoryHomCarrier}(a, r, l) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(r), c, g) \wedge \mathsf{Cont}(\mathsf{E}
\end{aligned}$$

Proof. Classify the left morphism history. If it is empty, the left hom-carrier identity ledger identifies a and b, while the composite continuation with empty left factor transports the right hom-carrier to morphism $\mathsf{E1}(k)$. If the left morphism is zero-headed, its unary morphism field contradicts zero-extension separation. If it is one-headed, the one-headed morphism target case theorem exposes $b = \mathsf{E1}(r)$ and the descended left hom-carrier $\mathsf{CategoryHomCarrier}(a, r, l)$; substituting this target equality keeps the original right hom-carrier at source $\mathsf{E1}(r)$, and the original composite ledger is the visible-tail continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp e1 morphism left factor cases`

Theorem 61.263 (Category nonempty one-headed composite morphism factors)**.** *For composable category hom-carriers $f : a \to b$ and $g : b \to c$, if their continuation composite is $\mathsf{E1}(k)$ and neither factor is internally the empty morphism, then both factors and both exposed target objects are one-headed:*

$$\begin{aligned}
&\mathsf{CategoryHomCarrier}(a, b, f) \wedge \mathsf{CategoryHomCarrier}(b, c, g) \wedge \mathsf{Cont}(f, g, \mathsf{E1}(k)) \\
&\quad \wedge (f\mathsf{hsamee} \to \mathsf{False}) \wedge (g\mathsf{hsamee} \to \mathsf{False}) \\
&\Longrightarrow \exists l, m, r, s : \mathsf{BHist}.\ f = \mathsf{E1}(l) \wedge g = \mathsf{E1}(m) \wedge b = \mathsf{E1}(r) \wedge c = \mathsf{E1}(s) \\
&\qquad \wedge \mathsf{CategoryHomCarrier}(a, r, l) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(r), s, m) \wedge \mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), \mathsf{E1}(k)).
\end{aligned}$$

Proof. Apply the left factor case split for one-headed composites. The empty-left branch contradicts nonemptiness of f, so the visible-left branch exposes $f = \mathsf{E1}(l)$, $b = \mathsf{E1}(r)$, a descended carrier $\mathsf{CategoryHomCarrier}(a, r, l)$, and a right carrier from $\mathsf{E1}(r)$. Apply the nonempty one-headed-source morphism case split to that right carrier. The empty-right branch contradicts nonemptiness of g, and the visible-right branch exposes $g = \mathsf{E1}(m)$ and $c = \mathsf{E1}(s)$. Repacking its unary and continuation witnesses gives $\mathsf{CategoryHomCarrier}(\mathsf{E1}(r), s, m)$, while substituting $g = \mathsf{E1}(m)$ keeps the displayed composite continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp nonempty e1 morphism factors`

Theorem 61.264 (Category nonempty one-headed composite factor tail uniqueness)**.** *For composable category hom-carriers $f : a \to b$ and $g : b \to c$, if the composite continuation is $\mathsf{E1}(k)$, neither factor is internally empty, and the displayed factors are $f = \mathsf{E1}(l')$ and $g = \mathsf{E1}(m')$, then the descended factor tails are forced:*

$$\begin{aligned}
&\mathsf{CategoryHomCarrier}(a, b, f) \wedge \mathsf{CategoryHomCarrier}(b, c, g) \wedge \mathsf{Cont}(f, g, \mathsf{E1}(k)) \\
&\quad \wedge (f\mathsf{hsamee} \to \mathsf{False}) \wedge (g\mathsf{hsamee} \to \mathsf{False}) \wedge f = \mathsf{E1}(l') \wedge g = \mathsf{E1}(m') \\
&\implies \exists r, s : \mathsf{BHist}.\ b = \mathsf{E1}(r) \wedge c = \mathsf{E1}(s) \wedge \mathsf{CategoryHomCarrier}(a, r, l') \\
&\qquad \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(r), s, m') \wedge \mathsf{Cont}(\mathsf{E1}(l'), \mathsf{E1}(m'), \mathsf{E1}(k)).
\end{aligned}$$

Proof. The nonempty factor theorem exposes one-headed witnesses for both factors. Substituting the displayed equalities $f = \mathsf{E1}(l')$ and $g = \mathsf{E1}(m')$ identifies the exposed tails with l' and m'. The same factor package then supplies the middle and target objects, the two descended hom-carriers, and the displayed one-headed composite continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp nonempty e1 morphism factor tail unique`

Theorem 61.265 (Category nonempty one-headed composite result descent)**.** *For composable category hom-carriers $f : a \to b$ and $g : b \to c$, if their continuation composite is $\mathsf{E1}(k)$ and neither factor is internally the empty morphism, then the exposed tail data also carries the descended composite hom-carrier:*

$$\begin{aligned}
&\mathsf{CategoryHomCarrier}(a, b, f) \wedge \mathsf{CategoryHomCarrier}(b, c, g) \wedge \mathsf{Cont}(f, g, \mathsf{E1}(k)) \\
&\quad \wedge (f\mathsf{hsamee} \to \mathsf{False}) \wedge (g\mathsf{hsamee} \to \mathsf{False}) \\
&\implies \exists l, m, r, s : \mathsf{BHist}.\ f = \mathsf{E1}(l) \wedge g = \mathsf{E1}(m) \wedge b = \mathsf{E1}(r) \wedge c = \mathsf{E1}(s) \\
&\qquad \wedge \mathsf{CategoryHomCarrier}(a, r, l) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(r), s, m) \wedge \mathsf{CategoryHomCarrier}(a, s, k).
\end{aligned}$$

Proof. The nonempty factor theorem exposes l, m, r, s together with $\mathsf{CategoryHomCarrier}(a, r, l)$, $\mathsf{CategoryHomCarrier}(\mathsf{E1}(r), s, m)$, and $\mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), \mathsf{E1}(k))$. Constructor inversion on the last continuation gives $\mathsf{Cont}(\mathsf{E1}(l), m, k)$. Combining the left carrier continuation $a \cdot l = r$ with the right carrier continuation $\mathsf{E1}(r) \cdot m = s$, associativity of BEDC continuation identifies $a \cdot k$ with s. The unary fields from the two carrier witnesses and the visible-tail continuation supply the remaining fields of $\mathsf{CategoryHomCarrier}(a, s, k)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp nonempty e1 morphism result descent`

Theorem 61.266 (Category nonempty one-headed composite result descent uniqueness)**.** *For composable category hom-carriers $f : a \to b$ and $g : b \to c$, if their continuation composite is $\mathsf{E1}(k)$, neither factor is internally empty, and a displayed carrier also presents $k : a \to s'$, then the descended target agrees with s':*

$$\begin{aligned}
&\mathsf{CategoryHomCarrier}(a, b, f) \wedge \mathsf{CategoryHomCarrier}(b, c, g) \wedge \mathsf{Cont}(f, g, \mathsf{E1}(k)) \\
&\quad \wedge (f\mathsf{hsamee} \to \mathsf{False}) \wedge (g\mathsf{hsamee} \to \mathsf{False}) \wedge \mathsf{CategoryHomCarrier}(a, s', k) \\
&\implies \exists l, m, r, s : \mathsf{BHist}.\ f = \mathsf{E1}(l) \wedge g = \mathsf{E1}(m) \wedge b = \mathsf{E1}(r) \wedge c = \mathsf{E1}(s) \\
&\qquad \wedge \mathsf{CategoryHomCarrier}(a, r, l) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(r), s, m) \wedge \mathsf{CategoryHomCarrier}(a, s, k) \wedge s\mathsf{hsame}s'.
\end{aligned}$$

Proof. The result-descent theorem supplies the exposed factors and the descended carrier $\mathsf{CategoryHomCarrier}(a, s, k$ Comparing that carrier with the displayed carrier $\mathsf{CategoryHomCarrier}(a, s', k)$ by target determinism gives $s\mathsf{hsame}s'$, while the exposed factor data is retained unchanged. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp nonempty e1 morphism result descent unique`

Theorem 61.267 (Category nonempty one-headed composite tail-result descent)**.** *For composable category hom-carriers $f : a \to b$ and $g : b \to c$, if their continuation composite is $\mathsf{E1}(k)$ and neither factor is internally the empty morphism, then the same exposed factor data also carries the visible tail continuation into the descended composite carrier:*

$$\begin{aligned}&\mathsf{CategoryHomCarrier}(a,b,f) \wedge \mathsf{CategoryHomCarrier}(b,c,g) \wedge \mathsf{Cont}(f,g,\mathsf{E1}(k))\\ &\quad \wedge (f\mathsf{hsamee} \to \mathsf{False}) \wedge (g\mathsf{hsamee} \to \mathsf{False})\\ &\Longrightarrow \exists l,m,r,s : \mathsf{BHist}.\ f = \mathsf{E1}(l) \wedge g = \mathsf{E1}(m) \wedge b = \mathsf{E1}(r) \wedge c = \mathsf{E1}(s)\\ &\qquad \wedge \mathsf{CategoryHomCarrier}(a,r,l) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(r),s,m) \wedge \mathsf{Cont}(\mathsf{E1}(l),m,k) \wedge \mathsf{CategoryHomCarrier}(a,s\end{aligned}$$

Proof. Apply the nonempty factor theorem to obtain the one-headed factor displays and the visible composite continuation $\mathsf{Cont}(\mathsf{E1}(l),\mathsf{E1}(m),\mathsf{E1}(k))$. Constructor inversion turns that ledger into $\mathsf{Cont}(\mathsf{E1}(l),m,k)$. The same carrier fields and continuation associativity then reconstruct the descended composite hom-carrier $\mathsf{CategoryHomCarrier}(a,s,k)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp nonempty e1 morphism tail result descent`

Corollary 61.268 (Category empty one-headed endpoint consumer determinacy)**.** *For histories $a,r,x,b,c,f,g,k,l',m' : \mathsf{BHist}$, suppose the nonempty composite surface fixes the displayed factor rows*

$$\begin{aligned}&\mathsf{CategoryHomCarrier}(x,b,f) \wedge \mathsf{CategoryHomCarrier}(b,c,g) \wedge \mathsf{Cont}(f,g,\mathsf{E1}(k))\\ &\quad \wedge (f\mathsf{hsamee} \to \mathsf{False}) \wedge (g\mathsf{hsamee} \to \mathsf{False}) \wedge f = \mathsf{E1}(l') \wedge g = \mathsf{E1}(m').\end{aligned}$$

Then the empty morphism between the one-headed endpoints has the single chapter exactness decision

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a),\mathsf{E1}(r),\mathsf{e}) \Longleftrightarrow \mathsf{UnaryHistory}(a) \wedge \mathsf{hsame}(a,r),$$

and the nonempty visible-composite readback has the forced finite factor route

$$\exists u,v : \mathsf{BHist}.\ b = \mathsf{E1}(u) \wedge c = \mathsf{E1}(v) \wedge \mathsf{CategoryHomCarrier}(x,u,l')$$

$$\wedge\ \mathsf{CategoryHomCarrier}(\mathsf{E1}(u),v,m') \wedge \mathsf{Cont}(\mathsf{E1}(l'),\mathsf{E1}(m'),\mathsf{E1}(k)).$$

Consequently, once these rows are fixed, every accepted consumer-facing route, normal-form read, or exactness decision for the empty one-headed endpoint and its attached nonempty visible composite factors through the same listed rows: the empty row supplies only $\mathsf{UnaryHistory}(a)$ *and* $\mathsf{hsame}(a,r)$*, while the nonempty row supplies only the displayed tails l',m' and the recovered endpoints u,v. There is no alternate hidden coordinate and no duplicate classifier source for this packet.*

Proof. The empty endpoint part is exactly Definition 61.252. It reads the carrier $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a),\mathsf{E1}(r),\mathsf{e}$ as unary membership of the exposed source tail together with the endpoint classifier $\mathsf{hsame}(a,r)$, and it provides the converse reconstruction from precisely those two rows. Thus the empty morphism exposes no visible tail, middle endpoint, or second classifier coordinate.

For the nonempty visible-composite part, apply Definition 61.264 to the fixed hom-carrier rows, the fixed continuation row, the two internal nonemptiness assumptions, and the displayed identities $f = \mathsf{E1}(l')$ and $g = \mathsf{E1}(m')$. The theorem returns histories u and v with $b = \mathsf{E1}(u)$ and $c = \mathsf{E1}(v)$, together with the descended carrier rows $\mathsf{CategoryHomCarrier}(x,u,l')$ and $\mathsf{CategoryHomCarrier}(\mathsf{E1}(u),v,m')$, and the visible composite continuation $\mathsf{Cont}(\mathsf{E1}(l'),\mathsf{E1}(m'),\mathsf{E1}(k))$.

These are exactly the route and readback rows displayed in the conclusion. An accepted consumer use that keeps the hypotheses fixed cannot choose a different empty exactness decision without contradicting the first iff, and cannot choose different visible factor tails without contradicting the factor-tail uniqueness readback, because the displayed equalities have already identified the exposed tails with l' and m'. Hence every accepted use factors through the listed finite rows and no unlisted coordinate remains available. □

Theorem 61.269 (Category visible composable morphism target cases)**.** *For histories a, b, c, l, m, k, if*

$$\mathsf{CategoryHomCarrier}(a, b, \mathsf{E1}(l)), \qquad \mathsf{CategoryHomCarrier}(b, c, \mathsf{E1}(m)), \qquad \mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), \mathsf{E1}(k)),$$

then there exist histories r, s such that

$$b = \mathsf{E1}(r) \wedge c = \mathsf{E1}(s) \wedge \mathsf{CategoryHomCarrier}(a, r, l) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(r), s, m) \wedge \mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), \mathsf{E1}(k)).$$

Proof. Apply the one-headed morphism target-case theorem to the left visible hom-carrier and to the right visible hom-carrier. The two applications expose tails r and s with $b = \mathsf{E1}(r)$ and $c = \mathsf{E1}(s)$. Substitute the first target equality into the right descended hom-carrier, retain the left descended hom-carrier, and carry the original visible continuation ledger into the existential package. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier visible composable morphisms target cases`

Theorem 61.270 (Category visible composable morphism tail cases)**.** *For histories a, b, c, l, m, k, if*

$$\mathsf{CategoryHomCarrier}(a, b, \mathsf{E1}(l)), \qquad \mathsf{CategoryHomCarrier}(b, c, \mathsf{E1}(m)), \qquad \mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), \mathsf{E1}(k)),$$

then there exist histories r, s such that

$$b = \mathsf{E1}(r) \wedge c = \mathsf{E1}(s) \wedge \mathsf{CategoryHomCarrier}(a, r, l) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(r), s, m) \wedge \mathsf{Cont}(\mathsf{E1}(l), m, k).$$

Proof. First apply the visible composable target-case theorem to expose the intermediate and final target tails r and s, together with the two descended hom-carriers. The remaining continuation ledger is obtained by right inversion of the one-headed step rule for $\mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), \mathsf{E1}(k))$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier visible composable morphisms tail cases`

Theorem 61.271 (Category hom-carrier composite visible morphisms result cases)**.** *For histories a, b, c, l, m, fg, if*

$$\mathsf{CategoryHomCarrier}(a, b, \mathsf{E1}(l)), \qquad \mathsf{CategoryHomCarrier}(b, c, \mathsf{E1}(m)), \qquad \mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), fg),$$

then there exists a history k such that

$$fg = \mathsf{E1}(k) \wedge \mathsf{Cont}(\mathsf{E1}(l), m, k) \wedge \mathsf{CategoryHomCarrier}(a, c, \mathsf{E1}(k)).$$

Proof. The continuation ledger unfolds the composite result as $\mathsf{append}(\mathsf{E1}(l), \mathsf{E1}(m))$, which is definitionally $\mathsf{E1}(\mathsf{append}(\mathsf{E1}(l), m))$. Choose $k = \mathsf{append}(\mathsf{E1}(l), m)$. The exposed tail continuation is the canonical append continuation, and the hom-carrier result is obtained by applying hom-carrier composition closure to the two visible morphisms and the same canonical continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp visible morphisms result cases`

Theorem 61.272 (Category hom-carrier nonempty morphism target visible)**.** *For histories* $source, target, morph$: BHist*, if*

$$\mathsf{CategoryHomCarrier}(source, target, morph)$$

and morph is not internally empty, then the morphism and target are both one-headed and the hom-continuation ledger descends through their exposed payloads:

$$\exists k, r.\ morph = \mathsf{E1}(k) \wedge target = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(source, k, r).$$

Proof. Unpack the hom-carrier witness. The morphism cannot be empty by the nonempty hypothesis, and it cannot be zero-headed because unary histories have no zero-headed extension. In the one-headed morphism case, the continuation ledger forces the result target to be one-headed; constructor inversion then exposes the target payload, both unary payload witnesses, and the descended continuation ledger. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier nonempty morphism target visible`

Theorem 61.273 (Category hom-carrier nonempty morphism visible endpoint cases)**.** *For histories* $source, target, morph$: BHist*, if*

$$\mathsf{CategoryHomCarrier}(source, target, morph)$$

and morph is not internally empty, then either the source is empty and the visible target and morphism coincide, or all three visible endpoints are one-headed:

$$\exists r.\ source = \mathsf{e} \wedge target = \mathsf{E1}(r) \wedge morph = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(r)$$
$$\vee \exists a, k, r.\ source = \mathsf{E1}(a) \wedge morph = \mathsf{E1}(k) \wedge target = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}($$

Proof. Inspect the source constructor. In the empty-source branch, the empty-source hom-carrier law identifies the morphism with the target; the nonempty morphism hypothesis removes the empty target case, and unary generation removes the zero-headed target case. In the one-headed source branch, the nonempty and unary hypotheses force the morphism to be one-headed, and the continuation ledger then forces the target to be one-headed. Constructor inversion exposes the three unary payloads and the descended continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier nonempty morphism visible endpoint cases`

Theorem 61.274 (Category visible composite result target cases)**.** *For histories* a, b, c, l, m, fg*, if*

$$\mathsf{CategoryHomCarrier}(a, b, \mathsf{E1}(l)), \qquad \mathsf{CategoryHomCarrier}(b, c, \mathsf{E1}(m)), \qquad \mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), fg),$$

then there exist histories k, r, s *such that*

$$fg = \mathsf{E1}(k) \wedge b = \mathsf{E1}(r) \wedge c = \mathsf{E1}(s) \wedge \mathsf{CategoryHomCarrier}(a, r, l) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(r), s, m) \wedge \mathsf{CategoryHom}$$

Proof. The visible composite result theorem exposes $fg = \mathsf{E1}(k)$ and the composite hom-carrier from a to c with morphism $\mathsf{E1}(k)$. Applying one-headed morphism target cases to the two visible factors exposes $b = \mathsf{E1}(r)$ and $c = \mathsf{E1}(s)$, with the descended factor hom-carriers. Substituting the target equalities gives the displayed target-specific composite carrier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp visible morphisms result target cases`

Theorem 61.275 (Category hom-carrier visible composite result is not empty)**.** *For histories* a, b, c, l, m, fg*, if*

$$\mathsf{CategoryHomCarrier}(a, b, \mathsf{E1}(l)), \qquad \mathsf{CategoryHomCarrier}(b, c, \mathsf{E1}(m)), \qquad \mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), fg),$$

then fg *cannot be internally the same as* e*.*

Proof. Invert the displayed continuation ledger. The result is definitionally $\mathsf{append}(\mathsf{E1}(l), \mathsf{E1}(m))$, hence one-headed. Constructor no-confusion rejects any hsame comparison between that one-headed result and e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp visible morphisms result not empty`

Theorem 61.276 (Category hom-carrier nonempty composite target visible)**.** *For the unary-continuation category, suppose*

$$\mathsf{CategoryHomCarrier}(a, b, f), \qquad \mathsf{CategoryHomCarrier}(b, c, g), \qquad \mathsf{Cont}(f, g, fg).$$

If the displayed composite morphism fg *is not internally empty, then* fg *and the target object* c *are both one-headed, and the composite continuation ledger is visible at that boundary:*

$$\exists k, r.\ fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(a, \mathsf{E1}(k), \mathsf{E1}(r)).$$

Proof. Composition closure turns the two hom-carriers and the displayed composite ledger into a hom-carrier from a to c over fg. The composite morphism is unary. The empty case contradicts the nonempty hypothesis, and the zero-headed case contradicts unary generation. In the one-headed case, the target cannot be empty or zero-headed because the continuation ledger has one-headed result shape; the remaining target case exposes $c = \mathsf{E1}(r)$ and carries the original continuation witness at the visible boundary. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result nonempty target visible`

Theorem 61.277 (Category hom-carrier nonempty composite target not empty)**.** *For the unary-continuation category, suppose*

$$\mathsf{CategoryHomCarrier}(a, b, f), \qquad \mathsf{CategoryHomCarrier}(b, c, g), \qquad \mathsf{Cont}(f, g, fg).$$

If the displayed composite morphism fg *is not internally empty, then the target object* c *is not internally empty:*

$$\neg\mathsf{hsame}(fg, \mathsf{e}) \Longrightarrow \neg\mathsf{hsame}(c, \mathsf{e}).$$

Proof. Apply the nonempty target-visible theorem. It presents the target as $c = \mathsf{E1}(r)$ for a unary payload r. Constructor separation rules out an internal equality between this one-headed target and e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result nonempty target not empty`

Theorem 61.278 (Category nonempty composite source-target cases)**.** *For the unary-continuation category, suppose*

$$\mathsf{CategoryHomCarrier}(a, b, f), \qquad \mathsf{CategoryHomCarrier}(b, c, g), \qquad \mathsf{Cont}(f, g, fg).$$

If the displayed composite morphism fg *is not internally empty, then either the source object is empty and the visible target boundary is carried directly, or the source object is itself one-headed and the whole visible source, composite, and target boundary is displayed:*

$$\begin{aligned}&(\mathsf{hsame}(a, \mathsf{e}) \wedge \exists k, r.\ fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(a, \mathsf{E1}(k), \mathsf{E1}(r)))\\ &\vee(\exists s, k, r.\ a = \mathsf{E1}(s) \wedge fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(s) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{E1}(s\end{aligned}$$

Proof. First apply the nonempty target-visible theorem to the displayed composite. This gives one-headed presentations of fg and c together with the continuation ledger at that visible target boundary. Inspect the source object a. The empty case gives the first disjunct. The zero-headed case contradicts the unary source field of the left hom-carrier. The one-headed case exposes the source tail and reuses the same visible continuation ledger. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp result nonempty source target cases`

Theorem 61.279 (Category nonempty result visible hom readback)**.** *For the unary-continuation category, suppose*

$$\mathsf{CategoryHomCarrier}(a, b, f), \qquad \mathsf{CategoryHomCarrier}(b, c, g), \qquad \mathsf{Cont}(f, g, fg).$$

If the displayed composite morphism fg is not internally empty, then its one-headed result presentation also reads back as a visible composite hom-carrier:

$$\exists k, r.\ fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{CategoryHomCarrier}(a, \mathsf{E1}(r), \mathsf{E1}(k)).$$

Proof. Apply the nonempty composite target-visible theorem. It exposes histories k, r with $fg = \mathsf{E1}(k)$ and $c = \mathsf{E1}(r)$, together with unary witnesses for k and r and the boundary continuation $\mathsf{Cont}(a, \mathsf{E1}(k), \mathsf{E1}(r))$. The source unary witness is already part of the left hom-carrier, so these fields assemble the visible hom-carrier $\mathsf{CategoryHomCarrier}(a, \mathsf{E1}(r), \mathsf{E1}(k))$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp nonempty result visible hom readback`

Theorem 61.280 (Category nonempty result visible source hom readback)**.** *For the unary-continuation category, suppose*

$$\mathsf{CategoryHomCarrier}(a, b, f), \qquad \mathsf{CategoryHomCarrier}(b, c, g), \qquad \mathsf{Cont}(f, g, fg).$$

If both the displayed composite morphism fg and the source object a are not internally empty, then the visible result presentation reads back with a visible source:

$$\exists s, k, r.\ a = \mathsf{E1}(s) \wedge fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{CategoryHomCarrier}(\mathsf{E1}(s), \mathsf{E1}(r), \mathsf{E1}(k)).$$

Proof. First apply the nonempty result visible hom readback theorem to obtain visible histories k, r and the hom-carrier $\mathsf{CategoryHomCarrier}(a, \mathsf{E1}(r), \mathsf{E1}(k))$. Inspect the source object a. The empty branch contradicts the nonempty source hypothesis; the zero branch contradicts the unary source field of the hom-carrier. In the one-headed branch, the exposed source tail supplies s, and the displayed hom-carrier is already the required visible-source carrier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier comp nonempty result visible source hom readback`

Theorem 61.281 (Category visible composite target bridge determinacy)**.** *For the unary-continuation category, suppose*

$$\mathsf{CategoryHomCarrier}(a, b, f), \qquad \mathsf{CategoryHomCarrier}(b, c, g), \qquad \mathsf{Cont}(f, g, fg).$$

If the displayed composite morphism fg is not internally empty, then every consumer-facing route, transport, readback, or handoff for the visible composite target boundary factors through the following finite local surface:

result readback: $\exists k, r.\ fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{CategoryHomCarrier}(a, \mathsf{E1}(r), \mathsf{E1}(k)),$

source-target cases: $(\mathsf{hsame}(a, \mathsf{e}) \wedge \exists k, r.\ fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(a, \mathsf{E}$
$\vee(\exists s, k, r.\ a = \mathsf{E1}(s) \wedge fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(s) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryH}$

Consequently the bridge exports only the displayed result history, visible target history, visible hom-carrier readback, empty-source branch, and one-headed source-target branch. It exports no separate coordinate for a host composite target, an alternate composite morphism, a chosen external category morphism, or a consumer-side target not obtained from these rows.

Proof. Apply Definition 61.279 to the three displayed hypotheses and the nonempty result premise. This gives the result readback row: histories k, r with $fg = \mathsf{E1}(k)$, $c = \mathsf{E1}(r)$, and the visible composite hom-carrier $\mathsf{CategoryHomCarrier}(a, \mathsf{E1}(r), \mathsf{E1}(k))$. Thus any consumer read of the nonempty composite target must first pass through the same visible result and target presentations.

Apply Definition 61.278 to the same hypotheses. Its first branch is exactly the empty-source route, where the boundary continuation is displayed as $\mathsf{Cont}(a, \mathsf{E1}(k), \mathsf{E1}(r))$ together with the unary witnesses for the result and target payloads. Its second branch is exactly the visible source-target route, where $a = \mathsf{E1}(s)$ and the boundary continuation descends to $\mathsf{Cont}(\mathsf{E1}(s), \mathsf{E1}(k), \mathsf{E1}(r))$ with unary witnesses for all three payloads.

The two cited rows account for every displayed consumer operation in the nonempty composite target boundary. Readback uses the first row, source or target transport uses the branch data in the second row, and any visible-source handoff is the second disjunct with the same $fg = \mathsf{E1}(k)$ and $c = \mathsf{E1}(r)$ presentations. Since the hypotheses supply only the two hom-carrier rows, the single continuation ledger, and the nonempty result premise, and since the cited theorems expose exactly the coordinates listed above, no unlisted bridge coordinate can be projected from this local surface. □

Corollary 61.282 (Category visible composite target consumer determinacy)**.** *For the unary-continuation category, suppose*

$$\mathsf{CategoryHomCarrier}(a, b, f), \qquad \mathsf{CategoryHomCarrier}(b, c, g), \qquad \mathsf{Cont}(f, g, fg).$$

If the displayed composite morphism fg is not internally empty, and if the result-readback and source-target rows displayed by Definition 61.281 are fixed, then every accepted consumer-facing use of the visible composite target boundary chooses the same finite route, normal form, or exactness decision named by this chapter. The fixed surface is exactly

result readback: $\exists k, r.\ fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{CategoryHomCarrier}(a, \mathsf{E1}(r), \mathsf{E1}(k)),$

source-target cases: $(\mathsf{hsame}(a, \mathsf{e}) \wedge \exists k, r.\ fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(a, \mathsf{E}$
$\vee (\exists s, k, r.\ a = \mathsf{E1}(s) \wedge fg = \mathsf{E1}(k) \wedge c = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(s) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryH}$

Consequently two accepted consumers over those fixed rows cannot select different finite routes, different visible target normal forms, or different exactness decisions, and no accepted use can introduce an alternate hidden coordinate or duplicate classifier source for the composite target.

Proof. Apply Definition 61.281 to the two displayed hom-carrier rows, the displayed continuation row, and the nonempty composite premise. Its determinacy statement says that every consumer-facing route, transport, readback, or handoff for the visible composite target boundary factors through the two-row local surface written above.

The first row is the result-readback normal form: it presents the composite morphism as $fg = \mathsf{E1}(k)$, the target as $c = \mathsf{E1}(r)$, and the consumer-visible hom-carrier as $\mathsf{CategoryHomCarrier}(a, \mathsf{E1}(r), \mathsf{E1}(k))$. Thus any accepted result readback has the same visible composite morphism coordinate, the same visible target coordinate, and the same hom-carrier readback route once that row is fixed.

For source and target transport, apply Definition 61.278 to the same three structural rows and the same nonempty premise. Its first branch is exactly the empty-source boundary row, carrying

$\mathsf{hsame}(a, \mathsf{e})$ together with $fg = \mathsf{E1}(k)$, $c = \mathsf{E1}(r)$, the two unary witnesses, and the boundary continuation $\mathsf{Cont}(a, \mathsf{E1}(k), \mathsf{E1}(r))$. Its second branch is exactly the one-headed source-target boundary row, carrying $a = \mathsf{E1}(s)$ together with the same visible result and target presentations and the descended continuation $\mathsf{Cont}(\mathsf{E1}(s), \mathsf{E1}(k), \mathsf{E1}(r))$. Hence every accepted source-target normal form or exactness decision is one of these two displayed branches.

It remains to exclude competing consumer choices. The bridge determinacy theorem exports no separate coordinate for a host composite target, alternate composite morphism, chosen external category morphism, or consumer-side target outside these rows. The source-target theorem consumes only the displayed hom-carrier rows, the displayed continuation row, and the nonempty premise, and returns only the two listed branches. Therefore an alleged alternate hidden coordinate or duplicate classifier source is neither a component of the result-readback row nor a component of either source-target branch. It has no local factor through the accepted visible composite target surface, so it cannot determine a second finite route, normal form, or exactness decision for the fixed rows. □

Theorem 61.283 (Continuation morphism composite visible tails result cases)**.** *For histories a, b, c, l, m, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$. If the two displayed tails are $\mathsf{hsame}(\mathsf{tail}(left), \mathsf{E1}(l))$ and $\mathsf{hsame}(\mathsf{tail}(right), \mathsf{E1}(m))$, then there exists a history k such that*

$$\mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{E1}(k)) \wedge \mathsf{Cont}(\mathsf{E1}(l), m, k).$$

Proof. Unpack the two continuation morphism records. The closed composite stores the append of the two visible tails as its displayed tail, which is definitionally one-headed. Choose the exposed payload append as k; the remaining continuation ledger is the canonical append continuation from $\mathsf{E1}(l)$ through m. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp visible tails result cases`

Theorem 61.284 (Continuation morphism visible-tail composite result is not empty)**.** *For histories a, b, c, l, m, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$. If the two displayed tails are $\mathsf{hsame}(\mathsf{tail}(left), \mathsf{E1}(l))$ and $\mathsf{hsame}(\mathsf{tail}(right), \mathsf{E1}(m))$, then the closed composite tail cannot be internally the same as e.*

Proof. Unpack the two continuation morphism records and substitute the visible-tail equalities. The closed composite tail is the append of two one-headed tails, which is itself one-headed. BEDC constructor separation rules out an internal history sameness proof from this one-headed tail to e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp visible tails result not empty`

Theorem 61.285 (Continuation morphism composite tail nonempty cases)**.** *For histories a, b, c, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$. If the closed composite tail is not internally empty, then at least one displayed factor tail is not internally empty:*

$$\neg\mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \Rightarrow \neg\mathsf{hsame}(\mathsf{tail}(left), \mathsf{e}) \vee \neg\mathsf{hsame}(\mathsf{tail}(right), \mathsf{e}).$$

Proof. Unpack the two continuation morphism records and inspect the left displayed tail. If it is empty, the composite tail reduces to the right displayed tail, so right-tail emptiness would contradict the composite nonemptiness hypothesis. If it is zero-headed or one-headed, BEDC constructor separation rules out any equality from that left tail to e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail nonempty cases`

Theorem 61.286 (Continuation morphism composite tail nonempty endpoint cases)**.** *For histories a, b, c, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If the closed composite tail is not internally empty, then at least one adjacent endpoint comparison fails:*

$$\neg\mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \Rightarrow \neg\mathsf{hsame}(a, b) \vee \neg\mathsf{hsame}(b, c).$$

Proof. First split composite tail nonemptiness into nonemptiness of one displayed factor tail. For each factor, use the empty-tail endpoint iff for continuation morphisms: an endpoint comparison would force the corresponding tail to be internally empty. This contradicts the selected tail-nonempty branch. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail nonempty endpoint cases`

Theorem 61.287 (Continuation morphism composite tail nonempty equivalence)**.** *For histories a, b, c, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. The closed composite tail is not internally empty exactly when at least one displayed factor tail is not internally empty:*

$$\neg\mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \iff \neg\mathsf{hsame}(\mathsf{tail}(left), \mathsf{e}) \vee \neg\mathsf{hsame}(\mathsf{tail}(right), \mathsf{e}).$$

Proof. Unpack the two continuation morphism records. The composite tail is the append of the displayed factor tails, so the append nonempty factor equivalence gives the displayed statement. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail nonempty iff`

Theorem 61.288 (Continuation morphism composite target empty iff)**.** *For histories a, b, c, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. The final target is empty exactly when both sources and both displayed factor tails are empty:*

$$\mathsf{hsame}(c, \mathsf{e}) \iff \mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(b, \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(left), \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(right), \mathsf{e}).$$

Proof. If $c\mathsf{hsamee}$, transport the right continuation ledger to empty target and apply two-stage empty-target inversion. This yields empty source, empty middle, and empty tails for the two displayed factors.

Conversely, destruct the right continuation morphism. The empty middle and empty right-tail witnesses reduce its continuation ledger to the canonical empty continuation, forcing the target to be e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp target empty iff`

Theorem 61.289 (Continuation morphism composite nonempty tail rejects empty target)**.** *For histories a, b, c, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If the closed composite tail is not internally empty, then the final target cannot be internally empty:*

$$\neg\mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{e}) \Rightarrow \neg\mathsf{hsame}(c, \mathsf{e}).$$

Proof. Transport the right continuation relation across an internal equality $c\mathsf{hsamee}$. The empty-target inversion for the two-stage continuation then forces both displayed tails to be internally empty. The composite-tail nonempty equivalence turns the composite nonemptiness hypothesis into nonemptiness of one displayed factor tail, contradicting the inversion data. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail nonempty target not empty`

Theorem 61.290 (Continuation morphism composite unary tails reject zero-headed result)**.** *For histories a, b, c, z, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If both displayed tails are unary histories, then the closed composite tail cannot be internally the same as $\mathsf{E0}(z)$.*

Proof. Unpack the two continuation morphism records. The closed composite tail is the append of the two component tails, and unary closure under append keeps that composite tail unary. A unary history cannot be internally the same as a zero-headed history, by the BEDC unary zero-exclusion rule. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp unary tail e0 absurd`

Theorem 61.291 (Continuation morphism composite one-headed tail left cases)**.** *For histories a, b, c, k, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If the composite displayed tail is classified by $\mathsf{E1}(k)$ and the left displayed tail is unary, then either the left displayed tail is empty and the right displayed tail is classified by $\mathsf{E1}(k)$, or the left displayed tail is itself one-headed and forms a continuation witness with the right displayed tail to $\mathsf{E1}(k)$.*

Proof. Unpack the two continuation morphism records and inspect the left tail. The empty case reduces the composite tail by left-unit append. The zero-headed case contradicts unary classification. In the one-headed case, the displayed composite equality is exactly the continuation witness from the exposed left tail and the right tail to $\mathsf{E1}(k)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp e1 tail left cases`

Theorem 61.292 (Continuation morphism composite one-headed tail right cases)**.** *For histories a, b, c, k, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If the composite displayed tail is classified by $\mathsf{E1}(k)$ and the right displayed tail is unary, then either the right displayed tail is empty and the left displayed tail is classified by $\mathsf{E1}(k)$, or the right displayed tail is itself one-headed and forms a continuation witness from the left displayed tail to $\mathsf{E1}(k)$.*

Proof. Unpack the two continuation morphism records and inspect the right tail. The empty case reduces the composite tail by right-unit append. The zero-headed case contradicts unary classification. In the one-headed case, the displayed composite equality is exactly the continuation witness from the left tail and the exposed right tail to $\mathsf{E1}(k)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp e1 tail right cases`

Theorem 61.293 (Continuation morphism composite zero-headed tail left cases)**.** *For histories a, b, c, k, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If the composite displayed tail is classified by $\mathsf{E0}(k)$ and the left displayed tail is unary, then either the left displayed tail is empty and the right displayed tail is classified by $\mathsf{E0}(k)$, or the left displayed tail is one-headed and forms a continuation witness with the right displayed tail to $\mathsf{E0}(k)$.*

Proof. Unpack the two continuation morphism records and inspect the left tail. The empty case reduces the composite tail by left-unit append. The zero-headed case contradicts unary classification of the left tail. In the one-headed case, the displayed composite equality is exactly the continuation witness from the exposed left tail and the right tail to $\mathsf{E0}(k)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp e0 tail left cases`

Theorem 61.294 (Continuation morphism composite zero-headed tail right cases)**.** *For histories a, b, c, k, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If the composite displayed tail is classified by $\mathsf{E0}(k)$ and the right displayed tail is unary, then the right displayed tail is empty and the left displayed tail is classified by $\mathsf{E0}(k)$.*

Proof. Unpack the two continuation morphism records and inspect the right tail. The empty case reduces the composite tail by right-unit append. The zero-headed case contradicts unary classification of the right tail. The one-headed case would classify a one-headed composite tail as zero-headed, contradicting BEDC constructor separation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp e0 tail right cases`

Theorem 61.295 (Continuation morphism nonempty one-headed composite factors)**.** *For histories a, b, c, k, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If both displayed tails are unary and nonempty, and the composite displayed tail is classified by $\mathsf{E1}(k)$, then there are histories l, m such that the left and right displayed tails are classified by $\mathsf{E1}(l)$ and $\mathsf{E1}(m)$, and*

$$\mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), \mathsf{E1}(k)).$$

Proof. Destructure both displayed tails. Empty tails contradict the corresponding nonempty hypotheses, and zero-headed tails contradict unary classification. The remaining one-headed–one-headed case exposes l and m directly, while the composite displayed equality supplies the continuation ledger. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp nonempty e1 tail factors`

Theorem 61.296 (Continuation morphism nonempty one-headed composite factors are unique)**.** *For histories a, b, c, k, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If both displayed tails are unary and nonempty, and the composite displayed tail is classified by $\mathsf{E1}(k)$, then there are histories l, m such that the left and right displayed tails are classified by $\mathsf{E1}(l)$ and $\mathsf{E1}(m)$, the visible boundary satisfies*

$$\mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), \mathsf{E1}(k)),$$

and any other visible payloads l', m' with the same two displayed tail classifications and the same visible boundary satisfy $\mathsf{hsame}(l, l') \wedge \mathsf{hsame}(m, m')$.

Proof. Destructure both displayed tails. Empty tails contradict nonemptiness and zero-headed tails contradict unary classification. In the remaining one-headed–one-headed case, the witnesses are the two exposed payloads. Constructor injectivity for $\mathsf{E1}$ turns any competing left and right tail classifications into the two payload equalities, while the displayed composite equality supplies the boundary continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp nonempty e1 tail factors unique`

Theorem 61.297 (Continuation morphism right one-headed tail target cases)**.** *For histories b, c, m, let $right$: $\mathsf{ContinuationMorphism}(b, c)$. If the displayed tail of $right$ is internally the same as $\mathsf{E1}(m)$, then the target is one-headed:*

$$\exists r : \mathsf{BHist}.\ c = \mathsf{E1}(r) \wedge \mathsf{Cont}(b, m, r).$$

Proof. Unpack the continuation morphism record and replace its displayed tail by $\mathsf{E1}(m)$. The BEDC continuation step-result inversion then exposes the unique one-headed target payload r and the descended continuation $\mathsf{Cont}(b, m, r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism right e1 tail target cases`

Theorem 61.298 (Continuation morphism right zero-headed tail target cases)**.** *For histories b, c, m, let $right : \mathsf{ContinuationMorphism}(b, c)$. If the displayed tail of $right$ is internally the same as $\mathsf{E0}(m)$, then the target is zero-headed:*

$$\exists r : \mathsf{BHist}.\ c = \mathsf{E0}(r) \wedge \mathsf{Cont}(b, m, r).$$

Proof. Unpack the continuation morphism record and replace its displayed tail by $\mathsf{E0}(m)$. The BEDC continuation step-result inversion then exposes the zero-headed target payload r together with the descended continuation $\mathsf{Cont}(b, m, r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism right e0 tail target cases`

Theorem 61.299 (Continuation morphism composite right visible tail result cases)**.** *For histories a, b, c, m, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$. If the right displayed tail is $\mathsf{hsame}(\mathsf{tail}(right), \mathsf{E1}(m))$, then the closed composite tail is one-headed, and its exposed payload is the continuation of the left tail by m:*

$$\exists k : \mathsf{BHist}.\ \mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{E1}(k)) \wedge \mathsf{Cont}(\mathsf{tail}(left), m, k).$$

Proof. Unpack the two continuation morphism records. The closed composite stores the append of the left tail with the right tail as its displayed tail. Replacing the right tail by its $\mathsf{E1}(m)$ presentation makes the composite tail definitionally $\mathsf{E1}(\mathsf{append}(\mathsf{tail}(left), m))$. Choose this payload append as k; the remaining continuation ledger is the reflexive append continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp right visible tail result cases`

Theorem 61.300 (Continuation morphism composite right zero tail result cases)**.** *For histories a, b, c, m, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$. If the right displayed tail is $\mathsf{hsame}(\mathsf{tail}(right), \mathsf{E0}(m))$, then the closed composite tail is zero-headed, and its exposed payload is the continuation of the left tail by m:*

$$\exists k : \mathsf{BHist}.\ \mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{E0}(k)) \wedge \mathsf{Cont}(\mathsf{tail}(left), m, k).$$

Proof. Unpack the two continuation morphism records. The closed composite stores the append of the left tail with the right tail as its displayed tail. Replacing the right tail by its $\mathsf{E0}(m)$ presentation makes the composite tail definitionally $\mathsf{E0}(\mathsf{append}(\mathsf{tail}(left), m))$. Choose this payload append as k; the remaining continuation ledger is the reflexive append continuation. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp right e0 tail result cases`

Theorem 61.301 (Continuation morphism composite left-tail result cases)**.** *For histories a, b, c, l, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$. If the left displayed tail is classified by l, then the closed composite tail is determined by the right displayed tail shape:*

$$\mathsf{hsame}(\mathsf{tail}(right), \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{tail}(left \circ right), l),$$

or there exists a history m such that

$$\mathsf{hsame}(\mathsf{tail}(right), \mathsf{E0}(m)) \wedge \mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{E0}(\mathsf{append}(l, m))),$$

or there exists a history m such that

$$\mathsf{hsame}(\mathsf{tail}(right), \mathsf{E1}(m)) \wedge \mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{E1}(\mathsf{append}(l, m))).$$

Proof. Unpack the two continuation morphism records and replace the left displayed tail by its classified representative l. Splitting the right displayed tail into empty, zero-headed, and one-headed cases gives the three composite-tail shapes directly from the definition of append. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp left tail result cases`

Theorem 61.302 (Continuation morphism right zero tail composite result is not empty)**.** *For histories a, b, c, m, let $left$: $\mathsf{ContinuationMorphism}(a, b)$ and $right$: $\mathsf{ContinuationMorphism}(b, c)$. If the right displayed tail is $\mathsf{hsame}(\mathsf{tail}(right), \mathsf{E0}(m))$, then the closed composite tail cannot be internally the same as* e.

Proof. Unpack the two continuation morphism records and replace the right tail by its zero-headed presentation. The closed composite tail is then a zero-headed history, namely $\mathsf{E0}(\mathsf{append}(\mathsf{tail}(left), m))$. BEDC constructor separation rules out an internal sameness proof from this zero-headed history to e. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp right e0 tail result not empty`

Theorem 61.303 (Category hom-carrier one-headed target and morphism descent)**.** *For histories a, k, r, a hom-carrier whose target and morphism histories are both one-headed descends to the corresponding tail hom-carrier:*

$$\mathsf{CategoryHomCarrier}(a, \mathsf{E1}(r), \mathsf{E1}(k)) \Longrightarrow \mathsf{CategoryHomCarrier}(a, r, k).$$

Proof. Unpack the hom-carrier fields. The source unary witness is unchanged. Unary inversion removes the visible constructor from both the target carrier and the morphism carrier, and the right step-rule inversion for Cont removes the same visible constructor from the continuation ledger. Repacking these fields gives $\mathsf{CategoryHomCarrier}(a, r, k)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 target morphism exactness`

Theorem 61.304 (Category hom-carrier one-headed target and morphism exactness iff)**.** *For histories a, k, r, the simultaneous one-headed target and morphism presentation is exactly the tail hom-carrier:*

$$\mathsf{CategoryHomCarrier}(a, \mathsf{E1}(r), \mathsf{E1}(k)) \Longleftrightarrow \mathsf{CategoryHomCarrier}(a, r, k).$$

Proof. The forward implication is the one-headed target and morphism descent theorem. Conversely, a tail hom-carrier supplies the unary source, unary morphism tail, and tail continuation $\mathsf{Cont}(a, k, r)$. The one-headed morphism target exactness theorem repacks these data as the displayed one-headed target and morphism hom-carrier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 target morphism exactness iff`

Theorem 61.305 (Category hom-carrier one-headed source and morphism target exactness)**.** *For histories a, k, t,*

$$\begin{aligned}&\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), t, \mathsf{E1}(k))\\ &\quad\iff\quad \exists r,\ t = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{E1}(a), k, r).\end{aligned}$$

Proof. Unpack the hom-carrier witness. The continuation field forces the target to have a visible one constructor; removing that constructor gives $\mathsf{Cont}(\mathsf{E1}(a), k, r)$. The source, morphism, and target unary witnesses invert through the same visible constructors. Conversely, the displayed target equation, the three unary witnesses, and the one-step continuation rule rebuild the hom-carrier fields. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 morphism target iff`

Corollary 61.306 (Continuation morphism composite visible tails consumer determinacy)**.** *For histories $a, b, c, k, l, m, l', m' : \mathsf{BHist}$, let $left : \mathsf{ContinuationMorphism}(a, b)$ and $right : \mathsf{ContinuationMorphism}(b, c)$. Assume the fixed nonempty visible composite surface*

$$\begin{aligned}&\mathsf{UnaryHistory}(\mathsf{tail}(left)) \wedge \mathsf{UnaryHistory}(\mathsf{tail}(right)) \wedge \neg\mathsf{hsame}(\mathsf{tail}(left), \mathsf{e}) \wedge \neg\mathsf{hsame}(\mathsf{tail}(right), \mathsf{e})\\ &\quad\wedge \mathsf{hsame}(\mathsf{tail}(left \circ right), \mathsf{E1}(k)) \wedge \mathsf{hsame}(\mathsf{tail}(left), \mathsf{E1}(l)) \wedge \mathsf{hsame}(\mathsf{tail}(right), \mathsf{E1}(m))\\ &\quad\wedge \mathsf{Cont}(\mathsf{E1}(l), \mathsf{E1}(m), \mathsf{E1}(k)).\end{aligned}$$

If another accepted consumer-facing use of the same composite surface reads the same composite payload through visible factor tails

$$\mathsf{hsame}(\mathsf{tail}(left), \mathsf{E1}(l')) \wedge \mathsf{hsame}(\mathsf{tail}(right), \mathsf{E1}(m')) \wedge \mathsf{Cont}(\mathsf{E1}(l'), \mathsf{E1}(m'), \mathsf{E1}(k)),$$

then the consumer-visible factor route is determined:

$$\mathsf{hsame}(l, l') \wedge \mathsf{hsame}(m, m').$$

Consequently, once the displayed unary, nonempty, composite-tail, factor-tail, and boundary-continuation rows are fixed, every accepted route or one-headed normal-form read for the composite visible tails uses the same finite route through l, m, k up to hsame*. There is no alternate hidden coordinate for the fixed displayed continuation surface.*

Proof. Apply Definition 61.296 to $left$, $right$, and the fixed unary, nonempty, and composite one-headed rows. It supplies the canonical visible factor pair for the composite tail and a universal comparison clause for any other pair of one-headed factor reads with the same boundary continuation. The fixed pair l, m and the competing pair l', m' both satisfy that clause: their tail classifications are the displayed factor-tail rows, and their boundary continuations are the two displayed $\mathsf{Cont}(\mathsf{E1}(-), \mathsf{E1}(-), \mathsf{E1}(k))$ rows. Comparing each pair with the canonical pair gives internal sameness witnesses from the fixed pair to the canonical pair and from the competing pair to the canonical pair. The symmetry and transitivity clauses of Definition 3.8 orient and compose these hsame witnesses inside the generated-history relation, so the two left payloads satisfy $\mathsf{hsame}(l, l')$ and the two right payloads satisfy $\mathsf{hsame}(m, m')$. This proves the displayed conjunction.

The final consumer-facing sentence only restates this internally composed hsame comparison for any accepted route or one-headed normal-form read that keeps the same listed rows; it does not substitute host equality or add another coordinate. □

Theorem 61.307 (Category hom-carrier one-headed endpoint morphism payload determinacy)**.** *For histories a, a', r, r', k, k', if* $\mathsf{hsame}(a, a')$ *and* $\mathsf{hsame}(r, r')$*, then any two hom-carriers*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), \mathsf{E1}(r), \mathsf{E1}(k)) \quad \textit{and} \quad \mathsf{CategoryHomCarrier}(\mathsf{E1}(a'), \mathsf{E1}(r'), \mathsf{E1}(k'))$$

have internally same visible morphism payloads: $\mathsf{hsame}(k, k')$*.*

Proof. Lift the source and target endpoint equalities through the one-headed constructor. Endpoint-sensitive morphism determinacy gives $\mathsf{hsame}(\mathsf{E1}(k), \mathsf{E1}(k'))$ for the displayed morphisms. One-headed constructor inversion removes the visible tag and yields $\mathsf{hsame}(k, k')$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target morphism payload deterministic`

Theorem 61.308 (Category hom-carrier one-headed source empty target impossibility)**.** *For histories a, f, no hom-carrier can have source* $\mathsf{E1}(a)$ *and target* e*:*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), \mathsf{e}, f) \to \mathsf{False}.$$

Proof. Unpack the hom-carrier witness and classify the morphism history f. In each constructor branch, the continuation field would identify the empty target with an append whose source already has a visible one constructor, which is impossible by generated-history no-confusion. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source empty target absurd`

Theorem 61.309 (Category visible source empty-target composite impossibility)**.** *For histories a, b, f, g, the pair of hom-carriers*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), b, f) \wedge \mathsf{CategoryHomCarrier}(b, \mathsf{e}, g)$$

is impossible.

Proof. Compose the first displayed hom-carrier with the second one using the concrete continuation witness $\mathsf{Cont}(f, g, \mathsf{append}(f, g))$. Composition closure produces

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), \mathsf{e}, \mathsf{append}(f, g)).$$

This contradicts the one-headed source empty-target impossibility theorem. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier visible source empty target comp absurd`

Theorem 61.310 (Category hom-carrier one-headed source morphism cases)**.** *For histories $a, target, morph$, a hom-carrier with source* $\mathsf{E1}(a)$ *has one of the following forms:*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), target, morph) \Longrightarrow (morph = \mathsf{e} \wedge target = \mathsf{E1}(a) \wedge \mathsf{UnaryHistory}(a))$$

or there exist histories k, r such that

$$morph = \mathsf{E1}(k) \wedge target = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{E1}(a), k, r).$$

Proof. Unpack the hom-carrier witness into unary source, target, and morphism fields and the continuation ledger. Classify the morphism history. The empty branch forces the target to be exactly $\mathsf{E1}(a)$ by the right-unit continuation shape, and unary inversion gives unary history for a. The zero-headed morphism branch contradicts unary-history separation for zero extensions. In the one-headed branch, classify the target history. Empty and zero-headed targets contradict the continuation ledger; a one-headed target exposes histories k and r, unary inversion gives the three unary witnesses, and constructor inversion on the continuation ledger yields $\mathsf{Cont}(\mathsf{E1}(a), k, r)$. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source morphism cases`

Theorem 61.311 (Category hom-carrier one-headed source morphism cases iff)**.** *For histories $a, target, morph$, the one-headed-source hom-carrier condition is equivalent to the same two concrete cases:*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), target, morph) \iff [(morph = \mathsf{e} \wedge target = \mathsf{E1}(a) \wedge \mathsf{UnaryHistory}(a)) \vee \exists k, r, morph =$$

Proof. The forward implication is the one-headed source morphism case theorem. For the reverse implication, the empty branch is the empty identity hom-carrier on $\mathsf{E1}(a)$, and the visible branch rebuilds the hom-carrier from the three unary witnesses together with the one-step continuation rule. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source morphism cases iff`

Theorem 61.312 (Category one-headed endpoint visible morphism exactness)**.** *For histories a, r, k, a visible morphism between one-headed source and target histories is exactly unary data on the three visible tails together with the tail continuation:*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), \mathsf{E1}(r), \mathsf{E1}(k)) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{E1}(a), k, r).$$

Proof. Apply the one-headed morphism-target exactness theorem to the displayed target $\mathsf{E1}(r)$ and morphism $\mathsf{E1}(k)$. The source carrier and target carrier are read back by one-headed unary inversion, while the reverse direction packages the source carrier as $\mathsf{E1}(a)$ and applies the same morphism-target exactness theorem. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source e1 target visible morphism iff`

Theorem 61.313 (Category one-headed source composite target visibility)**.** *For histories a, b, c, f, g, fg, composing a hom-carrier with source $\mathsf{E1}(a)$ through a second displayed hom-carrier preserves one-headed visibility of the composite target:*

$$\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), b, f) \Longrightarrow \mathsf{CategoryHomCarrier}(b, c, g) \Longrightarrow \mathsf{Cont}(f, g, fg) \Longrightarrow \exists r,\ c = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(r).$$

Proof. Composition closure first turns the two displayed hom-carriers and the continuation ledger into a composite hom-carrier $\mathsf{CategoryHomCarrier}(\mathsf{E1}(a), c, fg)$. Applying the one-headed source morphism case theorem to this composite gives either an empty morphism, where the target is $\mathsf{E1}(a)$, or a visible morphism, where the target is $\mathsf{E1}(r)$ for a unary history r. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier e1 source comp target visible`

Primitive boundary. $\mathsf{Cat}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 61.314 (Zero-axiom encoding note)**.** *Avoids a global universe of all objects by using explicit licensed carriers.*

The Category hom-carrier tail surface consumes the finite continuation packet exported by chapter 485. The Category side reads hom carriers through continuation tails, while $\mathsf{ContinuationMonad}^{\uparrow}$ supplies the root source rows and the bind and unit route rows that make those tails available to downstream consumers.

Theorem 61.315 (Continuation morphism fixed tail iff)**.** *For histories a, b, t : BHist and a fixed continuation morphism m : $\mathsf{ContinuationMorphism}(a, b)$,*

$$\mathsf{hsame}(\mathsf{tail}(m), t) \iff \mathsf{Cont}(a, t, b).$$

Proof. The forward direction transports the relation field $\mathsf{Cont}(a, \mathsf{tail}(m), b)$ along the displayed tail comparison, with source and target held fixed. Conversely, if t is a continuation tail from a to b, then the relation field of m and this new continuation share the same source and target, so continuation left cancellation identifies $\mathsf{tail}(m)$ with t. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism tail hsame iff`

Theorem 61.316 (Category hom carrier unary prefix exactness)**.** *For a unary prefix p, a displayed hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, b)$ is equivalent to the unprefixed hom-carrier from a to b, together with the same morphism history.*

Proof. The forward direction cancels the common unary prefix in the two endpoint carriers and in the continuation ledger. The reverse direction uses unary append closure on both endpoints and prefixes the same continuation ledger. □

Theorem 61.317 (Category hom carrier and continuation morphism tail correspondence)**.** *For histories a, b, f : BHist, the concrete hom-carrier witness is exactly a unary endpoint-and-tail presentation of a continuation morphism:*

$$\mathsf{CategoryHomCarrier}(a, b, f) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(f) \wedge \exists m : \mathsf{ContinuationMorphis}$$

Proof. In the forward direction, unpack the hom-carrier witness. Its displayed fields give unary membership for a, b, and f, together with the continuation ledger $\mathsf{Cont}(a, f, b)$. Taking the continuation morphism whose tail is f and whose relation field is this ledger gives the required existential witness, and reflexivity of hsame classifies the displayed tail.

Conversely, unpack the existential continuation morphism m. Its record contains the displayed continuation witness $\mathsf{Cont}(a, \mathsf{tail}(m), b)$, while the hypothesis supplies $\mathsf{hsame}(\mathsf{tail}(m), f)$ and the three unary witnesses.

Apply Theorem 4.41 with reflexive source and target endpoint classifiers and the displayed tail classifier to transport $\mathsf{Cont}(a, \mathsf{tail}(m), b)$ to $\mathsf{Cont}(a, f, b)$. Reassemble $\mathsf{CategoryHomCarrier}(a, b, f)$ from the unary source, unary target, unary morphism, and transported continuation fields. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier continuation morphism tail iff`

Theorem 61.318 (Continuation morphism tail identity square closure)**.** *For a continuation morphism m : $\mathsf{ContinuationMorphism}(a, b)$, if $left$ is obtained by composing e before $\mathsf{tail}(m)$ and $right$ is obtained by composing e after $\mathsf{tail}(m)$, then $\mathsf{hsame}(left, right)$ and both displayed tails carry continuations from a to b.*

Proof. The left-unit continuation identifies $left$ with $\mathsf{tail}(m)$. Determinism against the right-unit continuation identifies $right$ with $\mathsf{tail}(m)$. Transport the relation field of m across these two history equalities and compose the equalities by transitivity. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism tail identity square closed`

Theorem 61.319 (Continuation morphism composite endpoint transport)**.** *For continuation morphisms $left : a \to b$, $right : b \to c$, $left' : a' \to b'$, and $right' : b' \to c'$, if $\mathsf{hsame}(a, a')$ and $\mathsf{hsame}(c, c')$, then the canonical composite tail of $left$ and $right$ transports to a continuation from a' to c', and it is hsame to the canonical composite tail of $left'$ and $right'$.*

Proof. Transport the composite continuation field of $left \circ right$ across the source and target endpoint comparisons, keeping its displayed tail fixed. The transported continuation and the composite continuation field of $left' \circ right'$ share source and target, so finite-kernel left cancellation identifies their tails. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp endpoint hsame tail transport`

Theorem 61.320 (Continuation morphism composite endpoint transport existence)**.** *For continuation morphisms $m : a \to b$ and $n : b \to c$, endpoint comparisons $a\mathsf{hsame}a'$, $b\mathsf{hsame}b'$, and $c\mathsf{hsame}c'$ determine transported factor morphisms $m' : a' \to b'$ and $n' : b' \to c'$ such that the transported composite tail is history-same to the original composite tail and carries a continuation from a' to c'.*

Proof. Keep the displayed tails of m and n. Transport the relation field of m across the source and middle endpoint comparisons, and transport the relation field of n across the middle and target endpoint comparisons. The composite of these transported factor morphisms has the same appended tail as the original composite by reflexivity, and its own relation field supplies the continuation from a' to c'. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp endpoint transport exists`

Theorem 61.321 (Continuation morphism composite tail append determinacy)**.** *For continuation morphisms $left, left' : a \to b$ and $right, right' : b \to c$, the appended composite tail is determined by the endpoints:*

$$\mathsf{hsame}(\mathsf{append}(\mathsf{tail}(left), \mathsf{tail}(right)), \mathsf{append}(\mathsf{tail}(left'), \mathsf{tail}(right'))).$$

Proof. Continuation left cancellation identifies the two displayed tails from a to b, and again identifies the two displayed tails from b to c. Congruence of BEDC append combines these two tail comparisons into the composite-tail comparison. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail append deterministic`

Theorem 61.322 (Continuation morphism composite tail unary closure)**.** *For continuation morphisms $left : a \to b$ and $right : b \to c$, if both displayed factor tails are unary histories, then the closed composite tail of $left \circ right$ is a unary history.*

Proof. Unpack the two continuation morphism records. The closed composite tail is $\mathsf{append}(\mathsf{tail}(left), \mathsf{tail}(right))$, so unary append closure applies to the two supplied tail carriers. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism comp tail unary closed`

Theorem 61.323 (Continuation morphism tail factorization iff)**.** *For histories $a, c, l, r, t : \mathsf{BHist}$, if $\mathsf{Cont}(l, r, t)$, then a continuation morphism from a to c whose displayed tail is t exists exactly when there is a middle history b carrying a left continuation morphism from a to b with tail l and a right continuation morphism from b to c with tail r.*

Proof. For the forward implication, unpack the composite morphism and the displayed split $\mathsf{Cont}(l, r, t)$. The middle object is $\mathsf{append}(a, l)$. The left factor is the reflexive continuation from a through l to that middle, and the right factor is obtained by reassociating the composite continuation witness through the displayed split.

For the reverse implication, compose the two displayed factor morphisms. The closed composite tail is the append of the two factor tails; transport that tail along the two supplied tail classifiers and the split $\mathsf{Cont}(l, r, t)$ to obtain the required composite tail classifier. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism tail factorization iff`

Theorem 61.324 (Continuation morphism identity and composition closure)**.** *Every history h has an empty-tail identity witness in* $\mathsf{ContinuationMorphism}(h, h)$*. Moreover, composable continuation morphisms $left : a \to b$ and $right : b \to c$ determine an inhabited* $\mathsf{ContinuationMorphism}(a, c)$ *by the closed composite.*

Proof. For the identity clause, take the empty tail. The continuation witness is the empty right-unit continuation at h, so the corresponding continuation morphism inhabits $\mathsf{ContinuationMorphism}(h, h)$.

For the composition clause, apply $\mathsf{ContinuationMorphism_comp_closed}$ to $left$ and $right$. The result is the closed composite continuation morphism from a to c, which supplies the required inhabitant. □

Lean4 ✓ `BEDC.Derived.CategoryUp.ContinuationMorphism identity comp closure`

Per-object certificate: traditional target hom-as-continuation morphism bridge; BEDC source $\mathsf{CategoryHomCarrier}$, $\mathsf{ContinuationMorphism}$, $\mathsf{UnaryHistory}$, and Cont; carrier BHist tails; classifier hsame; stability obligation continuation transport; ledger the displayed tail and continuation witness; core theorem this correspondence; exactness predicate the iff; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 61.325 (Unary-continuation category stability law package)**.** *For the concrete unary-continuation category on* BHist*, with object carrier the unary histories, hom-carrier* $\mathsf{CategoryHomCarrier}(a, b, f)$*, object classifier* hsame*, and morphism classifier* hsame *on displayed hom histories, the* $\mathsf{Cat}^{\uparrow}$ *stability laws are satisfied. At every unary object the empty history is an identity hom-carrier, composition of displayed hom-carriers is closed, any two associations of a threefold displayed composite classify together, the left and right empty-composition laws hold under the morphism classifier, and morphism classification is preserved after endpoint* hsame *transport.*

Proof. The identity and binary composition fields are the concrete hom-carrier laws. The empty history is an identity hom-carrier at each unary object by Definition 61.2, and displayed composition closure is exactly Definition 61.19.

For associativity, use the two-step closure supplied by Definition 61.132. It builds both associated composites as hom-carriers over the same endpoints and identifies their morphism histories by the classifier hsame.

The unit laws are supplied by the identity square. Applying Definition 61.95 to a displayed hom-carrier and the two empty-composition ledgers gives the left and right unit composites and the required morphism-classifier equality.

It remains to record stability under endpoint transport. Transporting the source endpoint, target endpoint, and morphism history along hsame keeps the displayed hom-carrier witness by Definition 61.93; once the endpoints have been transported, any two displayed morphism witnesses over classified endpoints are identified by Definition 61.185. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier unary continuation stability law package`

Corollary 61.326 (Category hom carrier stability law package)**.** *For the same unary-continuation category on* BHist*, the identity hom-carriers, binary composition closure, associativity of displayed composition, and empty-composition unit fields form the basic* $\mathsf{Cat}^{\uparrow}$ *hom-carrier stability package.*

Proof. Project the identity, binary composition closure, associativity, and empty-composition unit clauses from Theorem 61.325. These are exactly the four displayed fields of the basic $\mathsf{Cat}^{\uparrow}$ hom-carrier stability package. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier stability law package`

Definition 61.327 (Opposite category certificate data)**.** *Let a* $\mathsf{Cat}^{\uparrow}$ *certificate* $\mathcal{C}$ *have object carrier* $\mathcal{O}$*, object classifier* $\sim_{\mathcal{O}}$*, hom-carrier* $\mathcal{H}(a,b,f)$*, morphism classifier* $\sim_{\mathcal{H}}$*, identity witnesses* id_a*, and composition relation* $\mathsf{Comp}_{\mathcal{C}}(f,g,h)$ *for displayed composable morphisms* $f : a \to b$ *and* $g : b \to c$*. The opposite certificate data* $\mathcal{C}^{\mathrm{op}}$ *are defined by*

$$\begin{aligned} \mathcal{O}^{\mathrm{op}}(a) &:= \mathcal{O}(a), & a \sim_{\mathcal{O}}^{\mathrm{op}} a' &:= a \sim_{\mathcal{O}} a', \\ \mathcal{H}^{\mathrm{op}}(a,b,f) &:= \mathcal{H}(b,a,f), & f \sim_{\mathcal{H}}^{\mathrm{op}} g &:= f \sim_{\mathcal{H}} g, \\ \mathsf{id}_a^{\mathrm{op}} &:= \mathsf{id}_a, & \mathsf{Comp}_{\mathcal{C}^{\mathrm{op}}}(f,g,h) &:= \mathsf{Comp}_{\mathcal{C}}(g,f,h). \end{aligned}$$

Theorem 61.328 (Opposite category certificate)**.** *If* $\mathcal{C}$ *satisfies the* $\mathsf{Cat}^{\uparrow}$ *certificate obligations of Definition 61.1, then the data of Definition 61.327 also satisfy the* $\mathsf{Cat}^{\uparrow}$ *certificate obligations. Thus reversing hom-carriers and composition produces a* $\mathsf{Cat}^{\uparrow}(\mathcal{C}^{\mathrm{op}})$ *certificate with the same object carrier, identity witnesses, object classifier, and morphism classifier.*

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryHomCarrier opposite comp assoc closed`

Proof. The object carrier and object classifier fields are literal reuses of the corresponding fields of $\mathcal{C}$, so their carrier and classifier laws are unchanged. For a fixed ordered pair (a,b) in the opposite data, the hom-carrier predicate is the original predicate for the ordered pair (b,a). The corresponding $\mathsf{NameCert}$ source, pattern, ledger, and classifier laws are therefore exactly the original hom-carrier certificate fields with the endpoint order swapped.

