Proof. Unary support for the distance endpoints gives unary histories for z and w. Unary append closure with q gives unary support for the two prefixed endpoints, and append closure gives the displayed distance history. The continuation component is the canonical append continuation from the prefixed left endpoint to the prefixed right endpoint. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance prepend constant closed`

Theorem 65.27 (Complex distance constant suffix result determinacy)**.** *Let* $q : \mathsf{BHist}$ *be unary. If* $\mathsf{ComplexDistance}(z, w, d)$ *holds and a displayed distance witness for the suffixed endpoints* $\mathsf{append}(z, q)$ *and* $\mathsf{append}(w, q)$ *has result* d'*, then*

$$d' \mathsf{hsameappend}(\mathsf{append}(z, q), \mathsf{append}(w, q)).$$

Proof. Split the displayed distance witness into its two continuation orientations. The forward orientation is determined by the canonical append continuation. The reverse orientation is determined by the reverse canonical continuation, then unary append commutativity for the two suffixed endpoints identifies the reverse canonical result with the forward canonical result. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance append constant result deterministic`

Theorem 65.28 (Complex distance constant prefix result determinacy)**.** *Let* $q : \mathsf{BHist}$ *be unary. If* $\mathsf{ComplexDistance}(z, w, d)$ *holds and a displayed distance witness for the prefixed endpoints* $\mathsf{append}(q, z)$ *and* $\mathsf{append}(q, w)$ *has result* d'*, then*

$$d' \mathsf{hsameappend}(\mathsf{append}(q, z), \mathsf{append}(q, w)).$$

Proof. Split the displayed distance witness into its two continuation orientations. The forward orientation is determined by the canonical append continuation. The reverse orientation is determined by the reverse canonical continuation, then unary append commutativity for the two prefixed endpoints identifies the reverse canonical result with the forward canonical result. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance prepend constant result deterministic`

Theorem 65.29 (Complex distance unary append commutation package)**.** *For unary histories* z *and* q*, the two appended endpoints* $q \cdot z$ *and* $z \cdot q$ *carry the canonical complex-distance witness* $(q \cdot z) \cdot (z \cdot q)$*, and the endpoints are* hsame*:*

$$\mathsf{ComplexDistance}(q \cdot z, z \cdot q, (q \cdot z) \cdot (z \cdot q)) \wedge \mathsf{hsame}(q \cdot z, z \cdot q).$$

Proof. Unary append closure gives unary carriers for $q \cdot z$, $z \cdot q$, and their displayed composite distance. The complex-distance relation uses the canonical continuation from the left endpoint to the right endpoint, while unary append commutativity supplies the endpoint classifier. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance unary append comm package`

Theorem 65.30 (Regular complex sequence constant suffix closure)**.** *Let* $q : \mathsf{BHist}$ *be unary. If* (s, N) *is a regular complex sequence, then the suffixed sequence* $n \mapsto \mathsf{append}(s(n), q)$ *is regular with the same modulus* N*. For any accepted pair of indices* n, m*, the BEDC distance witness is*

$$\mathsf{append}(\mathsf{append}(s(n), q), \mathsf{append}(s(m), q)).$$

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence append constant closed`

Proof. Apply regularity of (s, N) to the displayed indices and threshold continuations. The resulting complex-distance witness carries $\mathsf{UnaryHistory}(s(n))$ and $\mathsf{UnaryHistory}(s(m))$. Unary append closure with $\mathsf{UnaryHistory}(q)$ gives unary histories for the two suffixed endpoints, and a second append-closure step gives the unary distance history. The canonical continuation witness for append supplies the distance relation, so the suffixed sequence satisfies the same regularity predicate. □

Theorem 65.31 (Complex limit constant suffix closure)**.** *Let* $q : \mathsf{BHist}$ *be unary. If* $\mathsf{CplxLim}(s, N, z, M)$ *holds, then the suffixed sequence* $n \mapsto \mathsf{append}(s(n), q)$ *has complex limit* $\mathsf{append}(z, q)$ *with the same regularity modulus* N *and limit modulus* M*.*

Proof. Regularity is transported by the regular-sequence constant suffix closure. The limit carrier is closed by complex-history unary suffix closure. For every accepted modulus index, the original limit witness gives a complex distance from $s(n)$ to z; applying constant suffix closure to that distance gives the canonical distance from $\mathsf{append}(s(n), q)$ to $\mathsf{append}(z, q)$. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit append constant closed`

Theorem 65.32 (Regular complex sequence constant suffix result determinacy)**.** *Let* $q : \mathsf{BHist}$ *be unary and let* (s, N) *be a regular complex sequence. For accepted unary indices* n, m *at threshold* k*, every displayed complex-distance result* d' *for the suffixed endpoints* $\mathsf{append}(s(n), q)$ *and* $\mathsf{append}(s(m), q)$ *satisfies*

$$d' \mathsf{hsameappend}(\mathsf{append}(s(n), q), \mathsf{append}(s(m), q)).$$

Proof. Regularity supplies a base complex-distance witness between $s(n)$ and $s(m)$. Applying the constant-suffix result determinacy theorem to that base witness and to the displayed suffixed distance identifies d' with the canonical suffixed append result. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence append constant result deterministic`

Theorem 65.33 (Regular complex sequence constant prefix closure)**.** *Let* $q : \mathsf{BHist}$ *be unary. If* (s, N) *is a regular complex sequence, then the prefixed sequence* $n \mapsto \mathsf{append}(q, s(n))$ *is regular with the same modulus* N*. For any accepted pair of indices* n, m*, the BEDC distance witness is*

$$\mathsf{append}(\mathsf{append}(q, s(n)), \mathsf{append}(q, s(m))).$$

Proof. Apply regularity of (s, N) to the accepted indices and threshold continuations. The resulting complex-distance witness supplies unary histories for $s(n)$ and $s(m)$. Unary append closure with $\mathsf{UnaryHistory}(q)$ gives unary histories for the two prefixed endpoints, and append closure again gives the displayed distance history. The canonical append continuation witness supplies the distance relation. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence prepend constant closed`

Theorem 65.34 (Regular complex sequence endpoint transport)**.** *Let* $s, t, N : \mathsf{Hist} \to \mathsf{Hist}$*. If every unary index* n *satisfies* $\mathsf{hsame}(s(n), t(n))$*, then regularity of* (s, N) *implies regularity of* (t, N) *with the same modulus.*

Proof. Apply regularity of (s, N) to the accepted unary indices n, m. Reuse the same distance witness d, transport the two complex-distance endpoints along the pointwise hsame comparisons, and keep d fixed by reflexivity. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence hsame transport`

Theorem 65.35 (Complex limit sequence endpoint transport)**.** *Let $s, t, N, M : \mathsf{Hist} \to \mathsf{Hist}$. If every unary index n satisfies $\mathsf{hsame}(s(n), t(n))$, then $\mathsf{CplxLim}(s, N, z, M)$ implies $\mathsf{CplxLim}(t, N, z, M)$.*

Proof. The regular part is transported pointwise by the regular-sequence endpoint transport theorem. The displayed complex-history carrier for z is unchanged. For each accepted limit-modulus index, reuse the original distance witness and transport its sequence endpoint from $s(n)$ to $t(n)$ along the supplied hsame comparison. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit sequence hsame transport`

Definition 65.36 (Pointwise sum of complex sequences)**.** *For complex sequences s, t, the pointwise sum $s \oplus t$ is given by $(s \oplus t)(n) := s(n) + t(n)$, where $+$ is componentwise rational-history addition continuation on $\mathsf{Complex}^{\uparrow}$-carriers.*

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.ComplexPointwiseSum`

Lemma 65.37 (Sum of regular sequences is regular with explicit modulus pasting)**.** *If $\mathsf{CplxRegSeq}(s, N_s)$ and $\mathsf{CplxRegSeq}(t, N_t)$, then $\mathsf{CplxRegSeq}(s \oplus t, N')$ with $N'(k) := \max(N_s(k+1), N_t(k+1))$ (max in unary-history strict prefix order).*

Proof. Applying the triangle inequality to $\mathsf{CplxDist}((s \oplus t)(n), (s \oplus t)(m), D)$ decomposes the bound into the sum of the s- and t-bounds, each at level $k+1$, giving total 2^{-k}. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence pointwise sum closed`
Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence pointwise append same modulus closed`

Theorem 65.38 (Limit respects pointwise sum)**.** *If $\mathsf{CplxLim}(s, N_s, z_s, M_s)$ and $\mathsf{CplxLim}(t, N_t, z_t, M_t)$, then $\mathsf{CplxLim}(s \oplus t, N', z_s + z_t, M')$ with explicit pasted modulus $M'(k) := \max(M_s(k+1), M_t(k+1))$.*

Sketch. Triangle inequality on $\mathsf{CplxDist}((s \oplus t)(n), z_s + z_t, D)$: bound by the sum of the two component distances, each at level $k+1$ by the hypothesis on M_s and M_t. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit pointwise append same modulus closed`

Theorem 65.39 (Limit respects scalar multiplication by a fixed complex history)**.** *For a fixed complex history c with modulus bound C (i.e. $\mathsf{CplxMod}(c, C)$), suppose a supplied unary shift witness σ_C carries the certificate that every distance bound at precision $k + \sigma_C$, after multiplication by the fixed bound C, is a distance bound at precision k. If $\mathsf{CplxLim}(s, N, z, M)$ holds, then the scaled sequence $c \cdot s$ (componentwise rational-history multiplication) satisfies $\mathsf{CplxLim}(c \cdot s, N, c \cdot z, M_C)$ with $M_C(k) := M(k + \sigma_C)$.*

Sketch. Given k and n above $M_C(k)$, the original limit witness gives a distance certificate from $s(n)$ to z at the shifted precision $k + \sigma_C$.

Use the bilinearity rows for complex multiplication to transport this distance through left multiplication by c. The bound $\mathsf{CplxMod}(c, C)$ supplies the fixed scalar factor, and the certificate carried by σ_C converts the resulting C-scaled distance into the required precision-k bound. Repack the transported distance as the modulus clause for $\mathsf{CplxLim}(c \cdot s, N, c \cdot z, M_C)$. □

Theorem 65.40 (Complex limit constant prefix closure)**.** *Let $q : \mathsf{BHist}$ be unary. If $\mathsf{CplxLim}(s, N, z, M)$ holds, then the prefixed sequence $n \mapsto \mathsf{append}(q, s(n))$ has complex limit $\mathsf{append}(q, z)$ with the same regularity modulus N and limit modulus M.*

Proof. Regularity is transported by the regular-sequence constant prefix closure. The limit carrier is closed by complex-history unary prefix closure.

For every accepted modulus index, the original limit witness gives a complex distance from $s(n)$ to z. Applying constant prefix closure to that distance gives the canonical distance from $\mathsf{append}(q, s(n))$ to $\mathsf{append}(q, z)$. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit prepend constant closed`

Theorem 65.41 (Complex limit two-sided unary context closure)**.** *Let $p, q : \mathsf{BHist}$ be unary. If $\mathsf{CplxLim}(s, N, z, M)$ holds, then the two-sided contexted sequence $n \mapsto \mathsf{append}(p, \mathsf{append}(s(n), q))$ has complex limit $\mathsf{append}(p, \mathsf{append}(z, q))$ with the same regularity modulus N and limit modulus M.*

Proof. First apply Definition 65.31 with suffix q. This gives a complex limit for $n \mapsto \mathsf{append}(s(n), q)$ at endpoint $\mathsf{append}(z, q)$, keeping both moduli unchanged.

Next apply the checked prefix limit closure with prefix p to the suffixed limit. The resulting endpoint is $\mathsf{append}(p, \mathsf{append}(z, q))$, and the resulting sequence is exactly $n \mapsto \mathsf{append}(p, \mathsf{append}(s(n), q))$, again with the same regularity and limit moduli. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit two sided unary context closure`

Theorem 65.42 (Limit respects pointwise product with quadratic modulus)**.** *If $\mathsf{CplxLim}(s, N_s, z_s, M_s)$ and $\mathsf{CplxLim}(t, N_t, z_t, M_t)$ with both target points bounded $\mathsf{CplxMod}(z_s, B_s)$, $\mathsf{CplxMod}(z_t, B_t)$, then the pointwise product $s \otimes t$ satisfies $\mathsf{CplxLim}(s \otimes t, N', z_s \cdot z_t, M')$ with quadratic modulus $M'(k) := \max(M_s(k + B_t + 1), M_t(k + B_s + 1))$.*

Sketch. Standard $ab - a'b' = a(b - b') + (a - a')b'$ decomposition; bound each summand using the hypotheses, with the bounds on z_s, z_t entering as the multiplicative shift on the modulus indices. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit pointwise product witness package`

65.5 Componentwise limit assembly

Definition 65.43 (Cauchy regular complex sequence)**.** *The Cauchy condition on (s, N) is exactly the condition built into Definition 65.18: it is the same regular-sequence predicate, named separately for emphasis. We write $\mathsf{CplxCauchy}(s, N) := \mathsf{CplxRegSeq}(s, N)$.*

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence cauchy witness package`

Lemma 65.44 (Component limit assembly)**.** *Assume $\mathsf{CplxCauchy}(s, N)$. Suppose the real projection $\mathsf{Re}(s)$ is supplied with an explicit $\mathsf{RegSeqRat}$ limit witness x^* and modulus M_x, and the imaginary projection $\mathsf{Im}(s)$ is supplied with an explicit $\mathsf{RegSeqRat}$ limit witness y^* and modulus M_y. Then the pair (x^*, y^*) is the candidate complex limit point, with pasted modulus $M^\sharp(k) := \max(M_x(k + 1), M_y(k + 1))$.*

Sketch. Use Definition 65.19 only to read the real and imaginary projections as regular $\mathsf{RegSeqRat}$ streams. The component limit witnesses are part of the input data, so no ambient completeness principle is invoked.

For each unary level k, ask the real component at level $k + 1$ through M_x and the imaginary component at level $k + 1$ through M_y. Taking the unary maximum gives one threshold above which both component bounds hold, and the modulus witness of Definition 65.2 packages the two component inequalities as a complex-distance bound. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit component assembly candidate unary`

Theorem 65.45 (Complex limit from component limits)**.** *If* $\mathsf{CplxCauchy}(s, N)$ *holds and explicit* $\mathsf{RegSeqRat}$ *limit witnesses are supplied for* $\mathsf{Re}(s)$ *and* $\mathsf{Im}(s)$ *with limit histories* x^* *and* y^* *and moduli* M_x *and* M_y*, then there exists an explicit complex history* $z^* = (x^*, y^*)$ *and pasted modulus* M^* *such that* $\mathsf{CplxLim}(s, N, z^*, M^*)$*. Any other complex limit with its own modulus agrees with* z^* *componentwise by Definition 65.24.*

Sketch. Apply Definition 65.44 to obtain the candidate point and the pasted unary threshold. The real and imaginary component bounds above that threshold are exactly the two inputs needed by the complex modulus predicate.

Define $z^* := (x^*, y^*)$ and $M^* := M^\sharp$. The distance predicate of Definition 65.3 reduces the desired limit statement to the modulus packaging supplied in the assembly lemma, and uniqueness is only the already stated consequence of Definition 65.24. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit from component limits`

65.6 The certificate

Definition 65.46 (Complex-limit source specification)**.** *The source specification on* Hist *restricts to pairs* $((s, N), (z, M))$ *such that* $\mathsf{CplxRegSeq}(s, N)$ *and* $\mathsf{CplxLim}(s, N, z, M)$*. The generator is the complex-limit predicate of Definition 65.21.*

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.ComplexLimitSourceSpec`
Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimitSourceSpec constant`

Definition 65.47 (Complex-limit pattern specification)**.** *The pattern of* $\mathsf{CplxLim}^\uparrow$ *is regular-sequence-bounded convergence: for an input regular complex sequence* (s, N)*, the pattern is the family of distances* $\mathsf{CplxDist}(s(n), z, D)$ *restricted to* n *above the modulus threshold* $M(k)$ *at each unary level* k*.*

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimitPatternSpec of limit`

Definition 65.48 (Complex-limit classifier specification)**.** *The classifier on complex-limit carriers is* hsame *componentwise: two complex-limit witnesses classify together iff their target points agree under* hsame *on both real and imaginary components.*

Definition 65.49 (Complex-limit stability certificate)**.** *The stability certificate consists of:*

1. *closure of* $\mathsf{CplxLim}$ *under* hsame *on each rational-history component of the limit point (Definition 65.22);*
2. *transport of regular-sequence status under pointwise* hsame *on each member of the sequence;*
3. *compatibility of the modulus function with* hsame *on its unary inputs and outputs.*

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit stability certificate fields`

Definition 65.50 (Complex-limit ledger policy)**.** *The checked ledger policy records:*

1. *composition of moduli under pointwise sum (Definition 65.38);*
2. *composition of moduli under pointwise product (Definition 65.42);*

3. componentwise limit assembly from supplied component witnesses (Definition 65.45).

The scalar multiplication law of Definition 65.39 is a paper-side proof obligation parameterized by supplied unary shift evidence, and is not part of the checked ledger policy until a matching Lean target is present.

Theorem 65.51 (Concrete $\mathsf{CplxLim}^{\uparrow}$ naming certificate)**.** *The data* (CplxLim, CplxRegSeq, hsame, CplxLimStabilityC *of Definition 65.46–Definition 65.50 forms a naming certificate over* Hist *for the complex-limit interface* $\mathsf{CplxLim}^{\uparrow}$*. The checked certificate is functional (Definition 65.24), closed under pointwise sum and product (Definition 65.38 and Definition 65.42), and supports componentwise limit assembly when component limit witnesses are part of the input (Definition 65.45). Scalar multiplication remains a paper-side obligation parameterized by the supplied unary shift witness of Definition 65.39.*

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.complex limit name certificate`

Sketch. The five fields satisfy the closure laws of the naming-certificate framework (chapter 9). Functionality is Definition 65.24. Checked additive closure is Definition 65.38; checked product closure is Definition 65.42. Componentwise limit assembly is Definition 65.45.

The scalar row is retained only as the paper-side obligation of Definition 65.39, whose statement explicitly requires a unary shift witness. It is not counted as checked certificate data by this Lean marker. The certificate uses no Classical.choice, no Quot.sound, and no propext, so its Lean targets fall under the project's axiom-purity gate. □

Theorem 65.52 (Semantic $\mathsf{CplxLim}^{\uparrow}$ naming certificate)**.** *The concrete certificate of Definition 65.51 satisfies the semantic naming-certificate schema of* NameCert *(chapter 9): the carrier is a* Hist*-predicate, the classifier is a restriction of* hsame *to complex-history components, and every closure law is given by an explicit constructive proof with explicit modulus pasting.*

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit semanticNameCert`

Sketch. Direct verification of the four NameCert field types using the constructions of this chapter. The certificate uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.complex limit semantic name certificate`

Theorem 65.53 (Constant complex sequence has constant complex limit)**.** *Let z be a complex history. Define the constant sequence $s : \mathsf{Unary} \to \mathsf{Complex}^{\uparrow}$ by $s(n) := z$, and define the two trivial moduli by*

$$N_{\mathrm{const}}(k) := \mathsf{e}, \qquad M_{\mathrm{const}}(k) := \mathsf{e}.$$

If $\mathsf{CplxRegSeq}(s, N_{\mathrm{const}})$ *holds by Definition 65.20, then*

$$\mathsf{CplxLim}(s, N_{\mathrm{const}}, z, M_{\mathrm{const}})$$

holds.

Proof. Fix a unary precision k and a unary index n satisfying the threshold clause in Definition 65.21 for $M_{\mathrm{const}}(k)$. Since $M_{\mathrm{const}}(k) = N_{\mathrm{const}}(k) = \mathsf{e}$, the same threshold clause makes n acceptable for the regularity condition of Definition 65.18. Take the second regularity index to be $m := \mathsf{e}$; it is acceptable because $\mathsf{hsame}(\mathsf{e}, N_{\mathrm{const}}(k))$ is reflexivity.

Apply $\mathsf{CplxRegSeq}(s, N_{\text{const}})$ at the indices n and m. This gives a distance witness D such that $\mathsf{CplxDist}(s(n), s(m), D)$ satisfies the unary representation of $D \leq 2^{-k}$. By the definition of the constant sequence, $s(m) = s(\mathsf{e}) = z$. Therefore the same witness D is exactly the distance estimate from $s(n)$ to z required in Definition 65.21. Since k and n were arbitrary, M_{const} is a valid complex-limit modulus for the constant sequence. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit constant of regular`

Theorem 65.54 (Eventually constant complex sequence has constant limit)**.** *Let* $s : \mathsf{Unary} \to \mathsf{Complex}^{\uparrow}$ *be a complex sequence, let* $N, M : \mathsf{Unary} \to \mathsf{Unary}$ *be unary moduli, and let* z *be a complex history. Suppose* $\mathsf{CplxRegSeq}(s, N)$ *and suppose that* s *is pointwise history-same to* z *above* M*:*

$$\forall k, n : \mathsf{Unary},\ \big(\mathsf{NatUnaryStrictPrefix}(M(k), n) \vee \mathsf{hsame}(n, M(k))\big) \Longrightarrow \mathsf{hsame}(s(n), z).$$

Then

$$\mathsf{CplxLim}(s, N, z, M).$$

Proof. Fix a unary precision k and a unary index n satisfying the threshold clause in Definition 65.21 for $M(k)$. Put $c(u) := z$ for the constant sequence. The empty threshold used in Definition 65.53 accepts every unary index: if $n\mathsf{hsamee}$ this is the non-strict branch, and otherwise the tail n with the left-unit continuation $\mathsf{Cont}(\mathsf{e}, n, n)$ gives $\mathsf{NatUnaryStrictPrefix}(\mathsf{e}, n)$ by Definition 28.10. Hence the constant-limit theorem supplies a distance witness D from $c(n) = z$ to z satisfying the unary estimate $D \leq 2^{-k}$.

The above-M hypothesis gives $\mathsf{hsame}(s(n), z)$, hence $\mathsf{hsame}(s(n), c(n))$. Apply Definition 65.6 to the distance witness for $c(n)$ and z, using reflexivity of hsame on the limit endpoint and on D. The transported witness has endpoints $s(n)$ and z, and the same distance history D, so the estimate $D \leq 2^{-k}$ is unchanged.

Since k and n were arbitrary among the accepted indices, these witnesses are exactly the convergence pattern required by Definition 65.21. The hypothesis $\mathsf{CplxRegSeq}(s, N)$ supplies the regular-sequence side of the predicate, so $\mathsf{CplxLim}(s, N, z, M)$ holds. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit eventually constant closed`

Definition 65.55 (Pointwise difference of complex sequences)**.** *For complex sequences* $s, t : \mathsf{Unary} \to \mathsf{Complex}^{\uparrow}$*, the pointwise difference* $s \ominus t$ *is the sequence*

$$(s \ominus t)(n) := s(n) - t(n),$$

where subtraction is the componentwise rational-history subtraction continuation on the two rational components of the complex carrier.

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.ComplexPointwiseDifference`

Lemma 65.56 (Difference of regular complex sequences is regular with explicit modulus pasting)**.** *If* $\mathsf{CplxRegSeq}(s, N_s)$ *and* $\mathsf{CplxRegSeq}(t, N_t)$ *hold, then* $\mathsf{CplxRegSeq}(s \ominus t, N_{\ominus})$ *holds for the explicit pasted modulus*

$$N_{\ominus}(k) := \max(N_s(k+1), N_t(k+1)).$$

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexRegularSequence pointwise difference closed`

Proof. Fix a unary precision k and accepted unary indices n, m above $N_\ominus(k)$. The maximum clause makes the same indices accepted above $N_s(k+1)$ and above $N_t(k+1)$. The two regularity hypotheses therefore give distance witnesses D_s and D_t for $s(n)$ to $s(m)$ and for $t(n)$ to $t(m)$, each bounded by the unary dyadic budget $2^{-(k+1)}$.

By the componentwise subtraction continuation,

$$(s(n) - t(n)) - (s(m) - t(m)) = (s(n) - s(m)) - (t(n) - t(m))$$

component by component. The distance predicate of Definition 65.3 reads this as the modulus of a componentwise difference. Applying the symmetry of complex distance from Definition 65.4 to the t-term if needed, and then applying the triangle inequality of Definition 65.17, gives a distance witness for $(s \ominus t)(n)$ to $(s \ominus t)(m)$ bounded by $D_s + D_t$. Since both summands are bounded by $2^{-(k+1)}$, unary dyadic addition gives $D_s + D_t \le 2^{-k}$. This is exactly the regularity clause of Definition 65.18 for $s \ominus t$ with modulus $N_\ominus$. □

Theorem 65.57 (Limit respects pointwise difference)**.** *If* $\mathsf{CplxLim}(s, N_s, z_s, M_s)$ *and* $\mathsf{CplxLim}(t, N_t, z_t, M_t)$ *hold, then*

$$\mathsf{CplxLim}(s \ominus t, N_\ominus, z_s - z_t, M_\ominus)$$

holds with explicit pasted moduli

$$N_\ominus(k) := \max(N_s(k+1), N_t(k+1)), \qquad M_\ominus(k) := \max(M_s(k+1), M_t(k+1)).$$

Proof. The regular-sequence part is Definition 65.56, applied to the regularity fields contained in the two limit hypotheses of Definition 65.21.

It remains to verify the limit estimate. Fix a unary precision k and a unary index n accepted above $M_\ominus(k)$. By the maximum clause, n is accepted above both $M_s(k+1)$ and $M_t(k+1)$. The two limit hypotheses provide distance witnesses E_s and E_t from $s(n)$ to z_s and from $t(n)$ to z_t, each bounded by $2^{-(k+1)}$.

The componentwise subtraction ledgers give the identity

$$(s \ominus t)(n) - (z_s - z_t) = (s(n) - z_s) - (t(n) - z_t).$$

Using Definition 65.3, the desired distance is the complex modulus of the right-hand side. Symmetry of complex distance from Definition 65.4 handles the signed second summand, and the triangle inequality of Definition 65.17 bounds the displayed distance by $E_s + E_t$. The dyadic half-budget calculation gives $E_s + E_t \le 2^{-k}$. Since k and n were arbitrary among the accepted indices, $M_\ominus$ satisfies the convergence clause of Definition 65.21 for the pointwise difference sequence and limit point $z_s - z_t$. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit pointwise difference`
Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit pointwise difference closed`

Definition 65.58 (Pointwise additive inverse of complex sequences)**.** *For a complex sequence* $s : \mathsf{Unary} \to \mathsf{Complex}^\uparrow$*, the pointwise additive inverse* $-s$ *is the sequence*

$$(-s)(n) := -(s(n)),$$

where the endpoint inverse is formed componentwise on the real and imaginary rational-history components of the complex carrier from Definition 39.2.

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.ComplexPointwiseNegation`

Lemma 65.59 (Complex distance is invariant under simultaneous negation)**.** *For complex histories a, b and a distance history D,*

$$\mathsf{CplxDist}(a, b, D) \Longrightarrow \mathsf{CplxDist}(-a, -b, D).$$

Proof. By Definition 65.3, the hypothesis is a complex-modulus witness for the componentwise difference $a - b$. The componentwise additive-inverse ledger gives

$$(-a) - (-b) = -(a - b)$$

on both rational-history components. In Definition 65.2, replacing both components of a difference by their additive inverses does not change the displayed square terms, since rational-history squaring is invariant under additive inverse. The same modulus witness D therefore certifies the distance from $-a$ to $-b$. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexDistance simultaneous negation`

Theorem 65.60 (Complex limit respects pointwise negation)**.** *If $\mathsf{CplxLim}(s, N, z, M)$ holds, then the pointwise additive-inverse sequence has complex limit $-z$ with the same regularity modulus and the same limit modulus:*

$$\mathsf{CplxLim}(-s, N, -z, M).$$

Proof. Unpack the limit hypothesis using Definition 65.21. Its regularity field is a witness for $\mathsf{CplxRegSeq}(s, N)$, its target field carries the complex history z, and its modulus field gives the distance estimates from $s(n)$ to z above M.

First verify regularity for $-s$ with the unchanged modulus N. For a unary precision k and accepted unary indices n, m in the sense of Definition 65.18, regularity of s gives a distance witness D from $s(n)$ to $s(m)$ with the required dyadic bound. Applying Definition 65.59 gives a distance witness with the same D from $(-s)(n)$ to $(-s)(m)$; the numerical bound is unchanged because the distance history has not changed. Thus $\mathsf{CplxRegSeq}(-s, N)$ holds.

The target carrier for $-z$ is supplied by the componentwise additive-inverse closure of the $\mathsf{Complex}^{\uparrow}$ carrier from Definition 39.2. Now fix a unary precision k and an accepted unary index n above $M(k)$ as in Definition 65.21. The original limit witness supplies a distance history E from $s(n)$ to z satisfying the 2^{-k} bound. Applying Definition 65.59 gives the same distance history E from $(-s)(n)$ to $-z$, and the same dyadic estimate remains valid. Since k and n were arbitrary among the accepted indices, M is a limit modulus for $-s$ at $-z$. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit pointwise negation closed`
Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit pointwise negation`

Definition 65.61 (Pointwise binary affine combination of complex sequences)**.** *For fixed complex histories a, b and complex sequences $s, t : \mathsf{Unary} \to \mathsf{Complex}^{\uparrow}$, the pointwise binary affine combination $a \cdot s + b \cdot t$ is the unary-indexed sequence $(a \cdot s + b \cdot t)(n) := (a \cdot s(n)) \oplus (b \cdot t(n))$. Here the scalar products are the componentwise complex products used in Definition 65.39, and $\oplus$ is the pointwise sum of Definition 65.36.*

Lean4 (definition) `BEDC.Derived.ComplexLimitUp.ComplexPointwiseBinaryAffineCombination`

Theorem 65.62 (Complex limit respects binary affine combinations)**.** *Let a, b be fixed complex histories with unary modulus bounds A, B, so $\mathsf{CplxMod}(a, A)$ and $\mathsf{CplxMod}(b, B)$. Let $\sigma_{ab} := \log_2(A + B + 1)$ be the standard unary scalar shift for the combined bound $A + B$. Suppose*

$\mathsf{CplxLim}(s, N_s, z_s, M_s)$ *and* $\mathsf{CplxLim}(t, N_t, z_t, M_t)$ *hold. Define pasted shifted moduli by* $N_{ab}(k) := \max\big(N_s(k+1+\sigma_{ab}), N_t(k+1+\sigma_{ab})\big)$ *and* $M_{ab}(k) := \max\big(M_s(k+1+\sigma_{ab}), M_t(k+1+\sigma_{ab})\big)$*. Then the binary affine combination has the displayed complex limit:*

$$\mathsf{CplxLim}(a \cdot s + b \cdot t, N_{ab}, a \cdot z_s + b \cdot z_t, M_{ab}).$$

Proof. The proof packages the scalar estimate of Definition 65.39 with the sum-pasting mechanism of Definition 65.38. Unpack the two limit hypotheses by Definition 65.21. Their regularity fields give $\mathsf{CplxRegSeq}(s, N_s)$ and $\mathsf{CplxRegSeq}(t, N_t)$, and their convergence fields give the distance estimates from $s(n)$ to z_s and from $t(n)$ to z_t above the displayed moduli. The target point $a \cdot z_s + b \cdot z_t$ is a complex history by the componentwise complex carrier of Definition 39.2, the scalar-product carrier used in Definition 65.39, and the sum carrier used in Definition 65.36. First verify regularity. Fix a unary precision k and unary indices n, m accepted above $N_{ab}(k)$ in the sense of Definition 65.18. The maximum clause makes both indices accepted above $N_s(k+1+\sigma_{ab})$ and above $N_t(k+1+\sigma_{ab})$. Regularity of s and t supplies distance histories D_s, D_t with $D_s \le 2^{-(k+1+\sigma_{ab})}$ and $D_t \le 2^{-(k+1+\sigma_{ab})}$. The scalar estimate underlying Definition 65.39 and the bounds $\mathsf{CplxMod}(a, A)$, $\mathsf{CplxMod}(b, B)$ give distance bounds AD_s for $a \cdot s(n)$ to $a \cdot s(m)$ and BD_t for $b \cdot t(n)$ to $b \cdot t(m)$. Applying the triangle inequality of Definition 65.17 after the pointwise sum construction of Definition 65.36 bounds the affine-distance witness by $AD_s + BD_t$. The defining dyadic property of σ_{ab} gives $AD_s + BD_t \le (A+B)2^{-(k+1+\sigma_{ab})} \le 2^{-k}$, so $\mathsf{CplxRegSeq}(a \cdot s + b \cdot t, N_{ab})$ holds. It remains to verify the convergence modulus. Fix a unary precision k and a unary index n accepted above $M_{ab}(k)$ as in Definition 65.21. The maximum clause makes n accepted above both $M_s(k+1+\sigma_{ab})$ and $M_t(k+1+\sigma_{ab})$. The two limit hypotheses give distance histories E_s, E_t with $E_s \le 2^{-(k+1+\sigma_{ab})}$ and $E_t \le 2^{-(k+1+\sigma_{ab})}$. Componentwise bilinearity gives $(a \cdot s + b \cdot t)(n) - (a \cdot z_s + b \cdot z_t) = a \cdot (s(n) - z_s) + b \cdot (t(n) - z_t)$. Using Definition 65.3, the same scalar estimates bound the two displayed summands by AE_s and BE_t, and Definition 65.17 bounds their sum by $AE_s + BE_t$. The same dyadic calculation gives $AE_s + BE_t \le 2^{-k}$. Since k and n were arbitrary among the accepted indices, M_{ab} satisfies the convergence clause for $a \cdot s + b \cdot t$ at $a \cdot z_s + b \cdot z_t$. Together with the regularity proved above, this is exactly the asserted $\mathsf{CplxLim}$ statement. □

Lean4 ✓ `BEDC.Derived.ComplexLimitUp.ComplexLimit binary affine combination closed`

Closure status for $\mathsf{NameCert}_{\mathsf{CplxLim}^\uparrow}$**.**

Constructive story: A complex limit is carried by a displayed package whose source history contains a regular complex sequence with a unary modulus and a proposed complex target with its own convergence witness; histories lacking the regular-sequence row, the target row, or the modulus comparison are simply outside the carrier. The classifier does not identify limits by an external topology, but compares the carried target point componentwise by hsame on the real and imaginary histories, while the source specification covers exactly the regular-sequence-and-limit pairs and the pattern records the distance rows $\mathsf{CplxDist}(s(n), z, D)$ once the unary index has passed the displayed threshold $M(k)$. The ledger keeps the raw sequence, target, and modulus data visible, and its checked rows paste moduli for constant sequences, pointwise sums, pointwise products, and componentwise assembly rather than hiding convergence behind choice. The five name-certificate obligations follow from the constant-sequence witness for nonemptiness, the componentwise hsame equivalence laws, and the stability rows saying that regularity, limit status, and modulus comparisons transport along the same component histories. A source history h lies in the signature gap of a $\mathsf{CplxLim}^\uparrow$ token p when the source-domain accepts the regular sequence and limit package, the signature relation pairs that package with an answer target and evidence ledger, and the token-introduction relation names that answer as p; unfolded, the target components must be the ones encoded by p and the ledger must display the modulus that proves the sequence is eventually within each requested distance. The chapter registers this regular-sequence convergence construction under the name $\mathsf{CplxLim}^\uparrow$; it introduces no completeness principle, no choice-based extraction of a limit point, and no standard complex-analysis bridge.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CplxLim}^\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: The bridged paper scope is the semantic name certificate surface, constant-sequence row, pointwise closure rows, explicit modulus rows, and the paper bridge from those rows to the standard complex-limit schema.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CplxLim}^\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.ComplexLimitUp.ComplexLimit\_semanticNameCert`

Bridge status: bridgeChecked

Not claimed: The chapter does not close completeness of complex Cauchy sequences, standard complex-analysis bridge theorems, or choice-based extraction of limit points.

Upgrade path: no further upgrade – chapter at top of formal axis.

Theorem 65.63 (Complex-limit seed closure register)**.** *The seed surface already present in the* $\mathsf{CplxLim}^\uparrow$ *carrier consists of the* $\mathsf{Complex}^\uparrow$ *coordinate rows, the* $\mathsf{Real}^\uparrow$ *coordinate seals, the unary modulus row, the complex-distance rows, and the local* $\mathsf{NameCert}_{\mathsf{CplxLim}^\uparrow}$ *source, pattern, classifier, stability, ledger, replay, provenance, and naming rows. A seed consumer may read those rows before it asks for closure under constant, difference, negation, or affine-combination operations, but it cannot replace them by host complex equality, quotient-limit data, selected representatives, or an ambient completeness theorem.*

Proof. Project the carrier through the sibling route of Definition 65.1. The source sequence first exposes $\mathsf{Complex}^\uparrow$ coordinates, and those coordinates are sealed componentwise by the $\mathsf{Real}^\uparrow$ rows before any limit-facing data is available.

The certificate file then supplies the local rows. The source and pattern specifications identify the unary modulus and complex-distance histories, while the classifier, stability certificate, ledger policy, replay, provenance, and local name are exactly the $\mathsf{NameCert}_{\mathsf{CplxLim}^\uparrow}$ seed rows.

All later closure files consume this seed surface. Constant, difference, negation, and affine-combination rows may extend the ledger, but they do not create a new seed source or import host complex equality, quotient limits, representatives, or completeness. □

The $\mathsf{CplxLim}^\uparrow$ coordinatewise limit surface reads its real-coordinate and regular-rational evidence through chapter 38 and chapter 301 before any complex limit consumer receives a seal. This dependency keeps complex convergence on the displayed $\mathsf{Real}^\uparrow$ and $\mathsf{RegSeqRat}^\uparrow$ route rather than on host complex completeness, quotient stream equality, or selected limit data. Before any $\mathsf{CplxLim}^\uparrow$ seal is read, the packet consumes the real-coordinate sibling of chapter 38 and the regular-rational sibling of chapter 301. This route keeps complex-limit convergence tied to displayed $\mathsf{Real}^\uparrow$ and $\mathsf{RegSeqRat}^\uparrow$ carrier rows rather than to host complex completeness, quotient stream equality, or selected coordinate limits.

Chapter 66

A Concrete Naming Certificate for $\mathsf{ConvRad}^{\uparrow}$

This chapter gives a concrete naming-certificate construction for the convergence radius of a complex power series $\sum a_n z^n$ at the paper-proof level. The certificate sits above $\mathsf{CplxLim}^{\uparrow}$ (chapter 65) and the formal power series chapter (chapter 51), and gives an explicit unary-history witness for the radius rather than a real-number supremum. Absolute convergence inside displayed strict subradii is proved by geometric majorant; Cauchy–Hadamard limsup exactness is recorded only as a separate analytic ledger row outside the checked-row reduct. The construction is fully constructive and uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate.

66.1 Power series carrier and partial sums

Definition 66.1 (Power series carrier)**.** *A complex power series carrier is a unary-indexed family* $a : \mathsf{Unary} \to \mathsf{Complex}^{\uparrow}$*-history of complex coefficient histories together with a complex history* z_0 *marking the origin of the expansion.*

Lean4 (definition) `BEDC.Derived.ConvergenceRadiusUp.PowerSeriesCarrier`

Lemma 66.2 (Power series origin and coefficient transport)**.** *If the origin history is transported along* hsame *and every displayed coefficient is classified by the complex-history classifier, then the target origin is unary and the transported coefficient family is again a power series carrier at that target origin.*

Proof. The origin carrier is transported by unary transport. For each coefficient, the target-carrier component of the complex-history classifier supplies the complex coefficient carrier, so the transported family satisfies the power series carrier predicate. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.PowerSeriesCarrier origin coefficient transport`

Lemma 66.3 (Power series carrier append-unary closure)**.** *If* (a, z_0) *is a power series carrier and* q *is unary, then appending* q *to the origin and to every coefficient gives another power series carrier:*

$$\mathsf{PowerSeriesCarrier}(\lambda n.\mathsf{append}(a_n, q), \mathsf{append}(z_0, q)).$$

Proof. Unpack the power-series carrier into the unary origin, coefficient-wise complex-history carrier, and complex-history origin carrier. Unary histories are closed under append, and complex-history carriers are closed under append of a unary suffix; apply the latter pointwise to every coefficient and once to the origin. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.PowerSeriesCarrier append unary closed`

Lemma 66.4 (Power series carrier prepend-unary closure)**.** *If (a, z_0) is a power series carrier and q is unary, then prepending q to the origin and to every coefficient gives another power series carrier:*

$$\mathsf{PowerSeriesCarrier}(\lambda n.\mathsf{append}(q, a_n), \mathsf{append}(q, z_0)).$$

Proof. Unpack the power-series carrier into the unary origin, coefficient-wise complex-history carrier, and complex-history origin carrier. Unary histories are closed under append, and complex-history carriers are closed under prepend by a unary history; apply the latter pointwise to every coefficient and once to the origin. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.PowerSeriesCarrier prepend unary closed`

Definition 66.5 (Partial sum at a point)**.** *For a power series (a, z_0) and a complex history z, the partial sum predicate $\mathsf{PartSum}(a, z_0, z, n, S_n)$ is the unary-indexed family of complex histories obtained by summing the first n terms $a_k(z - z_0)^k$ via explicit unary recursion, using the complex multiplication and addition of chapter 39.*

Lean4 (definition) `BEDC.Derived.ConvergenceRadiusUp.PowerSeriesPartSum`

Lemma 66.6 (Partial sums are complex histories)**.** *For every power series (a, z_0), every complex history z, and every unary n, there is a unique complex history S_n with $\mathsf{PartSum}(a, z_0, z, n, S_n)$, up to hsame on both real components.*

Proof. By unary induction on n, using totality and functionality of complex multiplication and addition. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.PowerSeriesCarrier constant coeff partSum exists unique`

66.2 Geometric bound predicate

Definition 66.7 (Geometric bound)**.** *For coefficients a, unary radius history r, and unary constant K, the geometric bound $\mathsf{GeomBound}(a, r, K)$ holds when for every unary n, the modulus comparison $|a_n| \cdot r^n \leq K$ is decidably true on the rational representation.*

Lean4 (definition) `BEDC.Derived.ConvergenceRadiusUp.GeomBound`

Lemma 66.8 (Geometric bound visible radius endpoint package)**.** *For coefficients a, constant history K, result history R, and tail history tail, if*

$$\mathsf{GeomBound}(a, \mathsf{E1}(tail), K) \qquad \textit{and} \qquad \mathsf{Cont}(\mathsf{E1}(tail), K, R),$$

then tail is unary and the continuation result is not internally empty:

$$\mathsf{UnaryHistory}(tail) \wedge \neg\mathsf{hsame}(R, \mathsf{e}).$$

Proof. The geometric-bound witness contains the unary carrier for the visible radius $\mathsf{E1}(tail)$, so unary inversion gives the payload carrier for *tail*. If the continuation result were empty, empty-result inversion would identify the visible radius endpoint $\mathsf{E1}(tail)$ with e, contradicting constructor separation. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound visible radius endpoint package`

Theorem 66.9 (Geometric bound visible constant endpoint package)**.** *For coefficients a, radius history r, result history R, and tail history tail, if*

$$\mathsf{GeomBound}(a, r, \mathsf{E1}(tail)) \qquad \textit{and} \qquad \mathsf{Cont}(r, \mathsf{E1}(tail), R),$$

then tail is unary and the continuation result is not internally empty:

$$\mathsf{UnaryHistory}(tail) \wedge \neg\mathsf{hsame}(R, \mathsf{e}).$$

Proof. The geometric-bound witness contains the unary carrier for the visible constant endpoint $\mathsf{E1}(tail)$, so unary inversion gives the payload carrier for *tail*. If the continuation result were empty, empty-result inversion would identify the visible constant endpoint $\mathsf{E1}(tail)$ with e, contradicting constructor separation. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound visible constant endpoint package`

Theorem 66.10 (Geometric bound radius semantic naming certificate)**.** *For fixed coefficients a and unary bound constant K, any witness of $\mathsf{GeomBound}(a, r, K)$ yields a semantic naming certificate whose carrier, pattern, and ledger are the same radius-indexed geometric-bound predicate and whose classifier is* hsame *on the displayed radius.*

Proof. The witnessed radius r inhabits the carrier. Reflexivity, symmetry, and transitivity are the finite-kernel hsame laws. Carrier transport moves only the unary radius component across the displayed hsame comparison and leaves the fixed coefficient and bound data unchanged. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound radius semanticNameCert`

Theorem 66.11 (Geometric bound semantic naming certificate)**.** *If $\mathsf{GeomBound}(a, r, K)$ holds, then the radius-indexed carrier $x \mapsto \mathsf{GeomBound}(a, x, K)$, with classifier* hsame*, forms a semantic naming certificate whose source, pattern, and ledger predicates are all this same concrete geometric-bound carrier.*

Proof. The displayed bound supplies the inhabited carrier witness. Reflexivity, symmetry, and transitivity are the kernel laws for hsame. Carrier transport along hsame transports only the unary radius field; the constant K and the coefficient carrier rows are preserved unchanged. Pattern and ledger soundness are direct because all three semantic predicates are the same geometric-bound carrier. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound semanticNameCert`

Lemma 66.12 (Geometric bound supplies the power series carrier)**.** *If $\mathsf{GeomBound}(a, r, K)$ holds and the expansion center z_0 is a complex history, then (a, z_0) is a power series carrier, and both r and K are unary histories.*

Proof. Unpack the geometric-bound predicate. Its fields give the unary radius, the unary constant, and the coefficient-wise complex carrier; combine the latter with the displayed carrier of z_0. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound powerSeriesCarrier`

Lemma 66.13 (Geometric bound radius and constant continuation closure)**.** *For coefficients a, radius histories r, R, constant histories K, K', and unary perturbations dr, dK, if*

$$\mathsf{GeomBound}(a, r, K), \qquad \mathsf{UnaryHistory}(dr), \qquad \mathsf{UnaryHistory}(dK),$$

and the continuation ledgers $\mathsf{Cont}(r, dr, R)$ and $\mathsf{Cont}(K, dK, K')$ hold, then the geometric bound persists at the transported radius and constant:

$$\mathsf{GeomBound}(a, R, K').$$

Proof. The geometric-bound witness contains unary carrier data for both r and K. Unary continuation closure transports those carriers along the two displayed continuation ledgers, while the coefficient carrier clause is unchanged. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound radius constant continuation closed`

Theorem 66.14 (Geometric bound radius and constant hsame transport)**.** *For coefficients a, radius histories r, r', and constant histories K, K', if*

$$r\mathsf{hsame}r', \qquad K\mathsf{hsame}K', \qquad \mathsf{GeomBound}(a, r, K),$$

then r' and K' are unary histories and

$$\mathsf{GeomBound}(a, r', K').$$

Proof. Unpack the geometric-bound witness into its unary radius field, unary constant field, and coefficient carrier family. Transport the two unary fields along the displayed hsame classifiers, and reuse the unchanged coefficient carrier family. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound radius constant hsame transport unary`

Theorem 66.15 (Geometric bound continuation visible radius endpoint package)**.** *For coefficients a, radius histories r, R, constant histories K, K', unary perturbations dr, dK, and visible tail $tail$, if*

$$\mathsf{GeomBound}(a, r, K), \qquad \mathsf{UnaryHistory}(dr), \qquad \mathsf{UnaryHistory}(dK),$$

and

$$\mathsf{Cont}(r, dr, \mathsf{E1}(tail)), \qquad \mathsf{Cont}(K, dK, K'), \qquad \mathsf{Cont}(\mathsf{E1}(tail), K', R),$$

then the visible tail is unary and the final endpoint is not internally empty:

$$\mathsf{UnaryHistory}(tail) \wedge \neg\mathsf{hsame}(R, \mathsf{e}).$$

Proof. First apply radius and constant continuation closure to transport the geometric bound from (r, K) to $(\mathsf{E1}(tail), K')$. The visible-radius endpoint package then gives unary readback for $tail$ and excludes an empty final endpoint. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound continuation visible radius endpoint package`

Lemma 66.16 (Geometric majorant inside the disk)**.** *If $\mathsf{GeomBound}(a, r, K)$ holds and z satisfies $|z - z_0| \le r' < r$ (decidable strict inequality on rational representations), then the partial sums of a at z form a regular complex Cauchy sequence with explicit modulus $N(k) = \lceil k/\log_2(r/r') \rceil$ computed as a unary function of the precision.*

Sketch. Each term is bounded above by $K(r'/r)^n$; apply the geometric series formula with the explicit ratio. □

66.3 Convergence radius predicate

Definition 66.17 (Convergence radius)**.** *For coefficients a, the convergence radius predicate* $\mathsf{ConvRad}(a, R)$ *holds when there is a constant-witness function $K : \mathsf{Unary} \to \mathsf{Unary}$ such that for every unary radius r with* $\mathsf{NatUnaryStrictPrefix}(r, R)$*,* $\mathsf{GeomBound}(a, r, K(r))$ *is satisfied.*

Lean4 (definition) `BEDC.Derived.ConvergenceRadiusUp.ConvRad`

Lemma 66.18 (Convergence radius supplies power series carriers along witnesses)**.** *If* $\mathsf{ConvRad}(a, R)$ *holds and z_0 is a complex history, then the constant-witness function K can be chosen so that every admitted radius row simultaneously gives* $\mathsf{PowerSeriesCarrier}(a, z_0)$ *and* $\mathsf{GeomBound}(a, r, K(r))$*.*

Proof. Open the witness function in the convergence-radius predicate. For each admitted radius row, apply Definition 66.12 to the resulting geometric bound and the carrier of z_0. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad powerSeriesCarrier witness`

Lemma 66.19 (Convergence radius append-unary power-series witness)**.** *If* $\mathsf{ConvRad}(a, R)$ *holds, z_0 is a complex history, and q is unary, then the convergence-radius witness function K can be chosen so that every admitted radius row simultaneously gives*

$$\mathsf{PowerSeriesCarrier}(\lambda n.\mathsf{append}(a_n, q), \mathsf{append}(z_0, q))$$

and

$$\mathsf{GeomBound}(\lambda n.\mathsf{append}(a_n, q), r, K(r)).$$

Proof. Choose the witness function supplied by Definition 66.18. For each admitted radius row, apply append-unary closure to the supplied power-series carrier and apply geometric-bound append-unary coefficient closure to the supplied geometric bound. The same K remains the witness function. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad powerSeriesCarrier append unary witness`

Lemma 66.20 (Convergence radius prepend-unary power-series witness)**.** *If* $\mathsf{ConvRad}(a, R)$ *holds, z_0 is a complex history, and q is unary, then the convergence-radius witness function K can be chosen so that every admitted radius row simultaneously gives*

$$\mathsf{PowerSeriesCarrier}(\lambda n.\mathsf{append}(q, a_n), \mathsf{append}(q, z_0))$$

and

$$\mathsf{GeomBound}(\lambda n.\mathsf{append}(q, a_n), r, K(r)).$$

Proof. Choose the witness function supplied by Definition 66.18. For each admitted radius row, apply prepend-unary closure to the supplied power-series carrier and apply geometric-bound prepend-unary coefficient closure to the supplied geometric bound. The same K remains the witness function. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad powerSeriesCarrier prepend unary witness`

Theorem 66.21 (Convergence radius visible radius witness endpoint package)**.** *If* $\mathsf{ConvRad}(a, R)$ *holds and* $\mathsf{E1}(tail)$ *is an admitted unary radius endpoint, then the convergence-radius witness function can be chosen so that any continuation*

$$\mathsf{Cont}(\mathsf{E1}(tail), K(\mathsf{E1}(tail)), R)$$

exposes the payload carrier and non-empty result boundary:

$$\mathsf{UnaryHistory}(tail) \wedge \neg\mathsf{hsame}(R, \mathsf{e}).$$

Proof. Open the witness function in $\mathsf{ConvRad}(a, R)$ and specialize it to the visible radius endpoint $\mathsf{E1}(tail)$. The resulting geometric-bound row, together with the displayed continuation, is exactly the visible-radius endpoint package for geometric bounds. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad visible radius witness endpoint package`

Theorem 66.22 (Convergence radius classifier-visible radius witness endpoint package)**.** *If* $\mathsf{hsame}(R, R')$*,* R' *is unary, the coefficient streams* a *and* b *are complex-history classified pointwise,* $\mathsf{ConvRad}(a, R)$ *holds, and* $\mathsf{E1}(tail)$ *is an admitted unary radius endpoint, then the transported convergence-radius witness function can be chosen so that every continuation*

$$\mathsf{Cont}(\mathsf{E1}(tail), K(\mathsf{E1}(tail)), R')$$

exposes

$$\mathsf{UnaryHistory}(tail) \wedge \neg\mathsf{hsame}(R', \mathsf{e}).$$

Proof. Transport the convergence radius along $\mathsf{hsame}(R, R')$ and the pointwise complex-history classifier for the coefficients. The visible-radius endpoint package then applies at the transported radius R'. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad classifier visible radius witness endpoint package`

Lemma 66.23 (Convergence radius transport)**.** *If* $\mathsf{hsame}(R, R')$*,* $\mathsf{ConvRad}(a, R)$*, and* R' *is unary, then the same geometric-bound witness function supplies* $\mathsf{ConvRad}(a, R')$*.*

Proof. Transport the radius endpoint along hsame. The unary carrier for the target radius is explicit, and the existing constant-witness function continues to provide the same geometric-bound data. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad radius transport`

Lemma 66.24 (Convergence radius coefficient classifier transport)**.** *If* $\mathsf{hsame}(R, R')$*,* R' *is unary, every coefficient* a_n *is classified with* b_n *by the complex-history classifier, and* $\mathsf{ConvRad}(a, R)$ *holds, then* R' *is unary and* $\mathsf{ConvRad}(b, R')$ *holds.*

Proof. First transport the radius endpoint from R to R', retaining the same constant-witness function for geometric bounds. For each supplied geometric bound, keep the radius and constant unary carriers, and use the target-carrier component of the complex-history classifier at every coefficient index to rebuild the coefficient side of the bound for b. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad radius coefficient classifier transport`

Theorem 66.25 (Convergence radius is unique)**.** *If* $\mathsf{ConvRad}(a, R)$ *and* $\mathsf{ConvRad}(a, R')$ *both hold, then* $\mathsf{hsame}(R, R')$ *on the rational representation.*

Sketch. Suppose $R \neq R'$. Pick a rational r strictly between them. $\mathsf{GeomBound}$ at r follows from one side and fails from the other, contradicting consistency of the witness. □

66.4 Opening Boundary

Theorem 66.26 (Convergence-radius opening boundary)**.** *The displayed witness* $\mathsf{ConvRad}(a, R)$ *supports absolute convergence for every strict subradius named by the geometric-bound ledger: whenever a unary radius* r *is displayed with* $r < R$ *and a finite witness* K *satisfies* $\mathsf{GeomBound}(a, r, K)$*, the power-series carrier admits the corresponding majorant read inside* r*. Cauchy–Hadamard limsup exactness is a separate analytic ledger row and is not exported by the checked-row reduct.*

Sketch. Unpack $\mathsf{ConvRad}(a, R)$ as the family of strict-subradius geometric bound witnesses. For a displayed $r < R$, the witness K gives the finite majorant row needed by Definition 66.16 and by the power-series carrier readback.

The checked-row reduct keeps these carrier, transport, and geometric-bound rows. It has no constructor for limsup exactness, so the Cauchy–Hadamard row can only be supplied through the separate analytic ledger policy. □

Theorem 66.27 (Absolute convergence inside the disk)**.** *If* $\mathsf{ConvRad}(a, R)$ *and* z *satisfies* $|z - z_0| < R$ *(strict inequality with explicit witness), then the power series* $\sum a_n(z - z_0)^n$ *converges absolutely with explicit modulus.*

Sketch. By Definition 66.16: pick a rational r with $|z - z_0| < r < R$; the series is bounded by a geometric majorant. □

66.5 Closure laws

Lemma 66.28 (Geometric bound classifier append-unary closure)**.** *If coefficient families* a *and* b *are pointwise classified as complex histories,* $\mathsf{GeomBound}(a, r, K)$ *holds, and* q *is unary, then appending* q *to every displayed* b_n *preserves the same geometric-bound radius and constant:*

$$\mathsf{GeomBound}(\lambda n.\mathsf{append}(b_n, q), r, K).$$

Proof. Each classifier row exposes the target coefficient b_n as a complex-history carrier. Complex-history carriers are closed under append of a unary suffix, so each appended coefficient remains in the carrier. The radius and constant unary witnesses are the ones already carried by $\mathsf{GeomBound}(a, r, K)$. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound coeff classifier append unary closed`

Lemma 66.29 (Geometric bound append-unary coefficient closure)**.** *If* $\mathsf{GeomBound}(a, r, K)$ *holds and* q *is unary, then appending* q *to every coefficient preserves the same radius and constant:*

$$\mathsf{GeomBound}(\lambda n.\mathsf{append}(a_n, q), r, K).$$

Proof. Unpack $\mathsf{GeomBound}(a, r, K)$ into its unary radius witness, unary constant witness, and coefficient carrier family. Apply complex-history carrier append-unary closure pointwise to each coefficient and keep the same radius and constant witnesses. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound append unary coeff closed`

Lemma 66.30 (Geometric bound prepend-unary coefficient closure)**.** *If* q *is unary and* $\mathsf{GeomBound}(a, r, K)$ *holds, then prepending* q *to every coefficient preserves the same radius and constant:*

$$\mathsf{GeomBound}(\lambda n.\mathsf{append}(q, a_n), r, K).$$

Proof. Unpack $\mathsf{GeomBound}(a, r, K)$ into its unary radius witness, unary constant witness, and coefficient carrier family. Apply complex-history carrier prepend-unary closure pointwise to each coefficient and keep the same radius and constant witnesses. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound prepend unary coeff closed`

Theorem 66.31 (Convergence radius append-unary coefficient closure)**.** *If* $\mathsf{ConvRad}(a, R)$ *holds and* q *is unary, then appending* q *to every coefficient preserves the same convergence radius:*

$$\mathsf{ConvRad}(\lambda n.\mathsf{append}(a_n, q), R).$$

Proof. Unfold $\mathsf{ConvRad}(a, R)$ and keep its constant-witness function K as the candidate witness for the appended coefficient family.

Take an arbitrary admitted radius row, together with its continuation ledger $\mathsf{Cont}(r, K(r), R)$. The original convergence-radius witness gives $\mathsf{GeomBound}(a, r, K(r))$ for that row. Apply Definition 66.29 to this geometric bound and the unary suffix q, yielding $\mathsf{GeomBound}(\lambda n.\mathsf{append}(a_n, q), r, K(r))$. Since the row was arbitrary and the witness function is unchanged, the displayed predicate is $\mathsf{ConvRad}(\lambda n.\mathsf{append}(a_n, q), R)$. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad append unary coeff closed`

Theorem 66.32 (Convergence radius prepend-unary coefficient closure)**.** *If* $\mathsf{ConvRad}(a, R)$ *holds and* q *is unary, then prepending* q *to every coefficient preserves the same convergence radius:*

$$\mathsf{ConvRad}(\lambda n.\mathsf{append}(q, a_n), R).$$

Proof. Unfold $\mathsf{ConvRad}(a, R)$ and keep its constant-witness function K as the candidate witness for the prepended coefficient family. For any admitted row r with continuation ledger $\mathsf{Cont}(r, K(r), R)$, the original witness gives $\mathsf{GeomBound}(a, r, K(r))$. Apply Definition 66.30 with the unary prefix q, and leave the radius witness, the continuation row, and the constant witness unchanged. □

Definition 66.38 (Convergence radius stability certificate)**.** *The stability certificate consists of* hsame*-respect of* ConvRad *on coefficient input, transport of constant-witness functions, and compatibility with the geometric-bound predicate under* hsame *on radii.*

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad stability certificate fields`

Definition 66.39 (Convergence radius ledger policy)**.** *The ledger policy records the analytic obligations for term-by-term differentiation, Cauchy product, absolute convergence inside the open disk, and the Cauchy-Hadamard limsup characterization.*

Lean4 (definition) `BEDC.Derived.ConvergenceRadiusUp.ConvRadLedgerPolicy`

Theorem 66.40 (Concrete ConvRad$^{\uparrow}$ certificate-obligation package)**.** *The convergence-radius construction supplies a concrete certificate-obligation package over* Hist *for* ConvRad$^{\uparrow}$*. Its checked rows are the* ConvRad *carrier,* hsame *classifier, radius transport, coefficient classifier transport, extraction of power-series carrier data from geometric bounds, the convergence-radius power-series carrier witness, and append-unary coefficient closure. The analytic ledger laws of Definition 66.39 remain policy obligations for this interface.*

Sketch. The carrier and classifier are the displayed ConvRad predicate and hsame on radius histories.

The checked transport rows are Definition 66.23 and Definition 66.24. The carrier witness rows are Definition 66.12 and Definition 66.18. The checked closure row is Definition 66.31.

These rows give the concrete proof obligations available to the semantic certificate target. The differentiation, Cauchy-product, absolute-convergence, and Cauchy-Hadamard rows are ledger-policy obligations in this chapter, not premises of the checked semantic NameCert target. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.conv rad name certificate`

Theorem 66.41 (Semantic ConvRad$^{\uparrow}$ naming certificate)**.** *The concrete package of Definition 66.40 supplies the checked semantic naming-certificate schema of* NameCert *(chapter 9) exactly for the* ConvRad *carrier, the* hsame *radius classifier, radius transport, coefficient classifier transport, the power-series carrier witness, and append-unary coefficient closure.*

Sketch. The witnessed radius inhabits the ConvRad carrier. The equivalence fields are the finite-kernel hsame laws.

Carrier transport is the radius-transport row, with unary transport of the displayed radius. Coefficient-family transport uses the checked classifier transport row, while the carrier witness and append-unary closure are supplied by their corresponding checked rows in this chapter. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad semanticNameCert`

Theorem 66.42 (Geometric bound is downward closed in the radius)**.** *For coefficients a, radius histories r' and r, and constant history K, if*

$$\mathsf{NatUnaryStrictPrefix}(r', r) \qquad \textit{and} \qquad \mathsf{GeomBound}(a, r, K),$$

then

$$\mathsf{GeomBound}(a, r', K).$$

Proof. By Definition 28.10, choose a unary tail t such that t is not e and $\mathsf{Cont}(r', t, r)$ holds. By Definition 66.7, the bound at r supplies the unary carrier for r, the unary carrier for K, the coefficient carrier rows, and the decidable comparison rows $|a_n| \cdot r^n \leq K$ for every unary index n. The strict-prefix witness is in particular a prefix witness from r' to r; applying Definition 52.22 to that witness and to the unary carrier of r gives the unary carrier of r'.

It remains to transport the comparison rows. In the rational representation of unary histories, the continuation ledger $\mathsf{Cont}(r', t, r)$ reads $r = r' + t$ with $t \geq 0$, hence $0 \leq r' \leq r$. Fix a unary index n. Unary induction on n gives $(r')^n \leq r^n$: the empty exponent gives equality of units, and the one-extension step multiplies the induction comparison by the nonnegative factor r' and then uses $r' \leq r$ with the nonnegative factor r^n. Since complex moduli are nonnegative, rational-history multiplication gives

$$|a_n| \cdot (r')^n \leq |a_n| \cdot r^n.$$

Composing this inequality with the comparison row supplied by $\mathsf{GeomBound}(a, r, K)$ yields $|a_n| \cdot (r')^n \leq K$. The constant carrier and coefficient carrier rows are unchanged, so Definition 66.7 repacks these data as $\mathsf{GeomBound}(a, r', K)$. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.GeomBound radius shrink closed`

Definition 66.43 (Convergence-radius compatible coefficient-ring inclusion)**.** *Let R and R' be coefficient sources equipped with $\mathsf{CommRing}^{\uparrow}$ certificates as in Definition 44.59. Write their carriers and classifiers as $C_R, \sim_R$ and $C_{R'}, \sim_{R'}$, their operations as $0_R, 1_R, +_R, -_R, \cdot_R$ and $0_{R'}, 1_{R'}, +_{R'}, -_{R'}, \cdot_{R'}$, and let γ_R and $\gamma_{R'}$ be complex-realization maps into $\mathsf{Complex}^{\uparrow}$ histories. A convergence-radius compatible coefficient-ring inclusion*

$$\iota : R \hookrightarrow R'$$

consists of the following data:

1. *Carrier and classifier rows: $C_R(x)$ implies $C_{R'}(\iota x)$; $x \sim_R y$ implies $\iota x \sim_{R'} \iota y$; and, for carried x, y, $\iota x \sim_{R'} \iota y$ implies $x \sim_R y$.*
2. *Operation rows: for carried inputs, $\iota(0_R) \sim_{R'} 0_{R'}$, $\iota(1_R) \sim_{R'} 1_{R'}$, $\iota(x +_R y) \sim_{R'} \iota x +_{R'} \iota y$, $\iota(-_R x) \sim_{R'} -_{R'} \iota x$, and $\iota(x \cdot_R y) \sim_{R'} \iota x \cdot_{R'} \iota y$.*
3. *Complex-realization rows: $\gamma_R(x)$ and $\gamma_{R'}(\iota x)$ are complex histories, and every carried x satisfies*

$$\mathsf{ComplexHistoryClassifier}(\gamma_R(x), \gamma_{R'}(\iota x)).$$

Lean4 (definition) `BEDC.Derived.ConvergenceRadiusUp.ConvRadCoefficientRingInclusion`

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRadCoefficientRingInclusion pointwise classifier`

Theorem 66.44 (Convergence radius monotonicity under coefficient-ring inclusion)**.** *Let R and R' be* $\mathsf{CommRing}^{\uparrow}$ *coefficient sources and let $\iota : R \hookrightarrow R'$ be a convergence-radius compatible coefficient-ring inclusion from Definition 66.43. For a pointwise carried formal coefficient sequence $f : \mathsf{Nat}^{\uparrow} \to R$ as in Definition 51.1, put*

$$a_n := \gamma_R(f_n), \qquad a'_n := \gamma_{R'}(\iota(f_n)).$$

If ρ is a unary radius history and $\mathsf{ConvRad}(a, \rho)$ *holds, then*

$$\mathsf{ConvRad}(a', \rho).$$

Thus every convergence-radius witness admitted by the R-view is also admitted by the R'-view.

Proof. For each unary index n, pointwise carriedness gives $C_R(f_n)$. The complex-realization row in Definition 66.43 therefore supplies

$$\mathsf{ComplexHistoryClassifier}(a_n, a'_n).$$

The operation rows in the inclusion identify a' as the coefficient sequence obtained by reading the same formal series in the larger coefficient source; these are the finite algebraic rows used by the partial-sum recursion of Definition 66.5. The convergence-radius argument only needs the resulting pointwise complex classifier family.

The radius endpoint is unchanged. Hence the radius-classifier input for Definition 66.24 is the reflexive history-sameness witness $\mathsf{hsame}(\rho, \rho)$, and the target-radius carrier input is the displayed unary witness for ρ. Applying that lemma to the coefficient families a and a' gives $\mathsf{ConvRad}(a', \rho)$.

Equivalently, unpacking Definition 66.17, the same constant-witness function K can be retained. For every strict subradius r of ρ, the source row gives $\mathsf{GeomBound}(a, r, K(r))$; the coefficient-classifier transport in Definition 66.24 sends this geometric-bound row to $\mathsf{GeomBound}(a', r, K(r))$, while the radius and constant histories are unchanged as in Definition 66.7. These rows reassemble the convergence-radius predicate for a' at ρ. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad coefficient ring inclusion monotone`

66.7 Cauchy–Hadamard Boundary

Definition 66.45 (Cauchy–Hadamard exactness row)**.** *For a coefficient family a and a unary radius history R, let* $\mathsf{CHExact}(a, R)$ *denote the analytic ledger row asserting that the* $\mathsf{ConvRad}(a, R)$ *endpoint is exact for the Cauchy–Hadamard limsup expression,*

$$R = 1/\mathsf{LimSup}_n |a_n|^{1/n}.$$

This is the Cauchy–Hadamard item in Definition 66.39. It is a ledger-policy row, not one of the checked carrier, classifier, transport, or closure rows of Definition 66.40.

Lean4 (definition) `BEDC.Derived.ConvergenceRadiusUp.ConvRadCauchyHadamardExactnessRow`

Definition 66.46 (Convergence-radius checked-row reduct)**.** *The checked-row reduct of the* $\mathsf{ConvRad}^{\uparrow}$ *package is the finite row set $\mathcal{Q}_{\mathrm{chk}}$ consisting of the following data:*

1. *the carrier row* $\mathsf{ConvRad}(a, R)$ *and the* hsame *classifier on radius histories;*
2. *radius transport, as in Definition 66.23;*
3. *coefficient-family classifier transport, as in Definition 66.24;*
4. *extraction of power-series carrier data from geometric bounds and from convergence-radius witnesses, as in Definition 66.12 and Definition 66.18;*
5. *append-unary coefficient closure, as in Definition 66.31.*

A policy interpretation over this reduct is a row assignment Π *with witnesses for every row in* $\mathcal{Q}_{\mathrm{chk}}$*. The assignment is constrained only on* $\mathcal{Q}_{\mathrm{chk}}$*; analytic ledger rows such as* $\mathsf{CHExact}(a, R)$ *are not constrained unless the ledger policy of Definition 66.39 is also supplied.*

Lean4 (definition) `BEDC.Derived.ConvergenceRadiusUp.ConvRadCheckedRowReduct`

Theorem 66.47 (Checked convergence-radius rows do not force Cauchy–Hadamard)**.** *Fix a coefficient family* a *and a unary radius history* R *for which the checked-row reduct of Definition 66.46 has the displayed carrier row* $\mathsf{ConvRad}(a, R)$*. In the* $\mathsf{ConvRad}^{\uparrow}$ *setup reduced to that checked row set, there are two policy interpretations* Π_+ *and* Π_- *over the same history carrier and the same radius classifier such that*

$$\forall q \in \mathcal{Q}_{\mathrm{chk}}, \quad \Pi_+(q) = \Pi_-(q),$$

but

$$\Pi_+(\mathsf{CHExact}(a, R)) = \mathsf{accept} \qquad \textit{and} \qquad \Pi_-(\mathsf{CHExact}(a, R)) = \mathsf{reject}.$$

Consequently, no finite derivation whose nonlogical inputs are only the checked rows of Definition 66.46 can prove $\mathsf{CHExact}(a, R)$*.*

Proof. By Definition 9.6, the naming-certificate template separates source, pattern, classifier, stability, and ledger fields. The concrete convergence-radius package in Definition 66.40 lists the checked carrier, classifier, transport, witness, and append-unary closure rows, and states that the analytic laws of Definition 66.39 remain ledger-policy obligations.

Let $\chi_{a,R}$ be the row name represented by $\mathsf{CHExact}(a, R)$. Since $\chi_{a,R}$ is not an element of $\mathcal{Q}_{\mathrm{chk}}$, define Π_+ and Π_- to use the same witness for every checked row $q \in \mathcal{Q}_{\mathrm{chk}}$. On the Cauchy–Hadamard row, set $\Pi_+(\chi_{a,R}) = \mathsf{accept}$ and $\Pi_-(\chi_{a,R}) = \mathsf{reject}$; all other analytic row names may be assigned identically in the two interpretations.

Every premise and conclusion of a checked row is read from $\mathcal{Q}_{\mathrm{chk}}$, so the two interpretations validate exactly the same checked carrier, classifier, transport, witness, and closure data. They therefore share the full checked-row reduct. They disagree only on the analytic ledger row $\mathsf{CHExact}(a, R)$, which the reduct does not mention.

If the checked rows alone forced $\mathsf{CHExact}(a, R)$, any two interpretations that agree on all rows used by the derivation would agree on that conclusion. Applying this to Π_+ and Π_- gives the displayed contradiction. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad checked rows do not force cauchy hadamard`

Theorem 66.48 (Cauchy–Hadamard sibling route)**.** *Any consumer that upgrades the checked* $\mathsf{ConvRad}^{\uparrow}$ *reduct to a Cauchy–Hadamard exactness row must pass through the sibling NameCert surfaces for* $\mathsf{CauchyHadamard}^{\uparrow}$*,* $\mathsf{RealPowerSeries}^{\uparrow}$*, and* $\mathsf{WeierstrassMTest}^{\uparrow}$*, together with the local convergence-radius rows. The local rows of Definition 66.46 expose the radius carrier, classifier, transport, power-series extraction, and append-unary coefficient closure; the sibling surfaces supply*

the missing Cauchy–Hadamard ledger, power-series endpoint route, and majorant-tail route. The resulting route is a horizontal dependency through chapter 3466, chapter 1583, and chapter 399, not an import of host limsup, quotient real equality, or ambient analytic completeness.

Proof. Apply Definition 66.47. It exhibits two policy interpretations that agree on every row of $\mathcal{Q}_{\mathrm{chk}}$ and disagree on $\mathsf{CHExact}(a, R)$, so the checked convergence-radius rows alone cannot force Cauchy–Hadamard exactness.

The missing row is analytic ledger data. The $\mathsf{CauchyHadamard}^{\uparrow}$ sibling provides the named Cauchy–Hadamard surface, while the $\mathsf{RealPowerSeries}^{\uparrow}$ sibling keeps coefficient windows, partial sums, radius reads, and endpoint seals visible as finite packet rows.

Finally the $\mathsf{WeierstrassMTest}^{\uparrow}$ sibling supplies the majorant-tail route used by power-series consumers before a real endpoint seal is exported. Combining these sibling rows with the local convergence-radius reduct records the exact horizontal route, without replacing it by host limsup, quotient real equality, or an unrecorded completeness theorem. □

Theorem 66.49 (Convergence radius coefficient-ring inclusion geometric-bound transport)**.** *Let*

$$\iota : R \hookrightarrow R'$$

be a convergence-radius compatible coefficient-ring inclusion in the sense of Definition 66.43. For a source coefficient family a and its transported family a' defined pointwise by the complex realization rows of ι, if

$$\mathsf{GeomBound}(a, r, K),$$

then

$$\mathsf{GeomBound}(a', r, K).$$

The radius history r and constant history K are unchanged.

Proof. Unfold the geometric-bound rows of Definition 66.7. The source bound supplies the coefficient carrier rows, the radius carrier row, the constant carrier row, and the pointwise comparison ledger for every unary index.

Use Definition 66.43 on each coefficient row. Its complex-realization clause identifies a_n with a'_n through the transported complex-history classifier, and its pointwise classifier transport keeps the displayed coefficient read in the target source.

Therefore the comparison row for a_n at radius r and constant K reads as the corresponding comparison row for a'_n. The radius and constant histories are not transported, so their carrier rows and ledger entries are copied unchanged. Repacking these rows by Definition 66.7 gives $\mathsf{GeomBound}(a', r, K)$. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRadCoefficientRingInclusion geomBound transport`

Theorem 66.50 (ConvergenceRadius checked-row reduct readback)**.** *For any coefficient family a, center z_0, and unary radius R, a $\mathsf{ConvRadSourceSpec}(a, z_0, R)$ row determines the checked-row reduct of Definition 66.46. The reduct consists of the source row together with the geometric-bound readback rows supplied by the source specification, and it contains no Cauchy–Hadamard exactness row.*

Proof. Unfold the source specification of Definition 66.35. Its displayed data give the coefficient family, center, unary radius, and the geometric-bound readback rows associated to the same source packet.

Now apply Definition 66.46. The reduct keeps exactly the checked rows read from that packet: the source row and the geometric-bound rows already exposed by the source specification.

There is no constructor in the reduct for Cauchy–Hadamard exactness. Repacking the displayed source and geometric-bound rows therefore gives precisely the checked-row reduct claimed above. □

Theorem 66.51 (ConvergenceRadius finite-prefix window stability)**.** *Let* ConvRadSourceSpec(a, z_0, R) *be a displayed convergence-radius source packet. Restrict the packet to a certified finite unary prefix window of coefficient indices and consumer reads. Then the checked-row reduct visible to downstream consumers preserves the same radius witness, the geometric-bound rows on the displayed prefix, the endpoint packages,* BHist *histories,* hsame *transport rows,* Cont *routes, and* Pkg *provenance.*

The restricted reduct introduces no Cauchy–Hadamard exactness row, no real-supremum row, and no host complex-analysis boundary beyond the rows already visible in the finite prefix.

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRadCheckedRowReduct prefix window stability`

Proof. Unfold Definition 66.35 and Definition 66.46. The source packet already displays the coefficient family, center, unary radius witness, geometric-bound rows, endpoint packages, transport rows, continuation routes, and provenance.

Project the rows whose coefficient indices lie in the certified finite prefix. The radius witness and endpoint packages are shared coordinates of the source packet, while the geometric-bound rows are retained only where the prefix contains the corresponding unary index.

Transport the retained entries componentwise by hsame. Continuation determinacy for the displayed Cont routes keeps the read paths attached to the same packet, and the Pkg row records the unchanged provenance.

Finally use Definition 66.54 only to identify which retained rows are consumer-visible. That boundary has no constructor for Cauchy–Hadamard exactness or real supremum, so the finite prefix reduct exposes exactly the listed checked rows. □

Theorem 66.52 (ConvergenceRadius SOne ComplexLimit consumer boundary)**.** *For a* $\mathsf{ConvRad}^{\uparrow}$ *source packet restricted to a certified finite unary prefix window, any* $\mathsf{S}^{1\uparrow}$ *or* $\mathsf{CplxLim}^{\uparrow}$ *consumer reads only the checked-row reduct, the geometric-bound rows on the displayed prefix, the* $\mathsf{CplxLim}^{\uparrow}$ *modulus rows, the* $\mathsf{S}^{1\uparrow}$ *unit-equation consumer rows,* BHist *histories,* hsame *transports,* Cont *routes, and* Pkg *provenance.*

The consumer receives no Cauchy–Hadamard exactness row, no real supremum, no host complex-analysis boundary, and no choice-based radius extraction.

Proof. Begin with the checked-row reduct readback of Definition 66.50. It identifies the source row and geometric-bound readbacks as the rows retained from the convergence-radius source packet.

Restrict to the certified finite unary prefix and apply Definition 66.51. The restricted consumer surface keeps the same radius witness, retained geometric-bound rows, endpoint packages, BHist histories, hsame transports, Cont routes, and Pkg provenance, and it adds no Cauchy–Hadamard or real-supremum row.

Now read the two sibling consumers through their own finite boundaries. The $\mathsf{CplxLim}^{\uparrow}$ semantic certificate supplies only modulus rows on displayed complex histories, while the $\mathsf{S}^{1\uparrow}$ componentwise RealUp and metric boundary supplies only unit-equation consumer rows. Neither sibling boundary adds a host complex-analysis theorem or a radius extractor, so the combined consumer reads exactly the listed finite-prefix rows. □

Theorem 66.53 (ConvergenceRadius public export)**.** *Definition 66.41 exports the public* $\mathsf{ConvRad}^{\uparrow}$ *boundary over the power-series carrier, geometric-bound rows, convergence-radius witness, radius classifier transport, endpoint packages, and checked semantic certificate rows. Consumers may cite this public boundary without treating Cauchy–Hadamard exactness or standard complex-analysis bridge rows as checked consequences.*

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRadCheckedRowReduct public export`
↪ variant `BEDC.Derived.ConvergenceRadiusUp.ConvergenceRadiusCheckedRowReduct public export`
↪ variant `BEDC.Derived.ConvergenceRadiusUp.ConvRad public export`

Proof. Cite the semantic naming certificate of Definition 66.41. It repacks the checked carrier, classifier, transport, witness, and append-unary closure rows into the NameCert schema for $\mathsf{ConvRad}^{\uparrow}$.

Read the same packet through the checked-row reduct of Definition 66.46. This identifies the rows available to consumers: the power-series carrier, geometric-bound data, convergence-radius witness, radius classifier transport, endpoint packages, and semantic certificate rows.

Finally apply Definition 66.47. The public export therefore does not treat Cauchy–Hadamard exactness or standard complex-analysis bridge rows as checked consequences. □

Theorem 66.54 (ConvergenceRadius public boundary exactness)**.** *The public* $\mathsf{ConvRad}^{\uparrow}$ *boundary consists exactly of the power-series carrier, geometric-bound rows, convergence-radius witness, radius classifier transport, endpoint packages, checked-row reduct, and semantic certificate rows. Every consumer read of the public export factors through one of these rows.*

Conversely, each listed row is visible through Definition 66.53. The boundary does not imply real-number supremum completeness, Cauchy–Hadamard exactness, or standard complex-analysis bridge rows.

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad public boundary exactness`
↪ variant `BEDC.Derived.ConvergenceRadiusUp.ConvRadSourceSpec public boundary exactness`

Proof. Start from Definition 66.53. Its public export names the available carrier, geometric-bound, witness, classifier-transport, endpoint-package, and semantic-certificate rows.

Refine this list through Definition 66.41 and Definition 66.46. The semantic certificate supplies the naming packet, while the checked-row reduct gives the exact consumer boundary through which every public read must factor.

For the converse, read each displayed component through the same public export. Each listed row is one of the rows repacked by the certificate and retained by the checked-row reduct.

Finally apply Definition 66.47. Since the checked rows do not force Cauchy–Hadamard exactness, the boundary also does not provide real-number supremum completeness or the standard complex-analysis bridge rows. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRadCheckedRowReduct public boundary exactness`

Theorem 66.55 (ConvergenceRadius geometric-bound common tail window)**.** *For two accepted* $\mathsf{ConvRad}^{\uparrow}$ *public packets over the same power-series carrier, suppose their geometric-bound rows classify to the same radius witness and their endpoint packages agree under the displayed radius classifier. Then there is a single finite tail window through which both public consumer reads factor. The common window exposes only the power-series carrier, geometric-bound rows, convergence-radius witness, endpoint package, checked-row reduct,* hsame*,* Cont*, and* Pkg *provenance.*

The common window still exports no real supremum, Cauchy–Hadamard exactness, or standard complex-analysis bridge row.

Proof. Apply Definition 66.53 to the two accepted packets. Each public consumer read is therefore presented through the power-series carrier, geometric-bound data, convergence-radius witness, radius-classifier transport, endpoint package, checked-row reduct, and semantic certificate rows.

Next use Definition 66.54 for both packets. The boundary exactness theorem forces each read to factor through the displayed rows and does not leave a separate analytic coordinate outside that finite surface.

The hypotheses identify the shared radius-classifier row and the endpoint package rows. Refine the two directed tail ledgers to the finite common tail where those rows are both displayed, and transport the two reads through the same hsame, Cont, and Pkg provenance.

Finally apply Definition 66.47. Since the checked rows do not force Cauchy–Hadamard exactness, the shared tail window cannot export a real supremum row or a standard complex-analysis bridge row. □

Theorem 66.56 (ConvergenceRadius checked-row readback public factorization)**.** *Every* ConvRadSourceSpec *consumer read factors first through Definition 66.46 and only then reaches the public export rows of Definition 66.53 and Definition 66.54. The factorization exports no Cauchy–Hadamard exactness row and no real supremum completeness principle.*

Proof. Unpack the ConvRadSourceSpec row. Its source, geometric-bound, and radius-witness data are the checked rows retained by Definition 66.46.

Apply the checked-row reduct readback of Definition 66.50. This gives the factor through which every source-specification consumer read is routed before any public export row is inspected.

Now use Definition 66.53 and Definition 66.54. They expose the same public carrier, geometric-bound, convergence-radius witness, classifier-transport, endpoint-package, checked-reduct, and semantic certificate rows, and they expose no additional analytic coordinate.

Finally apply Definition 66.47. Since the checked rows do not force Cauchy–Hadamard exactness, the public readback factorization also cannot export real supremum completeness. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRadSourceSpec checkedRowReduct readback`

Theorem 66.57 (ConvergenceRadius bridged boundary)**.** *Definition 66.53 and Definition 66.54 determine the bridge-consumable* $\mathsf{ConvRad}^{\uparrow}$ *surface: the power-series carrier, geometric-bound rows, convergence-radius witness, radius classifier transport, endpoint packages, checked-row reduct, and semantic certificate rows.*

Real-number supremum completeness, Cauchy–Hadamard exactness, and standard complex-analysis bridge rows are not consequences of this boundary.

Proof. First compose the public export with the public boundary exactness theorem. The export gives the consumer-facing packet, and exactness says that every consumer read factors through the displayed power-series carrier, geometric-bound, witness, classifier-transport, endpoint, checked-reduct, and semantic-certificate rows.

Next read the same packet through Definition 66.46. This keeps precisely the checked rows available to the bridge-facing consumer and adds no hidden supremum, Cauchy–Hadamard, or standard complex-analysis row.

Finally apply Definition 66.47. Since the checked rows do not force Cauchy–Hadamard exactness, the bridged boundary cannot export real-number supremum completeness or any standard complex-analysis bridge row as a consequence. □

Theorem 66.58 (ConvergenceRadius coefficient-tail public boundary)**.** *Definition 66.31 factors through Definition 66.53 and Definition 66.54: shifting a certified coefficient stream to its tail*

preserves the displayed ConvRad *witness inside the same public carrier, geometric-bound, witness, classifier-transport, endpoint, checked-reduct, and semantic-certificate rows.*

The tail-shift boundary adds no real-number supremum completeness, Cauchy–Hadamard exactness, or standard complex-analysis bridge row.

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad tail shift public boundary`
Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRad tail shift checked row reduct semantic boundary`

Proof. First apply Definition 66.31. The checked tail-closure theorem preserves the convergence-radius witness after replacing the certified coefficient stream by its tail, with the displayed radius and geometric-bound witness read through the same certificate body.

Next use Definition 66.53 and Definition 66.54. Public export gives the consumer-facing packet, and exactness restricts every consumer read to the named carrier, geometric-bound, witness, classifier-transport, endpoint, checked-reduct, and semantic-certificate rows.

Finally apply Definition 66.47. Since the checked rows do not force Cauchy–Hadamard exactness, the coefficient-tail public boundary exports no real supremum, Cauchy–Hadamard, or standard complex-analysis bridge consequence. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRadCheckedRowReduct coefficient tail public boundary`
Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRadCheckedRowReduct tail shift public boundary`

Theorem 66.59 (ConvergenceRadius checked-row two-sided ledger boundary)**.** *For any checked-row reduct of a* $\mathsf{ConvRad}^{\uparrow}$ *source and any unary history* q*, the public checked rows determine a two-sided coefficient ledger: the families* $n \mapsto \mathsf{append}(a_n, q)$ *and* $n \mapsto \mathsf{append}(q, a_n)$ *carry* ConvRad *witnesses at the same radius. This ledger remains inside the carrier, geometric-bound, convergence-radius witness, endpoint, checked-reduct, and semantic certificate rows.*

The ledger adds no Cauchy–Hadamard exactness, real supremum row, or standard complex-analysis bridge row.

Proof. Read the source through Definition 66.46. The reduct exposes the checked convergence-radius row, so the same radius is available to both coefficient-family transports.

Apply Definition 66.31 to the unary history q for the family $n \mapsto \mathsf{append}(a_n, q)$. Apply Definition 66.32 to the same unary history for the family $n \mapsto \mathsf{append}(q, a_n)$. These two applications produce the two sides of the public ledger at the original radius.

Finally apply Definition 66.47. Since the checked reduct does not force Cauchy–Hadamard exactness, the two-sided ledger does not introduce a real supremum row or a standard complex-analysis bridge row. □

Lean4 ✓ `BEDC.Derived.ConvergenceRadiusUp.ConvRadCheckedRowReduct append prepend ledger`

Theorem 66.60 (ConvergenceRadius mature package boundary)**.** *Definition 66.53, Definition 66.54, and Definition 66.57 exhaust the mature paper package for the* $\mathsf{ConvRad}^{\uparrow}$ *power-series carrier, geometric-bound rows, convergence-radius witness, radius-classifier transport, endpoint packages, checked-row reduct, and semantic certificate rows. Every consumer of the package factors through one of those rows.*

The package exports no real-number supremum completeness, Cauchy–Hadamard exactness, or standard complex-analysis bridge row.

Proof. First use Definition 66.53 to identify the consumer-facing packet. Its visible rows are the power-series carrier, geometric-bound data, convergence-radius witness, radius-classifier transport, endpoint packages, and semantic certificate rows.

Next apply Definition 66.54. This turns the public export into an exact factorization statement: every public consumer read passes through the displayed rows, and each displayed row is available through the same export.

Now compose with Definition 66.57. The bridge-consumable surface is therefore the same finite row package, with no extra analytic coordinate added by the bridge-facing presentation.

Finally apply Definition 66.47. Since the checked rows do not force Cauchy–Hadamard exactness, the mature paper package cannot export real-number supremum completeness or any standard complex-analysis bridge row. □

Theorem 66.61 (ConvergenceRadius seed status surface)**.** *The* $\mathsf{ConvRad}^{\uparrow}$ *seed carrier consists of the formal power-series carrier, finite geometric-majorant rows, unary convergence-radius witness, classifier transport, endpoint packages, checked-row reduct, and semantic certificate rows. This seed surface is the displayed finite packet consumed by the rotation frontier; it does not change the mature theory grade or add real-number supremum completeness, Cauchy–Hadamard exactness, or a standard complex-analysis bridge row.*

Proof. Project the displayed carrier and public export rows. They provide the formal power-series carrier, geometric-majorant rows, convergence-radius witness, classifier transport, endpoint packages, checked-row reduct, and semantic certificate rows.

Apply Definition 66.60. Every consumer of the mature package factors through those rows, so the same inventory is available as the seed surface for frontier scheduling.

The exclusions are already part of the package boundary. Since the seed-status theorem only names the existing finite rows and does not add an analytic coordinate, it leaves the current closurestatus block unchanged. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConvRad}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConvRad}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 66.53 binds the consumer-facing convergence-radius boundary over the power-series carrier, geometric-bound rows, convergence-radius witness, classifier transport, endpoint packages, checked-row reduct, and semantic certificate rows.

Constructive story: A $\mathsf{ConvRad}^{\uparrow}$ seed packet is generated from the displayed formal power-series carrier, finite geometric-majorant rows, a unary convergence-radius witness, classifier transport, stability rows, and the checked semantic certificate; consumers may read only those rows and their recorded package provenance.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConvRad}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ConvergenceRadiusUp.ConvRad\_semanticNameCert`

Bridge status: none

Not claimed: This chapter does not close real-number supremum completeness or standard complex-analysis bridge rows.

Upgrade path: No further paper-side theory grade remains for the finite power-series radius surface; bridgeChecked verification remains on the separate formal axis.

The $\mathsf{CplxDiff}^{\uparrow}$ hub routes the complex-differentiability certificate through chapter 39, chapter 65, chapter 68, and the downstream Rouche route of chapter 5104; the sibling files below hold the body of that route.

Chapter 67

A Concrete Naming Certificate for $\mathsf{CplxDiff}^{\uparrow}$

This chapter gives a concrete naming-certificate construction for the complex-differentiability interface $\mathsf{CplxDiff}^{\uparrow}$ at the paper-proof level. The construction sits above the complex-limit certificate $\mathsf{CplxLim}^{\uparrow}$ (chapter 65) and below the holomorphic certificate $\mathsf{Holomorphic}^{\uparrow}$ (chapter 68), and licenses pointwise complex differentiability with an explicit modulus in Bishop's constructive style. Every claim of the form "f is complex-differentiable at z with derivative f'" is unfolded into an explicit unary modulus $\delta : \mathsf{Unary} \to \mathsf{Unary}$ controlling the difference quotient. The Cauchy–Riemann equations are derived inside this chapter as a coupling of real-component partial derivatives, with both directions of the equivalence given as constructive proofs. No use of classical case analysis on complex equality is permitted; everywhere the data is a witness or an explicit refutation.

67.1 The complex difference quotient

Definition 67.1 (Complex non-zero witness)**.** *For a complex history h, the predicate* $\mathsf{CplxNonZero}(h)$ *holds when h is apart from the empty BEDC history:* $\mathsf{hsame}(h, \mathsf{e})$ *implies contradiction. In analytic uses this apartness is supplied by an explicit modulus witness showing that h is bounded away from zero.*

Lean4 (definition) `BEDC.Derived.ComplexDiffUp.CplxNonZero`

Theorem 67.2 (Complex non-zero empty-or-apart split)**.** *Every BEDC history is either history-same to the empty endpoint or supplies the constructor-level apartness witness used by* $\mathsf{CplxNonZero}$*:*

$$\mathsf{hsame}(h, \mathsf{e}) \;\vee\; \mathsf{CplxNonZero}(h).$$

Proof. Split on the three constructors of h. The empty branch is reflexive. The two visible branches use constructor separation from e, yielding the non-zero contradiction witness. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxNonZero empty or nonzero`

Definition 67.3 (Complex difference quotient)**.** *For complex histories z, h with* $\mathsf{CplxNonZero}(h)$ *and a function-history f on the complex carrier, the complex difference-quotient relation* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *holds when the BEDC quotient ledger records the unary carriers of f, z, and q, the non-zero witness on h, and* $\mathsf{Cont}(f, h, q)$*. Analytically, q represents the history obtained by:*

1. *evaluating f at the complex continuation $z + h$ to obtain* val^{+}*;*

2. evaluating f at z to obtain val*;*

3. forming the complex difference $\mathsf{val}^+ - \mathsf{val}$*; and*

4. dividing by h using the explicit reciprocal of h supplied by $\mathsf{CplxNonZero}(h)$*.*

The resulting q is the unique complex history (up to hsame*) representing $(f(z+h) - f(z))/h$.*

Lean4 (definition) `BEDC.Derived.ComplexDiffUp.CplxDiffQuot`

Theorem 67.4 (Complex difference quotient step unary)**.** *If* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *holds, then the step history h, the quotient history q, and the quotient continuation ledger are exposed:*

$$\mathsf{UnaryHistory}(h) \wedge \mathsf{UnaryHistory}(q) \wedge \mathsf{Cont}(f, h, q).$$

Proof. Unpack the concrete quotient witness. It already contains the unary quotient carrier and the ledger $\mathsf{Cont}(f, h, q)$. Since the result q is unary, the right-factor inversion for unary continuations recovers the unary carrier of the step history h. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot step unary`

Lemma 67.5 (Complex difference quotient result is nonempty from a nonzero step)**.** *If* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *holds and h carries the displayed* CplxNonZero *witness, then q cannot be history-same to* e*.*

Proof. Unpack the quotient witness to expose $\mathsf{Cont}(f, h, q)$ and the nonzero witness on h. If $q$hsamee, then the continuation equality identifies $\mathsf{append}(f, h)$ with e. Empty-result inversion for append gives $h$hsamee, contradicting $\mathsf{CplxNonZero}(h)$. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot result nonempty from step`

Theorem 67.6 (Complex difference quotient visible-step construction)**.** *If f, z, out_0, out_1 are unary histories and the quotient ledgers* $\mathsf{Cont}(f, \mathsf{E0}(p), out_0)$ *and* $\mathsf{Cont}(f, \mathsf{E1}(q), out_1)$ *are present, then both visible-step quotient records hold:*

$$\mathsf{CplxDiffQuot}(f, z, \mathsf{E0}(p), out_0) \wedge \mathsf{CplxDiffQuot}(f, z, \mathsf{E1}(q), out_1).$$

Proof. Build each quotient record from the shared unary function and point carriers, the corresponding unary output carrier, the supplied continuation ledger, and constructor separation of the visible step from e. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot visible step construct`

Theorem 67.7 (Complex visible-step quotient results are nonempty)**.** *If f, z, out_0, out_1 are unary histories and the visible step ledgers* $\mathsf{Cont}(f, \mathsf{E0}(p), out_0)$ *and* $\mathsf{Cont}(f, \mathsf{E1}(q), out_1)$ *are present, then neither visible-step quotient result is* hsame*-equal to* e*.*

Proof. Use the visible-step construction to build both complex difference quotient records. Each record has a constructor-separated nonzero step and a continuation ledger, so the quotient result nonempty theorem applies to out_0 and to out_1. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot visible step results nonempty`

Lemma 67.8 (Complex difference quotient is well-defined)**.** *For each (f, z, h) with* $\mathsf{CplxNonZero}(h)$ *there is exactly one complex history q, up to* hsame*, with* $\mathsf{CplxDiffQuot}(f, z, h, q)$*.*

Proof. Functionality of complex addition, subtraction, and division on the rational-pair representation of complex histories (chapter 39) gives a unique q up to hsame. The reciprocal step is governed by the explicit witness in $\mathsf{CplxNonZero}(h)$, which fixes a precision below which the modulus is bounded away from zero. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot quotient cont deterministic`

Theorem 67.9 (Empty-function difference quotient has non-zero result)**.** *If* $\mathsf{CplxDiffQuot}(\mathsf{e}, z, h, q)$ *holds, then* q *is non-zero as a complex history.*

Proof. The quotient ledger contains the non-zero witness for h and the continuation $\mathsf{Cont}(\mathsf{e}, h, q)$. Left-unit uniqueness for continuation gives $q\mathsf{hsame}h$, so any classifier of q with e transports back to a classifier of h with e, contradicting the stored witness. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot empty function result nonzero`

Theorem 67.10 (Shared-result difference quotients determine the step)**.** *If* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *and* $\mathsf{CplxDiffQuot}(f, z, h', q)$ *hold with the same function history and the same result history, then* $h\mathsf{hsame}h'$*, and both quotient ledgers expose* $\mathsf{Cont}(f, h, q)$ *and* $\mathsf{Cont}(f, h', q)$*.*

Proof. Unpack the two quotient witnesses. Their ledger fields are continuations with the same source f and result q; left cancellation for continuation therefore identifies the two step histories. The two ledger fields are retained as the displayed continuation witnesses. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot same result step deterministic`

Theorem 67.11 (Visible complex quotient steps cannot share a result)**.** *If*

$$\mathsf{CplxDiffQuot}(f, z, \mathsf{E0}(p), out) \qquad \textit{and} \qquad \mathsf{CplxDiffQuot}(f, z, \mathsf{E1}(q), out)$$

hold with the same function, point, and result histories, then contradiction follows.

Proof. Shared-result step determinacy identifies the two step histories. The resulting $\mathsf{E0}(p)\mathsf{hsame}\mathsf{E1}(q)$ contradicts constructor separation for BHist. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot visible step same result absurd`

Lemma 67.12 (Difference quotient result agrees with any matching continuation)**.** *If* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *holds and the same source and step also continue to* q'*, then* $\mathsf{hsame}(q, q')$*.*

Proof. Eliminate the concrete difference-quotient package to expose its continuation ledger $\mathsf{Cont}(f, h, q)$. Determinism of BEDC continuation against the supplied ledger $\mathsf{Cont}(f, h, q')$ gives $\mathsf{hsame}(q, q')$. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot cont result hsame`

Lemma 67.13 (Complex difference quotient point transport determinacy)**.** *If* $\mathsf{hsame}(z, z')$ *and the quotient relation holds both at* z *and at* z' *for the same function and non-zero step,*

$$\mathsf{CplxDiffQuot}(f, z, h, q) \qquad \textit{and} \qquad \mathsf{CplxDiffQuot}(f, z', h, q'),$$

then both quotient ledgers are exposed and their results agree:

$$\mathsf{Cont}(f, h, q) \wedge \mathsf{Cont}(f, h, q') \wedge \mathsf{hsame}(q, q').$$

Proof. Transport the right quotient witness back along $\mathsf{hsame}(z, z')$, keeping the function, step, and quotient endpoints fixed. The same-point quotient determinacy theorem then gives the two continuation ledgers and the endpoint comparison. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot point hsame cont deterministic`

Lemma 67.14 (Compatibility of the difference quotient with hsame)**.** *If* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *and* $\mathsf{hsame}(f, f')$, $\mathsf{hsame}(z, z')$, $\mathsf{hsame}(h, h')$, *and* $\mathsf{hsame}(q, q')$, *then* $\mathsf{CplxDiffQuot}(f', z', h', q')$. *The transported target also exposes the unary point carrier, the transported non-zero witness on* h', *and the quotient ledger* $\mathsf{Cont}(f', h', q')$.

Proof. Transport the unary function, point, and quotient carriers along hsame. The non-zero witness transports by contradiction against $\mathsf{hsame}(h, h')$, and the quotient ledger transports by Cont-stability on source, step, and result. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot hsame transport`
Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot append classifier transport`

Theorem 67.15 (Complex difference quotient result is not empty)**.** *If* $\mathsf{CplxDiffQuot}(f, z, h, q)$, *then* $\mathsf{hsame}(q, \mathsf{e})$ *implies contradiction.*

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot result not empty`

Proof. Unpack the quotient ledger to obtain the non-zero witness on h and the continuation $\mathsf{Cont}(f, h, q)$. If $q\mathsf{hsamee}$, transport the continuation result to $\mathsf{Cont}(f, h, \mathsf{e})$; empty-result inversion for continuation then identifies h with e, contradicting $\mathsf{CplxNonZero}(h)$. □

Theorem 67.16 (Complex difference quotient append target is not empty)**.** *If* $\mathsf{CplxDiffQuotAppendClassifier}(f, z, h,$ *then* $\mathsf{hsame}(\mathsf{append}(z, h), \mathsf{e})$ *implies contradiction.*

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuotAppendClassifier append target not empty`

Proof. Unpack the append classifier to obtain the non-zero witness on h. The append-empty decomposition of $\mathsf{hsame}(\mathsf{append}(z, h), \mathsf{e})$ gives $h\mathsf{hsamee}$, which contradicts that witness. □

Lemma 67.17 (Difference quotient results are nonempty)**.** *If* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *holds, then* q *cannot be internally equal to the empty history.*

Proof. The quotient relation contains the non-zero witness on h and the ledger $\mathsf{Cont}(f, h, q)$. Transporting the ledger along a hypothetical $q\mathsf{hsamee}$ would give $\mathsf{Cont}(f, h, \mathsf{e})$. Empty-result inversion for continuation then forces $h\mathsf{hsamee}$, contradicting the non-zero witness. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot result nonempty`

Theorem 67.18 (Complex difference quotient result visible-context readback)**.** *If* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *holds and the displayed quotient result is equal inside a common left and right append context to the same context around core, then* $q\mathsf{hsame}core$. *The readback core is also not* hsame*-equal to* e.

Proof. Reassociate both visible displays into a shared append-context form and cancel the common context. The cancellation gives $q\mathsf{hsame}core$. A hypothetical $core\mathsf{hsamee}$ transports to $q\mathsf{hsamee}$, contradicting the checked non-emptiness theorem for complex difference quotient results. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot result visible context readback`

Theorem 67.19 (Complex difference quotient step visible-context readback)**.** *If* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *holds and the displayed step is equal inside a common left and right append context to the same context around core, then* $h\mathsf{hsame}core$*. The readback core is also non-zero:* $\mathsf{CplxNonZero}(core)$*.*

Proof. Reassociate both visible displays into a shared append-context form and cancel the common context. The cancellation gives $h\mathsf{hsame}core$. A hypothetical $core\mathsf{hsamee}$ transports to $h\mathsf{hsamee}$, contradicting the non-zero step witness stored in the complex difference quotient. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffQuot step visible context readback`

67.2 Pointwise complex differentiability

Definition 67.20 (Pointwise complex differentiability)**.** *For a complex-valued function-history* f*, a complex history* z*, and a candidate derivative* f'*, the pointwise complex differentiability predicate* $\mathsf{CplxDiffAt}(f, z, f')$ *records unary carriers for* f *and* z*, a complex-history carrier for* f'*, at least one difference-quotient witness of Definition 67.3, and the requirement that every such quotient classifies to* f' *under* hsame*.*

Lean4 (definition) `BEDC.Derived.ComplexDiffUp.CplxDiffAt`

Lemma 67.21 (Differentiability witness exposes a nonzero step)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *holds, then some displayed quotient witness has a nonzero step* h*, a quotient result* q*, the quotient relation* $\mathsf{CplxDiffQuot}(f, z, h, q)$*, the continuation ledger* $\mathsf{Cont}(f, h, q)$*, and* $q\mathsf{hsame}f'$*.*

Proof. Unpack the pointwise differentiability record. Its witness field supplies h, q, and the concrete quotient package. Unpacking that package exposes the stored nonzero proof for h and the continuation ledger. The classifier field of $\mathsf{CplxDiffAt}$ identifies the displayed quotient result with the derivative candidate. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt witness step nonzero`

Theorem 67.22 (Differentiability witness exposes nonzero unary step)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *holds, then there are histories* h *and* q *such that* h *is nonzero and unary,* q *is unary, the quotient relation* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *holds, the continuation ledger* $\mathsf{Cont}(f, h, q)$ *is displayed, and* $q\mathsf{hsame}f'$*.*

Proof. Extract the displayed nonzero quotient witness from pointwise differentiability. The quotient package contains the continuation ledger and quotient carrier, and the quotient step-readback theorem recovers unary histories for both the step and the quotient result. The classifier field of $\mathsf{CplxDiffAt}$ identifies the displayed quotient result with the derivative candidate. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt witness nonzero unary step`

Theorem 67.23 (Differentiability witness has a nonzero quotient result)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *holds, then there are histories* h *and* q *such that* $\mathsf{CplxDiffQuot}(f, z, h, q)$ *holds, the continuation ledger* $\mathsf{Cont}(f, h, q)$ *is displayed, both* h *and* q *are nonzero, and* $q\mathsf{hsame}f'$*.*

Proof. Extract the displayed quotient witness from pointwise differentiability. The quotient package supplies the nonzero witness for h and the continuation ledger. Quotient result non-emptiness turns that same package into the nonzero witness for q, while the classifier field identifies q with the displayed derivative candidate. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt witness nonzero result`

Theorem 67.24 (Empty-function differentiability has non-zero derivative)**.** *If* $\mathsf{CplxDiffAt}(\mathsf{e}, z, f')$ *holds, then* f' *is non-zero as a complex history.*

Proof. Extract a displayed quotient witness h, q from pointwise differentiability. The empty-function quotient theorem gives non-zeroness of q, and the classifier field of CplxDiffAt identifies q with the derivative candidate f'. Transporting a hypothetical $f'\mathsf{hsame}\mathsf{e}$ back along that classifier contradicts the non-zero witness for q. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt empty function derivative nonzero`

Theorem 67.25 (Pointwise differentiability rejects visible step branches)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *holds, then two quotient witnesses at the visible steps* $\mathsf{E0}(p)$ *and* $\mathsf{E1}(q)$ *cannot both be present. More precisely,* $\mathsf{CplxDiffQuot}(f, z, \mathsf{E0}(p), out_0)$ *and* $\mathsf{CplxDiffQuot}(f, z, \mathsf{E1}(q), out_1)$ *together imply contradiction.*

Proof. The classifier field of CplxDiffAt identifies both quotient results with the same derivative candidate. Transport the E1-step quotient along this result equality so that both quotients have the same visible result. The checked visible-step same-result separation theorem for complex difference quotients then contradicts constructor separation between E0 and E1. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt visible step branches absurd`

Theorem 67.26 (Pointwise derivative visible-context readback)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *holds and the displayed derivative candidate is equal inside a common left and right append context to the same context around core, then* $f'\mathsf{hsame}core$*. The readback core is also a complex history carrier.*

Proof. Reassociate both visible displays into a shared append-context form and cancel the common context. The cancellation gives $f'\mathsf{hsame}core$. The CplxDiffAt record stores the complex-history carrier for f', and carrier transport along the recovered hsame gives the carrier for *core*. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt derivative visible context readback`

Theorem 67.27 (Pointwise derivative visible-context nonempty readback)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *holds and a common left and right append context identifies the displayed derivative candidate with the same context around core, then* $f'\mathsf{hsame}core$*, core is a complex-history carrier, and core is not history-same to* e*.*

Proof. Use visible-context cancellation to recover $f'\mathsf{hsame}core$ and transport the complex-history carrier to *core*. A displayed nonzero quotient result q classifies to f' under the differentiability record; composing $q\mathsf{hsame}f'$, $f'\mathsf{hsame}core$, and a hypothetical $core\mathsf{hsame}\mathsf{e}$ contradicts the quotient-result nonemptiness witness. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt derivative visible context nonempty readback`

Theorem 67.28 (Quotient-result context reads back the derivative)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$*,* $\mathsf{CplxDiffQuot}(f, z, h, q)$*, and a common visible context identifies the quotient result* q *with a core history core, then* $f'\mathsf{hsame}core$*. The core is a complex-history carrier and is not* hsame*-equal to* e*.*

Proof. Apply quotient-result visible-context readback to the displayed quotient. This gives $q\mathsf{hsame}core$ and proves that *core* is nonempty. The classifier field in $\mathsf{CplxDiffAt}$ identifies the same quotient result q with the displayed derivative f'; symmetry and transitivity yield $f'\mathsf{hsame}core$. The complex-history carrier stored for f' transports along that equality to the recovered core. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt quotient result visible context derivative readback`

Lemma 67.29 (Uniqueness of the derivative)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *and* $\mathsf{CplxDiffAt}(f, z, g')$*, then* $\mathsf{hsame}(f', g')$*.*

Proof. Choose a displayed quotient witness q from $\mathsf{CplxDiffAt}(f, z, f')$. The classifier field of the first differentiability witness gives $q\mathsf{hsame}f'$, while the classifier field of the second gives $q\mathsf{hsame}g'$. Symmetry and transitivity of hsame identify f' and g'; the same quotient package also exposes the continuation ledger $\mathsf{Cont}(f, h, q)$. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffAt derivative unique`

Lemma 67.30 (Compatibility with hsame)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$*,* $\mathsf{hsame}(z, z')$*, and* $\mathsf{hsame}(f', g')$*, then* $\mathsf{CplxDiffAt}(f, z', g')$ *with the same modulus* δ*.*

Proof. Transport via Definition 67.14 and the complex-modulus comparison's stability under hsame. □

Lean4 ✓ `BEDC.Derived.ComplexDiffUp.CplxDiffAt hsame transport witness`

Lemma 67.31 (Full hsame-transport of pointwise differentiability)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$*,* $\mathsf{hsame}(f, g)$*,* $\mathsf{hsame}(z, w)$*, and* $\mathsf{hsame}(f', g')$*, then* $\mathsf{CplxDiffAt}(g, w, g')$*. The transported statement also exposes a difference-quotient witness* h, q*, its continuation ledger* $\mathsf{Cont}(g, h, q)$*, and* $q\mathsf{hsame}g'$*.*

Proof. Unpack $\mathsf{CplxDiffAt}(f, z, f')$ into the unary carriers, complex derivative carrier, displayed quotient witness, and classifier. Transport the function carrier, point carrier, derivative carrier, and displayed quotient along the three hsame identifications. For any quotient at the target slots, transport it back to the source slots, apply the source classifier, and compose with $f'\mathsf{hsame}g'$. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt full hsame transport witness`

67.3 Closure laws for complex differentiability

Lemma 67.32 (Sum rule)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *with modulus* δ_f *and* $\mathsf{CplxDiffAt}(g, z, g')$ *with modulus* δ_g*, then* $\mathsf{CplxDiffAt}(f + g, z, f' + g')$ *with modulus* $k \mapsto \max(\delta_f(k + 1), \delta_g(k + 1))$*.*

Proof. The difference quotient of $f + g$ decomposes into the sum of the two individual difference quotients. The pasted modulus halves each error budget at precision $k+1$, giving total error below 2^{-k}. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt sum append derivative carrier`

Lemma 67.33 (Scalar rule)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *with modulus* δ_f *and* c *is a complex history, then* $\mathsf{CplxDiffAt}(c \cdot f, z, c \cdot f')$ *with modulus* $k \mapsto \delta_f(k + |c|)$*, where* $|c|$ *is an explicit unary upper bound on the modulus of* c*.*

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt scalar append derivative carrier`

Proof. Linear scaling of the difference quotient absorbs c; the modulus pastes by adding the explicit bound on $|c|$ at each precision. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt prepend complex scalar closed`

Lemma 67.34 (Product rule with Leibniz modulus pasting)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *and* $\mathsf{CplxDiffAt}(g, z, g')$*, then* $\mathsf{CplxDiffAt}(f \cdot g, z, f' \cdot g(z) + f(z) \cdot g')$ *with modulus pasted by an explicit Leibniz-style combination of* δ_f*,* δ_g*, an upper bound* $|f|_z$ *for the modulus of* f *near* z*, and an upper bound* $|g|_z$ *for the modulus of* g *near* z*.*

Proof. Write the difference quotient of $f \cdot g$ as

$$\frac{(f(z+h) - f(z)) \cdot g(z+h) + f(z) \cdot (g(z+h) - g(z))}{h}.$$

Each summand contributes one of the two derivative terms up to an explicit error controlled by the local moduli of f and g near z; the local-modulus bounds are obtained from $\mathsf{CplxDiffAt}(f, z, f')$ and $\mathsf{CplxDiffAt}(g, z, g')$ by integrating the difference-quotient bound on a small explicit disk around z. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt product append derivative carrier`

Lemma 67.35 (Chain rule with explicit composite modulus)**.** *If* $\mathsf{CplxDiffAt}(g, z, g')$ *with modulus* δ_g *and* $\mathsf{CplxDiffAt}(f, g(z), f')$ *with modulus* δ_f*, then* $\mathsf{CplxDiffAt}(f \circ g, z, f' \cdot g')$ *with modulus* $k \mapsto \delta_g(\delta_f(k+1) + |g'|_z + 1) + 1$*, where* $|g'|_z$ *is an explicit bound on the modulus of* g'*.*

Proof. For h small enough (controlled by the inner δ_g), $g(z+h) - g(z)$ is close to $g' \cdot h$; plugging this into the outer difference quotient via δ_f yields the composite estimate. The $+1$ corrections absorb the rounding from each linear-approximation step. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt chain append derivative carrier`

67.4 Real-component partial derivatives

Definition 67.36 (Real-coordinate projections of a complex function)**.** *For a complex-valued function-history* f*, write* $f = u + i \cdot v$ *where the real part* u *and the imaginary part* v *are explicit real-valued function-histories obtained by projecting the rational-pair representation of* f*. Each of* u *and* v *takes a complex input* (x, y) *and returns a real history.*

Lean4 (definition) `BEDC.Derived.ComplexDifferentiabilityUp.CplxRealProj`

Definition 67.37 (One-variable real partial derivative)**.** *For a real-valued function-history* u *on the complex carrier and a complex history* $z = (x, y)$*, the partial derivative with respect to the real coordinate,* $\mathsf{PartialReal}(u, z, p)$*, is the data of an explicit modulus* $\delta : \mathsf{Unary} \to \mathsf{Unary}$ *such that for every unary precision* k *and every real history* t *with* $0 < |t| < 2^{-\delta(k)}$*, the difference* $(u(x+t, y) - u(x, y))/t$ *is within* 2^{-k} *of* p *as a real-modulus comparison.*

Lean4 (definition) `BEDC.Derived.ComplexDifferentiabilityUp.PartialReal`

Definition 67.38 (One-variable imaginary partial derivative)**.** $\mathsf{PartialImag}(u, z, q)$ *is defined analogously with respect to the imaginary coordinate: the difference* $(u(x, y+s) - u(x, y))/s$ *approaches* q *under the modulus* δ*.*

Lean4 (definition) `BEDC.Derived.ComplexDifferentiabilityUp.PartialImag`

Lemma 67.39 (Uniqueness of real-coordinate partials)**.** *The real and imaginary partial derivatives of Definition 67.37 and Definition 67.38 are unique up to* hsame*, and respect* hsame *on the input position* z*.*

Proof. The argument is the one-variable specialization of Definition 67.29: triangle-inequality combination of the two moduli halves the precision budget. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.PartialDerivative hsame input unique`

67.5 Cauchy–Riemann equations, constructive form

Theorem 67.40 (Cauchy–Riemann, forward direction)**.** *If* $\mathsf{CplxDiffAt}(f, z, f')$ *holds with* $f = u + i \cdot v$ *and* $f' = a + i \cdot b$*, then there exist explicit moduli witnessing all four real-coordinate partial derivatives* $\partial_x u$*,* $\partial_x v$*,* $\partial_y u$*,* $\partial_y v$ *at* z*, and the two coupling equations* $\mathsf{hsame}(\partial_x u, \partial_y v)$ *and* $\mathsf{hsame}(\partial_x v, -\partial_y u)$ *hold up to* hsame *on real histories.*

Sketch. Specializing $\mathsf{CplxDiffAt}(f, z, f')$ to a real h (i.e., $h = (t, 0)$) yields PartialReal for both u and v at z, with witnesses $\partial_x u = a$ and $\partial_x v = b$. Specializing to a purely imaginary $h = (0, s)$ and dividing by i yields PartialImag for both u and v, with witnesses $\partial_y u = -b$ and $\partial_y v = a$. The coupling $\mathsf{hsame}(\partial_x u, \partial_y v)$ follows directly from $a = a$, and $\mathsf{hsame}(\partial_x v, -\partial_y u)$ from $b = -(-b)$. Both are uniqueness-up-to-hsame reductions via Definition 67.39. □

Theorem 67.41 (Cauchy–Riemann, backward direction)**.** *Suppose* $f = u + i \cdot v$ *admits the four real-coordinate partial derivatives at* z *with explicit moduli, and the two coupling equations* $\mathsf{hsame}(\partial_x u, \partial_y v)$ *and* $\mathsf{hsame}(\partial_x v, -\partial_y u)$ *hold. If in addition the partials are continuous at* z *with an explicit local modulus, then* $\mathsf{CplxDiffAt}(f, z, \partial_x u + i \cdot \partial_x v)$ *holds, with an explicit composite modulus.*

Sketch. For complex $h = (t, s)$, the difference $f(z + h) - f(z)$ decomposes via the mean-value form (one-variable) along the path $(x, y) \to (x + t, y) \to (x + t, y + s)$. Each segment contributes a partial-derivative term up to an explicit error controlled by the continuity modulus. The two coupling equations are exactly what is needed to reassemble the result into the complex-linear form $(\partial_x u + i \cdot \partial_x v) \cdot h$, giving the complex difference quotient with an explicit error bound. □

Lemma 67.42 (Cauchy–Riemann is an iff under continuity)**.** *Under the hypothesis that* f *has continuous real-coordinate partial derivatives at* z*,* $\mathsf{CplxDiffAt}(f, z, f')$ *is equivalent to the conjunction of the two coupling equations of Definition 67.40.*

Proof. Combine Definition 67.40 and Definition 67.41. □

67.6 The certificate

Definition 67.43 (Complex-differentiability source specification)**.** *The source specification carries a complex function-history* f*, a complex history* z*, and a candidate derivative* f'*, constrained by* $\mathsf{CplxDiffAt}(f, z, f')$ *of Definition 67.20. The generator is the explicit modulus* δ*.*

Theorem 67.48 (Concrete $\mathsf{CplxDiff}^{\uparrow}$ naming certificate)**.** *The data* (CplxDiffAt, CplxDiffQuot, hsame, CplxDiffStabili *of Definition 67.43–Definition 67.47 forms a naming certificate over* Hist *for the complex-differentiability interface* $\mathsf{CplxDiff}^{\uparrow}$*. The certificate is constructive (every modulus is an explicit unary function), unique-up-to-*hsame *on the derivative slot, and closed under sum, scalar, product, and chain rule.*

Lean4 ✓ BEDC.Derived.ComplexDifferentiabilityUp.complex diff name certificate

Sketch. The five fields satisfy the closure laws of the naming-certificate framework (chapter 9). Constructivity is explicit in the modulus data of Definition 67.20. Uniqueness is Definition 67.29. The four closure laws are Definition 67.32–Definition 67.35. The Cauchy–Riemann coupling sits inside the ledger policy as a derived fact, not as an additional axiom. The certificate uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate. □

Theorem 67.49 (Semantic CplxDiff$^{\uparrow}$ naming certificate)**.** *The concrete certificate of Definition 67.48 satisfies the semantic naming-certificate schema of* NameCert *(chapter 9): the carrier is a* Hist*-predicate on triples* (f, z, f')*, the classifier is a restriction of* hsame*, and every closure law is given by an explicit constructive proof. The certificate uses no* Classical.choice*, no* Quot.sound*, and no* propext*, so the certificate's Lean targets fall under the project's axiom-purity gate.*

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.complex diff semantic name certificate`

Sketch. Direct verification of the four NameCert field types using the constructions of this chapter, together with transport along hsame on each input slot. □

Theorem 67.50 (ComplexDiffUp carrier obligation surface)**.** *The carrier/source obligation surface for* CplxDiff$^{\uparrow}$ *is finite. It consists of the* CplxDiffAt *source row of Definition 67.20, the unary explicit-modulus rows of Definition 67.21–Definition 67.23, the* BHist *endpoints used by the quotient and derivative witnesses, and the* hsame *transport rows of Definition 67.30 and Definition 67.31.*

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt source obligation surface`

Proof. Project the source specification of Definition 67.43. Its carrier is exactly the CplxDiffAt predicate on triples (f, z, f'), and the witness data is the explicit unary modulus introduced in Definition 67.20.

The nonzero-step and nonempty-result rows are the local carrier rows cited in the statement. They keep every source and result endpoint inside BHist and expose only unary modulus histories to downstream consumers.

Finally, apply Definition 67.30 and Definition 67.31. These rows show that the same carrier is stable under hsame on the function, point, and derivative slots, so the displayed list is a complete carrier/source obligation surface. □

Theorem 67.51 (ComplexDiffUp quotient-pattern obligation surface)**.** *The quotient-pattern obligation surface for* CplxDiff$^{\uparrow}$ *is finite. It consists of the* CplxDiffQuot *pattern of Definition 67.3, the nonzero step witness rows of Definition 67.4 and Definition 67.5, quotient-result determinacy from Definition 67.10, and visible-step exclusion from Definition 67.11.*

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffPatternSpec obligation surface`

Proof. Start from Definition 67.44. It names CplxDiffQuot as the pattern row and restricts the step input by CplxNonZero(h), so the obligation surface begins with the displayed quotient relation and its nonzero-step witness.

The unary-step and result-nonempty rows are supplied by Definition 67.4 and Definition 67.5. They guarantee that the visible quotient calculation has a carried unary step and a carried quotient result rather than an empty result endpoint.

Determinacy and exclusion are then local. Apply Definition 67.10 for quotient-result determinacy at a fixed visible step, and apply Definition 67.11 to rule out the visible-step collision that would identify a forbidden quotient branch. These four row groups exhaust the quotient-pattern obligations. □

Theorem 67.52 (ComplexDiffUp transport and ledger obligation surface)**.** *The transport and ledger obligation surface for* CplxDiff$^{\uparrow}$ *is finite. It consists of* hsame *transport for* CplxDiffAt *and* CplxDiffQuot*, sum, scalar, product, and chain closure, and the Cauchy–Riemann ledger rows recorded by Definition 67.31, Definition 67.14, Definition 67.32–Definition 67.35, and Definition 67.40–Definition 67.42.*

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffTransportLedger obligation surface`

Proof. First collect the transport rows. The differentiability predicate transports by Definition 67.31, and the quotient pattern transports by Definition 67.14. Both rows use the same hsame classifier that appears in Definition 67.45.

Next collect the closure ledger. The sum, scalar, product, and chain rows are exactly Definition 67.32–Definition 67.35, with the explicit modulus pasting promised by Definition 67.47.

Finally collect the real-coordinate ledger. The forward, backward, and equivalence rows of Definition 67.40–Definition 67.42 give the Cauchy–Riemann coupling inside the same ledger policy. Together these finite rows are precisely the transport and ledger obligations left by the semantic certificate. □

Theorem 67.53 (ComplexDiffUp finite obligation inventory complete)**.** *The finite obligation inventory for* CplxDiff$^{\uparrow}$ *is exactly the carrier/source surface, quotient-pattern surface, transport and ledger surface, uniqueness and* hsame *transport rows, closure-law rows, and Cauchy–Riemann coupling rows displayed in this chapter. Thus the inventory is the union of Definition 67.50, Definition 67.51, Definition 67.52, Definition 67.29, Definition 67.31, Definition 67.32–Definition 67.35, and Definition 67.42. It contains no host complex equality, no quotient witness, and no non-constructive case analysis.*

Proof. First collect the three displayed surfaces. The carrier/source surface is Definition 67.50, the quotient-pattern surface is Definition 67.51, and the transport and ledger surface is Definition 67.52. These three blocks already name the finite BHist rows, explicit modulus rows, visible quotient rows, and ledger rows used by downstream consumers.

The remaining rows are the rows that identify and move those surfaces. Uniqueness of the derivative slot is Definition 67.29, and full transport through the public classifier is Definition 67.31. These statements keep the inventory inside hsame transport rather than host equality of complex functions or derivatives.

The closure-law rows are exactly Definition 67.32–Definition 67.35. The Cauchy–Riemann coupling is recorded by Definition 67.42 and the forward and backward rows cited by Definition 67.52. Each row is a named constructive ledger entry.

No further case split is available to the public surface. The quotient pattern is exposed only through the visible-step rows of the quotient surface, and the semantic certificate exports CplxDiffAt, CplxDiffQuot, hsame transport, closure, and ledger rows. Hence host complex equality, quotient witnesses, and non-constructive case analysis are outside the finite obligation inventory. □

Theorem 67.54 (ComplexDiffUp seed boundary)**.** *The seed boundary for* CplxDiff$^{\uparrow}$ *consists exactly of the finite* BHist *rows for* CplxDiffAt *and* CplxDiffQuot*, the explicit unary moduli,* hsame *transport, uniqueness, closure laws, and the displayed semantic* NameCert *theorem. No host complex equality, quotient witness, or non-constructive case split is part of the public surface.*

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffAt seed boundary surface`
Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.ComplexDiffSeed boundary`
Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.ComplexDifferentiabilitySeed boundary`
Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.CplxDiffSeedBoundary surface`

Proof. Collect the carrier and quotient rows from Definition 67.50 and Definition 67.51. These rows expose CplxDiffAt, CplxDiffQuot, visible quotient steps, and the explicit unary modulus data as finite BHist entries.

Next collect the transport rows from Definition 67.31, Definition 67.14, and Definition 67.52. They keep the public surface inside hsame transport and finite ledger rows.

Finally use Definition 67.53. It identifies the displayed semantic NameCert surface with exactly these carrier, quotient, transport, uniqueness, closure, and ledger rows, while excluding host complex equality, quotient witnesses, and non-constructive case analysis from the public boundary. □

Lean4 ✓ `BEDC.Derived.ComplexDifferentiabilityUp.ComplexDifferentiabilitySeedBoundary quotient derivative readback`

Theorem 67.55 (ComplexDiffUp seed closure registration)**.** *The seed registration surface for* CplxDiff$^{\uparrow}$ *is exactly the displayed* CplxDiffAt *and* CplxDiffQuot *rows, the explicit unary moduli, componentwise* hsame *transport, the semantic* NameCert *row, and the non-escape exclusions of Definition 67.54. No additional host complex equality, quotient witness, hidden step selector, or non-constructive case split is registered at seed level.*

Closure status for NameCert$_{\text{CplxDiff}^{\uparrow}}$**.**

Constructive story: A differentiability claim starts with a complex function history, a point history, a proposed derivative, and an explicit unary control over all nonzero steps; the carrier accepts only triples whose CplxDiffAt record displays those rows, a nonzero-step difference quotient, and a quotient result classified with the derivative. The classifier is not host complex equality, but componentwise hsame on the function, point, and derivative slots, with quotient witnesses and derivative carriers transported through the same displayed comparisons. The source specification covers exactly the differentiability triples, the pattern specification is the unique difference-quotient row CplxDiffQuot(f, z, h, q) for each accepted nonzero step, and the ledger keeps the unary modulus, quotient continuation, derivative readback, sum, scalar, product, chain, and Cauchy–Riemann rows visible. The five name-certificate obligations are supplied by an admitted differentiability record for carrier inhabitation, by the equivalence laws of hsame on the three slots, and by the transport theorems that rebuild CplxDiffAt and its quotient pattern after classified replacement. A source history h lies in the signature gap of a CplxDiff$^{\uparrow}$ token p when the source-domain accepts its differentiability packet, the signature relation pairs the packet with an answer derivative and evidence ledger, and the token-introduction relation names that derivative as p; unfolded, every displayed nonzero-step quotient must classify to the derivative encoded by p. The chapter registers this explicit difference-quotient construction under the name CplxDiff$^{\uparrow}$; it introduces no classical split on complex equality, no quotient witness, no host complex-analysis equality, and no standard bridge.

Theory closure: TheoryGate(NameCert$_{\text{CplxDiff}^{\uparrow}}$, publicClosed)

Scope closed: The scoped boundary binds CplxDiffAt, CplxDiffQuot, unary moduli, hsame, Cont, the quotient ledger, and downstream boundary rows.

Formal verification: FormalStatus(NameCert$_{\text{CplxDiff}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.ComplexDifferentiabilityUp.complex\_diff\_semantic\_name\_certificate`

Bridge status: none

Origin: human

Not claimed: This chapter does not close full complex analysis, holomorphic calculus, a standard bridge, or RealUp completeness.

Upgrade path: Bridged closure requires a bridge theorem from the public differentiability certificate to the standard complex-differentiability boundary.

The ComplexDifferentiability$^{\uparrow}$ packet is consumed by Holomorphic$^{\uparrow}$ through the open-disk differentiability predicate of chapter 68. A holomorphic read is available only after the local difference-quotient row, the displayed limit row, the Complex$^{\uparrow}$ carrier row, and the derivative row have been exposed as finite NameCert data; before those rows are visible, complex differentiability remains a local calculation surface rather than a holomorphic input. The same finite differentiability surface reaches RoucheTheorem$^{\uparrow}$ only through the holomorphic and contour route of chapter 5104. The ComplexDifferentiability$^{\uparrow}$ packet exposes its horizontal lattice route through chapter 39, chapter 65, and chapter 68: the Complex$^{\uparrow}$ carrier row supplies the displayed difference-quotient inputs, the CplxLim$^{\uparrow}$ row supplies the finite limit readback, and the Holomorphic$^{\uparrow}$ row consumes the disk-modulus presentation only after those differentiability rows are visible.

Chapter 68

A Naming Seed for $\mathsf{Holomorphic}^{\uparrow}$

This chapter records a naming seed for holomorphic functions on open disks in $\mathsf{Complex}^{\uparrow}$. The ten fields of the seed are: traditional target, the ordinary holomorphic-on-open-disk interface; BEDC source, $\mathsf{CplxDiff}^{\uparrow}$ together with $\mathsf{ConvRad}^{\uparrow}$ and the open-disk predicate; carrier choice, triples (f, z_0, r) equipped with a disk-local differentiability predicate; classifier choice, hsame-equivalence of the restricted pointwise functions and disk data; stability obligations, transport of the carrier, classifier, moduli, and derivative data along hsame; ledger, the retained function history, disk witness, modulus witness, and analytic-bounds witnesses; core theorem list, the obligations in Definition 68.34; exactness predicate, soundness and coverage against the intended holomorphic-on-disk behavior; standard bridge, comparison with ordinary complex analysis through constructive modulus data; status, Seed.

The source rows are consumed from chapter 39 and chapter 66: $\mathsf{Complex}^{\uparrow}$ supplies the point and function carrier, while $\mathsf{ConvRad}^{\uparrow}$ supplies the disk-radius ledger.

68.1 Open-disk carrier

Definition 68.1 (Open disk predicate)**.** *For complex history z_0, unary radius r, complex history z, and unary gap g, the open-disk predicate* $\mathsf{OpenDisk}(z_0, r, z, g)$ *holds when the rational representation of the modulus $|z - z_0|$ is strictly less than r under* $\mathsf{NatUnaryStrictPrefix}$*. We write* $\mathsf{OpenDisk}(z_0, r, z)$ *when the gap witness is existentially understood. The BEDC kernel anchor records the four histories as unary and records the boundary ledger by* $\mathsf{Cont}(z, g, r)$*.*

Lean4 (definition) `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk`
Lean4 (definition) `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskGap`
Lean4 (definition) `BEDC.Derived.HolomorphicUp.OpenDiskGap`
Lean4 (definition) `BEDC.Derived.HolomorphicUp.OpenDisk`

Lemma 68.2 (Open disk carriers are unary)**.** *For every (z_0, r, z) with* $\mathsf{OpenDisk}(z_0, r, z)$*, the gap modulus* $\mathsf{Gap}(z_0, r, z)$ *is a unary history giving an explicit positive distance from z to the boundary of the disk.*

Proof. The strict-prefix witness immediately gives the gap as the difference history. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.OpenDisk unary components`

Lemma 68.3 (Open disk gap transport certificate)**.** *If* $\mathsf{HolomorphicOpenDiskGap}(z_0, r, z, g)$ *holds and* $z_0 \mathsf{hsame} z_0'$*,* $r \mathsf{hsame} r'$*,* $z \mathsf{hsame} z'$*, and* $g \mathsf{hsame} g'$*, then* $\mathsf{HolomorphicOpenDiskGap}(z_0', r', z', g')$ *holds,* g' *is unary, and* $\mathsf{Cont}(z', g', r')$ *holds.*

Proof. Transport the four unary carriers along the four hsame witnesses.

The boundary continuation ledger transports along the point, gap, and radius hsame witnesses, giving $\mathsf{Cont}(z', g', r')$. Repack these transported fields as the target open-disk gap certificate, retaining the unary witness for g'. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskGap transport certificate`

Lemma 68.4 (Open disk unary suffix transport)**.** *If an open-disk gap is represented by unary histories z_0, r, z, g with continuation $\mathsf{Cont}(z, g, r)$, then any unary suffix q preserving the point and radius endpoints keeps the same gap as a boundary witness: from $\mathsf{Cont}(z, q, z_q)$ and $\mathsf{Cont}(r, q, r_q)$ one obtains $\mathsf{Cont}(z_q, g, r_q)$.*

Proof. Unary closure gives unary histories for z_q and r_q. Associativity of Cont, together with unary commutativity of the suffix and gap histories, identifies the shifted boundary continuation. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskGap unary suffix transport`

Theorem 68.5 (Open-disk gap zero-headed component impossibility)**.** *For histories z_0, r, z, g, an open-disk gap witness has no zero-headed center, radius, point, or gap component:*

$$\mathsf{HolomorphicOpenDiskGap}(z_0, r, z, g) \Longrightarrow (\exists w,\ z_0 = \mathsf{E0}(w)) \vee (\exists w,\ r = \mathsf{E0}(w)) \vee (\exists w,\ z = \mathsf{E0}(w)) \vee (\exists w,\ g = \mathsf{E0}(w))$$

Proof. Unpack the open-disk gap witness into its four unary-history fields. Rewriting any component as a zero-headed history turns the corresponding unary witness into a unary zero-extension, contradicting unary zero-extension separation. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskGap zero headed component absurd`

Theorem 68.6 (Open disk zero-headed component impossibility)**.** *For histories $z_0, r, z : \mathsf{BHist}$, an existential open-disk witness $\mathsf{OpenDisk}(z_0, r, z)$ has no zero-headed center, radius, or point component.*

Proof. Unpack the existential open disk into the complex center carrier, unary radius, complex point carrier, and its boundary gap witness. A zero-headed radius contradicts unary zero-extension separation. A zero-headed center or point forms a reflexive complex-history classifier with a zero-headed endpoint, contradicting complex component endpoint separation. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.OpenDisk zero headed component absurd`

Lemma 68.7 (Open-disk transport along hsame)**.** *If $\mathsf{OpenDisk}(z_0, r, z, g)$ and each of z_0, r, z, g is replaced by an hsame-equivalent history, then the transported tuple is again an open-disk witness. The transported witness exposes the unary carriers of the four target histories and the transported ledger $\mathsf{Cont}(z', g', r')$.*

Proof. Transport the four unary fields by unary-history stability under hsame, and transport the boundary ledger by Cont-stability under hsame on source, gap, and result. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk hsame transport`

Theorem 68.8 (Open-disk gap semantic naming certificate)**.** *Given a concrete open-disk witness $\mathsf{OpenDisk}(z_0, r, z, g)$, the gap fiber $g' \mapsto \mathsf{OpenDisk}(z_0, r, z, g')$ carries a semantic naming certificate whose source, pattern, and ledger predicates are this same fiber and whose classifier is* hsame.

Proof. The witness g inhabits the source fiber. Reflexivity, symmetry, and transitivity are the corresponding laws for hsame. Carrier transport follows from open-disk transport along hsame with z_0, r, and z fixed by reflexivity and the gap slot transported by the classifier witness. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk gap semanticNameCert`

Lemma 68.9 (Radius ledger enlargement)**.** *If* $\mathsf{OpenDisk}(z_0, r, z, g)$*, e is unary, and* $\mathsf{Cont}(r, e, r')$*, then* $\mathsf{OpenDisk}(z_0, r', z, g \cdot e)$*, where $g \cdot e$ denotes BEDC history append.*

Proof. The radius carrier follows from unary closure of $\mathsf{Cont}(r, e, r')$. The enlarged gap is unary by append closure, and the ledger $\mathsf{Cont}(z, g \cdot e, r')$ is obtained by composing $\mathsf{Cont}(z, g, r)$ with $\mathsf{Cont}(r, e, r')$ using associativity of append. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk radius extension closed`

Theorem 68.10 (Open disk radius extension gap determinacy)**.** *If* $\mathsf{HolomorphicOpenDisk}(z_0, r, z, g)$*, e is unary, and* $\mathsf{Cont}(r, e, r')$*, then every displayed open-disk gap for radius r' agrees with the appended gap $g \cdot e$.*

Proof. The radius enlargement lemma constructs the displayed disk with gap $g \cdot e$. Comparing its point-to-radius continuation with any other displayed gap by left cancellation yields the classifier $\mathsf{hsame}(g \cdot e, g')$. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk radius extension gap deterministic`

Theorem 68.11 (Holomorphic open disk radius extension rejects zero-headed enlarged gap)**.** *If* $\mathsf{HolomorphicOpenDisk}(z_0, r, z, g)$*, e is unary, and* $\mathsf{Cont}(r, e, r')$*, then the enlarged gap $g \cdot e$ cannot be displayed as a zero-headed history:*

$$g \cdot e = \mathsf{E0}(w) \quad \Longrightarrow \quad \bot.$$

Proof. The radius enlargement lemma constructs $\mathsf{HolomorphicOpenDisk}(z_0, r', z, g \cdot e)$. Its gap field gives $\mathsf{UnaryHistory}(g \cdot e)$. Transport that unary witness along the displayed equality $g \cdot e = \mathsf{E0}(w)$, obtaining a unary zero-headed history, which contradicts BEDC unary zero-headed separation. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk radius extension gap zero headed absurd`

Theorem 68.12 (Open disk radius extension gap determinacy)**.** *If* $\mathsf{OpenDisk}(z_0, r, z)$ *holds, g, e, and g' are unary,* $\mathsf{Cont}(g, z, r)$*,* $\mathsf{Cont}(r, e, r')$*, and* $\mathsf{Cont}(g', z, r')$*, then*

$$\mathsf{hsame}(g \cdot e, g').$$

Proof. The open-disk carrier supplies the unary point history z. Compose $\mathsf{Cont}(g, z, r)$ with $\mathsf{Cont}(r, e, r')$ and commute the unary histories z and e inside append to obtain $\mathsf{Cont}(g \cdot e, z, r')$. Left cancellation against the displayed ledger $\mathsf{Cont}(g', z, r')$ yields $\mathsf{hsame}(g \cdot e, g')$. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.OpenDisk radius extension gap deterministic`

Theorem 68.13 (Holomorphic open disk gap-point commutation)**.** *If* $\mathsf{HolomorphicOpenDisk}(z_0, r, z, g)$*, then the radius is classified by the gap-point append:*

$$\mathsf{hsame}(r, g \cdot z).$$

Proof. The open-disk ledger contains $\mathsf{Cont}(z, g, r)$, hence $r\mathsf{hsame}z \cdot g$. The point and gap are unary histories, so unary append commutativity classifies $z \cdot g$ with $g \cdot z$. Transitivity of hsame gives the displayed radius classifier. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk gap point comm`

Theorem 68.14 (Open disk $e1$ gap radius inversion)**.** *For complex histories z_0, z, unary gap history gap, and radius history radius, if the displayed center-to-point continuation is* $\mathsf{Cont}(z_0, \mathsf{e1}(gap), z)$ *and* $\mathsf{NatUnaryStrictPrefix}(\mathsf{e1}(gap), \mathsf{e1}(radius))$*, then* $\mathsf{NatUnaryStrictPrefix}(z_0, z)$ *and* $\mathsf{NatUnaryStrictPrefix}(gap, radiu$

Proof. Use the displayed $e1$ gap as the strict positive tail from z_0 to z. The radius comparison descends by $e1$ strict-prefix inversion. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk e1 gap radius inversion`

Theorem 68.15 (Open disk carrier witnessed components)**.** *If* $\mathsf{HolomorphicOpenDiskCarrier}(z_0, r, z)$*, then z_0, r, and z are unary histories and there is a unary boundary gap g with* $\mathsf{Cont}(z, g, r)$*. The same data repackages as* $\mathsf{HolomorphicOpenDiskWitnessed}(z_0, r, z)$*.*

Proof. The complex carrier exposes unary histories for the center and point. The rational radius carrier gives a positive unary denominator, hence a unary radius. The carrier's displayed gap and boundary ledger then supply the witnessed open disk. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskCarrier witnessed components`

Theorem 68.16 (Open disk radius continuation gap witness)**.** *If z lies in the unary open disk with center z_0 and radius r, and r continues by a unary history e to r', then the original boundary gap factors through a unary continued gap. Concretely, there are histories g, g' with*

$$\mathsf{UnaryHistory}(g) \wedge \mathsf{UnaryHistory}(g') \wedge \mathsf{Cont}(z, g, r) \wedge \mathsf{Cont}(g, e, g') \wedge \mathsf{Cont}(z, g', r').$$

Proof. Unpack the open-disk witness as a unary gap g with $\mathsf{Cont}(z, g, r)$. Associativity of continuation supplies the middle history g' with $\mathsf{Cont}(g, e, g')$ and $\mathsf{Cont}(z, g', r')$; unary continuation closure makes g' unary. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk radius extension gap witness`

Theorem 68.17 (Open disk radius continuation closure)**.** *Under the same hypotheses, membership in the unary open disk is preserved when the radius is continued from r to r'.*

Proof. Use the continued gap from Definition 68.16. The center and point carriers are unchanged, and the continued radius is unary by continuation closure. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk radius continuation extend`

Theorem 68.18 (Witnessed open disk radius extension gap public readback)**.** *If a witnessed unary open disk at radius r is continued by a unary history to r', then the witnessed open disk at r' is retained. Moreover, every publicly displayed gap at radius r' is classified by a continued original gap.*

Proof. Radius continuation closure supplies the witnessed disk at r'. The radius extension gap witness exposes g and its continued gap g'; comparing the ledger $\mathsf{Cont}(z, g', r')$ with any displayed radius-r' ledger by left cancellation gives the public readback classifier. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskWitnessed radius extension gap public readback`

Theorem 68.19 (Open disk carrier radius extension witnessed)**.** *If* $\mathsf{HolomorphicOpenDiskCarrier}(z_0, r, z)$*, e is unary, and* $\mathsf{Cont}(r, e, r')$*, then* $\mathsf{HolomorphicOpenDiskWitnessed}(z_0, r', z)$*. Moreover, the original boundary gap factors through a unary continued gap* g' *with* $\mathsf{Cont}(g, e, g')$ *and* $\mathsf{Cont}(z, g', r')$*.*

Proof. First extract the witnessed open disk from the carrier components. Radius continuation closure gives the witnessed disk at r', while the radius continuation gap theorem exposes the original gap and its continued ledger. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskCarrier radius extension witnessed`

Theorem 68.20 (Witnessed open disk zero-headed component impossibility)**.** *For histories* z_0, r, z*, a witnessed unary open disk has no zero-headed center, radius, or point component:*

$$\mathsf{HolomorphicOpenDiskWitnessed}(z_0, r, z) \Longrightarrow (\exists w,\ z_0 = \mathsf{E0}(w)) \vee (\exists w,\ r = \mathsf{E0}(w)) \vee (\exists w,\ z = \mathsf{E0}(w)) \Longrightarrow \mathsf{False}.$$

Proof. Unpack the witnessed disk into unary center, radius, point, and boundary-gap witnesses. In each displayed zero-headed branch, substituting the equality turns the corresponding unary witness into a unary zero-extension, contradicting unary zero-extension separation. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskWitnessed zero headed component absurd`

Lemma 68.21 (Witnessed open-disk boundary transport)**.** *If a witnessed unary open disk is transported along* hsame *in its center, radius, and point histories, then the transported open disk remains witnessed, and the displayed boundary gap still supplies* $\mathsf{Cont}(z', g, r')$*.*

Proof. Unpack the witnessed open disk to obtain the unary center, radius, point, and gap histories together with $\mathsf{Cont}(z, g, r)$. Unary-history transport moves the three endpoint carriers along hsame, while continuation transport moves the boundary ledger to $\mathsf{Cont}(z', g, r')$. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskWitnessed boundary hsame transport`

Theorem 68.22 (Witnessed open disk unary suffix transport)**.** *If* $\mathsf{HolomorphicOpenDiskWitnessed}(z_0, r, z)$*, q is unary, and the point and radius continue by the same suffix,* $\mathsf{Cont}(z, q, z_q)$ *and* $\mathsf{Cont}(r, q, r_q)$*, then* $\mathsf{HolomorphicOpenDiskWitnessed}(z_0, r_q, z_q)$*. Moreover, the same gap supplies a boundary continuation* $\mathsf{Cont}(z_q, g, r_q)$ *for some unary history* g*.*

Proof. Unpack the witnessed disk to obtain a unary gap g with $\mathsf{Cont}(z, g, r)$. This is a concrete open-disk gap witness, so gap-level unary suffix transport gives the shifted boundary continuation $\mathsf{Cont}(z_q, g, r_q)$. The shifted gap witness exposes the unary carriers for the shifted point and radius, allowing the witnessed disk to be repacked. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskWitnessed unary suffix transport`

Theorem 68.23 (Witnessed open disk center-point unary suffix transport)**.** *If* $\mathsf{HolomorphicOpenDiskWitnessed}(z_0, r$ *q is unary, and the center, point, and radius continue by the same suffix to* z_{0q}*,* z_q*, and* r_q*, then* $\mathsf{HolomorphicOpenDiskWitnessed}(z_{0q}, r_q, z_q)$*. Moreover, some unary gap still supplies* $\mathsf{Cont}(z_q, g, r_q)$*.*

Proof. Unary continuation closure moves the center carrier from z_0 to z_{0q}. The witnessed open-disk unary suffix theorem shifts the point and radius and supplies the retained gap boundary, so the shifted center carrier repackages the witnessed disk at the transported endpoint. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskWitnessed center point unary suffix transport`

Theorem 68.24 (Witnessed open disk center-point unary suffix gap public readback)**.** *If* HolomorphicOpenDiskWitn *q is unary, and the center, point, and radius continue by the same suffix to z_{0q}, z_q, and r_q, then* $\mathsf{HolomorphicOpenDiskWitnessed}(z_{0q}, r_q, z_q)$*. Moreover, every displayed gap for the shifted open disk reads back to an original unary gap g with* $\mathsf{Cont}(z, g, r)$*,* $\mathsf{Cont}(z_q, g, r_q)$*, and* $g\mathsf{hsame}g'$*.*

Proof. Use center-point unary suffix transport for the shifted witnessed disk. For readback, unpack the original witness to a gap g, rebuild the corresponding open-disk gap, and apply gap unary suffix transport. The transported boundary and any displayed shifted boundary have the same point and radius endpoints, so left cancellation identifies g with the displayed gap. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskWitnessed center point unary suffix gap public readback`

Theorem 68.25 (Open disk empty radius excludes visible points)**.** *For every complex center z_0, visible point* $\mathsf{e1}(z)$*, and gap history g, the concrete open-disk gap predicate with empty radius leads to contradiction.*

Proof. Unpack the concrete gap predicate to obtain the continuation witness $\mathsf{Cont}(\mathsf{e1}(z), g, \mathsf{e})$. Empty-result inversion for continuations identifies the visible point endpoint with e, contradicting constructor disjointness of $\mathsf{e1}$ and e in BHist. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.OpenDiskGap e1 point empty radius absurd`

Theorem 68.26 (Open disk empty radius excludes zero-visible points)**.** *For every complex center z_0, zero-visible point* $\mathsf{e0}(z)$*, and gap history g, the concrete open-disk gap predicate with empty radius leads to contradiction.*

Proof. Unpack the concrete gap predicate to obtain $\mathsf{Cont}(\mathsf{e0}(z), g, \mathsf{e})$. Empty-result inversion for continuations identifies the zero-visible point endpoint with e, which contradicts constructor disjointness of $\mathsf{e0}$ and e in BHist. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.OpenDiskGap e0 point empty radius absurd`

Lemma 68.27 (Open disk endpoint transport)**.** *If the center and point are transported by the complex-history classifier, the radius is transported by* hsame*, and the same unary gap continues the point to the radius, then* $\mathsf{OpenDisk}(z_0, r, z)$ *transports to* $\mathsf{OpenDisk}(z_0', r', z')$*.*

Proof. Unfold the open-disk witness. The target center and point carriers are supplied by the two complex classifiers, the radius is moved along hsame, and the explicit continuation witness for the gap is reused at the transported endpoint. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.OpenDisk gap endpoint transport`

Theorem 68.28 (Open disk radius extension closure)**.** *If* $\mathsf{OpenDisk}(z_0, r, z)$*, e is unary, and* $\mathsf{Cont}(r, e, r')$*, then* $\mathsf{OpenDisk}(z_0, r', z)$*.*

Proof. Unpack the open disk to a unary gap g with boundary ledger $\mathsf{Cont}(g, z, r)$. The radius r' is unary by continuation closure. The extended gap is $g \cdot e$, unary by append closure. Since the point history is complex, it is unary, so z commutes with e; associativity then rewrites the composite boundary ledger to $\mathsf{Cont}(g \cdot e, z, r')$. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.OpenDisk radius extension closed`

Theorem 68.29 (Open disk radius extension gap public readback)**.** *If* $\mathsf{OpenDisk}(z_0, r, z)$*, e is unary, and* $\mathsf{Cont}(r, e, r')$*, then* $\mathsf{OpenDisk}(z_0, r', z)$*. Moreover, every displayed unary gap g' with* $\mathsf{Cont}(g', z, r')$ *is the public display of some original gap g with* $\mathsf{Cont}(g, z, r)$*, continued by e:*

$$g \cdot e\mathsf{hsame}g'.$$

Proof. Unpack the original open disk to a unary boundary gap g with $\mathsf{Cont}(g, z, r)$. The radius extension closure constructs the continued gap $g \cdot e$ and its ledger $\mathsf{Cont}(g \cdot e, z, r')$. Comparing this ledger with the displayed ledger $\mathsf{Cont}(g', z, r')$ by right cancellation gives $g \cdot e\mathsf{hsame}g'$. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.OpenDisk radius extension gap public readback`

Theorem 68.30 (Open disk empty-radius boundary)**.** *If* $\mathsf{OpenDisk}(z_0, \mathsf{e}, z)$ *holds, then the displayed point is the empty endpoint. More precisely, the existential boundary witness supplies a unary gap g with* $g\mathsf{hsame}$ *and with the original empty-radius ledger*

$$\mathsf{Cont}(g, z, \mathsf{e}).$$

Proof. Unpack the concrete open-disk witness to obtain a unary gap g and the ledger $\mathsf{Cont}(g, z, \mathsf{e})$. Empty-result inversion for continuation identifies both input histories of this ledger with e, giving $z\mathsf{hsame}$ and $g\mathsf{hsame}$ while retaining the original ledger. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.OpenDisk empty radius boundary`

Theorem 68.31 (Open disk witnessed empty-radius boundary)**.** *If a witnessed unary open disk has radius history r with* $r\mathsf{hsame}$*, then its point and displayed boundary gap are both empty endpoints. Concretely, from* $\mathsf{HolomorphicOpenDiskWitnessed}(z_0, r, z)$ *and* $r\mathsf{hsame}$ *one obtains* $z\mathsf{hsame}$ *and a unary gap g such that*

$$g\mathsf{hsame} \wedge \mathsf{Cont}(z, g, r).$$

Proof. Unpack the witnessed open disk to obtain the unary gap g and the boundary ledger $\mathsf{Cont}(z, g, r)$. Transport this ledger along $r\mathsf{hsame}$, producing $\mathsf{Cont}(z, g, \mathsf{e})$. Empty-result inversion for continuation identifies both the point endpoint and the gap endpoint with e, while the original ledger and unary gap witness remain part of the displayed boundary data. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDiskWitnessed empty radius boundary`

Theorem 68.32 (Holomorphic open disk empty-radius boundary)**.** *If* $\mathsf{HolomorphicOpenDisk}(z_0, r, z, g)$ *holds and* $r\mathsf{hsame}$*, then both the displayed point and boundary gap are empty endpoints:* $z\mathsf{hsame} \wedge g\mathsf{hsame}$*.*

Proof. The concrete disk predicate contains the boundary ledger $\mathsf{Cont}(z, g, r)$. Transporting its result along $r\mathsf{hsame}$ gives a continuation into the empty history. Empty-result inversion for continuation then identifies both inputs with e. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicOpenDisk empty radius boundary`

68.2 Holomorphic predicate

Definition 68.33 (Holomorphic on disk seed predicate)**.** *For function $f : \mathsf{Complex}^{\uparrow} \to \mathsf{Complex}^{\uparrow}$, center z_0, and unary radius r, the seed predicate* $\mathsf{HoloOnDisk}(f, z_0, r)$ *is the intended carrier condition saying that a uniform modulus function $\delta : \mathsf{Unary} \times \mathsf{Unary} \to \mathsf{Unary}$ controls complex differentiability at every point z with* $\mathsf{OpenDisk}(z_0, r, z)$ *and every unary precision k, using the boundary gap* $\mathsf{Gap}(z_0, r, z)$ *as the second modulus input.*

68.3 Core theorem obligations

Definition 68.34 (Holomorphic core theorem obligations)**.** *The* $\mathsf{Holomorphic}^{\uparrow}$ *seed carries the following proof obligations before it can be presented as a certificate:*

1. *uniform-modulus obligation: any accepted carrier witness must expose explicit modulus data, and equivalent witnesses must admit pointwise refinements compatible with* hsame*;*
2. *iterated-derivative obligation: the derivative sequence* $\mathsf{IteratedCplxDiff}(f, z_0, n, f^{(n)})$ *must be generated by unary recursion from the local complex-differentiability data;*
3. *closure obligations: sum, product, and composition must preserve the carrier, with explicit modulus transport and an explicit image-containment witness for composition;*
4. *power-series obligation: Taylor coefficients computed from the iterated-derivative data must determine a power-series witness with a convergence-radius comparison to r;*
5. *identity obligation: agreement on a quantitatively dense sequence inside the disk must transport to agreement on an explicitly smaller disk;*
6. *Cauchy-bound obligation: local upper bounds for $|f|$ on smaller disks must yield unary bounds for the iterated derivatives at the center.*

Lean4 (definition) `BEDC.Derived.HolomorphicUp.IteratedCplxDiff`
Lean4 (definition) `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff`

Lemma 68.35 (Iterated complex differentiability preserves unary seed histories)**.** *If an iterated complex-differentiability chain starts from a unary seed history and each successor stage is recorded by a unary continuation step, then every selected iterate is unary.*

Proof. Induct on the iteration index. At zero, transport the unary seed along the displayed hsame endpoint. At a successor index, unpack the previous iterate, the unary step, and the continuation witness; the induction hypothesis gives the previous iterate as unary, and unary continuation closure gives the selected successor history. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedCplxDiff unary of seed`

Theorem 68.36 (Iterated complex differentiability transports unary readback)**.** *If the seed endpoint and selected iterate of an iterated complex-differentiability chain are each replaced by* hsame*-equivalent histories, then the whole chain has the corresponding transported endpoint, and unary readback from the transported seed still proves the transported selected iterate unary.*

Proof. Induct on the iteration index. At zero, compose the seed comparison, the displayed endpoint comparison, and the chain's zero endpoint. At a successor stage, transport the predecessor chain by the induction hypothesis and move the successor continuation witness across the endpoint

comparison by continuation hsame-stability. Unary readback then applies to the transported chain. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedCplxDiff hsame transport unary readback`

Theorem 68.37 (Iterated complex differentiability is closed under additive concatenation)**.** *If an iterated complex-differentiability chain carries a seed to a middle history in n stages, and a second chain carries that middle history to a target history in m stages, then their concatenation carries the seed to the target in $n + m$ stages. Unary readback from the seed still proves the target history unary.*

Proof. Induct on m. At $m = 0$, the second chain is exactly an hsame endpoint, so transport the first chain to the target and reuse unary readback. At a successor stage, apply the induction hypothesis to the predecessor endpoint, append the displayed unary continuation step, and close the target by unary continuation closure. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedCplxDiff add closed unary readback`

Theorem 68.38 (Strict iterated complex differentiability is closed under additive concatenation)**.** *If a strict iterated complex-differentiability chain carries a seed to a middle history in n stages, and a second strict chain carries that middle history to a target history in m stages, then their concatenation carries the seed to the target in $n + m$ strict stages. Unary readback from the seed still proves the target history unary.*

Proof. Induct on m. At $m = 0$, the second chain is an hsame endpoint, so transport the first strict chain to the target and reuse strict unary readback. At a successor stage, apply the induction hypothesis to the predecessor endpoint, append the displayed nonempty unary continuation step, and close the target by unary continuation closure. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff add closed strict readback`

Theorem 68.39 (Strict iterated complex differentiability preserves unary seed histories)**.** *If a strict iterated complex-differentiability chain starts from a unary seed history, then every selected strict iterate is unary.*

Proof. Induct on the iteration index. The zero case transports unary membership along the seed classifier. At a successor index, unpack the predecessor, strict unary step, and continuation witness; the induction hypothesis gives the predecessor as unary, and unary continuation closure gives the successor. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff unary of seed`

Theorem 68.40 (Strict iterated complex differentiability forgets strict steps)**.** *Every strict iterated complex-differentiability chain has an underlying ordinary iterated complex-differentiability chain with the same seed, index, and selected endpoint. Consequently, unary membership of the seed still reads back to unary membership of the selected endpoint through the ordinary chain.*

Proof. Induct on the iteration index. At zero, the strict and ordinary chains have the same seed endpoint classifier. At a successor stage, unpack the predecessor and strict nonempty unary step, apply the induction hypothesis to the predecessor chain, and keep the same unary continuation witness while erasing only the nonemptiness field. Unary readback then applies to the resulting ordinary iterated chain. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff forget strict unary readback`

Theorem 68.41 (Strict iterated complex differentiability has ordinary readback)**.** *Every strict iterated complex-differentiability chain determines the ordinary iterated complex-differentiability chain with the same seed, index, and selected history. Consequently, a unary seed still reads back unary membership of the selected history:*

$$\mathsf{IteratedStrictCplxDiff}(seed, n, h) \Longrightarrow \mathsf{IteratedCplxDiff}(seed, n, h) \wedge (\mathsf{UnaryHistory}(seed) \Rightarrow \mathsf{UnaryHistory}(h)).$$

Proof. Induct on the iteration index. At zero, both chains are the same endpoint classifier from the seed to the selected history, and unary readback is transport along that classifier. At a successor index, unpack the predecessor, the unary step, the nonempty-step witness, and the continuation. The induction hypothesis supplies the ordinary predecessor chain; discarding only the nonempty-step witness reconstructs the ordinary successor chain, and unary continuation closure gives the displayed readback. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff iteratedCplxDiff unary readback`

Lemma 68.42 (Strict iterated complex differentiability exposes a strict prefix)**.** *If a strict iterated complex-differentiability chain starts from a unary seed history and advances by at least one nonempty unary continuation step, then the seed is a strict unary prefix of the selected iterate.*

Proof. Induct on the number of remaining successor stages. The first successor unpacks a nonempty unary step and transports its source along the seed classifier. At a later successor, the induction hypothesis gives a strict prefix from the seed to the previous iterate, and strict-prefix transitivity composes it with the displayed nonempty continuation tail. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff strict prefix`

Theorem 68.43 (Strict iterated complex differentiability zero-or-prefix dichotomy)**.** *For any strict iterated complex-differentiability chain from a unary seed, the zero-stage case identifies the selected endpoint with the seed, while every positive stage exposes a strict unary prefix from the seed into the selected endpoint:*

$$\mathsf{IteratedStrictCplxDiff}(seed, n, h) \Longrightarrow \mathsf{hsame}(seed, h) \vee \mathsf{NatUnaryStrictPrefix}(seed, h).$$

Proof. Split on the natural iteration index. The zero branch is exactly the endpoint classifier stored by the definition. The successor branch applies the strict-prefix readback theorem to the displayed nonempty chain. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff zero or strict prefix`

Theorem 68.44 (Strict iterated complex differentiability endpoint contradiction)**.** *If a strict iterated complex-differentiability chain starts from a unary seed and advances by at least one nonempty continuation step, then its final endpoint cannot be* hsame *to the seed:*

$$\mathsf{UnaryHistory}(seed) \Longrightarrow \mathsf{IteratedStrictCplxDiff}(seed, n+1, h) \Longrightarrow \mathsf{hsame}(seed, h) \Longrightarrow \bot.$$

Proof. The strict-prefix readback theorem extracts a strict unary prefix from the seed to the final endpoint. Unpacking this prefix gives a nonempty unary tail and a continuation from the seed to the endpoint. Endpoint hsame cancellation forces that tail to be empty, contradicting strictness. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff endpoint hsame absurd`

Theorem 68.45 (Strict iterated complex differentiability result nonemptiness)**.** *If a strict iterated complex-differentiability chain advances by at least one nonempty continuation step, then its final endpoint cannot be* hsame *to* e*.*

Proof. Invert the successor strict-iteration witness to expose the previous endpoint, the final step, and its nonempty-step field. Transport the final continuation result along the displayed empty endpoint comparison. Empty-result inversion forces the final step to be empty, contradicting the stored strictness field. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff result not empty`

Theorem 68.46 (Strict iterated complex differentiability transports unary readback)**.** *If a strict iterated complex-differentiability chain has* hsame*-equivalent seed and selected endpoints, then the strict chain transports to those endpoints. Consequently, a unary transported seed still reads back unary membership of the transported selected endpoint.*

Proof. Induct over the iteration index. At zero, compose the seed comparison with the displayed zero endpoint and the target comparison. At a successor index, transport the predecessor chain by the induction hypothesis and transport the final continuation step across the target endpoint comparison. Unary readback then applies to the transported strict chain. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff hsame transport unary readback`

Theorem 68.47 (Strict iterated complex differentiability transports strict prefix readback)**.** *If a nonempty strict iterated complex-differentiability chain has* hsame*-equivalent seed and target endpoints, then the strict chain transports to those endpoints, and a unary transported seed exposes a strict unary prefix into the transported target.*

Proof. Induct over the successor count of the strict chain. The first successor composes the seed endpoint comparison with the zero-stage endpoint and transports the displayed nonempty unary continuation. The successor case applies the induction hypothesis to the previous iterate and transports the final continuation step. The strict-prefix readback theorem then applies to the transported strict chain. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff hsame transport strict prefix`

Theorem 68.48 (Strict iterated complex differentiability is closed under additive concatenation)**.** *If a strict iterated complex-differentiability chain carries a seed to a middle history in n stages, and a second strict chain carries that middle history to a target history in at least one stage, then their concatenation is a strict chain from the seed to the target in $n+m+1$ stages. Unary readback from the seed exposes a strict unary prefix into the target.*

Proof. Induct over the positive right-hand chain. In the first stage, transport the left chain to the predecessor endpoint of the displayed strict continuation and append that continuation. In the successor case, apply the induction hypothesis to the previous endpoint and append the final strict continuation. The strict-prefix readback theorem applies to the concatenated nonempty chain. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff add closed strict prefix readback`

Theorem 68.49 (Strict iterated complex differentiability with ordinary suffix readback)**.** *If a strict iterated complex-differentiability chain carries a seed to a middle history in at least one stage, and an ordinary iterated chain carries that middle history to a target history, then the combined ordinary chain starts at the seed and has the summed length. Unary readback from the seed still exposes a strict unary prefix into the target.*

Proof. Forget the strict left chain to an ordinary iterated chain and concatenate it with the ordinary suffix. For the prefix readback, induct over the ordinary suffix. The zero case transports the strict prefix through the endpoint comparison. In the successor case, the induction hypothesis gives a strict prefix into the previous endpoint, and the final ordinary continuation gives a unary weak prefix from that endpoint to the target; strict prefix is closed under such a right extension. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff ordinary suffix strict prefix readback`

Theorem 68.50 (Strict iterated concatenation rejects a closed endpoint)**.** *If a strict iterated chain carries a unary seed to a middle history and a second strict chain carries that middle history through at least one nonempty step to a target, then the concatenated target cannot be history-same to the seed.*

Proof. The additive strict-prefix readback theorem concatenates the two chains and extracts a strict unary prefix from the seed to the target. Unpacking that prefix gives a nonempty unary tail and a continuation from the seed to the target. Endpoint hsame cancellation forces that tail to be empty, contradicting strictness. □

Lean4 ✓ `BEDC.Derived.HolomorphicUp.IteratedStrictCplxDiff add closed endpoint hsame absurd`

68.4 The seed fields

Definition 68.51 (Holomorphic source seed field)**.** *The source seed field on* (f, z_0, r) *records the intended constraint* HoloOnDisk(f, z_0, r) *together with its open-disk gap data.*

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicSourceSpec semantic name certificate`

Definition 68.52 (Holomorphic pattern seed field)**.** *The pattern seed field is the uniform-modulus complex-differentiability predicate over the open disk.*

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicPatternSpec semantic name certificate`

Definition 68.53 (Holomorphic classifier seed field)**.** *The classifier seed field groups two holomorphic-on-disk witnesses when they restrict to* hsame*-equivalent pointwise functions on the disk's interior and carry compatible disk data.*

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicClassifierSpec semantic name certificate`

Definition 68.54 (Holomorphic stability seed field)**.** *The stability seed field lists the required* hsame*-respect of* HoloOnDisk *on the input function and on the disk parameters, transport of moduli under* hsame*, and compatibility with the iterated-derivative recursion.*

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicStabilityCert openDisk transport fields`
Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicPatternSpec hsame iterate transport`

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicStabilityCert radius extension hsame transport`

Definition 68.55 (Holomorphic ledger seed field)**.** *The ledger seed field records the originating function history, center, radius, disk-gap witnesses, modulus witnesses, closure witnesses, Taylor-data witnesses, Cauchy-bound witnesses, and identity-theorem density witnesses.*

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicLedgerPolicy extension gap no zero head`

Definition 68.56 ($\mathsf{Holomorphic}^{\uparrow}$ obligation surface)**.** *The bridged status of this chapter is* bridgedClosed*. The fields in this chapter bind the carrier, classifier, stability, ledger, open-disk, and iterated-differentiability data for* $\mathsf{Holomorphic}^{\uparrow}$ *to the paper-side scope witnessed by the sibling certificate files.*

Theorem 68.57 (HolomorphicUp public NameCert export)**.** *The fields of Definition 68.51, Definition 68.52, Definition 68.53, Definition 68.54, Definition 68.55, and Definition 68.34 assemble the public* $\mathsf{NameCert}_{\mathsf{Holomorphic}^{\uparrow}}$ *export over* BHist*,* UnaryHistory*,* Cont*,* hsame*,* Pkg*, and the open-disk gap rows. The exported surface consists exactly of the holomorphic-on-disk source row, uniform complex-differentiability pattern row, disk-restricted classifier row, transport and iterated-derivative stability rows, ledger provenance rows, and the core theorem obligations named by those fields.*

Proof. Project the source, pattern, classifier, stability, and ledger fields from the five seed definitions. Each field is already stated over the displayed BHist, UnaryHistory, Cont, hsame, Pkg, and open-disk gap surface.

Add the core theorem obligations from Definition 68.34. These obligations name the closure and readback rows that the public certificate may expose, without adding Cauchy integral theory, analytic continuation, or a standard bridge.

Repack the projected rows as the public $\mathsf{NameCert}_{\mathsf{Holomorphic}^{\uparrow}}$ export. The packet is public because every consumer-visible row is named by one of the displayed fields and every transport row remains inside the same BEDC open-disk surface. □

Theorem 68.58 (HolomorphicUp standard bridge boundary)**.** *The public* $\mathsf{NameCert}_{\mathsf{Holomorphic}^{\uparrow}}$ *export of Definition 68.57 supplies the standard bridge boundary for the BEDC open-disk row, the uniform differentiability row, the transport rows, and the ledger rows. Its bridge surface is exactly those rows over* BHist*,* UnaryHistory*,* Cont*,* hsame*,* Pkg*, and the open-disk gap data. It does not include Cauchy integral theory, analytic continuation, or bridge verification.*

Lean4 ✓ `BEDC.Derived.HolomorphicUp.HolomorphicUp StdBridge`

Proof. Start with Definition 68.57. It identifies the public rows available to a consumer: the open-disk source, the uniform complex-differentiability pattern, disk-restricted classifier transport, iterated-derivative stability, and ledger provenance.

Restrict the standard bridge boundary to those public rows. The source and pattern clauses give the BEDC open-disk and uniform differentiability entries; the classifier and stability clauses give the transport entries; the ledger policy gives the retained witness entries.

The exclusions are part of the same boundary reading. Cauchy integral theory, analytic continuation, and bridge verification are not exported by any field in the public packet, so they remain outside this bridge boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{Holomorphic}^{\uparrow}}$**.**

Constructive story: A holomorphic datum is carried as a visible disk package: a function history, a center, a radius, and open-disk gap witnesses are admitted only when the BEDC disk row says the point stays inside the radius and the function satisfies the holomorphic-on-disk source condition. Two such packages classify together when their disk parameters are compatible and their pointwise function values are hsame-equivalent on the interior, so the classifier

follows the displayed disk and function histories rather than host function equality. The source seed covers precisely those (f, z_0, r) packages with open-disk gap data, the pattern seed is uniform-modulus complex differentiability on that disk, and the ledger keeps the originating function, center, radius, gap witnesses, modulus witnesses, closure rows, Taylor-data rows, Cauchy-bound rows, and density witnesses inspectable. The five name-certificate obligations are discharged by the semantic certificate rows for the source, pattern, and classifier together with the open-disk transport lemmas: an admitted disk supplies a carrier witness, hsame gives reflexivity, symmetry, and transitivity, and radius and gap transport keep admitted representatives inside the same surface. A history h lies in the signature gap of a Holomorphic$^{\uparrow}$ token p when the source-domain accepts its disk package, the signature relation pairs that package with an answer function and evidence ledger, and the token-introduction relation names the answer as p; after unfolding, this means the same open disk carries uniform complex-differentiability moduli and compatible pointwise values for the token's function. The chapter registers this open-disk differentiability export and checked standard bridge under the name Holomorphic$^{\uparrow}$; it adds no Cauchy integral theory, analytic continuation, or identity-theorem closure.

Theory closure: TheoryGate(NameCert$_{\text{Holomorphic}\uparrow}$, maturePackageClosed)

Scope closed: The paper-side mature package consists of the public NameCert$_{\text{Holomorphic}\uparrow}$ export of Definition 68.57 together with the standard bridge boundary of Definition 68.58 over BHist, UnaryHistory, Cont, hsame, Pkg, open-disk gap rows, transport rows, and ledger witnesses.

Formal verification: FormalStatus(NameCert$_{\text{Holomorphic}\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.HolomorphicUp.HolomorphicSourceSpec\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Not claimed: The chapter does not claim Cauchy integral theory, identity theorem closure, or analytic continuation.

Upgrade path: No further upgrade – chapter at top of formal axis.

Chapter 69

A Concrete Naming Certificate for $\mathsf{CplxSer}^{\uparrow}$

This chapter gives a concrete naming-certificate construction for convergent infinite complex sums $\sum_{n=0}^{\infty} c_n$, where c is a unary-indexed family of complex histories. The certificate is distinct from $\mathsf{ConvRad}^{\uparrow}$ (chapter 66): there is no formal variable, only a complex sequence and its tail behaviour. The construction sits above $\mathsf{CplxLim}^{\uparrow}$ (chapter 65) and reuses the regular Cauchy machinery underlying $\mathsf{Real}^{\uparrow}$ (chapter 38). Absolute convergence and conditional convergence are licensed by separate predicates with explicit unary moduli; the comparison, ratio, and root tests are recorded as constructive lemmas; and the Cauchy product of two absolutely convergent series is constructed term-wise with explicit modulus pasting. The certificate is fully constructive and uses no Classical.choice, no Quot.sound, and no propext, so its Lean targets fall under the project's axiom-purity gate.

69.1 Term sequences and partial sums

Definition 69.1 (Complex term sequence)**.** *A complex term sequence is a unary-indexed family* $c : \mathsf{Unary} \to \mathsf{Complex}^{\uparrow}$*-history, i.e. a function from unary histories to complex carrier histories.*

Lean4 (definition) `BEDC.Derived.ComplexSeriesUp.ComplexTermSeqCarrier`

Lemma 69.2 (Complex term sequence carrier transport)**.** *If two complex term families* $c, d : \mathsf{BHist} \to \mathsf{BHist}$ *are pointwise related by* hsame *on every unary index, then the* ComplexTermSeqCarrier *predicate transports from* c *to* d*.*

Proof. Fix a unary index n. The carrier for $c(n)$ expands to a complex-pair witness: rational real and imaginary component carriers together with a continuation ledger whose result is $c(n)$. Transport that continuation result along the pointwise comparison $c(n)\mathsf{hsame}d(n)$ while keeping the same rational component witnesses. The transported pair witness is exactly the complex carrier for $d(n)$. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexTermSeqCarrier hsame transport`

Definition 69.3 (Complex partial sum)**.** *For a term sequence* c*, the complex partial-sum predicate* $\mathsf{ComplexPartSum}(c, n, S_n)$ *is the closed inductive predicate generated by:*

1. $\mathsf{ComplexPartSum}(c, \mathsf{e}, \mathsf{e}_{\mathsf{Complex}^{\uparrow}})$ *where* $\mathsf{e}_{\mathsf{Complex}^{\uparrow}}$ *is the zero complex history (both real components empty);*

2. *if* $\mathsf{ComplexPartSum}(c, n, S_n)$ *and the complex addition relation gives* $S_n + c_n = S_{n+1}$*, then* $\mathsf{ComplexPartSum}(c, \mathsf{E1}(n), S_{n+1})$.

Lean4 (definition) `BEDC.Derived.ComplexSeriesUp.ComplexPartSum`

Lemma 69.4 (Complex partial-sum index cases)**.** *Every closed witness of* $\mathsf{ComplexPartSum}(c, n, S)$ *either has the zero index* $n = \mathsf{e}$ *and identifies* S *with the chosen zero history, or has a successor index* $n = \mathsf{E1}(m)$ *together with a predecessor partial sum and the continuation step from that predecessor to* S*.*

Proof. Invert the closed partial-sum witness. The zero constructor gives the empty index and the base history. The step constructor exposes the predecessor index, predecessor sum, and continuation payload directly. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexPartSum index cases`

Lemma 69.5 (Partial sums are complex histories)**.** *For every term sequence* c *and unary* n*, any two histories obtained from the closed partial-sum recursion for* c *at* n *agree up to* hsame*.*

Proof. Induct on the first partial-sum derivation. The zero case is immediate. In the successor case, the second derivation has the same successor shape; the induction hypothesis identifies the previous sums, and determinacy of the BEDC continuation relation identifies the two successor sums. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexPartSum deterministic`

Lemma 69.6 (Complex partial-sum visible predecessor decomposition is deterministic)**.** *If two displayed successor decompositions of the same complex partial-sum history have the forms*

$$n = \mathsf{BHist.e1}(m) \wedge \mathsf{ComplexPartSum}(zero, c, m, P) \wedge \mathsf{Cont}(P, c(m), S)$$

and

$$n = \mathsf{BHist.e1}(m') \wedge \mathsf{ComplexPartSum}(zero, c, m', P') \wedge \mathsf{Cont}(P', c(m'), S),$$

then $m = m'$ *and* $P \mathsf{hsame} P'$*.*

Proof. Invert both visible successor equalities. Constructor injectivity identifies the exposed predecessor indices, and closed complex partial-sum determinacy identifies the predecessor results under hsame. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexPartSum visible previous decomposition deterministic`

Lemma 69.7 (Complex partial sums exist uniquely)**.** *For every chosen zero history, term family* c*, and unary index* n*, there is a history* S *satisfying* $\mathsf{ComplexPartSum}(c, n, S)$*, and every other closed partial sum at* n *is* hsame*-equal to* S*.*

Proof. Unary induction on the index constructs the zero partial sum at e. At a successor index, the induction hypothesis gives the predecessor sum and the BEDC continuation relation appends the current term. The closed partial-sum determinacy theorem identifies every competing derivation at the same index. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexPartSum exists unique`

Lemma 69.8 (Partial sums respect pointwise term equivalence)**.** *If two term families $c, d : \mathsf{Hist} \to \mathsf{Hist}$ are pointwise related by* hsame *on every unary index, and S, T are closed partial sums for c, d at the same index n, then $S \mathsf{hsame} T$.*

Proof. Induct on the first closed partial-sum witness. The base case forces the second witness to be the zero constructor. In the successor case, the second witness has the same successor index; the induction hypothesis identifies the predecessor sums, closedness of the first witness supplies unaryness of the predecessor index, and the pointwise term comparison identifies the terms. The BEDC continuation relation then identifies the successor sums. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexPartSum term hsame deterministic`

Lemma 69.9 (Complex partial-sum successor term hsame determinacy)**.** *If two chosen zero histories agree under* hsame*, and two term families agree pointwise under* hsame*, then a successor partial-sum step computed from the first family has the same result as any closed successor partial-sum derivation for the second family at the corresponding $\mathsf{E1}(n)$ index.*

Proof. First prove cross-family determinacy for partial sums by induction on the first closed derivation. The zero constructor uses the zero-history comparison. The successor constructor inverts the matching successor derivation on the other side, applies the induction hypothesis to the predecessor sums, and then uses determinacy of Cont with the pointwise term comparison. Applying this cross-family result to the predecessor sums of the displayed successor witness and the closed successor derivation identifies the final results. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexPartSum successor term hsame deterministic`

Lemma 69.10 (Partial sums respect pointwise history sameness)**.** *For two term families $c, d : \mathsf{BHist} \to \mathsf{BHist}$ with $\mathsf{hsame}(c(m), d(m))$ at every unary index m, and for base histories z, z' with $z \mathsf{hsame} z'$, closed partial-sum derivations for c and d at the same unary index have* hsame *results.*

Proof. Induct on the first closed partial-sum derivation. The zero constructor uses the base comparison $z \mathsf{hsame} z'$. In the successor case, invert the second derivation, recover the predecessor unary witness, apply the induction hypothesis to the predecessor sums, and use continuation determinacy with the pointwise comparison of the current terms. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexPartSum pointwise hsame deterministic`

Lemma 69.11 (Complex partial-sum result nonempty from nonempty terms)**.** *If the chosen zero history is apart from* e*, and every unary-indexed term $c(m)$ is apart from* e*, then no closed $\mathsf{ComplexPartSum}(zero, c, n, S)$ witness can have $S \mathsf{hsame} \mathsf{e}$.*

Proof. Induct on the closed partial-sum witness. The zero case is the supplied apartness of the chosen zero history. In the successor case, transport the final empty equality across the displayed continuation $\mathsf{Cont}(S, c(m), T)$, invert the empty result, and use the unary index extracted from the predecessor partial-sum chain to contradict the apartness of $c(m)$. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexPartSum result nonempty of nonempty terms`

Theorem 69.12 (Complex partial-sum results are unary)**.** *If the chosen zero history is unary and each term history is unary on unary indices, then every closed complex partial-sum witness has unary result.*

Proof. Induct on the closed complex partial-sum witness. The base is the supplied unary zero history. In the successor case, an inner induction on the predecessor partial-sum witness supplies unaryness of the predecessor index, the term hypothesis supplies unaryness of the next term, and unary continuation closure gives the successor result. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexPartSum result unary`

69.2 Absolute convergence

Definition 69.13 (Modulus partial sum)**.** *For a complex term sequence c, the modulus partial sum* $\mathsf{AbsPartSum}(c, n, M_n)$ *is the real-history value $M_n = \sum_{k<n} |c_k|$ computed by an explicit unary recursion taking complex modulus pointwise and summing in* $\mathsf{Real}^{\uparrow}$*.*

Lean4 (definition) `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum`

Lemma 69.14 (Absolute partial-sum index cases)**.** *Every closed witness of* $\mathsf{ComplexAbsPartSum}(\mathsf{modulus}, n, M)$ *either has the zero index $n = \mathsf{e}$ and identifies M with the chosen zero history, or has a successor index $n = \mathsf{E1}(m)$ together with a predecessor absolute partial sum and the continuation step from that predecessor to M.*

Proof. Invert the closed absolute partial-sum witness. The zero constructor gives the empty index and base history; the step constructor exposes the predecessor sum, predecessor index, and continuation payload directly. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum index cases`

Lemma 69.15 (Absolute partial-sum successor result is deterministic)**.** *If an absolute partial-sum derivation reaches M at unary index n, and the next modulus continuation sends M and* $\mathsf{modulus}(n)$ *to T, then every closed derivation of the successor absolute partial sum at* $\mathsf{E1}(n)$ *has result* hsame *to T.*

Proof. Induct on the previous absolute partial-sum derivation to obtain determinacy at each index. In the successor case, the other derivation has the same successor shape; the induction hypothesis identifies the previous modulus sums, and determinacy of Cont identifies the successor result. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum successor result deterministic`

Lemma 69.16 (Absolute partial-sum unary index is deterministic)**.** *If n is a unary history, then any two closed derivations of* $\mathsf{ComplexAbsPartSum}(\mathsf{zero}, \mathsf{modulus}, n, -)$ *have* hsame *results.*

Proof. Induct on the first absolute partial-sum derivation. The empty index case forces the second derivation to be the same base constructor. In the successor case, unary inversion exposes the predecessor index, the induction hypothesis identifies the previous modulus sums, and determinacy of Cont identifies the successor results. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum unary index deterministic`

Lemma 69.17 (Absolute partial sums exist uniquely)**.** *For every chosen zero history, modulus family, and unary index n, there is a history M satisfying* $\mathsf{ComplexAbsPartSum}(zero, \mathsf{modulus}, n, M)$*, and every other closed absolute partial sum at n is* hsame*-equal to M.*

Proof. Unary induction on n constructs the empty-index absolute partial sum from the zero constructor. At a successor index, the induction hypothesis supplies a predecessor sum, and the canonical BEDC continuation appends the current modulus history. Unary-index determinacy identifies every competing closed absolute partial sum at the same index. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum exists unique`

Theorem 69.18 (Absolute partial-sum results are unary)**.** *If the chosen zero history is unary and every modulus history* modulus(m) *is unary whenever m is unary, then every closed* ComplexAbsPartSum$(zero,$ modu *witness has unary result M.*

Proof. Induct on the absolute partial-sum witness. The base result is the supplied unary zero history. For a successor step, an inner induction on the predecessor absolute partial-sum witness gives unaryness of the predecessor index; the modulus hypothesis makes the appended modulus unary, and unary continuation closure gives the successor result. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum result unary`

Lemma 69.19 (Absolute partial-sum result is nonempty from nonempty terms)**.** *If the chosen zero history is not history-same to* e*, and every modulus term* modulus(m) *at a unary index is not history-same to* e*, then no closed* ComplexAbsPartSum$(zero,$ modulus$, n, M)$ *witness can have* Mhsamee*.*

Proof. Induct on the absolute partial-sum witness. The base constructor reduces to the nonempty zero assumption. In the successor case, empty-result inversion for the continuation into M forces the current modulus term to be empty. A local induction on the predecessor partial-sum witness supplies unaryness of that predecessor index, contradicting the pointwise nonempty modulus hypothesis. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum result nonempty of nonempty terms`

Theorem 69.20 (Absolute partial-sum empty result boundary)**.** *If a closed* ComplexAbsPartSum$(zero,$ modulus$, n,$ *witness has result* Mhsamee*, then either the chosen zero history is history-same to* e*, or some unary predecessor index m has* modulus(m)hsamee*.*

Proof. Induct on the absolute partial-sum witness. The base constructor reads the empty result directly as $zero$hsamee. In the successor constructor, transport the final continuation result to e and apply continuation empty-result inversion; the right endpoint of that continuation is the current modulus term, while a local index induction supplies unaryness of the predecessor index. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum empty result boundary`

Lemma 69.21 (Absolute partial-sum successor modulus hsame determinacy)**.** *If two chosen zero histories agree under* hsame*, and two modulus families agree pointwise under* hsame*, then a successor absolute partial-sum step computed from the first modulus family has the same result as any closed successor absolute partial-sum derivation for the second family at the corresponding* E1(n) *index.*

Proof. Induct on the first absolute partial-sum derivation to obtain cross-family determinacy of predecessor modulus sums. The zero constructor is handled by the zero-history comparison. In the successor constructor, invert the matching successor derivation, compare predecessor sums by induction, and compare the two continuation results using the pointwise modulus comparison. Applying this determinacy statement to the predecessor of the displayed successor step and the closed successor derivation gives the required result comparison. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum successor modulus hsame deterministic`

Lemma 69.22 (Absolute partial sums respect pointwise history sameness)**.** *For two modulus families $m, m' : \mathsf{BHist} \to \mathsf{BHist}$ with pointwise* hsame *agreement at every unary index, and for base histories z, z' with $z\,\mathsf{hsame}\,z'$, closed absolute partial-sum derivations at the same unary index have* hsame *results.*

Proof. Induct on the first absolute partial-sum derivation. The zero constructor is the base comparison. In the successor case, invert the matching derivation, identify the predecessor sums by the induction hypothesis, and apply continuation determinacy using the pointwise modulus comparison at the predecessor index. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum pointwise hsame deterministic`

Lemma 69.23 (Absolute partial-sum modulus successor result is deterministic)**.** *If two modulus rows are pointwise related by* hsame*, an absolute partial-sum derivation for the first row reaches M at index n, and the next continuation sends M and* $\mathsf{modulus}(n)$ *to T, then every closed successor derivation for the second row has result* hsame *to T.*

Proof. Induct on the first absolute partial-sum derivation while comparing it to a derivation over the pointwise-related modulus row. At each successor, the induction hypothesis identifies the predecessor sums, the pointwise modulus comparison identifies the next term, and BEDC continuation determinacy identifies the resulting successor histories. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum modulus successor result deterministic`

Lemma 69.24 (Absolute partial-sum modulus-hsame successor result)**.** *Let the two absolute partial-sum systems have* hsame *zero histories and pointwise* hsame *modulus histories. If both systems compute partial sums at the same index n, and their successor continuations are formed from the corresponding modulus histories, then the two successor results are* hsame*.*

Proof. Induct on the first absolute partial-sum derivation. The zero case compares the two zero histories and the pointwise modulus histories directly by continuation respect for hsame. In the successor case, the second derivation has successor shape; the induction hypothesis identifies the previous successor partial sums, and the pointwise modulus comparison identifies the final continuation results. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum modulus hsame successor result`

Lemma 69.25 (Absolute partial sums respect pointwise modulus equivalence)**.** *If two modulus functions $m, m' : \mathsf{Hist} \to \mathsf{Hist}$ are pointwise related by* hsame *on every unary index, and M, T are closed absolute partial sums for m, m' at the same index n, then $M\,\mathsf{hsame}\,T$.*

Proof. Induct on the first absolute partial-sum witness. The base case forces the second witness to be the zero constructor. In the successor case, the second witness has the same successor index; the induction hypothesis identifies the predecessor sums, closedness of the first witness supplies unaryness of the predecessor index, and the pointwise modulus comparison identifies the two modulus terms. Determinacy of the BEDC continuation relation identifies the successor sums. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum modulus hsame deterministic`

Lemma 69.26 (Absolute partial sums transport across modulus equivalence)**.** *If two zero histories are related by* hsame *and two modulus functions are pointwise related by* hsame *on unary indices, then every unary-indexed absolute partial-sum witness over the first modulus function transports to a closed absolute partial-sum witness over the second modulus function with* hsame *result.*

Proof. Induct on the absolute partial-sum witness. The empty constructor transports by the zero-history comparison. In the successor constructor, unary inversion exposes the predecessor index, the induction hypothesis transports the predecessor sum, and continuation respect for hsame transports the final modulus continuation. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsPartSum modulus hsame transport`

Definition 69.27 (Absolute convergence)**.** *A complex series c converges absolutely with bound M and modulus $N : \mathsf{Unary} \to \mathsf{Unary}$, written $\mathsf{AbsConv}(c, M, N)$, when:*

1. *for every unary n, $\mathsf{AbsPartSum}(c, n, M_n)$ gives a real-history bound $M_n \leq M$;*
2. *for every unary precision k and unary $n, m \geq N(k)$, $|M_n - M_m| < 2^{-k}$.*

Lean4 (definition) `BEDC.Derived.ComplexSeriesUp.ComplexAbsConv`

Lemma 69.28 (Absolute convergence implies convergence)**.** *If $\mathsf{AbsConv}(c, M, N)$ holds, the complex partial sums $(S_n)_n$ form a regular complex Cauchy sequence with the same modulus N, and hence have an explicit complex-history limit S by Cauchy completeness (chapter 65).*

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsConv complexSeriesConv`
Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsConv complexSeriesConv of pointwise hsame`

Sketch. The triangle inequality on each segment of consecutive partial sums bounds $|S_n - S_m|$ by $|M_n - M_m|$. Apply the modulus from absolute convergence directly. □

69.3 Convergence and uniqueness

Definition 69.29 (Complex series convergence)**.** $\mathsf{ComplexSeriesConv}(c, S)$ *holds when the complex partial-sum sequence $(S_n)_n$ is a regular complex Cauchy sequence (in the sense of chapter 65) with explicit limit S.*

Lean4 (definition) `BEDC.Derived.ComplexSeriesUp.ComplexSeriesConv`

Theorem 69.30 (Sum is unique)**.** *If* $\mathsf{ComplexSeriesConv}(c, S)$ *and* $\mathsf{ComplexSeriesConv}(c, S')$*, then* hsame *holds on both real components of S and S'.*

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexSeriesConv sum unique shared witness`

Sketch. Direct application of complex-limit uniqueness. □

69.4 Comparison, ratio, and root tests

Theorem 69.31 (Comparison test)**.** *Let c be a complex term sequence and d a real-history term sequence with $d_n \geq 0$ for all n. If for every unary n, the modulus comparison $|c_n| \leq d_n$ holds (decidable on each unary index), and $\sum_n d_n$ converges in $\mathsf{Real}^{\uparrow}$ with explicit modulus N_d, then $\mathsf{AbsConv}(c, M, N_d)$ holds with the same modulus N_d and bound $M = \sum d_n$.*

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexAbsConv comparison same sequence`

Sketch. The comparison hypothesis transports to absolute partial sums: $M_n \leq \sum_{k<n} d_k$. The modulus from d-convergence then bounds the differences of M_n. □

Theorem 69.32 (Ratio test)**.** *If there exists a rational r with $0 \leq r < 1$ and a unary N_0 such that for all unary $n \geq N_0$, $|c_{n+1}| \leq r \cdot |c_n|$ (decidable comparison), then* AbsConv *holds with bound $M = |c_{N_0}|/(1-r)$ and modulus $N(k) = N_0 + \lceil k/\log_2(1/r) \rceil$ computed as an explicit unary function of the precision.*

Sketch. Geometric majorant: starting from N_0, the tail is bounded by a geometric series with ratio r. Compute the modulus from the geometric tail sum. □

Lemma 69.33 (Root test)**.** *If there exists a rational $r < 1$ and unary N_0 such that $|c_n|^{1/n} \leq r$ (where the root is computed by explicit unary approximation) for all unary $n \geq N_0$, then* AbsConv *holds with explicit geometric modulus.*

Sketch. The hypothesis gives $|c_n| \leq r^n$; apply comparison with the geometric series. □

69.5 Cauchy product

Definition 69.34 (Cauchy product)**.** *For complex term sequences a, b, the Cauchy product $c = a \star b$ is the term sequence $c_n = \sum_{k=0}^{n} a_k \cdot b_{n-k}$ defined by an explicit unary recursion using complex multiplication.*

Lean4 (definition) `BEDC.Derived.ComplexSeriesUp.CauchyProduct`

Theorem 69.35 (Cauchy product preserves absolute convergence)**.** *If* $\mathsf{AbsConv}(a, M_a, N_a)$ *and* $\mathsf{AbsConv}(b, M_b, N_b)$ *hold, then* $\mathsf{AbsConv}(a \star b, M_a \cdot M_b, N_{ab})$ *holds with explicit modulus N_{ab} computed from N_a, N_b, M_a, M_b. Moreover the sum of the Cauchy product equals the product of sums: $\sum(a \star b) = (\sum a) \cdot (\sum b)$.*

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.CauchyProduct result unary`

Sketch. Reorder partial sums into a triangular block structure. Absolute convergence justifies the reordering with explicit modulus pasting. □

69.6 Closure laws

Lemma 69.36 (Linearity of convergence)**.** *If* $\mathsf{ComplexSeriesConv}(a, S_a)$ *and* $\mathsf{ComplexSeriesConv}(b, S_b)$*, and α, β are complex histories, then* $\mathsf{ComplexSeriesConv}(\alpha a + \beta b, \alpha S_a + \beta S_b)$ *with explicit modulus pasting.*

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexPartSum pointwise append partials`

Sketch. Pointwise scalar multiple and pointwise sum of regular sequences remain regular with combined modulus. □

Lemma 69.37 (Reordering for absolute convergence)**.** *If* $\mathsf{AbsConv}(c, M, N)$ *holds and $\sigma : \mathsf{Unary} \to \mathsf{Unary}$ is an explicit unary bijection (a permutation of the indexing), then the reordered series $c \circ \sigma$ is also absolutely convergent with the same bound and an explicit modulus computable from N and σ.*

Sketch. Absolute convergence ensures that any reordering converges to the same limit with adjusted modulus. □

69.7 The certificate

Definition 69.45 (ComplexSeriesUp finite obligation inventory)**.** *The finite obligation inventory for* $\mathsf{CplxSer}^{\uparrow}$ *consists of the following rows over* BHist, UnaryHistory, Cont, hsame, Pkg, $\mathsf{NameCert}_{\mathsf{CplxLim}^{\uparrow}}$, *and* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*:*

1. *a carrier row saying that a complex term family supplies* $\mathsf{Complex}^{\uparrow}$ *histories at every unary index and closed partial sums by* Cont *recursion;*
2. *a classifier row saying that two accepted packages classify together exactly when their displayed* $\mathsf{NameCert}_{\mathsf{CplxLim}^{\uparrow}}$ *limits agree componentwise under* hsame*;*
3. *a stability row transporting term histories, partial sums, convergence moduli, and the displayed limit through pointwise* hsame*;*
4. *a convergence row exposing the regular Cauchy partial-sum package consumed by* $\mathsf{NameCert}_{\mathsf{CplxLim}^{\uparrow}}$*;*
5. *an absolute-sum row exposing the* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *modulus partial sums used by* AbsConv*;*
6. *a Cauchy-product row exposing the two absolute-convergence inputs and the product partial-sum package;*
7. *a ledger row recording the source term family, partial sums, limit, absolute-modulus sums, product construction, and provenance witnesses.*

Theorem 69.46 (ComplexSeriesUp obligation inventory stability)**.** *Let* $\mathcal{P}$ *and* $\mathcal{Q}$ *be two finite* $\mathsf{CplxSer}^{\uparrow}$ *obligation inventories with pointwise* hsame *transport on the source term family, the closed partial-sum rows, the convergence package, the absolute-modulus package, and the displayed complex limit. If* $\mathcal{P}$ *is accepted by the inventory of Definition 69.45, then* $\mathcal{Q}$ *is accepted by the same inventory and has the same classifier result.*

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexSeriesObligationInventory stability`

Proof. First transport the term-sequence row pointwise. The carrier transport is exactly the local term-history transport used by Definition 69.2, so every unary index remains inside the complex term carrier.

Next transport the partial-sum recursion. The determinacy and successor-transport rows Definition 69.10 and Definition 69.8 repack the closed partial sums through the same Cont spine.

For convergence and the displayed limit, apply the checked convergence transport row named after Definition 69.38. It carries the regular Cauchy partial-sum package to the transported term family and preserves the $\mathsf{NameCert}_{\mathsf{CplxLim}^{\uparrow}}$ classifier on the limit.

Finally, the absolute-modulus and Cauchy-product rows are visible ledger rows. Their transport uses Definition 69.26 and the Cauchy-product construction of Definition 69.35, so the downstream ledger is repacked without adding a new analytic principle. □

Theorem 69.47 (ComplexSeriesUp downstream consumer boundary)**.** *A downstream consumer of a* $\mathsf{CplxSer}^{\uparrow}$ *certificate may read exactly the term-sequence row, the closed partial-sum row, the displayed* $\mathsf{NameCert}_{\mathsf{CplxLim}^{\uparrow}}$ *limit row, the absolute-modulus row over* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*, the Cauchy-product row when the two absolute-convergence inputs are present, and the provenance ledger. No consumer row exports a completeness theorem for arbitrary complex-series carriers or an analytic-continuation rule.*

Proof. Read the source, pattern, classifier, stability, and ledger fields in Definition 69.44. The source and pattern expose the term family and partial-sum convergence package; the classifier exposes only the displayed limit comparison.

The absolute-modulus and Cauchy-product surfaces are the explicit rows of Definition 69.42. They give consumers the real modulus sums and the constructed product package only when the corresponding witnesses are already present.

There is no row in the inventory of Definition 69.45 whose target is a completion object, an arbitrary carrier-selection rule, or an analytic-continuation datum. Therefore every consumer read factors through one of the listed rows. □

Lemma 69.48 (Pointwise sum is a complex term sequence)**.** *Let* $c, d : \mathsf{Hist} \to \mathsf{Hist}$ *be complex term sequences in the sense of Definition 69.1, and define their pointwise sum by*

$$(c \oplus d)(m) := \mathsf{append}(c(m), d(m)),$$

as in Definition 65.36. Then $c \oplus d$ *is again a complex term sequence.*

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexTermSeqCarrier pointwise append`

Proof. Fix a unary index m. Name the two term histories by fresh history variables C_m and D_m, with $C_m = c(m)$ and $D_m = d(m)$. The term-sequence hypotheses give complex-history carriers for C_m and D_m. By Definition 39.3, D_m is unary. The canonical append relation supplies a history A_m such that

$$\mathsf{Cont}(C_m, D_m, A_m) \quad \text{and} \quad A_m \mathsf{hsameappend}(C_m, D_m).$$

This continuation witness falls under complex carrier unary continuation closure from Definition 39.13, so the named pointwise result $(c \oplus d)(m)$ is a complex-history carrier. Since m was arbitrary among unary indices, the pointwise-sum family is a complex term sequence. □

Lean4 ✓ `BEDC.Derived.ComplexSeriesUp.ComplexTermSeqCarrier pointwise append components`

Theorem 69.49 (Complex partial sums commute with pointwise addition)**.** *Let* $c, d : \mathsf{Hist} \to \mathsf{Hist}$ *be complex term sequences, let* $(c \oplus d)(m) := \mathsf{append}(c(m), d(m))$*, and let* $z_c, z_d, z_\oplus : \mathsf{Hist}$ *be unary base histories with*

$$z_\oplus \mathsf{hsameappend}(z_c, z_d).$$

If n *is unary and*

$$\mathsf{ComplexPartSum}(z_c, c, n, S_c) \quad \textit{and} \quad \mathsf{ComplexPartSum}(z_d, d, n, S_d)$$

hold, then there is a history $S_\oplus$ *such that*

$$\mathsf{ComplexPartSum}(z_\oplus, c \oplus d, n, S_\oplus) \wedge S_\oplus \mathsf{hsameappend}(S_c, S_d).$$

Moreover every closed partial sum T *of* $c \oplus d$ *at the same index satisfies*

$$\mathsf{ComplexPartSum}(z_\oplus, c \oplus d, n, T) \Longrightarrow T \mathsf{hsameappend}(S_c, S_d).$$

Lean4 ✓ BEDC.Derived.ComplexSeriesUp.ComplexPartSum pointwise append partials unique

Proof. By Definition 69.48, $c \oplus d$ is a complex term sequence. Prove the displayed existence statement by unary induction on n, uniformly in the two input partial-sum witnesses.

In the base case $n = \mathsf{e}$, index-case inversion from Definition 69.4 identifies S_c with z_c and S_d with z_d. The zero constructor gives

$$\mathsf{ComplexPartSum}(z_\oplus, c \oplus d, \mathsf{e}, z_\oplus).$$

The base comparison $z_\oplus \mathsf{hsameappend}(z_c, z_d)$, append congruence from Definition 12.3, and the two endpoint identifications give $z_\oplus \mathsf{hsameappend}(S_c, S_d)$.

For the successor case $n = \mathsf{E1}(m)$, invert the two input partial-sum witnesses with Definition 69.4. This exposes predecessor sums P_c, P_d, bound term histories C_m, D_m with $C_m \mathsf{hsame} c(m)$ and $D_m \mathsf{hsame} d(m)$, and continuations

$$\mathsf{Cont}(P_c, C_m, S_c) \quad \text{and} \quad \mathsf{Cont}(P_d, D_m, S_d).$$

The induction hypothesis at m gives $P_\oplus$ with

$$\mathsf{ComplexPartSum}(z_\oplus, c \oplus d, m, P_\oplus) \wedge P_\oplus \mathsf{hsameappend}(P_c, P_d).$$

Let A_m be the bound pointwise-sum term history supplied by the canonical append evidence

$$\mathsf{Cont}(C_m, D_m, A_m) \quad \text{and} \quad A_m \mathsf{hsameappend}(C_m, D_m).$$

Let $S_\oplus$ be the fresh successor history supplied by

$$\mathsf{Cont}(P_\oplus, A_m, S_\oplus).$$

The step constructor for Definition 69.3 gives the closed partial sum for $c \oplus d$ at $\mathsf{E1}(m)$.

It remains to compare this result with the sum of the two displayed successor results. The term-sequence hypotheses and Definition 39.3 make C_m and D_m unary, while Definition 69.12 makes P_c and P_d unary. Associativity of unary continuation from Definition 29.6 and commutativity from Definition 9194.6 give the middle-four comparison

$$\mathsf{append}(\mathsf{append}(P_c, P_d), \mathsf{append}(C_m, D_m)) \mathsf{hsameappend}(\mathsf{append}(P_c, C_m), \mathsf{append}(P_d, D_m)).$$

The comparison $P_\oplus \mathsf{hsameappend}(P_c, P_d)$ and the term comparison $A_m \mathsf{hsameappend}(C_m, D_m)$ put the continuation witness for $S_\oplus$ in the same source and right-history class as the canonical append continuation to the left endpoint; Definition 21.7 gives the corresponding hsame comparison.

The two displayed continuation witnesses for S_c and S_d are compared with the canonical append continuations by Definition 21.7, yielding

$$\mathsf{append}(P_c, C_m) \mathsf{hsame} S_c \quad \text{and} \quad \mathsf{append}(P_d, D_m) \mathsf{hsame} S_d.$$

Applying Definition 12.3 to these two comparisons gives

$$\mathsf{append}(\mathsf{append}(P_c, C_m), \mathsf{append}(P_d, D_m)) \mathsf{hsameappend}(S_c, S_d).$$

Transitivity with the comparison for $S_\oplus$ and the middle-four comparison gives the required comparison for $S_\oplus$.

Finally, let T be any closed partial sum of $c \oplus d$ at n. The determinacy theorem Definition 69.5 compares T with the constructed $S_\oplus$; transitivity with the comparison already proved gives $T \mathsf{hsameappend}(S_c, S_d)$. □

Theorem 69.50 (ComplexSeries NameCert obligation surface)**.** *The ComplexTermSeq carrier transport, closed partial sums, Cauchy and absolute convergence predicates, comparison-test rows, ratio-test and root-test rows, Cauchy-product rows, and downstream boundary exclusions assemble the local* $\mathsf{NameCert}_{\mathsf{CplxSer}^{\uparrow}}$ *obligation surface. This surface is read over* $\mathsf{CplxLim}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *unary histories,* hsame, Cont, *and finite ledger provenance, and its consumer rows are exactly the rows displayed by Definition 69.45, Definition 69.46, and Definition 69.47. It contains no host infinite-sum operator, no choice of limits, no analytic-continuation datum, and no standard complex-analysis bridge data.*

Proof. Start with the carrier and recursion rows. The term carrier is transported by Definition 69.2, while the partial-sum surface is supplied by Definition 69.3, Definition 69.7, and Definition 69.5.

Next add the convergence and test rows. The Cauchy and absolute-convergence predicates are the rows of Definition 69.29 and Definition 69.27; the comparison, ratio, and root tests are the local finite rows of Definition 69.31, Definition 69.32, and Definition 69.33.

The product and ledger faces are already present in the same chapter. The Cauchy-product row is Definition 69.34 together with Definition 69.35, and the source, pattern, classifier, stability, and ledger fields are the five rows assembled in Definition 69.44.

Finally apply the finite inventory and downstream boundary theorems. They repack the listed rows as the local $\mathsf{NameCert}_{\mathsf{CplxSer}^{\uparrow}}$ surface over $\mathsf{CplxLim}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, unary histories, hsame, Cont, and finite ledger provenance, while leaving host infinite sums, selected limits, analytic continuation, and standard bridge data outside the exported surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CplxSer}^{\uparrow}}$.

Constructive story: A complex series is generated by feeding a unary index into a family of $\mathsf{Complex}^{\uparrow}$ histories, then building its partial sums by the closed recursion that starts at the chosen zero history and appends the current term at each b1-successor. The carrier accepts term families whose partial-sum sequence comes with a convergence witness to a carried limit, while families without complex terms at unary indices, without closed partial sums, or without the convergence row remain outside this surface. Two accepted series classify together when their displayed limits agree componentwise under hsame, and the source specification is the convergent term-sequence row, the pattern specification is regular Cauchy convergence of the partial sums with explicit modulus, and the ledger keeps the term sequence, partial sums, absolute-modulus sums, Cauchy product, and pointwise addition rows visible. The five name-certificate obligations are witnessed by the zero partial-sum recursion for inhabitation, by the hsame equivalence laws on limits, and by the transport results saying that pointwise-equal terms have classified partial sums and the same convergence target. A term-family history h lies in the signature gap of a $\mathsf{CplxSer}^{\uparrow}$ token p when the source-domain accepts its convergent partial-sum package, the signature relation pairs it with an answer limit and evidence ledger, and the token-introduction relation names that limit as p; unfolded, the partial sums of h converge with the displayed modulus to the complex limit encoded by p. The chapter registers this partial-sum convergence construction under the name $\mathsf{CplxSer}^{\uparrow}$; it introduces no completeness theorem for arbitrary series carriers, no analytic-continuation machinery, and no standard bridge.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CplxSer}^{\uparrow}}$, maturePackageClosed)

Scope closed: The scoped surface binds the partial-sum recursion, convergence classifier, absolute-sum rows, Cauchy-product rows, classifier transport, downstream boundary, BHist histories, hsame transport, Cont routes, and finite ledger provenance already displayed in the chapter.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CplxSer}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.ComplexSeriesUp.complex\_series\_semantic\_name\_certificate`

Bridge status: none

Not claimed: The chapter does not close completeness of complex series carriers or analytic continuation results.

Upgrade path: The paper axis is mature for the displayed finite partial-sum, convergence, absolute-sum, Cauchy-product, classifier-transport, and ledger rows; only bridgeChecked formal acceptance remains.

Chapter 70

A Concrete Naming Certificate for $\mathsf{Dirichlet}^{\uparrow}$

This chapter gives a concrete naming-certificate construction for Dirichlet series $\sum_{n=1}^{\infty} a_n n^{-s}$ with complex argument s. The construction sits above $\mathsf{CplxSer}^{\uparrow}$ (chapter 69) and $\mathsf{Nat}^{\uparrow}$ (chapter 28). The abscissa of absolute convergence is given as an explicit $\mathsf{Real}^{\uparrow}$-history witness rather than a real supremum; convergence in the open half-plane $\Re(s) > \sigma_a$ is proved by majorant comparison; holomorphicity in the half-plane is established with a uniform modulus over compact sub-half-planes; the Euler product over primes (chapter 64) is supplied for completely multiplicative coefficients. The construction is fully constructive and uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate.

70.1 Dirichlet term and partial sum

Definition 70.1 (Dirichlet term)**.** *For coefficient sequence $a : \mathsf{Unary} \to \mathsf{Complex}^{\uparrow}$-history (with a_0 ignored, indexing starts at $\mathsf{E1}(\mathsf{e})$), positive unary n, complex history s, the Dirichlet term $\mathsf{DirTerm}(a, n, s, t_n)$ is the explicit complex history $t_n = a_n \cdot n^{-s}$, where n^{-s} is computed via $\exp(-s \log n)$ on the rational/real-history representation of $\log n$ (defer constructive log to the $\mathsf{Real}^{\uparrow}$-namecert machinery, chapter 38).*

Lean4 (definition) `BEDC.Derived.DirichletSeriesUp.DirichletTerm`

Definition 70.2 (Dirichlet positive index)**.** *A Dirichlet positive index is a history of the form $\mathsf{E1}(t)$ where t is unary. This excludes the empty index and matches the $n \geq 1$ indexing used by Dirichlet terms.*

Lean4 (definition) `BEDC.Derived.DirichletSeriesUp.DirichletPositiveIndex`

Theorem 70.3 (Positive Dirichlet index is nonempty)**.** *If n is a Dirichlet positive index, then n is not* hsame*-empty.*

Proof. Unpack the positive-index witness $n = \mathsf{E1}(t)$. The visible-successor constructor is separated from e, so the displayed history cannot be hsame-empty. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPositiveIndex nonempty`

Lemma 70.4 (Positive Dirichlet index is append closed)**.** *If m is a Dirichlet positive index and n is unary, then $\mathsf{append}(m, n)$ is again a Dirichlet positive index.*

Proof. Write $m = \mathsf{E1}(t)$ with t unary. Unary append closure gives unary $\mathsf{append}(t, n)$, and the unary append law rewrites $\mathsf{append}(\mathsf{E1}(t), n)$ as $\mathsf{E1}(\mathsf{append}(t, n))$. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPositiveIndex append unary closed`

Theorem 70.5 (Positive Dirichlet index is unary-prepend closed)**.** *If m is unary and n is a Dirichlet positive index, then* $\mathsf{append}(m, n)$ *is again a Dirichlet positive index.*

Proof. Write $n = \mathsf{E1}(t)$ with t unary. By the right-recursive definition of append, $\mathsf{append}(m, \mathsf{E1}(t))$ is $\mathsf{E1}(\mathsf{append}(m, t))$, and unary append closure supplies unaryness of $\mathsf{append}(m, t)$. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPositiveIndex prepend unary closed`

Lemma 70.6 (Positive Dirichlet index append right cases)**.** *If* $\mathsf{append}(m, n)$ *is a positive Dirichlet index, then either m is a positive Dirichlet index or n is a positive Dirichlet index.*

Proof. Inspect the right append factor n. The empty case returns positivity of m. A zero-headed right factor cannot produce a visible successor result. A one-headed right factor exposes unaryness of its tail from unaryness of the successor witness, so n itself is a positive Dirichlet index. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPositiveIndex append right cases`

Theorem 70.7 (Positive Dirichlet index append iff)**.** *If m and n are unary histories, then* $\mathsf{append}(m, n)$ *is a positive Dirichlet index exactly when m is positive or n is positive.*

Proof. The forward implication is the append right case split. Conversely, positivity in the left component is closed under appending a unary right component, and positivity in the right component is closed under prepending a unary left component. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPositiveIndex append iff`

Lemma 70.8 (Dirichlet term well-defined)**.** *For every (a, n, s) with positive unary n and complex history s,* $\mathsf{DirTerm}(a, n, s, t_n)$ *determines a unique complex history t_n up to* hsame.

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletTerm complex carrier well defined`

Proof. Constructive existence and uniqueness of $\log n$ on positive unary n; composition with constructive complex exp and complex multiplication. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletTerm positive index append hsame transport`

Definition 70.9 (Dirichlet partial sum)**.** *For a, s and unary N, the Dirichlet partial sum* $\mathsf{DirPartSum}(a, s, N, S_N)$ *is the complex-history value of $\sum_{n=1}^{N} a_n n^{-s}$, defined by an explicit unary recursion.*

Lean4 (definition) `BEDC.Derived.DirichletSeriesUp.DirichletPartSum`

Lemma 70.10 (Dirichlet partial-sum index cases)**.** *Every closed witness of* $\mathsf{DirichletPartSum}(\mathsf{term}, s, n, S)$ *either has the zero index $n = \mathsf{e}$ and identifies S with e, or has a successor index $n = \mathsf{E1}(m)$ together with a predecessor partial sum and the continuation step from that predecessor to S.*

Proof. Invert the closed partial-sum witness. The zero constructor gives the empty index and empty partial sum. The step constructor exposes the predecessor index, predecessor sum, and continuation payload directly. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum index cases`

Lemma 70.11 (Dirichlet partial-sum index is unary)**.** *Every closed witness of* $\mathsf{DirichletPartSum}(\mathsf{term}, s, n, S)$ *forces the index history* n *to be unary.*

Proof. Induct on the closed partial-sum witness. The zero constructor gives the empty unary history, and the step constructor applies unary closure under BHist.e1 to the predecessor index. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum index unary`

Theorem 70.12 (Dirichlet partial-sum results are unary)**.** *If every Dirichlet term history* $\mathsf{term}(m, s)$ *is unary whenever* m *is unary, then every closed* $\mathsf{DirichletPartSum}(\mathsf{term}, s, n, S)$ *witness has unary result* S*.*

Proof. Induct on the closed Dirichlet partial-sum witness. The zero constructor gives the empty unary history. In the successor case, the predecessor result is unary by induction, the predecessor index is unary by DirichletPartSum index closure, and unary continuation closure gives the successor result. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum result unary`

Theorem 70.13 (Dirichlet partial-sum nonempty index is positive)**.** *Every closed witness of* $\mathsf{DirichletPartSum}(\mathsf{term}, s, n, S)$ *whose index is not* hsame*-empty has a positive Dirichlet index* n*.*

Proof. The partial-sum witness makes n unary. Applying nonempty unary-tail inversion to n exposes $n = \mathsf{E1}(t)$ for a unary tail t, which is exactly the positive Dirichlet index witness. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum nonempty index positive`

Theorem 70.14 (Dirichlet positive-index partial-sum result is nonempty)**.** *Assume every unary-indexed Dirichlet term* $\mathsf{term}(m, s)$ *is not* hsame*-empty. If a closed partial-sum witness* $\mathsf{DirichletPartSum}(\mathsf{term}, s, n, S)$ *has a positive Dirichlet index* n*, then* S *is not* hsame*-empty.*

Proof. Unpack the positive-index witness as $n = \mathsf{E1}(t)$ with t unary. Inverting the matching partial-sum derivation exposes the predecessor sum and the final continuation step from the predecessor to $\mathsf{term}(t, s)$. If the result were empty, continuation result transport and empty-result inversion would make $\mathsf{term}(t, s)$ empty, contradicting the term nonemptiness hypothesis at the unary tail t. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum positive index result nonempty`

Theorem 70.15 (Dirichlet partial-sum positive index exposes predecessor)**.** *Every closed witness of* $\mathsf{DirichletPartSum}(\mathsf{term}, s, n, S)$ *whose index is a positive Dirichlet index exposes histories* m *and* P *such that*

$$n = \mathsf{E1}(m) \wedge \mathsf{UnaryHistory}(m) \wedge \mathsf{DirichletPartSum}(\mathsf{term}, s, m, P) \wedge \mathsf{Cont}(P, \mathsf{term}(m, s), S).$$

Proof. Case-split the closed partial-sum witness. The zero constructor is incompatible with a positive Dirichlet index, since positive indices are nonempty. The successor constructor directly exposes the predecessor index, its unary carrier, the predecessor partial-sum witness, and the continuation ledger into S. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum positive index predecessor`

Theorem 70.16 (Dirichlet append-successor partial-sum predecessor)**.** *Every closed witness of* $\mathsf{DirichletPartSum}(\mathsf{term}, s, \mathsf{append}(m, \mathsf{E1}(n)), S)$ *exposes a predecessor partial sum at* $\mathsf{append}(m, n)$*:*

$$\exists P : \mathsf{BHist},\ \mathsf{DirichletPartSum}(\mathsf{term}, s, \mathsf{append}(m, n), P) \wedge \mathsf{Cont}(P, \mathsf{term}(\mathsf{append}(m, n), s), S).$$

Proof. By the definition of history append, $\mathsf{append}(m, \mathsf{E1}(n))$ is the successor history $\mathsf{E1}(\mathsf{append}(m, n))$. Inverting the closed partial-sum witness therefore exposes the predecessor sum at $\mathsf{append}(m, n)$ and the continuation step into S. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum append successor predecessor`

Lemma 70.17 (Dirichlet partial-sum successor result is deterministic)**.** *If the Dirichlet partial-sum recursion reaches* S *at unary index* n*, and the next term continuation sends* S *and* $\mathsf{term}(n, s)$ *to* T*, then every closed derivation of the successor partial sum at* $\mathsf{E1}(n)$ *has result* hsame *to* T*.*

Proof. Induct on the previous Dirichlet partial-sum derivation to obtain determinacy at each index. In the successor case, the other derivation has the same successor shape; the induction hypothesis identifies the previous sums, and determinacy of Cont identifies the successor result. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum successor result deterministic`

Lemma 70.18 (Dirichlet successor term nonempty forces result nonempty)**.** *For any Dirichlet term function* term*, if*

$$\mathsf{DirichletPartSum}(\mathsf{term}, s, \mathsf{E1}(n), S)$$

holds and $\mathsf{term}(n, s)$ *is not* hsame *to* e*, then* S *is not* hsame *to* e*.*

Proof. Invert the successor partial-sum witness. Its displayed continuation ledger has the form $\mathsf{Cont}(P, \mathsf{term}(n, s), S)$ for the previous partial sum P. If $S\mathsf{hsamee}$, result transport gives a continuation into e; empty-result continuation inversion then forces $\mathsf{term}(n, s)\mathsf{hsamee}$, contradicting the term nonemptiness assumption. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum successor term nonempty result nonempty`

Theorem 70.19 (Dirichlet partial-sum successor result is nonempty)**.** *Assume every unary-indexed Dirichlet term is not* hsame*-empty. Then any closed successor partial sum* $\mathsf{DirichletPartSum}(\mathsf{term}, s, \mathsf{BHist.e1}(n), S)$ *has nonempty result:*

$$\mathsf{hsame}(S, \mathsf{e}) \to \bot.$$

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum successor result nonempty`

Proof. Invert the successor partial-sum witness. If the successor result were empty, transport the displayed continuation step to an empty result and apply $\mathsf{cont_empty_result_inversion}$. The current term is then hsame-empty, while the predecessor partial-sum witness proves its index is unary by $\mathsf{DirichletPartSum}$ index closure, contradicting the term-nonempty hypothesis. □

Lemma 70.20 (Dirichlet partial-sum unary index is deterministic)**.** *If* n *is a unary history, then any two closed derivations of* $\mathsf{DirichletPartSum}(\mathsf{term}, s, n, -)$ *have* hsame *results.*

Proof. Induct on the first Dirichlet partial-sum derivation. The empty index case forces the second derivation to be the base constructor. In the successor case, unary inversion gives the predecessor index, the induction hypothesis identifies the previous partial sums, and determinacy of Cont identifies the successor results. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum unary index deterministic`

Lemma 70.21 (Dirichlet partial sums respect pointwise term equivalence)**.** *If two Dirichlet term functions are pointwise related by* hsame *on every unary index for the fixed complex argument s, and S, T are closed Dirichlet partial sums for those two term functions at the same index n, then* $S\,\mathsf{hsame}\,T$.

Proof. Induct on the first closed Dirichlet partial-sum witness. The base case forces the second witness to be the zero constructor. In the successor case, the second witness has the same successor index; the induction hypothesis identifies the predecessor sums, the first witness supplies unaryness of the predecessor index, and the pointwise term comparison identifies the two terms at that index. Determinacy of Cont identifies the successor sums. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum term hsame deterministic`

Lemma 70.22 (Dirichlet partial-sum term transport is deterministic)**.** *Suppose two Dirichlet term functions agree under* hsame *at every unary index after transporting the ambient parameter from s to s'. If n is unary, then a closed partial sum S for* term *at (s, n) and a closed partial sum T for* term' *at (s', n) satisfy* $S\,\mathsf{hsame}\,T$.

Proof. Transport the first closed partial-sum witness along the pointwise term-history comparison to obtain a closed witness for term' at the same unary index. Unary-index determinacy for Dirichlet partial sums then compares that transported witness with the displayed T witness. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum term hsame transport deterministic`

Lemma 70.23 (Dirichlet partial sums are complex histories)**.** *For every (a, s, N), there is a unique complex history S_N with* $\mathsf{DirPartSum}(a, s, N, S_N)$*, up to* hsame.

Proof. Unary induction on N constructs the empty partial sum at the base index and extends the predecessor sum by the concrete continuation step carrying the current Dirichlet term. At each unary index, the partial-sum determinacy theorem identifies any competing closed derivation with the constructed result. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum exists unique`

Theorem 70.24 (Dirichlet series successor index tail is nonempty)**.** *For every history n :* BHist*, if n is a unary index, then* $\mathsf{BHist.e1}(n)$ *is again a unary index and* $\mathsf{hsame}(\mathsf{BHist.e1}(n), \mathsf{e}) \to \bot$.

Proof. Unary indices are closed under the E1 constructor. The constructor BHist.e1 is disjoint from e, so the successor index supplies a nonempty tail witness for Dirichlet indexing. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletSeriesIndex e1 tail nonempty`

Theorem 70.25 (Dirichlet series appended unary tail is nonempty)**.** *For histories $n, tail$:* BHist*, if n is a unary index distinct from* e *and tail is unary, then* $\mathsf{append}(n, tail)$ *is unary and* $\mathsf{hsame}(\mathsf{append}(n, tail), \mathsf{e}) \to \bot$.

Proof. Unary histories are closed under append. If the appended history were empty, append-empty inversion would force the left factor n to be empty, contrary to the supplied nonempty index witness. □

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletSeriesIndex append unary tail nonempty`

70.2 Abscissa of absolute convergence

Definition 70.26 (Abscissa of absolute convergence)**.** *For coefficient sequence a, the abscissa of absolute convergence* $\mathsf{AbsConvAbscissa}(a, \sigma_a)$ *is the located boundary predicate on a real-history σ_a with two clauses.*

The right clause says that for every unary precision k and every complex s, if a BEDC real-history witness supplies the rational comparison $\Re(s) - \sigma_a \geq 2^{-k}$, then the modulus partial sums of the Dirichlet series at s are uniformly bounded above by an explicit constant.

The left clause says that for every unary precision k, every rational probe q, and every BEDC real-history witness supplying the rational comparison $\sigma_a - q \geq 2^{-k}$, the modulus partial sums at the probe point with real part q fail to admit any such uniform bound. All uses of order in the predicate are therefore supplied by displayed real-history comparison witnesses, not inferred from distinctness of candidates.

Lean4 (definition) `BEDC.Derived.DirichletSeriesUp.AbsConvAbscissa`

Theorem 70.27 (Abscissa is unique)**.** *If* $\mathsf{AbsConvAbscissa}(a, \sigma_a)$ *and* $\mathsf{AbsConvAbscissa}(a, \sigma'_a)$*, then* $\mathsf{hsame}(\sigma_a, \sigma'_a)$ *on the rational representation of the real-history.*

Sketch. It is enough to rule out every explicit rational gap between the two real-histories. Suppose a unary precision k and BEDC comparison witnesses exhibit the oriented gap

$$\sigma'_a + 2^{-k} \leq q \leq \sigma_a - 2^{-k}.$$

Apply the right clause for σ'_a to the probe point with real part q. The right comparison witness gives a uniform bound for the corresponding modulus partial sums.

Apply the left clause for σ_a to the same q and the displayed gap witness. It says that no such uniform bound exists. This contradiction excludes the oriented gap from σ'_a to σ_a.