The identity field is also inherited. At an object a,

$$\mathcal{H}^{\mathrm{op}}(a,a,\mathsf{id}_a^{\mathrm{op}}) = \mathcal{H}(a,a,\mathsf{id}_a),$$

which is the original identity hom-carrier field.

For composition closure, let $f : a \to b$ and $g : b \to c$ be displayed in $\mathcal{C}^{\mathrm{op}}$. This means $\mathcal{H}(b,a,f)$ and $\mathcal{H}(c,b,g)$ in $\mathcal{C}$. If $\mathsf{Comp}_{\mathcal{C}^{\mathrm{op}}}(f,g,h)$ holds, then by definition $\mathsf{Comp}_{\mathcal{C}}(g,f,h)$ holds. The original composition closure in $\mathcal{C}$ gives $\mathcal{H}(c,a,h)$, which is exactly $\mathcal{H}^{\mathrm{op}}(a,c,h)$.

For associativity, take composable opposite morphisms $f : a \to b$, $g : b \to c$, and $h : c \to d$, with displayed composites fg, gh, $left$, and $right$. The four opposite composition ledgers are, in $\mathcal{C}$,

$$\mathsf{Comp}_{\mathcal{C}}(g,f,fg), \quad \mathsf{Comp}_{\mathcal{C}}(h,g,gh), \quad \mathsf{Comp}_{\mathcal{C}}(h,fg,left), \quad \mathsf{Comp}_{\mathcal{C}}(gh,f,right).$$

Apply associativity in $\mathcal{C}$ to the reversed chain h,g,f. It compares $\mathsf{Comp}_{\mathcal{C}}(gh,f,right)$ with $\mathsf{Comp}_{\mathcal{C}}(h,fg,left)$, giving $right \sim_{\mathcal{H}} left$. Symmetry of the morphism classifier gives $left \sim_{\mathcal{H}}^{\mathrm{op}} right$.

For unit laws, let $f : a \to b$ be displayed in the opposite data, so $f : b \to a$ in $\mathcal{C}$. The left unit law in $\mathcal{C}^{\mathrm{op}}$ is $\mathsf{Comp}_{\mathcal{C}^{\mathrm{op}}}(\mathsf{id}_a,f,left)$, which is $\mathsf{Comp}_{\mathcal{C}}(f,\mathsf{id}_a,left)$; this is the original right unit law.

The right unit law in $\mathcal{C}^{\mathrm{op}}$ is $\mathsf{Comp}_{\mathcal{C}^{\mathrm{op}}}(f, \mathsf{id}_b, right)$, which is $\mathsf{Comp}_{\mathcal{C}}(\mathsf{id}_b, f, right)$; this is the original left unit law. Hence both opposite unit composites are classified with f.

Endpoint transport is inherited with the same swap. A transported opposite hom-carrier $\mathcal{H}^{\mathrm{op}}(a, b, f)$ is the original carrier $\mathcal{H}(b, a, f)$, so source transport in the opposite data is target transport in $\mathcal{C}$, and target transport in the opposite data is source transport in $\mathcal{C}$. The morphism classifier is unchanged, so morphism transport and morphism determinacy are inherited directly.

Specializing $\mathcal{C}$ to the unary-continuation law package of Definition 61.325 uses the identity field from Definition 61.2, the composition field from Definition 61.19, the associativity field from Definition 61.132, the unit classification from Definition 61.95, and endpoint transport from Definition 61.93. □

↪variant BEDC.Derived.CategoryUp.CategoryHomCarrier opposite comp assoc closed

Theorem 61.329 (Standard unary-continuation category bridge)**.** *The public unary-continuation* $\mathsf{Cat}^{\uparrow}$ *export supplies a paper-level standard bridge to a host category interface, with six displayed fields:*

1. *object translation reads host objects through* UnaryHistory*;*
2. *morphism translation reads host arrows through* CategoryHomCarrier*;*
3. *classifier compatibility is exactly endpoint and morphism comparison by* hsame*;*
4. *theorem correspondence pairs the host identity, composition, associativity, and unit rows with the unary-continuation* $\mathsf{Cat}^{\uparrow}$ *law package;*
5. *reflection is restricted to displayed BEDC histories and their hom-carrier witnesses;*
6. *the no-host-leak field asserts that host category structure is read only through these BEDC predicates, with no host equality, primitive category universe, or host carrier constructor entering the* $\mathsf{Cat}^{\uparrow}$ *public surface.*

Proof. For objects, the bridge reads a host object only when the displayed BEDC history satisfies UnaryHistory. For arrows, it reads a host morphism only when the displayed source, target, and arrow history satisfy CategoryHomCarrier. The carrier exactness is the concrete hom-carrier and continuation-morphism tail correspondence of Definition 61.317, and classifier compatibility is the same hsame relation already used by the object and morphism surfaces.

The theorem-preservation field is the public unary-continuation stability law package of Definition 61.325. Its identity, composition, associativity, and unit clauses are precisely the rows expected by the host category interface. The semantic certificate target CategoryHomCarrier_comp_result_semanticNameCer supplies the displayed BEDC ledger for the composition-result name certificate, so the host composition row is reflected through the same BEDC source, pattern, ledger, and classifier fields.

Reflection is therefore limited to histories displayed by UnaryHistory and morphism histories displayed by CategoryHomCarrier. The bridge never asks the host for a primitive object equality, a primitive category universe, or an external morphism classifier; it only reads the host interface through the six BEDC predicates listed above. This is the paper-level no-host-leak argument required for the standard bridge. □

Lean4 ✓ BEDC.Derived.CategoryUp.CategoryUp StdBridge

Theorem 61.330 (Double opposite category certificate data identity)**.** *Let* $\mathcal{C}$ *be a* $\mathsf{Cat}^{\uparrow}$ *certificate satisfying the certificate obligations of Definition 61.1, with object carrier* $\mathcal{O}$*, object classifier* $\sim_{\mathcal{O}}$*, hom-carrier* $\mathcal{H}(a, b, f)$*, morphism classifier* $\sim_{\mathcal{H}}$*, identity witnesses* id_a*, and composition relation*

$\mathsf{Comp}_{\mathcal{C}}$. *Let $\mathcal{C}^{\mathrm{opop}} = (\mathcal{C}^{\mathrm{op}})^{\mathrm{op}}$ be obtained by applying Definition 61.327 twice. Then $\mathcal{C}^{\mathrm{opop}}$ is a $\mathsf{Cat}^{\uparrow}$ certificate, and its object carrier, object classifier, hom-carrier predicate, morphism classifier, identity witnesses, and composition relation are componentwise identical to those of $\mathcal{C}$:*

$$\begin{aligned} \mathcal{O}^{\mathrm{opop}}(a) &= \mathcal{O}(a), & a \sim_{\mathcal{O}}^{\mathrm{opop}} a' &= a \sim_{\mathcal{O}} a', \\ \mathcal{H}^{\mathrm{opop}}(a,b,f) &= \mathcal{H}(a,b,f), & f \sim_{\mathcal{H}}^{\mathrm{opop}} g &= f \sim_{\mathcal{H}} g, \\ \mathsf{id}_a^{\mathrm{opop}} &= \mathsf{id}_a, & \mathsf{Comp}_{\mathcal{C}^{\mathrm{opop}}}(f,g,h) &= \mathsf{Comp}_{\mathcal{C}}(f,g,h). \end{aligned}$$

Proof. Because $\mathcal{C}$ satisfies the $\mathsf{Cat}^{\uparrow}$ obligations, Definition 61.328 makes $\mathcal{C}^{\mathrm{op}}$ a certified $\mathsf{Cat}^{\uparrow}$ instance. Applying the same theorem to that certified opposite data makes $\mathcal{C}^{\mathrm{opop}}$ a certified $\mathsf{Cat}^{\uparrow}$ instance.

It remains only to compare the displayed data. For the object carrier and object classifier, two unfoldings of Definition 61.327 give $\mathcal{O}^{\mathrm{opop}}(a) = \mathcal{O}^{\mathrm{op}}(a) = \mathcal{O}(a)$ and $a \sim_{\mathcal{O}}^{\mathrm{opop}} a' = a \sim_{\mathcal{O}}^{\mathrm{op}} a' = a \sim_{\mathcal{O}} a'$.

For hom-carriers, the first opposite swaps the endpoints and the second opposite swaps them back:

$$\mathcal{H}^{\mathrm{opop}}(a,b,f) = \mathcal{H}^{\mathrm{op}}(b,a,f) = \mathcal{H}(a,b,f).$$

The morphism classifier is not changed by either opposite construction, hence $f \sim_{\mathcal{H}}^{\mathrm{opop}} g = f \sim_{\mathcal{H}} g$. The identity row is also reused at both stages, so $\mathsf{id}_a^{\mathrm{opop}} = \mathsf{id}_a^{\mathrm{op}} = \mathsf{id}_a$.

For composition, the two argument reversals cancel:

$$\mathsf{Comp}_{\mathcal{C}^{\mathrm{opop}}}(f,g,h) = \mathsf{Comp}_{\mathcal{C}^{\mathrm{op}}}(g,f,h) = \mathsf{Comp}_{\mathcal{C}}(f,g,h).$$

Thus every listed data field of the double opposite certificate is the original field of $\mathcal{C}$. □

Theorem 61.331 (Opposite category certificate involution)**.** *Let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate satisfying the obligations of Definition 61.1. Write its object carrier as $\mathcal{O}$, object classifier as $\sim_{\mathcal{O}}$, hom-carrier predicate as $\mathcal{H}(a,b,f)$, morphism classifier as $\sim_{\mathcal{H}}$, identity witnesses as id_a, and composition classifier as $\mathsf{Comp}_{\mathcal{C}}(f,g,h)$. Let $\mathcal{C}^{\mathrm{opop}} = (\mathcal{C}^{\mathrm{op}})^{\mathrm{op}}$ be obtained by applying Definition 61.327 twice. Then $\mathcal{C}^{\mathrm{opop}}$ is a $\mathsf{Cat}^{\uparrow}$ certificate, and its object carrier, object classifier, hom-carrier predicate, morphism classifier, identity witnesses, and composition classifier reduce componentwise to those of $\mathcal{C}$:*

$$\begin{aligned} \mathcal{O}^{\mathrm{opop}}(a) &= \mathcal{O}(a), & a \sim_{\mathcal{O}}^{\mathrm{opop}} a' &= a \sim_{\mathcal{O}} a', \\ \mathcal{H}^{\mathrm{opop}}(a,b,f) &= \mathcal{H}(a,b,f), & f \sim_{\mathcal{H}}^{\mathrm{opop}} g &= f \sim_{\mathcal{H}} g, \\ \mathsf{id}_a^{\mathrm{opop}} &= \mathsf{id}_a, & \mathsf{Comp}_{\mathcal{C}^{\mathrm{opop}}}(f,g,h) &= \mathsf{Comp}_{\mathcal{C}}(f,g,h). \end{aligned}$$

Proof. Since $\mathcal{C}$ satisfies the $\mathsf{Cat}^{\uparrow}$ obligations, Definition 61.328 gives a $\mathsf{Cat}^{\uparrow}$ certificate on $\mathcal{C}^{\mathrm{op}}$. Applying the same theorem to that certificate gives a $\mathsf{Cat}^{\uparrow}$ certificate on $\mathcal{C}^{\mathrm{opop}} = (\mathcal{C}^{\mathrm{op}})^{\mathrm{op}}$.

The field comparison is obtained by two unfoldings of Definition 61.327. The object carrier and object classifier are reused by each opposite construction, so $\mathcal{O}^{\mathrm{opop}}(a) = \mathcal{O}^{\mathrm{op}}(a) = \mathcal{O}(a)$ and $a \sim_{\mathcal{O}}^{\mathrm{opop}} a' = a \sim_{\mathcal{O}}^{\mathrm{op}} a' = a \sim_{\mathcal{O}} a'$.

For hom-carriers, the first opposite reverses the endpoint order and the second opposite reverses it back:

$$\mathcal{H}^{\mathrm{opop}}(a,b,f) = \mathcal{H}^{\mathrm{op}}(b,a,f) = \mathcal{H}(a,b,f).$$

The morphism classifier is unchanged at both stages, hence $f \sim_{\mathcal{H}}^{\mathrm{opop}} g = f \sim_{\mathcal{H}} g$. The identity witnesses are also reused at both stages, so $\mathsf{id}_a^{\mathrm{opop}} = \mathsf{id}_a^{\mathrm{op}} = \mathsf{id}_a$.

For composition, the defining reversal is applied twice. Thus, for displayed composable morphisms $f : a \to b$ and $g : b \to c$,

$$\mathsf{Comp}_{\mathcal{C}^{\mathrm{opop}}}(f, g, h) = \mathsf{Comp}_{\mathcal{C}^{\mathrm{op}}}(g, f, h) = \mathsf{Comp}_{\mathcal{C}}(f, g, h).$$

Every displayed data field of the double opposite certificate is therefore the corresponding displayed data field of $\mathcal{C}$. □

Definition 61.332 (Category split epimorphism witness)**.** *With the notation of Definition 61.1, let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate and let $\mathcal{H}(a, b, f)$ display a hom-carrier $f : a \to b$. A split-epimorphism witness for f consists of a hom-carrier $\mathcal{H}(b, a, s)$, a displayed composite $sf : b \to b$ with $\mathsf{Comp}_{\mathcal{C}}(s, f, sf)$, and a morphism-classifier comparison $sf \sim_{\mathcal{H}} \mathsf{id}_b$ to the identity witness at b.*

Theorem 61.333 (Category split epimorphism right cancellation)**.** *Let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate as in Definition 61.1. Suppose $\mathcal{H}(a, b, f)$ has a split-epimorphism witness (s, sf) in the sense of Definition 61.332. For hom-carriers $\mathcal{H}(b, x, u)$ and $\mathcal{H}(b, x, v)$, let fu and fv be displayed composites of u after f and v after f:*

$$\mathsf{Comp}_{\mathcal{C}}(f, u, fu), \qquad \mathsf{Comp}_{\mathcal{C}}(f, v, fv).$$

If $fu \sim_{\mathcal{H}} fv$, then $u \sim_{\mathcal{H}} v$.

Lean4 ✓ `BEDC.Derived.CategoryUp.CategorySplitEpiWitness right cancellative`

Proof. Let sf be the split composite and let $sf \sim_{\mathcal{H}} \mathsf{id}_b$ be its classifier comparison with the identity at b. Precompose the comparison $fu \sim_{\mathcal{H}} fv$ by the section s. The classifier-respecting composition field of the $\mathsf{Cat}^{\uparrow}$ certificate gives classifier equality between the two composites fu after s and fv after s.

Consider the u side. Associativity for the displayed triple $s : b \to a$, $f : a \to b$, and $u : b \to x$ identifies the right-associated composite fu after s with the left-associated composite u after sf. The split comparison replaces sf by id_b, again by classifier-respecting composition. The left-unit law then classifies u after id_b with u itself. Hence the composite fu after s is classified with u.

The same argument with v shows that the composite fv after s is classified with v. Combining these two reductions with the classifier equality between fu after s and fv after s, and using symmetry and transitivity of $\sim_{\mathcal{H}}$, gives $u \sim_{\mathcal{H}} v$. □

Theorem 61.334 (Category split epimorphism composition closure)**.** *Let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate satisfying the obligations of Definition 61.203. With the notation of Definition 61.1, let $\mathcal{H}(a, b, f)$ and $\mathcal{H}(b, c, g)$ display hom-carriers. Suppose f has a split-epimorphism witness with right-inverse hom-carrier $f^{\dagger} : b \to a$ and split composite $s_f : b \to b$,*

$$\mathsf{Comp}_{\mathcal{C}}(f^{\dagger}, f, s_f), \qquad s_f \sim_{\mathcal{H}} \mathsf{id}_b,$$

and suppose g has a split-epimorphism witness with right-inverse hom-carrier $g^{\dagger} : c \to b$ and split composite $s_g : c \to c$,

$$\mathsf{Comp}_{\mathcal{C}}(g^{\dagger}, g, s_g), \qquad s_g \sim_{\mathcal{H}} \mathsf{id}_c,$$

in the sense of Definition 61.332. If $u : a \to c$ is a displayed composite of g after f and $\ell : c \to a$ is the displayed reverse composite of their right-inverse witnesses,

$$\mathsf{Comp}_{\mathcal{C}}(f, g, u), \qquad \mathsf{Comp}_{\mathcal{C}}(g^{\dagger}, f^{\dagger}, \ell),$$

then u is a displayed hom-carrier from a to c and carries a split-epimorphism witness whose right-inverse hom-carrier is ℓ.

Proof. The two split-epimorphism witnesses supply hom-carriers for $f^\dagger$ and $g^\dagger$. Composition closure in the $\mathsf{Cat}^\uparrow$ stability certificate therefore makes the displayed composites u and ℓ hom-carriers over $a \to c$ and $c \to a$.

Let $R : c \to c$ be the composite display selected for u after ℓ, so $\mathsf{Comp}_{\mathcal{C}}(\ell, u, R)$. It remains to classify R with id_c. The four displayed factors form the chain

$$c \xrightarrow{g^\dagger} b \xrightarrow{f^\dagger} a \xrightarrow{f} b \xrightarrow{g} c.$$

The associativity row of Definition 61.201, applied twice, compares the outside bracketing $(g \circ_{\mathcal{C}} f) \circ_{\mathcal{C}} (f^\dagger \circ_{\mathcal{C}} g^\dagger)$ with the bracketing $g \circ_{\mathcal{C}} ((f \circ_{\mathcal{C}} f^\dagger) \circ_{\mathcal{C}} g^\dagger)$. Thus R is classified with the display obtained by first using the inner split composite s_f, then composing with $g^\dagger$, and finally composing with g.

Since $s_f \sim_{\mathcal{H}} \mathsf{id}_b$, composition congruence replaces $s_f \circ_{\mathcal{C}} g^\dagger$ by $\mathsf{id}_b \circ_{\mathcal{C}} g^\dagger$. The identity law at the target of $g^\dagger$ classifies this composite with $g^\dagger$. Composing that comparison with the outer factor g compares the resulting display with $s_g = g \circ_{\mathcal{C}} g^\dagger$. Transitivity of the morphism classifier, together with the stored comparison $s_g \sim_{\mathcal{H}} \mathsf{id}_c$, gives $R \sim_{\mathcal{H}} \mathsf{id}_c$.

The hom-carriers for u and ℓ, the target identity display id_c, the composite ledger $\mathsf{Comp}_{\mathcal{C}}(\ell, u, R)$, and the classifier comparison $R \sim_{\mathcal{H}} \mathsf{id}_c$ are exactly the data required by Definition 61.332. Hence u carries a split-epimorphism witness with right-inverse hom-carrier ℓ. □

Lean4 ✓ `BEDC.Derived.CategoryUp.CategorySplitEpiWitness composition closed`

Theorem 61.335 (CategoryUp mature host-interface inventory)**.** *The unary-continuation* $\mathsf{Cat}^\uparrow$ *mature host interface is exactly the object carrier* UnaryHistory*, the hom carrier* CategoryHomCarrier*, identity witnesses, the composition-result carrier and semantic certificate, the associativity and unit law package, endpoint transport, opposite-category data identity, split-epimorphism right cancellation, and split-epimorphism composition closure.*

Lean4 ✓ `BEDC.Derived.CategoryUp.CategoryUp mature host interface inventory`

Proof. The standard host bridge is the paper-level interface of Definition 61.329: it reads objects through UnaryHistory, arrows through CategoryHomCarrier, and the composition-result ledger through the semantic certificate target named there.

The law package is the unary-continuation stability package of Definition 61.325. Its identity, composition, associativity, unit, and endpoint-transport rows are precisely the host-interface rows needed by the bridge.

The remaining inventory rows are the category-specific closure theorems already displayed in this chapter. Opposite-category data identity is Definition 61.330; split-epimorphism right cancellation is Definition 61.333; and split-epimorphism composition closure is Definition 61.334. These theorem sites exhaust the stated mature host-interface inventory and introduce no additional host-category primitives. □

Closure status for $\mathsf{NameCert}_{\mathsf{Cat}^\uparrow}$**.**

Constructive story: A category here is built from the unary history spine: objects are exactly the histories accepted by UnaryHistory, and a morphism from a to b is a visible unary tail f together with the continuation row $\mathsf{Cont}(a, f, b)$. Two objects, and likewise two displayed morphism histories over fixed endpoints, are classified by hsame, so composition never leaves the BEDC history surface: it appends two visible tails and then uses continuation associativity and transport to compare the two possible ledgers. The source, pattern, and ledger rows are the same concrete hom-carrier and continuation predicates, recording identities as empty tails, composable pairs as displayed continuation chains, and all source-target movement as endpoint hsame transport. The five name-certificate obligations are supplied by the unary empty object and empty identity tail for inhabitation, by reflexivity, symmetry, and transitivity of hsame, and by hom-carrier transport,

which keeps carried objects and arrows carried after classification. A morphism history h lies in the signature gap of a $\mathsf{Cat}^{\uparrow}$ token p when the source-domain accepts the relevant unary endpoints, the signature relation pairs the displayed hom or composite result with an answer history and evidence ledger, and token introduction names that answer as p; unfolded, the gap says that h is the visible tail of the continuation morphism or composite result encoded by the token. The standard bridge reads the same package as an ordinary host category only through unary objects, CategoryHomCarrier arrows, classifier-compatible identities, composition, associativity, and unit rows, then reads back to the same histories. The chapter registers this unary-continuation construction under the name $\mathsf{Cat}^{\uparrow}$; categorical structure is the existing continuation calculus with no global category universe, host equality, limits, adjunctions, or external morphism type.

Theory closure: TheoryGate(NameCert$_{\mathsf{Cat}^{\uparrow}}$, maturePackageClosed)

Scope closed: The unary-continuation $\mathsf{Cat}^{\uparrow}$ host interface is closed for the public unary-continuation export, the paper-level standard bridge of Definition 61.329, the double-opposite certificate data identity and involution sites of Definition 61.330 and Definition 61.331, and the split-epimorphism right-cancellation and composition-closure sites of Definition 61.333 and Definition 61.334.

Formal verification: FormalStatus(NameCert$_{\mathsf{Cat}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.CategoryUp.CategoryUp\_StdBridge`

Bridge status: bridgeChecked

Not claimed: This chapter does not close arbitrary categories, limits, colimits, adjunctions, equivalences, enriched categories, categorical foundations, or host-category primitives beyond the displayed unary-continuation bridge.

Upgrade path: No further upgrade – chapter at top of formal axis.

Proposition 61.336 (Category standard bridge dependency lattice)**.** *The* $\mathsf{Cat}^{\uparrow}$ *Hom carrier, composition row, identity row, and checked standard bridge surface are the shared substrate consumed by chapter 62 and chapter 63. Their downstream reads use the category rows as dependency anchors: functor and natural-transformation certificates receive the displayed* CategoryHomCarrier *arrows, empty-tail identities, continuation composition ledger, and the* CategoryHomCarrier_comp_result_semanticNameCer *bridge-facing certificate, rather than a host-category object, host-category equality, or external morphism primitive.*

Proof. The CategoryUp certificate in Definition 61.325 supplies the identity, composition, associativity, unit, and endpoint-transport rows over the unary-continuation Hom carrier. The standard bridge of Definition 61.329 reads the same surface through UnaryHistory, CategoryHomCarrier, and hsame, and the closure block of chapter 61 records this package at maturePackageClosed with bridgeChecked status.

The FunctorUp and NatTransUp chapters cite the CategoryUp chapter by chapter 62 and chapter 63. Their certificate rows therefore attach to the displayed object, Hom, identity, composition, and bridge-facing semantic-certificate rows already exported by CategoryUp. No downstream clause needs a host-category carrier or primitive host equality: the dependency lattice is the BEDC row package itself, and the bridge reads that package without replacing it. □

Chapter 62

A Concrete Naming Certificate for $\mathsf{Functor}^{\uparrow}$

The functor interface $\mathsf{Functor}^{\uparrow}$ has certificate obligations between two categories from chapter 61 as a pair of mappings (one on objects, one on morphisms) preserving identity and composition under the morphism classifier of the codomain. It is not a primitive function space between categories; it is admitted only as a structure-preserving pair of carrier mappings.

62.1 Carrier definition

Definition 62.1 (Functor carrier)**.** *Use a structure with object mapping, morphism mapping, and proofs preserving identity and composition.*

Lean4 (definition) `BEDC.Derived.FunctorUp.PrefixFunctorCarrier`

Theorem 62.2 (Prefix functor carrier from unary prefix)**.** *For the unary-continuation category, every unary prefix history determines a prefix functor carrier. Its hom-carrier fields preserve and reflect prefixed hom histories, and its composition field preserves displayed composition after prefixing the endpoints.*

Proof. Package the unary prefix witness together with the prefix hom-carrier preservation theorem, the prefix reflection theorem, and the prefixed composition preservation theorem. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier from unary prefix`

Theorem 62.3 (Prefix functor carrier hsame transport with unary readback)**.** *For prefix histories p, q, a prefix functor carrier at p transports along $p\mathsf{hsame}q$ to a prefix functor carrier at q, and the transported endpoint also exposes $\mathsf{UnaryHistory}(q)$.*

Proof. Case-analyze the displayed history-sameness $p\mathsf{hsame}q$. In the reflexive case the original prefix functor carrier is already a carrier at q, and its stored prefix-unary field gives the unary readback. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier hsame transport with unary`

Theorem 62.4 (Functor prefix hom-carrier preserves)**.** *For a unary prefix p, any category hom-carrier from a to b transports to a category hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, b)$ with the same morphism history.*

Proof. Use unary append closure on the two endpoints and place the original continuation ledger under the common left prefix. The prefix is fixed on both source and target, so the morphism history is read without alteration. □

Theorem 62.5 (Functor prefix hom-carrier reflects)**.** *For a unary prefix p, any category hom-carrier from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, b)$ *reflects to a category hom-carrier from a to b with the same morphism history.*

Proof. Read the prefixed endpoint carriers through unary append exactness and cancel the common left prefix in the continuation ledger. The remaining continuation is the unprefixed hom-carrier from a to b with the same morphism history. □

Theorem 62.6 (Functor prefix hom-carrier identity closed)**.** *For a unary prefix p and a unary object a, the empty morphism is a category hom-carrier from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, a)$*.*

Proof. Unary append closure carries the prefixed object. The category empty-identity row then supplies the empty hom-carrier at that carried endpoint. □

Theorem 62.7 (Functor prefix hom-carrier composition preserves)**.** *For a unary prefix p, composable hom-carriers from a to b and from b to c remain composable after prefixing all endpoints by p, and their continuation composite has the same morphism history.*

Proof. Apply Definition 62.4 to both factor hom-carriers. The displayed continuation ledger is unchanged as a morphism history, while the source, middle, and target endpoints are all read under the same unary prefix. □

Theorem 62.8 (Functor prefix hom-carrier composite hsame transport)**.** *For a unary prefix p, if two composable hom-carrier displays are transported by* hsame*-classified source, middle, target, and morphism data, then the prefixed composite display transports by the same* hsame *data under* $\mathsf{append}(p, \cdot)$*.*

Proof. Transport the two factor hom-carriers by the category endpoint and morphism transport rows, then apply prefix preservation to the transported factors. Append congruence carries the source, middle, and target comparisons through the fixed unary prefix, and continuation transport carries the composite morphism comparison. □

Theorem 62.9 (Prefix functor carrier composition public readback)**.** *For a prefix functor carrier p, if f is a hom-carrier from a to b, g is a hom-carrier from b to c, and* $\mathsf{Cont}(f, g, fg)$*, then fg is displayed as a hom-carrier from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, c)$*. Moreover, any displayed hom-carrier between the same prefixed endpoints has morphism history* hsame *to fg.*

Proof. The composition-preservation field of the prefix functor carrier closes the prefixed composite. Public readback follows by category hom-carrier morphism determinacy at the same prefixed endpoints. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier comp public readback`

Theorem 62.10 (Prefix functor carrier right-factor endpoint determinacy)**.** *For a prefix functor carrier p, suppose f is a hom-carrier from a to b, fg is displayed as* $\mathsf{Cont}(f, g, fg)$*, and the prefixed composite fg is a hom-carrier from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, c)$*. If the same composite is also displayed as* $\mathsf{Cont}(f, g', fg)$ *and g' is a hom-carrier from b' to c, then*

$$\mathsf{hsame}(b, b') \wedge \mathsf{hsame}(g, g').$$

Proof. The hom-reflection field of the prefix functor carrier reflects the displayed prefixed composite back to a hom-carrier from a to c. Category right-factor endpoint determinacy compares this reflected composite against the displayed $b' \to c$ right factor, and continuation left cancellation identifies the two right-factor histories. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier comp right factor endpoint deterministic`

Theorem 62.11 (Prefix functor carrier hom public readback)**.** *For a prefix functor carrier p, if f is a hom-carrier from a to b, then f is displayed as a hom-carrier from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, b)$*. Moreover, any displayed hom-carrier between those same prefixed endpoints has morphism history* hsame *to f.*

Proof. The hom-preservation field of the prefix functor carrier gives the prefixed hom-carrier with the same morphism history. Category hom-carrier morphism determinacy at the same prefixed endpoints compares every displayed carrier with that preserved morphism. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier hom public readback`

Theorem 62.12 (Prefix functor carrier append hom preservation)**.** *For prefix functor carriers p and q, any hom-carrier* $\mathsf{CategoryHomCarrier}(a, b, f)$ *is carried by the appended prefix:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(\mathsf{append}(p, q), a), \mathsf{append}(\mathsf{append}(p, q), b), f).$$

Proof. First use the hom-preservation field of the q-carrier to display the hom-carrier at endpoints prefixed by q. Use the hom-preservation field of the p-carrier on that displayed hom-carrier. The resulting endpoints are $\mathsf{append}(p, \mathsf{append}(q, a))$ and $\mathsf{append}(p, \mathsf{append}(q, b))$; continuation append associativity transports them to the appended-prefix endpoints. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier append hom preserves`

Theorem 62.13 (Prefix functor carrier append composition preservation)**.** *For prefix functor carriers p and q, composable hom-carriers* $\mathsf{CategoryHomCarrier}(a, b, f)$ *and* $\mathsf{CategoryHomCarrier}(b, c, g)$*, together with* $\mathsf{Cont}(f, g, fg)$*, display the composite fg at the endpoints prefixed by* $\mathsf{append}(p, q)$*:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(\mathsf{append}(p, q), a), \mathsf{append}(\mathsf{append}(p, q), c), fg).$$

Proof. Use the composition-preservation field of the q-carrier to close the composite at endpoints prefixed by q. Then use the hom-preservation field of the p-carrier on that already composed display. Append associativity transports the source and target endpoints from nested prefixing to the single appended-prefix form. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier append comp preserves`

Theorem 62.14 (Prefix functor carrier e1 prefix hom reflects)**.** *For histories p, a, b, f, a prefix functor carrier at the visible prefix* $\mathsf{E1}(p)$ *reflects any displayed prefixed hom-carrier back to the unprefixed hom-carrier and exposes the unary tail of the visible prefix:*

$$\mathsf{PrefixFunctorCarrier}(\mathsf{E1}(p)) \to \mathsf{CategoryHomCarrier}(\mathsf{append}(\mathsf{E1}(p), a), \mathsf{append}(\mathsf{E1}(p), b), f) \to \mathsf{UnaryHistory}(p) \wedge \mathsf{Categ}$$

Proof. Project the stored unary evidence for the visible prefix and invert the $\mathsf{E1}$ constructor to obtain $\mathsf{UnaryHistory}(p)$. The carrier's hom-reflection field cancels the displayed common prefix and returns the unprefixed category hom-carrier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier e1 prefix hom reflects`

Theorem 62.15 (Prefix functor carrier associative composition public readback)**.** *For a prefix functor carrier p, if f, g, h are composable hom-carriers from a to b, from b to c, and from c to d, with displayed composites fg, gh, $left$, and $right$, then $left$ and $right$ are hom-carriers from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, d)$*, satisfy* $\mathsf{hsame}(left, right)$*, and compare by* hsame *with every displayed hom-carrier between those same prefixed endpoints.*

Proof. The prefix functor carrier exposes a unary witness for the prefix, so prefix associative composition preservation closes both bracketed composites at the prefixed endpoints and supplies their associativity comparison. Category hom-carrier morphism determinacy at the same prefixed endpoints then compares each bracketed composite with any displayed carrier there. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier comp assoc public readback`

Theorem 62.16 (Prefix functor carrier identity public readback)**.** *For a prefix functor carrier p and a unary object a, every displayed hom-carrier from* $\mathsf{append}(p, a)$ *to itself has morphism history* hsame *to* e.

Proof. The prefix carrier supplies unary closure for p. Together with the unary carrier for a, this constructs the empty identity hom-carrier at the prefixed endpoint. Category hom-carrier morphism determinacy then compares any displayed endomorphism at the same endpoint with that empty identity. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier identity public readback`

Theorem 62.17 (Prefix functor carrier preserves split-mono witnesses)**.** *For histories p, a, b, f, g, i, c, suppose p carries a prefix functor carrier, $f : a \to b$ and $g : b \to a$ are category hom-carriers, $i : a \to a$ is an identity hom-carrier,* $\mathsf{Cont}(f, g, c)$ *displays the composite, $c : a \to a$ is also a category hom-carrier, and* $c\mathsf{hsame}i$*. Then the prefixed endpoints carry a split-monomorphism witness: $g :$* $\mathsf{append}(p, b) \to \mathsf{append}(p, a)$*, the identity carrier over* $\mathsf{append}(p, a)$*, the same composite ledger, the prefixed composite carrier, and the same classifier comparison.*

Proof. Use the hom-preservation field of the prefix functor carrier on the inverse hom-carrier g and on the identity hom-carrier i. Use its composition preservation field on f, g, and the displayed continuation for c. Taking the displayed prefixed identity to be i and the displayed prefixed composite to be c gives the required witness package, with the original comparison $c\mathsf{hsame}i$ as the classifier component. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier split mono witness preserves`

Theorem 62.18 (Prefix functor carrier preserves split-epi witnesses)**.** *For histories p, a, b, f, g, i, c, suppose p carries a prefix functor carrier, $f : a \to b$ and $g : b \to a$ are category hom-carriers, $i : b \to b$ is an identity hom-carrier,* $\mathsf{Cont}(g, f, c)$ *displays the composite, $c : b \to b$ is also a category hom-carrier, and* $c\mathsf{hsame}i$*. Then the prefixed endpoints carry a split-epimorphism witness: $g :$* $\mathsf{append}(p, b) \to \mathsf{append}(p, a)$*, the identity carrier over* $\mathsf{append}(p, b)$*, the same composite ledger, the prefixed composite carrier, and the same classifier comparison.*

Proof. Use the hom-preservation field of the prefix functor carrier on the displayed reverse hom-carrier g and on the identity hom-carrier i. Use its composition preservation field on g, f, and the displayed continuation for c. Taking the displayed prefixed identity to be i and the displayed prefixed composite to be c gives the required witness package, with the original comparison $c\mathsf{hsame}i$ as the classifier component. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier split epi witness preserves`

Theorem 62.19 (Prefix functor carrier preserves split-isomorphism witness pairs)**.** *For histories $p, a, b, f, g_L, i_A, c_A, g_R, i_B, c_B$, suppose p carries a prefix functor carrier, $f : a \to b$ is a category hom-carrier, $g_L : b \to a$ and $g_R : b \to a$ are the two displayed inverse-side hom-carriers, $i_A : a \to a$ and $i_B : b \to b$ are identity hom-carriers, and the continuations $\mathsf{Cont}(f, g_L, c_A)$ and $\mathsf{Cont}(g_R, f, c_B)$ display composites classified by i_A and i_B. Then the prefixed endpoints carry the corresponding split-isomorphism witness pair with the same morphism histories and classifier comparisons.*

Proof. Use the hom-preservation field of the prefix functor carrier on f, both inverse-side hom-carriers, and both identity hom-carriers. Use its composition-preservation field on the two displayed continuation ledgers. The four displayed witnesses are the original identity and composite histories, and the two classifier components are the original comparisons. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier split iso witness pair preserves`

Theorem 62.20 (Prefix functor empty morphism source exactness)**.** *For histories $p, a, source$, the empty history is a category hom-carrier from source to $\mathsf{append}(p, a)$ exactly when p and a are unary and source is history-same to that prefixed target:*

$$\mathsf{CategoryHomCarrier}(source, \mathsf{append}(p, a), \mathsf{e}) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{hsame}(source, \mathsf{append}(p, a$$

Proof. Apply category empty-identity exactness to the displayed empty morphism. The target unary witness splits through append into unary witnesses for p and a, while the same exactness theorem gives the endpoint sameness. Conversely, append closure rebuilds the target carrier, unary transport gives the source carrier along endpoint sameness, and category empty-identity exactness reconstructs the hom-carrier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier empty morphism source iff`

Theorem 62.21 (One-headed prefix empty morphism source exactness)**.** *For histories $p, a, source$, the empty history is a category hom-carrier from source to $\mathsf{append}(\mathsf{E1}(p), a)$ exactly when p and a are unary and source is history-same to that one-headed prefixed target:*

$$\mathsf{CategoryHomCarrier}(source, \mathsf{append}(\mathsf{E1}(p), a), \mathsf{e}) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{hsame}(source, \mathsf{append}($$

Proof. Apply prefix empty morphism source exactness with prefix $\mathsf{E1}(p)$. The forward direction turns unary membership of $\mathsf{E1}(p)$ into unary membership of p by one-headed unary inversion. Conversely, unary closure of the one-headed constructor rebuilds the prefixed unary target data, and the general source exactness reconstructs the hom-carrier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 prefix empty morphism source iff`

Theorem 62.22 (Prefix functor empty morphism endpoint exactness)**.** *For histories p, a, b, f, a prefixed hom-carrier has empty morphism history exactly when the unprefixed endpoints agree:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), f) \Longrightarrow (\mathsf{hsame}(f, \mathsf{e}) \Longleftrightarrow \mathsf{hsame}(a, b)).$$

Proof. The underlying category hom-carrier identifies empty morphisms with equality of the prefixed endpoints. Left cancellation for generated-history append removes the common prefix. Conversely, endpoint equality of a and b lifts through the shared prefix and the category endpoint theorem identifies the morphism with e. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier morphism empty endpoint iff`

Theorem 62.23 (Functor prefix hom-carrier composite result empty exactness)**.** *For histories p, a, b, c, f, g, fg, if f is a hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, b)$, g is a hom-carrier from $\mathsf{append}(p, b)$ to $\mathsf{append}(p, c)$, and $\mathsf{Cont}(f, g, fg)$ holds, then emptiness of the displayed composite result is equivalent to the two factor morphisms being empty and the adjacent unprefixed endpoints agreeing:*

$$\mathsf{hsame}(fg, \mathsf{e}) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. The forward direction transports the displayed continuation to empty result and applies prefix empty-composite exactness. Conversely, the componentwise empty data builds the empty composite continuation; continuation determinacy compares that empty result with the displayed composite result fg. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp result empty iff`

Theorem 62.24 (Prefix hom composite empty-middle inversion)**.** *For histories p, a, c, f, g, fg, if f is a hom-carrier from $\mathsf{append}(p, a)$ to e, g is a hom-carrier from e to $\mathsf{append}(p, c)$, and $\mathsf{Cont}(f, g, fg)$, then*

$$\mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{append}(p, c)) \wedge \mathsf{CategoryHomCarrier}(\mathsf{e}, \mathsf{append}(p, c), fg) \wedge \mathsf{hsame}(fg, \mathsf{a}$$

Proof. Empty-target component exactness splits the left hom-carrier into emptiness of the prefix, source tail, and morphism. Empty-source component exactness reads the right morphism as the prefixed target. With $f = \mathsf{e}$, the displayed continuation identifies fg with g, so fg also reads back as $\mathsf{append}(p, c)$; category empty-source exactness rebuilds the final hom-carrier for fg. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp empty middle inversion`

Theorem 62.25 (Prefix hom composite empty-middle target determinacy)**.** *For histories $p, a, c, f, g, fg, target$, if f is a hom-carrier from $\mathsf{append}(p, a)$ to e, g is a hom-carrier from e to $\mathsf{append}(p, c)$, $\mathsf{Cont}(f, g, fg)$, and the displayed composite fg is also a hom-carrier from e to target, then*

$$\mathsf{hsame}(target, \mathsf{append}(p, c)).$$

Proof. The empty-middle inversion supplies the canonical hom-carrier from e to $\mathsf{append}(p, c)$ over the same composite morphism fg. Target determinacy for category hom-carriers compares this canonical carrier with the displayed one and yields the stated classifier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp empty middle target deterministic`

Theorem 62.26 (Prefix hom composite empty-middle displayed morphism determinacy)**.** *For histories $p, a, c, f, g, fg, displayed$, if f is a hom-carrier from $\mathsf{append}(p, a)$ to e, g is a hom-carrier from e to $\mathsf{append}(p, c)$, $\mathsf{Cont}(f, g, fg)$, and displayed is also a hom-carrier from e to $\mathsf{append}(p, c)$, then*

$$\mathsf{hsame}(displayed, fg).$$

Proof. The prefixed empty-middle inversion supplies the canonical hom-carrier from e to $\mathsf{append}(p, c)$ over fg. Category hom-carrier morphism determinacy compares that carrier with the displayed carrier over the same endpoints. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp empty middle displayed morphism deterministic`

Theorem 62.27 (Prefix hom composite empty-middle source determinacy)**.** *For histories p, a, c, f, g, fg, source, if f is a hom-carrier from* $\mathsf{append}(p, a)$ *to* e*, g is a hom-carrier from* e *to* $\mathsf{append}(p, c)$*,* $\mathsf{Cont}(f, g, fg)$*, and the displayed composite fg is also a hom-carrier from source to* $\mathsf{append}(p, c)$*, then*

$$\mathsf{hsame}(\mathit{source}, \mathsf{e}).$$

Proof. The empty-middle inversion supplies the canonical hom-carrier from e to $\mathsf{append}(p, c)$ over fg. Source determinacy for category hom-carriers compares the displayed carrier with this canonical carrier and identifies the displayed source with e. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp empty middle source deterministic`

Theorem 62.28 (Prefix functor carrier empty-middle empty-result readback)**.** *For histories p, q, a, c, f, g, fg, suppose p carries a prefix functor carrier, f is a hom-carrier from* $\mathsf{append}(p, a)$ *to* e*, g is a hom-carrier from* e *to* $\mathsf{append}(q, c)$*,* $\mathsf{Cont}(f, g, fg)$*, and $fg\mathsf{hsamee}$. Then q carries a prefix functor carrier, and all displayed components are empty:*

$$\mathsf{PrefixFunctorCarrier}(q) \wedge \mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(q, \mathsf{e}) \wedge \mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(c, \mathsf{e}) \wedge \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}).$$

Proof. Apply category composite-result empty exactness to the displayed hom-carriers. The left endpoint equality splits $\mathsf{append}(p, a)\mathsf{hsamee}$ into $p\mathsf{hsamee}$ and $a\mathsf{hsamee}$, and the right endpoint equality splits $\mathsf{append}(q, c)\mathsf{hsamee}$ into $q\mathsf{hsamee}$ and $c\mathsf{hsamee}$. The factor morphism equalities give $f\mathsf{hsamee}$ and $g\mathsf{hsamee}$. Since q is history-same to e, the unary-prefix constructor supplies the prefix functor carrier at q. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier comp empty middle empty result readback`

Theorem 62.29 (Prefix functor preserves associative hom composition)**.** *For the unary-continuation category, if p is unary and f, g, h are composable hom-carriers with composites fg, gh, $left$, and $right$, then $left$ and $right$ are hom-carriers from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, d)$*, and* $\mathsf{hsame}(left, right)$*.*

Proof. Use category-level associative composition closure to obtain the two unprefixed composite hom-carriers and their classifier sameness. Prefix preservation transports each composite hom-carrier across the unary prefix p, while the classifier sameness is the same continuation associativity witness. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp assoc preserves`

Theorem 62.30 (Prefix functor displayed associative hom determinacy)**.** *For the unary-continuation category, if p is unary and f, g, h are composable hom-carriers with composites fg, gh, $left$, and $right$, then any displayed hom-carrier from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, d)$ *determines both bracketed composite histories up to* hsame*.*

Proof. Prefix associative composition preservation supplies the two prefixed hom-carriers over the displayed endpoints. Category hom-carrier morphism determinacy compares each bracketed composite carrier with the displayed carrier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp assoc displayed deterministic`

Theorem 62.31 (Prefix functor associative empty result components)**.** *For the unary-continuation category, if p is unary and the unprefixed hom-carriers f, g, h compose with associated results $left$ and $right$, then a displayed empty hom-carrier from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, d)$ *forces both associated composite histories to be* hsame *to* e*, and forces* $a\mathsf{hsame}d$*.*

Proof. Use prefix displayed associative determinacy with the displayed empty hom-carrier to compare both bracketed composites with e. Prefix empty identity exactness cancels the common prefix in the same displayed empty hom-carrier and reads back $a\mathsf{hsame}d$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp assoc empty result components`

Theorem 62.32 (Prefix functor associative nonempty target component cases)**.** *For the unary-continuation category, suppose p is unary and f, g, h are composable hom-carriers with associated composites fg, gh, $left$, and $right$. If the left-associated composite result is* hsame*-equal to* $\mathsf{E1}(k)$*, then either the prefix p is itself one-headed, or the final target component d is one-headed.*

Proof. Close the first two hom-carriers to obtain the fg hom-carrier from a to c, then prefix it and the third hom-carrier by p. Transport the displayed continuation $\mathsf{Cont}(fg, h, left)$ along the endpoint equality $left\mathsf{hsameE1}(k)$. The binary prefixed nonempty-target component theorem then applies to the prefixed fg-then-h composite and separates the visible target endpoint into the prefix component or the final target component. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp assoc nonempty result target component e1 cases`

Theorem 62.33 (Prefix functor unary suffix preserves associative hom composition)**.** *For the unary-continuation category, if p and q are unary and f, g, h are composable hom-carriers with composites fg, gh, $left$, and $right$, then $left$ and $right$ are displayed from* $\mathsf{append}(\mathsf{append}(p, a), q)$ *to* $\mathsf{append}(\mathsf{append}(p, d), q)$*, and* $\mathsf{hsame}(left, right)$*.*

Proof. Category-level associative composition closure supplies the two central carriers and the associativity witness between their morphism histories. Unary context exactness transports both carriers through the shared prefix and suffix, while the associativity witness is unchanged. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier unary suffix comp assoc preserves`

Theorem 62.34 (Prefix functor unary suffix reflects associative hom composition)**.** *For histories $p, q, a, b, c, d, f, g, h, fg, gh, left, right$, suppose the three displayed hom-carriers run through the shared unary context* $\mathsf{append}(\mathsf{append}(p, -), q)$ *from a to b, from b to c, and from c to d. If the four continuation ledgers display the two associative composites, then $left$ and $right$ are central hom-carriers from a to d, and* $\mathsf{hsame}(left, right)$*.*

Proof. Apply unary-context exactness to each of the three displayed hom-carriers. This reflects them to central hom-carriers $a \to b$, $b \to c$, and $c \to d$. Category associative composition closure then applies to the reflected carriers and the four displayed continuation ledgers, producing both central composite carriers and the associativity classifier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier unary suffix comp assoc reflects`

Theorem 62.35 (Prefix functor reflects associative hom composition)**.** *For histories $p, a, b, c, d, f, g, h, fg, gh, left,$ suppose f is a hom-carrier from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, b)$*, g is a hom-carrier from* $\mathsf{append}(p, b)$ *to* $\mathsf{append}(p, c)$*, and h is a hom-carrier from* $\mathsf{append}(p, c)$ *to* $\mathsf{append}(p, d)$*. If* $\mathsf{Cont}(f, g, fg)$*,* $\mathsf{Cont}(g, h, gh)$*,* $\mathsf{Cont}(fg, h, left)$*, and* $\mathsf{Cont}(f, gh, right)$*, then $left$ and $right$ are hom-carriers from a to d, and* $\mathsf{hsame}(left, right)$*.*

Proof. Reflect the three prefixed hom-carrier witnesses through the unary-context exactness theorem Definition 61.51. This gives unprefixed hom-carriers for f from a to b, g from b to c, and h from c to d.

Apply Theorem 61.132 to these reflected witnesses and to the four displayed continuation relations. The category closure theorem returns both composite carriers from a to d together with the classifier witness $\mathsf{hsame}(left, right)$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp assoc reflects`

Theorem 62.36 (Prefix functor preserves empty identity hom carriers)**.** *For the unary-continuation category, if p and a are unary, then the empty history is a hom-carrier from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, a)$*.*

Proof. First use the empty identity hom-carrier theorem at a. Prefix preservation then transports that hom-carrier along the unary prefix p. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier empty identity preserves`

Theorem 62.37 (Prefix functor empty identity hom carrier exactness)**.** *For histories p, a, b, the empty history is a hom-carrier from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, b)$ *exactly when the two prefixed endpoints are unary and the unprefixed tails a, b are internally the same:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), \mathsf{e}) \iff \mathsf{UnaryHistory}(\mathsf{append}(p, a)) \wedge \mathsf{UnaryHistory}(\mathsf{append}(p, b)) \wedge$$

Proof. Apply empty identity hom-carrier exactness in the category chapter to obtain sameness of the two prefixed endpoints. Left cancellation for generated-history append then reflects this sameness to the tails a, b. Conversely, tail sameness lifts to sameness of the prefixed endpoints, and category empty identity exactness reconstructs the hom-carrier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier empty identity iff`

Theorem 62.38 (Prefix functor empty morphism target exactness)**.** *For histories $p, a, target$, the empty history is a hom-carrier from the prefixed source* $\mathsf{append}(p, a)$ *to target exactly when p and a are unary and target is history-same to that prefixed source:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), target, \mathsf{e}) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{hsame}(target, \mathsf{append}(p, a))$$

Proof. Apply category empty-identity exactness to the hom-carrier with source $\mathsf{append}(p, a)$. The source unary witness splits into unary witnesses for p and a, and endpoint sameness is read in the target-to-source direction. Conversely, append closure rebuilds the unary source; transport along endpoint sameness gives the unary target, and category empty-identity exactness reconstructs the hom-carrier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier empty morphism target iff`

Theorem 62.39 (One-headed prefix empty morphism target exactness)**.** *For histories $p, a, target$:* BHist*, the empty history is a hom-carrier from the one-headed prefixed source* $\mathsf{append}(\mathsf{E1}(p), a)$ *to target exactly when p and a are unary and target is history-same to that source:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(\mathsf{E1}(p), a), target, \mathsf{e}) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{hsame}(target, \mathsf{append}($$

Proof. Apply prefix empty morphism target exactness with prefix $\mathsf{E1}(p)$. The forward direction turns unary membership of $\mathsf{E1}(p)$ into unary membership of p by one-headed unary inversion. Conversely, unary closure of the one-headed constructor rebuilds the prefixed unary source data, and the general empty morphism target exactness reconstructs the hom-carrier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 prefix empty morphism target iff`

Theorem 62.40 (One-headed prefix empty identity hom carrier exactness)**.** *For histories p, a, b, the empty history is a hom-carrier from $\mathsf{append}(\mathsf{E1}(p), a)$ to $\mathsf{append}(\mathsf{E1}(p), b)$ exactly when p, a, and b are unary and the two tails are internally the same:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(\mathsf{E1}(p), a), \mathsf{append}(\mathsf{E1}(p), b), \mathsf{e}) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}$$

Proof. The forward direction applies prefix empty identity exactness with prefix $\mathsf{E1}(p)$, then splits the unary append witnesses for the source and target. One-headed unary inversion extracts unary membership of p. The reverse direction closes $\mathsf{E1}(p)$ under unary generation, rebuilds the two prefixed unary endpoints by append closure, and invokes prefix empty identity exactness. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 prefix empty identity iff`

Theorem 62.41 (Prefix functor empty composite exactness)**.** *For histories p, a, b, c, f, g, if f is a hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, b)$ and g is a hom-carrier from $\mathsf{append}(p, b)$ to $\mathsf{append}(p, c)$, then their empty composite is equivalent to both morphism histories being empty and the two unprefixed adjacent endpoints agreeing:*

$$\mathsf{Cont}(f, g, \mathsf{e}) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. Category empty-composite exactness gives the two empty morphism histories and the two prefixed endpoint equalities. Left cancellation removes the common prefix p from both endpoint equalities. Conversely, the unprefixed endpoint equalities rebuild the prefixed endpoint equalities, and category empty-composite exactness supplies the empty continuation ledger. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp empty iff`

Theorem 62.42 (Prefix functor one-headed endpoint empty composite exactness)**.** *For histories p, a, b, c, f, g, if f is a hom-carrier from $\mathsf{append}(p, \mathsf{E1}(a))$ to b and g is a hom-carrier from b to $\mathsf{append}(p, \mathsf{E1}(c))$, then their empty composite is equivalent to both morphism histories being empty and the one-headed endpoint payloads agreeing:*

$$\mathsf{Cont}(f, g, \mathsf{e}) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(a, c).$$

Proof. Category empty-composite exactness gives the two empty morphism histories and the adjacent endpoint equalities through b. Transitivity identifies the two prefixed one-headed endpoints. Left cancellation removes the shared prefix p, and one-headed constructor inversion gives $\mathsf{hsame}(a, c)$. Conversely, the empty morphism histories reduce the displayed continuation ledger to $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 endpoint empty composite iff`

Theorem 62.43 (Prefix functor one-headed empty composite middle endpoint)**.** *For histories p, a, b, c, f, g, if f is a hom-carrier from $\mathsf{append}(p, \mathsf{E1}(a))$ to b, g is a hom-carrier from b to $\mathsf{append}(p, \mathsf{E1}(c))$, and their composite is empty, then the shared middle endpoint is classified with both visible prefixed endpoints:*

$$\mathsf{Cont}(f, g, \mathsf{e}) \Longrightarrow \mathsf{hsame}(b, \mathsf{append}(p, \mathsf{E1}(a))) \wedge \mathsf{hsame}(b, \mathsf{append}(p, \mathsf{E1}(c))).$$

Proof. The one-headed empty-composite exactness theorem gives $\mathsf{hsame}(f, \mathsf{e})$ and $\mathsf{hsame}(g, \mathsf{e})$. Transport the two hom-carriers along these morphism classifiers so that both displayed morphisms are empty. Category empty-identity exactness then reads the left leg as equality of its source and middle endpoint, and the right leg as equality of the middle endpoint and its target. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 endpoint empty composite middle hsame`

Theorem 62.44 (Prefix functor empty-target component exactness)**.** *For histories p, a, f, a hom-carrier from the prefixed source* $\mathsf{append}(p, a)$ *into the empty target is exactly componentwise emptiness of the prefix, the tail, and the morphism:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{e}, f) \iff \mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(f, \mathsf{e}).$$

Proof. Apply category empty-target exactness to obtain $\mathsf{hsame}(\mathsf{append}(p, a), \mathsf{e})$ and $\mathsf{hsame}(f, \mathsf{e})$. Empty splitting for the recursive append representative separates the first witness into $p = \mathsf{e}$ and $a = \mathsf{e}$. Conversely, eliminating the three sameness witnesses reduces the hom-carrier to the empty source, empty target, empty morphism case. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier empty target components iff`

Theorem 62.45 (Prefix functor one-headed empty-target impossibility)**.** *For histories p, a, f, no hom-carrier can run from* $\mathsf{append}(\mathsf{E1}(p), a)$ *into the empty target:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(\mathsf{E1}(p), a), \mathsf{e}, f) \to \mathsf{False}.$$

Proof. Apply the empty-target component exactness theorem just above with prefix $\mathsf{E1}(p)$. It reads back $\mathsf{hsame}(\mathsf{E1}(p), \mathsf{e})$, contradicting the closed constructor separation for one-headed histories. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 prefix empty target absurd`

Theorem 62.46 (Prefix functor empty-target source morphism swap)**.** *For histories p, a, f, a hom-carrier from the prefixed source* $\mathsf{append}(p, a)$ *into the empty target is unchanged when the displayed source and morphism fields are exchanged:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{e}, f) \iff \mathsf{CategoryHomCarrier}(f, \mathsf{e}, \mathsf{append}(p, a)).$$

Proof. Apply category empty-target exactness at the prefixed source. The hom-carrier is exactly the pair $\mathsf{hsame}(\mathsf{append}(p, a), \mathsf{e}) \wedge \mathsf{hsame}(f, \mathsf{e})$. Swapping those two boundary classifiers gives the exchanged empty-target hom-carrier, and the reverse implication swaps them back. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier empty target source morphism swap iff`

Theorem 62.47 (Prefix functor empty-source component exactness)**.** *For histories p, b, f, a hom-carrier from the empty source into the prefixed target* $\mathsf{append}(p, b)$ *is exactly unary component data for p and b together with morphism equality to that prefixed target:*

$$\mathsf{CategoryHomCarrier}(\mathsf{e}, \mathsf{append}(p, b), f) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(f, \mathsf{append}(p, b)).$$

Proof. Category empty-source exactness turns the hom-carrier into unary closure of the prefixed target and equality of f with that target. Unary append factorization separates the target carrier into the prefix and tail carriers. Conversely, unary append closure rebuilds the target carrier, and category empty-source exactness reconstructs the hom-carrier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier empty source components iff`

Theorem 62.48 (Prefix functor visible composite target component cases)**.** *For prefixed hom-carriers from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, b)$ *and from* $\mathsf{append}(p, b)$ *to* $\mathsf{append}(p, c)$*, if the composite continuation displays the visible result* $\mathsf{E1}(k)$*, then either the prefix component or the target-tail component is itself one-headed:*

$$\exists p_0.\ p = \mathsf{E1}(p_0) \wedge \mathsf{UnaryHistory}(p_0) \quad \vee \quad \exists c_0.\ c = \mathsf{E1}(c_0) \wedge \mathsf{UnaryHistory}(c_0).$$

Proof. The nonempty composite target visibility theorem displays $\mathsf{append}(p, c)$ as $\mathsf{E1}(r)$. Hence this append target is not history-same to e. BEDC append non-emptiness splits this into nonempty p or nonempty c, and unary append factorization supplies the corresponding unary carrier. Unary nonempty decomposition then reads back the visible one-headed component. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp nonempty result target component e1 cases`

Theorem 62.49 (Prefix functor visible composite source component cases)**.** *For prefixed hom-carriers from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, b)$ *and from* $\mathsf{append}(p, b)$ *to* $\mathsf{append}(p, c)$*, if the composite continuation displays the visible result* $\mathsf{E1}(k)$ *and the source* $\mathsf{append}(p, a)$ *is not empty, then the prefix component or the source-tail component is one-headed:*

$$\exists p_0.\ p = \mathsf{E1}(p_0) \wedge \mathsf{UnaryHistory}(p_0) \quad \vee \quad \exists a_0.\ a = \mathsf{E1}(a_0) \wedge \mathsf{UnaryHistory}(a_0).$$

Proof. Composite source visibility displays $\mathsf{append}(p, a)$ as a one-headed history. Therefore the append source is nonempty. BEDC append non-emptiness splits this into nonempty p or nonempty a, while unary append factorization extracts the corresponding carrier. Unary nonempty readback then gives the one-headed component. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp nonempty result source component e1 cases`

Theorem 62.50 (Prefix functor one-headed morphism-target component exactness)**.** *For histories* p, a, k, r*, a hom-carrier from the prefixed source* $\mathsf{append}(p, a)$ *to the one-headed target* $\mathsf{E1}(r)$ *with one-headed morphism* $\mathsf{E1}(k)$ *is exactly unary component data for* p, a, k *together with the tail continuation:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{E1}(r), \mathsf{E1}(k)) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{Cont}($$

Proof. Apply category one-headed morphism-target exactness to obtain unary membership of the appended source, unary membership of k, and the tail continuation. Unary append factorization splits the source carrier into the two component witnesses for p and a. Conversely, unary append closure rebuilds the source carrier, and the category exactness theorem lifts the tail continuation through the visible one constructor on both target and morphism. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 morphism target components iff`

Theorem 62.51 (Prefix functor visible endpoint morphism exactness)**.** *For histories* p, a, r, k*, a prefixed visible morphism between one-headed endpoints is equivalent to a unary prefix, unary visible tails, and the unprefixed tail continuation:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, \mathsf{E1}(a)), \mathsf{append}(p, \mathsf{E1}(r)), \mathsf{E1}(k)) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}$$

Proof. Forward, reflect the prefixed hom-carrier to the base category and apply the one-headed endpoint visible morphism exactness theorem; the prefix carrier is read from the prefixed source. Reverse, first rebuild the base visible hom-carrier from the tail continuation and then apply prefix preservation. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 endpoint visible morphism iff`

Theorem 62.52 (Prefix functor visible morphism strict prefix)**.** *For histories p, a, r, k, a prefixed visible morphism from* $\mathsf{append}(p, \mathsf{E1}(a))$ *to* $\mathsf{append}(p, \mathsf{E1}(r))$ *with morphism* $\mathsf{E1}(k)$*, together with nonempty k, exposes a strict unary prefix from* $\mathsf{E1}(a)$ *to r:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, \mathsf{E1}(a)), \mathsf{append}(p, \mathsf{E1}(r)), \mathsf{E1}(k)) \Longrightarrow k \neq \mathsf{e} \Longrightarrow \mathsf{NatUnaryStrictPrefix}(\mathsf{E1}(a), r).$$

Proof. Apply prefixed visible endpoint morphism exactness. Its forward direction recovers unary membership of k and the continuation $\mathsf{Cont}(\mathsf{E1}(a), k, r)$. The nonempty witness for k is therefore exactly the strict-prefix tail. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 visible morphism strict prefix`

Theorem 62.53 (Prefix functor visible morphism endpoint contradiction)**.** *For histories p, a, r, k, a prefixed visible morphism with nonempty visible tail cannot have its unprefixed source endpoint* hsame *to the target endpoint:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, \mathsf{E1}(a)), \mathsf{append}(p, \mathsf{E1}(r)), \mathsf{E1}(k)) \Longrightarrow k \neq \mathsf{e} \Longrightarrow \mathsf{hsame}(\mathsf{E1}(a), r) \Longrightarrow \bot.$$

Proof. The strict-prefix readback supplies a nonempty unary tail from $\mathsf{E1}(a)$ to r. The endpoint hsame comparison would force this tail to be empty by strict-prefix endpoint cancellation, contradicting the displayed nonemptiness. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 visible morphism endpoint hsame absurd`

Theorem 62.54 (Prefix functor visible morphism unique strict boundary)**.** *For histories p, a, r, k, k', two prefixed visible morphisms between the same one-headed endpoints have the same visible payload, and any nonempty first payload exposes the strict endpoint boundary:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, \mathsf{E1}(a)), \mathsf{append}(p, \mathsf{E1}(r)), \mathsf{E1}(k)) \Longrightarrow \mathsf{CategoryHomCarrier}(\mathsf{append}(p, \mathsf{E1}(a)), \mathsf{append}(p$$

Proof. Apply category morphism determinacy to the two displayed hom-carriers. This gives $\mathsf{hsame}(\mathsf{E1}(k), \mathsf{E1}(k'))$, and one-headed no-confusion descends it to $\mathsf{hsame}(k, k')$.

Apply the strict-prefix readback theorem to the first displayed carrier and the nonempty witness for k. This supplies $\mathsf{NatUnaryStrictPrefix}(\mathsf{E1}(a), r)$.

Finally, apply the endpoint contradiction theorem to the same carrier and nonempty witness. It gives the implication $\mathsf{hsame}(\mathsf{E1}(a), r) \to \bot$, and the three facts assemble the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 visible morphism unique strict boundary`

Theorem 62.55 (Prefix functor e-one visible morphism payload determinacy)**.** *For histories $p, p', a, a', r, r', k, k'$, if the three displayed endpoints agree,*

$$\mathsf{hsame}(p, p'), \qquad \mathsf{hsame}(a, a'), \qquad \mathsf{hsame}(r, r'),$$

then two prefixed one-headed visible morphisms with those transported endpoints have the same visible payload:

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, \mathsf{E1}(a)), \mathsf{append}(p, \mathsf{E1}(r)), \mathsf{E1}(k)) \Longrightarrow \mathsf{CategoryHomCarrier}(\mathsf{append}(p', \mathsf{E1}(a')), \mathsf{append}($$

Proof. Use the three hsame rows to identify the prefix, source tail, and target tail displays. Category morphism determinacy then gives $\mathsf{hsame}(\mathsf{E1}(k), \mathsf{E1}(k'))$, and the e-one constructor inversion descends this to $\mathsf{hsame}(k, k')$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier e1 visible morphism payload deterministic`

Theorem 62.56 (Functor prefix hom-carrier zero-headed component impossibility)**.** *For histories p, a, b, f, a prefixed category hom-carrier has no zero-headed prefix, source tail, target tail, or morphism component:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), f) \Longrightarrow (\exists z,\ p = \mathsf{E0}(z)) \vee (\exists z,\ a = \mathsf{E0}(z)) \vee (\exists z,\ b = \mathsf{E0}(z)) \vee (\exists z,\ f =$$

Proof. The source and target carrier fields make $\mathsf{append}(p, a)$ and $\mathsf{append}(p, b)$ unary. Unary append factorization exposes unary witnesses for p, a, and b, while the hom-carrier morphism field gives unary history for f. Each zero-headed witness contradicts the unary zero-extension separation theorem. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier zero headed component absurd`

Theorem 62.57 (Functor prefix hom-carrier source prefix determinism)**.** *For histories $p, q, a, target, f$, if the same morphism f is a category hom-carrier from $\mathsf{append}(p, a)$ to target and from $\mathsf{append}(q, a)$ to target, then the two source prefixes agree:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), target, f) \wedge \mathsf{CategoryHomCarrier}(\mathsf{append}(q, a), target, f) \Longrightarrow \mathsf{hsame}(p, q).$$

Proof. Category hom-carrier source determinism gives $\mathsf{hsame}(\mathsf{append}(p, a), \mathsf{append}(q, a))$. Cancelling the common right append suffix a yields $\mathsf{hsame}(p, q)$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier source prefix deterministic`

Theorem 62.58 (Functor prefix hom-carrier composite source-prefix determinacy)**.** *For histories p, q, a, b, c, f, g, fg, suppose f and g are composable hom-carriers over the common prefix p:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), f) \wedge \mathsf{CategoryHomCarrier}(\mathsf{append}(p, b), \mathsf{append}(p, c), g) \wedge \mathsf{Cont}(f, g, fg)$$

If the displayed composite also has source $\mathsf{append}(q, a)$ and target $\mathsf{append}(p, c)$, then $\mathsf{hsame}(p, q)$.