The reverse orientation is identical with σ_a and σ'_a exchanged. Thus every BEDC rational-history separation witness is impossible, which is exactly $\mathsf{hsame}(\sigma_a, \sigma'_a)$. □

70.3 Convergence and holomorphicity in the half-plane

Theorem 70.28 (Half-plane convergence)**.** *If* $\mathsf{AbsConvAbscissa}(a, \sigma_a)$ *and s satisfies $\Re(s) > \sigma_a$ (decidable strict inequality with explicit witness gap ϵ), then $\sum a_n n^{-s}$ converges absolutely in* $\mathsf{CplxSer}^{\uparrow}$ *with explicit modulus given by majorant comparison to $\sum n^{-(\sigma_a+\epsilon/2)}$.*

Sketch. The bound $|a_n n^{-s}| \leq C n^{-(\sigma_a+\epsilon/2)}$ is given by $\mathsf{AbsConvAbscissa}$ at precision k chosen by ϵ; the resulting series converges with explicit geometric-like modulus. □

Theorem 70.29 (Half-plane holomorphicity)**.** *The Dirichlet sum function $s \mapsto \sum_{n=1}^{\infty} a_n n^{-s}$ is holomorphic in the open half-plane $\Re(s) > \sigma_a$, with uniform modulus over each compact sub-half-plane $\{s : \Re(s) \geq \sigma_a + \epsilon, |\Im(s)| \leq T\}$ for explicit unary ϵ, T (cite chapter 68).*

Sketch. Term-wise complex differentiability of n^{-s} gives derivative $-(\log n)n^{-s}$; the differentiated series converges absolutely on the compact sub-half-plane by the same majorant. □

70.4 Euler product for multiplicative coefficients

Definition 70.30 (Completely multiplicative coefficient)**.** *A coefficient sequence a is completely multiplicative when $a_1 = \mathsf{E1}(\mathsf{e})$ and for all positive unary m, n, $a_{m \cdot n} = a_m \cdot a_n$ (product in* $\mathsf{Complex}^{\uparrow}$*).*

Lean4 (definition) `BEDC.Derived.DirichletSeriesUp.DirichletCoefficient completely multiplicative`

Theorem 70.31 (Euler product)**.** *If a is completely multiplicative and $\Re(s) > \sigma_a$, the Dirichlet series factors as the explicit Euler product $\sum a_n n^{-s} = \prod_p (1 - a_p p^{-s})^{-1}$ over primes p (in the sense of* $\mathsf{Prime}^{\uparrow}$*, chapter 64). The product converges absolutely with explicit modulus over compact sub-half-planes.*

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletCoefficient completely multiplicative product nonempty`

Sketch. Group terms by prime factorization (factorization_exists of chapter 64); the geometric series $\sum_k (a_p p^{-s})^k$ gives the local factor at each prime. □

70.5 The certificate

Definition 70.32 (Dirichlet source specification)**.** *The source specification on (a, s) carries the constraint* $\mathsf{AbsConvAbscissa}(a, \sigma_a)$ *and $\Re(s) > \sigma_a$.*

Lean4 (definition) `BEDC.Derived.DirichletSeriesUp.DirichletSourceSpec`
Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletSourceSpec witness result carrier`

Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.DirichletPartSum semanticNameCert`
Lean4 ✓ `BEDC.Derived.DirichletSeriesUp.dirichlet semantic name certificate`

Sketch. Direct verification of the four NameCert field types using the constructions of this chapter. □

Closure status for NameCert$_{\text{Dirichlet}\uparrow}$**.**

Constructive story: A Dirichlet$^{\uparrow}$ packet is generated from finite BHist rows for positive unary indices, coefficient histories, Dirichlet terms, partial sums, convergence windows, abscissa witnesses, and Euler-product source rows. Each term is built by Cont from the coefficient row and the displayed n^{-s} complex-history row, and partial sums are finite continuation folds over positive unary indices. The classifier transports indices, terms, sums, convergence ledgers, and product rows by hsame, while Pkg records the complex-series, natural-number, prime, real, and analytic dependencies. The packet names the constructive Dirichlet-series surface without importing a host infinite sum.

Theory closure: TheoryGate(NameCert$_{\text{Dirichlet}\uparrow}$, seed)

Scope closed: This chapter binds Dirichlet terms, positive-index facts, partial sums, convergence witnesses, Euler-product rows, and the semantic NameCert surface for Dirichlet$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{Dirichlet}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: It does not claim a host analytic function object, classical supremum abscissa, quotient equality of series, nonconstructive convergence selection, or an external infinite-sum primitive.

Upgrade path: Obligation closure requires Lean encodings of the term and index carriers, finite partial-sum routes, convergence ledgers, Euler-product rows, and semantic NameCert theorem.

Chapter 71

A Concrete Naming Certificate for $\mathsf{ZetaBasic}^{\uparrow}$ on $\Re(s) > 1$

This chapter gives a concrete naming-certificate construction for the Riemann zeta function $\zeta(s) = \sum_{n=1}^{\infty} n^{-s}$ on the open half-plane $\Re(s) > 1$, where the defining Dirichlet series converges absolutely. It is a direct specialization of $\mathsf{Dirichlet}^{\uparrow}$ (chapter 70) at the unit coefficient sequence $a_n = \mathsf{E1}(\mathsf{e})$. The chapter does NOT extend ζ to $\mathsf{Complex}^{\uparrow} \setminus \{1\}$ — that is a separate operation chapter ($\mathsf{ZetaCont}^{\uparrow}$, chapter 9342). Two faces of the same object are presented: the Dirichlet sum and the Euler product over primes; non-vanishing on the half-plane is supplied with explicit lower bound; holomorphicity is inherited from $\mathsf{Dirichlet}^{\uparrow}$. The construction is fully constructive and uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate.

71.1 The constant-coefficient Dirichlet sum

Definition 71.1 (Zeta basic predicate)**.** *For complex history s and complex history z, the predicate* $\mathsf{ZetaBasic}(s, z)$ *holds when z is the explicit complex-history limit of the Dirichlet partial sums of the constant-unit coefficient sequence $a_n = \mathsf{E1}(\mathsf{e})$ at s; equivalently,* $\mathsf{ZetaBasic}(s, z)$ *is the specialization of the* $\mathsf{Dirichlet}^{\uparrow}$ *carrier (chapter 70) at unit coefficients.*

Lean4 (definition) `BEDC.Derived.ZetaBasicUp.ZetaBasic`

Definition 71.2 (Unit Dirichlet part sum)**.** *For a complex history s, the unit term at unary index n is the visible unit extension* $\mathsf{E1}(s)$*, and* $\mathsf{ZetaBasicPartSum}(s, n, z)$ *is the specialized* DirichletPartSum *witness for this unit term.*

Lean4 (definition) `BEDC.Derived.ZetaBasicUp.ZetaBasicUnitTerm`
Lean4 (definition) `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum`

Theorem 71.3 (Unit Dirichlet part sums are unary)**.** *If s and n are unary histories and* $\mathsf{ZetaBasicPartSum}(s, n, z)$ *holds, then z is a unary history.*

Proof. Induct on the concrete DirichletPartSum witness. The zero result is e, and the successor case appends the prior unary partial sum to the visible unit term $\mathsf{E1}(s)$, which is closed by unary continuation. □

Lean4 ✓ `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum unary result`

Theorem 71.4 (Unit Dirichlet part-sum indices are unary)**.** *If* $\mathsf{ZetaBasicPartSum}(s, n, z)$ *holds, then* n *is a unary history.*

Proof. Induct on the specialized DirichletPartSum witness. The zero constructor gives the empty unary index, and the step constructor preserves unaryness by applying the visible unit successor constructor to the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum index unary`

Theorem 71.5 (Unit Dirichlet successor part sums are nonempty)**.** *If* $\mathsf{ZetaBasicPartSum}(s, \mathsf{E1}(n), z)$ *holds, then* z *is not* hsame *to* e.

Proof. Invert the successor partial-sum witness. Its final step appends the previous sum to $\mathsf{E1}(s)$. If the result were empty, empty-result inversion for Cont would force $\mathsf{E1}(s)$hsamee, contradicting visible-successor separation. □

Lean4 ✓ `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum successor result nonempty`

Theorem 71.6 (Unit Dirichlet positive-index part sums are nonempty)**.** *If* n *is a positive Dirichlet index and* $\mathsf{ZetaBasicPartSum}(s, n, z)$ *holds, then* z *is not* hsame *to* e.

Proof. The positive-index witness exposes $n = \mathsf{E1}(t)$ for a unary tail t. After substituting this visible successor shape, the successor nonempty theorem applies to the displayed partial-sum witness. □

Lean4 ✓ `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum positive index result nonempty`

Theorem 71.7 (Unit Dirichlet successor part-sum step inversion)**.** *If* $\mathsf{ZetaBasicPartSum}(s, \mathsf{E1}(n), z)$ *holds, then there is a previous partial sum* p *such that* $\mathsf{ZetaBasicPartSum}(s, n, p)$ *holds and* $\mathsf{Cont}(p, \mathsf{E1}(s), z)$ *is the successor continuation step.*

Proof. Invert the specialized partial-sum witness at successor index $\mathsf{E1}(n)$. The step constructor exposes the predecessor partial sum and its continuation by the unit term, which unfolds to $\mathsf{E1}(s)$. □

Lean4 ✓ `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum successor step inversion`

Theorem 71.8 (Unit Dirichlet empty-source successor result shape)**.** *If* $\mathsf{ZetaBasicPartSum}(\mathsf{e}, \mathsf{E1}(n), z)$ *holds, then there is a previous partial sum* p *such that* $\mathsf{ZetaBasicPartSum}(\mathsf{e}, n, p)$ *holds and* $z\mathsf{hsame}\mathsf{E1}(p)$.

Proof. Invert the successor part-sum witness. At empty source the unit term unfolds to $\mathsf{E1}(\mathsf{e})$, so the exposed continuation has result $p \cdot \mathsf{E1}(\mathsf{e})$. The append right-unit law rewrites this result as $\mathsf{E1}(p)$. □

Lean4 ✓ `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum empty source successor result shape`

Theorem 71.9 (Unit Dirichlet successor source transport step)**.** *If* $s\mathsf{hsame}t$ *and* $\mathsf{ZetaBasicPartSum}(s, \mathsf{E1}(n), z)$ *holds, then there are histories* p *and* u *such that* $\mathsf{ZetaBasicPartSum}(t, n, p)$, $\mathsf{Cont}(p, \mathsf{E1}(t), u)$, *and* $z\mathsf{hsame}u$.

Proof. Invert the successor part-sum witness at source s. The predecessor index is unary by the part-sum index theorem, so termwise hsame-transport along $s\mathsf{hsame}t$ moves the predecessor partial sum to source t. Rebuild the visible unit continuation step at t, and use continuation congruence to compare its result with the original successor sum. □

Lean4 ✓ `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum successor source hsame transport step`

Theorem 71.10 (Unit Dirichlet successor previous-sum determinism)**.** *If* $s\mathsf{hsame}t$ *and both sources carry successor-index unit partial sums at the same predecessor index* n*,*

$$\mathsf{ZetaBasicPartSum}(s, \mathsf{E1}(n), z) \quad \textit{and} \quad \mathsf{ZetaBasicPartSum}(t, \mathsf{E1}(n), u),$$

then their predecessor sums can be chosen as histories p, q *with* $\mathsf{ZetaBasicPartSum}(s, n, p)$*,* $\mathsf{ZetaBasicPartSum}(t, n, q)$*,* $p\mathsf{hsame}q$*, the two visible unit continuation steps* $\mathsf{Cont}(p, \mathsf{E1}(s), z)$*,* $\mathsf{Cont}(q, \mathsf{E1}(t), u)$*, and* $z\mathsf{hsame}u$*.*

Proof. Invert both successor partial-sum witnesses. The predecessor index is unary by the index theorem, so termwise source transport compares the two predecessor sums. The visible unit terms compare by $s\mathsf{hsame}t$, and continuation congruence compares the two successor results. □

Lean4 ✓ `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum successor source hsame previous deterministic`

Theorem 71.11 (Unit Dirichlet successor source transport result nonempty)**.** *If* $s\mathsf{hsame}t$ *and* $\mathsf{ZetaBasicPartSum}(s, \mathsf{E1}(n), z)$ *holds, then there are histories* p *and* u *such that* $\mathsf{ZetaBasicPartSum}(t, n, p)$*,* $\mathsf{Cont}(p, \mathsf{E1}(t), u)$*,* $z\mathsf{hsame}u$*, and* u *is not* hsame *to* e*.*

Proof. Apply the source-transport step theorem to obtain the transported predecessor partial sum and the rebuilt visible-unit continuation at source t. This continuation is a successor $\mathsf{ZetaBasicPartSum}$ witness at source t, so successor result nonemptiness rules out $u\mathsf{hsame}\mathsf{e}$. □

Lean4 ✓ `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum successor source hsame transport result nonempty`

Theorem 71.12 (Unit Dirichlet successor source transport preserves nonempty result)**.** *If* $s\mathsf{hsame}t$ *and* $\mathsf{ZetaBasicPartSum}(s, \mathsf{E1}(n), z)$ *holds, then there is a transported successor partial sum* u *at source* t *such that* $\mathsf{ZetaBasicPartSum}(t, \mathsf{E1}(n), u)$*,* $z\mathsf{hsame}u$*, and* u *is not* hsame *to* e*.*

Proof. Use successor source transport to obtain the transported predecessor sum and its visible unit continuation at t. Rebuild the successor $\mathsf{ZetaBasicPartSum}$ witness from that continuation step, retain the result comparison with z, and apply successor-result nonemptiness to the rebuilt target sum. □

Lean4 ✓ `BEDC.Derived.ZetaBasicUp.ZetaBasicPartSum successor source result nonempty transport`

Lemma 71.13 (Zeta basic well-defined for $\Re(s) > 1$)**.** *For every* s *with rational representation of* $\Re(s)$ *strictly greater than* $\mathsf{E1}(\mathsf{e})$ *(decidable on the rational representation), the predicate* $\mathsf{ZetaBasic}(s, z)$ *holds for some complex history* z*, and* z *is unique up to* hsame *on both real components.*

Sketch. Specialize Definition 70.28 of $\mathsf{Dirichlet}^{\uparrow}$ at unit coefficients with abscissa of absolute convergence exactly $\mathsf{E1}(\mathsf{e})$; existence and uniqueness of the limit follow from the $\mathsf{CplxLim}^{\uparrow}$ certificate (chapter 65). □

Theorem 71.14 (Zeta basic unique)**.** *If* $\mathsf{ZetaBasic}(s, z)$ *and* $\mathsf{ZetaBasic}(s, z')$ *both hold for the same* s*, then* hsame *holds on both real components of* z *and* z'*.*

Proof. Direct uniqueness from $\mathsf{Dirichlet}^{\uparrow}$ limit uniqueness. □

71.2 Convergence and abscissa

Theorem 71.15 (Abscissa is exactly 1)**.** *The abscissa of absolute convergence for the unit Dirichlet series is the rational unit* $\mathsf{E1(e)}$*:* $\mathsf{AbsConvAbscissa}(\mathbf{1}, \mathsf{E1(e)})$*. The harmonic series at* $s = 1$ *diverges with explicit lower-bound logarithmic-rate witness, so the abscissa cannot be smaller; the geometric majorant for* $s > 1$ *shows that the abscissa is exactly 1.*

Sketch. The harmonic divergence is constructively witnessed by the explicit comparison $\sum_{n=1}^{2^k} 1/n \geq k/2$, proving abscissa is at least 1; the half-plane convergence theorem at any s with $\Re(s) > 1$ shows the abscissa is at most 1. □

71.3 The Euler product over primes

Theorem 71.16 (Euler product for ζ)**.** *For every* s *with* $\Re(s) > 1$*, the explicit factorization*

$$\zeta(s) = \prod_p (1 - p^{-s})^{-1}$$

holds, where the product runs over primes p *in the sense of* $\mathsf{Prime}^{\uparrow}$ *(chapter 64). The product converges absolutely with explicit modulus over compact sub-half-planes* $\{s : \Re(s) \geq 1 + \epsilon, |\Im(s)| \leq T\}$ *for unary* ϵ, T*.*

Sketch. Direct specialization of the Euler product theorem of $\mathsf{Dirichlet}^{\uparrow}$ (Definition 70.31) at completely multiplicative coefficients $a_n = \mathsf{E1(e)}$ with $a_p = \mathsf{E1(e)}$ for each prime p. □

71.4 Non-vanishing on the half-plane

Theorem 71.17 (ζ non-vanishing for $\Re(s) > 1$)**.** *For every* s *with* $\Re(s) > 1$*,* $\zeta(s) \neq 0$ *in the strict sense: the modulus* $|\zeta(s)|$ *admits an explicit positive lower bound depending on* $\Re(s)$*, given by the geometric tail of the Euler product.*

Sketch. The Euler product factors are each bounded below in modulus by $1 - p^{-\Re(s)} > 0$; the infinite product converges with explicit modulus, so the limiting modulus is bounded below by an explicit positive constant. □

71.5 Holomorphicity on the half-plane

Theorem 71.18 (ζ holomorphic on $\Re(s) > 1$)**.** *The function* $s \mapsto \zeta(s)$ *is holomorphic in the open half-plane* $\Re(s) > 1$ *in the sense of* $\mathsf{Holomorphic}^{\uparrow}$ *(chapter 68), with uniform modulus over compact sub-half-planes.*

Proof. Direct specialization of Definition 70.29 of $\mathsf{Dirichlet}^{\uparrow}$ at unit coefficients. □

71.6 The certificate

Definition 71.19 (Zeta basic source specification)**.** *The source specification on* s *carries the constraint* $\Re(s) > 1$ *(decidable on the rational representation).*

Lean4 (definition) BEDC.Derived.ZetaBasicUp.ZetaBasicSourceSpec

Closure status for $\mathsf{NameCert}_{\mathsf{ZetaBasic}^{\uparrow}}$.

Constructive story: A $\mathsf{ZetaBasic}^{\uparrow}$ packet is generated by specializing the $\mathsf{Dirichlet}^{\uparrow}$ rows to the constant unit coefficient sequence over the open half-plane $\Re(s) > 1$. Finite BHist rows record unit terms, unary partial sums, positivity of indices, Euler-product factors, lower-bound ledgers, and holomorphic readbacks inherited through displayed routes. The defining sum and product are replayed by Cont through the Dirichlet-series and prime-row dependencies, and hsame transports the same unit-term and partial-sum witnesses. Pkg records the Dirichlet, complex, real, and prime sources, so the packet remains a constructive half-plane certificate.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ZetaBasic}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the zeta-basic predicate, unit term and partial-sum rows, index facts, half-plane convergence and nonvanishing rows, Euler-product surface, and semantic NameCert.

Formal verification: FormalStatus(NameCert$_{\mathsf{ZetaBasic}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: It does not claim meromorphic continuation, the pole at 1, functional equation, critical-strip information, host analytic equality, or zeros outside the displayed half-plane surface.

Upgrade path: Obligation closure requires Lean encodings of the unit Dirichlet specialization, partial-sum route, half-plane ledgers, Euler-product rows, and semantic NameCert theorem.

Chapter 72

A Concrete Naming Certificate for $\mathsf{CritStrip}^{\uparrow}$

This chapter records the finite-unary obstruction boundary for $\mathsf{CritStrip}^{\uparrow}$ as predicates on $\mathsf{Complex}^{\uparrow}$-history. The nominal strip predicate is written with strict unary prefix witnesses between e and $\mathsf{E1}(\mathsf{e})$, so the finite carrier exposes an empty open interval rather than a nonempty analytic critical strip. The chapter isolates that obstruction before $\mathsf{ZetaCont}^{\uparrow}$ (chapter 9342) and $\mathsf{ZetaZeros}^{\uparrow}$ (chapter 73) consume any strip-shaped interface. The construction is fully constructive and uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate.

72.1 The strip and critical-line predicates

Definition 72.1 (Critical strip membership)**.** *For complex history s with rational real component σ, the predicate* $\mathsf{InCritStrip}(s)$ *holds when both* $\mathsf{NatUnaryStrictPrefix}(\mathsf{e}, \sigma)$ *and* $\mathsf{NatUnaryStrictPrefix}(\sigma, \mathsf{E1}(\mathsf{e}))$ *are decidably true on the rational representation, i.e.* $0 < \sigma < 1$ *strictly.*

Lean4 (definition) `BEDC.Derived.CritStripUp.InCritStrip`

Definition 72.2 (Critical strip open interval)**.** *For a rational real-component history σ, the open-interval core of the critical strip is the pair of strict unary prefix witnesses*

$$\mathsf{NatUnaryStrictPrefix}(\mathsf{e}, \sigma) \quad \textit{and} \quad \mathsf{NatUnaryStrictPrefix}(\sigma, \mathsf{E1}(\mathsf{e})).$$

Lean4 (definition) `BEDC.Derived.CritStripUp.CritStripOpenInterval`

Lemma 72.3 (Critical strip membership decidable)**.** *For every complex history s,* $\mathsf{InCritStrip}(s)$ *is decidable: an explicit unary algorithm returns either a witness for both strict inequalities or a witness for at least one failure.*

Proof. Both inequalities are decidable on rational representations by the strict-prefix decidability of $\mathsf{NatUnaryStrictPrefix}$ (chapter 28). □

Lean4 (definition) `BEDC.Derived.CritStripUp.InCritStrip open interval decidable`

Definition 72.4 (Critical line membership)**.** *For complex history s with rational real component σ, the predicate* $\mathsf{OnCritLine}(s)$ *holds when* $\mathsf{hsame}(\sigma, \mathsf{Half})$*, where* Half *is the rational representation of* $1/2$*.*

Lean4 (definition) `BEDC.Derived.CritStripUp.OnCritLine`

Lemma 72.5 (Critical line membership decidable)**.** *For every complex history s with rational real component,* $\mathsf{OnCritLine}(s)$ *is decidable.*

Proof. Decidable from hsame-decidability on rational representations of unary histories (chapter 37). □

Lean4 ✓ `BEDC.Derived.CritStripUp.OnCritLine decidable`

72.2 Compact sub-strips and boundary witnesses

Definition 72.6 (Compact sub-strip)**.** *For unary ϵ (with $\epsilon < 1/2$) and unary T, the compact sub-strip predicate* $\mathsf{CompactSubStrip}(\epsilon, T, s)$ *holds when $\epsilon \leq \sigma \leq 1 - \epsilon$ (rational comparisons) and $|t| \leq T$ (modulus comparison on the imaginary part).*

Lean4 (definition) `BEDC.Derived.CritStripUp.CompactSubStrip`

Lemma 72.7 (Compact sub-strip decidable)**.** *For every (ϵ, T, s),* $\mathsf{CompactSubStrip}(\epsilon, T, s)$ *is decidable; the decision procedure returns either witnesses for all three bounds or an explicit failed-bound witness.*

Proof. Each bound is a decidable rational comparison. □

Lean4 ✓ `BEDC.Derived.CritStripUp.CompactSubStrip empty unit obstruction decidable`

Theorem 72.8 (Boundary excluded)**.** *For every complex history s with* $\mathsf{hsame}(\sigma, \mathsf{e})$ *or* $\mathsf{hsame}(\sigma, \mathsf{E1}(\mathsf{e}))$, $\neg\mathsf{InCritStrip}(s)$. *Both edges $\Re(s) = 0$ and $\Re(s) = 1$ are explicitly excluded by the strict-inequality witnesses.*

Proof. Direct: the strict-prefix relations require non-equality witnesses. □

Lean4 ✓ `BEDC.Derived.CritStripUp.InCritStrip boundary excluded`

Theorem 72.9 (Critical strip open interval unary boundary exclusion)**.** *If σ lies in the strict unary open interval between* e *and* $\mathsf{E1}(\mathsf{e})$, *then σ is unary and is internally same to neither boundary.*

Proof. The lower strict-prefix witness is a continuation from e to σ by a nonempty unary tail; the empty left-unit law transports that tail's unary structure to σ. If $\sigma\mathsf{hsame}\mathsf{e}$, the lower strict-prefix witness would have empty right endpoint, contradicting strictness. If $\sigma\mathsf{hsame}\mathsf{E1}(\mathsf{e})$, the upper strict-prefix witness becomes a strict self-prefix at $\mathsf{E1}(\mathsf{e})$, contradicting asymmetry. □

Lean4 ✓ `BEDC.Derived.CritStripUp.CritStripOpenInterval unary boundary exclusion`

Theorem 72.10 (Critical strip empty-to-unit open interval absurdity)**.** *There is no unary history strictly between the empty endpoint and the one-step unit endpoint:*

$$\mathsf{NatUnaryStrictPrefix}(\mathsf{e}, \sigma) \wedge \mathsf{NatUnaryStrictPrefix}(\sigma, \mathsf{E1}(\mathsf{e})) \Longrightarrow \bot.$$

Proof. The lower strict-prefix witness transports unary structure from e to σ. Split the unary history σ. If it is empty, the lower strict-prefix witness has empty right endpoint, impossible by strictness. If it is one-headed, the upper strict-prefix witness descends through the one-head constructor to a strict prefix into e, again impossible by strictness. □

Lean4 ✓ `BEDC.Derived.CritStripUp.CritStripOpenInterval empty unit absurd`

Definition 72.11 (Critical strip complex carrier)**.** *A complex strip history s with rational components σ, τ is carried when σ and τ are rational histories,* $\mathsf{Cont}(\sigma, \tau, s)$ *assembles the complex endpoint, and σ lies in the strict critical strip.*

Lean4 (definition) `BEDC.Derived.CritStripUp.CritStripComplexCarrier`

Theorem 72.12 (Critical strip complex carrier nonemptiness)**.** *If s is carried by the critical-strip complex carrier, then* $s\mathsf{hsamee}$ *is impossible.*

Proof. Transport the stored continuation endpoint along $s\mathsf{hsamee}$. The empty result inversion for Cont identifies both rational components with e, contradicting the nonempty denominator witness contained in the real rational carrier. □

Lean4 ✓ `BEDC.Derived.CritStripUp.CritStripComplexCarrier not empty`

Theorem 72.13 (Critical strip component boundary exclusion)**.** *If* $\mathsf{CritStripComplexCarrier}(s, \sigma, \tau)$*, then σ is not* hsame*-equal to either boundary* e *or* $\mathsf{E1}(\mathsf{e})$*, τ is not* hsame*-equal to* e*, and s is not* hsame*-equal to* e*.*

Proof. The strip field supplies the two boundary exclusions for σ. The rational carrier for τ contains a positive unary denominator, excluding the empty history. The complex endpoint exclusion is the nonemptiness theorem for the assembled carrier. □

Lean4 ✓ `BEDC.Derived.CritStripUp.CritStripComplexCarrier component boundary exclusion`

Theorem 72.14 (Critical strip complex carrier is empty)**.** *If* $\mathsf{CritStripComplexCarrier}(s, \sigma, \tau)$*, then* $\bot$*.*

Proof. Unpack the carrier fields. Its strip field gives the strict unary interval witnesses for σ between e and $\mathsf{E1}(\mathsf{e})$.

Apply Definition 72.10 to those two strict-prefix witnesses. □

Lean4 ✓ `BEDC.Derived.CritStripUp.CritStripComplexCarrier strict interval absurd`

72.3 Closure laws

Lemma 72.15 (Strip respects hsame)**.** *If* $\mathsf{InCritStrip}(\sigma)$ *and* $\sigma\mathsf{hsame}\sigma'$*, then* $\mathsf{InCritStrip}(\sigma')$*, and σ' is internally same to neither boundary* e *nor* $\mathsf{E1}(\mathsf{e})$*.*

Proof. Transport the lower and upper strict-prefix witnesses along hsame, then apply boundary exclusion at the transported strip point. □

Lean4 ✓ `BEDC.Derived.CritStripUp.InCritStrip hsame transport boundary exclusion`

Theorem 72.16 (Critical strip complex carrier respects hsame)**.** *If* $s\mathsf{hsame}s'$*,* $\sigma\mathsf{hsame}\sigma'$*,* $\tau\mathsf{hsame}\tau'$*, and* $\mathsf{CritStripComplexCarrier}(s, \sigma, \tau)$*, then* $\mathsf{CritStripComplexCarrier}(s', \sigma', \tau')$*, the continuation* $\mathsf{Cont}(\sigma', \tau', s')$ *holds, and the strict interval obstruction gives $\bot$.*

Proof. Transport the two rational carrier fields along the component equalities, transport the strict-strip field along $\sigma\mathsf{hsame}\sigma'$, and transport the stored continuation ledger along all three endpoint equalities. These fields rebuild the carried complex strip package at the primed endpoint, where the strict interval obstruction applies. □

Lean4 ✓ `BEDC.Derived.CritStripUp.CritStripComplexCarrier hsame transport`

72.4 The certificate

Definition 72.17 (Critical strip source specification)**.** *The source specification on complex history s carries the constraint* InCritStrip(s) *or its complement at the boundary.*

Lean4 (definition) `BEDC.Derived.CritStripUp.CritStripSourceSpec`

Lean4 ✓ `BEDC.Derived.CritStripUp.CritStripSourceSpec empty boundary`

Lean4 ✓ `BEDC.Derived.CritStripUp.CritStripClassifierSpec component transport`

Definition 72.20 (Critical strip stability certificate)**.** *The stability certificate consists of* hsame-*respect of* InCritStrip*,* OnCritLine*, and* CompactSubStrip*; transport of all three under* hsame *on each component.*

Lean4 ✓ `BEDC.Derived.CritStripUp.CritStripStabilityCert fields`

Definition 72.21 (Critical strip ledger policy)**.** *The ledger policy records: (i) decidability of strip and critical-line membership, (ii) decidability of compact sub-strip predicate, (iii) boundary exclusion witnesses, (iv) closure under* hsame *on inputs.*

Lean4 (definition) `BEDC.Derived.CritStripUp.CritStripLedgerPolicy`

Theorem 72.22 (Concrete $\mathsf{CritStrip}^{\uparrow}$ obstruction-boundary certificate)**.** *The five fields above form the finite-unary obstruction-boundary certificate over* Hist *for the critical-strip interface* $\mathsf{CritStrip}^{\uparrow}$*. The certificate records the strict-prefix boundary laws and the emptiness of the finite unary complex carrier; it does not certify a nonempty analytic open strip.*

Sketch. The five fields satisfy the closure laws of the naming-certificate framework (chapter 9) after the strip field is read as the finite-unary boundary object. The empty-carrier theorem above supplies the obstruction side of the certificate. The certificate uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate. □

Lean4 ✓ `BEDC.Derived.CritStripUp.crit strip name certificate`

Theorem 72.23 (Critical strip empty boundary semantic certificate)**.** *The boundary carrier*

$$h \mapsto h\mathsf{hsamee} \wedge \neg\mathsf{InCritStrip}(h)$$

forms a semantic naming certificate with the same source, pattern, and ledger predicate, and with hsame *as classifier.*

Proof. The carrier is inhabited by e. Boundary exclusion supplies the non-membership field, and hsame reflexivity, symmetry, and transitivity give the classifier laws. Carrier transport composes the source classifier with the stored equality to e, then applies boundary exclusion at the transported history. □

Lean4 ✓ `BEDC.Derived.CritStripUp.CritStripEmptyBoundary semanticNameCert`

Theorem 72.24 (Semantic CritStrip$^{\uparrow}$ obstruction-boundary certificate)**.** *The concrete obstruction-boundary certificate of Definition 72.22 satisfies the semantic naming-certificate schema of* NameCert *(chapter 9) for the finite-unary* CritStrip$^{\uparrow}$ *boundary.*

Sketch. Direct verification of the four NameCert field types using the boundary constructions and the empty-carrier theorem of this chapter. □

Lean4 ✓ `BEDC.Derived.CritStripUp.crit strip semantic name certificate`

Closure status for NameCert$_{\text{CritStrip}^{\uparrow}}$**.**

Constructive story: A CritStrip$^{\uparrow}$ packet is generated from finite BHist rows for complex-history inputs, rational real-component readbacks, strict unary-prefix witnesses for $0 < \sigma < 1$, critical-line classifier rows, compact sub-strip data, and the obstruction boundary. The displayed unary inequalities are checked by finite prefix procedures and replayed by Cont through the complex and rational readback rows. hsame transports the same real-component and boundary witnesses, while Pkg records the complex, rational, and zeta-continuation dependencies. In this finite-unary presentation the open strip surface is an explicit boundary object rather than a host analytic domain.

Theory closure: TheoryGate(NameCert$_{\text{CritStrip}^{\uparrow}}$, seed)

Scope closed: This chapter binds critical-strip membership, critical-line membership, compact sub-strip predicates, boundary witnesses, empty-carrier behavior, and semantic NameCert surface for CritStrip$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{CritStrip}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: It does not claim a nonempty analytic critical strip, host complex-domain equality, zeta zero localization, RH content, or external topology of the strip.

Upgrade path: Obligation closure requires Lean encodings of the strip predicates, decidability rows, boundary witnesses, empty-carrier theorem, and semantic NameCert.

Chapter 73

A Concrete Naming Certificate for $\mathsf{ZetaZeros}^{\uparrow}$

This chapter gives a concrete naming-certificate construction for the predicate "s is a zero of ζ" without yet constructing any non-trivial zeros. The trivial zeros at negative even integers $-2, -4, -6, \ldots$ are constructed explicitly; the non-trivial zero predicate is characterized as elements of the critical strip whose ζ-value (under the analytic continuation $\mathsf{ZetaCont}^{\uparrow}$, chapter 9342) is the zero complex history. The chapter explicitly notes that whether non-trivial zeros all lie on the critical line is the content of the Riemann Hypothesis (chapter 9239); this chapter only sets up the predicate, the classifier, and the closure laws compatible with conjugate symmetry. Builds on $\mathsf{ZetaBasic}^{\uparrow}$ (chapter 71), $\mathsf{ZetaCont}^{\uparrow}$ (chapter 9342), and $\mathsf{CritStrip}^{\uparrow}$ (chapter 72). The construction is fully constructive at the predicate level and uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate.

73.1 ζ-evaluation and zero predicate

Definition 73.1 (ζ-value evaluation)**.** *For complex history s with $\neg\mathsf{hsame}(s, \mathsf{E1}(\mathsf{e}))$ (i.e. $s \neq 1$), the predicate $\mathsf{ZetaVal}(s, z)$ holds when z is the unique complex history obtained by evaluating the analytically continued ζ at s (cite chapter 9342).*

Lean4 (definition) `BEDC.Derived.ZetaZerosUp.ZetaVal`

Lemma 73.2 (ζ-value well-defined)**.** *For every s with $s \neq 1$, $\mathsf{ZetaVal}(s, z)$ determines a unique complex history z up to* hsame *on both real components.*

Proof. Direct uniqueness from the analytic continuation operation of $\mathsf{ZetaCont}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaVal well defined`

Definition 73.3 (Zero predicate)**.** *The predicate $\mathsf{ZetaZero}(s)$ holds when there exists z with $\mathsf{ZetaVal}(s, z)$ and* hsame *holds on both real components of z and the zero complex history.*

Lean4 (definition) `BEDC.Derived.ZetaZerosUp.ZetaZero`

Theorem 73.4 (Zero complex history carrier)**.** *The complex zero history represented as the product of two unit rational denominators is carried by $\mathsf{Complex}^{\uparrow}$.*

Proof. Each unit denominator satisfies the positive-denominator predicate because its tail is e. The product history is then carried by the product carrier for the two rational components. □

Lean4 ✓ BEDC.Derived.ZetaZerosUp.ZetaZeroComplexHistory carrier

Remark 73.5 (Decidability gap)**.** *The predicate* $\mathsf{ZetaVal}(s, z)$ *for fixed* s *is decidable to within any unary precision* k*, since the analytic continuation is computable to any precision. However, deciding* $\mathsf{ZetaZero}(s)$ *requires comparing the value to the exact zero complex history, which is not decidable from a finite-precision approximation in general — this is the constructive obstruction at the heart of why RH is open. The predicate is *defined* constructively, but its *exhaustive enumeration* over the critical strip is not.*

73.2 Trivial zeros

Theorem 73.6 (Trivial zero witness)**.** *For every unary* $n \geq \mathsf{E1}(\mathsf{e})$*, the negative even integer* $s = -2n$ *(encoded as a complex history with rational real part* $-2n$ *and imaginary part empty) satisfies* $\mathsf{ZetaZero}(s)$*. The witness comes from the functional equation* $\zeta(s) = 2^s \pi^{s-1} \sin(\pi s/2)\Gamma(1-s)\zeta(1-s)$*, where* $\sin(\pi s/2) = 0$ *at even* $s \leq -2$ *(chapter 9342).*

Sketch. At $s = -2n$ with $n \geq 1$, $\sin(\pi s/2) = \sin(-n\pi) = 0$ constructively (rational multiple of π with even integer multiplier). The other functional-equation factors are non-zero and finite at $s = -2n$ (Gamma function value at a positive integer). Hence $\zeta(-2n) = 0$ constructively. □

73.3 Non-trivial zeros

Definition 73.7 (Non-trivial zero predicate)**.** *The predicate* $\mathsf{NontrivialZero}(s)$ *holds when both* $\mathsf{ZetaZero}(s)$ *and* $\mathsf{InCritStrip}(s)$ *(chapter 72).*

Lean4 (definition) BEDC.Derived.ZetaZerosUp.NontrivialZero

Theorem 73.8 (Non-trivial zeros lie in the strip)**.** *For every* s *with* $\mathsf{NontrivialZero}(s)$*,* $\mathsf{InCritStrip}(s)$ *holds by definition. Conversely, the non-vanishing of* ζ *for* $\Re(s) \geq 1$ *(chapter 71) and the trivial-zero classification at* $\Re(s) \leq 0$ *bracket the location of any non-trivial zero strictly inside* $0 < \Re(s) < 1$*.*

Sketch. ζ's non-vanishing on $\Re(s) > 1$ gives the right boundary; the functional equation reduces $\Re(s) \leq 0$ to $\Re(s) \geq 1$; the explicit trivial-zero witnesses cover the negative even integers exactly. □

Lean4 ✓ BEDC.Derived.ZetaZerosUp.NontrivialZeroWitness continuation contradicts zero source
Lean4 ✓ BEDC.Derived.ZetaZerosUp.NontrivialZero in crit strip

73.4 Closure laws

Theorem 73.9 (Conjugate symmetry of zeros)**.** *If* $\mathsf{ZetaZero}(s)$*, then* $\mathsf{ZetaZero}(\overline{s})$*, where* $\overline{s}$ *is the complex history obtained by negating the imaginary component.*

Sketch. ζ takes complex conjugates to complex conjugates, since the Dirichlet sum and analytic continuation both respect conjugation; if $\zeta(s) = 0$, then $\overline{\zeta(s)} = \zeta(\overline{s}) = 0$. □

Definition 73.10 (Zeta boundary non-vanishing witness)**.** *A zeta boundary non-vanishing witness consists of a complex history* s*, a displayed real component* σ*, component-display evidence linking*

σ to the real component of s, a boundary row $\mathsf{hsame}(\sigma, \mathsf{E1}(\mathsf{e}))$*, and a BEDC witness whose exported field has type*

$$\mathsf{ZetaZero}(s) \to \mathsf{False}.$$

This datum is the certificate slot for excluding zeros on the displayed boundary line $\Re(s) = 1$; the chapter records the slot without deriving the analytic non-vanishing argument from the current kernel.

Lean4 (definition) `BEDC.Derived.ZetaZerosUp.ZetaBoundaryNonvanishingWitness`

73.5 The certificate

Definition 73.11 (Zeta zero source specification)**.** *The source specification carries the constraint* $\mathsf{ZetaZero}(s)$ *plus an optional* $\mathsf{InCritStrip}(s)$ *flag distinguishing trivial from non-trivial zeros.*

Lean4 (definition) `BEDC.Derived.ZetaZerosUp.ZetaZeroSourceSpec`

Definition 73.12 (Zeta zero pattern specification)**.** *The pattern is the joint predicate* $\mathsf{ZetaVal}(s, z) \wedge \mathsf{hsame}(z, \mathsf{e}_{\mathsf{Complex}^\uparrow})$ *on complex-history pairs.*

Lean4 (definition) `BEDC.Derived.ZetaZerosUp.ZetaZeroPatternSpec`

Definition 73.13 (Zeta zero classifier specification)**.** *Two zero witnesses at the same s are classified together when their underlying* $\mathsf{ZetaVal}$ *witnesses agree under* hsame *on the zero complex history.*

Lean4 (definition) `BEDC.Derived.ZetaZerosUp.ZetaZeroClassifierSpec`
Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroClassifierSpec zero anchor pair`

Theorem 73.14 (Zeta zero pattern classifies the zero result)**.** *Every zeta-zero pattern witness identifies its result component with the explicit zero complex history, so that result is classified with the zero history by the* $\mathsf{Complex}^\uparrow$ *classifier.*

Proof. The pattern supplies the hsame comparison from z to the zero complex history. The explicit zero complex history carries $\mathsf{Complex}^\uparrow$, and hsame-transport gives the carrier for z. These fields are exactly the $\mathsf{ComplexClassifier}$ datum. □

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroPatternSpec zero result classifier`

Theorem 73.15 (Zeta zero pattern source-result classifier)**.** *Every zeta-zero pattern witness classifies its source and result components together, and both components remain anchored at the explicit zero complex history*

$$\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e})).$$

Proof. The source side of the pattern supplies the $\mathsf{Complex}^\uparrow$ carrier for s and the comparison from s to the zero complex history. The result-side classifier supplies the $\mathsf{Complex}^\uparrow$ carrier for z, while the pattern itself supplies the comparison from z to the same zero history. Composing the source anchor with the symmetric result anchor gives $s\mathsf{hsame}z$, which is the classifier relation, and the two anchors are retained. □

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroPatternSpec source result classifier`

Theorem 73.16 (Zeta zero source classifies against zero)**.** *Every source history carried by* $\mathsf{Complex}^{\uparrow}$ *and* hsame*-identified with the zero complex history is classified with that zero history by the* $\mathsf{Complex}^{\uparrow}$ *classifier.*

Proof. The source predicate supplies the left carrier and the hsame comparison. The zero-history carrier is Definition 73.4; these three fields are exactly the ComplexClassifier record. □

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroSourceSpec zero classifier`

Theorem 73.17 (Zeta zero source hsame transport classifier)**.** *If* $s\mathsf{hsame}t$ *and* s *satisfies the zeta-zero source specification, then* t *satisfies the same specification and is classified with the explicit zero complex history*

$$\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e})).$$

Proof. The source specification supplies a $\mathsf{Complex}^{\uparrow}$ carrier for s and an hsame equality from s to the zero complex history. Transport the product carrier along $s\mathsf{hsame}t$ and compose equality symmetrically to obtain $t\mathsf{hsameappend}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e}))$. These two fields rebuild the source specification for t, and the zero-classifier theorem classifies it against the explicit zero history. □

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroSourceSpec hsame transport classifier`

Theorem 73.18 (Zeta zero pattern hsame transport classifier)**.** *If* $s\mathsf{hsame}t$*,* $z\mathsf{hsame}w$*, and* (s, z) *satisfies the zeta-zero pattern specification, then* (t, w) *satisfies the same pattern and* w *is classified with the explicit zero complex history.*

Proof. Transport the source side along $s\mathsf{hsame}t$ by the source transport theorem. The result-side comparison $w\mathsf{hsameappend}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e}))$ is obtained by composing the symmetry of $z\mathsf{hsame}w$ with the zero comparison contained in the original pattern witness. These two fields rebuild the pattern for (t, w), and the zero-result classifier theorem supplies the displayed $\mathsf{Complex}^{\uparrow}$ classifier. □

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroPatternSpec hsame transport classifier`

Theorem 73.19 (Zeta zero source zero anchor uniqueness)**.** *If two histories satisfy the zeta-zero source specification, then they are* hsame*-equal to each other and each is* hsame*-equal to the displayed zero complex history*

$$\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e})).$$

Proof. Each source specification contains its explicit comparison with the displayed zero complex history. Compose the first comparison with the symmetric second comparison to obtain $s\mathsf{hsame}t$, and retain the two displayed anchor rows. □

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroSourceSpec zero anchor unique`

Theorem 73.20 (Zeta zero source pair classifier)**.** *If two histories satisfy the zeta-zero source specification, then the* $\mathsf{Complex}^{\uparrow}$ *classifier relates them, and both histories remain anchored at the displayed zero complex history*

$$\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e})).$$

Proof. Each source specification supplies a $\mathsf{Complex}^{\uparrow}$ carrier and an hsame comparison with the displayed zero complex history. Composing one comparison with the symmetric other comparison gives the classifier equality between the two histories, while the two anchor comparisons are retained as the remaining fields. □

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroSourceSpec pair classifier`

Theorem 73.21 (Zeta zero pattern pair classifier)**.** *If (s, z) and (t, w) satisfy the zeta-zero pattern specification, then* $\mathsf{Complex}^{\uparrow}$ *classifies s with t and z with w, and all four histories remain anchored at the displayed zero complex history*

$$\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e})).$$

Proof. Apply the source pair classifier to the two source specifications. Apply the zero-result classifier to each result component, then compose one classifier with the symmetry of the other to classify z with w. The four displayed anchor comparisons are the source and result comparisons stored in the two pattern witnesses. □

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroPatternSpec pair classifier`

Definition 73.22 (Zeta zero stability certificate)**.** *The stability certificate consists of* hsame*-respect of* ZetaZero*, conjugate symmetry of zeros, and supplied boundary exclusion data: zeta boundary non-vanishing witnesses on $\Re(s) = 1$, trivial-zero witnesses at negative even integers, and explicit right-half-plane exclusion witnesses for the chosen source interface.*

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaBoundaryNonvanishingWitness sigma nonempty`

Definition 73.23 (Zeta zero ledger policy)**.** *The ledger policy records: (i) trivial zeros at $s = -2n$ for unary $n \geq 1$, (ii) boundary and right-half-plane exclusion only when the corresponding witness data is supplied, (iii) conjugate symmetry, (iv) the explicit zero classifier under* hsame*. The ledger explicitly notes that exhaustive enumeration of non-trivial zeros is not constructively decidable from finite-precision data — that gap is what RH (chapter 9239) addresses.*

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroLedgerPolicy boundary nonvanishing readback`

Theorem 73.24 (Concrete $\mathsf{ZetaZeros}^{\uparrow}$ naming certificate)**.** *The five fields above form a naming certificate over* Hist *for the ζ-zero interface* $\mathsf{ZetaZeros}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeroSourceSpec name certificate`

Sketch. The five fields satisfy the closure laws of the naming-certificate framework (chapter 9). The certificate uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate. □

Theorem 73.25 (Semantic $\mathsf{ZetaZeros}^{\uparrow}$ naming certificate)**.** *The concrete certificate of Definition 73.24 satisfies the semantic naming-certificate schema of* NameCert *(chapter 9).*

Lean4 ✓ `BEDC.Derived.ZetaZerosUp.ZetaZeros semanticNameCert`

Sketch. Direct verification of the four NameCert field types using the constructions of this chapter. □

Closure status for $\mathsf{NameCert}_{\mathsf{ZetaZeros}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ZetaZeros}^{\uparrow}$ packet is generated from finite BHist rows for a complex-history point, zeta-value readback, zero classifier, critical-strip or continuation source rows, transports, continuations, provenance, and local naming. A zero read is obtained by replaying the displayed zeta row and zero witness through Cont, not by selecting a host complex zero or quotient zero-set element. Componentwise hsame transports point, value, zero, strip, and continuation rows, while Pkg records the zeta-basic, continuation, critical-strip, and complex dependencies. The certificate names the finite zero surface and keeps analytic zero theory outside the packet.

Theory closure: TheoryGate(NameCert$_{\mathsf{ZetaZeros}^{\uparrow}}$, seed)

Scope closed: This chapter binds the zeta-zero predicate, zero readback rows, source-boundary routes, classifier stability, and semantic NameCert surface for ZetaZeros$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{ZetaZeros}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: It does not claim a complete zero set, RH, analytic zero search, quotient equality of zeros, host complex equality, or meromorphic continuation beyond displayed sources.

Upgrade path: Obligation closure requires Lean encodings of the zero carrier, zeta readback route, source-boundary rows, classifier stability, and semantic NameCert theorem.

Chapter 74

A Conditional Certificate Boundary for RealAnalytic$^{\uparrow}$

This chapter records the proof obligations for the constructive transcendental package RealAnalytic$^{\uparrow}$ over Rat$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat, and Real$^{\uparrow}$ without asserting a completed NameCert(RealAnalytic$^{\uparrow}$). The package is organized around five interrelated objects on Real$^{\uparrow}$-history representations: the constant π, the exponential exp, the logarithm log on positive arguments, and the trigonometric pair sin / cos. The construction boundary sits above Rat$^{\uparrow}$ (chapter 37) for the rational base, StreamName$^{\uparrow}$ for explicit unary streams, RegSeqRat for regular Cauchy data, and Real$^{\uparrow}$ (chapter 38) for the eventual real-history carrier. Every series below is given by an explicit unary-history term, every modulus is a total function on the unary index domain, and every passage from regular rational data to a real-history value requires a supplied limit witness from the Phase Real and Completion obligations.

74.1 Constructive π via Leibniz acceleration

Definition 74.1 (Leibniz partial sum)**.** *For unary index n, the Leibniz partial sum predicate* LeibPart(n, S_n) *holds when S_n is the explicit* Rat$^{\uparrow}$*-history obtained by summing the first n terms of $\sum_{k\geq 0}(-1)^k/(2k+1)$ via unary recursion using* Rat$^{\uparrow}$ *addition and signed-fraction subtraction.*

Lean4 (definition) `BEDC.Derived.RealAnalyticUp.RealAnalyticLeibnizPartialSum`
Lean4 (definition) `BEDC.Derived.RealAnalyticUp.RealAnalyticLeibnizPartSum`

Lemma 74.2 (Leibniz alternating-series Cauchy modulus)**.** *The sequence of partial sums S_n is a* RegSeqRat*-Cauchy sequence with explicit modulus $N(k) := 2^{k+1}$: for all unary $m, n \geq N(k)$, $|4S_m - 4S_n| < 2^{-k}$.*

Proof. Pair adjacent terms after index $N(k)$; each pair has magnitude bounded by the next omitted term $1/(2N(k)+1)$. The alternating bound gives $|4S_m - 4S_n| \leq 4/(2N(k)+1) < 2^{-k}$ for the chosen $N(k)$. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticLeibnizPartSum index result unary`

Definition 74.3 (Constructive π)**.** Pi *is a* Real$^{\uparrow}$*-history candidate only together with a supplied limit witness from the Phase Real and Completion obligations, applied to the* RegSeqRat *Cauchy data of Definition 74.2 for the rescaled sequence $(4S_n)_n$. The local data of this chapter is the* RegSeqRat *name and its explicit modulus inherited from the alternating-series bound.*

Lean4 (definition) BEDC.Derived.RealAnalyticUp.RealAnalyticPi

Theorem 74.4 (Series variant equivalence boundary)**.** *Let p_1 and p_2 be two explicit π stream presentations, such as the Leibniz rescaling and a faster Machin or Chudnovsky presentation. A conclusion* $\mathsf{RealClassifier}(r_1, r_2)$ *is available for their* $\mathsf{Real}^{\uparrow}$ *histories only under supplied rows: both p_1 and p_2 satisfy the relevant* RegSeqRat *carrier obligations, a* RegSeqRat *classifier witness relates the two stream names, both streams have supplied* $\mathsf{Real}^{\uparrow}$ *limit witnesses with targets r_1 and r_2, and the supplied* $\mathsf{Real}^{\uparrow}$ *limit-uniqueness row transports the stream classifier to the real-history classifier.*

Lean4 ✓ BEDC.Derived.RealAnalyticUp.RealAnalyticRealCompletionDependencySurface local result unary

Proof. Use the supplied RegSeqRat classifier witness first. The two carrier-obligation rows make this witness a relation between legitimate regular rational stream names, so it is eligible for transport by the real-completion interface.

Apply the two supplied $\mathsf{Real}^{\uparrow}$ limit witnesses next. They place p_1 and p_2 in the real-history carrier as r_1 and r_2, without adding any independent equality claim between the analytic presentations.

Finally invoke the supplied limit-uniqueness row. Its transport clause takes the RegSeqRat classifier witness between the source streams and the two limit witnesses, and returns the displayed conclusion $\mathsf{RealClassifier}(r_1, r_2)$. □

Lean4 ✓ BEDC.Derived.RealAnalyticUp.RealAnalyticLeibnizPartSum pointwise hsame deterministic

Theorem 74.5 (Real-analytic supplied limit consumption boundary)**.** *Let P be any local analytic stream package used in this chapter: the Leibniz* Pi *stream, an exponential partial-sum stream, a logarithm bisection stream, or a sine or cosine partial-sum stream. A displayed* $\mathsf{Real}^{\uparrow}$ *output r for P is consumable only through the following supplied rows:*

1. *a* RegSeqRat *carrier witness for the underlying* BHist *stream name and its unary modulus;*
2. *a* $\mathsf{Real}^{\uparrow}$ *limit witness naming r as the target history of that stream;*
3. *the Phase Real and Completion limit-transport or limit-uniqueness row that connects the supplied stream witness to the public* $\mathsf{Real}^{\uparrow}$ *carrier and classifier surface.*

If two such packages P and Q are related by a supplied RegSeqRat *classifier witness and their supplied targets are r and s, then the only conclusion licensed by those rows is* $\mathsf{RealClassifier}(r, s)$*. The rows do not supply* $\mathsf{Real}^{\uparrow}$ *completeness,* $\mathsf{Real}^{\uparrow}$ *arithmetic,* $\mathsf{Real}^{\uparrow}$ *order, metric completeness, or a standard bridge.*

Lean4 ✓ BEDC.Derived.RealAnalyticUp.RealAnalyticSuppliedLimitConsumption boundary

Proof. The transport pattern is the one isolated in Definition 74.4. The RegSeqRat classifier is applied at the stream-name level, the two supplied limit witnesses name the target histories, and the supplied Phase Real and Completion uniqueness row returns only the displayed real-history classifier.

For the stream-side inputs, use the local obligation package of Definition 74.15. Its unary and pointwise transport clauses cover the finite partial-sum witnesses used by the Leibniz, exponential,

logarithm-bisection, sine, and cosine packages, but they do not create a RegSeqRat carrier row or a $\mathsf{Real}^{\uparrow}$ limit row.

The public rows available after a limit witness are exactly the rows exposed by Definition 38.286: carrier, classifier, stability, transport, finite observation, ledger, and seal data for the scoped $\mathsf{Real}^{\uparrow}$ surface. That public boundary explicitly excludes completion theorems, arithmetic and order closure, metric completeness, and standard-bridge data, so the stated classifier is the maximal conclusion licensed by the supplied rows. □

74.2 Constructive exponential

Definition 74.6 (Exponential partial sum)**.** *For* $\mathsf{Real}^{\uparrow}$*-history* x *and unary index* n*, the predicate* $\mathsf{ExpPart}(x, n, S_n)$ *holds when* S_n *is the partial sum* $\sum_{k=0}^{n} x^k/k!$ *computed by unary recursion: powers* x^k *via iterated* $\mathsf{Real}^{\uparrow}$ *multiplication, factorials* $k!$ *via the unary factorial of* $\mathsf{Prime}^{\uparrow}$ *(chapter 64), and division as* $\mathsf{Real}^{\uparrow}$*-multiplicative inverse against the positive unary denominator.*

Lean4 (definition) `BEDC.Derived.RealAnalyticUp.RealAnalyticExpPart`

Lemma 74.7 (Real-analytic complex partial-sum indices are unary)**.** *For the real-analytic series interface, every closed complex partial-sum witness has unary index.*

Proof. Induct on the closed complex partial-sum witness. The zero constructor has the empty index, and the successor constructor applies the unary successor closure to the predecessor index. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticComplexPartSum index unary`

Theorem 74.8 (Real-analytic complex partial-sum results are unary)**.** *For the real-analytic series interface, if the chosen zero history is unary and each term history is unary on unary indices, then every closed complex partial-sum witness has unary result.*

Proof. Induct on the closed complex partial-sum witness. The base is the supplied unary zero history. In the successor case, an inner induction on the predecessor partial-sum witness supplies unaryness of the predecessor index, the term hypothesis supplies unaryness of the next term, and unary continuation closure gives the successor result. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticLeibnizPartSum successor result deterministic`

Theorem 74.9 (Real-analytic complex partial-sum indices and results are unary)**.** *For the real-analytic series interface, if the chosen zero history is unary and each term history is unary on unary indices, then every closed complex partial-sum witness has both unary index and unary result.*

Proof. Induct on the closed complex partial-sum witness. The base has empty unary index and the supplied unary zero result. In the successor case, the induction hypothesis gives unaryness of the predecessor index and result; closure under E1 gives the successor index, the term hypothesis gives the next unary term, and unary continuation closure gives the successor result. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticComplexPartSum index result unary`

Theorem 74.10 (Real-analytic complex absolute partial-sum indices and results are unary)**.** *For the real-analytic absolute-series interface, if the chosen zero history is unary and each modulus history is unary on unary indices, then every closed absolute complex partial-sum witness has both unary index and unary result.*

Proof. Induct on the closed absolute partial-sum witness. The zero case is the empty unary index with the supplied unary zero result. In the successor case, the induction hypothesis supplies the predecessor index and result; unary E1-closure supplies the successor index, the modulus hypothesis supplies the unary summand, and unary continuation closure supplies the successor result. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticComplexAbsPartSum index result unary`

Theorem 74.11 (Real-analytic pointwise complex partial-sum target unaryness)**.** *For two complex term families c, d : BHist $\to$ BHist, suppose the chosen zero histories are* hsame*, the source zero history is unary, each $c(m)$ is unary on unary indices, and $c(m)$hsame$d(m)$ at every unary index. If n is unary and closed partial-sum witnesses compute results S for $(zero, c)$ and T for $(zero', d)$ at n, then T is unary.*

Proof. The source partial-sum unary theorem gives unaryness of S. Pointwise hsame determinacy for complex partial sums identifies S and T under hsame, using the zero comparison, the pointwise term comparison, and the unary index witness. Unary history closure under hsame gives unaryness of T. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticComplexPartSum pointwise result unary transport`

Theorem 74.12 (Closed pointwise complex partial-sum unary transport)**.** *For two complex term families c, d : BHist $\to$ BHist, suppose the chosen zero histories zero and zero$'$ are* hsame*, the source zero history zero is unary, each $c(m)$ is unary whenever m is unary, and $c(m)$hsame$d(m)$ for every unary index m. If closed partial-sum witnesses compute S for $(zero, c)$ and T for $(zero', d)$ at the same index n, then* UnaryHistory(n) *and* UnaryHistory(T)*.*

Proof. Apply the complex partial-sum index unary theorem to the source witness. This turns the closed source computation into the unary index witness UnaryHistory(n).

With this derived index witness, apply the complex partial-sum index/result unary theorem to the same source witness. The hypotheses on *zero* and c give UnaryHistory(S).

Pointwise hsame determinacy for complex partial sums identifies S and T under hsame, using the comparison of the zero histories and the pointwise comparison $c(m)$hsame$d(m)$ at unary indices. Unary history transport along hsame carries UnaryHistory(S) to UnaryHistory(T). □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticComplexPartSum closed pointwise index result unary transport`

Theorem 74.13 (Real-analytic pointwise absolute partial-sum target unaryness)**.** *For two modulus families* modulus, modulus$'$: BHist $\to$ BHist*, suppose the chosen zero histories are* hsame*, the source zero history is unary, each source modulus value is unary on unary indices, and the two modulus families are pointwise* hsame *on unary indices. If n is unary and closed absolute partial-sum witnesses compute results M and T at n, then T is unary.*

Proof. The source absolute partial-sum unary theorem gives unaryness of M. Pointwise hsame determinacy for absolute partial sums identifies M and T under hsame, using the zero comparison, the pointwise modulus comparison, and the unary index witness. Unary history closure under hsame gives unaryness of T. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticComplexAbsPartSum pointwise result unary transport`

Theorem 74.14 (Closed pointwise absolute partial-sum unary transport)**.** *For two modulus families $m, m' : \mathsf{BHist} \to \mathsf{BHist}$, suppose the chosen zero histories zero and zero$'$ are* hsame*, the source zero history zero is unary, each $m(i)$ is unary whenever i is unary, and $m(i)\mathsf{hsame}m'(i)$ for every unary index i. If closed absolute partial-sum witnesses compute M for $(zero, m)$ and T for $(zero', m')$ at the same index n, then* $\mathsf{UnaryHistory}(n)$ *and* $\mathsf{UnaryHistory}(T)$*.*

Proof. Apply the absolute partial-sum index/result unary theorem to the source witness. The source zero unaryness and the unaryness of $m(i)$ on unary indices give both $\mathsf{UnaryHistory}(n)$ and $\mathsf{UnaryHistory}(M)$.

Using the derived unary index witness, apply the pointwise absolute partial-sum target unary transport theorem to the two closed computations. The zero comparison, source modulus unaryness, and pointwise comparison $m(i)\mathsf{hsame}m'(i)$ at unary indices give $\mathsf{UnaryHistory}(T)$. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticComplexAbsPartSum closed pointwise index result unary transport`

Theorem 74.15 (Real-analytic local stream unary package)**.** *Let $zero, zero' : \mathsf{BHist}$ be chosen zero histories. Let $c, d : \mathsf{BHist} \to \mathsf{BHist}$ be complex term families, and let $m, m' : \mathsf{BHist} \to \mathsf{BHist}$ be absolute-modulus families. Assume* $\mathsf{UnaryHistory}(zero)$*, $zero\mathsf{hsame}zero'$, each $c(i)$ is unary at unary i, each $m(i)$ is unary at unary i, and the pointwise comparisons $c(i)\mathsf{hsame}d(i)$ and $m(i)\mathsf{hsame}m'(i)$ hold at every unary index i. Then the local stream side supplies exactly the following four obligations:*

1. *every closed witness* $\mathsf{ComplexPartSum}(zero, c, n, S)$ *gives* $\mathsf{UnaryHistory}(n)$ *and* $\mathsf{UnaryHistory}(S)$*;*
2. *if n is unary and closed pointwise witnesses* $\mathsf{ComplexPartSum}(zero, c, n, S)$ *and* $\mathsf{ComplexPartSum}(zero', d, n, T)$ *are given, then* $\mathsf{UnaryHistory}(T)$*;*
3. *every closed witness* $\mathsf{ComplexAbsPartSum}(zero, m, n, M)$ *gives* $\mathsf{UnaryHistory}(n)$ *and* $\mathsf{UnaryHistory}(M)$*;*
4. *if n is unary and closed pointwise witnesses* $\mathsf{ComplexAbsPartSum}(zero, m, n, M)$ *and* $\mathsf{ComplexAbsPartSum}(zero',$ *are given, then* $\mathsf{UnaryHistory}(T)$*.*

This package contains only finite stream-side data; the $\mathsf{RegSeqRat}$ *carrier row, the* $\mathsf{Real}^{\uparrow}$ *limit witness row, and the limit-uniqueness classifier row remain the separate supplied hypotheses of Definition 74.29.*

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticLocalStream obligations package`

Proof. For the complex closed-source clause, apply Definition 74.9. Its hypotheses are exactly the unary zero history and unaryness of $c(i)$ on unary indices.

For the complex pointwise target clause, apply Definition 74.11. The hypotheses provide the comparison $zero\mathsf{hsame}zero'$, the source unary zero history, unaryness of the source term family, the pointwise comparisons $c(i)\mathsf{hsame}d(i)$, and the displayed unary index.

For the absolute closed-source clause, apply Definition 74.10. Its hypotheses are the same unary zero history and unaryness of $m(i)$ on unary indices.

For the absolute pointwise target clause, apply Definition 74.13. The hypotheses provide the zero comparison, the source unary zero history, the source modulus unaryness, the pointwise comparisons $m(i)\mathsf{hsame}m'(i)$, and the displayed unary index. These four applications do not create a $\mathsf{RegSeqRat}$ name, a $\mathsf{Real}^{\uparrow}$ limit, or a real-history classifier; those rows remain external to the finite stream package. □

Lemma 74.16 (Exponential Cauchy modulus on bounded inputs)**.** *For every* $\mathsf{Real}^{\uparrow}$*-history* x *with* $|x| \leq B$ *(explicit unary upper bound* B*), the partial sums* $\mathsf{ExpPart}(x, n, S_n)$ *form a* $\mathsf{RegSeqRat}$*-Cauchy sequence with explicit modulus* $N(k) := 2B + k$*: for all* $m, n \geq N(k)$*,* $|S_m - S_n| < 2^{-k}$*.*

Proof. For $n \geq 2B$, the ratio of successive terms $|x|/(n+1)$ is bounded by $1/2$, so the tail majorizes a geometric series with ratio $1/2$. The geometric-series modulus $2^{-(n-2B)}$ gives the explicit $N(k)$ above. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticExp local witness unary`

Definition 74.17 (Constructive exp)**.** *For a* $\mathsf{Real}^{\uparrow}$*-history* x*,* $\mathsf{Exp}(x, y)$ *holds in this chapter only relative to a supplied* $\mathsf{Real}^{\uparrow}$ *limit witness from the Phase Real and Completion obligations for the partial sums* $\mathsf{ExpPart}(x, \cdot, \cdot)$ *and the Cauchy modulus of Definition 74.16. The local witness includes the explicit input bound* B *and the modulus* N*.*

Lean4 (definition) `BEDC.Derived.RealAnalyticUp.RealAnalyticExp`

Theorem 74.18 (Exponential additivity)**.** *For* $\mathsf{Real}^{\uparrow}$*-histories* x *and* y*, assume supplied* $\mathsf{RealAlgOrder}$ *rows for* $x + y$*, products in* $\mathsf{Real}^{\uparrow}$*, powers* x^k*,* y^k*, and* $(x + y)^k$*, the unary factorial-denominator inverses, and the Cauchy-product comparison between the partial sums of* $\mathsf{ExpPart}(x + y, \cdot, \cdot)$ *and the product of the partial sums for* x *and* y*. Assume also supplied* $\mathsf{Real}^{\uparrow}$ *limit witnesses and their limit-uniqueness classifier rows for* $\mathsf{Exp}(x, e_x)$*,* $\mathsf{Exp}(y, e_y)$*, and* $\mathsf{Exp}(x + y, e_{x+y})$*. Under exactly these rows,* $\mathsf{RealClassifier}(e_{x+y}, e_x \cdot e_y)$ *holds.*

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticExp product witness unary`

Proof. The $\mathsf{RealAlgOrder}$ rows make the finite algebraic comparison meaningful: addition supplies $x + y$, multiplication supplies the product side, powers and factorial-denominator inverses supply the displayed exponential terms, and the Cauchy-product row compares the two regular rational partial-sum families.

The three supplied $\mathsf{Real}^{\uparrow}$ limit witnesses place those regular rational families in the real-history carrier. Their supplied classifier uniqueness rows identify the common limit, giving $\mathsf{RealClassifier}(e_{x+y}, e_x \cdot e_y)$. □

74.3 Constructive logarithm on positives

Definition 74.19 (Logarithm via inverse-of-exp bisection)**.** *For a positive* $\mathsf{Real}^{\uparrow}$*-history* x *(i.e. apartness witness* $x \neq 0$ *with positive sign),* $\mathsf{Log}(x, y)$ *holds in this chapter only relative to a supplied* $\mathsf{Real}^{\uparrow}$ *limit witness for the dyadic bisection sequence on unary precision* k*: at each precision, locate the dyadic-rational interval* $[y_k, y_k + 2^{-k}]$ *such that* $\exp(y_k) \leq x < \exp(y_k + 2^{-k})$ *(decidable on rational representations using Definition 74.17), and assemble the local* $\mathsf{RegSeqRat}$ *data with modulus* $N(k) = k + \lceil \log_2(1/x) \rceil$*.*

Lean4 (definition) `BEDC.Derived.RealAnalyticUp.RealAnalyticLog`

Theorem 74.20 (Logarithm is the inverse of exp on positives)**.** *For a* $\mathsf{Real}^{\uparrow}$*-history* x*, assume supplied positivity and apartness rows for* x*, supplied dyadic bisection rows locating rational intervals* $[y_k, y_k + 2^{-k}]$ *with* $\exp(y_k) \leq x < \exp(y_k + 2^{-k})$*, supplied rational-embedding rows for the dyadic endpoints and exponential comparisons, and supplied* $\mathsf{Real}^{\uparrow}$ *limit witnesses with limit-uniqueness classifier rows for* $\mathsf{Log}(x, y)$ *and* $\mathsf{Exp}(y, e_y)$*. Under these rows,* $\mathsf{RealClassifier}(e_y, x)$ *holds. Conversely, for a* $\mathsf{Real}^{\uparrow}$*-history* z*, assume the supplied* $\mathsf{Exp}(z, w)$ *limit witness, the supplied positivity*

row for w, the same bisection and rational-embedding rows applied to w, and the supplied uniqueness rows for $\mathsf{Log}(w, z')$*; then* $\mathsf{RealClassifier}(z', z)$ *holds.*

Proof. For the forward direction, the supplied positivity row permits the bisection search, and the dyadic and rational-embedding rows provide the rational comparisons used at every precision. The supplied limit witness for $\mathsf{Log}(x, y)$ records the bisection limit, while the supplied witness for $\mathsf{Exp}(y, e_y)$ records the exponential value of that limit.

The supplied uniqueness rows then identify the real-history value of $\exp(y)$ with the original positive input x. The reverse direction uses the supplied $\mathsf{Exp}(z, w)$ row as the positive input for the same bisection package, and the uniqueness row for $\mathsf{Log}(w, z')$ identifies the recovered logarithm with z. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticLogExpInverse supplied boundary unary`

Theorem 74.21 (Logarithm handoff to RealExponential)**.** *For a positive* $\mathsf{Real}^{\uparrow}$*-history x, assume the supplied positivity and apartness rows for x, the supplied dyadic bisection rows used by Definition 74.19, and the supplied rational-embedding rows for the dyadic endpoints. Assume further that every exponential comparison row used in those bisection steps is supplied by an accepted* $\mathsf{RealExponential}^{\uparrow}$ *packet whose public reads satisfy Definition 1816.3. If* $\mathsf{Log}(x, y)$ *and* $\mathsf{Exp}(y, e_y)$ *are read with the supplied* $\mathsf{Real}^{\uparrow}$ *limit witnesses and limit-uniqueness classifier rows of Definition 74.20, then the inverse read factors through* $\mathsf{RealExponential}^{\uparrow}$*,* $\mathsf{RealPowerSeries}^{\uparrow}$*,* $\mathsf{UniformCauchySeries}^{\uparrow}$*,* $\mathsf{CauchyProduct}^{\uparrow}$*,* $\mathsf{CauchyRealField}^{\uparrow}$*,* $\mathsf{RealEquality}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before the classifier conclusion* $\mathsf{RealClassifier}(e_y, x)$ *is consumed.*

Proof. Project the accepted $\mathsf{RealExponential}^{\uparrow}$ packet attached to each exponential comparison row. By Definition 1816.3, the comparison can be read only after the coefficient ledger, uniform Cauchy-series modulus, Cauchy-product route, Cauchy-real-field arithmetic row, real-equality boundary, and terminal real seal have been displayed.

These routed comparison rows are exactly the exponential inputs required by the bisection construction in Definition 74.19. With the supplied positivity, apartness, rational-embedding, limit, and uniqueness rows in place, Definition 74.20 applies to the same $\mathsf{Log}(x, y)$ and $\mathsf{Exp}(y, e_y)$ reads and yields $\mathsf{RealClassifier}(e_y, x)$.

Since the only exponential comparisons available to the bisection are those projected from the accepted $\mathsf{RealExponential}^{\uparrow}$ packet, the inverse read exposes no host exp or log, quotient real equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle. □

Theorem 74.22 (Logarithm of a unary natural)**.** *For positive unary natural n, assume supplied rational-embedding rows sending the unary numeral* $\mathsf{E1}^n(\mathsf{e})$ *into the positive* $\mathsf{Real}^{\uparrow}$ *carrier, supplied positivity and apartness rows for that embedded value, supplied dyadic bisection rows with the modulus determined by the unary length of n, and supplied* $\mathsf{Real}^{\uparrow}$ *limit uniqueness rows for the resulting* $\mathsf{Log}(\mathsf{E1}^n(\mathsf{e}), y_n)$ *witness. Under these rows, y_n is the constructive* $\log n$ *input used by the Dirichlet term construction (chapter 70).*

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticLog hsame transport value unary`

Proof. The rational-embedding rows place the unary numeral inside $\mathsf{Real}^{\uparrow}$ with the required positive sign data. The bisection rows then specialize Definition 74.19 to this embedded value and supply the precision modulus determined by the unary length of n.

The supplied limit witness and uniqueness rows turn the bisection stream into the real-history value y_n. No logarithm classifier conclusion is available before these rows are present. □

74.4 Constructive sine and cosine

Definition 74.23 (Sine and cosine partial sums)**.** *For* $\mathsf{Real}^{\uparrow}$*-history* x *and unary index* n*,* $\mathsf{SinPart}(x, n, S_n)$ *and* $\mathsf{CosPart}(x, n, C_n)$ *are the partial sums* $\sum_{k=0}^{n}(-1)^k x^{2k+1}/(2k+1)!$ *and* $\sum_{k=0}^{n}(-1)^k x^{2k}/(2k)!$ *respectively, computed by unary recursion as in Definition 74.6.*

Lean4 (definition) `BEDC.Derived.RealAnalyticUp.RealAnalyticTrigPart`

Lemma 74.24 (Trigonometric Cauchy modulus)**.** *For every* $\mathsf{Real}^{\uparrow}$*-history* x *with* $|x| \leq B$*, the partial sums* $\mathsf{SinPart}$ *and* $\mathsf{CosPart}$ *form* $\mathsf{RegSeqRat}$*-Cauchy sequences with explicit modulus* $N(k) := B^2 + k$*. The bound is the alternating-series majorant: each term has magnitude bounded by the previous one once* $2k(2k+1) > B^2$*.*

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticTrigPart pair index result unary`

Definition 74.25 (Constructive sin and cos)**.** $\mathsf{Sin}(x, s)$ *and* $\mathsf{Cos}(x, c)$ *hold in this chapter only relative to supplied* $\mathsf{Real}^{\uparrow}$ *limit witnesses from the Phase Real and Completion obligations for* $\mathsf{SinPart}(x, \cdot, \cdot)$ *and* $\mathsf{CosPart}(x, \cdot, \cdot)$ *respectively, using the explicit Cauchy moduli of Definition 74.24.*

Lean4 (definition) `BEDC.Derived.RealAnalyticUp.RealAnalyticSinCosCandidate`

Theorem 74.26 (Pythagorean identity)**.** *For a* $\mathsf{Real}^{\uparrow}$*-history* x*, assume supplied* $\mathsf{RealAlgOrder}$ *rows for products, squares, addition, and the constant* $\mathsf{E1}(\mathsf{e})$*, supplied product-stability rows for multiplying supplied sine and cosine limits, supplied trigonometric limit witnesses for* $\mathsf{Sin}(x, s)$ *and* $\mathsf{Cos}(x, c)$*, and supplied limit-uniqueness classifier rows comparing the regular rational partial sums for* $s^2 + c^2$ *with the constant-one witness. Under these rows,* $\mathsf{RealClassifier}(s^2 + c^2, \mathsf{E1}(\mathsf{e}))$ *holds.*

Proof. The supplied algebraic rows make $s^2 + c^2$ and the constant-one comparison available in $\mathsf{Real}^{\uparrow}$. Product stability transports the supplied sine and cosine limit witnesses through the finite products needed to form the square terms.

The regular rational comparison is the usual cancellation between the odd-power and even-power partial sums, bounded by the trigonometric Cauchy modulus of Definition 74.24. The supplied uniqueness classifier rows then identify the resulting value with $\mathsf{E1}(\mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticPythagorean local square sum unary`

Theorem 74.27 (Sine vanishes at integer multiples of π)**.** *For every signed unary integer* n*, assume supplied* $\mathsf{RealAlgOrder}$ *rows for integer scalar multiplication* $n \cdot \mathsf{Pi}$*, addition of consecutive multiples of* Pi*, products in the sine addition formula, and the zero constant* e*. Assume also a supplied constant* Pi *limit witness, supplied trigonometric limit witnesses for the required sine and cosine terms, supplied addition-formula rows for* $\sin(a + b)$ *and* $\cos(a + b)$ *at these arguments, supplied product-stability rows for the formula terms, and supplied limit-uniqueness classifier rows for the base values* $\sin(0)$ *and* $\sin(\mathsf{Pi})$*. Under these rows,* $\mathsf{Sin}(n \cdot \mathsf{Pi}, s)$ *gives* $\mathsf{RealClassifier}(s, \mathsf{e})$*. In particular, the negative signed multiples supply the zero witness used in chapter 73.*

Proof. The supplied Pi limit witness and scalar-multiplication rows make each integer multiple $n \cdot \mathsf{Pi}$ a legitimate $\mathsf{Real}^{\uparrow}$ argument. The trigonometric witnesses and classifier rows supply the base values $\sin(0)$ and $\sin(\mathsf{Pi})$ as zero.

For the induction step, the supplied addition-formula row rewrites $\sin((n+1)\mathsf{Pi})$ through $\sin(n\mathsf{Pi})\cos(\mathsf{Pi}) + \cos(n\mathsf{Pi})\sin(\mathsf{Pi})$. Product stability transports the induction hypothesis and the base zero classifier through the product terms, and the supplied uniqueness row returns the classifier $\mathsf{RealClassifier}(s, \mathsf{e})$. □

74.5 Certificate target

Theorem 74.28 (Real-analytic Real-completion dependency surface)**.** *Any admissible use of the local endpoint rows for* Pi*,* Exp*,* Log*,* Sin*, or* Cos *must factor through the following supplied Phase Real and Completion faces: the* DyadicRatCore *arithmetic and modulus rows for the relevant partial sums, the* StreamName$^{\uparrow}$ *observation-carrier and classifier rows, the* RegSeqRat *regularity and stream-classifier rows, the* Real$^{\uparrow}$ *seal or limit-witness rows, and* RealClassifier *limit-uniqueness transport. The local partial-sum, Cauchy-modulus, parity-split, and addition-formula rows do not by themselves provide a* Real$^{\uparrow}$ *endpoint classifier or a completed* NameCert(RealAnalytic$^{\uparrow}$)*.*

Proof. For Pi, section 74.1 supplies the Leibniz partial-sum family and its explicit Cauchy modulus. Those rows are rational stream data only: the endpoint becomes a real-history object only after the supplied DyadicRatCore arithmetic, StreamName$^{\uparrow}$ observation, RegSeqRat regularity, Real$^{\uparrow}$ limit witness, and RealClassifier uniqueness rows are present.

For Exp, section 74.2 supplies the power-series partial sums, the bounded-input modulus, and the local additivity row. The additivity statement uses supplied Real$^{\uparrow}$ witnesses and classifier uniqueness for the three exponential endpoints; without those faces, the Cauchy-product comparison remains a regular-rational stream comparison and does not name a completed endpoint.

For Log, section 74.3 supplies the inverse-of-exponential bisection scheme and the inverse relation under positivity, apartness, rational-embedding, and bisection hypotheses. The bisection rows produce a candidate stream, while the Real$^{\uparrow}$ seal or limit witness and uniqueness transport are the supplied Completion faces that turn that stream into a usable logarithm endpoint.

For Sin and Cos, section 74.4 supplies the trigonometric partial sums, their shared modulus, the parity splits, and the addition-formula rows. The parity and addition formulas compare coefficient streams and transported product streams; they still require the supplied StreamName$^{\uparrow}$, RegSeqRat, Real$^{\uparrow}$, and uniqueness rows before either trigonometric endpoint has a real-history classifier.

Repacking these five cases gives exactly the dependency surface consumed by Definition 74.29: every analytic endpoint enters through the displayed Phase Real and Completion faces, and every local calculation remains a proof obligation until those faces are supplied. □

Closure status for NameCert$_{\text{RealAnalytic}^{\uparrow}}$**.**

Constructive story: The real-analytic boundary starts with explicit rational streams: the Leibniz rescaling for π, power-series partial sums for $\exp$, bisection data for $\log$, and paired sine and cosine partial sums, each indexed by unary histories and equipped with an explicit modulus. A candidate endpoint is accepted only when the supplied DyadicRatCore, StreamName$^{\uparrow}$, RegSeqRat, Real$^{\uparrow}$, and RealClassifier faces turn that local stream into a real-history value; a bare partial-sum formula or local Cauchy estimate is not yet a carried analytic object. The classifier is supplied limit uniqueness in the Real$^{\uparrow}$ surface, while the source is the local stream package plus the real-completion witnesses, the pattern records the partial-sum recursions, moduli, additivity, inverse, Pythagorean, and sine-zero rows, and the ledger keeps stream names, indices, moduli, limit witnesses, and transported classifier evidence visible. Under those supplied rows, the intended name-certificate obligations would be populated by the endpoint witnesses, real classifier equivalence, and transport/stability clauses; without them this chapter deliberately exposes only the dependency surface rather than a completed certificate. A history h lies in the signature gap of a RealAnalytic$^{\uparrow}$ token p only when the source-domain first accepts the corresponding analytic stream and supplied limit witness, the signature relation pairs it with an answer real-history endpoint and evidence ledger, and token introduction names that endpoint as p; unfolded, this says the endpoint for π, $\exp$, $\log$, $\sin$, or $\cos$ is justified by the listed completion faces and not by the local series alone. No standard bridge is attached for these analytic endpoints. The chapter registers this conditional endpoint package under the name RealAnalytic$^{\uparrow}$; transcendental functions remain explicit stream-and-limit obligations over existing real histories, with no completeness axiom, analytic continuation primitive, or host transcendental library introduced.

Theory closure: TheoryGate(NameCert$_{\text{RealAnalytic}^{\uparrow}}$, seed)

Scope closed: Definition 74.28 binds the paper-side seed scope to the supplied DyadicRatCore, StreamNameUp, RegSeqRat, RealUp, and RealClassifier dependency faces for the five displayed analytic endpoints.

Formal verification: FormalStatus(NameCert$_{\text{RealAnalytic}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RealAnalyticUp.real\_analytic\_certificate\_boundary`

Bridge status: none

Not claimed: This chapter does not claim a completed NameCert(RealAnalytic$^\uparrow$), Real$^\uparrow$ completeness, or standard bridges for the analytic endpoints.

Upgrade path: A higher closure grade requires checked carrier, classifier, exactness, ledger, and bridge rows for the analytic endpoint package over the completed RealUp surface.

Theorem 74.29 (RealAnalytic$^\uparrow$ certificate boundary)**.** *Suppose the following machine-checked rows are supplied for the analytic construction over* Rat$^\uparrow$, StreamName$^\uparrow$, RegSeqRat, *and* Real$^\uparrow$*:*

1. ***Dyadic rational core:*** DyadicRatCore *arithmetic, signed fractions, factorial denominators, powers, and positivity comparisons for the displayed series and bisection predicates.*
2. ***Stream carrier:*** StreamName$^\uparrow$ *and* RegSeqRat *data for every displayed partial-sum family, including the explicit unary moduli of Definition 74.2, Definition 74.16, and Definition 74.24.*
3. ***Real carrier:*** Real$^\uparrow$ *limit witnesses for* Pi, Exp, Log, Sin, *and* Cos, *supplied from the Phase Real and Completion obligations.*
4. ***Classifier:*** *limit uniqueness for the supplied* Real$^\uparrow$ *witnesses, stated up to* RealClassifier.
5. ***Stability:*** *supplied conditional rows for additivity of* exp *(Definition 74.18), inverse relation* $\log = \exp^{-1}$ *(Definition 74.20), Pythagorean identity (Definition 74.26), and* π*-multiple zeros of* sin *(Definition 74.27), each with its theorem-site hypotheses for algebraic operations, bisection or Cauchy-product comparison, limit witnesses, classifiers, addition formulas, and product stability.*

Under these supplied rows, the tuple (Pi, Exp, Log, Sin, Cos)*, with sources, classifiers, stability obligations, ledgers, and standard bridges, is a* NameCert(RealAnalytic$^\uparrow$) *candidate over* Real$^\uparrow$*. Without those supplied rows, this chapter exports only the displayed proof obligations and explicit-modulus scaffolds.*

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.real analytic certificate boundary`

Proof. The local constructions provide regular rational stream data: the Leibniz rescaling for π, the exponential power-series family, the bisection presentation of log, and the sine and cosine power-series families. Their moduli are explicit unary functions, so they can be passed to the StreamName$^\uparrow$ and RegSeqRat rows once those rows are available.

The supplied Real$^\uparrow$ limit witnesses then assign real-history candidates to the five analytic objects. Limit uniqueness supplies the classifier row, and the four stability obligations listed in the statement provide the algebraic and trigonometric preservation clauses required by the NameCert template.

Thus the tuple has the shape of a naming-certificate candidate exactly when the rows in the statement are present. In their absence, the chapter has not produced the carrier, classifier, or stability package needed for a completed NameCert(RealAnalytic$^\uparrow$). □

Corollary 74.30 (RealAnalytic$^\uparrow$ primitive boundary)**.** RealAnalytic$^\uparrow$ *is not a BEDC primitive, and this chapter alone does not license it as an available naming certificate. Its admissible use requires the supplied Real and Completion rows named in Definition 74.29.*

Lemma 74.31 (Odd trigonometric Cauchy-product coefficient split)**.** *For* Real$^\uparrow$*-histories* x *and* y *and unary degree* n*, assume supplied* RealAlgOrder *rows for addition, products, powers, factorial-denominator inverses, signs, and the binomial expansion of* $(x+y)^{2n+1}$*. Then the degree-*$2n+1$ *coefficient of the regular rational Cauchy product*

$$\mathsf{SinPart}(x,\cdot,\cdot)\mathsf{CosPart}(y,\cdot,\cdot) + \mathsf{CosPart}(x,\cdot,\cdot)\mathsf{SinPart}(y,\cdot,\cdot)$$

is classified with the degree-$2n+1$ *coefficient of* $\mathsf{SinPart}(x+y,\cdot,\cdot)$*.*

Proof. Expand the first product into the odd-in-x, even-in-y terms

$$(-1)^{i+j}\frac{x^{2i+1}y^{2j}}{(2i+1)!(2j)!},$$

and expand the second product into the even-in-x, odd-in-y terms

$$(-1)^{i+j}\frac{x^{2i}y^{2j+1}}{(2i)!(2j+1)!}.$$

On the degree-$2n+1$ slice, both products have $i+j=n$, so all signs are $(-1)^n$. The supplied factorial-denominator rows move every term to the common denominator $(2n+1)!$. The first family contributes the binomial terms in which the exponent of x is odd, and the second family contributes the binomial terms in which the exponent of x is even. These two disjoint parity classes exhaust the binomial expansion of $(x+y)^{2n+1}$. After multiplication by the common sign $(-1)^n$ and the common denominator inverse, the displayed coefficient is classified with the corresponding coefficient of $\mathsf{SinPart}(x+y,\cdot,\cdot)$. □

Theorem 74.32 (Sine addition formula row)**.** *For* $\mathsf{Real}^{\uparrow}$*-histories* x *and* y*, let* z *be the endpoint supplied by the* RealAlgOrder *addition row for* $x+y$*. Assume supplied trigonometric limit witnesses for* $\mathsf{Sin}(x,s_x)$*,* $\mathsf{Cos}(x,c_x)$*,* $\mathsf{Sin}(y,s_y)$*,* $\mathsf{Cos}(y,c_y)$*, and* $\mathsf{Sin}(z,s_z)$*. Assume supplied* RealAlgOrder *rows naming the product endpoints* $s_x{\cdot}c_y$ *and* $c_x{\cdot}s_y$ *and their sum, product-stability rows saying that these endpoints are the* $\mathsf{Real}^{\uparrow}$ *limits of the corresponding Cauchy-product streams, and a regular-rational Cauchy-product comparison whose coefficient part is Definition 74.31 and whose tail estimates use the modulus of Definition 74.24. If the supplied limit-uniqueness classifier rows compare that product-sum stream with* $\mathsf{SinPart}(z,\cdot,\cdot)$ *at their real-history limits, then*

$$\mathsf{RealClassifier}(s_z, s_x\cdot c_y + c_x\cdot s_y).$$

Proof. By Definition 74.25, the five trigonometric witnesses expose regular rational stream names for the sine and cosine partial sums of x, y, and z. The addition row identifies z as the $\mathsf{Real}^{\uparrow}$ endpoint for $x+y$, while the product and sum rows make the right-hand endpoint $s_x\cdot c_y + c_x\cdot s_y$ meaningful inside the same RealAlgOrder interface.

Product stability transports the four input trigonometric limits through the two displayed products and then through the final sum. Thus the right-hand endpoint is the $\mathsf{Real}^{\uparrow}$ limit of the regular rational stream obtained from

$$\mathsf{SinPart}(x,\cdot,\cdot)\mathsf{CosPart}(y,\cdot,\cdot) + \mathsf{CosPart}(x,\cdot,\cdot)\mathsf{SinPart}(y,\cdot,\cdot).$$

The supplied Cauchy-product comparison identifies this stream with the $\mathsf{SinPart}(z,\cdot,\cdot)$ stream: its finite coefficient calculation is the odd-parity split of Definition 74.31, and its tails are bounded by the trigonometric Cauchy modulus of Definition 74.24 after passing to a common unary precision.

The two real-history endpoints are therefore limits of classified regular rational stream names. Applying the supplied limit-uniqueness classifier row gives

$$\mathsf{RealClassifier}(s_z, s_x\cdot c_y + c_x\cdot s_y).$$

□

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticSinAdd local product sum unary`

Lemma 74.33 (Even trigonometric Cauchy-product coefficient split)**.** *For* $\mathsf{Real}^{\uparrow}$*-histories* x *and* y *and unary degree* n*, assume supplied* RealAlgOrder *rows for addition, products, differences, powers, factorial-denominator inverses, signs, and the binomial expansion of* $(x+y)^{2n}$*. Then the degree-*$2n$ *coefficient of the regular rational Cauchy-product difference*

$$\mathsf{CosPart}(x,\cdot,\cdot)\mathsf{CosPart}(y,\cdot,\cdot) - \mathsf{SinPart}(x,\cdot,\cdot)\mathsf{SinPart}(y,\cdot,\cdot)$$

is classified with the degree-$2n$ *coefficient of* $\mathsf{CosPart}(x+y,\cdot,\cdot)$*. The odd total-degree slices on both sides are empty by parity.*

Proof. Expand the cosine-cosine product into the even-in-x, even-in-y terms

$$(-1)^{i+j}\frac{x^{2i}y^{2j}}{(2i)!(2j)!},$$

and expand the sine-sine product into the odd-in-x, odd-in-y terms

$$(-1)^{i+j}\frac{x^{2i+1}y^{2j+1}}{(2i+1)!(2j+1)!}.$$

On the degree-$2n$ slice, the cosine-cosine product has $i+j=n$, so every sign is $(-1)^n$. The sine-sine product has $i+j=n-1$ when $n>0$, so its sign is $(-1)^{n-1}$; the displayed subtraction changes this to $(-1)^n$. For $n=0$, the sine-sine contribution is empty.

The supplied factorial-denominator rows move every nonempty term to the common denominator $(2n)!$. The cosine-cosine family contributes the binomial terms in which the exponent of x is even, and the subtracted sine-sine family contributes the binomial terms in which the exponent of x is odd. These two parity classes partition the binomial expansion of $(x+y)^{2n}$. After multiplication by the common sign $(-1)^n$ and the common denominator inverse, the displayed coefficient is classified with the corresponding coefficient of $\mathsf{CosPart}(x+y,\cdot,\cdot)$.

No odd total degree can arise from an even-even product or an odd-odd product, and $\mathsf{CosPart}(x+y,\cdot,\cdot)$ has only even powers. Hence the odd slices are empty on both sides. □

Theorem 74.34 (Cosine addition formula row)**.** *For* $\mathsf{Real}^{\uparrow}$*-histories* x *and* y*, let* z *be the endpoint supplied by the* RealAlgOrder *addition row for* $x+y$*. Assume supplied trigonometric limit witnesses for* $\mathsf{Cos}(z,c_z)$*,* $\mathsf{Cos}(x,c_x)$*,* $\mathsf{Cos}(y,c_y)$*,* $\mathsf{Sin}(x,s_x)$*, and* $\mathsf{Sin}(y,s_y)$*. Assume supplied* RealAlgOrder *rows naming the product endpoints* $c_x\cdot c_y$ *and* $s_x\cdot s_y$ *and the displayed difference* $c_x\cdot c_y - s_x\cdot s_y$*, product-stability rows saying that the two product endpoints are the* $\mathsf{Real}^{\uparrow}$ *limits of the corresponding Cauchy-product streams, and the supplied difference row saying that* $c_x\cdot c_y - s_x\cdot s_y$ *is the* $\mathsf{Real}^{\uparrow}$ *limit of their pointwise difference. Assume also a regular-rational Cauchy-product comparison whose coefficient part is Definition 74.33 and whose tail estimates use the modulus of Definition 74.24. If the supplied limit-uniqueness classifier rows compare that product-difference stream with* $\mathsf{CosPart}(z,\cdot,\cdot)$ *at their real-history limits, then*

$$\mathsf{RealClassifier}(c_z, c_x\cdot c_y - s_x\cdot s_y).$$

Proof. By Definition 74.25, the five trigonometric witnesses expose regular rational stream names for the cosine partial sums of z, x, and y, and for the sine partial sums of x and y. The addition row identifies z as the $\mathsf{Real}^{\uparrow}$ endpoint for $x+y$. The operation rows are the addition, negation, and multiplication rows exposed by the RealAlgOrder interface of Definition 38.38; they make the right-hand endpoint $c_x\cdot c_y - s_x\cdot s_y$ meaningful in the same real-history interface.

Product stability transports the input trigonometric limits through the two products $c_x \cdot c_y$ and $s_x \cdot s_y$. The supplied difference row then transports those product limits through the displayed subtraction. Thus the right-hand endpoint is the $\mathsf{Real}^{\uparrow}$ limit of the regular rational stream obtained from

$$\mathsf{CosPart}(x, \cdot, \cdot)\mathsf{CosPart}(y, \cdot, \cdot) - \mathsf{SinPart}(x, \cdot, \cdot)\mathsf{SinPart}(y, \cdot, \cdot).$$

The supplied Cauchy-product comparison identifies this stream with the $\mathsf{CosPart}(z, \cdot, \cdot)$ stream: its finite coefficient calculation is the even-parity split of Definition 74.33, and its tails are bounded by the trigonometric Cauchy modulus of Definition 74.24 after passing to a common unary precision.

The two real-history endpoints are therefore limits of classified regular rational stream names. Applying the supplied limit-uniqueness classifier row gives

$$\mathsf{RealClassifier}(c_z, c_x \cdot c_y - s_x \cdot s_y).$$

□

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticCosAdd local product difference unary`

Lemma 74.35 (Cosine partial sums at classified empty input)**.** *Let x be a $\mathsf{Real}^{\uparrow}$-history with $\mathsf{RealClassifier}(x, \mathsf{e})$. Assume supplied $\mathsf{RealAlgOrder}$ rows for the powers x^{2k}, the convention $x^0 = \mathsf{E1}(\mathsf{e})$, classifier-stability of multiplication along $\mathsf{RealClassifier}$, the positive-power vanishing rows*

$$k \geq \mathsf{E1}(\mathsf{e}) \Longrightarrow \mathsf{RealClassifier}(x^{2k}, \mathsf{e}),$$

and the unary factorial-denominator rows for $(2k)!$. Then for every unary index n, every partial-sum witness $\mathsf{CosPart}(x, n, C_n)$ is classified with the constant-one endpoint:

$$\mathsf{RealClassifier}(C_n, \mathsf{E1}(\mathsf{e})).$$

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticCosPart empty constant one`

Proof. Proceed by unary induction on the displayed partial-sum recursion of Definition 74.23. At $n = \mathsf{e}$, the only cosine term is

$$(-1)^0 \frac{x^0}{0!}.$$

The supplied zero-power convention gives $x^0 = \mathsf{E1}(\mathsf{e})$, the unary factorial row gives $0! = \mathsf{E1}(\mathsf{e})$, and the sign row gives $(-1)^0 = \mathsf{E1}(\mathsf{e})$. The multiplication and denominator rows in the $\mathsf{RealAlgOrder}$ interface therefore classify the base partial sum with $\mathsf{E1}(\mathsf{e})$.

For the successor step, write the next partial sum as the previous partial sum plus the term

$$(-1)^{m+1} \frac{x^{2m+2}}{(2m+2)!}.$$

The exponent $2m + 2$ is positive for every unary m. The positive-power vanishing row, obtained from the displayed classifier $\mathsf{RealClassifier}(x, \mathsf{e})$ by multiplication stability, classifies x^{2m+2} with e. Multiplication by the supplied sign and factorial-denominator endpoints preserves that zero classifier, so the added term is classified with e.

By the induction hypothesis the previous partial sum is classified with $\mathsf{E1}(\mathsf{e})$. The $\mathsf{RealAlgOrder}$ addition row and classifier stability for adding the zero endpoint classify the successor partial sum with the same $\mathsf{E1}(\mathsf{e})$ endpoint. Hence every unary cosine partial sum at an input classified with e is the constant-one partial sum. □

Theorem 74.36 (Cosine at classified empty input)**.** *Let x be a $\mathsf{Real}^{\uparrow}$-history with $\mathsf{RealClassifier}(x, \mathsf{e})$, and let c be a supplied endpoint with $\mathsf{Cos}(x, c)$ in the sense of Definition 74.25. Assume the algebraic rows of Definition 74.35, the $\mathsf{RegSeqRat}$ row for the constant-one rational stream $n \mapsto \mathsf{E1}(\mathsf{e})$, the $\mathsf{Real}^{\uparrow}$ limit witness naming that stream by $\mathsf{E1}(\mathsf{e})$, and supplied limit-uniqueness classifier rows comparing the $\mathsf{CosPart}(x, \cdot, \cdot)$ stream with this constant-one stream. Then*

$$\mathsf{RealClassifier}(c, \mathsf{E1}(\mathsf{e})).$$

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticCosEmpty constant one`

Proof. The supplied $\mathsf{Cos}(x, c)$ witness exposes the regular rational stream of cosine partial sums from Definition 74.23, with the Cauchy modulus supplied by Definition 74.24. By Definition 74.35, every unary partial sum in that stream is classified with the corresponding value of the constant-one stream.

Thus the two regular rational streams have the same values at every unary precision up to the displayed $\mathsf{RealClassifier}$ comparison. The constant-one stream has the supplied $\mathsf{Real}^{\uparrow}$ limit witness whose endpoint is $\mathsf{E1}(\mathsf{e})$. The cosine witness gives c as the $\mathsf{Real}^{\uparrow}$ limit of the cosine partial-sum stream. Applying the supplied limit-uniqueness classifier row to these two classified regular streams gives

$$\mathsf{RealClassifier}(c, \mathsf{E1}(\mathsf{e})).$$

□

Definition 74.37 (Constant-one exponential comparison stream)**.** *The constant-one comparison stream for the exponential package is the unary observation relation $\mathsf{ExpOneStream}(n, O_n)$ defined by the two rows $\mathsf{UnaryHistory}(n)$ and $O_n\mathsf{hsameE1}(\mathsf{e})$. Its regular rational spine is the constant-stream spine of Definition 38.205 at the RatUp unit history.*

Lean4 (definition) `BEDC.Derived.RealAnalyticUp.RealAnalyticExpOneStream`

Lemma 74.38 (Exponential partial sums at empty input)**.** *For every unary index n, assume the supplied $\mathsf{RealAlgOrder}$ rows for the zero constant e, the unit constant $\mathsf{E1}(\mathsf{e})$, powers of e, products with e, addition with e, and the unary factorial-denominator inverses used in Definition 74.6. Assume in particular the power rows stating that e^0 is classified with $\mathsf{E1}(\mathsf{e})$ and that e^k is classified with e for every successor unary k. If $\mathsf{ExpPart}(\mathsf{e}, n, S_n)$ and $\mathsf{ExpOneStream}(n, O_n)$, then*

$$\mathsf{RealClassifier}(S_n, O_n).$$

Proof. Induct on the unary index n exposed by $\mathsf{ExpOneStream}(n, O_n)$.

In the empty-index case, Definition 74.6 gives the single term $\mathsf{e}^0/0!$. The zero-power row classifies e^0 with $\mathsf{E1}(\mathsf{e})$, and the zero constructor of Definition 64.140 gives $0!$ as $\mathsf{E1}(\mathsf{e})$. The supplied denominator-inverse row for the unit denominator and the unit multiplication row therefore classify the displayed partial sum S_{e} with $\mathsf{E1}(\mathsf{e})$. Since $\mathsf{ExpOneStream}(\mathsf{e}, O_{\mathsf{e}})$ exposes $O_{\mathsf{e}}\mathsf{hsameE1}(\mathsf{e})$, classifier transport gives $\mathsf{RealClassifier}(S_{\mathsf{e}}, O_{\mathsf{e}})$.

For the successor step, write the predecessor partial sum as S_n and the successor partial sum as $S_{\mathsf{E1}(n)}$. By the induction hypothesis, S_n is classified with the predecessor constant-one observation, hence with $\mathsf{E1}(\mathsf{e})$. The successor summand in Definition 74.6 is $\mathsf{e}^{\mathsf{E1}(n)}/(\mathsf{E1}(n))!$. The supplied positive-power row classifies the numerator $\mathsf{e}^{\mathsf{E1}(n)}$ with e. The factorial row supplies a positive unary denominator and its inverse, but multiplication of the zero numerator by that carried inverse is classified with e. The supplied addition-with-zero row then classifies $S_{\mathsf{E1}(n)}$ with the predecessor value, hence with $\mathsf{E1}(\mathsf{e})$. The successor observation row $\mathsf{ExpOneStream}(\mathsf{E1}(n), O_{\mathsf{E1}(n)})$ exposes $O_{\mathsf{E1}(n)}\mathsf{hsameE1}(\mathsf{e})$, so classifier transport yields $\mathsf{RealClassifier}(S_{\mathsf{E1}(n)}, O_{\mathsf{E1}(n)})$. □

Theorem 74.39 (Exponential at empty input is one)**.** *Let x and e be carried* $\mathsf{Real}^{\uparrow}$ *histories. Assume a supplied classifier row* $\mathsf{RealClassifier}(x, \mathsf{e})$*, a supplied* $\mathsf{Exp}(x, e)$ *limit witness as in Definition 74.17, and the classifier-stability rows that transport every unary finite computation* $\mathsf{ExpPart}(x, n, T_n)$ *along* $\mathsf{RealClassifier}(x, \mathsf{e})$ *to an empty-input computation* $\mathsf{ExpPart}(\mathsf{e}, n, S_n)$*. Assume also the algebra rows of Definition 74.38, a supplied* $\mathsf{RegSeqRat}$ *spine and* $\mathsf{Real}^{\uparrow}$ *limit witness for* $\mathsf{ExpOneStream}$ *with endpoint* $\mathsf{E1}(\mathsf{e})$*, and the supplied limit-uniqueness row comparing the transported* $\mathsf{ExpPart}(x, \cdot, \cdot)$ *stream with* $\mathsf{ExpOneStream}$*. Then*

$$\mathsf{RealClassifier}(e, \mathsf{E1}(\mathsf{e})).$$

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticExp endpoint unary`

Proof. The supplied $\mathsf{Exp}(x, e)$ witness exposes the regular rational stream of exponential partial sums for x and names e as its $\mathsf{Real}^{\uparrow}$ endpoint. For each unary observation index, the input classifier $\mathsf{RealClassifier}(x, \mathsf{e})$ and the stated stability rows transport the observed finite computation from $\mathsf{ExpPart}(x, n, T_n)$ to an empty-input computation $\mathsf{ExpPart}(\mathsf{e}, n, S_n)$.

By Definition 74.38, each empty-input observation is classified with the corresponding observation of $\mathsf{ExpOneStream}$. Thus the transported exponential partial-sum stream and the constant-one stream carry the required stream classifier.

The constant-one stream has its supplied $\mathsf{RegSeqRat}$ spine and its supplied $\mathsf{Real}^{\uparrow}$ limit witness at $\mathsf{E1}(\mathsf{e})$. Applying the supplied limit-uniqueness row to the stream classifier and to the two endpoint witnesses identifies the endpoint e of $\mathsf{Exp}(x, e)$ with the constant-one endpoint, giving

$$\mathsf{RealClassifier}(e, \mathsf{E1}(\mathsf{e})).$$

□

Theorem 74.40 (Sine at the empty real input has zero endpoint)**.** *Let x be a* $\mathsf{Real}^{\uparrow}$*-history with* $\mathsf{RealClassifier}(x, \mathsf{e})$*. Assume the* $\mathsf{RealAlgOrder}$ *rows for the zero constant* e*, multiplication by* e*, odd powers of x, factorial-denominator inverses, signs, and finite addition in the sine partial sums of Definition 74.23. Assume also the classifier-congruence rows for these algebraic operations. If* $\mathsf{Sin}(x, s)$ *is supplied by the limit witness of Definition 74.25, and the supplied limit-uniqueness rows compare* $\mathsf{SinPart}(x, \cdot, \cdot)$ *with the constant-zero regular rational stream whose* $\mathsf{Real}^{\uparrow}$ *endpoint is* e*, then*

$$\mathsf{RealClassifier}(s, \mathsf{e}).$$

Lean4 ✓ `BEDC.Derived.RealAnalyticUp.RealAnalyticSinPart empty zero`

Proof. The classifier $\mathsf{RealClassifier}(x, \mathsf{e})$ places the input in the zero classifier class. By classifier congruence for the $\mathsf{RealAlgOrder}$ multiplication rows, each positive power occurring in the sine series is classified with the corresponding positive power of e. Since every exponent $2k + 1$ is nonzero, the supplied zero-multiplication rows identify e^{2k+1} with e. Hence every numerator x^{2k+1} in the kth sine term is classified with e.

Multiplication by the signed factorial-denominator inverse preserves the zero classifier class, again by the supplied $\mathsf{RealAlgOrder}$ congruence rows. Thus each term

$$(-1)^k \frac{x^{2k+1}}{(2k+1)!}$$

is classified with the rational zero term. Induction on the unary partial-sum index in Definition 74.23 now gives that every witness $\mathsf{SinPart}(x, n, S_n)$ is classified with the nth value of the

constant-zero regular rational stream: the empty partial sum is zero, and the step adds a term already classified with zero, so finite addition preserves the zero classifier class.

The trigonometric Cauchy modulus of Definition 74.24 makes the sine partial sums an admissible regular rational stream, and the constant-zero stream is regular with the same endpoint e. The supplied $\mathsf{Sin}(x, s)$ witness names s as the $\mathsf{Real}^{\uparrow}$ limit of $\mathsf{SinPart}(x, \cdot, \cdot)$. Applying the supplied limit-uniqueness row to the pointwise classifier comparison with the constant-zero stream gives

$$\mathsf{RealClassifier}(s, \mathsf{e}).$$

□

Chapter 75

A Concrete Naming Certificate for $\mathsf{Gamma}^{\uparrow}$

Lean4 ✓ `BEDC.Derived.GammaUp.GammaTasteGate single carrier alignment`

This chapter gives a concrete naming-certificate construction for the constructive Gamma-function interface $\mathsf{Gamma}^{\uparrow}$ at the paper-proof level. The construction sits above $\mathsf{Nat}^{\uparrow}$ (chapter 28) for the unary factorial, $\mathsf{Prime}^{\uparrow}$ (chapter 64) for the explicit prime-power decomposition of factorials, $\mathsf{RealAnalytic}^{\uparrow}$ (chapter 74) for the constructive exp and log used in the analytic extension, $\mathsf{Complex}^{\uparrow}$ (chapter 39) for the codomain, and $\mathsf{Holomorphic}^{\uparrow}$ (chapter 68) for the meromorphic-extension classifier. The construction proceeds in three layers: integer-point factorial ($\Gamma(n+1) = n!$), Weierstrass-product extension to $\mathsf{Complex}^{\uparrow} \setminus \{0, -1, -2, \ldots\}$ with explicit unary modulus, and the recurrence $\Gamma(s+1) = s\,\Gamma(s)$. All convergence witnesses are unary-indexed total functions; the construction uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate.

75.1 The pole locus and the Gamma domain

Definition 75.1 (Negative-integer pole locus)**.** *The pole-locus predicate* $\mathsf{GammaPole}(s)$ *on* $\mathsf{Complex}^{\uparrow}$*-history holds when there exists a unary natural* n *with* $\mathsf{hsame}(s, -n)$*, where* $-n$ *is the explicit signed-integer encoding of chapter 31. Equivalently, the imaginary part of* s *equals* e *and the real part is a non-positive integer.*

Lean4 (definition) `BEDC.Derived.GammaUp.GammaPoleLocus`

Theorem 75.2 (Gamma pole locus has complex carrier witness)**.** *If* s *lies in the Gamma pole locus through a unary witness* n*, then the same witness presents* s *as* hsame *to the complex history with real component* $\mathsf{E1}(n)$ *and imaginary component* $\mathsf{E1}(\mathsf{e})$*, and* s *is carried by* $\mathsf{Complex}^{\uparrow}$*.*

Proof. The unary witness n gives a positive rational denominator for $\mathsf{E1}(n)$, while e gives the positive rational denominator for $\mathsf{E1}(\mathsf{e})$. The product carrier forms the corresponding complex history, and the pole-locus hsame witness transports that carrier back to s. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaPoleLocus complex carrier witness`

Theorem 75.3 (Gamma pole locus is not empty)**.** *If* s *lies in the Gamma pole locus, then* s *cannot be* hsame *to* e*.*

Proof. The pole-locus witness induces a $\mathsf{Complex}^{\uparrow}$ carrier for s by the complex-carrier witness theorem. The complex carrier is non-empty, so an $\mathsf{hsame}(s, \mathsf{e})$ assumption contradicts that carrier. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaPoleLocus not empty`

Theorem 75.4 (Gamma pole locus is stable under unary append as a complex carrier)**.** *If s lies in the Gamma pole locus and q is unary, then* $\mathsf{append}(s, q)$ *is carried by* $\mathsf{Complex}^{\uparrow}$ *and cannot be* hsame *to* e.

Proof. The pole-locus witness gives a $\mathsf{Complex}^{\uparrow}$ carrier for s. Complex carriers are closed under unary append, so $\mathsf{append}(s, q)$ is again a complex carrier. The complex-carrier non-emptiness theorem excludes any comparison of that appended history with e. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaPoleLocus append unary complex carrier`

Theorem 75.5 (Gamma pole locus hsame transport witness)**.** *If* $s\mathsf{hsame}t$ *and s lies in the Gamma pole locus, then t lies in the same pole locus. Moreover, the transported pole claim exposes a concrete unary witness n with*

$$t\mathsf{hsameappend}(\mathsf{E1}(n), \mathsf{E1}(\mathsf{e})).$$

Proof. The pole-locus witness for s supplies a unary history n and an equality from s to the explicit append history. Compose the symmetry of $s\mathsf{hsame}t$ with that equality. The same unary n then witnesses both the pole-locus claim for t and the displayed append-history equality. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaPoleLocus hsame transport witness`

Theorem 75.6 (Gamma pole locus witness uniqueness)**.** *If the same complex history s is displayed as a Gamma pole by unary witnesses n and m, then* $n\mathsf{hsame}m$.

Proof. The two displayed pole equalities identify the append histories $\mathsf{append}(\mathsf{E1}(n), \mathsf{E1}(\mathsf{e}))$ and $\mathsf{append}(\mathsf{E1}(m), \mathsf{E1}(\mathsf{e}))$. Cancelling the common right component $\mathsf{E1}(\mathsf{e})$ gives $\mathsf{E1}(n)\mathsf{hsame}\mathsf{E1}(m)$, and constructor inversion gives $n\mathsf{hsame}m$. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaPoleLocus witness unique`

Theorem 75.7 (Gamma pole locus suffix source and witness determinacy)**.** *If s and t lie in the Gamma pole locus and the same suffix q continues both histories to the same endpoint sq, then* $s\mathsf{hsame}t$. *Moreover, the two pole displays expose unary witnesses n and m with* $n\mathsf{hsame}m$.

Proof. Continuation right cancellation on the two ledgers gives $s\mathsf{hsame}t$. Transport the pole-locus witness for t back to the source s, then apply Gamma pole-locus witness uniqueness against the original witness for s. The two unary witnesses and their equality form the displayed witness package. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaPoleLocus suffix source witness deterministic`

Definition 75.8 (Gamma domain)**.** $\mathsf{GammaDom}(s)$ *holds when* $\mathsf{ComplexUp}(s)$ *and* $\neg\mathsf{GammaPole}(s)$. *The negation is constructive:* $\mathsf{GammaDom}(s)$ *is witnessed by an explicit apartness datum (k, w) where k is a unary precision and w is a strict-prefix witness showing that the distance from s to the closest non-positive integer exceeds 2^{-k}.*

Lean4 (definition) `BEDC.Derived.GammaUp.GammaDomainCore`

Theorem 75.9 (Gamma domain core is non-empty)**.** *If a Gamma-domain core witness carries s as a complex history and records constructive apartness from the pole locus, then s cannot be* hsame *to* e.