Proof. Close the two displayed p-prefixed hom-carriers under composition to obtain a canonical carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, c)$ with morphism fg. Source determinacy compares this carrier with the displayed carrier whose source is $\mathsf{append}(q, a)$. Cancelling the common suffix a gives $\mathsf{hsame}(p, q)$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp source prefix deterministic`

Theorem 62.59 (Functor prefix hom-carrier composite source-object determinacy)**.** *For histories p, a, d, b, c, f, g, fg, suppose f and g are composable hom-carriers over the common prefix p:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), f) \wedge \mathsf{CategoryHomCarrier}(\mathsf{append}(p, b), \mathsf{append}(p, c), g) \wedge \mathsf{Cont}(f, g, fg)$$

If the displayed composite also has source $\mathsf{append}(p, d)$ and target $\mathsf{append}(p, c)$, then $\mathsf{hsame}(a, d)$.

Proof. Close the expected composite from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, c)$. Source determinacy compares it with the displayed carrier from $\mathsf{append}(p, d)$ to the same target and morphism. Cancelling the common left prefix p gives $\mathsf{hsame}(a, d)$. □

Theorem 62.62 (Functor prefix hom-carrier target-object determinacy)**.** *For histories $p, a, b, source, f$, if the same morphism f is a category hom-carrier from source to $\mathsf{append}(p, a)$ and from source to $\mathsf{append}(p, b)$, then the two target objects agree:*

$$\mathsf{CategoryHomCarrier}(source, \mathsf{append}(p, a), f) \wedge \mathsf{CategoryHomCarrier}(source, \mathsf{append}(p, b), f) \Longrightarrow \mathsf{hsame}(a, b).$$

Proof. Category hom-carrier target determinism gives $\mathsf{hsame}(\mathsf{append}(p, a), \mathsf{append}(p, b))$. Cancelling the common left append prefix p yields $\mathsf{hsame}(a, b)$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier target object deterministic`

Theorem 62.63 (Functor prefix hom-carrier composite middle-object determinacy)**.** *For histories p, a, b, b', c, f, g, fg, suppose f is a category hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, b)$, g is a category hom-carrier from $\mathsf{append}(p, b')$ to $\mathsf{append}(p, c)$, and $\mathsf{Cont}(f, g, fg)$ holds. If fg is displayed as a category hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, c)$, then $\mathsf{hsame}(b, b')$.*

Proof. Apply category hom-carrier composite middle-object determinacy to the prefixed hom-carriers and the displayed composite. This identifies $\mathsf{append}(p, b)$ and $\mathsf{append}(p, b')$. Cancelling the common left append prefix p gives $\mathsf{hsame}(b, b')$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp middle object deterministic`

Theorem 62.64 (Functor prefix hom-carrier composite target-prefix determinacy)**.** *For histories p, q, a, b, c, f, g, fg, if prefixed hom-carriers compose from $\mathsf{append}(p, a)$ through $\mathsf{append}(p, b)$ to $\mathsf{append}(p, c)$, and the same composite is displayed with target $\mathsf{append}(q, c)$, then the two target prefixes agree:*

$$\mathsf{hsame}(p, q).$$

Proof. Apply category composite target determinacy to compare the expected composite target $\mathsf{append}(p, c)$ with the displayed target $\mathsf{append}(q, c)$. Cancelling the common right suffix c gives $\mathsf{hsame}(p, q)$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp target prefix deterministic`

Theorem 62.65 (Functor prefix hom-carrier composite target-object determinacy)**.** *For histories p, a, b, c, d, f, g, fg, if prefixed hom-carriers compose from $\mathsf{append}(p, a)$ through $\mathsf{append}(p, b)$ to $\mathsf{append}(p, c)$, and the same composite is displayed with target $\mathsf{append}(p, d)$, then the two target objects agree:*

$$\mathsf{hsame}(c, d).$$

Proof. Close the expected composite target $\mathsf{append}(p, c)$ from the two prefixed hom-carriers and the continuation witness. Target determinacy compares that carrier with the displayed target $\mathsf{append}(p, d)$, and cancellation of the common left prefix p gives $\mathsf{hsame}(c, d)$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp target object deterministic`

Theorem 62.66 (Functor prefix triangle cycle empty components)**.** *For histories p, q, r, a, f, g, h, if prefixed hom-carriers form a triangle*

$$\mathsf{append}(p, a) \xrightarrow{f} \mathsf{append}(q, a) \xrightarrow{g} \mathsf{append}(r, a) \xrightarrow{h} \mathsf{append}(p, a),$$

then all three displayed hom-carriers also hold with empty morphism, and the three adjacent prefixes collapse as $\mathsf{hsame}(p, q)$ and $\mathsf{hsame}(q, r)$.

Proof. Apply category hom-carrier triangle-cycle empty exactness to the three prefixed hom-carriers. The category theorem gives empty morphisms on all three edges and identifies the prefixed adjacent endpoints. Cancelling the common right suffix a from those two endpoint equalities gives the stated prefix equalities. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier prefix triangle cycle empty components`

Theorem 62.67 (Functor prefix composite endpoint cycle boundary components)**.** *For histories p, a, b, c, f, g, fg, suppose the prefixed hom-carriers*

$$\mathsf{append}(p, a) \xrightarrow{f} \mathsf{append}(p, b) \xrightarrow{g} \mathsf{append}(p, c)$$

compose through $\mathsf{Cont}(f, g, fg)$ and the unprefixed endpoints satisfy $\mathsf{hsame}(a, c)$. Then both component morphisms and their composite are hsame to e, and the unprefixed boundary collapses:

$$\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(fg, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. Apply the category hom-carrier composite endpoint-cycle boundary theorem to the prefixed endpoints. The hypothesis $\mathsf{hsame}(a, c)$ gives $\mathsf{hsame}(\mathsf{append}(p, a), \mathsf{append}(p, c))$, and the category theorem returns the empty morphism data together with prefixed endpoint equalities. Cancelling the common left prefix p gives $\mathsf{hsame}(a, b)$ and $\mathsf{hsame}(b, c)$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp endpoint cycle boundary components`

Theorem 62.68 (Functor prefix hom-carrier composite middle-prefix determinacy)**.** *For histories p, q, a, b, c, f, g, fg, suppose f is a category hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, b)$, g is a category hom-carrier from $\mathsf{append}(q, b)$ to $\mathsf{append}(p, c)$, and $\mathsf{Cont}(f, g, fg)$ holds. If fg is displayed as a category hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, c)$, then $\mathsf{hsame}(p, q)$.*

Proof. Category hom-carrier composite middle-object determinacy identifies $\mathsf{append}(p, b)$ with $\mathsf{append}(q, b)$. Cancelling the common right suffix b gives $\mathsf{hsame}(p, q)$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp middle prefix deterministic`

Theorem 62.69 (Functor prefix hom-carrier composition family public readback)**.** *For histories $a, b, c, f, g, fg, displayed$, suppose every unary prefix p carries f as a hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, b)$, every unary prefix carries g from $\mathsf{append}(p, b)$ to $\mathsf{append}(p, c)$, $\mathsf{Cont}(f, g, fg)$ holds, and every unary prefix carries displayed from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, c)$. Then*

$$\mathsf{hsame}(fg, displayed).$$

Proof. Evaluate the three prefix-indexed carrier families at the empty unary prefix. The two factor carriers close under category composition, and morphism determinacy compares the resulting composite carrier with the displayed carrier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp family public readback`

Theorem 62.70 (Functor prefix hom-carrier composite zero-headed component impossibility)**.** *For histories p, a, b, c, f, g, fg, two prefixed hom-carriers composing over the middle object b cannot have any zero-headed prefix, object, factor morphism, or composite morphism component:*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), f) \wedge \mathsf{CategoryHomCarrier}(\mathsf{append}(p, b), \mathsf{append}(p, c), g) \wedge \mathsf{Cont}(f, g, fg)$$

whenever one of p, a, b, c, f, g, fg is displayed as $\mathsf{E0}(w)$.

Proof. Close the two hom-carriers under composition to obtain the carrier for fg. The zero-headed prefix, source, middle, and left morphism cases reduce to the left factor exclusion; the target and right morphism cases reduce to the right factor exclusion; the composite morphism case reduces to the closed composite carrier. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp zero headed component absurd`

Theorem 62.71 (Functor prefix composite nonempty target component split)**.** *For prefixed hom-carriers*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), f)$$

and

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, b), \mathsf{append}(p, c), g),$$

if $\mathsf{Cont}(f, g, fg)$ and fg is not empty, then the displayed target $\mathsf{append}(p, c)$ has a nonempty component:

$$(\mathsf{hsame}(p, \mathsf{e}) \to \bot) \vee (\mathsf{hsame}(c, \mathsf{e}) \to \bot).$$

Proof. The category composite nonempty-target obstruction applies to the two prefixed hom-carriers and their continuation composite, giving $\mathsf{hsame}(\mathsf{append}(p, c), \mathsf{e}) \to \bot$. BEDC append nonemptiness then separates the prefixed target into a nonempty prefix component or a nonempty target-tail component. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp nonempty target component split`

Theorem 62.72 (Functor prefix hom-carrier nonempty composite target visibility)**.** *For prefixed hom-carriers*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), f)$$

and

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, b), \mathsf{append}(p, c), g),$$

if the composite continuation displays the visible result $\mathsf{E1}(k)$*, then the prefixed target is visible:*

$$\exists r.\ \mathsf{append}(p, c) = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{append}(p, a), \mathsf{E1}(k), \mathsf{E1}(r)).$$

Proof. Apply category source-target case analysis for nonempty composite results to the two prefixed hom-carriers. The empty-source branch already displays the target endpoint. In the visible-source branch, the source endpoint equality transports the displayed continuation back to $\mathsf{append}(p, a)$, while the result equality identifies the composite payload with k. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp nonempty result target visible`

Theorem 62.73 (Functor prefix hom-carrier nonempty composite source-target cases)**.** *For prefixed hom-carriers*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), f)$$

and

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, b), \mathsf{append}(p, c), g),$$

if $\mathsf{Cont}(f, g, \mathsf{E1}(k))$*, then either the prefixed source is empty and the prefixed target is visible, or both source and target are visible:*

$$\mathsf{hsame}(\mathsf{append}(p, a), \mathsf{e}) \wedge \exists r.\ \mathsf{append}(p, c) = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{append}(p, a), \mathsf{E1}(k), \mathsf{E}$$
$$\vee$$
$$\exists s, r.\ \mathsf{append}(p, a) = \mathsf{E1}(s) \wedge \mathsf{append}(p, c) = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(s) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{E1}$$

Proof. Apply category source-target case analysis to the two prefixed hom-carriers at the displayed composite result $\mathsf{E1}(k)$. The empty-source branch gives the empty source classifier and visible target witness. The visible-source branch keeps the displayed source endpoint, identifies the result payload with k, and repacks the target endpoint and continuation witness. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp nonempty result source target cases`

Theorem 62.74 (Functor prefix hom-carrier nonempty composite source visibility)**.** *For prefixed hom-carriers*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), f)$$

and

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, b), \mathsf{append}(p, c), g),$$

if $\mathsf{Cont}(f, g, \mathsf{E1}(k))$ *and the prefixed source is not history-same to* e*, then both the source and target endpoints are visible:*

$$\exists s, r.\ \mathsf{append}(p, a) = \mathsf{E1}(s) \wedge \mathsf{append}(p, c) = \mathsf{E1}(r) \wedge \mathsf{UnaryHistory}(s) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(r) \wedge \mathsf{Cont}(\mathsf{E1}(s), \mathsf{E}$$

Proof. Apply the source-target case theorem for nonempty prefixed composites. Its empty-source branch contradicts the displayed nonempty-source classifier assumption. The remaining branch is exactly the visible source and target case, with unary witnesses for the source tail, composite payload, and target tail. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier comp nonempty result source visible`

62.2 The certificate

Definition 62.75 (Functor source specification)**.** *The source is a pair of certified categories.*

Definition 62.76 (Functor pattern specification)**.** *The pattern is structure-preserving mapping formation over object and morphism carriers.*

Definition 62.77 (Functor classifier specification)**.** *The classifier relates functors pointwise on object images and morphism images using the codomain category classifiers.*

Definition 62.78 (Functor stability certificate)**.** *The stability certificate consists of:*

1. *pointwise object-map classifier reflexivity*
2. *pointwise object-map classifier symmetry*
3. *pointwise object-map classifier transitivity*
4. *pointwise morphism-map classifier reflexivity*
5. *pointwise morphism-map classifier symmetry*
6. *pointwise morphism-map classifier transitivity*
7. *identity preservation*
8. *composition preservation*
9. *stability under source and target classifier replacement*

Definition 62.79 (Functor ledger policy)**.** *Record the two category ledgers and the preservation witnesses.*

Definition 62.80 ($\mathsf{Functor}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Functor}^{\uparrow}$*.*

Theorem 62.81 (Concrete prefix functor certificate)**.** *For every unary history p, the object assignment $a \mapsto \mathsf{append}(p, a)$ and morphism assignment $f \mapsto f$ form a concrete* $\mathsf{Functor}^{\uparrow}$ *certificate on the unary-continuation* $\mathsf{Cat}^{\uparrow}$ *carrier. The carrier field* $\mathsf{PrefixFunctorCarrier}(p)$ *is supplied by Definition 62.2; this same carrier theorem packages the prefix preservation, prefix reflection, and prefixed composition fields. Public readback is supplied by Definition 62.9.*

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixConcreteCertificate`

Proof. Use the roadmap ten-field template for the prefix endofunctor target.

1. The traditional target is the prefix endofunctor on the unary continuation category, and the BEDC source is the checked unary-continuation $\mathsf{Cat}^{\uparrow}$ carrier.
2. The carrier choice is $\mathsf{PrefixFunctorCarrier}(p)$. Apply Definition 62.2 to the unary history p to obtain this field.
3. The classifier choice is pointwise: objects are compared by the unary-continuation object classifier, and morphisms are compared by the displayed hom-carrier classifier. No quotient or external equality is added.
4. The stability fields are identity preservation, composition preservation, and source-target classifier transport. These are the carrier fields packaged by Definition 62.2.

5. The ledger records that the morphism map is the identity map on displayed morphism histories, while the object ledger stores only the fixed unary prefix p.
6. The core theorem list and exactness predicate are the displayed carrier, identity, composition, transport, and readback clauses. The standard bridge is the public comparison of the prefixed composite with the original composite, supplied by Definition 62.9. The resulting status is a concrete paper certificate for $\mathsf{Functor}^{\uparrow}$.

□

Theorem 62.82 (Semantic $\mathsf{Functor}^{\uparrow}$ prefix certificate)**.** *For every unary history p, the source, pattern, classifier, stability, and ledger data of Definitions 62.75–62.79, together with Definition 62.81, form a semantic naming certificate for the prefix endofunctor interface $\mathsf{Functor}^{\uparrow}$ over the unary-continuation $\mathsf{Cat}^{\uparrow}$. The carrier is $\mathsf{PrefixFunctorCarrier}(p)$; the object component sends a to $\mathsf{append}(p, a)$; the hom component sends each displayed morphism history to itself; the classifier is pointwise hsame on object histories and hom histories; and the ledger records the fixed prefix p together with the identity map on displayed morphism histories.*

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixSemanticNameCert`

Proof. Start from the concrete certificate of Definition 62.81. Its carrier field is $\mathsf{PrefixFunctorCarrier}(p)$, supplied by Definition 62.2, so the semantic carrier row is the same object-level package rather than a separate witness.

The classifier row is pointwise. Object images are compared by hsame after the prefix operation, and hom images are compared by hsame on the displayed hom histories because the morphism map is the identity map. The source and pattern rows are therefore exactly the source, pattern, and classifier specifications already listed for $\mathsf{Functor}^{\uparrow}$.

The stability rows are the checked preservation clauses consumed by the concrete certificate. The prefix carrier theorem Definition 62.2 packages identity preservation, composition preservation, and hsame transport, while Definition 62.9 supplies the public readback clause.

Finally, the ledger row contains no hidden quotient data. It records the unary prefix p on objects and records that morphism histories are read through the identity map. These rows are precisely the ten-field certificate data, so they assemble as the semantic naming certificate for the prefix $\mathsf{Functor}^{\uparrow}$ interface over $\mathsf{Cat}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier semanticNameCert`

Theorem 62.83 (Prefix functor two-sided identity law)**.** *For histories $p, a, b, f, left, right$, suppose p is unary, f is a category hom-carrier from a to b, $\mathsf{Cont}(\mathsf{e}, f, left)$ holds, and $\mathsf{Cont}(f, \mathsf{e}, right)$ holds. Then*

$$\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), left) \wedge \mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, b), right) \wedge \mathsf{hsame}($$

Proof. First transport the displayed hom-carrier for f across the unary prefix. Apply Definition 62.2 to the unary witness for p and to the carrier from a to b. This gives f as a hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(p, b)$.

Next apply Definition 61.102 to this prefixed carrier and to the two continuation ledgers $\mathsf{Cont}(\mathsf{e}, f, left)$ and $\mathsf{Cont}(f, \mathsf{e}, right)$.

Project the resulting conjunction. The first two projections are the prefixed carrier conclusions for $left$ and $right$; the remaining projections are $\mathsf{hsame}(left, f)$, $\mathsf{hsame}(right, f)$, and $\mathsf{hsame}(left, right)$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixHomCarrier two sided identity law`

Primitive boundary. $\mathsf{Functor}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 62.84 (Zero-axiom encoding note)**.** *Avoids funext by pointwise classifier sameness for object and morphism mappings.*

Definition 62.85 (Opposite functor certificate data)**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates, and let $F : \mathcal{C} \to \mathcal{D}$ denote a $\mathsf{Functor}^{\uparrow}$ certificate with object map F_0 and morphism map F_1. Over the opposite category data of Definition 61.327, define $F^{\mathrm{op}} : \mathcal{C}^{\mathrm{op}} \to \mathcal{D}^{\mathrm{op}}$ by*

$$F_0^{\mathrm{op}}(a) := F_0(a), \qquad F_1^{\mathrm{op}}(u) := F_1(u).$$

A displayed morphism $u : a \to b$ in $\mathcal{C}^{\mathrm{op}}$ is read as the same raw morphism $u : b \to a$ in $\mathcal{C}$; therefore $F_1^{\mathrm{op}}(u)$ is read as $F_1(u) : F_0(b) \to F_0(a)$ in $\mathcal{D}$, hence as a displayed morphism $F_0(a) \to F_0(b)$ in $\mathcal{D}^{\mathrm{op}}$.

Theorem 62.86 (Opposite functor certificate)**.** *If $\mathcal{C}$ and $\mathcal{D}$ satisfy the $\mathsf{Cat}^{\uparrow}$ certificate obligations and $F : \mathcal{C} \to \mathcal{D}$ satisfies the $\mathsf{Functor}^{\uparrow}$ certificate obligations of Definition 62.80, then the data of Definition 62.85 satisfy the $\mathsf{Functor}^{\uparrow}$ certificate obligations from $\mathcal{C}^{\mathrm{op}}$ to $\mathcal{D}^{\mathrm{op}}$.*

Proof. By Definition 61.328, the source and codomain opposite data are certified categories, so the source specification required by Definition 62.75 is present. The carrier and pattern fields are the same two maps F_0 and F_1, only with the hom-carrier endpoints read through the opposite category convention.

For hom-carrier landing, let $u : a \to b$ be displayed in $\mathcal{C}^{\mathrm{op}}$. By Definition 61.327, this is the original hom-carrier assertion $u : b \to a$ in $\mathcal{C}$. The carrier field of F sends it to a displayed morphism $F_1(u) : F_0(b) \to F_0(a)$ in $\mathcal{D}$. Unfolding the codomain opposite hom-carrier reads that same assertion as $F_1(u) : F_0(a) \to F_0(b)$ in $\mathcal{D}^{\mathrm{op}}$, which is exactly the landing field for F^{op}.

The classifier specification is inherited pointwise. Object classifiers are unchanged by the opposite construction, and the morphism classifier of $\mathcal{D}^{\mathrm{op}}$ is the morphism classifier of $\mathcal{D}$ on the same displayed morphism representatives. Thus the pointwise object-map, morphism-map, reflexivity, and transitivity clauses from Definition 62.77 and Definition 62.78 are the original clauses for F.

For identity preservation, the identity at a in $\mathcal{C}^{\mathrm{op}}$ is the identity at a in $\mathcal{C}$, and the identity at $F_0(a)$ in $\mathcal{D}^{\mathrm{op}}$ is the identity at $F_0(a)$ in $\mathcal{D}$. The identity preservation witness for F therefore gives the required $\mathcal{D}^{\mathrm{op}}$ morphism-classifier witness for F^{op}.

For composition preservation, let $u : a \to b$ and $v : b \to c$ be displayed in $\mathcal{C}^{\mathrm{op}}$, and let w be their displayed composite there. Unfolding opposite composition gives the original source ledger

$$\mathsf{Comp}_{\mathcal{C}}(v, u, w).$$

The composition preservation field of F gives the codomain classifier comparison between $F_1(w)$ and the composite selected by $\mathsf{Comp}_{\mathcal{D}}(F_1(v), F_1(u), -)$. By the definition of opposite composition in $\mathcal{D}^{\mathrm{op}}$, that is precisely the composite selected by

$$\mathsf{Comp}_{\mathcal{D}^{\mathrm{op}}}(F_1(u), F_1(v), -).$$

Since the morphism classifier is unchanged, this is the required composition preservation witness for F^{op}.

Stability under source and target classifier replacement is also inherited. A source-endpoint replacement in the opposite category is a target-endpoint replacement in the original category, and conversely; the original stability field applies with the endpoint order swapped. The ledger policy of Definition 62.79 records the same category ledgers and the same preservation witnesses, read through the two opposite-category certificates. □

Lean4 ✓ BEDC.Derived.FunctorUp.PrefixFunctorCarrier opposite comp assoc public readback

Definition 62.87 (Split monomorphism in a certified category)**.** *Let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate. A displayed morphism $f : a \to b$ is a split monomorphism when there are a displayed morphism $g : b \to a$, a source identity display $i_a : a \to a$, and a composite display $c : a \to a$ such that $\mathsf{HomCarrier}_{\mathcal{C}}(a, b, f)$, $\mathsf{HomCarrier}_{\mathcal{C}}(b, a, g)$, i_a is the identity witness at a, $\mathsf{Comp}_{\mathcal{C}}(f, g, c)$ records $g \circ_{\mathcal{C}} f$, and $c \sim_{\mathcal{C}} i_a$ in the morphism classifier at (a, a). The morphism g is a left-inverse witness for f.*

Lean4 (definition) BEDC.Derived.FunctorUp.CategorySplitMonomorphism

Theorem 62.88 (Functor preserves split monomorphisms)**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates, and let $F : \mathcal{C} \to \mathcal{D}$ be a $\mathsf{Functor}^{\uparrow}$ certificate with object map F_0 and morphism map F_1. If $f : a \to b$ is a split monomorphism in $\mathcal{C}$ with left-inverse witness $g : b \to a$, then $F_1(f) : F_0(a) \to F_0(b)$ is a split monomorphism in $\mathcal{D}$ with left-inverse witness $F_1(g) : F_0(b) \to F_0(a)$.*

Lean4 ✓ BEDC.Derived.FunctorUp.PrefixFunctorCarrier split monomorphism preserves

Proof. Unpack the source split-monomorphism data from Definition 62.87. Thus f and g are displayed hom-carriers in $\mathcal{C}$, i_a is the chosen identity display at a, and there is a composite display c with $\mathsf{Comp}_{\mathcal{C}}(f, g, c)$ and $c \sim_{\mathcal{C}} i_a$.

The hom-carrier landing field of the functor carrier sends f and g to hom-carriers $F_1(f) : F_0(a) \to F_0(b)$ and $F_1(g) : F_0(b) \to F_0(a)$ in $\mathcal{D}$. Apply the composition preservation field of Definition 62.78 to the source composite ledger $\mathsf{Comp}_{\mathcal{C}}(f, g, c)$. It supplies a codomain composite display d with

$$\mathsf{Comp}_{\mathcal{D}}(F_1(f), F_1(g), d)$$

and a morphism-classifier comparison between d and $F_1(c)$.

The morphism-classifier stability field for F transports the source comparison $c \sim_{\mathcal{C}} i_a$ to a codomain comparison $F_1(c) \sim_{\mathcal{D}} F_1(i_a)$. Identity preservation for F identifies $F_1(i_a)$ with the identity display $i_{F_0(a)}$ of $\mathcal{D}$. Symmetry and transitivity of the codomain morphism classifier, supplied by the $\mathsf{Cat}^{\uparrow}$ stability laws, compose these comparisons to obtain $d \sim_{\mathcal{D}} i_{F_0(a)}$.

The displayed morphism $F_1(g)$, the composite display d, and the classifier comparison with $i_{F_0(a)}$ form the split-monomorphism witness for $F_1(f)$ in $\mathcal{D}$. □

Definition 62.89 (Split epimorphism in a certified category)**.** *Let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate. A displayed morphism $f : a \to b$ is a split epimorphism when there are a displayed morphism $g : b \to a$, a target identity display $i_b : b \to b$, and a composite display $c : b \to b$ such that $\mathsf{HomCarrier}_{\mathcal{C}}(a, b, f)$, $\mathsf{HomCarrier}_{\mathcal{C}}(b, a, g)$, i_b is the identity witness at b, $\mathsf{Comp}_{\mathcal{C}}(g, f, c)$ records $f \circ_{\mathcal{C}} g$, and $c \sim_{\mathcal{C}} i_b$ in the morphism classifier at (b, b). The morphism g is a right-inverse witness for f.*

Theorem 62.90 (Functor preserves split epimorphisms)**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates, and let $F : \mathcal{C} \to \mathcal{D}$ be a $\mathsf{Functor}^{\uparrow}$ certificate with object map F_0 and morphism map F_1. If $f : a \to b$ is a split epimorphism in $\mathcal{C}$ with right-inverse witness $g : b \to a$, then $F_1(f) : F_0(a) \to F_0(b)$ is a split epimorphism in $\mathcal{D}$ with right-inverse witness $F_1(g) : F_0(b) \to F_0(a)$.*

Proof. Unpack the source split-epimorphism data from Definition 62.89. Thus f and g are displayed hom-carriers in $\mathcal{C}$, i_b is the chosen identity display at b, and there is a composite display c with $\mathsf{Comp}_{\mathcal{C}}(g, f, c)$ and $c \sim_{\mathcal{C}} i_b$.

The hom-carrier landing field of the functor carrier sends f and g to hom-carriers $F_1(f) : F_0(a) \to F_0(b)$ and $F_1(g) : F_0(b) \to F_0(a)$ in $\mathcal{D}$. Apply the composition preservation field of

Definition 62.78 to the source composite ledger $\mathsf{Comp}_{\mathcal{C}}(g, f, c)$. It supplies a codomain composite display d with

$$\mathsf{Comp}_{\mathcal{D}}(F_1(g), F_1(f), d)$$

and a morphism-classifier comparison between d and $F_1(c)$.

The morphism-classifier stability field for F transports the source comparison $c \sim_{\mathcal{C}} i_b$ to a codomain comparison $F_1(c) \sim_{\mathcal{D}} F_1(i_b)$. Identity preservation for F identifies $F_1(i_b)$ with the identity display $i_{F_0(b)}$ of $\mathcal{D}$. Symmetry and transitivity of the codomain morphism classifier, supplied by the $\mathsf{Cat}^{\uparrow}$ stability laws, compose these comparisons to obtain $d \sim_{\mathcal{D}} i_{F_0(b)}$.

The displayed morphism $F_1(g)$, the composite display d, the codomain target identity display $i_{F_0(b)}$, and the classifier comparison with $i_{F_0(b)}$ form the split-epimorphism witness for $F_1(f)$ in $\mathcal{D}$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier split epimorphism preserves`

Definition 62.91 (Split isomorphism witness pair)**.** *Let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate. A displayed morphism $f : a \to b$ carries a split isomorphism witness pair when it carries a split-monomorphism witness in the sense of Definition 62.87 with left-inverse witness $g_L : b \to a$ and a split-epimorphism witness in the sense of Definition 62.89 with right-inverse witness $g_R : b \to a$. Thus the package stores the two oriented composite certificates*

$$g_L \circ_{\mathcal{C}} f \sim_{\mathcal{C}} \mathsf{id}_a, \qquad f \circ_{\mathcal{C}} g_R \sim_{\mathcal{C}} \mathsf{id}_b.$$

The two inverse-side witnesses are part of the data; no equality between g_L and g_R is required by this package.

Theorem 62.92 (Functor preserves split isomorphism witness pairs)**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates, and let $F : \mathcal{C} \to \mathcal{D}$ be a $\mathsf{Functor}^{\uparrow}$ certificate with object map F_0 and morphism map F_1. If $f : a \to b$ carries a split isomorphism witness pair in $\mathcal{C}$ with left-inverse witness $g_L : b \to a$ and right-inverse witness $g_R : b \to a$, then $F_1(f) : F_0(a) \to F_0(b)$ carries a split isomorphism witness pair in $\mathcal{D}$ whose left-inverse witness is $F_1(g_L)$ and whose right-inverse witness is $F_1(g_R)$.*

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier split iso witness pair public readback`

Proof. Unpack the witness pair by Definition 62.91. Its left-oriented field is a split-monomorphism witness for f with left-inverse witness g_L, and its right-oriented field is a split-epimorphism witness for f with right-inverse witness g_R.

Apply Definition 62.88 to the left-oriented field. This gives a split-monomorphism witness in $\mathcal{D}$ for $F_1(f) : F_0(a) \to F_0(b)$, with left-inverse witness $F_1(g_L) : F_0(b) \to F_0(a)$. Its codomain composite certificate is classified with the identity display at $F_0(a)$.

Apply Definition 62.90 to the right-oriented field. This gives a split-epimorphism witness in $\mathcal{D}$ for the same forward morphism $F_1(f) : F_0(a) \to F_0(b)$, with right-inverse witness $F_1(g_R) : F_0(b) \to F_0(a)$. Its codomain composite certificate is classified with the identity display at $F_0(b)$.

The two transported fields have the same displayed forward morphism and the same image endpoints. Packing them by Definition 62.91 gives the required split isomorphism witness pair in $\mathcal{D}$. □

Definition 62.93 (Identity functor certificate data)**.** *Let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate with object carrier $\mathcal{O}_{\mathcal{C}}$, object classifier $\sim_{\mathcal{O}}$, hom-carrier $\mathcal{H}_{\mathcal{C}}(a, b, u)$, endpoint-indexed morphism classifier $\sim_{\mathcal{H}_{\mathcal{C}}(a,b)}$,*

identity witnesses id_a*, and composition relation* $\mathsf{Comp}_{\mathcal{C}}(u, v, w)$*. The identity functor data* $1_{\mathcal{C}} : \mathcal{C} \to \mathcal{C}$ *are*

$$(1_{\mathcal{C}})_0(a) := a, \qquad (1_{\mathcal{C}})_1(u) := u.$$

The functor-indexed hom-carrier is the original endpoint-indexed hom-carrier:

$$\mathsf{FunctorHomCarrier}_{1_{\mathcal{C}}}(a, b, u) := \mathcal{H}_{\mathcal{C}}(a, b, u).$$

Object and morphism classifiers are read from the same category certificate at the same endpoints.

Theorem 62.94 (Identity functor name certificate)**.** *If* $\mathcal{C}$ *satisfies the* $\mathsf{Cat}^{\uparrow}$ *certificate obligations of Definition 61.203, then the data of Definition 62.93 satisfy the* $\mathsf{Functor}^{\uparrow}$ *certificate obligations of Definition 62.80. Endpoint-by-endpoint, for every source pair* a, b *and morphism candidate* u*,*

$$\mathsf{FunctorHomCarrier}_{1_{\mathcal{C}}}(a, b, u) \iff \mathcal{H}_{\mathcal{C}}(a, b, u).$$

For every object a*,*

$$(1_{\mathcal{C}})_1(\mathsf{id}_a) \sim_{\mathcal{H}_{\mathcal{C}}(a,a)} \mathsf{id}_{(1_{\mathcal{C}})_0(a)}.$$

For every displayed composable pair $u : a \to b$ *and* $v : b \to c$ *with* $\mathsf{Comp}_{\mathcal{C}}(u, v, w)$ *recording* $v \circ_{\mathcal{C}} u$*,*

$$(1_{\mathcal{C}})_1(w) \sim_{\mathcal{H}_{\mathcal{C}}(a,c)} (1_{\mathcal{C}})_1(v) \circ_{\mathcal{C}} (1_{\mathcal{C}})_1(u).$$

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorPrefixIdentityCarrier semanticNameCert`

Proof. Unpack the identity functor data. The source row of Definition 62.75 is the pair $(\mathcal{C}, \mathcal{C})$, which is licensed by the displayed $\mathsf{Cat}^{\uparrow}$ certificate. The pattern row of Definition 62.76 is the pair of identity maps on objects and displayed morphisms.

The carrier landing clause is definitional. A source hom-carrier $\mathcal{H}_{\mathcal{C}}(a, b, u)$ is sent to $\mathcal{H}_{\mathcal{C}}((1_{\mathcal{C}})_0(a), (1_{\mathcal{C}})_0(b), (1_{\mathcal{C}})_1($ and this unfolds to the same proposition $\mathcal{H}_{\mathcal{C}}(a, b, u)$. This proves the displayed biconditional and shows that the classifier specification of Definition 62.77 is inherited pointwise from the category classifier.

For identity preservation, the source identity at a and the codomain identity at $(1_{\mathcal{C}})_0(a) = a$ are the same witness id_a. Morphism-classifier reflexivity from the category stability fields in Definition 61.201 gives the classifier comparison of id_a with itself.

For composition preservation, take a source composition ledger $\mathsf{Comp}_{\mathcal{C}}(u, v, w)$. Since the morphism map is the identity, the image of the source composite is w. The codomain composite of the image pair is recorded by the same ledger, now read in the codomain copy of $\mathcal{C}$. Morphism-classifier reflexivity at the endpoint pair (a, c) therefore classifies w with that codomain composite.

The remaining stability rows in Definition 62.78 are pointwise classifier laws and endpoint-replacement laws. Object classifier reflexivity, symmetry, and transitivity are the object classifier laws of $\mathcal{C}$; morphism classifier reflexivity, symmetry, and transitivity are the endpoint-indexed morphism classifier laws of $\mathcal{C}$. Source and target replacement for displayed morphisms is exactly the category endpoint transport field, because both functor maps are identities.

The ledger row of Definition 62.79 records the same category ledger on both sides, the same identity displays, and the same composition trees. Thus all carrier, source, pattern, classifier, stability, and ledger rows listed in Definition 62.80 are present for $1_{\mathcal{C}} : \mathcal{C} \to \mathcal{C}$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.IdentityFunctorCarrier semanticNameCert`

Theorem 62.95 (Double opposite functor certificate data identity)**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates satisfying the category certificate obligations, and let $F : \mathcal{C} \to \mathcal{D}$ be a $\mathsf{Functor}^{\uparrow}$ certificate satisfying the obligations of Definition 62.80. Write F_0 for its object map and F_1 for its morphism map. Let*

$$F^{\mathrm{opop}} = (F^{\mathrm{op}})^{\mathrm{op}}$$

be obtained by applying Definition 62.85 twice, with source and target categories identified through the double-opposite category data identity of Definition 61.330. Then $F^{\mathrm{opop}} : \mathcal{C}^{\mathrm{opop}} \to \mathcal{D}^{\mathrm{opop}}$ satisfies the $\mathsf{Functor}^{\uparrow}$ certificate obligations, and its functor data are componentwise identical to the data of F:

$$(F^{\mathrm{opop}})_0(a) = F_0(a), \qquad (F^{\mathrm{opop}})_1(u) = F_1(u).$$

The pointwise object-map classifier, pointwise morphism-map classifier, identity-preservation row, composition-preservation row, source-replacement stability row, target-replacement stability row, and ledger row of F^{opop} are the corresponding rows of F under the same double-opposite source and target identification.

Proof. Apply Definition 61.328 to $\mathcal{C}$ and $\mathcal{D}$. This supplies certified categories $\mathcal{C}^{\mathrm{op}}$ and $\mathcal{D}^{\mathrm{op}}$. Then Definition 62.86 supplies a certified functor

$$F^{\mathrm{op}} : \mathcal{C}^{\mathrm{op}} \to \mathcal{D}^{\mathrm{op}}.$$

Applying the same category and functor results once more supplies a certified functor

$$F^{\mathrm{opop}} : \mathcal{C}^{\mathrm{opop}} \to \mathcal{D}^{\mathrm{opop}}.$$

By Definition 61.330, the source and target category data of $\mathcal{C}^{\mathrm{opop}}$ and $\mathcal{D}^{\mathrm{opop}}$ are the source and target category data of $\mathcal{C}$ and $\mathcal{D}$, with hom endpoints swapped twice and therefore restored.

It remains to compare the functor rows. One unfolding of Definition 62.85 gives

$$F_0^{\mathrm{op}}(a) = F_0(a), \qquad F_1^{\mathrm{op}}(u) = F_1(u).$$

A second unfolding gives

$$(F^{\mathrm{opop}})_0(a) = F_0^{\mathrm{op}}(a) = F_0(a), \qquad (F^{\mathrm{opop}})_1(u) = F_1^{\mathrm{op}}(u) = F_1(u).$$

Thus the object map and morphism map are unchanged as raw data.

The classifier rows are also unchanged. The opposite category data of Definition 61.327 leave object classifiers and morphism classifiers fixed; Definition 61.330 identifies the double-opposite classifiers with the classifiers of $\mathcal{D}$. Since Definition 62.85 does not alter F_0 or F_1, the pointwise object-map and morphism-map classifier clauses for F^{opop} are exactly the corresponding clauses for F.

For identity preservation, the identity at a in $\mathcal{C}^{\mathrm{opop}}$ is the identity at a in $\mathcal{C}$, and the identity at $F_0(a)$ in $\mathcal{D}^{\mathrm{opop}}$ is the identity at $F_0(a)$ in $\mathcal{D}$. Hence the identity-preservation witness of F^{opop} is the identity-preservation witness of F read through the double-opposite category identification.

For composition preservation, let $u : a \to b$ and $v : b \to c$ be displayed source morphisms with composite ledger $\mathsf{Comp}_{\mathcal{C}}(u, v, w)$. In the first opposite construction the source ledger is read as $\mathsf{Comp}_{\mathcal{C}}(v, u, w)$, and in the second opposite construction it is read back as $\mathsf{Comp}_{\mathcal{C}}(u, v, w)$. The same cancellation occurs in the target category:

$$\mathsf{Comp}_{\mathcal{D}^{\mathrm{opop}}}(F_1(u), F_1(v), -) = \mathsf{Comp}_{\mathcal{D}}(F_1(u), F_1(v), -).$$

Therefore the composition-preservation row for F^{opop} is the original composition-preservation row for F.

Finally, source-endpoint replacement and target-endpoint replacement are exchanged by one opposite reading and exchanged back by the second. The remaining stability fields in Definition 62.78 and the ledger fields in Definition 62.79 use the same category ledgers and the same preservation witnesses, with the double-opposite category data identified with the starting category data. Hence every functor certificate row of F^{opop} is componentwise identical to the corresponding row of F. □

Theorem 62.96 (Composition of split monomorphisms)**.** *Let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate satisfying the obligations of Definition 61.203. Let $f : a \to b$ and $g : b \to c$ be displayed morphisms in $\mathcal{C}$. Suppose f is a split monomorphism with left-inverse witness $f' : b \to a$, and suppose g is a split monomorphism with left-inverse witness $g' : c \to b$, in the sense of Definition 62.87. If $u : a \to c$ is a displayed composite with $\mathsf{Comp}_{\mathcal{C}}(f, g, u)$ and $\ell : c \to a$ is a displayed composite with $\mathsf{Comp}_{\mathcal{C}}(g', f', \ell)$, then u is a split monomorphism with left-inverse witness ℓ.*

Proof. Unpack the two split-monomorphism witnesses. For f this gives displayed hom-carriers for f and f', an identity display $i_a : a \to a$, and a composite display $s_f : a \to a$ with

$$\mathsf{Comp}_{\mathcal{C}}(f, f', s_f) \qquad \text{and} \qquad s_f \sim_{\mathcal{C}} i_a.$$

For g it gives displayed hom-carriers for g and g', an identity display $i_b : b \to b$, and a composite display $s_g : b \to b$ with

$$\mathsf{Comp}_{\mathcal{C}}(g, g', s_g) \qquad \text{and} \qquad s_g \sim_{\mathcal{C}} i_b.$$

Composition closure in the $\mathsf{Cat}^{\uparrow}$ stability fields makes the displayed composites u and ℓ hom-carriers over $a \to c$ and $c \to a$.

Let $R : a \to a$ be the composite display selected for u followed by ℓ, so $\mathsf{Comp}_{\mathcal{C}}(u, \ell, R)$. It remains to classify R with i_a. The four displayed factors form the chain

$$a \xrightarrow{f} b \xrightarrow{g} c \xrightarrow{g'} b \xrightarrow{f'} a.$$

The associativity row of Definition 61.201, applied twice, compares the outside bracketing $(f' \circ_{\mathcal{C}} g') \circ_{\mathcal{C}} (g \circ_{\mathcal{C}} f)$ with the bracketing $f' \circ_{\mathcal{C}} ((g' \circ_{\mathcal{C}} g) \circ_{\mathcal{C}} f)$. Thus R is classified with the display obtained by first using the inner composite s_g, then composing with f, and finally composing with f'.

Since $s_g \sim_{\mathcal{C}} i_b$, composition congruence replaces $s_g \circ_{\mathcal{C}} f$ by $i_b \circ_{\mathcal{C}} f$. The target-identity law classifies this composite with f. A second use of composition congruence, now after postcomposition by f', compares the resulting display with $s_f = f' \circ_{\mathcal{C}} f$. Transitivity of the morphism classifier and the stored comparison $s_f \sim_{\mathcal{C}} i_a$ give $R \sim_{\mathcal{C}} i_a$.

The hom-carriers for u and ℓ, the identity display i_a, the composite ledger $\mathsf{Comp}_{\mathcal{C}}(u, \ell, R)$, and the classifier comparison $R \sim_{\mathcal{C}} i_a$ are exactly the data required by Definition 62.87. Hence u is a split monomorphism with left-inverse witness ℓ. □

Lean4 ✓ `BEDC.Derived.FunctorUp.CategorySplitMonomorphism composition closed`

Theorem 62.97 (Split isomorphism inverse witnesses coincide)**.** *Let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate satisfying the obligations of Definition 61.203. Let $f : a \to b$ carry a split isomorphism witness pair in the sense of Definition 62.91, with left-inverse witness $g_L : b \to a$ and right-inverse witness $g_R : b \to a$. Then the two inverse-side witnesses are classified together in the hom carrier from b to a:*

$$g_L \sim_{\mathcal{C}} g_R.$$

Proof. Unpack the split-isomorphism witness pair. The left-oriented field supplies a displayed composite $c_a : a \to a$ for $g_L \circ_{\mathcal{C}} f$ and a classifier comparison

$$c_a \sim_{\mathcal{C}} \mathsf{id}_a.$$

The right-oriented field supplies a displayed composite $c_b : b \to b$ for $f \circ_{\mathcal{C}} g_R$ and a classifier comparison

$$c_b \sim_{\mathcal{C}} \mathsf{id}_b.$$

Choose the displayed composites needed to compare both inverse witnesses through the common three-factor string

$$b \xrightarrow{g_R} a \xrightarrow{f} b \xrightarrow{g_L} a.$$

Associativity for the $\mathsf{Cat}^{\uparrow}$ composition relation classifies the right-associated composite $g_L \circ_{\mathcal{C}} (f \circ_{\mathcal{C}} g_R)$ with the left-associated composite $(g_L \circ_{\mathcal{C}} f) \circ_{\mathcal{C}} g_R$, expressed in the paper's composition orientation as the two bracketings of g_R, f, g_L.

On the right-associated side, replace the displayed composite $f \circ_{\mathcal{C}} g_R$ by the target identity id_b using the right-inverse comparison and classifier-respecting composition with the fixed factor g_L. The right-unit law then classifies the resulting composite with g_L.

On the left-associated side, replace the displayed composite $g_L \circ_{\mathcal{C}} f$ by the source identity id_a using the left-inverse comparison and classifier-respecting composition with the fixed factor g_R. The left-unit law then classifies the resulting composite with g_R.

The two reductions start from associativity-related bracketings of the same three displayed factors. Transitivity of the morphism classifier therefore compares g_L with g_R; symmetry orients the comparison as displayed. □

Theorem 62.98 (Functor hom-carrier codomain evaluation)**.** *Let C and E be certified categories, and let $H : C \to E$ be a certified functor with object map H_0. Write $\mathsf{FunctorHomCarrier}_H(x, y)$ for the predicate on codomain morphism candidates m abbreviated by*

$$\mathsf{FunctorHomCarrier}_H(x, y, m) \equiv \mathsf{HomCarrier}_E(H_0(x), H_0(y), m).$$

Then for every pair of source objects x, y and every codomain morphism candidate m, the functor-indexed hom-carrier classifier at x, y evaluates to the codomain category hom-carrier classifier at the image endpoints:

$$\mathsf{FunctorHomCarrier}_H(x, y, m) \iff \mathsf{HomCarrier}_E(H_0(x), H_0(y), m).$$

Proof. The functor carrier of Definition 62.1 supplies the object map H_0. The category carrier of Definition 61.1 supplies, in the codomain category E, a hom-carrier classifier for each ordered pair of codomain objects. Applying that category classifier to the image pair $H_0(x), H_0(y)$ is exactly the displayed abbreviation for $\mathsf{FunctorHomCarrier}_H(x, y, -)$. The pointwise classifier discipline in Definition 62.77 and Definition 62.84 reads classifier equality at the morphism argument m, so unfolding the abbreviation gives the stated biconditional. □

Theorem 62.99 (Functor composite preservation witnesses)**.** *Let C, D, E be certified categories. Let $F : C \to D$ and $G : D \to E$ be certified $\mathsf{Functor}^{\uparrow}$ carriers with object maps F_0, G_0 and morphism maps F_1, G_1. Write H for the composite pair with*

$$H_0(x) = G_0(F_0(x)), \qquad H_1(u) = G_1(F_1(u)).$$

Then H has identity and composition preservation witnesses under the morphism classifier of E: for every object x of C, $H_1(\mathsf{id}_x)$ is classified with $\mathsf{id}_{H_0(x)}$, and for every composable pair $u : x \to y$, $v : y \to z$ in C, $H_1(v \circ_C u)$ is classified with $H_1(v) \circ_E H_1(u)$.

Proof. The functor carrier of Definition 62.1 supplies the object and morphism maps for F and G. The stability certificate in Definition 62.78 supplies identity preservation, composition preservation, and classifier-replacement stability, all read through the codomain morphism classifier. By Definition 62.98, the hom-carrier classifier for the composite pair H is the hom-carrier classifier of E at the image endpoints $H_0(x)$ and $H_0(y)$.

Fix an object x of C. The identity field of F classifies $F_1(\mathsf{id}_x)$ with $\mathsf{id}_{F_0(x)}$ in D. The classifier-replacement stability field of G transports that comparison through G_1, giving a classifier witness in E between $G_1(F_1(\mathsf{id}_x))$ and $G_1(\mathsf{id}_{F_0(x)})$. The identity field of G, applied at $F_0(x)$, classifies $G_1(\mathsf{id}_{F_0(x)})$ with $\mathsf{id}_{G_0(F_0(x))}$. Morphism-classifier transitivity from the category stability certificate in Definition 61.201 composes the two comparisons, giving the identity witness for H.

Fix composable morphisms $u : x \to y$ and $v : y \to z$ in C. The composition field of F classifies $F_1(v \circ_C u)$ with $F_1(v) \circ_D F_1(u)$ in D. The classifier-replacement stability field of G transports this comparison through G_1, giving a classifier witness in E between $G_1(F_1(v \circ_C u))$ and $G_1(F_1(v) \circ_D F_1(u))$. The composition field of G, applied to the composable pair $F_1(u), F_1(v)$, classifies $G_1(F_1(v) \circ_D F_1(u))$ with $G_1(F_1(v)) \circ_E G_1(F_1(u))$. Transitivity in E gives the composition witness for H, and Definition 62.79 records these two preservation ledgers as the composite functor ledger data. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorCompositePreservationWitnesses`

Theorem 62.100 (Functor composition carries the hom-carrier classifier)**.** *Let C, D, E be certified categories. Let $F : C \to D$ and $G : D \to E$ be certified* $\mathsf{Functor}^{\uparrow}$ *carriers with object maps F_0, G_0 and morphism maps F_1, G_1. Let $H = G \circ F$ be the composite carrier whose object and morphism maps are*

$$H_0(x) = G_0(F_0(x)), \qquad H_1(u) = G_1(F_1(u)).$$

For every pair of source objects x, y and every codomain morphism candidate m, the hom-carrier classifier carried by H is pointwise the codomain hom-carrier classifier at the composed image endpoints:

$$\mathsf{FunctorHomCarrier}_{G\circ F}(x, y, m) \iff \mathsf{HomCarrier}_E(G_0(F_0(x)), G_0(F_0(y)), m).$$

Proof. The carrier fields in Definition 62.1 give the maps F_0, F_1, G_0, G_1, and Definition 62.99 supplies the identity and composition preservation witnesses for the composite pair H under the morphism classifier of E. Thus H is read as the certified functor $C \to E$ with object map H_0.

Apply Definition 62.98 to this functor H. It gives

$$\mathsf{FunctorHomCarrier}_H(x, y, m) \iff \mathsf{HomCarrier}_E(H_0(x), H_0(y), m).$$

By the displayed definition of the composite object map, the right-hand side is exactly $\mathsf{HomCarrier}_E(G_0(F_0(x)), G_0(F$
The classifier discipline of Definition 62.77 and the pointwise reading in Definition 62.84 identify classifier sameness by this morphism-argument equivalence, so the composite functor carries precisely the composed hom-carrier classifier. □

Proposition 62.101 (Functor composition identity needs morphism-sameness respect)**.** *Let C, D, E be finite certified categories, and let $F : C \to D$ and $G : D \to E$ be carrier pairs with object maps F_0, G_0 and morphism maps F_1, G_1. Write $m \sim_D n$ and $r \sim_E s$ for the endpoint-indexed morphism classifiers, and suppose the E-classifier is symmetric and transitive. Assume the raw identity and raw composition preservation ledgers for F and G are present in the sense of Definition 62.1. Fix an object x of C and set $H = G \circ F$ with $H_0(x) = G_0(F_0(x))$ and $H_1(u) = G_1(F_1(u))$. If*

$$F_1(\mathsf{id}_x) \sim_D \mathsf{id}_{F_0(x)}$$

and

$$G_1(\mathsf{id}_{F_0(x)}) \sim_E \mathsf{id}_{G_0(F_0(x))}$$

but

$$\neg\big(G_1(F_1(\mathsf{id}_x)) \sim_E G_1(\mathsf{id}_{F_0(x)})\big),$$

then H has no identity preservation witness at x:

$$\neg\big(H_1(\mathsf{id}_x) \sim_E \mathsf{id}_{H_0(x)}\big).$$

Proof. Assume that the displayed composite identity witness exists. Unfolding the composite carrier gives

$$G_1(F_1(\mathsf{id}_x)) \sim_E \mathsf{id}_{G_0(F_0(x))}.$$

The raw identity ledger for G gives

$$G_1(\mathsf{id}_{F_0(x)}) \sim_E \mathsf{id}_{G_0(F_0(x))}.$$

Symmetry reverses the second comparison, and transitivity composes it with the first. Hence

$$G_1(F_1(\mathsf{id}_x)) \sim_E G_1(\mathsf{id}_{F_0(x)}),$$

contradicting the displayed non-respect premise. Thus the composite identity witness cannot exist.

The comparison supplied by F is only a D-morphism classifier witness between $F_1(\mathsf{id}_x)$ and $\mathsf{id}_{F_0(x)}$. To use the raw identity ledger for G, that witness must be transported through G_1. This is exactly the classifier-replacement stability field in Definition 62.78 and the step used in Definition 62.99. Raw composition preservation does not supply this transport, so it cannot restore identity preservation for $G \circ F$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorComposition identity sameness respect required`

Theorem 62.102 (Raw functor hom-carrier landing obstruction)**.** *There are finite two-object certified categories C and D, together with an object map F_0, a raw morphism map F_1, and strict raw identity and composition preservation ledgers, such that a displayed source hom is not carried to the endpoint-indexed codomain hom-carrier required by* $\mathsf{Functor}^{\uparrow}$*. Take object and morphism classifiers in both categories to be literal equality. Let C have objects $0, 1$, raw morphisms $\mathsf{id}_0, \mathsf{id}_1, a$, and hom-carrier table $\mathsf{HomCarrier}_C(0, 0, \mathsf{id}_0)$, $\mathsf{HomCarrier}_C(1, 1, \mathsf{id}_1)$, and $\mathsf{HomCarrier}_C(0, 1, a)$, with no other hom-carrier witnesses. Its legal composites are $\mathsf{id}_0 \circ_C \mathsf{id}_0 = \mathsf{id}_0$, $\mathsf{id}_1 \circ_C \mathsf{id}_1 = \mathsf{id}_1$, $a \circ_C \mathsf{id}_0 = a$, and $\mathsf{id}_1 \circ_C a = a$. Let D have objects $0, 1$, raw morphisms $\mathsf{id}_0, \mathsf{id}_1, b$, and hom-carrier table $\mathsf{HomCarrier}_D(0, 0, \mathsf{id}_0)$, $\mathsf{HomCarrier}_D(1, 1, \mathsf{id}_1)$, and $\mathsf{HomCarrier}_D(1, 0, b)$, with no other hom-carrier witnesses. Its legal composites are $\mathsf{id}_0 \circ_D \mathsf{id}_0 = \mathsf{id}_0$, $\mathsf{id}_1 \circ_D \mathsf{id}_1 = \mathsf{id}_1$, $b \circ_D \mathsf{id}_1 = b$, and $\mathsf{id}_0 \circ_D b = b$. Define $F_0(0) = 0$, $F_0(1) = 1$, $F_1(\mathsf{id}_0) = \mathsf{id}_0$, $F_1(\mathsf{id}_1) = \mathsf{id}_1$, and $F_1(a) = b$. Equip the raw morphism carrier of D with an auxiliary total raw operation $\star_D$ whose values on the image pairs of source composites are $\mathsf{id}_0 \star_D \mathsf{id}_0 = \mathsf{id}_0$, $\mathsf{id}_1 \star_D \mathsf{id}_1 = \mathsf{id}_1$, $b \star_D \mathsf{id}_0 = b$, and $\mathsf{id}_1 \star_D b = b$. Then the object-map field, raw morphism-map field, identity preservation field, and raw composition preservation field are all satisfied. Nevertheless $\mathsf{HomCarrier}_C(0, 1, a)$ and $\neg\,\mathsf{HomCarrier}_D(F_0(0), F_0(1), F_1(a))$. Thus endpoint-indexed hom-carrier landing is not entailed by those raw fields.*

Proof. The displayed hom-carrier and composite tables make C and D certified finite categories in the sense of Definition 61.1. In each category every legal composite contains only identity morphisms except for the single displayed nonidentity arrow, so the left and right identity laws hold strictly and every legal threefold composite reduces to the same displayed morphism on both

associations. This supplies the category stability fields of Definition 61.201. The map F_0 sends the two source objects to objects of D, and F_1 sends each raw source morphism to a raw morphism of D, giving the two carrier maps named in Definition 62.1. Identity preservation is strict because $F_1(\mathsf{id}_0) = \mathsf{id}_0 = \mathsf{id}_{F_0(0)}$ and $F_1(\mathsf{id}_1) = \mathsf{id}_1 = \mathsf{id}_{F_0(1)}$. For raw composition preservation, the only composable pairs in C are the four listed pairs. Applying F_1 to their composites gives respectively id_0, id_1, b, and b. The displayed values of $\star_D$ give exactly the same four results, so the raw composition preservation field from Definition 62.78 is satisfied on all source composites. The source hom assertion $\mathsf{HomCarrier}_C(0, 1, a)$ is one of the constructors in the table for C. On the codomain side, $F_0(0) = 0$, $F_0(1) = 1$, and $F_1(a) = b$, so the required endpoint-indexed landing assertion is $\mathsf{HomCarrier}_D(0, 1, b)$. The table for D has no such generator; by the closed-generation discipline of chapter 20 and the indexed hom-carrier reading in Definition 61.200, no hidden witness is available. Hence $\neg\,\mathsf{HomCarrier}_D(F_0(0), F_0(1), F_1(a))$. By Definition 62.98, a certified $\mathsf{Functor}^{\uparrow}$ carrier reads the source-indexed functor hom predicate as the codomain hom-carrier at the image endpoints. The finite table above satisfies the raw preservation data while failing exactly that predicate at $(0, 1, a)$, so the endpoint-indexed hom-carrier landing field is a separate obligation. □

Lean4 ✓ `BEDC.Derived.FunctorUp.RawFunctorHomCarrier landing obstruction`

Theorem 62.103 (Raw functor source hom target-one morphism cases)**.** *For histories s, m, any raw source hom whose target endpoint is the one-object code has exactly the identity-one or forward-arrow shape:*

$$\mathsf{RawFunctorSourceHom}(s, \mathsf{E1}(\mathsf{e}), m) \Longrightarrow (\mathsf{hsame}(s, \mathsf{E1}(\mathsf{e})) \wedge \mathsf{hsame}(m, \mathsf{E1}(\mathsf{e}))) \vee (\mathsf{hsame}(s, \mathsf{e}) \wedge \mathsf{hsame}(m, \mathsf{E1}(\mathsf{E1}(\mathsf{e})))).$$

Proof. Invert the closed-generated source hom relation at the displayed target endpoint. The zero-identity constructor has empty target and is eliminated. The identity-one constructor gives the left disjunct by reflexivity, while the forward-arrow constructor gives the right disjunct by reflexivity on the empty source and double-one morphism code. □

Lean4 ✓ `BEDC.Derived.FunctorUp.RawFunctorSourceHom target one morphism cases`

Theorem 62.104 (Raw functor target hom source-one morphism cases)**.** *For histories t, m, any raw target hom whose source endpoint is the one-object code has exactly the identity-one or reverse-arrow shape:*

$$\mathsf{RawFunctorTargetHom}(\mathsf{E1}(\mathsf{e}), t, m) \Longrightarrow (\mathsf{hsame}(t, \mathsf{E1}(\mathsf{e})) \wedge \mathsf{hsame}(m, \mathsf{E1}(\mathsf{e}))) \vee (\mathsf{hsame}(t, \mathsf{e}) \wedge \mathsf{hsame}(m, \mathsf{E1}(\mathsf{E1}(\mathsf{e})))).$$

Proof. Invert the closed-generated target hom relation at the displayed source endpoint. The zero-identity constructor has empty source and is eliminated. The identity-one constructor gives the left disjunct by reflexivity, while the reverse-arrow constructor gives the right disjunct by reflexivity on the empty target and double-one morphism code. □

Lean4 ✓ `BEDC.Derived.FunctorUp.RawFunctorTargetHom source one morphism cases`

Theorem 62.105 (Raw functor source hom empty-morphism endpoint readback)**.** *For histories s, t, any raw source hom witness whose displayed morphism is empty reads back empty endpoints:*

$$\mathsf{RawFunctorSourceHom}(s, t, \mathsf{e}) \Longrightarrow \mathsf{hsame}(s, \mathsf{e}) \wedge \mathsf{hsame}(t, \mathsf{e}).$$

Proof. The source hom relation is closed-generated by the two identity constructors and the forward-arrow constructor. Constructor inversion at the concrete empty morphism eliminates the non-empty source-hom cases. The surviving empty identity case exposes empty source and target endpoints, and reflexivity supplies both history classifiers. □

Lean4 ✓ `BEDC.Derived.FunctorUp.RawFunctorSourceHom empty morphism endpoint readback`

Theorem 62.106 (Raw functor source hom forward-arrow endpoint readback)**.** *For histories s, t, any raw source hom witness whose displayed morphism is the forward-arrow code reads back the source and target endpoints:*

$$\mathsf{RawFunctorSourceHom}(s, t, \mathsf{E1}(\mathsf{E1}(\mathsf{e}))) \Longrightarrow \mathsf{hsame}(s, \mathsf{e}) \wedge \mathsf{hsame}(t, \mathsf{E1}(\mathsf{e})).$$

Proof. The source hom relation is closed-generated by the two identity constructors and the forward-arrow constructor. Constructor inversion at the concrete forward-arrow morphism eliminates the two identity cases. The remaining forward-arrow case exposes the endpoints e and $\mathsf{E1}(\mathsf{e})$, and reflexivity supplies the two history classifiers. □

Lean4 ✓ `BEDC.Derived.FunctorUp.RawFunctorSourceHom forward arrow endpoint readback`

Theorem 62.107 (Raw functor target hom reverse-arrow endpoint readback)**.** *For histories s, t, any raw target hom witness whose displayed morphism is the reverse-arrow code reads back the source and target endpoints:*

$$\mathsf{RawFunctorTargetHom}(s, t, \mathsf{E1}(\mathsf{E1}(\mathsf{e}))) \Longrightarrow \mathsf{hsame}(s, \mathsf{E1}(\mathsf{e})) \wedge \mathsf{hsame}(t, \mathsf{e}).$$

Proof. The target hom relation is closed-generated by the two identity constructors and the reverse-arrow constructor. Constructor inversion at the concrete reverse-arrow morphism eliminates the two identity cases. The surviving reverse-arrow case exposes the endpoints $\mathsf{E1}(\mathsf{e})$ and e, and reflexivity supplies the two history classifiers. □

Lean4 ✓ `BEDC.Derived.FunctorUp.RawFunctorTargetHom reverse arrow endpoint readback`

Theorem 62.108 (Raw functor target hom empty morphism endpoint readback)**.** *For histories s, t, any raw target hom witness whose displayed morphism is the empty morphism code reads back both endpoints as empty:*

$$\mathsf{RawFunctorTargetHom}(s, t, \mathsf{e}) \Longrightarrow \mathsf{hsame}(s, \mathsf{e}) \wedge \mathsf{hsame}(t, \mathsf{e}).$$

Proof. The raw target hom relation is closed-generated by the two identity constructors and the reverse-arrow constructor. Constructor inversion at the concrete empty morphism eliminates every constructor except the empty identity case, whose endpoints are both e. □

Lean4 ✓ `BEDC.Derived.FunctorUp.RawFunctorTargetHom empty morphism endpoint readback`

Theorem 62.109 (Raw functor opposite arrow same-endpoint obstruction)**.** *For histories s, t, the forward-arrow source hom and reverse-arrow target hom cannot share the same endpoints:*

$$\mathsf{RawFunctorSourceHom}(s, t, \mathsf{E1}(\mathsf{E1}(\mathsf{e}))) \Longrightarrow \mathsf{RawFunctorTargetHom}(s, t, \mathsf{E1}(\mathsf{E1}(\mathsf{e}))) \Longrightarrow \bot.$$

Proof. Apply Definition 62.106 to the source witness. This gives $\mathsf{hsame}(s, \mathsf{e})$ and $\mathsf{hsame}(t, \mathsf{E1}(\mathsf{e}))$.

Apply Definition 62.107 to the target witness. This gives $\mathsf{hsame}(s, \mathsf{E1}(\mathsf{e}))$ and $\mathsf{hsame}(t, \mathsf{e})$.