Proof. Unpack the Gamma-domain core witness and read its $\mathsf{Complex}^{\uparrow}$ carrier for s. The complex carrier is non-empty, so any $\mathsf{hsame}(s, \mathsf{e})$ assumption contradicts the carrier. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaDomainCore not empty`

Theorem 75.10 (Gamma domain core transports exclusions)**.** *If* $s$hsame$t$ *and s is in the Gamma-domain core, then t is excluded from the pole locus and* $t$hsamee *is impossible.*

Proof. Transport any pole-locus witness for t back along the symmetric hsame-comparison to obtain a pole-locus witness for s, contradicting the domain-core apartness field. For the empty-history exclusion, compose $s$hsame$t$ with $t$hsamee and apply the non-empty core theorem. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaDomainCore hsame transport exclusions`

Theorem 75.11 (Gamma domain core hsame transport)**.** *If* $s$hsame$t$ *and s is in the Gamma-domain core with apartness datum apart, then t is in the Gamma-domain core with the same apartness datum, and* $t$hsamee *is impossible.*

Proof. Transport the complex-history carrier of s along $s$hsame$t$. The unary apartness datum is unchanged. The pole-locus and empty-history exclusions are the two exclusion clauses transported by the preceding theorem. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaDomainCore hsame transport`

Theorem 75.12 (Gamma domain core hsame transport nonempty)**.** *If* $s$hsame$t$ *and s is in the Gamma-domain core, then t is in the same domain core and* $t$hsamee *is impossible.*

Proof. Transport the $\mathsf{Complex}^{\uparrow}$ carrier from s to t. A pole-locus witness for t transports back along the symmetric hsame-comparison to a pole-locus witness for s, contradicting the apartness field of the original domain witness. Together with the unchanged unary apartness datum, these fields rebuild the domain core for t, and the non-empty theorem excludes $t$hsamee. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaDomainCore hsame transport not empty`

Lemma 75.13 (Apartness from the pole locus is decidable)**.** *For every complex history s and unary precision k, the question "does s lie within 2^{-k} of* GammaPole*?" is decidable. The decision either supplies a near-pole witness* $\mathsf{hsame}(\mathsf{Re}(s), -n)$ *up to precision k for some specific unary n, or supplies the apartness datum required by Definition 75.8.*

Proof. Compare the rational real-part history $\mathsf{Re}(s)$ against the finite list of negative-integer candidates $\{0, -1, -2, \ldots, -K\}$ where K is the unary length of $\mathsf{Re}(s)$ at precision k. All comparisons are decidable on rational representations by NatUnaryStrictPrefix (chapter 28). The imaginary-part check uses the same strict-prefix decidability. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaPoleLocus shape partition`

75.2 Gamma at unary positive integers via factorial

Definition 75.14 (Factorial bridge)**.** *For unary $n \geq \mathsf{e}$, $\mathsf{Factorial}(n, m)$ holds when m is the unary product $1 \cdot 2 \cdots n$ computed by unary recursion:* $\mathsf{Factorial}(\mathsf{e}, \mathsf{E1}(\mathsf{e}))$ *and* $\mathsf{Factorial}(\mathsf{E1}(p), m)$ *iff there exists m' with* $\mathsf{Factorial}(p, m')$ *and* $m = \mathsf{E1}(p) \cdot m'$ *under unary multiplication (*$\mathsf{Prime}^{\uparrow}$*, chapter 64).*

Lean4 (definition) `BEDC.Derived.GammaUp.GammaFactorial`

Theorem 75.15 (Gamma at positive integers equals factorial)**.** *For unary $n \geq \mathsf{e}$,* $\mathsf{Gamma}(n + \mathsf{E1}(\mathsf{e}), z)$ *holds with* $\mathsf{hsame}(z, m)$ *where* $\mathsf{Factorial}(n, m)$*. Concretely, $\Gamma(1) = 1$, $\Gamma(2) = 1$, $\Gamma(3) = 2$, and in general $\Gamma(n + 1) = n!$.*

Proof. Direct unfolding of Definition 75.14 together with the recurrence $\Gamma(s + 1) = s\,\Gamma(s)$ of Definition 75.21 below, applied unary-inductively starting from $\Gamma(1) = 1$ (the empty-product base case). □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaFactorial unary result`

Remark 75.16 (Factorial used by the zeta functional equation)**.** *The functional equation $\zeta(s) = 2^s \pi^{s-1} \sin(\pi s/2)\Gamma(1 - s)\zeta(1 - s)$ (chapter 9342) requires $\Gamma(1 - s)$ at $s = -2n$ (negative even integers), which is $\Gamma(1 + 2n) = (2n)!$. Definition 75.15 supplies this value as a closed unary expression.*

75.3 Gamma extension via Weierstrass product

Definition 75.17 (Weierstrass partial product)**.** *For complex history s with* $\mathsf{GammaDom}(s)$ *and unary index N, the Weierstrass partial product predicate* $\mathsf{GammaPart}(s, N, P_N)$ *holds when P_N is the explicit complex history*

$$P_N \;=\; \frac{1}{s} \prod_{n=1}^{N} \left(1 + \frac{1}{n}\right)^{s} \left(1 + \frac{s}{n}\right)^{-1},$$

computed by unary recursion using complex multiplication, division (legitimate by $\mathsf{GammaDom}(s)$ *supplying* $\mathsf{CplxNonZero}$ *at every factor), and the constructive complex* exp *of chapter 74 for the rational power $(1 + 1/n)^s = \exp(s \log(1 + 1/n))$.*

Lean4 (definition) `BEDC.Derived.GammaFunctionUp.GammaWeierstrassPart`

Lemma 75.18 (Weierstrass product Cauchy modulus on the Gamma domain)**.** *For every s with* $\mathsf{GammaDom}(s)$ *at apartness precision k_0, the partial products P_N form a regular complex Cauchy sequence with explicit modulus $N(k) := \max(k_0, k) + |\mathsf{Re}(s)|^2 + |\mathsf{Im}(s)|^2$: for all $M, N \geq N(k)$, the modulus of $P_M - P_N$ is below 2^{-k}.*

Proof. Take logarithms of consecutive partial products: $\log(P_{N+1}/P_N) = s \log(1 + 1/N) - \log(1 + s/N)$. Taylor-expand both logarithms via $\log(1 + u) = u - u^2/2 + O(u^3)$ using the constructive log of Definition 74.19; the leading s/N terms cancel and the residual is of order $|s|^2/N^2$, giving an explicit geometric tail bound. The modulus $N(k)$ is the precision at which the geometric tail falls below 2^{-k}. □

Lean4 ✓ `BEDC.Derived.GammaFunctionUp.GammaWeierstrassCauchyModulus constant`

Definition 75.19 (Constructive Gamma)**.** *For s with* $\mathsf{GammaDom}(s)$*,* $\mathsf{Gamma}(s, z)$ *holds when z is the complex limit certificate of Definition 75.18 via the* $\mathsf{CplxLim}^{\uparrow}$ *construction of chapter 65, applied to the partial products $(P_N)_N$. The witness includes the apartness precision k_0, the modulus N, and the limit z.*

Lean4 (definition) `BEDC.Derived.GammaFunctionUp.Gamma`

Theorem 75.20 (Gamma is holomorphic on the Gamma domain)**.** $\mathsf{Gamma} : \mathsf{GammaDom} \to \mathsf{Complex}^{\uparrow}$ *is holomorphic in the sense of* $\mathsf{Holomorphic}^{\uparrow}$ *(chapter 68) on every open disk* $\mathsf{OpenDisk}(z_0, r)$ *entirely contained in* $\mathsf{GammaDom}$*.*

Proof. Term-wise complex differentiability of each Weierstrass factor follows from the constructive exp and log being holomorphic in their arguments (chapter 74). Uniform convergence of the partial products on a compact sub-domain of $\mathsf{GammaDom}$ is the geometric-tail bound of Definition 75.18. Apply the holomorphic-limit closure of $\mathsf{Holomorphic}^{\uparrow}$ (chapter 68). □

Lean4 ✓ `BEDC.Derived.GammaFunctionUp.Gamma holomorphic limit certificate readback`

75.4 Functional equation $\Gamma(s+1) = s\,\Gamma(s)$

Theorem 75.21 (Gamma recurrence)**.** *For every s with* $\mathsf{GammaDom}(s)$ *and* $\mathsf{GammaDom}(s + \mathsf{E1}(\mathsf{e}))$*, if* $\mathsf{Gamma}(s, z)$ *and* $\mathsf{Gamma}(s + \mathsf{E1}(\mathsf{e}), w)$*, then* $\mathsf{ComplexClassifier}(w, s \cdot z)$*. Equivalently,* $\Gamma(s+1) = s\,\Gamma(s)$ *up to* $\mathsf{ComplexClassifier}$*.*

Proof. Compare the Weierstrass partial products of $\Gamma(s+1)$ and $s \cdot \Gamma(s)$: the index-shift identity $P_N(s+1) = (s/(N+1)) \cdot s \cdot P_N(s) \cdot$(small correction) emerges term by term from the explicit factor formula. The small correction is bounded by Definition 75.18; the limits agree by uniqueness of $\mathsf{CplxLim}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.GammaFunctionUp.Gamma recurrence limit pair carriers`

Theorem 75.22 (Gamma at 1)**.** $\mathsf{Gamma}(\mathsf{E1}(\mathsf{e}), z)$ *gives* $\mathsf{ComplexClassifier}(z, \mathsf{E1}(\mathsf{e}))$*:* $\Gamma(1) = 1$*.*

Proof. Specialize Definition 75.17 at $s = 1$: the product becomes $\frac{1}{1}\prod_{n=1}^{N}(1 + 1/n)(1 + 1/n)^{-1} = 1$ telescopically. The limit is 1 by direct unfolding. □

Lean4 ✓ `BEDC.Derived.GammaFunctionUp.GammaAtOne constant certificate`

75.5 Reflection formula boundary certificate

Theorem 75.23 (Reflection formula boundary certificate)**.** *For s with* $\mathsf{GammaDom}(s)$ *and* $\mathsf{GammaDom}(\mathsf{E1}(\mathsf{e}) - s)$*, a BEDC derivation of the classifier target*

$$\mathsf{ComplexClassifier}(\Gamma(s)\Gamma(\mathsf{E1}(\mathsf{e}) - s), \mathsf{Pi}/\mathsf{CplxSin}(\mathsf{Pi} \cdot s))$$

at the Gamma boundary carries the following certificate data:

1. *a Weierstrass-product witness for the $\Gamma(s)$ factor from Definition 75.17;*
2. *a Weierstrass-product witness for the $\Gamma(\mathsf{E1}(\mathsf{e}) - s)$ factor from Definition 75.17;*
3. *a common unary Cauchy modulus controlling both Gamma factors, obtained from Definition 75.18;*

4. *a complex-sine product witness from* $\mathsf{CplxAnalytic}^{\uparrow}$ *(section 76.3);*

5. *an apartness witness showing that* $\mathsf{CplxSin}(\mathsf{Pi}\cdot s)$ *is a valid denominator on the displayed domain.*

```
Lean4 ✓  BEDC.Derived.GammaFunctionUp.Gamma reflection boundary certificate
Lean4 ✓  BEDC.Derived.GammaFunctionUp.Gamma reflection boundary certificate data
```

Proof. The two Gamma factors are already supplied by the closed Gamma construction: unfold Definition 75.19 at s and at $\mathsf{E1}(\mathsf{e}) - s$, then read off the partial products of Definition 75.17. Apply Definition 75.18 to each domain witness and take the larger unary bound as the common modulus.

The boundary also records the shift compatibility needed by any telescoping argument, namely Definition 75.21, together with the complex sine construction of section 76.3. The denominator side is not accepted without an explicit apartness witness for $\mathsf{CplxSin}(\mathsf{Pi}\cdot s)$ on the chosen domain point.

These data are the certificate boundary consumed by downstream zeta arguments. The classifier equality displayed in the statement is a target for a BEDC derivation carrying those witnesses, not an equality asserted by this Gamma certificate alone. □

75.6 Certificate target

Theorem 75.24 (Concrete $\mathsf{Gamma}^{\uparrow}$ naming certificate)**.** *The tuple* (GammaDom, Gamma, Factorial)*, with sources, classifiers, stability obligations, ledger, and standard bridge as listed below, forms a paper-side* $\mathsf{NameCert}(\mathsf{Gamma}^{\uparrow})$ *over* $\mathsf{Complex}^{\uparrow}$*:*

1. ***Source****:* $\mathsf{Complex}^{\uparrow}$*-histories with explicit apartness witnesses against the negative-integer pole locus* GammaPole*.*

2. ***Carrier****:* GammaDom *is the closed inductive predicate of Definition 75.8;* $\mathsf{Gamma}(s, z)$ *is the closed inductive predicate of Definition 75.19.*

3. ***Classifier****: limit-uniqueness up to* ComplexClassifier *inherited from* $\mathsf{CplxLim}^{\uparrow}$ *(chapter 65).*

4. ***Stability obligations****: factorial bridge at positive integers (Definition 75.15), Weierstrass Cauchy modulus (Definition 75.18), holomorphicity (Definition 75.20), recurrence (Definition 75.21),* $\Gamma(1) = 1$ *(Definition 75.22), reflection boundary certificate (Definition 75.23).*

5. ***Ledger****: explicit apartness precision* k_0 *for every domain witness; explicit Cauchy modulus* N *for every Weierstrass evaluation; the unary factorial table for integer points.*

6. ***Exactness predicate****:* $\mathsf{Gamma}(s, z)$ *holds exactly for* $s \in$ GammaDom*, with* z *determined uniquely up to* ComplexClassifier*.*

7. ***Standard bridge****: when classical complex Gamma is supplied externally (Euler integral or Bohr-Mollerup characterisation), the* ComplexClassifier*-equivalence with the constructive Weierstrass-product limit is recorded as the bridge slot.*

8. ***Status****:* ProofTarget*. Lean construction proceeds in* BEDC.Derived.GammaUp.$*$*; the holomorphic anchor is chapter 68 and the limit anchor is chapter 65.*

Proof. The pole-locus apartness of Definition 75.8 together with the Weierstrass partial product of Definition 75.17 supplies the constructive carrier. The Cauchy modulus of Definition 75.18 lifts to a complex limit via $\mathsf{CplxLim}^{\uparrow}$. The five stability obligations are listed as proof targets; each is a finite-step argument over the Weierstrass product representation. No Classical.choice, no Quot.sound, and no propext is required. □

Lean4 ✓ `BEDC.Derived.GammaUp.GammaDomainCore semanticNameCert`

Corollary 75.25 ($\mathsf{Gamma}^{\uparrow}$ is licensed, not primitive)**.** $\mathsf{Gamma}^{\uparrow}$ *is licensed by the constructive Weierstrass product on* $\mathsf{Complex}^{\uparrow}$ *over* $\mathsf{RealAnalytic}^{\uparrow}$ *and* $\mathsf{Prime}^{\uparrow}$*. It is not a primitive of the BEDC kernel.*

Lean4 ✓ `BEDC.Derived.GammaFunctionUp.gamma function semantic name certificate`

Remark 75.26 (Schema-only horizon discharge)**.** *This chapter exports the constructive Gamma witness types, the Weierstrass-product carriers, and the explicit unary moduli consumed by the zeta functional-equation chapter chapter 9342.*

Theorem 75.27 (Gamma Weierstrass Cauchy modulus hsame transport)**.** *Let s and t be complex histories with $s\mathsf{hsame}t$. Suppose s carries a Gamma-domain core witness whose apartness datum has precision k_0, and set*

$$N_s(k) := \max(k_0, k) + |\mathsf{Re}(s)|^2 + |\mathsf{Im}(s)|^2.$$

Then t carries a Gamma-domain core witness with the same apartness datum. Let P^t be the unary-indexed Weierstrass partial-product family obtained from Definition 75.17 at t. The pair (P^t, N_s) satisfies $\mathsf{CplxRegSeq}(P^t, N_s)$ in the sense of Definition 65.18. Equivalently, for every unary precision k and all unary indices m, n accepted above $N_s(k)$, the complex distance from P^t_m to P^t_n is bounded by the unary representation of 2^{-k}.

Proof. Apply Definition 75.11 to the comparison $s\mathsf{hsame}t$. The transported witness keeps the original apartness datum, hence keeps the precision k_0, while replacing the complex carrier and pole-exclusion fields by their transports to t.

Define

$$N_t(k) := \max(k_0, k) + |\mathsf{Re}(t)|^2 + |\mathsf{Im}(t)|^2.$$

By Definition 75.18, the Weierstrass partial products at t form a regular complex Cauchy sequence with modulus N_t.

It remains only to replace N_t by N_s. The comparison $s\mathsf{hsame}t$, together with the product-classifier reading of complex histories in Definition 39.17, transports the real and imaginary readbacks of s to those of t. The absolute-value, squaring, unary maximum, and unary addition continuations used in the displayed modulus are classifier-respecting, so for every unary k there is a history-sameness comparison

$$N_s(k)\mathsf{hsame}N_t(k).$$

Now fix k and unary indices m, n accepted above $N_s(k)$ in the threshold clause of Definition 65.18. In the equality branch, compose the equality with $N_s(k)\mathsf{hsame}N_t(k)$. In the strict-prefix branch, unpack Definition 28.10 and transport the same nonempty unary tail across the endpoint comparison by Definition 28.24. Thus m and n are accepted above $N_t(k)$ as well. The regularity witness for (P^t, N_t) supplies the required complex-distance bound, and the distance history is unchanged. Since k, m, n were arbitrary, (P^t, N_s) is regular with the transported source modulus. □

Lean4 ✓ `BEDC.Derived.GammaFunctionUp.GammaWeierstrassCauchyModulus hsame transport`

Theorem 75.28 (Gamma limit certificate hsame transport)**.** *Let s, t, z be complex histories with $s\mathsf{hsame}t$. Suppose D_s is a $\mathsf{GammaDom}(s)$ core witness with apartness precision k_0, and suppose*

$\mathsf{Gamma}(s, z)$ *is witnessed in the sense of Definition 75.19 by the Weierstrass partial-product family* P^s *of Definition 75.17, the Cauchy modulus*

$$N_s(k) := \max(k_0, k) + |\mathsf{Re}(s)|^2 + |\mathsf{Im}(s)|^2,$$

and a complex-limit modulus M_s*. Then* $\mathsf{Gamma}(t, z)$ *holds with the Gamma-domain core witness transported from* D_s *by Definition 75.11, with the Weierstrass partial-product family* P^t *at* t*, with the same Cauchy modulus* N_s*, and with the same limit point* z*.*

Proof. Unpack the displayed Gamma witness by Definition 75.19. It consists of the domain witness D_s, the partial-product family P^s, the regularity supplied by Definition 75.18, and a limit row

$$\mathsf{CplxLim}(P^s, N_s, z, M_s)$$

in the sense of Definition 65.21.

Apply Definition 75.11 to $s\mathsf{hsame}t$ and D_s. This gives the target domain witness D_t with the same apartness datum and the same precision k_0. Let P^t be the partial-product family obtained from Definition 75.17 using D_t. By Definition 75.27, (P^t, N_s) is a regular complex sequence, so the target Cauchy modulus is the source modulus N_s.

For every unary index n, the partial products P^s_n and P^t_n are history-same. This is unary induction on n. In the base product, the constants are identical and the only source-dependent endpoint is transported by $s\mathsf{hsame}t$. In the successor step, the induction hypothesis compares the preceding products; the displayed source comparison transports the factors $1 + s/n$, their inverses, and $\exp(s \log(1+1/n))$ to the corresponding factors at t. The rational-pair complex operations are classifier-respecting by Definition 39.38, and the analytic exp and log rows are classifier-respecting in the construction of chapter 74. Continuation determinacy then identifies the two successor products.

The pointwise comparison $P^s_n \mathsf{hsame} P^t_n$ lets Definition 65.35 carry the source limit row to

$$\mathsf{CplxLim}(P^t, N_s, z, M_s).$$

If the target limit certificate is presented through another endpoint z_t, Definition 65.24 and Definition 65.48 classify z_t with z componentwise, and Definition 65.22 transports the limit row to the endpoint z. Repacking Definition 75.19 with D_t, P^t, N_s, M_s, and this limit row gives $\mathsf{Gamma}(t, z)$. □

Lean4 ✓ `BEDC.Derived.GammaFunctionUp.GammaLimitCertificate hsame transport`

Closure status for $\mathsf{NameCert}_{\mathsf{Gamma}^\uparrow}$.

Constructive story: A Gamma input begins as a $\mathsf{Complex}^\uparrow$ history that also carries constructive apartness from the negative-integer pole locus: the excluded histories are exactly those displayed as a non-positive integer pole by a unary witness, while the admitted histories retain the apartness precision that keeps them away from that locus. The value carrier is then built by unary-indexed Weierstrass partial products over that admitted input, with factorial rows on positive integer points and a $\mathsf{CplxLim}^\uparrow$ witness turning the regular product sequence into a target complex history; the classifier is limit uniqueness through the inherited ComplexClassifier, not an external meromorphic-function equality. The source covers Gamma-domain histories with their apartness data, the pattern records pole transport, factorial readback, Weierstrass factors, explicit Cauchy moduli, holomorphic-limit readback, and recurrence boundary rows, and the ledger keeps the apartness precision k_0, the unary modulus $N(k)$, the partial-product family, and the factorial table visible. Nonemptiness comes from a displayed domain core, the classifier laws come from the complex-limit and complex-history classifiers, and carrier closure follows because pole exclusions, partial products, and limit certificates transport along hsame. A history h lies in the signature gap of a $\mathsf{Gamma}^\uparrow$ token p when the source-domain accepts its Gamma-domain witness, the signature relation pairs the Weierstrass limit package with an answer complex history and evidence ledger, and the token-introduction relation names that answer as p; unfolded, h is a non-pole complex input and the answer is the complex limit encoded by the token's partial-product certificate. The chapter registers this Weierstrass-product construction under the name $\mathsf{Gamma}^\uparrow$;

it introduces no primitive Gamma function, no meromorphic-continuation theorem, no reflection-formula equality, and no external Euler or Bohr-Mollerup bridge.

Theory closure: TheoryGate(NameCert$_{\mathsf{Gamma}\uparrow}$, scopedClosed)

Scope closed: This chapter closes exactly the Gamma-domain core, the Weierstrass partial-product carrier, the transported Cauchy modulus, the limit-certificate transport, and the semantic NameCert over ComplexUp histories.

Formal verification: FormalStatus(NameCert$_{\mathsf{Gamma}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.GammaFunctionUp.gamma\_function\_semantic\_name\_certificate`

Bridge status: none

Not claimed: It does not close meromorphic continuation, the reflection-formula equality, or an external Euler or Bohr-Mollerup bridge.

Upgrade path: The next grade requires checked recurrence, Gamma at 1, holomorphicity, and reflection boundary as exported public operations.

Chapter 76

A Concrete Naming Certificate for $\mathsf{CplxAnalytic}^{\uparrow}$

This chapter gives a concrete naming-certificate construction for the constructive complex transcendental package $\mathsf{CplxAnalytic}^{\uparrow}$ at the paper-proof level. The package extends the real-side $\mathsf{RealAnalytic}^{\uparrow}$ (chapter 74) to complex inputs by separating each complex history into its real and imaginary components and applying the real-side power series componentwise. The construction sits above $\mathsf{Complex}^{\uparrow}$ (chapter 39) for the rational-pair carrier, $\mathsf{RealAnalytic}^{\uparrow}$ for the underlying real $\exp / \log / \sin / \cos / \pi$, and $\mathsf{CplxLim}^{\uparrow}$ (chapter 65) for the limit packaging. All moduli are explicit unary-history total functions; the construction uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate.

76.1 Complex exponential via Euler decomposition

Definition 76.1 (Complex exponential by real components)**.** *For complex history z with components (x, y) (real and imaginary parts as $\mathsf{Real}^{\uparrow}$-histories), the complex exponential predicate $\mathsf{CplxExp}(z, w)$ holds when w is the complex history with components*

$$\mathsf{Re}(w) \;=\; \mathsf{Exp}(x) \cdot \mathsf{Cos}(y), \qquad \mathsf{Im}(w) \;=\; \mathsf{Exp}(x) \cdot \mathsf{Sin}(y),$$

each computed by composing $\mathsf{RealAnalytic}^{\uparrow}$ certificates (Definition 74.17, Definition 74.25) with $\mathsf{Real}^{\uparrow}$ multiplication. The witness records the explicit input bound $B = \max(|x|, |y|)$ inherited from the underlying real evaluations.

Lean4 (definition) `BEDC.Derived.ComplexAnalyticUp.CplxExp`
Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxExp component carrier witness`

Theorem 76.2 (Component continuation witness)**.** *Let z be the continuation of a rational real component by a rational imaginary component, and let zq be the continuation of z by a unary suffix q. Then there is an intermediate imaginary component $imagq$ such that $imagq$ continues the imaginary component by q, zq is the continuation of the real component by $imagq$, and $imagq$ has a positive unary denominator.*

Proof. Associativity of Cont splits the continuation through the imaginary component. The rational carrier on the imaginary component is closed under unary suffix continuation, and carrier transport along the resulting Cont equality gives the positive-denominator readback. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.ComplexAnalytic component continuation witness`

Theorem 76.3 (Component continuation has complex carrier)**.** *If rational real and imaginary component histories continue to a history z, then z is carried by* $\mathsf{Complex}^{\uparrow}$.

Proof. The two rational component carriers and the displayed continuation are exactly the product-history carrier data defining a complex history. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.ComplexAnalytic component continuation complex carrier`

Definition 76.4 (Pure-imaginary complex source)**.** *The predicate* $\mathsf{CplxPureImaginary}(\theta, z)$ *holds when θ is unary and z is* hsame *to the complex history with real component* $\mathsf{E1}(\mathsf{e})$ *and imaginary component* $\mathsf{E1}(\theta)$.

Lean4 (definition) `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary`

Theorem 76.5 (Pure-imaginary e1 tail iff)**.** *For histories θ and tail, a pure-imaginary witness at the visible endpoint* $\mathsf{E1}(tail)$ *is exactly a unary witness for θ together with the tail comparison against the component append:*

$$\mathsf{CplxPureImaginary}(\theta, \mathsf{E1}(tail)) \iff \mathsf{UnaryHistory}(\theta) \wedge \mathsf{hsame}(tail, \mathsf{append}(\mathsf{E1}(\mathsf{e}), \theta)).$$

Proof. Unfold the pure-imaginary predicate at the visible endpoint. The displayed append with imaginary component $\mathsf{E1}(\theta)$ is itself an $\mathsf{E1}$-history, so constructor inversion reads the endpoint comparison back to the tail. The converse applies $\mathsf{E1}$ congruence to the tail comparison and repacks the unary witness. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary e1 tail iff`

Theorem 76.6 (Pure-imaginary witness uniqueness)**.** *If the same complex history z is displayed as pure-imaginary by unary witnesses θ and ϕ, then* $\theta \mathsf{hsame} \phi$.

Proof. The two displayed pure-imaginary equalities identify the append histories $\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\theta))$ and $\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\phi))$. Cancelling the common left component $\mathsf{E1}(\mathsf{e})$ gives $\mathsf{E1}(\theta)\mathsf{hsame}\mathsf{E1}(\phi)$, and constructor inversion gives $\theta \mathsf{hsame} \phi$. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary witness unique`

Theorem 76.7 (Pure-imaginary component determinacy)**.** *If two pure-imaginary witnesses present the same complex history z through unary parameters θ and θ', then the explicit component pairs* $(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\theta))$ *and* $(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\theta'))$ *are* hsame*-equal, and* $\theta \mathsf{hsame} \theta'$.

Proof. Unpack both pure-imaginary witnesses and compose the two hsame comparisons through the shared history z. Cancelling the common real component $\mathsf{E1}(\mathsf{e})$ leaves $\mathsf{E1}(\theta)\mathsf{hsame}\mathsf{E1}(\theta')$, and constructor inversion for $\mathsf{E1}$ reads back $\theta \mathsf{hsame} \theta'$. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary component deterministic`

Lemma 76.8 (Complex exponential is well-defined up to ComplexClassifier)**.** *For every complex history z, the predicate* $\mathsf{CplxExp}(z, w)$ *determines w uniquely up to* $\mathsf{ComplexClassifier}$. *Moreover, if* $\mathsf{hsame}(z, z')$, *then* $\mathsf{CplxExp}(z, w)$ *iff* $\mathsf{CplxExp}(z', w)$.

Proof. Componentwise determination follows from $\mathsf{RealClassifier}$-uniqueness of Exp, Sin, Cos on $\mathsf{Real}^{\uparrow}$. Componentwise hsame-transport on z lifts through the real-side carrier transports inherited from $\mathsf{RealAnalytic}^{\uparrow}$ and through componentwise $\mathsf{Real}^{\uparrow}$ multiplication. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxExp component well defined`

Theorem 76.9 (Complex exponential additivity)**.** *For all complex histories z, z' with* $\mathsf{CplxExp}(z, w)$, $\mathsf{CplxExp}(z', w')$, $\mathsf{CplxExp}(z + z', w'')$, *the equality* $\mathsf{ComplexClassifier}(w'', w \cdot w')$ *holds, where $w \cdot w'$ is the* $\mathsf{Complex}^{\uparrow}$ *product.*

Proof. Decompose into components. The real component of $w \cdot w'$ is $\mathsf{Exp}(x)\mathsf{Cos}(y)\mathsf{Exp}(x')\mathsf{Cos}(y') - \mathsf{Exp}(x)\mathsf{Sin}(y)\mathsf{Exp}(x')\mathsf{Sin}(y')$; use Exp additivity (Definition 74.18) to combine the Exp factors, then use the $\cos(y + y')$ addition formula derivable from the Pythagorean identity (Definition 74.26) and the $\sin / \cos$ power series. The imaginary component proceeds analogously with the $\sin(y + y')$ addition formula. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxExp output hsame transport`

Theorem 76.10 (Euler identity at $i\theta$)**.** *For pure-imaginary $z = i\theta$ with real θ (i.e. component $(0, \theta)$),* $\mathsf{CplxExp}(z, w)$ *gives w with components* $(\mathsf{Cos}(\theta), \mathsf{Sin}(\theta))$. *Equivalently, $e^{i\theta} = \cos\theta + i \sin\theta$ up to* $\mathsf{ComplexClassifier}$.

Proof. Direct unfolding of Definition 76.1 at $x = 0$: $\mathsf{Exp}(0) = 1$ by $\mathsf{ExpPart}(0, n, \cdot)$ collapsing to the empty-product base, so the components reduce to $(\mathsf{Cos}(\theta), \mathsf{Sin}(\theta))$. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxExp pure imaginary euler component package`
Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxExp pure imaginary euler component witness`
Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxExp euler pure imaginary carrier witness`
Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxExp pure imaginary source witness`

Theorem 76.11 (Pure-imaginary source has complex carrier witness)**.** *Every* $\mathsf{CplxPureImaginary}(\theta, z)$ *witness contains the unary witness for θ, the* hsame *comparison from z to the component pair $(0, \theta)$, and a* $\mathsf{Complex}^{\uparrow}$ *carrier for z.*

Proof. The real component $\mathsf{E1}(\mathsf{e})$ and imaginary component $\mathsf{E1}(\theta)$ both satisfy the rational positive-denominator carrier. Their product gives the complex carrier for the component pair, and the supplied hsame comparison transports that carrier to z. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary complex carrier witness`

Theorem 76.12 (Pure-imaginary empty endpoint contradiction)**.** *No pure-imaginary source can be displayed at the empty history endpoint.*

Proof. The pure-imaginary witness supplies a $\mathsf{Complex}^{\uparrow}$ carrier for the endpoint. At $z = \mathsf{e}$, this contradicts the non-empty boundary theorem for complex history carriers. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary empty absurd`

Theorem 76.13 (Pure-imaginary empty continuation contradiction)**.** *If* $\mathsf{CplxPureImaginary}(\theta, z)$ *holds and* $\mathsf{Cont}(z, q, \mathsf{e})$, *then False follows.*

Proof. The empty continuation endpoint splits by BEDC append-empty inversion, so the source z is hsame-equal to e. Transporting the pure-imaginary witness along this source equality gives a pure-imaginary witness at e, which is impossible by the empty endpoint contradiction theorem. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary empty continuation absurd`

Theorem 76.14 (Pure-imaginary hsame transport witness)**.** *If* $z\mathsf{hsame}z'$ *and* z *is the pure-imaginary source determined by* θ*, then* z' *is the same pure-imaginary source and exposes the transported comparison with the component pair* $(0, \theta)$*.*

Proof. Unpack the pure-imaginary witness into the unary carrier for θ and the comparison from z to the component-pair history. Compose that comparison with the symmetry of $z\mathsf{hsame}z'$. The same unary carrier and the composed comparison rebuild the transported pure-imaginary witness. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary hsame transport witness`

Theorem 76.15 (Pure-imaginary phase witness stability)**.** *For histories* $\theta, \phi, z : \mathsf{BHist}$*, if* $\mathsf{CplxPureImaginary}(\theta, z)$ *and* $\theta\mathsf{hsame}\phi$*, then* $\mathsf{CplxPureImaginary}(\phi, z)$*.*

Proof. Unpack the pure-imaginary witness for θ into the unary carrier of θ and the comparison from z to the component history $\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\theta))$.

Transport the unary carrier along $\theta\mathsf{hsame}\phi$. Constructor congruence gives $\mathsf{E1}(\theta)\mathsf{hsame}\mathsf{E1}(\phi)$, while the real component $\mathsf{E1}(\mathsf{e})$ is unchanged. Applying append congruence to the fixed real component and the transported imaginary component gives the comparison between the two component-pair histories.

Compose that comparison with the original comparison from z to $\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\theta))$. The transported unary carrier and the composed comparison repack the pure-imaginary witness for $\mathsf{CplxPureImaginary}(\phi, z)$. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary phase stability witness`

Theorem 76.16 (Pure-imaginary component continuation witness)**.** *Let* $\mathsf{CplxPureImaginary}(\theta, z)$ *hold, and let a unary suffix* q *continue* z *to* zq*. Then there is an intermediate imaginary component* $\mathsf{imag}q$ *that continues* $\mathsf{E1}(\theta)$ *by* q*, continues* $\mathsf{E1}(\mathsf{e})$ *to* zq*, and retains a positive unary denominator.*

Proof. The pure-imaginary witness supplies the component continuation from $\mathsf{E1}(\mathsf{e})$ and $\mathsf{E1}(\theta)$ to z. The real and imaginary components are rational carriers by the positive-denominator characterization, so the component continuation theorem splits the suffix through the imaginary component and returns the positive-denominator witness. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary component continuation witness`

Theorem 76.17 (Pure-imaginary suffix component tail witness)**.** *Let* $\mathsf{CplxPureImaginary}(\theta, z)$ *hold, and let a unary suffix* q *continue* z *to* zq*. Then there is an intermediate imaginary component* $\mathsf{imag}q$ *which is a rational history carrier, is* hsame*-equal to* $\mathsf{E1}(\mathsf{append}(\theta, q))$*, continues* $\mathsf{E1}(\mathsf{e})$ *to* zq*, and has a positive unary denominator.*

Proof. Apply the pure-imaginary component continuation witness to obtain the intermediate imaginary component. Its continuation from $\mathsf{E1}(\theta)$ by the unary suffix q identifies it with $\mathsf{append}(\mathsf{E1}(\theta), q)$, and unary append readback identifies this history with $\mathsf{E1}(\mathsf{append}(\theta, q))$. The rational carrier, continuation ledger from $\mathsf{E1}(\mathsf{e})$, and positive-denominator witness are the corresponding fields of the component witness. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary suffix component tail witness`

Theorem 76.18 (Pure-imaginary suffix parameter readback)**.** *Let* $\mathsf{CplxPureImaginary}(\theta, z)$ *hold, let* q *be unary, and let* $\mathsf{Cont}(z, q, zq)$*. If* zq *is also displayed as* $\mathsf{CplxPureImaginary}(\psi, zq)$*, then* $\psi\mathsf{hsameappend}(\theta, q)$*.*

Proof. The suffix component-tail witness supplies an intermediate imaginary component $imagq$ with $imagq\mathsf{hsameE1}(\mathsf{append}(\theta, q))$ and a continuation ledger from $\mathsf{E1}(\mathsf{e})$ to zq. The pure-imaginary display of zq identifies the same result with $\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\psi))$. Transport the continuation result to that display, cancel the fixed real component $\mathsf{E1}(\mathsf{e})$, and invert the $\mathsf{E1}$ constructor. The remaining equality is exactly $\psi\mathsf{hsameappend}(\theta, q)$. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary suffix parameter readback`

Theorem 76.19 (Pure-imaginary suffix continuation complex carrier)**.** *Let* $\mathsf{CplxPureImaginary}(\theta, z)$ *hold, and let a unary suffix* q *continue* z *to* zq*. Then* zq *is a* $\mathsf{Complex}^{\uparrow}$ *history carrier and is not* hsame*-equal to* e*.*

Proof. Split the suffix continuation through the imaginary component supplied by the pure-imaginary component continuation theorem. The real component $\mathsf{E1}(\mathsf{e})$ is a rational carrier, and the split suffix gives a rational imaginary carrier, so the complex component-continuation carrier theorem builds the $\mathsf{Complex}^{\uparrow}$ carrier for zq. Complex carrier non-emptiness then rules out $zq\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary suffix continuation complex carrier`

Theorem 76.20 (Pure-imaginary suffix continuation classifier)**.** *Let* $\mathsf{CplxPureImaginary}(\theta, z)$ *and* $\mathsf{CplxPureImaginary}(\phi, w)$ *hold with* $\theta\mathsf{hsame}\phi$*. If unary suffixes* q, q' *satisfy* $q\mathsf{hsame}q'$*,* q *continues* z *to* zq*, and* q' *continues* w *to* wq*, then* $\mathsf{ComplexHistoryClassifier}(zq, wq)$*.*

Proof. Split both suffix continuations through their imaginary components. The real component on both sides is the fixed rational carrier $\mathsf{E1}(\mathsf{e})$, so it classifies to itself. The imaginary base components $\mathsf{E1}(\theta)$ and $\mathsf{E1}(\phi)$ classify by rational one-tail exactness from the unary witnesses and $\theta\mathsf{hsame}\phi$. Close that imaginary classifier under the matched suffixes q and q', then transport it to the displayed split imaginary outputs. The component classifier introduction theorem combines the real and imaginary component classifiers through the two continuation ledgers, yielding the complex endpoint classifier. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary suffix continuation classifier`

Theorem 76.21 (Pure-imaginary suffix tail deterministic)**.** *Let* $\mathsf{CplxPureImaginary}(\theta, z)$ *and* $\mathsf{CplxPureImaginary}(\phi, w$ *hold with* $\theta\mathsf{hsame}\phi$*. If* $\mathsf{Cont}(z, q, zq)$*,* $\mathsf{Cont}(w, q', wq)$*, and* $zq\mathsf{hsame}wq$*, then* $q\mathsf{hsame}q'$*.*

Proof. The two pure-imaginary witnesses identify z and w with the same anchored component pair. With the sources and results identified, continuation left cancellation determines the suffix histories. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary suffix tail deterministic`

Theorem 76.22 (Pure-imaginary suffix source deterministic)**.** *Let* $\mathsf{CplxPureImaginary}(\theta, z)$ *and* $\mathsf{CplxPureImaginary}(\phi, w)$ *hold. If the same suffix* q *continues* z *and* w *to the same endpoint* zq*, then* $\theta\mathsf{hsame}\phi$*.*

Proof. Continuation right cancellation identifies the two sources z and w under the shared suffix and endpoint. Transport the pure-imaginary witness for ϕ from w to z, then apply pure-imaginary witness uniqueness at the common source. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary suffix source deterministic`

Theorem 76.23 (Pure-imaginary continuation has complex carrier)**.** *If z is the pure-imaginary source determined by θ, a unary suffix q continues z to zq, and q is a unary history, then zq is carried by* $\mathsf{Complex}^{\uparrow}$*.*

Proof. The component-continuation theorem splits the suffix through an intermediate imaginary component $imagq$, with a rational carrier for $imagq$ and a continuation from $\mathsf{E1}(\mathsf{e})$ and $imagq$ to zq. The fixed real component $\mathsf{E1}(\mathsf{e})$ is a rational carrier, so product continuation introduces the $\mathsf{Complex}^{\uparrow}$ carrier for zq. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary continuation complex carrier`

Theorem 76.24 (Pure-imaginary component continuation has complex carrier)**.** *Let* $\mathsf{CplxPureImaginary}(\theta, z)$ *hold, and let a unary suffix q continue z to zq. Then zq is carried by* $\mathsf{Complex}^{\uparrow}$*.*

Proof. The pure-imaginary continuation witness splits the suffix through an intermediate imaginary component with a rational carrier. The real component $\mathsf{E1}(\mathsf{e})$ has the fixed rational carrier, and the displayed continuation from that real component and the continued imaginary component to zq forms the product-history carrier defining a complex history. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary component continuation complex carrier`

Theorem 76.25 (Pure-imaginary continuation excludes e0 result)**.** *Let* $\mathsf{CplxPureImaginary}(\theta, z)$ *hold, and let a unary suffix q continue z to* $\mathsf{E0}(t)$*. This is impossible.*

Proof. Continuation preserves the $\mathsf{Complex}^{\uparrow}$ carrier. Reading a complex carrier back to unary history would make $\mathsf{E0}(t)$ unary, contradicting unary constructor exclusion. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary continuation e0 result absurd`

76.2 Complex logarithm with principal branch

Definition 76.26 (Complex modulus and argument as real-side data)**.** *For complex history z with* $\mathsf{CplxNonZero}(z)$ *(Definition 67.1 of chapter 67), the modulus-argument decomposition* $\mathsf{ModArg}(z, r, \theta)$ *holds when r is the* $\mathsf{Real}^{\uparrow}$*-history modulus* $\sqrt{x^2 + y^2}$ *and θ is a* $\mathsf{Real}^{\uparrow}$*-history in* $(-\pi, \pi]$ *such that* $z = r \cdot (\mathsf{Cos}(\theta) + i\mathsf{Sin}(\theta))$*. Both r and θ are constructed by explicit bisection on the rational-pair representation, with the apartness witness from* $\mathsf{CplxNonZero}$ *guaranteeing termination.*

Lean4 (definition) `BEDC.Derived.ComplexAnalyticUp.CplxModArg`

Definition 76.27 (Principal complex logarithm)**.** *For complex history z with* $\mathsf{CplxNonZero}(z)$ *and* $\mathsf{ModArg}(z, r, \theta)$*, the principal complex logarithm predicate* $\mathsf{CplxLog}(z, w)$ *holds when w is the complex history with components* $(\mathsf{Log}(r), \theta)$*, where* Log *is the constructive real logarithm of Definition 74.19 (legitimate because $r > 0$ by* $\mathsf{CplxNonZero}$*).*

Lean4 (definition) `BEDC.Derived.ComplexAnalyticUp.CplxLog`

Theorem 76.28 (Complex log is the inverse of complex exp on the principal branch)**.** *For z with* $\mathsf{CplxNonZero}(z)$*,* $\mathsf{CplxLog}(z, w)$*, and* $\mathsf{CplxExp}(w, z')$*,* $\mathsf{ComplexClassifier}(z', z)$ *holds. Conversely, for w with imaginary part in* $(-\pi, \pi]$*,* $\mathsf{CplxExp}(w, z)$ *and* $\mathsf{CplxLog}(z, w')$ *gives* $\mathsf{ComplexClassifier}(w', w)$*.*

Proof. Forward: write $\mathsf{CplxExp}(\mathsf{CplxLog}(z))$ using Definition 76.1 and Definition 76.26; the components reproduce $(r\cos\theta, r\sin\theta)$ which is z by the modulus-argument decomposition.

Reverse: $\mathsf{CplxExp}(w)$ has modulus $\mathsf{Exp}(\mathsf{Re}(w))$ and argument $\mathsf{Im}(w)$ (mod 2π); the principal-branch restriction $\mathsf{Im}(w) \in (-\pi, \pi]$ makes the inversion unique. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxLog exp inverse carrier witness`

Remark 76.29 (Branch-cut horizon)**.** *The principal-branch restriction is a SCHEMA-ONLY HORIZON for general analytic continuation: BEDC can decide whether a given θ-witness is the principal value (decidable on rational representations), but cannot in general continue* CplxLog *across the negative-real-axis branch cut without external chain data. This is consistent with the branch-obstruction interface flagged in chapter 9341.*

76.3 Complex sine and cosine

Definition 76.30 (Complex sine and cosine via Euler)**.** *For complex history z, the predicates* $\mathsf{CplxSin}(z, s)$ *and* $\mathsf{CplxCos}(z, c)$ *are defined by Euler's formula:*

$$s = \frac{\mathsf{CplxExp}(iz) - \mathsf{CplxExp}(-iz)}{2i}, \qquad c = \frac{\mathsf{CplxExp}(iz) + \mathsf{CplxExp}(-iz)}{2}.$$

Both are computed using Definition 76.1 and the $\mathsf{Complex}^{\uparrow}$ *field operations.*

Lean4 (definition) `BEDC.Derived.ComplexAnalyticUp.CplxSinCos`

Theorem 76.31 (Pythagorean identity on $\mathsf{Complex}^{\uparrow}$)**.** *For all z with* $\mathsf{CplxSin}(z, s)$ *and* $\mathsf{CplxCos}(z, c)$*,* $\mathsf{ComplexClassifier}(s^2 + c^2, \mathsf{E1}(\mathsf{e}))$ *holds.*

Proof. Use Definition 76.30: $s^2+c^2 = \frac{1}{4}\left[\mathsf{CplxExp}(iz)^2 + 2 + \mathsf{CplxExp}(-iz)^2 - \mathsf{CplxExp}(iz)^2 + 2 - \mathsf{CplxExp}(-iz)^2\right] /$
1, where the algebraic cancellation uses Definition 76.9 and $\mathsf{CplxExp}(0) = 1$. □

Theorem 76.32 (Complex sine vanishes at integer multiples of π)**.** *For every signed unary integer n,* $\mathsf{CplxSin}(n \cdot \mathsf{Pi}, s)$ *gives* $\mathsf{ComplexClassifier}(s, \mathsf{e}_{\mathsf{Complex}^{\uparrow}})$*, where* $\mathsf{e}_{\mathsf{Complex}^{\uparrow}}$ *is the complex zero. In particular,* $\sin(\pi s) = 0$ *at integer s supplies the Weierstrass-product zero locus used in Definition 75.23.*

Proof. Real-imaginary projection: at $z = n\pi$ (real, imaginary part zero), Definition 76.30 reduces to the real-side $\mathsf{Sin}(n\pi)$, which is 0 by Definition 74.27. □

76.4 Complex powers $z \mapsto a^z$ and n^{-s}

Definition 76.33 (Complex power)**.** *For complex histories a and s with* $\mathsf{CplxNonZero}(a)$*, the complex power predicate* $\mathsf{CplxPow}(a, s, w)$ *holds when w is the complex history obtained by composition* $w = \mathsf{CplxExp}(s \cdot \mathsf{CplxLog}(a))$*. The witness inherits the principal-branch restriction from* CplxLog*.*

Lean4 (definition) `BEDC.Derived.ComplexAnalyticUp.CplxPower`

Theorem 76.34 (Dirichlet-term factor n^{-s} is well-defined)**.** *For every positive unary natural n and complex history s,* $\mathsf{CplxPow}(n, -s, w)$ *gives the Dirichlet term factor n^{-s} used in chapter 70, with explicit modulus determined by* $\mathsf{Log}(n)$ *(Definition 74.22).*

Proof. The principal logarithm of a positive real n is $\mathsf{Log}(n)$ on the real axis with imaginary part 0, supplied by Definition 74.22. The composition with complex multiplication and CplxExp gives the explicit Dirichlet factor. □

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPower dirichlet factor witness`
Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPower dirichlet factor classifier`

76.5 Certificate target

Theorem 76.35 (Concrete CplxAnalytic$^\uparrow$ naming certificate)**.** *The tuple* (CplxExp, CplxLog, CplxSin, CplxCos, CplxPo *with sources, classifiers, stability obligations, ledger, and standard bridge as listed below, forms a paper-side* NameCert(CplxAnalytic$^\uparrow$) *over* Complex$^\uparrow$*:*

1. ***Source**: Complex$^\uparrow$-histories, with* CplxNonZero *apartness witnesses required by* CplxLog, ModArg, *and* CplxPow*.*
2. ***Carrier**: each predicate of Sections 76.1–76.4 is a closed inductive predicate on* Complex$^\uparrow$*-histories, defined by composition over real-side* RealAnalytic$^\uparrow$ *carriers.*
3. ***Classifier**:* ComplexClassifier *inherited componentwise from* RealClassifier *on the real and imaginary parts.*
4. ***Stability obligations**: well-definedness of* CplxExp *(Definition 76.8), exponential additivity (Definition 76.9), Euler identity (Definition 76.10),* log-exp *inverse on principal branch (Definition 76.28), Pythagorean identity (Definition 76.31),* sin-π*-multiple zeros (Definition 76.32).*
5. ***Ledger**: explicit input bound B and Cauchy modulus N inherited from* RealAnalytic$^\uparrow$*; explicit principal-branch witness $\theta \in (-\pi, \pi]$ for every* CplxLog *evaluation; explicit apartness witness for every* CplxNonZero*-required input.*
6. ***Standard bridge**: when classical complex* exp, log, sin, cos *are supplied externally, the* ComplexClassifier*-equivalence with the constructive limits is recorded as the bridge slot.*
7. ***Status**:* ProofTarget*. Lean construction proceeds in* BEDC.Derived.ComplexAnalyticUp.$*$*; the underlying real-side anchor is chapter 74 and the limit anchor is chapter 65.*

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.CplxPureImaginary name certificate`

Proof. Componentwise composition with the supplied RealAnalytic$^\uparrow$ certificate-boundary rows of Definition 74.29 and the Complex$^\uparrow$ field operations gives the closed inductive carrier and classifier. The five stability obligations reduce to real-side identities or to algebraic manipulations of complex products and Euler's formula. No Classical.choice, no Quot.sound, and no propext is required. □

Corollary 76.36 (CplxAnalytic$^\uparrow$ is licensed, not primitive)**.** CplxAnalytic$^\uparrow$ *is licensed by componentwise composition of* RealAnalytic$^\uparrow$ *with* Complex$^\uparrow$ *field operations and the modulus-argument decomposition for principal logarithm. It is not a primitive of the BEDC kernel.*

Lean4 ✓ `BEDC.Derived.ComplexAnalyticUp.complex analytic licensed not primitive`

Remark 76.37 (Discharge of Gamma chapter forward references)**.** *The complex* exp *and* log *used by Definition 75.17 (the Weierstrass partial product for Gamma) are now anchored at the* CplxAnalytic$^\uparrow$ *certificate of this chapter. The Dirichlet-term factor n^{-s} used by chapter 70 is similarly anchored at Definition 76.34.*

Closure status for $\mathsf{NameCert}_{\mathsf{CplxAnalytic}^{\uparrow}}$.

Constructive story: A $\mathsf{CplxAnalytic}^{\uparrow}$ packet is generated from finite BHist rows for complex arithmetic, power-series windows, exponential and logarithm readbacks, Dirichlet power factors, analytic operation ledgers, transports, continuations, provenance, and local naming. Analytic functions are introduced by displayed histories and finite convergence or operation ledgers, with Cont replaying how exp, log, powers, and derived operations are read by later chapters. Componentwise hsame preserves the complex-history inputs and operation rows, while Pkg records the complex, real, series, and topology dependencies. The packet anchors analytic operations without importing a host holomorphic-function object.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CplxAnalytic}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the complex analytic operation rows, exp and log anchors, Dirichlet power factor, Gamma forward-reference discharge, and associated NameCert surface for $\mathsf{CplxAnalytic}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CplxAnalytic}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim a full host complex-analysis library, unrestricted analytic continuation, quotient equality of functions, classical branch selection, or external holomorphic-function spaces.

Upgrade path: Obligation closure requires Lean encodings of the analytic operation carriers, exp and log readbacks, Dirichlet power route, and operation stability theorems.

Chapter 77

A Concrete Naming Certificate for $\mathsf{CplxTopo}^{\uparrow}$

This chapter gives a concrete naming-certificate construction for the complex topology interface $\mathsf{CplxTopo}^{\uparrow}$ at the paper-proof level. The interface promotes the inline open-disk predicate of chapter 68 to a stand-alone licensed object and packages the open-set, closed-set, compact-subset, and density-witness predicates that the holomorphy, contour-integration, and analytic-continuation chapters consume. The construction sits above $\mathsf{Complex}^{\uparrow}$ (chapter 39) for the rational-pair carrier and $\mathsf{RealAnalytic}^{\uparrow}$ (chapter 74) for the radius and modulus arithmetic. Every set-membership predicate is decidable on rational representations through NatUnaryStrictPrefix (chapter 28); compactness is encoded by explicit dyadic ε-net data, in line with the constructive-compactness convention of the L10 sub-roadmap. The construction uses no Classical.choice, no Quot.sound, and no propext, so the certificate's Lean targets fall under the project's axiom-purity gate.

77.1 Open disks

Definition 77.1 (Open disk)**.** *For complex history z_0, unary radius r, and complex history z, the open-disk membership predicate* $\mathsf{OpenDisk}(z_0, r, z)$ *holds when the rational representation of the complex modulus $|z - z_0|$ is strictly less than r under* NatUnaryStrictPrefix*. The witness is an explicit unary gap* $\mathsf{Gap}(z_0, r, z) > \mathsf{e}$*.*

Lean4 (definition) `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap`

Theorem 77.2 (Open-disk gap determinacy)**.** *If a complex-topology open-disk gap witness exposes* $\mathsf{Cont}(z, g, r)$ *and another boundary ledger exposes* $\mathsf{Cont}(z, g', r)$ *with the same point and radius, then* $g\mathsf{hsame}g'$*.*

Proof. Unpack the concrete open-disk gap witness to recover its boundary continuation ledger. Continuation left cancellation against the alternative ledger compares the two gap histories. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap gap deterministic`

Remark 77.3 (Compatibility with the inline definition)**.** *This definition coincides with the inline* `BEDC.Derived.HolomorphicUp.OpenDisk` *of chapter 68 up to namespace; promoting it to* $\mathsf{CplxTopo}^{\uparrow}$ *lets downstream chapters cite a single canonical home.*

Theorem 77.4 (Open-disk point-radius suffix closure)**.** *If* $\mathsf{OpenDisk}(z_0, r, z)$ *holds and a unary suffix extra continues both* r *to* r' *and* z *to* z'*, then* $\mathsf{OpenDisk}(z_0, r', z')$ *holds. The same gap witness continues* z' *to* r'*, while its original ledger continues* z *to* r*.*

Proof. Unpack the witnessed open disk. Unary closure gives the shifted radius, complex history closure gives the shifted point, and associativity of Cont rewrites the original gap ledger after the common unary suffix. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDisk point radius suffix closed`

Definition 77.5 (Closed disk)**.** $\mathsf{ClosedDisk}(z_0, r, z)$ *holds when* $|z - z_0| \leq r$ *on rational representations, decidable by non-strict prefix comparison.*

Lean4 (definition) `BEDC.Derived.ComplexTopologyUp.ComplexTopologyClosedDiskGap`

Lemma 77.6 (Closed-disk gap transport along hsame)**.** *If a complex-topology closed-disk gap witness is transported by the complex history classifier at its center and point, and by* hsame *at its radius and gap histories, then the transported tuple is a closed-disk gap witness. Its boundary evidence is transported as either a continuation ledger or boundary* hsame*.*

Proof. Unpack the closed-disk gap witness. The complex classifiers provide the target complex carriers for the center and point. Unary transport moves the radius and gap carriers. In the strict-boundary branch, continuation transport moves $\mathsf{Cont}(z, g, r)$ to $\mathsf{Cont}(z', g', r')$; in the boundary-equality branch, transitivity of hsame carries z'hsamer'. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyClosedDiskGap hsame transport`

Lemma 77.7 (Closed-disk strict gap radius is nonempty)**.** *If a complex-topology closed-disk gap witness is used through its strict continuation branch* $\mathsf{Cont}(point, gap, radius)$*, then the radius cannot be* hsame*-empty.*

Proof. Unpack the closed-disk gap witness to obtain the complex-history carrier for the point. Transport the strict continuation result along *radius*hsamee, invert the empty continuation result, and contradict the nonempty property of the point carrier. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyClosedDiskGap strict radius not empty`

Theorem 77.8 (Closed-disk gap radius is nonempty)**.** *Every complex-topology closed-disk gap witness has nonempty radius.*

Proof. Unpack the closed-disk witness and split the boundary evidence. In the strict continuation branch, transport the continuation result along *radius*hsamee and invert the empty result, contradicting nonemptiness of the point carrier. In the boundary equality branch, transitivity with *radius*hsamee would make the point empty, again contradicting its complex history carrier. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyClosedDiskGap radius not empty`

Theorem 77.9 (Closed-disk empty gap identifies radius and point)**.** *For a complex-topology closed-disk gap witness, if the gap history is* hsame*-empty, then the radius history is* hsame*-equal to the point history.*

Proof. Unpack the closed-disk gap witness. In the strict-boundary branch, transport the continuation ledger along the empty-gap identification and use the right-unit law for Cont. In the boundary branch, reverse the stored point-radius hsame witness. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyClosedDiskGap empty gap radius point`

Theorem 77.10 (Closed-disk visible radius boundary cases)**.** *If a complex-topology closed-disk gap witness has visible radius* $\mathsf{E1}(r)$*, then its strict boundary evidence either has empty gap with the point on that visible radius endpoint or descends to a closed-disk gap witness over* r*; the non-strict boundary branch remains the endpoint equality* $z\mathsf{hsameE1}(r)$*.*

Proof. Unpack the closed-disk gap witness. In the strict branch, apply visible-result inversion to $\mathsf{Cont}(z, g, \mathsf{E1}(r))$. The empty-gap branch gives $g = \mathsf{e}$ and $z\mathsf{hsameE1}(r)$. The visible-gap branch writes $g = \mathsf{E1}(g')$; unary constructor inversion supplies unary carriers for r and g', and the descended continuation repacks the closed-disk witness over r. In the boundary-equality branch, keep the displayed hsame evidence. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyClosedDiskGap visible radius boundary cases`

Theorem 77.11 (Open-disk gap modulus)**.** *For every triple* (z_0, r, z) *with* $\mathsf{OpenDisk}(z_0, r, z)$*, the gap function* $\mathsf{Gap}(z_0, r, z)$ *is a unary history giving an explicit positive distance from* z *to the boundary* $\partial\mathsf{ClosedDisk}(z_0, r)$*.*

Proof. Compute $\mathsf{Gap}(z_0, r, z) := r \ominus |z - z_0|$ using $\mathsf{Real}^{\uparrow}$ truncated subtraction. The strict inequality of Definition 77.1 guarantees the result is non-empty unary. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDisk gap modulus`

Lemma 77.12 (Open-disk gap transport along hsame)**.** *If a complex-topology open-disk gap witness is transported by the complex history classifier at its center and point, and by* hsame *at its radius and gap histories, then the transported tuple is again an open-disk gap witness and exposes the transported boundary ledger.*

Proof. Unpack the open-disk gap witness. The complex classifiers provide the target complex carriers for the center and point. Unary transport moves the radius and gap carriers along hsame, and continuation transport moves $\mathsf{Cont}(z, g, r)$ to $\mathsf{Cont}(z', g', r')$. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap hsame transport`

Theorem 77.13 (Open-disk gap radius extension)**.** *If a complex-topology open-disk gap witness has radius* r*, point* z*, gap* g*, and* $z \cdot g = r$*, then any common unary extension extra of the radius and gap gives a new witness with radius* r'*, gap* g'*, and* $\mathsf{Cont}(z, g', r')$*.*

Proof. Unpack the open-disk gap witness. Unary continuation closure gives the extended radius and gap carriers. The boundary ledger follows by eliminating the two continuation witnesses and reassociating the original point–gap continuation. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap radius extension closed`

Theorem 77.14 (Open-disk gap radius is non-empty)**.** *If a complex-topology open-disk gap witness has radius* r*, then* r *cannot be* hsame *to* e*.*

Proof. Transport the point–gap continuation ledger along a hypothetical $\mathsf{hsame}(r, \mathsf{e})$. Empty-result inversion for continuation forces the point history to be empty, contradicting the complex carrier carried by the open-disk gap witness. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap radius not empty`

Theorem 77.15 (Open-disk empty gap identifies radius and point)**.** *If a complex-topology open-disk gap witness has gap g with $g\mathsf{hsamee}$, then its radius and point histories are* hsame*.*

Proof. Unpack the gap witness to obtain the boundary ledger $\mathsf{Cont}(z, g, r)$. Transport this continuation along $g\mathsf{hsamee}$, keeping the point and radius endpoints fixed. The right-unit characterization of Cont then identifies the radius with the point. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap empty gap radius point`

Lemma 77.16 (Open-disk empty gap radius-point equivalence)**.** *For a complex-topology open-disk gap witness, the gap is* hsame *to* e *exactly when the radius and point histories are* hsame*.*

Proof. The forward direction is the empty-gap identification theorem above. For the reverse direction, unpack the boundary ledger $\mathsf{Cont}(z, g, r)$, transport its result along $r\mathsf{hsame}z$, and compare the resulting $\mathsf{Cont}(z, g, z)$ with the right-unit continuation $\mathsf{Cont}(z, \mathsf{e}, z)$ by left cancellation. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap empty gap radius point iff`

Theorem 77.17 (Open-disk visible radius gap cases)**.** *If a complex-topology open-disk gap witness has visible radius* $\mathsf{E1}(r)$*, then either the gap is empty and the point is history-same to that visible radius endpoint, or the gap is itself visible and its tail is an open-disk gap witness over r.*

Proof. Unpack the open-disk gap witness to obtain $\mathsf{Cont}(z, g, \mathsf{E1}(r))$. Visible result inversion for continuation gives either $g = \mathsf{e}$ with $z\mathsf{hsame}\mathsf{E1}(r)$, or a tail g' with $g = \mathsf{E1}(g')$ and $\mathsf{Cont}(z, g', r)$. Unary constructor inversion on the radius and gap carriers supplies the carriers for r and g', so the second branch repacks the descended open-disk gap witness. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap visible radius gap cases`

Theorem 77.18 (Open-disk two visible-radius descent)**.** *If a concrete complex-topology open-disk gap witness has visible radius* $\mathsf{E1}(\mathsf{E1}(r))$*, then either the gap is empty and the point is* hsame *to* $\mathsf{E1}(\mathsf{E1}(r))$*, or the gap is visible with tail g_0 and the descended witness over* $\mathsf{E1}(r)$ *further splits into the empty-tail endpoint case, where the point is* hsame *to* $\mathsf{E1}(r)$*, or a visible tail g_1 carrying an open-disk gap witness over r.*

Proof. Apply Theorem 77.17 to the displayed open-disk witness with radius $\mathsf{E1}(\mathsf{E1}(r))$. Its empty-gap branch gives the first alternative directly, with the point identified with the displayed radius endpoint.

In the visible-gap branch, write the exposed gap as $\mathsf{E1}(g_0)$ and keep the descended open-disk gap witness over $\mathsf{E1}(r)$. Apply Theorem 77.17 again to that descended witness. The empty branch yields the endpoint case $z\mathsf{hsame}\mathsf{E1}(r)$, while the visible branch writes g_0 as $\mathsf{E1}(g_1)$ and supplies the open-disk gap witness over r. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap visible radius double descent`

Theorem 77.19 (Open-disk gap unary suffix transport)**.** *If a complex-topology open-disk gap witness has boundary ledger* $\mathsf{Cont}(z, g, r)$*, and a unary suffix q continues both z to zq and r to rq, then the shifted point zq and shifted radius rq form another open-disk gap witness with the same center and gap, and expose* $\mathsf{Cont}(zq, g, rq)$*.*

Proof. Unpack the witness. The point carrier is closed under unary suffix continuation, the radius carrier is closed under unary continuation, and the boundary ledger follows by reassociating Cont after commuting the unary gap and suffix histories. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap unary suffix transport`

Theorem 77.20 (Open-disk gap center-point unary suffix transport)**.** *If a complex-topology open-disk gap witness has center z_0, point z, radius r, and boundary ledger* $\mathsf{Cont}(z, g, r)$*, and a unary suffix q continues z_0, z, and r to z_{0q}, z_q, and r_q, then (z_{0q}, r_q, z_q, g) is again an open-disk gap witness and exposes* $\mathsf{Cont}(z_q, g, r_q)$*.*

Proof. The preceding unary suffix theorem shifts the point and radius while retaining the gap ledger. Complex carrier closure under the same unary suffix shifts the center carrier from z_0 to z_{0q}, so the transported center, shifted radius, shifted point, and original gap repack the open-disk gap witness. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap center point unary suffix transport`

77.2 Open sets and finite intersections

Definition 77.21 (Open-set membership)**.** *A complex open set is encoded as a closed inductive predicate $U : \mathsf{Complex}^{\uparrow}$-history $\to \mathsf{Prop}$ generated by finite unions and finite intersections of open-disk predicates.* $\mathsf{IsOpen}(U)$ *holds when every membership witness $U(z)$ supplies an explicit interior open-disk* $\mathsf{OpenDisk}(z, r_z, z)$ *of positive unary radius r_z, with r_z given by an explicit total function on the membership-witness data.*

Theorem 77.22 (Finite intersection of open sets is open)**.** *If* $\mathsf{IsOpen}(U_1)$ *and* $\mathsf{IsOpen}(U_2)$*, then* $\mathsf{IsOpen}(U_1 \cap U_2)$ *with explicit interior radius $r_{12}(z) := \min(r_1(z), r_2(z))$.*

Proof. Combine the two interior-disk witnesses by taking the minimum unary radius pointwise; the minimum is decidable on unary representations. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenSet intersection witness closed`
Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenSet intersection radius witnesses nonempty`
Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenSet intersection witnesses`

Theorem 77.23 (Arbitrary union of open sets is open)**.** *For any classifier-respecting family $\{U_i\}_{i \in I}$ of open sets indexed by an inductive carrier I, the union $\bigcup_i U_i$ is open with interior radius inherited from the witnessing branch.*

Proof. Membership in the union is by case analysis on I; each case provides the interior-disk witness from the corresponding U_i. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenSet union closed`

77.3 Compact subsets via dyadic ε-nets

Definition 77.24 (Dyadic ε-net)**.** *For a complex-set predicate K and unary precision k, a dyadic 2^{-k}-net is a finite list of complex histories $[z_1, \ldots, z_N]$ such that for every z with $K(z)$, there exists an index $i \leq N$ with* $\mathsf{OpenDisk}(z_i, 2^{-k}, z)$*. The net function* $\mathsf{Net}_K : \mathsf{Unary} \to \mathsf{List}(\mathsf{Complex}^{\uparrow})$ *is required to be a total explicit function on the precision domain.*

Lean4 (definition) `BEDC.Derived.ComplexTopologyUp.ComplexTopologyDyadicNet`

Definition 77.25 (Compact subset)**.** $\mathsf{IsCompact}(K)$ *holds when K is bounded (contained in some* $\mathsf{ClosedDisk}(\mathsf{e}, R)$ *for explicit unary R) and possesses an explicit dyadic 2^{-k}-net for every unary precision k (i.e. a witnessing total function* $\mathsf{Net}_K : \mathsf{Unary} \to \mathsf{List}(\mathsf{Complex}^{\uparrow})$*).*

Lean4 (definition) `BEDC.Derived.ComplexTopologyUp.ComplexTopologyCompact`
Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyCompact precision radius not empty`

Theorem 77.26 (Closed disk is compact)**.** *For every z_0 and unary r,* $\mathsf{IsCompact}(\mathsf{ClosedDisk}(z_0, r))$ *holds with explicit dyadic ε-net obtained by tiling the disk with rational-grid points at spacing 2^{-k}.*

Proof. At precision k, enumerate the rational pairs (p, q) with $|p - \mathsf{Re}(z_0)| \leq r$ and $|q - \mathsf{Im}(z_0)| \leq r$ on the dyadic-rational grid of mesh $2^{-k}/2$; the resulting finite list witnesses every disk point within distance $2^{-k}/\sqrt{2} \leq 2^{-k}$. The list construction is by unary recursion over the grid bounds, which are given explicitly by R and k. □

Theorem 77.27 (Compact subsets of half-planes)**.** *For unary parameters σ_a, ϵ, T, the compact sub-half-plane*

$$K(\sigma_a, \epsilon, T) \;:=\; \{s : \mathsf{Re}(s) \geq \sigma_a + \epsilon, |\mathsf{Im}(s)| \leq T\}$$

is compact in the sense of Definition 77.25, with explicit dyadic ε-nets given by tiling the rectangle $[\sigma_a + \epsilon, R(\sigma_a, T)] \times [-T, T]$ for explicit $R(\sigma_a, T)$.

Proof. The half-plane predicate is a finite intersection of closed half-planes, each compact on bounded restriction. The bound $R(\sigma_a, T)$ is taken to enclose the witnessing region needed by the consuming chapter (typically the half-plane $\Re(s) > 1$ of the Dirichlet-series majorants in chapter 70). □

77.4 Density witnesses and clustering points

Definition 77.28 (Quantitative density witness)**.** *For a center $z_c \in \mathsf{Complex}^{\uparrow}$ and an open set U with $U(z_c)$, a quantitative density witness inside U is an explicit sequence* $\mathsf{Cluster} : \mathsf{Unary} \to \mathsf{Complex}^{\uparrow}$ *of distinct points $(z_n)_n$ with $U(z_n)$, $z_n \neq z_c$, and $|z_n - z_c| \leq 2^{-n}$ for every unary n. The witness is a total explicit function on the precision domain.*

Lean4 (definition) `BEDC.Derived.ComplexTopologyUp.ComplexTopologyDensityWitness`

Theorem 77.29 (Open disks contain quantitative cluster sequences)**.** *For every z_0 and unary $r > 0$, the open disk* $\mathsf{OpenDisk}(z_0, r)$ *admits a quantitative density witness centered at z_0: the sequence $z_n := z_0 + 2^{-n}r/2$ is in the disk, distinct from z_0, and within distance $2^{-n}r/2 \leq 2^{-n}$ for $n \geq 1$.*

Proof. Construct the sequence by explicit unary recursion. The membership condition holds because the point lies at distance $2^{-n}r/2 < r$ from z_0; distinctness holds because the offset is non-empty unary for each n. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap density witness with boundary`
Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap constant density witness`

Remark 77.30 (Clustering for the constructive identity theorem)**.** *The quantitative density witness of Definition 77.28 is the precise data required by the constructive identity theorem of chapter 68: two holomorphic functions agreeing on an explicit cluster sequence agree on a smaller open disk. This chapter supplies the witness type that the holomorphy chapter consumes.*

77.5 Domain compatibility for analytic continuation

Definition 77.31 (Domain compatibility)**.** *For two open sets D_1, D_2 and an overlap region U,* $\mathsf{DomCompat}(D_1, D_2, U)$ *holds when* $\mathsf{IsOpen}(U)$*, $U \subseteq D_1 \cap D_2$ with explicit intersection-membership witness, and U contains an open disk* $\mathsf{OpenDisk}(z_c, r_c)$ *with quantitative density witness* $\mathsf{Cluster}(z_c, U)$ *of Definition 77.28.*

Lean4 (definition) `BEDC.Derived.ComplexTopologyUp.ComplexTopologyDomainCompat`

Remark 77.32 (Domain compatibility consumed by analytic continuation)**.** *chapter 9341 requires exactly this data to invoke the constructive identity theorem when extending a holomorphic function across overlapping domains; the present definition fixes the schema so the analytic-continuation chapter cites a single canonical interface.*

77.6 Certificate target

Theorem 77.33 (Concrete $\mathsf{CplxTopo}^{\uparrow}$ naming certificate)**.** *The tuple* (OpenDisk, ClosedDisk, IsOpen, IsCompact, Clu *with sources, classifiers, stability obligations, ledger, and standard bridge as listed below, forms a paper-side* $\mathsf{NameCert}(\mathsf{CplxTopo}^{\uparrow})$ *over* $\mathsf{Complex}^{\uparrow}$*:*

1. ***Source**:* $\mathsf{Complex}^{\uparrow}$*-histories with rational-pair carrier representations.*
2. ***Carrier**: each predicate of Sections 77.1–77.5 is a closed inductive predicate on* $\mathsf{Complex}^{\uparrow}$*-histories.*
3. ***Classifier**:* ComplexClassifier*-equivariance for set membership inherited from* hsame*-transport on the underlying complex carriers.*
4. ***Stability obligations**: open-disk gap modulus (Definition 77.11), finite-intersection closure (Definition 77.22), arbitrary-union closure (Definition 77.23), closed-disk compactness (Definition 77.26), half-plane compactness (Definition 77.27), open-disk clustering (Definition 77.29).*
5. ***Ledger**: explicit interior-radius function for every open-set witness; explicit dyadic ε-net function for every compact-set witness; explicit cluster sequence for every density witness.*
6. ***Standard bridge**: when classical complex topology (Heine-Borel compactness, open covers) is supplied externally, the explicit-net witnesses interpret as classical compactness witnesses on bounded subsets only; the bridge slot records this restricted correspondence.*
7. ***Status**:* ProofTarget*. Lean construction proceeds in* BEDC.Derived.ComplexTopologyUp.$*$*. The inline* OpenDisk *of chapter 68 is to be re-exported from* BEDC.Derived.ComplexTopologyUp *as the canonical home; the holomorphic chapter retains a re-export alias for backward compatibility with existing markers.*

Proof. Each carrier predicate is closed inductive over $\mathsf{Complex}^{\uparrow}$-histories with decidable membership on rational representations. The six stability obligations are the section-by-section theorems above, each established by explicit construction of the witness data (gap modulus, dyadic net, cluster sequence). The bridge slot is the standard interpretation under the bounded-subset restriction. No Classical.choice, no Quot.sound, and no propext is required. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap semanticNameCert`

Corollary 77.34 ($\mathsf{CplxTopo}^{\uparrow}$ is licensed, not primitive)**.** $\mathsf{CplxTopo}^{\uparrow}$ *is licensed by closed inductive predicates over rational-pair representations of complex histories, with constructive compactness encoded as explicit dyadic ε-nets. It is not a primitive of the BEDC kernel, and in particular does not assume Heine-Borel compactness as a general theorem.*

Remark 77.35 (Discharge of holomorphy/contour/analytic-continuation forward references)**.** *The open-disk, compact-half-plane, cluster-sequence, and domain-compatibility witnesses inline-defined or implicitly used in chapter 68, chapter 9340, chapter 9341, and chapter 71 are now anchored at the present* $\mathsf{CplxTopo}^{\uparrow}$ *certificate. Future restructuring should re-export the inline* OpenDisk *from* BEDC.Derived.HolomorphicUp *as an alias of the canonical* BEDC.Derived.ComplexTopologyUp.OpenDisk.

Definition 77.36 (Certified subdisk radius)**.** *For unary radii r' and r, a certified subdisk radius from r' to r is a unary history e together with a radius-continuation ledger* $\mathsf{Cont}(r', e, r)$*. We write this datum as* $\mathsf{Subradius}(r', r; e)$*. The empty tail is the equality case.*

Lean4 (definition) `BEDC.Derived.ComplexTopologyUp.ComplexTopologyCertifiedSubradius`

Lemma 77.37 (Certified subdisk radii compose)**.** *If* $\mathsf{Subradius}(r_0, r_1; e_0)$ *and* $\mathsf{Subradius}(r_1, r_2; e_1)$*, then* $\mathsf{Subradius}(r_0, r_2; e_0 \cdot e_1)$*.*

Proof. Unpack the two subradius certificates. Unary append closure makes $e_0 \cdot e_1$ unary. Associativity of Cont composes $\mathsf{Cont}(r_0, e_0, r_1)$ with $\mathsf{Cont}(r_1, e_1, r_2)$ and gives $\mathsf{Cont}(r_0, e_0 \cdot e_1, r_2)$. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyCertifiedSubradius comp`

Theorem 77.38 (HoloOnDisk subdisk restriction)**.** *Let $f : \mathsf{Complex}^{\uparrow} \to \mathsf{Complex}^{\uparrow}$, let z_0 be a complex center history, and let r' and r be unary radii. If* $\mathsf{HoloOnDisk}(f, z_0, r)$ *is witnessed by a displayed* $\mathsf{Holomorphic}^{\uparrow}$ *seed witness W with uniform modulus ledger δ_r, and if* $\mathsf{Subradius}(r', r; e)$ *is certified, then* $\mathsf{HoloOnDisk}(f, z_0, r')$ *is witnessed by a subdisk witness $W \restriction_e$.*

More explicitly, for every point z and displayed smaller-disk gap g',

$$\mathsf{OpenDisk}(z_0, r', z, g') \wedge \mathsf{Subradius}(r', r; e) \Longrightarrow \mathsf{OpenDisk}(z_0, r, z, g' \cdot e).$$

The restricted modulus is obtained by reading every smaller boundary gap through this inclusion:

$$\delta_{r'}(k, g') := \delta_r(k, g' \cdot e).$$

If the parent witness uses a displayed large-disk gap g instead of $g' \cdot e$, then $g\mathsf{hsame}g' \cdot e$ by Definition 68.29, so the modulus and derivative ledgers transport along the stability field of Definition 68.54. The classifier on $W \restriction_e$ is the parent pointwise classifier restricted to points admitted by $\mathsf{OpenDisk}(z_0, r', -)$*; its radius slot is r' on both restricted representatives, and the comparison back to W is recorded by the subradius ledger e. The ledger of $W \restriction_e$ keeps the same function history, center history, pointwise complex-differentiability data, derivative-recursion data, Taylor data, Cauchy-bound data, and identity data, with each disk-local admission transported through the subradius certificate.*

Proof. Unpack the seed predicate of Definition 68.33. The parent witness W supplies, for every z admitted by $\mathsf{OpenDisk}(z_0, r, z)$ and every unary precision k, the corresponding complex-differentiability witness controlled by δ_r and the displayed boundary gap.

Now fix z, k, and a smaller-disk gap g' with $\mathsf{OpenDisk}(z_0, r', z, g')$. The subradius certificate gives a unary e and $\mathsf{Cont}(r', e, r)$. Applying Definition 68.28 to the smaller open disk gives $\mathsf{OpenDisk}(z_0, r, z)$. In gap form, Definition 68.29 reads the large boundary as the appended gap $g' \cdot e$, up to hsame against any displayed parent gap. Therefore the parent holomorphic witness applies at the same point z and precision k.

Define the restricted modulus by $\delta_{r'}(k, g') = \delta_r(k, g' \cdot e)$. The input $g' \cdot e$ is unary by unary append closure, so this is a total unary modulus ledger. If a canonical parent gap is chosen differently, the public readback theorem gives the required hsame comparison, and Definition 68.54 transports the modulus and differentiability witness across that comparison.

All remaining fields are inherited by narrowing the domain of quantification. The function history and center history are unchanged. Disk-gap ledgers are sent to the parent disk by $g' \mapsto g' \cdot e$. Any ledger entry indexed by a further subradius of r' is read in the parent ledger by composing that subradius with e using Definition 77.37. The pointwise classifier clause of Definition 68.53 is therefore exactly the parent pointwise classifier after the open-disk inclusion, while the restricted radius data are compared by reflexivity inside the smaller carrier and related to the parent carrier by the retained subradius ledger. These data satisfy the source, classifier, and ledger fields of Definition 68.51, Definition 68.53, and Definition 68.55 for radius r'. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyOpenDiskGap certified subradius extension`

Theorem 77.39 (HoloOnDisk additive closure)**.** *In the* $\mathsf{Holomorphic}^{\uparrow}$ *seed setup, let* $f, g : \mathsf{Complex}^{\uparrow} \to \mathsf{Complex}^{\uparrow}$*, let* z_0 *be a complex history, and let* r *be a unary radius. Suppose* $\mathsf{HoloOnDisk}(f, z_0, r)$ *and* $\mathsf{HoloOnDisk}(g, z_0, r)$ *are witnessed by uniform modulus data*

$$(\delta_f, D_f, L_f) \qquad \text{and} \qquad (\delta_g, D_g, L_g),$$

where $D_f(z)$ *and* $D_g(z)$ *are the derivative histories selected at a point* z *and* L_f, L_g *are the corresponding disk-gap ledgers. Assume the witnesses are compatible in the following sense: for every boundary witness* $\mathsf{OpenDisk}(z_0, r, z, gap)$*, both* L_f *and* L_g *read the displayed gap up to* hsame *and use it as the second input of their uniform moduli. Define*

$$D_{f+g}(z) := D_f(z) + D_g(z), \qquad \delta_{f+g}(k, gap) := \max(\delta_f(k+1, gap), \delta_g(k+1, gap)).$$

Then the pointwise complex sum satisfies

$$\mathsf{HoloOnDisk}(f + g, z_0, r).$$

Proof. Unpack the two $\mathsf{HoloOnDisk}$ witnesses using Definition 68.33. Fix a point z and a boundary witness $\mathsf{OpenDisk}(z_0, r, z, gap)$. The f-witness supplies $\mathsf{CplxDiffAt}(f, z, D_f(z))$ with the one-variable modulus $k \mapsto \delta_f(k, gap)$, and the g-witness supplies $\mathsf{CplxDiffAt}(g, z, D_g(z))$ with the one-variable modulus $k \mapsto \delta_g(k, gap)$.

If either source witness presents an hsame-equivalent boundary gap rather than the displayed gap, compatibility identifies it with gap. The open-disk transport theorem Definition 68.7 keeps the same disk membership, and full pointwise differentiability transport Definition 67.31 moves the corresponding differentiability witness to the displayed point and displayed gap representative.

Apply the complex differentiability sum rule Definition 67.32 at this fixed point. It gives

$$\mathsf{CplxDiffAt}(f + g, z, D_f(z) + D_g(z))$$

with modulus $k \mapsto \max(\delta_f(k + 1, gap), \delta_g(k + 1, gap))$, which is exactly $k \mapsto \delta_{f+g}(k, gap)$. The proof of Definition 67.32 decomposes the difference quotient of $f + g$ into the sum of the two source quotients and uses the shifted precision $k + 1$ on each side, so the pasted error is below the requested precision k.

The construction is uniform in z and in the displayed boundary gap. The center z_0, the radius r, and the open-disk witness are unchanged, while the output ledger records the two source ledgers, the common gap ledger, the pointwise complex-sum quotient ledger, and the pasted unary modulus δ_{f+g}. The stability seed field of Definition 68.54 transports these ledgers along hsame, and the ledger composition principle Definition 8.12 supplies the composite ledger for the sum witness.

Thus every point of the disk carries complex differentiability of $f+g$ with the displayed uniform modulus and derivative selector D_{f+g}. By Definition 68.33, this is precisely $\mathsf{HoloOnDisk}(f + g, z_0, r)$. □

Definition 77.40 (Certified holomorphic dense-sequence agreement)**.** *Let $f, g : \mathsf{Complex}^{\uparrow} \to \mathsf{Complex}^{\uparrow}$, let z_0 be a complex center, let r be a unary radius, and let z_c be a complex history in $\mathsf{OpenDisk}(z_0, r)$. The predicate*

$$\mathsf{HoloDenseSeqEq}(f, g, z_0, r, z_c, s)$$

holds when $s : \mathsf{UnaryHistory} \to \mathsf{Complex}^{\uparrow}$ is the quantitative density witness of Definition 77.28 for the open set $\mathsf{OpenDisk}(z_0, r)$ centered at z_c, and every unary index carries the pointwise classifier

$$\forall n,\ \mathsf{UnaryHistory}(n) \Longrightarrow \mathsf{ComplexClassifier}(f(s(n)), g(s(n))).$$

Definition 77.41 (Certified smaller holomorphic disk)**.** *For a complex center w, unary radius ρ, ambient disk $\mathsf{OpenDisk}(z_0, r)$, and cluster center z_c, the predicate*

$$\mathsf{HoloSubDisk}(w, \rho; z_0, r, z_c)$$

holds when every point of $\mathsf{OpenDisk}(w, \rho)$ is carried into $\mathsf{OpenDisk}(z_0, r)$, and for every such point y there is a finite list of centers $c_0, \ldots, c_N$ and unary radii $\eta_0, \ldots, \eta_N$ with $c_0 = z_c$, $y \in \mathsf{OpenDisk}(c_N, \eta_N)$, each $\mathsf{OpenDisk}(c_i, \eta_i)$ contained in $\mathsf{OpenDisk}(z_0, r)$, and each consecutive pair carrying a $\mathsf{DomCompat}$ overlap in the sense of Definition 77.31. The overlap witness includes the quantitative cluster sequence supplied by Definition 77.29.

Lemma 77.42 (Cluster zeros force a local holomorphic zero classifier)**.** *Let $h : \mathsf{Complex}^{\uparrow} \to \mathsf{Complex}^{\uparrow}$ satisfy $\mathsf{HoloOnDisk}(h, z_0, r)$. If s is a quantitative density witness for $\mathsf{OpenDisk}(z_0, r)$ centered at z_c and*

$$\forall n,\ \mathsf{UnaryHistory}(n) \Longrightarrow \mathsf{ComplexClassifier}(h(s(n)), 0_{\mathsf{Complex}^{\uparrow}}),$$

then there is a unary radius η with $\mathsf{OpenDisk}(z_c, \eta) \subseteq \mathsf{OpenDisk}(z_0, r)$ *such that*

$$\forall y,\ \mathsf{OpenDisk}(z_c, \eta, y) \Longrightarrow \mathsf{ComplexClassifier}(h(y), 0_{\mathsf{Complex}^\uparrow}).$$

Proof. The holomorphic seed predicate of Definition 68.33 gives a uniform complex-differentiability modulus at every point of the ambient disk. At z_c, the iterated-derivative and power-series clauses listed in Definition 68.34 give Taylor coefficients a_m and a unary convergence radius η whose open disk is contained in $\mathsf{OpenDisk}(z_0, r)$.

The coefficients are classified by zero by unary induction on m. For $m = 0$, the density witness gives $s(n) \to z_c$ with explicit modulus, and the displayed zero classifier on $h(s(n))$ transports through the continuity part of the holomorphic modulus, so $h(z_c)$ is classified by $0_{\mathsf{Complex}^\uparrow}$. For the successor step, assume $a_0, \ldots, a_{m-1}$ are classified by zero. On every cluster point $s(n) \neq z_c$, the m-th normalized Taylor remainder is defined; the numerator is classified by zero because $h(s(n))$ is zero and the lower Taylor terms are zero. The differentiability modulus identifies the limit of these normalized remainders with a_m, while the constant-zero quotient sequence has limit $0_{\mathsf{Complex}^\uparrow}$. The uniqueness classifier of $\mathsf{CplxLim}^\uparrow$ therefore gives $\mathsf{ComplexClassifier}(a_m, 0_{\mathsf{Complex}^\uparrow})$.

For any $y \in \mathsf{OpenDisk}(z_c, \eta)$, every finite Taylor partial sum at y is classified by $0_{\mathsf{Complex}^\uparrow}$ because all coefficients are. The power-series convergence witness and complex-limit uniqueness identify the value $h(y)$ with that zero limit. □

Theorem 77.43 (Holo dense-sequence identity classifier)**.** *Let $f, g : \mathsf{Complex}^\uparrow \to \mathsf{Complex}^\uparrow$ satisfy* $\mathsf{HoloOnDisk}(f, z_0, r)$ *and* $\mathsf{HoloOnDisk}(g, z_0, r)$*. If* $\mathsf{HoloDenseSeqEq}(f, g, z_0, r, z_c, s)$ *and* $\mathsf{HoloSubDisk}(w, \rho; z_0, r, z_c)$ *hold, then the restrictions of f and g to the certified smaller disk are identified by the* $\mathsf{Holomorphic}^\uparrow$ *classifier:*

$$\forall y,\ \mathsf{OpenDisk}(w, \rho, y) \Longrightarrow \mathsf{ComplexClassifier}(f(y), g(y)).$$

Proof. Form the certified difference $h = f - g$ using the $\mathsf{Complex}^\uparrow$ additive inverse and addition operations. The closure clause in Definition 68.34 gives $\mathsf{HoloOnDisk}(h, z_0, r)$. The dense-sequence agreement predicate of Definition 77.40 gives $\mathsf{ComplexClassifier}(f(s(n)), g(s(n)))$ at every unary index, and additive cancellation in $\mathsf{Complex}^\uparrow$ rewrites this as $\mathsf{ComplexClassifier}(h(s(n)), 0_{\mathsf{Complex}^\uparrow})$.

Apply Definition 77.42 at z_c. This gives an initial open disk on which h is classified by zero. Fix $y \in \mathsf{OpenDisk}(w, \rho)$. The certified smaller-disk predicate of Definition 77.41 supplies a finite chain of open disks from the initial disk to a terminal disk containing y, all contained in $\mathsf{OpenDisk}(z_0, r)$ and with consecutive disks related by $\mathsf{DomCompat}$ overlaps.

Induct along the finite chain. Suppose h is zero on the current disk. The next overlap carries, by Definition 77.31 and Definition 77.29, a quantitative cluster sequence lying in the current disk and in the next disk. Hence h is zero on that cluster. Restricting the ambient holomorphic witness to the next disk is allowed by open-disk transport and the stability clause of Definition 68.54. Applying Definition 77.42 inside the next disk makes h zero there. The terminal disk contains y, so $\mathsf{ComplexClassifier}(h(y), 0_{\mathsf{Complex}^\uparrow})$.

Finally, the definition of $h = f - g$ and cancellation in the additive group of $\mathsf{Complex}^\uparrow$ convert $\mathsf{ComplexClassifier}(h(y), 0_{\mathsf{Complex}^\uparrow})$ into $\mathsf{ComplexClassifier}(f(y), g(y))$. This is exactly the pointwise component required by the holomorphic classifier seed field of Definition 68.53; the compatible disk data are supplied by Definition 77.41. □

Theorem 77.44 (HoloOnDisk nested subdisk functoriality)**.** *Let $f : \mathsf{Complex}^\uparrow \to \mathsf{Complex}^\uparrow$, let z_0 be a complex center history, and let r_2, r_1, and r_0 be unary radii. Let W be a displayed* $\mathsf{Holomorphic}^\uparrow$ *seed witness for* $\mathsf{HoloOnDisk}(f, z_0, r_0)$ *with uniform modulus ledger δ_{r_0}. Suppose*

$$\mathsf{Subradius}(r_1, r_0; e_0) \qquad \textit{and} \qquad \mathsf{Subradius}(r_2, r_1; e_1).$$

Let $W_1 := W \restriction_{e_0}$ be the restricted witness on r_1, let $W_{21} := W_1 \restriction_{e_1}$ be the iterated restricted witness on r_2, and let $W_{20} := W \restriction_{e_1 \cdot e_0}$ be the direct restricted witness obtained from the composed subradius certificate. Then W_{21} and W_{20} are compared by the $\mathsf{Holomorphic}^{\uparrow}$ *classifier over* $\mathsf{HoloOnDisk}(f, z_0, r_2)$.

More explicitly, for every displayed smaller-disk gap g'' and every unary precision k, let

$$d_{21} := \delta_{r_0}(k, (g'' \cdot e_1) \cdot e_0), \qquad d_{20} := \delta_{r_0}(k, g'' \cdot (e_1 \cdot e_0))$$

be the displayed parent ledger-result histories. The iterated and direct modulus ledgers read the parent ledger as

$$\delta_{W_{21}}(k, g'') = \delta_{r_1}(k, g'' \cdot e_1) = d_{21}, \qquad \delta_{W_{20}}(k, g'') = d_{20}, \qquad d_{21}\mathsf{hsame}d_{20}.$$

The final classifier is the associativity comparison from Definition 21.29 together with continuation transport by Definition 4.41. If the public composed tail is displayed as $e_0 \cdot e_1$, unary append commutativity supplies a classifier from $e_1 \cdot e_0$ to $e_0 \cdot e_1$; the corresponding continuation comparison is carried by Definition 24.7 and Definition 4.41, and the same classifier comparison applies to the direct witness $W \restriction_{e_0 \cdot e_1}$.

Proof. Unpack the two certified subradius data. They supply unary histories e_0 and e_1 together with radius ledgers $\mathsf{Cont}(r_1, e_0, r_0)$ and $\mathsf{Cont}(r_2, e_1, r_1)$. Applying Definition 77.37, with its three radius variables read as r_2, r_1, and r_0, gives the composed certificate $\mathsf{Subradius}(r_2, r_0; e_1 \cdot e_0)$.

The first restriction theorem Definition 77.38 constructs W_1 and defines its modulus by

$$\delta_{r_1}(k, g') := \delta_{r_0}(k, g' \cdot e_0).$$

Applying the same theorem to W_1 along e_1 constructs W_{21} and gives

$$\delta_{W_{21}}(k, g'') = \delta_{r_1}(k, g'' \cdot e_1) = \delta_{r_0}(k, (g'' \cdot e_1) \cdot e_0).$$

The direct restriction along the composed subradius certificate constructs W_{20} with

$$\delta_{W_{20}}(k, g'') = \delta_{r_0}(k, g'' \cdot (e_1 \cdot e_0)).$$

Let d_{21} and d_{20} denote these two displayed parent ledger-result histories. History-append associativity, as classified by Definition 21.29, compares $(g'' \cdot e_1) \cdot e_0$ with $g'' \cdot (e_1 \cdot e_0)$, and Definition 4.41 carries the corresponding continuation ledger across that comparison. The stability seed field of Definition 68.54 then reads the parent modulus and the corresponding differentiability witness through the two displayed parent gaps, giving $d_{21}\mathsf{hsame}d_{20}$.

The same comparison controls disk admission. Given z with a displayed r_2-gap g'', the iterated route records the radius-r_1 boundary gap $g'' \cdot e_1$ and then the radius-r_0 parent gap $(g'' \cdot e_1) \cdot e_0$. The direct route records the parent gap $g'' \cdot (e_1 \cdot e_0)$. These two parent gaps are classified by Definition 21.29, and Definition 4.41 carries the continuation ledger across the classifier. Any alternative displayed parent gap is classified against them by the public readback theorem Definition 68.29, with the displayed result comparison carried by Definition 4.42. Thus both witnesses invoke the same parent holomorphic data after the gap comparison.

All remaining ledger fields are inherited from the same parent witness W: the function history, center history, derivative-recursion data, Taylor data, Cauchy-bound data, and identity data are unchanged. Their disk-local indices are related exactly by the two gap maps just compared. Hence the pointwise-function clause and the compatible disk-data clause of Definition 68.53 hold for W_{21}

and W_{20} over the radius r_2, with the inherited ledger policy of Definition 68.55. If the composed tail is displayed as $e_0 \cdot e_1$, unary append commutativity supplies the classifier from $e_1 \cdot e_0$ to that public display; applying Definition 24.7 and Definition 4.41 carries the relevant continuation ledgers to that display before the same argument is applied. □

Lean4 ✓ `BEDC.Derived.ComplexTopologyUp.ComplexTopologyCertifiedSubradius nested gap readback`

Closure status for $\mathsf{NameCert}_{\mathsf{CplxTopo}^{\uparrow}}$.

Constructive story: A $\mathsf{CplxTopo}^{\uparrow}$ packet is generated from finite BHist rows for complex disks, centers, radii, holomorphic witnesses, derivative recursion, Taylor data, Cauchy-bound ledgers, identity rows, subradius routes, transports, provenance, and local naming. Disk-local information is produced by Cont through nested gap maps and certified subradius readbacks, so a smaller disk inherits displayed ledger fields from its parent witness rather than from an ambient topology object. Componentwise hsame transports function, center, derivative, Taylor, Cauchy-bound, and identity rows, while Pkg records the complex analytic and topology dependencies. The packet names finite holomorphic-disk data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CplxTopo}^{\uparrow}}$, seed)

Scope closed: This chapter binds complex-topology disk and holomorphic witness rows, classifier specification, ledger policy, certified subradius routes, and nested-gap readback for $\mathsf{CplxTopo}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CplxTopo}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: It does not claim a host topology space, quotient equality of functions, unrestricted analytic continuation, classical open-cover reasoning, or external sheaf machinery.

Upgrade path: Obligation closure requires Lean encodings of the holomorphic witness carrier, disk ledger policy, subradius route, nested-gap readback, and classifier transport.

Chapter 78

A Concrete Naming Certificate for $\mathsf{Magma}^{\uparrow}$

The magma interface $\mathsf{Magma}^{\uparrow}$ packages a carrier endowed with a single binary operation, with no associativity, identity, or inverse demands. It is the smallest algebraic naming certificate above the inductive carriers of chapter 32–chapter 36 and the entry point of the algebraic ladder culminating in $\mathsf{NameCert}_{\mathsf{Field}^{\uparrow}}$ (chapter 45).

78.1 Carrier definition

Definition 78.1 (Concrete unary-history magma instance)**.** *Let $U(h)$ abbreviate* $\mathsf{UnaryHistory}(h)$*. The concrete unary-history magma instance has carrier U, binary operation* $\mathsf{mul}_U(h,k) := \mathsf{append}(h,k)$*, equivalently witnessed by* $\mathsf{Cont}(h,k,\mathsf{append}(h,k))$*, and carrier-aware classifier*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

The classifier only compares unary endpoints, so every public equality claim retains both endpoint carrier witnesses.

Theorem 78.2 (Concrete unary-history magma laws)**.** *For the instance of Definition 78.1,* mul_U *is closed on unary histories. Moreover, if $R_U(h,h')$ and $R_U(k,k')$, then*

$$R_U(\mathsf{mul}_U(h,k), \mathsf{mul}_U(h',k')).$$

Proof. Closure is exactly `BEDC.FKernel.Unary.unary_append_closed`: two unary endpoint witnesses for h and k produce a unary endpoint witness for $\mathsf{append}(h,k)$.

For congruence, unpack $R_U(h,h')$ and $R_U(k,k')$ into unary carrier witnesses and endpoint hsame proofs. The two products are witnessed by their canonical continuation facts $\mathsf{Cont}(h,k,\mathsf{append}(h,k))$ and $\mathsf{Cont}(h',k',\mathsf{append}(h',k'))$. Transport the continuation result along the endpoint hsame data using `BEDC.FKernel.Cont.cont_result_hsame_transport`; the closure clause supplies the carrier witnesses for both products, and the transported result is the classifier equality required by R_U. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont laws`

Theorem 78.3 (Concrete unary-history magma continuation result unary exactness)**.** *For histories $h,k,r : \mathsf{BHist}$, if $\mathsf{Cont}(h,k,r)$, then the continuation result is unary exactly when both continuation inputs are unary:*

$$\mathsf{Unary}(r) \iff \mathsf{Unary}(h) \wedge \mathsf{Unary}(k).$$

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont result unary iff`

Proof. The continuation ledger identifies r with $\mathsf{append}(h, k)$. The unary append factor theorem says precisely that $\mathsf{Unary}(h) \wedge \mathsf{Unary}(k)$ is equivalent to $\mathsf{Unary}(\mathsf{append}(h, k))$. Transporting along the continuation equality gives the displayed result-side exactness. □

Theorem 78.4 (Concrete unary-history magma visible-right continuation result nonempty)**.** *For histories $h, t, r : \mathsf{BHist}$, a continuation whose right input is $\mathsf{E0}(t)$ or $\mathsf{E1}(t)$ cannot have an empty result:*

$$(\mathsf{Cont}(h, \mathsf{E0}(t), r) \Rightarrow \neg\mathsf{hsame}(r, \mathsf{e})) \quad \wedge \quad (\mathsf{Cont}(h, \mathsf{E1}(t), r) \Rightarrow \neg\mathsf{hsame}(r, \mathsf{e})).$$

Proof. Transport the displayed continuation result along $r\mathsf{hsamee}$. Empty-result continuation inversion would then force the visible right input itself to be e. The zero- and one-headed cases are both excluded by constructor separation for BHist. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont visible right result nonempty`

Theorem 78.5 (Concrete unary-history magma visible-left continuation result nonempty)**.** *For histories $h, t, r : \mathsf{BHist}$, a continuation whose left input is $\mathsf{E0}(t)$ or $\mathsf{E1}(t)$ cannot have an empty result:*

$$(\mathsf{Cont}(\mathsf{E0}(t), h, r) \Rightarrow \neg\mathsf{hsame}(r, \mathsf{e})) \quad \wedge \quad (\mathsf{Cont}(\mathsf{E1}(t), h, r) \Rightarrow \neg\mathsf{hsame}(r, \mathsf{e})).$$

Proof. Transport the displayed continuation result along $r\mathsf{hsamee}$. Empty-result continuation inversion would then force the visible left input itself to be e. The zero- and one-headed cases are both excluded by constructor separation for BHist. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont visible left result nonempty`

Theorem 78.6 (Concrete unary-history magma classifier append factors)**.** *For histories $h, h', k, k' : \mathsf{BHist}$, the concrete unary-history magma classifier relates the two appended endpoints exactly when all four factors are unary histories and the two appended endpoints are history-same:*

$$R_U(\mathsf{append}(h, k), \mathsf{append}(h', k')) \iff U(h) \wedge U(k) \wedge U(h') \wedge U(k') \wedge \mathsf{hsame}(\mathsf{append}(h, k), \mathsf{append}(h', k')).$$

Proof. Unfold R_U. The forward direction gives unary carrier witnesses for the two appended endpoints. Apply unary append factor exactness to each carrier witness, obtaining the unary witnesses for h, k, h', k', and retain the classifier's endpoint hsame component. Conversely, the four unary factor witnesses close both appended endpoints under unary append closure, and the displayed endpoint hsame proof repackages the concrete classifier. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma classifier append factors iff`

Theorem 78.7 (Concrete unary-history magma classifier append-empty endpoints)**.** *Let $U(h)$ abbreviate $\mathsf{UnaryHistory}(h)$ and let*

$$R_U(h, k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h, k).$$

For histories $h, k : \mathsf{BHist}$, the concrete unary-history magma classifier relates $\mathsf{append}(h, k)$ to e exactly when both append endpoints are empty:

$$R_U(\mathsf{append}(h, k), \mathsf{e}) \iff h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. Unfold R_U. The forward direction reads $\mathsf{append}(h,k)\mathsf{hsamee}$ from the classifier and applies append-empty exactness to recover $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$. Conversely, the two empty endpoints make the append endpoint unary and history-same to e, while e itself is unary. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma classifier append empty endpoints iff`

Theorem 78.8 (Concrete unary-history magma continuation result classifier factors)**.** *For histories $h, h', k, k', r, r' : \mathsf{BHist}$, if $\mathsf{Cont}(h,k,r)$ and $\mathsf{Cont}(h',k',r')$, then the concrete unary-history magma classifier relates the two continuation results exactly when all four source factors are unary and the two results are history-same:*

$$R_U(r,r') \iff U(h) \wedge U(k) \wedge U(h') \wedge U(k') \wedge \mathsf{hsame}(r,r').$$

Proof. Eliminate the two continuation witnesses. The results become the displayed append endpoints $\mathsf{append}(h,k)$ and $\mathsf{append}(h',k')$. The append-factor classifier exactness theorem then supplies the four unary factor witnesses in the forward direction and rebuilds the result classifier from the four witnesses and the endpoint hsame proof in the reverse direction. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont result classifier factors iff`

Theorem 78.9 (Concrete unary-history magma continuation left-context classifier)**.** *Let $U(h)$ abbreviate $\mathsf{UnaryHistory}(h)$ and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

If $R_U(l,l')$, $\mathsf{Cont}(l,r,a)$, and $\mathsf{Cont}(l',r',a')$, then the concrete magma classifier relates the two continuation results exactly when the two right inputs are unary and history-same:

$$R_U(a,a') \iff U(r) \wedge U(r') \wedge \mathsf{hsame}(r,r').$$

Proof. In the forward direction, unary exactness for each continuation recovers the two right-input carriers from the result carriers. The classifier equality between results cancels the shared classified left context, giving $r\mathsf{hsame}r'$. Conversely, unary closure for the two continuations supplies the result carriers, and continuation respect for hsame transports the left classifier and the right-input comparison to the result classifier. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont left context classifier iff`

Theorem 78.10 (Concrete unary-history magma continuation left-unit classifier)**.** *Let $U(h)$ abbreviate $\mathsf{UnaryHistory}(h)$ and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

If $\mathsf{Cont}(h,k,r)$, then classifying the result against the right endpoint is equivalent to saying that the right endpoint is unary and the left endpoint is the continuation left unit:

$$R_U(r,k) \iff U(k) \wedge \mathsf{hsame}(h,\mathsf{e}).$$

Proof. In the forward direction, the classifier exposes the carrier of k. Transporting the continuation result along $r\mathsf{hsame}k$ gives a continuation from h by k back to k, and left-unit uniqueness forces $h\mathsf{hsamee}$. Conversely, $\mathsf{hsame}(h,\mathsf{e})$ gives the unary carrier for h and turns the continuation into the left-unit continuation, while unary closure rebuilds the result carrier. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont left unit classifier iff`

Theorem 78.11 (Concrete unary-history magma continuation right-unit classifier)**.** *Let $U(h)$ abbreviate* $\mathsf{UnaryHistory}(h)$ *and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

If $\mathsf{Cont}(h,k,r)$*, then classifying the result against the left endpoint is equivalent to saying that the left endpoint is unary and the right endpoint is the continuation right unit:*

$$R_U(r,h) \iff U(h) \wedge \mathsf{hsame}(k,\mathsf{e}).$$

Proof. In the forward direction, the classifier already exposes the carrier of h. Transporting the continuation result along $r\mathsf{hsame}h$ gives a continuation from h by k back to h, and right-unit uniqueness forces $k\mathsf{hsame}\mathsf{e}$. Conversely, $\mathsf{hsame}(k,\mathsf{e})$ gives the unary carrier for k and turns the continuation into the right-unit continuation, while unary closure rebuilds the result carrier. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont right unit classifier iff`

Theorem 78.12 (Concrete unary-history magma continuation result both-input classifiers)**.** *Let $U(h)$ abbreviate* $\mathsf{UnaryHistory}(h)$ *and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

If $\mathsf{Cont}(h,k,r)$*, then the result is classified with both inputs exactly when both inputs are unary and both are history-same to* e*:*

$$R_U(r,h) \wedge R_U(r,k) \iff U(h) \wedge U(k) \wedge \mathsf{hsame}(h,\mathsf{e}) \wedge \mathsf{hsame}(k,\mathsf{e}).$$

Proof. Apply the right-unit classifier characterization to the $R_U(r,h)$ side and the left-unit classifier characterization to the $R_U(r,k)$ side. These two readbacks give the two carriers and the two empty-endpoint equations. The reverse direction repacks the same data through the two unit classifier characterizations. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont result both inputs classifier empty iff`

Theorem 78.13 (Concrete unary-history magma continuation right-context classifier)**.** *Let $U(h)$ abbreviate* $\mathsf{UnaryHistory}(h)$ *and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

If $R_U(r,r')$, $\mathsf{Cont}(l,r,a)$*, and* $\mathsf{Cont}(l',r',a')$*, then the concrete magma classifier relates the two continuation results exactly when the two left inputs are unary and history-same:*

$$R_U(a,a') \iff U(l) \wedge U(l') \wedge \mathsf{hsame}(l,l').$$

Proof. Unary exactness for the two continuations reads the left-input carriers back from the result carriers. The result classifier equality cancels the shared classified right context, giving $l\mathsf{hsame}l'$. The reverse direction uses unary continuation closure for the two result carriers and continuation respect for hsame across the classified left and right inputs. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont right context classifier iff`

Theorem 78.14 (Concrete unary-history magma classifier middle-context cancellation)**.** *Let* $U(h)$ *abbreviate* $\mathsf{UnaryHistory}(h)$ *and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

If $U(l)$ *and* $U(r)$*, then the common append context cancels from the concrete magma classifier:*

$$R_U(\mathsf{append}(l,\mathsf{append}(m,r)),\mathsf{append}(l,\mathsf{append}(m',r))) \iff U(m) \wedge U(m') \wedge \mathsf{hsame}(m,m').$$

Proof. The forward direction first applies unary append-factor exactness to the two classified contextual endpoints, exposing unary witnesses for the two middle histories. The classifier equality then cancels the common left append context and the common right append context, yielding $\mathsf{hsame}(m,m')$. Conversely, unary closure rebuilds both contextual endpoints, and the middle equality transports through the two fixed append contexts. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma classifier append middle cancel iff`

Theorem 78.15 (Concrete unary-history magma classifier rotated middle cancellation)**.** *Let* $U(h)$ *abbreviate* $\mathsf{UnaryHistory}(h)$ *and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

If $U(l)$ *and* $U(r)$*, then the concrete magma classifier also cancels a common context when the right endpoint is bracketed as a left append followed by the right context:*

$$R_U(\mathsf{append}(l,\mathsf{append}(m,r)),\mathsf{append}(\mathsf{append}(l,m'),r)) \iff U(m) \wedge U(m') \wedge \mathsf{hsame}(m,m').$$

Proof. Append associativity identifies the rotated right endpoint with the nested right endpoint used by middle-context cancellation. The forward direction transports the classifier to that nested bracketing and applies the middle-cancellation theorem. Conversely, the nested classifier supplied by middle cancellation is transported back across associativity. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma classifier append rotated middle cancel iff`

Theorem 78.16 (Concrete unary-history magma continuation common-context classifier)**.** *Let* $U(h)$ *abbreviate* $\mathsf{UnaryHistory}(h)$ *and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

For histories $l,l',m,m',r,r',a,a' : \mathsf{BHist}$*, if* $R_U(l,l')$ *and* $R_U(r,r')$*, then continuations through the two classified contexts expose exactly the middle classifier:*

$$\mathsf{Cont}(l,\mathsf{append}(m,r),a) \wedge \mathsf{Cont}(l',\mathsf{append}(m',r'),a') \Longrightarrow (R_U(a,a') \iff U(m) \wedge U(m') \wedge \mathsf{hsame}(m,m')).$$

Proof. The context classifiers identify the left contexts and the right contexts while carrying all four endpoints as unary histories. Eliminating the two continuation witnesses turns the results into the two displayed append contexts. The middle-context cancellation theorem then cancels the common unary left context and common unary right context, giving exactly the two middle carrier witnesses and the middle hsame comparison; the reverse direction rebuilds the contextual classifier by unary append closure. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont common context classifier iff`

Theorem 78.17 (Concrete unary-history magma nested continuation common-context classifier)**.** *Let $U(h)$ abbreviate* $\mathsf{UnaryHistory}(h)$ *and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

For histories $l, l', m, m', r, r', lm, lm', a, a' : \mathsf{BHist}$, if $R_U(l,l')$ and $R_U(r,r')$, and if the two results are obtained through nested continuations

$$\mathsf{Cont}(l,m,lm), \quad \mathsf{Cont}(lm,r,a), \quad \mathsf{Cont}(l',m',lm'), \quad \mathsf{Cont}(lm',r',a'),$$

then the result classifier exposes exactly the middle classifier:

$$R_U(a,a') \iff U(m) \wedge U(m') \wedge \mathsf{hsame}(m,m').$$

Proof. The context classifiers identify the two left contexts and the two right contexts while retaining their unary carrier witnesses. Eliminating the nested continuation witnesses presents the two results as left-associated append contexts. Associativity transports those endpoints to the common middle-context form, where the concrete magma middle-cancellation theorem cancels the fixed unary left and right contexts. The reverse direction rebuilds the two left-associated results by transporting the same classifier back across associativity. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont nested common context classifier iff`

Theorem 78.18 (Concrete unary-history magma nested left-unit classifier)**.** *Let $U(h)$ abbreviate* $\mathsf{UnaryHistory}(h)$ *and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

For histories $l, m, r, lm, a : \mathsf{BHist}$, if $\mathsf{Cont}(l,m,lm)$ and $\mathsf{Cont}(lm,r,a)$, then classifying the nested result against the right endpoint is equivalent to the right endpoint being unary and both visible left factors being empty:

$$R_U(a,r) \iff U(r) \wedge \mathsf{hsame}(l,\mathsf{e}) \wedge \mathsf{hsame}(m,\mathsf{e}).$$

Proof. Apply the one-step left-unit classifier to the second continuation. The forward direction gives $U(r)$ and $lm\mathsf{hsamee}$; decomposing the first continuation then splits $lm\mathsf{hsamee}$ into $l\mathsf{hsamee}$ and $m\mathsf{hsamee}$. Conversely, the two empty-factor equalities compose through the first continuation to give $lm\mathsf{hsamee}$, and the one-step left-unit classifier rebuilds $R_U(a,r)$ for the second continuation. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont nested left unit classifier iff`

Theorem 78.19 (Concrete unary-history magma nested right-unit classifier)**.** *Let $U(h)$ abbreviate* $\mathsf{UnaryHistory}(h)$ *and let*

$$R_U(h,k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k).$$

For histories $l, m, r, lm, a : \mathsf{BHist}$, if $\mathsf{Cont}(l,m,lm)$ and $\mathsf{Cont}(lm,r,a)$, then classifying the nested result against the left endpoint is equivalent to the left endpoint being unary and both visible right factors being empty:

$$R_U(a,l) \iff U(l) \wedge \mathsf{hsame}(m,\mathsf{e}) \wedge \mathsf{hsame}(r,\mathsf{e}).$$

Proof. Compose the two continuation ledgers by associativity into a continuation from l through $\mathsf{append}(m, r)$ to a. If $R_U(a, l)$ holds, right unit uniqueness forces $\mathsf{append}(m, r)$ to be empty, and append-empty inversion splits this into empty m and empty r. Conversely, empty m makes lm agree with l, and empty r lets the one-step right-unit classifier for the second continuation rebuild $R_U(a, l)$. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma cont nested right unit classifier iff`

The ten-field per-object fit is: traditional target magma; BEDC source BHist restricted to unary histories; carrier UnaryHistory; classifier carrier-aware hsame on unary endpoints; stability closure and congruence for unary append; ledger append provenance through Cont; core theorem Definition 78.2; exactness endpoint classification by R_U; standard bridge free unary append magma; status ProofTarget.

78.2 The certificate

Lemma 78.20 (Concrete unary-history magma classifier stability)**.** *Let $U(h)$ abbreviate* $\mathsf{UnaryHistory}(h)$ *and define*

$$R_U(h, k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h, k).$$

Then R_U has carrier reflexivity on every $U(h)$, symmetry, transitivity, and carrier transport in both endpoints. Concretely:

1. *if $U(h)$, then $R_U(h, h)$;*
2. *if $R_U(h, k)$, then $R_U(k, h)$;*
3. *if $R_U(h, k)$ and $R_U(k, l)$, then $R_U(h, l)$;*
4. *if $R_U(h, k)$, then both carrier witnesses $U(h)$ and $U(k)$ are available for the certificate endpoint fields.*

Proof. Unpack R_U as the triple consisting of the left carrier witness, the right carrier witness, and the endpoint hsame proof.

For carrier reflexivity, a witness $U(h)$ supplies both endpoint carrier fields, and `BEDC.FKernel.Hist.hsame_ref` supplies the endpoint classifier proof.

For symmetry, swap the two carrier witnesses and apply `BEDC.FKernel.Hist.hsame_symm` to the endpoint proof.

For transitivity, retain the outer carrier witnesses $U(h)$ and $U(l)$ from the two packed classifiers. Compose the endpoint equalities with `BEDC.FKernel.Hist.hsame_trans`, then repack the outer carrier witnesses with the composed endpoint proof.

The carrier-transport fields are the two carrier projections already stored in each packed $R_U(h, k)$ witness. □

Lean4 ✓ `BEDC.Derived.MagmaUp.concrete unary history magma classifier stability`

Theorem 78.21 (Concrete unary-history MagmaUp semantic certificate)**.** *Let $U(h)$ abbreviate* $\mathsf{UnaryHistory}(h)$*, let* $\mathsf{mul}_U(h, k) := \mathsf{append}(h, k)$*, and let*

$$R_U(h, k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h, k).$$

The tuple with source, pattern, and ledger all equal to U, classifier R_U, and operation mul_U *is the concrete* $\mathsf{Magma}^{\uparrow}$ *semantic naming certificate over* BHist*. Its certificate fields are: carrier*

inhabitation by e*; classifier reflexivity, symmetry, transitivity, and carrier transport; operation closure; operation congruence; ledger append provenance through* Cont*; exactness*

$$R_U(h,k) \iff U(h) \wedge U(k) \wedge \mathsf{hsame}(h,k);$$

and status ProofTarget*.*

Proof. The carrier field is supplied by the empty unary history. The classifier fields are exactly Definition 78.20: carrier reflexivity, symmetry, transitivity, and the two endpoint carrier projections for R_U.

The operation fields are the concrete laws of Theorem 78.2, whose checked Lean target is `BEDC.Derived.MagmaUp.concrete_unary_history_magma_cont_laws`. Closure is the unary append-closure component, congruence is the append classifier-transport component, and the ledger row is the canonical continuation witness $\mathsf{Cont}(h,k,\mathsf{append}(h,k))$. Exactness is the definition of R_U, so the displayed predicate is both the public classifier and the certificate's endpoint criterion. □

Lean4 ✓ `BEDC.Derived.MagmaUp.ConcreteUnaryHistoryMagma semanticNameCert`

Theorem 78.22 (Magma mature downstream consumption boundary)**.** *The concrete semantic certificate of Definition 78.21, the* $\mathsf{Semigroup}^{\uparrow}$ *forgetful consumer Definition 79.7, and the concrete* $\mathsf{Monoid}^{\uparrow}$ *history instance of section 40.2 together witness the downstream-consumption boundary required for* $\mathsf{Magma}^{\uparrow}$ *mature paper closure.*

Lean4 ✓ `BEDC.Derived.MagmaUp.MagmaUp StdBridge`

Proof. The $\mathsf{Magma}^{\uparrow}$ certificate names the carrier by unary histories in BHist, uses the classifier $R_U(h,k)$ as the carrier-aware hsame relation, takes append as the binary operation, and records the Cont ledger row for the append output. Its exactness clause identifies the public classifier with those same carrier and hsame conditions, so the exported object contains no quotient layer and no ambient host magma.

The $\mathsf{Semigroup}^{\uparrow}$ consumer of Definition 79.7 reads the same carrier, classifier, and append operation after omitting associativity from the semigroup certificate. The resulting $\mathsf{Magma}^{\uparrow}$ surface is therefore not a new host algebra: it is the $\mathsf{Magma}^{\uparrow}$ part of the concrete unary-history semigroup surface.

The $\mathsf{Monoid}^{\uparrow}$ instance of section 40.2 extends the same append and Cont surface by the unit rows for e. Forgetting the unit data leaves the same unary-history append carrier and classifier already used by the $\mathsf{Magma}^{\uparrow}$ certificate. Thus the downstream algebra ladder consumes the concrete certificate without introducing extra magma data or quotient identifications. □

Closure status for $\mathsf{NameCert}_{\mathsf{Magma}^{\uparrow}}$**.**

Constructive story: A magma at this point is the unary history spine with one operation exposed: two admitted histories h and k are put in sequence by kernel append, equivalently by the visible continuation witness $\mathsf{Cont}(h,k,\mathsf{append}(h,k))$, and only histories built from e by b1-stacking are accepted while every b0 branch remains outside the carrier. Two carried products are classified by the carrier-aware unary relation R_U: both endpoints must still be unary and their underlying histories must be hsame, so the operation is not a host binary table and there is no quotient layer hiding representatives. The source, pattern, and ledger all return to the same unary predicate, with the pattern adding the binary append shape, closure, congruence, nonempty visible-input readback, and exact endpoint criterion, while the ledger keeps the raw continuation that produced each visible product. The five name-certificate obligations follow from e as the inhabited unary carrier, from reflexivity, symmetry, and transitivity of history-sameness, and from the fact that a packed $R_U(h,k)$ witness already contains the carrier rows needed to keep recognized endpoints inside the unary surface. A history h lies in the signature gap of a $\mathsf{Magma}^{\uparrow}$ token p when the source-domain accepts the displayed unary input or product, the signature relation pairs it with an answer history and evidence ledger, and the token-introduction relation names that answer as p; unfolded here, the answer is exactly the unary append endpoint classified by R_U together with its continuation provenance.

The paper bridge reads the same object as the free unary append magma for downstream Semigroup$^{\uparrow}$ and Monoid$^{\uparrow}$ consumers, but the readback is only the displayed append surface and not an arbitrary host magma. The chapter registers this unary-append binary operation under the name Magma$^{\uparrow}$; it introduces no associativity, identity, inverse, quotient magma, or independent algebraic carrier beyond the existing history continuation calculus.

Chapter 79

A Concrete Naming Certificate for $\mathsf{Semigroup}^{\uparrow}$

The semigroup interface $\mathsf{Semigroup}^{\uparrow}$ adds associativity to $\mathsf{Magma}^{\uparrow}$ (chapter 78). It sits between the magma layer and $\mathsf{NameCert}_{\mathsf{Monoid}^{\uparrow}}$ (chapter 40), exposing the closure law that distinguishes free semigroups from arbitrary binary structures.

79.1 Carrier definition

Definition 79.1 (Concrete unary-history semigroup instance)**.** *The concrete unary-history semigroup instance reuses the magma carrier, operation, and classifier from Definition 78.1. Thus the carrier is* $\mathsf{UnaryHistory}$*, multiplication is* $\mathsf{mul}_U(h,k) := \mathsf{append}(h,k)$*, the continuation witness is* $\mathsf{Cont}(h,k,\mathsf{append}(h,k))$*, and endpoint comparison is the carrier-aware relation*

$$R_U(h,k) := \mathsf{UnaryHistory}(h) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{hsame}(h,k).$$

Theorem 79.2 (Concrete unary-history semigroup laws)**.** *The instance of Definition 79.1 satisfies the magma closure and multiplication congruence laws of Definition 78.2. In addition, for unary histories* $h,k,l : \mathsf{BHist}$*,*

$$R_U(\mathsf{mul}_U(\mathsf{mul}_U(h,k),l), \mathsf{mul}_U(h,\mathsf{mul}_U(k,l))).$$

Proof. The closure and multiplication congruence clauses are the magma laws from Definition 78.2, applied to the same carrier $\mathsf{UnaryHistory}$, operation append, and classifier R_U.

For associativity, first apply unary append closure to h and k, and again to k and l. These witnesses place the intermediate products $\mathsf{append}(h,k)$ and $\mathsf{append}(k,l)$ in the carrier, so the two outer products are also unary by the same closure theorem.

The four continuation witnesses $\mathsf{Cont}(h,k,\mathsf{append}(h,k))$, $\mathsf{Cont}(\mathsf{append}(h,k),l,\mathsf{append}(\mathsf{append}(h,k),l))$, $\mathsf{Cont}(k,l,\mathsf{append}(k,l))$, and $\mathsf{Cont}(h,\mathsf{append}(k,l),\mathsf{append}(h,\mathsf{append}(k,l)))$ are then fed to `BEDC.FKernel.Cont.cont` The result is the endpoint hsame proof between the two parenthesizations, and the carrier witnesses already built above package it as R_U. □

Lean4 ✓ `BEDC.Derived.SemigroupUp.concrete unary history semigroup cont assoc classifier`

Theorem 79.3 (Concrete unary-history semigroup fourfold coherence)**.** *For unary histories* $h,k,l,m : \mathsf{BHist}$*, the left-nested and right-nested fourfold products are classified by* R_U*:*

$$R_U(\mathsf{mul}_U(\mathsf{mul}_U(\mathsf{mul}_U(h,k),l),m), \mathsf{mul}_U(h,\mathsf{mul}_U(k,\mathsf{mul}_U(l,m)))).$$

The ten-field per-object fit is: traditional target fourfold semigroup associativity coherence; BEDC source BHist *restricted to* UnaryHistory*; carrier* UnaryHistory*; classifier carrier-aware* hsame*; stability from unary append closure, the checked ternary semigroup law, and classifier transitivity; ledger the two fourfold append trees; core theorem Definition 79.3; exactness endpoint classification by R_U; standard bridge free unary append semigroup; status* ProofTarget.

Proof. First use unary append closure to keep all intermediate products in the carrier. In particular, $\mathsf{mul}_U(l, m)$, $\mathsf{mul}_U(h, k)$, $\mathsf{mul}_U(\mathsf{mul}_U(h, k), l)$, and the outer products on both sides are again unary histories.

Apply Definition 79.2 to $(\mathsf{mul}_U(h, k), l, m)$. This classifies the left-nested product with the middle bracketing

$$\mathsf{mul}_U(\mathsf{mul}_U(h, k), \mathsf{mul}_U(l, m)).$$

Apply Definition 79.2 again to $(h, k, \mathsf{mul}_U(l, m))$. This classifies the same middle bracketing with the right-nested product.

Finally compose the two classifier witnesses using Definition 78.20. Its transitivity component gives the displayed R_U classification between the two fourfold append trees. □

The ten-field per-object fit is: traditional target semigroup; BEDC source BHist restricted to unary histories; carrier UnaryHistory; classifier carrier-aware hsame on unary endpoints; stability closure, congruence, and associativity for unary append; ledger append provenance through Cont; core theorem Definition 79.2; exactness endpoint classification by R_U; standard bridge free unary append semigroup; status ProofTarget.

79.2 The certificate

Theorem 79.4 (Concrete unary-history SemigroupUp semantic certificate)**.** *Let $U(h)$ abbreviate* $\mathsf{UnaryHistory}(h)$*, let* $\mathsf{mul}_U(h, k) := \mathsf{append}(h, k)$*, and let*

$$R_U(h, k) := U(h) \wedge U(k) \wedge \mathsf{hsame}(h, k).$$

The tuple with source, pattern, and ledger all equal to U, classifier R_U, and multiplication mul_U *is the concrete* $\mathsf{Semigroup}^{\uparrow}$ *semantic naming certificate over* BHist*. Its certificate fields are: carrier inhabitation by* e*; classifier reflexivity, symmetry, transitivity, and carrier transport; multiplication closure; multiplication congruence; associativity; ledger append provenance through* Cont*; and exactness*

$$R_U(h, k) \Longleftrightarrow U(h) \wedge U(k) \wedge \mathsf{hsame}(h, k).$$

Proof. The carrier field is supplied by e, which is a unary history. The classifier fields are the four stability components of Definition 78.20: reflexivity on carrier points, symmetry, transitivity, and the two endpoint carrier projections stored in each $R_U(h, k)$ witness.

The multiplication closure and multiplication congruence fields are inherited from Definition 78.2, applied to the same carrier U, multiplication append, and classifier R_U. The ledger row is the canonical append provenance $\mathsf{Cont}(h, k, \mathsf{append}(h, k))$ for the displayed multiplication.

Associativity is the additional semigroup law in Definition 79.2. Its checked Lean source, `BEDC.Derived.SemigroupUp.concrete_unary_history_semigroup_cont_assoc_classifier`, packages the two parenthesized append products as carrier-aware R_U-equivalent endpoints.

Finally, exactness is definitional: the public classifier R_U is precisely the triple consisting of the two unary carrier witnesses and the endpoint hsame proof. Thus the displayed biconditional is the certificate's endpoint criterion, with no extra cases beyond the concrete unary-history carrier. □

Lean4 ✓ `BEDC.Derived.SemigroupUp.ConcreteUnaryHistorySemigroup semanticNameCert`

Definition 79.5 (Semigroup certificate fields)**.** *Let C be a carrier with classifier $\sim_C$ and multiplication $\cdot$. A $\mathsf{Semigroup}^{\uparrow}(C)$ certificate consists of the carrier, source, pattern, classifier, stability, exactness, and ledger rows whose operation language is generated by carried endpoints and binary multiplication. The classifier rows are carrier inhabitation, reflexivity, symmetry, transitivity, and carrier transport for $\sim_C$. The algebraic rows are multiplication closure, multiplication congruence in both arguments, and associativity under $\sim_C$. The exactness row is the public endpoint criterion attached to the same classifier, and the ledger records carrier witnesses and the multiplication operation tree behind each product expression. This abstracts the field list realized in Definition 79.4. No distinguished identity element, left identity row, or right identity row belongs to the $\mathsf{Semigroup}^{\uparrow}$ row set.*

Proposition 79.6 (Monoid forgets to Semigroup certificate)**.** *Let C carry a $\mathsf{Monoid}^{\uparrow}(C)$ certificate with multiplication $\cdot$, identity e, and classifier $\sim_C$. If the identity element is not exported, the left and right identity stability rows are omitted, and every ledger entry whose expression provenance uses the distinguished identity symbol is omitted, then the retained carrier, source, semigroup pattern, classifier, semigroup stability fields, exactness row, and multiplication ledger form a $\mathsf{Semigroup}^{\uparrow}(C)$ certificate. The carrier C, multiplication $\cdot$, and classifier $\sim_C$ are unchanged.*

Proof. By Definition 40.34, the given certificate supplies carrier, source, pattern, classifier, stability, and ledger data for $\mathsf{Monoid}^{\uparrow}(C)$. The construction keeps exactly the rows whose endpoint claims and expression provenance use only the carrier classifier and binary multiplication.

By Definition 40.1, a monoid carrier is a carrier C with classifier $\sim_C$, operation $\cdot : C \times C \to C$, identity e, and law fields. Suppressing the identity coordinate leaves the same carrier, classifier, and binary operation. The operation type already gives the multiplication closure row required by Definition 79.5.

By Definition 40.9, the source is the carrier C with its classifier and operation data, so the retained source is still over the same C, $\sim_C$, and $\cdot$. By Definition 40.10, the monoid pattern forms expressions from e, carrier witnesses, and binary multiplication. Restricting that pattern to expressions containing no identity symbol leaves precisely the product-expression language of Definition 79.5. By Definition 40.11, the classifier is the supplied carrier sameness relation, so the classifier and its endpoint exactness row are copied without changing endpoints.

For stability, Definition 40.13 lists classifier reflexivity, classifier transitivity, associativity under the classifier, left identity, right identity, and multiplication congruence. Retaining the first, second, third, and sixth rows gives the semigroup algebraic stability rows: classifier reflexivity and transitivity, associativity, and multiplication congruence. The classifier symmetry and carrier-transport rows belong to the underlying NameCert core exhibited for monoids in Definition 40.35; they mention only C and $\sim_C$, so they are retained verbatim. The two discarded identity rows mention e and are not semigroup obligations.

Finally, Definition 40.33 records carrier witnesses and operation trees behind monoid expressions. Removing the entries whose operation tree uses the identity symbol leaves the carrier witnesses and binary multiplication provenance for product expressions. These are exactly the ledger rows required by Definition 79.5. Hence the retained rows satisfy the $\mathsf{Semigroup}^{\uparrow}(C)$ certificate fields with the original carrier, multiplication, and classifier. □

Proposition 79.7 (Semigroup forgets to Magma certificate)**.** *Let C be a carrier with classifier $\sim_C$ and multiplication $\cdot$. If C carries a $\mathsf{Semigroup}^{\uparrow}(C)$ certificate with these data, then the retained carrier, source, binary-operation pattern, classifier, exactness row, operation closure row, operation*

congruence row, and binary-operation ledger form a $\mathsf{Magma}^{\uparrow}(C)$ *certificate after the associativity stability row is omitted. The carrier* C*, multiplication* $\cdot$*, and classifier* $\sim_C$ *are unchanged.*

Proof. By Definition 79.5, a $\mathsf{Semigroup}^{\uparrow}(C)$ certificate contains carrier, source, pattern, classifier, stability, exactness, and ledger rows whose operation language is generated by carried endpoints and binary multiplication. Its classifier rows are carrier inhabitation, reflexivity, symmetry, transitivity, and carrier transport for $\sim_C$. Its algebraic rows are multiplication closure, multiplication congruence in both arguments, and associativity under $\sim_C$.

The magma interface in chapter 78 requires a carrier with one binary operation and no associativity, identity, or inverse demands. The concrete field realization in Definition 78.21 records exactly the rows needed by that interface: carrier inhabitation; classifier reflexivity, symmetry, transitivity, and carrier transport; operation closure; operation congruence; binary-operation ledger provenance; and exactness for the same public classifier.

Retain the carrier C, the source over C, the classifier $\sim_C$, and the exactness row attached to that classifier. Interpret the semigroup multiplication $\cdot$ as the magma operation. The pattern and ledger remain well formed because both interfaces use the same single binary operation language; associativity is a stability law, not an additional operation symbol or carrier coordinate.

The closure row and the congruence row of the semigroup certificate are copied as the operation closure and operation congruence rows of the magma certificate. The classifier rows are copied without changing endpoints. The associativity row has no corresponding $\mathsf{Magma}^{\uparrow}$ obligation, so omitting it leaves every magma row supplied. Hence the retained rows satisfy the $\mathsf{Magma}^{\uparrow}(C)$ certificate fields over the original carrier, multiplication, and classifier. □

Definition 79.8 (Opposite semigroup operation)**.** *Let* C *be a carrier with binary multiplication* $\cdot$*. The opposite multiplication on the same carrier is the binary operation* $\star$ *defined by*

$$x \star y := y \cdot x.$$

It introduces no additional carrier element and no additional classifier relation.

Lean4 (definition) `BEDC.Derived.SemigroupUp.ConcreteUnaryHistorySemigroupOppositeMul`
Lean4 (definition) `BEDC.Derived.SemigroupUp.ConcreteUnaryHistorySemigroup oppMul`

Proposition 79.9 (Opposite semigroup certificate)**.** *Let* C *be a carrier with classifier* $\sim_C$ *and multiplication* $\cdot$*. If* C *carries a* $\mathsf{Semigroup}^{\uparrow}(C)$ *certificate for* $\cdot$*, then the same carrier and classifier carry a* $\mathsf{Semigroup}^{\uparrow}(C)$ *certificate for the opposite multiplication* $\star$ *of Definition 79.8.*

Lean4 ✓ `BEDC.Derived.SemigroupUp.ConcreteUnaryHistorySemigroup opposite semanticNameCert`
Lean4 ✓ `BEDC.Derived.SemigroupUp.concrete unary history semigroup opposite cont assoc classifier`

Proof. By Definition 79.5, the semigroup certificate consists of the carrier, source, pattern, classifier, stability, exactness, and ledger rows for carried endpoints and one binary multiplication. The carrier rows and the classifier rows are retained unchanged, since the carrier is still C and the classifier is still $\sim_C$. The exactness row is also retained unchanged, because it is attached to this same public classifier.

The operation source for $\star$ is the displayed definition $x \star y := y \cdot x$. Closure follows immediately from the original multiplication closure row: if $x, y \in C$, then $y \cdot x \in C$, hence $x \star y \in C$.

For congruence, assume $x \sim_C x'$ and $y \sim_C y'$. The original multiplication congruence applied to the ordered pair of witnesses $y \sim_C y'$ and $x \sim_C x'$ gives

$$y \cdot x \sim_C y' \cdot x'.$$

By the definition of $\star$, this is exactly

$$x \star y \sim_C x' \star y'.$$

Thus the opposite operation satisfies the semigroup multiplication-congruence row.

For associativity, let $x, y, z \in C$. The two opposite products unfold as

$$(x \star y) \star z = z \cdot (y \cdot x)$$

and

$$x \star (y \star z) = (z \cdot y) \cdot x.$$

The original associativity row for $\cdot$, applied to the triple (z, y, x), gives a classifier witness

$$(z \cdot y) \cdot x \sim_C z \cdot (y \cdot x).$$

The classifier symmetry row from the same certificate reverses this witness, yielding

$$z \cdot (y \cdot x) \sim_C (z \cdot y) \cdot x,$$

which is precisely the associativity row for $\star$ in the displayed orientation.

It remains only to account for the pattern and ledger rows. A $\star$-expression tree is read as a $\cdot$-expression tree by exchanging the two children at each binary node. Leaves remain carried endpoints, and each binary node is licensed by the original multiplication source. The same tree reading transports the operation-tree provenance in the ledger. Since Definition 79.5 includes no identity, inverse, left-unit, or right-unit row, there is no further handed obligation to check. These rows together form the required $\mathsf{Semigroup}^{\uparrow}(C)$ certificate for the opposite multiplication. □

Closure status for $\mathsf{NameCert}_{\mathsf{Semigroup}^{\uparrow}}$.

Constructive story: A semigroup here keeps the same unary histories and the same append operation as the magma layer, then records the extra fact that three visible append steps can be rebracketed by the kernel continuation associativity theorem. The carrier admits exactly the b1-generated unary spine and rejects b0-headed histories, while the classifier remains the carrier-aware relation R_U: two endpoints are the same only when both are unary and their histories are hsame. The source, pattern, and ledger therefore cover unary endpoints with binary product trees; the pattern adds closure, product congruence, ternary associativity, fourfold coherence, the forgetful rows to and from neighboring algebra layers, and the opposite multiplication row obtained by swapping the two inputs at each binary node. Since e inhabits the carrier, history-sameness supplies reflexivity, symmetry, and transitivity, and unary append closure plus the stored endpoint carrier witnesses keep every classified representative inside the carrier, the five name-certificate obligations are the same spine obligations strengthened by associativity. A unary product history h lies in the signature gap of a $\mathsf{Semigroup}^{\uparrow}$ token p when the source-domain accepts the relevant unary product tree, the signature relation pairs its displayed append result with an answer history and evidence ledger, and the token-introduction relation names that answer as p; after unfolding, h is the append endpoint encoded by p, independent of parenthesization up to R_U. The paper bridge reads this as the free unary append semigroup, and the forgetful interfaces merely omit or retain rows over the same carrier rather than changing the underlying histories. The chapter registers this associative unary-append construction under the name $\mathsf{Semigroup}^{\uparrow}$; identity, inverse, commutativity, ring structure, field structure, and checked standard-bridge verification are not introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Semigroup}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature paper-side package consists of the concrete unary-history $\mathsf{Semigroup}^{\uparrow}$ semantic certificate over UnaryHistory, append, carrier-aware hsame, Cont provenance, associativity, congruence, and exactness; the forgetful bridge from $\mathsf{Monoid}^{\uparrow}$ in Definition 79.6; the forgetful bridge to $\mathsf{Magma}^{\uparrow}$ in Definition 79.7; and the opposite semigroup certificate in Definition 79.9.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Semigroup}^{\uparrow}}$, axiomClean)

Not claimed: Checked bridge verification, identity, inverse, commutativity, ring or field structure remain outside this claim.

Upgrade path: Bridge verification can promote the paper bridge rows to checked bridge status without changing the mature semigroup package recorded here.

Chapter 80

A Concrete Naming Certificate for $\mathsf{Subgroup}^{\uparrow}$

The subgroup interface $\mathsf{Subgroup}^{\uparrow}$ packages a subset of a group carrier closed under the group operation, identity, and inverse. It depends on $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ (chapter 41) and is the first sub-object construction in BEDC, prerequisite to the quotient and ideal certificates that follow.

80.1 Carrier definition

Definition 80.1 (Centralizer SubgroupUp instance)**.** *Fix a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *source over* BHist *with operation* mul*, unit* e*, inverse operation* inv*, and fixed element* $a : \mathsf{BHist}$*. The centralizer* $\mathsf{Subgroup}^{\uparrow}$ *instance uses the carrier* Z_a *from Definition 41.84. Its classifier is the restriction of* hsame *to that carrier: two carried histories* x *and* y *represent the same subgroup element exactly when* $x\mathsf{hsame}y$*. The operation, unit, and inverse are inherited from the ambient* $\mathsf{Group}^{\uparrow}$ *source, and the ledger records the fixed element* a *together with the commuting witnesses certifying membership in* Z_a*.*

Lean4 (definition) `BEDC.Derived.SubgroupUp.SubgroupCentralizerCarrier`
Lean4 (definition) `BEDC.Derived.SubgroupUp.SubgroupCentralizerClassifier`

80.2 The certificate

Theorem 80.2 (Centralizer SubgroupUp certificate target)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying associativity, left and right unit laws for* e*, multiplication congruence, and two-sided inverse laws, the instance of Definition 80.1 satisfies the* $\mathsf{Subgroup}^{\uparrow}$ *rows:*

1. *the carrier is inhabited by* e*, and* $Z_a(e)$*;*
2. *if* $Z_a(x)$ *and* $Z_a(y)$*, then* $Z_a(\mathsf{mul}(x, y))$*;*
3. *if* $Z_a(x)$*, then* $Z_a(\mathsf{inv}(x))$*;*
4. *if* $Z_a(x)$ *and* $x\mathsf{hsame}y$*, then* $Z_a(y)$*;*
5. *for every* $x : \mathsf{BHist}$*,*
$$Z_a(x) \iff \mathsf{comm}(x, a)\mathsf{hsame}e.$$

Thus the centralizer carrier is a concrete certificate target for $\mathsf{NameCert}_{\mathsf{Subgroup}^\uparrow}$ *over the ambient history classifier.*

Proof. The inhabited, product-closure, inverse-closure, and commutator-fiber rows are the rows of Definition 41.87. The inverse row uses the ambient inverse congruence from Definition 41.60 and the reverse-product description of inverses from Definition 41.65; these are exactly the sources cited by the GroupUp centralizer proof.

For carrier transport, unfold Z_a. A witness $x\mathsf{hsame}y$ transports $\mathsf{mul}(x,a)\mathsf{hsamemul}(a,x)$ to $\mathsf{mul}(y,a)\mathsf{hsamemul}(a,y)$ by multiplication congruence on the left and right arguments, followed by symmetry and transitivity of hsame. Therefore the restricted classifier preserves the subgroup carrier.

The exactness row is the commutator criterion from Definition 41.82 applied to the ordered pair (x,a), with the definition of Z_a supplying the displayed orientation. Repacking these rows with the inherited operation, unit, inverse, and ledger gives the advertised $\mathsf{Subgroup}^\uparrow$ certificate target. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizer certificate target from empty unit`
Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerCarrier mul closed from empty unit`
Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizer semanticNameCert`

Definition 80.3 (Two-centralizer intersection carrier)**.** *For two fixed histories* $a,b : \mathsf{BHist}$ *in the same BEDC history-level* $\mathsf{Group}^\uparrow$ *source, let* Z_a *and* Z_b *be the centralizer carriers of Definition 41.84. Define the two-centralizer carrier by*

$$Z_{a,b}(x) :\Longleftrightarrow Z_a(x) \wedge Z_b(x).$$

Its $\mathsf{Subgroup}^\uparrow$ *classifier is the restriction of* hsame *to this carrier: two carried histories represent the same element exactly when their ambient histories satisfy* $x\mathsf{hsame}y$*.*

Lean4 (definition) `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersectionCarrier`
Lean4 (definition) `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersectionClassifier`

Theorem 80.4 (Centralizer intersection SubgroupUp certificate)**.** *For a BEDC history-level* $\mathsf{Group}^\uparrow$ *operation over* BHist *satisfying the same associativity, left and right unit laws, multiplication congruence, and two-sided inverse laws as in Definition 80.2, and for fixed histories* $a,b : \mathsf{BHist}$*, the carrier* $Z_{a,b}$ *of Definition 80.3 has the following* $\mathsf{Subgroup}^\uparrow$ *certificate rows:*

1. *The restricted* hsame *classifier is a semantic naming certificate for* $Z_{a,b}$*.*
2. $Z_{a,b}(e)$*.*
3. *If* $Z_{a,b}(x)$ *and* $Z_{a,b}(y)$*, then* $Z_{a,b}(\mathsf{mul}(x,y))$*.*
4. *If* $Z_{a,b}(x)$*, then* $Z_{a,b}(\mathsf{inv}(x))$*.*
5. *If* $Z_{a,b}(x)$ *and* $x\mathsf{hsame}y$*, then* $Z_{a,b}(y)$*.*

Thus the simultaneous centralizer of a *and* b *is a reusable* $\mathsf{Subgroup}^\uparrow$ *certificate target over the ambient history classifier.*

Proof. Apply Definition 80.2 twice, once to the fixed history a and once to the fixed history b. The two identity rows give $Z_a(e)$ and $Z_b(e)$, which package directly as $Z_{a,b}(e)$ by Definition 80.3.

For product closure, unpack $Z_{a,b}(x)$ and $Z_{a,b}(y)$ into their two centralizer components. The a-row gives $Z_a(\mathsf{mul}(x,y))$, and the b-row gives $Z_b(\mathsf{mul}(x,y))$; pairing these witnesses proves the displayed product row for $Z_{a,b}$.

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersectionCarrier mul closed from empty unit`

The inverse row is componentwise in the same sense. From $Z_a(x)$ obtain $Z_a(\mathsf{inv}(x))$, and from $Z_b(x)$ obtain $Z_b(\mathsf{inv}(x))$; the pair is exactly $Z_{a,b}(\mathsf{inv}(x))$.

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersectionCarrier inv closed from empty unit`

Carrier transport also separates into the two coordinates. Given $Z_{a,b}(x)$ and $x\mathsf{hsame}y$, use the centralizer transport row for a to move $Z_a(x)$ to $Z_a(y)$, and use the centralizer transport row for b to move $Z_b(x)$ to $Z_b(y)$. The restricted hsame classifier on $Z_{a,b}$ is therefore stable under ambient history equality.

Finally, the restricted classifier is reflexive on carried histories, symmetric by symmetry of hsame, and transitive by transitivity of hsame. Its carrier-respect row is the second carrier component already stored in the classifier witness, and the source, pattern, and ledger predicates are all the same concrete intersection carrier. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersection certificate from empty unit`

Theorem 80.5 (Centralizer intersection classifier product closure)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *associativity, right unit, and multiplication congruence laws, if the restricted classifier on* $Z_{a,b}$ *relates* x *to* x' *and also relates* y *to* y'*, then it relates the products:*

$$\mathsf{SubgroupCentralizerIntersectionClassifier}(mul, a, b, x, x') \wedge \mathsf{SubgroupCentralizerIntersectionClassifier}(mul, a, b, y, y') \Rightarrow$$

Proof. Unpack both classifier witnesses. Product closure for the carrier $Z_{a,b}$ supplies the left product membership from x, y and the right product membership from x', y'. Multiplication congruence carries the stored comparisons $x\mathsf{hsame}x'$ and $y\mathsf{hsame}y'$ to the product comparison, which repackages the restricted classifier witness. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersectionClassifier mul closed from empty unit`

Theorem 80.6 (Centralizer intersection classifier inverse closure)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *associativity, two-sided unit, multiplication congruence, and inverse laws, if the restricted classifier on* $Z_{a,b}$ *relates* x *to* y*, then it relates their inverses:*

$$\mathsf{SubgroupCentralizerIntersectionClassifier}(mul, a, b, x, y) \Rightarrow \mathsf{SubgroupCentralizerIntersectionClassifier}(mul, a, b, \mathsf{inv}(x),$$

Proof. Unpack the classifier witness into its two carrier rows and its stored $x\mathsf{hsame}y$ comparison. Inverse closure for the two-centralizer intersection carrier supplies the carrier witnesses for $\mathsf{inv}(x)$ and $\mathsf{inv}(y)$. The ambient group inverse congruence transports $x\mathsf{hsame}y$ to $\mathsf{inv}(x)\mathsf{hsame}\mathsf{inv}(y)$, which repackages the restricted classifier witness. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersectionClassifier inv closed from empty unit`

Theorem 80.7 (Centralizer intersection self-conjugation closure)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *laws, if* $Z_{a,b}(t)$ *and* $Z_{a,b}(x)$*, then both conjugation words*

$$\mathsf{mul}(\mathsf{mul}(t, x), \mathsf{inv}(t))$$

and

$$\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(t), x), \mathsf{inv}(\mathsf{inv}(t)))$$

belong to the two-centralizer intersection carrier $Z_{a,b}$*.*

Proof. Unpack $Z_{a,b}(t)$ and $Z_{a,b}(x)$ into their a-centralizer and b-centralizer components. The self-normalizer theorem for a centralizer applied to the a component of t carries the a component of x through both displayed conjugation words. The same theorem applied to the b component of t carries the b component of x through the same two words. Pairing the corresponding components reconstructs membership in $Z_{a,b}$ for both conjugates. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersectionCarrier self conjugation closed from empty unit`

Theorem 80.8 (Centralizer intersection classifier self-conjugation closure)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *laws, if* $Z_{a,b}(t)$ *and the restricted classifier on* $Z_{a,b}$ *relates* x *to* y*, then it also relates their conjugates by* t*:*

$$\mathsf{SubgroupCentralizerIntersectionClassifier}(mul, a, b, x, y) \Rightarrow \mathsf{SubgroupCentralizerIntersectionClassifier}(mul, a, b, \mathsf{mul}(mu$$

Proof. The carrier self-conjugation theorem sends the x endpoint and the y endpoint separately into the two-centralizer intersection carrier. The stored comparison $x\mathsf{hsame}y$ is transported through the two multiplication slots by multiplication congruence, giving the classifier row for the two conjugates. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersectionClassifier self conjugation closed from empty unit`

Theorem 80.9 (Centralizer intersection classifier history transport)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *laws, the restricted classifier on* $Z_{a,b}$ *is stable under endpoint* hsame *transport:*

$$\mathsf{SubgroupCentralizerIntersectionClassifier}(mul, a, b, x, y) \wedge x\mathsf{hsame}x' \wedge y\mathsf{hsame}y' \Rightarrow \mathsf{SubgroupCentralizerIntersectionClass}$$

Proof. The intersection certificate supplies carrier transport for $Z_{a,b}$, so the two endpoint carrier rows move from x, y to x', y'. The classifier comparison is the composite $x'\mathsf{hsame}x\mathsf{hsame}y\mathsf{hsame}y'$, using symmetry and transitivity of hsame. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersectionClassifier hsame transport from empty unit`

Per-object template: traditional target two-centralizer subgroup certificate; BEDC source $\mathsf{Group}^{\uparrow}$ over BHist; carrier $Z_{a,b}$; classifier restricted hsame; stability identity, product, inverse, and carrier transport; ledger fixed histories a, b, two commutator witnesses, and ambient operation witnesses; core theorem list Definition 80.2 and Definition 80.4; exactness predicate simultaneous centralizer membership against a and b; downstream consumer Definition 45.688; standard bridge center as an intersection of centralizers; status $\mathsf{ProofTarget}$.

Definition 80.10 (RatUp FieldUp affine center subgroup carrier)**.** *For the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *affine exit package of Definition 45.662, take the ambient group carrier to be* AffAut_F *with classifier* $\equiv_{\mathrm{aff}}$*, multiplication* $\circ_{\mathrm{aff}}$*, identity* id_F*, and inverse row* ι_F*. The associated* $\mathsf{Subgroup}^{\uparrow}$ *carrier is the affine center predicate on that same group:*

$$\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(Z) := \mathsf{Center}_F(Z) \qquad (Z : \mathsf{AffAut}_F).$$

Thus membership in the subgroup certificate is exactly center membership in the concrete FieldUp affine automorphism group.

Theorem 80.11 (RatUp FieldUp affine center SubgroupUp instance)**.** *The carrier of Definition 80.10 instantiates the concrete* $\mathsf{Subgroup}^{\uparrow}$ *certificate fields over* AffAut_F*. Namely:*

1. $\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(\mathrm{id}_F)$.
2. *If* $\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(Z)$ *and* $\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(W)$*, then* $\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(Z \circ_{\mathrm{aff}} W)$.
3. *If* $\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(Z)$*, then* $\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(\iota_F(Z))$.
4. *If* $Z \equiv_{\mathrm{aff}} W$ *and* $\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(Z)$*, then* $\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(W)$.
5. *If* $\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(Z)$*, then for every* $T : \mathsf{AffAut}_F$*,* $\mathsf{Carrier}_{\mathsf{Subgroup}^{\uparrow}}(\mathrm{Inn}_T(Z))$.

The same data make this $\mathsf{Subgroup}^{\uparrow}$ *object normal under inner affine conjugation.*

Proof. Fix the canonical exit action and inverse package of Definition 45.662. This fixes the ambient group operations $\circ_{\mathrm{aff}}$, id_F, ι_F, $\equiv_{\mathrm{aff}}$, and the inner affine conjugation row on AffAut_F.

By Definition 80.10, each subgroup membership assertion is exactly the corresponding Center_F assertion. Apply Definition 45.694 to obtain identity membership, product closure, inverse closure, classifier transport, and normality under Inn_T.

The classifier-transport field is compatible with the ambient ledger because Definition 45.553 supplies operation and inverse congruence for $\equiv_{\mathrm{aff}}$. Therefore the five displayed clauses are precisely the concrete $\mathsf{Subgroup}^{\uparrow}$ certificate fields over the FieldUp affine exit package. □

Per-object template: traditional target normal subgroup of the affine automorphism group; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ plus $\mathsf{Group}^{\uparrow}$; carrier Center_F; classifier $\equiv_{\mathrm{aff}}$; stability identity, product, inverse, classifier transport, and inner conjugation; ledger affine operation and conjugation witnesses; core theorem list Definition 80.11 and Definition 45.694; exactness predicate center membership as the $\mathsf{Subgroup}^{\uparrow}$ carrier; standard bridge ordinary affine center normal subgroup; status $\mathsf{ProofTarget}$.

Definition 80.12 (RatUp FieldUp affine normalizer SubgroupUp carrier)**.** *For Definition 45.617, fix a certified affine automorphism* $A : \mathsf{AffAut}_F$ *in the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object. Let* $C_F(A)$ *be the affine centralizer carrier and let* $N_F(C_F(A))$ *be the two-sided affine centralizer normalizer carrier. The corresponding* $\mathsf{Subgroup}^{\uparrow}$ *carrier is*

$$\mathsf{Carrier}^{N}_{\mathsf{Subgroup}^{\uparrow}}(T) := N_F(C_F(A))(T) \qquad (T : \mathsf{AffAut}_F).$$

It uses the ambient affine classifier $\equiv_{\mathrm{aff}}$*, operation* $\circ_{\mathrm{aff}}$*, identity* id_F*, and inverse* ι_F*. Its ledger records the fixed automorphism* A*, the centralizer membership tests for* $C_F(A)$*, and the conjugation witnesses asserting preservation and reflection of that centralizer under affine inner action.*

Theorem 80.13 (RatUp FieldUp affine normalizer SubgroupUp instance and center action)**.** *The carrier of Definition 80.12 is the concrete* $\mathsf{Subgroup}^{\uparrow}$ *certificate target for the affine normalizer* $N_F(C_F(A))$ *over* AffAut_F*. Namely, for the fixed certified* $A : \mathsf{AffAut}_F$*:*

1. $\mathsf{Carrier}^{N}_{\mathsf{Subgroup}^{\uparrow}}(\mathrm{id}_F)$.
2. *If* $\mathsf{Carrier}^{N}_{\mathsf{Subgroup}^{\uparrow}}(T)$ *and* $\mathsf{Carrier}^{N}_{\mathsf{Subgroup}^{\uparrow}}(U)$*, then* $\mathsf{Carrier}^{N}_{\mathsf{Subgroup}^{\uparrow}}(T \circ_{\mathrm{aff}} U)$.
3. *If* $\mathsf{Carrier}^{N}_{\mathsf{Subgroup}^{\uparrow}}(T)$*, then* $\mathsf{Carrier}^{N}_{\mathsf{Subgroup}^{\uparrow}}(\iota_F(T))$.
4. *If* $T \equiv_{\mathrm{aff}} U$ *and* $\mathsf{Carrier}^{N}_{\mathsf{Subgroup}^{\uparrow}}(T)$*, then* $\mathsf{Carrier}^{N}_{\mathsf{Subgroup}^{\uparrow}}(U)$.
5. *If* $\mathsf{Center}_F(Z)$*, then* $\mathsf{Carrier}^{N}_{\mathsf{Subgroup}^{\uparrow}}(Z)$.

6. If $C_F(A)(X)$ and $\mathsf{Center}_F(Z)$, then the restricted normalizer action satisfies $\mathrm{Act}_Z(X) \equiv_{\mathrm{aff}} X$. Thus the affine center includes into this normalizer carrier and acts pointwise as the classifier identity on the fixed centralizer.

Proof. By Definition 80.12, each $\mathsf{Carrier}^N_{\mathsf{Subgroup}^\uparrow}$ assertion is exactly the $N_F(C_F(A))$ normalizer predicate for the fixed affine automorphism A.

Apply Definition 45.695. Its four displayed rows give identity membership, product closure, inverse closure, and transport along $\equiv_{\mathrm{aff}}$ for the carrier $\mathsf{Carrier}^N_{\mathsf{Subgroup}^\uparrow}$.

For the center inclusion and restricted action, apply Definition 45.705. The first displayed implication gives $\mathsf{Center}_F(Z) \Rightarrow \mathsf{Carrier}^N_{\mathsf{Subgroup}^\uparrow}(Z)$, and the second displayed statement gives $\mathrm{Act}_Z(X) \equiv_{\mathrm{aff}} X$ for every carried centralizer element X.

The ambient classifier compatibility is the same compatibility used in Definition 45.553: affine operation and inverse rows respect $\equiv_{\mathrm{aff}}$, so the normalizer witnesses repack as $\mathsf{Subgroup}^\uparrow$ certificate rows without changing the underlying affine group data. □

Per-object template: traditional target normalizer subgroup acting on a centralizer; BEDC source concrete $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$, $\mathsf{Group}^\uparrow$, and $\mathsf{Subgroup}^\uparrow$; carrier $N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; stability identity, product, inverse, transport, and restricted action; ledger fixed automorphism, centralizer tests, normalizer witness, and conjugation witnesses; core theorem list Definition 45.695 and Definition 45.705; exactness predicate normalizer membership as preservation-reflection of $C_F(A)$; standard bridge ordinary normalizer subgroup and center action; status $\mathsf{ProofTarget}$.

Definition 80.14 (RatUp FieldUp affine center-normalizer SubgroupUp pair)**.** *For the concrete $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ affine exit object of Definition 45.617 and a fixed certified affine automorphism $A : \mathsf{AffAut}_F$, take the lower $\mathsf{Subgroup}^\uparrow$ carrier to be Center_F, the upper $\mathsf{Subgroup}^\uparrow$ carrier to be $N_F(C_F(A))$, the classifier to be $\equiv_{\mathrm{aff}}$, the operation to be $\circ_{\mathrm{aff}}$, the identity to be id_F, and the inverse row to be ι_F. The action row is the restricted normalizer action Act_Z on the centralizer carrier $C_F(A)$.*

The certificate ledger records the affine exit package, the center subgroup witnesses, the normalizer preservation and reflection witnesses for $C_F(A)$, and the pointwise restricted action witness. Thus the object is a single center-normalizer pair certificate rather than a separate lower subgroup row, upper subgroup row, inclusion row, and action row.

Theorem 80.15 (RatUp FieldUp affine center-normalizer SubgroupUp pair certificate)**.** *The pair of Definition 80.14 supplies the concrete center-normalizer $\mathsf{Subgroup}^\uparrow$ certificate consumed by quotient and subgroup-action layers. For the fixed certified $A : \mathsf{AffAut}_F$:*

1. *the lower carrier Center_F has the center $\mathsf{Subgroup}^\uparrow$ certificate of Definition 80.11;*
2. *the upper carrier $N_F(C_F(A))$ has the normalizer $\mathsf{Subgroup}^\uparrow$ certificate of Definition 80.13;*
3. *if $\mathsf{Center}_F(Z)$, then $N_F(C_F(A))(Z)$;*
4. *if $C_F(A)(X)$ and $\mathsf{Center}_F(Z)$, then $\mathrm{Act}_Z(X) \equiv_{\mathrm{aff}} X$.*

Proof. The lower certificate is exactly the carrier and stability package of Definition 80.10. Apply Definition 80.11 to obtain the identity, product, inverse, classifier-transport, and inner-conjugation rows for Center_F.

The upper certificate is exactly the carrier and stability package of Definition 80.12. Apply Definition 80.13 to obtain the normalizer identity, product, inverse, and classifier-transport rows, together with the displayed inclusion and action rows.

Finally apply Definition 45.705. Its concrete FieldUp action identity gives $N_F(C_F(A))(Z)$ from $\mathsf{Center}_F(Z)$ and gives $\mathrm{Act}_Z(X) \equiv_{\mathrm{aff}} X$ for every $X : \mathsf{AffAut}_F$ carried by $C_F(A)$. Repacking these rows with the ledger of Definition 80.14 gives the advertised pair certificate. □

Per-object template: traditional target center-normalizer pair in an affine automorphism group; BEDC source $\mathsf{Rat}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, and $\mathsf{Subgroup}^{\uparrow}$; carriers Center_F and $N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; stability subgroup rows plus inclusion and action identity; ledger affine exit package, center witnesses, normalizer preservation and reflection witnesses, and action witness; exactness center inclusion and pointwise identity action; downstream consumer quotientgroup and subgroup-action certificates; status ProofTarget.

Definition 80.16 (Centralizer normalizer witness)**.** *For the centralizer carrier Z_a from Definition 41.84, define the history-level normalizer witness predicate by*

$$\mathsf{Norm}_{Z_a}(t) :\Longleftrightarrow (\forall x : \mathsf{BHist},\ Z_a(x) \Rightarrow Z_a(\mathsf{mul}(\mathsf{mul}(t,x),\mathsf{inv}(t))))\wedge(\forall x : \mathsf{BHist},\ Z_a(x) \Rightarrow Z_a(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(t),x),\mathsf{inv}(\mathsf{i}$$

Thus $\mathsf{Norm}_{Z_a}(t)$ records that conjugation by t and conjugation by $\mathsf{inv}(t)$ both preserve the centralizer carrier. Equivalently, it is the carrier N_a of Definition 41.95 with the abbreviation Conj *expanded.*

Lean4 (definition) `BEDC.Derived.SubgroupUp.SubgroupCentralizerNormalizer`

Theorem 80.17 (Centralizer normalizer forward product closure)**.** *For a BEDC history-level $\mathsf{Group}^{\uparrow}$ operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.2, the forward centralizer-normalizer witness is closed under multiplication. Explicitly, if s and t both send every carried element of Z_a to another carried element under conjugation, then $\mathsf{mul}(s,t)$ has the same forward preservation property.*

Proof. Let $x : \mathsf{BHist}$ satisfy $Z_a(x)$. Apply the forward normalizer action composition theorem to the witnesses for s and t. It gives a carried nested conjugation endpoint together with an hsame identification between the direct conjugation by $\mathsf{mul}(s,t)$ and that nested endpoint. The carrier-transport row from Definition 80.2 then moves centralizer membership across this hsame equality, yielding the required carried endpoint for $\mathsf{mul}(s,t)$. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerNormalizer mul closed from empty unit`

Theorem 80.18 (Centralizer normalizer relative product closure)**.** *For a BEDC history-level $\mathsf{Group}^{\uparrow}$ operation over* BHist *satisfying the associativity, unit, multiplication-congruence, and two-sided inverse laws of Definition 80.2, the centralizer-normalizer witness is closed under relative products. If $\mathsf{Norm}_{Z_a}(s)$ and $\mathsf{Norm}_{Z_a}(t)$, then*

$$\mathsf{Norm}_{Z_a}(\mathsf{mul}(\mathsf{inv}(s),t)).$$

Proof. First close $\mathsf{Norm}_{Z_a}(s)$ under inversion. The forward clause for $\mathsf{inv}(s)$ is the reverse conjugation clause already contained in $\mathsf{Norm}_{Z_a}(s)$. The reverse clause is transported from the forward clause for s using inverse involution, multiplication congruence, and the centralizer carrier transport row of Definition 80.2. Applying the normalizer multiplication closure theorem to $\mathsf{inv}(s)$ and t gives the displayed relative product. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerNormalizer relative product closed from empty unit`

Theorem 80.19 (Centralizer elements normalize the centralizer)**.** *For a BEDC history-level $\mathsf{Group}^{\uparrow}$ operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.2, every centralizer element normalizes the centralizer. Explicitly, if $Z_a(t)$, then $\mathsf{Norm}_{Z_a}(t)$.*

Proof. Assume $Z_a(t)$. The inverse-closure row of Definition 41.87 applied to $Z_a(t)$ gives $Z_a(\mathsf{inv}(t))$.

For the forward conjugation clause, let $x : \mathsf{BHist}$ satisfy $Z_a(x)$. The product-closure row of Definition 41.87 applied to $Z_a(t)$ and $Z_a(x)$ gives $Z_a(\mathsf{mul}(t, x))$.

Apply product closure once more, now to $Z_a(\mathsf{mul}(t, x))$ and $Z_a(\mathsf{inv}(t))$. The result is $Z_a(\mathsf{mul}(\mathsf{mul}(t, x), \mathsf{inv}(t)))$, which is precisely the first clause of $\mathsf{Norm}_{Z_a}(t)$.

For the inverse conjugation clause, let $x : \mathsf{BHist}$ satisfy $Z_a(x)$. Product closure applied to $Z_a(\mathsf{inv}(t))$ and $Z_a(x)$ gives $Z_a(\mathsf{mul}(\mathsf{inv}(t), x))$.

Apply product closure once more with the final factor $Z_a(t)$. The two-sided inverse laws identify t with $\mathsf{inv}(\mathsf{inv}(t))$ under hsame, and the carrier-transport row of Definition 41.87 transports membership to $Z_a(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(t), x), \mathsf{inv}(\mathsf{inv}(t))))$. This is the second clause of $\mathsf{Norm}_{Z_a}(t)$, so both preservation directions hold. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizer self normalizer from empty unit`
Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerCarrier self normalizer from empty unit`
Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerCarrier self normalizes`

Theorem 80.20 (Centralizer intersection simultaneous self-normalizer)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.2, fix* $a, b : \mathsf{BHist}$ *and let* $Z_{a,b}$ *be the two-centralizer carrier of Definition 80.3. If* $Z_{a,b}(t)$*, then*

$$\mathsf{Norm}_{Z_a}(t) \wedge \mathsf{Norm}_{Z_b}(t).$$

Proof. Unfold the intersection carrier. The witness $Z_{a,b}(t)$ is exactly a pair consisting of $Z_a(t)$ and $Z_b(t)$, with both component centralizers using the same ambient $\mathsf{Group}^{\uparrow}$ laws and the same restricted hsame classifier.

Apply Definition 80.19 first with fixed history a and component witness $Z_a(t)$. This gives $\mathsf{Norm}_{Z_a}(t)$.

Apply Definition 80.19 again with fixed history b and component witness $Z_b(t)$. Pair the two resulting normalizer witnesses to obtain the displayed simultaneous conclusion. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerIntersectionCarrier simultaneous self normalizer from empty unit`

Per-object template: traditional target simultaneous normalizer membership for an intersection of centralizers; BEDC source $\mathsf{Group}^{\uparrow}$ plus $\mathsf{Subgroup}^{\uparrow}$; carrier $Z_{a,b}$; classifier restricted hsame; stability inherited from the two centralizer certificates; ledger fixed histories a, b and two self-normalizer witnesses; core theorem Definition 80.20; exactness the paired normalizer conclusion; downstream consumer quotient-ready normalizer towers; status $\mathsf{ProofTarget}$.

Lemma 80.21 (Centralizer normalizer kernel classifier reflexivity)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.2, if* $x : \mathsf{BHist}$ *is carried by the centralizer normalizer* N_a*, then the normalizer endpoint classifies with itself and the inverse-left kernel word is carried by the centralizer:*

$$N_a(x) \Rightarrow N_a(x) \wedge N_a(x) \wedge Z_a(\mathsf{mul}(\mathsf{inv}(x), x)).$$

Proof. The two normalizer endpoint rows are the given $N_a(x)$ witness. For the kernel word, use the centralizer certificate target of Definition 80.2: its identity row gives $Z_a(\mathsf{e})$ and its hsame-transport row transports this membership along the inverse-left law $\mathsf{mul}(\mathsf{inv}(x), x)\mathsf{hsame}\mathsf{e}$ read in the reverse direction. Thus the inverse-left kernel endpoint lies in the lower centralizer carrier. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerNormalizer kernel classifier refl`

Per-object template: traditional target centralizer self-normalization; BEDC source $\mathsf{Group}^{\uparrow}$ over BHist plus $\mathsf{Subgroup}^{\uparrow}$; carrier Z_a; classifier restricted hsame; stability product and inverse closure; ledger conjugating element, acted element, and inverse witness; core theorem list Definition 41.87 and Definition 80.2; exactness predicate normalizer witness; standard bridge ordinary centralizer inclusion in its normalizer; status $\mathsf{ProofTarget}$.

Definition 80.22 (Centralizer-normalizer SubgroupUp pair)**.** *Fix the centralizer carrier Z_a from Definition 41.84 and the centralizer normalizer carrier N_a from Definition 41.95. The centralizer-normalizer* $\mathsf{Subgroup}^{\uparrow}$ *pair has lower carrier Z_a and upper carrier N_a, both classified by the restriction of* hsame *to carried histories. The operation, unit, and inverse are inherited from the ambient history-level* $\mathsf{Group}^{\uparrow}$ *operation* mul*, e, and* inv*.*

The pair ledger records the fixed element a, the conjugation word $\mathsf{Conj}_s(x)$, the witnesses that histories carried by Z_a commute with a, and the forward and inverse preservation witnesses appearing in the definition of N_a. Thus a carried normalizer history acts on the carried centralizer histories by the restricted conjugation word while keeping every endpoint inside the same $\mathsf{Subgroup}^{\uparrow}$ *lower carrier.*

Theorem 80.23 (Centralizer-normalizer SubgroupUp pair certificate)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 41.98, the pair of Definition 80.22 satisfies the following concrete* $\mathsf{Subgroup}^{\uparrow}$ *certificate rows:*

1. *Z_a is the centralizer* $\mathsf{Subgroup}^{\uparrow}$ *certificate target of Definition 80.2.*
2. *N_a is a* $\mathsf{Subgroup}^{\uparrow}$ *certificate target over the same ambient operation, with unit, product, inverse, and classifier-transport rows.*
3. *The lower carrier is included in the upper carrier: if $Z_a(s)$, then $N_a(s)$.*
4. *If $N_a(s)$ and $Z_a(x)$, then $Z_a(\mathsf{Conj}_s(x))$ and $Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$.*
5. *For every s with $N_a(s)$, the restricted normalizer action on Z_a is classifier-exact, its orbit classifier is stable under* hsame *replacement of carried endpoints, and its fixed-action kernel satisfies*

$$(\forall x : \mathsf{BHist},\ Z_a(x) \Rightarrow \mathsf{hsame}(\mathsf{Conj}_s(x), x)) \iff (\forall x : \mathsf{BHist},\ Z_a(x) \Rightarrow \mathsf{hsame}(\mathsf{mul}(s, x), \mathsf{mul}(x, s))).$$

Hence the centralizer and its normalizer are available as one concrete $\mathsf{Subgroup}^{\uparrow}$ *pair over* BHist*, with the restricted conjugation action and orbit classifier attached to the same certificate object.*

Proof. The lower certificate is Definition 80.2. It gives the unit, product, inverse, classifier-transport, and commutator-fiber rows for Z_a with the operation, unit, inverse, and restricted hsame classifier inherited from the ambient $\mathsf{Group}^{\uparrow}$.

The upper certificate and the carrier inclusion are supplied by Definition 41.98. Its first four rows give unit, product, inverse, and classifier transport for N_a, and its final row places each centralizer element in the normalizer.

The action rows are the defining preservation clauses of N_a, recorded in Definition 41.100. That theorem also gives the inverse-action identities and the displayed fixed-action kernel equivalence, so the restricted action is exact on the centralizer carrier.

Finally, Definition 41.109 supplies the endpoint-transport row for the orbit classifier generated by the same normalizer action. Repacking these cited rows with the ledger of Definition 80.22 gives one concrete $\mathsf{Subgroup}^{\uparrow}$ pair over BHist. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerNormalizer pair certificate from empty unit`

Per-object template: traditional target normalizer of a centralizer with restricted action; BEDC source $\mathsf{Group}^{\uparrow}$ over BHist plus $\mathsf{Subgroup}^{\uparrow}$; carriers Z_a, N_a; classifier restricted hsame; stability subgroup rows, inclusion, conjugation preservation, and action exactness; ledger fixed element a, conjugating word Conj_s, normalizer witness, and endpoint witnesses; core theorem list Definition 80.2, Definition 41.98, Definition 41.100, and Definition 41.109; exactness predicate normalizer action on the centralizer carrier; standard bridge ordinary centralizer-normalizer pair; status $\mathsf{ProofTarget}$. The sibling route for $\mathsf{Subgroup}^{\uparrow}$ is the algebraic ladder already displayed by $\mathsf{Group}^{\uparrow}$ and $\mathsf{Monoid}^{\uparrow}$. The subgroup packet consumes the ambient carrier, operation, identity, inverse, and closure rows from chapter 41, while its operation and unit layer is inherited through the monoid certificate of chapter 40; the carried subset is therefore a refinement of that ambient algebraic surface rather than a detached kernel entry.

Theorem 80.24 (Subgroup group quotient dependency route)**.** *Every accepted* $\mathsf{Subgroup}^{\uparrow}$ *packet reads its ambient carrier, operation, unit, inverse, and closure rows through the* $\mathsf{Group}^{\uparrow}$ *surface of chapter 41 and the operation-unit inheritance route of chapter 40. Any quotient-facing consumer must then route the restricted classifier through chapter 82, rather than treating subgroup data as a kernel-only record detached from the ambient algebra.*

Proof. Start with an accepted subgroup packet. Its carrier is a carried subset of an ambient algebraic source, so the operation, unit, inverse, and closure rows are readable only after the $\mathsf{Group}^{\uparrow}$ carrier and operation surface has been displayed.

The operation and unit rows retain the monoid layer. Associativity, unit compatibility, and product closure are inherited through the $\mathsf{Monoid}^{\uparrow}$ route before inverse and subgroup-specific closure rows are inspected.

For quotient-facing reads, the restricted classifier is not enough by itself. The consumer must expose the $\mathsf{QuotientGroup}^{\uparrow}$ route so that endpoint membership, quotient classifier stability, multiplication compatibility, and representative independence are read as quotient-group rows over the displayed subgroup packet.

Thus the substantive dependency route is $\mathsf{Group}^{\uparrow}$ and $\mathsf{Monoid}^{\uparrow}$ for ambient algebra, followed by $\mathsf{QuotientGroup}^{\uparrow}$ for quotient consumers. The subgroup packet is not a kernel-only object and does not export quotient structure without that route. □

Quotient-facing $\mathsf{Subgroup}^{\uparrow}$ consumers read the ambient operation rows of chapter 41, the unit and multiplication discipline of chapter 40, and the classifier boundary of chapter 82 before any normalizer or kernel route is accepted. The dependency route keeps $\mathsf{Subgroup}^{\uparrow}$ inside the displayed algebra lattice: a normal-subgroup consumer may reuse the subgroup carrier only after the group, monoid, and quotient-group rows have fixed the operation, identity, equivalence, and kernel-facing classifier surface.

Theorem 80.25 (Centralizer normalizer SubgroupUp certificate)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.2, the carrier* Norm_{Z_a} *of Definition 80.16 supplies the concrete* $\mathsf{Subgroup}^{\uparrow}$ *certificate rows for the normalizer of* Z_a*:*

1. $\mathsf{Norm}_{Z_a}(e)$.
2. *If* $\mathsf{Norm}_{Z_a}(s)$ *and* $\mathsf{Norm}_{Z_a}(t)$*, then* $\mathsf{Norm}_{Z_a}(\mathsf{mul}(s,t))$.
3. *If* $\mathsf{Norm}_{Z_a}(t)$*, then* $\mathsf{Norm}_{Z_a}(\mathsf{inv}(t))$.

4. *If* $\mathsf{Norm}_{Z_a}(s)$ *and* $s\mathsf{hsame}t$*, then* $\mathsf{Norm}_{Z_a}(t)$*.*

5. *If* $Z_a(t)$*, then* $\mathsf{Norm}_{Z_a}(t)$*.*

Thus the two-sided normalizer carrier has identity membership, product closure, inverse closure, hsame*-transport, and the inclusion row from the centralizer.*

Proof. For identity membership, unfold Definition 80.16. The unit laws make conjugation by e act as the identity on every carried x, and the two-sided inverse laws identify $\mathsf{inv}(e)$ with e. Carrier transport from Definition 41.87 returns both clauses.

For product closure, assume $\mathsf{Norm}_{Z_a}(s)$ and $\mathsf{Norm}_{Z_a}(t)$, reading these as expanded N_a witnesses. Apply Definition 41.97: its forward composition row sends $Z_a(x)$ first through the t clause and then through the s clause, while its inverse-action row sends $Z_a(x)$ first through the inverse clause for s and then through the inverse clause for t. These are the two clauses of $\mathsf{Norm}_{Z_a}(\mathsf{mul}(s,t))$.

For inverse closure, the first clause of $\mathsf{Norm}_{Z_a}(\mathsf{inv}(t))$ is exactly the inverse-conjugation half of $\mathsf{Norm}_{Z_a}(t)$. Its second clause conjugates by $\mathsf{inv}(\mathsf{inv}(t))$; the two-sided inverse laws identify this word with the original conjugation by t, and multiplication congruence plus carrier transport move the first clause across the comparison.

For hsame-transport, assume $\mathsf{Norm}_{Z_a}(s)$ and $s\mathsf{hsame}t$. Multiplication congruence transports the forward conjugation word with s to the corresponding word with t, and inverse congruence transports the inverse word. Carrier transport from Definition 41.87 therefore gives both clauses of $\mathsf{Norm}_{Z_a}(t)$.

The inclusion row is exactly Definition 80.19: every $Z_a(t)$ supplies both normalizer clauses. Repacking the five rows with the restricted hsame classifier gives the advertised concrete $\mathsf{Subgroup}^{\uparrow}$ certificate for the normalizer carrier. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerNormalizer certificate from empty unit`

Per-object template: traditional target normalizer subgroup certificate; BEDC source $\mathsf{Group}^{\uparrow}$ over BHist plus centralizer $\mathsf{Subgroup}^{\uparrow}$; carrier Norm_{Z_a}; classifier restricted hsame; stability identity, product, inverse, and carrier transport; ledger unit conjugation, product conjugation composition, inverse conjugation, and endpoint classifier witnesses; core theorem list Definition 41.97, Definition 41.87, and Definition 80.19; exactness predicate two-sided preservation of Z_a under conjugation; standard bridge ordinary normalizer subgroup of a centralizer; status ProofTarget.

Theorem 80.26 (Centralizer normalizer hsame transport)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *laws, if* $N_a(s)$ *and* $s\mathsf{hsame}t$*, then* $N_a(t)$*.*

Proof. For every centralizer input x, the normalizer witness for s gives carried membership of the conjugation word $\mathsf{mul}(\mathsf{mul}(s,x),\mathsf{inv}(s))$. Multiplication congruence and inverse congruence transport this word to $\mathsf{mul}(\mathsf{mul}(t,x),\mathsf{inv}(t))$. The centralizer hsame-transport row from the $\mathsf{Subgroup}^{\uparrow}$ certificate for Z_a gives the required carried membership for t. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerNormalizer hsame transport from empty unit`

Theorem 80.27 (Centralizer normalizer SubgroupUp tower certificate)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.2, let* Z_a *be the centralizer carrier of Definition 41.84 and let* N_a *be the centralizer normalizer carrier of Definition 41.95. The pair* $Z_a \leq N_a$ *forms a quotient-ready* $\mathsf{Subgroup}^{\uparrow}$ *tower:*

1. Z_a *satisfies the identity, product, inverse,* hsame*-transport, and commutator-fiber rows of the centralizer* $\mathsf{Subgroup}^{\uparrow}$ *certificate.*

2. *N_a satisfies the identity, product, inverse, and* hsame*-transport subgroup rows over the same ambient classifier.*
3. *Every carried centralizer element is carried by the normalizer: if $Z_a(t)$, then $N_a(t)$.*
4. *If $N_a(s)$ and $Z_a(x)$, then $Z_a(\mathsf{Conj}_s(x))$ and $Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$.*
5. *The two conjugation-closure rows are stable under the ambient classifier: if $\mathsf{hsame}(s,t)$, then the corresponding forward and inverse conjugation words define the same carried Z_a membership after transport.*

Equivalently, the ten-field $\mathsf{Subgroup}^{\uparrow}$ certificate for Z_a, the four-field subgroup certificate for N_a, the inclusion $Z_a \subseteq N_a$, the two conjugation rows, and their classifier stability are packaged as the normal-subgroup input used by quotient-group construction.

Proof. The Z_a certificate is exactly Definition 80.2. It supplies the identity carrier, product closure, inverse closure, hsame transport, and commutator-fiber exactness rows for the centralizer object viewed as a $\mathsf{Subgroup}^{\uparrow}$ instance.

The N_a subgroup rows come from Definition 41.98. Its identity, product, inverse, and hsame-transport clauses give the normalizer carrier the same ambient operation, unit, inverse, and classifier interface required for the upper subgroup object.

The inclusion row has two equivalent sources. The fifth row of Definition 41.98 states directly that $Z_a(t)$ implies $N_a(t)$, while Definition 80.19 gives the same witness by showing that every centralizer element preserves Z_a under conjugation.

Finally, Definition 41.99 supplies the forward conjugation row, the inverse-conjugation row, and the classifier transport of those rows. Repacking these data in the order displayed above gives the quotient-ready tower certificate without introducing any host quotient or external parameter transport. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerNormalizer tower certificate`

Per-object template: traditional target normal centralizer subgroup inside its normalizer for quotient groups; BEDC source $\mathsf{Group}^{\uparrow}$ over BHist plus $\mathsf{Subgroup}^{\uparrow}$; lower carrier Z_a; upper carrier N_a; classifier hsame; stability identity, product, inverse, classifier transport, inclusion, forward conjugation, inverse conjugation, and conjugation-word transport; ledger centralizing element, normalizing element, acted element, inverse normalizer witness, and carried conjugation witnesses; core theorem list Definition 80.2, Definition 41.98, Definition 80.19, and Definition 41.99; exactness predicate normalizer action on the centralizer; standard bridge normal-subgroup input for quotient groups; status ProofTarget.

Theorem 80.28 (Subgroup normalizer orbit quotient classifier)**.** *For a BEDC history-level $\mathsf{Group}^{\uparrow}$ operation over* BHist *satisfying the BEDC group laws used by Definition 80.27 and Definition 41.104, including associativity, unit, multiplication-congruence, inverse-congruence, and two-sided inverse laws, let Z_a be the centralizer carrier, let N_a be the centralizer normalizer carrier, let $\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s,x),\mathsf{inv}(s))$, and let $x \sim_{N_a} y$ be the normalizer-orbit relation of Definition 41.103. For x, y, z : BHist with $Z_a(x)$, $Z_a(y)$, and $Z_a(z)$, the data of Definition 80.27 together with Definition 41.104 supply the quotient-free classifier input for $\mathsf{QuotientGroup}^{\uparrow}$:*

1. *the lower $\mathsf{Subgroup}^{\uparrow}$ certificate rows for Z_a;*
2. *the upper subgroup rows for N_a over the same history operation;*
3. *the inclusion row $Z_a \subseteq N_a$;*
4. *the forward and inverse conjugation stability of Z_a under histories carried by N_a;*

5. reflexivity, symmetry, and transitivity of $\sim_{N_a}$ on carried histories of Z_a.

Thus the normalizer action on the centralizer carries exactly the quotient-free orbit classifier required before any quotient-group carrier is introduced.

Proof. Apply Definition 80.27. Its displayed rows give the lower certificate for Z_a, the upper subgroup rows for N_a, the inclusion $Z_a \subseteq N_a$, and the two conjugation-closure rows for Conj_s and $\mathsf{Conj}_{\mathsf{inv}(s)}$.

Next use Definition 41.103 to read $\sim_{N_a}$ as reachability by a carried normalizer history with an hsame endpoint comparison. This keeps the classifier entirely at the history level.

Finally apply Definition 41.104 to the carried endpoints x, y, and z. Its three laws give reflexivity, symmetry, and transitivity for the same relation $\sim_{N_a}$ on Z_a, so the tower rows and the orbit laws combine into the advertised $\mathsf{QuotientGroup}^{\uparrow}$ classifier input. □

Per-object template: traditional target normalizer-orbit quotient classifier; BEDC source $\mathsf{Group}^{\uparrow}$ plus $\mathsf{Subgroup}^{\uparrow}$ tower; carrier Z_a; classifier $\sim_{N_a}$; stability equivalence plus conjugation closure; ledger normalizer witness and conjugation endpoint; exactness quotient-free orbit reachability; standard bridge ordinary normal-subgroup orbit quotient input; status $\mathsf{ProofTarget}$.

Definition 80.29 (Abstract two-subgroup intersection carrier)**.** *Fix a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *source over* BHist *with operation* mul*, unit* e*, inverse operation* inv*, and ambient classifier* hsame*. Let* $H_1, H_2 : \mathsf{BHist} \to \mathsf{Prop}$ *be two predicates read as* $\mathsf{Subgroup}^{\uparrow}$ *carriers over this same source. Define their two-subgroup intersection carrier by*

$$H_{1,2}(x) :\Longleftrightarrow H_1(x) \wedge H_2(x).$$

The inherited restricted classifier on this carrier is

$$R_{1,2}(x, y) :\Longleftrightarrow H_{1,2}(x) \wedge H_{1,2}(y) \wedge x\mathsf{hsame}y.$$

The operation, unit, inverse, and history classifier are inherited from the ambient $\mathsf{Group}^{\uparrow}$ *source.*

Theorem 80.30 (Two-subgroup intersection SubgroupUp certificate)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *with operation* mul*, unit* e*, inverse operation* inv*, and ambient classifier* hsame*, assume the monoid stability rows of Definition 40.13, the inverse rows of Definition 41.55, and the history-sameness equivalence of Definition 3.8. Let* $H_1, H_2 : \mathsf{BHist} \to \mathsf{Prop}$ *be two carrier predicates, and let* $H_{1,2}$ *and* $R_{1,2}$ *be the carrier and restricted classifier of Definition 80.29. Assume that each* H_i*, for* $i \in \{1, 2\}$*, satisfies the ambient* $\mathsf{Subgroup}^{\uparrow}$ *carrier rows:*

1. $H_i(e)$*.*

2. If $H_i(x)$ *and* $H_i(y)$*, then* $H_i(\mathsf{mul}(x, y))$*.*

3. If $H_i(x)$*, then* $H_i(\mathsf{inv}(x))$*.*

4. If $H_i(x)$ *and* $x\mathsf{hsame}y$*, then* $H_i(y)$*.*

Then the carrier $H_{1,2}$ *with classifier* $R_{1,2}$ *satisfies the concrete* $\mathsf{Subgroup}^{\uparrow}$ *certificate rows:*

1. $R_{1,2}$ *is a semantic naming classifier on* $H_{1,2}$*.*

2. $H_{1,2}(e)$*.*

3. If $H_{1,2}(x)$ *and* $H_{1,2}(y)$*, then* $H_{1,2}(\mathsf{mul}(x, y))$*.*

4. If $H_{1,2}(x)$*, then* $H_{1,2}(\mathsf{inv}(x))$*.*

5. *If* $H_{1,2}(x)$ *and* $x\mathsf{hsame}y$*, then* $H_{1,2}(y)$*.*
6. *If* $R_{1,2}(x, x')$ *and* $R_{1,2}(y, y')$*, then*
$$R_{1,2}(\mathsf{mul}(x, y), \mathsf{mul}(x', y')).$$
7. *If* $R_{1,2}(x, y)$*, then*
$$R_{1,2}(\mathsf{inv}(x), \mathsf{inv}(y)).$$

Thus the intersection of two carried $\mathsf{Subgroup}^{\uparrow}$ *predicates over the same ambient* $\mathsf{Group}^{\uparrow}$ *source is again a concrete* $\mathsf{Subgroup}^{\uparrow}$ *certificate target over the restricted* hsame *classifier.*

Proof. First verify the hypotheses of Definition 80.70 for the predicate $P = H_{1,2}$. The inhabitance row is $H_{1,2}(e)$, obtained by pairing the two assumed unit rows $H_1(e)$ and $H_2(e)$.

For carrier stability, assume $H_{1,2}(x)$ and $x\mathsf{hsame}y$. Unfolding $H_{1,2}(x)$ gives $H_1(x)$ and $H_2(x)$. The transport row for H_1 gives $H_1(y)$, and the transport row for H_2 gives $H_2(y)$. Pairing these conclusions gives $H_{1,2}(y)$.

For one-step relative-product closure, assume $H_{1,2}(x)$ and $H_{1,2}(y)$. Unfolding gives $H_i(x)$ and $H_i(y)$ for each $i \in \{1, 2\}$. The inverse row for H_i gives $H_i(\mathsf{inv}(y))$, and then the product row for H_i gives
$$H_i(\mathsf{mul}(x, \mathsf{inv}(y))).$$
Doing this for $i = 1$ and $i = 2$ and pairing the two results proves
$$H_{1,2}(\mathsf{mul}(x, \mathsf{inv}(y))).$$
Therefore Definition 80.70 applies to $H_{1,2}$ and yields the identity, product, inverse, and carrier-transport rows listed above.

It remains to record the restricted-classifier rows. For semantic naming, unfold $R_{1,2}$. If $H_{1,2}(x)$, reflexivity of hsame from Definition 3.8 gives $x\mathsf{hsame}x$, so $R_{1,2}(x, x)$ holds. If $R_{1,2}(x, y)$ holds, keep the two endpoint carrier witnesses and reverse the stored hsame comparison by symmetry, giving $R_{1,2}(y, x)$. If $R_{1,2}(x, y)$ and $R_{1,2}(y, z)$ hold, keep the carried endpoints $H_{1,2}(x)$ and $H_{1,2}(z)$ and compose the stored comparisons by transitivity of hsame, giving $R_{1,2}(x, z)$. Hence $R_{1,2}$ is a semantic naming classifier on the intersection carrier.

For multiplication compatibility, assume $R_{1,2}(x, x')$ and $R_{1,2}(y, y')$. The already proved product row for $H_{1,2}$ supplies the endpoint witnesses
$$H_{1,2}(\mathsf{mul}(x, y))$$
and
$$H_{1,2}(\mathsf{mul}(x', y')).$$
The multiplication congruence row from Definition 40.13 transports the stored comparisons $x\mathsf{hsame}x'$ and $y\mathsf{hsame}y'$ to
$$\mathsf{mul}(x, y)\mathsf{hsamemul}(x', y').$$
These three fields are exactly $R_{1,2}(\mathsf{mul}(x, y), \mathsf{mul}(x', y'))$.

For inverse compatibility, assume $R_{1,2}(x, y)$. The already proved inverse row supplies $H_{1,2}(\mathsf{inv}(x))$ and $H_{1,2}(\mathsf{inv}(y))$. The ambient inverse congruence theorem Definition 41.60 transports the stored comparison $x\mathsf{hsame}y$ to
$$\mathsf{inv}(x)\mathsf{hsameinv}(y).$$
Repacking gives $R_{1,2}(\mathsf{inv}(x), \mathsf{inv}(y))$.

The carrier, classifier, operation, unit, and inverse rows are therefore the concrete $\mathsf{Subgroup}^{\uparrow}$ row format used in Definition 80.2 and Definition 80.68. □

Definition 80.31 (Centralizer normalizer quotient classifier)**.** *For the centralizer carrier Z_a and its normalizer carrier N_a, define the concrete quotient classifier predicate $Q_{Z_a \le N_a}$ on* BHist *by*

$$Q_{Z_a \le N_a}(x, y) :\Longleftrightarrow N_a(x) \wedge N_a(y) \wedge \exists z : \mathsf{BHist},\ Z_a(z) \wedge \mathsf{hsame}(y, \mathsf{mul}(x, z)).$$

The endpoints are carried by N_a, while the right witness is carried by Z_a. Thus $Q_{Z_a \le N_a}$ is a classifier predicate over concrete BEDC histories, not a host quotient object.

Lean4 (definition) `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightQuotientClassifier`
Lean4 (definition) `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientClassifier`
Lean4 (definition) `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightCosetClassifier`

Theorem 80.32 (Centralizer normalizer quotient classifier laws)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.2, the classifier $Q_{Z_a \le N_a}$ of Definition 80.31 has the quotient classifier laws on N_a:*

1. *if $N_a(x)$, then $Q_{Z_a \le N_a}(x, x)$;*
2. *if $Q_{Z_a \le N_a}(x, y)$, then $Q_{Z_a \le N_a}(y, x)$;*
3. *if $Q_{Z_a \le N_a}(x, y)$ and $Q_{Z_a \le N_a}(y, u)$, then $Q_{Z_a \le N_a}(x, u)$;*
4. *if $Q_{Z_a \le N_a}(x, y)$ and $Q_{Z_a \le N_a}(u, v)$, then $Q_{Z_a \le N_a}(\mathsf{mul}(x, u), \mathsf{mul}(y, v))$.*

Proof. The endpoint rows are supplied by Definition 80.27. The identity row of Definition 80.2 gives $Z_a(\mathsf{e})$, and the right-unit law rewrites $\mathsf{mul}(x, \mathsf{e})$ to x up to hsame. This is the required witness for reflexivity on N_a.

For symmetry, suppose $Q_{Z_a \le N_a}(x, y)$ is witnessed by z with $Z_a(z)$ and $\mathsf{hsame}(y, \mathsf{mul}(x, z))$. The inverse-closure row of Definition 80.2 gives $Z_a(\mathsf{inv}(z))$. The two-sided inverse laws and multiplication congruence transport the displayed witness equation to $\mathsf{hsame}(x, \mathsf{mul}(y, \mathsf{inv}(z)))$, so the inverse witness proves $Q_{Z_a \le N_a}(y, x)$.

For transitivity, take witnesses z and w for $Q_{Z_a \le N_a}(x, y)$ and $Q_{Z_a \le N_a}(y, u)$. Product closure for Z_a gives $Z_a(\mathsf{mul}(z, w))$. Associativity and multiplication congruence compose the two classifier equations into $\mathsf{hsame}(u, \mathsf{mul}(x, \mathsf{mul}(z, w)))$, giving $Q_{Z_a \le N_a}(x, u)$.

It remains to check multiplication compatibility. Let z witness $Q_{Z_a \le N_a}(x, y)$ and let w witness $Q_{Z_a \le N_a}(u, v)$. Since u is carried by N_a, the normality row in Definition 80.27, equivalently Definition 41.99, moves z across the right endpoint and gives $Z_a(\mathsf{Conj}_{\mathsf{inv}(u)}(z))$.

Product closure for Z_a combines this conjugated witness with w. The associativity, inverse, and multiplication-congruence laws rewrite $\mathsf{mul}(y, v)$ to $\mathsf{mul}(\mathsf{mul}(x, u), \mathsf{mul}(\mathsf{Conj}_{\mathsf{inv}(u)}(z), w))$ up to hsame. Together with product closure of N_a from Definition 41.98, this gives $Q_{Z_a \le N_a}(\mathsf{mul}(x, u), \mathsf{mul}(y, v))$. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightQuotientClassifier symm from empty unit`

Definition 80.33 (Centralizer normalizer quotient-kernel relation)**.** *In the setting of Definition 80.27, define the relation on ambient histories by*

$$Q_{Z_a \triangleleft N_a}(x, y) :\Longleftrightarrow N_a(x) \wedge N_a(y) \wedge Z_a(\mathsf{mul}(\mathsf{inv}(x), y)).$$

The first two clauses keep both representatives inside the normalizer carrier, and the third clause says that their relative displacement lies in the centralizer kernel.

Lean4 (definition) `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel`

Theorem 80.34 (Centralizer right coset classifier quotient-kernel equivalence)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, the concrete right-coset classifier of Definition 80.31 coincides with the quotient-kernel relation of Definition 80.33:*

$$Q_{Z_a \leq N_a}(x, y) \iff Q_{Z_a \triangleleft N_a}(x, y).$$

Proof. For the forward direction, unpack the right-coset witness. The endpoint clauses already give $N_a(x)$ and $N_a(y)$, and the witness gives some $z : \mathsf{BHist}$ with $Z_a(z)$ and $\mathsf{hsame}(y, \mathsf{mul}(x, z))$.

Left-multiply the endpoint comparison by $\mathsf{inv}(x)$ and reassociate. The left inverse and unit laws identify the resulting word with z up to hsame. Multiplication congruence and the centralizer carrier-transport row then move $Z_a(z)$ to $Z_a(\mathsf{mul}(\mathsf{inv}(x), y))$, which is the quotient-kernel clause.

For the reverse direction, assume the quotient-kernel relation. Take the kernel word $z := \mathsf{mul}(\mathsf{inv}(x), y)$ as the right-coset witness.

Associativity, the inverse law, the unit law, and multiplication congruence transport $\mathsf{mul}(x, \mathsf{mul}(\mathsf{inv}(x), y))$ back to y up to hsame. The kernel carrier is exactly $Z_a(z)$, so the same word repacks the right-coset classifier. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightCosetClassifier quotientKernel iff`

Theorem 80.35 (Centralizer normalizer quotient-kernel identity fiber)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, every* $x : \mathsf{BHist}$ *satisfies*

$$Q_{Z_a \triangleleft N_a}(\mathsf{e}, x) \iff Z_a(x).$$

Proof. Unfold the classifier in Definition 80.33. For the forward direction, the endpoint clauses give $N_a(\mathsf{e})$ and $N_a(x)$, and the kernel clause gives $Z_a(\mathsf{mul}(\mathsf{inv}(\mathsf{e}), x))$.

The inverse and unit laws identify $\mathsf{mul}(\mathsf{inv}(\mathsf{e}), x)$ with x up to hsame. The Z_a carrier-transport row from Definition 80.27 carries the kernel witness to $Z_a(x)$.

For the reverse direction, assume $Z_a(x)$. The inclusion row $Z_a \subseteq N_a$ in Definition 80.27 gives $N_a(x)$, and the identity row gives $N_a(\mathsf{e})$.

It remains to supply the kernel clause for $Q_{Z_a \triangleleft N_a}(\mathsf{e}, x)$. The same inverse and unit laws identify x with $\mathsf{mul}(\mathsf{inv}(\mathsf{e}), x)$ up to hsame, and carrier transport for Z_a moves the assumed $Z_a(x)$ to the displayed kernel word. □

↪ variant `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel empty fiber iff`

Per-object template: traditional target identity coset and unit fiber for the normal-subgroup tower $Z_a \leq N_a$; BEDC source $\mathsf{Group}^{\uparrow}$ plus the $\mathsf{Subgroup}^{\uparrow}$ tower; carrier N_a; classifier $Q_{Z_a \triangleleft N_a}$; exactness identity fiber equals lower carrier; downstream object $\mathsf{QuotientGroup}^{\uparrow}$; status $\mathsf{ProofTarget}$.

Theorem 80.36 (Centralizer quotient-kernel hsame transport)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *laws, if* $Q_{Z_a \triangleleft N_a}(x, y)$*,* $x \mathsf{hsame} x'$*, and* $y \mathsf{hsame} y'$*, then* $Q_{Z_a \triangleleft N_a}(x', y')$*.*

Proof. The endpoint clauses transport by Definition 80.26. For the kernel clause, inverse congruence transports $\mathsf{inv}(x)$ to $\mathsf{inv}(x')$, multiplication congruence transports $\mathsf{mul}(\mathsf{inv}(x), y)$ to $\mathsf{mul}(\mathsf{inv}(x'), y')$, and the centralizer carrier hsame-transport row moves the stored kernel witness across this comparison. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel hsame transport`

Theorem 80.37 (Centralizer quotient-kernel left endpoint right centralizer multiplication)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *laws, if* $Q_{Z_a \triangleleft N_a}(x, y)$ *and* $Z_a(c)$*, then*

$$Q_{Z_a \triangleleft N_a}(\mathsf{mul}(x, c), y).$$

Proof. The endpoint $\mathsf{mul}(x, c)$ lies in N_a because x is already carried by N_a, every centralizer element is carried by N_a, and the normalizer is closed under multiplication. For the kernel word, inverse closure gives $Z_a(\mathsf{inv}(c))$, while the original quotient-kernel hypothesis gives $Z_a(\mathsf{mul}(\mathsf{inv}(x), y))$. Product closure for Z_a therefore gives $Z_a(\mathsf{mul}(\mathsf{inv}(c), \mathsf{mul}(\mathsf{inv}(x), y)))$. Associativity and inverse-of-product reversal identify this history with $\mathsf{mul}(\mathsf{inv}(\mathsf{mul}(x, c)), y)$ up to hsame, and the centralizer carrier transport row gives the displayed kernel clause. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel left endpoint right centralizer mul closed from empty unit`

Theorem 80.38 (Centralizer quotient-kernel right endpoint right centralizer multiplication)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *laws, if* $Q_{Z_a \triangleleft N_a}(x, y)$ *and* $Z_a(c)$*, then*

$$Q_{Z_a \triangleleft N_a}(x, \mathsf{mul}(y, c)).$$

Proof. The endpoint $\mathsf{mul}(y, c)$ lies in N_a because the quotient-kernel hypothesis carries y in N_a, the inclusion $Z_a \subseteq N_a$ carries c in N_a, and product closure for N_a keeps their product in the carrier.

For the kernel word, the original quotient-kernel hypothesis gives $Z_a(\mathsf{mul}(\mathsf{inv}(x), y))$, and the endpoint factor gives $Z_a(c)$. Product closure for Z_a yields $Z_a(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(x), y), c))$. Associativity compares this history with $\mathsf{mul}(\mathsf{inv}(x), \mathsf{mul}(y, c))$, and the centralizer carrier transport row moves the witness across that hsame comparison. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel right endpoint right centralizer mul closed from empty unit`

Theorem 80.39 (Centralizer quotient-kernel two-sided centralizer endpoint multiplication)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *laws, if* $Q_{Z_a \triangleleft N_a}(x, y)$*,* $Z_a(c)$*, and* $Z_a(d)$*, then*

$$Q_{Z_a \triangleleft N_a}(\mathsf{mul}(x, c), \mathsf{mul}(y, d)).$$

Proof. First apply Definition 80.37 with the centralizer factor c. This gives $Q_{Z_a \triangleleft N_a}(\mathsf{mul}(x, c), y)$.

Then apply Definition 80.38 with the centralizer factor d. The result is the displayed two-endpoint quotient-kernel relation. □

Per-object template: traditional target endpoint stability of a normal-subgroup quotient classifier; BEDC source $\mathsf{Group}^{\uparrow}$ plus $\mathsf{Subgroup}^{\uparrow}$ over BHist; carrier N_a; classifier $Q_{Z_a \triangleleft N_a}$; stability centralizer endpoint multiplication; ledger left representative, right representative, and centralizer endpoint factors; downstream consumer $\mathsf{QuotientGroup}^{\uparrow}$; status $\mathsf{ProofTarget}$.

Theorem 80.40 (Centralizer quotient-kernel centralizer endpoint invariance)**.** *Under the same BEDC history-level* $\mathsf{Group}^{\uparrow}$ *laws, if* $Z_a(c)$ *and* $Z_a(d)$*, then*

$$Q_{Z_a \triangleleft N_a}(\mathsf{mul}(x, c), \mathsf{mul}(y, d)) \Longleftrightarrow Q_{Z_a \triangleleft N_a}(x, y).$$

Proof. For the direction from the original endpoints to the translated endpoints, apply Definition 80.39 with the endpoint factors c and d.

For the direction from the translated endpoints back to the original endpoints, use inverse closure for Z_a from Definition 80.27 to obtain $Z_a(\mathsf{inv}(c))$ and $Z_a(\mathsf{inv}(d))$. Apply Definition 80.39 to the translated quotient-kernel relation with these inverse factors.

The resulting relation has endpoints $\mathsf{mul}(\mathsf{mul}(x, c), \mathsf{inv}(c))$ and $\mathsf{mul}(\mathsf{mul}(y, d), \mathsf{inv}(d))$. Associativity, the two-sided inverse laws, the unit laws, and multiplication congruence compare these histories with x and y up to hsame. The transport theorem Definition 80.36 then moves the quotient-kernel witness back to $Q_{Z_a \triangleleft N_a}(x, y)$. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel centralizer endpoint invariance`
Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel centralizer endpoint mul invariant from empty unit`

Per-object template: traditional target representative independence in a normal-subgroup quotient; BEDC source $\mathsf{Group}^{\uparrow}$ plus $\mathsf{Subgroup}^{\uparrow}$ over BHist; carrier N_a; classifier $Q_{Z_a \triangleleft N_a}$; stability endpoint-factor invariance; ledger lower-centralizer factors and inverse factors; core theorem this equivalence plus the one-way endpoint rows and quotient-kernel transport; exactness representative choice does not change the quotient-kernel classifier; downstream consumer $\mathsf{QuotientGroup}^{\uparrow}$.

Theorem 80.41 (Centralizer normalizer quotient-kernel transitivity)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, the relation* $Q_{Z_a \triangleleft N_a}$ *of Definition 80.33 is transitive:*

$$Q_{Z_a \triangleleft N_a}(x, y) \wedge Q_{Z_a \triangleleft N_a}(y, z) \Longrightarrow Q_{Z_a \triangleleft N_a}(x, z).$$

Proof. Expand the two hypotheses. Their endpoint rows provide the required $N_a(x)$ and $N_a(z)$ clauses. Their kernel rows give

$$Z_a(\mathsf{mul}(\mathsf{inv}(x), y)) \qquad \text{and} \qquad Z_a(\mathsf{mul}(\mathsf{inv}(y), z)).$$

Product closure for Z_a gives a centralizer witness for the product of these two relative kernel words. Associativity rewrites that product to

$$\mathsf{mul}(\mathsf{inv}(x), \mathsf{mul}(y, \mathsf{mul}(\mathsf{inv}(y), z))),$$

and the right inverse law for y followed by the left unit law cancels the middle $y, \mathsf{inv}(y)$ pair. The carrier transport row for Z_a moves the product witness to $Z_a(\mathsf{mul}(\mathsf{inv}(x), z))$, which is exactly the kernel clause for $Q_{Z_a \triangleleft N_a}(x, z)$. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel trans from empty unit`

Theorem 80.42 (Centralizer normalizer quotient-kernel right identity fiber)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, every* $x : \mathsf{BHist}$ *satisfies*

$$Q_{Z_a \triangleleft N_a}(x, \mathsf{e}) \Longleftrightarrow Z_a(x).$$

Proof. Unfold the quotient-kernel relation. The forward direction starts from the kernel witness $Z_a(\mathsf{mul}(\mathsf{inv}(x), \mathsf{e}))$. The right unit law identifies this word with $\mathsf{inv}(x)$, inverse closure gives $Z_a(\mathsf{inv}(\mathsf{inv}(x)))$, and inverse involution transports it to $Z_a(x)$. Conversely, from $Z_a(x)$ the tower gives both normalizer endpoints, inverse closure gives $Z_a(\mathsf{inv}(x))$, and the right unit law transports that witness to the displayed kernel word. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel empty right fiber iff`

Theorem 80.43 (Centralizer normalizer quotient-kernel symmetry)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, the quotient-kernel relation is symmetric:*

$$Q_{Z_a \triangleleft N_a}(x, y) \Longrightarrow Q_{Z_a \triangleleft N_a}(y, x).$$

Proof. The endpoint clauses swap directly. For the kernel clause, invert the witness $Z_a(\mathsf{mul}(\mathsf{inv}(x), y))$ using the inverse-closure row of Z_a. The inverse-product-reversal law identifies the resulting word with $\mathsf{mul}(\mathsf{inv}(y), \mathsf{inv}(\mathsf{inv}(x)))$, and inverse involution followed by carrier transport gives the displayed $Z_a(\mathsf{mul}(\mathsf{inv}(y), x))$ witness. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel symm from empty unit`

Theorem 80.44 (Append centralizer carrier unary word)**.** *For the concrete BEDC append operation, centralizing the visible singleton* $\mathsf{E1}(\mathsf{e})$ *forces the carried word to be unary:*

$$Z^{\mathsf{append}}_{\mathsf{E1}(\mathsf{e})}(w) \Longrightarrow \mathsf{UnaryHistory}(w).$$

Proof. Unfold the centralizer carrier as the displayed comparison $\mathsf{append}(w, \mathsf{E1}(\mathsf{e}))\mathsf{hsameappend}(\mathsf{E1}(\mathsf{e}), w)$. Induct on the concrete history w. The empty word is unary. A zero-headed word displays opposite visible constructors on the two sides, contradicting constructor separation. A one-headed word has matching $\mathsf{E1}$ constructors; injectivity descends the same centralizer comparison to the tail, and the induction hypothesis gives unary evidence. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerCarrier append e1 unit unary`

Theorem 80.45 (Append centralizer quotient-kernel unary word)**.** *Let the centralizer quotient-kernel relation be instantiated with the concrete BEDC append operation and centralizer seed* $\mathsf{E1}(\mathsf{e})$*. For any history endomap* inv *and histories* x, y*, the kernel relation forces the relative append word to be unary:*

$$Q^{\mathsf{append},\mathsf{inv}}_{\mathsf{E1}(\mathsf{e})}(x, y) \Longrightarrow \mathsf{UnaryHistory}(\mathsf{append}(\mathsf{inv}(x), y)).$$

Proof. Unfold the quotient-kernel row and write $w = \mathsf{append}(\mathsf{inv}(x), y)$. The centralizer carrier says $\mathsf{append}(w, \mathsf{E1}(\mathsf{e}))\mathsf{hsameappend}(\mathsf{E1}(\mathsf{e}), w)$. Induct on the concrete word w. The empty case is the unary generator. A zero-headed word puts an $\mathsf{E1}$ head on the left and an $\mathsf{E0}$ head on the right, contradicting constructor separation. A one-headed word descends by $\mathsf{E1}$ injectivity to the same statement for the tail, and the induction hypothesis supplies unary evidence. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel append e1 unit kernel unary`

Theorem 80.46 (Centralizer quotient-kernel multiplication compatibility)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, the quotient-kernel relation is compatible with multiplication:*

$$Q_{Z_a \triangleleft N_a}(x, y) \wedge Q_{Z_a \triangleleft N_a}(u, v) \Longrightarrow Q_{Z_a \triangleleft N_a}(\mathsf{mul}(x, u), \mathsf{mul}(y, v)).$$

Proof. Translate both quotient-kernel hypotheses through the right quotient classifier equivalence. The right quotient classifier multiplication row supplies the product relation, and the same equivalence translates the product classifier back to the quotient-kernel relation. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel mul compatible from empty unit`

Theorem 80.47 (Centralizer normalizer quotient-kernel equivalence laws)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, the relation* $Q_{Z_a \lhd N_a}$ *of Definition 80.33 is a quotient-kernel equivalence relation on the upper carrier:*

1. *if* $N_a(x)$*, then* $Q_{Z_a \lhd N_a}(x, x)$*;*
2. *if* $Q_{Z_a \lhd N_a}(x, y)$*, then* $Q_{Z_a \lhd N_a}(y, x)$*;*
3. *if* $Q_{Z_a \lhd N_a}(x, y)$ *and* $Q_{Z_a \lhd N_a}(y, z)$*, then* $Q_{Z_a \lhd N_a}(x, z)$*;*

Proof. Reflexivity uses the identity row of Definition 80.27. From $N_a(x)$ the endpoint clauses are immediate, and the two-sided inverse law identifies $\mathsf{mul}(\mathsf{inv}(x), x)$ with e. Transport along hsame carries the centralizer identity witness $Z_a(e)$ to the required kernel witness.

For symmetry, expand $Q_{Z_a \lhd N_a}(x, y)$. The endpoint clauses swap because both x and y already lie in N_a. The kernel witness $Z_a(\mathsf{mul}(\mathsf{inv}(x), y))$ is inverted by the inverse-closure row for Z_a, and inverse-product reversal identifies the inverse word with $\mathsf{mul}(\mathsf{inv}(y), x)$ after the ambient inverse laws. The hsame-transport row for Z_a gives the displayed symmetric witness.

For transitivity, take kernel witnesses $Z_a(\mathsf{mul}(\mathsf{inv}(x), y))$ and $Z_a(\mathsf{mul}(\mathsf{inv}(y), z))$. Product closure in Z_a gives a witness for their product. Associativity and the inverse laws cancel the middle factors y and $\mathsf{inv}(y)$, and transport turns the product witness into $Z_a(\mathsf{mul}(\mathsf{inv}(x), z))$. The endpoint clauses are the retained $N_a(x)$ and $N_a(z)$ clauses. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel classifier laws`

Theorem 80.48 (Centralizer quotient-kernel diagonal carrier exactness)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, every* $x : \mathsf{BHist}$ *satisfies*

$$Q_{Z_a \lhd N_a}(x, x) \Longleftrightarrow N_a(x).$$

Proof. For the forward direction, unfold Definition 80.33. A witness for $Q_{Z_a \lhd N_a}(x, x)$ contains both endpoint carrier clauses in N_a, so projecting either endpoint gives $N_a(x)$.

For the reverse direction, assume $N_a(x)$. Apply the reflexivity row of Definition 80.47 to obtain $Q_{Z_a \lhd N_a}(x, x)$. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel diagonal carrier exactness`

Per-object template: traditional target quotient classifier for the normal-subgroup tower $Z_a \leq N_a$; BEDC source $\mathsf{Group}^{\uparrow}$ over BHist plus $\mathsf{Subgroup}^{\uparrow}$; lower carrier Z_a; upper carrier N_a; classifier $Q_{Z_a \lhd N_a}$; stability identity/reflexivity, symmetry, transitivity, endpoint membership, kernel membership, and kernel transport; ledger left representative, right representative, relative kernel witness, and transported kernel witness; core theorem list Definition 80.27, Definition 80.47, Definition 80.48, Definition 41.65, and the ambient $\mathsf{Group}^{\uparrow}$ laws; exactness predicate relative displacement in Z_a inside N_a; downstream object $\mathsf{QuotientGroup}^{\uparrow}$; status $\mathsf{ProofTarget}$.

Theorem 80.49 (Centralizer quotient-kernel centralizer representative step)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, if* $N_a(x)$ *and* $Z_a(c)$*, then*

$$Q_{Z_a \lhd N_a}(x, \mathsf{mul}(x, c)) \wedge Q_{Z_a \lhd N_a}(\mathsf{mul}(x, c), x).$$

Proof. From $N_a(x)$, the reflexivity row of Definition 80.47 gives the diagonal relation $Q_{Z_a \triangleleft N_a}(x, x)$.

For the forward representative step, apply Definition 80.38 to the diagonal relation with the centralizer factor c. Since the right endpoint of the diagonal relation is x, this gives $Q_{Z_a \triangleleft N_a}(x, \mathsf{mul}(x, c))$.

For the reverse representative step, apply Definition 80.37 to the same diagonal relation with the same factor c. This gives $Q_{Z_a \triangleleft N_a}(\mathsf{mul}(x, c), x)$, and the two displayed relations pair into the asserted conjunction. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel centralizer representative step`

Per-object template: traditional target representative generation in a normal-subgroup quotient; BEDC source $\mathsf{Group}^{\uparrow}$ plus $\mathsf{Subgroup}^{\uparrow}$ over BHist; carrier N_a; classifier $Q_{Z_a \triangleleft N_a}$; stability one normalizer endpoint with one centralizer factor; ledger selected representative and lower-centralizer factor; core theorem this block plus Definition 80.47, Definition 80.38, and Definition 80.37; exactness centralizer-factor representative reachability; downstream consumer $\mathsf{QuotientGroup}^{\uparrow}$; status $\mathsf{ProofTarget}$. The quotient-classifier and kernel-witness rows below consume the concrete $\mathsf{Group}^{\uparrow}$ operation surface of chapter 41: associativity, unit, inverse, multiplication-congruence, and carrier-transport rows are the ambient algebra used before the $\mathsf{Subgroup}^{\uparrow}$ carrier restricts the classifier.

Theorem 80.50 (Centralizer quotient classifier kernel equivalence)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, carrier-transport, and two-sided inverse laws as in Definition 80.27, every* $x, y : \mathsf{BHist}$ *satisfies*

$$Q^{\mathrm{std}}_{Z_a \leq N_a}(x, y) \iff Q^{\mathrm{ker}}_{Z_a \triangleleft N_a}(x, y).$$

Proof. For the forward direction, unpack the standard quotient classifier. The endpoint clauses give $N_a(x)$ and $N_a(y)$, and the quotient witness gives a centralizer element whose right multiplication carries x to y.

It remains to expose the relative kernel word. Multiply the endpoint comparison on the left by $\mathsf{inv}(x)$; associativity, the left inverse law, the unit law, and multiplication congruence identify the witness with $\mathsf{mul}(\mathsf{inv}(x), y)$ up to hsame. Carrier transport for Z_a then moves centralizer membership to the displayed kernel carrier.

For the reverse direction, start from the relative kernel classifier. Its endpoint clauses are already the two normalizer clauses needed by the standard quotient classifier.

Choose the quotient witness $z := \mathsf{mul}(\mathsf{inv}(x), y)$. Associativity and the right inverse law identify $\mathsf{mul}(x, z)$ with y up to hsame, so the kernel clause supplies the carried centralizer witness and the classifier repacks. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientClassifier kernel iff`

Theorem 80.51 (Centralizer quotient-kernel witness classifier equivalence)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, carrier-transport, and two-sided inverse laws as in Definition 80.27, every* $x, y : \mathsf{BHist}$ *satisfies*

$$Q^{\mathrm{wit}}_{Z_a \leq N_a}(x, y) \iff Q^{\mathrm{ker}}_{Z_a \triangleleft N_a}(x, y).$$

Here Q^{wit} *presents the quotient by a right witness* z *with* $Z_a(z)$ *and* $\mathsf{hsame}(y, \mathsf{mul}(x, z))$.

Proof. In the forward direction, unpack the right-witness classifier. Left-multiply the endpoint comparison by $\mathsf{inv}(x)$ and reassociate; the left inverse and unit laws reduce the exposed word to the witness z.

Carrier transport for Z_a moves $Z_a(z)$ across that comparison, producing $Z_a(\mathsf{mul}(\mathsf{inv}(x), y))$. Together with the two endpoint normalizer clauses this is the relative kernel classifier.

Conversely, take the relative kernel word itself as the right witness. Associativity, the right inverse law, and the unit law identify y with $\mathsf{mul}(x, \mathsf{mul}(\mathsf{inv}(x), y))$ up to hsame, so the same kernel carrier repacks as the witness classifier. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel witness classifier iff`

Theorem 80.52 (Centralizer right quotient classifier kernel equivalence)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, carrier-transport, and two-sided inverse laws as in Definition 80.27, every* $x, y : \mathsf{BHist}$ *satisfies*

$$Q^{\mathrm{right}}_{Z_a \leq N_a}(x, y) \iff Q^{\ker}_{Z_a \lhd N_a}(x, y).$$

Proof. For the forward direction, unpack the right quotient witness and expose $\mathsf{mul}(\mathsf{inv}(x), y)$ by multiplying the endpoint comparison on the left. Associativity, left inverse, unit, and multiplication congruence identify the exposed word with the carried witness.

Carrier transport converts that witness membership into the kernel carrier, and the two endpoint normalizer clauses pass through unchanged.

For the reverse direction, use the kernel word as the right quotient witness. Reassociation followed by the right inverse and unit laws gives the endpoint comparison required by the right quotient classifier. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightQuotientClassifier kernel iff`

Theorem 80.53 (Centralizer normalizer quotient classifiers coincide)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, carrier-transport, and two-sided inverse laws as in Definition 80.27, every* $x, y : \mathsf{BHist}$ *satisfies*

$$Q^{\cos}_{Z_a \leq N_a}(x, y) \iff Q^{\ker}_{Z_a \lhd N_a}(x, y).$$

Proof. This is the canonical coincidence row for the centralizer-normalizer quotient site. It reads the right-coset classifier and the relative-kernel classifier as two presentations of the same normalizer quotient relation. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerNormalizerQuotientClassifier coincide`

Theorem 80.54 (Centralizer quotient presentation equivalence package)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, carrier-transport, and two-sided inverse laws as in Definition 80.27, every* $x, y : \mathsf{BHist}$ *has a quotient presentation independent of the chosen centralizer-normalizer classifier. The standard quotient classifier* $Q^{\mathrm{std}}_{Z_a \leq N_a}(x, y)$*, the right-witness classifier* $Q^{\mathrm{wit}}_{Z_a \leq N_a}(x, y)$*, the right-coset classifier* $Q^{\cos}_{Z_a \leq N_a}(x, y)$*, and the relative-kernel classifier* $Q^{\ker}_{Z_a \lhd N_a}(x, y)$ *are mutually pinned by the three displayed equivalence rows*

$$Q^{\mathrm{std}}_{Z_a \leq N_a}(x, y) \iff Q^{\ker}_{Z_a \lhd N_a}(x, y),$$

$$Q^{\mathrm{wit}}_{Z_a \leq N_a}(x, y) \iff Q^{\ker}_{Z_a \lhd N_a}(x, y),$$

$$Q^{\cos}_{Z_a \leq N_a}(x, y) \iff Q^{\ker}_{Z_a \lhd N_a}(x, y),$$

and the derived equivalence between the right-witness and right-coset presentations obtained through the shared quotient-kernel classifier.

Proof. Apply Theorem 80.50 to identify the standard classifier with the relative-kernel classifier. Apply Theorem 80.51 to identify the right-witness classifier with the same kernel classifier.

Apply Theorem 80.34 to identify the right-coset classifier with that kernel classifier. Apply Theorem 80.52 for the parallel right quotient presentation.

The right-witness/right-coset equivalence is obtained by composing the right-witness-to-kernel implication with the kernel-to-right-coset implication, and conversely composing the right-coset-to-kernel implication with the kernel-to-right-witness implication. Thus all four presentations classify the same pairs (x, y) in the normalizer carrier N_a.

The ten-field fit is: traditional target quotient presentation independence; BEDC source $\mathsf{Group}^{\uparrow}$ plus $\mathsf{Subgroup}^{\uparrow}$ over BHist; carrier N_a; classifier the shared quotient-kernel relation; stability the checked equivalence rows above; ledger right witness, coset witness, and relative kernel word; core theorem this package; exactness mutual presentation equivalence; downstream consumer $\mathsf{QuotientGroup}^{\uparrow}$; status $\mathsf{ProofTarget}$. □

Theorem 80.55 (Centralizer normalizer right quotient classifier transitivity)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, the right-witness quotient classifier* $Q_{Z_a \leq N_a}$ *is transitive:*

$$Q_{Z_a \leq N_a}(x, y) \wedge Q_{Z_a \leq N_a}(y, z) \Longrightarrow Q_{Z_a \leq N_a}(x, z).$$

Proof. Convert both right-witness classifier hypotheses to the relative-kernel classifier using the centralizer-normalizer quotient classifier equivalence. The kernel classifier is transitive by the empty-unit centralizer quotient kernel theorem: the two relative kernel words multiply, and the middle endpoint cancels by associativity, unit, congruence, and inverse laws. Convert the resulting kernel classifier back to the right-witness classifier. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightQuotientClassifier trans from empty unit`

Theorem 80.56 (Centralizer right quotient classifier hsame transport)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, if* $Q_{Z_a \leq N_a}(x, y)$ *is presented by the right-witness quotient classifier and* $x \mathsf{hsame} x'$ *and* $y \mathsf{hsame} y'$*, then the same right-witness quotient classifier holds at* (x', y')*.*

Proof. Translate the right-witness quotient classifier through the quotient-kernel equivalence to obtain $Q_{Z_a \triangleleft N_a}(x, y)$. The quotient-kernel transport theorem moves both endpoints and the centralizer kernel row across the two hsame comparisons. Translating back through the same equivalence repackages the transported kernel as the right-witness quotient classifier at (x', y'). □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightQuotientClassifier hsame transport`

Theorem 80.57 (Centralizer right quotient product witness carrier)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying associativity, two-sided unit, multiplication-congruence, and two-sided inverse laws, let* u *be carried by the centralizer normalizer and let* p, q *be carried by the centralizer* Z_a*. Then the product witness*

$$\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(u), p), u), q)$$

is again carried by Z_a*.*

Proof. The normalizer row for u sends the centralizer witness p through the inverse conjugation word $\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(u), p), \mathsf{inv}(\mathsf{inv}(u)))$. The inverse-involution law transports this carrier witness to $\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(u), p), u)$. Product closure for Z_a then multiplies the transported conjugation witness with the carried element q, giving the displayed product witness carrier. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightQuotientClassifier product witness carrier from empty unit`

Theorem 80.58 (Centralizer right quotient product witness endpoint)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying associativity, left unit, multiplication-congruence, and right inverse laws, if* $y\mathsf{hsamemul}(x, p)$ *and* $v\mathsf{hsamemul}(u, q)$*, then*

$$\mathsf{mul}(y, v)\mathsf{hsamemul}(\mathsf{mul}(x, u), \mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(u), p), u), q)).$$

Proof. Multiplication congruence first replaces y and v by their right quotient presentations. Associativity moves the middle u next to $\mathsf{inv}(u)$, the right inverse law contracts $\mathsf{mul}(u, \mathsf{inv}(u))$ to the empty unit, and the left-unit law removes that empty factor. A final associativity comparison restores the endpoint as $\mathsf{mul}(\mathsf{mul}(x, u), \mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(u), p), u), q))$. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightQuotientClassifier product witness endpoint from empty unit`

Theorem 80.59 (Centralizer right quotient classifier multiplication compatibility)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying associativity, two-sided unit, multiplication-congruence, and two-sided inverse laws, the centralizer right-witness quotient classifier is compatible with multiplication:*

$$Q_{Z_a \leq N_a}(x, y) \wedge Q_{Z_a \leq N_a}(u, v) \Longrightarrow Q_{Z_a \leq N_a}(\mathsf{mul}(x, u), \mathsf{mul}(y, v)).$$

Proof. Unpack the two right quotient witnesses as centralizer elements p and q with $y\mathsf{hsamemul}(x, p)$ and $v\mathsf{hsamemul}(u, q)$. Product closure gives normalizer membership for $\mathsf{mul}(x, u)$ and $\mathsf{mul}(y, v)$.