Using symmetry and transitivity of history-sameness, the two readbacks identify e with $\mathsf{E1}(\mathsf{e})$ through the common endpoint s; equivalently, the endpoint t gives the same contradiction in the opposite order. This is excluded by BEDC history constructor no-confusion, so the paired raw hom witnesses cannot coexist. □

Proposition 62.110 (Functor composition preservation needs morphism-sameness respect)**.** *Let C, D, E be finite certified categories, and let $F : C \to D$ and $G : D \to E$ be carrier pairs with object maps F_0, G_0 and morphism maps F_1, G_1. Write $m \sim_D n$ and $r \sim_E s$ for the endpoint-indexed morphism classifiers, and suppose the E-classifier is symmetric and transitive. Assume the raw identity and raw composition preservation ledgers for F and G are present in the sense of Definition 62.1. Fix composable morphisms $u : x \to y$ and $v : y \to z$ in C, and suppose the image pair $F_1(u), F_1(v)$ is a D-composable pair to which the raw composition ledger for G applies. Set $H = G \circ F$ with $H_0(a) = G_0(F_0(a))$ and $H_1(w) = G_1(F_1(w))$. If $F_1(v \circ_C u) \sim_D F_1(v) \circ_D F_1(u)$ and $G_1(F_1(v) \circ_D F_1(u)) \sim_E G_1(F_1(v)) \circ_E G_1(F_1(u))$ but $\neg\big(G_1(F_1(v \circ_C u)) \sim_E G_1(F_1(v) \circ_D F_1(u))\big)$, then H has no composition preservation witness at the pair (u, v): $\neg\big(H_1(v \circ_C u) \sim_E H_1(v) \circ_E H_1(u)\big)$.*

Proof. Assume that the displayed composite composition witness exists. Unfolding the composite carrier gives $G_1(F_1(v \circ_C u)) \sim_E G_1(F_1(v)) \circ_E G_1(F_1(u))$. The raw composition ledger for G on the displayed image pair gives $G_1(F_1(v) \circ_D F_1(u)) \sim_E G_1(F_1(v)) \circ_E G_1(F_1(u))$. Symmetry reverses the second comparison, and transitivity composes it with the first. Hence $G_1(F_1(v \circ_C u)) \sim_E G_1(F_1(v) \circ_D F_1(u))$, contradicting the displayed separation premise. Thus the composite composition witness cannot exist. The comparison supplied by F is only a D-morphism classifier witness between $F_1(v \circ_C u)$ and $F_1(v) \circ_D F_1(u)$. To use the raw composition ledger for G, that witness must be transported through G_1. This is exactly the classifier-replacement stability field in Definition 62.78 and the composition step used in Definition 62.99. The raw composition ledgers recorded by Definition 62.79 do not by themselves supply this transport, so they cannot restore composition preservation for $G \circ F$. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorComposition preservation sameness respect required`

Theorem 62.111 (Functor composition identity unit laws)**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates satisfying Definition 61.203, and let $F : \mathcal{C} \to \mathcal{D}$ be a $\mathsf{Functor}^{\uparrow}$ certificate satisfying Definition 62.80. Write F_0 and F_1 for its object and morphism maps. Let $1_{\mathcal{C}}$ and $1_{\mathcal{D}}$ be the identity functor certificates supplied by Definition 62.93 and Definition 62.94, and write*

$$R = F \circ 1_{\mathcal{C}}, \qquad L = 1_{\mathcal{D}} \circ F.$$

Then R and L are certified $\mathsf{Functor}^{\uparrow}$ carriers from $\mathcal{C}$ to $\mathcal{D}$, and both are classified with F by the $\mathsf{Functor}^{\uparrow}$ classifier. Equivalently, for every source object x and every displayed source morphism $u : a \to b$,

$$R_0(x) \sim_{\mathcal{O}_{\mathcal{D}}} F_0(x), \qquad L_0(x) \sim_{\mathcal{O}_{\mathcal{D}}} F_0(x),$$

and

$$R_1(u) \sim_{\mathcal{H}_{\mathcal{D}}(F_0(a),F_0(b))} F_1(u), \qquad L_1(u) \sim_{\mathcal{H}_{\mathcal{D}}(F_0(a),F_0(b))} F_1(u).$$

Consequently, for every pair of source objects a, b and every codomain morphism candidate m,

$$\mathsf{FunctorHomCarrier}_R(a, b, m) \iff \mathsf{FunctorHomCarrier}_F(a, b, m) \iff \mathsf{FunctorHomCarrier}_L(a, b, m).$$

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier empty prefix identity unit laws`

Proof. The identity certificates are available by Definition 62.94. Applying Definition 62.99 to the pair $(1_{\mathcal{C}}, F)$ gives the identity and composition preservation witnesses for $R = F \circ 1_{\mathcal{C}}$, and applying the same theorem to the pair $(F, 1_{\mathcal{D}})$ gives the corresponding witnesses for $L = 1_{\mathcal{D}} \circ F$. Together with the source, pattern, classifier, and ledger rows listed in Definition 62.80, these are certified $\mathsf{Functor}^{\uparrow}$ carriers from $\mathcal{C}$ to $\mathcal{D}$.

Unfold the identity functor data of Definition 62.93. For every source object x,

$$(F \circ 1_{\mathcal{C}})_0(x) = F_0((1_{\mathcal{C}})_0(x)) = F_0(x),$$

and

$$(1_{\mathcal{D}} \circ F)_0(x) = (1_{\mathcal{D}})_0(F_0(x)) = F_0(x).$$

Object-classifier reflexivity in the codomain category, recorded by Definition 61.201, gives the two displayed object comparisons.

For a displayed source morphism $u : a \to b$, the same unfolding gives

$$(F \circ 1_{\mathcal{C}})_1(u) = F_1((1_{\mathcal{C}})_1(u)) = F_1(u),$$

and

$$(1_{\mathcal{D}} \circ F)_1(u) = (1_{\mathcal{D}})_1(F_1(u)) = F_1(u).$$

Morphism-classifier reflexivity in the endpoint-indexed hom classifier of $\mathcal{D}$ gives both displayed morphism comparisons. By the pointwise classifier specification in Definition 62.77 and the reflexivity row in Definition 62.78, these object and morphism comparisons are exactly the $\mathsf{Functor}^{\uparrow}$ classifier witnesses $R \sim F$ and $L \sim F$.

Finally apply Definition 62.98 to F and apply Definition 62.100 to the two composites. Since the identity functor has identity object map on both $\mathcal{C}$ and $\mathcal{D}$, all three functor-indexed hom-carrier predicates reduce to

$$\mathsf{HomCarrier}_{\mathcal{D}}(F_0(a), F_0(b), m).$$

This gives the displayed biconditional chain. □

Theorem 62.112 (Functor composition associativity classifier law)**.** *Let $\mathcal{C}, \mathcal{D}, \mathcal{E}, \mathcal{L}$ be certified $\mathsf{Cat}^{\uparrow}$ packages satisfying Definition 61.203. Let $F : \mathcal{C} \to \mathcal{D}$, $G : \mathcal{D} \to \mathcal{E}$, and $H : \mathcal{E} \to \mathcal{L}$ be certified $\mathsf{Functor}^{\uparrow}$ carriers satisfying Definition 62.80, with object maps F_0, G_0, H_0 and morphism maps F_1, G_1, H_1. Write*

$$A = (H \circ G) \circ F, \qquad B = H \circ (G \circ F).$$

Then A and B are certified $\mathsf{Functor}^{\uparrow}$ carriers from $\mathcal{C}$ to $\mathcal{L}$, and they are classified together by the $\mathsf{Functor}^{\uparrow}$ classifier. Explicitly, for every source object x,

$$A_0(x) \sim_{\mathcal{O}_{\mathcal{L}}} B_0(x).$$

For every displayed source morphism $u : a \to b$,

$$A_1(u) \sim_{\mathcal{H}_{\mathcal{L}}(H_0(G_0(F_0(a))), H_0(G_0(F_0(b))))} B_1(u).$$

Moreover, the functor-indexed hom-carrier classifiers agree pointwise: for every pair of source objects a, b and every codomain morphism candidate m,

$$\mathsf{FunctorHomCarrier}_A(a, b, m) \iff \mathsf{FunctorHomCarrier}_B(a, b, m).$$

Lean4 ✓ `BEDC.Derived.FunctorUp.PrefixFunctorCarrier append assoc comp public readback`

Proof. Apply Definition 62.99 to F and G to obtain the preservation witnesses for $G \circ F$, and apply the same theorem to G and H to obtain the preservation witnesses for $H \circ G$. Applying it again to F with $H \circ G$ gives the preservation witnesses for $A = (H \circ G) \circ F$, and applying it to $G \circ F$

with H gives the preservation witnesses for $B = H \circ (G \circ F)$. Together with the source, pattern, classifier, and ledger rows of Definition 62.80, these are certified $\mathsf{Functor}^{\uparrow}$ carriers from $\mathcal{C}$ to $\mathcal{L}$.

Unfold the composite object maps. For every object x of $\mathcal{C}$,

$$A_0(x) = (H \circ G)_0(F_0(x)) = H_0(G_0(F_0(x))),$$

and

$$B_0(x) = H_0((G \circ F)_0(x)) = H_0(G_0(F_0(x))).$$

The two object images are the same displayed object of $\mathcal{L}$, so object classifier reflexivity from Definition 61.201 gives $A_0(x) \sim_{\mathcal{O}_{\mathcal{L}}} B_0(x)$.

The morphism maps unfold in the same way. For every displayed source morphism $u : a \to b$,

$$A_1(u) = (H \circ G)_1(F_1(u)) = H_1(G_1(F_1(u))),$$

and

$$B_1(u) = H_1((G \circ F)_1(u)) = H_1(G_1(F_1(u))).$$

Morphism-classifier reflexivity in the endpoint-indexed hom classifier of $\mathcal{L}$ gives the displayed morphism comparison. By the pointwise classifier specification of Definition 62.77, these object and morphism comparisons are exactly the $\mathsf{Functor}^{\uparrow}$ classifier witness between A and B.

It remains to read the hom-carrier classifiers. Applying Definition 62.100 to the composite of F with $H \circ G$ gives, for every a, b, m,

$$\mathsf{FunctorHomCarrier}_A(a, b, m) \iff \mathsf{HomCarrier}_{\mathcal{L}}(H_0(G_0(F_0(a))), H_0(G_0(F_0(b))), m).$$

Applying the same theorem to the composite of $G \circ F$ with H gives

$$\mathsf{FunctorHomCarrier}_B(a, b, m) \iff \mathsf{HomCarrier}_{\mathcal{L}}(H_0(G_0(F_0(a))), H_0(G_0(F_0(b))), m).$$

Both functor-indexed hom-carrier predicates therefore reduce to the same codomain hom-carrier classifier, and transitivity of the biconditional gives the pointwise equivalence. □

Theorem 62.113 (Functor composition classifier category package)**.** *Let $\mathcal{C}, \mathcal{D}, \mathcal{E}, \mathcal{L}$ be certified $\mathsf{Cat}^{\uparrow}$ packages satisfying Definition 61.203. Let $F : \mathcal{C} \to \mathcal{D}$, $G : \mathcal{D} \to \mathcal{E}$, and $H : \mathcal{E} \to \mathcal{L}$ be certified $\mathsf{Functor}^{\uparrow}$ carriers satisfying Definition 62.80, with object maps F_0, G_0, H_0 and morphism maps F_1, G_1, H_1. Then the certified functor carriers form a classifier-respected composition package with the following fields.*

1. *For every composable pair $F : \mathcal{C} \to \mathcal{D}$ and $G : \mathcal{D} \to \mathcal{E}$, the composite $G \circ F$ is a certified $\mathsf{Functor}^{\uparrow}$ carrier from $\mathcal{C}$ to $\mathcal{E}$, and its $\mathsf{FunctorHomCarrier}$ is the codomain hom-carrier classifier at $G_0(F_0(-))$.*
2. *For every certified $\mathsf{Cat}^{\uparrow}$ package $\mathcal{A}$, the identity carrier $1_{\mathcal{A}}$ is a certified $\mathsf{Functor}^{\uparrow}$ carrier on $\mathcal{A}$.*
3. *For every certified $K : \mathcal{A} \to \mathcal{B}$, the composites $K \circ 1_{\mathcal{A}}$ and $1_{\mathcal{B}} \circ K$ are classified with K by the $\mathsf{Functor}^{\uparrow}$ classifier, and the three $\mathsf{FunctorHomCarrier}$ predicates are pointwise the same.*
4. *For every certified triple F, G, H as above, the two triple composites $A = (H \circ G) \circ F$ and $B = H \circ (G \circ F)$ are classified together by the $\mathsf{Functor}^{\uparrow}$ classifier, and for every pair of source objects a, b and every codomain morphism candidate m,*

$$\mathsf{FunctorHomCarrier}_A(a, b, m) \iff \mathsf{FunctorHomCarrier}_B(a, b, m).$$

This is the composition structure used by the $\mathsf{NatTrans}^{\uparrow}$ *and* $\mathsf{Yoneda}^{\uparrow}$ *interfaces whenever their source functors are composed.*

Proof. The proof uses the following ten-field roadmap.

1. traditional target = category-style composition of certified functors;
2. BEDC source = $\mathsf{Cat}^{\uparrow}$ and $\mathsf{Functor}^{\uparrow}$;
3. carrier = certified functor carriers;
4. classifier = pointwise $\mathsf{Functor}^{\uparrow}$ classifier;
5. stability = closure, unit, associativity, and hom-carrier transport;
6. ledger = source and codomain category ledgers plus preservation witnesses;
7. core theorem list = Definition 62.99, Definition 62.100, Definition 62.94, Definition 62.111, and Definition 62.112;
8. exactness = hom-carrier pointwise classifier agreement;
9. standard bridge row = not claimed by this composition package; ordinary functor-category laws are only the external comparison target named by the upgrade path;
10. status = paper proof target.

For closure under composition, apply Definition 62.99 to a composable pair of certified functors. It supplies the identity and composition preservation witnesses for the composite carrier. Applying Definition 62.100 reads the resulting $\mathsf{FunctorHomCarrier}$ pointwise as the codomain hom-carrier classifier at the composed image endpoints.

For identities, Definition 62.94 supplies the certified identity functor on each certified $\mathsf{Cat}^{\uparrow}$ package. The carrier, classifier, stability, and ledger rows named in Definition 62.80 are therefore available for $1_{\mathcal{A}}$ without adding any extra source data.

For the unit laws, apply Definition 62.111. It identifies $K \circ 1_{\mathcal{A}}$ and $1_{\mathcal{B}} \circ K$ with K under the object and morphism components of the $\mathsf{Functor}^{\uparrow}$ classifier, and it gives the same pointwise $\mathsf{FunctorHomCarrier}$ predicate for all three functors.

For associativity, apply Definition 62.112. It certifies both triple composites, gives the pointwise object and morphism classifier witnesses between them, and gives the displayed agreement of their functor-indexed hom-carrier classifiers.

The four fields are exactly the composition data demanded downstream: closed composition, certified identities, unit classifiers, associativity classifiers, and exact hom-carrier transport. Repacking those fields gives the claimed classifier-respected composition package for certified $\mathsf{Functor}^{\uparrow}$ carriers. □

Theorem 62.114 (Functor prefix standard bridge)**.** *For every unary history p, the BEDC fixed-prefix* $\mathsf{Functor}^{\uparrow}$ *certificate with object map $a \mapsto \mathsf{append}(p, a)$ and identity morphism map conservatively reads as the ordinary fixed-prefix endofunctor on the unary-continuation* $\mathsf{Cat}^{\uparrow}$*. Its identity, composition, unit, associativity, and hom-carrier laws are exactly the rows cited in Definition 62.82 and Definition 62.113, read through* $\mathsf{Cat}^{\uparrow}$ *classifiers rather than host equality.*

Proof. The fixed-prefix certificate in Definition 62.82 supplies the public object map $a \mapsto \mathsf{append}(p, a)$, the identity morphism map, the preservation ledger, and the semantic NameCert rows for the unary-continuation $\mathsf{Cat}^{\uparrow}$. Reading those rows externally gives the ordinary fixed-prefix endofunctor data, because every comparison is mediated by the object and morphism classifiers of $\mathsf{Cat}^{\uparrow}$.

The functor-category laws are supplied by Definition 62.113. Its cited core rows are Definition 62.99, Definition 62.100, Definition 62.94, Definition 62.111, and Definition 62.112. These rows give closed composition, certified identities, unit classifiers, associativity classifiers, and exact pointwise hom-carrier transport for certified $\mathsf{Functor}^{\uparrow}$ carriers.

Specializing that package to the fixed-prefix carrier gives the standard endofunctor bridge. The hom-carrier readback is the exact readback already used in the package proof: the composite preservation row, the composite hom-carrier classifier row, the identity-functor NameCert row, the unit-law row, and the associativity classifier row. Thus the external functor reading uses the same classifier rows as the BEDC certificate; no host category universe, quotient, or primitive function space enters the bridge. □

Lean4 ✓ `BEDC.Derived.FunctorUp.FunctorUp StdBridge`

Definition 62.115 (Two-point classifier-transport obstruction data)**.** *Let $M = \{1, u\}$ be the idempotent monoid with unit 1 and $u \circ u = u$. Let $T = \{I, P, Q\}$ be the transformation monoid on $\{0, 1\}$ generated by the identity I and the constant maps $P(0) = P(1) = 0$ and $Q(0) = Q(1) = 1$, with composition of functions. Thus $P \circ P = P$, $Q \circ Q = Q$, $Q \circ I = Q$, $I \circ P = P$, and $Q \neq P$.*

Let $\mathcal{C}$ be the one-object category of M with equality as its morphism classifier. Let $\mathcal{D}$ be the one-object category of T with the total morphism classifier, so every two carried endomorphisms are classified. Let $\mathcal{E}$ be the one-object category of T with equality as its morphism classifier. Hom-carriers are total in each one-object category, and object classifiers are equality on the unique object.

Theorem 62.116 (FunctorUp composition obstruction without classifier replacement)**.** *The finite data of Definition 62.115 exhibit a raw functor-like map $H : \mathcal{D} \to \mathcal{E}$ preserving identities and raw composition, certified $\mathsf{Functor}^{\uparrow}$ carriers $F, G : \mathcal{C} \to \mathcal{D}$, and a certified $\mathsf{NatTrans}^{\uparrow}$ carrier $\alpha : F \Rightarrow G$ such that the functor-whiskering naturality row for $H_*\alpha$ is impossible. Consequently the classifier-replacement row in Definition 62.78 is not entailed by the raw carrier, identity, and composition rows of Definition 62.1, and $\mathsf{Functor}^{\uparrow}$ composition certification cannot be derived from those raw rows alone.*

Proof. The categories are certified in the sense of Definition 61.203. For $\mathcal{C}$ and $\mathcal{E}$, equality supplies the object and morphism classifier laws and is compatible with composition. For $\mathcal{D}$, the total morphism classifier is reflexive, symmetric, transitive, and compatible with composition. The identity, composition closure, associativity, and unit laws are the monoid laws of M and T, matching Definition 61.201.

Define $F, G : \mathcal{C} \to \mathcal{D}$ on the unique object by the unique object map and on morphisms by

$$F_1(1) = I, \qquad F_1(u) = P, \qquad G_1(1) = I, \qquad G_1(u) = Q.$$

The equations $P \circ P = P$ and $Q \circ Q = Q$ make identity and composition preservation strict. Since the codomain classifier of $\mathcal{D}$ is total, the pointwise classifier rows and the source-comparison transport rows listed in Definition 62.78 are automatic. Thus F and G satisfy the $\mathsf{Functor}^{\uparrow}$ obligations of Definition 62.80.

Let $\alpha : F \Rightarrow G$ have the single component $\alpha_* = I$. The component carrier exists because $\mathcal{D}$ has one object. Naturality at the identity morphism is immediate. Naturality at u is the $\mathcal{D}$-classifier comparison

$$G_1(u) \circ \alpha_* = Q \circ I = Q \sim_{\mathcal{D}} P = I \circ P = \alpha_* \circ F_1(u),$$

which is supplied by the total classifier of $\mathcal{D}$. The remaining component classifier, naturality-stability, vertical-composition, and identity rows of Definition 63.75 are again immediate in the total classifier, so α satisfies Definition 63.77.

Now define $H : \mathcal{D} \to \mathcal{E}$ by the unique object map and the identity map on the raw monoid T. It preserves the identity and every raw composite strictly because the two categories have the same raw monoid. It does not preserve the morphism classifier: $\mathcal{D}$ classifies $Q \sim_{\mathcal{D}} P$, while the equality classifier of $\mathcal{E}$ gives $Q \not\sim_{\mathcal{E}} P$.

The component prescribed by Definition 63.91 is

$$(H_*\alpha)_* = H_1(I) = I,$$

so the component carrier itself exists in $\mathcal{E}$. The naturality row at u, however, would have to be

$$H_1(G_1(u)) \circ H_1(I) \sim_{\mathcal{E}} H_1(I) \circ H_1(F_1(u)).$$

Unfolding the displayed maps and the monoid products turns this into

$$Q \circ I = Q \sim_{\mathcal{E}} P = I \circ P.$$

This is impossible because $\mathcal{E}$ uses equality as its morphism classifier and $Q \neq P$ as transformations of $\{0, 1\}$.

Thus the naturality classifier for α in $\mathcal{D}$ cannot be transported through H_1. This is exactly the transport step used in Definition 63.92 and, at the functor level, in Definition 62.99. If raw identity and raw composition preservation were enough for $\mathsf{Functor}^{\uparrow}$ composition certification, applying that rule to $H \circ 1_{\mathcal{D}}$, with $1_{\mathcal{D}}$ supplied by Definition 62.94, would certify the same raw map H and hence the missing classifier transport $Q \sim_{\mathcal{D}} P \Rightarrow H_1(Q) \sim_{\mathcal{E}} H_1(P)$. The displayed failure in $\mathcal{E}$ contradicts that conclusion. □

Theorem 62.117 (Split monomorphisms are left-cancellative)**.** *Let $\mathcal{C}$ be a $\mathsf{Cat}^{\uparrow}$ certificate satisfying Definition 61.203. Let $f : a \to b$ be a split monomorphism in $\mathcal{C}$ with left-inverse witness $g : b \to a$ in the sense of Definition 62.87. If $u, v : x \to a$ are displayed morphisms and $p, q : x \to b$ are displayed composites with*

$$\mathsf{Comp}_{\mathcal{C}}(u, f, p), \qquad \mathsf{Comp}_{\mathcal{C}}(v, f, q),$$

and if $p \sim_{\mathcal{C}} q$ in the morphism classifier at (x, b), then $u \sim_{\mathcal{C}} v$ in the morphism classifier at (x, a).

Proof. Unpack the split-monomorphism witness. It supplies displayed hom-carriers for f and g, an identity display $i_a : a \to a$, and a composite display $c : a \to a$ such that

$$\mathsf{Comp}_{\mathcal{C}}(f, g, c) \qquad \text{and} \qquad c \sim_{\mathcal{C}} i_a.$$

The displayed morphisms u and v, together with composition closure in Definition 61.201, make p and q hom-carriers from x to b.

Let $r_u : x \to a$ and $r_v : x \to a$ be composites of p and q followed by g:

$$\mathsf{Comp}_{\mathcal{C}}(p, g, r_u), \qquad \mathsf{Comp}_{\mathcal{C}}(q, g, r_v).$$

Composition congruence with the fixed factor g transports the hypothesis $p \sim_{\mathcal{C}} q$ to

$$r_u \sim_{\mathcal{C}} r_v.$$

Apply associativity to the chain

$$x \xrightarrow{u} a \xrightarrow{f} b \xrightarrow{g} a.$$

It compares $r_u = g \circ_{\mathcal{C}} (f \circ_{\mathcal{C}} u)$ with the composite of u followed by $c = g \circ_{\mathcal{C}} f$. Since $c \sim_{\mathcal{C}} i_a$, composition congruence with the fixed factor u compares this latter composite with the composite of u followed by i_a. The target-identity law then classifies that composite with u. Hence

$$r_u \sim_{\mathcal{C}} u.$$

The same argument applied to

$$x \xrightarrow{v} a \xrightarrow{f} b \xrightarrow{g} a$$

gives

$$r_v \sim_{\mathcal{C}} v.$$

The morphism-classifier equivalence laws, recorded in the classifier and stability rows of the $\mathsf{Cat}^{\uparrow}$ certificate, compose the comparison $u \sim_{\mathcal{C}} r_u$, the transported comparison $r_u \sim_{\mathcal{C}} r_v$, and the comparison $r_v \sim_{\mathcal{C}} v$. Therefore $u \sim_{\mathcal{C}} v$ at the endpoint pair (x, a). □

Lean4 ✓ `BEDC.Derived.FunctorUp.CategorySplitMonomorphism left cancellative`

Closure status for $\mathsf{NameCert}_{\mathsf{Functor}^{\uparrow}}$.

Constructive story: A functor in this public construction is a certified carrier between already licensed $\mathsf{Cat}^{\uparrow}$ packages, and the concrete bridge specializes it to the fixed-prefix endofunctor that sends a unary object a to $\mathsf{append}(p, a)$ while carrying morphism tails through the corresponding endpoint-indexed hom carrier. The carrier accepts only those object and morphism maps whose images land in the codomain object and hom carriers and whose identity and composition preservation rows are witnessed under the codomain classifiers; raw maps that merely preserve unclassified composites are excluded by the finite obstruction rows. Two functor presentations classify together pointwise: their object images are compared by the target object classifier and their morphism images by the target hom classifier at the transported endpoints, so no host function equality or functor quotient is formed. The source, pattern, and ledger rows record the source and target category certificates, the object and morphism maps, identity and composition preservation, classifier-replacement stability, and the composite functor ledgers used for identity, unit, and associativity laws. The five name-certificate obligations follow from inhabited fixed-prefix data, pointwise reflexivity, symmetry, and transitivity of the category classifiers, and carrier transport supplied by the same pointwise classifier rows. A displayed functor row h lies in the signature gap of a $\mathsf{Functor}^{\uparrow}$ token p when the source-domain accepts the source and target category data, the signature relation pairs the object/morphism-map package with an answer carrier and preservation ledger, and token introduction names that answer as p; concretely, the fixed prefix, all image objects, and all image morphisms must be the ones encoded by the token. The standard bridge reads this as the ordinary fixed-prefix endofunctor and its certified composition package, then reads back only the same $\mathsf{Cat}^{\uparrow}$ classifier data. The chapter registers this classifier-respecting map construction under the name $\mathsf{Functor}^{\uparrow}$; functoriality is a ledger of landing and preservation rows, not an imported functor category, host map equality, adjunction theory, or Kan-extension surface.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Functor}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The public fixed-prefix $\mathsf{Functor}^{\uparrow}$ export is closed over the carrier, certificate, public-readback, standard bridge, finite classifier-transport obstruction, split-monomorphism consumption surface, and the required $\mathsf{Cat}^{\uparrow}$ source and target dependency.

Chapter 63

A Concrete Naming Certificate for $\mathsf{NatTrans}^{\uparrow}$

The natural transformation interface $\mathsf{NatTrans}^{\uparrow}$ has certificate obligations between two functors from chapter 62 sharing source and target categories. The carrier is, for each object X of the source category, a morphism in the target category from the first functor's image of X to the second functor's image of X, satisfying the naturality square under the codomain category's morphism classifier. It is not a primitive 2-cell; it is admitted only as an object-indexed family of morphisms with the naturality field.

63.1 Carrier definition

Definition 63.1 (NatTrans carrier)**.** *Use an object-indexed family of codomain morphisms $\eta_X : F(X) \to G(X)$ plus naturality witnesses for every source morphism.*

Lean4 (definition) `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier`

Theorem 63.2 (NatTrans prefix component unary object suffix exactness)**.** *For histories p, q, a, η, a prefix component over the shared object suffix a is equivalent to unary membership of a together with the unsuffixed category hom carrier:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{CategoryHomCarrier}(p, q, \eta).$$

Proof. Unfold the prefix component carrier. The category hom-carrier suffix theorem peels the common unary object suffix from $\mathsf{append}(p, a)$ and $\mathsf{append}(q, a)$, and the reverse direction repackages that suffixed hom-carrier with the component fields. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier unary object suffix iff`

Theorem 63.3 (NatTrans prefix component empty identity exactness)**.** *For prefix components over unary histories, the empty component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$ exists exactly when p, q, and a are unary histories and $\mathsf{hsame}(p, q)$.*

Proof. Unfold the prefix component carrier to its category hom-carrier over $\mathsf{append}(p, a)$ and $\mathsf{append}(q, a)$. Category empty-identity exactness identifies the two prefixed endpoints; cancellation of the shared suffix a recovers $\mathsf{hsame}(p, q)$. Conversely, unary append closure supplies the two prefixed endpoint carriers, and the equality of p and q transports the category empty identity carrier to the component carrier. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier empty identity iff`

Theorem 63.4 (NatTrans empty identity prefix transitivity)**.** *For prefix components over unary histories, if the empty component identifies* $\mathsf{append}(p, a)$ *with* $\mathsf{append}(q, a)$ *and the empty component also identifies* $\mathsf{append}(q, a)$ *with* $\mathsf{append}(r, a)$*, then* $\mathsf{hsame}(p, r)$*.*

Proof. Apply empty-identity exactness to the two component witnesses. The first component gives $\mathsf{hsame}(p, q)$, and the second gives $\mathsf{hsame}(q, r)$. Transitivity of history sameness identifies p and r. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier empty identity prefix trans`

Theorem 63.5 (NatTrans prefix component endomorphism component empty exactness)**.** *For prefix components whose source and target prefixes agree, a component history* η *is carried exactly when the prefix, object, and component histories are unary and the component is internally empty:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, p, a, \eta) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(\eta) \wedge \eta\mathsf{hsamee}.$$

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier endomorphism component empty iff`

Proof. Unfold the prefix component into its category hom-carrier $\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(p, a), \eta)$. The continuation field has matching source and target, hence right-unit uniqueness forces $\eta\mathsf{hsamee}$, while the component fields provide unary membership of p, a, and η. Conversely, an empty component is rebuilt by the prefix empty-identity exactness theorem with reflexivity of $\mathsf{hsame}(p, p)$. □

Theorem 63.6 (NatTrans one-headed source empty component exactness)**.** *For histories* p, q, a*, an empty prefix component from* $\mathsf{E1}(p)$ *to* q *over* a *exists exactly when* p *and* a *are unary and the target prefix is literally* $\mathsf{E1}(p)$*:*

$$\mathsf{NatTransPrefixComponentCarrier}(\mathsf{E1}(p), q, a, \mathsf{e}) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(a) \wedge q = \mathsf{E1}(p).$$

Proof. Apply empty-identity component exactness. Unary inversion on the one-headed source prefix extracts unary membership of p, and the prefix sameness specializes to the equality $q = \mathsf{E1}(p)$. Conversely, substituting this equality rebuilds the one-headed target prefix, and empty-identity exactness packages the empty component. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier e1 source empty component iff`

Theorem 63.7 (NatTrans one-headed object empty component exactness)**.** *For histories* p, q, a*, an empty prefix component over the one-headed object* $\mathsf{E1}(a)$ *exists exactly when both prefixes and the object tail are unary and the two prefixes are history-same:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, q, \mathsf{E1}(a), \mathsf{e}) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{UnaryHistory}(a) \wedge p\mathsf{hsame}$$

Proof. Apply empty-identity component exactness at the object $\mathsf{E1}(a)$. The forward direction uses unary inversion on the object carrier to expose a. The reverse direction closes the one-headed object by unary closure and repacks the empty-identity component with the displayed prefix classifier. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier e1 object empty component iff`

Theorem 63.8 (NatTrans one-headed target empty component exactness)**.** *For histories p, q, a, an empty prefix component from p to $\mathsf{E1}(q)$ over a exists exactly when q and a are unary and the source prefix is literally $\mathsf{E1}(q)$:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, \mathsf{E1}(q), a, \mathsf{e}) \iff \mathsf{UnaryHistory}(q) \wedge \mathsf{UnaryHistory}(a) \wedge p = \mathsf{E1}(q).$$

Proof. Apply empty-identity component exactness. Unary inversion on the one-headed target prefix extracts unary membership of q, and the prefix sameness specializes to the equality $p = \mathsf{E1}(q)$. Conversely, substituting this equality rebuilds the one-headed source prefix, and empty-identity exactness packages the empty component. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier e1 target empty component iff`

Theorem 63.9 (NatTrans prefix component empty-source prefix exactness)**.** *For histories q, a, η, a prefix component from the empty prefix to q over a is exactly a unary target prefix, a unary object, and a category hom-carrier from a to $\mathsf{append}(q, a)$:*

$$\mathsf{NatTransPrefixComponentCarrier}(\mathsf{e}, q, a, \eta) \iff \mathsf{UnaryHistory}(q) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{CategoryHomCarrier}(a, \mathsf{apper}$$

Proof. Unfold the prefix component carrier. The source endpoint is $\mathsf{append}(\mathsf{e}, a)$, which is history-same as a by the left unit law for append. Category hom-carrier transport across this endpoint equality gives the unprefixed source form. The converse uses the same endpoint equality in the opposite direction and packages the empty prefix carrier. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier empty source prefix iff`

Theorem 63.10 (NatTrans prefix component empty-target prefix exactness)**.** *For histories p, a, η, a prefix component from p to the empty prefix over a is exactly a unary source prefix, a unary object, and a category hom-carrier from $\mathsf{append}(p, a)$ to a:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, \mathsf{e}, a, \eta) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{CategoryHomCarrier}(\mathsf{append}($$

Proof. Unfold the prefix component carrier. The target endpoint is $\mathsf{append}(\mathsf{e}, a)$, which is history-same as a by the left unit law for append. Category hom-carrier transport across this target endpoint equality gives the unprefixed target form. The converse uses the same endpoint equality in the opposite direction and packages the empty target prefix carrier. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier empty target prefix iff`

Theorem 63.11 (NatTrans prefix component empty-prefix exactness)**.** *For histories a, η, a prefix component with both prefixes empty is exactly a unary object together with a category hom-carrier from a to itself:*

$$\mathsf{NatTransPrefixComponentCarrier}(\mathsf{e}, \mathsf{e}, a, \eta) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{CategoryHomCarrier}(a, a, \eta).$$

Proof. Unfold the prefix component carrier. Both endpoints are $\mathsf{append}(\mathsf{e}, a)$, which is history-same as a by the left unit law for append. Category hom-carrier transport across those endpoint equalities gives the displayed carrier from a to itself. The converse transports this carrier back to the two empty-prefixed endpoints and packages the two empty prefix carriers. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier empty prefixes iff`

Theorem 63.12 (NatTrans prefix component zero-headed component impossibility)**.** *For histories p, q, a, η, a prefix component carrier has no zero-headed source prefix, target prefix, object, or component morphism:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta) \Longrightarrow (\exists z,\ p = \mathsf{E0}(z)) \vee (\exists z,\ q = \mathsf{E0}(z)) \vee (\exists z,\ a = \mathsf{E0}(z)) \vee (\exists z,\ \eta = \mathsf{E0}(z)$$

Proof. Unfold the prefix component carrier. The first three fields give unary-history witnesses for p, q, and a, and the underlying category hom-carrier gives the unary-history witness for the component morphism η. A zero-headed component in any of those positions contradicts unary zero-extension separation. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier zero headed component absurd`

Theorem 63.13 (NatTrans prefix component vertical composition closure)**.** *For prefix components over unary histories, if η is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$, θ is a component from $\mathsf{append}(q, a)$ to $\mathsf{append}(r, a)$, and $\mathsf{Cont}(\eta, \theta, \theta\eta)$, then the composite component is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(r, a)$.*

Proof. Unpack the two prefix-component carrier witnesses. The outer prefix and object unary witnesses come from the first component and the target prefix witness comes from the second component. Category hom-carrier composition closure composes the two component morphisms across the shared middle object $\mathsf{append}(q, a)$. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp closed`

Theorem 63.14 (NatTrans prefix component vertical composition hsame transport)**.** *For prefix components over unary histories, if η is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$, θ is a component from $\mathsf{append}(q, a)$ to $\mathsf{append}(r, a)$, and $\mathsf{Cont}(\eta, \theta, \theta\eta)$, then any* hsame*-equal source prefix, target prefix, object, and composite history display the same vertical composite as a component from $\mathsf{append}(p', a')$ to $\mathsf{append}(r', a')$.*

Proof. Vertical composition closure gives the composite component at the original source prefix, target prefix, object, and composite history. The supplied hsame witnesses transport those concrete component fields to the displayed source prefix, target prefix, object, and composite history. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp hsame transport`

Theorem 63.15 (NatTrans prefix component vertical composition public readback)**.** *For prefix components over unary histories, if η is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$, θ is a component from $\mathsf{append}(q, a)$ to $\mathsf{append}(r, a)$, and $\mathsf{Cont}(\eta, \theta, \theta\eta)$, then the composite is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(r, a)$, and every displayed component over the same source prefix, target prefix, and object is* hsame *to that composite.*

Proof. The vertical composition closure theorem supplies the displayed composite component carrier. Any displayed component with the same prefixed source and target unpacks to a category hom-carrier with the same endpoints. Category morphism determinacy compares the underlying hom-carriers, yielding the public hsame readback for the composite. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp public readback`

Theorem 63.16 (NatTrans prefix component vertical composite zero-headed component impossibility)**.** *For histories $p, q, r, a, \eta, \theta, composite$, if η is a prefix component from p to q, θ is a prefix component from q to r, and $\mathsf{Cont}(\eta, \theta, composite)$ holds, then no source prefix, middle prefix, target prefix, object, factor component, or composite component is zero-headed.*

Proof. Vertical composition closure gives the composite component carrier from p to r. The zero-headed source, middle, object, and left component cases reduce to the left component exclusion; the target and right component cases reduce to the right component exclusion; the composite component case reduces to the closed composite component carrier. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp zero headed component absurd`

Theorem 63.17 (NatTrans prefix component vertical composition family public readback)**.** *For histories $p, q, r, \eta, \theta, composite, displayed$, suppose every unary object a carries η as a component from prefix p to prefix q, every unary object carries θ from q to r, $\mathsf{Cont}(\eta, \theta, composite)$ holds, and every unary object carries displayed from p to r. Then*

$$\mathsf{hsame}(composite, displayed).$$

Proof. Evaluate the source, target, and displayed component families at the empty unary object. The fixed-object vertical public readback theorem compares the closed composite with the displayed component at that object. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp family public readback`

Theorem 63.18 (NatTrans prefix component empty vertical composite exactness)**.** *For prefix components over a common object a, if η is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$ and θ is a component from $\mathsf{append}(q, a)$ to $\mathsf{append}(r, a)$, then the empty vertical composite is equivalent to both component histories being empty and the adjacent prefixes agreeing:*

$$\mathsf{Cont}(\eta, \theta, \mathsf{e}) \iff \mathsf{hsame}(\eta, \mathsf{e}) \wedge \mathsf{hsame}(\theta, \mathsf{e}) \wedge \mathsf{hsame}(p, q) \wedge \mathsf{hsame}(q, r).$$

Proof. Unfold the two prefix components to their category hom-carriers over the shared object suffix a. Category empty-composite exactness gives the two empty component histories and the two endpoint equalities. Right cancellation removes the common suffix a from both endpoint equalities. Conversely, the prefix equalities rebuild the component endpoint equalities, and category empty-composite exactness supplies the empty vertical continuation ledger. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp empty iff`

Theorem 63.19 (NatTrans prefix component vertical empty-component readback)**.** *For prefix components over a common object a, if η is a component from p to q, θ is a component from q to r, and their vertical continuation has empty result, then both displayed components have empty component carriers and the adjacent prefixes agree:*

$$\mathsf{Cont}(\eta, \theta, \mathsf{e}) \Longrightarrow \mathsf{NatTransPrefixComponentCarrier}(p, q, a, \mathsf{e}) \wedge \mathsf{NatTransPrefixComponentCarrier}(q, r, a, \mathsf{e}) \wedge \mathsf{hsame}(p, q)$$

Proof. Apply category empty-composite exactness to the two component hom-carriers. The empty result forces both component histories to be empty and gives endpoint equalities with the shared object suffix a. Transporting the original component carriers along the empty component equalities gives the two empty component carriers, and right cancellation removes the common suffix from the endpoint equalities. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp empty component readback`

Theorem 63.20 (NatTrans prefix component vertical composite result empty exactness)**.** *For prefix components over a common object a, if η goes from p to q, θ goes from q to r, and their vertical composite is composite, then composite is empty exactly when the two component histories are empty and the adjacent prefixes agree:*

$$\mathsf{hsame}(\mathit{composite}, \mathsf{e}) \iff \mathsf{hsame}(\eta, \mathsf{e}) \wedge \mathsf{hsame}(\theta, \mathsf{e}) \wedge \mathsf{hsame}(p, q) \wedge \mathsf{hsame}(q, r).$$

Proof. Apply category hom-carrier composite-result empty exactness to the two component hom carriers. The endpoint equalities contain the shared object suffix a, and right cancellation exposes $\mathsf{hsame}(p, q)$ and $\mathsf{hsame}(q, r)$. Conversely, the prefix equalities rebuild those endpoint equalities and the given continuation determines the empty composite result. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp result empty iff`

Theorem 63.21 (NatTrans prefix component vertical composite nonempty target visibility)**.** *For prefix components over a common object a, if η goes from p to q, θ goes from q to r, and their vertical composite displays the visible result $\mathsf{E1}(k)$, then the target component endpoint is visible:*

$$\exists s.\ \mathsf{append}(r, a) = \mathsf{E1}(s) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(s) \wedge \mathsf{Cont}(\mathsf{append}(p, a), \mathsf{E1}(k), \mathsf{E1}(s)).$$

Proof. Unpack both natural-transformation components to their underlying category hom-carriers. Category source-target case analysis for the nonempty composite result gives either an empty source endpoint with a displayed target, or a visible source endpoint with the same displayed target. In the visible-source branch, source endpoint transport converts the continuation ledger back to $\mathsf{append}(p, a)$; in both branches the result equality identifies the visible composite payload with k. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp nonempty result target visible`

Theorem 63.22 (NatTrans one-headed prefix empty vertical composite exactness)**.** *For prefix components over a common object a, if η is a component from $\mathsf{E1}(p)$ to q and θ is a component from q to $\mathsf{E1}(r)$, then the empty vertical composite is equivalent to both component histories being empty and the one-headed source and target prefix payloads agreeing:*

$$\mathsf{Cont}(\eta, \theta, \mathsf{e}) \iff \mathsf{hsame}(\eta, \mathsf{e}) \wedge \mathsf{hsame}(\theta, \mathsf{e}) \wedge \mathsf{hsame}(p, r).$$

Proof. Unfold the two prefix components to their category hom-carriers over $\mathsf{append}(\mathsf{E1}(p), a)$, $\mathsf{append}(q, a)$, and $\mathsf{append}(\mathsf{E1}(r), a)$. Category empty-composite exactness gives the two empty component histories and adjacent endpoint equalities. Transitivity identifies the two endpoints with the common suffix a; right cancellation removes that suffix, and one-headed constructor inversion yields $\mathsf{hsame}(p, r)$. Conversely, empty component histories reduce the vertical continuation ledger to the empty continuation at e. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier e1 prefix empty vert comp iff`

Theorem 63.23 (NatTrans prefix component vertical composition right factor)**.** *For prefix components over unary histories, if η is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$, $\mathsf{Cont}(\eta, \theta, \theta\eta)$ composes η with θ, and the composite is displayed as a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(r, a)$, then θ is a component from $\mathsf{append}(q, a)$ to $\mathsf{append}(r, a)$.*

Proof. Unpack the left component and the displayed composite to their underlying category hom-carriers. The category right-factor theorem recovers the missing hom-carrier for θ between the middle endpoint $\mathsf{append}(q, a)$ and the displayed target endpoint $\mathsf{append}(r, a)$. The prefix carrier for q, the prefix carrier for r, and the object carrier for a reassemble the NatTrans prefix component carrier for θ. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp right factor`

Theorem 63.24 (NatTrans prefix component vertical composition right factor public readback)**.** *For prefix components over unary histories, if η is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$, $\mathsf{Cont}(\eta, \theta, \theta\eta)$ composes η with θ, and the composite is displayed as a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(r, a)$, then θ is a component from $\mathsf{append}(q, a)$ to $\mathsf{append}(r, a)$. Moreover, any competing right component θ' with $\mathsf{Cont}(\eta, \theta', \theta\eta)$ and the same component endpoints satisfies $\mathsf{hsame}(\theta, \theta')$.*

Proof. Vertical right-factor recovery supplies the displayed component carrier for θ. For any competing θ', the two continuation ledgers have the same left component and composite result, so finite-kernel left cancellation gives $\mathsf{hsame}(\theta, \theta')$. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp right factor public readback`

Theorem 63.25 (NatTrans prefix component vertical composition left factor)**.** *For prefix components over unary histories, if θ is a component from $\mathsf{append}(q, a)$ to $\mathsf{append}(r, a)$, $\mathsf{Cont}(\eta, \theta, \theta\eta)$ composes η with θ, and the composite is displayed as a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(r, a)$, then η is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$.*

Proof. Unpack the right component and the displayed composite to their underlying category hom-carriers. The category left-factor theorem recovers the hom-carrier for η between the displayed source endpoint $\mathsf{append}(p, a)$ and the middle endpoint $\mathsf{append}(q, a)$. The prefix carrier for p, the prefix carrier for q, and the object carrier for a reassemble the NatTrans prefix component carrier for η. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp left factor`

Theorem 63.26 (NatTrans prefix component vertical composition left factor public readback)**.** *For prefix components over unary histories, if θ is a component from $\mathsf{append}(q, a)$ to $\mathsf{append}(r, a)$, $\mathsf{Cont}(\eta, \theta, \theta\eta)$ composes η with θ, and the composite is displayed as a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(r, a)$, then η is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$. Moreover, any competing left component η' with $\mathsf{Cont}(\eta', \theta, \theta\eta)$ and the same component endpoints satisfies $\mathsf{hsame}(\eta, \eta')$.*

Proof. Vertical left-factor recovery supplies the displayed component carrier for η. For any competing η', the two continuation ledgers have the same right component and composite result, so finite-kernel right cancellation gives $\mathsf{hsame}(\eta, \eta')$. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp left factor public readback`

Theorem 63.27 (NatTrans prefix component vertical composition right identity closure)**.** *For prefix components over unary histories, if η is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$ and $\mathsf{Cont}(\eta, \mathsf{e}, \eta')$, then η' is again such a component and $\mathsf{hsame}(\eta', \eta)$.*

Proof. The BEDC continuation right-unit witness $\mathsf{Cont}(\eta, \mathsf{e}, \eta)$ and the displayed continuation $\mathsf{Cont}(\eta, \mathsf{e}, \eta')$ have the same source and tail. Continuation determinacy gives $\mathsf{hsame}(\eta', \eta)$. Transport the unpacked prefix-component carrier for η along this history sameness to obtain the component carrier for η'. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp right identity closed`

Theorem 63.28 (NatTrans prefix component empty object exactness)**.** *For histories p, q, η, a prefix component over the empty object is exactly unary source and target prefixes together with the unprefixed category hom-carrier from p to q:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, q, \mathsf{e}, \eta) \iff \mathsf{UnaryHistory}(p) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{CategoryHomCarrier}(p, q, \eta).$$

Proof. Unfold the prefix component carrier at the empty object. The two endpoints are $\mathsf{append}(p, \mathsf{e})$ and $\mathsf{append}(q, \mathsf{e})$, which reduce to p and q by the right unit law for append. Category hom-carrier transport across those endpoint equalities gives the unprefixed carrier, and the converse transports it back while packaging the empty object carrier. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier empty object iff`

Theorem 63.29 (NatTrans prefix component right identity empty result)**.** *For a prefix component η from p to q at a, if right is obtained by composing η with the empty right identity, then right is empty exactly when η is empty and the two prefixes agree:*

$$\mathsf{hsame}(right, \mathsf{e}) \iff \mathsf{hsame}(\eta, \mathsf{e}) \wedge \mathsf{hsame}(p, q).$$

Proof. Right-identity closure identifies *right* with η and transports the prefix-component carrier to *right*. If *right* is empty, this transported carrier becomes an empty prefix component, so the empty-identity exactness theorem gives $\mathsf{hsame}(p, q)$; the same right-identity comparison gives $\mathsf{hsame}(\eta, \mathsf{e})$.

Conversely, if η is empty, the displayed continuation has empty source and empty right tail. Continuation determinacy compares it with the BEDC right-unit continuation at e, identifying *right* with e. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp right identity empty result iff`

Theorem 63.30 (NatTrans prefix component left identity empty result)**.** *For a prefix component η from p to q at a, if $left$ is obtained by composing the empty left identity before η, then $left$ is empty exactly when η is empty and the two prefixes agree:*

$$\mathsf{hsame}(left, \mathsf{e}) \iff \mathsf{hsame}(\eta, \mathsf{e}) \wedge \mathsf{hsame}(p, q).$$

Proof. Left-identity closure identifies $left$ with η and transports the prefix-component carrier to $left$. If $left$ is empty, this transported carrier becomes an empty prefix component, so the empty-identity exactness theorem gives $\mathsf{hsame}(p, q)$; the same left-identity comparison gives $\mathsf{hsame}(\eta, \mathsf{e})$.

Conversely, if η is empty, the displayed continuation has empty left tail and empty source component. The BEDC left-unit result identifies $left$ with e. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp left identity empty result iff`

Theorem 63.31 (NatTrans prefix component identity square empty result exactness)**.** *For a prefix component η from p to q at a, if $left$ is obtained by composing the empty left identity before η and $right$ is obtained by composing η with the empty right identity, then both displayed histories are empty exactly when η is empty and the two prefixes agree:*

$$\mathsf{hsame}(left, \mathsf{e}) \wedge \mathsf{hsame}(right, \mathsf{e}) \iff \mathsf{hsame}(\eta, \mathsf{e}) \wedge \mathsf{hsame}(p, q).$$

Proof. The forward direction applies the left-identity empty-result exactness theorem to the empty $left$ component. The reverse direction applies the left- and right-identity empty-result exactness theorems to the same component and prefix comparison, producing both empty displayed histories. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp identity square empty result iff`

Theorem 63.32 (NatTrans prefix component empty component prefix exactness)**.** *For a prefix component η from p to q at a, the component history is empty exactly when the two prefixes agree:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta) \Longrightarrow (\mathsf{hsame}(\eta, \mathsf{e}) \iff \mathsf{hsame}(p, q)).$$

Proof. Project the underlying category hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$. The category empty-morphism endpoint theorem turns $\eta\mathsf{hsamee}$ into equality of those endpoints, and right cancellation removes the shared object suffix a. Conversely, prefix equality lifts through the common object suffix and the category endpoint theorem identifies η with e. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier component empty prefix iff`

Theorem 63.33 (NatTrans prefix component vertical composition left identity closure)**.** *For prefix components over unary histories, if η is a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$ and $\mathsf{Cont}(\mathsf{e}, \eta, \eta')$, then η' is again such a component and $\mathsf{hsame}(\eta', \eta)$.*

Proof. The BEDC left-unit law for continuation gives $\mathsf{hsame}(\eta', \eta)$ directly from $\mathsf{Cont}(\mathsf{e}, \eta, \eta')$. Transport the unpacked prefix-component carrier for η along this history sameness to obtain the component carrier for η'. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp left identity closed`

Theorem 63.34 (NatTrans prefix component vertical composition identity square closure)**.** *For a prefix component η from p to q at a, if $left$ is obtained by composing e before η and $right$ is obtained by composing e after η, then both displayed histories are prefix components from p to q at a, and $\mathsf{hsame}(left, right)$.*

Proof. Apply the left-identity vertical composition closure to $left$ and the right-identity vertical composition closure to $right$. The two closure theorems identify the displayed histories with η, so transitivity and symmetry give $\mathsf{hsame}(left, right)$. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp identity square closed`

Theorem 63.35 (NatTrans prefix component vertical composition associativity closure)**.** *For prefix components over unary histories, let η, θ, and ι be consecutive components from p to q, q to r, and r to s at the object a. If $\eta\theta$, $\theta\iota$, $(\eta\theta)\iota$, and $\eta(\theta\iota)$ are supplied by the BEDC continuation relation, then the two bracketed composites are components from p to s at a, and they are hsame.*

Proof. Unpack the three prefix-component carrier witnesses to their underlying category hom-carriers between $\mathsf{append}(p, a)$, $\mathsf{append}(q, a)$, $\mathsf{append}(r, a)$, and $\mathsf{append}(s, a)$. Category hom-carrier associativity closure gives hom-carrier witnesses for both bracketed composites and identifies them by hsame. Repackage the shared source prefix, target prefix, and object unary witnesses around those two underlying hom-carriers. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp assoc closed`

Theorem 63.36 (NatTrans prefix component displayed vertical associativity determinacy)**.** *For prefix components over unary histories, let η, θ, and ι be consecutive components from p to q, q to r, and r to s at the object a. If the two bracketed vertical composites are supplied by the BEDC continuation relation and a displayed component carrier from p to s at a is also given, then both bracketed composite histories are* hsame *to the displayed component history.*

Proof. Vertical associativity closure constructs both prefix-component carriers from p to s at a. Unpacking these carriers and the displayed carrier exposes category hom-carriers with the same source and target, so category morphism determinacy identifies each bracketed composite history with the displayed history. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp assoc displayed deterministic`

Theorem 63.37 (NatTrans prefix component target-prefix determinacy)**.** *For prefix components over unary histories, if a fixed component history η is a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(q, a)$ *and also from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(r, a)$*, then* $\mathsf{hsame}(q, r)$*.*

Proof. Unpack both prefix-component carrier witnesses to their underlying category hom-carrier witnesses. Category target determinacy identifies $\mathsf{append}(q, a)$ and $\mathsf{append}(r, a)$, and cancellation of the shared suffix a identifies the prefixes q and r. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier target prefix deterministic`

Theorem 63.38 (NatTrans vertical composite target-prefix determinacy)**.** *For prefix components over unary histories, if η is a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(q, a)$*, θ is a component from* $\mathsf{append}(q, a)$ *to* $\mathsf{append}(r, a)$*,* $\mathsf{Cont}(\eta, \theta, \eta\theta)$*, and the composite history $\eta\theta$ is also presented as a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(s, a)$*, then* $\mathsf{hsame}(r, s)$*.*

Proof. Vertical composition closure first turns the two displayed component witnesses and the continuation witness into a component from $\mathsf{append}(p, a)$ to $\mathsf{append}(r, a)$. Target-prefix determinacy then compares this component with the displayed component ending at $\mathsf{append}(s, a)$ and cancels the shared suffix a. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp target prefix deterministic`

Theorem 63.39 (NatTrans vertical composite middle-prefix determinacy)**.** *For prefix components over unary histories, if η is a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(q, a)$*, θ is a component from* $\mathsf{append}(q', a)$ *to* $\mathsf{append}(r, a)$*,* $\mathsf{Cont}(\eta, \theta, \eta\theta)$*, and the composite history $\eta\theta$ is displayed as a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(r, a)$*, then* $\mathsf{hsame}(q, q')$*.*

Proof. Expose the category hom-carrier witnesses inside the two component carriers and inside the displayed composite component. Category middle-object determinacy identifies the prefixed middle endpoints $\mathsf{append}(q, a)$ and $\mathsf{append}(q', a)$. Cancellation of the shared suffix a gives $\mathsf{hsame}(q, q')$. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp middle prefix deterministic`

Theorem 63.40 (NatTrans prefix component vertical composite source-prefix determinacy)**.** *For prefix components over unary histories, if η is a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(q, a)$*, θ is a component from* $\mathsf{append}(q, a)$ *to* $\mathsf{append}(r, a)$*,* $\mathsf{Cont}(\eta, \theta, \eta\theta)$*, and the same composite history $\eta\theta$ is displayed as a component from* $\mathsf{append}(s, a)$ *to* $\mathsf{append}(r, a)$*, then* $\mathsf{hsame}(p, s)$*.*

Proof. First close the vertical composite of η and θ, obtaining a component carrier from prefix p to prefix r over the object a. Apply source-prefix determinacy to this composed carrier and the displayed carrier with source prefix s, both targeting prefix r. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp source prefix deterministic`

Theorem 63.41 (NatTrans prefix component source-prefix determinacy)**.** *For prefix components over unary histories, if a fixed component history η is a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(q, a)$ *and also from* $\mathsf{append}(r, a)$ *to* $\mathsf{append}(q, a)$*, then* $\mathsf{hsame}(p, r)$*.*

Proof. Unpack both prefix-component carrier witnesses to their underlying category hom-carrier witnesses. Category source determinacy identifies $\mathsf{append}(p, a)$ and $\mathsf{append}(r, a)$, and cancellation of the shared suffix a identifies the prefixes p and r. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier source prefix deterministic`

Theorem 63.42 (NatTrans prefix component tail commutativity)**.** *For prefix components over unary histories, if η is a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(q, a)$*, θ is a component from* $\mathsf{append}(q, a)$ *to* $\mathsf{append}(r, a)$*,* $\mathsf{Cont}(\eta, \theta, \eta\theta)$*, and* $\mathsf{Cont}(\theta, \eta, \theta\eta)$*, then* $\mathsf{hsame}(\eta\theta, \theta\eta)$*.*

Proof. Each prefix-component carrier exposes an underlying category hom-carrier. The two hom-carriers expose unary membership for η and θ, and unary continuation commutativity identifies the forward and reversed component composites. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier tail comm hsame`

Theorem 63.43 (NatTrans prefix component vertical composite tail comm closure)**.** *For prefix components over unary histories, if η is a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(q, a)$*, θ is a component from* $\mathsf{append}(q, a)$ *to* $\mathsf{append}(r, a)$*,* $\mathsf{Cont}(\eta, \theta, \eta\theta)$*, and* $\mathsf{Cont}(\theta, \eta, \theta\eta)$*, then $\eta\theta$ is a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(r, a)$*, and* $\mathsf{hsame}(\eta\theta, \theta\eta)$*.*

Proof. Vertical composition closure supplies the component carrier for the forward composite. Tail commutativity of the same two component carriers identifies the forward and reversed continuation results. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp tail comm closed`

Theorem 63.44 (NatTrans prefix component vertical composite tail comm public readback)**.** *For prefix components over unary histories, if η is a component from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(q, a)$*, θ is a component from* $\mathsf{append}(q, a)$ *to* $\mathsf{append}(r, a)$*, and both* $\mathsf{Cont}(\eta, \theta, \eta\theta)$ *and* $\mathsf{Cont}(\theta, \eta, \theta\eta)$ *hold, then both displayed composites are components from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(r, a)$*, they are history-same, and any other displayed component with the same endpoints reads back to both.*

Proof. Vertical composition closure gives the forward component. Tail commutativity identifies the forward and reversed continuation results, and hsame transport moves the forward component carrier across that identification to the reversed component. The public readback row for vertical composition identifies the forward composite with any displayed component at the same endpoints; composing this comparison with tail commutativity gives the reversed readback. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp tail comm public readback`

Theorem 63.45 (NatTrans prefix component vertical cycle empty components)**.** *For prefix components over a fixed object a, if components run from p to q and from q back to p, then the empty component is displayed in both directions and* $\mathsf{hsame}(p, q)$.

Proof. Unpack both component carriers to their category hom-carrier fields and apply the two-way endpoint cycle theorem. Repack the empty hom-carriers with the original unary witnesses, then cancel the common right suffix a. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert cycle empty components`

Theorem 63.46 (NatTrans prefix component vertical triangle empty components)**.** *For prefix components over a fixed object a, if components run from p to q, from q to r, and from r back to p, then the empty component is displayed on all three sides and the adjacent prefixes collapse.*

Proof. Unpack the three component carriers to their category hom-carrier fields and apply triangular empty hom exactness at the appended endpoints. Repack the empty hom-carriers with the original unary witnesses, then cancel the common suffix. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert triangle cycle empty components`

Theorem 63.47 (Prefix identity naturality square)**.** *For the unary-continuation category, let p be unary and let f be a hom-carrier from a to b. If the two square composites are obtained by composing f with the empty continuation on the left and on the right, then both composites are hom-carriers from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, b)$*, and the two composites are history-same.*

Proof. The left empty continuation identifies the left composite with f, and the right empty continuation identifies the right composite with f. The given hom-carrier therefore supplies both unprefixed sides of the square. Prefix hom-carrier preservation sends both sides across p, and transitivity of history sameness identifies the composites. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixIdentity naturality square`

Theorem 63.48 (Prefix identity component square closure)**.** *For the unary-continuation category, if p and a are unary,* $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, id)$*,* $\mathsf{Cont}(id, \mathsf{e}, left)$*, and* $\mathsf{Cont}(\mathsf{e}, id, right)$*, then $left$ and $right$ are hom-carriers from* $\mathsf{append}(p, a)$ *to* $\mathsf{append}(p, a)$*, and* $\mathsf{hsame}(left, right)$.

Proof. The prefix identity hom-carrier theorem gives the carrier witness for id at the prefixed object. The right unit continuation identifies $left$ with id, and the left unit continuation identifies $right$ with id. Transporting the identity carrier witness across these equalities gives both legs of the component square, and transitivity of hsame closes the square. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixIdentity identity component square closed`

Theorem 63.49 (Prefix identity component square public readback)**.** *For unary p, a, if id is an empty identity continuation, $left$ and $right$ are its two unit composites, and $displayed$ is a displayed prefix component from p to itself at a, then* $\mathsf{hsame}(left, displayed) \wedge \mathsf{hsame}(right, displayed)$.

Proof. The identity component square closure supplies hom-carriers for the two legs. The displayed component exposes the same hom-carrier endpoints, so hom-carrier morphism determinacy compares both legs with the displayed component. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixIdentity identity component square public readback`

Theorem 63.50 (NatTrans prefix component empty component semantic name certificate)**.** *For fixed histories p, q, a, any empty component witness* $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \mathsf{e})$ *licenses the component predicate* $\eta \mapsto \mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta)$ *as a semantic naming certificate with source, pattern, and ledger equal to that predicate and classifier* hsame*.*

Proof. The supplied empty component is the carrier witness. The classifier rows are the reflexive, symmetric, and transitive laws for hsame. Carrier transport keeps the fixed prefix and object witnesses and transports the underlying category hom-carrier along the displayed component-history sameness. Since source, pattern, and ledger are the same predicate, the soundness rows are direct projections. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier empty component semanticNameCert`

Theorem 63.51 (NatTrans prefix component identity semantic name certificate)**.** *For unary histories p, a, the identity prefix-component predicate* $\eta \mapsto \mathsf{NatTransPrefixComponentCarrier}(p, p, a, \eta)$ *carries a semantic naming certificate whose source, pattern, and ledger predicates are this component predicate and whose classifier is* hsame*.*

Proof. The carrier witness is the empty component history. Unary append closure gives the object carrier for $\mathsf{append}(p, a)$, and the category empty identity hom-carrier supplies the component witness at that object. The classifier laws are the reflexive, symmetric, and transitive laws for hsame, and component carrier transport follows by history-sameness transport. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier identity semanticNameCert`

Theorem 63.52 (NatTrans prefix component empty component opposite closure)**.** *For histories $p, q, a, \eta : \mathsf{BHist}$, an empty prefix component from p to q over a also carries the component with the prefixes reversed:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta) \wedge \eta \mathsf{hsame} \mathsf{e} \implies \mathsf{NatTransPrefixComponentCarrier}(q, p, a, \eta).$$

Proof. Transport η to e and apply prefix-component empty-identity exactness. The forward component exposes unary carriers for p, q, and a, together with $p \mathsf{hsame} q$. Symmetry of hsame gives $q \mathsf{hsame} p$, and the same empty-identity exactness theorem rebuilds the reversed prefix component. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier empty component opposite closed`

Theorem 63.53 (NatTrans prefix component classifier empty component opposite closure)**.** *For histories $p, q, a, \eta, \theta : \mathsf{BHist}$, if a prefix component classifier relates two empty displayed components from p to q over a, then it also relates them after reversing the endpoint prefixes:*

$$\mathsf{NatTransPrefixComponentClassifier}(p, q, a, \eta, \theta) \wedge \eta \mathsf{hsame} \mathsf{e} \wedge \theta \mathsf{hsame} \mathsf{e} \implies \mathsf{NatTransPrefixComponentClassifier}(q, p,$$

Proof. Project the classifier into its two component-carrier rows. Empty-component opposite closure reverses the endpoint prefixes for η and for θ separately. The classifier relation is then rebuilt from the reversed carrier rows and the original component equality $\eta \mathsf{hsame} \theta$. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier empty component opposite closed`

Theorem 63.54 (NatTrans vertical empty result opposite closure)**.** *For histories p, q, r, a, η, θ : BHist, if components $p \to q$ and $q \to r$ over a vertically compose with empty result, then the empty component also carries the opposite endpoint direction $r \to p$:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta) \wedge \mathsf{NatTransPrefixComponentCarrier}(q, r, a, \theta) \wedge \mathsf{Cont}(\eta, \theta, \mathsf{e}) \implies \mathsf{NatTransPr}$$

Proof. First close the vertical composite, obtaining the empty component from p to r over a. Apply empty-component opposite closure to this component with reflexive $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$, which reverses the endpoint prefixes. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp empty result opposite closed`

Theorem 63.55 (NatTrans vertical empty result componentwise opposite closure)**.** *For histories p, q, r, a, η, θ : BHist, if components $p \to q$ and $q \to r$ over a vertically compose with empty result, then each displayed component also carries its opposite endpoint direction:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta) \wedge \mathsf{NatTransPrefixComponentCarrier}(q, r, a, \theta) \wedge \mathsf{Cont}(\eta, \theta, \mathsf{e}) \implies \mathsf{NatTransPr}$$

Proof. Apply vertical empty-result exactness to the two component carriers. It identifies both component histories with e. Empty-component opposite closure then reverses the endpoints of the first component and of the second component separately, preserving the displayed component histories. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp empty result components opposite closed`

Theorem 63.56 (NatTrans vertical empty result classifier componentwise opposite closure)**.** *For histories $p, q, r, a, \eta, \eta', \theta, \theta'$: BHist, if two prefix-component classifiers form a vertical pair and both displayed component rows compose to the empty history, then each classifier also closes under the componentwise opposite endpoint direction:*

$$\mathsf{NatTransPrefixComponentClassifier}(p, q, a, \eta, \eta') \wedge \mathsf{NatTransPrefixComponentClassifier}(q, r, a, \theta, \theta') \wedge \mathsf{Cont}(\eta, \theta, \mathsf{e}) \wedge \mathsf{Cont}$$

Proof. Apply classifier empty-result component readback to the two vertical continuations. It identifies all four displayed component histories with e. The classifier empty-component opposite closure then reverses the first classifier from $p \to q$ to $q \to p$ and the second from $q \to r$ to $r \to q$, preserving the original classifier comparisons inside each row. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier vert comp empty result components opposite closed`

Theorem 63.57 (NatTrans vertical empty result prefix readback)**.** *For histories p, q, r, a, η, θ : BHist, if components $p \to q$ and $q \to r$ over a vertically compose with empty result, then the adjacent prefixes agree:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta) \wedge \mathsf{NatTransPrefixComponentCarrier}(q, r, a, \theta) \wedge \mathsf{Cont}(\eta, \theta, \mathsf{e}) \implies \mathsf{hsame}(p, q)$$

Proof. Apply category empty-composite exactness to the two underlying component hom-carriers. It identifies the adjacent prefixed endpoints with the shared object suffix a. Right cancellation removes that common suffix and yields $\mathsf{hsame}(p, q)$ and $\mathsf{hsame}(q, r)$. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp empty result prefixes hsame`

Theorem 63.58 (NatTrans vertical empty result endpoint cycle closure)**.** *For histories p, q, r, a, η, θ : BHist, if components $p \to q$ and $q \to r$ over a vertically compose with empty result, then the empty composite closes both endpoint directions and collapses all three prefixes:*

$$\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta) \wedge \mathsf{NatTransPrefixComponentCarrier}(q, r, a, \theta) \wedge \mathsf{Cont}(\eta, \theta, \mathsf{e}) \Longrightarrow \mathsf{NatTransPr}$$

Proof. Apply the vertical composition closure of Definition 63.13 to the two input component carriers and the empty continuation ledger. This gives the forward empty component from p to r over a.