The normalizer witness for u carries p through conjugation, so $\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(u), p), u)$ is again a centralizer element. Multiplying it with q gives the new right quotient witness. The endpoint equation follows by associativity, unit laws, inverse cancellation, and multiplication congruence: $\mathsf{mul}(y, v)$ is transported to $\mathsf{mul}(\mathsf{mul}(x, u), \mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(u), p), u), q))$. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightQuotientClassifier mul compatible from empty unit`

Theorem 80.60 (Centralizer right coset classifier hsame transport)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 80.27, if* $Q_{Z_a \leq N_a}(x, y)$ *is presented by the right-coset classifier and* $x\mathsf{hsame}x'$ *and* $y\mathsf{hsame}y'$*, then the same right-coset classifier holds at* (x', y')*.*

Proof. Translate the right-coset classifier through the quotient-kernel equivalence to obtain $Q_{Z_a \triangleleft N_a}(x, y)$. The quotient-kernel transport row moves both normalizer endpoints and the displayed kernel carrier across the two hsame endpoint comparisons. Translating back through the same coset/kernel equivalence repackages the transported kernel as the right-coset classifier at (x', y'). □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightCosetClassifier hsame transport`

Theorem 80.61 (Centralizer right coset classifier transitivity)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying associativity, right-unit, and multiplication-congruence laws, the centralizer right-coset classifier is transitive:*

$$Q^{\text{right}}_{Z_a \le N_a}(x, y) \wedge Q^{\text{right}}_{Z_a \le N_a}(y, z) \Longrightarrow Q^{\text{right}}_{Z_a \le N_a}(x, z).$$

Proof. Unpack the two right-coset witnesses. The first supplies a centralizer element u with $y\mathsf{hsamemul}(x, u)$, and the second supplies a centralizer element v with $z\mathsf{hsamemul}(y, v)$. Product closure for the centralizer carrier gives a carried witness $\mathsf{mul}(u, v)$. Multiplication congruence transports the second endpoint along the first comparison, and associativity identifies $\mathsf{mul}(\mathsf{mul}(x, u), v)$ with $\mathsf{mul}(x, \mathsf{mul}(u, v))$. The endpoint clauses are inherited from the two classifier hypotheses. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightCosetClassifier trans from empty unit`

Theorem 80.62 (Centralizer quotient kernel empty fiber)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, carrier-transport, and two-sided inverse laws as in Definition 80.27, every* $x : \mathsf{BHist}$ *satisfies*

$$Q_{Z_a \triangleleft N_a}(\mathsf{e}, x) \Longleftrightarrow Z_a(x).$$

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel empty fiber iff`

Proof. For the forward direction, unpack the relative-kernel classifier $Q_{Z_a \triangleleft N_a}(\mathsf{e}, x)$. Its kernel clause gives $Z_a(\mathsf{mul}(\mathsf{inv}(\mathsf{e}), x))$.

The inverse identity row identifies $\mathsf{inv}(\mathsf{e})$ with e, and the left-unit law identifies $\mathsf{mul}(\mathsf{e}, x)$ with x. The Z_a carrier-transport row from Definition 80.27 carries the kernel witness across this endpoint comparison and gives $Z_a(x)$.

For the reverse direction, assume $Z_a(x)$. The empty centralizer row gives $Z_a(\mathsf{e})$, and Definition 80.19 sends both $Z_a(\mathsf{e})$ and $Z_a(x)$ into the normalizer carrier N_a.

It remains to supply the kernel word. The same inverse identity and left-unit comparison identify $\mathsf{mul}(\mathsf{inv}(\mathsf{e}), x)$ with x; by transporting $Z_a(x)$ along the reverse comparison, we obtain the carried kernel clause and package $Q_{Z_a \triangleleft N_a}(\mathsf{e}, x)$. □

Theorem 80.63 (Centralizer normalizer coset classifier identity fiber)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, carrier-transport, and two-sided inverse laws as in Definition 80.27, every* $x : \mathsf{BHist}$ *satisfies*

$$Q_{Z_a \le N_a}(\mathsf{e}, x) \Longleftrightarrow Z_a(x).$$

Proof. Apply Definition 80.53 at the endpoint pair (e, x). It identifies the right-coset classifier $Q_{Z_a \le N_a}(\mathsf{e}, x)$ with the relative-kernel classifier $Q_{Z_a \triangleleft N_a}(\mathsf{e}, x)$.

Then apply Definition 80.62. Its empty fiber calculation identifies $Q_{Z_a \triangleleft N_a}(\mathsf{e}, x)$ with $Z_a(x)$. Transitivity of these two equivalences gives the displayed identity fiber for $Q_{Z_a \le N_a}$. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightQuotientClassifier empty fiber iff`

Per-object template: traditional target identity coset fiber for the centralizer-normalizer quotient; BEDC source $\mathsf{Group}^{\uparrow}$ plus $\mathsf{Subgroup}^{\uparrow}$ over BHist; carrier N_a; classifier $Q_{Z_a \le N_a}$; stability identity, inclusion, left-unit endpoint transport, and Z_a carrier transport; ledger identity representative and right witness; exactness predicate identity fiber equals lower carrier; downstream consumer $\mathsf{QuotientGroup}^{\uparrow}$; status $\mathsf{ProofTarget}$.

Theorem 80.64 (Centralizer right quotient diagonal carrier exactness)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, carrier-transport, and two-sided inverse laws as in Definition 80.27, every* $x : \mathsf{BHist}$ *satisfies*

$$Q_{Z_a \leq N_a}(x, x) \iff N_a(x).$$

Proof. For the forward direction, unpack the right quotient classifier at the diagonal. Its endpoint clauses assert that both displayed endpoints lie in the upper carrier N_a. Since both endpoints are the same history x, projecting either endpoint clause gives $N_a(x)$.

For the reverse direction, assume $N_a(x)$. The reflexivity row of Definition 80.32 applies to this upper-carrier witness and gives the diagonal classifier instance $Q_{Z_a \leq N_a}(x, x)$. □

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerRightQuotientClassifier diagonal carrier iff`

Theorem 80.65 (Centralizer quotient identity-fiber bridge package)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, carrier-transport, and two-sided inverse laws as in Definition 80.27, every* $x : \mathsf{BHist}$ *satisfies the following two identity-fiber packages.*

1. *The quotient-kernel identity fibers agree on the two sides of the unit:*

$$Q_{Z_a \lhd N_a}(\mathsf{e}, x) \iff Q_{Z_a \lhd N_a}(x, \mathsf{e}),$$

   and both displayed sides are equivalent to $Z_a(x)$*.*

2. *The right-witness quotient identity fibers agree on the two sides of the unit:*

$$Q_{Z_a \leq N_a}(\mathsf{e}, x) \iff Q_{Z_a \leq N_a}(x, \mathsf{e}),$$

   and both displayed sides are equivalent to $Z_a(x)$*.*

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotient identity fiber bridge package`

Proof. For the quotient-kernel package, apply Definition 80.62 to identify $Q_{Z_a \lhd N_a}(\mathsf{e}, x)$ with $Z_a(x)$. Apply Definition 80.42 to identify $Q_{Z_a \lhd N_a}(x, \mathsf{e})$ with the same centralizer carrier. Composing the two identity-fiber equivalences gives the two-sided unit bridge, and the two cited equivalences record the exactness clauses.

For the right-witness quotient package, apply Definition 80.63 to identify $Q_{Z_a \leq N_a}(\mathsf{e}, x)$ with $Z_a(x)$. Then apply Definition 80.52 at the endpoint pair (x, e) and use Definition 80.42 to identify $Q_{Z_a \leq N_a}(x, \mathsf{e})$ with $Z_a(x)$. Composing these equivalences gives the right-witness two-sided unit bridge, with the same centralizer exactness on both sides. □

Per-object template: traditional target two-sided identity coset fiber; BEDC source $\mathsf{Group}^{\uparrow}$ plus $\mathsf{Subgroup}^{\uparrow}$ over BHist; carrier N_a; classifier the quotient-kernel and right-witness quotient relations; stability unit, inverse, transport, and kernel equivalence rows; ledger identity representative side; core theorem Definition 80.65; exactness identity fiber equals Z_a; downstream consumer $\mathsf{QuotientGroup}^{\uparrow}$; status $\mathsf{ProofTarget}$.

Theorem 80.66 (Centralizer quotient diagonal presentation package)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same associativity, unit, multiplication-congruence, carrier-transport, and two-sided inverse laws as in Definition 80.27, every* $x : \mathsf{BHist}$ *with* $N_a(x)$ *satisfies the four diagonal quotient classifiers*

$$Q^{\mathrm{std}}_{Z_a \leq N_a}(x, x), \qquad Q^{\mathrm{wit}}_{Z_a \leq N_a}(x, x), \qquad Q^{\mathrm{cos}}_{Z_a \leq N_a}(x, x), \qquad Q^{\mathrm{ker}}_{Z_a \lhd N_a}(x, x).$$

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupUp StdBridge`

Proof. Apply Definition 80.21 to the normalizer endpoint $N_a(x)$. This gives the diagonal relative-kernel classifier $Q^{\mathrm{ker}}_{Z_a \triangleleft N_a}(x, x)$.

Next transport the same diagonal relation through Definition 80.50. Reading the equivalence from the kernel side yields $Q^{\mathrm{std}}_{Z_a \leq N_a}(x, x)$.

Apply Definition 80.51 at the same endpoint pair. The kernel-to-witness direction gives $Q^{\mathrm{wit}}_{Z_a \leq N_a}(x, x)$.

Finally apply Definition 80.34 to obtain $Q^{\mathrm{cos}}_{Z_a \leq N_a}(x, x)$. The parallel Definition 80.52 records that the public right quotient presentation is classified by the same diagonal kernel word, so the displayed standard, witness, coset, and kernel presentations share one reflexive source. □

Per-object template: traditional target diagonal quotient presentation package; BEDC source $\mathsf{Group}^{\uparrow}$ plus $\mathsf{Subgroup}^{\uparrow}$ over BHist; carrier N_a; classifier the standard, right-witness, right-coset, and relative-kernel quotient relations; stability carrier transport, multiplication congruence, unit, inverse, and quotient-kernel equivalence rows; ledger diagonal endpoint $x = x$ and empty relative kernel word; core theorem Definition 80.66; exactness every normalizer endpoint carries all four diagonal classifiers; downstream consumer $\mathsf{QuotientGroup}^{\uparrow}$; status ProofTarget.

Closure status for $\mathsf{NameCert}_{\mathsf{Subgroup}^{\uparrow}}$.

Constructive story: A subgroup in this chapter is generated inside an already licensed $\mathsf{Group}^{\uparrow}$ history surface by fixing a history a and accepting exactly those carried group endpoints that commute with it; the identity endpoint enters because it commutes with a, products enter by the group multiplication rows, inverses enter by the inverse rows, and histories without the displayed centralizer witness stay outside. Two accepted subgroup elements are classified by restricting ambient history-sameness to this centralizer carrier, so equality is neither a new subgroup equality nor a quotient of the ambient group but the same hsame comparison with both membership witnesses retained. The source is the ambient group plus the centralizer predicate, the pattern records identity, product, inverse, transport, commutator-fiber exactness, intersections, chain composition, the trivial subgroup, and the one-step subgroup criterion, and the ledger keeps the fixed element a, the commuting witnesses, and the inherited group-operation rows visible. The five name-certificate obligations close because the unit gives an inhabited carrier, ambient hsame gives reflexivity, symmetry, and transitivity on carried endpoints, and the centralizer transport row moves membership across any recognized endpoint comparison. A history h lies in the signature gap of a $\mathsf{Subgroup}^{\uparrow}$ token p when the source-domain accepts h as a carried centralizer or related subgroup endpoint, the signature relation pairs it with an answer endpoint and evidence ledger, and the token-introduction relation names that answer as p; unfolded, h must satisfy the relevant membership row, with the answer classified by the restricted ambient comparison. The checked bridge package then exposes centralizer quotient fibers, diagonal quotient presentations, and the identity-fiber readback used by downstream quotient consumers, always through the same membership and classifier rows. The chapter registers this inherited centralizer-and-subobject construction under the name $\mathsf{Subgroup}^{\uparrow}$; it does not introduce arbitrary subgroup lattices, Sylow theory, general isomorphism theorems, or a separate subgroup carrier outside the displayed group history surface.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Subgroup}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public $\mathsf{Subgroup}^{\uparrow}$ surface binds subgroup membership, inherited classifiers, the centralizer quotient bridge, the diagonal presentation package, the trivial subgroup certificate, the subgroup chain composition certificate, and the one-step subgroup criterion.

Definition 80.67 (Trivial SubgroupUp carrier)**.** *Fix a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *source over* BHist *with operation* mul*, unit* e*, inverse operation* inv*, and ambient classifier* hsame*. Define*

$$\mathsf{Triv}_G(x) :\Longleftrightarrow x \mathsf{hsame} e.$$

The inherited classifier on this carrier is the carrier-aware restriction of hsame*:*

$$\mathsf{TrivRel}_G(x, y) :\Longleftrightarrow \mathsf{Triv}_G(x) \wedge \mathsf{Triv}_G(y) \wedge x\mathsf{hsame}y.$$

The operation, unit, and inverse are inherited unchanged from the ambient $\mathsf{Group}^{\uparrow}$ *source.*

Theorem 80.68 (Trivial subgroup SubgroupUp certificate)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the monoid stability rows of Definition 40.13 and the inverse rows of Definition 41.55, the carrier and classifier of Definition 80.67 satisfy the concrete* $\mathsf{Subgroup}^{\uparrow}$ *certificate rows:*

1. $\mathsf{TrivRel}_G$ *is a semantic naming classifier on* Triv_G*.*
2. $\mathsf{Triv}_G(e)$*.*
3. *If* $\mathsf{Triv}_G(x)$ *and* $\mathsf{Triv}_G(y)$*, then* $\mathsf{Triv}_G(\mathsf{mul}(x, y))$*.*
4. *If* $\mathsf{Triv}_G(x)$*, then* $\mathsf{Triv}_G(\mathsf{inv}(x))$*.*
5. *If* $\mathsf{Triv}_G(x)$ *and* $x\mathsf{hsame}y$*, then* $\mathsf{Triv}_G(y)$*.*
6. *If* $\mathsf{TrivRel}_G(x, x')$ *and* $\mathsf{TrivRel}_G(y, y')$*, then* $\mathsf{TrivRel}_G(\mathsf{mul}(x, y), \mathsf{mul}(x', y'))$*.*
7. *If* $\mathsf{TrivRel}_G(x, y)$*, then* $\mathsf{TrivRel}_G(\mathsf{inv}(x), \mathsf{inv}(y))$*.*

Thus the singleton fiber of the group unit carries a $\mathsf{Subgroup}^{\uparrow}$ *certificate over the inherited classifier.*

Lean4 ✓ `BEDC.Derived.SubgroupUp.SubgroupTrivialCarrier certificate`

Proof. The semantic classifier row is inherited from hsame. Reflexivity on a carried endpoint x packages the carrier witness $\mathsf{Triv}_G(x)$ twice with $x\mathsf{hsame}x$. Symmetry and transitivity unpack the stored hsame comparisons, apply the corresponding ambient law, and repack the endpoint carrier fields already present in the classifier witnesses.

The identity row is the reflexive witness $e\mathsf{hsame}e$, which is exactly $\mathsf{Triv}_G(e)$ by Definition 80.67.

For product closure, assume $\mathsf{Triv}_G(x)$ and $\mathsf{Triv}_G(y)$. These are the comparisons $x\mathsf{hsame}e$ and $y\mathsf{hsame}e$. Multiplication congruence from the monoid stability rows gives

$$\mathsf{mul}(x, y)\mathsf{hsamemul}(e, e).$$

The left identity law at e gives $\mathsf{mul}(e, e)\mathsf{hsame}e$. Transitivity proves $\mathsf{mul}(x, y)\mathsf{hsame}e$, hence $\mathsf{Triv}_G(\mathsf{mul}(x, y))$.

For inverse closure, assume $\mathsf{Triv}_G(x)$, so $x\mathsf{hsame}e$. The derived inverse congruence theorem Definition 41.60 gives

$$\mathsf{inv}(x)\mathsf{hsameinv}(e).$$

The identity-inverse theorem Definition 41.56 gives $\mathsf{inv}(e)\mathsf{hsame}e$. Transitivity proves $\mathsf{Triv}_G(\mathsf{inv}(x))$.

For carrier transport, assume $\mathsf{Triv}_G(x)$ and $x\mathsf{hsame}y$. Symmetry gives $y\mathsf{hsame}x$, and transitivity with $x\mathsf{hsame}e$ gives $y\mathsf{hsame}e$. This is $\mathsf{Triv}_G(y)$.

For multiplication compatibility of the inherited classifier, unpack the two $\mathsf{TrivRel}_G$ witnesses. Product closure supplies the two endpoint carrier rows for $\mathsf{mul}(x, y)$ and $\mathsf{mul}(x', y')$, while multiplication congruence transports the stored comparisons $x\mathsf{hsame}x'$ and $y\mathsf{hsame}y'$ to the product comparison. These three fields repack $\mathsf{TrivRel}_G(\mathsf{mul}(x, y), \mathsf{mul}(x', y'))$.

For inverse compatibility, unpack $\mathsf{TrivRel}_G(x, y)$. Inverse closure supplies the endpoint carrier rows for $\mathsf{inv}(x)$ and $\mathsf{inv}(y)$, and Definition 41.60 transports the stored comparison $x\mathsf{hsame}y$ to $\mathsf{inv}(x)\mathsf{hsameinv}(y)$. Repacking gives the displayed inverse-classifier row.

These are the identity, product, inverse, transport, and restricted-classifier fields required by the $\mathsf{Subgroup}^{\uparrow}$ row format used in Definition 80.2. □

Theorem 80.69 (Subgroup chain composition certificate)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *with operation* mul*, unit* e*, inverse operation* inv*, and ambient classifier* hsame*, assume the monoid stability rows of Definition 40.13, the inverse rows of Definition 41.55, and the history-sameness equivalence of Definition 3.8. Let* $P_K, P_H : \mathsf{BHist} \to \mathsf{Prop}$ *be carrier predicates and define*

$$P_{H\leq G}(x) :\Longleftrightarrow P_K(x) \wedge P_H(x),$$

$$R_{H\leq G}(x,y) :\Longleftrightarrow P_{H\leq G}(x) \wedge P_{H\leq G}(y) \wedge x\mathsf{hsame}y,$$

and

$$R_H^K(x,y) :\Longleftrightarrow P_K(x) \wedge P_H(x) \wedge P_K(y) \wedge P_H(y) \wedge x\mathsf{hsame}y.$$

Assume the P_K *carrier has the ambient* $\mathsf{Subgroup}^{\uparrow}$ *carrier rows:*

1. $P_K(e)$.
2. *If* $P_K(x)$ *and* $P_K(y)$*, then* $P_K(\mathsf{mul}(x,y))$.
3. *If* $P_K(x)$*, then* $P_K(\mathsf{inv}(x))$.
4. *If* $P_K(x)$ *and* $x\mathsf{hsame}y$*, then* $P_K(y)$.

Assume P_H *has the following rows over the* P_K*-restricted carrier:*

1. $P_H(e)$.
2. *If* $P_K(x)$*,* $P_H(x)$*,* $P_K(y)$*, and* $P_H(y)$*, then* $P_H(\mathsf{mul}(x,y))$.
3. *If* $P_K(x)$ *and* $P_H(x)$*, then* $P_H(\mathsf{inv}(x))$.
4. *If* $P_K(x)$*,* $P_K(y)$*,* $P_H(x)$*, and* $x\mathsf{hsame}y$*, then* $P_H(y)$.
5. *If* $R_H^K(x,x')$ *and* $R_H^K(y,y')$*, then* $R_H^K(\mathsf{mul}(x,y),\mathsf{mul}(x',y'))$.
6. *If* $R_H^K(x,y)$*, then* $R_H^K(\mathsf{inv}(x),\mathsf{inv}(y))$.

Then the carrier $P_{H\leq G}$ *with restricted classifier* $R_{H\leq G}$ *satisfies the concrete* $\mathsf{Subgroup}^{\uparrow}$ *certificate rows over* G *in the row format of Definition 80.68 and Definition 80.2.*

Proof. The relation R_H^K is the same restricted relation as $R_{H\leq G}$ after reassociating the endpoint carrier conjunctions. Thus either presentation stores exactly two endpoint witnesses for $P_K \wedge P_H$ and one ambient hsame comparison.

First verify the semantic naming classifier required by Definition 9.7. If $P_{H\leq G}(x)$, ambient reflexivity gives $x\mathsf{hsame}x$, so $R_{H\leq G}(x,x)$ holds. If $R_{H\leq G}(x,y)$ holds, swap the two endpoint carrier witnesses and apply symmetry of hsame to obtain $R_{H\leq G}(y,x)$. If $R_{H\leq G}(x,y)$ and $R_{H\leq G}(y,z)$ hold, keep the stored carrier witnesses for x and z and compose $x\mathsf{hsame}y$ with $y\mathsf{hsame}z$ by transitivity of hsame. Hence $R_{H\leq G}$ is a semantic naming classifier on the conjunction carrier.

For the identity row, pair the ambient $P_K(e)$ row with the internal $P_H(e)$ row. This is exactly $P_{H\leq G}(e)$.

For product closure, assume $P_{H\leq G}(x)$ and $P_{H\leq G}(y)$. Unfolding these hypotheses gives $P_K(x)$, $P_H(x)$, $P_K(y)$, and $P_H(y)$. The P_K product row gives $P_K(\mathsf{mul}(x,y))$, while the internal P_H product row gives $P_H(\mathsf{mul}(x,y))$. Pairing the two conclusions gives $P_{H\leq G}(\mathsf{mul}(x,y))$.

For inverse closure, unfold $P_{H\leq G}(x)$ into $P_K(x)$ and $P_H(x)$. The P_K inverse row gives $P_K(\mathsf{inv}(x))$, and the internal P_H inverse row gives $P_H(\mathsf{inv}(x))$. Together these prove $P_{H\leq G}(\mathsf{inv}(x))$.

For carrier transport, assume $P_{H\leq G}(x)$ and $x\mathsf{hsame}y$. The P_K transport row first gives $P_K(y)$. With $P_K(x)$, this target $P_K(y)$, $P_H(x)$, and the same comparison $x\mathsf{hsame}y$, the internal P_H transport row gives $P_H(y)$. Therefore $P_{H\leq G}(y)$.

For multiplication compatibility of the restricted classifier, unpack the two $R_{H\leq G}$ witnesses as $R_H^K(x,x')$ and $R_H^K(y,y')$. The internal restricted-classifier product row gives $R_H^K(\mathsf{mul}(x,y),\mathsf{mul}(x',y'))$, which is precisely $R_{H\leq G}(\mathsf{mul}(x,y),\mathsf{mul}(x',y'))$ after unfolding the conjunction carrier.

For inverse compatibility, unpack $R_{H\leq G}(x,y)$ as $R_H^K(x,y)$. The internal restricted-classifier inverse row gives $R_H^K(\mathsf{inv}(x),\mathsf{inv}(y))$, equivalently $R_{H\leq G}(\mathsf{inv}(x),\mathsf{inv}(y))$.

These are exactly the semantic classifier, identity, product, inverse, carrier-transport, multiplication-classifier, and inverse-classifier rows of a $\mathsf{Subgroup}^{\uparrow}$ certificate over the original ambient group G. □

Theorem 80.70 (Subgroup one-step criterion)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *with operation* mul*, unit* e*, inverse operation* inv*, and ambient classifier* hsame*, assume the monoid stability rows of Definition 40.13 and the inverse rows of Definition 41.55. Let* $P : \mathsf{BHist} \to \mathsf{Prop}$ *be a carrier predicate, and let the inherited restricted classifier be*

$$R_P(x,y) :\Longleftrightarrow P(x) \wedge P(y) \wedge x\mathsf{hsame}y.$$

Assume:

1. *P is inhabited: $P(a)$ for some $a : \mathsf{BHist}$.*
2. *P is stable under the ambient classifier: if $P(x)$ and $x\mathsf{hsame}y$, then $P(y)$.*
3. *P is closed under the one-step relative product: if $P(x)$ and $P(y)$, then $P(\mathsf{mul}(x,\mathsf{inv}(y)))$.*

Then the carrier P with classifier R_P satisfies the concrete $\mathsf{Subgroup}^{\uparrow}$ *identity, product, inverse, and carrier-transport rows:*

1. *$P(e)$.*
2. *If $P(x)$ and $P(y)$, then $P(\mathsf{mul}(x,y))$.*
3. *If $P(x)$, then $P(\mathsf{inv}(x))$.*
4. *If $P(x)$ and $x\mathsf{hsame}y$, then $P(y)$.*

Proof. Choose an inhabitant a with $P(a)$. The relative-product row applied to a and a gives $P(\mathsf{mul}(a,\mathsf{inv}(a)))$. The right inverse row from Definition 41.55 identifies this endpoint with e:

$$\mathsf{mul}(a,\mathsf{inv}(a))\mathsf{hsame}e.$$

Classifier stability for P transports the witness to $P(e)$, proving the identity row.

For inverse closure, assume $P(x)$. The identity row gives $P(e)$, so the relative-product row applied to e and x gives $P(\mathsf{mul}(e,\mathsf{inv}(x)))$. The left identity row from Definition 40.13 gives

$$\mathsf{mul}(e,\mathsf{inv}(x))\mathsf{hsame}\mathsf{inv}(x),$$

and carrier stability transports the witness to $P(\mathsf{inv}(x))$.

For product closure, assume $P(x)$ and $P(y)$. The inverse row just obtained gives $P(\mathsf{inv}(y))$. Apply the relative-product row to x and $\mathsf{inv}(y)$ to get

$$P(\mathsf{mul}(x,\mathsf{inv}(\mathsf{inv}(y)))).$$

By Definition 41.57, $\mathsf{inv}(\mathsf{inv}(y))\mathsf{hsame}y$. Multiplication congruence from Definition 40.13, together with reflexivity on x, gives

$$\mathsf{mul}(x,\mathsf{inv}(\mathsf{inv}(y)))\mathsf{hsame}\mathsf{mul}(x,y).$$

Carrier stability transports the displayed witness to $P(\mathsf{mul}(x,y))$.

The transport row is exactly the classifier-stability hypothesis on P. These four conclusions are the carrier rows in the $\mathsf{Subgroup}^{\uparrow}$ row format used in Definition 80.2 and Definition 80.68. □

Chapter 81

A Concrete Naming Certificate for $\mathsf{Ideal}^{\uparrow}$

The ideal interface $\mathsf{Ideal}^{\uparrow}$ packages a sub-rng of a ring carrier closed under multiplication by every ambient ring element. It depends on $\mathsf{NameCert}_{\mathsf{Ring}^{\uparrow}}$ (chapter 43) and supplies the kernel object for the quotient-ring construction $\mathsf{NameCert}_{\mathsf{QuotientRing}^{\uparrow}}$ (chapter 83).

81.1 Carrier definition

Definition 81.1 (Ideal carried predicate rows)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate over BEDC histories, with $\mathsf{NameCert}_{\mathsf{Ring}^{\uparrow}}$ carrier predicate $C : \mathsf{BHist} \to \mathsf{Prop}$, classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. An $\mathsf{Ideal}^{\uparrow}$ carried predicate over R is a predicate*

$$I : \mathsf{BHist} \to \mathsf{Prop}$$

together with the following certificate rows:

1. *carrier support: $I(x) \Longrightarrow C(x)$;*
2. *zero membership: $I(0_R)$;*
3. *additive closure: $I(x) \wedge I(y) \Longrightarrow I(x +_R y)$;*
4. *additive inverse closure: $I(x) \Longrightarrow I(-_R x)$;*
5. *internal multiplication closure: $I(x) \wedge I(y) \Longrightarrow I(x \cdot_R y)$;*
6. *classifier transport: $I(x) \wedge x \sim_R y \Longrightarrow I(y)$;*
7. *left and right ambient absorption: for every carried ambient endpoint r with $C(r)$,*

$$I(x) \Longrightarrow I(r \cdot_R x) \wedge I(x \cdot_R r).$$

81.2 The certificate

Definition 81.2 (Ideal obligation inventory)**.** *An $\mathsf{Ideal}^{\uparrow}$ certificate over a fixed $\mathsf{Ring}^{\uparrow}$ certificate is the ten-field $\mathsf{NameCert}_{\mathsf{Ideal}^{\uparrow}}$ inventory whose rows are fixed as follows.*

1. *The traditional target is a two-sided ideal of a ring.*

2. *The BEDC source is* $\mathsf{Ring}^{\uparrow}$ *over* BHist*, with the ambient carrier, classifier, addition, additive inverse, zero, and multiplication already named by the ring certificate.*
3. *The carrier is a predicate* $I : \mathsf{BHist} \to \mathsf{Prop}$ *supported by the ambient ring carrier* C*.*
4. *The classifier is inherited from the ambient ring classifier* $\sim_R$*.*
5. *The stability rows are zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and two-sided absorption by every carried ambient ring endpoint.*
6. *The ledger records hidden membership witnesses for* $I(x)$ *and the ambient absorber witnesses* $C(r)$ *consumed by the two absorption rows.*
7. *The core theorem list consists of Definition 81.3, Definition 81.4, Definition 81.5, Definition 81.19, Definition 81.44, and Definition 81.47.*
8. *Exactness is row exhaustion: the certificate consumes exactly the carrier support, zero, additive, inverse, internal multiplication, classifier transport, and two-sided absorption rows displayed here.*
9. *The standard bridge row is absent at this paper site.*
10. *The boundary package is the scoped* $\mathsf{Ideal}^{\uparrow}$ *obligation surface used by quotient-ring, ideal-class, intersection, finite-meet, and preimage constructions.*

Lean4 (definition) `BEDC.Derived.IdealUp.IdealObligationInventory`

Theorem 81.3 (Ideal carrier support obligation)**.** *Let* R *carry a* $\mathsf{Ring}^{\uparrow}$ *certificate over* BHist *with ambient carrier* C *and classifier* $\sim_R$*. Let* $I : \mathsf{BHist} \to \mathsf{Prop}$ *satisfy the inventory of Definition 81.2. Then the inventory supplies the carrier-support row*

$$I(x) \Longrightarrow C(x).$$

Consequently every endpoint admitted by the ideal predicate is a carried $\mathsf{Ring}^{\uparrow}$ *endpoint.*

Proof. Project the carrier row of Definition 81.2. That row states that I is supported by the ambient $\mathsf{Ring}^{\uparrow}$ carrier C.

Applying this projection to a membership witness $I(x)$ gives $C(x)$. The endpoint x therefore lies in the same BHist carrier scope as the ambient ring operations and classifier $\sim_R$. □

Theorem 81.4 (Ideal zero and additive obligations)**.** *Let* R *carry a* $\mathsf{Ring}^{\uparrow}$ *certificate over* BHist *with addition* $+_R$*, additive inverse* $-_R$*, zero* 0_R*, multiplication* $\cdot_R$*, ambient carrier* C*, and classifier* $\sim_R$*. Let* $I : \mathsf{BHist} \to \mathsf{Prop}$ *satisfy the inventory of Definition 81.2. Then the inventory supplies*

$$I(0_R),$$

$$I(x) \wedge I(y) \Longrightarrow I(x +_R y),$$

$$I(x) \Longrightarrow I(-_R x),$$

and

$$I(x) \wedge I(y) \Longrightarrow I(x \cdot_R y).$$

Lean4 ✓ `BEDC.Derived.IdealUp.IdealCarriedPredicateRows zero add neg mul rows`

Proof. Project the stability field of Definition 81.2. Its zero row is exactly $I(0_R)$, using the zero endpoint named by the surrounding $\mathsf{Ring}^{\uparrow}$ certificate.

The same stability field contains the additive closure and additive inverse rows. Projecting those rows gives closure under $+_R$ and $-_R$ for every pair or endpoint already carrying an I-membership witness.

Finally project the internal multiplication row from the same inventory. Since the multiplication symbol $\cdot_R$ is the one named by the ambient $\mathsf{Ring}^{\uparrow}$ certificate, the resulting endpoint remains in the ring carrier scope supplied by the carrier-support row. □

Theorem 81.5 (Ideal classifier and absorption obligations)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate over BHist with carrier C, classifier $\sim_R$, and multiplication $\cdot_R$. Let $I : \mathsf{BHist} \to \mathsf{Prop}$ satisfy the inventory of Definition 81.2. Then the inventory supplies classifier transport*

$$I(x) \wedge x \sim_R y \Longrightarrow I(y)$$

and two-sided absorption by every carried ambient ring endpoint:

$$C(r) \wedge I(x) \Longrightarrow I(r \cdot_R x) \wedge I(x \cdot_R r).$$

Proof. Project the classifier row and the classifier-transport stability row of Definition 81.2. The classifier row identifies the ideal comparison relation with the ambient $\mathsf{Ring}^{\uparrow}$ classifier $\sim_R$, and the transport row carries I-membership along that comparison.

Project the absorption rows from the same stability field. Given an ambient absorber witness $C(r)$ and an ideal membership witness $I(x)$, the left row gives $I(r \cdot_R x)$ and the right row gives $I(x \cdot_R r)$.

The ledger row records exactly the membership witness for x and the carried ambient witness for r consumed in these projections, so no extra absorber or classifier datum is introduced outside the surrounding $\mathsf{Ring}^{\uparrow}$ scope. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealObligationInventory classifier absorption rows`

Definition 81.6 (Ambient carrier ideal predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate over BHist with ambient carrier C, classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. The ambient carrier ideal predicate is*

$$W_R(x) \Longleftrightarrow C(x).$$

Its carried-predicate certificate rows are the following ten-field package: traditional target the whole ring ideal, BEDC source the surrounding $\mathsf{Ring}^{\uparrow}$ certificate over BHist, carrier C, classifier $\sim_R$, stability from $\mathsf{Ring}^{\uparrow}$ carrier transport and operation closure, ledger empty except for the ambient carrier witnesses consumed by the rows, exactness by exhaustion of the displayed row inventory, standard bridge absent, and status proof target.

Theorem 81.7 (Ambient carrier IdealUp closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate over BHist with notation as in Definition 81.6. Then W_R is an $\mathsf{Ideal}^{\uparrow}$ predicate over R: it has carrier support, zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and two-sided absorption by every carried ambient ring endpoint.*

Proof. Unfold Definition 81.6. Carrier support is identity: a witness $W_R(x)$ is exactly a witness $C(x)$.

Zero membership is the zero-carrier row of the surrounding $\mathsf{Ring}^{\uparrow}$ certificate. Additive closure, additive inverse closure, and internal multiplication closure are exactly the carrier-closure rows for $+_R$, $-_R$, and $\cdot_R$ after replacing W_R by C.

Classifier transport is the carrier-transport row of the same $\mathsf{Ring}^{\uparrow}$ certificate along $\sim_R$. If $W_R(x)$ and $x \sim_R y$, transport gives $C(y)$, hence $W_R(y)$.

For absorption, assume $W_R(x)$ and $C(r)$. The multiplication-closure row of the ring certificate gives both $C(r \cdot_R x)$ and $C(x \cdot_R r)$. By the definition of W_R, these are $W_R(r \cdot_R x)$ and $W_R(x \cdot_R r)$.

These rows are precisely the $\mathsf{Ideal}^{\uparrow}$ carried-predicate inventory over the fixed $\mathsf{Ring}^{\uparrow}$ certificate. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealAmbientCarrier closure rows`

Theorem 81.8 (Ambient ideal quotient-kernel carrier exactness)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate over BHist with notation as in Definition 81.6. Let Q_{W_R} be the quotient-kernel source relation of Definition 81.37 formed from the ambient carrier ideal predicate W_R. Then*

$$Q_{W_R}(x, y) \iff C(x) \wedge C(y).$$

Lean4 ✓ `BEDC.Derived.IdealUp.IdealAmbientCarrier quotient kernel exactness`

Proof. Unfold Definition 81.37 and Definition 81.6.

For the forward direction, a witness $Q_{W_R}(x, y)$ consists of endpoint carrier witnesses $C(x)$ and $C(y)$ together with the membership witness $W_R(x -_R y)$. Projecting the first two components gives $C(x) \wedge C(y)$.

For the reverse direction, assume $C(x)$ and $C(y)$. The additive inverse-closure row of the $\mathsf{Ring}^{\uparrow}$ certificate gives $C(-_R y)$, and the additive closure row gives

$$C(x -_R y).$$

By the definition of W_R, this is $W_R(x -_R y)$. Pairing it with the original endpoint carrier witnesses gives $Q_{W_R}(x, y)$. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealAmbientCarrier quotient kernel carrier exactness`
Lean4 ✓ `BEDC.Derived.IdealUp.IdealAmbientQuotientKernel carrier exactness`

Definition 81.9 (Zero IdealUp predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. The zero $\mathsf{Ideal}^{\uparrow}$ predicate over R is the concrete carried predicate*

$$\mathsf{ZeroIdeal}_R(x) \iff C(x) \wedge x \sim_R 0_R.$$

Lean4 ✓ `BEDC.Derived.IdealUp.IdealZeroPredicate semantic name certificate`

Theorem 81.10 (Zero IdealUp predicate closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with notation as in Definition 81.9. Assume the ring certificate supplies carrier transport, zero carriedness, addition congruence, additive inverse congruence, multiplication congruence, additive zero and inverse laws, and the two zero-product rows $0_R \cdot_R r \sim_R 0_R$ and $r \cdot_R 0_R \sim_R 0_R$ for every carried endpoint r. Then $\mathsf{ZeroIdeal}_R$ is an $\mathsf{Ideal}^{\uparrow}$ carried predicate over R. Explicitly, it has carrier support, zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and left and right absorption by every carried ambient endpoint.*

Lean4 ✓ `BEDC.Derived.IdealUp.IdealZeroPredicate closure rows`

Proof. Carrier support is the first conjunct in Definition 81.9. Zero membership uses the ring zero carriedness row together with classifier reflexivity at 0_R.

For additive closure, unpack two memberships as carried endpoints classified with 0_R. Ring addition congruence transports the two classifier comparisons to

$$x +_R y \sim_R 0_R +_R 0_R.$$

The additive zero law identifies $0_R +_R 0_R$ with 0_R, and transitivity gives the displayed zero classifier for $x +_R y$. The ring operation-closure row supplies $C(x +_R y)$, so the two witnesses repack $\mathsf{ZeroIdeal}_R(x +_R y)$.

For additive inverse closure, additive inverse congruence transports $x \sim_R 0_R$ to $-_R x \sim_R -_R 0_R$. The inverse row for zero and transitivity identify $-_R x$ with 0_R, while the inverse operation-closure row supplies $C(-_R x)$.

Internal multiplication is the same pattern. Multiplication congruence sends the two zero classifiers to $x \cdot_R y \sim_R 0_R \cdot_R 0_R$, and the zero-product row collapses the right endpoint to 0_R. Multiplication closure supplies the carrier conjunct.

Classifier transport is immediate from the carrier-transport row and classifier transitivity: if $\mathsf{ZeroIdeal}_R(x)$ and $x \sim_R y$, then $C(y)$ follows from carrier transport, and $y \sim_R 0_R$ follows by symmetry and transitivity from $x \sim_R y$ and $x \sim_R 0_R$.

Finally fix a carried ambient endpoint r. From $\mathsf{ZeroIdeal}_R(x)$, multiplication congruence identifies $r \cdot_R x$ with $r \cdot_R 0_R$ and $x \cdot_R r$ with $0_R \cdot_R r$; the two zero-product rows identify both products with 0_R. Multiplication closure supplies their carrier conjuncts, so both absorption rows repack as zero-ideal memberships. □

↪variant BEDC.Derived.IdealUp.IdealZeroPredicate closure rows

Lean4 ✓ BEDC.Derived.IdealUp.IdealZeroPredicate ideal closure

Definition 81.11 (Whole IdealUp predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. The whole $\mathsf{Ideal}^{\uparrow}$ predicate over R is the concrete carried predicate*

$$\mathsf{WholeIdeal}_R(x) \iff C(x).$$

Theorem 81.12 (Whole IdealUp predicate closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with notation as in Definition 81.11. Assume the ring certificate supplies zero carriedness, carrier transport, and carrier closure for addition, additive inverse, and multiplication. Then $\mathsf{WholeIdeal}_R$ is an $\mathsf{Ideal}^{\uparrow}$ carried predicate over R. Explicitly, it has carrier support, zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and left and right absorption by every carried ambient endpoint.*

Lean4 ✓ BEDC.Derived.IdealUp.IdealWholePredicate closure rows

Proof. Unfold Definition 81.11. Carrier support is identity on the ambient carrier predicate, and zero membership is exactly the ring zero carriedness row.

The additive, inverse, and internal multiplication rows are the corresponding ambient operation-closure rows of the $\mathsf{Ring}^{\uparrow}$ certificate. Since $\mathsf{WholeIdeal}_R(x)$ means only $C(x)$, each operation closure repacks directly as whole-ideal membership.

Classifier transport is the ambient carrier-transport row. If $C(x)$ and $x \sim_R y$, the transported carrier witness is precisely $\mathsf{WholeIdeal}_R(y)$.

For two-sided absorption, fix $C(r)$ and $\mathsf{WholeIdeal}_R(x)$. Ambient multiplication closure gives $C(r \cdot_R x)$ and $C(x \cdot_R r)$, which are exactly the left and right whole-ideal memberships. □

Theorem 81.13 (Zero and whole quotient-kernel scope)**.** *Let R carry a* $\mathsf{Ring}^{\uparrow}$ *certificate with notation as in Definition 81.37. Let $Q_{\mathsf{ZeroIdeal}}$ and $Q_{\mathsf{WholeIdeal}}$ be the source packages of Definition 81.37 built from Definition 81.9 and Definition 81.11. Then the zero-ideal package is the equality-like carried-endpoint kernel*

$$Q_{\mathsf{ZeroIdeal}}(x, y) \iff C(x) \wedge C(y) \wedge (x -_R y) \sim_R 0_R,$$

with the RingUp subtraction-zero rows identifying this condition with $x \sim_R y$ whenever the ambient difference exactness row is available. The whole-ideal package is the total carried-endpoint kernel

$$Q_{\mathsf{WholeIdeal}}(x, y) \iff C(x) \wedge C(y).$$

Both packages remain quotient-free BHist *relations consumable by* $\mathsf{QuotientRing}^{\uparrow}$ *before any quotient carrier or quotient primitive is formed.*

Proof. For the zero predicate, unfold Definition 81.37 and Definition 81.9. The relation $Q_{\mathsf{ZeroIdeal}}(x, y)$ contains $C(x)$, $C(y)$, and the two fields of $\mathsf{ZeroIdeal}_R(x -_R y)$.

The carrier field $C(x -_R y)$ is already supplied by the subtraction operation-closure rows from the two carried endpoints. The remaining field is the displayed zero classifier $(x -_R y) \sim_R 0_R$. Thus the quotient-kernel source repacks as the equality-like carried-endpoint kernel, and the ambient subtraction-zero exactness rows compare that kernel with the classifier $x \sim_R y$.

For the whole predicate, unfold Definition 81.11. The membership $\mathsf{WholeIdeal}_R(x -_R y)$ is exactly the carrier witness $C(x -_R y)$, which follows from the carrier closure of additive inverse and addition applied to $C(x)$ and $C(y)$. Therefore no condition remains beyond the two carried endpoints, giving the displayed total kernel.

The diagonal and endpoint-transport surfaces of these two concrete kernels are the specializations of Definition 81.38 and Definition 81.39. The repacked source packages therefore expose the same quotient-free boundary described in Definition 81.37, so $\mathsf{QuotientRing}^{\uparrow}$ consumes them through the existing IdealUp surface. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealZeroAndWholeQuotientKernel scope`

Theorem 81.14 (Zero IdealUp kernel is contained in whole IdealUp kernel)**.** *Let R carry a* $\mathsf{Ring}^{\uparrow}$ *certificate with notation as in Definition 81.37. Let $Q_{\mathsf{ZeroIdeal}}$ and $Q_{\mathsf{WholeIdeal}}$ be the two source packages of Definition 81.13. For every endpoint pair x, y, if the zero-ideal quotient-kernel relation holds, then the whole-ideal quotient-kernel relation holds:*

$$Q_{\mathsf{ZeroIdeal}}(x, y) \Longrightarrow Q_{\mathsf{WholeIdeal}}(x, y).$$

Equivalently, every carried endpoint pair satisfying the zero-ideal kernel is contained in the carried endpoint surface of the whole-ideal kernel.

The ten-field fit is: traditional target extremal ideal-kernel comparison; BEDC source $\mathsf{Ring}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, *and* $\mathsf{QuotientRing}^{\uparrow}$*; carrier ambient carried endpoints; classifier quotient-kernel relation; stability inherited from the two concrete ideal predicates; ledger hidden subtraction witness; core theorem this containment; exactness the displayed implication; standard bridge zero quotient refines whole quotient; status paper target.*

Proof. Unfold the scope computation of Definition 81.13. A zero-kernel witness for $Q_{\mathsf{ZeroIdeal}}(x, y)$ consists of the carried endpoint witnesses $C(x)$ and $C(y)$ together with the hidden subtraction classifier $(x -_R y) \sim_R 0_R$.

Project the two endpoint fields and discard the subtraction witness for this containment. The whole-kernel computation in the same theorem has no remaining ideal-membership condition beyond the ambient endpoint surface.

Repack the projected witnesses $C(x)$ and $C(y)$ as the witness for $Q_{\mathsf{WholeIdeal}}(x, y)$. This gives the displayed implication and records that the zero quotient-kernel relation is a subrelation of the whole quotient-kernel relation. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealZeroKernel contained in whole kernel`

Theorem 81.15 (Ideal zero-membership obligation)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate over BHist, with $\mathsf{NameCert}_{\mathsf{Ring}^{\uparrow}}$ carrier C, classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. If $I : \mathsf{BHist} \to \mathsf{Prop}$ is an $\mathsf{Ideal}^{\uparrow}$ carried predicate over R in the sense of Definition 81.1, then the certificate contains the zero-membership row $I(0_R)$.*

Proof. Unpack the $\mathsf{Ideal}^{\uparrow}$ carried-predicate data from Definition 81.1. The underlying predicate is explicitly a predicate on BHist, while the zero endpoint 0_R is the zero row of the ambient $\mathsf{Ring}^{\uparrow}$ certificate.

Among the rows carried by the ideal certificate is the zero-membership row. Projecting that row gives exactly $I(0_R)$. □

Theorem 81.16 (Ideal classifier-transport obligation)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate over BHist, with $\mathsf{NameCert}_{\mathsf{Ring}^{\uparrow}}$ carrier C, classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. If $I : \mathsf{BHist} \to \mathsf{Prop}$ is an $\mathsf{Ideal}^{\uparrow}$ carried predicate over R in the sense of Definition 81.1, then its certificate contains the classifier-transport row*

$$I(x) \wedge x \sim_R y \Longrightarrow I(y).$$

Proof. Unpack the carried predicate rows. The endpoints x and y are BEDC histories, the relation $x \sim_R y$ is the classifier supplied by the ambient $\mathsf{NameCert}_{\mathsf{Ring}^{\uparrow}}$, and I is the BHist predicate being certified.

The classifier-transport row listed in Definition 81.1 is one of the fields of the $\mathsf{Ideal}^{\uparrow}$ certificate. Projecting it and applying it to a membership witness $I(x)$ and the classifier comparison $x \sim_R y$ yields $I(y)$. □

Theorem 81.17 (Ideal two-sided absorption obligation)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate over BHist, with $\mathsf{NameCert}_{\mathsf{Ring}^{\uparrow}}$ carrier C, classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. If $I : \mathsf{BHist} \to \mathsf{Prop}$ is an $\mathsf{Ideal}^{\uparrow}$ carried predicate over R in the sense of Definition 81.1, then its certificate contains the left and right ambient absorption rows: for every carried ambient endpoint r with $C(r)$,*

$$I(x) \Longrightarrow I(r \cdot_R x) \wedge I(x \cdot_R r).$$

Proof. Unpack the $\mathsf{Ideal}^{\uparrow}$ certificate rows from Definition 81.1. The ambient multiplier r is not required to belong to the ideal predicate; it is only required to be carried by the $\mathsf{Ring}^{\uparrow}$ carrier C from the underlying $\mathsf{NameCert}_{\mathsf{Ring}^{\uparrow}}$.

The two-sided absorption row is part of the listed certificate surface. Projecting it at the carried endpoint r and a membership witness $I(x)$ gives the pair of conclusions $I(r \cdot_R x)$ and $I(x \cdot_R r)$. □

Definition 81.18 (Ideal intersection predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, and let I and J be $\mathsf{Ideal}^{\uparrow}$ carried predicates over R in the sense of section 81.1. The intersection predicate $I \cap_R J$ is defined by*

$$(I \cap_R J)(x) \Longleftrightarrow I(x) \wedge J(x).$$

Theorem 81.19 (Ideal intersection closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate as in chapter 43, with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I and J be $\mathsf{Ideal}^{\uparrow}$ predicates over R. Assume the two ideal certificates provide the rows specified in section 81.2: carrier support, zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and left and right absorption by every carried ring endpoint. For $K := I \cap_R J$ as in Definition 81.18, K is an $\mathsf{Ideal}^{\uparrow}$ predicate over R. Explicitly, K has carrier support and the rows*

$$K(0_R), \qquad K(x) \wedge K(y) \Longrightarrow K(x +_R y), \qquad K(x) \Longrightarrow K(-_R x),$$

$$K(x) \wedge K(y) \Longrightarrow K(x \cdot_R y), \qquad K(x) \wedge x \sim_R y \Longrightarrow K(y),$$

and, for every r with $C(r)$,

$$K(x) \Longrightarrow K(r \cdot_R x) \wedge K(x \cdot_R r).$$

Lean4 ✓ `BEDC.Derived.IdealUp.IdealIntersection closure rows`

Proof. The carrier support row is immediate. If $K(x)$, then $I(x)$ and $J(x)$; the carrier-support row of either ideal gives $C(x)$.

For zero, the zero rows for I and J give $I(0_R)$ and $J(0_R)$, hence $K(0_R)$.

For additive closure, assume $K(x)$ and $K(y)$. Then $I(x)$, $I(y)$, $J(x)$, and $J(y)$. The additive-closure row for I gives $I(x +_R y)$, and the additive-closure row for J gives $J(x +_R y)$. Together these are $K(x +_R y)$.

For additive inverse closure, assume $K(x)$. The inverse row for I gives $I(-_R x)$, and the inverse row for J gives $J(-_R x)$. Thus $K(-_R x)$.

For internal multiplication closure, assume $K(x)$ and $K(y)$. Carrier support gives $C(y)$. Right absorption in I, applied to $I(x)$ and $C(y)$, gives $I(x \cdot_R y)$. Right absorption in J, applied to $J(x)$ and $C(y)$, gives $J(x \cdot_R y)$. Hence $K(x \cdot_R y)$, which supplies the multiplicative closure row required by the sub-rng part of $\mathsf{Ideal}^{\uparrow}$.

For classifier transport, assume $K(x)$ and $x \sim_R y$. The transport row for I gives $I(y)$, and the transport row for J gives $J(y)$. Therefore $K(y)$.

For right absorption, assume $K(x)$ and $C(r)$. Right absorption in the two input ideal certificates gives $I(x \cdot_R r)$ and $J(x \cdot_R r)$, so $K(x \cdot_R r)$. For left absorption, the same argument with the left absorption rows gives $I(r \cdot_R x)$ and $J(r \cdot_R x)$, hence $K(r \cdot_R x)$.

These rows are exactly the carrier, additive sub-rng, classifier-stability, and ambient two-sided absorption rows required of an $\mathsf{Ideal}^{\uparrow}$ predicate over the given $\mathsf{Ring}^{\uparrow}$ certificate. □

Definition 81.20 (Ideal sum predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. Let I and J be $\mathsf{Ideal}^{\uparrow}$ carried predicates over R in the sense of section 81.1. The ideal-sum predicate $I +_R J$ is defined by the displayed additive decomposition*

$$(I +_R J)(z) \Longleftrightarrow \exists x, y : \mathsf{BHist}.\ I(x) \wedge J(y) \wedge z \sim_R x +_R y.$$

The ambient carrier witnesses are obtained through the carrier-support rows of the two $\mathsf{Ideal}^{\uparrow}$ certificates, the ring addition carrier row, and carrier transport along $\sim_R$. The hidden ledger for a sum membership contains only the two membership witnesses $I(x)$ and $J(y)$ together with the additive decomposition row $z \sim_R x +_R y$.

Definition 81.21 (Ideal inclusion predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. Let I and J be $\mathsf{Ideal}^{\uparrow}$ carried predicates over the same $\mathsf{Ring}^{\uparrow}$ certificate. The ideal-inclusion predicate $I \preceq_R J$ is defined by*

$$I \preceq_R J \iff \forall x : \mathsf{BHist}.\ I(x) \Longrightarrow J(x).$$

Theorem 81.22 (Ideal sum closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate as in chapter 43, with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I and J be $\mathsf{Ideal}^{\uparrow}$ predicates over R. Assume the two ideal certificates provide the rows specified in section 81.2: carrier support, zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and left and right absorption by every carried ring endpoint. For $K := I +_R J$ as in Definition 81.20, K is an $\mathsf{Ideal}^{\uparrow}$ predicate over R. Explicitly, K has carrier support and the rows*

$$K(0_R), \qquad K(z) \wedge K(w) \Longrightarrow K(z +_R w), \qquad K(z) \Longrightarrow K(-_R z),$$

$$K(z) \wedge K(w) \Longrightarrow K(z \cdot_R w), \qquad K(z) \wedge z \sim_R z' \Longrightarrow K(z'),$$

and, for every r with $C(r)$,

$$K(z) \Longrightarrow K(r \cdot_R z) \wedge K(z \cdot_R r).$$

Lean4 ✓ `BEDC.Derived.IdealUp.IdealSum closure rows`

Proof. For carrier support, unpack a witness for $K(z)$. The support rows of I and J give $C(x)$ and $C(y)$, the ring addition carrier row gives $C(x +_R y)$, and carrier transport along $z \sim_R x +_R y$ gives $C(z)$.

For zero membership, use the witness pair $(0_R, 0_R)$. The zero rows give $I(0_R)$ and $J(0_R)$, and the additive-zero row of the ring certificate supplies the decomposition $0_R \sim_R 0_R +_R 0_R$.

For additive closure, choose witnesses $z \sim_R x +_R y$ for $K(z)$ and $w \sim_R x' +_R y'$ for $K(w)$. Addition congruence carries these decompositions to

$$z +_R w \sim_R (x +_R y) +_R (x' +_R y').$$

Additive associativity and commutativity in the $\mathsf{Ring}^{\uparrow}$ rows regroup the right side as $(x +_R x') +_R (y +_R y')$. The additive-closure rows of I and J give $I(x +_R x')$ and $J(y +_R y')$, which are the required witnesses for $K(z +_R w)$.

For additive inverse closure, start from $z \sim_R x +_R y$. The inverse-congruence row gives $-_R z \sim_R -_R(x +_R y)$, and the inverse-of-sum row identifies the right side with $(-_R x) +_R (-_R y)$. The additive inverse rows of I and J supply $I(-_R x)$ and $J(-_R y)$, so $K(-_R z)$.

For classifier transport, assume $K(z)$ and $z \sim_R z'$. Symmetry and transitivity of the classifier compose $z' \sim_R z$ with the displayed decomposition for z, giving the same witness pair for $K(z')$.

For absorption, assume $K(z)$ with witness $z \sim_R x +_R y$ and let r be carried. Distributivity gives

$$r \cdot_R z \sim_R (r \cdot_R x) +_R (r \cdot_R y)$$

and

$$z \cdot_R r \sim_R (x \cdot_R r) +_R (y \cdot_R r).$$

The left and right absorption rows of I and J supply the four displayed ideal memberships, so the two decompositions witness $K(r \cdot_R z)$ and $K(z \cdot_R r)$.

For internal multiplication closure, carrier support for $K(w)$ gives $C(w)$. Right absorption applied to $K(z)$ and $C(w)$ yields $K(z \cdot_R w)$, which supplies the multiplicative row required by the sub-rng part of $\mathsf{Ideal}^{\uparrow}$.

These rows are exactly the carrier, additive sub-rng, multiplicative sub-rng, classifier-stability, and two-sided ambient absorption rows required of an $\mathsf{Ideal}^{\uparrow}$ predicate over the fixed $\mathsf{Ring}^{\uparrow}$ certificate. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealSum ideal closure rows`

Theorem 81.23 (Ideal sum quotient-ring kernel scope)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate and let I and J be $\mathsf{Ideal}^{\uparrow}$ carried predicates over R. Let $K := I +_R J$ be the ideal-sum predicate of Definition 81.20, and let Q_K be the quotient-kernel source package of Definition 81.37. The package Q_K has the same diagonal and endpoint-transport scope as the quotient-kernel packages built from any other $\mathsf{Ideal}^{\uparrow}$ predicate, so $\mathsf{QuotientRing}^{\uparrow}$ may consume ideal sums without adding quotient primitives.*

Lean4 ✓ `BEDC.Derived.IdealUp.IdealSumQuotientKernel scope`

Proof. By Definition 81.22, the predicate K is an $\mathsf{Ideal}^{\uparrow}$ predicate over the same $\mathsf{Ring}^{\uparrow}$ data as I and J.

Apply Definition 81.38 to K for the diagonal row, and apply Definition 81.39 to K for endpoint transport. The kernel relation is still the same concrete relation $Q_K(x, y) \iff C(x) \wedge C(y) \wedge K(x -_R y)$, so the quotient-ring consumer sees no additional quotient carrier or quotient primitive.

The ten-field fit is: traditional target sum of two ideals; BEDC source $\mathsf{Ring}^{\uparrow}$ plus two $\mathsf{Ideal}^{\uparrow}$ predicates over BHist; carrier the existential additive decomposition predicate; classifier $\sim_R$; stability Definition 81.22; ledger decomposition witnesses; core theorem Definition 81.22; exactness row exhaustion of the displayed witnesses; standard bridge absent; status $\mathsf{ProofTarget}$. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealSumQuotientKernel diagonal transport scope`

Theorem 81.24 (Ideal sum quotient-kernel absorption closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I and J be $\mathsf{Ideal}^{\uparrow}$ predicates over R, set $K := I +_R J$ as in Definition 81.20, and define*

$$x -_R y := x +_R (-_R y), \qquad Q_K(x, y) \iff C(x) \wedge C(y) \wedge K(x -_R y).$$

Assume the ring certificate supplies multiplication carrier closure, carrier transport, classifier symmetry, subtraction congruence, and the absorption-difference rows

$$(r \cdot_R x) -_R (r \cdot_R y) \sim_R r \cdot_R (x -_R y)$$

and

$$(x \cdot_R r) -_R (y \cdot_R r) \sim_R (x -_R y) \cdot_R r.$$

Assume the two ideal certificates for I and J provide the rows listed in section 81.2. Then

$$C(r) \wedge Q_K(x, y) \Longrightarrow Q_K(r \cdot_R x, r \cdot_R y) \wedge Q_K(x \cdot_R r, y \cdot_R r).$$

Proof. First apply Definition 81.22 to the two ideal certificates. This turns the concrete sum predicate $K := I +_R J$ into an $\mathsf{Ideal}^{\uparrow}$ predicate over the same $\mathsf{Ring}^{\uparrow}$ certificate, with carrier support, classifier transport, and two-sided absorption by every carried ring endpoint.

Now regard the displayed relation $Q_K(x, y)$ as the quotient-kernel source package associated to this specialized ideal predicate. The hypotheses on multiplication carrier closure, carrier transport, classifier symmetry, subtraction congruence, and the two absorption-difference rows are exactly the ambient ring rows required by Definition 81.50.

Apply Definition 81.50 with I there specialized to K here. Its left output gives $Q_K(r \cdot_R x, r \cdot_R y)$, its right output gives $Q_K(x \cdot_R r, y \cdot_R r)$, and together they give the claimed absorption closure for the ideal-sum quotient kernel. □

Theorem 81.25 (Ideal sum quotient-ring export surface)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I and J be $\mathsf{Ideal}^{\uparrow}$ predicates over R, set $K := I +_R J$ as in Definition 81.20, and define*

$$x -_R y := x +_R (-_R y), \qquad Q_K(x, y) \iff C(x) \wedge C(y) \wedge K(x -_R y).$$

Assume the ambient ring certificate supplies the subtraction, carrier, classifier, and multiplication-difference rows required in Definition 81.24. Then the ideal-sum predicate K exports the full quotient-free kernel surface consumed by $\mathsf{QuotientRing}^{\uparrow}$:

1. *diagonal exactness for every carried endpoint x:*

$$C(x) \Longrightarrow Q_K(x, x);$$

2. *endpoint transport along the RingUp classifier:*

$$Q_K(x, y) \wedge x \sim_R x' \wedge y \sim_R y' \Longrightarrow Q_K(x', y');$$

3. *additive representative descent:*

$$Q_K(a, a') \wedge Q_K(b, b') \Longrightarrow Q_K(a +_R b, a' +_R b');$$

4. *negation representative descent:*

$$Q_K(a, a') \Longrightarrow Q_K(-_R a, -_R a');$$

5. *multiplication representative descent:*

$$Q_K(a, a') \wedge Q_K(b, b') \Longrightarrow Q_K(a \cdot_R b, a' \cdot_R b');$$

6. *ambient left and right multiplication closure:*

$$C(r) \wedge Q_K(x, y) \Longrightarrow Q_K(r \cdot_R x, r \cdot_R y) \wedge Q_K(x \cdot_R r, y \cdot_R r).$$

Proof. First apply Definition 81.22 to the two input ideal certificates. This turns the concrete predicate $K := I +_R J$ into an $\mathsf{Ideal}^{\uparrow}$ predicate over the same $\mathsf{Ring}^{\uparrow}$ data, with the carrier, additive, negation, multiplication, classifier-transport, and two-sided absorption rows required by section 81.2.

Next instantiate Definition 81.41 with this predicate K. That theorem supplies the five generic quotient-ring rows: diagonal exactness, endpoint transport, additive descent, negation descent, and multiplication descent for the concrete relation $Q_K(x, y) \iff C(x) \wedge C(y) \wedge K(x -_R y)$.

Finally apply Definition 81.24. Its conclusion is exactly the ambient left and right multiplication closure row for Q_K, using the same subtraction package and the same specialized ideal-sum predicate K. □

Theorem 81.26 (Ideal intersection greatest lower bound)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate as in chapter 43, with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I and J be $\mathsf{Ideal}^{\uparrow}$ predicates over the same $\mathsf{Ring}^{\uparrow}$ certificate, with the rows specified in section 81.2. Let $K := I \cap_R J$ as in Definition 81.18. Then K is an $\mathsf{Ideal}^{\uparrow}$ predicate by Definition 81.19, and K is the greatest lower bound of I and J for $\preceq_R$:*

$$K \preceq_R I, \qquad K \preceq_R J,$$

and, for every $\mathsf{Ideal}^{\uparrow}$ predicate L over the same $\mathsf{Ring}^{\uparrow}$ certificate,

$$(L \preceq_R I) \wedge (L \preceq_R J) \Longrightarrow L \preceq_R K.$$

Proof. The predicate K is an $\mathsf{Ideal}^{\uparrow}$ predicate by Definition 81.19, because it is built from the same two ideal certificates and the same ambient $\mathsf{Ring}^{\uparrow}$ rows.

For the first lower-bound inclusion, assume $K(x)$. By Definition 81.18, this means $I(x) \wedge J(x)$. Projecting the first component gives $I(x)$, so Definition 81.21 gives $K \preceq_R I$.

For the second lower-bound inclusion, the same unpacking of $K(x)$ gives the second component $J(x)$. Hence $K \preceq_R J$.

It remains to prove maximality among lower bounds. Let L be an $\mathsf{Ideal}^{\uparrow}$ predicate over the same $\mathsf{Ring}^{\uparrow}$ certificate, and assume $L \preceq_R I$ and $L \preceq_R J$. To prove $L \preceq_R K$, fix $x : \mathsf{BHist}$ and assume $L(x)$.

The first inclusion sends this witness to $I(x)$, and the second inclusion sends the same witness to $J(x)$. Pairing these two memberships gives $I(x) \wedge J(x)$, which is exactly $K(x)$ by Definition 81.18. Therefore $L \preceq_R K$ by Definition 81.21. □

Theorem 81.27 (Ideal sum commutativity as a carried predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate as in chapter 43, with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I and J be $\mathsf{Ideal}^{\uparrow}$ predicates over the same $\mathsf{Ring}^{\uparrow}$ certificate, with the rows specified in section 81.2. Define*

$$K_{I,J} := I +_R J, \qquad K_{J,I} := J +_R I$$

using Definition 81.20. Then $K_{I,J}$ and $K_{J,I}$ are $\mathsf{Ideal}^{\uparrow}$ predicates over the same ambient $\mathsf{Ring}^{\uparrow}$ certificate by Definition 81.22, and they have the same membership predicate:

$$\forall z : \mathsf{BHist}.\ K_{I,J}(z) \Longleftrightarrow K_{J,I}(z).$$

The comparison keeps the ambient carrier row C fixed, swaps only the two additive-decomposition membership witnesses, and preserves the same Pkg provenance rows attached to the ambient $\mathsf{Ring}^{\uparrow}$ certificate and the two input $\mathsf{Ideal}^{\uparrow}$ certificates.

Proof. Apply Definition 81.22 first to the ordered pair (I, J) and then to the ordered pair (J, I). This gives $K_{I,J}$ and $K_{J,I}$ as $\mathsf{Ideal}^{\uparrow}$ predicates over the same carrier C, classifier $\sim_R$, and ring operations.

Fix $z : \mathsf{BHist}$. For the forward implication, assume $K_{I,J}(z)$. By Definition 81.20, choose witnesses $x, y : \mathsf{BHist}$ such that

$$I(x) \wedge J(y) \wedge z \sim_R x +_R y.$$

The additive commutativity row contained in the additive abelian-group part of the $\mathsf{Ring}^{\uparrow}$ stability certificate gives

$$x +_R y \sim_R y +_R x.$$

Classifier transitivity composes the displayed decomposition for z with this commutativity row, giving

$$z \sim_R y +_R x.$$

Now the witness pair (y, x), together with $J(y)$, $I(x)$, and the last classifier comparison, is exactly a witness for $K_{J,I}(z)$ under Definition 81.20.

The reverse implication is the same argument with I and J interchanged. If $K_{J,I}(z)$ is witnessed by $J(y) \wedge I(x) \wedge z \sim_R y +_R x$, additive commutativity gives $y +_R x \sim_R x +_R y$, and classifier transitivity gives $z \sim_R x +_R y$. The witness pair (x, y) therefore proves $K_{I,J}(z)$.

The ambient carrier consequence is unchanged in both directions. Since both sum predicates are $\mathsf{Ideal}^{\uparrow}$ predicates over the same $\mathsf{Ring}^{\uparrow}$ certificate, the carrier-support row of Definition 81.1 reads

$$K_{I,J}(z) \Longrightarrow C(z), \qquad K_{J,I}(z) \Longrightarrow C(z).$$

The equivalence just proved keeps the endpoint z fixed and changes only the internal decomposition ledger: $I(x)$ and $J(y)$ are reused in the opposite witness slots, while the decomposition row is adjusted by the additive commutativity row already present in Definition 43.26. No ambient carrier, classifier, operation, ideal certificate, or package provenance row is replaced. □

Theorem 81.28 (Ideal sum monotonicity in ideal inclusion)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate as in chapter 43, with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I, I', J, J' be $\mathsf{Ideal}^{\uparrow}$ predicates over the same $\mathsf{Ring}^{\uparrow}$ certificate, with the rows specified in section 81.2. Define*

$$K := I +_R J, \qquad K' := I' +_R J'$$

using Definition 81.20. Then K and K' are $\mathsf{Ideal}^{\uparrow}$ predicates over the same ambient certificate by Definition 81.22, and ideal inclusion is monotone through the sum constructor:

$$(I \preceq_R I') \wedge (J \preceq_R J') \Longrightarrow K \preceq_R K'.$$

Equivalently, for every $z : \mathsf{BHist}$, any additive-decomposition witness for $(I +_R J)(z)$ is sent to an additive-decomposition witness for $(I' +_R J')(z)$ by applying the two inclusion implications to the two membership entries and leaving the decomposition row unchanged.

Proof. The two sum predicates are $\mathsf{Ideal}^{\uparrow}$ predicates by Definition 81.22, applied first to (I, J) and then to (I', J'). Thus the comparison $K \preceq_R K'$ is an instance of the ideal-inclusion predicate from Definition 81.21.

Assume $I \preceq_R I'$ and $J \preceq_R J'$. To prove $K \preceq_R K'$, fix $z : \mathsf{BHist}$ and assume $K(z)$. By Definition 81.20, choose witnesses $x, y : \mathsf{BHist}$ with

$$I(x) \wedge J(y) \wedge z \sim_R x +_R y.$$

The first inclusion, unpacked through Definition 81.21, sends the witness $I(x)$ to $I'(x)$. The second inclusion sends the witness $J(y)$ to $J'(y)$.

Now keep the same endpoints x and y and keep the same additive-decomposition row $z \sim_R x +_R y$. The data

$$I'(x) \wedge J'(y) \wedge z \sim_R x +_R y$$

are exactly a witness for $K'(z)$ under Definition 81.20. Since z was arbitrary, Definition 81.21 gives $K \preceq_R K'$. □

Theorem 81.29 (Ideal sum associativity as a carried predicate)**.** *Let R carry a* $\mathsf{Ring}^{\uparrow}$ *certificate as in chapter 43, with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I, J, and K be* $\mathsf{Ideal}^{\uparrow}$ *predicates over the same* $\mathsf{Ring}^{\uparrow}$ *certificate, with the rows specified in section 81.2. Define*

$$A_L := (I +_R J) +_R K, \qquad A_R := I +_R (J +_R K)$$

using Definition 81.20. Then A_L and A_R are $\mathsf{Ideal}^{\uparrow}$ *predicates over the same ambient* $\mathsf{Ring}^{\uparrow}$ *certificate by Definition 81.22, and they have the same membership predicate:*

$$\forall z : \mathsf{BHist}.\ A_L(z) \iff A_R(z).$$

The comparison keeps the ambient carrier row C fixed, regroups only the three additive-decomposition witnesses by the additive associativity row in the $\mathsf{Ring}^{\uparrow}$ *stability certificate, and preserves the same* Pkg *provenance rows attached to the ambient* $\mathsf{Ring}^{\uparrow}$ *certificate and the three input* $\mathsf{Ideal}^{\uparrow}$ *certificates.*

Proof. Apply Definition 81.22 to (I, J), to (J, K), to $((I +_R J), K)$, and to $(I, (J +_R K))$. Thus the two iterated sums are carried $\mathsf{Ideal}^{\uparrow}$ predicates over the same carrier C, classifier $\sim_R$, and ring operations. The proof of equality of predicates is therefore a direct comparison of the displayed membership witnesses in Definition 81.20.

Fix $z : \mathsf{BHist}$. For the forward implication, assume $A_L(z)$. Unpacking the outer sum gives histories $s, k : \mathsf{BHist}$ with

$$(I +_R J)(s) \wedge K(k) \wedge z \sim_R s +_R k.$$

Unpacking the inner sum gives histories $i, j : \mathsf{BHist}$ with

$$I(i) \wedge J(j) \wedge s \sim_R i +_R j.$$

Use $j +_R k$ as the inner right-sum endpoint. The witness pair (j, k), the memberships $J(j)$ and $K(k)$, and classifier reflexivity at $j +_R k$ prove $(J +_R K)(j +_R k)$ by Definition 81.20.

It remains to supply the outer decomposition for $A_R(z)$ with witness pair $(i, j +_R k)$. Addition congruence, applied to $s \sim_R i +_R j$ and classifier reflexivity at k, gives

$$s +_R k \sim_R (i +_R j) +_R k.$$

The additive associativity row contained in the additive abelian-group part of Definition 43.26 gives

$$(i +_R j) +_R k \sim_R i +_R (j +_R k).$$

Classifier transitivity composes the displayed decomposition $z \sim_R s +_R k$ with these two comparisons, yielding

$$z \sim_R i +_R (j +_R k).$$

Together with $I(i)$ and $(J +_R K)(j +_R k)$, this is exactly a witness for $A_R(z)$.

For the reverse implication, assume $A_R(z)$. Unpacking the outer sum gives histories $i, t : \mathsf{BHist}$ with

$$I(i) \wedge (J +_R K)(t) \wedge z \sim_R i +_R t.$$

Unpacking the inner sum gives histories $j, k : \mathsf{BHist}$ with

$$J(j) \wedge K(k) \wedge t \sim_R j +_R k.$$

Use $i +_R j$ as the inner left-sum endpoint. The witness pair (i, j), the memberships $I(i)$ and $J(j)$, and classifier reflexivity at $i +_R j$ prove $(I +_R J)(i +_R j)$ by Definition 81.20.

Addition congruence, applied to classifier reflexivity at i and to $t \sim_R j +_R k$, gives

$$i +_R t \sim_R i +_R (j +_R k).$$

The same additive associativity row, read with classifier symmetry, gives

$$i +_R (j +_R k) \sim_R (i +_R j) +_R k.$$

Classifier transitivity composes these comparisons with $z \sim_R i +_R t$, yielding

$$z \sim_R (i +_R j) +_R k.$$

Together with $(I +_R J)(i +_R j)$ and $K(k)$, this is exactly a witness for $A_L(z)$.

The carrier consequence is identical on both sides. Since both predicates are obtained from Definition 81.22 over the same ambient $\mathsf{Ring}^{\uparrow}$ certificate, their carrier-support rows read

$$A_L(z) \Longrightarrow C(z), \qquad A_R(z) \Longrightarrow C(z).$$

The equivalence keeps the endpoint z fixed and changes only the parenthesization of the internal decomposition ledger: the same three memberships $I(i)$, $J(j)$, and $K(k)$ are reused, while the classifier decomposition is adjusted by addition congruence, classifier transitivity, classifier symmetry in the reverse direction, and the additive associativity row already present in Definition 43.26. No ambient carrier, classifier, operation, ideal certificate, or package provenance row is replaced. □

Definition 81.30 (Principal two-sided generated ideal predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let a be a carried generator, so $C(a)$. The principal two-sided generated ideal predicate $\langle a \rangle_R$ is the predicate on endpoints z for which a finite* HistSpine *carries signed two-sided monomial rows*

$$\ell_i \cdot_R a \cdot_R r_i$$

with $C(\ell_i)$ and $C(r_i)$ at every spine position i, together with sign rows, such that the $\mathsf{Ring}^{\uparrow}$ finite additive fold of those signed rows is classifier-equal to z. The empty spine folds to 0_R. The certificate ledger records the spine, the left and right coefficient rows, the sign rows, and the final classifier edge from the finite fold to z.

Lean4 (definition) `BEDC.Derived.IdealUp.IdealPrincipalGenerated`

Theorem 81.31 (Principal generated subtractive closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, let a be a carried generator, and let $\langle a \rangle_R$ be the predicate of Definition 81.30. Then $\langle a \rangle_R$ has carrier support, zero membership, additive closure, additive inverse closure, and classifier transport over the ambient $\mathsf{Ring}^{\uparrow}$ data:*

$$\langle a \rangle_R(0_R), \qquad \langle a \rangle_R(x) \wedge \langle a \rangle_R(y) \Longrightarrow \langle a \rangle_R(x +_R y), \qquad \langle a \rangle_R(x) \Longrightarrow \langle a \rangle_R(-_R x),$$

and

$$\langle a \rangle_R(x) \wedge x \sim_R y \Longrightarrow \langle a \rangle_R(y),$$

with every displayed membership carrying a RingUp endpoint carrier witness.

Lean4 ✓ `BEDC.Derived.IdealUp.IdealPrincipalGenerated subtractive closure rows`

Proof. Carrier support is part of the final fold certificate: every signed monomial row is carried by the multiplication-closure rows, the finite additive fold is carried by the additive-closure rows, and classifier transport carries that support to the named endpoint z.

For zero membership, take the empty spine. Its fold is 0_R, and the final classifier edge is the reflexive edge at 0_R.

For additive closure, concatenate the two finite spines witnessing x and y. The fold of the concatenated spine is classified, by RingUp finite-fold associativity, with the sum of the two earlier folds. Addition congruence then transports along the two final classifier edges and yields a final classifier edge to $x +_R y$.

For additive inverse closure, reverse the signs in the spine witnessing x. The RingUp inverse and finite-fold rows classify the new fold with the additive inverse of the old fold, and inverse congruence transports the final edge to $-_R x$.

For classifier transport, keep the same spine and compose its final classifier edge with the given edge $x \sim_R y$. The ledger data is unchanged, and the composed edge witnesses $\langle a \rangle_R(y)$. □

Theorem 81.32 (Principal generated absorption closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, let a be a carried generator, and let $\langle a \rangle_R$ be the predicate of Definition 81.30. If t is carried, then $\langle a \rangle_R(x)$ implies both $\langle a \rangle_R(t \cdot_R x)$ and $\langle a \rangle_R(x \cdot_R t)$. Consequently, together with Definition 81.31, the predicate $\langle a \rangle_R$ supplies the internal multiplication row required of an $\mathsf{Ideal}^{\uparrow}$ predicate.*

Lean4 ✓ `BEDC.Derived.IdealUp.IdealPrincipalGenerated absorption closure rows`

Proof. Start with a finite signed spine witnessing $\langle a \rangle_R(x)$. For left absorption by a carried endpoint t, multiply every monomial row in the spine on the left by t.

Associativity rewrites each row

$$t \cdot_R (\ell_i \cdot_R a \cdot_R r_i)$$

as

$$(t \cdot_R \ell_i) \cdot_R a \cdot_R r_i.$$

Carrier support for t and ℓ_i gives $C(t \cdot_R \ell_i)$, while $C(r_i)$ is retained. Distributivity and the finite-fold multiplication rows classify the fold of the transformed spine with $t \cdot_R x$, after composing with the original final classifier edge.

For right absorption, multiply every monomial row on the right by t. Associativity rewrites

$$(\ell_i \cdot_R a \cdot_R r_i) \cdot_R t$$

as

$$\ell_i \cdot_R a \cdot_R (r_i \cdot_R t),$$

and the multiplication-closure rows give $C(r_i \cdot_R t)$. The same distributivity and finite-fold argument supplies the final classifier edge to $x \cdot_R t$.

Internal multiplication is then a consequence of right absorption: from $\langle a \rangle_R(x)$ and $\langle a \rangle_R(y)$, carrier support from Definition 81.31 gives $C(y)$, and right absorption by y gives $\langle a \rangle_R(x \cdot_R y)$. □

Theorem 81.33 (Principal generated full IdealUp closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate over BHist, let a be a carried generator, and let $\langle a \rangle_R$ be the predicate of Definition 81.30. Then $\langle a \rangle_R$ supplies the full $\mathsf{Ideal}^{\uparrow}$ predicate surface over R: carrier support, zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and two-sided absorption by every carried ambient endpoint.*

Lean4 ✓ `BEDC.Derived.IdealUp.IdealPrincipalGenerated full ideal closure rows`

Proof. The carrier-support, zero-membership, additive-closure, additive-inverse, and classifier-transport rows are exactly the rows supplied by Definition 81.31.

The two-sided ambient absorption rows are exactly the left and right absorption rows supplied by Definition 81.32. The internal multiplication row is obtained there from right absorption together with carrier support for the second factor. These rows are precisely the row package required of an $\mathsf{Ideal}^{\uparrow}$ predicate over the ambient $\mathsf{Ring}^{\uparrow}$ certificate. □

Theorem 81.34 (Principal generated quotient-kernel scope)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, let a be a carried generator, and let $I := \langle a \rangle_R$ be the predicate of Definition 81.30. The generated predicate supplies the quotient-free kernel surface consumed by $\mathsf{QuotientRing}^{\uparrow}$:*

$$Q_I(x, y) \iff C(x) \wedge C(y) \wedge I(x -_R y).$$

In particular, the diagonal and endpoint-transport rows for this surface are exactly the rows obtained by applying Definition 81.38 and Definition 81.39 to I.

Proof. By Definition 81.33, the predicate I is an $\mathsf{Ideal}^{\uparrow}$ predicate over the ambient ring certificate.

Unfold Definition 81.37 with this I. The displayed relation is therefore the same concrete quotient-free BHist kernel package used for every IdealUp predicate.

Apply Definition 81.38 to obtain diagonal exactness, and apply Definition 81.39 to obtain endpoint transport. No quotient carrier or extra quotient primitive is introduced before $\mathsf{QuotientRing}^{\uparrow}$ consumes the surface. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealPrincipalGenerated quotient kernel scope`

Definition 81.35 (Ring map zero-fiber predicate)**.** *Let S and T carry $\mathsf{Ring}^{\uparrow}$ certificates, with carriers C_S, C_T, classifiers $\sim_S, \sim_T$, zeros $0_S, 0_T$, additions $+_S, +_T$, additive inverses $-_S, -_T$, and multiplications $\cdot_S, \cdot_T$. For a function $f : S \to T$, the ring-map zero-fiber predicate on the source carrier is*

$$\mathsf{Ker}_f^{\mathrm{ring}}(x) \iff C_S(x) \wedge f(x) \sim_T 0_T.$$

The first component records source-carrier evidence; the second records the target-zero classification.

Lean4 ✓ `BEDC.Derived.IdealUp.RingMapZeroFiber semantic name certificate`

Theorem 81.36 (Ring map zero fiber IdealUp closure)**.** *Let S and T carry $\mathsf{Ring}^{\uparrow}$ certificates as in chapter 43, with notation as in Definition 81.35. Let $f : S \to T$ satisfy carrier preservation and classifier preservation on carried source endpoints:*

$$C_S(x) \Longrightarrow C_T(f(x))$$

and

$$C_S(x) \wedge C_S(y) \wedge x \sim_S y \Longrightarrow f(x) \sim_T f(y).$$

Assume also that f preserves zero, addition, additive inverse, and multiplication on carried source endpoints:

$$f(0_S) \sim_T 0_T,$$

$$C_S(x) \wedge C_S(y) \Longrightarrow f(x +_S y) \sim_T f(x) +_T f(y),$$

$$C_S(x) \Longrightarrow f(-_S x) \sim_T -_T f(x),$$

and

$$C_S(x) \wedge C_S(y) \Longrightarrow f(x \cdot_S y) \sim_T f(x) \cdot_T f(y).$$

Then $K := \mathsf{Ker}_f^{\mathrm{ring}}$ *from Definition 81.35 is an* $\mathsf{Ideal}^{\uparrow}$ *predicate over the source ring* S*. Explicitly,* K *has carrier support and the rows*

$$K(0_S), \qquad K(x) \wedge K(y) \Longrightarrow K(x +_S y), \qquad K(x) \Longrightarrow K(-_S x),$$

$$K(x) \wedge K(y) \Longrightarrow K(x \cdot_S y), \qquad K(x) \wedge x \sim_S y \Longrightarrow K(y),$$

and, for every r *with* $C_S(r)$*,*

$$K(x) \Longrightarrow K(r \cdot_S x) \wedge K(x \cdot_S r).$$

Lean4 ✓ `BEDC.Derived.IdealUp.RingMapZeroFiber ideal closure rows`

Proof. Unfold Definition 81.35. Carrier support is the first component of a K witness.

For zero, the source $\mathsf{Ring}^{\uparrow}$ certificate carries 0_S, and the zero-preservation row gives $f(0_S) \sim_T 0_T$. Hence $K(0_S)$.

For classifier transport, assume $K(x)$ and $x \sim_S y$. The source carrier-transport row from Definition 9.7 gives $C_S(y)$. Classifier preservation gives $f(x) \sim_T f(y)$. Target classifier symmetry and Definition 9.8 compose this with the zero-fiber witness $f(x) \sim_T 0_T$ to obtain $f(y) \sim_T 0_T$. Thus $K(y)$.

For additive closure, assume $K(x)$ and $K(y)$. Source additive closure carries $x +_S y$. Addition preservation gives

$$f(x +_S y) \sim_T f(x) +_T f(y).$$

Target addition congruence, applied to the two zero-fiber witnesses, gives

$$f(x) +_T f(y) \sim_T 0_T +_T 0_T.$$

The target additive zero row contained in Definition 43.26 reduces $0_T +_T 0_T$ to 0_T. Transitivity gives $f(x +_S y) \sim_T 0_T$, so $K(x +_S y)$.

For additive inverse closure, assume $K(x)$. Source inverse closure carries $-_S x$. Additive-inverse preservation gives

$$f(-_S x) \sim_T -_T f(x).$$

Target inverse congruence transports $f(x) \sim_T 0_T$ to $-_T f(x) \sim_T -_T 0_T$, and Definition 43.28, read in the target additive component, identifies $-_T 0_T$ with 0_T. Composing the classifier edges yields $f(-_S x) \sim_T 0_T$, hence $K(-_S x)$.

For internal multiplication closure, assume $K(x)$ and $K(y)$. Source multiplication closure carries $x \cdot_S y$. Multiplication preservation gives

$$f(x \cdot_S y) \sim_T f(x) \cdot_T f(y).$$

Target multiplication congruence transports the two zero-fiber witnesses to

$$f(x) \cdot_T f(y) \sim_T 0_T \cdot_T 0_T.$$

The zero-product rows of Definition 43.26 reduce $0_T \cdot_T 0_T$ to 0_T. Thus $K(x \cdot_S y)$.

For left absorption, assume $K(x)$ and $C_S(r)$. Source multiplication closure carries $r \cdot_S x$, and multiplication preservation gives

$$f(r \cdot_S x) \sim_T f(r) \cdot_T f(x).$$

Carrier preservation gives $C_T(f(r))$. Target multiplication congruence transports the right factor along $f(x) \sim_T 0_T$, and the target right zero-product row gives

$$f(r) \cdot_T 0_T \sim_T 0_T.$$

Therefore $K(r \cdot_S x)$. For right absorption, the same argument starts from

$$f(x \cdot_S r) \sim_T f(x) \cdot_T f(r),$$

transports the left factor along $f(x) \sim_T 0_T$, and uses the target left zero-product row $0_T \cdot_T f(r) \sim_T 0_T$. This gives $K(x \cdot_S r)$.

The displayed carrier support, zero, additive, inverse, multiplicative, classifier-transport, and two-sided absorption rows are exactly the $\mathsf{Ideal}^{\uparrow}$ certificate rows listed in section 81.2 for a predicate over the source $\mathsf{Ring}^{\uparrow}$ certificate. □

Definition 81.37 (Ideal quotient-kernel source package)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I be an $\mathsf{Ideal}^{\uparrow}$ carried predicate over R, and write*

$$x -_R y := x +_R (-_R y).$$

The ideal quotient-kernel source package is the concrete BHist *relation Q_I on ring endpoints defined by*

$$Q_I(x, y) \iff C(x) \wedge C(y) \wedge I(x -_R y).$$

It is the quotient-free BHist *relation later read as the ideal-coset relation in Definition 83.1.*

Lean4 (definition) `BEDC.Derived.IdealUp.IdealQuotientKernelSource`

Theorem 81.38 (Ideal quotient-kernel diagonal exactness)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with notation as in Definition 81.37, and let I be an $\mathsf{Ideal}^{\uparrow}$ carried predicate over R. Assume the ideal certificate supplies zero membership and classifier transport, and the ring certificate supplies the additive inverse and zero rows. If $C(x)$, then $Q_I(x, x)$.*

Proof. Unfold Definition 81.37. The two endpoint carrier witnesses are both the given evidence $C(x)$.

It remains to show $I(x -_R x)$. By the additive inverse row in the underlying ring certificate, $x +_R (-_R x)$ is classified with 0_R. The ideal zero row gives $I(0_R)$, and classifier symmetry orients the comparison from 0_R to $x -_R x$.

Classifier transport for I carries zero membership across this edge. Repacking the two carrier witnesses with the transported ideal membership gives $Q_I(x, x)$. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealQuotientKernel diagonal exactness`

Theorem 81.39 (Ideal quotient-kernel transport surface)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with notation as in Definition 81.37, and let I be an $\mathsf{Ideal}^{\uparrow}$ carried predicate over R. Assume the ring certificate supplies carrier transport, additive inverse congruence, addition congruence, and the classifier-equivalence rows, and assume the ideal certificate supplies classifier transport. If $Q_I(x, y)$, $x \sim_R x'$, and $y \sim_R y'$, then $Q_I(x', y')$.*

Proof. Unfold Definition 81.37. From $Q_I(x, y)$ we have $C(x)$, $C(y)$, and $I(x -_R y)$.

Carrier transport along $x \sim_R x'$ and $y \sim_R y'$ gives $C(x')$ and $C(y')$. Additive inverse congruence sends $y \sim_R y'$ to $-_R y \sim_R -_R y'$, and addition congruence combines this with $x \sim_R x'$ to obtain

$$x -_R y \sim_R x' -_R y'.$$

The ideal classifier-transport row carries $I(x -_R y)$ across this subtraction comparison, giving $I(x' -_R y')$. Pairing this membership with the transported carriers gives $Q_I(x', y')$. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealQuotientKernel endpoint transport`

Theorem 81.40 (Ideal quotient-kernel multiplication descent)**.** *Let R carry a* $\mathsf{Ring}^{\uparrow}$ *certificate with notation as in Definition 81.37, and let I be an* $\mathsf{Ideal}^{\uparrow}$ *carried predicate over R. Assume the ring certificate supplies multiplication carrier rows and the product-difference classifier row, and assume the ideal certificate supplies classifier transport, additive closure, and left and right absorption by every carried endpoint. If $Q_I(a, a')$ and $Q_I(b, b')$, then the IdealUp rows give*

$$I((a \cdot_R b) -_R (a' \cdot_R b')).$$

Together with the RingUp multiplication carrier rows, this repacks as

$$Q_I(a \cdot_R b, a' \cdot_R b').$$

Ten-field fit: traditional target quotient-kernel multiplication descent; BEDC source $\mathsf{Ring}^{\uparrow}$ *plus* $\mathsf{Ideal}^{\uparrow}$ *over* BHist*; carrier Q_I endpoints; classifier $\sim_R$; stability absorption, additive closure, and classifier transport; ledger two representative differences and two absorbed products; core theorem this block; exactness the displayed repacking; standard bridge absent; status proof target.*

Lean4 ✓ `BEDC.Derived.IdealUp.IdealQuotientKernel multiplication descent`

Proof. Unfold Definition 81.37. From $Q_I(a, a')$ and $Q_I(b, b')$ we obtain carried endpoints $C(a)$, $C(a')$, $C(b)$, and $C(b')$, together with ideal memberships for the representative differences. Write

$$d_a := a -_R a', \qquad d_b := b -_R b'.$$

Right absorption applies $I(d_a)$ against the carried endpoint b, giving $I(d_a \cdot_R b)$. Left absorption applies $I(d_b)$ against the carried endpoint a', giving $I(a' \cdot_R d_b)$. Additive closure combines these two absorbed products into membership of their ring sum.

The product-difference classifier row identifies that sum with $(a \cdot_R b) -_R (a' \cdot_R b')$. Classifier transport for the ideal predicate carries the combined membership across this comparison, yielding

$$I((a \cdot_R b) -_R (a' \cdot_R b')).$$

Finally, multiplication carrier rows applied to $C(a), C(b)$ and to $C(a'), C(b')$ give the two product carrier witnesses. Pairing those witnesses with the transported product-difference membership is exactly $Q_I(a \cdot_R b, a' \cdot_R b')$. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealQuotientKernel product difference membership`

Theorem 81.41 (Ideal quotient-ring export surface)**.** *Let R carry a* $\mathsf{Ring}^{\uparrow}$ *certificate and let I be an* $\mathsf{Ideal}^{\uparrow}$ *carried predicate over R, with Q_I as in Definition 81.37. The IdealUp rows export the full quotient-free kernel surface consumed by* $\mathsf{QuotientRing}^{\uparrow}$ *in chapter 83:*

1. *diagonal exactness for every carried endpoint x:*

$$C(x) \Longrightarrow Q_I(x, x);$$

2. *endpoint transport along the RingUp classifier:*

$$Q_I(x, y) \wedge x \sim_R x' \wedge y \sim_R y' \Longrightarrow Q_I(x', y');$$

3. *additive representative descent:*

$$Q_I(a, a') \wedge Q_I(b, b') \Longrightarrow Q_I(a +_R b, a' +_R b');$$

4. *negation representative descent:*

$$Q_I(a, a') \Longrightarrow Q_I(-_R a, -_R a');$$

5. *multiplication representative descent:*

$$Q_I(a, a') \wedge Q_I(b, b') \Longrightarrow Q_I(a \cdot_R b, a' \cdot_R b').$$

The zero-fiber and preimage constructions of Definition 81.35, Definition 81.36, Definition 81.46, and Definition 81.47 therefore produce concrete inputs to this same quotient-kernel surface.

Lean4 ✓ `BEDC.Derived.IdealUp.IdealQuotientKernel export surface`

Proof. The diagonal component is exactly Definition 81.38. The endpoint-transport component is exactly Definition 81.39.

The additive component is the additive representative row of the same checked export surface. It combines the two input kernel witnesses by the ideal additive row, transports across the RingUp comparison between the sum of representative differences and the difference of sums, and repacks the two sum carriers. This is the surface used by Definition 83.3.

The negation component is the negation representative row of the same checked export surface. It applies the ideal additive-inverse row to the representative difference, transports across the RingUp comparison between the negated difference and the difference of negated representatives, and repacks the two negated carriers.

The multiplication component is exactly Definition 81.40, which isolates the product-difference membership used in Definition 83.2.

Together these five rows are the diagonal, endpoint transport, additive descent, negation descent, and multiplication descent projections returned by the checked Lean package. Thus an IdealUp predicate, including one obtained as a zero fiber or as a ring-map preimage, supplies the concrete quotient-kernel source required before any quotient carrier is formed. □

Theorem 81.42 (Principal generated ideal is least over its generator)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate over BHist, with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let a be a carried generator, let $\langle a \rangle_R$ be the principal two-sided generated ideal predicate of Definition 81.30, and let $I : \mathsf{BHist} \to \mathsf{Prop}$ be an $\mathsf{Ideal}^{\uparrow}$ carried predicate over R in the sense of Definition 81.1. If $I(a)$, then*

$$\langle a \rangle_R \preceq_R I.$$

Equivalently, every endpoint admitted by the finite signed two-sided monomial ledger defining $\langle a \rangle_R$ is a member of any carried ideal predicate that contains the generator a.

Proof. By Definition 81.21, it is enough to fix an endpoint $z : \mathsf{BHist}$ and show that a witness for $\langle a \rangle_R(z)$ yields a witness for $I(z)$.

Unpack the principal witness from Definition 81.30. It consists of a finite $\mathsf{HistSpine}$, carried coefficient rows $C(\ell_i)$ and $C(r_i)$, a sign row at each position, a finite additive fold of the signed rows, and a final classifier edge from that fold to z.

First consider one unsigned monomial row. From the assumed generator membership $I(a)$ and the left ambient absorption row of the $\mathsf{Ideal}^{\uparrow}$ certificate, applied to the carried coefficient $C(\ell_i)$, obtain

$$I(\ell_i \cdot_R a).$$

Applying the right ambient absorption row to the carried coefficient $C(r_i)$ gives

$$I((\ell_i \cdot_R a) \cdot_R r_i).$$

The ambient $\mathsf{Ring}^{\uparrow}$ associativity and classifier-transport row for I read this as membership of the displayed two-sided monomial $\ell_i \cdot_R a \cdot_R r_i$ used in the principal ledger.

If the sign row is positive, this is the required membership for the signed row. If the sign row is negative, the additive-inverse row of the $\mathsf{Ideal}^{\uparrow}$ certificate sends the monomial membership to membership of its additive inverse. Thus every signed row in the finite principal ledger lies in I.

Now fold the finite spine. For the empty spine, the $\mathsf{Ideal}^{\uparrow}$ zero-membership row gives $I(0_R)$, matching the empty fold. For a nonempty spine, induct along the displayed finite order of the ledger: the induction hypothesis gives membership of the partial fold, the preceding paragraph gives membership of the next signed row, and the additive-closure row of the $\mathsf{Ideal}^{\uparrow}$ certificate gives membership of the extended fold. Hence the whole finite additive fold lies in I.

Finally, project the classifier edge from the principal witness, unfold the classifier-transport row of the $\mathsf{Ideal}^{\uparrow}$ certificate, and repack the fold membership across that edge as $I(z)$. Since z and its principal witness were arbitrary, Definition 81.21 gives $\langle a \rangle_R \preceq_R I$. □

Definition 81.43 (Finite ideal-intersection predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let $xs : \mathsf{HistSpine}$ be a finite BEDC-history spine, and let $\mathcal{I}$ assign to every position $i : \mathsf{Pos}(xs)$ a predicate $\mathcal{I}_i : \mathsf{BHist} \to \mathsf{Prop}$ over the same ring data. The finite relative intersection predicate is*

$$\mathsf{FinIdealMeet}_{C,xs,\mathcal{I}}(x) \iff C(x) \wedge \forall i : \mathsf{Pos}(xs).\, \mathcal{I}_i(x).$$

The carrier conjunct makes the empty finite spine denote the ambient carried ring predicate, while a nonempty spine is the usual pointwise intersection of the displayed ideal predicates.

Lean4 (definition) `BEDC.Derived.IdealUp.FiniteIdealMeet`

Theorem 81.44 (Finite ideal intersection closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate as in chapter 43, with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let $xs : \mathsf{HistSpine}$ be a finite BEDC-history spine, and let $\mathcal{I}$ assign to every position $i : \mathsf{Pos}(xs)$ a predicate $\mathcal{I}_i : \mathsf{BHist} \to \mathsf{Prop}$. Assume that, for every $i : \mathsf{Pos}(xs)$, the predicate $\mathcal{I}_i$ is an $\mathsf{Ideal}^{\uparrow}$ predicate over the same $\mathsf{Ring}^{\uparrow}$ data, with the rows specified in section 81.2: carrier support, zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and left and right absorption by every carried ring endpoint. For*

$$K(x) \iff \mathsf{FinIdealMeet}_{C,xs,\mathcal{I}}(x),$$

the predicate K is an $\mathsf{Ideal}^{\uparrow}$ *predicate over R. Explicitly, K has carrier support and the rows*

$$K(0_R), \qquad K(x) \wedge K(y) \Longrightarrow K(x +_R y), \qquad K(x) \Longrightarrow K(-_R x),$$

$$K(x) \wedge K(y) \Longrightarrow K(x \cdot_R y), \qquad K(x) \wedge x \sim_R y \Longrightarrow K(y),$$

and, for every r with $C(r)$,

$$K(x) \Longrightarrow K(r \cdot_R x) \wedge K(x \cdot_R r).$$

Lean4 ✓ `BEDC.Derived.IdealUp.FiniteIdealMeet closure rows`

Proof. Unfold Definition 81.43. The carrier support row is the first conjunct of $K(x)$.

For zero membership, the ring certificate supplies $C(0_R)$. Fix a position $i : \mathsf{Pos}(xs)$. The zero row in the ith ideal certificate gives $\mathcal{I}_i(0_R)$. Since i was arbitrary, 0_R satisfies every predicate in the finite family, and together with $C(0_R)$ this is $K(0_R)$.

For additive closure, assume $K(x)$ and $K(y)$. The carrier conjuncts give $C(x)$ and $C(y)$, so the additive closure row of the ring certificate gives $C(x +_R y)$. For an arbitrary position i, the universal conjuncts of $K(x)$ and $K(y)$ give $\mathcal{I}_i(x)$ and $\mathcal{I}_i(y)$. The additive closure row of the ith ideal certificate gives $\mathcal{I}_i(x +_R y)$. Thus every indexed predicate holds at $x +_R y$, and the carrier witness just obtained repacks as $K(x +_R y)$.

For additive inverse closure, assume $K(x)$. The ring inverse-closure row gives $C(-_R x)$ from $C(x)$. For each position i, the inverse row of the ith ideal certificate gives $\mathcal{I}_i(-_R x)$ from $\mathcal{I}_i(x)$. Hence all finite-family predicates hold at $-_R x$, and $K(-_R x)$ follows.

For internal multiplication closure, assume $K(x)$ and $K(y)$. The ring multiplication-closure row gives $C(x \cdot_R y)$ from $C(x)$ and $C(y)$. For every position i, the universal conjuncts give $\mathcal{I}_i(x)$ and $\mathcal{I}_i(y)$, and the internal multiplication row of the ith ideal certificate gives $\mathcal{I}_i(x \cdot_R y)$. Therefore $K(x \cdot_R y)$.

For classifier transport, assume $K(x)$ and $x \sim_R y$. Carrier transport from the naming certificate underlying the $\mathsf{Ring}^{\uparrow}$ data carries $C(x)$ along $x \sim_R y$ to obtain $C(y)$. For each position i, the classifier-transport row of the ith ideal certificate gives $\mathcal{I}_i(y)$ from $\mathcal{I}_i(x)$ and the same classifier witness. Pairing these facts gives $K(y)$.

For absorption, assume $K(x)$ and $C(r)$. The ring multiplication-closure row gives both $C(r \cdot_R x)$ and $C(x \cdot_R r)$. For each position i, left absorption in the ith ideal certificate gives $\mathcal{I}_i(r \cdot_R x)$ from $C(r)$ and $\mathcal{I}_i(x)$, and right absorption gives $\mathcal{I}_i(x \cdot_R r)$ from the same data. Hence the finite family holds at both absorbed endpoints. Together with the carrier witnesses, this gives $K(r \cdot_R x)$ and $K(x \cdot_R r)$.

These are exactly the carrier, additive sub-rng, multiplicative sub-rng, classifier-stability, and two-sided ambient absorption rows required of an $\mathsf{Ideal}^{\uparrow}$ predicate over the fixed $\mathsf{Ring}^{\uparrow}$ certificate. □

Theorem 81.45 (Finite ideal meet quotient-ring kernel scope)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let $xs : \mathsf{HistSpine}$ be a finite BEDC-history spine, and let $\mathcal{I}$ assign to every position $i : \mathsf{Pos}(xs)$ a predicate $\mathcal{I}_i : \mathsf{BHist} \to \mathsf{Prop}$ over the same ring data. Assume that every indexed predicate $\mathcal{I}_i$ is an* $\mathsf{Ideal}^{\uparrow}$ *predicate over these ring rows, and put*

$$K(x) \Longleftrightarrow \mathsf{FinIdealMeet}_{C,xs,\mathcal{I}}(x).$$

Let Q_K be the quotient-kernel source package of Definition 81.37. The package Q_K has the same diagonal, endpoint-transport, and multiplication-descent scope as the quotient-kernel packages built

from any other $\mathsf{Ideal}^{\uparrow}$ *predicate. Thus* $\mathsf{QuotientRing}^{\uparrow}$ *may consume finite intersections of ideals through the quotient-free kernel interface, with no finite-meet-specific quotient carrier or quotient primitive.*

Proof. By Definition 81.44, the predicate K is an $\mathsf{Ideal}^{\uparrow}$ predicate over the same $\mathsf{Ring}^{\uparrow}$ certificate as the finite family $\mathcal{I}$. This supplies the carrier support, sub-rng, classifier-stability, and two-sided ambient absorption rows required by the quotient-kernel source package.

Apply Definition 81.38 to K to obtain diagonal exactness. Apply Definition 81.39 to K to obtain endpoint transport along $\sim_R$ for carried endpoints.

Finally apply Definition 81.40 to K. The multiplication row is therefore the same product-difference membership row used by arbitrary $\mathsf{Ideal}^{\uparrow}$ predicates, so the quotient-ring consumer reads the finite meet only through $Q_K(x, y) \iff C(x) \wedge C(y) \wedge K(x -_R y)$. □

Definition 81.46 (Ring map ideal preimage predicate)**.** *Let S and T carry* $\mathsf{Ring}^{\uparrow}$ *certificates, with carriers C_S, C_T, classifiers $\sim_S, \sim_T$, zeros $0_S, 0_T$, additions $+_S, +_T$, additive inverses $-_S, -_T$, and multiplications $\cdot_S, \cdot_T$. Let J be an* $\mathsf{Ideal}^{\uparrow}$ *carried predicate over T in the sense of section 81.1. For a function $f : S \to T$, the source-carried ideal preimage predicate is*

$$\mathsf{Preim}^{\mathrm{ideal}}_{f,J}(x) \iff C_S(x) \wedge J(f(x)).$$

The first component records source-carrier evidence, and the second component records membership of the image endpoint in the target ideal.

Theorem 81.47 (Ring map ideal preimage IdealUp closure)**.** *Let S and T carry* $\mathsf{Ring}^{\uparrow}$ *certificates as in chapter 43, with notation as in Definition 81.46. Let $f : S \to T$ satisfy carrier preservation and classifier preservation on carried source endpoints:*

$$C_S(x) \Longrightarrow C_T(f(x))$$

and

$$C_S(x) \wedge C_S(y) \wedge x \sim_S y \Longrightarrow f(x) \sim_T f(y).$$

Assume also that f preserves zero, addition, additive inverse, and multiplication on carried source endpoints:

$$f(0_S) \sim_T 0_T,$$
$$C_S(x) \wedge C_S(y) \Longrightarrow f(x +_S y) \sim_T f(x) +_T f(y),$$
$$C_S(x) \Longrightarrow f(-_S x) \sim_T -_T f(x),$$

and

$$C_S(x) \wedge C_S(y) \Longrightarrow f(x \cdot_S y) \sim_T f(x) \cdot_T f(y).$$

Let J be an $\mathsf{Ideal}^{\uparrow}$ *predicate over T. Assume its ideal certificate supplies the rows specified in section 81.2: carrier support, zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and left and right absorption by every carried target ring endpoint. For $K := \mathsf{Preim}^{\mathrm{ideal}}_{f,J}$ from Definition 81.46, K is an* $\mathsf{Ideal}^{\uparrow}$ *predicate over the source ring S. Explicitly, K has carrier support and the rows*

$$K(0_S), \qquad K(x) \wedge K(y) \Longrightarrow K(x +_S y), \qquad K(x) \Longrightarrow K(-_S x),$$
$$K(x) \wedge K(y) \Longrightarrow K(x \cdot_S y), \qquad K(x) \wedge x \sim_S y \Longrightarrow K(y),$$

and, for every r with $C_S(r)$,

$$K(x) \Longrightarrow K(r \cdot_S x) \wedge K(x \cdot_S r).$$

Lean4 ✓ BEDC.Derived.IdealUp.RingMapIdealPreimage closure rows

Proof. Unfold Definition 81.46. Carrier support is the first component of a K witness.

For zero membership, the source $\mathsf{Ring}^{\uparrow}$ certificate carries 0_S. The target ideal zero row gives $J(0_T)$. The zero-preservation row gives $f(0_S) \sim_T 0_T$, and target classifier symmetry from Definition 9.7 gives $0_T \sim_T f(0_S)$. Target ideal classifier transport therefore gives $J(f(0_S))$, so $K(0_S)$.

For additive closure, assume $K(x)$ and $K(y)$. The source carrier components give $C_S(x)$ and $C_S(y)$, hence the source ring certificate carries $x +_S y$. The target ideal additive row gives $J(f(x) +_T f(y))$ from $J(f(x))$ and $J(f(y))$. The addition-preservation row gives $f(x +_S y) \sim_T f(x) +_T f(y)$, and target classifier symmetry reverses this comparison. Applying target ideal classifier transport gives $J(f(x +_S y))$. Together with the source carrier witness this is $K(x +_S y)$.

For additive inverse closure, assume $K(x)$. Source inverse closure carries $-_S x$. The target ideal inverse row gives $J(-_T f(x))$. The inverse-preservation row gives $f(-_S x) \sim_T -_T f(x)$, whose symmetric form transports $J(-_T f(x))$ to $J(f(-_S x))$. Thus $K(-_S x)$.

For internal multiplication closure, assume $K(x)$ and $K(y)$. Source multiplication closure carries $x \cdot_S y$. The target ideal internal multiplication row gives $J(f(x) \cdot_T f(y))$. The multiplication-preservation row gives $f(x \cdot_S y) \sim_T f(x) \cdot_T f(y)$, and target classifier symmetry orients this comparison for ideal transport. Hence $J(f(x \cdot_S y))$, so $K(x \cdot_S y)$.

For source classifier transport, assume $K(x)$ and $x \sim_S y$. Source carrier transport from Definition 9.7 carries $C_S(x)$ along $x \sim_S y$ to obtain $C_S(y)$. Classifier preservation gives $f(x) \sim_T f(y)$. Target ideal classifier transport sends $J(f(x))$ along this comparison to $J(f(y))$. Therefore $K(y)$.

For left absorption, assume $K(x)$ and $C_S(r)$. Source multiplication closure carries $r \cdot_S x$, and carrier preservation gives $C_T(f(r))$. The target ideal left-absorption row gives $J(f(r) \cdot_T f(x))$ from $C_T(f(r))$ and $J(f(x))$. Multiplication preservation gives $f(r \cdot_S x) \sim_T f(r) \cdot_T f(x)$; after target classifier symmetry, ideal transport yields $J(f(r \cdot_S x))$. Thus $K(r \cdot_S x)$.

For right absorption, the same data carry $x \cdot_S r$ in the source, and the target ideal right-absorption row gives $J(f(x) \cdot_T f(r))$. Multiplication preservation for $x \cdot_S r$, followed by target classifier symmetry and ideal transport, gives $J(f(x \cdot_S r))$. Hence $K(x \cdot_S r)$.

The displayed carrier support, zero, additive, inverse, multiplicative, classifier-transport, and two-sided absorption rows are exactly the $\mathsf{Ideal}^{\uparrow}$ certificate rows listed in section 81.2 for a predicate over the source $\mathsf{Ring}^{\uparrow}$ certificate. □

Theorem 81.48 (Ring map ideal preimage quotient-kernel export surface)**.** *Let S and T carry $\mathsf{Ring}^{\uparrow}$ certificates as in chapter 43, with notation as in Definition 81.46. Let $f : S \to T$ satisfy the carrier-preservation, classifier-preservation, zero-preservation, addition-preservation, additive-inverse-preservation, and multiplication-preservation hypotheses of Definition 81.47. Let J be an $\mathsf{Ideal}^{\uparrow}$ predicate over T with the carrier support, zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and two-sided target absorption rows listed in section 81.2. For $K := \mathsf{Preim}^{\mathrm{ideal}}_{f,J}$, let Q_K be the quotient-kernel source package of Definition 81.37. Then Q_K exports the five quotient-free rows consumed by $\mathsf{QuotientRing}^{\uparrow}$:*

1. *diagonal exactness for every carried source endpoint x:*

$$C_S(x) \Longrightarrow Q_K(x, x);$$

2. *endpoint transport along the source classifier:*

$$Q_K(x, y) \wedge x \sim_S x' \wedge y \sim_S y' \Longrightarrow Q_K(x', y');$$

3. additive representative descent:

$$Q_K(a, a') \wedge Q_K(b, b') \Longrightarrow Q_K(a +_S b, a' +_S b');$$

4. negation representative descent:

$$Q_K(a, a') \Longrightarrow Q_K(-_S a, -_S a');$$

5. multiplication representative descent:

$$Q_K(a, a') \wedge Q_K(b, b') \Longrightarrow Q_K(a \cdot_S b, a' \cdot_S b').$$

Thus a ring-map ideal preimage can be passed to the quotient-ring construction through the same quotient-kernel interface as any source-side $\mathsf{Ideal}^{\uparrow}$ *predicate.*

Proof. Apply Definition 81.47 to the displayed hypotheses. This proves that K is an $\mathsf{Ideal}^{\uparrow}$ predicate over the source $\mathsf{Ring}^{\uparrow}$ certificate on S.

Instantiate Definition 81.41 with the source ring S and the ideal predicate K. The quotient-kernel source package in that theorem is exactly the relation Q_K obtained from Definition 81.37.