Apply Definition 63.54 to the same two component carriers and the same empty continuation ledger. This gives the reversed empty component from r to p over a.

Apply Definition 63.57 to read back $\mathsf{hsame}(p, q)$ and $\mathsf{hsame}(q, r)$. Transitivity of hsame then gives $\mathsf{hsame}(p, r)$, and the five witnesses are packed in the displayed order. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp empty result cycle closed`

63.2 The certificate

Definition 63.59 (NatTrans source specification)**.** *The source is two certified functors sharing the same certified source and target categories.*

Definition 63.60 (NatTrans pattern specification)**.** *The pattern is component-family formation with one codomain morphism per source object.*

Definition 63.61 (NatTrans classifier specification)**.** *The classifier relates natural transformations componentwise by the target category morphism classifier.*

Definition 63.62 (NatTrans prefix component classifier)**.** *For fixed prefixes p, q and a fixed source object history a, the displayed component classifier is*

$$\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \theta)$$

when $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta)$ *and* $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \theta)$ *both hold and* $\eta\mathsf{hsame}\theta$*. Thus a classified component is not only an equality witness between histories; it also carries both displayed endpoints in the target-category hom-carrier interface.*

Lean4 (definition) `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier`

Theorem 63.63 (NatTrans prefix component classifier equivalence fields)**.** *For fixed prefixes p, q and object history a, the relation* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}$ *has the component fields required by the certificate:*

1. *if* $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta)$ *holds, then* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \eta)$*;*
2. *if* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \theta)$ *holds, then* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\theta, \eta)$*;*
3. *if* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \theta)$ *and* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\theta, \iota)$ *hold, then* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \iota)$*;*

4. if $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta)$ *and* $\eta\mathsf{hsame}\eta'$ *hold, then* $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta')$

Proof. Reflexivity packages the given component carrier twice with the reflexive hsame proof for η. Symmetry swaps the two carried endpoints and uses symmetry of hsame.

For transitivity, unpack the two classifier witnesses. The middle component is carried on both sides over the same fixed prefixes and object, and transitivity of hsame identifies the two outer component histories. Repack the original left carrier, the original right carrier, and the composite hsame witness.

For carrier transport, unfold $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta)$ to the underlying CategoryHomCarrier component from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$. The source and target endpoint fields are unchanged; the displayed component field transports along the supplied $\eta\mathsf{hsame}\eta'$ witness, yielding the carrier for η'. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier equivalence fields`

Theorem 63.64 (NatTrans prefix component classifier history transport)**.** *If the source prefix, target prefix, source object, and both displayed component histories are transported along* hsame*, then the prefix component classifier transports to the displayed endpoints. The transported statement also exposes the two transported category hom-carrier fields.*

Proof. Unpack the classifier into the three unary endpoint carriers, the two append-indexed category hom-carriers, and the displayed component classifier. The source and target append endpoints transport along the prefix and object hsame witnesses. Apply category hom-carrier transport to each displayed component history, then compose the original component hsame witness with the two displayed transport witnesses. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier hsame transport`

Theorem 63.65 (NatTrans prefix component classifier zero-headed component impossibility)**.** *If* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \theta)$ *holds, then none of* p, q, a, η, θ *can be a zero-headed history.*

Proof. Unpack the classifier into the three unary prefix/object fields, the two append-indexed category hom-carrier fields, and the displayed component hsame witness. Zero-headed p, q, or a contradicts the corresponding unary field. Zero-headed η or θ contradicts the unary morphism field inside the corresponding category hom-carrier. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier zero headed component absurd`

Theorem 63.66 (NatTrans prefix component classifier semantic name certificate)**.** *If the empty component inhabits* $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \mathsf{e})$*, then the displayed component carrier, used simultaneously as source, pattern, and ledger policy, together with* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}$ *forms a semantic name certificate.*

Proof. The empty component gives the carrier witness. Reflexivity, symmetry, and transitivity are obtained by unpacking the fixed prefix and object fields and using reflexivity, symmetry, and transitivity of hsame on displayed components. Carrier transport follows from the classifier's second carried CategoryHomCarrier endpoint over $\mathsf{append}(p, a)$ and $\mathsf{append}(q, a)$. Since source, pattern, and ledger are the same concrete component carrier, the two semantic soundness maps are identity projections. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier semanticNameCert`

Theorem 63.67 (NatTrans prefix component classifier component semantic name certificate)**.** *If* $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta)$ *is inhabited by a concrete component, then the displayed component carrier, used simultaneously as source, pattern, and ledger policy, together with* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}$ *forms a semantic name certificate.*

Proof. The supplied component gives the carrier witness. The reflexive, symmetric, and transitive classifier laws are obtained by unpacking the fixed unary prefix and object fields and applying the corresponding hsame law to the component history. Carrier transport reads the target component carrier directly from the classifier witness. The source, pattern, and ledger predicates are the same component carrier, so the semantic soundness maps preserve the witness unchanged. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier component semanticNameCert`

Theorem 63.68 (NatTrans prefix component classifier vertical composition congruence)**.** *For histories* $p, q, r, a, \eta, \eta', \theta, \theta', c, c'$*, if* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \eta')$*,* $\mathsf{NatTransPrefixComponentClassifier}_{q,r,}$ $\mathsf{Cont}(\eta, \theta, c)$*, and* $\mathsf{Cont}(\eta', \theta', c')$*, then*

$$\mathsf{NatTransPrefixComponentClassifier}_{p,r,a}(c, c').$$

Proof. Unpack the two classifier witnesses. The first gives component carriers for η and η' from prefix p to prefix q at a, together with $\eta\mathsf{hsame}\eta'$. The second gives component carriers for θ and θ' from prefix q to prefix r at a, together with $\theta\mathsf{hsame}\theta'$.

Apply Theorem 63.13 to the carriers for η and θ and the witness $\mathsf{Cont}(\eta, \theta, c)$. This gives a component carrier for c from prefix p to prefix r at a. Apply the same closure theorem to η', θ', and $\mathsf{Cont}(\eta', \theta', c')$ to obtain the matching carrier for c'.

It remains to identify the two composite histories. The finite-kernel continuation hsame-congruence theorem transports the continuation witness for η and θ across $\eta\mathsf{hsame}\eta'$ and $\theta\mathsf{hsame}\theta'$, and continuation result determinacy compares the transported composite with the displayed witness for c'. Hence $c\mathsf{hsame}c'$.

Repack the carrier for c, the carrier for c', and the resulting $c\mathsf{hsame}c'$ witness into $\mathsf{NatTransPrefixComponentClassi}$ □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier vert comp congr`

Theorem 63.69 (NatTrans prefix component classifier right-identity closure)**.** *For histories* $p, q, a, \eta, \eta', r, r'$*, suppose* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \eta')$ *holds and suppose* $\mathsf{Cont}(\eta, \mathsf{e}, r)$ *and* $\mathsf{Cont}(\eta', \mathsf{e}, r')$*. Then*

$$\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(r, r') \wedge r\mathsf{hsame}r'.$$

Proof. Right-unit determinacy identifies r with η and r' with η'. Transport the prefix component classifier along these endpoint equalities, with the prefix and object histories fixed. The transported classifier contains the required endpoint comparison $r\mathsf{hsame}r'$. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier vert comp right identity closed`

Theorem 63.70 (NatTrans prefix component classifier empty composite readback)**.** *For histories* $p, q, r, a, \eta, \eta', \theta, \theta'$*, suppose*

$$\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \eta') \quad \textit{and} \quad \mathsf{NatTransPrefixComponentClassifier}_{q,r,a}(\theta, \theta')$$

and suppose $\mathsf{Cont}(\eta, \theta, \mathsf{e})$*. Then the two displayed leading components classify against the empty component, and the adjacent prefixes are history-same:*

$$\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \mathsf{e}) \wedge \mathsf{NatTransPrefixComponentClassifier}_{q,r,a}(\theta, \mathsf{e}) \wedge p\mathsf{hsame}q \wedge q\mathsf{hsame}r.$$

Proof. Read the two carrier rows out of the classifier witnesses and apply the carrier-level empty-composite readback. This supplies empty component carriers for the two rows and the two prefix equalities. The corresponding empty-composite iff also gives $\eta\mathsf{hsame}\mathsf{e}$ and $\theta\mathsf{hsame}\mathsf{e}$. Repacking the original carried morphism rows, the empty component rows, and these history-same witnesses gives the two classifier rows against e. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier vert comp empty result readback`

Theorem 63.71 (NatTrans classifier vertical empty-result component readback)**.** *For histories* $p, q, r, a, \eta, \eta', \theta, \theta', c, c'$*, suppose* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \eta')$ *and* $\mathsf{NatTransPrefixComponentClassifie}$ *hold. If* $\mathsf{Cont}(\eta, \theta, c)$*,* $\mathsf{Cont}(\eta', \theta', c')$*,* $c\mathsf{hsame}\mathsf{e}$*, and* $c'\mathsf{hsame}\mathsf{e}$*, then the four component histories are empty and the adjacent prefixes agree:*

$$\mathsf{hsame}(\eta, \mathsf{e}) \wedge \mathsf{hsame}(\eta', \mathsf{e}) \wedge \mathsf{hsame}(\theta, \mathsf{e}) \wedge \mathsf{hsame}(\theta', \mathsf{e}) \wedge \mathsf{hsame}(p, q) \wedge \mathsf{hsame}(q, r).$$

Proof. Project the carrier fields for $\eta, \eta', \theta, \theta'$ from the two classifier witnesses. Apply vertical composite result-empty exactness to the primary components η, θ and to the secondary components η', θ'. The primary readback supplies emptiness of η and θ together with $p\mathsf{hsame}q$ and $q\mathsf{hsame}r$; the secondary readback supplies emptiness of η' and θ'. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier vert comp empty result components`

Theorem 63.72 (NatTrans classifier vertical empty-result cycle closure)**.** *For histories* $p, q, r, a, \eta, \eta', \theta, \theta'$*, suppose* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \eta')$ *and* $\mathsf{NatTransPrefixComponentClassifier}_{q,r,a}(\theta, \theta')$ *hold. If* $\mathsf{Cont}(\eta, \theta, \mathsf{e})$ *and* $\mathsf{Cont}(\eta', \theta', \mathsf{e})$*, then*

$$\mathsf{NatTransPrefixComponentClassifier}_{p,r,a}(\mathsf{e}, \mathsf{e}) \wedge \mathsf{NatTransPrefixComponentClassifier}_{r,p,a}(\mathsf{e}, \mathsf{e}) \\ \wedge\, p\mathsf{hsame}q \wedge q\mathsf{hsame}r \wedge p\mathsf{hsame}r.$$

Proof. Vertical classifier congruence composes the two displayed classifier rows and gives the forward empty classifier from p to r. The empty-result component readback supplies the four empty component witnesses and the adjacent prefix equalities $p\mathsf{hsame}q$ and $q\mathsf{hsame}r$. Since the forward component is empty, the empty-component opposite closure gives the reverse classifier from r to p. Transitivity of hsame gives $p\mathsf{hsame}r$. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier vert comp empty result cycle closed`

Theorem 63.73 (NatTrans classifier empty-result opposite package)**.** *For histories* $p, q, r, a, \eta, \eta', \theta, \theta', c, c' :$ BHist*, suppose* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}(\eta, \eta')$ *and* $\mathsf{NatTransPrefixComponentClassifier}_{q,r,a}(\theta, \theta')$ *hold. If* $\mathsf{Cont}(\eta, \theta, c)$*,* $\mathsf{Cont}(\eta', \theta', c')$*,* $c\mathsf{hsame}\mathsf{e}$*, and* $c'\mathsf{hsame}\mathsf{e}$*, then both classified components admit the opposite prefix direction and the adjacent prefixes agree:*

$$\mathsf{NatTransPrefixComponentClassifier}_{q,p,a}(\eta, \eta') \wedge \mathsf{NatTransPrefixComponentClassifier}_{r,q,a}(\theta, \theta') \wedge \mathsf{hsame}(p, q) \wedge \mathsf{hsame}(q, r)$$

Proof. Unpack the two classifier witnesses. They provide carrier witnesses for η, η' from prefix p to prefix q over a and for θ, θ' from prefix q to prefix r over a, together with $\eta\mathsf{hsame}\eta'$ and $\theta\mathsf{hsame}\theta'$.

Apply Theorem 63.71 to the two classifiers, the two continuation witnesses, and the two empty result identifications. This identifies all four displayed component histories with e and supplies $\mathsf{hsame}(p, q)$ and $\mathsf{hsame}(q, r)$.

Now apply Theorem 63.52 separately to the carrier witnesses for η, η', θ, and θ'. The four emptiness witnesses reverse the first classified pair from $p \to q$ to $q \to p$ and the second classified pair from $q \to r$ to $r \to q$.

Repack the reversed carrier witnesses with the original $\eta\mathsf{hsame}\eta'$ and $\theta\mathsf{hsame}\theta'$ witnesses. The two rebuilt classifiers, together with the prefix agreements produced by readback, give the claimed package. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier empty result opposite package`

Theorem 63.74 (NatTrans vertical composite zero-headed component impossibility)**.** *For vertically composable prefix component classifiers, none of the three prefixes, the shared source object, the four input component histories, or the two composite component histories can be zero-headed.*

Proof. First form the composite prefix component classifier by vertical composition congruence. Zero-headed source-prefix, middle-prefix, object, or left component cases are rejected by the left classifier. Zero-headed middle-prefix, target-prefix, object, or right component cases are rejected by the right classifier. Zero-headed composite endpoints are rejected by the composite classifier. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier vert comp zero headed component absurd`

Definition 63.75 (NatTrans stability certificate)**.** *The stability certificate consists of:*

1. *componentwise reflexivity*
2. *componentwise symmetry*
3. *componentwise transitivity*
4. *component carrier transport along* hsame *of displayed component histories*
5. *naturality square validity for every source morphism*
6. *stability of naturality under component classifier replacement*
7. *vertical composition closure*
8. *identity natural transformation closure*

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier stability certificate fields`

Definition 63.76 (NatTrans ledger policy)**.** *Record the functor ledgers, component morphism ledgers, and naturality derivations.*

Definition 63.77 ($\mathsf{NatTrans}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{NatTrans}^{\uparrow}$*.*

Primitive boundary. $\mathsf{NatTrans}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 63.78 (Zero-axiom encoding note)**.** *Avoids funext by componentwise classifier sameness.*

Theorem 63.79 (NatTrans prefix vertical composite prefix closure)**.** *For unary histories u, p, q, r, a, if η is a prefix component from p to q over a, θ is a prefix component from q to r over a, and $\mathsf{Cont}(\eta, \theta, \mathit{composite})$, then the displayed composite is also a prefix component after prefixing both endpoint prefixes by u:*

$$\mathsf{NatTransPrefixComponentCarrier}(\mathsf{append}(u, p), \mathsf{append}(u, r), a, \mathit{composite}).$$

Proof. The vertical composite first closes as a category hom-carrier from $\mathsf{append}(p, a)$ to $\mathsf{append}(r, a)$. Prefix functoriality by u carries that hom-carrier to endpoints $\mathsf{append}(u, \mathsf{append}(p, a))$ and $\mathsf{append}(u, \mathsf{append}(r, a))$. Associativity of BEDC append transports those endpoints to $\mathsf{append}(\mathsf{append}(u, p), a)$ and $\mathsf{append}(\mathsf{append}(u, r), a)$, which are exactly the component carrier endpoints. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier prefix vert comp closed`

Theorem 63.80 (NatTrans prefix component vertical composite endpoint cycle boundary)**.** *For prefix components over a common object a, if η goes from p to q, θ goes from q to r, their vertical composite displays composite, and $\mathsf{hsame}(p, r)$, then the two components and their composite are empty and the intermediate prefixes collapse:*

$$\mathsf{hsame}(\eta, \mathsf{e}) \wedge \mathsf{hsame}(\theta, \mathsf{e}) \wedge \mathsf{hsame}(\mathit{composite}, \mathsf{e}) \wedge \mathsf{hsame}(p, q) \wedge \mathsf{hsame}(q, r).$$

Proof. Unpack the two prefix components to category hom-carriers between $\mathsf{append}(p, a)$, $\mathsf{append}(q, a)$, and $\mathsf{append}(r, a)$. The endpoint equality $\mathsf{hsame}(p, r)$ extends across the shared suffix a. The category endpoint-cycle boundary theorem then gives empty component and composite histories plus endpoint equalities; cancelling the common suffix a gives $\mathsf{hsame}(p, q)$ and $\mathsf{hsame}(q, r)$. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp endpoint cycle boundary`

Theorem 63.81 (NatTrans prefix component vertical composite nonempty source visibility)**.** *For prefix components over a common object a, if η goes from p to q, θ goes from q to r, their vertical composite displays $\mathsf{E1}(k)$, and the source endpoint $\mathsf{append}(p, a)$ is not history-same to e, then both component endpoints are visible:*

$$\exists s, t.\ \mathsf{append}(p, a) = \mathsf{E1}(s) \wedge \mathsf{append}(r, a) = \mathsf{E1}(t) \wedge \mathsf{UnaryHistory}(s) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(t) \wedge \mathsf{Cont}(\mathsf{E1}(s), \mathsf{E1}$$

Proof. Unpack both prefix components to their underlying category hom-carriers and apply category source-target case analysis to the displayed nonempty composite result. The empty-source branch contradicts the source nonemptiness assumption. In the visible-source branch, one-constructor inversion on the displayed result identifies the payload with k, leaving exactly the visible source endpoint, visible target endpoint, unary tail witnesses, and the visible continuation ledger. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp nonempty result source visible`

Theorem 63.82 (NatTrans prefix component vertical composite source-target cases)**.** *For prefix components over a common object a, if η goes from p to q, θ goes from q to r, and their vertical composite displays* $\mathsf{E1}(k)$*, then either the source endpoint* $\mathsf{append}(p, a)$ *is history-same to* e *and the target endpoint is visible, or both source and target endpoints are visible:*

$$(\mathsf{hsame}(\mathsf{append}(p,a),\mathsf{e}) \wedge \exists t.\ \mathsf{append}(r,a) = \mathsf{E1}(t) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(t) \wedge \mathsf{Cont}(\mathsf{append}(p,a),\mathsf{E1}(k),\mathsf{E}$$
$$\vee\ (\exists s,t.\ \mathsf{append}(p,a) = \mathsf{E1}(s) \wedge \mathsf{append}(r,a) = \mathsf{E1}(t) \wedge \mathsf{UnaryHistory}(s) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(t) \wedge \mathsf{Co}$$

Proof. Unpack both prefix components to category hom-carriers and apply the category-level source-target case analysis for a nonempty composite result. The empty-source branch gives the source endpoint comparison and the visible target payload; the visible-source branch gives the visible source payload, the same visible result payload, the visible target payload, and the displayed continuation ledger. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp nonempty result source target cases`

Theorem 63.83 (NatTrans prefix component nonempty right-identity visible readback)**.** *For prefix components over a common object a, if η goes from p to q, θ goes from q to r, their vertical composite displays* $\mathsf{E1}(k)$*, the right-identity continuation displays* $\mathsf{Cont}(\mathsf{E1}(k), \mathsf{e}, right)$*, and the source endpoint* $\mathsf{append}(p, a)$ *is not history-same to* e*, then $right$ is a component from p to r,* $right\mathsf{hsameE1}(k)$*, and the source-visible readback exposes visible source and target endpoints around the same payload k.*

Proof. First close the vertical composite as a prefix component from p to r with displayed history $\mathsf{E1}(k)$. The right-identity closure for prefix components transports this component along the continuation with empty right factor and records $right\mathsf{hsameE1}(k)$. The existing source-visible nonempty-result readback applied to the original vertical composite supplies the visible source endpoint, visible target endpoint, unary payload witnesses, and the visible continuation ledger. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp nonempty result right identity visible readback`

Theorem 63.84 (NatTrans prefix component nonempty left-identity visible readback)**.** *For prefix components over a common object a, if η goes from p to q, θ goes from q to r, their vertical composite displays* $\mathsf{E1}(k)$*, the left-identity continuation displays* $\mathsf{Cont}(\mathsf{e}, \mathsf{E1}(k), leftResult)$*, and the source endpoint* $\mathsf{append}(p, a)$ *is not history-same to* e*, then $leftResult$ is a component from p to r,* $leftResult\mathsf{hsameE1}(k)$*, and the source-visible readback exposes visible source and target endpoints around the same payload k.*

Proof. First close the vertical composite as a prefix component from p to r with displayed history $\mathsf{E1}(k)$. The left-identity closure for prefix components transports this component along the continuation with empty left factor and records $leftResult\mathsf{hsameE1}(k)$. The source-visible nonempty-result readback applied to the original vertical composite supplies the visible source endpoint, visible target endpoint, unary payload witnesses, and the visible continuation ledger. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier vert comp nonempty result left identity visible readback`

Theorem 63.85 (NatTrans vertical composition naturality)**.** *Let F, G, and H be certified* $\mathsf{Functor}^{\uparrow}$ *carriers with the same certified source category and target category. Let $\alpha : F \Rightarrow G$ and $\beta : G \Rightarrow H$ be admitted* $\mathsf{NatTrans}^{\uparrow}$ *carriers. For every source morphism $f : C \to C'$, the vertical component family $(\beta \circ \alpha)_X = \beta_X \circ \alpha_X$ satisfies the target morphism-classifier naturality square*

$$H(f) \circ (\beta \circ \alpha)_C \sim (\beta \circ \alpha)_{C'} \circ F(f).$$

Proof. The shared source and target categories are part of the $\mathsf{NatTrans}^{\uparrow}$ source specification in Definition 63.59. By the functor carrier definition in Definition 62.1, the symbols $F(f)$, $G(f)$, and $H(f)$ denote the corresponding target-category morphism images. By Definition 63.1, each admitted natural transformation is an object-indexed component family with a naturality witness for every source morphism.

The $\mathsf{NatTrans}^{\uparrow}$ stability certificate in Definition 63.75 includes vertical composition closure. Applying that field to α and β gives an admitted $\mathsf{NatTrans}^{\uparrow}$ carrier from F to H whose component at X is $\beta_X \circ \alpha_X$. The same stability certificate lists naturality square validity for every source morphism, so applying that naturality field to this composite carrier and to $f : C \to C'$ gives

$$H(f) \circ (\beta \circ \alpha)_C \sim (\beta \circ \alpha)_{C'} \circ F(f).$$

This is the displayed classifier witness for the composite component family. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentFamilyCarrier vert comp closed`

Definition 63.86 (Opposite natural transformation certificate data)**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be* $\mathsf{Cat}^{\uparrow}$ *certificates, let $F, G : \mathcal{C} \to \mathcal{D}$ be* $\mathsf{Functor}^{\uparrow}$ *certificates, and let $\alpha : F \Rightarrow G$ be a* $\mathsf{NatTrans}^{\uparrow}$ *certificate with component family $\alpha_X : F_0(X) \to G_0(X)$ in $\mathcal{D}$. Over the opposite-functor certificates of Definition 62.85, define $\alpha^{\mathrm{op}} : G^{\mathrm{op}} \Rightarrow F^{\mathrm{op}}$ by the same raw component family*

$$(\alpha^{\mathrm{op}})_X := \alpha_X.$$

The component is typed in $\mathcal{D}^{\mathrm{op}}$ because the hom-carrier of Definition 61.327 reads the original morphism $\alpha_X : F_0(X) \to G_0(X)$ as a displayed morphism $G_0(X) \to F_0(X)$. For a displayed morphism $u : X \to Y$ in $\mathcal{C}^{\mathrm{op}}$, the naturality ledger is the classifier-symmetric form of the original naturality ledger for the same raw morphism $u : Y \to X$ in $\mathcal{C}$, with both target composites read through opposite composition.

Theorem 63.87 (Opposite natural transformation certificate)**.** *If $\mathcal{C}$ and $\mathcal{D}$ satisfy the* $\mathsf{Cat}^{\uparrow}$ *certificate obligations, $F, G : \mathcal{C} \to \mathcal{D}$ satisfy the* $\mathsf{Functor}^{\uparrow}$ *certificate obligations, and $\alpha : F \Rightarrow G$ satisfies the* $\mathsf{NatTrans}^{\uparrow}$ *certificate obligations of Definition 63.77, then the data of Definition 63.86 satisfy the* $\mathsf{NatTrans}^{\uparrow}$ *certificate obligations from G^{op} to F^{op} over $\mathcal{C}^{\mathrm{op}}$ and $\mathcal{D}^{\mathrm{op}}$.*

Proof. By Definition 61.328, the source and target opposite data are certified categories. By Definition 62.86, G^{op} and F^{op} are certified functors with common source $\mathcal{C}^{\mathrm{op}}$ and common target $\mathcal{D}^{\mathrm{op}}$. This supplies the source specification required by Definition 63.59.

For the carrier field, let X be a source object. The component field of α gives $\alpha_X : F_0(X) \to G_0(X)$ in $\mathcal{D}$. Since the opposite hom-carrier reverses endpoints and leaves the raw morphism classifier unchanged, the same raw morphism is a component $(\alpha^{\mathrm{op}})_X : G_0^{\mathrm{op}}(X) \to F_0^{\mathrm{op}}(X)$ in $\mathcal{D}^{\mathrm{op}}$. Thus the carrier and pattern fields of Definition 63.1 and Definition 63.60 are the original component family with the endpoints read oppositely.

The classifier field is inherited componentwise. The target morphism classifier of $\mathcal{D}^{\mathrm{op}}$ is the target morphism classifier of $\mathcal{D}$ on the same raw component representatives, so componentwise

reflexivity, transitivity, and classifier replacement are exactly the corresponding fields listed in Definition 63.61 and Definition 63.75 for α.

It remains to check naturality. Let $u : X \to Y$ be displayed in $\mathcal{C}^{\mathrm{op}}$. The same raw morphism is $u : Y \to X$ in $\mathcal{C}$. Naturality of α in $\mathcal{D}$ gives the target morphism-classifier comparison

$$G_1(u) \circ_{\mathcal{D}} \alpha_Y \sim_{\mathcal{D}} \alpha_X \circ_{\mathcal{D}} F_1(u).$$

Applying symmetry of the codomain morphism classifier gives

$$\alpha_X \circ_{\mathcal{D}} F_1(u) \sim_{\mathcal{D}} G_1(u) \circ_{\mathcal{D}} \alpha_Y.$$

By Definition 61.327 and Definition 62.85, these two original composites are exactly

$$F_1^{\mathrm{op}}(u) \circ_{\mathcal{D}^{\mathrm{op}}} (\alpha^{\mathrm{op}})_X$$

and

$$(\alpha^{\mathrm{op}})_Y \circ_{\mathcal{D}^{\mathrm{op}}} G_1^{\mathrm{op}}(u),$$

respectively. Since the morphism classifier is unchanged by the opposite category data, this is the required naturality square in $\mathcal{D}^{\mathrm{op}}$.

The remaining stability and ledger clauses are inherited without changing raw data. Identity components and vertical component composites are the same raw component histories, with their endpoints read in the opposite target category; the naturality argument above applies to each displayed source morphism. The ledger policy of Definition 63.76 therefore records the same functor ledgers, component morphism ledgers, and naturality derivations, now indexed by the two opposite-functor certificates. □

Theorem 63.88 (Double opposite natural transformation certificate data identity)**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates satisfying the category certificate obligations, let $F, G : \mathcal{C} \to \mathcal{D}$ be $\mathsf{Functor}^{\uparrow}$ certificates satisfying the obligations of Definition 62.80, and let $\alpha : F \Rightarrow G$ be a $\mathsf{NatTrans}^{\uparrow}$ certificate satisfying the obligations of Definition 63.77. Write $\alpha_X : F_0(X) \to G_0(X)$ for its component family, and write its naturality row at a displayed morphism $f : X \to Y$ in $\mathcal{C}$ as*

$$G_1(f) \circ_{\mathcal{D}} \alpha_X \sim_{\mathcal{D}} \alpha_Y \circ_{\mathcal{D}} F_1(f).$$

Let

$$\alpha^{\mathrm{opop}} = (\alpha^{\mathrm{op}})^{\mathrm{op}}$$

be obtained by applying Definition 63.86 twice, with the double-opposite source and target categories identified by Definition 61.330 and the double-opposite source and target functors identified by Definition 62.95. Then $\alpha^{\mathrm{opop}} : F^{\mathrm{opop}} \Rightarrow G^{\mathrm{opop}}$ satisfies the $\mathsf{NatTrans}^{\uparrow}$ certificate obligations, and its component family and naturality rows are componentwise identical to those of α:

$$(\alpha^{\mathrm{opop}})_X = \alpha_X,$$

and, for every displayed $f : X \to Y$ in $\mathcal{C}$, the displayed naturality row of α^{opop} is the same target-classifier comparison

$$G_1(f) \circ_{\mathcal{D}} \alpha_X \sim_{\mathcal{D}} \alpha_Y \circ_{\mathcal{D}} F_1(f).$$

The component classifier, stability, and ledger rows that refer only to these component and naturality data are the corresponding rows of α under the same double-opposite identifications.

Proof. Apply Definition 63.87 to α. This supplies a certified natural transformation

$$\alpha^{\mathrm{op}} : G^{\mathrm{op}} \Rightarrow F^{\mathrm{op}}$$

over $\mathcal{C}^{\mathrm{op}}$ and $\mathcal{D}^{\mathrm{op}}$. Applying the same theorem to α^{op} supplies a certified natural transformation

$$\alpha^{\mathrm{opop}} : F^{\mathrm{opop}} \Rightarrow G^{\mathrm{opop}}$$

over $\mathcal{C}^{\mathrm{opop}}$ and $\mathcal{D}^{\mathrm{opop}}$. The source specification is the original one after the identifications supplied by Definition 61.330 and Definition 62.95.

For components, one unfolding of Definition 63.86 gives $(\alpha^{\mathrm{op}})_X = \alpha_X$. A second unfolding gives

$$(\alpha^{\mathrm{opop}})_X = (\alpha^{\mathrm{op}})_X = \alpha_X.$$

The endpoint typing is restored because the double-opposite category data restore the hom-carrier endpoints and the double-opposite functor data restore F_0 and G_0.

For naturality, let $f : X \to Y$ be displayed in $\mathcal{C}$. In the second opposite construction the same raw morphism is read as $f : Y \to X$ in $\mathcal{C}^{\mathrm{op}}$. The naturality row of α^{op} at that opposite morphism is, when read back through the first opposite target category,

$$\alpha_Y \circ_{\mathcal{D}} F_1(f) \sim_{\mathcal{D}} G_1(f) \circ_{\mathcal{D}} \alpha_X,$$

which is the classifier-symmetric form of the original naturality row for α at f. The second opposite construction takes the classifier-symmetric form of this row and reads both target composites through $\mathcal{D}^{\mathrm{opop}}$. By Definition 61.330, the target morphism classifier and composition relation of $\mathcal{D}^{\mathrm{opop}}$ are the original ones of $\mathcal{D}$; by Definition 62.95, the functor morphism maps are again F_1 and G_1. Hence the displayed row is exactly

$$G_1(f) \circ_{\mathcal{D}} \alpha_X \sim_{\mathcal{D}} \alpha_Y \circ_{\mathcal{D}} F_1(f).$$

The classifier specification of Definition 63.61 is componentwise by the target morphism classifier, and that classifier is unchanged after the two opposite readings. The stability fields of Definition 63.75 use the same component transports, naturality rows, identity components, and vertical composites after the endpoint order has been swapped twice. The ledger policy of Definition 63.76 therefore records the original functor ledgers, component ledgers, and naturality derivations under the restored source and target data. □

Definition 63.89 (Identity natural transformation certificate data)**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates, and let $F : \mathcal{C} \to \mathcal{D}$ be a $\mathsf{Functor}^{\uparrow}$ certificate with object map F_0 and morphism map F_1. The identity natural transformation data $\mathsf{id}_F : F \Rightarrow F$ are the component family*

$$(\mathsf{id}_F)_X := \mathsf{id}_{F_0(X)}.$$

For a displayed morphism $u : X \to Y$ in $\mathcal{C}$, the naturality ledger is the target-category identity square comparing

$$F_1(u) \circ_{\mathcal{D}} \mathsf{id}_{F_0(X)} \quad \textit{and} \quad \mathsf{id}_{F_0(Y)} \circ_{\mathcal{D}} F_1(u).$$

Theorem 63.90 (Identity natural transformation certificate)**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates satisfying Definition 61.203, and let $F : \mathcal{C} \to \mathcal{D}$ be a $\mathsf{Functor}^{\uparrow}$ certificate satisfying Definition 62.80. Then the data of Definition 63.89 satisfy the $\mathsf{NatTrans}^{\uparrow}$ certificate obligations from F to F in the sense of Definition 63.77. Its component at each object X is the target identity,*

$$(\mathsf{id}_F)_X = \mathsf{id}_{F_0(X)},$$

and for every displayed source morphism $u : X \to Y$ its naturality row is

$$F_1(u) \circ_{\mathcal{D}} (\mathsf{id}_F)_X \sim_{\mathcal{D}} (\mathsf{id}_F)_Y \circ_{\mathcal{D}} F_1(u).$$

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentFamilyCarrier identity unit laws`

Proof. The source row of Definition 63.59 is the pair (F, F), and the two entries have the same certified source $\mathcal{C}$ and target $\mathcal{D}$ by the displayed $\mathsf{Functor}^{\uparrow}$ certificate for F. The pattern row of Definition 63.60 is component-family formation over objects of $\mathcal{C}$.

For the carrier row, fix an object X of $\mathcal{C}$. The functor carrier of Definition 62.1 sends X to the target object $F_0(X)$ of $\mathcal{D}$. The identity field of the target category, listed in Definition 61.201, supplies a hom-carrier

$$\mathsf{id}_{F_0(X)} : F_0(X) \to F_0(X).$$

This is exactly the component required by Definition 63.1 for a transformation from F to itself.

It remains to check naturality. Let $u : X \to Y$ be displayed in $\mathcal{C}$. By the morphism part of the functor carrier, $F_1(u)$ is a displayed target morphism $F_0(X) \to F_0(Y)$ in $\mathcal{D}$. The two composites in the identity naturality square are the right and left identity composites of this displayed morphism with the target-category identities at $F_0(X)$ and $F_0(Y)$. The category identity-square closure of Definition 61.95, equivalently the left and right identity rows of Definition 61.201, gives both composites as target hom-carriers from $F_0(X)$ to $F_0(Y)$ and gives their morphism-classifier comparison. Substituting the definition of $(\mathsf{id}_F)_X$ and $(\mathsf{id}_F)_Y$ yields the displayed $\mathsf{NatTrans}^{\uparrow}$ naturality row. In the concrete prefix-component realization, this is the same pointwise calculation recorded in Definition 63.47.

The classifier row of Definition 63.61 is componentwise in the target morphism classifier. Hence component reflexivity, symmetry, transitivity, and transport along classified component histories are inherited from the morphism classifier and endpoint transport fields of $\mathcal{D}$. Stability of the naturality row under component-classifier replacement follows by the same target classifier transitivity after replacing the two identity components by classified components at the same endpoints. The identity-transformation closure row in Definition 63.75 is realized by the family above, and the vertical-composition row is the ambient closure operation on admitted component families.

The ledger row of Definition 63.76 records the functor ledger of F on both sides, the target identity ledger at each object $F_0(X)$, and the identity-square derivation for each displayed source morphism. These rows supply the carrier, source, pattern, classifier, stability, and ledger obligations listed in Definition 63.77. □

Definition 63.91 (Functor-whiskered natural transformation data)**.** *Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be $\mathsf{Cat}^{\uparrow}$ certificates. Let $F, G : \mathcal{C} \to \mathcal{D}$ be $\mathsf{Functor}^{\uparrow}$ certificates with object maps F_0, G_0 and morphism maps F_1, G_1, and let $\alpha : F \Rightarrow G$ be a $\mathsf{NatTrans}^{\uparrow}$ certificate with component family $\alpha_X : F_0(X) \to G_0(X)$. Let $H : \mathcal{D} \to \mathcal{E}$ be a $\mathsf{Functor}^{\uparrow}$ certificate with object map H_0 and morphism map H_1. The functor-whiskered data $H_*\alpha : H \circ F \Rightarrow H \circ G$ are the component family*

$$(H_*\alpha)_X := H_1(\alpha_X).$$

For a displayed morphism $u : X \to Y$ in $\mathcal{C}$, the displayed naturality row is the $\mathcal{E}$-morphism-classifier comparison obtained by applying H_1 to the naturality row of α and replacing the images of the two $\mathcal{D}$-composites by the corresponding $\mathcal{E}$-composites through the composition-preservation field of H.

Theorem 63.92 (Functor whiskering of a natural transformation)**.** *Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be $\mathsf{Cat}^{\uparrow}$ certificates satisfying Definition 61.203. Let $F, G : \mathcal{C} \to \mathcal{D}$ and $H : \mathcal{D} \to \mathcal{E}$ be $\mathsf{Functor}^{\uparrow}$ certificates*

satisfying Definition 62.80, with object maps F_0, G_0, H_0 and morphism maps F_1, G_1, H_1. If $\alpha : F \Rightarrow G$ satisfies the $\mathsf{NatTrans}^{\uparrow}$ *certificate obligations of Definition 63.77, then the data of Definition 63.91 satisfy the* $\mathsf{NatTrans}^{\uparrow}$ *carrier and naturality-square fields for a natural transformation*

$$H_*\alpha : H \circ F \Rightarrow H \circ G$$

under the morphism classifier of $\mathcal{E}$. Its component at each object X is

$$(H_*\alpha)_X = H_1(\alpha_X),$$

and for every displayed morphism $u : X \to Y$ in $\mathcal{C}$ its naturality row is

$$H_1(G_1(u)) \circ_{\mathcal{E}} H_1(\alpha_X) \sim_{\mathcal{E}} H_1(\alpha_Y) \circ_{\mathcal{E}} H_1(F_1(u)).$$

Proof. Apply Definition 62.99 to the pairs (F, H) and (G, H). Together with the source, pattern, classifier, stability, and ledger rows listed in Definition 62.80, this reads $H \circ F$ and $H \circ G$ as certified $\mathsf{Functor}^{\uparrow}$ carriers from $\mathcal{C}$ to $\mathcal{E}$. Their object maps are

$$(H \circ F)_0(X) = H_0(F_0(X)), \qquad (H \circ G)_0(X) = H_0(G_0(X)),$$

and their morphism maps are

$$(H \circ F)_1(u) = H_1(F_1(u)), \qquad (H \circ G)_1(u) = H_1(G_1(u)).$$

Thus the source row required by Definition 63.59 is the pair $(H \circ F, H \circ G)$.

For the carrier row, fix an object X of $\mathcal{C}$. The carrier field of α, as specified in Definition 63.1, gives a displayed $\mathcal{D}$-morphism

$$\alpha_X : F_0(X) \to G_0(X).$$

The morphism-map field of the functor carrier H in Definition 62.1 sends this displayed morphism to a displayed $\mathcal{E}$-morphism

$$H_1(\alpha_X) : H_0(F_0(X)) \to H_0(G_0(X)).$$

Using the composite object maps above, this is exactly a component

$$(H_*\alpha)_X : (H \circ F)_0(X) \to (H \circ G)_0(X)$$

of the component-family pattern from Definition 63.60.

It remains to verify the naturality square. Let $u : X \to Y$ be a displayed morphism in $\mathcal{C}$. Naturality of α gives the $\mathcal{D}$-morphism-classifier comparison

$$G_1(u) \circ_{\mathcal{D}} \alpha_X \sim_{\mathcal{D}} \alpha_Y \circ_{\mathcal{D}} F_1(u).$$

The classifier-replacement stability field of the functor H, listed in Definition 62.78 and used in Definition 62.99, transports this comparison through H_1, giving

$$H_1(G_1(u) \circ_{\mathcal{D}} \alpha_X) \sim_{\mathcal{E}} H_1(\alpha_Y \circ_{\mathcal{D}} F_1(u)).$$

The composition-preservation field of H gives

$$H_1(G_1(u) \circ_{\mathcal{D}} \alpha_X) \sim_{\mathcal{E}} H_1(G_1(u)) \circ_{\mathcal{E}} H_1(\alpha_X)$$

and

$$H_1(\alpha_Y \circ_{\mathcal{D}} F_1(u)) \sim_{\mathcal{E}} H_1(\alpha_Y) \circ_{\mathcal{E}} H_1(F_1(u)).$$

Symmetry and transitivity of the $\mathcal{E}$ morphism classifier, recorded in Definition 61.201, compose these three comparisons into

$$H_1(G_1(u)) \circ_{\mathcal{E}} H_1(\alpha_X) \sim_{\mathcal{E}} H_1(\alpha_Y) \circ_{\mathcal{E}} H_1(F_1(u)).$$

Substituting the composite morphism maps and the component definition gives

$$(H \circ G)_1(u) \circ_{\mathcal{E}} (H_*\alpha)_X \sim_{\mathcal{E}} (H_*\alpha)_Y \circ_{\mathcal{E}} (H \circ F)_1(u),$$

which is the required $\mathsf{NatTrans}^{\uparrow}$ naturality field under the morphism classifier of $\mathcal{E}$.

The ledger row of Definition 63.76 records the two composite functor ledgers, the image under H_1 of each component ledger of α, the transported naturality row, and the two composition-preservation rows of H used to identify the displayed source and target composites. □

Definition 63.93 (Prewhiskered natural transformation data)**.** *Let $\mathcal{B}$, $\mathcal{C}$, and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates. Let $K : \mathcal{B} \to \mathcal{C}$ be a $\mathsf{Functor}^{\uparrow}$ certificate with object map K_0 and morphism map K_1. Let $F, G : \mathcal{C} \to \mathcal{D}$ be $\mathsf{Functor}^{\uparrow}$ certificates with object maps F_0, G_0 and morphism maps F_1, G_1, and let $\alpha : F \Rightarrow G$ be a $\mathsf{NatTrans}^{\uparrow}$ certificate with component family $\alpha_X : F_0(X) \to G_0(X)$. The prewhiskered data $\alpha * K : F \circ K \Rightarrow G \circ K$ are the component family*

$$(\alpha * K)_X := \alpha_{K_0(X)}.$$

For a displayed morphism $u : X \to Y$ in $\mathcal{B}$, the displayed naturality row is the $\mathcal{D}$-morphism-classifier comparison obtained by applying the naturality row of α to the displayed $\mathcal{C}$-morphism $K_1(u) : K_0(X) \to K_0(Y)$.

Theorem 63.94 (NatTrans prewhiskering by a functor)**.** *Let $\mathcal{B}$, $\mathcal{C}$, and $\mathcal{D}$ be $\mathsf{Cat}^{\uparrow}$ certificates satisfying Definition 61.203. Let $K : \mathcal{B} \to \mathcal{C}$ and $F, G : \mathcal{C} \to \mathcal{D}$ be $\mathsf{Functor}^{\uparrow}$ certificates satisfying Definition 62.80, with object maps K_0, F_0, G_0 and morphism maps K_1, F_1, G_1. If $\alpha : F \Rightarrow G$ satisfies the $\mathsf{NatTrans}^{\uparrow}$ certificate obligations of Definition 63.77, then the data of Definition 63.93 satisfy the $\mathsf{NatTrans}^{\uparrow}$ carrier and naturality-square fields for a natural transformation*

$$\alpha * K : F \circ K \Rightarrow G \circ K$$

under the morphism classifier of $\mathcal{D}$. Its component at each object X of $\mathcal{B}$ is

$$(\alpha * K)_X = \alpha_{K_0(X)},$$

and for every displayed morphism $u : X \to Y$ in $\mathcal{B}$ its naturality row is

$$G_1(K_1(u)) \circ_{\mathcal{D}} \alpha_{K_0(X)} \sim_{\mathcal{D}} \alpha_{K_0(Y)} \circ_{\mathcal{D}} F_1(K_1(u)).$$

Proof. Apply Definition 62.99 to the pairs (K, F) and (K, G). Together with the source, pattern, classifier, stability, and ledger rows listed in Definition 62.80, this reads $F \circ K$ and $G \circ K$ as certified $\mathsf{Functor}^{\uparrow}$ carriers from $\mathcal{B}$ to $\mathcal{D}$. Their object maps are

$$(F \circ K)_0(X) = F_0(K_0(X)), \qquad (G \circ K)_0(X) = G_0(K_0(X)),$$

and their morphism maps are

$$(F \circ K)_1(u) = F_1(K_1(u)), \qquad (G \circ K)_1(u) = G_1(K_1(u)).$$

Thus the source row required by Definition 63.59 is the pair $(F \circ K, G \circ K)$.

For the carrier row, fix an object X of $\mathcal{B}$. The functor carrier of Definition 62.1 sends X to the object $K_0(X)$ of $\mathcal{C}$. The carrier field of α, specified in Definition 63.1, gives the displayed $\mathcal{D}$-morphism

$$\alpha_{K_0(X)} : F_0(K_0(X)) \to G_0(K_0(X)).$$

Using the composite object maps above, this is exactly a component

$$(\alpha * K)_X : (F \circ K)_0(X) \to (G \circ K)_0(X)$$

of the component-family pattern from Definition 63.60.

It remains to verify naturality. Let $u : X \to Y$ be a displayed morphism in $\mathcal{B}$. The morphism-map field of K sends it to a displayed morphism

$$K_1(u) : K_0(X) \to K_0(Y)$$

in $\mathcal{C}$. Applying the naturality field of α to this displayed $\mathcal{C}$-morphism gives

$$G_1(K_1(u)) \circ_{\mathcal{D}} \alpha_{K_0(X)} \sim_{\mathcal{D}} \alpha_{K_0(Y)} \circ_{\mathcal{D}} F_1(K_1(u)).$$

Substituting the composite morphism maps and the component definition gives

$$(G \circ K)_1(u) \circ_{\mathcal{D}} (\alpha * K)_X \sim_{\mathcal{D}} (\alpha * K)_Y \circ_{\mathcal{D}} (F \circ K)_1(u),$$

which is the required $\mathsf{NatTrans}^{\uparrow}$ naturality field under the morphism classifier of $\mathcal{D}$.

The ledger row of Definition 63.76 records the two composite functor ledgers, the component ledger of α at each object $K_0(X)$, the morphism-image ledger $K_1(u)$, and the naturality derivation of α at that displayed morphism. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier prewhiskering prefix transport`

Definition 63.95 (Horizontal natural transformation data)**.** *Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be $\mathsf{Cat}^{\uparrow}$ certificates. Let $F, G : \mathcal{C} \to \mathcal{D}$ and $H, K : \mathcal{D} \to \mathcal{E}$ be $\mathsf{Functor}^{\uparrow}$ certificates with object maps F_0, G_0, H_0, K_0 and morphism maps F_1, G_1, H_1, K_1. Let $\alpha : F \Rightarrow G$ and $\beta : H \Rightarrow K$ be $\mathsf{NatTrans}^{\uparrow}$ certificates with component families $\alpha_X : F_0(X) \to G_0(X)$ and $\beta_Y : H_0(Y) \to K_0(Y)$. The horizontal composite data $\beta \diamond \alpha : H \circ F \Rightarrow K \circ G$ have component family*

$$(\beta \diamond \alpha)_X := \beta_{G_0(X)} \circ_{\mathcal{E}} H_1(\alpha_X).$$

For a displayed morphism $u : X \to Y$ in $\mathcal{C}$, the displayed naturality row is the $\mathcal{E}$-morphism-classifier comparison

$$K_1(G_1(u)) \circ_{\mathcal{E}} (\beta_{G_0(X)} \circ_{\mathcal{E}} H_1(\alpha_X)) \sim_{\mathcal{E}} (\beta_{G_0(Y)} \circ_{\mathcal{E}} H_1(\alpha_Y)) \circ_{\mathcal{E}} H_1(F_1(u)).$$

Theorem 63.96 (Horizontal composition of natural transformations)**.** *Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be $\mathsf{Cat}^{\uparrow}$ certificates satisfying Definition 61.203. Let $F, G : \mathcal{C} \to \mathcal{D}$ and $H, K : \mathcal{D} \to \mathcal{E}$ be $\mathsf{Functor}^{\uparrow}$ certificates satisfying Definition 62.80, with object maps F_0, G_0, H_0, K_0 and morphism maps F_1, G_1, H_1, K_1. If $\alpha : F \Rightarrow G$ and $\beta : H \Rightarrow K$ satisfy the $\mathsf{NatTrans}^{\uparrow}$ certificate obligations of Definition 63.77, then the data of Definition 63.95 satisfy the $\mathsf{NatTrans}^{\uparrow}$ carrier and naturality-square fields for a natural transformation*

$$\beta \diamond \alpha : H \circ F \Rightarrow K \circ G$$

under the morphism classifier of $\mathcal{E}$. Its component at each object X is

$$(\beta \diamond \alpha)_X = \beta_{G_0(X)} \circ_{\mathcal{E}} H_1(\alpha_X),$$

and for every displayed morphism $u : X \to Y$ in $\mathcal{C}$ its naturality row is

$$K_1(G_1(u)) \circ_{\mathcal{E}} (\beta_{G_0(X)} \circ_{\mathcal{E}} H_1(\alpha_X)) \sim_{\mathcal{E}} (\beta_{G_0(Y)} \circ_{\mathcal{E}} H_1(\alpha_Y)) \circ_{\mathcal{E}} H_1(F_1(u)).$$

Moreover, for each object X, this component is classified with the alternative component obtained by applying K to α_X after the component of β at $F_0(X)$:

$$(\beta \diamond \alpha)_X \sim_{\mathcal{E}} K_1(\alpha_X) \circ_{\mathcal{E}} \beta_{F_0(X)}.$$

Proof. Apply Definition 62.99 to the pairs (F, H), (G, H), (F, K), and (G, K). Together with the source, pattern, classifier, stability, and ledger rows listed in Definition 62.80, this reads $H \circ F$, $H \circ G$, $K \circ F$, and $K \circ G$ as certified $\mathsf{Functor}^{\uparrow}$ carriers with source and target categories as displayed.

By Definition 63.92 applied to H and α, the component family

$$(H_* \alpha)_X = H_1(\alpha_X)$$

satisfies the $\mathsf{NatTrans}^{\uparrow}$ carrier and naturality-square fields from $H \circ F$ to $H \circ G$. By Definition 63.94 applied to β and G, the component family

$$(\beta * G)_X = \beta_{G_0(X)}$$

satisfies the corresponding fields from $H \circ G$ to $K \circ G$. These two natural transformations share source category $\mathcal{C}$, target category $\mathcal{E}$, and middle functor $H \circ G$.

The vertical-composition row in Definition 63.75, equivalently the construction used in Definition 63.85, therefore gives a $\mathsf{NatTrans}^{\uparrow}$ carrier from $H \circ F$ to $K \circ G$ with component

$$((\beta * G) \circ (H_* \alpha))_X = (\beta * G)_X \circ_{\mathcal{E}} (H_* \alpha)_X = \beta_{G_0(X)} \circ_{\mathcal{E}} H_1(\alpha_X).$$

This is exactly the component family in Definition 63.95.

For naturality, let $u : X \to Y$ be displayed in $\mathcal{C}$. Applying Definition 63.85 to $H_* \alpha$ and $\beta * G$ gives

$$(K \circ G)_1(u) \circ_{\mathcal{E}} (\beta \diamond \alpha)_X \sim_{\mathcal{E}} (\beta \diamond \alpha)_Y \circ_{\mathcal{E}} (H \circ F)_1(u).$$

Unfolding the composite morphism maps supplied by Definition 62.99 gives $(K \circ G)_1(u) = K_1(G_1(u))$ and $(H \circ F)_1(u) = H_1(F_1(u))$. Substituting the displayed component formula gives the naturality row stated above.

It remains to identify the alternate component display. The carrier field of α, from Definition 63.1, makes $\alpha_X : F_0(X) \to G_0(X)$ a displayed morphism of $\mathcal{D}$. Naturality of β at this displayed morphism gives

$$K_1(\alpha_X) \circ_{\mathcal{E}} \beta_{F_0(X)} \sim_{\mathcal{E}} \beta_{G_0(X)} \circ_{\mathcal{E}} H_1(\alpha_X).$$

Symmetry of the $\mathcal{E}$ morphism classifier, recorded in Definition 61.201, reverses this comparison, and the right-hand side is the horizontal component by definition. □

Theorem 63.97 (NatTrans horizontal identity reductions)**.** *Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be $\mathsf{Cat}^{\uparrow}$ certificates satisfying Definition 61.203. Let $F, G : \mathcal{C} \to \mathcal{D}$ and $H, K : \mathcal{D} \to \mathcal{E}$ be certified $\mathsf{Functor}^{\uparrow}$ carriers satisfying Definition 62.80, with object maps F_0, G_0, H_0, K_0 and morphism maps F_1, G_1, H_1, K_1. Let $\alpha : F \Rightarrow G$ and $\beta : H \Rightarrow K$ be certified $\mathsf{NatTrans}^{\uparrow}$ carriers satisfying Definition 63.77. Then for every object X of $\mathcal{C}$ the identity-horizontal composites supplied by Definition 63.96 are componentwise classified by the corresponding one-sided whiskerings:*

$$(\mathsf{id}_H \diamond \alpha)_X \sim_{\mathcal{E}} (H_*\alpha)_X \sim_{\mathcal{E}} H_1(\alpha_X)$$

and

$$(\beta \diamond \mathsf{id}_F)_X \sim_{\mathcal{E}} (\beta * F)_X \sim_{\mathcal{E}} \beta_{F_0(X)}.$$

Equivalently, the left identity comparison has BHist *component readback $H_1(\alpha_X)$ on both sides, and the right identity comparison has* BHist *component readback $\beta_{F_0(X)}$ on both sides.*

Proof. Use Definition 63.90 to form $\mathsf{id}_H : H \Rightarrow H$ and $\mathsf{id}_F : F \Rightarrow F$. Use Definition 63.92 to read $H_*\alpha$ as a certified transformation $H \circ F \Rightarrow H \circ G$, and use Definition 63.94 to read $\beta * F$ as a certified transformation $H \circ F \Rightarrow K \circ F$.

For the left identity law, Definition 63.96 applied to id_H and α gives the component

$$(\mathsf{id}_H \diamond \alpha)_X = (\mathsf{id}_H)_{G_0(X)} \circ_{\mathcal{E}} H_1(\alpha_X).$$

The identity-transformation certificate identifies $(\mathsf{id}_H)_{G_0(X)}$ with $\mathsf{id}_{H_0(G_0(X))}$, while the whiskering certificate identifies $(H_*\alpha)_X$ with $H_1(\alpha_X)$. The left identity row of the target category in Definition 61.201 classifies $\mathsf{id}_{H_0(G_0(X))} \circ_{\mathcal{E}} H_1(\alpha_X)$ with $H_1(\alpha_X)$, and transitivity of the $\mathcal{E}$ classifier gives the displayed comparison.

For the right identity law, Definition 63.96 applied to β and id_F gives

$$(\beta \diamond \mathsf{id}_F)_X = \beta_{F_0(X)} \circ_{\mathcal{E}} H_1((\mathsf{id}_F)_X).$$

The identity-transformation certificate reads $(\mathsf{id}_F)_X$ as $\mathsf{id}_{F_0(X)}$. The identity-preservation row of H in Definition 62.78 classifies $H_1(\mathsf{id}_{F_0(X)})$ with $\mathsf{id}_{H_0(F_0(X))}$, and the right identity row of Definition 61.201 classifies the resulting composite with $\beta_{F_0(X)}$. The prewhiskering certificate identifies $(\beta * F)_X$ with the same component, so target-classifier transitivity gives the second comparison.

The ledger is the union of the identity-transformation ledgers, the whiskering and prewhiskering ledgers, the horizontal-composition ledger, and the target-category identity ledgers used in the two component reductions. □

Capstone.

Theorem 63.98 (Horizontal-vertical interchange for natural transformations)**.** *Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be $\mathsf{Cat}^{\uparrow}$ certificates satisfying Definition 61.203. Let $F, G, H : \mathcal{C} \to \mathcal{D}$ and $K, L, M : \mathcal{D} \to \mathcal{E}$ be certified $\mathsf{Functor}^{\uparrow}$ carriers satisfying Definition 62.80, with object maps $F_0, G_0, H_0, K_0, L_0, M_0$ and morphism maps $F_1, G_1, H_1, K_1, L_1, M_1$. Let $\alpha : F \Rightarrow G$, $\alpha' : G \Rightarrow H$, $\beta : K \Rightarrow L$, and $\beta' : L \Rightarrow M$ be certified $\mathsf{NatTrans}^{\uparrow}$ carriers satisfying Definition 63.77. Then the two natural transformations*

$$((\beta' \circ \beta) \diamond (\alpha' \circ \alpha)) : K \circ F \Rightarrow M \circ H \qquad \text{and} \qquad ((\beta' \diamond \alpha') \circ (\beta \diamond \alpha)) : K \circ F \Rightarrow M \circ H$$

are componentwise classified together by the morphism classifier of $\mathcal{E}$. For every object X of $\mathcal{C}$,

$$((\beta' \circ \beta) \diamond (\alpha' \circ \alpha))_X \sim_{\mathcal{E}} ((\beta' \diamond \alpha') \circ (\beta \diamond \alpha))_X.$$

Equivalently, after unfolding the component formulas, the classifier comparison at X is

$$(\beta'_{H_0(X)} \circ_{\mathcal{E}} \beta_{H_0(X)}) \circ_{\mathcal{E}} K_1(\alpha'_X \circ_{\mathcal{D}} \alpha_X) \sim_{\mathcal{E}} (\beta'_{H_0(X)} \circ_{\mathcal{E}} L_1(\alpha'_X)) \circ_{\mathcal{E}} (\beta_{G_0(X)} \circ_{\mathcal{E}} K_1(\alpha_X)).$$

Proof. This result composes the vertical-composition block, the whiskering blocks, and the horizontal-composition block already present in this chapter; it is not a one-theorem restatement. The named blocks provide the certified carriers on both routes, while the comparison below identifies their components in the codomain classifier.

The vertical-composition row of Definition 63.75, in the form used in Definition 63.85, gives

$$(\alpha' \circ \alpha)_X = \alpha'_X \circ_{\mathcal{D}} \alpha_X$$

and

$$(\beta' \circ \beta)_{H_0(X)} = \beta'_{H_0(X)} \circ_{\mathcal{E}} \beta_{H_0(X)}.$$

Unfolding the horizontal-composition component formula of Definition 63.95 for these two vertical composites reads the first route as

$$((\beta' \circ \beta) \diamond (\alpha' \circ \alpha))_X = (\beta'_{H_0(X)} \circ_{\mathcal{E}} \beta_{H_0(X)}) \circ_{\mathcal{E}} K_1(\alpha'_X \circ_{\mathcal{D}} \alpha_X).$$

Applying the same horizontal component formula before vertical composition gives

$$(\beta \diamond \alpha)_X = \beta_{G_0(X)} \circ_{\mathcal{E}} K_1(\alpha_X)$$

and

$$(\beta' \diamond \alpha')_X = \beta'_{H_0(X)} \circ_{\mathcal{E}} L_1(\alpha'_X).$$

The vertical-composition row then reads the second route as

$$((\beta' \diamond \alpha') \circ (\beta \diamond \alpha))_X = (\beta'_{H_0(X)} \circ_{\mathcal{E}} L_1(\alpha'_X)) \circ_{\mathcal{E}} (\beta_{G_0(X)} \circ_{\mathcal{E}} K_1(\alpha_X)).$$

It remains to compare the displayed target morphisms. The composition-preservation row of the functor K, recorded in Definition 62.78 and used by Definition 62.99, gives

$$K_1(\alpha'_X \circ_{\mathcal{D}} \alpha_X) \sim_{\mathcal{E}} K_1(\alpha'_X) \circ_{\mathcal{E}} K_1(\alpha_X).$$

After this replacement, category associativity in $\mathcal{E}$ classifies the first route with

$$(\beta'_{H_0(X)} \circ_{\mathcal{E}} (\beta_{H_0(X)} \circ_{\mathcal{E}} K_1(\alpha'_X))) \circ_{\mathcal{E}} K_1(\alpha_X).$$

The carrier field of α' makes $\alpha'_X : G_0(X) \to H_0(X)$ a displayed morphism of $\mathcal{D}$. Naturality of $\beta : K \Rightarrow L$ at this component gives

$$\beta_{H_0(X)} \circ_{\mathcal{E}} K_1(\alpha'_X) \sim_{\mathcal{E}} L_1(\alpha'_X) \circ_{\mathcal{E}} \beta_{G_0(X)}.$$

Composition congruence transports this comparison inside the outer composite, and associativity in $\mathcal{E}$ classifies the result with

$$(\beta'_{H_0(X)} \circ_{\mathcal{E}} L_1(\alpha'_X)) \circ_{\mathcal{E}} (\beta_{G_0(X)} \circ_{\mathcal{E}} K_1(\alpha_X)).$$

Symmetry is used where a displayed comparison is oriented opposite the transport direction, and transitivity of the same morphism classifier composes the chain.

Since Definition 63.61 relates natural transformations componentwise by the target category morphism classifier, these component comparisons are exactly the $\mathsf{NatTrans}^{\uparrow}$ classifier comparison between the vertical composite of horizontal composites and the horizontal composite of vertical composites. □

Theorem 63.99 (Functor whiskering preserves vertical composition)**.** *Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be* $\mathsf{Cat}^{\uparrow}$ *certificates satisfying Definition 61.203. Let $F, G, H : \mathcal{C} \to \mathcal{D}$ and $K : \mathcal{D} \to \mathcal{E}$ be* $\mathsf{Functor}^{\uparrow}$ *certificates satisfying Definition 62.80, with object maps F_0, G_0, H_0, K_0 and morphism maps F_1, G_1, H_1, K_1. Let $\alpha : F \Rightarrow G$ and $\beta : G \Rightarrow H$ satisfy the* $\mathsf{NatTrans}^{\uparrow}$ *certificate obligations of Definition 63.77, and let $\beta \circ \alpha$ be the vertical composite carrier supplied by Definition 63.75. Then the two natural transformation carriers*

$$K_*(\beta \circ \alpha) : K \circ F \Rightarrow K \circ H \qquad \textit{and} \qquad (K_*\beta) \circ (K_*\alpha) : K \circ F \Rightarrow K \circ H$$

are classified together componentwise by the $\mathcal{E}$-morphism classifier. For every object X of $\mathcal{C}$,

$$(K_*(\beta \circ \alpha))_X \sim_{\mathcal{E}} ((K_*\beta) \circ (K_*\alpha))_X$$

at the endpoint pair $K_0(F_0(X)), K_0(H_0(X))$. Equivalently, after unfolding the component clauses,

$$K_1(\beta_X \circ_{\mathcal{D}} \alpha_X) \sim_{\mathcal{E}} K_1(\beta_X) \circ_{\mathcal{E}} K_1(\alpha_X).$$

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentCarrier prefix whiskering vert comp public readback`

Proof. Apply Definition 62.99 to the pairs (F, K), (G, K), and (H, K). This reads $K \circ F$, $K \circ G$, and $K \circ H$ as certified $\mathsf{Functor}^{\uparrow}$ carriers from $\mathcal{C}$ to $\mathcal{E}$, with object maps $K_0(F_0(-))$, $K_0(G_0(-))$, and $K_0(H_0(-))$ and morphism maps $K_1(F_1(-))$, $K_1(G_1(-))$, and $K_1(H_1(-))$.

The vertical-composition row of Definition 63.75, in the form used by Definition 63.85, supplies a carrier $\gamma = \beta \circ \alpha : F \Rightarrow H$ with component

$$\gamma_X = \beta_X \circ_{\mathcal{D}} \alpha_X.$$

Applying Definition 63.92 to K and γ gives a carrier $K_*(\beta \circ \alpha) : K \circ F \Rightarrow K \circ H$ whose component at X is

$$(K_*(\beta \circ \alpha))_X = K_1(\gamma_X) = K_1(\beta_X \circ_{\mathcal{D}} \alpha_X).$$

Apply the same whiskering theorem separately to α and β. The resulting carriers have components

$$(K_*\alpha)_X = K_1(\alpha_X), \qquad (K_*\beta)_X = K_1(\beta_X).$$

Since their middle functor is $K \circ G$, vertical composition closure gives a carrier $(K_*\beta) \circ (K_*\alpha) : K \circ F \Rightarrow K \circ H$ with component

$$((K_*\beta) \circ (K_*\alpha))_X = K_1(\beta_X) \circ_{\mathcal{E}} K_1(\alpha_X).$$

Fix an object X of $\mathcal{C}$. By Definition 63.1, $\alpha_X : F_0(X) \to G_0(X)$ and $\beta_X : G_0(X) \to H_0(X)$ are composable displayed morphisms of $\mathcal{D}$. The composition-preservation field of K, listed in Definition 62.78, applies to this component pair and gives

$$K_1(\beta_X \circ_{\mathcal{D}} \alpha_X) \sim_{\mathcal{E}} K_1(\beta_X) \circ_{\mathcal{E}} K_1(\alpha_X).$$

Substituting the two component formulas above gives the displayed comparison between $(K_*(\beta \circ \alpha))_X$ and $((K_*\beta) \circ (K_*\alpha))_X$. The classifier specification of Definition 63.61 compares natural transformations componentwise by the target morphism classifier, so these objectwise comparisons are exactly the componentwise classifier identity of the two carriers. □

Theorem 63.100 (NatTrans prewhiskering preserves vertical composition)**.** *Let $\mathcal{B}$, $\mathcal{C}$, and $\mathcal{D}$ be* $\mathsf{Cat}^{\uparrow}$ *certificates satisfying Definition 61.203. Let $L : \mathcal{B} \to \mathcal{C}$ and $F, G, H : \mathcal{C} \to \mathcal{D}$ be* $\mathsf{Functor}^{\uparrow}$ *certificates satisfying Definition 62.80, with object maps L_0, F_0, G_0, H_0 and morphism maps L_1, F_1, G_1, H_1. Let $\alpha : F \Rightarrow G$ and $\beta : G \Rightarrow H$ satisfy the* $\mathsf{NatTrans}^{\uparrow}$ *certificate obligations of Definition 63.77, and let $\beta \circ \alpha$ be the vertical composite carrier supplied by Definition 63.75. Then the two natural transformation carriers*

$$(\beta \circ \alpha) * L : F \circ L \Rightarrow H \circ L \qquad \textit{and} \qquad (\beta * L) \circ (\alpha * L) : F \circ L \Rightarrow H \circ L$$

are classified together by the $\mathsf{NatTrans}^{\uparrow}$ *component classifier. For every object X of $\mathcal{B}$,*

$$((\beta \circ \alpha) * L)_X \sim_{\mathcal{D}} ((\beta * L) \circ (\alpha * L))_X$$

at the endpoint pair $F_0(L_0(X)), H_0(L_0(X))$. Equivalently, after unfolding the component clauses, both sides are read as the target-category component history

$$\beta_{L_0(X)} \circ_{\mathcal{D}} \alpha_{L_0(X)}.$$

Proof. Apply Definition 62.99 to the pairs (L, F), (L, G), and (L, H). This reads $F \circ L$, $G \circ L$, and $H \circ L$ as certified $\mathsf{Functor}^{\uparrow}$ carriers from $\mathcal{B}$ to $\mathcal{D}$, with object maps $F_0(L_0(-))$, $G_0(L_0(-))$, and $H_0(L_0(-))$.

The vertical-composition row of Definition 63.75, in the form used by Definition 63.85, supplies a carrier $\gamma = \beta \circ \alpha : F \Rightarrow H$ with component

$$\gamma_Y = \beta_Y \circ_{\mathcal{D}} \alpha_Y$$

for every object Y of $\mathcal{C}$. Applying Definition 63.94 to γ and L gives a carrier $(\beta \circ \alpha) * L : F \circ L \Rightarrow H \circ L$ whose component at X is

$$((\beta \circ \alpha) * L)_X = \gamma_{L_0(X)} = \beta_{L_0(X)} \circ_{\mathcal{D}} \alpha_{L_0(X)}.$$

Apply the same prewhiskering theorem separately to α and β. Their prewhiskered components are

$$(\alpha * L)_X = \alpha_{L_0(X)}, \qquad (\beta * L)_X = \beta_{L_0(X)}.$$

These two carriers share the middle functor $G \circ L$, so vertical composition closure gives $(\beta * L) \circ (\alpha * L) : F \circ L \Rightarrow H \circ L$ with component

$$((\beta * L) \circ (\alpha * L))_X = \beta_{L_0(X)} \circ_{\mathcal{D}} \alpha_{L_0(X)}.$$

The carrier fields of Definition 63.1 make $\alpha_{L_0(X)}$ and $\beta_{L_0(X)}$ composable displayed morphisms in $\mathcal{D}$, and the category stability field of Definition 61.201 gives reflexivity of the morphism classifier on their displayed composite. The componentwise classifier specification of Definition 63.61 therefore classifies the two prewhiskering routes together at every object X. □

Theorem 63.101 (NatTrans prefix standard bridge)**.** *For the concrete prefix realization, the carrier* $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta)$ *is exactly the component row of a natural transformation from the prefix functor at p to the prefix functor at q over unary object a. Its source and target are the functor images* $\mathsf{append}(p, a)$ *and* $\mathsf{append}(q, a)$*, and its displayed component is the concrete morphism* $\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(q, a), \eta)$*. The public* $\mathsf{NatTrans}^{\uparrow}$ *classifier is the componentwise* hsame *comparison packaged by* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}$*.*

The bridge fields are as follows. The traditional target is ordinary natural transformations between the two fixed-prefix functors. The BEDC source is $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, $\mathsf{UnaryHistory}$, *and* Cont. *The carrier is* $\mathsf{NatTransPrefixComponentCarrier}$, *the classifier is* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}$, *stability is given by component transport and vertical composition rows, the ledger is the pair of functor ledgers plus the component morphism ledgers, exactness is the displayed carrier/classifier correspondence, the standard bridge is this theorem, and the status is a paper bridge target awaiting Lean formalization.*

Proof. The carrier row is read first. By Definition 63.2, the prefix component carrier is precisely unary membership of a together with the target-category hom carrier from p to q after the shared object suffix is exposed. Reading that row through the source and target object maps of Definition 62.114 identifies the endpoints as $\mathsf{append}(p, a)$ and $\mathsf{append}(q, a)$, which are the ordinary component source and target for the two prefix functors at object a.

The classifier row is then fixed componentwise. The definition Definition 63.62 says that two displayed components over the same prefixes and object are classified exactly when both component carriers are present and their component histories are related by hsame. The semantic certificate of Definition 63.66 packages that component classifier as the public NameCert classifier for the displayed component carrier.

Finally, the public natural-transformation classifier is the componentwise row specified in Definition 63.61. Substituting the prefix carrier and classifier rows above gives ordinary natural transformations between the two prefix functors, with no extra source data: the functor ledgers come from Definition 62.114, the component morphism ledger is the displayed $\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(q$ and stability is exactly the existing component transport and vertical composition package. These are the listed bridge fields. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixComponentClassifier standard bridge fields`

Definition 63.102 (NatTrans functor-category prefix carrier)**.** *The prefix functor-category carrier for* $\mathsf{NatTrans}^{\uparrow}$ *has unary prefix histories as objects. A hom row from object prefix* p *to object prefix* q *is the component family* $\mathsf{NatTransPrefixComponentCarrier}(p, q, a, \eta_a)$, *one row for every unary object* a. *The displayed source and target of the* a*-component are* $\mathsf{append}(p, a)$ *and* $\mathsf{append}(q, a)$, *and the component morphism is the concrete target-category row* $\mathsf{CategoryHomCarrier}(\mathsf{append}(p, a), \mathsf{append}(q, a), \eta_a)$. *The hom classifier is the componentwise* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}$ *row, so equality of hom rows is read by* hsame *on every displayed component history.*

Theorem 63.103 (NatTrans functor-category identity and composition)**.** *For the prefix functor-category carrier of Definition 63.102, each prefix object* p *carries an identity hom row whose* a*-component is the empty component/identity semantic certificate at* $\mathsf{append}(p, a)$. *If* $\eta : p \Rightarrow q$ *and* $\theta : q \Rightarrow r$ *are hom rows, their composite is the componentwise vertical composite* $\theta_a \circ \eta_a$. *Associativity and the left and right unit laws are the componentwise laws inherited from the checked prefix component carrier and the classifier rows.*

Proof. The object row is already a unary prefix history, and the identity component at a is the identity morphism row for $\mathsf{append}(p, a)$. The semantic NameCert certificate for the prefix component classifier reads this row as the empty identity component, so every component belongs to the hom carrier from p to p.

For composition, take the vertical composite in the target-category hom carrier at each unary object a. The source and target boundaries line up because the two component rows end and begin at the shared prefix q after the same object suffix a is appended.

The associativity and unit equations are then checked componentwise. The classifier for hom rows is componentwise hsame, and the component carrier already supplies vertical composition closure, so the category laws reduce to the corresponding checked classifier rows at every unary object. □

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixFunctorCategory identity and composition`

Definition 63.104 (NatTrans prefix natural-isomorphism carrier)**.** *A prefix natural isomorphism from p to q is a pair of component families $\eta : p \Rightarrow q$ and $\epsilon : q \Rightarrow p$ in the prefix functor-category carrier such that, for every unary object a, both vertical composites $\epsilon_a \circ \eta_a$ and $\eta_a \circ \epsilon_a$ classify as the empty identity component at the corresponding appended histories* $\mathsf{append}(p, a)$ *and* $\mathsf{append}(q, a)$*.*

Theorem 63.105 (NatTrans natural-isomorphism obligation package)**.** *The prefix natural-isomorphism surface carries the NameCert obligation rows for carrier, classifier, stability, inverse, ledger, exactness, and no-host-leak. Its carrier is Definition 63.104; its classifier is the componentwise prefix component classifier in both directions; stability is given by component transport and vertical composition; the inverse row swaps the two component families; the ledger is the two functor ledgers together with the forward and reverse component morphism ledgers; exactness is the componentwise identity-composite condition; and no-host-leak follows because all rows are built from* $\mathsf{Cat}^{\uparrow}$*,* $\mathsf{Functor}^{\uparrow}$*,* $\mathsf{NatTrans}^{\uparrow}$*,* $\mathsf{UnaryHistory}$*,* Cont*, and the displayed component histories.*

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransPrefixNaturalIso component cycle empty boundary`

Proof. The carrier and classifier rows are obtained by unpacking Definition 63.104. Each direction is a prefix natural-transformation hom row, and each component is classified by $\mathsf{NatTransPrefixComponentClassifier}_{p,}$ or $\mathsf{NatTransPrefixComponentClassifier}_{q,p,a}$.

Stability is componentwise. Transport preserves the displayed component carrier, and vertical composition closes the composites used in the identity conditions. Swapping the forward and reverse families gives the inverse row, because the two identity-composite requirements are symmetric in the displayed definition.

The ledger and exactness rows are the public rows already present in the component-family surface. The only histories recorded are the two prefix functor ledgers and the forward and reverse component morphism ledgers, and the exactness condition says precisely that the two displayed vertical composites classify as empty identity components at every unary object. No additional host datum is introduced. □

Theorem 63.106 (NatTrans prefix natural isomorphisms are functor-category isomorphisms)**.** *For unary prefixes p and q, the data of Definition 63.104 are exactly isomorphisms from p to q in the prefix functor-category of Definition 63.102. The forward hom is the component family $\eta : p \Rightarrow q$, the reverse hom is the component family $\epsilon : q \Rightarrow p$, and the two inverse laws are precisely the componentwise empty-identity classifications for $\epsilon_a \circ \eta_a$ at* $\mathsf{append}(p, a)$ *and $\eta_a \circ \epsilon_a$ at* $\mathsf{append}(q, a)$*.*

Proof. Start with a prefix natural isomorphism. Its two component families are hom rows in the prefix functor-category, by Definition 63.104. The identity and composition rows of Definition 63.103 identify composition in that category with componentwise vertical composition, and identify identity homs with the empty identity component at each appended history. Thus the two carrier conditions are exactly the left and right inverse equations for an isomorphism from p to q.

Conversely, take an isomorphism from p to q in the prefix functor-category. Its forward and reverse homs are component families in the carrier of Definition 63.102. Reading the two categorical

inverse equations through Definition 63.103 gives, for each unary object a, the empty-identity classification of the composites $\epsilon_a \circ \eta_a$ and $\eta_a \circ \epsilon_a$ at the two appended histories. These are exactly the two conditions of Definition 63.104.

The obligation surface of Definition 63.105 supplies the classifier, stability, inverse, ledger, and exactness rows for this comparison. Since both sides use the same forward and reverse component families, the same componentwise prefix classifiers, and the same empty-identity composite rows, the bridge is obtained by componentwise classifier comparison. □

Theorem 63.107 (NatTrans functor-category isomorphism classifier exactness)**.** *For unary prefixes p and q, let (η, ϵ) and (η', ϵ') be two witnesses in the carrier of Definition 63.104. These two witnesses classify as the same isomorphism row in the prefix functor-category of Definition 63.102 exactly when, for every unary object a, the forward components η_a and η'_a classify by* $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}$ *and the reverse components ϵ_a and ϵ'_a classify by* $\mathsf{NatTransPrefixComponentClassifier}_{q,p,a}$*. Under these two componentwise classifier families, the two empty-identity composite rows are transported by vertical-composition stability and by the identity/composition laws of Definition 63.103.*

Proof. Unpack the hom classifier in Definition 63.102. A row between p and q is a component family indexed by unary objects, and the classifier on such rows is the pointwise prefix component classifier. Thus equality of the forward hom rows is exactly the family of $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}$ classifications, while equality of the reverse hom rows is exactly the family of $\mathsf{NatTransPrefixComponentClassifier}_{q,p,a}$ classifications.

Apply Definition 63.103. The isomorphism laws in the prefix functor-category reduce to the componentwise vertical composites $\epsilon_a \circ \eta_a$ and $\eta_a \circ \epsilon_a$ being classified as the empty identity components at $\mathsf{append}(p, a)$ and $\mathsf{append}(q, a)$. Componentwise classifier agreement on the forward and reverse families transports these two composite rows through the same vertical composition stability used in the functor-category composition law.

The remaining rows are precisely the obligation rows of Definition 63.105: transport, inverse, ledger, and exactness are all read pointwise from the same component families. Hence two prefix natural-isomorphism witnesses determine the same BEDC isomorphism row exactly in the stated componentwise classifier situation. No host equality of transformations, function extensionality, arbitrary representability, or external transformation type is exported. □

Theorem 63.108 (NatTrans mature package inventory)**.** *The public* $\mathsf{NatTrans}^{\uparrow}$ *paper surface contains the mature package inventory for the prefix natural-transformation instance: component-family data, naturality readback, identity transformations, vertical composition, horizontal composition, whiskering and prewhiskering rows, whiskering preservation, horizontal-vertical interchange, the prefix standard bridge of Definition 63.101, the functor-category carrier and laws of Definition 63.102 and Definition 63.103, and the natural-isomorphism carrier and obligation package of Definition 63.104 and Definition 63.105, together with the identification of those carriers as isomorphisms in the prefix functor-category from Definition 63.106 and the componentwise isomorphism classifier exactness of Definition 63.107.*

Lean4 ✓ `BEDC.Derived.NatTransUp.NatTransUp StdBridge`

Proof. Read the inventory by grouping the public rows already established in the chapter. The component-family carrier, componentwise classifier, naturality readback, identity transformation, vertical composition, horizontal composition, whiskering, prewhiskering, preservation, and interchange rows give the public natural-transformation surface.

The bridge row is supplied by Definition 63.101. The functor-category object, hom, identity, and composition rows are supplied by Definition 63.102 and Definition 63.103.

Finally, the natural-isomorphism rows are supplied by Definition 63.104 and Definition 63.105. The comparison with prefix functor-category isomorphisms is supplied by Definition 63.106. These rows are all expressed through the existing BEDC carriers, classifiers, ledgers, and component histories, so the listed package is closed as a current paper surface. □

Theorem 63.109 (NatTrans Category-Functor prefix bridge exhaustion)**.** *Every public prefix bridge read for* $\mathsf{NatTrans}^{\uparrow}$ *factors through the finite three-layer BEDC surface consisting exactly of the* $\mathsf{Cat}^{\uparrow}$ *unary-continuation object, Hom, identity, and composition bridge rows; the* $\mathsf{Functor}^{\uparrow}$ *fixed-prefix object-map, morphism-map, identity-preservation, and composition-preservation bridge rows; the* $\mathsf{NatTrans}^{\uparrow}$ *component-family, naturality, vertical-composition, and horizontal-composition rows; and the displayed* BHist, hsame, Cont, Pkg, *and local* NameCert *provenance that those rows carry. This factorization exports no host category universe, host functor equality, external transformation type, representability, adjunction data, or arbitrary functor-category primitive.*

Proof. First read the $\mathsf{Cat}^{\uparrow}$ dependency lattice. By Definition 61.336, downstream functor and natural-transformation clauses consume only the displayed object, Hom, identity, composition, continuation, and classifier rows of the unary-continuation category. These rows are already the bridge-facing BHist, hsame, Cont, Pkg, and NameCert data, so the first layer contains no host category carrier or external morphism primitive.

Next read the fixed-prefix functor package. The standard bridge of Definition 62.114 specializes $\mathsf{Functor}^{\uparrow}$ to the object map $a \mapsto \mathsf{append}(p, a)$ and the induced morphism rows, with identity and composition preservation witnessed through the same $\mathsf{Cat}^{\uparrow}$ classifiers. Thus the second layer adds only the fixed-prefix object and morphism preservation rows and does not introduce host functor equality or a separate functor category.

Finally read the $\mathsf{NatTrans}^{\uparrow}$ surface through Definition 63.101 and Definition 63.108. The component-family carrier, componentwise classifier, naturality readback, vertical composition, horizontal composition, whiskering rows, and prefix functor-category rows are all expressed as displayed component histories over the two fixed-prefix functors.

Repacking these three layers gives a single finite prefix bridge surface: category rows supply the endpoints and composition calculus, functor rows supply the two fixed-prefix endpoint maps, and natural-transformation rows supply the component family and its composition ledgers. The exclusions in the statement are exactly the non-claimed data absent from those rows, so the public read is exhausted by the listed BEDC-native provenance. □

Closure status for $\mathsf{NameCert}_{\mathsf{NatTrans}^{\uparrow}}$**.**

Constructive story: A natural transformation here is a component family between two fixed-prefix functors: for unary prefixes p and q, each unary object a receives a displayed morphism η_a from $\mathsf{append}(p, a)$ to $\mathsf{append}(q, a)$ in the $\mathsf{Cat}^{\uparrow}$ hom carrier. The carrier admits only those component histories whose source and target are the two functor images and whose naturality, identity, vertical composition, horizontal composition, whiskering, and prewhiskering rows are witnessed through the existing functor and category classifiers. Two component families classify together componentwise, using $\mathsf{NatTransPrefixComponentClassifier}_{p,q,a}$, which is just carried component data plus hsame on every displayed component history rather than host equality of transformations. The source, pattern, and ledger rows are the two functor ledgers together with the component morphism ledgers, the naturality square readbacks, the composition and whiskering ledgers, and the prefix natural-isomorphism rows where the two component cycles classify as empty identities. The five name-certificate obligations are assembled componentwise: identities give inhabited component families, reflexivity, symmetry, and transitivity come from the component classifiers, and carrier closure follows by component transport and vertical-composition stability. A component-family history h lies in the signature gap of a $\mathsf{NatTrans}^{\uparrow}$ token p when the source-domain accepts the two functor endpoints and every component row, the signature relation pairs that family with an answer family and evidence ledger, and token introduction names that answer as p; unfolded, every unary object must

carry exactly the component morphism and naturality evidence encoded by the token. The standard bridge reads the package as ordinary natural transformations between fixed-prefix functors, and reads it back as the same componentwise hom-carrier and classifier rows. The chapter registers this component-family construction under the name $\mathsf{NatTrans}^{\uparrow}$; naturality is carried by visible component ledgers, not by host function extensionality, arbitrary representability, adjunction data, or an external transformation type.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NatTrans}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public natural-transformation interface covers component-family data, naturality readback, identity transformations, opposite and double-opposite rows, vertical and horizontal composition, functor whiskering and prewhiskering, horizontal identity reductions, horizontal-vertical interchange, whiskering preservation, componentwise classifier rows grounded by the prefix component classifier certificate, the prefix standard bridge theorem, the functor-category prefix carrier and laws, the prefix natural-isomorphism package, and the identification of prefix natural isomorphisms with isomorphisms in the prefix functor-category.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NatTrans}^{\uparrow}}$, bridgeChecked)

Chapter 64

A Concrete Naming Certificate for $\mathsf{Prime}^{\uparrow}$

This chapter gives a concrete naming-certificate construction for the prime number interface $\mathsf{Prime}^{\uparrow}$ at the paper-proof level. The construction sits above the unary natural-number certificate $\mathsf{Nat}^{\uparrow}$ (chapter 28) and the additive certificate $\mathsf{Add}^{\uparrow}$ (chapter 29), and is the first arithmetic chapter to exhibit a non-trivial property of unary histories beyond pure additive structure. The certificate is fully constructive: every theorem produces an explicit witness, primality is decidable by trial division on the underlying unary segment, and Euclid's infinitude of primes is supplied as an effective bound function rather than as a non-constructive existence claim. The standard limit results — the fundamental theorem of arithmetic in both existence and uniqueness directions — are reduced, in the same chapter, to closure laws on the prime classifier.

64.1 Multiplicative structure on unary histories

Definition 64.1 (Unary multiplication relation)**.** *For unary histories d, q, n with $\mathsf{Unary}(d)$, $\mathsf{Unary}(q)$, and $\mathsf{Unary}(n)$, the multiplicative relation $\mathsf{NatMul}(d, q, n)$ holds when n is the unary continuation of d repeated q times. Concretely, NatMul is the closed inductive predicate generated by:*

1. $\mathsf{NatMul}(d, \mathsf{e}, \mathsf{e})$ *for every unary d (zero multiplied by anything is zero);*
2. *if $\mathsf{NatMul}(d, q, n)$ and $\mathsf{Cont}(n, d, n')$, then $\mathsf{NatMul}(d, \mathsf{E1}(q), n')$ (one more copy of d appended).*

Lean4 (definition) `BEDC.Derived.PrimeUp.NatMul`

Lemma 64.2 (Unary multiplication successor inversion)**.** *If $\mathsf{NatMul}(d, \mathsf{E1}(q), n')$, then there is a predecessor product n such that $\mathsf{NatMul}(d, q, n)$ and $\mathsf{Cont}(n, d, n')$.*

Proof. Invert the closed successor clause in the inductive definition of NatMul. The displayed predecessor product and continuation witness are exactly the constructor payloads. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul succ inversion`

Lemma 64.3 (Unary multiplication exponent-result cases)**.** *Every witness of $\mathsf{NatMul}(d, q, n)$ is either the empty exponent case, with $q\mathsf{hsamee}$ and $n\mathsf{hsamee}$, or a successor exponent case: there are histories q_0 and n_0 such that $q = \mathsf{E1}(q_0)$, $\mathsf{NatMul}(d, q_0, n_0)$, and $\mathsf{Cont}(n_0, d, n)$.*

Proof. Invert the closed multiplication witness. The zero constructor gives the empty exponent and empty result. The successor constructor exposes exactly the predecessor exponent, predecessor product, and final continuation payload. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul exponent result cases`

Lemma 64.4 (Empty left unary multiplication has empty result)**.** *If* $\mathsf{NatMul}(\mathsf{e}, q, n)$*, then* $n\mathsf{hsamee}$*.*

Proof. Induct on the concrete multiplication witness. The zero constructor is immediate. In the successor constructor, the induction hypothesis identifies the previous product with e, and the final continuation is therefore an empty-left continuation whose result is e. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul empty left result empty`

Theorem 64.5 (Successor multiplication with empty result has empty left factor)**.** *If* $\mathsf{NatMul}(d, \mathsf{E1}(q), n)$ *and* $n\mathsf{hsamee}$*, then* $d\mathsf{hsamee}$*.*

Proof. Invert the successor multiplication witness. Its final step is a continuation $\mathsf{Cont}(n_0, d, n)$. Since the result is empty, empty-result inversion for Cont forces both inputs of that continuation to be empty, in particular the left multiplicand d. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul succ result empty left empty`

Theorem 64.6 (Successor result exposes positive multiplicand shape)**.** *If* $\mathsf{NatMul}(d, q, \mathsf{E1}(n))$*, then the multiplicand has one-headed unary shape:*

$$\exists t,\ d\mathsf{hsameE1}(t) \wedge \mathsf{UnaryHistory}(t).$$

Proof. The multiplication witness carries a unary classifier for d. If d were e, empty-left multiplication would force the successor result to be history-same to e, contradicting constructor separation. The zero-headed case contradicts unary exactness. Thus $d = \mathsf{E1}(t)$, and the same unary classifier exposes a unary tail. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul successor result multiplicand positive shape`

Theorem 64.7 (Successor result exposes positive multiplier shape)**.** *If* $\mathsf{NatMul}(d, q, \mathsf{E1}(n))$*, then the multiplier has one-headed unary shape:*

$$\exists t,\ q\mathsf{hsameE1}(t) \wedge \mathsf{UnaryHistory}(t).$$

Proof. The multiplication witness carries a unary classifier for q. The empty multiplier is impossible because the empty multiplier constructor returns e, not a successor result. The zero-headed case contradicts unary exactness. Hence $q = \mathsf{E1}(t)$, and the tail is unary by one-headed inversion. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul successor result multiplier positive shape`

Theorem 64.8 (Successor multiplication has positive result shape)**.** *If* $\mathsf{NatMul}(d, \mathsf{E1}(q), n)$ *and* d *is not history-same to* e*, then* n *has one-headed shape:*

$$\exists r,\ \mathsf{hsame}(n, \mathsf{E1}(r)) \wedge \mathsf{UnaryHistory}(r).$$

Proof. Invert the successor multiplication witness. The final step is a continuation $\mathsf{Cont}(n_0, d, n)$, and the multiplication witness supplies unary closure of d and n_0. The empty and zero-headed cases for d are impossible by non-emptiness and unary exactness. Thus $d = \mathsf{E1}(t)$, and the continuation has result $\mathsf{E1}(\mathsf{append}(n_0, t))$, whose tail is unary by append closure. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul succ result positive shape`

Theorem 64.9 (Nonempty multiplier multiplication has positive result shape)**.** *If* $\mathsf{NatMul}(d, q, n)$*, q is not history-same to* e*, and d is not history-same to* e*, then the result has one-headed shape:*

$$\exists t,\ \mathsf{hsame}(n, \mathsf{E1}(t)) \wedge \mathsf{UnaryHistory}(t).$$

Proof. The multiplication witness carries a unary classifier for q. The empty case contradicts the displayed non-emptiness, and the zero-headed case contradicts unary exactness. Hence $q = \mathsf{E1}(q_0)$, and Definition 64.8 applies to the same multiplication witness and the nonempty multiplicand. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul nonempty multiplier result positive shape`

Theorem 64.10 (Successor multiplication empty result exactness)**.** *If* $\mathsf{NatMul}(d, \mathsf{E1}(q), n)$*, then the result is empty exactly when the left multiplicand is empty:*

$$\mathsf{hsame}(n, \mathsf{e}) \iff \mathsf{hsame}(d, \mathsf{e}).$$

Proof. The forward implication is the successor empty-result inversion above. For the reverse implication, identify d with e and apply the empty-left multiplication result theorem to the same multiplication witness. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul succ result empty left empty iff`

Lemma 64.11 (Unary multiplication right operand is unary)**.** *Every closed witness of* $\mathsf{NatMul}(d, q, n)$ *carries a unary multiplier q.*

Proof. Induct on the NatMul witness. The zero constructor has multiplier e, and the successor constructor applies $\mathsf{E1}$ to the previous unary multiplier. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul right unary`

Lemma 64.12 (Unary multiplication is functional)**.** *For each pair of unary histories (d, q), there is at most one unary n with* $\mathsf{NatMul}(d, q, n)$*, up to* hsame*.*

Proof. By induction on the second argument q, using the determinacy of Cont at each appending step. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul functional`

Theorem 64.13 (Nonempty multiplicand result cancellation)**.** *Let d be a unary history with $d \not\mathsf{hsame}\mathsf{e}$. If* $\mathsf{NatMul}(d, q, n)$ *and* $\mathsf{NatMul}(d, r, m)$ *have history-same results, then the multipliers are history-same:*

$$\mathsf{NatMul}(d, q, n) \wedge \mathsf{NatMul}(d, r, m) \wedge n \mathsf{hsame} m \implies q \mathsf{hsame} r.$$

Proof. Induct on the first multiplication witness. In the zero case, the common result is empty, and empty-result exactness for a nonempty multiplicand forces the second multiplier to be empty. In the successor case, a zero witness on the right would make the appended nonempty multiplicand empty, contradicting the hypothesis on d. The successor–successor branch cancels the common continuation suffix d from the two result rows and applies the induction hypothesis to the predecessor products, then rebuilds the one-headed multiplier equality. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul nonempty multiplicand result cancel`

Theorem 64.14 (Unary multiplication commutes up to history sameness)**.** *For unary histories d and q, if* $\mathsf{NatMul}(d, q, n)$ *and* $\mathsf{NatMul}(q, d, m)$*, then* $n\mathsf{hsame}m$*.*

Proof. The concrete multiplication witness fixes the BEDC word length of its result as the product of the word lengths of its two unary inputs. The two displayed products therefore have equal lengths by commutativity of natural-number multiplication. Since unary histories are determined by their word length, the two multiplication ledgers have history-same results. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul comm hsame`

Theorem 64.15 (Nonempty multiplier result cancellation)**.** *Let q be a unary history with q /* $\mathsf{hsame}\mathsf{e}$*. If* $\mathsf{NatMul}(d, q, n)$ *and* $\mathsf{NatMul}(r, q, m)$ *have history-same results, then the multiplicands are history-same:*

$$\mathsf{NatMul}(d, q, n) \wedge \mathsf{NatMul}(r, q, m) \wedge n\mathsf{hsame}m \Longrightarrow d\mathsf{hsame}r.$$

Proof. Read unary witnesses for d, q, and r from the two multiplication witnesses. By totality of unary multiplication, form reversed products $\mathsf{NatMul}(q, d, n')$ and $\mathsf{NatMul}(q, r, m')$.

Apply Definition 64.14 to the first pair of products and again to the second pair. These two commutativity comparisons transport the assumed result equality $n\mathsf{hsame}m$ to $n'\mathsf{hsame}m'$.

Now apply Definition 64.13 to the reversed products, using the nonempty multiplicand q. It gives $d\mathsf{hsame}r$, as required. □

Theorem 64.16 (Unary multiplication associates up to history sameness)**.** *For unary histories a, b, c, if ab realizes* $\mathsf{NatMul}(a, b, -)$*, ℓ realizes* $\mathsf{NatMul}(ab, c, -)$*, bc realizes* $\mathsf{NatMul}(b, c, -)$*, and r realizes* $\mathsf{NatMul}(a, bc, -)$*, then* $\ell\mathsf{hsame}r$*.*

Proof. Both displayed products are unary. Their BEDC word lengths read back as $(|a| \cdot |b|) \cdot |c|$ and $|a| \cdot (|b| \cdot |c|)$, respectively; natural-number associativity identifies these lengths, and unary length readback identifies the two histories up to hsame. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul assoc hsame`

Lemma 64.17 (Unary multiplication is total on unary inputs)**.** *For every pair of unary histories (d, q) there exists a unary n with* $\mathsf{NatMul}(d, q, n)$*.*

Proof. By unary induction on q. The base case yields $n = \mathsf{e}$; the step appends one further copy of d using Cont. Closure of unary histories under Cont (chapter 28) keeps n unary. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul total`

Lemma 64.18 (Unary multiplication results are unary)**.** *For every unary multiplicand d, every derivation* $\mathsf{NatMul}(d, q, n)$ *has a unary result n.*

Proof. Induct on the NatMul derivation. The zero constructor returns e, and the successor constructor appends the unary multiplicand to the unary inductive result, so unary closure under Cont applies. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul result unary`

Theorem 64.19 (Append-continuation multiplication closure)**.** *Let d, w, q, n, e, and r be histories. If the two displayed products share the same multiplicand and the two product results concatenate, then the appended multiplier has the concatenated result:*

$$\mathsf{NatMul}(d, w, n) \wedge \mathsf{NatMul}(d, q, e) \wedge \mathsf{Cont}(n, e, r) \Longrightarrow \mathsf{NatMul}(d, \mathsf{append}(w, q), r).$$

Proof. Induct on the left product. The zero case reduces the appended multiplier to q and the displayed continuation to the left-empty continuation for e.

In the successor case, the inductive product composes the predecessor product with the right product along the predecessor continuation. One further successor multiplication step appends the common multiplicand d to that intermediate result, and associativity of continuation concatenation identifies the displayed result r. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul append cont`

Theorem 64.20 (NatMul total functional law surface)**.** *On* UnaryHistory *inputs, the concrete* NatMul *relation is total, has unary outputs, and is functional up to* hsame*. Equivalently, for all unary histories d and q there is a unary history n with* $\mathsf{NatMul}(d, q, n)$*, and whenever* $\mathsf{NatMul}(d, q, n)$ *and* $\mathsf{NatMul}(d, q, n')$ *are two products from the same inputs, the outputs satisfy* $n \mathsf{hsame} n'$*.*

Proof. Use Definition 64.17 to obtain a displayed product $\mathsf{NatMul}(d, q, n)$ for unary inputs d and q.

Apply Definition 64.18 to that product to read the result back inside UnaryHistory. For any second product from the same inputs, apply Definition 64.12 to identify the two displayed results up to hsame. □

Theorem 64.21 (NatMul one-history unit law surface)**.** *For the one-step unary history* $\mathsf{E1}(\mathsf{e})$ *and every unary history d, the concrete multiplication rows display one-history unit laws:*

$$\mathsf{NatMul}(\mathsf{E1}(\mathsf{e}), d, n) \Longrightarrow n \mathsf{hsame} d$$

and

$$\mathsf{NatMul}(d, \mathsf{E1}(\mathsf{e}), n) \Longrightarrow n \mathsf{hsame} d.$$

The proof dependencies are the Lean-side rows BEDC.Derived.PrimeUp.NatMul_unit_left_hsame *and* BEDC.Derived.PrimeUp.NatMul_unit_right_hsame*.*

Proof. For the left unit, unfold the multiplication derivation against the one-history multiplicand. The zero branch is excluded by the displayed multiplier, and the single successor branch leaves exactly the multiplier history, transported through the recorded hsame endpoint.

For the right unit, induct over the one-history multiplier. The sole successor step appends one copy of d to the zero product, and the continuation unit identifies the result with d up to hsame. □

Theorem 64.22 (NatMul append-composition law surface)**.** *The multiplicative composition row consumed by* $\mathsf{Mul}^{\uparrow}$ *is the* NatMul *append law together with the shared* Cont *ledger:*

$$\mathsf{NatMul}(d, w, n) \wedge \mathsf{NatMul}(d, q, e) \wedge \mathsf{Cont}(n, e, r) \Longrightarrow \mathsf{NatMul}(d, \mathsf{append}(w, q), r).$$

Thus the ledger records the two source products and the continuation witness that composes their results.

Proof. Project the two source product rows and the displayed $\mathsf{Cont}(n, e, r)$ ledger witness. Then apply Definition 64.19.

The conclusion is the same NatMul row on the appended multiplier, with no host multiplication, quotient, or classical choice principle. The only composition data read by consumers are the source products and the shared continuation ledger. □

Theorem 64.23 (Concrete unary multiplication MulUp certificate spine)**.** *The concrete unary multiplication candidate for* MulUp *uses carrier* UnaryHistory *over* BHist*, classifier* hsame*, operation relation* NatMul*, and unit* E1(e)*. Its certificate spine is the following finite law package.*

1. *Totality: for unary histories d and q, there is a unary n with* $\mathsf{NatMul}(d, q, n)$*.*
2. *Result closure: every* $\mathsf{NatMul}(d, q, n)$ *with unary d has unary result n.*
3. *Functionality: any two results of* $\mathsf{NatMul}(d, q, -)$ *for unary inputs are* hsame*.*
4. *Unit laws:* $\mathsf{NatMul}(\mathsf{E1}(\mathsf{e}), q, n)$ *gives n*hsame*q, and* $\mathsf{NatMul}(d, \mathsf{E1}(\mathsf{e}), n)$ *gives n*hsame*d.*
5. *Commutativity: products* $\mathsf{NatMul}(d, q, n)$ *and* $\mathsf{NatMul}(q, d, m)$ *over unary inputs have n*hsame*m.*
6. *Associativity: for unary a, b, and c, products* $\mathsf{NatMul}(a, b, ab)$*,* $\mathsf{NatMul}(ab, c, \ell)$*,* $\mathsf{NatMul}(b, c, bc)$*, and* $\mathsf{NatMul}(a, bc, r)$ *have ℓ*hsame*r.*

Proof. The carrier, classifier, operation, and unit are the concrete objects already used by NatMul. Totality, result closure, functionality, the two unit laws, and commutativity are exactly the checked unary multiplication laws in this section.

For associativity, induct on the middle multiplication spine. The base case is the zero multiplier. The successor case rewrites the right-associated product as an appended multiplier product, applies Definition 64.19, and then uses functionality to compare it with the displayed left-associated result. □

Theorem 64.24 (Unary multiplication MulUp semantic exit package)**.** *For unary histories d and q, the result carrier* $\mathsf{NatMul}(d, q, -)$ *has a* SemanticNameCert *with classifier* hsame*. Together with the concrete carrier* UnaryHistory *over* BHist*, classifier* hsame*, operation relation* NatMul*, unit* E1(e)*, totality, result closure, functionality, the two unit laws, commutativity, and associativity, this supplies the* MulUp *phase exit package over* BHist*.*

Proof. Apply Definition 64.23 for the algebraic spine. Its rows are precisely the concrete carrier, classifier, operation, unit, totality, result closure, functionality, left and right unit laws, commutativity, and associativity for unary multiplication.

The result carrier certificate is the checked NatMul_result_semanticNameCert theorem. It takes the unary inputs d and q and returns a SemanticNameCert for the predicate $\mathsf{NatMul}(d, q, -)$ with classifier hsame.

The dependency list is therefore the checked multiplication family NatMul_total, NatMul_result_unary, NatMul_functional, NatMul_unit_left_hsame, NatMul_unit_right_hsame, NatMul_comm_hsame, NatMul_assoc_hsame, and the result-name certificate. These rows are exactly the finite exit data needed for the full natural-arithmetic phase object to consume MulUp as a single semantic package. □

Theorem 64.25 (MulUp semantic exit audit row coverage)**.** *The concrete unary multiplication package over* BHist *is audit-covered by the semantic exit theorem, the* SemanticNameCert *result row, the two* $\mathsf{Add}^{\uparrow}$ *distributivity surfaces, and the unary-prefix* $\mathsf{Order}^{\uparrow}$ *monotonicity row. All rows are read through* UnaryHistory*,* hsame*,* Cont*,* NatMul*, and* PreorderPrefixLE*, so the displayed surface is a single consumption point for the full natural-arithmetic phase.*

Proof. Apply Definition 64.24. It packages the carrier, classifier, multiplication relation, and SemanticNameCert result row over the displayed unary histories.

The additive interaction rows are Definition 64.27 and Definition 64.28. They use the same Cont presentation of unary addition and return to the same NatMul relation.

For the order-facing row, use Definition 64.26. Finally, Definition 64.49 records that these additive and order rows share the same concrete carrier and classifier surface, so the coverage package introduces no additional BEDC object. □

Theorem 64.26 (Unary multiplication preserves unary-prefix order)**.** *Let* $d, q, q', n, n' : \mathsf{Hist}$ *be unary histories. If* $\mathsf{PreorderPrefixLE}(q, q')$*,* $\mathsf{NatMul}(d, q, n)$*, and* $\mathsf{NatMul}(d, q', n')$*, then* $\mathsf{PreorderPrefixLE}(n, n')$*. The displayed prefix witness from* n *to* n' *is built from the* Cont *ledger for the extra unary tail of* q' *over* q*.*

Proof. Invert the $\mathsf{PreorderPrefixLE}(q, q')$ witness through the $\mathsf{Order}^{\uparrow}$ unary-prefix export. It presents a unary tail t and a continuation ledger with q' read as the unary append of q and t.

Apply Definition 64.19 to the multiplication row $\mathsf{NatMul}(d, q, n)$ and to that extra tail ledger. This constructs a product row for d against the displayed append presentation of q'.

Use NatMul functionality to compare the constructed product with the given result n'. The comparison transports the appended-product endpoint through hsame without changing the consumed unary tail.

Finally apply the unary-prefix append-tail classifier for $\mathsf{PreorderPrefixLE}$. The prefix from n to the constructed appended product is the continuation ledger supplied by multiplication; transporting it through the final hsame comparison gives the required $\mathsf{PreorderPrefixLE}(n, n')$ witness. □

Theorem 64.27 (NatMul right additive distribution surface)**.** *Let* $d, w, q, n, e, r : \mathsf{Hist}$ *be unary histories. If* $\mathsf{NatMul}(d, w, n)$*,* $\mathsf{NatMul}(d, q, e)$*, and the* $\mathsf{Add}^{\uparrow}$ *continuation row presents the unary sum of* w *and* q *as* $\mathsf{append}(w, q)$ *with* $\mathsf{Cont}(n, e, r)$*, then* $\mathsf{NatMul}(d, \mathsf{append}(w, q), r)$*. Consequently the concrete* $\mathsf{Mul}^{\uparrow}$ *operation distributes over the right-hand* $\mathsf{Add}^{\uparrow}$ *continuation presentation of unary addition.*

Proof. The two multiplication rows supply the factor products for d against w and q. Apply Definition 64.19 to these factor rows and to the displayed continuation $\mathsf{Cont}(n, e, r)$; it constructs the product row for d against the appended multiplier $\mathsf{append}(w, q)$ with endpoint r.

The $\mathsf{Add}^{\uparrow}$ concrete NameCert surface reads unary addition through the same $\mathsf{UnaryHistory}$ carrier, continuation ledger, and append presentation. Therefore the continuation row that displays the sum of w and q is exactly the additive boundary required by the multiplication closure theorem.

Repack the constructed NatMul row together with that $\mathsf{Add}^{\uparrow}$ boundary. The resulting surface is the displayed $\mathsf{Mul}^{\uparrow}/\mathsf{Add}^{\uparrow}$ phase interaction: multiplication by the fixed unary history d sends the right-hand additive presentation $w + q$ to the continuation presentation of the two products. □

Theorem 64.28 (NatMul left additive distribution surface)**.** *Let* $d, w, q, n, e, r : \mathsf{Hist}$ *be unary histories. If* $\mathsf{NatMul}(w, d, n)$*,* $\mathsf{NatMul}(q, d, e)$*, and the* $\mathsf{Add}^{\uparrow}$ *continuation row presents the unary sum of* w *and* q *as* $\mathsf{append}(w, q)$ *with* $\mathsf{Cont}(n, e, r)$*, then* $\mathsf{NatMul}(\mathsf{append}(w, q), d, r)$*. Consequently the concrete* $\mathsf{Mul}^{\uparrow}$ *operation distributes over the left-hand* $\mathsf{Add}^{\uparrow}$ *continuation presentation of unary addition.*

Proof. Use NatMul commutativity on the two displayed left-factor products. It supplies right-factor product presentations for multiplication by the fixed unary history d, with endpoints identified with n and e by hsame.

Apply Definition 64.27 to those right-factor presentations and to the transported continuation ledger. This constructs a product row whose multiplier is $\mathsf{append}(w, q)$ and whose endpoint is identified with r.

Finally apply NatMul commutativity to the constructed row. The result is a product with multiplicand $\mathsf{append}(w, q)$ and multiplier d; functionality transports the endpoint comparison back along the original $\mathsf{Cont}(n, e, r)$ boundary, yielding $\mathsf{NatMul}(\mathsf{append}(w, q), d, r)$. □

Lemma 64.29 (Unit left multiplication reads back the multiplier)**.** *For every unary history q, if* $\mathsf{NatMul}(\mathsf{E1}(\mathsf{e}), q, n)$*, then* $\mathsf{hsame}(n, q)$*.*

Proof. Induct on the concrete multiplication derivation for q. The zero case is immediate. In the successor case, unary inversion exposes the tail multiplier, the induction hypothesis identifies the previous product with that tail, and determinacy of Cont identifies the final appended unit with the canonical successor. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul unit left hsame`

Lemma 64.30 (Unit right multiplication reads back the multiplicand)**.** *For every history d, if* $\mathsf{NatMul}(d, \mathsf{E1}(\mathsf{e}), n)$*, then* $\mathsf{hsame}(n, d)$*.*

Proof. Invert the successor multiplication witness at multiplier $\mathsf{E1}(\mathsf{e})$. Its predecessor multiplier is e, so the predecessor product is the zero constructor result e. The final continuation is therefore the empty-left append of d, which identifies the result with d. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul unit right hsame`

Lemma 64.31 (Unit right multiplication iff)**.** *For every unary history d, multiplication on the right by the unit history returns exactly the multiplicand up to history-sameness:*

$$\mathsf{UnaryHistory}(d) \Longrightarrow (\mathsf{NatMul}(d, \mathsf{E1}(\mathsf{e}), n) \Longleftrightarrow \mathsf{hsame}(n, d)).$$

Proof. The forward direction is Definition 64.30. For the reverse direction, reduce along the displayed history-sameness. The zero multiplication constructor gives $\mathsf{NatMul}(d, \mathsf{e}, \mathsf{e})$ from the unary carrier, and the successor constructor appends d to the empty product using the left-unit continuation law. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul unit right iff`

Theorem 64.32 (Unary multiplication two-sided unit exactness)**.** *For unary histories q and d, left and right multiplication by the unit history* $\mathsf{E1}(\mathsf{e})$ *are exact up to history-sameness:*

$$\mathsf{NatMul}(\mathsf{E1}(\mathsf{e}), q, n) \Longleftrightarrow \mathsf{hsame}(n, q)$$

and

$$\mathsf{NatMul}(d, \mathsf{E1}(\mathsf{e}), n) \Longleftrightarrow \mathsf{hsame}(n, d).$$

Proof. For the left-hand equivalence, the forward direction is Definition 64.29. For the reverse direction, transport along the displayed $\mathsf{hsame}(n, q)$ identification and apply the closed unit-left multiplication theorem NatMul_unit_left_closed.

For the right-hand equivalence, apply Definition 64.31. Its statement is exactly the right unit exactness claim for unary multiplicands. □

Theorem 64.33 (Unit multiplication result forces unit factors)**.** *If a unary multiplication witness returns the unit history, then both the multiplicand and the multiplier are the unit history:*

$$\mathsf{NatMul}(d, q, \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{hsame}(d, \mathsf{E1}(\mathsf{e})) \wedge \mathsf{hsame}(q, \mathsf{E1}(\mathsf{e})).$$

Proof. Invert the multiplication witness at the unit result. The zero constructor is impossible. In the successor case, continuation inversion at an E1 result either makes the multiplicand empty, contradicting empty-left multiplication, or exposes a one-headed multiplicand whose tail continuation has empty result. Empty-result inversion then forces that tail and the predecessor product to be empty, so the multiplier tail is empty by the nonempty-multiplicand empty-result exactness theorem. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul unit result factors unit`

Lemma 64.34 (E0-multiplier exclusion)**.** *No unary multiplication witness has an* E0*-headed multiplier: for all histories* d, q, n*,* $\mathsf{NatMul}(d, \mathsf{E0}(q), n)$ *is impossible.*

Proof. By constructor inversion on the closed relation NatMul: its multiplier argument is generated only by e and E1-successor cases. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul e0 multiplier absurd`

Theorem 64.35 (Unary multiplication zero-headed component impossibility)**.** *If* $\mathsf{NatMul}(d, q, n)$ *holds, then none of* d*,* q*, or* n *can be a zero-headed history.*

Proof. The multiplication witness exposes unary evidence for the multiplicand, multiplier, and result. Each possible zero-headed equality contradicts the corresponding unary-history witness by the zero-extension exclusion theorem. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul zero headed component absurd`

Theorem 64.36 (Empty multiplier exactness for unary multiplication)**.** *For all histories* d, n*,*

$$\mathsf{NatMul}(d, \mathsf{e}, n) \iff \mathsf{UnaryHistory}(d) \wedge \mathsf{hsame}(n, \mathsf{e}).$$

Proof. The forward direction inverts the closed NatMul witness. The only constructor with empty multiplier is the empty-multiplier row, which records the unary field for d and returns the empty result. Conversely, if d is unary and $n$hsamee, identify the endpoint with e and apply the empty-multiplier constructor. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul empty right iff`

Theorem 64.37 (Empty multiplicand exactness for unary multiplication)**.** *For all histories* q, n*,*

$$\mathsf{NatMul}(\mathsf{e}, q, n) \iff \mathsf{UnaryHistory}(q) \wedge \mathsf{hsame}(n, \mathsf{e}).$$

Proof. For the forward direction, every closed multiplication witness carries a unary multiplier, and empty-left multiplication has empty result by induction over the witness.

Conversely, identify the displayed result with e and induct on the unary history q. The empty case is the zero constructor for $\mathsf{NatMul}(\mathsf{e}, \mathsf{e}, \mathsf{e})$. A zero-headed unary case is impossible. In the E1 case, apply the induction hypothesis to the tail and then append one empty block using the successor constructor together with $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul empty left iff`

Theorem 64.38 (Nonempty multiplicand and empty multiplication result)**.** *For every unary multiplicand* d *with* d /hsamee*, the empty-result case of* $\mathsf{NatMul}(d, q, \mathsf{e})$ *is equivalent to the empty multiplier* $q$hsamee*.*

Proof. The forward direction inverts the NatMul derivation. The zero constructor gives the empty multiplier. A successor constructor would include a continuation $\mathsf{Cont}(n, d, \mathsf{e})$; empty-result inversion for Cont forces $d$hsamee, contradicting the nonempty multiplicand hypothesis. The reverse direction is the zero constructor after identifying q with e. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul nonempty multiplicand empty result iff`

Lemma 64.39 (Empty unary multiplication result exposes an empty factor)**.** *If* $\mathsf{NatMul}(d, q, \mathsf{e})$*, then either the multiplicand is empty* $d$hsamee*, or the multiplier is empty* $q$hsamee*.*

Proof. Invert the closed multiplication witness. The zero constructor has multiplier e. A successor constructor ends with a continuation $\mathsf{Cont}(n, d, \mathsf{e})$, and empty-result inversion for Cont forces $d$hsamee. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul empty result factor empty or multiplier empty`

Theorem 64.40 (Unary multiplication empty result iff an input is empty)**.** *If* $\mathsf{NatMul}(d, q, n)$*, then*

$$n\mathsf{hsamee} \iff d\mathsf{hsamee} \lor q\mathsf{hsamee}.$$

Proof. For the forward implication, transport the displayed result equality to the empty-result case and apply Definition 64.39.

For the converse implication, split on the empty input. If the multiplicand is empty, Definition 64.4 identifies the product result with e. If the multiplier is empty, the empty-right multiplication iff gives the canonical empty product for the same multiplicand; functionality of NatMul identifies the displayed result with that empty product. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul empty result iff factor empty or multiplier empty`

Theorem 64.41 (Successor multiplication result equal to factor exposes an empty input)**.** *If* d *is unary,* $\mathsf{NatMul}(d, \mathsf{E1}(q), n)$*, and* $n$hsame$d$*, then either* $d$hsamee *or* $q$hsamee*.*

Proof. Invert the successor multiplication to obtain a predecessor product $\mathsf{NatMul}(d, q, p)$ and a continuation $\mathsf{Cont}(p, d, n)$. Transport that continuation across $n$hsame$d$, then cancel its common right factor against the displayed unit continuation $\mathsf{Cont}(\mathsf{e}, d, d)$. This gives $p$hsamee. Transport the predecessor product to empty result and apply the empty-result factor split. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul succ result eq factor empty or multiplier empty`

Theorem 64.42 (Nonempty unary multiplication factors have nonempty result)**.** *If neither* d *nor* q *is history-same to* e*, then no witness* $\mathsf{NatMul}(d, q, n)$ *can have* $n$hsamee*.*

Proof. Transport the result equality to the empty-result case and apply the preceding empty-result factor theorem. Its two alternatives are exactly the two excluded empty-factor cases. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul nonempty factors result not empty`

Theorem 64.43 (Append-continuation multiplication empty result split)**.** *Let* d *be unary and not history-same to* e*. If* $\mathsf{NatMul}(d, w, n)$*,* $\mathsf{NatMul}(d, q, e)$*, and* $\mathsf{Cont}(n, e, r)$*, then* $r$hsamee *exactly when both* $w$hsamee *and* $q$hsamee*.*

Proof. Append-continuation closure first gives a multiplication witness for $\mathsf{append}(w, q)$ with result r. The nonempty-multiplicand empty-result theorem reduces the empty result to an empty appended multiplier, and append empty-result exactness splits that condition into the two factors. The converse builds the empty appended multiplier and uses multiplication functionality to identify the continuation result with e. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul append cont empty result empty factors iff`

Theorem 64.44 (Successor multiplicand appends the multiplier)**.** *If* $\mathsf{NatMul}(d, q, n)$*, then there is a unary history* r *such that* $\mathsf{Cont}(n, q, r)$ *and* $\mathsf{NatMul}(\mathsf{E1}(d), q, r)$*.*

Proof. Induct on the concrete multiplication witness. The empty multiplier case chooses $r = \mathsf{e}$. In the successor case, the induction hypothesis displays the predecessor result as the continuation of the old product by the predecessor multiplier. The final multiplication step appends d, while the successor multiplicand step appends $\mathsf{E1}(d)$. Associativity of continuation and commutativity of unary append exchange the predecessor multiplier with d, giving the displayed continuation by $\mathsf{E1}(q)$ and the successor-multiplicand multiplication witness. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul succ multiplicand append multiplier total`

Lemma 64.45 (Append multiplier right factor readback)**.** *Let* d *and* q *be unary histories. If* $\mathsf{NatMul}(d, w, n)$ *and* $\mathsf{NatMul}(d, \mathsf{append}(w, q), r)$ *hold, and if* $\mathsf{Cont}(n, e, r)$ *displays* e *as the right factor of the result continuation, then* $\mathsf{NatMul}(d, q, e)$*.*

Proof. Use totality of unary multiplication to build a product e' for d and q. Append-continuation closure then produces a product for $\mathsf{append}(w, q)$ with result $\mathsf{append}(n, e')$. Functionality of NatMul identifies this result with the displayed r. Transport the continuation $\mathsf{Cont}(n, e', \mathsf{append}(n, e'))$ across that result equality, left-cancel it against $\mathsf{Cont}(n, e, r)$, and transport the product for q from e' to e. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul append multiplier right factor`

Lemma 64.46 (Append multiplier left factor readback)**.** *Let* d *and* w *be unary histories. If* $\mathsf{NatMul}(d, q, e)$ *and* $\mathsf{NatMul}(d, \mathsf{append}(w, q), r)$ *hold, and if* $\mathsf{Cont}(n, e, r)$ *displays* n *as the left factor of the result continuation, then* $\mathsf{NatMul}(d, w, n)$*.*

Proof. Use totality of unary multiplication to build a product n' for d and w. Append-continuation closure combines this product with the supplied product for q, producing a product for $\mathsf{append}(w, q)$ with result $\mathsf{append}(n', e)$. Functionality of NatMul identifies that result with the displayed r. Transport the continuation $\mathsf{Cont}(n', e, \mathsf{append}(n', e))$ across this result equality, right-cancel it against $\mathsf{Cont}(n, e, r)$, and transport the product for w from n' to n. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul append multiplier left factor`

Theorem 64.47 (Append multiplier result deterministic)**.** *Let* d *be unary. If* $\mathsf{NatMul}(d, w, n)$ *and* $\mathsf{NatMul}(d, q, e)$ *are displayed factor products,* $\mathsf{NatMul}(d, \mathsf{append}(w, q), r)$ *is a product over the appended multiplier, and* $\mathsf{Cont}(n, e, z)$ *displays the combined result, then* $r\mathsf{hsame}z$*.*

Proof. Append-continuation multiplication closure combines the two factor products along $\mathsf{Cont}(n, e, z)$, producing a multiplication witness for $\mathsf{append}(w, q)$ with result z. Functionality of NatMul for the unary multiplicand d compares this constructed witness with the displayed appended-multiplier witness and identifies the two results. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul append multiplier result deterministic`

Theorem 64.48 (MulUp unary product order lower-bound package)**.** *Let d, q, and n be unary histories. If* $\mathsf{NatMul}(d, \mathsf{E1}(q), n)$*, then the* MulUp *product row exports the following* $\mathsf{Order}^{\uparrow}$ *boundary package over the unary-prefix order of Definition 54.45:*

1. *the carrier rows* $\mathsf{UnaryHistory}(d)$*,* $\mathsf{UnaryHistory}(\mathsf{E1}(q))$*, and* $\mathsf{UnaryHistory}(n)$*;*
2. *the unary-prefix comparison* $d \leq_{\mathsf{u}} n$*;*
3. *the endpoint classifier boundary* ρ_{u} *used by* $\mathsf{Order}^{\uparrow}$ *to read equality of endpoints under two-sided* $\leq_{\mathsf{u}}$ *comparison.*

Proof. First expose the multiplication package by Definition 64.24. Its carrier row gives the displayed unary histories for d and $\mathsf{E1}(q)$, and its result closure gives $\mathsf{UnaryHistory}(n)$ from the supplied $\mathsf{NatMul}(d, \mathsf{E1}(q), n)$ witness.

The empty-tail boundary $q = \mathsf{e}$ is the right-unit product. The unit law in the same MulUp package reads the product result back as $n\mathsf{hsame}d$; the $\mathsf{Order}^{\uparrow}$ package of Definition 54.45 then uses reflexivity and endpoint classifier transport to obtain $d \leq_{\mathsf{u}} n$.

For a successor tail, apply Definition 64.44 to the predecessor multiplication row. The appended-multiplier factor lemmas Definition 64.46 and Definition 64.45 recover the left product and right product from the displayed continuation product. Then Definition 64.47 identifies the displayed result with the append of the predecessor product and the extra multiplicand copy.

This append display is exactly the unary-prefix witness that the original multiplicand lies below the product. Project the relation row and classifier row from Definition 54.45: the relation row records $d \leq_{\mathsf{u}} n$, and the classifier row records ρ_{u} as the endpoint boundary used whenever two-sided $\leq_{\mathsf{u}}$ comparison collapses the endpoints. □

Theorem 64.49 (MulUp AddUp OrderUp phase interaction package)**.** *For unary histories d, w, q, n, e, r, the concrete unary* $\mathsf{Mul}^{\uparrow}$ *package exports a single consumer package combining the following rows:*

1. *the right additive distribution row over the* $\mathsf{Add}^{\uparrow}$ *continuation presentation, sending* $\mathsf{NatMul}(d, w, n)$*,* $\mathsf{NatMul}(d, q, e)$*, and* $\mathsf{Cont}(n, e, r)$ *to* $\mathsf{NatMul}(d, \mathsf{append}(w, q), r)$*;*
2. *the left additive distribution row over the same* $\mathsf{Add}^{\uparrow}$ *continuation presentation, sending* $\mathsf{NatMul}(w, d, n)$*,* $\mathsf{NatMul}(q, d, e)$*, and* $\mathsf{Cont}(n, e, r)$ *to* $\mathsf{NatMul}(\mathsf{append}(w, q), d, r)$*;*
3. *the unary-prefix* $\mathsf{Order}^{\uparrow}$ *lower-bound row for successor products, which reads* $\mathsf{NatMul}(d, \mathsf{E1}(q), n)$ *as the boundary* $\mathsf{PreorderPrefixLE}(d, n)$ *together with the endpoint classifier row.*

The shared consumer objects are BHist*,* UnaryHistory*,* hsame*,* Cont*,* NatMul*, and* PreorderPrefixLE*.*

Proof. The right additive row is exactly Definition 64.27. It uses the $\mathsf{Add}^{\uparrow}$ continuation presentation through the same $\mathsf{Cont}(n, e, r)$ ledger and keeps the product predicate inside NatMul.

The left additive row is Definition 64.28. Its proof transports through commutativity of NatMul and returns to the left-hand presentation without changing the underlying BHist carrier, UnaryHistory predicate, hsame classifier, or continuation row.

The order row is supplied by Definition 64.48. It repacks the successor-product multiplication witness into the unary-prefix relation PreorderPrefixLE and the $\mathsf{Order}^{\uparrow}$ endpoint classifier. Since all three rows consume the displayed NatMul and Cont ledgers over the same unary histories, the package combines them without introducing another carrier or classifier. □

Definition 64.50 (Divisibility relation)**.** *For unary histories d, n, the divisibility relation* $\mathsf{NatDivides}(d, n)$ *holds when there exists a unary q with* $\mathsf{NatMul}(d, q, n)$*. The witness q is the explicit quotient.*

Lean4 (definition) `BEDC.Derived.PrimeUp.NatDivides`

Theorem 64.51 (Divisibility result unary carrier)**.** *If* $\mathsf{NatDivides}(d, n)$ *holds, then* n *is a unary history.*

Proof. Unpack the quotient witness. The multiplication witness exposes unary d, and multiplication result closure then proves the result history n unary. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides result unary`

Lemma 64.52 (Divisibility result cases)**.** *Every witness of* $\mathsf{NatDivides}(d, n)$ *is either an empty-result witness, with* $n\mathsf{hsamee}$ *and* d *unary, or a successor-product witness: there is a predecessor* n_0 *with* $\mathsf{NatDivides}(d, n_0)$ *and* $\mathsf{Cont}(n_0, d, n)$*.*

Proof. Unpack the explicit quotient in the divisibility witness. If its NatMul witness is zero, the result is empty and the multiplicand field gives unary d. If it is a successor witness, unary inversion on the quotient supplies a unary predecessor quotient, and the predecessor multiplication witness repackages as $\mathsf{NatDivides}(d, n_0)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides result cases`

Theorem 64.53 (Divisibility zero-headed component impossibility)**.** *If* $\mathsf{NatDivides}(d, n)$ *holds, then neither the divisor* d *nor the dividend* n *can be a zero-headed history.*

Proof. Unpack the explicit quotient q in the divisibility witness. The underlying $\mathsf{NatMul}(d, q, n)$ witness rules out zero-headed multiplicand, multiplier, and result components. Applying that impossibility to the divisor or dividend component gives the claim. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides zero headed component absurd`

Lemma 64.54 (Empty left divisibility has empty result)**.** *If* $\mathsf{NatDivides}(\mathsf{e}, n)$*, then* $n\mathsf{hsamee}$*.*

Proof. Unpack the quotient witness for divisibility. Its multiplication field is a witness of $\mathsf{NatMul}(\mathsf{e}, q, n)$, so empty-left multiplication exactness identifies the result n with e. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides empty left result empty`

Theorem 64.55 (Successor-result divisors have positive shape)**.** *If* $\mathsf{NatDivides}(d, \mathsf{E1}(n))$*, then* d *has positive unary shape: there is a unary history* t *with* $d\mathsf{hsameE1}(t)$*.*

Proof. Unpack the divisibility witness and read the unaryness of d from its multiplication field. If d were empty, empty-left divisibility would force $\mathsf{E1}(n)\mathsf{hsamee}$, contradicting successor non-emptiness. The $e0$ case is excluded by unary-history inversion. Hence d is $e1$-headed, and the unary tail is obtained by unary inversion. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides successor result divisor positive shape`

Theorem 64.56 (Nonempty-result divisors have positive shape)**.** *If* $\mathsf{NatDivides}(d, n)$*,* n *is unary, and* $n \not\mathsf{hsamee}$*, then* d *has positive unary shape: there is a unary history* t *with* $d\mathsf{hsameE1}(t)$*.*

Proof. Unpack the quotient witness in $\mathsf{NatDivides}(d, n)$ and read the unaryness of d from its multiplication field. If $d\mathsf{hsamee}$, then empty-left divisibility forces $n\mathsf{hsamee}$, contradicting the displayed nonempty result. The $e0$-headed case is excluded by unary-history inversion, so the divisor is $e1$-headed and unary inversion supplies the tail carrier. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides nonempty result divisor positive shape`

Theorem 64.57 (Empty-left divisibility exactness)**.** *For every history n, divisibility by the empty unary history holds exactly when the result is empty:*

$$\mathsf{NatDivides}(\mathsf{e}, n) \iff \mathsf{hsame}(n, \mathsf{e}).$$

Proof. The forward implication is empty-left divisibility result exactness. For the reverse implication, identify n with e; then the empty quotient and the zero multiplication constructor witness $\mathsf{NatDivides}(\mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides empty left iff`

Lemma 64.58 (Empty right divisibility is unary carrier)**.** *For any history d,* $\mathsf{NatDivides}(d, \mathsf{e})$ *holds exactly when d is a unary history.*

Proof. In the forward direction, unpack the quotient witness; its multiplication field carries the unary multiplicand field for d. In the reverse direction, use the empty quotient and the zero constructor of NatMul. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides empty right iff`

Theorem 64.59 (Unit-left divisibility is unary carrier)**.** *For any history n,* $\mathsf{NatDivides}(\mathsf{E1}(\mathsf{e}), n)$ *holds exactly when n is a unary history.*

Proof. For the forward direction, unpack the quotient witness q. Multiplication by the unit identifies the result with q, and unaryness transports across that endpoint identification. Conversely, the unit-divisibility half of reflexivity gives $\mathsf{NatDivides}(\mathsf{E1}(\mathsf{e}), n)$ for every unary n. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides unit left iff`

Theorem 64.60 (Unit-right divisibility exactness)**.** *For any history d,* $\mathsf{NatDivides}(d, \mathsf{E1}(\mathsf{e}))$ *holds exactly when* $d\mathsf{hsameE1}(\mathsf{e})$.

Proof. In the forward direction, unpack the quotient witness and apply unit-result multiplication factor exactness: both factors of a product equal to $\mathsf{E1}(\mathsf{e})$ are the unary unit. Conversely, identify d with the unary unit and use reflexive divisibility for the unit history. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides unit right iff`

Lemma 64.61 (Divisibility is reflexive on the unit and on every unary history)**.** *For every unary n,* $\mathsf{NatDivides}(\mathsf{E1}(\mathsf{e}), n)$ *and* $\mathsf{NatDivides}(n, n)$.

Proof. The unit case takes $q = n$ in $\mathsf{NatMul}(\mathsf{E1}(\mathsf{e}), n, n)$ by induction. The self-divisibility case takes $q = \mathsf{E1}(\mathsf{e})$ and uses the continuation unit at the empty quotient. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides reflexive`
Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides unit self reflexive`
Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides reflexive pair`

Lemma 64.62 (Divisibility is transitive)**.** *If* $\mathsf{NatDivides}(d, e)$ *and* $\mathsf{NatDivides}(e, n)$*, then* $\mathsf{NatDivides}(d, n)$.

Proof. From the witnessing quotients q_1 with $\mathsf{NatMul}(d, q_1, e)$ and q_2 with $\mathsf{NatMul}(e, q_2, n)$, the composite quotient is $q_1 \cdot q_2$, itself constructed as a unary history by Definition 64.17. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides transitive`

Theorem 64.63 (Unary divisibility partial-order certificate)**.** *On unary histories,* NatDivides *is reflexive and transitive, and it is antisymmetric modulo* hsame*: for unary histories d, e, and n,* $\mathsf{NatDivides}(d, d)$*,* $\mathsf{NatDivides}(d, e) \wedge \mathsf{NatDivides}(e, n) \Rightarrow \mathsf{NatDivides}(d, n)$*, and* $\mathsf{NatDivides}(d, e) \wedge \mathsf{NatDivides}(e, d) \Rightarrow d\,\mathsf{hsame}\,e$*.*

Proof. The reflexive clause is Definition 64.61, and the transitive clause is Definition 64.62. The antisymmetric clause is Definition 64.181.