Reading off the five displayed components gives diagonal exactness, endpoint transport, additive representative descent, negation representative descent, and multiplication representative descent for Q_K. No quotient carrier or preimage-specific quotient primitive is introduced; the consumer sees only the quotient-free kernel rows listed above. □

Theorem 81.49 (Finite preimage meet quotient-kernel export)**.** *Let S carry a* $\mathsf{Ring}^{\uparrow}$ *certificate with carrier C_S, classifier $\sim_S$, addition $+_S$, additive inverse $-_S$, zero 0_S, and multiplication $\cdot_S$. Let $xs : \mathsf{HistSpine}$ be finite. For every $i : \mathsf{Pos}(xs)$, let T_i carry a* $\mathsf{Ring}^{\uparrow}$ *certificate with target carrier C_i, classifier $\sim_i$, zero 0_i, addition $+_i$, additive inverse $-_i$, and multiplication $\cdot_i$; let $f_i : S \to T_i$ be a carried ring map in the sense of Definition 81.47; and let J_i be an* $\mathsf{Ideal}^{\uparrow}$ *predicate over T_i. Define the source preimage rows*

$$P_i(x) \Longleftrightarrow \mathsf{Preim}^{\mathrm{ideal}}_{f_i, J_i}(x)$$

and their finite source meet

$$K(x) \Longleftrightarrow \mathsf{FinIdealMeet}_{C_S, xs, P}(x).$$

Then K is an $\mathsf{Ideal}^{\uparrow}$ *predicate over S, and the predicate K supplies the quotient-free kernel surface consumed by* $\mathsf{QuotientRing}^{\uparrow}$ *through Definition 81.41.*

Proof. Fix a position $i : \mathsf{Pos}(xs)$. The hypotheses on f_i are exactly the carrier, classifier, zero, addition, inverse, and multiplication preservation rows required by Definition 81.47. Applying that theorem to f_i and J_i gives an $\mathsf{Ideal}^{\uparrow}$ certificate for the source predicate P_i over the fixed ring S.

The preceding construction is pointwise in i, so every row in the finite spine is now an $\mathsf{Ideal}^{\uparrow}$ predicate over the same source $\mathsf{Ring}^{\uparrow}$ certificate. Apply Definition 81.44 to the family P to obtain an $\mathsf{Ideal}^{\uparrow}$ certificate for K.

Finally instantiate Definition 81.41 with this resulting predicate K. The export theorem returns the diagonal, endpoint transport, additive descent, negation descent, and multiplication descent rows for the kernel relation generated by K, which is the quotient-free surface required before $\mathsf{QuotientRing}^{\uparrow}$ forms its quotient carrier. □

Theorem 81.50 (Ideal quotient-kernel absorption closure)**.** *Let R carry a* $\mathsf{Ring}^{\uparrow}$ *certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I be an* $\mathsf{Ideal}^{\uparrow}$ *carried predicate over R, and define*

$$x -_R y := x +_R (-_R y), \qquad Q_I(x, y) \iff C(x) \wedge C(y) \wedge I(x -_R y).$$

Assume the ring certificate supplies multiplication carrier closure, carrier transport, classifier symmetry, subtraction congruence, and the two absorption-difference rows

$$(r \cdot_R x) -_R (r \cdot_R y) \sim_R r \cdot_R (x -_R y)$$

and

$$(x \cdot_R r) -_R (y \cdot_R r) \sim_R (x -_R y) \cdot_R r.$$

Assume the ideal certificate supplies classifier transport and left and right absorption by every carried ring endpoint. Then

$$C(r) \wedge Q_I(x, y) \Longrightarrow Q_I(r \cdot_R x, r \cdot_R y) \wedge Q_I(x \cdot_R r, y \cdot_R r).$$

Proof. Unfold the displayed definition of Q_I. From $Q_I(x, y)$ obtain $C(x)$, $C(y)$, and $I(x -_R y)$. The multiplication carrier row applied to $C(r)$ with $C(x)$ and $C(y)$ gives the carried endpoints $C(r \cdot_R x)$, $C(r \cdot_R y)$, $C(x \cdot_R r)$, and $C(y \cdot_R r)$.

For the left-multiplied pair, ideal left absorption gives $I(r \cdot_R (x -_R y))$ from $C(r)$ and $I(x -_R y)$. The left absorption-difference row compares $(r \cdot_R x) -_R (r \cdot_R y)$ with $r \cdot_R (x -_R y)$. Classifier symmetry orients this comparison from the absorbed representative difference to the displayed product difference, and ideal classifier transport yields

$$I((r \cdot_R x) -_R (r \cdot_R y)).$$

For the right-multiplied pair, ideal right absorption gives $I((x -_R y) \cdot_R r)$. The right absorption-difference row compares $(x \cdot_R r) -_R (y \cdot_R r)$ with $(x -_R y) \cdot_R r$. Again classifier symmetry orients the comparison for the ideal transport row, giving

$$I((x \cdot_R r) -_R (y \cdot_R r)).$$

Pair the first transported membership with $C(r \cdot_R x)$ and $C(r \cdot_R y)$ to obtain $Q_I(r \cdot_R x, r \cdot_R y)$. Pair the second transported membership with $C(x \cdot_R r)$ and $C(y \cdot_R r)$ to obtain $Q_I(x \cdot_R r, y \cdot_R r)$. These two witnesses are exactly the claimed ambient left and right multiplication closure for the ideal quotient-kernel relation. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealQuotientKernel absorption closure`

Theorem 81.51 (Ideal finite meet, sum, and preimage lattice surface)**.** *Let R carry a* $\mathsf{Ring}^{\uparrow}$ *certificate over* BHist *with carrier C_R, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let $\mathcal{I}$ be a finite family of* $\mathsf{Ideal}^{\uparrow}$ *predicates over R, and let I and J be* $\mathsf{Ideal}^{\uparrow}$ *predicates over the same ambient ring. Let S be another* $\mathsf{Ring}^{\uparrow}$ *certificate over* BHist*, and let $f : S \to R$ satisfy the carrier, classifier, zero, addition, inverse, and multiplication preservation rows required in Definition 81.47. Then the predicates*

$$\mathsf{FinIdealMeet}_{C_R, xs, \mathcal{I}}, \qquad I +_R J, \qquad \mathsf{Preim}^{\mathrm{ideal}}_{f,J}$$

are $\mathsf{Ideal}^{\uparrow}$ *predicates over their ambient source rings: the finite meet and sum over* R*, and the preimage over* S*. For each resulting predicate* K *with ambient carrier* C*, classifier* $\sim$*, addition* $+$*, inverse* $-$*, zero* 0*, and multiplication* $\cdot$*, write* $x - y$ *for* $x + (-y)$ *and define the quotient-kernel package*

$$Q_K(x, y) \iff C(x) \wedge C(y) \wedge K(x - y)$$

Then Q_K *has the quotient-free surface consumed by* $\mathsf{QuotientRing}^{\uparrow}$*:*

$$C(x) \Longrightarrow Q_K(x, x),$$

$$Q_K(x, y) \wedge x \sim x' \wedge y \sim y' \Longrightarrow Q_K(x', y'),$$

and, for every carried ambient endpoint r*,*

$$C(r) \wedge Q_K(x, y) \Longrightarrow Q_K(r \cdot x, r \cdot y) \wedge Q_K(x \cdot r, y \cdot r).$$

Proof. For the finite meet branch, Definition 81.44 gives the $\mathsf{Ideal}^{\uparrow}$ rows for $\mathsf{FinIdealMeet}_{C_R, xs, \mathcal{I}}$. The quotient-kernel package for that predicate is then the same package used by arbitrary $\mathsf{Ideal}^{\uparrow}$ predicates, so its diagonal and endpoint-transport rows are the quotient-ring scope recorded in Definition 81.45.

For the sum branch, Definition 81.22 gives the $\mathsf{Ideal}^{\uparrow}$ rows for $I +_R J$. The quotient-ring consumer reads that predicate through the kernel package described in Definition 81.23, whose relation is still the displayed carrier-and-difference predicate.

For the preimage branch, Definition 81.47 gives the $\mathsf{Ideal}^{\uparrow}$ rows over the source ring S. Since the result is an ordinary $\mathsf{Ideal}^{\uparrow}$ predicate on the source carrier, the same quotient-kernel construction applies with the source carrier, classifier, subtraction, and multiplication rows.

Finally, Definition 81.50 supplies the common ambient absorption row for every branch after the corresponding $\mathsf{Ideal}^{\uparrow}$ predicate has been built. Thus the three lattice-facing constructors expose one uniform quotient-free package: diagonal, endpoint transport, and absorption, all expressed by $Q_K(x, y)$ and the ambient ring rows.

The ten-field fit is: traditional target ideal-lattice surface; BEDC source $\mathsf{Ring}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, and $\mathsf{QuotientRing}^{\uparrow}$ over BHist; carriers finite meet, sum decomposition, and preimage predicates; classifier the ambient ring classifier; stability the cited closure rows; ledger finite-position witnesses, additive decomposition witnesses, and image-membership witnesses; core theorem this block; exactness the displayed row package; standard bridge supplied by Definition 81.52; status paper target. □

81.3 Standard bridge

Theorem 81.52 (Ideal public surface standard bridge)**.** *Let* R *carry a* $\mathsf{Ring}^{\uparrow}$ *certificate with carrier* C*, classifier* $\sim_R$*, addition* $+_R$*, additive inverse* $-_R$*, zero* 0_R*, multiplication* $\cdot_R$*, and subtraction* $x -_R y := x +_R (-_R y)$*. Assume the ambient* $\mathsf{Ring}^{\uparrow}$ *certificate has a standard bridge to an ordinary ring surface. Then the public* $\mathsf{Ideal}^{\uparrow}$ *surface interprets over that standard ring as the ordinary ideal-predicate surface and re-encodes through the BEDC rows: carried predicates, zero membership, additive closure, additive inverse closure, internal multiplication, two-sided ambient absorption, finite meet, sum, ring-map preimage, principal generated ideals, and the quotient-kernel export surface. The bridge exports no host quotient carrier, host quotient primitive, or classifier-changing host equality to BEDC.*

Lean4 ✓ `BEDC.Derived.IdealUp.IdealUp StdBridge`

Proof. Unpack the $\mathsf{Ideal}^{\uparrow}$ carrier inventory of Definition 81.1. The ordinary surface reads the BEDC predicate as a carried subset of the standard ring supplied by the ambient $\mathsf{Ring}^{\uparrow}$ bridge. Carrier support, zero membership, addition, additive inverse, internal multiplication, classifier transport, and left and right absorption are exactly the rows displayed in section 81.2.

The finite-meet constructor is interpreted pointwise. Apply Definition 81.44: every indexed ordinary ideal row is carried back to the finite BEDC family, and the carrier conjunct supplies the empty-spine case. The sum constructor is interpreted by the additive decomposition ledger of Definition 81.22; its least-upper-bound surface is the ordinary inclusion property recorded in the same public BEDC rows.

The preimage constructor uses the ambient bridges on the source and target $\mathsf{Ring}^{\uparrow}$ certificates. Apply Definition 81.47: carrier preservation, classifier preservation, and operation preservation turn the standard inverse-image ideal into the BEDC source predicate. Principal generated ideals are supplied by Definition 81.33, whose generator ledger is again expressed only by carried endpoints, classifier transport, and ideal rows.

For the quotient-kernel part, unfold Definition 81.37. Its comparison data are precisely the two carrier witnesses $C(x)$ and $C(y)$ and membership of the displayed difference in the ideal predicate. Apply Definition 81.41; the exported diagonal, endpoint-transport, additive-descent, negation-descent, and multiplication-descent rows are the quotient-free standard comparison boundary.

Thus each public constructor is interpreted through the ambient standard ring bridge and then repacked by the BEDC certificate rows already cited in this chapter. Since the quotient-kernel surface exports only carried endpoints, classifier transport, and difference-membership rows, no host quotient carrier or host quotient primitive enters the BEDC interface. □

Lean4 ✓ `BEDC.Derived.IdealUp.IdealUp concrete to schema`

Closure status for $\mathsf{NameCert}_{\mathsf{Ideal}^{\uparrow}}$.

Constructive story: An ideal is carried as a predicate on the histories of an ambient $\mathsf{Ring}^{\uparrow}$ certificate, together with the rows saying that its members are ring-carried, contain zero, close under addition, additive inverse, internal multiplication, classifier transport, and multiplication by every carried ambient endpoint. The carrier accepts exactly predicates with those rows, while the quotient-kernel surface accepts pairs x, y only when both endpoints are carried and the displayed difference $x -_R y$ lies in the ideal; sameness is transported by the ambient ring classifier rather than by forming a quotient carrier. The source is the ambient ring certificate plus the carried ideal predicate, the pattern records finite meet, sum by additive decomposition, ring-map preimage, principal generated ideals, and the quotient-kernel diagonal and descent rows, and the ledger keeps membership witnesses, decomposition witnesses, image-membership witnesses, and difference-membership rows visible. The name-certificate obligations are supplied by zero membership for inhabitation, ambient classifier reflexivity, symmetry, and transitivity for endpoint comparison, and the ideal classifier-transport row for closure of membership under classified replacement. A pair history h lies in the signature gap of an $\mathsf{Ideal}^{\uparrow}$ token p when the source-domain accepts the ambient ring endpoints and ideal predicate, the signature relation pairs the pair with an answer quotient-kernel package and evidence ledger, and token introduction names that answer as p; unfolded, the endpoint difference is a displayed ideal member and all additive, negation, and multiplication descent rows are those encoded by p. The standard bridge reads the BEDC predicate as an ordinary ideal predicate over the standard ring supplied by the ambient $\mathsf{Ring}^{\uparrow}$ bridge and reads it back through the same row inventory, while explicitly exporting no host quotient carrier. The chapter registers this carried-predicate and quotient-kernel construction under the name $\mathsf{Ideal}^{\uparrow}$; ideals remain predicates with transport and absorption rows over existing ring histories, with no host quotient primitive or classifier-changing equality introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Ideal}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature IdealUp boundary covers carried predicates, finite meet, sum, preimage, principal ideals, the quotient-kernel export surface, and the paper-level standard bridge of Definition 81.52.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Ideal}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.IdealUp.IdealQuotientKernel\_export\_surface`

Bridge status: bridgeChecked

Not claimed: This chapter does not close host quotient carriers, full standard ideal theory, or host quotient primitives.

Upgrade path: No further upgrade – chapter at top of formal axis.

The $\mathsf{Ideal}^{\uparrow}$ packet consumes the $\mathsf{Ring}^{\uparrow}$ carrier, classifier, and operation rows of chapter 43. It supplies the kernel row used by chapter 83, so the quotient-ring route reads the ideal certificate as a ring-indexed kernel surface rather than as an isolated naming packet.

Theorem 81.53 (Ideal ring carrier dependency)**.** *Any* $\mathsf{Ideal}^{\uparrow}$ *absorption read must expose the* $\mathsf{Ring}^{\uparrow}$ *multiplication surface of chapter 43 before it consumes ambient products* $r \cdot_R x$ *or* $x \cdot_R r$*. When the same read is used as a kernel or submodule-like row over a fixed scalar carrier, it must also expose the* $\mathsf{Module}^{\uparrow}$ *scalar-action surface of chapter 46. The dependency is a carrier route for absorption data, not a new algebraic theorem about rings or modules.*

Proof. Project the $\mathsf{Ideal}^{\uparrow}$ carrier along its absorption rows. The only available ambient products are read through the displayed $\mathsf{Ring}^{\uparrow}$ multiplication surface, so the absorption consumer must first expose that sibling route.

For a kernel or submodule-like consumption, project the scalar-action row in the same carrier reading. The $\mathsf{Module}^{\uparrow}$ surface records the scalar action over the fixed scalar carrier, and the ideal read merely reuses that route to name the absorption pattern. No additional ring or module property is asserted. □

Chapter 82

A Concrete Naming Certificate for $\mathsf{QuotientGroup}^{\uparrow}$

The quotient-group interface $\mathsf{QuotientGroup}^{\uparrow}$ packages the carrier of cosets of a normal subgroup of a group. It depends on $\mathsf{NameCert}_{\mathsf{Subgroup}^{\uparrow}}$ (chapter 80) plus the normality witness, and produces a psame-classifier on cosets without invoking host-level `Quot`-soundness.

82.1 Carrier definition

Definition 82.1 (QuotientGroup singleton carrier)**.** *For the concrete singleton quotient-group object over histories, the carrier is the empty-history class*

$$Q_{\mathsf{e}}(h) \iff \mathsf{hsame}(h, \mathsf{e}).$$

Lean4 (definition) `BEDC.Derived.QuotientGroupUp.QuotientGroupSingletonCarrier`

Definition 82.2 (QuotientGroup singleton classifier)**.** *The concrete singleton quotient-group classifier is*

$$\rho_Q(h, k) \iff Q_{\mathsf{e}}(h) \wedge Q_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

It records both endpoint carrier witnesses together with their BEDC history-sameness witness.

Lean4 (definition) `BEDC.Derived.QuotientGroupUp.QuotientGroupSingletonClassifier`

Definition 82.3 (Centralizer coset carrier)**.** *For a BEDC multiplication operation* mul*, parameter a, and representative* repr*, the centralizer-coset carrier contains a history h exactly when* repr *centralizes a and h*hsamerepr*.*

Lean4 (definition) `BEDC.Derived.QuotientGroupUp.CentralizerCosetCarrier`

Definition 82.4 (Centralizer coset classifier)**.** *The centralizer-coset classifier relates two carried histories when both lie in the same representative carrier and are internally history-same.*

Lean4 (definition) `BEDC.Derived.QuotientGroupUp.CentralizerCosetClassifier`

Definition 82.5 (Centralizer-normalizer QuotientGroupUp carrier)**.** *In the BEDC history-level* $\mathsf{Group}^{\uparrow}$ *setting of Definition 80.27, let Z_a be the centralizer carrier of Definition 41.84 and let N_a be the centralizer normalizer carrier of Definition 41.95. The centralizer-normalizer* $\mathsf{QuotientGroup}^{\uparrow}$

representative carrier is N_a, with classifier $Q_{Z_a \triangleleft N_a}$ from Definition 80.33. Represented multiplication, unit, and inversion are given by $\mathsf{mul}(x, y)$, e, *and* $\mathsf{inv}(x)$.

The certificate ledger records the representative endpoints in N_a, the relative kernel witness $Z_a(\mathsf{mul}(\mathsf{inv}(x), y))$, and the tower rows for the lower centralizer subgroup, the upper normalizer subgroup, inclusion $Z_a \subseteq N_a$, and conjugation preservation of Z_a by carried elements of N_a. Thus the carrier is a concrete history-level representative system equipped with a classifier, not a host quotient type.

Theorem 82.6 (Centralizer-normalizer empty representative)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *whose represented unit is* e, *assume the unit, multiplication-congruence, and right-inverse laws used in Definition 82.5. Then the representative carrier N_a contains* e.

Proof. Unfold N_a as the centralizer normalizer carrier. The right-inverse law at e, together with the left unit law, identifies $\mathsf{inv}(\mathsf{e})$ with e.

For the forward conjugation clause, multiplication congruence and the unit laws transport $\mathsf{mul}(\mathsf{mul}(\mathsf{e}, x), \mathsf{inv}(\mathsf{e}))$ to x. The centralizer row for x can therefore be read as the required centralizer row for the conjugated word.

The inverse conjugation clause is the same calculation applied to $\mathsf{inv}(\mathsf{inv}(\mathsf{e}))$. The unit and right-inverse laws identify the outer inverse word with e, so the second normalizer clause reduces to the same centralizer transport. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer empty unit`

Theorem 82.7 (Centralizer-normalizer empty representative transport)**.** *Under the same BEDC history-level group laws, plus inverse congruence, every history t with* $\mathsf{ehsame}t$ *also lies in the representative carrier N_a.*

Proof. Apply Definition 82.6 to get $N_a(\mathsf{e})$.

For the forward normalizer clause at t, multiplication congruence transports $\mathsf{mul}(\mathsf{mul}(t, x), \mathsf{inv}(t))$ back to $\mathsf{mul}(\mathsf{mul}(\mathsf{e}, x), \mathsf{inv}(\mathsf{e}))$, using inverse congruence on the endpoint comparison $\mathsf{ehsame}t$. The empty representative row then supplies the required carried centralizer witness.

The inverse clause uses inverse congruence once more to compare $\mathsf{inv}(t)$ with $\mathsf{inv}(\mathsf{e})$, and again on the outer inverse. Multiplication congruence transports the whole inverse-conjugation word back to the empty representative word, where the previous theorem supplies the row. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer empty hsame transport unit`

Theorem 82.8 (Centralizer normalizer orbit-kernel quotient equivalence)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the hypotheses of Definition 80.32 and Definition 80.47, and for x, y :* BHist *with $N_a(x)$ and $N_a(y)$, the two representative classifiers on the carrier N_a agree:*

$$Q_{Z_a \leq N_a}(x, y) \Longleftrightarrow Q_{Z_a \triangleleft N_a}(x, y).$$

Proof. For the forward direction, expand Definition 80.31. The witness is a history z with $Z_a(z)$ and $\mathsf{hsame}(y, \mathsf{mul}(x, z))$, together with the endpoint rows $N_a(x)$ and $N_a(y)$.

Multiply the endpoint comparison on the left by $\mathsf{inv}(x)$. By associativity, the two-sided inverse law, the unit laws, and multiplication congruence, the word $\mathsf{mul}(\mathsf{inv}(x), y)$ is transported by hsame to z. The hsame transport row for the centralizer carrier therefore turns $Z_a(z)$ into $Z_a(\mathsf{mul}(\mathsf{inv}(x), y))$, which is exactly the kernel clause of $Q_{Z_a \triangleleft N_a}(x, y)$.

For the reverse direction, expand Definition 80.33. Let

$$w = \mathsf{mul}(\mathsf{inv}(x), y).$$

The kernel clause gives $Z_a(w)$, and the endpoint clauses give the same representative carrier rows $N_a(x)$ and $N_a(y)$.

Associativity, the left inverse law, the left unit law, and multiplication congruence rewrite $\mathsf{mul}(x, w)$ to y up to hsame. Thus w is the centralizer witness required by Definition 80.31, so $Q_{Z_a \leq N_a}(x, y)$ follows. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer orbit kernel equivalence iff`

Per-object template: traditional target quotient group by a normal subgroup; BEDC source $\mathsf{Group}^{\uparrow}$ plus the centralizer-normalizer $\mathsf{Subgroup}^{\uparrow}$ tower; carrier N_a; classifier either $Q_{Z_a \leq N_a}$ or $Q_{Z_a \triangleleft N_a}$; stability Definition 80.32, Definition 80.47, and Definition 82.8; ledger representative pair plus coset or kernel witness; core theorem list Definition 80.31, Definition 80.33, and Definition 80.27; exactness the displayed iff; standard bridge ordinary coset/kernel criterion; status ProofTarget.

Theorem 82.9 (Centralizer-normalizer QuotientGroupUp identity fiber)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the hypotheses of Definition 82.8, for every* $x : \mathsf{BHist}$ *the left identity fibers of the two representative quotient classifiers satisfy*

$$Q_{Z_a \leq N_a}(\mathsf{e}, x) \iff Q_{Z_a \triangleleft N_a}(\mathsf{e}, x) \iff Z_a(x),$$

and the right identity fibers satisfy

$$Q_{Z_a \leq N_a}(x, \mathsf{e}) \iff Q_{Z_a \triangleleft N_a}(x, \mathsf{e}) \iff Z_a(x).$$

Proof. For the left fiber, first compare the coset classifier with the relative-kernel classifier at (e, x). Apply Definition 82.8. The endpoint rows needed by that theorem are either fields of the classifier edge being transported or are supplied by the kernel relation itself.

Next identify the kernel classifier fiber. Apply Definition 80.35 and, at the Lean level, its empty-fiber form `BEDC.Derived.SubgroupUp.SubgroupCentralizerQuotientKernel_empty_fiber_iff`. This turns $Q_{Z_a \triangleleft N_a}(\mathsf{e}, x)$ into $Z_a(x)$. The group-level normalization behind the identity endpoint is `BEDC.Derived.GroupUp.group_inverse_identity`, which identifies the inverse of the represented identity with the identity before the relative kernel word is read.

For the right fiber, repeat the same transport at (x, e). The orbit-kernel equivalence passes between $Q_{Z_a \leq N_a}(x, \mathsf{e})$ and $Q_{Z_a \triangleleft N_a}(x, \mathsf{e})$, and the empty-right-fiber form `BEDC.Derived.SubgroupUp.SubgroupCentra` identifies the kernel classifier fiber with $Z_a(x)$. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer identity fiber iff`

Per-object template: traditional target quotient projection kernel; BEDC source $\mathsf{Group}^{\uparrow}$ + $\mathsf{Subgroup}^{\uparrow}$ + $\mathsf{QuotientGroup}^{\uparrow}$ over BHist; ambient sort BHist; carrier N_a; classifiers $Q_{Z_a \leq N_a}$ and $Q_{Z_a \triangleleft N_a}$; stability orbit-kernel equivalence plus identity-fiber transport; ledger identity representative and relative-kernel word; endpoint normalization by group inverse identity; exactness identity fiber equals centralizer; status ProofTarget.

Theorem 82.10 (Centralizer coset representative context classifier)**.** *If* e *and* repr *centralize* a *and* $\mathsf{reprhsamee}$*, then for histories* $l, h, r, k : \mathsf{BHist}$ *the representative centralizer-coset classifier of a three-part append context is equivalent to the four component representative carriers:*

$$\mathsf{CentralizerCosetClassifier}(\mathsf{mul}, a, \mathsf{repr}, \mathsf{append}(l, \mathsf{append}(h, r)), k) \iff \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{repr}, l) \wedge \mathsf{Centraliz}$$

The ten-field fit is: traditional target representative-level decomposition of a centralizer coset classifier across a three-part append context; BEDC source $\mathsf{Subgroup}^{\uparrow}$*,* $\mathsf{QuotientGroup}^{\uparrow}$*,* append*, and* hsame*; carrier centralizer-coset histories; classifier* $\mathsf{CentralizerCosetClassifier}$*; stability from empty-representative classifier transport, empty-representative context splitting, and carrier transport along* $\mathsf{reprhsamee}$*; ledger the empty representative bridge plus the four endpoint carrier witnesses; core theorem this block; exactness the displayed iff; downstream consumer nested quotient-coset context normalization; status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, apply Definition 82.16 to transport the representative classifier to the empty representative. Unfold Definition 82.4. The left endpoint is the empty-representative carrier of $\mathsf{append}(l, \mathsf{append}(h, r))$, and the right endpoint is the empty-representative carrier of k.

Apply Definition 82.21 to split the left endpoint into empty-representative carriers for l, h, and r. Then apply Definition 82.18 to transport those three carriers, and the right endpoint carrier for k, back to the representative carrier.

Conversely, transport the four representative carriers to empty-representative carriers with Definition 82.18. The reverse direction of Definition 82.21 rebuilds the empty-representative carrier of the nested append endpoint. Together with the empty-representative carrier of k, the unfolded classifier is obtained by composing both endpoint comparisons through e. Transporting back with Definition 82.16 gives the representative classifier. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCosetClassifier representative context classifier iff`

82.2 The certificate

Theorem 82.11 (QuotientGroup singleton semantic naming certificate)**.** *The singleton quotient-group carrier and classifier form a semantic naming certificate whose source, pattern, and ledger predicates are all* Q_{e}*.*

Proof. The inhabited endpoint is e, witnessed by reflexive $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. Reflexivity of the classifier packages the source carrier twice with reflexive $\mathsf{hsame}(h, h)$. Symmetry swaps the endpoint carriers and reverses the hsame component. Transitivity composes the two hsame components and keeps the outer endpoint carrier witnesses. Carrier transport along a classifier edge is the right endpoint carrier field. Since the semantic source, pattern, and ledger predicates are the same singleton predicate, their soundness clauses are direct projections of the source witness. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupSingleton semanticNameCert`

Theorem 82.12 (QuotientGroup singleton normalizer orbit classifier collapse)**.** *For histories* $x, y : \mathsf{BHist}$*, in the concrete singleton history group instance of Definition 41.3 and the singleton* $\mathsf{QuotientGroup}^{\uparrow}$ *classifier of Definition 82.2,*

$$x \sim_{N_{\mathsf{e}}} y \iff \rho_Q(x, y).$$

The ten-field fit is: traditional target the quotient of the terminal group by its terminal normalizer action; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *plus singleton* $\mathsf{QuotientGroup}^{\uparrow}$*; carrier* $Q_{\mathsf{e}} = A_{\mathsf{e}}$ *by Definitions 36.169, 41.3, and 82.1; classifier* ρ_Q *compared with* $\sim_{N_{\mathsf{e}}}$*; stability from Definition 41.151, Definition 82.11, and symmetry and transitivity for* hsame*; ledger the hidden conjugator endpoint; core theorem this block; exactness the displayed iff; downstream consumer first-isomorphism-style quotient-kernel exactness; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 41.151. It identifies the terminal normalizer orbit relation with $A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y)$. By Definitions 36.169, 41.3, and 82.1, this is the same endpoint data as $Q_{\mathsf{e}}(x) \wedge Q_{\mathsf{e}}(y)$.

For the forward direction, the orbit witness therefore supplies $Q_{\mathsf{e}}(x)$ and $Q_{\mathsf{e}}(y)$. Unfold Definition 82.2. The two carrier fields remain, and the final $\mathsf{hsame}(x, y)$ component is obtained by composing the singleton identifications $x\mathsf{hsamee}$ and $y\mathsf{hsamee}$, using symmetry on the second and then transitivity.

Conversely, a $\rho_Q(x, y)$ witness contains the two endpoint carrier fields. Under the same carrier identification these are $A_{\mathsf{e}}(x)$ and $A_{\mathsf{e}}(y)$, so the reverse direction of Definition 41.151 yields $x \sim_{N_{\mathsf{e}}} y$. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupSingletonClassifier normalizer orbit collapse iff`

Theorem 82.13 (QuotientGroup singleton continuation classifier)**.** *If* $\mathsf{Cont}(p, q, r)$*, then the singleton classifier at the continuation result reads back exactly as singleton carriers on the two inputs and the right endpoint:*

$$\mathsf{QuotientGroupSingletonClassifier}(r, h) \iff \mathsf{QuotientGroupSingletonCarrier}(p) \wedge \mathsf{QuotientGroupSingletonCarrier}(q) \wedge \mathsf{Qu}$$

Proof. Unfold the singleton carrier and classifier. A classifier witness gives $r\mathsf{hsamee}$, and empty-append inversion along $\mathsf{Cont}(p, q, r)$ splits this into the two input singleton carriers. Conversely, the two input carriers rebuild $r\mathsf{hsamee}$, and the endpoint carrier for h supplies the remaining classifier fields. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupSingletonClassifier continuation classifier iff`

Theorem 82.14 (QuotientGroup singleton classifier visible endpoint exclusion)**.** *For histories* $p, q, k : \mathsf{BHist}$*, no classifier edge can have a visible* $\mathsf{e0}$ *or* $\mathsf{e1}$ *endpoint on either side:*

$$\rho_Q(\mathsf{e0}(p), k), \quad \rho_Q(\mathsf{e1}(p), k), \quad \rho_Q(k, \mathsf{e0}(q)), \quad \rho_Q(k, \mathsf{e1}(q))$$

are all impossible.

Proof. Unfold the classifier. A visible left endpoint gives its left carrier field, which identifies $\mathsf{e0}(p)$ or $\mathsf{e1}(p)$ with e. A visible right endpoint gives the same contradiction from the right carrier field. Each case is excluded by constructor separation for generated BEDC histories. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupSingletonClassifier visible endpoint absurd`

Theorem 82.15 (Centralizer coset SemanticNameCert)**.** *If the representative* repr *centralizes* a*, then the centralizer-coset carrier, used as source, pattern, and ledger policy, with the centralizer-coset classifier forms a* $\mathsf{SemanticNameCert}$*.*

Proof. The representative itself inhabits the carrier. Reflexivity, symmetry, and transitivity of the classifier are inherited from hsame, while carrier respect follows from the carried right endpoint stored in the classifier. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCoset semanticNameCert`

Theorem 82.16 (Centralizer coset empty representative classifier transport)**.** *If the representative* repr *and the empty history both centralize a, and* reprhsamee*, then the centralizer-coset classifier for* repr *agrees with the centralizer-coset classifier for* e*:*

$$\mathsf{CentralizerCosetClassifier}(\mathsf{mul}, a, \mathsf{repr}, h, k) \iff \mathsf{CentralizerCosetClassifier}(\mathsf{mul}, a, \mathsf{e}, h, k).$$

Proof. Unfold the two coset classifiers. Each endpoint carrier consists of the chosen representative's centralizer witness and an endpoint comparison with that representative. The comparison reprhsamee converts the two endpoint comparisons in either direction, while the corresponding centralizer witness supplies the carrier field for the chosen representative. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCosetClassifier empty representative transport iff`

Theorem 82.17 (Centralizer coset empty representative classifier hsame endpoint transport)**.** *For histories h, k, h', k' : BHist, if the empty-representative centralizer-coset classifier relates h and k, and $h\mathsf{hsame}h'$ and $k\mathsf{hsame}k'$, then*

$$\mathsf{CentralizerCosetClassifier}(\mathsf{mul}, a, \mathsf{e}, h', k') \wedge h'\mathsf{hsamee} \wedge k'\mathsf{hsamee}.$$

Proof. The empty-representative classifier stores the empty centralizer witness together with $h$hsamee, $k$hsamee, and $h$hsame$k$. Compose the two endpoint comparisons with the symmetries of $h$hsameh' and $k$hsamek' to obtain the empty endpoints for h' and k'. Reuse the stored centralizer witness at both endpoints and compose the two empty endpoints to repack the classifier on (h', k'). □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCosetClassifier empty hsame endpoint transport`

Theorem 82.18 (Centralizer coset carrier empty representative transport)**.** *If the representative* repr *and the empty history both centralize a, and* reprhsamee*, then the centralizer-coset carrier for* repr *agrees with the centralizer-coset carrier for* e*:*

$$\mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{repr}, h) \iff \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{e}, h).$$

Proof. Unfold the two carrier predicates. A carrier witness for repr contains the centralizer witness for repr and the endpoint comparison $h$hsamerepr; composing with reprhsamee gives the empty-representative endpoint comparison. The reverse direction composes with symmetry of the same comparison and uses the centralizer witness for repr. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCosetCarrier empty representative transport iff`

Theorem 82.19 (Centralizer coset empty representative visible absurdity)**.** *For any multiplication operation* mul *and histories a, z, no visible one-step history is carried by the centralizer-coset carrier over the empty representative:*

$$\mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{e}, \mathsf{e0}(z)) \Rightarrow \bot, \qquad \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{e}, \mathsf{e1}(z)) \Rightarrow \bot.$$

Proof. Unfold the carrier only to read its endpoint comparison. A carried visible endpoint would give $\mathsf{e0}(z)\mathsf{hsamee}$ or $\mathsf{e1}(z)\mathsf{hsamee}$, respectively. Both are excluded by constructor separation for generated BEDC histories. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCosetCarrier empty representative visible absurd`

Theorem 82.20 (Centralizer coset empty continuation carrier pair)**.** *If* e *centralizes* a *and* $\mathsf{Cont}(p, q, r)$*, then the empty-representative centralizer-coset carrier of the continuation result is equivalent to the two endpoint carriers:*

$$\mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{e}, r) \iff \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{e}, p) \wedge \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{e}, q).$$

Proof. Forwards, the result carrier gives $r\mathsf{hsamee}$. Transport the displayed continuation to an empty result and apply empty-result inversion, giving $p\mathsf{hsamee}$ and $q\mathsf{hsamee}$; combine each with the assumed centralizer witness for e.

Conversely, the two endpoint carriers give $p\mathsf{hsamee}$ and $q\mathsf{hsamee}$. The displayed continuation is therefore determined by the empty append result, so $r\mathsf{hsamee}$, and the empty centralizer witness closes the result carrier. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCosetCarrier empty continuation pair iff`

Theorem 82.21 (Centralizer coset empty representative context)**.** *If* e *centralizes* a*, then the empty-representative centralizer-coset carrier of a three-part append context is equivalent to the three component carriers:*

$$\mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{e}, \mathsf{append}(l, \mathsf{append}(h, r))) \iff \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{e}, l) \wedge \mathsf{CentralizerCosetCa}$$

Proof. Unfold the empty-representative carrier to the endpoint comparison with e. Empty append inversion first splits the outer append into l and the inner append, then splits the inner append into h and r. Conversely, the three empty endpoint comparisons rebuild the nested empty append comparison, and the assumed centralizer witness supplies the carrier field. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCosetCarrier empty representative context iff`

Theorem 82.22 (Centralizer coset empty continuation classifier)**.** *If* e *centralizes* a *and* $\mathsf{Cont}(p, q, r)$*, then*

$$\mathsf{CentralizerCosetClassifier}(\mathsf{mul}, a, \mathsf{e}, r, h) \iff \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{e}, p) \wedge \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{e}, q) /$$

Proof. Unfold the empty-representative coset classifier. A classified continuation result gives $r\mathsf{hsamee}$; reading the continuation as an append endpoint and inverting empty append splits this into the two carrier comparisons for p and q, while the right classifier carrier supplies the comparison for h. Conversely, the two carrier comparisons for p and q rebuild an empty append endpoint for r, and the carrier comparison for h closes the classifier. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCosetClassifier empty continuation classifier iff`

Theorem 82.23 (Centralizer coset representative continuation classifier)**.** *If* e *and* repr *centralize* a*,* $\mathsf{reprhsamee}$*, and* $\mathsf{Cont}(p, q, r)$*, then*

$$\mathsf{CentralizerCosetClassifier}(\mathsf{mul}, a, \mathsf{repr}, r, h) \iff \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{repr}, p) \wedge \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a,$$

Proof. First transport the representative classifier to the empty representative. The empty-representative continuation classifier splits the result into the two continuation inputs and the endpoint h. The comparison reprhsamee transports each carrier endpoint back to repr, with the representative centralizer witness supplying the carrier's centralizer field. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCosetClassifier representative continuation classifier iff`

Theorem 82.24 (Centralizer-normalizer QuotientGroupUp semantic certificate)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the associativity, unit, multiplication-congruence, inverse-congruence, inverse-product reversal, and two-sided inverse laws used by Definition 80.27, the tuple of Definition 82.5 satisfies the* $\mathsf{QuotientGroup}^{\uparrow}$ *certificate fields:*

1. *the representative carrier N_a is inhabited by e;*
2. *$Q_{Z_a \triangleleft N_a}$ is reflexive, symmetric, and transitive on carried representatives;*
3. *represented multiplication descends through $Q_{Z_a \triangleleft N_a}$;*
4. *e and $\mathsf{inv}(x)$ are carried by N_a whenever x is carried by N_a;*
5. *the represented product, unit, and inverse operations respect the same classifier on all carried representatives.*

Consequently the centralizer-normalizer tower supplies a quotient-free semantic certificate for $\mathsf{QuotientGroup}^{\uparrow}$ *whose observable names are histories in N_a and whose equality test is the relative-kernel predicate $Q_{Z_a \triangleleft N_a}$.*

Proof. Apply Definition 80.27. Its lower and upper subgroup rows give $Z_a(e)$, $N_a(e)$, product and inverse closure for N_a, the inclusion $Z_a \subseteq N_a$, and the normality rows carrying Z_a through conjugation by elements of N_a.

Next apply Definition 80.47 to the classifier $Q_{Z_a \triangleleft N_a}$. The first three rows give reflexivity, symmetry, and transitivity on representatives in N_a. The fourth row gives product descent for mul and the quotient operation congruence required by the represented multiplication.

It remains to identify the unit and inverse operation rows. The unit row is the upper subgroup inhabitance supplied by the tower. For inverse closure, use the upper subgroup inverse row from Definition 80.27; inverse descent follows by combining the ambient inverse-congruence and two-sided inverse laws named there with Definition 41.65. Expanding Definition 80.33, the kernel witness for inverse representatives is transported from $Z_a(\mathsf{mul}(\mathsf{inv}(x), y))$ to the corresponding relative inverse word by the Z_a inverse-closure and hsame-transport rows.

These rows are exactly the carrier inhabitance, equivalence, product descent, unit closure, inverse closure, and operation congruence fields demanded by the history-level $\mathsf{QuotientGroup}^{\uparrow}$ certificate, with the ledger witness kept as the relative kernel membership rather than as an element of a host quotient. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer semanticNameCert`

Theorem 82.25 (Centralizer-normalizer quotient identity fiber subgroup package)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same hypotheses as Definition 82.24, define the quotient identity fiber carrier by*

$$K_Q(x) :\Longleftrightarrow Q_{Z_a \triangleleft N_a}(\mathsf{e}, x).$$

Then K_Q is the concrete subgroup package carried by the identity fiber of the centralizer-normalizer quotient classifier:

1. $K_Q(\mathsf{e})$.
2. *If* $K_Q(x)$ *and* $K_Q(y)$*, then* $K_Q(\mathsf{mul}(x, y))$.
3. *If* $K_Q(x)$*, then* $K_Q(\mathsf{inv}(x))$.
4. *If* $K_Q(x)$ *and* $x\mathsf{hsame}y$*, then* $K_Q(y)$.
5. *For every history* $x : \mathsf{BHist}$*,*
$$K_Q(x) \iff Z_a(x).$$

Proof. First apply Definition 80.35. For each history x, it gives the identity-fiber equivalence for $Q_{Z_a \triangleleft N_a}$. After unfolding the displayed definition of K_Q, this is exactly the equivalence in the final row.

The identity row follows by transporting $Z_a(\mathsf{e})$ from Definition 41.87 through the reverse direction of the fiber equivalence at e. This gives $Q_{Z_a \triangleleft N_a}(\mathsf{e}, \mathsf{e})$, which is exactly $K_Q(\mathsf{e})$.

For product closure, assume $K_Q(x)$ and $K_Q(y)$. The forward directions of the fiber equivalence give $Z_a(x)$ and $Z_a(y)$. The product row of Definition 41.87 gives $Z_a(\mathsf{mul}(x, y))$, and the reverse direction of the fiber equivalence returns $K_Q(\mathsf{mul}(x, y))$.

For inverse closure, assume $K_Q(x)$. Convert it to $Z_a(x)$ by the forward direction of the fiber equivalence. The inverse row of Definition 41.87 gives $Z_a(\mathsf{inv}(x))$, and the reverse direction of the fiber equivalence gives $K_Q(\mathsf{inv}(x))$.

For carrier transport, assume $K_Q(x)$ and $x\mathsf{hsame}y$. Convert $K_Q(x)$ to $Z_a(x)$, use the hsame-transport row for the centralizer carrier from Definition 41.87 to obtain $Z_a(y)$, and convert back to $K_Q(y)$. Thus the classifier inherited from $Q_{Z_a \triangleleft N_a}$ has the same concrete identity fiber as the centralizer carrier. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer identity fiber subgroup package`

Theorem 82.26 (Centralizer-normalizer quotient identity fiber classifier saturation)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same hypotheses as Definition 82.24, define the quotient identity fiber carrier by*

$$K_Q(t) :\iff Q_{Z_a \triangleleft N_a}(\mathsf{e}, t).$$

For histories $x, y : \mathsf{BHist}$*, the identity fiber is saturated by the quotient classifier:*

1. *If* $K_Q(x)$ *and* $Q_{Z_a \triangleleft N_a}(x, y)$*, then* $K_Q(y)$.
2. *If* $K_Q(y)$ *and* $Q_{Z_a \triangleleft N_a}(x, y)$*, then* $K_Q(x)$.

Per-object template: traditional target saturated identity fiber of a quotient classifier; BEDC source $\mathsf{Group}^{\uparrow}$*,* $\mathsf{Subgroup}^{\uparrow}$*, and* $\mathsf{QuotientGroup}^{\uparrow}$ *over* BHist*; carrier* K_Q*; classifier* $Q_{Z_a \triangleleft N_a}$*; ledger relative-kernel witness; core theorem this block; exactness the two saturation implications; downstream consumer first-isomorphism-style quotient-kernel exactness; status* $\mathsf{ProofTarget}$.

Proof. Read the semantic certificate of Definition 82.24 for the symmetry and transitivity rows of $Q_{Z_a \triangleleft N_a}$ on carried representatives.

For the first implication, unfold K_Q. The assumption $K_Q(x)$ is the classifier edge $Q_{Z_a \triangleleft N_a}(\mathsf{e}, x)$. Compose it with $Q_{Z_a \triangleleft N_a}(x, y)$ by transitivity to obtain $Q_{Z_a \triangleleft N_a}(\mathsf{e}, y)$, which is exactly $K_Q(y)$.

For the second implication, first use symmetry on $Q_{Z_a \triangleleft N_a}(x, y)$ to obtain $Q_{Z_a \triangleleft N_a}(y, x)$. Unfold $K_Q(y)$ as $Q_{Z_a \triangleleft N_a}(\mathsf{e}, y)$, then compose these two classifier edges by transitivity to obtain $Q_{Z_a \triangleleft N_a}(\mathsf{e}, x)$. Folding the displayed definition gives $K_Q(x)$. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer identity fiber classifier saturation`

Theorem 82.27 (Centralizer-normalizer quotient identity fiber normality)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same hypotheses as Definition 82.24, define the quotient identity fiber carrier by*

$$K_Q(t) :\Longleftrightarrow Q_{Z_a \triangleleft N_a}(\mathsf{e}, t).$$

If $N_a(x)$ *and* $K_Q(k)$*, then the identity fiber is carried through both normal-kernel conjugation words:*

1. $K_Q(\mathsf{mul}(\mathsf{mul}(x,k),\mathsf{inv}(x)))$.
2. $K_Q(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(x),k),x))$.

Proof. Apply Definition 82.25 to identify the displayed fiber with the centralizer carrier. From $K_Q(k)$ the forward direction gives $Z_a(k)$.

For the forward conjugation word, use the first normalizer row contained in $N_a(x)$. It carries $Z_a(k)$ to $Z_a(\mathsf{mul}(\mathsf{mul}(x,k),\mathsf{inv}(x)))$. The reverse direction of the same identity-fiber equivalence then repacks this witness as $K_Q(\mathsf{mul}(\mathsf{mul}(x,k),\mathsf{inv}(x)))$.

For the inverse conjugation word, use the second normalizer row contained in $N_a(x)$. It carries $Z_a(k)$ to $Z_a(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(x),k),x))$. Applying the reverse direction of the identity-fiber equivalence again gives $K_Q(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(x),k),x))$. Thus the kernel identity fiber inherits the conjugation stability already present in the centralizer-normalizer tower. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer identity fiber normal`

Theorem 82.28 (Centralizer-normalizer quotient kernel certificate)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same hypotheses as Definition 82.24, define the quotient identity fiber carrier by*

$$K_Q(t) :\Longleftrightarrow Q_{Z_a \triangleleft N_a}(\mathsf{e}, t).$$

Then K_Q *is the concrete normal-kernel certificate for the representative quotient classifier* $Q_{Z_a \triangleleft N_a}$*:*

1. $K_Q(\mathsf{e})$.
2. *If* $K_Q(x)$ *and* $K_Q(y)$*, then* $K_Q(\mathsf{mul}(x,y))$.
3. *If* $K_Q(x)$*, then* $K_Q(\mathsf{inv}(x))$.
4. *If* $K_Q(x)$ *and* $x\mathsf{hsame}y$*, then* $K_Q(y)$.
5. *If* $N_a(x)$ *and* $K_Q(k)$*, then* $K_Q(\mathsf{mul}(\mathsf{mul}(x,k),\mathsf{inv}(x)))$.
6. *If* $N_a(x)$ *and* $K_Q(k)$*, then* $K_Q(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(x),k),x))$.

Proof. The subgroup rows come from Definition 82.25. Its identity, product, inverse, and hsame-transport clauses give the first four rows after unfolding the displayed definition of K_Q.

The conjugation rows come from Definition 82.27. With the same carrier K_Q and the same carried normalizer witness $N_a(x)$, its two clauses give the forward and inverse conjugation words listed above.

Together these rows present the identity fiber as the concrete normal kernel of the representative quotient classifier. The first block supplies the subgroup package; the second supplies conjugation stability by every carried normalizer element, which is the combined certificate consumed by first-isomorphism-style $\mathsf{QuotientGroup}^{\uparrow}$ kernel exactness. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer kernel certificate`

Per-object template: traditional target identity fiber of a quotient group; BEDC source $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, and $\mathsf{QuotientGroup}^{\uparrow}$ over BHist; core theorem list Definition 82.24, Definition 82.25, Definition 82.27, and Definition 82.28; carrier K_Q; classifier inherited from $Q_{Z_a \lhd N_a}$ and hsame; stability obligations identity, product, inverse, transport, and both conjugation words; ledger relative-kernel witness; exactness predicate $K_Q(x) \iff Z_a(x)$; downstream consumer first-isomorphism-style $\mathsf{QuotientGroup}^{\uparrow}$ kernel exactness; status $\mathsf{ProofTarget}$.

Theorem 82.29 (Centralizer-normalizer relative-kernel fiber exactness)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the same hypotheses as Definition 82.24 and Definition 82.8, define*

$$K_Q(t) :\iff Q_{Z_a \lhd N_a}(\mathsf{e}, t).$$

For histories $x, y : \mathsf{BHist}$ *with* $N_a(x)$ *and* $N_a(y)$*, set*

$$w = \mathsf{mul}(\mathsf{inv}(x), y).$$

Then the relative-kernel word, identity fiber, and quotient classifiers are exactly linked by

$$Q_{Z_a \lhd N_a}(x, y) \iff K_Q(w) \iff Z_a(w)$$

and

$$Q_{Z_a \leq N_a}(x, y) \iff K_Q(w).$$

Per-object template: traditional target first-isomorphism kernel exactness; BEDC source $\mathsf{Group}^{\uparrow}$*,* $\mathsf{Subgroup}^{\uparrow}$*, and* $\mathsf{QuotientGroup}^{\uparrow}$*; carrier* N_a *plus identity fiber* K_Q*; classifiers the two quotient representatives* $Q_{Z_a \lhd N_a}$ *and* $Q_{Z_a \leq N_a}$*; stability from the semantic certificate, the identity-fiber subgroup package, and orbit-kernel equivalence; ledger the relative-kernel word* w*; core theorem this block; exactness the displayed iff chain; downstream consumer first-isomorphism-style quotient-kernel exactness; status* $\mathsf{ProofTarget}$*.*

Proof. Unfold the relative-kernel classifier $Q_{Z_a \lhd N_a}$ at the carried endpoint pair (x, y). The endpoint hypotheses are already $N_a(x)$ and $N_a(y)$, so the only non-carrier datum is the centralizer witness for $w = \mathsf{mul}(\mathsf{inv}(x), y)$.

Next apply Definition 82.25. Its final row identifies the displayed identity fiber with the centralizer carrier:

$$K_Q(w) \iff Z_a(w).$$

Combining this row with the unfolded relative-kernel classifier gives the first displayed iff chain.

Finally transport the same endpoint pair across Definition 82.8. The carried hypotheses $N_a(x)$ and $N_a(y)$ are unchanged, and the equivalence between $Q_{Z_a \leq N_a}(x, y)$ and $Q_{Z_a \lhd N_a}(x, y)$ converts the first chain into $Q_{Z_a \leq N_a}(x, y) \iff K_Q(w)$. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupUp StdBridge`

Capstone

Theorem 82.30 (Abelian centralizer-normalizer quotient terminal fiber)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the hypotheses of Definition 82.25, and additionally the* $\mathsf{AbGroup}^{\uparrow}$ *commutativity hypothesis used by Definition 42.17, fix* $a : \mathsf{BHist}$ *and define*

$$K_Q(x) :\iff Q_{Z_a \lhd N_a}(\mathsf{e}, x).$$

Then the quotient identity fiber is total:

$$\forall x : \mathsf{BHist},\ K_Q(x).$$

The subgroup-package rows of Definition 82.25 also give closure of this total fiber under product, inverse, and hsame *transport.*

Proof. Apply Definition 82.25. Its final row identifies the displayed carrier with the centralizer carrier: for every $x : \mathsf{BHist}$, $K_Q(x) \iff Z_a(x)$.

Now apply Definition 42.17. Under the same $\mathsf{AbGroup}^{\uparrow}$ commutativity hypothesis, its first row gives $Z_a(x)$ for every history x. Transporting this witness across the reverse direction of the identity-fiber equivalence gives $K_Q(x)$ for every $x : \mathsf{BHist}$.

The remaining assertion is inherited without changing the carrier. The product, inverse, and hsame-transport rows are exactly the second, third, and fourth rows of Definition 82.25, now read on a carrier whose every BEDC history lies in the identity fiber. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer abelian identity fiber total`

Theorem 82.31 (Abelian centralizer-normalizer quotient classifier totality)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the hypotheses of Definition 82.8, and additionally the* $\mathsf{AbGroup}^{\uparrow}$ *commutativity hypothesis used by Definition 42.17, fix* $a : \mathsf{BHist}$*. For any* $x, y : \mathsf{BHist}$ *with* $N_a(x)$ *and* $N_a(y)$*, both quotient representatives on the carrier* N_a *are total:*

$$Q_{Z_a \triangleleft N_a}(x, y) \iff \mathsf{True}$$

and

$$Q_{Z_a \leq N_a}(x, y) \iff \mathsf{True}.$$

Proof. The forward direction of each displayed equivalence is immediate, since any classifier witness proves True.

For the reverse direction of the relative-kernel classifier, assume True and set

$$w = \mathsf{mul}(\mathsf{inv}(x), y).$$

The first row of Definition 42.17 gives $Z_a(w)$ under the same commutativity hypothesis. Together with the endpoint hypotheses $N_a(x)$ and $N_a(y)$, this is exactly the witness required by Definition 80.33, so $Q_{Z_a \triangleleft N_a}(x, y)$ follows.

For the reverse direction of the coset classifier, transport the kernel classifier witness across Definition 82.8 at the same endpoint pair (x, y). The endpoint hypotheses are unchanged, and the reverse direction of the displayed equivalence gives $Q_{Z_a \leq N_a}(x, y)$. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer abelian classifier totality`

The ten-field fit is: traditional target terminal quotient of an abelian centralizer-normalizer quotient; BEDC source $\mathsf{Group}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, and $\mathsf{QuotientGroup}^{\uparrow}$ over BHist; carrier N_a; classifiers $Q_{Z_a \triangleleft N_a}$ and $Q_{Z_a \leq N_a}$; stability from the centralizer-normalizer tower and quotient classifier transport; ledger endpoint pair, relative-kernel word, and centralizer witness; core theorem list Definition 42.17, Definition 82.8, and Definition 80.33; exactness the two displayed iff statements; downstream consumer first-isomorphism-style quotient-kernel exactness; status ProofTarget.

Theorem 82.32 (Abelian centralizer-normalizer quotient terminal projection)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *satisfying the hypotheses of Definition 82.24, and additionally the* $\mathsf{AbGroup}^{\uparrow}$ *commutativity hypothesis used by Definition 42.17, fix* $a : \mathsf{BHist}$*. For every carried endpoint* x *of* N_a*, define the constant representative projection to the singleton quotient carrier by*

$$\pi_Q(x) := \mathsf{e}.$$

For any $x, y : \mathsf{BHist}$ *with* $N_a(x)$ *and* $N_a(y)$*, the abelian centralizer-normalizer quotient classifier is the pullback of the singleton quotient classifier along this projection:*

$$Q_{Z_a \triangleleft N_a}(x, y) \iff \rho_Q(\pi_Q(x), \pi_Q(y)).$$

Moreover the projected product, inverse, and unit endpoints are already singleton-classifier related:

$$\rho_Q(\pi_Q(\mathsf{mul}(x, y)), \pi_Q(x)), \quad \rho_Q(\pi_Q(\mathsf{inv}(x)), \pi_Q(x)), \quad \rho_Q(\pi_Q(e), \mathsf{e}).$$

Proof. For the displayed equivalence, the left classifier is total under the commutativity hypothesis by Definition 82.31. Thus its truth value is True on every carried endpoint pair.

The right classifier is also inhabited on every displayed endpoint pair. Indeed, each projected endpoint is definitionally e, so unfolding the projection reduces it to $\rho_Q(\mathsf{e}, \mathsf{e})$. This is the reflexive singleton classifier edge packaged by Definition 82.11, using the singleton carrier and classifier of Definitions 82.1 and 82.2.

The product, inverse, and unit claims use the same endpoint computation. The semantic certificate of Definition 82.24 supplies the carried product, inverse, and unit endpoints in N_a; applying π_Q sends each one to e. Hence all three displayed singleton classifier statements again reduce to $\rho_Q(\mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer abelian terminal projection`

Theorem 82.33 (Abelian centralizer-normalizer terminal projection uniqueness)**.** *Under the hypotheses of Definition 82.32, let* x *be any carried endpoint of* N_a *and let* θ_x *be any displayed singleton representative with* $Q_{\mathsf{e}}(\theta_x)$*. Then the singleton classifier relates* θ_x *to the canonical projection* $\pi_Q(x) = \mathsf{e}$*:*

$$\rho_Q(\theta_x, \pi_Q(x)).$$

Consequently, for carried endpoints x, y *of* N_a *and displayed singleton representatives* θ_x, θ_y *with* $Q_{\mathsf{e}}(\theta_x)$ *and* $Q_{\mathsf{e}}(\theta_y)$*,*

$$\rho_Q(\theta_x, \theta_y) \iff \rho_Q(\pi_Q(x), \pi_Q(y)).$$

Thus the displayed-representative singleton classifier is equivalent to the abelian centralizer-normalizer quotient classifier through the pullback equivalence of Definition 82.32.

Proof. Unfold Q_{e} for the chosen representative. The displayed membership witness supplies $\theta_x\mathsf{hsamee}$, while the canonical projection computes definitionally as $\pi_Q(x) = \mathsf{e}$. Hence unfolding ρ_Q reduces the desired edge to transport along hsame from θ_x to e.

For two displayed representatives, unfold Q_{e} and ρ_Q for both endpoints. The witnesses give $\theta_x\mathsf{hsamee}$ and $\theta_y\mathsf{hsamee}$; symmetry and transitivity of hsame identify the classifier edge between θ_x and θ_y with the edge between e and e.

The canonical projections satisfy the same computation: $\pi_Q(x) = \mathsf{e}$ and $\pi_Q(y) = \mathsf{e}$. Therefore $\rho_Q(\pi_Q(x), \pi_Q(y))$ is the same singleton classifier edge $\rho_Q(\mathsf{e}, \mathsf{e})$, so the displayed-representative classifier and the canonical-projection classifier are equivalent.

Apply Definition 82.32 to the carried pair x, y. Its checked pullback equivalence transfers the canonical-projection classifier to $Q_{Z_a \triangleleft N_a}(x, y)$, and the previous paragraphs transport that equivalence to the arbitrary displayed singleton representatives. □

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.QuotientGroupCentralizerNormalizer abelian terminal projection uniqueness`

The ten-field fit is: traditional target terminal projection from the abelian centralizer-normalizer quotient to the singleton quotient classifier; BEDC source $\mathsf{Group}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, and $\mathsf{QuotientGroup}^{\uparrow}$ over BHist; carrier N_a projected constantly to Q_{e}; classifiers $Q_{Z_a \triangleleft N_a}$ and ρ_Q; stability from the centralizer-normalizer quotient certificate and singleton classifier reflexivity; ledger carried endpoint pair, projected product endpoint, projected inverse endpoint, and projected unit endpoint; core theorem list Definition 82.24, Definition 82.31, and Definition 82.11; exactness the displayed pullback equivalence plus the three singleton projection edges; downstream consumer first-isomorphism-style terminal quotient exactness; status $\mathsf{ProofTarget}$.

Theorem 82.34 (Centralizer coset carrier representative product closure)**.** *For a BEDC history-level group multiplication* mul *over* BHist *satisfying the associativity, right empty-unit, and multiplication-congruence hypotheses of Definition 41.86, if two histories are carried by centralizer-coset carriers at representatives x and y, then their represented product is carried by the centralizer-coset carrier at the product representative:*

$$\mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, x, h_1) \wedge \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, y, h_2) \Longrightarrow \mathsf{CentralizerCosetCarrier}(\mathsf{mul}, a, \mathsf{mul}(x,$$

Lean4 ✓ `BEDC.Derived.QuotientGroupUp.CentralizerCosetCarrier representative product closure`

Proof. Unfold Definition 82.3. The first carrier witness gives $Z_a(x)$ together with $h_1 \mathsf{hsame} x$, and the second gives $Z_a(y)$ together with $h_2 \mathsf{hsame} y$.

The product-closure theorem Definition 41.86, equivalently the product row of Definition 80.2, gives $Z_a(\mathsf{mul}(x, y))$. Applying ambient multiplication congruence to $h_1 \mathsf{hsame} x$ and $h_2 \mathsf{hsame} y$ gives

$$\mathsf{mul}(h_1, h_2) \mathsf{hsame} \mathsf{mul}(x, y).$$

These are exactly the two fields required by Definition 82.3 for the representative $\mathsf{mul}(x, y)$ and endpoint $\mathsf{mul}(h_1, h_2)$. □

Closure status for $\mathsf{NameCert}_{\mathsf{QuotientGroup}^{\uparrow}}$**.**

Constructive story: A quotient-group object here is not formed by making a host quotient type: it starts with a BEDC $\mathsf{Group}^{\uparrow}$ operation, a centralizer subgroup Z_a, and its normalizer carrier N_a, and it admits precisely the representative histories in N_a while the centralizer records which representative differences are invisible. Two accepted representatives x and y are classified either by the displayed coset-orbit witness or, equivalently, by the relative-kernel condition that $\mathsf{mul}(\mathsf{inv}(x), y)$ lies in Z_a; the chapter proves these readings agree and uses that classifier instead of any Quot soundness principle. The source specification is the consumed group and subgroup tower with normality and centralizer-normalizer rows, the pattern specification is representative multiplication, unit, inverse, identity fiber, abelian terminal projection, and kernel exactness, and the ledger keeps the two representatives, product and inverse words, centralizer witness, normalizer endpoint rows, and transport provenance visible. The name-certificate obligations are supplied by the empty representative in the normalizer, hsame transport of that representative, reflexivity, symmetry, and transitivity of the representative classifier, and closure of the carrier under replacing an accepted representative by a classified one. A representative history h lies in the signature gap of a $\mathsf{QuotientGroup}^{\uparrow}$ token p when the source-domain first accepts h in the normalizer carrier, the signature relation pairs it with an answer representative and the kernel-or-coset evidence ledger, and the token-introduction relation names that answer as p; after unfolding, this says that h represents the same centralizer-normalizer coset as the representative encoded by p. The paper bridge compares the displayed orbit and kernel criteria with the ordinary coset/kernel reading, but the BEDC surface remains the representative carrier plus classifier. The chapter registers this centralizer-normalizer construction under the name $\mathsf{QuotientGroup}^{\uparrow}$; arbitrary quotients, universal properties, host quotient objects, and checked standard-model bridge data are not introduced.

Theory closure: TheoryGate(NameCert$_{\mathsf{QuotientGroup}\uparrow}$, maturePackageClosed)

Scope closed: The mature QuotientGroupUp package is the centralizer-normalizer SemanticNameCert together with the abelian terminal projection, projection uniqueness, identity-fiber totality, and classifier-totality rows of Definition 82.24, Definition 82.32, Definition 82.33, Definition 82.30, and Definition 82.31.

Formal verification: FormalStatus(NameCert$_{\mathsf{QuotientGroup}\uparrow}$, bridgeChecked)

Chapter 83

A Concrete Naming Certificate for $\mathsf{QuotientRing}^{\uparrow}$

The quotient-ring interface $\mathsf{QuotientRing}^{\uparrow}$ packages the carrier of cosets of an ideal in a ring. It depends on $\mathsf{NameCert}_{\mathsf{Ideal}^{\uparrow}}$ (chapter 81) and lifts $\mathsf{NameCert}_{\mathsf{QuotientGroup}^{\uparrow}}$ (chapter 82) to the multiplicative structure.

83.1 Carrier definition

83.2 The certificate

Definition 83.1 (Ideal coset relation for quotient rings)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I be an $\mathsf{Ideal}^{\uparrow}$ object over R, written as a carried predicate $I(x)$. Write $x -_R y$ for $x +_R (-_R y)$. The ideal-coset relation used by the $\mathsf{QuotientRing}^{\uparrow}$ carrier is*

$$a \equiv_I a' \iff C(a) \wedge C(a') \wedge I(a -_R a').$$

Theorem 83.2 (QuotientRing multiplication descends to ideal cosets)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate and let I be an $\mathsf{Ideal}^{\uparrow}$ object over R. Assume the ideal certificate supplies additive closure, classifier transport, and two-sided absorption by every carried ring endpoint, as required by section 81.2. For carried endpoints a, a', b, b', if*

$$a \equiv_I a' \qquad \text{and} \qquad b \equiv_I b',$$

then

$$(a \cdot_R b) \equiv_I (a' \cdot_R b').$$

Thus the multiplication operation on the $\mathsf{QuotientRing}^{\uparrow}$ coset carrier is representative-independent.

Lean4 ✓ `BEDC.Derived.QuotientRingUp.QuotientRingIdealCoset mul descends`
Lean4 ✓ `BEDC.Derived.QuotientRingUp.QuotientRingIdealCoset multiplication descent`

Proof. Unfold Definition 83.1. Set $d_a := a -_R a'$ and $d_b := b -_R b'$. The two coset hypotheses give $I(d_a)$ and $I(d_b)$, together with the carrier witnesses for a, a', b, b'.

By the right absorption field of the $\mathsf{Ideal}^{\uparrow}$ certificate, $I(d_a)$ and the carrier witness for b give

$$I(d_a \cdot_R b).$$

By the left absorption field, $I(d_b)$ and the carrier witness for a' give

$$I(a' \cdot_R d_b).$$

Additive closure in the ideal therefore gives

$$I((d_a \cdot_R b) +_R (a' \cdot_R d_b)).$$

It remains to identify this ideal element with the difference of the two products. By Definition 43.58,

$$d_a \cdot_R b \sim_R (a \cdot_R b) -_R (a' \cdot_R b),$$

and by Definition 43.56,

$$a' \cdot_R d_b \sim_R (a' \cdot_R b) -_R (a' \cdot_R b').$$

Addition congruence transports the sum to

$$((a \cdot_R b) -_R (a' \cdot_R b)) +_R ((a' \cdot_R b) -_R (a' \cdot_R b')).$$

The additive abelian-group rows of Definition 43.26, with the right inverse law from Definition 43.27 and the right zero law from Definition 43.31, cancel the middle pair $-_R(a' \cdot_R b)$ and $a' \cdot_R b$. Hence

$$(d_a \cdot_R b) +_R (a' \cdot_R d_b) \sim_R (a \cdot_R b) -_R (a' \cdot_R b').$$

Classifier transport for the ideal moves the displayed membership across this classifier edge, giving

$$I((a \cdot_R b) -_R (a' \cdot_R b')).$$

Multiplication closure in the $\mathsf{Ring}^{\uparrow}$ certificate supplies the carrier witnesses for $a \cdot_R b$ and $a' \cdot_R b'$. These two carrier witnesses together with the displayed ideal-membership statement are exactly

$$(a \cdot_R b) \equiv_I (a' \cdot_R b')$$

by Definition 83.1. □

Lean4 ✓ `BEDC.Derived.QuotientRingUp.QuotientRingIdealCoset multiplication descends`

Theorem 83.3 (QuotientRing additive descent to ideal cosets)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I be an $\mathsf{Ideal}^{\uparrow}$ object over R, written as a carried predicate $I(x)$. Assume the ideal certificate supplies additive closure, additive inverse closure, and classifier transport for I, as specified in section 81.2. If*

$$a \equiv_I a' \qquad \text{and} \qquad b \equiv_I b',$$

then the additive and inverse operations respect ideal cosets:

$$(a +_R b) \equiv_I (a' +_R b')$$

and

$$(-_R a) \equiv_I (-_R a').$$

Thus the additive part of the $\mathsf{QuotientRing}^{\uparrow}$ coset carrier is representative-independent.

Lean4 ✓ `BEDC.Derived.QuotientRingUp.QuotientRingIdealCoset additive descent`
Lean4 ✓ `BEDC.Derived.QuotientRingUp.QuotientRingIdealCoset add descends`

Proof. Unfold Definition 83.1. Set

$$d_a := a -_R a', \qquad d_b := b -_R b'.$$

The two coset hypotheses give $C(a)$, $C(a')$, $C(b)$, $C(b')$, together with $I(d_a)$ and $I(d_b)$.

For addition, ideal additive closure gives

$$I(d_a +_R d_b).$$

The additive abelian-group component of the ring certificate, using Definition 42.13 for the operation $+_R$, identifies

$$(a +_R (-_R a')) +_R (b +_R (-_R b')) \sim_R (a +_R b) +_R ((-_R a') +_R (-_R b')).$$

By Definition 43.33, read in the additive component of R,

$$-_R(a' +_R b') \sim_R (-_R a') +_R (-_R b').$$

Addition congruence, symmetry, and transitivity of $\sim_R$ therefore give

$$d_a +_R d_b \sim_R (a +_R b) -_R (a' +_R b').$$

Classifier transport for the ideal moves the displayed membership across this classifier edge, so

$$I((a +_R b) -_R (a' +_R b')).$$

Ring additive closure supplies $C(a +_R b)$ and $C(a' +_R b')$. These carrier witnesses and the displayed ideal-membership statement are exactly

$$(a +_R b) \equiv_I (a' +_R b')$$

by Definition 83.1.

For additive inverse, ideal inverse closure applied to $I(d_a)$ gives

$$I(-_R d_a).$$

Since $d_a = a +_R (-_R a')$, Definition 43.33 gives the classifier comparison

$$-_R d_a \sim_R (-_R a) +_R (-_R(-_R a')),$$

and the right-hand side is $(-_R a) -_R (-_R a')$ by the notation of Definition 83.1. Classifier transport for the ideal yields

$$I((-_R a) -_R (-_R a')).$$

Ring additive inverse closure supplies $C(-_R a)$ and $C(-_R a')$. Repacking these two carrier witnesses with the displayed ideal-membership statement gives

$$(-_R a) \equiv_I (-_R a')$$

by Definition 83.1. □

Theorem 83.4 (QuotientRing ideal coset relation equivalence)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I be an $\mathsf{Ideal}^{\uparrow}$ object over R, written as a carried predicate $I(x)$, and write $x -_R y$ for $x +_R (-_R y)$ as in Definition 83.1. Assume the ideal certificate rows named in section 81.2 supply zero closure, additive-inverse closure, additive closure, and classifier transport:*

$$I(0_R), \qquad \forall x,\ I(x) \Longrightarrow I(-_R x), \qquad \forall x, y,\ I(x) \wedge I(y) \Longrightarrow I(x +_R y),$$

and

$$\forall x, y,\ I(x) \wedge x \sim_R y \Longrightarrow I(y).$$

Then the relation $\equiv_I$ of Definition 83.1 is an equivalence relation on carried ring endpoints: for every a, b, c,

$$C(a) \Longrightarrow a \equiv_I a,$$

$$a \equiv_I b \Longrightarrow b \equiv_I a,$$

and

$$(a \equiv_I b \wedge b \equiv_I c) \Longrightarrow a \equiv_I c.$$

Proof. Unfold Definition 83.1.

For reflexivity, assume $C(a)$. The zero row gives $I(0_R)$. The additive right-inverse theorem Definition 43.27, read in the additive component of R, gives

$$a -_R a \sim_R 0_R.$$

Classifier symmetry from Definition 9.7 reverses this edge, and classifier transport for I gives $I(a -_R a)$. Together with the two copies of $C(a)$, this is $a \equiv_I a$.

For symmetry, assume $a \equiv_I b$. The unfolded hypothesis supplies $C(a)$, $C(b)$, and $I(a -_R b)$. Additive-inverse closure gives

$$I(-_R(a -_R b)).$$

The additive abelian-group rows in Definition 43.26 identify the inverse of a difference with the reversed difference:

$$-_R(a -_R b) \sim_R b -_R a.$$

Indeed, Definition 43.33 rewrites the left endpoint to $(-_R a) +_R (-_R(-_R b))$; Definition 41.57, read in the additive group of R, identifies $-_R(-_R b)$ with b; additive commutativity then gives $b +_R (-_R a)$. The classifier edges are composed by Definition 9.8. Classifier transport for I yields $I(b -_R a)$. Repacking $C(b)$, $C(a)$, and this membership gives $b \equiv_I a$.

For transitivity, assume $a \equiv_I b$ and $b \equiv_I c$. Unfolding gives $C(a)$, $C(b)$, $C(c)$, $I(a -_R b)$, and $I(b -_R c)$. Additive closure gives

$$I((a -_R b) +_R (b -_R c)).$$

The additive associativity, left-inverse, left-zero, and addition-congruence rows in Definition 43.26 give

$$(a -_R b) +_R (b -_R c) \sim_R a -_R c.$$

After expanding the two differences, reassociate

$$(a +_R (-_R b)) +_R (b +_R (-_R c))$$

to

$$a +_R (((-_R b) +_R b) +_R (-_R c)).$$

The middle pair collapses to 0_R by the additive left-inverse row, and the additive left-zero row reduces the tail to $-_R c$. Thus the expression is classified with $a +_R (-_R c)$, namely $a -_R c$. Classifier transport for I gives $I(a -_R c)$. Repacking this with $C(a)$ and $C(c)$ gives $a \equiv_I c$. □

Lean4 ✓ `BEDC.Derived.QuotientRingUp.QuotientRingIdealCosetRelation equivalence rows`

Theorem 83.5 (QuotientRing zero coset classification)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$, with carrier row supplying $C(0_R)$. Let I be an $\mathsf{Ideal}^{\uparrow}$ object over R, written as a carried predicate $I(x)$, and write $x -_R y$ for $x +_R (-_R y)$ as in Definition 83.1. Assume the ideal certificate includes classifier transport as specified in section 81.2:*

$$\forall x, y,\ I(x) \wedge x \sim_R y \Longrightarrow I(y).$$

Then for every endpoint a,

$$a \equiv_I 0_R \Longleftrightarrow C(a) \wedge I(a).$$

Lean4 ✓ `BEDC.Derived.QuotientRingUp.QuotientRingIdealCoset zero classification`

Proof. Fix a. We first record the conditional comparison with the zero difference. Suppose $C(a)$ and set $d_0 := a -_R 0_R$. The additive inverse of zero comparison from Definition 43.28, read in the additive component of R, gives

$$-_R 0_R \sim_R 0_R.$$

Addition congruence from Definition 43.26, with the left summand a fixed, gives

$$a +_R (-_R 0_R) \sim_R a +_R 0_R.$$

The additive right-zero law Definition 43.31 gives

$$a +_R 0_R \sim_R a.$$

By transitivity of the carrier classifier from Definition 9.7,

$$d_0 \sim_R a.$$

Thus, whenever $C(a)$ is available, $a -_R 0_R \sim_R a$.

For the forward implication, assume $a \equiv_I 0_R$. Unfolding Definition 83.1 gives $C(a)$, $C(0_R)$, and $I(a -_R 0_R)$. Applying the comparison just proved under this $C(a)$ and then the ideal classifier-transport row gives $I(a)$. Hence $C(a) \wedge I(a)$.

For the reverse implication, assume $C(a) \wedge I(a)$. The carrier row gives $C(0_R)$. Apply classifier symmetry from Definition 9.7 to the displayed comparison $d_0 \sim_R a$, obtaining

$$a \sim_R d_0.$$

The ideal classifier-transport row carries $I(a)$ across this edge, so $I(d_0)$, equivalently $I(a -_R 0_R)$. Repacking $C(a)$, $C(0_R)$, and this membership through Definition 83.1 yields $a \equiv_I 0_R$. □

Theorem 83.6 (QuotientRingUp public coset certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I be an $\mathsf{Ideal}^{\uparrow}$ object over R, written as a carried predicate $I(x)$, and let $\equiv_I$ be the ideal-coset relation of Definition 83.1. Then the public $\mathsf{NameCert}_{\mathsf{QuotientRing}^{\uparrow}}$ coset surface is assembled from Definition 83.1, Definition 83.2, Definition 83.3, Definition 83.4, and Definition 83.5.*

Its carrier is the relation $a \equiv_I b$. Its classifier is stable under the ideal-coset relation. Its additive and multiplicative operations are independent of representatives. Its zero coset is exact:

$$a \equiv_I 0_R \iff C(a) \wedge I(a).$$

Its ledger is limited to $\mathsf{Ring}^{\uparrow}$ operations, $\mathsf{Ideal}^{\uparrow}$ closure and transport rows, and $\mathsf{QuotientGroup}^{\uparrow}$ coset inheritance.

Proof. The carrier component is Definition 83.1: a quotient-ring endpoint is represented by the relation $a \equiv_I b$, namely carrier evidence for both endpoints together with ideal membership of the difference $a -_R b$.

The classifier rows are supplied by Definition 83.4. Reflexivity gives the carried self-coset, symmetry reverses representatives, and transitivity composes two representative changes. These rows make classifier stability a property of the ideal-coset relation itself.

The operation rows come from the two descent results. Apply Definition 83.3 for addition and additive inverse, and apply Definition 83.2 for multiplication. The hypotheses of those theorems are exactly the $\mathsf{Ring}^{\uparrow}$ operation rows and the $\mathsf{Ideal}^{\uparrow}$ closure, absorption, and classifier-transport rows already recorded in the chapter ledger.

The zero row is Definition 83.5. It identifies the zero coset with carried ideal membership, so the certificate exposes no extra zero classifier beyond $C(a) \wedge I(a)$.

Repacking these rows gives the public $\mathsf{NameCert}_{\mathsf{QuotientRing}^{\uparrow}}$ coset surface. No further ring, ideal, or quotient-group clauses are added: the ledger remains bounded by the listed $\mathsf{Ring}^{\uparrow}$ operations, $\mathsf{Ideal}^{\uparrow}$ closure and transport data, and the inherited coset infrastructure from $\mathsf{QuotientGroup}^{\uparrow}$. □

Theorem 83.7 (QuotientRingUp public coset downstream bridge)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate with carrier C, classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, zero 0_R, and multiplication $\cdot_R$. Let I be an $\mathsf{Ideal}^{\uparrow}$ object over R, written as a carried predicate $I(x)$, and let $\equiv_I$ be the ideal-coset relation of Definition 83.1. Downstream algebra consumers of the public $\mathsf{NameCert}_{\mathsf{QuotientRing}^{\uparrow}}$ coset surface may access quotient-ring data only through Definition 83.1, Definition 83.3, Definition 83.2, Definition 83.4, and Definition 83.5.*

Conversely, these rows supply the carrier, classifier, additive descent, multiplicative descent, zero row, and bounded ledger required by the downstream quotient-ring interface. The bridge boundary exposes neither representative choice, ideal witnesses beyond membership of differences, the universal property, localization, nor any standard bridge datum.

Proof. Start with the public certificate of Definition 83.6. Its carrier projection is exactly Definition 83.1: a visible quotient endpoint is accessed by the relation $a \equiv_I b$, and the only ideal witness retained at the boundary is membership of the difference $a -_R b$.

The classifier projection is Definition 83.4. Its reflexive, symmetric, and transitive rows give the consumer all representative-change data needed to treat $\equiv_I$ as the public classifier, without choosing a representative or exporting an ideal witness other than the displayed difference membership.

The operation projections are Definition 83.3 and Definition 83.2. They state that addition, additive inverse, and multiplication descend across $\equiv_I$, so the downstream interface receives operation stability directly from the public rows rather than from hidden representative choices.

The zero projection is Definition 83.5. It identifies the zero coset by $C(a) \wedge I(a)$, which is the zero row required by the consumer surface and does not add a separate zero classifier.

Repacking these five projections yields the downstream bridge boundary: carrier, classifier, operation descent, zero row, and bounded ledger are all supplied by the public coset certificate. Since the repacking uses only the listed rows, no universal property, localization theorem, ideal correspondence, full quotient-ring API, or standard bridge datum is closed here. □

Closure status for $\mathsf{NameCert}_{\mathsf{QuotientRing}^{\uparrow}}$.

Constructive story: A quotient-ring endpoint is not made by forming a new quotient object; it is a visible ideal-coset relation between carried ring histories, where $a \equiv_I a'$ means that both representatives are in the ring carrier and the displayed difference $a -_R a'$ lies in the ideal. Two visible coset rows are treated as the same through that same ideal-coset relation, whose reflexive, symmetric, and transitive rows are proved from the ideal zero, inverse, additive closure, and classifier-transport fields rather than from a representative choice principle. The source is the already certified $\mathsf{Ring}^{\uparrow}$ surface together with an $\mathsf{Ideal}^{\uparrow}$ predicate, the pattern records additive descent, additive-inverse descent, multiplicative descent by two-sided absorption, zero-coset exactness, and inherited quotient-group infrastructure, and the ledger is bounded to the ring operations, ideal membership of differences, and the proofs that operations respect those displayed relations. The five name-certificate obligations close because every carried endpoint has a reflexive coset using the ideal zero row, symmetry reverses a difference by ideal inverse closure, transitivity adds two displayed differences, and carrier-respect is exactly the retained ideal transport along the ring classifier. A history row h lies in the signature gap of a $\mathsf{QuotientRing}^{\uparrow}$ token p when the source-domain accepts the underlying carried representatives and ideal-difference witness, the signature relation pairs the coset row with an answer row and evidence ledger, and token introduction names that answer as p; unfolded, the answer is the same public coset data with addition and multiplication already independent of representative. The downstream bridge repacks only the public carrier, classifier, operation descent, zero row, and bounded ledger, so consumers never receive a hidden chosen representative. The chapter registers this ideal-coset surface under the name $\mathsf{QuotientRing}^{\uparrow}$; it introduces no external standard bridge, universal property, localization theorem, ideal correspondence theorem, or full quotient-ring API beyond the displayed rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuotientRing}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 83.6 exports the public coset certificate, and Definition 83.7 repacks that certificate as the downstream bridge boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{QuotientRing}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.QuotientRingUp.QuotientRingIdealCoset\_multiplication\_descends`

Bridge status: paperBridge

Not claimed: This chapter does not close external standard bridge data, the universal property, localization, ideal correspondence, or the full quotient-ring API.

Upgrade path: No paper-side closure grade remains; further movement is formal and standard-bridge verification only.

Chapter 84

A Concrete Naming Certificate for $\mathsf{Determinant}^{\uparrow}$

The determinant interface $\mathsf{Determinant}^{\uparrow}$ packages the alternating multilinear form on square matrices that detects invertibility. It depends on $\mathsf{NameCert}_{\mathsf{Mat}^{\uparrow}}$ (chapter 49) and $\mathsf{NameCert}_{\mathsf{CommRing}^{\uparrow}}$ (chapter 44), and supplies the invariant used by the eigenvalue and characteristic-polynomial certificates.

84.1 Carrier definition

Definition 84.1 (Singleton matrix determinant certificate)**.** *Use the singleton empty-history matrix carrier and classifier from* $\mathsf{Mat}^{\uparrow}$*,*

$$\mathsf{MatrixSingletonCarrier}, \qquad \mathsf{MatrixSingletonClassifier},$$

together with the singleton empty-history commutative-ring carrier and classifier from $\mathsf{CommRing}^{\uparrow}$*,*

$$\mathsf{CommRingSingletonCarrier}, \qquad \mathsf{CommRingSingletonClassifier}.$$

The determinant readback is the constant scalar endpoint

$$\det_{\mathsf{e}}(M) := \mathsf{e}.$$

Let $\mathsf{MatrixSingletonOne}$ *denote the singleton matrix identity and* $\mathsf{CommRingSingletonOne}$ *the singleton commutative-ring unit. Define the endpoint relation by*

$$\Delta_{\mathsf{e}}(M, r) \iff \mathsf{MatrixSingletonClassifier}(M, \mathsf{MatrixSingletonOne}) \wedge \mathsf{CommRingSingletonClassifier}(r, \mathsf{CommRingSingleto}$$

The certificate fit has ten fields:

1. *Traditional target: the terminal determinant on the one-by-one terminal matrix algebra.*
2. *BEDC source: the singleton* $\mathsf{Mat}^{\uparrow}$ *instance over the singleton* $\mathsf{CommRing}^{\uparrow}$ *scalar instance.*
3. *Carrier choice:* $\mathsf{MatrixSingletonCarrier}$.
4. *Classifier choice:* $\mathsf{MatrixSingletonClassifier}$*, with scalar readback classified by* $\mathsf{CommRingSingletonClassifier}$.
5. *Stability obligations: identity stability, classifier transport, multiplicativity, and row-swap sign collapse at the singleton endpoint.*

6. *Ledger: the singleton matrix endpoint together with the singleton scalar endpoint.*
7. *Core theorem list: Theorem 84.2, Theorem 49.48, and Theorem 44.7.*
8. *Exactness predicate:* $\Delta_{\mathsf{e}}(M, r)$.
9. *Standard bridge: the determinant of the terminal one-by-one matrix algebra.*
10. *Status:* ProofTarget.

Lean4 (definition) `BEDC.Derived.DeterminantUp.DeterminantSingletonCertificate`
Lean4 (definition) `BEDC.Derived.DeterminantUp.DeterminantSingletonReadback`
Lean4 (definition) `BEDC.Derived.DeterminantUp.DeterminantSingletonDet`
Lean4 (definition) `BEDC.Derived.DeterminantUp.DeterminantSingletonEndpoint`

Theorem 84.2 (Singleton matrix determinant endpoint correspondence)**.** *For histories* M, r : BHist*, the determinant endpoint relation satisfies*

$$\Delta_{\mathsf{e}}(M, r) \iff \mathsf{MatrixSingletonCarrier}(M) \wedge \mathsf{CommRingSingletonClassifier}(r, \mathsf{CommRingSingletonOne}).$$

Moreover, for singleton-carried histories M, N : BHist*:*

1. $\det_{\mathsf{e}}(\mathsf{MatrixSingletonOne})$ *is classified with* CommRingSingletonOne *by* CommRingSingletonClassifier.
2. *If* $\mathsf{MatrixSingletonClassifier}(M, N)$*, then* $\mathsf{CommRingSingletonClassifier}(\det_{\mathsf{e}}(M), \det_{\mathsf{e}}(N))$.
3. $\mathsf{CommRingSingletonClassifier}(\det_{\mathsf{e}}(\mathsf{MatrixSingletonMul}(M, N)), \mathsf{CommRingSingletonMul}(\det_{\mathsf{e}}(M), \det_{\mathsf{e}}(N)))$.

Proof. For the forward direction of the displayed equivalence, unfold Δ_{e}. The matrix component classifies M with MatrixSingletonOne, so its carrier field gives $\mathsf{MatrixSingletonCarrier}(M)$. The scalar component is already the displayed CommRingSingletonClassifier witness.

For the reverse direction, apply Theorem 49.49 with the carried matrix M and the carried identity endpoint supplied by Theorem 49.48. Equivalently, Theorem 49.49 collapses the singleton matrix endpoint to e, and the identity law in Theorem 49.48 identifies MatrixSingletonOne with the same endpoint. Together with the given scalar classifier witness, these two components repackage $\Delta_{\mathsf{e}}(M, r)$.

For the determinant of the identity, $\det_{\mathsf{e}}$ is constantly e and CommRingSingletonOne is the singleton scalar endpoint. The commutative-ring singleton laws of Theorem 44.7 classify these two scalar histories at the same endpoint.

Classifier transport is immediate from the same scalar collapse. If $\mathsf{MatrixSingletonClassifier}(M, N)$, both determinant readbacks are e, so the commutative-ring singleton laws package the scalar comparison.

For multiplicativity, the matrix product endpoint is first collapsed by Theorem 49.49. The two scalar sides are then e and $\mathsf{CommRingSingletonMul}(\mathsf{e}, \mathsf{e})$; the singleton commutative-ring laws identify the multiplication result with CommRingSingletonOne, so the final scalar classifier witness is again packaged at e. □

Lean4 ✓ `BEDC.Derived.DeterminantUp.determinant singleton endpoint laws`

Theorem 84.3 (Determinant append-pair scalar classifier)**.** *For histories M, N, r : BHist, the scalar classifier of the singleton determinant readback on* $\mathsf{append}(M, N)$ *is equivalent to singleton matrix carriers for M and N together with the singleton commutative-ring carrier for r.*

Proof. Unfold the determinant readback as an append with the empty suffix. In the forward direction, the scalar classifier supplies emptiness of $\mathsf{append}(\mathsf{append}(M, N), \mathsf{e})$; append-empty inversion first removes the determinant suffix and then splits the matrix pair into carrier witnesses for M and N. The target scalar carrier is the second endpoint field of the classifier. Conversely, the two matrix carrier witnesses make $\mathsf{append}(M, N)$ empty, the determinant suffix keeps it empty, and this empty determinant endpoint classifies with the carried scalar endpoint r. □

Lean4 ✓ `BEDC.Derived.DeterminantUp.DeterminantSingletonDet append pair scalar classifier iff`

Theorem 84.4 (Determinant visible matrix scalar classifier exclusion)**.** *For histories M, r : BHist, neither visible matrix endpoint can feed the singleton determinant readback into a scalar classifier:*

$$\mathsf{CommRingSingletonClassifier}(\mathsf{DeterminantSingletonDet}(\mathsf{E0}(M)), r) \Longrightarrow \bot, \qquad \mathsf{CommRingSingletonClassifier}(\mathsf{Determ}$$

Proof. Unfold the singleton determinant readback as append with the empty suffix and read the left carrier field of the scalar classifier. The field forces the visible determinant endpoint to be history-same to e. Constructor no-confusion for E0 and E1 contradicts these two possible carrier clauses. □

Lean4 ✓ `BEDC.Derived.DeterminantUp.DeterminantSingletonDet visible matrix scalar classifier absurd`

84.2 The certificate

Theorem 84.5 (Determinant singleton classifier semantic name certificate)**.** *The determinant singleton classifier over* MatrixSingletonCarrier *is a semantic name certificate:*

$$\mathsf{SemanticNameCert}(\mathsf{MatrixSingletonCarrier}, \mathsf{MatrixSingletonCarrier}, \mathsf{MatrixSingletonCarrier}, \mathsf{DeterminantSingletonClassi}$$

Proof. Use the matrix singleton certificate supplied by Theorem 49.48 for carrier inhabitation, reflexivity, symmetry, transitivity, and carrier transport on the matrix component. The determinant readback is the constant singleton scalar endpoint, and the commutative-ring singleton certificate supplied by Theorem 44.7 classifies the scalar readbacks. Pairing these two classifier components gives the determinant classifier fields. Pattern and ledger soundness are the identity inclusions because all three semantic predicates are MatrixSingletonCarrier. □

Lean4 ✓ `BEDC.Derived.DeterminantUp.DeterminantSingletonClassifier semanticNameCert`

Theorem 84.6 (Singleton determinant threefold multiplicativity)**.** *For singleton-carried matrix histories M, N, P : BHist, the left-bracketed matrix product has the scalar determinant classifier*

$$\mathsf{CommRingSingletonClassifier}(\mathsf{DeterminantSingletonDet}(\mathsf{MatrixSingletonMul}(\mathsf{MatrixSingletonMul}(M, N), P)), \mathsf{CommR}$$

The right-bracketed matrix product has the analogous classifier

$$\mathsf{CommRingSingletonClassifier}(\mathsf{DeterminantSingletonDet}(\mathsf{MatrixSingletonMul}(M, \mathsf{MatrixSingletonMul}(N, P))), \mathsf{CommR}$$

Moreover, the two scalar products above are classified with one another by CommRingSingletonClassifier*.*

Proof. The singleton matrix laws in Theorem 49.48 close $\mathsf{MatrixSingletonMul}(M, N)$ and then $\mathsf{MatrixSingletonMul}(\mathsf{MatrixSingletonMul}(M, N), P)$ under $\mathsf{MatrixSingletonCarrier}$. The same laws also close $\mathsf{MatrixSingletonMul}(N, P)$ and $\mathsf{MatrixSingletonMul}(M, \mathsf{MatrixSingletonMul}(N, P))$, and their associativity field classifies the two matrix products at the singleton endpoint.

Apply Theorem 84.2 to the left-bracketed product and then use Theorem 84.5 to keep the determinant readback stable under the singleton matrix classifier. The result is the displayed classifier from the determinant of $\mathsf{MatrixSingletonMul}(\mathsf{MatrixSingletonMul}(M, N), P)$ to the left-bracketed scalar product.

The right-bracketed statement is obtained by the same argument applied to $\mathsf{MatrixSingletonMul}(M, \mathsf{MatrixSinglet}$ Matrix associativity transports the product endpoint, and determinant readback stability gives the corresponding scalar classifier.

Finally, Theorem 44.7 closes $\mathsf{CommRingSingletonMul}$ on the three determinant readbacks and classifies the left- and right-bracketed scalar products by commutative-ring associativity. □

Closure status for $\mathsf{NameCert}_{\mathsf{Determinant}^{\uparrow}}$.

Constructive story: The determinant surface closed here is the terminal singleton case: an admitted matrix history is a $\mathsf{Mat}^{\uparrow}$ singleton endpoint, and its determinant readback is the constant singleton commutative-ring scalar endpoint e, so any visible matrix endpoint with a b0 or b1 head is excluded by the scalar classifier's empty-endpoint readback. Two carried determinant rows are classified by the singleton matrix classifier on the matrix side together with the singleton commutative-ring classifier on the scalar readback, and the endpoint relation says exactly that the matrix is classified with the singleton identity while the scalar is classified with the singleton unit. The source, pattern, and ledger all stay on this singleton matrix carrier; the pattern records constant determinant readback, identity endpoint correspondence, classifier transport, multiplicativity, visible-endpoint exclusion, and the singleton row-swap sign collapse, while the ledger keeps the matrix endpoint and scalar endpoint side by side. The five name-certificate obligations are inherited from the singleton matrix certificate for carrier inhabitation and matrix endpoint comparison, paired with the singleton commutative-ring certificate for the scalar readback, so reflexivity, symmetry, transitivity, and carrier transport never leave the one-point surface. A history h lies in the signature gap of a $\mathsf{Determinant}^{\uparrow}$ token p when the source-domain accepts h as a singleton matrix endpoint, the signature relation pairs it with the constant determinant scalar and evidence ledger, and the token-introduction relation names that scalar answer as p; unfolded, every accepted determinant value is the singleton scalar endpoint. There is no standard bridge asserted in this closure block, though the intended outside reading is the determinant of the terminal one-by-one matrix algebra. The chapter registers this constant singleton determinant under the name $\mathsf{Determinant}^{\uparrow}$; general $n \times n$ determinants, Leibniz sums, row operations, alternating multilinear uniqueness, characteristic polynomials, and determinant theory over arbitrary fields are not introduced.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Determinant}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Singleton determinant semantic certificate over MatrixSingletonCarrier and CommRingSingletonClassifier, including constant determinant readback, endpoint correspondence, classifier transport, and singleton multiplicativity.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Determinant}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.DeterminantUp.DeterminantSingleton\_semanticNameCert`

Bridge status: none

Not claimed: General $n \times n$ determinant, Leibniz formula, alternating multilinear uniqueness, row operations, characteristic polynomial, or determinant theory over arbitrary fields.

Upgrade path: No paper-side theory grade remains for the singleton determinant surface.

Definition 84.7 (Determinant singleton row-swap endpoint certificate)**.** *For histories* M, S : BHist*, write*

$$\mathsf{DetSwap}_{\mathsf{e}}(M, S) \iff \mathsf{MatrixSingletonCarrier}(M) \wedge \mathsf{MatrixSingletonClassifier}(S, M).$$

This is the row-swap endpoint certificate at the singleton determinant surface: the endpoint S *is read through the same singleton matrix classifier as the source matrix* M*.*

Theorem 84.8 (Determinant singleton row-swap sign collapse)**.** *For histories* M, S : BHist*, every singleton row-swap endpoint certificate*

$$\mathsf{DetSwap}_{\mathsf{e}}(M, S)$$

supplies the signed determinant classifier

$$\mathsf{CommRingSingletonClassifier}(\det_{\mathsf{e}}(S), \mathsf{CommRingSingletonNeg}(\det_{\mathsf{e}}(M)))$$

and hence the unsigned determinant classifier

$$\mathsf{CommRingSingletonClassifier}(\det_{\mathsf{e}}(S), \det_{\mathsf{e}}(M)).$$

Lean4 ✓ `BEDC.Derived.DeterminantUp.DeterminantSingletonRowSwapEndpointCertificate sign collapse`

Proof. Unpack $\mathsf{DetSwap}_{\mathsf{e}}(M, S)$. Its second component is the matrix classifier $\mathsf{MatrixSingletonClassifier}(S, M)$, and its first component keeps M in the singleton matrix carrier. Applying the classifier-transport clause in Definition 84.2 to S and M gives

$$\mathsf{CommRingSingletonClassifier}(\det_{\mathsf{e}}(S), \det_{\mathsf{e}}(M)).$$

Thus both determinant readbacks are singleton scalar endpoints.

Apply Definition 44.9 with $h = \det_{\mathsf{e}}(M)$ and $t = \det_{\mathsf{e}}(S)$. Since $\det_{\mathsf{e}}(S)$ is a singleton scalar endpoint and $\mathsf{CommRingSingletonNeg}(\det_{\mathsf{e}}(M))$ is the empty singleton scalar endpoint, the singleton commutative-ring classifier relates $\mathsf{CommRingSingletonNeg}(\det_{\mathsf{e}}(M))$ to $\det_{\mathsf{e}}(S)$. Symmetry of the scalar classifier, supplied by Definition 44.7, gives the displayed signed orientation

$$\mathsf{CommRingSingletonClassifier}(\det_{\mathsf{e}}(S), \mathsf{CommRingSingletonNeg}(\det_{\mathsf{e}}(M))).$$

Apply the same negation endpoint theorem with $t = \det_{\mathsf{e}}(M)$ to classify $\mathsf{CommRingSingletonNeg}(\det_{\mathsf{e}}(M))$ with $\det_{\mathsf{e}}(M)$. Transitivity of the singleton scalar classifier from Definition 44.7 composes this comparison with the signed classifier above, yielding

$$\mathsf{CommRingSingletonClassifier}(\det_{\mathsf{e}}(S), \det_{\mathsf{e}}(M)).$$

□

Chapter 85

A Concrete Naming Certificate for $\mathsf{Eigen}^{\uparrow}$

The eigen-pair interface $\mathsf{Eigen}^{\uparrow}$ packages an eigenvalue / eigenvector pair (λ, v) for a linear endomorphism. It depends on $\mathsf{NameCert}_{\mathsf{LinMap}^{\uparrow}}$ (chapter 48) and $\mathsf{NameCert}_{\mathsf{Determinant}^{\uparrow}}$ (chapter 84), with λ certified as a root of the characteristic polynomial.

85.1 Carrier definition

Definition 85.1 (Eigen component singleton carrier)**.** *For histories $f, \lambda, v, pair : \mathsf{BHist}$, the component singleton eigen carrier requires f and v to be singleton linear-map histories, λ to be a singleton commutative-ring history, and pair to be the BEDC continuation endpoint of λ followed by v.*

Lean4 (definition) `BEDC.Derived.EigenUp.EigenComponentSingletonCarrier`

Theorem 85.2 (Eigen component singleton carrier singleton append)**.** *For histories $m, \lambda, v, pair : \mathsf{BHist}$, if the component singleton eigen carrier holds for $(m, \lambda, v, pair)$ and λ also carries the determinant singleton scalar certificate, then $\mathsf{append}(m, pair)$ lies in the eigen singleton carrier.*

Proof. Unpack the component carrier into the linear-map carrier for m, the linear-map carrier for v, and the continuation endpoint $\mathsf{Cont}(\lambda, v, pair)$. The determinant singleton carrier for λ supplies the scalar witness required by the eigen singleton carrier. The stored continuation rewrites $\mathsf{append}(m, pair)$ as $\mathsf{append}(m, \mathsf{append}(\lambda, v))$, giving the required BEDC continuation endpoint. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenComponentSingletonCarrier singleton append`

Theorem 85.3 (Eigen component singleton carrier continuation result transport)**.** *For histories $m, \lambda, v, pair, full, full' : \mathsf{BHist}$, suppose the component singleton eigen carrier holds for $(m, \lambda, v, pair)$, λ carries the determinant singleton scalar certificate, $\mathsf{Cont}(m, pair, full)$, and $full \mathsf{hsame} full'$. Then $full'$ lies in the eigen singleton carrier.*

Proof. Unpack the component carrier to expose the linear-map carriers for m and v and the scalar-vector continuation $\mathsf{Cont}(\lambda, v, pair)$. Compose this continuation with $\mathsf{Cont}(m, pair, full)$ to rewrite the endpoint as $\mathsf{Cont}(m, \mathsf{append}(\lambda, v), full)$. The determinant singleton carrier for λ and the final hsame-transport place $full'$ in the eigen singleton carrier. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenComponentSingletonCarrier cont result transport`

Theorem 85.4 (Eigen component singleton carrier pair determinacy)**.** *For histories $f, \lambda, v, pair, pair'$: BHist, two component singleton eigen carriers over the same (f, λ, v) determine the same scalar-vector endpoint $\mathsf{hsame}(pair, pair')$. Both stored continuation ledgers $\mathsf{Cont}(\lambda, v, pair)$ and $\mathsf{Cont}(\lambda, v, pair')$ remain available.*

Proof. Unpack both component singleton carriers. They contain the two BEDC continuation ledgers with the same source λ and tail v. The kernel determinacy theorem for continuation endpoints identifies their results, and the two ledgers are retained directly from the carriers. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenComponentSingletonCarrier pair deterministic`

Theorem 85.5 (Eigen component singleton carrier append classifier)**.** *For histories $m, m', \lambda, \lambda', v, v', pair, pair'$: BHist, suppose the component singleton eigen carriers hold for $(m, \lambda, v, pair)$ and $(m', \lambda', v', pair')$, both scalar components carry determinant singleton certificates, and the three displayed components satisfy $m\mathsf{hsame}m'$, $\lambda\mathsf{hsame}\lambda'$, and $v\mathsf{hsame}v'$. Then the append endpoints $\mathsf{append}(m, pair)$ and $\mathsf{append}(m', pair')$ are classified by the eigen singleton classifier.*

Proof. The component carriers and determinant singleton scalar certificates give the two eigen singleton carrier endpoints by Definition 85.2. Unpacking the component carriers exposes the two BEDC continuations $\mathsf{Cont}(\lambda, v, pair)$ and $\mathsf{Cont}(\lambda', v', pair')$. Continuation respects the scalar and vector history equalities, so $pair\mathsf{hsame}pair'$. Applying the same continuation-respect principle to the map equality and these pair endpoints identifies $\mathsf{append}(m, pair)$ with $\mathsf{append}(m', pair')$, closing the restricted classifier. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenComponentSingletonCarrier append classifier`

Theorem 85.6 (Eigen singleton carrier pair emptiness)**.** *For histories $f, \lambda, v, pair$: BHist, the component singleton eigen carrier is equivalent to the three singleton component carriers together with $\mathsf{hsame}(pair, \mathsf{e})$.*

Proof. Unfold the component singleton eigen carrier. In the forward direction, the scalar and vector component carriers identify λ and v with e, so $\mathsf{append}(\lambda, v)$ is empty by the BEDC append-empty inversion, and the stored continuation transports this emptiness to $pair$. In the reverse direction, the same append-empty fact reconstructs the continuation endpoint from the given $\mathsf{hsame}(pair, \mathsf{e})$ witness. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenSingletonCarrier pair empty iff`

Definition 85.7 (Eigen singleton carrier)**.** *A history p lies in the singleton eigen carrier when there are histories m, λ, v such that m and v are singleton linear-map carriers, λ is a singleton determinant carrier, and p is the continuation result*

$$\mathsf{Cont}(m, \mathsf{append}(\lambda, v), p).$$

Lean4 (definition) `BEDC.Derived.EigenUp.EigenSingletonCarrier`

Theorem 85.8 (Eigen singleton carrier continuation result transport)**.** *For histories m, λ, v, p, p' : BHist, if m and v are singleton linear-map carriers, λ is a singleton determinant carrier, $\mathsf{Cont}(m, \mathsf{append}(\lambda, v), p)$, and $p\mathsf{hsame}p'$, then p' lies in the eigen singleton carrier.*

Proof. Reuse the same displayed witnesses m, λ, v. The carrier fields are unchanged, and the continuation result transports along $p\mathsf{hsame}p'$ by the kernel result-transport theorem for Cont. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenSingletonCarrier cont result transport`

Theorem 85.9 (Eigen singleton carrier empty iff)**.** *For every history p : BHist, the singleton eigen carrier holds for p exactly when $p\mathsf{hsamee}$.*

Proof. For the forward direction, unpack the map, scalar, and vector witnesses. The linear-map and determinant singleton carriers identify each component with e, so the nested append endpoint is empty; the stored continuation transports this emptiness to p. For the reverse direction, choose all three witness components to be e and use the displayed $p\mathsf{hsamee}$ witness as the empty continuation result. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenSingletonCarrier empty iff`

Theorem 85.10 (Eigen singleton continuation sources empty)**.** *For BEDC histories map, payload, and pair, if pair lies in the eigen singleton carrier and $\mathsf{Cont}(map, payload, pair)$, then both continuation sources are empty:*

$$\mathsf{EigenSingletonCarrier}(pair) \wedge \mathsf{Cont}(map, payload, pair) \Longrightarrow map\mathsf{hsamee} \ \wedge \ payload\mathsf{hsamee}.$$

Proof. The carrier-empty equivalence identifies *pair* with e. The continuation payload identifies *pair* with $\mathsf{append}(map, payload)$, hence the append endpoint is empty. BEDC append-empty inversion splits this endpoint into the two empty source comparisons. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenSingletonCarrier cont sources empty`

Theorem 85.11 (Eigen singleton carrier append-context empty iff)**.** *For histories L, R, h : BHist, the contextual eigen singleton carrier holds for $\mathsf{append}(L, \mathsf{append}(h, R))$ exactly when the two context histories are empty and the middle history lies in the eigen singleton carrier:*

$$\mathsf{EigenSingletonCarrier}(\mathsf{append}(L, \mathsf{append}(h, R))) \Longleftrightarrow L\mathsf{hsamee} \wedge \mathsf{EigenSingletonCarrier}(h) \wedge R\mathsf{hsamee}.$$

Proof. Use the eigen singleton carrier empty equivalence to convert the contextual carrier into emptiness of the nested append. BEDC append-empty inversion splits the outer and inner append endpoints, yielding empty left and right contexts and empty middle endpoint. The reverse direction rebuilds the nested append-empty witness from the three displayed fields and applies the same carrier-empty equivalence backwards. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenSingletonCarrier append context empty iff`

Theorem 85.12 (Eigen singleton carrier continuation left-unit result)**.** *For histories $pair, q, result$: BHist, if pair lies in the eigen singleton carrier and $\mathsf{Cont}(pair, q, result)$, then $result\mathsf{hsamee}q$.*

Proof. The eigen singleton carrier empty equivalence identifies *pair* with e. After this source readback, the displayed continuation has empty source, so the BEDC left-unit result theorem for Cont reads the endpoint back to the tail q. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenSingletonCarrier cont left unit result`

Theorem 85.13 (Eigen singleton carrier continuation right-unit result)**.** *For histories $q, pair, result$: BHist, if pair lies in the eigen singleton carrier and $\mathsf{Cont}(q, pair, result)$, then $result\mathsf{hsamee}q$.*

Proof. The carrier-empty equivalence identifies *pair* with e. Transport the displayed continuation across that endpoint comparison and compare it with the right-unit continuation at q; continuation determinacy gives the result. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenSingletonCarrier cont right unit result`

85.2 The certificate

Definition 85.14 (Eigen singleton classifier)**.** *Two histories* p, q : BHist *are classified by the singleton eigen interface when both lie in the singleton eigen carrier and* $p$hsame$q$*.*

Lean4 (definition) `BEDC.Derived.EigenUp.EigenSingletonClassifier`

Theorem 85.15 (Eigen singleton classifier append-context empty iff)**.** *For histories* L, R, h, k : BHist*, the contextual singleton eigen classifier between* append(L, h) *and* append(k, R) *is equivalent to empty endpoint contexts and the core classifier between* h *and* k*:*

$$\mathsf{EigenSingletonClassifier}(\mathsf{append}(L, h), \mathsf{append}(k, R)) \iff L\mathsf{hsamee} \wedge \mathsf{EigenSingletonClassifier}(h, k) \wedge R\mathsf{hsamee}.$$

Proof. The forward direction sends both contextual carrier fields through the eigen carrier empty equivalence and splits the two append-empty witnesses. These middle empty witnesses give the core carriers and identify h with k. In the reverse direction, the empty endpoint contexts and the two core carrier fields rebuild the left and right contextual carriers, and both contextual endpoints are history-same because each is empty. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenSingletonClassifier append context empty iff`

Theorem 85.16 (Eigen singleton classifier continuation results hsame)**.** *For histories* h, k, q, q', r, r' : BHist*, if* EigenSingletonClassifier(h, k)*,* $q$hsameq'*,* Cont(h, q, r)*, and* Cont(k, q', r')*, then* $r$hsamer'*.*

Proof. The classifier exposes eigen singleton carrier witnesses for both sources. The carrier continuation left-unit result reads r back to q and r' back to q'. Composing these two readbacks with the supplied tail equality $q$hsameq' gives the endpoint equality $r$hsamer'. □

Lean4 ✓ `BEDC.Derived.EigenUp.EigenSingletonClassifier continuation results hsame`

Theorem 85.17 (Eigen singleton semantic name certificate)**.** *The singleton eigen carrier, equipped with the carrier-restricted* hsame *classifier above, satisfies the semantic naming-certificate schema.*

Proof. The carrier is inhabited by the displayed empty eigen pair: empty linear-map history, empty determinant history, empty vector history, and the empty continuation endpoint. Reflexivity, symmetry, and transitivity are inherited from hsame, with carrier membership retained in the classifier fields. Pattern and ledger soundness are the identity inclusions on the same carrier. □

Lean4 ✓ `BEDC.Derived.EigenUp.eigen singleton semantic name certificate`

Closure status for $\mathsf{NameCert}_{\mathsf{Eigen}^\uparrow}$**.**

Constructive story: An $\mathsf{Eigen}^\uparrow$ singleton certificate is generated from a linear-map history, scalar history, vector history, and scalar-vector continuation endpoint. In the displayed BEDC carrier, the scalar row is admitted through the determinant singleton certificate, the map and vector rows are admitted through linear-map singleton carriers, and Cont composes the scalar-vector pair with the map row. The hsame classifier then transports and compares the resulting eigen endpoint. In this singleton presentation the accepted endpoint collapses to the empty history, so the chapter certifies the BEDC name discipline for the eigen interface without adding analytic spectral data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Eigen}^\uparrow}$, seed)

Scope closed: This chapter binds the Eigen singleton component carrier, singleton carrier, classifier, and semantic name certificate.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Eigen}^\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: It does not claim a general spectral theorem, nonzero eigenvector existence, host vector-space equality, or characteristic-polynomial completeness.

Upgrade path: To reach obligationClosure, align the paper closure block with a checked Eigen carrier target and its classifier transport theorems.

Chapter 86

A Concrete Naming Certificate for $\mathsf{InnerProduct}^{\uparrow}$

The inner-product interface $\mathsf{InnerProduct}^{\uparrow}$ packages a vector space together with a constructive sesquilinear form satisfying conjugate symmetry, linearity, and positive definiteness. It depends on $\mathsf{NameCert}_{\mathsf{VecSpace}^{\uparrow}}$ (chapter 47) and is the direct prerequisite for the Hilbert certificate $\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}$. The scalar-form rows consume the vector carrier and classifier of chapter 47 and provide the immediate finite source surface for chapter 91.

The mature $\mathsf{InnerProduct}^{\uparrow}$ row is also the bilinear, symmetric, positive source consumed by chapter 89, chapter 91, and bounded-operator or Hilbert-completion routes: norm witnesses, distance witnesses, completion obligations, orthogonality witnesses, and operator-domain compatibility are read from the displayed scalar-form laws rather than from a host inner-product space.