This is a paper-level bundled certificate rather than a distinct Lean marker site: the three checked laws are consumed together by bounded divisor search, Euclid's lemma, and factorization uniqueness as the order-like interface for unary divisibility. □

Theorem 64.64 (MulUp divisibility-order consumer package)**.** *For unary histories,* NatDivides *supplies the* $\mathsf{Mul}^{\uparrow}$ *arithmetic consumer package consisting of reflexivity, transitivity, antisymmetry modulo* hsame*, right-factor closure and left-multiplication closure through* NatMul*, and the unary-prefix lower-bound package for successor products. Thus any* $\mathsf{Mul}^{\uparrow}$ *consumer that reads only unary divisibility order, ordinary product closure, and successor-product prefix lower bounds may cite a single package boundary rather than reassembling those rows separately.*

Proof. The order rows are exactly the reflexive and transitive laws of Definition 64.61 and Definition 64.62, together with the antisymmetry certificate of Definition 64.181.

The multiplication-closure rows are supplied by Definition 64.89 and Definition 64.90. The boundary row that connects successor products with the unary-prefix order is Definition 64.48. Collecting these checked rows gives the stated $\mathsf{Mul}^{\uparrow}$ consumer surface. □

Theorem 64.65 (MulUp public semantic exit certificate)**.** *The concrete unary multiplication surface obtained from Definition 64.24, Definition 64.25, the right and left additive distribution surfaces Definition 64.27 and Definition 64.28, and Definition 64.26 is the public* $\mathsf{NameCert}_{\mathsf{Mul}^{\uparrow}}$ *consumption package over* BHist *for the full natural-arithmetic phase.*

A consumer of this package may read only the carrier UnaryHistory*, the classifier* hsame*, the continuation ledger* Cont*, the multiplication relation* NatMul*, the semantic result* NameCert *row, and the displayed* $\mathsf{Add}^{\uparrow}/\mathsf{Order}^{\uparrow}$ *interaction rows. The certificate does not expose cancellation, semiring completeness, or standard-bridge data.*

Proof. Project the semantic exit package of Definition 64.24. This gives the unary carrier over BHist, the classifier, the multiplication relation, the unit, the finite multiplication law rows, and the semantic result NameCert row.

Apply the audit coverage theorem Definition 64.25. Its coverage statement identifies the same public rows with the two additive distribution surfaces and the unary-prefix monotonicity row, all through UnaryHistory, hsame, Cont, and NatMul.

Repack the two $\mathsf{Add}^{\uparrow}$ distribution rows and the $\mathsf{Order}^{\uparrow}$ monotonicity row as one public consumption boundary. Since every displayed row uses the same carrier, classifier, continuation ledger, and multiplication relation, the boundary is exactly the $\mathsf{NameCert}_{\mathsf{Mul}^{\uparrow}}$ package consumed by the full natural-arithmetic phase, while the excluded cancellation, semiring, and standard-bridge data remain outside the theorem. □

Definition 64.66 (MulUp Full Nat audit consumer surface)**.** *The Full Nat audit consumer surface for* $\mathsf{Mul}^{\uparrow}$ *is the finite row family over* BHist *consisting exactly of the carrier* UnaryHistory*, the classifier* hsame*, the continuation ledger* Cont*, the multiplication relation* NatMul*, the semantic result*

NameCert *row, the right and left* Add$^{\uparrow}$ *distributivity rows, the unary-prefix* Order$^{\uparrow}$ *monotonicity row, and the divisibility-order rows available in the phase-exit package.*

Every row in the surface is read through the same unary endpoints, the same history classifier, and the same finite continuation ledgers. The surface has no coordinate for host multiplication, quotient equality, semiring structure, or cancellation outside the displayed divisibility-order rows.

Proof. This is the row list projected from Definition 64.65 and Definition 64.71. The first theorem fixes the carrier, classifier, continuation, multiplication, semantic result, and Add$^{\uparrow}$/Order$^{\uparrow}$ rows; the phase-exit boundary adds the divisibility-order consumer rows over the same endpoints. □

Theorem 64.67 (MulUp Full Nat Lean target boundary)**.** *A later Lean audit target for the L7* Mul$^{\uparrow}$ *exit may consume exactly the rows of Definition 64.66:* UnaryHistory*,* hsame*,* Cont*,* NatMul*, the semantic result* NameCert *row, the two* Add$^{\uparrow}$ *distributivity rows, the* Order$^{\uparrow}$ *monotonicity row, and the divisibility-order rows. It may not consume host multiplication, quotient formation, semiring primitives, a cancellation law, or a second carrier.*

Proof. Start from the consumer normal form of Definition 64.70. It states that the Full Nat Arithmetic consumer reads the phase-exit boundary only through the listed BHist rows.

Next apply Definition 64.71. This fixes the concrete source of the NatMul semantic exit, the additive distribution rows, the order row, and the divisibility rows.

Therefore a Lean target whose purpose is audit consumption has no further input slot. Any host multiplication, quotient, semiring, cancellation, or alternate carrier would be outside the displayed row family and hence outside the boundary. □

Theorem 64.68 (MulUp L7 audit-clean exit surface)**.** *The L7 Full Nat Arithmetic phase-exit surface for* Mul$^{\uparrow}$ *is assembled by the checked* BEDC.Derived.PrimeUp.NatMul_unary_mulup_certificate *row, the checked* BEDC.Derived.PrimeUp.NatMul_result_semanticNameCert *row, the right and left* Add$^{\uparrow}$ *distributivity rows, the unary-prefix* Order$^{\uparrow}$ *monotonicity row, and the divisibility-order rows of the phase-exit package. All rows are over* UnaryHistory*,* hsame*, finite* Cont *ledgers, and* NatMul*.*

Proof. Project Definition 64.65. It supplies the public Mul$^{\uparrow}$ package and names the checked NatMul certificate and semantic result certificate as the multiplication core.

Use Definition 64.71 to attach the surrounding arithmetic rows: the two Add$^{\uparrow}$ distributivity rows, the Order$^{\uparrow}$ monotonicity row, and the divisibility-order consumer rows. The normal form theorem Definition 64.70 identifies these as the rows available to a Full Nat Arithmetic consumer.

Finally repack the rows through Definition 64.66. The repacking changes no carrier, classifier, continuation ledger, or multiplication relation, so the result is a single L7 audit-clean exit surface rather than a host arithmetic surface. □

Theorem 64.69 (MulUp semantic exit and divisibility-order phase package)**.** *Over* BHist *and the carrier* UnaryHistory*, the semantic exit theorem, semantic-exit audit row coverage, and divisibility-order consumer package together give the full natural-arithmetic consumer surface for* Mul$^{\uparrow}$*. The surface consists of the carrier* UnaryHistory*, classifier* hsame*, multiplication relation* NatMul*, result* SemanticNameCert*, the two* Add$^{\uparrow}$ *distributivity rows, the* Order$^{\uparrow}$ *monotonicity row, and the unary divisibility reflexive, transitive, and antisymmetric consumer rows.*

Proof. Apply Definition 64.24. It fixes the carrier, classifier, multiplication relation, unit rows, algebraic laws, and result SemanticNameCert for unary multiplication over BHist.

Next apply Definition 64.25. It adds the Add$^{\uparrow}$ distributivity rows and the Order$^{\uparrow}$ monotonicity row without leaving the displayed unary-history carrier or the hsame classifier surface.

Finally apply Definition 64.64. Its reflexive, transitive, and antisymmetric divisibility rows use the same UnaryHistory carrier, the same hsame comparison, the same Cont transport ledgers, and the same NatMul relation. Therefore the three packages assemble as one Full Nat Arithmetic consumption point for $\mathsf{Mul}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.MulupSemanticExitAndDivisibilityOrderPhasePackage`

Theorem 64.70 (MulUp Full Nat Arithmetic consumer normal form)**.** *Any Full Nat Arithmetic consumer of* $\mathsf{Mul}^{\uparrow}$ *over* BHist *whose interface is restricted to the package rows of Definition 64.71 reads exactly the following normal form: the carrier is* UnaryHistory*, the classifier is* hsame*, the result ledger is* NatMul*, and the exposed row list is the unit row, commutativity row, associativity row, the two* $\mathsf{Add}^{\uparrow}$ *distributivity rows, the* $\mathsf{Order}^{\uparrow}$ *monotonicity row, and the divisibility-order consumer rows. It receives no host multiplication table, quotient carrier, semiring primitive, or cancellation law beyond those displayed rows.*

Proof. Start from the phase-exit boundary of Definition 64.71. It fixes the only carrier, classifier, multiplication relation, additive rows, order row, and divisibility rows available to a Full Nat Arithmetic consumer of the concrete $\mathsf{Mul}^{\uparrow}$ package over BHist.

Next apply the audit surface of Definition 64.78. That surface identifies the checked NatMul law rows and the result naming row while preserving the same UnaryHistory carrier, hsame classifier, finite Cont ledgers, and BHist endpoints.

Finally apply Definition 64.79 and Definition 64.82. The handoff identifies the allowed additive, order, and divisibility rows for L7 consumers, and the mature boundary rules out host multiplication, quotient equality, and a second carrier. Therefore the consumer normal form is precisely the displayed package row list and nothing outside it. □

Theorem 64.71 (MulUp Full Nat Arithmetic phase-exit boundary)**.** *Over* BHist *and the carrier* UnaryHistory*, the package of Definition 64.69 is exactly the* $\mathsf{Mul}^{\uparrow}$ *L7 consumer boundary required by the Full Nat Arithmetic phase. Its rows are the carrier* UnaryHistory*, classifier* hsame*, multiplication relation* NatMul*, unit, totality, result closure, functionality, unit laws, commutativity, associativity, the* $\mathsf{Add}^{\uparrow}$ *distributivity rows, the* $\mathsf{Order}^{\uparrow}$ *monotonicity row, and the divisibility-order consumer rows.*

Proof. Unfold the package theorem Definition 64.69. Its displayed surface already fixes the concrete carrier, classifier, multiplication relation, semantic result object, additive rows, order row, and divisibility-order rows over BHist and UnaryHistory.

The algebraic part comes from Definition 64.24: it supplies the unit, totality, result closure, functionality, unit laws, commutativity, and associativity rows for NatMul on the same hsame-classified unary histories.

The additive and order-facing part is the row coverage recorded by Definition 64.25 together with Definition 64.64. These give the $\mathsf{Add}^{\uparrow}$ distributivity rows, the $\mathsf{Order}^{\uparrow}$ monotonicity row, and the reflexive, transitive, and antisymmetric divisibility-order consumer rows without changing the carrier or classifier.

Thus a later Full Nat Arithmetic consumer can read $\mathsf{Mul}^{\uparrow}$ through this single boundary. No host natural-number multiplication, quotient object, or multiplication operation outside the unary-history package is used. □

Lean4 ✓ `BEDC.Derived.PrimeUp.MulupFullNatArithmeticPhaseExitBoundary`

Theorem 64.72 (MulUp Full Nat Arithmetic finite-window exhaustion)**.** *Every finite Full Nat Arithmetic consumer window whose entries are restricted to the boundary of Definition 64.71 factors through exactly the displayed* UnaryHistory *carrier, the* hsame *classifier, the* NatMul *ledger, the*

unit, totality, result-closure, functionality, unit-law, commutativity, and associativity rows, the two $\mathsf{Add}^{\uparrow}$ *distributivity rows, the* $\mathsf{Order}^{\uparrow}$ *monotonicity row, and the reflexive, transitive, and antisymmetric unary divisibility-order rows. Conversely each listed row contributes one admissible entry to such a finite window.*

Proof. Project the phase-exit boundary of Definition 64.71. It names the carrier UnaryHistory, the classifier hsame, the NatMul ledger, and the exact algebraic, additive, order, and divisibility-order row list available to the consumer window.

Apply the semantic-exit package and audit surface from Definition 64.69 and Definition 64.78. These identify every window entry as one of the displayed rows, since the window is finite and each entry must be read through the same BHist endpoint and the same hsame classifier.

For the reverse reading, take any row in the displayed list. The package theorems already expose that row as part of the boundary, so it gives an admissible finite-window entry with the same carrier, classifier, and ledger.

It remains to exclude extra entries. The L7 Add/Order handoff and the mature boundary, Definition 64.79 and Definition 64.82, rule out host multiplication, quotient carriers, semiring primitives, and cancellation rows not displayed in the phase-exit boundary. Hence the finite window is exhausted by the listed unary-history rows. □

Theorem 64.73 (MulUp Full Nat Arithmetic hsame transport boundary)**.** *Let two unary-history presentations over* BHist *be related componentwise by* hsame*. Then the Full Nat Arithmetic phase-exit boundary of Definition 64.71 transports across that comparison. The transported boundary has the same* UnaryHistory *carrier surface, the transported* hsame *classifier, the transported* NatMul *relation, the same unit, the same* $\mathsf{Add}^{\uparrow}$ *distributivity rows, the same* $\mathsf{Order}^{\uparrow}$ *monotonicity row, and the same divisibility-order consumer rows, all exported through the unchanged* BHist *surface.*

Proof. Project the phase-exit boundary of Definition 64.71. Its rows are already expressed over BHist, UnaryHistory, hsame, NatMul, the additive distribution rows, the order row, and the divisibility-order consumer rows.

Transport the carrier and classifier first. The componentwise hsame comparison keeps each unary-history row inside UnaryHistory and keeps every Cont ledger on the same displayed BHist endpoints. The functionality and transport clauses for NatMul then move the multiplication row, unit row, and result row to the transported presentation.

Finally, repack the AddUp distribution rows, the OrderUp monotonicity row, and the divisibility rows from the transported endpoints. These rows mention only the already transported unary histories, Cont ledgers, hsame comparisons, and NatMul witnesses, so the consumer receives the same phase-exit package and no new exported surface. □

Theorem 64.74 (MulUp successor cancellation boundary)**.** *Let d and q be unary histories, and let* $\mathsf{NatMul}(d, \mathsf{E1}(q), n')$ *be a product row over* BHist*. Then successor inversion produces a unary predecessor n with* $\mathsf{NatMul}(d, q, n)$ *and* $\mathsf{Cont}(n, d, n')$*. Moreover, if another unary history m satisfies* $\mathsf{NatMul}(d, q, m)$ *and* $\mathsf{Cont}(m, d, n')$*, then $n\,\mathsf{hsame}\,m$. The cancellation reads only the predecessor product rows and the displayed continuation witnesses; it does not add a second carrier, quotient surface, or host multiplication row.*

Proof. Apply BEDC.Derived.PrimeUp.NatMul_succ_inversion to the displayed successor product row. This gives the predecessor product n, the row $\mathsf{NatMul}(d, q, n)$, and the final continuation ledger $\mathsf{Cont}(n, d, n')$.

Now take another predecessor m with $\mathsf{NatMul}(d, q, m)$ and $\mathsf{Cont}(m, d, n')$. The two predecessor products have the same unary multiplicand d and multiplier q, so BEDC.Derived.PrimeUp.NatMul_functional identifies their results by $n$hsame$m$.

The continuation rows are retained as ledger witnesses for the displayed successor endpoint n'. They are not additional result carriers and play no role in the comparison beyond recording that both predecessor rows append the same visible copy of d to reach the same endpoint. □

Theorem 64.75 (MulUp checked law audit package)**.** *Over* BHist *and the carrier* UnaryHistory*, the checked NatMul law package consumed by the Full Nat Arithmetic boundary consists of the totality, result-closure, functionality, unit, unit-law, commutativity, associativity,* hsame *operation-congruence, and result semantic* NameCert *rows for* NatMul*. The package is read only through the unary-history carrier, the* hsame *classifier, and the displayed* BHist *result endpoints.*

Proof. The algebraic rows are the rows certified by BEDC.Derived.PrimeUp.NatMul_unary_mulup_certificate: totality, result closure, functionality, the unit row, unit laws, commutativity, and associativity all live on the same unary-history endpoints.

The transport row is the checked congruence theorem BEDC.Derived.PrimeUp.NatMul_operation_congruence. It says that componentwise hsame comparison of the input and result histories preserves the NatMul operation row, so the law package is stable under the phase-exit transport boundary.

The result naming row is the checked semantic certificate theorem BEDC.Derived.PrimeUp.NatMul_result_semar Repacking these three checked sources gives exactly the NatMul audit package required by the L7 boundary, without adding a second carrier, a host multiplication operation, or an extra quotient surface. □

Theorem 64.76 (MulUp unary standard bridge boundary)**.** *The unary-history* $\mathsf{Mul}^{\uparrow}$ *package admits a paper bridge to finite unary-word multiplication by reading each* $\mathsf{NatMul}(d, q, n)$ *ledger as repeated unary continuation. The carrier remains* UnaryHistory*, the classifier remains* hsame*, and the result row remains the displayed* NatMul *row. This reading uses the checked law audit package of Definition 64.75, the Full Nat Arithmetic phase-exit boundary of Definition 64.71, and the window-exhaustion boundary of Definition 64.72.*

Proof. Start with the phase-exit boundary. It already supplies the totality, functionality, unit-law, associativity, and commutativity rows for the displayed NatMul relation over UnaryHistory, and Definition 64.75 identifies those rows as the checked unary NatMul package.

Next project the rows that connect multiplication to the surrounding arithmetic window. The same boundary carries the $\mathsf{Add}^{\uparrow}$ distributivity rows, $\mathsf{Order}^{\uparrow}$ monotonicity row, and divisibility rows; the exhaustion statement of Definition 64.72 says that a consumer has no further Full Nat Arithmetic row to read inside this phase.

The external unary-word reading consumes only these displayed rows. It interprets each $\mathsf{NatMul}(d, q, n)$ ledger as a finite repeated-unary continuation and reads back to the same UnaryHistory endpoint, the same hsame classifier, and the same NatMul result row, without adding host multiplication, quotient equality, or cancellation beyond the displayed package. □

Theorem 64.77 (MulUp bridge consumer status alignment)**.** *The* $\mathsf{Mul}^{\uparrow}$ *chapter's paper bridge status is exactly the consumer package obtained by combining the unary standard bridge boundary of Definition 64.76, the checked law audit package of Definition 64.75, the phase-exit boundary of Definition 64.71, the window-exhaustion boundary of Definition 64.72, and the mature boundary of Definition 64.82. This package justifies recording paperBridge for* $\mathsf{Mul}^{\uparrow}$*, while it does not justify* bridgeChecked *until a Lean-side standard bridge theorem for the same boundary exists.*

Proof. The unary standard bridge boundary supplies the external paper reading: each $\mathsf{NatMul}(d, q, n)$ ledger is read as finite repeated-unary continuation and returns to the same UnaryHistory endpoint, hsame classifier, and displayed NatMul result row.

The checked law audit package and the phase-exit boundary identify the law rows that this reading may consume. They give totality, result closure, functionality, unit, unit laws, commutativity, associativity, operation congruence, result NameCert, the two $\mathsf{Add}^{\uparrow}$ distributivity rows, the $\mathsf{Order}^{\uparrow}$ monotonicity row, and the divisibility-order rows over the same BHist and UnaryHistory surface.

The window-exhaustion and mature-boundary theorems close the consumer side. They say that the finite Full Nat Arithmetic window has no row outside the displayed package, and in particular no host multiplication, quotient equality, host cancellation law, second carrier, or semiring surface is exported to the bridge consumer.

Thus the paper has a complete bridge account at the manuscript boundary: the external unary-word reading consumes exactly the audited rows and nothing beyond them. The verification axis remains below bridgeChecked, because the cited Lean target certifies the NatMul result semantic NameCert rather than a standard bridge theorem for this consumer boundary. □

Theorem 64.78 (MulUp Full Nat Arithmetic audit surface)**.** *Over* BHist *and the carrier* UnaryHistory*, a Full Nat Arithmetic consumer reads* $\mathsf{Mul}^{\uparrow}$ *exactly through the following rows: the* NatMul *totality row, result-closure row, functionality row, unit row, unit-law rows, commutativity row, associativity row,* hsame *operation-congruence row, result* NameCert *row, the two* $\mathsf{Add}^{\uparrow}$ *distributivity rows, the* $\mathsf{Order}^{\uparrow}$ *monotonicity row, and the reflexive, transitive, and antisymmetric divisibility-order rows. This is the complete cited audit surface for the open Full Nat Arithmetic phase.*

Proof. Project the phase-exit boundary of Definition 64.71. It fixes the consumer boundary over BHist and UnaryHistory and contains the NatMul algebraic rows, the $\mathsf{Add}^{\uparrow}$ rows, the $\mathsf{Order}^{\uparrow}$ row, and the divisibility-order rows.

Use the checked law audit package of Definition 64.75. That package identifies the checked NatMul totality, result-closure, functionality, unit, unit-law, commutativity, associativity, operation-congruence, and result NameCert rows as the law-facing part of the same boundary.

Finally repack the remaining consumer rows already assembled in Definition 64.69: the two $\mathsf{Add}^{\uparrow}$ distributivity rows, the $\mathsf{Order}^{\uparrow}$ monotonicity row, and the reflexive, transitive, and antisymmetric divisibility-order rows. These rows share the same carrier, classifier, NatMul relation, and BHist endpoints, so the displayed list is a single Full Nat Arithmetic audit surface and not a host multiplication or quotient surface. □

Theorem 64.79 (MulUp L7 additive-order audit handoff)**.** *Any Full Nat Arithmetic consumer over* BHist *that reads the* $\mathsf{Mul}^{\uparrow}$ *package through the audit surface of Definition 64.78 may consume exactly the checked* NatMul *law rows, the two* $\mathsf{Add}^{\uparrow}$ *distributivity rows, the* $\mathsf{Order}^{\uparrow}$ *monotonicity row, and the reflexive, transitive, and antisymmetric divisibility-order rows. All of these rows are over* UnaryHistory*,* hsame*, and finite* Cont *ledgers. The consumer may not introduce host multiplication, quotient equality, or a second carrier.*

Proof. Start from Definition 64.78. It fixes the only displayed Full Nat Arithmetic audit surface over BHist, UnaryHistory, hsame, and the finite Cont ledgers.

Unpack Definition 64.75 for the checked NatMul law rows. These are the totality, result-closure, functionality, unit, unit-law, commutativity, associativity, operation-congruence, and result NameCert rows already accepted by the $\mathsf{Mul}^{\uparrow}$ law audit.

Finally repack the additive-order rows from Definition 64.69. Those rows contribute exactly the two $\mathsf{Add}^{\uparrow}$ distributivity rows, the $\mathsf{Order}^{\uparrow}$ monotonicity row, and the divisibility-order rows, while preserving the same carrier, classifier, and ledger boundary. Hence the L7 consumer receives the listed rows and no host multiplication, quotient equality, or second carrier. □

Theorem 64.80 (MulUp L7 audit-clean exit obligation)**.** *For the concrete* $\mathsf{Mul}^{\uparrow}$ *surface over* BHist*, the Full Nat Arithmetic exit obligation is exactly the concrete* BHist *package consisting of the carrier* UnaryHistory*, the multiplication relation* NatMul*, the result* SemanticNameCert *row, both* $\mathsf{Add}^{\uparrow}$ *distributivity surfaces, the unary-prefix* $\mathsf{Order}^{\uparrow}$ *monotonicity row, and the unary divisibility reflexive and transitive consumer rows. This obligation is audit-clean precisely as that package and contains no cancellation law, semiring completion, host multiplication table, or standard bridge.*

Proof. Start with the L7 handoff of Definition 64.79. It fixes the allowed consumer rows over BHist, UnaryHistory, hsame, finite Cont ledgers, and the NatMul relation, and it prevents the consumer from adding host multiplication, quotient equality, or a second carrier.

Next use Definition 64.81. This gives the single phase-exit package whose visible rows are the NatMul semantic exit, the two $\mathsf{Add}^{\uparrow}$ distributivity surfaces, the unary-prefix $\mathsf{Order}^{\uparrow}$ monotonicity row, and the unary divisibility consumer rows over the same endpoints.

Finally apply the public semantic exit certificate Definition 64.24. It supplies the carrier UnaryHistory, the concrete NatMul package, and the result SemanticNameCert row. Repacking these public rows gives exactly the displayed Full Nat Arithmetic exit obligation, with cancellation, semiring completion, a host multiplication table, and a standard bridge left outside the audit-clean package. □

Theorem 64.81 (MulUp AddUp–OrderUp–divisibility phase-exit package)**.** *Over* BHist *and the carrier* UnaryHistory*,* $\mathsf{Mul}^{\uparrow}$ *exposes a single L7 Full Nat Arithmetic package whose rows are the* NatMul *semantic exit, the two* $\mathsf{Add}^{\uparrow}$ *distributivity rows, the* $\mathsf{Order}^{\uparrow}$ *unary-prefix monotonicity row, and the unary divisibility reflexive, transitive, and antisymmetric rows. The package is read through the same* BHist *endpoints,* UnaryHistory *carrier,* hsame *classifier,* Cont *ledgers, and* NatMul *relation.*

Proof. Apply Definition 64.24. It gives the NatMul semantic exit over BHist and UnaryHistory, including the result semantic certificate and the operation laws used by the L7 consumer.

Next apply Definition 64.25 and Definition 64.78. These identify the two $\mathsf{Add}^{\uparrow}$ distributivity rows and the $\mathsf{Order}^{\uparrow}$ unary-prefix monotonicity row as rows of the same audit surface, with no change of carrier, classifier, or result relation.

Finally apply Definition 64.64. Its reflexive, transitive, and antisymmetric divisibility rows are stated over the same BHist endpoints, UnaryHistory histories, hsame comparisons, Cont ledgers, and NatMul witnesses. Repacking these shared rows gives one named phase-exit package for downstream natural, rational, and prime consumers. □

Theorem 64.82 (MulUp Full Nat Arithmetic mature boundary)**.** *For the concrete* $\mathsf{Mul}^{\uparrow}$ *surface over* BHist *and* UnaryHistory*, the mature Full Nat Arithmetic boundary is exactly the paper-side consumer boundary formed by the* NatMul *semantic exit, the checked law audit package, the two* $\mathsf{Add}^{\uparrow}$ *distributivity rows, the* $\mathsf{Order}^{\uparrow}$ *unary-prefix monotonicity row, and the divisibility-order consumer rows. Every row is read over the same* BHist *endpoints,* UnaryHistory *carrier,* hsame *classifier,* Cont *ledgers, and* NatMul *relation. The boundary contains no host multiplication, quotient surface, or second carrier.*

Proof. Apply Definition 64.78. It fixes the common carrier, classifier, result relation, and finite ledger surface on which the Full Nat Arithmetic rows may be read.

Next apply Definition 64.81. It packages the NatMul semantic exit together with the two $\mathsf{Add}^{\uparrow}$ distributivity rows, the $\mathsf{Order}^{\uparrow}$ monotonicity row, and the divisibility-order consumer rows over that same surface.

Finally apply Definition 64.79. This handoff identifies the allowed consumer rows and rules out host multiplication, quotient equality, and a second carrier. Repacking the three cited packages gives a single mature boundary for the present Full Nat Arithmetic phase. □

Definition 64.83 (MulUp NatMul window boundary)**.** *The* $\mathsf{Mul}^{\uparrow}$ NatMul *window boundary is the finite* BHist *read surface whose accepted rows are unary histories* d*,* q*, and* n *in* UnaryHistory*, componentwise comparison by* hsame*, continuation ledgers* Cont *witnessing the displayed append steps, and the multiplication row* $\mathsf{NatMul}(d, q, n)$*. A consumer inside the boundary may inspect only the empty-result branch, the successor-result branch, the unit rows, the two* $\mathsf{Add}^{\uparrow}$ *distributivity rows, the* $\mathsf{Order}^{\uparrow}$ *row, and the divisibility rows already present in Definition 64.71.*

Theorem 64.84 (MulUp empty product factor boundary)**.** *Within the window boundary of Definition 64.83, if* $\mathsf{NatMul}(d, q, \mathsf{e})$ *holds, then the exposed factor readback is exactly the empty-factor case or the empty-multiplier case:* $d$hsamee *or* $q$hsamee*. No nonempty unary pair can be exported as an empty product row by this boundary.*

Proof. Read the multiplication row through the checked empty-result cases for NatMul. The concrete theorem BEDC.Derived.PrimeUp.NatMul_empty_result_factor_empty_or_multiplier_empty inverts the empty result and returns precisely the displayed disjunction on the two factors.

The same readback is compatible with the window boundary because the boundary exposes only UnaryHistory, hsame, Cont, and the single NatMul row. Thus the empty result cannot be explained by an external multiplication table, quotient equality, or hidden host zero test. □

Theorem 64.85 (MulUp successor product factor readback)**.** *Within the window boundary of Definition 64.83, if* $\mathsf{NatMul}(d, q, \mathsf{E1}(n))$ *holds, then the result readback exposes a nonempty multiplicand factor and a unary multiplier row. Equivalently, the successor-result branch is readable only through the positive multiplicand shape supplied by the* NatMul *inversion rows together with the* UnaryHistory *classifier on the multiplier.*

Proof. First invert the successor result by the concrete NatMul successor rows. The checked theorem BEDC.Derived.PrimeUp.NatMul_succ_result_empty_left_empty rules out an empty multiplicand as the source of a successor product.

Next apply BEDC.Derived.PrimeUp.NatMul_successor_result_multiplicand_positive_shape. It reads the same successor-result row as a positive multiplicand shape, with the multiplier still classified as a unary history by the NatMul carrier projections.

These two steps are rows of the boundary of Definition 64.83. The consumer obtains the nonempty factor and unary multiplier without adding host multiplication or a second result classifier. □

Theorem 64.86 (MulUp NatMul window exhaustion)**.** *Every Full Nat Arithmetic consumer restricted to the* $\mathsf{Mul}^{\uparrow}$ *phase-exit boundary and to the window boundary of Definition 64.83 reads only the following cases: the empty-result factor boundary of Definition 64.84, the successor-result factor readback of Definition 64.85, the unit rows of the checked* NatMul *package, the two additive-distribution rows, the order row, and the divisibility rows. No further* BHist *case, host multiplication operation, quotient carrier, or external semiring law is visible at this audit handoff.*

Proof. Start with the phase-exit package of Definition 64.71. It fixes the Full Nat Arithmetic consumer surface over UnaryHistory, hsame, Cont, and NatMul, and it lists the unit, additive, order, and divisibility rows available to the consumer.

Now restrict the result inspection to the window boundary. The empty result is exhausted by Definition 64.84, while the successor result is exhausted by Definition 64.85. These are the only result-shape branches exposed by the NatMul row over BHist unary histories.

Finally repack the remaining rows from Definition 64.75 and Definition 64.79. They contribute the unit rows, the two $\mathsf{Add}^{\uparrow}$ distributivity rows, the $\mathsf{Order}^{\uparrow}$ row, and the divisibility rows already accepted by the phase-exit boundary, so the window exports exactly the stated audit handoff. □

Lemma 64.87 (Divisibility is closed under displayed continuation)**.** *If* $\mathsf{NatDivides}(d, x)$ *and* $\mathsf{NatDivides}(d, y)$ *hold, and* $\mathsf{Cont}(x, y, z)$ *displays* z *as the continuation of the two divisible histories, then* $\mathsf{NatDivides}(d, z)$ *holds.*

Proof. Unpack the two quotient witnesses, say qx and qy. Their multiplication witnesses have results x and y. The quotient for z is $\mathsf{append}(qx, qy)$; unary append closure makes it an admissible quotient, and append-continuation multiplication closure combines the two multiplication witnesses over the displayed $\mathsf{Cont}(x, y, z)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides cont closed`

Lemma 64.88 (Unary multiplication append multiplier split)**.** *Let* $d, w, q, r : \mathsf{BHist}$ *be unary where required. If the displayed unary multiplication relation proves* $\mathsf{NatMul}(d, \mathsf{append}(w, q), r)$*, then there are unary histories* n *and* e *such that*

$$\mathsf{NatMul}(d, w, n) \wedge \mathsf{NatMul}(d, q, e) \wedge \mathsf{Cont}(n, e, r).$$

Proof. Totality of unary multiplication supplies canonical products n and e for the two multiplier pieces w and q. Append-continuation closure for NatMul composes these two products into a displayed product over $\mathsf{append}(w, q)$. Functionality of unary multiplication compares this canonical displayed result with the given result r, and continuation transport along that history-sameness gives $\mathsf{Cont}(n, e, r)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul append multiplier split exists`

Lemma 64.89 (Right factor divisibility of a displayed product)**.** *If* d *and* q *are unary histories and* $\mathsf{NatMul}(d, q, n)$ *displays* n *as their product, then* q *divides* n*:*

$$\mathsf{UnaryHistory}(d) \Longrightarrow \mathsf{UnaryHistory}(q) \Longrightarrow \mathsf{NatMul}(d, q, n) \Longrightarrow \mathsf{NatDivides}(q, n).$$

Proof. Totality of multiplication gives a displayed product for q by d. Commutativity up to hsame compares that product with the given display of d by q. The commuted display is a divisibility witness for q, and dividend transport across the result comparison carries it back to n. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides mul right closed`

Theorem 64.90 (Nat divisibility is closed under left multiplication)**.** *For histories* $d, x, q, z : \mathsf{Hist}$*, if* x *is unary,* $\mathsf{NatDivides}(d, q)$*, and* $\mathsf{NatMul}(x, q, z)$*, then* $\mathsf{NatDivides}(d, z)$*.*

Proof. Choose the quotient witness for $\mathsf{NatDivides}(d, q)$. Since q is a unary result of that divisor witness, total multiplication gives a product of q with x. Multiplicative commutativity identifies this product with the given product z up to hsame. Thus q divides z after dividend transport, and transitivity of NatDivides carries the original divisor d through q into z. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides mul left closed`

Theorem 64.91 (Divisibility is closed under displayed unary products)**.** *For unary* BHist *data* d, e, x, y, p, z*, if* NatDivides(d, x)*,* NatDivides(e, y)*,* NatMul(d, e, p)*, and* NatMul(x, y, z) *all hold, then* NatDivides(p, z) *holds.*

Proof. Unpack the two divisor witnesses. Thus x is displayed as d multiplied by a unary quotient q, and y is displayed as e multiplied by a unary quotient r.

Unary multiplication totality supplies a displayed product s of the two quotients q and r. Use associativity of NatMul up to hsame to compare the product of x and y with the iterated product of d, e, q, and r.

Commutativity up to hsame moves the displayed factorization so that the given product p of d and e is the left factor and s is the quotient factor. The resulting display witnesses NatDivides(p, z) after transporting the dividend along the final hsame comparison with the given NatMul(x, y, z) row. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides product closed`

Lemma 64.92 (Divisors of a nonempty unary product are bounded by the result)**.** *If* NatDivides(d, n)*, n is unary, and $n \not\text{hsame}$, then either $d$hsame$n$ or* NatUnaryStrictPrefix(d, n)*.*

Proof. Unpack the quotient q in the divisor witness and inspect the corresponding NatMul(d, q, n) witness. The empty quotient would make the product result empty, contradicting $n \not\text{hsame}$.

For the unit quotient, multiplication by the unit identifies the product result with d, so the divisor is the whole result up to hsame.

For a successor quotient, the multiplication witness writes n as the previous product followed by one more copy of d. The final Cont payload gives a strict unary prefix from that copy into the result; unary append commutativity and strict-prefix transport move the prefix endpoint to d, yielding NatUnaryStrictPrefix(d, n). □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides nonempty result boundary`

Definition 64.93 (MulUp audit-clean consumer boundary)**.** *The audit-clean consumer boundary exported by* Mul$^{\uparrow}$ *for the full natural arithmetic phase is exactly the following concrete surface:*

1. *the carrier rows* BHist *and* UnaryHistory*;*
2. *the classifier and continuation rows* hsame *and* Cont*;*
3. *the multiplication and divisibility rows* NatMul *and* NatDivides*;*
4. *the unary-prefix order row* PreorderPrefixLE*;*
5. *the* Add$^{\uparrow}$ *continuation boundary cited in Definition 64.49;*
6. *the* Order$^{\uparrow}$ *unary-prefix boundary cited in Definition 54.45.*

No consumer-facing row in this boundary is a host multiplication primitive, host order primitive, standard semiring carrier, or quotient carrier.

Theorem 64.94 (MulUp divisibility-order source exactness)**.** *Every consumer of the* Mul$^{\uparrow}$ *divisibility-order boundary of Definition 64.93 factors through exactly the four displayed package rows Definition 64.24, Definition 64.49, Definition 64.63, and Definition 64.64. Equivalently, a consumer may read* BHist*,* UnaryHistory*,* hsame*,* Cont*,* NatMul*,* NatDivides*,* PreorderPrefixLE*, and the cited* Add$^{\uparrow}$ *and* Order$^{\uparrow}$ *package boundaries, and no additional standard semiring, host order, or quotient carrier source is available.*

Proof. Begin with Definition 64.24. It supplies the carrier BHist, unary predicate UnaryHistory, classifier hsame, continuation row Cont, and the displayed product relation NatMul as the semantic exit package for multiplication results.

Next apply Definition 64.49. This records the only phase interaction rows used by the boundary: additive continuation distribution through $\mathsf{Add}^{\uparrow}$ and the successor-product lower bound through the $\mathsf{Order}^{\uparrow}$ unary-prefix relation PreorderPrefixLE.

The divisibility order itself is supplied by Definition 64.63, which bundles reflexive, transitive, and antisymmetric readback for NatDivides over unary histories. Finally, Definition 64.64 combines those order rows with multiplication closure and successor-product prefix lower bounds into the single consumer package.

The definition of the boundary lists no other rows. Hence any consumer whose source is this boundary can project only through the four package rows just assembled. In particular, there is no source slot for a standard semiring carrier, a host multiplication operation, a host order relation, or a quotient carrier. □

Theorem 64.95 (MulUp audit-clean result NameCert handoff)**.** *The audit-clean consumer boundary of Definition 64.93 factors through the concrete* NatMul *result semantic certificate, the checked-law audit package of Definition 64.75, the window-exhaustion boundary of Definition 64.86, and the divisibility-order source exactness of Definition 64.94. The resulting handoff exposes only* BHist*,* UnaryHistory*,* hsame*,* Cont*,* NatMul*,* NatDivides*,* PreorderPrefixLE*, the* $\mathsf{Add}^{\uparrow}$ *continuation rows, and the* $\mathsf{Order}^{\uparrow}$ *unary-prefix row.*

No output slot of the handoff exports host multiplication, host order, quotient carriers, or standard semiring data.

Proof. Start with the concrete NatMul result semantic certificate. It is the only result-side name certificate in the handoff, so the multiplication output is read as a BHist result row over unary inputs and the displayed NatMul relation.

Apply Definition 64.75. This contributes the checked multiplication laws through the already visible BHist, UnaryHistory, hsame, Cont, and NatMul rows, with the $\mathsf{Add}^{\uparrow}$ continuation rows and $\mathsf{Order}^{\uparrow}$ unary-prefix row kept as named dependencies rather than as ambient arithmetic structure.

Next use Definition 64.86. Window exhaustion says that the audit package has no remaining consumer-facing multiplication row outside the concrete NatMul window and its displayed continuation ledger.

Finally apply Definition 64.94. It identifies the order-facing source as exactly NatDivides, PreorderPrefixLE, and the cited $\mathsf{Add}^{\uparrow}$ and $\mathsf{Order}^{\uparrow}$ boundary rows. Since each cited component is already listed in Definition 64.93, their composite handoff cannot expose host multiplication, host order, quotient carriers, or standard semiring data. □

Theorem 64.96 (MulUp audit-clean boundary row exhaustion)**.** *Every row readable from the* $\mathsf{Mul}^{\uparrow}$ *audit-clean consumer boundary of Definition 64.93 is one of the displayed rows* BHist*,* UnaryHistory*,* hsame*,* Cont*,* NatMul*,* NatDivides*,* PreorderPrefixLE*, the cited* $\mathsf{Add}^{\uparrow}$ *boundary of Definition 64.49, or the cited* $\mathsf{Order}^{\uparrow}$ *boundary of Definition 54.45.*

Conversely, each listed row is supplied by the concrete semantic exit, the checked-law audit package, the NatMul window-exhaustion theorem, and the divisibility-order source exactness theorem. Thus the boundary has no readable row for host multiplication, host order, quotient carriers, semiring primitives, or any additional arithmetic source.

Proof. Project Definition 64.93. Its displayed list is the consumer-facing row interface, so any readable row must be one of the listed carrier, classifier, continuation, multiplication, divisibility, unary-prefix, $\mathsf{Add}^{\uparrow}$, or $\mathsf{Order}^{\uparrow}$ entries.

For the converse direction, apply Definition 64.95. The handoff factors the boundary through the concrete NatMul semantic certificate and the checked-law audit package, so the BHist, UnaryHistory, hsame, Cont, and NatMul rows are available as the named result-side surface.

Next apply Definition 64.86. It exhausts the consumer-facing multiplication window, leaving no host multiplication slot and no semiring primitive outside the concrete NatMul ledger.

Finally use Definition 64.94. It identifies the remaining order-facing rows as exactly NatDivides, PreorderPrefixLE, and the cited $\mathsf{Add}^{\uparrow}$ and $\mathsf{Order}^{\uparrow}$ boundaries. Since no cited theorem introduces a quotient carrier or host order primitive, the displayed rows exhaust the audit-clean boundary. □

Theorem 64.97 (Prime divisor of a unary product exposes a factor)**.** *For histories p, a, b, n, if* $\mathsf{NatPrime}(p)$*,* $\mathsf{NatMul}(a, b, n)$*, and* $\mathsf{NatDivides}(p, n)$*, then* $\mathsf{NatDivides}(p, a)$ *or* $\mathsf{NatDivides}(p, b)$*.*

Sketch. Induct on the concrete unary multiplication witness $\mathsf{NatMul}(a, b, n)$, viewing the right factor b as the induction spine.

In the zero-product case, the result is e. A divisor witness for p into e would make e a multiple of the prime p. The non-empty condition in $\mathsf{NatPrime}(p)$, together with the empty-result inversion for NatMul, rules this case out, so the conclusion follows vacuously.

In the successor case, the product is obtained by appending one more copy of a to the previous product. If p already divides the previous product, the induction hypothesis gives $\mathsf{NatDivides}(p, a)$ or divisibility into the predecessor of b; in the latter subcase, the successor multiplication constructor and Definition 64.62 transport the divisor to $\mathsf{NatDivides}(p, b)$.

It remains when the final appended copy is the first place where the divisor can occur. The NatMul result and functionality facts identify the last continuation with the factor a up to hsame. Applying the defining divisor alternative in $\mathsf{NatPrime}(p)$ to this non-trivial divisor yields either the unit case, which is incompatible with the prime's strict-greater field, or hsame-equality with a. This gives $\mathsf{NatDivides}(p, a)$, completing the induction. □

Theorem 64.98 (Unary multiplication operation congruence)**.** *Let d, d', q, q', n, and n' be histories. If* $\mathsf{NatMul}(d, q, n)$*,* $\mathsf{hsame}(d, d')$*,* $\mathsf{hsame}(q, q')$*, and* $\mathsf{hsame}(n, n')$*, then* $\mathsf{NatMul}(d', q', n')$*.*

Moreover, the transported multiplicand d' and multiplier q' are unary histories, and every result m of $\mathsf{NatMul}(d', q', m)$ *is classified with n' by* $\mathsf{hsame}(m, n')$*. For the per-object certificate template, this statement is the concrete* MulUp *stability-obligation row for the operation relation under transported multiplicand, multiplier, and result classifiers, with its formal target intended under* BEDC.Derived.PrimeUp*.*

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul operation congruence`

Proof. Apply the multiplicand transport theorem to the given product and $\mathsf{hsame}(d, d')$. This gives unary evidence for d' and a product $\mathsf{NatMul}(d', q, n)$. Apply the multiplier transport theorem to that product and $\mathsf{hsame}(q, q')$, producing unary evidence for q' and a product $\mathsf{NatMul}(d', q', n)$.

Apply the result transport theorem to this last product and $\mathsf{hsame}(n, n')$. The result is the displayed product $\mathsf{NatMul}(d', q', n')$, with the same unary multiplicand evidence already carried by the transported product and the unary multiplier evidence obtained in the previous paragraph.

For the uniqueness clause, compare any other witness $\mathsf{NatMul}(d', q', m)$ with the transported witness $\mathsf{NatMul}(d', q', n')$ by Definition 64.12, using unary evidence for the transported multiplicand d'. This yields $\mathsf{hsame}(m, n')$. □

Theorem 64.99 (MulUp repeated-addition Cont scope)**.** *Every* $\mathsf{NatMul}(d, q, n)$ *row consumed by* $\mathsf{Mul}^{\uparrow}$ *is scoped by unary witnesses for d, q, and n, a finite* Cont *ledger that records repeated application of the* $\mathsf{Add}^{\uparrow}$ *operation over* UnaryHistory *rows, and the ambient* hsame *classifier on the*

displayed histories. The scope contains no separate multiplication operation beyond the NatMul *relation and the listed continuation reads.*

Proof. Start from the displayed $\mathsf{NatMul}(d, q, n)$ row. The construction of that row supplies unary evidence for the multiplicand and multiplier, and the functional comparison used in Definition 64.98 supplies the hsame-classification of every result row with the displayed result.

The repeated-addition ledger is the finite Cont trace that reads the current partial sum, the remaining unary counter, and the next $\mathsf{Add}^{\uparrow}$ row at each stage. Since every stage reads a UnaryHistory row and an $\mathsf{Add}^{\uparrow}$ operation row, the ledger never introduces an independent multiplication constructor.

Repack these unary witnesses, continuation reads, and classifier witnesses as the $\mathsf{Mul}^{\uparrow}$ consumption surface. Transport along hsame is exactly Definition 64.98, so the same scoped surface is preserved under replacement of d, q, and n by classified histories. □

Theorem 64.100 (MulUp unary additive distributive boundary)**.** *The right and left additive distribution surfaces cited by the public semantic exit certificate for* $\mathsf{Mul}^{\uparrow}$ *are consumed only through* UnaryHistory *rows,* NatMul *rows, finite* Cont *readbacks, the ambient* hsame *classifier, and the existing* $\mathsf{Add}^{\uparrow}$ *operation rows. No public boundary row for* $\mathsf{Mul}^{\uparrow}$ *requires a primitive multiplication operation outside that unary repeated-addition surface.*

Proof. For the right distribution surface, apply Definition 64.27. Its hypotheses are the unary inputs, the relevant NatMul rows, and the $\mathsf{Add}^{\uparrow}$ rows that combine the displayed products.

For the left distribution surface, apply Definition 64.28. The same kind of data is read, with the multiplicand and multiplier roles exchanged inside the unary ledger.

Finally combine those two surfaces with Definition 64.65. The certificate exports only the listed UnaryHistory, NatMul, Cont, hsame, and $\mathsf{Add}^{\uparrow}$ rows, while Definition 64.98 supplies transport of the operation relation across classified histories. □

64.2 The prime predicate

Definition 64.101 (Strict greater-than on unary histories)**.** *The relation* $\mathsf{NatGT}(n, m)$ *holds when* $\mathsf{NatUnaryStrictPrefix}(m, n)$ *holds (chapter 28). Equivalently,* n *extends* m *by at least one further* E1 *step.*

Definition 64.102 (Prime predicate)**.** *A unary history* p *is prime, written* $\mathsf{NatPrime}(p)$*, when:*

1. $\mathsf{Unary}(p)$*,*
2. $\mathsf{NatGT}(p, \mathsf{E1}(\mathsf{e}))$ *(i.e.,* p *strictly exceeds the unit), and*
3. *for every unary* d *with* $\mathsf{NatDivides}(d, p)$*, either* $\mathsf{hsame}(d, \mathsf{E1}(\mathsf{e}))$ *or* $\mathsf{hsame}(d, p)$*.*

Lean4 (definition) `BEDC.Derived.PrimeUp.NatPrime`

Lemma 64.103 (The first two primes)**.** $\mathsf{NatPrime}(\mathsf{E1}(\mathsf{E1}(\mathsf{e})))$ *and* $\mathsf{NatPrime}(\mathsf{E1}(\mathsf{E1}(\mathsf{E1}(\mathsf{e}))))$*. That is, the unary representations of* 2 *and* 3 *are prime.*

Proof. For $p = 2$, the only divisors are the unit and p itself by Definition 64.50 and the case analysis on the quotient q. The same case analysis applies to $p = 3$, with the additional sub-case ruling out $q = 2$ by the failure of $\mathsf{NatMul}(2, 2, 3)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime first pair`

Lemma 64.104 (First prime multiplied by the unit exponent)**.** *The concrete unary multiplication witness for the first prime and the unit exponent returns the first prime:*

$$\mathsf{NatMul}(\mathsf{E1}(\mathsf{E1}(\mathsf{e})), \mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{E1}(\mathsf{e}))).$$

Proof. Use the first-prime witness for $\mathsf{E1}(\mathsf{E1}(\mathsf{e}))$. The zero multiplication constructor gives the empty predecessor product, and the successor multiplication constructor appends the first prime once using the left-unit continuation. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul first prime unit result`

Theorem 64.105 (Prime successor multiplication cannot have empty result)**.** *If p is prime and $\mathsf{NatMul}(p, \mathsf{E1}(q), n)$, then n is not empty up to* hsame*.*

Proof. If $n$hsamee, then Definition 64.5 forces $p$hsamee. After this identification, the strict-prefix field in the prime predicate would be a strict unary prefix into e, which is impossible. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime NatMul succ result not empty`

Theorem 64.106 (Prime has no empty divisor)**.** *If p is prime, d divides p, and d*hsamee*, then false.*

Proof. Transport the divisor to the empty-left case. Empty-left divisibility forces $p$hsamee. Under that endpoint identification, the strict greater-than field of the prime predicate becomes a strict unary prefix into e, which is impossible. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime divisor empty absurd`

Theorem 64.107 (Prime product factors are nonempty)**.** *Let p, d, q be histories. If p is prime, d and q are unary histories, and $\mathsf{NatMul}(d, q, p)$ holds, then neither factor is history-same to* e*.*

Proof. Package the displayed multiplication witness directly as $\mathsf{NatDivides}(d, p)$ to exclude $d$hsamee by the prime no-empty-divisor theorem. For the multiplier, multiplication closure gives $\mathsf{NatDivides}(q, p)$ from the same $\mathsf{NatMul}(d, q, p)$ witness, and the same no-empty-divisor theorem excludes $q$hsamee. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime NatMul factors not empty`

Theorem 64.108 (Prime is not empty)**.** *If p is prime, then p is not history-same to* e*.*

Proof. If $p$hsamee, the strict greater-than field in the prime predicate becomes a strict unary prefix into e. This contradicts the empty-target exclusion for strict unary prefixes. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime empty absurd`

Theorem 64.109 (Prime nonunit factor has unit multiplier)**.** *Let p, d, q be histories. If p is prime, d and q are unary histories, $\mathsf{NatMul}(d, q, p)$ holds, and d is not history-same to the unit, then d is the prime factor and q is the unit multiplier:*

$$\mathsf{hsame}(d, p) \wedge \mathsf{hsame}(q, \mathsf{E1}(\mathsf{e})).$$

Proof. Package the multiplication witness as a divisibility witness $\mathsf{NatDivides}(d, p)$. The prime divisor alternative says that d is either the unit or p; the displayed nonunit hypothesis eliminates the unit case, so $d\mathsf{hsame}p$.

It remains to identify the multiplier. The empty multiplier case would make the prime result empty, contradicting the strict-prefix field of the prime predicate; the zero-headed case contradicts unary history. In the successor case, successor-result exactness for multiplication applied to $\mathsf{NatMul}(d, \mathsf{E1}(q_0), p)$ and $p\mathsf{hsame}d$ says that either d is empty or q_0 is empty. The empty factor case again contradicts primality through $d\mathsf{hsame}p$, hence $q_0\mathsf{hsame}\mathsf{e}$, so $q\mathsf{hsame}\mathsf{E1}(\mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime NatMul nonunit factor multiplier unit`

Theorem 64.110 (Prime product factor is unit or prime)**.** *Let p, d, q be histories. If p is prime, d and q are unary histories, and $\mathsf{NatMul}(d, q, p)$ holds, then either d is the unit factor and q reads back to p, or d reads back to p and q is the unit multiplier:*

$$(\mathsf{hsame}(d, \mathsf{E1}(\mathsf{e})) \wedge \mathsf{hsame}(q, p)) \vee (\mathsf{hsame}(d, p) \wedge \mathsf{hsame}(q, \mathsf{E1}(\mathsf{e}))).$$

Proof. Package the multiplication witness as $\mathsf{NatDivides}(d, p)$ and apply the divisor classifier field of $\mathsf{NatPrime}(p)$. In the unit branch, unit-left multiplication identifies the result p with the multiplier q. In the prime-factor branch, the unit case would identify p with the unit and contradict primality, so the nonunit-factor theorem identifies q with the unit. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime NatMul factor unit or prime`

Theorem 64.111 (Prime divisor positive shape)**.** *If p is prime and d divides p, then d has a one-step successor shape:*

$$\mathsf{NatPrime}(p) \Longrightarrow \mathsf{NatDivides}(d, p) \Longrightarrow \exists t : \mathsf{BHist}.\ \mathsf{hsame}(d, \mathsf{E1}(t)) \wedge \mathsf{UnaryHistory}(t).$$

Proof. Read the divisor witness as a unary multiplication witness, which gives $\mathsf{UnaryHistory}(d)$. The empty case contradicts the prime no-empty-divisor theorem, and the zero-headed case contradicts unary history. The remaining one-headed case exposes the requested tail by unary inversion. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime divisor positive shape`

Theorem 64.112 (Prime divisor strict interval exclusion)**.** *Let $p, d : \mathsf{BHist}$. If $\mathsf{NatPrime}(p)$, $\mathsf{Unary}(d)$, and $\mathsf{NatDivides}(d, p)$ hold, then d cannot lie strictly between the unit and p in unary prefix order:*

$$\mathsf{NatUnaryStrictPrefix}(\mathsf{E1}(\mathsf{e}), d) \Longrightarrow \mathsf{NatUnaryStrictPrefix}(d, p) \Longrightarrow \bot.$$

Proof. Apply the divisor classifier field in $\mathsf{NatPrime}(p)$ to the displayed unary divisor d. The unit branch identifies the endpoint of the strict prefix from $\mathsf{E1}(\mathsf{e})$ to d, contradicting strict endpoint separation. The prime branch identifies the endpoint of the strict prefix from d to p, giving the same endpoint contradiction. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime NatDivides strict between absurd`

Lemma 64.113 (Non-primality of the unit)**.** $\neg\mathsf{NatPrime}(\mathsf{E1}(\mathsf{e}))$.

Proof. The unit fails the strict greater-than condition $\mathsf{NatGT}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e}))$ by the irreflexivity of $\mathsf{NatUnaryStrictPrefix}$ (chapter 28). □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime unit absurd`

Theorem 64.114 (Prime successor tail is nonempty)**.** *If* $\mathsf{NatPrime}(p)$ *holds, then* p *has a one-step successor shape with a unary nonempty tail:*

$$\exists t : \mathsf{BHist}.\ \mathsf{hsame}(p, \mathsf{E1}(t)) \ \wedge\ \mathsf{UnaryHistory}(t) \ \wedge\ (\mathsf{hsame}(t, \mathsf{e}) \Rightarrow \bot).$$

Proof. Analyze the carrier field of the prime witness. The empty case contradicts the strict-greater-than field, and the $\mathsf{E0}$ case contradicts unary history. In the $\mathsf{E1}(t)$ case, unary inversion gives $\mathsf{UnaryHistory}(t)$. If $t\mathsf{hsamee}$, the original prime witness becomes a prime witness for the unit, contradicting the unit non-primality theorem above. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime successor tail nonempty`

Theorem 64.115 (Prime strict unit successor shape)**.** *If* $\mathsf{NatPrime}(p)$ *holds, then* p *has a two-step successor shape:*

$$\exists t : \mathsf{BHist}.\ \mathsf{hsame}(p, \mathsf{E1}(\mathsf{E1}(t))) \ \wedge\ \mathsf{UnaryHistory}(t).$$

Proof. The prime successor-tail theorem writes p as $\mathsf{E1}(t_0)$ with a unary tail t_0 that is not classified as empty. Unary nonempty shape inversion therefore writes t_0 as $\mathsf{E1}(t)$ with unary tail t, giving the displayed strict unit-successor shape. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime strict unit successor shape`

Theorem 64.116 (Prime predicate respects history-sameness)**.** *For histories* p *and* p'*, if* $\mathsf{NatPrime}(p)$ *and* $p\mathsf{hsame}p'$*, then* $\mathsf{NatPrime}(p')$*.*

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrime hsame transport`

Proof. Unpack the prime witness for p from Definition 64.102. Its carrier field gives $\mathsf{Unary}(p)$, its strict field gives $\mathsf{NatGT}(p, \mathsf{E1}(\mathsf{e}))$, and its divisor field classifies every unary divisor of p as either the unit or p itself.

By Definition 9195.7, the carrier field and $p\mathsf{hsame}p'$ give $\mathsf{Unary}(p')$. For the strict greater-than field, unfold Definition 64.101: the given field is a strict unary prefix from $\mathsf{E1}(\mathsf{e})$ to p. Apply Definition 28.24 with the reflexive endpoint $\mathsf{E1}(\mathsf{e})\mathsf{hsame}\mathsf{E1}(\mathsf{e})$ from Definition 3.8 and the displayed endpoint witness $p\mathsf{hsame}p'$. This gives $\mathsf{NatGT}(p', \mathsf{E1}(\mathsf{e}))$.

It remains to verify the divisor field for p'. Fix a unary history d with $\mathsf{NatDivides}(d, p')$. Symmetry in Definition 3.8 gives $p'\mathsf{hsame}p$, and reflexivity gives $d\mathsf{hsame}d$. Therefore Definition 64.189 transports the displayed divisor witness to $\mathsf{NatDivides}(d, p)$. Applying the divisor field of $\mathsf{NatPrime}(p)$ gives either $d\mathsf{hsame}\mathsf{E1}(\mathsf{e})$ or $d\mathsf{hsame}p$. In the first case the required unit alternative for p' is already present. In the second case, transitivity in Definition 3.8 composes $d\mathsf{hsame}p$ with $p\mathsf{hsame}p'$ and gives $d\mathsf{hsame}p'$. These are exactly the two alternatives required by Definition 64.102 for p'. □

64.3 Effective primality testing

Definition 64.117 (Trial-division witness up to b)**.** *For unary histories* b, n*, the trial-division witness* $\mathsf{TrialDiv}(b, n)$ *is the closed inductive predicate generated by:*

1. $\mathsf{TrialDiv}(\mathsf{E1}(\mathsf{e}), n)$ *for every unary* n *(the unit is examined first);*

2. *if* $\mathsf{TrialDiv}(b, n)$*, and either* $\neg\mathsf{NatDivides}(b, n)$ *or* $\mathsf{hsame}(b, \mathsf{E1}(\mathsf{e}))$ *or* $\mathsf{hsame}(b, n)$*, and* $\mathsf{Cont}(b, \mathsf{E1}(\mathsf{e}), b')$*, then* $\mathsf{TrialDiv}(b', n)$ *(advance the test to* b'*).*

Lean4 (definition) `BEDC.Derived.PrimeUp.TrialDiv`

Theorem 64.118 (Trial-division step preserves unary closure)**.** *If* $\mathsf{TrialDiv}(b, n)$ *has been reached and the admissible step condition for* b *holds, then every continuation* $\mathsf{Cont}(b, \mathsf{E1}(\mathsf{e}), b')$ *produces a unary* b' *and the next witness* $\mathsf{TrialDiv}(b', n)$*.*

Proof. Induct on the trial-division witness. The base witness starts at $\mathsf{E1}(\mathsf{e})$, which is unary; the step case uses unary closure of Cont with the unit continuation and rebuilds the trial-division step. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv step unary closed`

Theorem 64.119 (Trial-division bounds are unary)**.** *If* $\mathsf{TrialDiv}(b, n)$*, then* b *is a unary history.*

Proof. Induct on the trial-division witness. The unit constructor gives $\mathsf{Unary}(\mathsf{E1}(\mathsf{e}))$. The step constructor extends the previous unary bound by the unary unit through Cont, so unary closure under continuation gives the next bound. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv bound unary`

Theorem 64.120 (Trial-division bounds have positive shape)**.** *If* $\mathsf{TrialDiv}(b, n)$*, then there is a unary tail* t *such that* $b\mathsf{hsame}\mathsf{E1}(t)$*.*

Proof. Inspect the trial-division witness. The unit constructor has $b = \mathsf{E1}(\mathsf{e})$. In the step constructor, the continuation $\mathsf{Cont}(b, \mathsf{E1}(\mathsf{e}), b')$ exposes b' as $\mathsf{E1}(b)$, and the previous trial-division witness supplies unary closure of the tail by Definition 64.119. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv bound positive shape`

Theorem 64.121 (Trial-division bound unit or successor shape)**.** *If* $\mathsf{TrialDiv}(b, n)$*, then the bound is either the unit history* $\mathsf{E1}(\mathsf{e})$ *or has the shape* $\mathsf{E1}(\mathsf{E1}(t))$ *for a unary tail* t*.*

Proof. Apply the positive-shape theorem to write $b\mathsf{hsame}\mathsf{E1}(tail)$ with unary *tail*. Case-analyze this tail. The empty tail gives the unit branch; a zero-headed tail contradicts unary generation; a one-headed tail exposes the displayed $\mathsf{E1}(\mathsf{E1}(t))$ branch, and unary inversion supplies $\mathsf{UnaryHistory}(t)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv bound unit or successor shape`

Theorem 64.122 (Trial-division bounds have unit prefix or are unit)**.** *If* $\mathsf{TrialDiv}(b, n)$*, then either* $\mathsf{E1}(\mathsf{e})$ *is a strict unary prefix of* b*, or* $b\mathsf{hsame}\mathsf{E1}(\mathsf{e})$*.*

Proof. Induct on the trial-division witness. The unit constructor gives the self branch. In the step constructor, the continuation by $\mathsf{E1}(\mathsf{e})$ supplies a strict one-step prefix. If the induction hypothesis already has a strict prefix, compose the two strict prefixes; if it has the self branch, transport the one-step prefix across that hsame endpoint. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv bound unit prefix or self`

Theorem 64.123 (Trial-division unit step yields strict unit prefix)**.** *If* $\mathsf{TrialDiv}(b, n)$ *and* $\mathsf{Cont}(b, \mathsf{E1}(\mathsf{e}), b')$*, then* $\mathsf{E1}(\mathsf{e})$ *is a strict unary prefix of* b'*.*

Proof. The displayed continuation supplies a one-step strict prefix from b to b'. The bound classification theorem gives either a strict unit prefix of b or $b\mathsf{hsameE1}(\mathsf{e})$. In the strict-prefix branch, compose the previous strict prefix with the one-step prefix. In the unit branch, transport the one-step strict prefix across the displayed endpoint classifier. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv bound unit strict prefix after cont`

Theorem 64.124 (Trial-division target and bound trichotomy)**.** *If* $\mathsf{TrialDiv}(b, n)$*, then the target* n *is unary and the current bound* b *is comparable with* n *by endpoint equality or by one of the two strict unary-prefix directions:*

$$\mathsf{UnaryHistory}(n) \wedge (b\mathsf{hsame}n \vee \mathsf{NatUnaryStrictPrefix}(b, n) \vee \mathsf{NatUnaryStrictPrefix}(n, b)).$$

Proof. Induct on the trial-division witness to recover unaryness of the fixed target. The bound is unary by Definition 64.119. Applying unary-prefix trichotomy to these two unary histories gives the displayed comparison. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv target unary and bound trichotomy`

Theorem 64.125 (Trial-division bounds are not empty)**.** *If* $\mathsf{TrialDiv}(b, n)$*, then* b *is not* e*.*

Proof. Use Definition 64.120 to write $b\mathsf{hsameE1}(t)$ for a unary tail t. An additional endpoint $b\mathsf{hsame}\mathsf{e}$ would identify $\mathsf{E1}(t)$ with e, contradicting the history no-confusion principle. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv bound not empty`

Theorem 64.126 (Trial-division unit step result is not unit)**.** *If* $\mathsf{TrialDiv}(b, n)$ *and* $\mathsf{Cont}(b, \mathsf{E1}(\mathsf{e}), b')$*, then* b' *cannot be equal to the unit history* $\mathsf{E1}(\mathsf{e})$*.*

Proof. Transport the displayed continuation result across $b'\mathsf{hsameE1}(\mathsf{e})$, obtaining a continuation $\mathsf{Cont}(b, \mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e}))$. Compare it with the left-unit continuation $\mathsf{Cont}(\mathsf{e}, \mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e}))$ and cancel the common right unit history. This gives $b\mathsf{hsame}\mathsf{e}$, contradicting Definition 64.125. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv unit step result not unit`

Theorem 64.127 (Trial-division unit step result successor shape)**.** *If* $\mathsf{TrialDiv}(b, n)$ *and* $\mathsf{Cont}(b, \mathsf{E1}(\mathsf{e}), b')$*, then the step result has a two-step successor shape:*

$$\exists t : \mathsf{BHist}.\ b'\mathsf{hsameE1}(\mathsf{E1}(t)) \wedge \mathsf{Unary}(t).$$

Proof. The trial-division bound is unary, and continuation with the unary unit keeps the result unary. The empty and zero-headed result cases contradict the continuation inversion and unary no-zero principles. The unit result case is excluded by the preceding unit-step theorem. The remaining unary case exposes the displayed tail. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv unit step result successor shape`

Theorem 64.128 (Terminal trial division excludes non-trivial divisors)**.** *Let* n *be unary with* $\mathsf{NatGT}(n, \mathsf{E1}(\mathsf{e}))$*. If* $\mathsf{TrialDiv}(n, n)$*, then every unary* d *with* $\mathsf{NatDivides}(d, n)$ *satisfies* $d\mathsf{hsameE1}(\mathsf{e})$ *or* $d\mathsf{hsame}n$*. Consequently* $\mathsf{NatPrime}(n)$*.*

Proof. Fix a unary divisor d of n. Since $\mathsf{NatGT}(n, \mathsf{E1}(\mathsf{e}))$ supplies a nonempty endpoint, Definition 64.92 applies to the divisor witness.

If the boundary lemma gives $d\mathsf{hsame}n$, the desired divisor alternative is the right branch. It remains to handle the strict-prefix branch $\mathsf{NatUnaryStrictPrefix}(d, n)$.

Induct on the terminal witness $\mathsf{TrialDiv}(n, n)$ while transporting the strict-prefix endpoint along each unit-continuation step. The induction recovers the trial-division step at the bound represented by d. Its admissible condition is

$$\neg\mathsf{NatDivides}(d, n) \quad \text{or} \quad d\mathsf{hsameE1}(\mathsf{e}) \quad \text{or} \quad d\mathsf{hsame}n.$$

The first branch contradicts the divisor hypothesis. The last branch contradicts strict-prefix asymmetry after transporting across the equality $d\mathsf{hsame}n$. Therefore the unit branch remains, so $d\mathsf{hsameE1}(\mathsf{e})$.

The prime predicate now follows by unfolding Definition 64.102: unaryness and strict greater-than are the hypotheses, and the preceding argument supplies the required alternative for every unary divisor. □

Lean4 ✓ `BEDC.Derived.PrimeUp.TrialDiv terminal excludes nontrivial divisors`

Theorem 64.129 (Decidability of primality)**.** *For every unary history n, the proposition $\mathsf{NatPrime}(n)$ is decidable: there is an explicit unary algorithm that returns either a proof of $\mathsf{NatPrime}(n)$ or an explicit non-trivial divisor of n.*

Sketch. The algorithm constructs $\mathsf{TrialDiv}(b, n)$ by unary induction on b up to n itself. At each step, it checks divisibility of n by b using Definition 64.17 and Definition 64.12: this is decidable because the search for a quotient q of $\mathsf{NatMul}(b, q, n)$ is bounded above by n.

If a non-trivial divisor is found, meaning b divides n and is neither the unit nor n, the algorithm returns it and refutes primality. Otherwise, $\mathsf{TrialDiv}$ reaches $b = n$, and Definition 64.128 gives $\mathsf{NatPrime}(n)$. □

Lemma 64.130 (Unit right multiplication reads back the multiplicand)**.** *For every unary history d, if $\mathsf{NatMul}(d, \mathsf{E1}(\mathsf{e}), n)$, then $\mathsf{hsame}(n, d)$.*

Proof. Apply Definition 64.2 to the multiplication witness. This gives a history m with $\mathsf{NatMul}(d, \mathsf{e}, m)$ and $\mathsf{Cont}(m, d, n)$. Inverting the zero-multiplier multiplication witness leaves only the zero constructor, so m is identified with e, and the displayed continuation becomes $\mathsf{Cont}(\mathsf{e}, d, n)$. The left-unit existence part of Definition 21.12 gives $\mathsf{Cont}(\mathsf{e}, d, d)$, and continuation determinacy from Definition 21.7 identifies n with d. □

Lemma 64.131 (Unit left multiplication is closed)**.** *For every unary history q,*

$$\mathsf{NatMul}(\mathsf{E1}(\mathsf{e}), q, q).$$

Proof. Induct on the unary generation of q. The empty case is the zero multiplication constructor with the unary unit multiplicand. The zero-headed case is impossible by unary-history inversion. In the one-headed case, the induction hypothesis gives the predecessor product $\mathsf{NatMul}(\mathsf{E1}(\mathsf{e}), q_0, q_0)$, and the successor constructor appends one unit copy by the definitional continuation $\mathsf{Cont}(q_0, \mathsf{E1}(\mathsf{e}), \mathsf{E1}(q_0))$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul unit left closed`

Lemma 64.132 (Unary division by a nonempty divisor)**.** *Let t and x be unary histories with $t \not\mathsf{hsamee}$. Then there are unary histories q, r, and w such that* $\mathsf{NatMul}(t, q, w)$, $\mathsf{Cont}(w, r, x)$, *and either* $r\mathsf{hsamee}$ *or* $\mathsf{NatUnaryStrictPrefix}(r, t)$.

Proof. Run unary induction on x, maintaining the invariant that x is the continuation of a t-multiple w by a remainder r which is empty or a strict prefix of t. The empty case uses $q = \mathsf{e}$, $w = \mathsf{e}$, and $r = \mathsf{e}$. For a one-extension step, first extend the current remainder by the unit history. Apply unary prefix totality from Definition 28.5 to this candidate remainder and t. If the candidate is still a strict prefix of t, keep the same quotient and replace the remainder by the candidate. If the candidate reaches t, append one more copy of t to the multiple using the successor constructor of Definition 64.1, reset the remainder to e, and use continuation associativity from Definition 29.6. The alternative in which t is a strict prefix of the candidate would make the old remainder and t strict prefixes of each other after one-step cancellation, contradicting Definition 28.14. Thus the invariant closes. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul division with remainder`

Lemma 64.133 (Unary multiplication commutes up to history-sameness)**.** *Let a and b be unary histories. If* $\mathsf{NatMul}(a, b, n)$ *and* $\mathsf{NatMul}(b, a, m)$, *then* $n\mathsf{hsame}m$.

Proof. Induct on the unary generation of b. The empty case reduces both products to e by constructor inversion and Definition 64.4. In the one-extension case, invert the first product with Definition 64.2. The predecessor is the product of a by the tail of b; by the induction hypothesis it agrees with the product of that tail by a. The final continuation appends one copy of a. On the other side, multiplication of $\mathsf{E1}(b_0)$ by a is built by appending one visible unit through each copy of a. Repeated use of unary continuation commutativity from Definition 9200.14 and associativity from Definition 29.6 moves that visible unit block past the tail product. Functionality of unary multiplication from Definition 64.12 identifies the two resulting histories. The $\mathsf{E0}$ case is impossible by Definition 28.3. □

Lemma 64.134 (Divisible prefix cancellation)**.** *Let d, x, y, and z be unary histories with d /* hsamee. *If* $\mathsf{Cont}(x, y, z)$, $\mathsf{NatDivides}(d, x)$, *and* $\mathsf{NatDivides}(d, z)$, *then* $\mathsf{NatDivides}(d, y)$.

Proof. Unpack the two divisibility witnesses from Definition 64.50, obtaining quotients q_x and q_z with products $dq_x = x$ and $dq_z = z$. Compare q_x and q_z by unary prefix totality. If q_z is obtained from q_x by a unary tail u, then Definition 64.1 and continuation associativity decompose the dq_z product as the continuation of x by the product du. Since z is also the continuation of x by y, continuation left-cancellation identifies y with du, and divisibility follows after endpoint transport by Definition 64.189.

In the other comparison direction, x is the continuation of z by a d-multiple. If that extra quotient tail is nonempty, the nonempty divisor d makes the extra product nonempty by Definition 64.38; then z is a strict unary prefix of x, while the displayed $\mathsf{Cont}(x, y, z)$ makes x a prefix of z unless $y\mathsf{hsamee}$. Strict-prefix asymmetry from Definition 28.14 rules out the nonempty tail. Hence the tail is empty, $x\mathsf{hsame}z$, and continuation unit uniqueness forces $y\mathsf{hsamee}$. The empty quotient witnesses $\mathsf{NatDivides}(d, y)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides prefix cancellation`

Theorem 64.135 (Divisible continuation left factor)**.** *Let d, x, y, and z be unary histories with $d \not\mathsf{hsamee}$. If* $\mathsf{NatDivides}(d, y)$, $\mathsf{NatDivides}(d, z)$, *and* $\mathsf{Cont}(x, y, z)$, *then* $\mathsf{NatDivides}(d, x)$.

Proof. The unary continuation ledger may be read in the opposite endpoint order by unary append commutativity, giving $\mathsf{Cont}(y, x, z)$. Applying divisible prefix cancellation to this commuted continuation removes the already-divisible factor y from the divisible result z, leaving divisibility of x by d. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides cont left factor`

Theorem 64.136 (Divisible continuation right factor iff)**.** *Let d, x, y, and z be unary histories with $d \not\mathsf{hsame}$. If $\mathsf{NatDivides}(d, x)$ and $\mathsf{Cont}(x, y, z)$, then divisibility of the continuation result is equivalent to divisibility of the displayed right factor:*

$$\mathsf{NatDivides}(d, z) \iff \mathsf{NatDivides}(d, y).$$

Proof. For the forward direction, apply divisible prefix cancellation to remove the already-divisible left factor x from the divisible result z. For the reverse direction, unpack the quotient witnesses for $\mathsf{NatDivides}(d, x)$ and $\mathsf{NatDivides}(d, y)$; appending the two quotients and using multiplication append closure builds a quotient witness for the displayed continuation result z. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides cont right factor iff`

Theorem 64.137 (Prime divisor dichotomy)**.** *For unary histories p and a, if $\mathsf{NatPrime}(p)$, then*

$$\mathsf{NatDivides}(p, a) \vee \neg\mathsf{NatDivides}(p, a).$$

Sketch. Use the $\mathsf{Prime}^{\uparrow}$ template with traditional target divisibility decidability by a fixed prime. The BEDC source data are the unary histories together with NatMul, $\mathsf{NatDivides}$, and $\mathsf{NatPrime}$.

The carrier is the bounded unary-prefix search over quotient candidates up to a. For each candidate q, Definition 64.17 supplies a product m_q for $\mathsf{NatMul}(p, q, m_q)$, and the classifier compares m_q with a by hsame.

Stability follows from Definition 64.17, Definition 64.12, Definition 28.5, and endpoint transport. Thus the bounded quotient scan is a ledger whose entries are stable under history-sameness of the multiplication result.

Exactness is immediate from the scan. If some candidate has product history-same to a, endpoint transport packages that quotient as $\mathsf{NatDivides}(p, a)$. If the scan exhausts every unary prefix up to a without such an endpoint, then every possible quotient is rejected, which is the negated divisor predicate. This supplies the displayed disjunction as a paper certificate. □

Lemma 64.138 (Least prime multiple period)**.** *Let p and a be unary histories with $\mathsf{NatPrime}(p)$ and $\neg\mathsf{NatDivides}(p, a)$. Among the nonempty unary histories t for which there is a product m_t with $\mathsf{NatMul}(a, t, m_t)$ and $\mathsf{NatDivides}(p, m_t)$, a strict-prefix least such t exists, and every such least t satisfies $t\mathsf{hsame}p$.*

Proof. The search set is inhabited. By Definition 64.17 there is a product of a by p; by Definition 64.133 it is history-same to the product of p by a, so Definition 64.189 gives divisibility by p. The strict-greater field in Definition 64.102 makes p nonempty. Bounded trial division as in Definition 64.129, using Definition 64.17 and Definition 64.12 to decide each product test, scans the nonempty prefixes up to p and returns a least period t.

Divide p by this nonempty t using Definition 64.132. Thus p is the continuation of a t-multiple by a remainder r, where r is empty or a strict prefix of t. Since p divides ap, and since p also divides a times the t-multiple part by repeated use of the period witness and Definition 64.62,

Definition 64.134 gives divisibility of ar by p. If r were nonempty, this would be a smaller positive period than t, contradicting leastness. Hence $r\mathsf{hsamee}$, so t divides p.

Apply the divisor-classifier field of Definition 64.102 to this divisor t of p. Either $t\mathsf{hsameE1}(\mathsf{e})$ or $t\mathsf{hsame}p$. In the unit case, the period witness is a product of a by the unit; Definition 64.130 and endpoint transport give $\mathsf{NatDivides}(p, a)$, contradicting the hypothesis. Therefore $t\mathsf{hsame}p$. □

Theorem 64.139 (Euclid's lemma for prime divisibility)**.** *Let p, a, b, and n be unary histories. If $\mathsf{NatPrime}(p)$, $\mathsf{NatMul}(a, b, n)$, and $\mathsf{NatDivides}(p, n)$, then*

$$\mathsf{NatDivides}(p, a) \vee \mathsf{NatDivides}(p, b).$$

Proof. Apply Definition 64.137 to p, a, and the prime hypothesis. In the left branch, take the left disjunct.

In the negated branch, let t be the least prime multiple period supplied by Definition 64.138; then $t\mathsf{hsame}p$.

Use Definition 64.132 to divide b by p. Write b as the continuation of a p-multiple part by a remainder r, where $r\mathsf{hsamee}$ or r is a strict unary prefix of p. The product of a with the p-multiple part is divisible by p, because the product of a with one copy of p is divisible by p by Definition 64.133, and repeated copies compose by Definition 64.62. The given product n is obtained from this divisible prefix by appending the product of a with r, using the successor clauses of Definition 64.1 and continuation associativity. Since p divides n, Definition 64.134 gives that p divides the product of a with r.

If r is nonempty, then r is a positive period for a modulo p and is a strict prefix of p, contradicting $t\mathsf{hsame}p$ and the leastness of t. Thus $r\mathsf{hsamee}$. The displayed division of b therefore has no remainder: b is history-same to a product with left factor p. By Definition 64.189, this is $\mathsf{NatDivides}(p, b)$, giving the right disjunct. □

64.4 Euclid's theorem on the infinitude of primes

Definition 64.140 (Unary factorial)**.** *The unary factorial $\mathsf{NatFact}(n, n!)$ is the closed inductive predicate generated by:*

1. $\mathsf{NatFact}(\mathsf{e}, \mathsf{E1}(\mathsf{e}))$ *(zero factorial is one);*
2. *if $\mathsf{NatFact}(n, m)$ and $\mathsf{NatMul}(\mathsf{E1}(n), m, m')$, then $\mathsf{NatFact}(\mathsf{E1}(n), m')$.*

Lean4 (definition) `BEDC.Derived.PrimeUp.NatFact`

Lemma 64.141 (Unary factorial inputs are unary)**.** *Every closed witness of $\mathsf{NatFact}(n, m)$ has a unary input n.*

Proof. Induct on the $\mathsf{NatFact}$ witness. The zero constructor has input e, which is unary. The successor constructor changes the input from n to $\mathsf{E1}(n)$, so unary closure under $\mathsf{E1}$ applied to the induction hypothesis gives the result. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact input unary`

Lemma 64.142 (Unary factorial successor inversion)**.** *If $\mathsf{NatFact}(\mathsf{E1}(n), m')$, then there is an m such that $\mathsf{NatFact}(n, m)$ and $\mathsf{NatMul}(\mathsf{E1}(n), m, m')$.*

Proof. Invert the closed factorial witness. The zero constructor has empty input and therefore cannot produce an $\mathsf{E1}$ input. The successor constructor exposes exactly the predecessor factorial witness and the multiplication witness. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact successor inversion`

Theorem 64.143 (Factorial successor input divides its result)**.** *If* $\mathsf{NatFact}(\mathsf{E1}(n), m)$*, then the successor input* $\mathsf{E1}(n)$ *divides the factorial result* m*:*

$$\mathsf{NatFact}(\mathsf{E1}(n), m) \Longrightarrow \mathsf{NatDivides}(\mathsf{E1}(n), m).$$

Proof. Successor inversion exposes a predecessor factorial value m_0 together with a multiplication witness $\mathsf{NatMul}(\mathsf{E1}(n), m_0, m)$. The predecessor factorial result is unary by factorial result closure. Thus m_0 is a valid quotient witness in the existential definition of $\mathsf{NatDivides}(\mathsf{E1}(n), m)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact successor input divides result`

Theorem 64.144 (Factorial successor step predecessor divides product)**.** *If* $\mathsf{NatFact}(n, m)$ *and* $\mathsf{NatMul}(\mathsf{E1}(n), m, m')$*, then the predecessor factorial value divides the displayed successor-step product:*

$$\mathsf{NatDivides}(m, m').$$

Proof. The factorial witness supplies unary evidence for n and for the predecessor factorial result m. Thus the displayed multiplication step has two unary inputs, and right-factor divisibility for unary multiplication applies directly to the factor m. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact successor step predecessor divides`

Theorem 64.145 (Factorial absorbs every positive bounded unary predecessor)**.** *Let* n, m, d *be histories. If* $\mathsf{NatFact}(n, m)$*,* $\mathsf{UnaryHistory}(d)$*,* $\mathsf{NatGT}(d, \mathsf{e})$*, and either* $d\mathsf{hsame}n$ *or* $\mathsf{NatUnaryStrictPrefix}(d, n)$*, then* $\mathsf{NatDivides}(d, m)$*.*

Sketch. Induct on the closed $\mathsf{NatFact}$ witness. In the empty-input case, positive boundedness would require either $d\mathsf{hsame}\mathsf{e}$ or a strict unary prefix of e, contradicting $\mathsf{NatGT}(d, \mathsf{e})$ and strict-prefix inversion.

For the successor step, write the input as $\mathsf{E1}(n_0)$ and the result as the product of $\mathsf{E1}(n_0)$ with the predecessor factorial result. If $d\mathsf{hsame}\mathsf{E1}(n_0)$, endpoint transport turns Definition 64.143 into the required divisibility statement for d.

It remains to treat the strict-predecessor branch. Invert the $\mathsf{NatUnaryStrictPrefix}(d, \mathsf{E1}(n_0))$ witness. The endpoint case is the previous paragraph, while the proper predecessor case gives either $d\mathsf{hsame}n_0$ or $\mathsf{NatUnaryStrictPrefix}(d, n_0)$. The induction hypothesis therefore gives divisibility of the predecessor factorial result by d.

Finally, push that divisibility through the final multiplication witness. Use the left-closure of $\mathsf{NatDivides}$ under multiplication, and transport along hsame endpoints where the constructor inversion changed the displayed representatives. Transitivity of $\mathsf{NatDivides}$ yields $\mathsf{NatDivides}(d, m)$ for the successor factorial result. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact bounded positive predecessor divides`

Lemma 64.146 (Unary factorial results are nonempty)**.** *Every closed witness of* $\mathsf{NatFact}(n, m)$ *has a result* m *distinct from* e *up to* hsame*.*

Proof. Induct on the $\mathsf{NatFact}$ witness. The zero case is the singleton $\mathsf{E1}(\mathsf{e})$, which cannot classify as empty. In the successor case, an empty product result would force the previous factorial result to be empty by the nonempty-multiplicand empty-result inversion for NatMul, contradicting the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact result not empty`

Lemma 64.147 (Factorial successor results have positive shape)**.** *If* $\mathsf{NatFact}(\mathsf{E1}(n), m)$*, then the factorial result has one-headed shape:*

$$\exists t,\ \mathsf{hsame}(m, \mathsf{E1}(t)) \wedge \mathsf{UnaryHistory}(t).$$

Proof. Successor inversion exposes a predecessor factorial value m_0 and a multiplication witness $\mathsf{NatMul}(\mathsf{E1}(n), m_0, m)$. Factorial non-emptiness rules out $m_0\mathsf{hsamee}$, and $\mathsf{E1}(n)$ is not history-same to e. The positive-shape theorem for multiplication with a nonempty multiplier therefore gives the displayed one-headed result. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact successor result positive shape`

Lemma 64.148 (Factorial results are unary)**.** *If* $\mathsf{NatFact}(n, m)$*, then* m *is a unary history.*

Proof. Induct on the factorial witness. The base constructor yields $\mathsf{E1}(\mathsf{e})$, which is unary. The successor constructor carries a multiplication witness, whose left factor is unary by multiplicand readback and whose result is unary by multiplication result closure. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact result unary`

Theorem 64.149 (Unary factorial zero-headed component impossibility)**.** *For histories* n, m*, a closed witness of* $\mathsf{NatFact}(n, m)$ *cannot have either its input or result displayed as a zero-headed history.*

Proof. Factorial input readback gives $\mathsf{UnaryHistory}(n)$, and factorial result readback gives $\mathsf{UnaryHistory}(m)$. In either displayed zero-headed branch, substituting the equality turns a zero-headed history into a unary history, contradicting unary zero-extension separation. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact zero headed component absurd`

Theorem 64.150 (Factorial results have positive shape)**.** *If* $\mathsf{NatFact}(n, m)$*, then there is a unary tail* t *such that* $\mathsf{hsame}(m, \mathsf{E1}(t))$*.*

Proof. Combine factorial result nonemptiness with factorial result unary closure. Case analysis on the generated history m eliminates the empty case by nonemptiness and the $\mathsf{E0}$ case by unary inversion. The remaining $\mathsf{E1}(t)$ case exposes the tail t, and unary inversion supplies the tail carrier. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact result positive shape`

Lemma 64.151 (Factorial is total and functional on unary histories)**.** *For every unary* n*, there is exactly one unary* m *with* $\mathsf{NatFact}(n, m)$*.*

Proof. By unary induction on n, using the totality and functionality of NatMul (Definition 64.17, Definition 64.12) at each step. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact total functional`

Lemma 64.152 (Bounded unary divisor divides factorial result)**.** *Let* n*,* m*, and* d *be histories. If* $\mathsf{NatFact}(n, m)$*,* $\mathsf{UnaryHistory}(d)$*,* $\neg\mathsf{hsame}(d, \mathsf{E1}(\mathsf{e}))$*, and* $\mathsf{NatGT}(n, d) \vee \mathsf{hsame}(d, n)$*, then* $\mathsf{NatDivides}(d, m)$*.*

Sketch. Induct on the factorial witness. In the base case, the bound by e gives no nonunit unary divisor, so the hypotheses cannot all hold.

For a successor factorial witness, use Definition 64.142 to expose the predecessor factorial and the displayed multiplication step. If $d\mathsf{hsame}n$ at the successor endpoint, endpoint transport and Definition 64.143 give $\mathsf{NatDivides}(d, m)$.

If d is strictly below the successor endpoint, successor inversion of the bound either identifies the endpoint case above or produces a predecessor bound. The induction hypothesis gives divisibility into the predecessor factorial result. Then Definition 64.17, Definition 64.12, and the displayed product divisibility closures Definition 64.89 and Definition 64.90 carry the inherited divisor through the successor multiplication display. □

Lemma 64.153 (Factorial successor has no bounded nonunit divisor)**.** *Let n, m, and d be histories. If* $\mathsf{NatFact}(n, m)$, $\mathsf{UnaryHistory}(d)$, $\neg\mathsf{hsame}(d, \mathsf{E1}(\mathsf{e}))$, *and* $\mathsf{NatGT}(n, d) \vee \mathsf{hsame}(d, n)$, *then* $\neg\mathsf{NatDivides}(d, \mathsf{E1}(m))$.

Sketch. Assume toward contradiction that d divides $\mathsf{E1}(m)$. By Definition 64.152, the same bounded nonunit divisor also divides the factorial result m.

The continuation $\mathsf{Cont}(m, \mathsf{E1}(\mathsf{e}), \mathsf{E1}(m))$ displays the successor as the factorial result followed by the unit. Divisible prefix cancellation Definition 64.134 removes the common divisible prefix and forces $\mathsf{NatDivides}(d, \mathsf{E1}(\mathsf{e}))$.

Finally, unit-right divisibility exactness Definition 64.60 identifies d with $\mathsf{E1}(\mathsf{e})$, contradicting the nonunit hypothesis. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatFact successor no bounded nonunit divisor`

Lemma 64.154 (Successor of factorial is coprime to all bounded predecessors)**.** *Let m be the unary factorial of n, and let m' be the successor* $\mathsf{E1}(m)$ *(i.e., $n! + 1$). Then for every unary d with* $\mathsf{E1}(\mathsf{e}) \neq d$ *and* $\mathsf{NatGT}(\mathsf{E1}(n), d) \vee \mathsf{hsame}(d, \mathsf{E1}(n)) \vee \mathsf{NatGT}(d, \mathsf{E1}(n)) \wedge \mathsf{NatDivides}(d, n)$, *we have* $\neg\mathsf{NatDivides}(d, m')$.

Sketch. For every positive unary d bounded by n, the factorial absorption theorem Definition 64.145 supplies $\mathsf{NatDivides}(d, m)$. If the same d also divides $m' = \mathsf{E1}(m)$, then the unit-successor subtraction argument shows that d divides the unit.

Unit divisibility forces $d\mathsf{hsame}\mathsf{E1}(\mathsf{e})$, contradicting the displayed non-unit hypothesis. Thus no such bounded non-unit divisor can divide m'. □

Theorem 64.155 (Euclid's theorem, constructive form)**.** *There exists an explicit total unary function* $\mathsf{NatNextPrime} : \mathsf{Unary} \to \mathsf{Unary}$ *such that for every unary n,* $\mathsf{NatPrime}(\mathsf{NatNextPrime}(n))$ *and* $\mathsf{NatGT}(\mathsf{NatNextPrime}(n), n)$.

Sketch. Given n, compute the unary factorial $m = n!$ by Definition 64.151, then form $m' = m + 1$. By Definition 64.154, every prime divisor of m' exceeds n. The primality test of Definition 64.129 either finds m' itself prime (return it) or returns an explicit non-trivial divisor; in the latter case, recursing on the divisor's prime factor (also exceeding n) terminates in a prime by well-foundedness of $\mathsf{NatUnaryStrictPrefix}$. The function is total because the search is bounded. □

64.5 The fundamental theorem of arithmetic

Definition 64.156 (Prime factorization list)**.** *A prime factorization of a unary history n is a finite list of unary primes $[p_1, \ldots, p_k]$ (in non-decreasing unary order) such that the iterated multiplicative continuation $p_1 \cdot p_2 \cdots p_k$ yields a unary history* hsame*-equal to n.*

Lean4 (definition) `BEDC.Derived.PrimeUp.NatPrimeFactorization`
Lean4 (definition) `BEDC.Derived.PrimeUp.PrimeFactorizationProduct`
Lean4 (definition) `BEDC.Derived.PrimeUp.PrimeFactorization`

Theorem 64.157 (Prime factorization cons head divides)**.** *If a prime factorization list of n has head p, then p is prime and divides n:*

$$\mathsf{PrimeFactorization}(n, p :: ps) \Longrightarrow \mathsf{NatPrime}(p) \wedge \mathsf{NatDivides}(p, n).$$

Proof. Unfold the cons clause of the concrete factorization-product predicate. It exposes the head primality proof, a tail product, and the multiplication witness $\mathsf{NatMul}(p, \mathsf{tail}, n)$. The multiplier unary field of that witness supplies the quotient carrier required by $\mathsf{NatDivides}$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.PrimeFactorization cons head divides`

Theorem 64.158 (Prime factorization product result transport)**.** *If a prime factorization product yields n, and $n\mathsf{hsame}n'$, then the same factorization product yields n'.*

Proof. Inspect the concrete list-product predicate. The empty product clause is transported by transitivity of hsame. In the cons clause, the tail product is unchanged, and the displayed NatMul result witness is transported along $n\mathsf{hsame}n'$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.PrimeFactorizationProduct result hsame transport`

Theorem 64.159 (Prime factorization products have unary result)**.** *If* $\mathsf{PrimeFactorizationProduct}(ps, n)$*, then n is a unary history.*

Proof. Induct on the factor list. The empty list identifies the product with the unit endpoint $\mathsf{E1}(\mathsf{e})$, which is unary, and unary carrier transport moves this along hsame. In the cons case, the head prime supplies a unary multiplicand and the displayed NatMul witness supplies unary closure of the result. □

Lean4 ✓ `BEDC.Derived.PrimeUp.PrimeFactorizationProduct result unary`

Theorem 64.160 (Prime factorization products have nonempty result)**.** *If* $\mathsf{PrimeFactorizationProduct}(ps, n)$*, then n is not history-same to* e*.*

Proof. Induct on the list ps. The empty product is $\mathsf{E1}(\mathsf{e})$, which is separated from e by constructor no-confusion. In the cons case, the head prime is nonempty, the induction hypothesis makes the tail product nonempty, and the nonempty-factor multiplication theorem applies to the displayed NatMul witness. □

Lean4 ✓ `BEDC.Derived.PrimeUp.PrimeFactorizationProduct result not empty`

Definition 64.161 (Natural prime product relation)**.** *The relation* $\mathsf{NatPrimeProduct}(ps, n)$ *is the closed list product relation generated by the empty product* $\mathsf{NatPrimeProduct}([], \mathsf{E1}(\mathsf{e}))$*, and by the cons rule: if* $\mathsf{NatPrime}(p)$*,* $\mathsf{NatPrimeProduct}(ps, m)$*, and* $\mathsf{NatMul}(p, m, n)$*, then* $\mathsf{NatPrimeProduct}(p :: ps, n)$*.*

Lean4 (definition) `BEDC.Derived.PrimeUp.NatPrimeProduct`

Theorem 64.162 (Natural prime products have nonempty result)**.** *If* $\mathsf{NatPrimeProduct}(ps, n)$*, then n is not history-same to* e*.*

Proof. Induct on the list-product witness. The empty product is $\mathsf{E1}(\mathsf{e})$, so history no-confusion separates it from e. In the cons case, primality exposes the head factor as a nonempty one-headed unary history, the induction hypothesis gives nonemptiness of the tail product, and the nonempty-factor multiplication result theorem applies to the displayed NatMul witness. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrimeProduct result not empty`

Theorem 64.163 (Natural prime factorizations have nonempty result)**.** *If* $\mathsf{NatPrimeFactorization}(ps, n)$*, then* n *is not history-same to* e*.*

Proof. Induct on the concrete factorization witness. The unit factorization has result $\mathsf{E1}(\mathsf{e})$, separated from e by constructor no-confusion. The singleton case is prime nonemptiness. In the cons case, primality makes the head factor nonempty, the induction hypothesis makes the tail product nonempty, and nonempty-factor multiplication excludes an empty result. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrimeFactorization result not empty`

Theorem 64.164 (Natural prime products have unary result)**.** *If* $\mathsf{NatPrimeProduct}(ps, n)$*, then* n *is a unary history.*

Proof. Induct on the list-product witness. The empty product is $\mathsf{E1}(\mathsf{e})$, hence unary by unary successor closure over the empty history. In the cons case, primality supplies the unary carrier of the head factor, and the multiplication-result carrier theorem applies to the displayed NatMul witness. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrimeProduct result unary`

Theorem 64.165 (Natural prime product cons tail divides)**.** *If* $\mathsf{NatPrimeProduct}(p :: ps, n)$*, then* p *is unary and there is a tail product* m *such that* $\mathsf{NatPrimeProduct}(ps, m)$ *and* $\mathsf{NatDivides}(m, n)$*.*

Proof. Invert the cons constructor of $\mathsf{NatPrimeProduct}$. The head prime gives the unary carrier of p, while the tail witness gives the product m. The preceding unary-result theorem supplies the unary carrier of m, and the multiplication closure theorem turns the displayed $\mathsf{NatMul}(p, m, n)$ witness into $\mathsf{NatDivides}(m, n)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrimeProduct cons tail divides`

Theorem 64.166 (Natural prime product member factor divides result)**.** *If* $p \in ps$ *and* $\mathsf{NatPrimeProduct}(ps, n)$*, then* p *is unary and* $\mathsf{NatDivides}(p, n)$*.*

Proof. Induct on the $\mathsf{NatPrimeProduct}$ witness. The empty product has no list member. In the cons case, head membership is witnessed directly by the displayed $\mathsf{NatMul}(p, m, n)$ relation and the unary carrier of the tail product. Tail membership applies the induction hypothesis to the tail product and composes the resulting divisibility through the head multiplication closure theorem. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatPrimeProduct factor mem unary divides result`

Theorem 64.167 (Existence of prime factorization)**.** *For every unary history* n *with* $\mathsf{NatGT}(n, \mathsf{e})$*, there exists a prime factorization list of* n*. The list is constructed explicitly by repeated trial division using Definition 64.129.*

Sketch. Strong induction on the unary history n along NatUnaryStrictPrefix. If $n = \mathsf{E1}(\mathsf{e})$, the empty list factors it. Otherwise apply Definition 64.129: either n is prime (return $[n]$) or a non-trivial divisor d is exhibited; recurse on d and on the quotient $q = n/d$, both strictly smaller than n, and concatenate the resulting lists. □

Theorem 64.168 (Uniqueness of prime factorization)**.** *If $[p_1, \ldots, p_j]$ and $[q_1, \ldots, q_k]$ are two prime factorization lists of the same unary history n, then $j = k$ and the lists agree pointwise up to* hsame*.*

Sketch. Apply Definition 64.97 to the leading prime of one factorization and the iterated product represented by the other factorization. Repeating this product-factor exposure across the second list locates a matching prime factor up to hsame.

Cancel the matched factor using the NatMul result and functionality facts, then continue by induction on the remaining lists. The induction gives pointwise agreement up to hsame and length agreement $j = k$. □

64.6 The certificate

Definition 64.169 (Prime source specification)**.** *The source specification on* Unary *carries the additional constraint* $\mathsf{NatPrime}(p)$*. Its generator is the prime predicate of Definition 64.102.*

Definition 64.170 (Prime pattern specification)**.** *The pattern of* $\mathsf{Prime}^{\uparrow}$ *is trial-division-bounded primality: for an input unary n, the pattern is the trial-division predicate* $\mathsf{TrialDiv}(n, n)$ *restricted to inputs satisfying* NatPrime *at the upper bound.*

Definition 64.171 (Prime classifier specification)**.** *The classifier on prime carriers is* hsame *restricted to unary primes. Two unary primes classify together iff they are* hsame*-equal as histories.*

Definition 64.172 (Prime stability certificate)**.** *The stability certificate consists of:*

1. *closure of the prime predicate under* hsame*: if* $\mathsf{NatPrime}(p)$ *and* $\mathsf{hsame}(p, p')$*, then* $\mathsf{NatPrime}(p')$*;*
2. *transport of divisibility under* hsame*: if* $\mathsf{NatDivides}(d, n)$*,* $\mathsf{hsame}(d, d')$*, and* $\mathsf{hsame}(n, n')$*, then* $\mathsf{NatDivides}(d', n')$*;*
3. *compatibility of the trial-division witness with* hsame *on bounds.*

Lean4 ✓ `BEDC.Derived.PrimeUp.PrimeStabilityCert fields`

Definition 64.173 (Prime ledger policy)**.** *The ledger policy records:*

1. *composition of factorizations: concatenation of prime factorization lists for products;*
2. *product-factor exposure by Definition 64.97;*
3. *infinitude closure:* NatNextPrime *of Definition 64.155 produces a new prime exceeding any given bound.*

Theorem 64.174 (Concrete $\mathsf{Prime}^{\uparrow}$ naming certificate)**.** *The data* (NatPrime, TrialDiv, hsame, PrimeStabilityCert, Pr *of Definition 64.169–Definition 64.173 forms a naming certificate over* Hist *for the prime number interface* $\mathsf{Prime}^{\uparrow}$*. The certificate is decidable (Definition 64.129), unbounded (Definition 64.155), and exhaustive (Definition 64.167, Definition 64.168).*

Sketch. The five fields satisfy the closure laws of the naming-certificate framework (chapter 9). Decidability is Definition 64.129. Unboundedness is Definition 64.155. Exhaustiveness follows from existence (Definition 64.167) together with uniqueness (Definition 64.168). The certificate uses no Classical.choice, no Quot.sound, and no propext, so its Lean targets fall under the project's axiom-purity gate. □

Lean4 ✓ `BEDC.Derived.PrimeUp.PrimeUp StdBridge`

Theorem 64.175 (Semantic $\mathsf{Prime}^{\uparrow}$ naming certificate)**.** *The concrete certificate of Definition 64.174 satisfies the semantic naming-certificate schema of* NameCert *(chapter 9): the carrier is a* Hist*-predicate, the classifier is a restriction of* hsame*, and every closure law is given by an explicit constructive proof.*

Sketch. Direct verification of the four NameCert field types using the constructions of this chapter. □

Lean4 ✓ `BEDC.Derived.PrimeUp.prime semantic name certificate`

Theorem 64.176 (Unary multiplication result semantic name certificate)**.** *For unary histories d and q, the result predicate* $\mathsf{NatMul}(d, q, -)$*, used as source, pattern, and ledger policy, together with* hsame *as classifier, forms a semantic naming certificate.*

Proof. Totality of unary multiplication supplies a carried result witness. The classifier laws are exactly reflexivity, symmetry, and transitivity of hsame. Carrier transport is result transport for NatMul along history-sameness, while the pattern and ledger maps are the shared concrete result predicate. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul result semanticNameCert`

Theorem 64.177 (Divisibility semantic name certificate)**.** *For a unary divisor d, the predicate* $\mathsf{NatDivides}(d, -)$*, used as source, pattern, and ledger policy, together with* hsame *as classifier, forms a semantic naming certificate.*

Proof. The empty dividend is inhabited exactly by the empty-right divisibility characterization. The classifier laws are inherited from hsame, and carrier transport is dividend transport for NatDivides along history-sameness. Since the source, pattern, and ledger predicates coincide, the semantic soundness fields are direct projections of the same witness. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides semanticNameCert`

Lemma 64.178 (Empty left factor has empty unary product)**.** *If* $\mathsf{NatMul}(\mathsf{e}, q, n)$*, then* $n\mathsf{hsamee}$*.*

Proof. Induct on the multiplication witness from Definition 64.1. The zero clause has result e. In the successor clause, the inductive result identifies the predecessor product with e, and the final continuation has empty right input. By the continuation unit law of Definition 29.5, the successor result is history-same to that predecessor, hence to e. □

Lemma 64.179 (Nonempty quotient exposes a multiplicand extension)**.** *Let d and q be unary histories. If* $\mathsf{NatMul}(d, q, n)$ *and* $q \not\mathsf{hsamee}$*, then there is a unary history t with* $\mathsf{Cont}(d, t, n)$*.*

Proof. Induct on the unary generation of q from Definition 28.1. The empty case contradicts $q \not\mathsf{hsame}\mathsf{e}$, and the zero-headed case is impossible by Definition 28.3. In the one-headed case write $q = \mathsf{E1}(q_0)$. By Definition 64.2, the multiplication witness has a predecessor product p with $\mathsf{NatMul}(d, q_0, p)$ and $\mathsf{Cont}(p, d, n)$.

If $q_0 \mathsf{hsame}\mathsf{e}$, the zero clause of Definition 64.1 identifies p with e. The displayed continuation is therefore the left-unit continuation from e by d, so $n \mathsf{hsame} d$; transporting the right-unit continuation of d across this identification gives $\mathsf{Cont}(d, \mathsf{e}, n)$, with unary tail e.

If $q_0 \not\mathsf{hsame}\mathsf{e}$, the induction hypothesis applied to $\mathsf{NatMul}(d, q_0, p)$ gives a unary tail t with $\mathsf{Cont}(d, t, p)$. Composing this continuation with $\mathsf{Cont}(p, d, n)$ and using continuation associativity gives $\mathsf{Cont}(d, \mathsf{append}(t, d), n)$. The tail $\mathsf{append}(t, d)$ is unary because continuation preserves unary histories. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul nonempty quotient product extension`

Lemma 64.180 (Divisibility exposes unary divisor)**.** *If* $\mathsf{NatDivides}(d, n)$ *holds, then* d *is a unary history.*

Proof. Unpack the quotient witness in $\mathsf{NatDivides}(d, n)$. The corresponding multiplication witness has d as its multiplicand, and the multiplicand readback for closed multiplication derivations reads the unary carrier directly from it. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides divisor unary`

Theorem 64.181 (Divisibility antisymmetry up to history-sameness)**.** *Let* d *and* e *be unary histories. If* $\mathsf{NatDivides}(d, e)$ *and* $\mathsf{NatDivides}(e, d)$*, then* $d \mathsf{hsame} e$*.*

Proof. Unpack Definition 64.50. Choose unary quotients q and r with $\mathsf{NatMul}(d, q, e)$ and $\mathsf{NatMul}(e, r, d)$.

If $q \mathsf{hsame}\mathsf{e}$, the first multiplication witness has empty multiplier, so $e \mathsf{hsame}\mathsf{e}$. After replacing e by e in the second witness, Definition 64.178 gives $d \mathsf{hsame}\mathsf{e}$, hence $d \mathsf{hsame} e$. The case $r \mathsf{hsame}\mathsf{e}$ is symmetric.

It remains to consider $q \not\mathsf{hsame}\mathsf{e}$ and $r \not\mathsf{hsame}\mathsf{e}$. By Definition 64.179, there are unary tails t and s with $\mathsf{Cont}(d, t, e)$ and $\mathsf{Cont}(e, s, d)$. By closed unary generation, each tail is either e or a one-extension. If $t \mathsf{hsame}\mathsf{e}$, the first continuation is a right-unit continuation and gives $e \mathsf{hsame} d$ by Definition 29.5; symmetry gives $d \mathsf{hsame} e$. If $s \mathsf{hsame}\mathsf{e}$, the second continuation gives $d \mathsf{hsame} e$ directly. If both tails are one-extensions, the two continuations are strict unary prefix witnesses in the sense of Definition 28.10, contradicting Definition 28.14. From that contradiction the desired history-sameness follows. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides antisymmetry hsame`

Lemma 64.182 (Unary multiplication transports along the multiplicand)**.** *Let* d, q, n *be unary histories, and let* d' *be a history with* $d \mathsf{hsame} d'$*. If* $\mathsf{NatMul}(d, q, n)$*, then* $\mathsf{NatMul}(d', q, n)$*.*

Proof. By Definition 9195.7, d' is unary. Induct on the closed $\mathsf{NatMul}(d, q, n)$ witness from Definition 64.1. In the zero-multiplier case, the result is e, and the zero constructor with the unary witness for d' gives $\mathsf{NatMul}(d', \mathsf{e}, \mathsf{e})$. In the successor case, the induction hypothesis gives $\mathsf{NatMul}(d', q, n_0)$ for the predecessor product. The original last step is a continuation $\mathsf{Cont}(n_0, d, n_1)$. Transport that continuation along reflexivity on n_0, the hypothesis $d \mathsf{hsame} d'$, and reflexivity on n_1 using Definition 4.41; this gives $\mathsf{Cont}(n_0, d', n_1)$. Applying the successor constructor of Definition 64.1 yields $\mathsf{NatMul}(d', \mathsf{E1}(q), n_1)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul multiplicand hsame transport`

Lemma 64.183 (Unary multiplication transports along the multiplier)**.** *Let d, q, n be unary multiplication histories, and let q' be a history with $q\mathsf{hsame}q'$. If $\mathsf{NatMul}(d, q, n)$, then q' is unary and $\mathsf{NatMul}(d, q', n)$.*

Proof. Case-analyze the displayed history-sameness $q\mathsf{hsame}q'$. In the reflexive case the original multiplication witness already has multiplier q', and the right-unary theorem for NatMul supplies the unary witness for that multiplier. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul multiplier hsame transport`

Lemma 64.184 (Unary multiplication successor result-continuation transport)**.** *Let d, q, n be unary histories, and let n' be a history with $n\mathsf{hsame}n'$. If $\mathsf{NatMul}(d, \mathsf{E1}(q), n)$, then there is a predecessor product p with $\mathsf{NatMul}(d, q, p)$ and $\mathsf{Cont}(p, d, n')$.*

Proof. Invert the successor multiplication witness to obtain a predecessor product p and the final continuation $\mathsf{Cont}(p, d, n)$. Transport this continuation along the displayed result history-sameness, leaving the predecessor product unchanged. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul succ result cont transport`

Theorem 64.185 (Divisibility transports along divisor history-sameness)**.** *Let d and e be unary histories, and let d' be any history with $d\mathsf{hsame}d'$. If $\mathsf{NatDivides}(d, e)$, then $\mathsf{NatDivides}(d', e)$.*

Proof. Unpack Definition 64.50. Choose a unary quotient q with $\mathsf{NatMul}(d, q, e)$. By Definition 64.182, the same quotient satisfies $\mathsf{NatMul}(d', q, e)$. Since the quotient witness itself remains unary, the existential clause in Definition 64.50 gives $\mathsf{NatDivides}(d', e)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides divisor hsame transport`

Lemma 64.186 (Unary multiplication transports along the result)**.** *Let d, q, n be unary histories, and let n' be a history with $n\mathsf{hsame}n'$. If $\mathsf{NatMul}(d, q, n)$, then $\mathsf{NatMul}(d, q, n')$.*

Proof. Case-analyze the closed witness for $\mathsf{NatMul}(d, q, n)$ from Definition 64.1. In the zero-multiplier case the result is e; by closed generation for hsame in Definition 3.2, the target n' is also e, so the zero constructor gives $\mathsf{NatMul}(d, \mathsf{e}, n')$.

In the successor case, the witness consists of a predecessor product $\mathsf{NatMul}(d, q_0, n_0)$ and a continuation $\mathsf{Cont}(n_0, d, n_1)$. The result hypothesis is $n_1\mathsf{hsame}n'$. Apply Definition 4.41 to this continuation, using reflexivity from Definition 3.8 on n_0 and d and the displayed result sameness. This yields $\mathsf{Cont}(n_0, d, n')$, and the successor constructor of Definition 64.1 gives $\mathsf{NatMul}(d, \mathsf{E1}(q_0), n')$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul result hsame transport`

Lemma 64.187 (Unary multiplication append multiplier totality)**.** *Let d, w, n, q be histories. If $\mathsf{NatMul}(d, w, n)$ and q is unary, then there is a unary result r with*

$$\mathsf{NatMul}(d, \mathsf{append}(w, q), r).$$

Proof. Read the unary multiplicand from the existing multiplication witness. Totality of unary multiplication supplies a unary product e for the appended multiplier tail q. The continuation from n to e gives the displayed result $r = \mathsf{append}(n, e)$, and append-continuation closure for NatMul combines the two multiplication witnesses into the product over $\mathsf{append}(w, q)$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul append multiplier total`

Theorem 64.188 (Divisibility transports along dividend history-sameness)**.** *Let d and e be unary histories, and let e' be a history with $e\mathsf{hsame}e'$. If* $\mathsf{NatDivides}(d, e)$*, then* $\mathsf{NatDivides}(d, e')$*.*

Proof. By Definition 9195.7, the history e' is unary, so it is an admissible dividend endpoint. Unpack Definition 64.50. Choose a unary quotient q with $\mathsf{NatMul}(d, q, e)$. By Definition 64.186, the same quotient satisfies $\mathsf{NatMul}(d, q, e')$. The quotient witness remains unary, so the existential clause in Definition 64.50 gives $\mathsf{NatDivides}(d, e')$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides dividend hsame transport`

Corollary 64.189 (Divisibility transports along both endpoints)**.** *Let d and e be unary histories, and let d' and e' be histories with $d\mathsf{hsame}d'$ and $e\mathsf{hsame}e'$. If* $\mathsf{NatDivides}(d, e)$*, then* $\mathsf{NatDivides}(d', e')$*.*

Proof. Unary transport puts d' and e' in the unary carrier. First apply Definition 64.185 to transport the divisor from d to d', obtaining $\mathsf{NatDivides}(d', e)$. Then apply Definition 64.188 to transport the dividend from e to e'. The result is $\mathsf{NatDivides}(d', e')$. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatDivides endpoint hsame transport`

Closure status for $\mathsf{NameCert}_{\mathsf{Prime}^{\uparrow}}$.

Constructive story: A prime candidate starts as a unary spine that has passed the first successor: it is unary, its b1-depth is at least two, and every unary divisor shown by a continuation $\mathsf{Cont}(d, q, h)$ is forced back to the unit spine E1(e) or to h itself. Thus divisibility is not an oracle but a displayed unary continuation factorization, and the classifier on accepted candidates is just history-equality of the prime spine. The source is the same unary-prime predicate, the pattern records unary shape, exclusion of the unit, and the rule that all divisibility tests use unary continuations, while the ledger keeps the visible prime history aligned with the raw spine being tested. Since history-equality is identity on histories and the primality condition is preserved by that identity, an admitted prime gives the carrier witness and the classifier is reflexive, symmetric, transitive, and closed over admitted candidates. A unary history h lies in the signature gap of a $\mathsf{Prime}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer history and evidence ledger, and the token-introduction relation names that answer as p; unfolded, h is unary, has depth at least two, every unary divisor collapses to the unit or to h, and the b1-depth of h matches the prime encoded by p. The infinitude row follows the Euclidean move already expressed in this language: from any finite prime list, inspect the unary factors of the product-plus-one spine to obtain a further prime. The chapter registers this divisor-tested construction under the name $\mathsf{Prime}^{\uparrow}$; primality is a finite condition on unary continuations, with no prime oracle, quotient class, or extra arithmetic primitive introduced.

Chapter 65

A Concrete Naming Certificate for $\mathsf{CplxLim}^{\uparrow}$

This chapter gives a concrete naming-certificate construction for the complex-limit interface $\mathsf{CplxLim}^{\uparrow}$ at the paper-proof level. The construction sits above the complex-history certificate $\mathsf{Complex}^{\uparrow}$ (chapter 39) and the RealUp chapter $\mathsf{Real}^{\uparrow}$ (chapter 38), with explicit unary-history moduli throughout. Every $\mathsf{CplxLim}^{\uparrow}$ limit-facing row first consumes the $\mathsf{Complex}^{\uparrow}$ coordinate packet and the $\mathsf{Real}^{\uparrow}$ or RegSeqRat tolerance route before any complex-distance, modulus, or local naming row is read.

Theorem 65.1 (Complex-limit real-coordinate sibling route)**.** *Every accepted* $\mathsf{CplxLim}^{\uparrow}$ *read first consumes the* $\mathsf{Complex}^{\uparrow}$ *coordinate carrier of chapter 39 and the* $\mathsf{Real}^{\uparrow}$ *real-coordinate seal of chapter 38. Only after those coordinate rows are displayed may the read expose the unary-history modulus, the complex-distance rows, and the local* $\mathsf{NameCert}_{\mathsf{CplxLim}^{\uparrow}}$ *rows. The route exports no host complex equality, quotient limit, selected representative, or ambient completeness theorem.*

Proof. Project the carrier already described by the chapter. Its source history is a regular complex sequence, hence its entries are read through the $\mathsf{Complex}^{\uparrow}$ coordinate carrier before any limit-facing row is available.

The $\mathsf{Complex}^{\uparrow}$ carrier itself is componentwise over real coordinates, so the real-coordinate seal is the $\mathsf{Real}^{\uparrow}$ dependency named by the same introductory route. A limit consumer therefore reaches the unary-history modulus only after the real and imaginary coordinate seals have been displayed.

The remaining rows are local to $\mathsf{CplxLim}^{\uparrow}$: they record the modulus comparison, the complex-distance history, replay, provenance, and the naming certificate. Since no coordinate in that carrier is a host complex equality, quotient limit, selected representative, or ambient completeness principle, the sibling route cannot export any of those objects. □

65.1 Modulus and complex distance on Hist

Definition 65.2 (Complex modulus on Hist)**.** *For a complex history z with components (x, y) in* $\mathsf{Rat}^{\uparrow}$*-carrier, the complex modulus* $\mathsf{CplxMod}(z, M)$ *is the closed inductive predicate asserting that M is a unary-indexed* $\mathsf{Real}^{\uparrow}$*-bound history witnessing $M^2 \geq x^2 + y^2$ under unary-history rational arithmetic. The witness is constructed by applying the rational squaring continuation to each component followed by additive composition.*

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.ComplexModulus`

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexModulus hsame transport`

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.CplxMod`

Definition 65.3 (Pairwise complex distance)**.** *For complex histories $z = (x_1, y_1)$ and $w = (x_2, y_2)$, the distance* $\mathsf{CplxDist}(z, w, D)$ *holds when D is the rational-history modulus of the difference $(x_1 - x_2, y_1 - y_2)$. Concretely,* $\mathsf{CplxDist}(z, w, D) := \mathsf{CplxMod}(z - w, D)$*, where $z - w$ is the pointwise rational subtraction continuation.*

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.ComplexDistance`

Lemma 65.4 (Complex distance is symmetric)**.** *For all complex histories z, w and unary-history bound D,* $\mathsf{CplxDist}(z, w, D)$ *iff* $\mathsf{CplxDist}(w, z, D)$*.*

Proof. The rational-subtraction continuation produces the additive inverse on each component; squaring is invariant under negation, so the modulus witness is identical. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance symm iff`

Theorem 65.5 (Complex distance from the empty left endpoint)**.** *For unary histories $w, d : \mathsf{BHist}$, the concrete complex-distance predicate from the empty left endpoint is equivalent to unary support of w and equality of the displayed distance result with w:*

$$\mathsf{ComplexDistance}(\mathsf{e}, w, d) \iff \mathsf{UnaryHistory}(w) \wedge \mathsf{hsame}(d, w).$$

Proof. Unfolding the distance predicate leaves unary support for the endpoints and a continuation branch. If the branch is $\mathsf{Cont}(\mathsf{e}, w, d)$, the left-unit law identifies d with w; if it is $\mathsf{Cont}(w, \mathsf{e}, d)$, the right-unit law gives the same identification. Conversely, unary support for w transports across $\mathsf{hsame}(d, w)$ to support d, and the left-unit continuation supplies the distance branch. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance empty left iff`

Theorem 65.6 (Complex distance transport with relation)**.** *For histories $z, z', w, w', d, d' : \mathsf{BHist}$, if z, w, d are respectively* hsame*-equal to z', w', d', then every concrete complex-distance witness for (z, w, d) transports to one for (z', w', d') and preserves an explicit continuation branch:*

$$\mathsf{ComplexDistance}(z, w, d) \Longrightarrow \mathsf{ComplexDistance}(z', w', d') \wedge (\mathsf{Cont}(z', w', d') \vee \mathsf{Cont}(w', z', d')).$$

Proof. Unary support of each endpoint transports along the three hsame witnesses. The continuation branch in the original distance witness is then transported across the same endpoint equalities and the result equality, preserving whether the branch is oriented from z to w or from w to z. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance hsame transport with relation`

Lemma 65.7 (Complex distance empty boundary)**.** *For all complex histories z, w, the empty complex distance* $\mathsf{CplxDist}(z, w, \mathsf{e})$ *is equivalent to unary carrier evidence for both endpoints together with z*hsamee *and w*hsamee*.*

Proof. Unpack the two possible continuation ledgers inside the distance witness. In either order, a continuation with empty result forces both inputs to be e. Conversely, empty endpoints and unary carrier evidence rebuild the empty-left continuation at e. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance empty iff`

Lemma 65.8 (Complex distance empty left endpoint)**.** *For every complex history w and distance history d,* $\mathsf{CplxDist}(\mathsf{e}, w, d)$ *is equivalent to unary carrier evidence for w together with $d\mathsf{hsame}w$.*

Proof. The forward direction splits the distance continuation into the empty-left and empty-right cases, both of which identify the result with w. The reverse direction transports d to w and uses the empty-left continuation. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance empty left endpoint iff`

Theorem 65.9 (Complex distance empty endpoint)**.** *For histories $z, w : \mathsf{BHist}$, a complex-distance witness with empty distance result is exactly the assertion that both endpoints are unary histories and both endpoints are history-same to* e*:*

$$\mathsf{ComplexDistance}(z, w, \mathsf{e}) \iff \mathsf{UnaryHistory}(z) \wedge \mathsf{UnaryHistory}(w) \wedge z\mathsf{hsame}\mathsf{e} \wedge w\mathsf{hsame}\mathsf{e}.$$

Proof. Unpack the symmetric continuation field inside $\mathsf{ComplexDistance}$. If the displayed continuation has result e, continuation empty-result inversion forces both endpoints of that continuation to be e; the two symmetric cases only exchange the endpoint order. Conversely, the two endpoint hsame witnesses reduce the claim to the canonical continuation $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$ together with unary emptiness. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance empty endpoint iff`

Lemma 65.10 (Complex distance from the empty source)**.** *For histories $w, d : \mathsf{BHist}$,*

$$\mathsf{ComplexDistance}(\mathsf{e}, w, d) \iff \mathsf{UnaryHistory}(w) \wedge d\mathsf{hsame}w.$$

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance empty source iff`

Proof. Unpack the distance witness. The left branch is a continuation $\mathsf{Cont}(\mathsf{e}, w, d)$, whose left-unit result gives $d\mathsf{hsame}w$. The right branch is $\mathsf{Cont}(w, \mathsf{e}, d)$, whose right-unit characterization gives the same endpoint identity. Conversely, transport unary membership from w to d along $d\mathsf{hsame}w$, and use the left-unit continuation witness. □

Definition 65.11 (Complex distance triangle bound)**.** *For distance histories $D_{12}, D_{23} : \mathsf{BHist}$, the explicit BEDC history-level triangle bound is*

$$\mathsf{ComplexDistanceTriangleBound}(D_{12}, D_{23}) := \mathsf{append}(D_{12}, D_{23}).$$

It is the native continuation composition used by the complex-distance triangle discussion.

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.ComplexDistanceTriangleBound`

Theorem 65.12 (Complex distance triangle bound unary)**.** *For complex histories z, w, u and distance witnesses d_{12}, d_{23}, if* $\mathsf{ComplexDistance}(z, w, d_{12})$ *and* $\mathsf{ComplexDistance}(w, u, d_{23})$ *hold, then the explicit triangle bound is unary:*

$$\mathsf{UnaryHistory}(\mathsf{ComplexDistanceTriangleBound}(d_{12}, d_{23})).$$

Proof. Each complex-distance witness contains a unary carrier for its distance endpoint. The triangle bound is the BEDC append of the two endpoints, so unary append closure gives the displayed unary carrier. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistanceTriangleBound unary`

Theorem 65.13 (Complex distance triangle bound unary carrier from distances)**.** *For complex histories z, w, u and distance histories d_{12}, d_{23}, two concrete distance witnesses*

$$\mathsf{ComplexDistance}(z, w, d_{12}) \quad \textit{and} \quad \mathsf{ComplexDistance}(w, u, d_{23})$$

make the explicit triangle bound a unary history and retain unary support for the outer endpoints:

$$\mathsf{UnaryHistory}(\mathsf{ComplexDistanceTriangleBound}(d_{12}, d_{23})) \wedge \mathsf{UnaryHistory}(z) \wedge \mathsf{UnaryHistory}(u).$$

Proof. Project the unary distance witnesses from the two distance hypotheses. Since the triangle bound is $\mathsf{append}(d_{12}, d_{23})$, unary append closure gives unary support for the bound. The same two distance hypotheses already store unary support for the outer endpoints z and u. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistanceTriangleBound unary of distances`

Theorem 65.14 (Complex distance triangle bound empty endpoints)**.** *For complex histories z, w, u and distance histories d_{12}, d_{23}, if the two concrete distance witnesses*

$$\mathsf{ComplexDistance}(z, w, d_{12}) \quad \textit{and} \quad \mathsf{ComplexDistance}(w, u, d_{23})$$

hold and the explicit triangle bound is history-same to e*, then all three endpoints are history-same to* e*.*

Proof. The triangle bound is $\mathsf{append}(d_{12}, d_{23})$, so append-empty inversion forces both displayed distance histories to be empty. Each empty-distance witness then exposes empty endpoints by continuation empty-result inversion; applying this to the two adjacent distances gives $z\mathsf{hsamee}$, $w\mathsf{hsamee}$, and $u\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistanceTriangleBound empty endpoints`

Lemma 65.15 (Complex distance nonempty endpoint cases)**.** *For complex histories z, w and distance endpoint d, if $\mathsf{CplxDist}(z, w, d)$ holds and d is not history-same to* e*, then at least one endpoint is not history-same to* e*:*

$$\neg(d\mathsf{hsamee}) \Longrightarrow \neg(z\mathsf{hsamee}) \vee \neg(w\mathsf{hsamee}).$$

Proof. Unfold the concrete distance predicate to its two continuation branches. In the branch $\mathsf{Cont}(z, w, d)$, nonemptiness of d is exactly nonemptiness of the append result, so append-empty inversion gives a nonempty source or a nonempty right endpoint. In the symmetric branch $\mathsf{Cont}(w, z, d)$, the same append nonempty readback is applied and the two alternatives are swapped. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance nonempty distance endpoint cases`

Lemma 65.16 (Complex distance endpoint nonempty distance nonempty)**.** *For complex histories z, w and distance endpoint d, if $\mathsf{CplxDist}(z, w, d)$ holds and at least one endpoint is not history-same to* e*, then d is not history-same to* e*:*

$$\neg(z\mathsf{hsamee}) \vee \neg(w\mathsf{hsamee}) \Longrightarrow \neg(d\mathsf{hsamee}).$$

Proof. Unpack the symmetric continuation branch inside the distance witness. If the distance result were e, continuation empty-result inversion would force both endpoints of the active branch to be e. In either branch orientation this contradicts the displayed nonempty endpoint alternative. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance endpoint nonempty distance nonempty`

Lemma 65.17 (Complex distance triangle inequality with explicit bound)**.** *For all complex histories z_1, z_2, z_3 with distances $\mathsf{CplxDist}(z_1, z_2, D_{12})$ and $\mathsf{CplxDist}(z_2, z_3, D_{23})$, there exists an explicit rational-history bound function $\mathsf{TriBound}(D_{12}, D_{23}, D_{13})$ with $\mathsf{CplxDist}(z_1, z_3, D_{13})$ and $D_{13} \leq D_{12} + D_{23}$ under rational-history ordering.*

Sketch. Componentwise application of the rational-history triangle inequality from $\mathsf{Real}^{\uparrow}$ machinery (chapter 38) to the real and imaginary parts, followed by composition under the modulus witness of Definition 65.2. The bound TriBound is explicit and unary-indexed. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance triangle explicit bound`

65.2 Regular complex sequences

Definition 65.18 (Regular complex sequence)**.** *A regular complex sequence is a pair (s, N) consisting of a unary-indexed family $s : \mathsf{Unary} \to \mathsf{Complex}^{\uparrow}$-history together with a unary modulus function $N : \mathsf{Unary} \to \mathsf{Unary}$ such that for every unary index k and unary indices n, m with $\mathsf{NatUnaryStrictPrefix}(N(k), n)$ (or $\mathsf{hsame}(n, N(k))$) and similarly for m, the distance $\mathsf{CplxDist}(s(n), s(m), D)$ is bounded by the unary representation of 2^{-k}. The predicate is written $\mathsf{CplxRegSeq}(s, N)$.*

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence`

Lemma 65.19 (Regular complex sequence has regular real and imaginary projections)**.** *If $\mathsf{CplxRegSeq}(s, N)$ holds, then the projection sequences $\mathsf{Re}(s)$ and $\mathsf{Im}(s)$ are each regular $\mathsf{Rat}^{\uparrow}$-Cauchy sequences with the same unary modulus N, in the sense of* RegSeqRat *from chapter 38.*

Proof. Each component bound is dominated by the modulus witness of Definition 65.2: if $D^2 \geq x^2 + y^2$, then $D \geq |x|$ and $D \geq |y|$. The unary modulus carries through unchanged. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence accepted pair unary witness`

Lemma 65.20 (Constant sequence is regular)**.** *For every complex history z, the constant sequence $s(n) := z$ together with the trivial modulus $N(k) := \mathsf{e}$ satisfies $\mathsf{CplxRegSeq}(s, N)$.*

Proof. For any accepted pair of indices, unary support of z supplies both endpoints. The BEDC distance witness is $\mathsf{append}(z, z)$, with the canonical continuation from z to z. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence constant`

65.3 The complex-limit predicate

Definition 65.21 (Complex limit predicate)**.** *For a regular complex sequence (s, N) and a complex history z, the predicate $\mathsf{CplxLim}(s, N, z, M)$ holds when $M : \mathsf{Unary} \to \mathsf{Unary}$ is an explicit modulus such that for every unary index k and every unary n with $\mathsf{NatUnaryStrictPrefix}(M(k), n)$ (or $\mathsf{hsame}(n, M(k))$), the distance $\mathsf{CplxDist}(s(n), z, D)$ satisfies the unary representation of $D \leq 2^{-k}$.*

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.ComplexLimit`

Lemma 65.22 (Complex limit functorial under hsame on the limit point)**.** *If* $\mathsf{CplxLim}(s, N, z, M)$ *and the components of* z *and* z' *are pairwise* hsame*-equal, then* $\mathsf{CplxLim}(s, N, z', M)$ *with the same modulus.*

Proof. The distance $\mathsf{CplxDist}(s(n), z, D)$ depends on z only via its rational-history components; hsame on each component preserves the modulus witness pointwise. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit hsame transport`

Theorem 65.23 (Constant complex sequence has its displayed limit)**.** *If* z *is a complex history, then the constant sequence* $s(n) := z$ *with the empty regularity modulus has complex limit* z*, witnessed by the empty limit modulus.*

Proof. The complex carrier of z gives unary support for the endpoint. The regular part is the constant regular-sequence theorem. For every accepted observation index, choose the canonical BEDC distance witness $\mathsf{append}(z, z)$; its unary support follows from unary append closure, and the distance relation is the canonical continuation from z to z. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit constant`

Theorem 65.24 (Uniqueness of complex limit)**.** *If* $\mathsf{CplxLim}(s, N, z, M)$ *and* $\mathsf{CplxLim}(s, N, z', M')$ *both hold for the same regular complex sequence, then* hsame *holds on the real components of* z *and* z' *and on the imaginary components.*

Sketch. From the two modulus witnesses construct the diagonal sequence $s(\max(M(k), M'(k)))$ and bound $\mathsf{CplxDist}(z, z', D)$ by 2^{-k+1} for every k using the triangle inequality (Definition 65.17). The componentwise rational-history archimedean property then forces hsame on each component. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit conditional unique boundary`

65.4 Closure laws on regular sequences

Lemma 65.25 (Complex distance constant suffix closure)**.** *Let* $q : \mathsf{BHist}$ *be unary. If* $\mathsf{ComplexDistance}(z, w, d)$ *holds, then the suffixed endpoints admit the canonical BEDC distance witness*

$$\mathsf{append}(\mathsf{append}(z, q), \mathsf{append}(w, q)).$$

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance append constant closed`

Proof. Unary support for the original distance supplies unary histories for z and w. Unary append closure with q gives the two suffixed endpoints, and another append-closure step gives the displayed witness. The continuation relation is the canonical append continuation from the suffixed left endpoint to the suffixed right endpoint. □

Lemma 65.26 (Complex distance constant prefix closure)**.** *Let* $q : \mathsf{BHist}$ *be unary. If* $\mathsf{ComplexDistance}(z, w, d)$ *holds, then the prefixed endpoints admit the canonical BEDC distance witness*

$$\mathsf{append}(\mathsf{append}(q, z), \mathsf{append}(q, w)).$$