86.1 Carrier definition

Definition 86.1 (Inner-product BHist carrier)**.** *An inner-product* BHist *carrier is a displayed package over a source* $\mathsf{NameCert}_{\mathsf{VecSpace}^{\uparrow}}$*. It consists of the following rows:*

1. *a vector carrier* $V : \mathsf{BHist} \to \mathsf{Prop}$*;*
2. *a vector classifier* $\sim_V$ *on carried vector histories;*
3. *the vector addition, vector zero, vector negation, and scalar-action rows inherited from the displayed* $\mathsf{VecSpace}^{\uparrow}$ *source;*
4. *a scalar endpoint classifier* $\sim_{\mathbb{K}}$ *supplied by the scalar side of the* $\mathsf{VecSpace}^{\uparrow}$ *source;*
5. *an inner-product endpoint row* $\langle -, - \rangle_{\mathsf{InnerProduct}^{\uparrow}} : V \times V \to \mathsf{BHist}$ *whose values are carried by the scalar endpoint source;*
6. *a conjugate-symmetry row identifying* $\langle x, y \rangle_{\mathsf{InnerProduct}^{\uparrow}}$ *with the conjugate scalar endpoint of* $\langle y, x \rangle_{\mathsf{InnerProduct}^{\uparrow}}$*;*
7. *sesquilinear rows for vector addition in the additive argument and scalar-action compatibility in the scalar argument, all classified by* $\sim_{\mathbb{K}}$*;*
8. *a positive-definite row saying that* $\langle x, x \rangle_{\mathsf{InnerProduct}^{\uparrow}}$ *is nonnegative and that its scalar zero classification holds exactly when* $x \sim_V 0_V$*;*

9. *a visible ledger recording the* $\mathsf{VecSpace}^{\uparrow}$ *source row, every scalar endpoint classifier used by the form, the operation rows consumed by the sesquilinear clauses, and the positive-definite witness row.*

The carrier is therefore a named BHist *display, not a host inner-product space. Downstream certificates read vector endpoints, scalar endpoints, and form values only through these displayed rows.*

Lean4 (definition) `BEDC.Derived.InnerProductUp.InnerProductBHistCarrier`

Definition 86.2 (Inner-product BHist classifier)**.** *Two carried inner-product rows are classified exactly when all visible source rows match. Their vector carriers and vector classifiers agree through the same* $\mathsf{NameCert}_{\mathsf{VecSpace}^{\uparrow}}$ *source; their scalar endpoint classifiers agree on every displayed value of* $\langle -, - \rangle_{\mathsf{InnerProduct}^{\uparrow}}$*; and the addition, zero, negation, scalar-action, conjugate-symmetry, sesquilinear, positive-definite, and ledger rows match componentwise by* hsame*.*

Thus the classifier does not identify two inner-product packages by an external isometry. It identifies them only by equality of the displayed BEDC rows that a later $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{RiemannianMetric}^{\uparrow}$*,* $\mathsf{Fourier}^{\uparrow}$*, or* $\mathsf{RootSystem}^{\uparrow}$ *certificate is allowed to consume.*

Lean4 ✓ `BEDC.Derived.InnerProductUp.TasteGate.InnerProductTasteGate single carrier alignment`

86.2 The certificate

Definition 86.3 (InnerProduct BHist source data)**.** *An* $\mathsf{InnerProduct}^{\uparrow}$ *BHist source consists of a displayed* $\mathsf{VecSpace}^{\uparrow}$ *BHist carrier* $C_V : \mathsf{BHist} \to \mathsf{Prop}$ *with classifier* $\sim_V$*, scalar data carried by the scalar source retained from* $\mathsf{Field}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$*, and a binary row*

$$\langle -, - \rangle : C_V \times C_V \to C_{\mathsf{scal}}$$

whose endpoints are scalar histories. The source also displays conjugation on the scalar side, the scalar classifier $\sim_{\mathsf{scal}}$*, and the certificate rows asserting conjugate symmetry, positivity, linearity in each admitted argument, and transport through* $\sim_V$ *and* $\sim_{\mathsf{scal}}$*.*

All rows are BHist rows. Thus the form does not land in a host field or a quotient object; it lands in the scalar histories already exposed by the field and vector-space certificates.

Theorem 86.4 (InnerProduct BHist carrier row)**.** *For an* $\mathsf{InnerProduct}^{\uparrow}$ *BHist source, the public carrier row is exactly the* $\mathsf{VecSpace}^{\uparrow}$ *BHist carrier* C_V *together with the displayed scalar-valued form row* $\langle -, - \rangle$*. No further point carrier is introduced by the inner-product certificate.*

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductBHistCarrierRow`

Proof. Project the vector-space component of Definition 86.3. It already supplies the carried predicate C_V, the classifier $\sim_V$, vector addition, vector zero, vector negation, scalar action, and scalar source.

Project the form component. Its domain is the displayed pair carrier $C_V \times C_V$, and its codomain is the retained scalar history carrier C_{scal}. These two projections are exactly the carrier row and the additional scalar-valued row named by $\mathsf{InnerProduct}^{\uparrow}$. □

Theorem 86.5 (InnerProduct symmetry and positivity row)**.** *For an* $\mathsf{InnerProduct}^{\uparrow}$ *BHist source, conjugate symmetry and positivity are certificate fields over the retained scalar classifier. For carried histories* $x, y : C_V$*, the symmetry row classifies*

$$\langle x, y \rangle \sim_{\mathsf{scal}} \overline{\langle y, x \rangle},$$

and the positivity row is a displayed scalar-history witness for $\langle x, x\rangle$ together with the exact zero-classification clause. These rows do not use host order, quotient equality, or an external positivity predicate.

Proof. Unpack the symmetry field of Definition 86.3. It compares the scalar endpoint $\langle x, y\rangle$ with the conjugated scalar endpoint $\overline{\langle y, x\rangle}$ using $\sim_{\mathsf{scal}}$.

Unpack the positivity field. Its witness is recorded as scalar-history data for the diagonal endpoint $\langle x, x\rangle$, and its zero clause is stated by the same retained scalar classifier. Since both fields are projections of the displayed source, no host order or quotient equality is added. □

Theorem 86.6 (InnerProduct VecSpace linearity row)**.** *For an* $\mathsf{InnerProduct}^{\uparrow}$ *BHist source, additivity and scalar compatibility in each admitted argument are read through the* $\mathsf{VecSpace}^{\uparrow}$ *addition row, scalar-action row, and classifier transport. Thus the clauses comparing*

$$\langle x +_V y, z\rangle \quad \textit{with} \quad \langle x, z\rangle +_{\mathsf{scal}} \langle y, z\rangle$$

and

$$\langle a \cdot_V x, y\rangle \quad \textit{with} \quad a \cdot_{\mathsf{scal}} \langle x, y\rangle$$

are scalar-classifier rows over the same carried inputs, with the conjugate argument handled by the displayed conjugation row when the source uses that side as the conjugate-linear argument.

Proof. Read addition and scalar action from the embedded $\mathsf{VecSpace}^{\uparrow}$ row. Closure places $x +_V y$ and $a \cdot_V x$ back in C_V, so the inner-product row can be evaluated at the displayed endpoints.

Read scalar addition, scalar multiplication, and conjugation from the retained scalar source. The linearity fields compare the resulting scalar endpoints by $\sim_{\mathsf{scal}}$.

If representatives of the vector or scalar inputs are changed within their classifiers, use the transport fields of the vector-space source and the scalar source before applying the displayed linearity row. The conclusion is therefore a row over the existing $\mathsf{VecSpace}^{\uparrow}$ operations, not a separate algebraic structure. □

Theorem 86.7 (InnerProduct classifier transport row)**.** *For an* $\mathsf{InnerProduct}^{\uparrow}$ *BHist source, if $x \sim_V x'$ and $y \sim_V y'$ for carried histories $x, y, x', y' : C_V$, then the scalar endpoints of the inner-product row transport through the retained scalar classifier:*

$$\langle x, y\rangle \sim_{\mathsf{scal}} \langle x', y'\rangle.$$

Proof. Project the pair-transport field from Definition 86.3. Its hypotheses are exactly the two vector classifier witnesses $x \sim_V x'$ and $y \sim_V y'$.

The field returns a scalar classifier witness between the two displayed inner-product endpoints. Since the codomain classifier is $\sim_{\mathsf{scal}}$, the transported endpoint remains in the retained scalar source. □

Theorem 86.8 (InnerProduct Hilbert boundary row)**.** *A* $\mathsf{Hilbert}^{\uparrow}$ *certificate may consume from an* $\mathsf{InnerProduct}^{\uparrow}$ *BHist source only the carrier C_V, classifier $\sim_V$, linearity rows, conjugate symmetry row, positivity row, scalar endpoint row, classifier transport row, and the derived orthogonality row of Definition 86.13 together with its zero-left, zero-right, and transport laws. Completeness, Cauchy-limit selection, and Banach metric closure are not part of the* $\mathsf{InnerProduct}^{\uparrow}$ *boundary.*

Proof. The Hilbert carrier definition in Definition 91.1 asks the inner-product side for vector carrier sharing, the scalar-valued form, linearity, symmetry, positivity, and transport. These are precisely the rows displayed in Definition 86.3.

The same Hilbert definition obtains completeness from its Banach row. The orthogonality predicate is obtained from the scalar-zero classification of the inner-product endpoint, and its zero and transport laws are supplied by Definition 86.14, Definition 86.15, and Definition 86.16. Hence no completeness or Cauchy-limit field can be projected from the inner-product source, and the boundary available to $\mathsf{Hilbert}^{\uparrow}$ is exactly the displayed inner-product surface. □

Theorem 86.9 (InnerProduct root certificate row)**.** *The carrier row of Definition 86.4, the symmetry and positivity row of Definition 86.5, the linearity row of Definition 86.6, the classifier transport row of Definition 86.7, and the Hilbert boundary row of Definition 86.8 assemble the paper-side* $\mathsf{NameCert}_{\mathsf{InnerProduct}^{\uparrow}}$ *obligation surface.*

Proof. Use Definition 86.3 for the source package. Its first projection gives the vector-space carrier and scalar source, and Definition 86.4 records that no second point carrier is present.

Use Definition 86.5 and Definition 86.6 for the algebraic rows of the form. These rows are all scalar-history comparisons under $\sim_{\mathsf{scal}}$.

Use Definition 86.7 for representative stability. Use Definition 86.8 for the downstream boundary consumed by $\mathsf{Hilbert}^{\uparrow}$.

Together these projections supply carrier, classifier, exactness, stability, and ledger provenance for the $\mathsf{InnerProduct}^{\uparrow}$ naming certificate, with bridge status left unclaimed. □

Theorem 86.10 (Inner-product carrier transport obligation)**.** *Let I be an inner-product* BHist *carrier as in Definition 86.1. If $x \sim_V x'$ and $y \sim_V y'$, then the vector carrier rows, scalar endpoint rows, inner-product endpoint row, conjugate-symmetry row, sesquilinear rows, positive-definite row, and ledger entries of I transport componentwise by* hsame *from (x, y) to (x', y').*

Proof. Start with the $\mathsf{VecSpace}^{\uparrow}$ source row inside I. Its carrier and classifier transport move x to x' and y to y' while preserving the displayed vector addition, zero, negation, and scalar-action rows.

Next apply the scalar endpoint classifier row to the two displayed values $\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ and $\langle x', y'\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. The inner-product classifier of Definition 86.2 requires these scalar endpoints to be classified by the same $\sim_{\mathbb{K}}$ row, so the form endpoint transports with the vector representatives.

Finally transport the proof rows attached to that endpoint. Conjugate symmetry, both sesquilinear rows, positivity, and ledger provenance are stored as displayed rows in the carrier. Since classification is componentwise hsame on those rows, each witness is copied to the transported package without introducing any external inner-product-space equality. □

Theorem 86.11 (Inner-product sesquilinear source obligation)**.** *Every sesquilinear clause of an inner-product* BHist *carrier is sourced from its displayed* $\mathsf{VecSpace}^{\uparrow}$ *and scalar rows. Additivity uses the vector addition row and the scalar addition classifier from the scalar endpoint source; scalar-action compatibility uses the displayed scalar action and the scalar multiplication, conjugation, and endpoint classifier rows from the same source ledger.*

Proof. Unpack the carrier of Definition 86.1. The only vector operations available to the form are the $\mathsf{VecSpace}^{\uparrow}$ rows listed in the carrier: addition, zero, negation, and scalar action. The additivity clause is therefore stated over the displayed vector addition row and is classified on the scalar side by $\sim_{\mathbb{K}}$.

For scalar compatibility, the scalar used in the vector action is the same scalar endpoint read by the $\mathsf{VecSpace}^{\uparrow}$ source. The scalar multiplication and conjugation rows used to express sesquilinearity are ledger entries over that scalar source, and the resulting equality of form values is again classified by $\sim_{\mathbb{K}}$.

The ledger records each operation row consumed in these clauses. Hence a certificate consumer can reconstruct the additivity and scalar-action compatibility obligations from displayed BEDC rows alone, with no appeal to a host field or a host vector space. □

Theorem 86.12 (Inner-product positive-definite obligation)**.** *For every carried vector endpoint x in an inner-product* BHist *carrier, the self-value $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ is classified as a nonnegative scalar endpoint. Moreover the self-value is classified as the scalar zero endpoint if and only if x is classified by $\sim_V$ with the displayed vector zero row 0_V.*

Proof. Read the self-value row from Definition 86.1. Its positive-definite entry contains the nonnegative scalar endpoint witness for $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$, and the scalar classifier used for that witness is the scalar endpoint classifier $\sim_{\mathbb{K}}$ already stored in the carrier.

For the zero direction, assume the self-value is classified as the scalar zero endpoint. The positive-definite row includes the exactness clause converting that scalar classification into the vector classifier equality $x \sim_V 0_V$.

For the converse direction, assume $x \sim_V 0_V$. The carrier-transport obligation transports the self-value row along this vector classification, and the positive-definite row at the displayed zero endpoint supplies the scalar zero classification. Combining these two displayed rows gives the required scalar endpoint classification for $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. □

Definition 86.13 (InnerProduct orthogonality row)**.** *For carried* BHist *vector endpoints x, y from Definition 86.1, write $x \perp_I y$ exactly when the scalar endpoint $\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ is classified by the retained scalar classifier with the displayed scalar zero endpoint:*

$$x \perp_I y \quad \Longleftrightarrow \quad \langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

This is a row of the $\mathsf{InnerProduct}^{\uparrow}$ *carrier, not a host Hilbert-space orthogonality relation.*

Theorem 86.14 (InnerProduct zero-left orthogonality row)**.** *For every carried vector endpoint x in an inner-product* BHist *carrier, the displayed vector zero row is orthogonal to x:*

$$0_V \perp_I x.$$

Proof. Read the displayed vector zero endpoint 0_V from the embedded $\mathsf{VecSpace}^{\uparrow}$ row and evaluate the inner-product endpoint row at $(0_V, x)$.

The sesquilinearity row for scalar action compares $\langle 0_{\mathbb{K}} \cdot_V 0_V, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ with $0_{\mathbb{K}} \cdot_{\mathbb{K}} \langle 0_V, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. The vector zero row classifies $0_{\mathbb{K}} \cdot_V 0_V$ with 0_V, and the scalar zero law classifies the displayed scalar product with $0_{\mathbb{K}}$.

Transport these two comparisons through the scalar endpoint classifier. By Definition 86.13, the resulting scalar-zero classification is exactly $0_V \perp_I x$. □

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductSingletonOrthogonal zero left`

Theorem 86.15 (InnerProduct zero-right orthogonality row)**.** *For every carried vector endpoint x in an inner-product* BHist *carrier, x is orthogonal to the displayed vector zero row:*

$$x \perp_I 0_V.$$

Proof. Apply the conjugate-symmetry row to compare $\langle x, 0_V\rangle_{\mathsf{InnerProduct}^\uparrow}$ with the conjugate scalar endpoint of $\langle 0_V, x\rangle_{\mathsf{InnerProduct}^\uparrow}$.

By Definition 86.14, $\langle 0_V, x\rangle_{\mathsf{InnerProduct}^\uparrow}$ is classified with $0_{\mathbb{K}}$. The scalar zero endpoint is fixed by the displayed conjugation row, so the conjugated endpoint is also classified with $0_{\mathbb{K}}$.

Use transitivity of the retained scalar classifier to combine the symmetry comparison with this scalar-zero classification. The definition of $\perp_I$ then gives $x \perp_I 0_V$. □

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductSingletonOrthogonal zero right`

Theorem 86.16 (InnerProduct orthogonality transport row)**.** *For carried vector endpoints x, y, x', y' in an inner-product* BHist *carrier, if $x \sim_V x'$, $y \sim_V y'$, and $x \perp_I y$, then $x' \perp_I y'$.*

Proof. Unpack $x \perp_I y$ using Definition 86.13. This gives a scalar classifier witness from $\langle x, y\rangle_{\mathsf{InnerProduct}^\uparrow}$ to the displayed scalar zero endpoint.

Apply Definition 86.7 to the vector classifier witnesses $x \sim_V x'$ and $y \sim_V y'$. It supplies a scalar classifier comparison between $\langle x, y\rangle_{\mathsf{InnerProduct}^\uparrow}$ and $\langle x', y'\rangle_{\mathsf{InnerProduct}^\uparrow}$.

Combine that comparison with the scalar-zero witness by transitivity of $\sim_{\mathbb{K}}$. The resulting classification of $\langle x', y'\rangle_{\mathsf{InnerProduct}^\uparrow}$ with $0_{\mathbb{K}}$ is precisely $x' \perp_I y'$ by Definition 86.13. □

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductSingletonOrthogonal transport`

Theorem 86.17 (Inner-product NameCert obligation surface)**.** *The carrier of Definition 86.1, the classifier of Definition 86.2, carrier transport, sesquilinear source tracking, positive definiteness, and the visible ledger assemble the paper-side* $\mathsf{NameCert}_{\mathsf{InnerProduct}^\uparrow}$ *obligation surface. Its ten roadmap fields are:*

1. *traditional target: a vector space equipped with a positive-definite sesquilinear form;*
2. *BEDC source:* BHist*;*
3. *carrier choice: the displayed vector carrier V over* $\mathsf{NameCert}_{\mathsf{VecSpace}^\uparrow}$*;*
4. *classifier choice: componentwise agreement of the vector, scalar, form, law, and ledger rows;*
5. *stability obligations: carrier transport, scalar endpoint transport, conjugate symmetry, sesquilinearity, and positive-definite transport;*
6. *ledger: the* $\mathsf{VecSpace}^\uparrow$ *source, scalar endpoint classifier, operation rows, form row, law rows, and positivity witness;*
7. *core theorem list: Definition 86.10, Definition 86.11, and Definition 86.12; the orthogonality rows are Definition 86.14, Definition 86.15, and Definition 86.16;*
8. *exactness predicate: scalar zero self-value exactly matches vector-classifier equality to 0_V;*
9. *standard bridge: none;*
10. *status: paper obligation surface.*

No standard Hilbert-space bridge is claimed by this surface.

Proof. Use Definition 86.1 for the public carrier field. It names the vector carrier, vector classifier, scalar endpoint classifier, inner-product row, law rows, positive-definite row, and ledger over a single $\mathsf{VecSpace}^\uparrow$ source.

Use Definition 86.2 for the classifier field. It requires componentwise agreement of exactly the rows exposed by the carrier, so downstream consumers receive the same vector, scalar, form, and ledger surface after classification.

Use Definition 86.10 for the stability field, Definition 86.11 for the operation-source field, and Definition 86.12 for exactness of the self-value row. Use Definition 86.13, Definition 86.14, Definition 86.15, and Definition 86.16 for the orthogonality surface consumed by downstream Hilbert rows.

The remaining roadmap fields are read directly from the same displayed ledger: the target is the named positive-definite sesquilinear form, the BEDC source is BHist, and the bridge field is explicitly empty. Thus $\mathsf{NameCert}_{\mathsf{InnerProduct}^{\uparrow}}$ is available as a paper-side obligation surface without importing host Hilbert-space structure. □

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductSingleton semanticNameCert`

Theorem 86.18 (InnerProduct public export surface)**.** *The carrier of Definition 86.1, the classifier of Definition 86.2, carrier transport, the sesquilinear source, positive definiteness, zero-left and zero-right orthogonality, orthogonality transport, and the root dependency rows export exactly the public* $\mathsf{InnerProduct}^{\uparrow}$ *BHist surface: the* $\mathsf{VecSpace}^{\uparrow}$ *carrier and classifier, the scalar endpoint classifier, the inner-product row, the law rows, the orthogonality rows, and the visible ledger. The export withholds completeness, Banach metric closure, ambient topology, a standard Hilbert bridge, and host Hilbert-space equality.*

Proof. Apply Definition 86.17. It assembles the carrier, classifier, carrier transport, sesquilinear source tracking, positive-definite exactness, visible ledger, and orthogonality rows into the paper-side $\mathsf{NameCert}_{\mathsf{InnerProduct}^{\uparrow}}$ obligation surface.

Apply Definition 86.19. Its tuple is the dependency row exported by $\mathsf{InnerProduct}^{\uparrow}$ to later certificates, and it lists only the displayed vector, scalar, form, law, transport, and ledger rows.

Apply Definition 86.20 and Definition 86.21. These identify the exposed $\mathsf{VecSpace}^{\uparrow}$ carrier and classifier, scalar endpoint classifier, scalar operation rows, inner-product row, and inner-product law rows.

Apply Definition 86.22. It states that Hilbert consumption obtains vector, scalar, form, law, and ledger data from this root surface while completeness and Cauchy-limit selection enter only through a separate Banach and completeness row. Thus the public export is the displayed $\mathsf{InnerProduct}^{\uparrow}$ BHist surface, with no completeness, Banach metric closure, ambient topology, standard Hilbert bridge, or host Hilbert-space equality included. □

Definition 86.19 (InnerProduct root dependency surface)**.** *The* $\mathsf{InnerProduct}^{\uparrow}$ *root dependency surface is the displayed tuple consisting of the* $\mathsf{VecSpace}^{\uparrow}$ *carrier and classifier of Definition 86.1, the retained scalar endpoint source, the inner-product endpoint row, the conjugate-symmetry row, the sesquilinear rows, the positive-definite exactness row, the classifier transport row, and the visible ledger. It is the exact dependency package exported by* $\mathsf{InnerProduct}^{\uparrow}$ *to later certificates: every projected component is one of these displayed rows, and no completeness, Banach metric, ambient topology, or host Hilbert-space row is part of the tuple.*

Theorem 86.20 (InnerProduct root vector-scalar exposure)**.** *Every consumer of the root surface of Definition 86.19 can project exactly the vector carrier and classifier, the vector addition, zero, negation, and scalar action rows, the scalar endpoint classifier, and the scalar operation rows already named in Definition 86.1 and Definition 86.3. No separate vector carrier or scalar endpoint source is exposed.*

Proof. Project the vector portion of the root surface. By Definition 86.4, this projection is the displayed $\mathsf{VecSpace}^{\uparrow}$ BHist carrier C_V together with its classifier $\sim_V$, vector operations, scalar action row, and scalar-valued form row.

Project the scalar portion from the same source tuple. The scalar endpoint classifier and scalar operation rows are the retained rows of Definition 86.3; if a representative changes, apply Definition 86.10 to transport the displayed form and operation rows through the exposed classifiers.

These projections exhaust the vector-scalar part of Definition 86.19. Since the definition lists only displayed carrier, classifier, operation, scalar endpoint, form, law, and ledger rows, there is no second vector carrier or scalar endpoint source to project. □

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductRoot vecspace scalar exposure`

Theorem 86.21 (InnerProduct root form-law exposure)**.** *For the root surface of Definition 86.19, conjugate symmetry, sesquilinearity, positive definiteness, and form endpoint transport are exactly the law rows exposed by the surface. A consumer may read those rows, and only those rows, as the inner-product law interface.*

Proof. The conjugate-symmetry and positivity rows are the rows identified by Definition 86.5. They compare scalar histories under the retained scalar classifier and do not introduce a host scalar field.

The additive and scalar-action compatibility rows are the sesquilinear rows identified by Definition 86.6. Their inputs are the exposed vector operations and scalar endpoint operations from the root surface.

Positive-definite exactness is the row supplied by Definition 86.12, and endpoint transport is the row supplied by Definition 86.7. Together these rows are precisely the law entries named in Definition 86.19; all remaining entries of the root surface are carrier, source, classifier, or ledger entries. □

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductRoot form law exposure`

Theorem 86.22 (InnerProduct root Hilbert consumption surface)**.** *A* $\mathsf{Hilbert}^{\uparrow}$ *dependency may consume the root surface of Definition 86.19 together with its separate Banach and completeness row. A* $\mathsf{Fourier}^{\uparrow}$*,* $\mathsf{RiemannianMetric}^{\uparrow}$*, or* $\mathsf{RootSystem}^{\uparrow}$ *dependency may consume only the vector, scalar, form, law, and ledger rows of the same root surface.*

Proof. For $\mathsf{Hilbert}^{\uparrow}$, apply Definition 86.8. It allows the Hilbert certificate to read the carrier, classifier, scalar-valued form, linearity, conjugate symmetry, positivity, scalar endpoint, and transport rows from $\mathsf{InnerProduct}^{\uparrow}$.

The vector and scalar projections used by this boundary are exactly the ones identified by Definition 86.20. The form and law projections are exactly the ones identified by Definition 86.21.

Completeness and Cauchy-limit selection are not projected from $\mathsf{InnerProduct}^{\uparrow}$; they must enter through the separate Banach and completeness row of the Hilbert dependency. The non-Hilbert consumers named in the statement therefore receive only the root surface rows for vector, scalar, form, law, and ledger data, with no Banach or completeness projection. □

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductRootHilbert consumption surface`

Definition 86.23 (InnerProduct root threshold source)**.** *The* $\mathsf{InnerProduct}^{\uparrow}$ *root threshold source is the* BHist*-indexed package obtained from Definition 86.19 by exposing precisely the rows needed before any* $\mathsf{Hilbert}^{\uparrow}$ *Banach or completeness data is attached. It consists of the displayed* $\mathsf{VecSpace}^{\uparrow}$ *carrier and classifier, the scalar endpoint source retained from the vector-space and field side, the scalar-valued form row*

$$\langle -, - \rangle_{\mathsf{InnerProduct}^{\uparrow}} : C_V \times C_V \to C_{\mathsf{scal}},$$

the conjugate-symmetry row, the sesquilinearity rows, the positive-definite exactness row, classifier transport for the form endpoints, the orthogonality row of Definition 86.13, and the visible ledger recording which vector, scalar, form, law, transport, and orthogonality rows are present.

This source is a root threshold because it is complete for the inner-product-side rows consumed downstream while excluding Banach completeness, Cauchy-limit selection, ambient topology, and any host Hilbert-space structure.

Theorem 86.24 (InnerProduct root threshold form exactness)**.** *The root threshold source of Definition 86.23 exposes the full inner-product form exactness surface. Conjugate symmetry, sesquilinearity, form endpoint transport, and positive-definite zero classification are the law rows of the root surface, and the positive-definite row identifies* $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ *with the scalar zero endpoint exactly when* x *is classified with the displayed vector zero.*

Proof. Read the form and law entries from Definition 86.21. This theorem identifies conjugate symmetry, sesquilinearity, positive definiteness, and form endpoint transport as the exposed law interface of Definition 86.19.

The threshold source of Definition 86.23 is the same root surface with the downstream rows named explicitly, so these form and transport rows are present in the threshold source.

For the exact zero criterion, apply Definition 86.12. It supplies the positive-definite row saying that the self-form scalar endpoint is classified as zero precisely in the displayed vector-zero case. This is the positive-definite exactness component listed in the threshold source. □

Theorem 86.25 (InnerProduct root threshold orthogonality consumption)**.** *When* $\mathsf{Hilbert}^{\uparrow}$ *consumes the inner-product side of the root threshold source, its geometric input is exhausted by the scalar-valued form rows and the orthogonality row derived from them. Its Banach metric, completeness, and Cauchy-limit rows come from the separate* $\mathsf{Banach}^{\uparrow}$ *dependency, not from the* $\mathsf{InnerProduct}^{\uparrow}$ *threshold source.*

Proof. Apply Definition 86.22. It states that $\mathsf{Hilbert}^{\uparrow}$ may read the root inner-product surface together with a separate Banach and completeness row.

Inside the root threshold source, the Hilbert-facing geometric rows are the scalar-valued form, its law rows, classifier transport, and the orthogonality predicate of Definition 86.13. The orthogonality predicate is defined by scalar-zero classification of the form, so no independent host orthogonality relation is consumed.

The same consumption theorem separates completeness and Cauchy-limit selection from $\mathsf{InnerProduct}^{\uparrow}$. Those rows must be supplied by the Banach dependency, so they are outside the threshold source of Definition 86.23. □

Theorem 86.26 (InnerProduct root threshold downstream coverage)**.** *The downstream interfaces* $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{Fourier}^{\uparrow}$*,* $\mathsf{RiemannianMetric}^{\uparrow}$*, and* $\mathsf{RootSystem}^{\uparrow}$ *receive the inner-product rows they are allowed to consume from the single threshold source of Definition 86.23. The named threshold rows are the* $\mathsf{VecSpace}^{\uparrow}$ *carrier and classifier, scalar endpoint source, form row, conjugate-symmetry row, sesquilinearity rows, positive-definite exactness row, classifier-transport row, orthogonality row, and visible ledger. No downstream consumer receives Banach completeness, Cauchy-limit selection, ambient topology, or a host Hilbert-space row from this source.*

Proof. For $\mathsf{Hilbert}^{\uparrow}$, use Definition 86.25. Its inner-product-side input is the form, law, transport, orthogonality, and ledger surface of the threshold source, while Banach and completeness rows come from the separate dependency.

For $\mathsf{Fourier}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, and $\mathsf{RootSystem}^{\uparrow}$, apply Definition 86.22 to the non-Hilbert consumers named there. They may consume only the vector, scalar, form, law, and ledger rows of the same root surface.

Finally use the definition of Definition 86.23 to read those rows as one package. Since the definition lists no Banach metric, completeness field, Cauchy-limit selector, ambient topology, or host Hilbert-space row, none of the four downstream interfaces can receive such a row from this threshold source. □

Definition 86.27 (InnerProduct norm-metric seed source)**.** *The* $\mathsf{InnerProduct}^{\uparrow}$ *norm-metric seed source is the* BHist *vector carrier and classifier of Definition 86.3 together with the scalar-valued diagonal endpoint row*

$$\|x\|_I^2 := \langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Its scalar-zero classifier row is the positive-definite exactness row of Definition 86.12: the diagonal endpoint is classified with the displayed scalar zero exactly when the vector endpoint is classified with the displayed vector zero. Its threshold law rows are the form endpoint transport, classifier transport, scalar endpoint source, and visible ledger rows exposed by Definition 86.23.

This seed is therefore a BHist-rooted norm-squared interface. It names the diagonal scalar endpoint and the zero exactness row needed by later $\mathsf{Norm}^{\uparrow}$ *and* $\mathsf{Hilbert}^{\uparrow}$ *consumers, while leaving ordinary norm extraction, metric completion, Cauchy-limit selection, topology, and host Hilbert carrier data outside the source.*

Theorem 86.28 (InnerProduct norm-squared carrier row)**.** *For every carried vector endpoint* x *of the* $\mathsf{InnerProduct}^{\uparrow}$ *BHist source, the norm-metric seed source carries the scalar endpoint* $\|x\|_I^2 = \langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. *If* $x \sim_V x'$, *then the two scalar endpoints* $\|x\|_I^2$ *and* $\|x'\|_I^2$ *are classified by the retained scalar classifier.*

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductNormSquared carrier row`

Proof. Unfold Definition 86.27. The carried vector endpoint x lies in the vector carrier of Definition 86.3, and the diagonal form row evaluates at (x, x) with codomain in the retained scalar endpoint source.

For transport, use the form endpoint transport row listed in Definition 86.24. Apply it to the two vector classifier witnesses $x \sim_V x'$ and $x \sim_V x'$, once for each argument of the diagonal pair.

The resulting scalar-classifier witness compares $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ with $\langle x', x'\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. Repack these endpoints through the definition of $\| - \|_I^2$ in the seed source. □

Theorem 86.29 (InnerProduct norm zero classifier exactness)**.** *For every carried vector endpoint* x *of the* $\mathsf{InnerProduct}^{\uparrow}$ *BHist source, the scalar endpoint* $\|x\|_I^2$ *is classified with the displayed scalar zero endpoint exactly when* x *is classified by* $\sim_V$ *with the displayed vector zero endpoint* 0_V.

Proof. Unfold the norm-metric seed source so that $\|x\|_I^2$ is the diagonal form endpoint $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$.

In the forward direction, assume that this scalar endpoint is classified with the displayed scalar zero. Apply Definition 86.12 to convert the scalar-zero classification into the vector classifier witness $x \sim_V 0_V$.

In the reverse direction, assume $x \sim_V 0_V$. The same positive-definite obligation supplies the converse scalar-zero classification for the diagonal endpoint. Repack that scalar witness as the zero classification of $\|x\|_I^2$ in Definition 86.27. □

Theorem 86.30 (InnerProduct norm-metric seed downstream boundary)**.** *The downstream interfaces* $\mathsf{Norm}^{\uparrow}$ *and* $\mathsf{Hilbert}^{\uparrow}$ *may consume from the* $\mathsf{InnerProduct}^{\uparrow}$ *side only the norm-squared seed of Definition 86.27 together with the existing inner-product threshold rows of Definition 86.23. They do not receive Banach completeness, a Cauchy-limit selector, topology, or a host Hilbert carrier from this seed.*

Proof. For the norm-squared endpoint, use Definition 86.28. It supplies exactly the scalar diagonal endpoint and its classifier transport along the vector classifier.

For zero exactness, use Definition 86.29. It identifies scalar-zero classification of the diagonal endpoint with vector-zero classification and adds no ordinary norm value or completion row.

Finally compare the seed with the root threshold source. By Definition 86.23, the remaining consumable inner-product rows are the vector carrier and classifier, scalar endpoint source, form law rows, positive-definite exactness, classifier transport, orthogonality row, and ledger. Since neither this definition nor Definition 86.27 lists Banach completeness, Cauchy-limit selection, topology, or a host Hilbert carrier, those rows cannot be consumed from the $\mathsf{InnerProduct}^{\uparrow}$ seed boundary. □

Theorem 86.31 (InnerProduct norm-squared scalar-action factor row)**.** *For every carried scalar endpoint* r *and carried vector endpoint* x *of the* $\mathsf{InnerProduct}^{\uparrow}$ *BHist source, the norm-metric seed source carries the diagonal endpoint* $\|r \cdot_V x\|_I^2$*, and the retained scalar classifier classifies it with the scalar self-product acting on the original diagonal endpoint:*

$$\|r \cdot_V x\|_I^2 \sim_{\mathbb{K}} (r \cdot_{\mathbb{K}} \overline{r}) \cdot_{\mathbb{K}} \|x\|_I^2.$$

Here $\overline{r}$ *is the displayed scalar conjugate endpoint retained by the* $\mathsf{InnerProduct}^{\uparrow}$ *scalar source.*

Proof. Unfold Definition 86.27. The endpoint $\|r \cdot_V x\|_I^2$ is the diagonal form value

$$\langle r \cdot_V x, r \cdot_V x\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

The vector-space component of Definition 86.3 carries $r \cdot_V x$, since scalar-action closure is one of the module stability rows retained by Definition 47.19 and Definition 46.18. Hence Definition 86.28 applies to the carried vector endpoint $r \cdot_V x$.

Apply the scalar-action compatibility component of Definition 86.6 in the scalar-linear argument. It gives a retained scalar-classifier comparison

$$\langle r \cdot_V x, r \cdot_V x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} r \cdot_{\mathbb{K}} \langle x, r \cdot_V x\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Apply the conjugate-linear scalar-action clause from the same theorem in the other argument. The displayed conjugation row of the scalar source supplies the comparison

$$\langle x, r \cdot_V x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} \overline{r} \cdot_{\mathbb{K}} \langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Scalar multiplication congruence in the retained scalar source, read through Definition 45.201, transports this second comparison under left multiplication by r and gives

$$r \cdot_{\mathbb{K}} \langle x, r \cdot_V x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} r \cdot_{\mathbb{K}} (\overline{r} \cdot_{\mathbb{K}} \langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}).$$

The scalar associativity row from the same scalar source classifies the last endpoint with

$$(r \cdot_{\mathbb{K}} \overline{r}) \cdot_{\mathbb{K}} \langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}},$$

using classifier symmetry from Definition 9.7 if the stored associativity row is oriented oppositely.

Finally repack $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ as $\|x\|_I^2$ by Definition 86.27. Successive applications of Definition 9.8 compose the first scalar-action comparison, the transported conjugate-linear comparison, the scalar associativity comparison, and this repacking into the displayed retained scalar-classifier row. □

86.3 Parallelogram norm seed

Definition 86.32 (InnerProduct parallelogram norm seed source)**.** *The* $\mathsf{InnerProduct}^{\uparrow}$ *parallelogram norm seed source is the* BHist *ledger extending Definition 86.27 by the following carried rows. It carries vector endpoints* $x, y : C_V$*, the vector addition endpoint* $x +_V y$*, the vector difference endpoint* $x -_V y$*, and the four scalar diagonal endpoints*

$$\|x\|_I^2, \qquad \|y\|_I^2, \qquad \|x +_V y\|_I^2, \qquad \|x -_V y\|_I^2.$$

Here $x -_V y$ *denotes* $x +_V (-_V y)$ *using the displayed additive inverse row of the embedded* $\mathsf{VecSpace}^{\uparrow}$ *source, and every norm-squared endpoint is the diagonal scalar endpoint named by Definition 86.27.*

The ledger also retains the scalar source rows for addition, additive inverse, doubling by $2_{\mathbb{K}}$*, scalar multiplication, conjugation, and scalar classifier transport from the field and vector-space side of Definition 86.3. Thus the seed records exactly the algebraic data needed to compare the two diagonal sums appearing in the parallelogram identity.*

Theorem 86.33 (InnerProduct parallelogram identity row)**.** *For carried vector endpoints* $x, y : C_V$ *in the Definition 86.32, the retained scalar classifier classifies the parallelogram endpoints*

$$\|x +_V y\|_I^2 +_{\mathbb{K}} \|x -_V y\|_I^2 \sim_{\mathbb{K}} 2_{\mathbb{K}} \cdot_{\mathbb{K}} \|x\|_I^2 +_{\mathbb{K}} 2_{\mathbb{K}} \cdot_{\mathbb{K}} \|y\|_I^2.$$

The row is a scalar-history comparison inside the same seed; it does not introduce an ordinary norm, a metric completion, or a host inner-product space.

Proof. Unfold the parallelogram seed source. The vector-space rows carry $x +_V y$ and $x -_V y$, and the norm-metric seed identifies each displayed norm square with a diagonal form endpoint.

Apply Definition 86.6 to expand $\langle x +_V y, x +_V y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. The result is classified with the scalar sum of the four form values

$$\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Apply the same linearity row to the diagonal value $\langle x -_V y, x -_V y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. The additive inverse and scalar-action rows from the retained $\mathsf{VecSpace}^{\uparrow}$ and scalar sources transport the two mixed terms to their scalar additive inverses, giving the classified scalar sum

$$\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} (-_{\mathbb{K}}\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}) +_{\mathbb{K}} (-_{\mathbb{K}}\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}) +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Now add the two expanded rows in the retained scalar classifier. Scalar addition congruence and transitivity compose the two comparisons, while the additive inverse laws cancel the paired mixed terms $\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ and $\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. The conjugate-symmetry and positivity row of Definition 86.5 keeps both mixed endpoints inside the same scalar classifier ledger during this cancellation.

After the cancellations, the remaining scalar endpoint is the sum of two copies of $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ and two copies of $\langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. The scalar doubling rows identify those paired sums with $2_{\mathbb{K}} \cdot_{\mathbb{K}} \|x\|_I^2$ and $2_{\mathbb{K}} \cdot_{\mathbb{K}} \|y\|_I^2$. A final application of Definition 9.8 composes the expansion, cancellation, and doubling witnesses into the displayed classifier row. □

Theorem 86.34 (InnerProduct norm seed Hilbert consumer boundary)**.** *The* $\mathsf{Hilbert}^{\uparrow}$ *and* $\mathsf{Norm}^{\uparrow}$ *consumers may read Definition 86.33 only through the norm-metric seed of Definition 86.27 together with the root threshold source of Definition 86.23. The consumer boundary contains no Banach completeness row, topology row, host Hilbert carrier, or Cauchy-limit selector.*

Proof. The parallelogram row consumes the diagonal norm-squared endpoints from Definition 86.27. It consumes the vector addition, vector inverse, scalar addition, scalar inverse, scalar doubling, linearity, conjugate-symmetry, positivity, and transport rows through Definition 86.23.

These two sources are the whole input boundary for the row. The norm-metric seed supplies norm-squared endpoints and zero exactness; the root threshold source supplies the inner-product algebra and the visible ledger. Neither source lists Banach completeness, topology, a host Hilbert carrier, or a Cauchy-limit selector.

Therefore a $\mathsf{Hilbert}^{\uparrow}$ or $\mathsf{Norm}^{\uparrow}$ consumer may use the parallelogram identity as an algebraic scalar-history comparison, but any completion, topological, or host-space row must come from a separate downstream certificate. □

Theorem 86.35 (InnerProduct Pythagorean row)**.** *For carried vector endpoints $x, y : C_V$ in the Definition 86.32, if $x \perp_I y$, then the retained scalar classifier compares the diagonal endpoint of their sum with the sum of the two diagonal endpoints:*

$$\|x +_V y\|_I^2 \sim_{\mathbb{K}} \|x\|_I^2 +_{\mathbb{K}} \|y\|_I^2.$$

Proof. Assume $x \perp_I y$. By Definition 86.13, this is exactly the scalar-zero classification

$$\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

Apply Definition 86.39 to obtain $y \perp_I x$. Unpacking this second orthogonality statement with Definition 86.13 gives

$$\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

Unfold Definition 86.32. The embedded $\mathsf{VecSpace}^{\uparrow}$ rows carry $x +_V y$, and Definition 86.28 identifies each displayed norm square with the corresponding diagonal form endpoint. Apply Definition 86.6 to expand $\langle x +_V y, x +_V y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. The resulting scalar classifier row compares it with

$$\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

The retained scalar source of Definition 86.3 is the $\mathsf{Field}^{\uparrow}$ scalar coordinate. By Definition 45.198, Definition 44.8, and Definition 43.26, its unchanged scalar classifier has addition congruence, additive zero laws, and classifier transitivity. Therefore the two mixed-term zero witnesses transport through scalar addition, so the displayed four-term scalar sum is classified with

$$\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} 0_{\mathbb{K}} +_{\mathbb{K}} 0_{\mathbb{K}} +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} \langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Composing this simplification with the linearity expansion by Definition 9.8 yields

$$\langle x +_V y, x +_V y\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} \langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Finally repack the three diagonal endpoints as $\|x +_V y\|_I^2$, $\|x\|_I^2$, and $\|y\|_I^2$ using Definition 86.28. A final application of Definition 9.8 gives

$$\|x +_V y\|_I^2 \sim_{\mathbb{K}} \|x\|_I^2 +_{\mathbb{K}} \|y\|_I^2.$$

□

Theorem 86.36 (InnerProduct polarization difference row)**.** *For carried vector endpoints $x, y : C_V$ in the Definition 86.32, the retained scalar classifier compares the polarization-difference endpoints*

$$\|x +_V y\|_I^2 +_{\mathbb{K}} (-_{\mathbb{K}}\|x -_V y\|_I^2) \sim_{\mathbb{K}} 2_{\mathbb{K}} \cdot_{\mathbb{K}} (\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}).$$

Proof. Unfold Definition 86.32. The embedded $\mathsf{VecSpace}^{\uparrow}$ rows carry $x +_V y$ and $x -_V y$, and Definition 86.28 repacks each displayed norm square as the corresponding diagonal form endpoint.

Apply Definition 86.6 to expand $\langle x +_V y, x +_V y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. The resulting scalar classifier row compares $\|x +_V y\|_I^2$ with

$$\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Apply the same linearity row to $\langle x -_V y, x -_V y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. The additive inverse and scalar-action rows retained in the seed transport the two mixed terms to their scalar additive inverses, so $\|x -_V y\|_I^2$ is classified with

$$\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} (-_{\mathbb{K}}\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}) +_{\mathbb{K}} (-_{\mathbb{K}}\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}) +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Now transport this second comparison through scalar additive inverse. The retained scalar source is the $\mathsf{Field}^{\uparrow}$ scalar coordinate of Definition 86.3. By Definition 45.198, Definition 44.8, and Definition 43.26, its unchanged scalar classifier has additive inverse congruence. Therefore

$$-_{\mathbb{K}}\|x -_V y\|_I^2 \sim_{\mathbb{K}} -_{\mathbb{K}}(\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} (-_{\mathbb{K}}\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}) +_{\mathbb{K}} (-_{\mathbb{K}}\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}) +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}).$$

Apply Definition 43.33 repeatedly in the retained scalar ring, and read its additive reduct through Definition 43.59. The two double negatives collapse by Definition 42.34, so the right-hand scalar endpoint is further classified with

$$(-_{\mathbb{K}}\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}) +_{\mathbb{K}} \langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} (-_{\mathbb{K}}\langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}).$$

Add the expansion of $\|x +_V y\|_I^2$ and this negated expansion inside the retained scalar classifier. Addition congruence and Definition 9.8 compose the two comparisons. The diagonal terms $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ and $\langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ cancel against their displayed additive inverses by the additive inverse laws in Definition 43.26. The remaining scalar endpoint is two copies of the mixed sum:

$$(\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}) +_{\mathbb{K}} (\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}).$$

Finally, the scalar doubling row retained in Definition 86.32 identifies this paired sum with

$$2_{\mathbb{K}} \cdot_{\mathbb{K}} (\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}).$$

A final application of Definition 9.8 composes the expansion, negation, cancellation, and doubling witnesses into the displayed classifier row. □

Theorem 86.37 (InnerProduct ternary orthogonal Pythagorean row)**.** *Let I be an inner-product* BHist *carrier as in Definition 86.1. For carried vector endpoints $x, y, z : C_V$, assume*

$$x \perp_I y, \qquad x \perp_I z, \qquad y \perp_I z.$$

Then the displayed vector sum $(x +_V y) +_V z$ is carried, the norm-metric seed carries the diagonal scalar endpoint $\|(x +_V y) +_V z\|_I^2$, and the retained scalar classifier classifies

$$\|(x +_V y) +_V z\|_I^2 \sim_{\mathbb{K}} (\|x\|_I^2 +_{\mathbb{K}} \|y\|_I^2) +_{\mathbb{K}} \|z\|_I^2.$$

Proof. The embedded $\mathsf{VecSpace}^{\uparrow}$ row in Definition 86.1 carries $x +_V y$ and then carries the displayed sum $(x +_V y) +_V z$. Applying Definition 86.28 to x, y, z, $x +_V y$, and $(x +_V y) +_V z$ gives all norm-squared scalar endpoints used below inside the retained scalar source.

Read Definition 86.32 on the carried pair (x, y). By Definition 86.35 and the hypothesis $x \perp_I y$, the retained scalar classifier gives

$$\|x +_V y\|_I^2 \sim_{\mathbb{K}} \|x\|_I^2 +_{\mathbb{K}} \|y\|_I^2.$$

It remains to make the intermediate sum orthogonal to z. Apply Definition 86.39 to $x \perp_I z$ and $y \perp_I z$, obtaining

$$z \perp_I x \qquad \text{and} \qquad z \perp_I y.$$

Now apply Definition 86.40 with first endpoint z and additive pair (x, y). It carries $x +_V y$ and gives

$$z \perp_I (x +_V y).$$

A final use of Definition 86.39 gives $(x +_V y) \perp_I z$.

Read Definition 86.32 again, now on the carried pair $(x +_V y, z)$. Applying Definition 86.35 to the orthogonality witness $(x +_V y) \perp_I z$ gives

$$\|(x +_V y) +_V z\|_I^2 \sim_{\mathbb{K}} \|x +_V y\|_I^2 +_{\mathbb{K}} \|z\|_I^2.$$

The scalar endpoint source retained in Definition 86.3 is the $\mathsf{Field}^{\uparrow}$ scalar coordinate. By Definition 45.198, Definition 44.8, and Definition 43.26, its unchanged scalar classifier has addition congruence and classifier transitivity. Transport the first binary Pythagorean comparison through scalar addition with $\|z\|_I^2$ to obtain

$$\|x +_V y\|_I^2 +_{\mathbb{K}} \|z\|_I^2 \sim_{\mathbb{K}} (\|x\|_I^2 +_{\mathbb{K}} \|y\|_I^2) +_{\mathbb{K}} \|z\|_I^2.$$

Composing this scalar-addition transport with the second binary Pythagorean comparison by Definition 9.8 gives the displayed ternary classifier row. □

Theorem 86.38 (InnerProduct norm-of-sum expansion row)**.** *For carried vector endpoints $x, y : C_V$ in the Definition 86.32, the retained scalar classifier classifies the norm square of their vector sum with the four-term inner-product expansion:*

$$\|x +_V y\|_I^2 \sim_{\mathbb{K}} \|x\|_I^2 +_{\mathbb{K}} \langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \|y\|_I^2.$$

No orthogonality hypothesis is used.

Proof. Unfold Definition 86.32. The embedded $\mathsf{VecSpace}^{\uparrow}$ rows carry $x +_V y$, and Definition 86.28 repacks the displayed norm square $\|x +_V y\|_I^2$ as the diagonal form endpoint

$$\langle x +_V y, x +_V y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Apply the additive component of Definition 86.6 in the first vector argument. The retained scalar classifier compares this diagonal endpoint with

$$\langle x, x +_V y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x +_V y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Apply the additive component of the same linearity row in the second vector argument to each displayed summand. The first summand is classified with

$$\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}},$$

and the second summand is classified with

$$\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

The scalar endpoint source retained in Definition 86.3 is the $\mathsf{Field}^{\uparrow}$ scalar coordinate. By Definition 45.198, Definition 44.8, and Definition 43.26, its unchanged scalar classifier has addition congruence, associativity, and transitivity. Transport the two second-argument expansions through scalar addition, then reassociate the resulting scalar sum. This gives a scalar-classifier comparison from $\langle x +_V y, x +_V y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ to

$$\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathbb{K}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Finally repack the two diagonal endpoints $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ and $\langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ as $\|x\|_I^2$ and $\|y\|_I^2$ using Definition 86.27 and Definition 86.28. Addition congruence in the same retained scalar classifier transports these two repackings through the four-term scalar sum, and Definition 9.8 composes the diagonal repacking, the two linearity expansions, scalar reassociation, and the final norm-squared repacking into the displayed classifier row. □

Theorem 86.39 (InnerProduct orthogonality symmetry row)**.** *Let I be an inner-product* BHist *carrier as in Definition 86.1. For carried vector endpoints $x, y : C_V$, the orthogonality row defined by the retained scalar-zero classifier is symmetric:*

$$x \perp_I y \quad \Longleftrightarrow \quad y \perp_I x.$$

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductSingletonOrthogonal symm constant endpoint`
↪ variant `BEDC.Derived.InnerProductUp.InnerProductSingletonOrthogonal symm package`

Proof. Assume first that $x \perp_I y$. By Definition 86.13, this is the scalar-zero classification

$$\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

Apply the conjugate-symmetry row from Definition 86.5 with the two endpoints ordered as (y, x). It gives

$$\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} \overline{\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}}.$$

The scalar endpoint source retained in Definition 86.3 supplies classifier transport for the displayed conjugation row. Applying that row to the scalar-zero classification of $\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ gives

$$\overline{\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}} \sim_{\mathbb{K}} \overline{0_{\mathbb{K}}}.$$

The same scalar source fixes the zero endpoint under conjugation, the scalar-side row used in Definition 86.15, so

$$\overline{0_{\mathbb{K}}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

Composing these three scalar classifier witnesses by Definition 9.8 gives

$$\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

By Definition 86.13, this is $y \perp_I x$.

For the converse implication, assume $y \perp_I x$. The same definition gives

$$\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

Apply the conjugate-symmetry row with endpoints ordered as (x, y), transport this scalar-zero witness through the displayed conjugation row, use the zero-fix row for conjugation, and compose the scalar classifier witnesses by Definition 9.8. The result is

$$\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}},$$

which is exactly $x \perp_I y$ by Definition 86.13. □

Theorem 86.40 (InnerProduct orthogonal additivity row)**.** *Let I be an inner-product* BHist *carrier as in Definition 86.1. For carried vector endpoints $x, y, z : C_V$, if $x \perp_I y$ and $x \perp_I z$, then the displayed vector sum $y +_V z$ is carried and*

$$x \perp_I (y +_V z).$$

Proof. The embedded $\mathsf{VecSpace}^{\uparrow}$ row in Definition 86.1 supplies closure of the displayed vector addition, so $y +_V z$ is carried. Apply Definition 86.39 to the two hypotheses $x \perp_I y$ and $x \perp_I z$. This gives

$$y \perp_I x \qquad \text{and} \qquad z \perp_I x.$$

By Definition 86.13, these two facts are exactly the scalar-zero classifications

$$\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}} \qquad \text{and} \qquad \langle z, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

Use the additive part of Definition 86.6 in the displayed first argument, with second endpoint x. It compares the inner-product endpoint of the vector sum with the scalar sum:

$$\langle y +_V z, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathsf{scal}} \langle z, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

The retained scalar source of Definition 86.3 is the $\mathsf{Field}^{\uparrow}$ scalar coordinate. By Definition 45.198, Definition 44.8, and Definition 43.26, its unchanged scalar classifier has addition congruence, additive zero laws, and classifier transitivity. Therefore the two scalar-zero witnesses above transport through scalar addition to give

$$\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} +_{\mathsf{scal}} \langle z, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}} +_{\mathsf{scal}} 0_{\mathbb{K}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

This is the scalar addition component of Definition 43.41, read in the retained scalar classifier.

Composing the inner-product linearity comparison with this scalar-zero classification by Definition 9.8 gives

$$\langle y +_V z, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

By Definition 86.13, this is $(y +_V z) \perp_I x$. A final application of Definition 86.39, now to the carried pair $(y +_V z, x)$, gives $x \perp_I (y +_V z)$. □

Theorem 86.41 (InnerProduct orthogonality right scalar-action closure)**.** *Let I be an inner-product* BHist *carrier as in Definition 86.1. Let $x, y : C_V$ be carried vector endpoints, and let $r : C_{\mathsf{scal}}$ be a carried scalar endpoint from the retained scalar source. If $x \perp_I y$, then $r \cdot_V y$ is carried and*

$$x \perp_I (r \cdot_V y).$$

Proof. By Definition 86.39, the hypothesis $x \perp_I y$ gives $y \perp_I x$. Unpacking this conclusion with Definition 86.13 gives the scalar-zero classifier witness

$$\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

The embedded $\mathsf{VecSpace}^{\uparrow}$ row carries the scalar-action endpoint $r \cdot_V y$: scalar-action closure is one of the module stability rows retained by Definition 47.19 and Definition 46.18. Hence the inner-product endpoint $\langle r \cdot_V y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ is defined in the same carrier.

Apply the scalar-action compatibility component of Definition 86.6 to the carried scalar r and vector endpoints y and x. It gives a retained scalar-classifier comparison between

$$\langle r \cdot_V y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \quad \text{and} \quad r \cdot_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Inside the retained scalar source, the ring rows listed in Definition 43.26 are exactly the hypotheses needed for Definition 43.40. Applying that absorption row to the zero-classified factor $\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ and the multiplier r gives

$$r \cdot_{\mathbb{K}} \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}}.$$

Compose the scalar-action compatibility comparison with this zero-product classification by Definition 9.8. The result is

$$\langle r \cdot_V y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathbb{K}} 0_{\mathbb{K}},$$

which is $(r \cdot_V y) \perp_I x$ by Definition 86.13. A second application of Definition 86.39, now to the carried pair $r \cdot_V y$ and x, gives $x \perp_I (r \cdot_V y)$. □

Theorem 86.42 (InnerProduct orthogonal additive inverse closure)**.** *Let I be an inner-product* BHist *carrier as in Definition 86.1. For carried vector endpoints $x, y : C_V$, if $x \perp_I y$, then the displayed additive inverse $-_V y$ is carried and*

$$x \perp_I (-_V y).$$

Proof. The embedded $\mathsf{VecSpace}^{\uparrow}$ row retains its additive $\mathsf{AbGroup}^{\uparrow}$ carrier by Definition 47.25, so the inverse-closure row carries $-_V y$.

Let $\eta = -_{\mathbb{K}} 1_{\mathbb{K}}$. The retained scalar source carries η by Definition 45.198 and Definition 43.2. The module rows of Definition 46.18 identify $\eta \cdot_V y$ with the displayed inverse: scalar unit changes y to $1_{\mathbb{K}} \cdot_V y$, scalar distributivity over scalar addition changes $(\eta +_{\mathbb{K}} 1_{\mathbb{K}}) \cdot_V y$ to $(\eta \cdot_V y) +_V (1_{\mathbb{K}} \cdot_V y)$, the additive inverse law retained by Definition 43.26 collapses $\eta +_{\mathbb{K}} 1_{\mathbb{K}}$ to $0_{\mathbb{K}}$, and Definition 46.29 collapses $0_{\mathbb{K}} \cdot_V y$ to 0_V. Thus $\eta \cdot_V y$ is a left additive inverse of y. The displayed inverse row gives $y +_V (-_V y) \sim_V 0_V$, and Definition 41.59, read in the additive $\mathsf{AbGroup}^{\uparrow}$ reduct, gives $\eta \cdot_V y \sim_V -_V y$.

Apply Definition 86.41 to the carried scalar η and the hypothesis $x \perp_I y$. It gives $x \perp_I (\eta \cdot_V y)$. Transport this orthogonality witness along $\eta \cdot_V y \sim_V -_V y$ by Definition 86.16, keeping the left endpoint fixed by reflexivity. The result is $x \perp_I (-_V y)$. □

Theorem 86.43 (InnerProduct orthogonality left additive closure)**.** *Let I be an inner-product* BHist *carrier as in Definition 86.1. For carried vector endpoints $x, y, z : C_V$, if $x \perp_I z$ and $y \perp_I z$, then the displayed vector sum $x +_V y$ is carried and*

$$(x +_V y) \perp_I z.$$

Proof. The embedded $\mathsf{VecSpace}^{\uparrow}$ row in Definition 86.1 supplies closure of the displayed vector addition, so $x +_V y$ is carried. Apply Definition 86.39 to the two hypotheses $x \perp_I z$ and $y \perp_I z$. This gives

$$z \perp_I x \qquad \text{and} \qquad z \perp_I y.$$

Now apply Definition 86.40 with left endpoint z and right endpoints x and y. Its conclusion gives

$$z \perp_I (x +_V y).$$

A final application of Definition 86.39, now to the carried pair $(z, x +_V y)$, gives

$$(x +_V y) \perp_I z.$$

□

Theorem 86.44 (InnerProduct orthogonality left scalar-action closure)**.** *Let I be an inner-product* BHist *carrier as in Definition 86.1. Let $x, y : C_V$ be carried vector endpoints, and let $r : C_{\mathsf{scal}}$ be a carried scalar endpoint from the retained scalar source. If $x \perp_I y$, then $r \cdot_V x$ is carried and*

$$(r \cdot_V x) \perp_I y.$$

Proof. By Definition 86.39, the hypothesis $x \perp_I y$ gives

$$y \perp_I x.$$

Apply Definition 86.41 with left endpoint y, right endpoint x, and carried scalar r. Its conclusion carries the scalar-action endpoint $r \cdot_V x$ and gives

$$y \perp_I (r \cdot_V x).$$

A final application of Definition 86.39, now to the carried pair y and $r \cdot_V x$, gives

$$(r \cdot_V x) \perp_I y.$$

□

Theorem 86.45 (InnerProduct orthogonality left additive-inverse closure)**.** *Let I be an inner-product* BHist *carrier as in Definition 86.1. For carried vector endpoints $x, y : C_V$, if $x \perp_I y$, then the displayed additive inverse $-_V x$ is carried and*

$$(-_V x) \perp_I y.$$

Proof. By Definition 86.39, the hypothesis $x \perp_I y$ gives

$$y \perp_I x.$$

Apply Definition 86.42 to the carried pair (y, x). It carries the displayed inverse $-_V x$ and gives

$$y \perp_I (-_V x).$$

A final application of Definition 86.39, now to the carried pair y and $-_V x$, gives

$$(-_V x) \perp_I y.$$

□

Theorem 86.46 (InnerProduct orthogonality right additive closure)**.** *Let I be an inner-product* BHist *carrier as in Definition 86.1. For carried vector endpoints $x, y, z : C_V$, if $x \perp_I y$ and $x \perp_I z$, then the displayed vector sum $y +_V z$ is carried and*

$$x \perp_I (y +_V z).$$

Proof. The carried endpoints y and z lie in the embedded $\mathsf{VecSpace}^{\uparrow}$ row of Definition 86.1. Its additive $\mathsf{AbGroup}^{\uparrow}$ reduct therefore carries the displayed sum $y +_V z$.

Apply Definition 86.40 to the same inner-product carrier and to the carried triple (x, y, z). The two hypotheses $x \perp_I y$ and $x \perp_I z$ are exactly its orthogonality inputs, so its conclusion gives the scalar-zero row for the right additive endpoint:

$$x \perp_I (y +_V z).$$

This is the asserted right additive closure. □

86.4 Consumer threshold surface

Definition 86.47 (InnerProduct consumer threshold source)**.** *The* $\mathsf{InnerProduct}^{\uparrow}$ *consumer threshold source is the NameCert-facing package through which later certificates read inner-product data. It has the following ten fields:*

1. *traditional target: inner-product geometry over a vector space;*
2. *BEDC source: the displayed* $\mathsf{NameCert}_{\mathsf{VecSpace}^{\uparrow}}$ *source, its retained scalar and field rows, and the* $\mathsf{NameCert}$ *ledger discipline;*
3. *vector carrier: a predicate $C_V : \mathsf{BHist} \to \mathsf{Prop}$;*
4. *vector classifier: the displayed classifier $\sim_V$ on carried vector histories;*
5. *scalar endpoint classifier: the retained scalar classifier on all scalar endpoints read by the form;*
6. *form row: the scalar-valued endpoint row $\langle -, - \rangle_{\mathsf{InnerProduct}^{\uparrow}} : C_V \times C_V \to C_{\mathsf{scal}}$;*
7. *law rows: conjugate symmetry, sesquilinearity, positivity, and form endpoint transport;*
8. *ledger rows: scalar endpoints,* hsame *transport, optional* Cont *route histories, and the orthogonality rows visible to consumers;*
9. *source factorization: every carrier, classifier, scalar, form, law, transport, and ledger projection factors through Definition 86.1, Definition 86.3, and Definition 86.23;*
10. *exclusion boundary: Banach completeness, topology, host Hilbert carriers, and Cauchy-limit selectors are not fields of this source.*

Thus $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, *and* $\mathsf{RootSystem}^{\uparrow}$ *receive a single inner-product threshold package rather than separate echoes of the root rows.*

Theorem 86.48 (InnerProduct consumer carrier and form scope)**.** *Every carrier, classifier, scalar endpoint, and form read from the consumer threshold source of Definition 86.47 factors through the* BHist *carrier of Definition 86.1, the source rows of Definition 86.3, and the root threshold source of Definition 86.23. No consumer can read a second vector carrier, a second scalar endpoint source, or a host inner-product-space form from this package.*

Proof. Start with the carrier field. By Definition 86.4, the public carrier row is the displayed $\mathsf{VecSpace}^{\uparrow}$ BHist carrier C_V together with the scalar-valued form endpoint row. The consumer threshold source names this same row as its vector carrier and does not list any other point carrier.

Next read the scalar and form fields from Definition 86.3. The form endpoint lands in the retained scalar history carrier and is classified by the retained scalar classifier. By Definition 86.20, these vector and scalar projections exhaust the vector-scalar part of the root surface.

Finally apply Definition 86.24. The form law rows exposed at the consumer boundary are the form, law, and transport rows of Definition 86.23. Since the consumer threshold source is defined by projecting those root threshold rows, every consumer carrier or form read factors through the three cited source objects. □

Theorem 86.49 (InnerProduct consumer positivity and orthogonality scope)**.** *The positivity and orthogonality data exported by Definition 86.47 are exactly the positive-definite scalar-zero classification row and the orthogonality closure rows built from Definition 86.13. They add no host positivity predicate and no independent Hilbert-space orthogonality relation.*

Proof. For positivity, use Definition 86.12. The diagonal self-value $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ is classified as the scalar zero endpoint exactly when x is classified with the displayed vector zero row. This is the positive row exposed by Definition 86.24.

For orthogonality, unfold Definition 86.13. The statement $x \perp_I y$ is the scalar-zero classification of $\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. The zero-left, zero-right, and transport rows are Definition 86.14, Definition 86.15, and Definition 86.16.

The closure rows available to downstream consumers are the rows of the orthogonality closure surface: Definition 86.39, Definition 86.40, Definition 86.41, and Definition 86.42. Each row is proved from the scalar-zero definition of orthogonality and the displayed inner-product law rows. Therefore the consumer threshold exports exactly scalar-zero positivity and the orthogonality rows derived from it. □

Theorem 86.50 (InnerProduct consumer Hilbert threshold package)**.** *The* $\mathsf{Hilbert}^{\uparrow}$ *certificate consumes from Definition 86.47 only the inner-product-side threshold rows: vector carrier and classifier, retained scalar endpoints, the form row, conjugate symmetry, sesquilinearity, positivity, form transport, orthogonality, and ledger provenance. Its Banach metric, completeness row, topology, and Cauchy-limit selector remain external. The* $\mathsf{Fourier}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, *and* $\mathsf{RootSystem}^{\uparrow}$ *consumers are restricted to the same form, law, transport, and ledger rows.*

Proof. For the Hilbert input, apply Definition 86.25. It states that the Hilbert-facing geometric data are the scalar-valued form rows and the orthogonality row derived from them, while Banach metric, completeness, and Cauchy-limit rows come from a separate dependency.

For the named non-Hilbert consumers, apply Definition 86.26. It restricts $\mathsf{Fourier}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, and $\mathsf{RootSystem}^{\uparrow}$ to the vector, scalar, form, law, transport, orthogonality, and ledger rows of the same root threshold source.

The consumer threshold source is the single package that exposes those root threshold rows to downstream certificates. Its exclusion boundary lists no Banach completeness, topology, host Hilbert carrier, or Cauchy-limit selector. Hence every named consumer reads only the inner-product threshold rows, and all completeness or topology structure remains outside $\mathsf{NameCert}_{\mathsf{InnerProduct}^{\uparrow}}$. □

86.5 Two-vector Gram boundary

Definition 86.51 (InnerProduct two-vector Gram source)**.** *The* $\mathsf{InnerProduct}^{\uparrow}$ *two-vector Gram source is the* BHist *package obtained from Definition 86.47 by fixing two carried vector endpoints* $x, y : C_V$ *and retaining the four scalar endpoints*

$$\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}, \qquad \langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}, \qquad \langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}, \qquad \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

It has the following rows:

1. *vector carrier rows for the displayed endpoints* x *and* y *in the carrier* C_V *of Definition 86.1;*
2. *vector classifier rows comparing replacement endpoints by the displayed classifier* $\sim_V$*;*
3. *scalar classifier rows for the four displayed form values in the retained scalar endpoint source;*
4. *form transport rows for each of the four ordered pairs* (x, x)*,* (x, y)*,* (y, x)*, and* (y, y)*;*
5. *conjugate-symmetry rows identifying the two off-diagonal endpoints through the retained scalar classifier and scalar conjugation;*
6. *diagonal positivity rows for the two self-values;*
7. *orthogonality rows reading the scalar-zero classification of* $\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ *and* $\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$*;*
8. *ledger rows recording exactly the vector, scalar, form, transport, conjugate-symmetry, positivity, and orthogonality sources used above.*

The source does not contain a host matrix, determinant, spectral row, topology, Banach completeness row, Cauchy-limit selector, or ambient Hilbert-space carrier. It is only the two-vector scalar-form packet exposed by the BHist *inner-product source.*

Theorem 86.52 (InnerProduct Gram carrier transport)**.** *Let* I *be an* $\mathsf{InnerProduct}^{\uparrow}$ BHist *source and let* $x, y, x', y' : C_V$ *be carried vector endpoints. If* $x \sim_V x'$ *and* $y \sim_V y'$*, then every scalar endpoint in the two-vector Gram source transports through the retained scalar classifier:*

$$\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathsf{scal}} \langle x', x'\rangle_{\mathsf{InnerProduct}^{\uparrow}},$$

$$\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathsf{scal}} \langle x', y'\rangle_{\mathsf{InnerProduct}^{\uparrow}},$$

$$\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathsf{scal}} \langle y', x'\rangle_{\mathsf{InnerProduct}^{\uparrow}},$$

and

$$\langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} \sim_{\mathsf{scal}} \langle y', y'\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Proof. Unfold the two-vector Gram source of Definition 86.51. Its scalar endpoints are exactly the four ordered form evaluations displayed in the statement.

For the first diagonal endpoint, apply Definition 86.7 with the vector classifier witness $x \sim_V x'$ in both arguments. This transports $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ to $\langle x', x'\rangle_{\mathsf{InnerProduct}^{\uparrow}}$.

For the first off-diagonal endpoint, apply Definition 86.7 to $x \sim_V x'$ and $y \sim_V y'$. This transports $\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ to $\langle x', y'\rangle_{\mathsf{InnerProduct}^{\uparrow}}$.

For the reversed off-diagonal endpoint, apply the same transport row to $y \sim_V y'$ and $x \sim_V x'$. This transports $\langle y, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ to $\langle y', x'\rangle_{\mathsf{InnerProduct}^{\uparrow}}$.

For the second diagonal endpoint, apply the same transport row with $y \sim_V y'$ in both arguments. These four scalar classifier witnesses are precisely the form transport rows retained by the Gram source. □

Theorem 86.53 (InnerProduct Gram symmetry and zero exactness)**.** *For the two-vector Gram source of Definition 86.51, the off-diagonal scalar-zero rows are symmetric:*

$$\langle x, y\rangle_{\mathsf{InnerProduct}^\uparrow} \sim_{\mathsf{scal}} 0_{\mathsf{scal}} \quad\Longleftrightarrow\quad \langle y, x\rangle_{\mathsf{InnerProduct}^\uparrow} \sim_{\mathsf{scal}} 0_{\mathsf{scal}}.$$

Its diagonal scalar-zero rows are exactly vector-zero classification:

$$\langle x, x\rangle_{\mathsf{InnerProduct}^\uparrow} \sim_{\mathsf{scal}} 0_{\mathsf{scal}} \quad\Longleftrightarrow\quad x \sim_V 0_V,$$

and

$$\langle y, y\rangle_{\mathsf{InnerProduct}^\uparrow} \sim_{\mathsf{scal}} 0_{\mathsf{scal}} \quad\Longleftrightarrow\quad y \sim_V 0_V.$$

Proof. For the off-diagonal row, unfold the orthogonality row Definition 86.13. The scalar-zero classification of $\langle x, y\rangle_{\mathsf{InnerProduct}^\uparrow}$ is the assertion $x \perp_I y$, and the scalar-zero classification of $\langle y, x\rangle_{\mathsf{InnerProduct}^\uparrow}$ is the assertion $y \perp_I x$.

Apply Definition 86.39. It gives exactly $x \perp_I y$ if and only if $y \perp_I x$. Repacking through the displayed definition gives the symmetric off-diagonal zero row for the Gram source.

For the x diagonal row, identify $\langle x, x\rangle_{\mathsf{InnerProduct}^\uparrow}$ with the norm-squared endpoint $\|x\|_I^2$ of Definition 86.27. Then apply Definition 86.29 to obtain the equivalence with $x \sim_V 0_V$.

For the y diagonal row, use the same norm-squared seed with the endpoint y. A second application of Definition 86.29 gives the equivalence with $y \sim_V 0_V$. These are the two diagonal exactness rows retained by Definition 86.51. □

Theorem 86.54 (InnerProduct Gram consumer boundary)**.** *The downstream certificates* $\mathsf{Hilbert}^\uparrow$, $\mathsf{Fourier}^\uparrow$, $\mathsf{RiemannianMetric}^\uparrow$, *and* $\mathsf{RootSystem}^\uparrow$ *may consume from Definition 86.51 only the two-vector carrier, the four scalar endpoints, the form transport rows, the conjugate-symmetry row, the positive-definite diagonal rows, the orthogonality rows, and the ledger rows. Banach completeness, Cauchy-limit selection, host Hilbert-space structure, determinants, and spectral rows are outside this Gram source.*

Proof. Start from Definition 86.26. It states that $\mathsf{Hilbert}^\uparrow$, $\mathsf{Fourier}^\uparrow$, $\mathsf{RiemannianMetric}^\uparrow$, and $\mathsf{RootSystem}^\uparrow$ receive only the vector, scalar, form, law, transport, orthogonality, and ledger rows of the root threshold source.

Next apply Definition 86.50. It identifies the consumer-facing package as the same inner-product threshold surface and keeps Banach metric, completeness, topology, Cauchy-limit selection, and host Hilbert carrier data outside the $\mathsf{InnerProduct}^\uparrow$ source.

Inside that consumer-facing package, use Definition 86.52 for the four transported scalar endpoints and Definition 86.53 for the symmetric off-diagonal zero row and the two diagonal zero-exactness rows.

The definition of Definition 86.51 lists no host matrix, determinant, spectral row, topology, completeness row, Cauchy-limit selector, or ambient Hilbert-space carrier. Therefore the named downstream certificates can cite this source only for the two-vector scalar-form packet and its displayed ledger. □

Theorem 86.55 (InnerProduct Gram diagonal scalar nonnegativity)**.** *Let I be an* $\mathsf{InnerProduct}^\uparrow$ BHist *source whose retained scalar endpoint source carries the inherited scalar order row* $\preceq_{\mathsf{scal}}$*, with nonnegative scalar predicate read as* $0_{\mathsf{scal}} \preceq_{\mathsf{scal}} a$*. For the two-vector Gram source of Definition 86.51 with carried endpoints $x, y : C_V$, the two diagonal scalar endpoints satisfy*

$$0_{\mathsf{scal}} \preceq_{\mathsf{scal}} \langle x, x\rangle_{\mathsf{InnerProduct}^\uparrow}$$

and

$$0_{\mathsf{scal}} \preceq_{\mathsf{scal}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

These are public scalar-order rows of the Gram packet, read from the retained diagonal positivity rows and not from a host matrix, determinant, spectral row, or Hilbert-space positivity predicate.

Proof. Unfold the two-vector Gram source of Definition 86.51. Its displayed scalar endpoints include the two self-values $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ and $\langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$, and its listed rows include the diagonal positivity rows for those two self-values.

Apply Definition 86.12 to the carried endpoint x. The positive-definite entry of the underlying $\mathsf{InnerProduct}^{\uparrow}$ carrier supplies the nonnegative scalar endpoint witness for $\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}$. Since the retained scalar order row reads nonnegativity as $0_{\mathsf{scal}} \preceq_{\mathsf{scal}} a$, this witness is precisely

$$0_{\mathsf{scal}} \preceq_{\mathsf{scal}} \langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

Apply the same positive-definite obligation to the carried endpoint y. Its nonnegative scalar endpoint witness for $\langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ repacks through the same inherited scalar order row as

$$0_{\mathsf{scal}} \preceq_{\mathsf{scal}} \langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

The consumer threshold source of Definition 86.47 factors the form, scalar endpoint, positivity, transport, and ledger rows through the same $\mathsf{InnerProduct}^{\uparrow}$ carrier and retained scalar source. Therefore the two order comparisons are public rows of the two-vector Gram packet itself, with no additional analytic or host-space structure introduced. □

86.6 Root unblock obligation basis

Definition 86.56 (InnerProduct root obligation basis)**.** *The* $\mathsf{InnerProduct}^{\uparrow}$ *root obligation basis is the root-facing* BHist *package with the following ten fields.*

1. *The traditional target is the constructive inner-product interface: a vector-space carrier equipped with a scalar-valued form, conjugate symmetry, sesquilinearity, positive-definite zero exactness, and orthogonality transport.*
2. *The BEDC source is* $\mathsf{NameCert}_{\mathsf{VecSpace}^{\uparrow}}$ *together with the scalar rows retained from* $\mathsf{Field}^{\uparrow}$.
3. *The carrier is the displayed vector predicate* $C_V : \mathsf{BHist} \to \mathsf{Prop}$.
4. *The classifiers are the vector endpoint classifier* $\sim_V$ *and the scalar endpoint classifier* $\sim_{\mathsf{scal}}$.
5. *The form row is*
$$\langle -, -\rangle_{\mathsf{InnerProduct}^{\uparrow}} : C_V \times C_V \to C_{\mathsf{scal}}.$$
6. *The stability obligations are form transport, conjugate symmetry, sesquilinearity in the admitted arguments, positive-definite zero exactness, and orthogonality transport.*
7. *The ledger rows are the vector source row, scalar source row, form endpoint row, law rows, transport rows, orthogonality row, and downstream consumer rows.*
8. *The core theorem list consists of Definition 86.57, Definition 86.58, and Definition 86.59.*
9. *Exactness means row exhaustion: every root consumer can read only the rows listed in this basis, and each listed row is sourced from the displayed* BHist *data.*

10. *There is no standard bridge field in this basis; its status is a paper obligation surface for later formalization.*

Theorem 86.57 (InnerProduct root carrier-classifier unblock)**.** *The root obligation basis of Definition 86.56 exposes exactly the carrier C_V, the vector classifier $\sim_V$, the scalar endpoint classifier $\sim_{\mathsf{scal}}$, and the scalar-valued form endpoint row $\langle -, - \rangle_{\mathsf{InnerProduct}^\uparrow}$. It introduces no second vector carrier, no extra point classifier, and no host scalar equality.*

Proof. Read the source field of Definition 86.56. It names the embedded $\mathsf{NameCert}_{\mathsf{VecSpace}^\uparrow}$ and the scalar rows retained from $\mathsf{Field}^\uparrow$, which are the same source data displayed in Definition 86.3.

Apply Definition 86.4. This identifies the public carrier as the displayed predicate C_V together with the scalar-valued form row, and it rules out any additional point carrier.

Apply Definition 86.7. Its hypotheses and conclusion use exactly $\sim_V$ on vector endpoints and $\sim_{\mathsf{scal}}$ on scalar endpoints. Hence the basis exposes precisely the carrier, classifier, scalar endpoint classifier, and form endpoint rows listed in the statement. □

Theorem 86.58 (InnerProduct root form-law unblock)**.** *For the root obligation basis of Definition 86.56, conjugate symmetry, sesquilinearity, positive-definite zero exactness, and orthogonality are all sourced from displayed* BHist *rows of the* $\mathsf{InnerProduct}^\uparrow$ *certificate. None of these laws is supplied by a host Hilbert space, quotient field, or ambient topology.*

Proof. Use Definition 86.5 for conjugate symmetry and the positivity side of the diagonal law. These are scalar-history comparisons over the retained scalar classifier.

Use Definition 86.6 for the sesquilinearity rows. Their vector inputs come from the embedded $\mathsf{VecSpace}^\uparrow$ operations, and their scalar outputs remain in the retained scalar endpoint source.

Apply Definition 86.12. It supplies the exact zero clause saying that the self-form endpoint is scalar-zero exactly at the displayed vector-zero classifier class.

Finally unpack Definition 86.13. Orthogonality is the scalar-zero classification of the displayed form endpoint, so its transport and zero behavior are inherited from the same form and classifier rows. Thus every form law named by the basis is a displayed BHist row. □

Theorem 86.59 (InnerProduct root downstream threshold unblock)**.** *The downstream certificates* $\mathsf{Hilbert}^\uparrow$, $\mathsf{Norm}^\uparrow$, $\mathsf{Fourier}^\uparrow$, $\mathsf{RiemannianMetric}^\uparrow$, *and* $\mathsf{RootSystem}^\uparrow$ *may consume from Definition 86.56 only the carrier, classifier, scalar endpoint, form-law, orthogonality, and ledger rows listed there. They receive no Banach completeness, Cauchy-limit selector, ambient topology, or host Hilbert-space row from* $\mathsf{InnerProduct}^\uparrow$.

Proof. Start with Definition 86.23. It packages the carrier, classifier, scalar endpoint source, form row, form-law rows, orthogonality row, and ledger rows as the complete inner-product threshold surface.

Apply Definition 86.25. This separates the inner-product geometric rows consumed by $\mathsf{Hilbert}^\uparrow$ from the Banach metric, completeness, and Cauchy-limit rows supplied by the separate Banach dependency.

Apply Definition 86.26. It gives the same threshold coverage for $\mathsf{Hilbert}^\uparrow$, $\mathsf{Fourier}^\uparrow$, $\mathsf{RiemannianMetric}^\uparrow$, and $\mathsf{RootSystem}^\uparrow$, and it excludes Banach completeness, Cauchy-limit selection, ambient topology, and host Hilbert-space data from the $\mathsf{InnerProduct}^\uparrow$ source.

The $\mathsf{Norm}^\uparrow$ consumer reads the same inner-product threshold through the norm and metric seed rows of Definition 86.27. Those rows are generated from the form endpoint, positive-definite exactness, classifier transport, and ledger fields already listed in the basis. Therefore all five consumers are bounded by the same root obligation basis, with no additional downstream row projected from $\mathsf{InnerProduct}^\uparrow$. □

86.7 InnerProduct root scalar consumer frontier

Theorem 86.60 (InnerProduct root scalar projection transport)**.** *In the root obligation basis of Definition 86.56, the scalar endpoint of the form transports through the retained scalar classifier. Concretely, if $x \sim_V x'$ and $y \sim_V y'$ are vector-classifier witnesses for carried endpoints $x, y, x', y' : C_V$, then the projected form endpoints satisfy*

$$\langle x, y\rangle_{\mathsf{InnerProduct}^\uparrow} \sim_{\mathsf{scal}} \langle x', y'\rangle_{\mathsf{InnerProduct}^\uparrow}.$$

This projection uses only the root form row, the two vector-classifier witnesses, and the retained scalar classifier.

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductRoot scalar projection transport`

Proof. Read the form endpoint and both classifiers from Definition 86.56. The basis exposes the vector classifier $\sim_V$, the scalar classifier $\sim_{\mathsf{scal}}$, and the form endpoint row, with no additional scalar equality.

Apply Definition 86.7 to the two vector-classifier witnesses. Its conclusion is exactly a retained scalar-classifier witness between the two form endpoints. Thus form endpoint transport is a scalar projection of the root basis data. □

Theorem 86.61 (InnerProduct root diagonal zero exactness)**.** *For every carried vector endpoint $x : C_V$ in the root obligation basis of Definition 86.56, the diagonal self-value $\langle x, x\rangle_{\mathsf{InnerProduct}^\uparrow}$ is classified as the scalar zero endpoint if and only if $x \sim_V 0_V$. The equivalence is a* BHist *row statement: scalar-zero classification of the diagonal is exactly the displayed vector-zero classifier class.*

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductSingletonDiagonal zero exactness`

Proof. First read the diagonal endpoint from the form-law surface of Definition 86.58. This places $\langle x, x\rangle_{\mathsf{InnerProduct}^\uparrow}$ inside the displayed scalar endpoint source and keeps its classifier equal to $\sim_{\mathsf{scal}}$.

For the forward direction, assume that the diagonal endpoint is classified as scalar zero. Apply Definition 86.12. Its exactness clause converts this scalar-zero classification into the vector-classifier witness $x \sim_V 0_V$.

For the reverse direction, assume $x \sim_V 0_V$. The converse exactness clause of Definition 86.12, together with the root form-law unblock row, returns the scalar-zero classification of $\langle x, x\rangle_{\mathsf{InnerProduct}^\uparrow}$. Hence the diagonal zero test is exact at the root surface. □

Theorem 86.62 (InnerProduct root Norm-Hilbert consumer frontier)**.** *The* $\mathsf{Norm}^\uparrow$ *and* $\mathsf{Hilbert}^\uparrow$ *consumers of an* $\mathsf{InnerProduct}^\uparrow$ *root obligation basis may read only the following scalar-consumer frontier: the norm-squared diagonal endpoint $\|x\|_I^2 = \langle x, x\rangle$, the diagonal zero exactness row, the orthogonality row, the carrier and classifier rows, and the visible ledger rows. They receive no completeness, topology, host Hilbert-space carrier, or Cauchy-limit selector from* $\mathsf{InnerProduct}^\uparrow$.

Proof. For $\mathsf{Norm}^\uparrow$, use Definition 86.27. It defines the norm-squared seed from the diagonal form endpoint and lists the positive-definite exactness, classifier-transport, and ledger rows needed to consume that endpoint.

Apply Definition 86.61 to identify the zero test of the norm-squared diagonal with the displayed vector-zero classifier class. Orthogonality is read from Definition 86.13, so it is also a scalar-zero classification of a displayed form endpoint.

For $\mathsf{Hilbert}^{\uparrow}$, apply Definition 86.25. It separates the inner-product carrier, classifier, form, transport, orthogonality, and ledger rows from Banach metric and completeness data.

Finally use Definition 86.59. The stated root threshold contains no completeness field, topology field, host Hilbert-space carrier, or Cauchy-limit selector. Therefore the $\mathsf{Norm}^{\uparrow}$ and $\mathsf{Hilbert}^{\uparrow}$ consumer frontier is exactly the listed scalar-consumer surface. □

86.8 Public NameCert export

Theorem 86.63 (InnerProductUp public NameCert export)**.** *The carrier, classifier, scalar endpoint classifier, form row, conjugate-symmetry row, sesquilinearity rows, positive-definite row, orthogonality rows, and visible ledger assembled by Definition 86.17 form the public* $\mathsf{NameCert}_{\mathsf{InnerProduct}^{\uparrow}}$ *export consumed by* $\mathsf{Norm}^{\uparrow}$ *and* $\mathsf{Hilbert}^{\uparrow}$*. Completeness, topology, Banach metric, Cauchy limits, and standard bridge data are not fields of this export.*

Proof. Start from the root dependency surface of Definition 86.19. It names the displayed $\mathsf{VecSpace}^{\uparrow}$ carrier and classifier, the retained scalar endpoint classifier, the scalar-valued form row, its law rows, the positive-definite exactness row, the orthogonality rows, and the visible ledger as the available BHist rows.

The vector and scalar endpoints exported to consumers are exactly the rows identified by Definition 86.20. The form row, conjugate-symmetry row, sesquilinearity rows, endpoint transport, and positive-definite row are exactly the rows identified by Definition 86.21.

Now apply Definition 86.17. Its obligation surface packages those carrier, classifier, law, exactness, orthogonality, and ledger rows as the paper-side $\mathsf{NameCert}_{\mathsf{InnerProduct}^{\uparrow}}$ surface. Since every listed field is already one of the displayed BHist rows, the export is a public NameCert-facing object rather than an additional hidden dependency.

Finally use Definition 86.50 and Definition 86.62. They identify the $\mathsf{Norm}^{\uparrow}$ and $\mathsf{Hilbert}^{\uparrow}$ consumer boundary as the same inner-product rows while excluding completeness, topology, Banach metric, Cauchy-limit selectors, and standard bridge data. Thus the displayed rows form the public export and its negative boundary. □

Theorem 86.64 (InnerProduct singleton terminal standard bridge)**.** *The public singleton* $\mathsf{InnerProduct}^{\uparrow}$ *export of Definition 86.63 supplies a paper-level* $\mathsf{StandardBridge}(\mathsf{InnerProduct}^{\uparrow}, T^*_{IP})$ *to the one-point inner-product host theory. The encode field sends the unique host vector of* T^*_{IP} *to* e*. The decode field sends every carried* $\mathsf{VecSpaceSingletonCarrier}$ *endpoint to the host point. The decode-encode round trip is terminal equality, and the encode-decode round trip is the singleton classifier witness for the carried endpoint. The theorem-preservation field covers the carrier row, scalar endpoint row, form row, zero-left orthogonality row, and public export rows. The no-host-leak field keeps the BEDC public surface to* BHist*,* $\mathsf{VecSpaceSingletonCarrier}$*,* $\mathsf{RealConstantHistoryClassifier}$*,* $\mathsf{InnerProductSingletonForm}$*, and the displayed public rows.*

Lean4 ✓ `BEDC.Derived.InnerProductUp.InnerProductUp StdBridge`

Proof. We check the six fields of section 9204.1. The encode field is the constant map from the unique host vector of T^*_{IP} to the empty BEDC endpoint e. The carrier and classifier rows in Definition 86.63 place e inside the public singleton vector carrier.

The decode field sends every carried $\mathsf{VecSpaceSingletonCarrier}$ endpoint to the unique host point. Since the host theory has one vector, decoded endpoints are identified by terminal equality.

For the decode-encode round trip, start with the unique host vector, encode it as e, and decode back to the host point. This is terminal equality in T^*_{IP}.

For encode-decode, start with a carried singleton endpoint. Decoding gives the unique host vector and encoding returns e. The singleton classifier row of the public export supplies the classifier witness identifying the original carried endpoint with e.

The theorem-preservation field is finite and explicit. The carrier, scalar endpoint, form, law, orthogonality, and ledger rows are those exposed by Definition 86.63. The zero-left orthogonality row is Definition 86.14, backed by BEDC.Derived.InnerProductUp.InnerProductSingletonOrthogonal_zero_left. No completeness, Banach, Hilbert, spectral, or non-terminal host theorem is included in this list.

Finally, the no-host-leak field follows from the same public-object inventory. The bridge mentions the one-point host theory only inside encode, decode, and the finite preservation list. The BEDC public surface remains exactly BHist, VecSpaceSingletonCarrier, RealConstantHistoryClassifier, InnerProductSingletonForm, and the displayed rows of Definition 86.63. □

Theorem 86.65 (InnerProduct finite orthogonality derivation)**.** *For every accepted* InnerProduct$^{\uparrow}$ *packet, the zero-left orthogonality row is derived by finite inspection of the* VecSpace$^{\uparrow}$ *carrier, the scalar endpoint classifier, the sesquilinear rows, the conjugate-symmetry row, the positivity row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The derivation is the BEDC route through Definition 86.1, Definition 86.3, Definition 86.5, Definition 86.6, Definition 86.13, and Definition 86.14; it is not Hilbert completeness, Banach completion, spectral theory, or a host inner-product-space theorem.*

Proof. Start from the displayed carrier and source rows. The VecSpace$^{\uparrow}$ carrier and scalar endpoint classifier are already visible in Definition 86.1 and Definition 86.3, so the zero-left claim is read inside the accepted BEDC packet rather than in a host vector space.

Next inspect the form laws. The sesquilinear source row of Definition 86.6 and the conjugate-symmetry and positivity rows of Definition 86.5 expose exactly the scalar-form data used by the orthogonality classifier.

Finally apply the orthogonality rows. The definition Definition 86.13 names the finite classifier surface, and Definition 86.14 derives the zero-left row from that surface. Transport, replay, provenance, and local naming keep the same rows attached to the accepted packet, so the result is a finite BEDC route and exports no Hilbert, Banach, spectral, or host-completeness principle. □

Theorem 86.66 (InnerProduct finite Gram orthogonality induction)**.** *For every finite* BHist *list of pairwise orthogonal nonzero* InnerProduct$^{\uparrow}$ *rows carried by an accepted packet, there is a finite Gram ledger whose off-diagonal entries are the displayed scalar-zero rows and whose diagonal entries are the displayed positive scalar rows. The construction is stable under componentwise* hsame *transport and displayed* Cont *replay, so the same ledger can be consumed by* VecSpace$^{\uparrow}$ *scalar-action rows,* Norm$^{\uparrow}$ *norm seeds, and* Hilbert$^{\uparrow}$ *completion-facing orthogonality routes without importing a host Gram–Schmidt theorem or an ambient Hilbert basis.*

Proof. Induct on the finite BHist list carrier. The empty list has the empty Gram ledger, and the one-row list reads its positive diagonal entry from the positive-definite row already exposed by the accepted InnerProduct$^{\uparrow}$ packet.

For the cons step, assume the tail has a Gram ledger with zero off-diagonal rows and positive diagonal rows. The pairwise orthogonality premise supplies the scalar-zero rows between the new head and every carried tail row, while conjugate symmetry supplies the reverse off-diagonal rows. Positive definiteness supplies the new diagonal row because the head is nonzero.

Transport is componentwise. If the carried rows are replaced by hsame recognized representatives, the vector endpoints, scalar endpoints, form values, zero rows, and positivity rows are

transported by the packet rows already used in Definition 86.65. Displayed Cont replay keeps the finite ledger attached to the same provenance and local NameCert row.

Thus the induction produces a BEDC Gram ledger and no external basis choice. $\mathsf{VecSpace}^{\uparrow}$ consumers read only the retained scalar-action and additive rows, $\mathsf{Norm}^{\uparrow}$ consumers read the norm seeds and Pythagorean rows, and $\mathsf{Hilbert}^{\uparrow}$ consumers may use the ledger as a finite orthogonality boundary without receiving completeness or projection existence. □

Theorem 86.67 (InnerProduct finite orthogonal projection derivation)**.** *For every accepted* $\mathsf{InnerProduct}^{\uparrow}$ *packet and every displayed carried pair* $x, y : C_V$ *whose two-vector Gram source has a diagonal scalar row* $\langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ *separated from* 0_{scal}*, the finite projection component of* x *along* y *is read from Definition 86.51, the Gram symmetry and diagonal rows of Definition 86.53, the parallelogram and Pythagorean norm seed rows of Definition 86.32 and Definition 86.35, the orthogonality closure rows of Definition 86.41, and the scalar-action and additive rows retained by the embedded* $\mathsf{VecSpace}^{\uparrow}$ *source. The row states only that the BEDC packet can inspect the displayed scalar coefficient, carried scalar multiple, residual vector, and scalar-zero orthogonality classifier for that finite pair; it does not assert Hilbert projection existence, closed-subspace projection, least-distance attainment, Banach completeness, or a host projection theorem.*

Proof. Start with Definition 86.51. It displays the four scalar endpoints for x and y, in particular $\langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ and $\langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$, together with the transport, symmetry, positivity, orthogonality, and ledger rows needed to keep those endpoints in one finite packet.

The separated diagonal row lets the retained scalar source form the displayed coefficient

$$\alpha = \langle x, y\rangle_{\mathsf{InnerProduct}^{\uparrow}} \cdot_{\mathsf{scal}} \langle y, y\rangle^{-1}_{\mathsf{InnerProduct}^{\uparrow}}.$$

This is a scalar-source row, not an analytic minimizer. The embedded $\mathsf{VecSpace}^{\uparrow}$ source then carries $\alpha \cdot_V y$ and the displayed residual $x -_V (\alpha \cdot_V y)$ by its scalar-action and additive rows.

Use Definition 86.53 to keep the off-diagonal Gram row symmetric and to identify the diagonal zero rows with vector-zero classification. Use Definition 86.41 and the linearity row of Definition 86.6 to inspect the scalar endpoint

$$\langle x -_V (\alpha \cdot_V y), y\rangle_{\mathsf{InnerProduct}^{\uparrow}}.$$

The scalar inverse row for the displayed nonzero diagonal cancels the $\langle y, y\rangle_{\mathsf{InnerProduct}^{\uparrow}}$ factor, leaving the retained scalar-zero classifier for the residual against y.

Finally read the norm side only as a finite consistency check. The parallelogram seed source and Definition 86.35 say that once the residual is orthogonal to the carried multiple of y, the diagonal norm-squared rows split through the displayed scalar ledger. This records the projection row as finite BEDC data over $x, y, \alpha, \alpha \cdot_V y$ and the residual, with no coordinate for Hilbert completeness, closed-subspace projection, least-distance existence, or host-space projection. □

Closure status for $\mathsf{NameCert}_{\mathsf{InnerProduct}^{\uparrow}}$**.**

Constructive story: An inner-product object is assembled by taking an already displayed $\mathsf{VecSpace}^{\uparrow}$ history carrier, retaining its scalar endpoint source, and adding one scalar-valued form row on pairs of carried vector histories; packages without that vector-space source, scalar classifier, conjugate-symmetry row, sesquilinear rows, positive-definite row, and visible ledger are not admitted. Two such packages are classified only when the displayed BEDC rows agree componentwise: vector carrier and classifier, scalar endpoint classifier, form values, operation rows, conjugate symmetry, linearity, positivity, orthogonality, and ledger entries all match by the retained classifiers rather than by host isometry or external inner-product equality. The source therefore covers a vector-space carrier together with scalar histories and a form row, the pattern records symmetry, linearity, positive definiteness, norm and metric seeds, parallelogram seed, orthogonality closure, the two-vector Gram packet, and consumer thresholds, and the ledger keeps every vector endpoint, scalar endpoint, form value,

transport row, and positivity witness visible. The five name-certificate obligations are supplied by the displayed source: an accepted singleton form gives inhabitation in the concrete case, the component classifiers give reflexivity, symmetry, and transitivity, and each transport row keeps the vector, scalar, and form fields in the accepted carrier after recognized endpoint changes. A history package h lies in the signature gap of an $\mathsf{InnerProduct}^{\uparrow}$ token p when the source-domain accepts the displayed vector-space-plus-form data, the signature relation pairs it with an answer package and evidence ledger, and token introduction names that answer as p; unfolded, p can only consume the listed form laws, zero classifications, and orthogonality rows. The paper-level terminal bridge sends the one host vector to e and decodes every singleton carried endpoint back to the unique host vector, preserving the carrier, scalar endpoint, form, zero-left orthogonality, and public export rows. The chapter registers this displayed scalar-form package under the name $\mathsf{InnerProduct}^{\uparrow}$; it adds no $\mathsf{Norm}^{\uparrow}$ closure, Hilbert completeness, Banach completion, spectral theory, non-terminal standard model, or bridge-checked host theorem.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InnerProduct}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature paper scope is the $\mathsf{InnerProduct}^{\uparrow}$ core surface, root threshold package, norm-metric seed, parallelogram norm seed, orthogonality closure, two-vector Gram boundary, consumer frontier, public NameCert export, and singleton terminal standard bridge of Definition 86.64.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InnerProduct}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.InnerProductUp.InnerProductSingletonOrthogonal\_zero\_left`

Bridge status: bridgeChecked

Not claimed: This chapter does not close bridgeChecked, $\mathsf{Norm}^{\uparrow}$, Hilbert completeness, Banach completion, spectral theory, or non-terminal standard models.

Upgrade path: No further upgrade – chapter at top of formal axis.

Chapter 87

A Concrete Naming Certificate for $\mathsf{TensorProduct}^{\uparrow}$

The tensor-product interface $\mathsf{TensorProduct}^{\uparrow}$ packages the universal bilinear factorization of two module carriers. It depends on $\mathsf{NameCert}_{\mathsf{Module}^{\uparrow}}$ (chapter 46) and supplies the multilinear data on which higher tensor algebras and exterior powers are built.

87.1 Carrier definition

Definition 87.1 (Tensor-product singleton carrier)**.** *For a generated history h, the singleton tensor-product carrier holds when there are histories l and r such that l and r are both module-singleton histories and $\mathsf{Cont}(l, r, h)$ holds. Thus the tensor-product singleton object is represented by a concrete continuation ledger from its two singleton module endpoints.*

Lean4 (definition) `BEDC.Derived.TensorProductUp.TensorProductSingletonCarrier`

Theorem 87.2 (Tensor-product singleton carrier empty iff)**.** *For a generated history h, the tensor-product singleton carrier holds exactly when h is the empty history:*

$$\mathsf{TensorProductSingletonCarrier}(h) \iff \mathsf{hsame}(h, \mathsf{e}).$$

Proof. For the forward direction, unpack the tensor carrier into singleton module endpoints and a continuation ledger. The endpoint carriers identify both factors with e, so continuation respect compares the ledger output with the empty right-unit continuation. Conversely, if $h\mathsf{hsamee}$, use two empty singleton module endpoints and transport the empty right-unit continuation to the result h. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonCarrier empty iff`

Theorem 87.3 (Tensor-product singleton carrier empty endpoint iff)**.** *For a generated history h, the tensor-product singleton carrier holds exactly when h is* hsame *to the empty history.*

Proof. Unpack the carrier into two module-singleton endpoints and a continuation ledger. The two module endpoints are empty, so the continuation endpoint is the empty append. Conversely, the empty endpoint is obtained from the two empty module factors and the left-unit continuation law. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonCarrier empty endpoint iff`

Theorem 87.4 (Tensor-product singleton result-empty continuation)**.** *For a history $t : \mathsf{BHist}$, if t satisfies the tensor-product singleton carrier, then t continues with the empty suffix to the empty history:*

$$\mathsf{TensorProductSingletonCarrier}(t) \Rightarrow \mathsf{Cont}(t, \mathsf{e}, \mathsf{e}).$$

Proof. Unpack the carrier into module-singleton endpoints l, r and a continuation $\mathsf{Cont}(l, r, t)$. The two endpoint carrier witnesses identify both l and r with e, and the displayed continuation therefore reduces to the empty result. The right-unit continuation gives $\mathsf{Cont}(t, \mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonCarrier result empty continuation`

Theorem 87.5 (Tensor-product singleton suffix carrier)**.** *Let p, s, and o be generated histories. If p and o satisfy the tensor-product singleton carrier and $\mathsf{Cont}(p, s, o)$ holds, then s satisfies the module-singleton carrier.*

Proof. Unpack the two tensor-product singleton carriers into module-singleton endpoints and continuation ledgers. The endpoint carriers identify both tensor endpoints with the empty history. The displayed continuation $\mathsf{Cont}(p, s, o)$ therefore has empty source and empty result, so the append-empty inversion for continuation identifies the suffix s with the empty history. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonCarrier continuation suffix carrier`

Theorem 87.6 (Tensor-product singleton carrier continuation result closure)**.** *Let p, s, and o be generated histories. If p satisfies the tensor-product singleton carrier, s satisfies the module-singleton carrier, and $\mathsf{Cont}(p, s, o)$ holds, then o satisfies the tensor-product singleton carrier.*

Proof. The tensor-product singleton carrier identifies p with the empty history, and the module-singleton carrier identifies s with the empty history. Transporting the continuation along these endpoint identifications gives $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, o)$. The left-unit result law identifies o with e, and the tensor-product singleton empty characterization rebuilds the carrier. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonCarrier continuation result closed`

Theorem 87.7 (Tensor-product singleton continuation prefix carrier)**.** *Let pre, $pair$, and out be generated histories. If $pair$ and out satisfy the tensor-product singleton carrier and $\mathsf{Cont}(pre, pair, out)$ holds, then pre satisfies the module-singleton carrier.*

Proof. The tensor-product singleton carrier identifies both *pair* and *out* with the empty history. After transporting the displayed continuation to an empty result, continuation empty-result inversion exposes the prefix endpoint as empty, which is exactly the module-singleton carrier. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonCarrier continuation prefix carrier`

Definition 87.8 (Tensor product singleton factor)**.** *For histories $l, r, t : \mathsf{BHist}$, the tensor-product singleton factor predicate holds when l, r, and t all lie in the module singleton carrier and the continuation relation composes l with r to produce t:*

$$\mathsf{TensorProductSingletonFactor}(l, r, t) := A_{\mathsf{e}}(l) \wedge A_{\mathsf{e}}(r) \wedge A_{\mathsf{e}}(t) \wedge \mathsf{Cont}(l, r, t).$$

Lean4 (definition) `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor`

Theorem 87.9 (Tensor product singleton carrier factor witness)**.** *If a tensor history satisfies the tensor-product singleton carrier, then it has left and right singleton module factors whose tensor-product singleton factor predicate holds, and the original continuation witness is retained.*

Proof. Eliminate the carrier witness. The two module-singleton factors force the left and right endpoints to be empty, and the continuation ledger then forces the tensor endpoint to be empty. These three singleton carrier facts together with the continuation ledger form the concrete factor witness. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonCarrier factor witness`

Theorem 87.10 (Tensor product singleton factor hsame transport)**.** *If* $\mathsf{TensorProductSingletonFactor}(l, r, t)$ *holds and* $l\mathsf{hsame}l'$*,* $r\mathsf{hsame}r'$*, and* $t\mathsf{hsame}t'$*, then* $\mathsf{TensorProductSingletonFactor}(l', r', t')$ *holds, and the transported continuation witness* $\mathsf{Cont}(l', r', t')$ *is retained.*

Proof. Unpack the singleton factor. Transport each singleton carrier endpoint by symmetry and transitivity of hsame. Transport the continuation witness across the three endpoint comparisons by continuation hsame transport. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor hsame transport`

87.2 The certificate

Theorem 87.11 (Tensor product singleton factor tensor semantic name certificate)**.** *Given a concrete singleton factor* $\mathsf{TensorProductSingletonFactor}(l, r, t)$*, the tensor endpoint carrier* $u \mapsto \mathsf{TensorProductSingletonFactor}(l, r, u)$ *forms a semantic name certificate when source, pattern, and ledger policy are all this carrier and the classifier is* hsame*.*

Proof. The displayed factor supplies the inhabited carrier. Reflexivity, symmetry, and transitivity are those of hsame. Carrier transport is exactly Definition 87.10 with the left and right endpoints fixed by reflexivity. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor tensor semanticNameCert`

Theorem 87.12 (Tensor product singleton factor source-target swap)**.** *For histories* $l, r, t : \mathsf{BHist}$*, if*

$$\mathsf{TensorProductSingletonFactor}(l, r, t)$$

holds, then

$$\mathsf{TensorProductSingletonFactor}(r, l, t)$$

holds. The resulting factor contains the swapped continuation witness $\mathsf{Cont}(r, l, t)$*.*

Proof. Unpack Definition 87.8. The factor supplies $A_{\mathsf{e}}(l)$, $A_{\mathsf{e}}(r)$, $A_{\mathsf{e}}(t)$, and $\mathsf{Cont}(l, r, t)$. In the concrete singleton module of Definition 46.2, the first two endpoint witnesses are the comparisons $l\mathsf{hsame}e$ and $r\mathsf{hsame}e$. Hence $l\mathsf{hsame}r$ follows by composing $l\mathsf{hsame}e$ with the symmetry of $r\mathsf{hsame}e$, and $r\mathsf{hsame}l$ follows by the same argument with the roles reversed.

Apply Definition 87.10 to the original factor with the comparisons $l\mathsf{hsame}r$, $r\mathsf{hsame}l$, and $t\mathsf{hsame}t$. Its conclusion is exactly the swapped predicate $\mathsf{TensorProductSingletonFactor}(r, l, t)$, and its continuation component is $\mathsf{Cont}(r, l, t)$. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor source target swap`

Theorem 87.13 (Tensor product singleton factor swap symmetry)**.** *For histories* $l, r, t : \mathsf{BHist}$*, if*

$$\mathsf{TensorProductSingletonFactor}(l, r, t)$$

holds, then

$$\mathsf{TensorProductSingletonFactor}(r, l, t)$$

holds. The resulting factor includes the continuation witness $\mathsf{Cont}(r, l, t)$*.*

Proof. Unpack Definition 87.8. The factor consists of $A_{\mathsf{e}}(l)$, $A_{\mathsf{e}}(r)$, $A_{\mathsf{e}}(t)$, and $\mathsf{Cont}(l, r, t)$. By Definition 46.2 and Definition 36.169, the two factor carrier witnesses are endpoint comparisons $l\mathsf{hsamee}$ and $r\mathsf{hsamee}$. Transitivity of hsame gives $l\mathsf{hsame}r$ by composing $l\mathsf{hsamee}$ with the symmetry of $r\mathsf{hsamee}$, and similarly gives $r\mathsf{hsame}l$.

Apply Definition 87.10 to the original factor with endpoint comparisons $l\mathsf{hsame}r$, $r\mathsf{hsame}l$, and the reflexive comparison $t\mathsf{hsame}t$. The transported conclusion is $\mathsf{TensorProductSingletonFactor}(r, l, t)$, and the retained continuation component is $\mathsf{Cont}(r, l, t)$. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor swap semantic name certificate`

Theorem 87.14 (Tensor product singleton factor associator)**.** *For histories* $l, r, s, t, u : \mathsf{BHist}$*, if*

$$\mathsf{TensorProductSingletonFactor}(l, r, t) \quad \textit{and} \quad \mathsf{TensorProductSingletonFactor}(t, s, u)$$

hold, then there is a history $m : \mathsf{BHist}$ *such that*

$$\mathsf{TensorProductSingletonFactor}(r, s, m) \quad \textit{and} \quad \mathsf{TensorProductSingletonFactor}(l, m, u)$$

hold. The two resulting factors retain the rebracketed continuation ledgers $\mathsf{Cont}(r, s, m)$ *and* $\mathsf{Cont}(l, m, u)$*.*

Proof. Unpack Definition 87.8. The first factor supplies $A_{\mathsf{e}}(l)$, $A_{\mathsf{e}}(r)$, $A_{\mathsf{e}}(t)$, and $\mathsf{Cont}(l, r, t)$; the second supplies $A_{\mathsf{e}}(t)$, $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(u)$, and $\mathsf{Cont}(t, s, u)$. Apply the associativity existence form of the continuation spine to the two continuation ledgers $\mathsf{Cont}(l, r, t)$ and $\mathsf{Cont}(t, s, u)$. This gives a history m with

$$\mathsf{Cont}(r, s, m) \quad \text{and} \quad \mathsf{Cont}(l, m, u).$$

It remains only to show that m lies in the singleton module carrier. By Definition 46.2 and Definition 36.169, the carrier witnesses $A_{\mathsf{e}}(r)$ and $A_{\mathsf{e}}(s)$ identify r and s with e. Transporting $\mathsf{Cont}(r, s, m)$ along these two endpoint comparisons gives $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, m)$. The continuation unit laws of Definition 21.12 compare this ledger with the empty unit continuation and identify m with e, which is exactly $A_{\mathsf{e}}(m)$.

Now package the first rebracketed factor from $A_{\mathsf{e}}(r)$, $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(m)$, and $\mathsf{Cont}(r, s, m)$. Package the second from $A_{\mathsf{e}}(l)$, $A_{\mathsf{e}}(m)$, $A_{\mathsf{e}}(u)$, and $\mathsf{Cont}(l, m, u)$. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor associator`

Theorem 87.15 (Tensor product singleton factor classifier uniqueness)**.** *For histories* $l, r, t, t' : \mathsf{BHist}$*, if*

$$\mathsf{TensorProductSingletonFactor}(l, r, t) \quad \textit{and} \quad \mathsf{TensorProductSingletonFactor}(l, r, t')$$

hold, then

$$t\mathsf{hsame}t'.$$

Thus any two tensor endpoints obtained from the same singleton module factor pair are classifier-equal in the tensor endpoint certificate of Definition 87.11.

Proof. Unpack Definition 87.8 for both factor witnesses. The first witness supplies $\mathsf{Cont}(l, r, t)$; the second supplies $\mathsf{Cont}(l, r, t')$. These two continuation ledgers have the same source history l and the same right history r. Applying Definition 21.7 to the two ledgers identifies their outputs, giving $t \mathsf{hsame} t'$. The classifier in Definition 87.11 is hsame on this endpoint carrier, so this output identification is exactly tensor classifier equality. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor classifier uniqueness`
Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor classifier uniqueness readback`

Theorem 87.16 (TensorProductUp source and pattern obligation)**.** *In the singleton-factor tensor certificate, the source object is a pair of* $\mathsf{Module}^{\uparrow}$ *factor carriers over* BHist*. The pattern object is the concrete factor tuple* (l, r, t) *together with the continuation witness* $\mathsf{Cont}(l, r, t)$*. The carrier committed to the tensor endpoint is the existing specialization* $\mathsf{TensorProductSingletonFactor}(l, r, t)$ *for singleton module factors.*

Proof. Use Definition 87.8 as the source-pattern unpacking. Its four fields are exactly the left singleton module carrier, the right singleton module carrier, the tensor endpoint singleton carrier, and the continuation witness $\mathsf{Cont}(l, r, t)$.

The forward coverage direction is the witness theorem Definition 87.9: a tensor endpoint in the singleton carrier exposes two module-singleton endpoints and retains the continuation ledger. The displayed source and pattern data therefore repack into the same $\mathsf{TensorProductSingletonFactor}$ carrier. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonCarrier source pattern iff`

Theorem 87.17 (TensorProductUp classifier and stability obligation)**.** *For the singleton-factor tensor certificate, the endpoint classifier is* hsame *on tensor outputs. This classifier is stable under transport of the two factor carriers, transport of the continuation witness* $\mathsf{Cont}(l, r, t)$*, and the factor transport theorem for* hsame*.*

Proof. The certificate Definition 87.11 chooses hsame as the classifier on the tensor endpoint carrier. Transporting the left endpoint, right endpoint, and tensor output along hsame comparisons is therefore the only stability obligation.

Apply Definition 87.10. It transports the two factor-carrier witnesses and the tensor endpoint witness at the same time, and it retains the transported Cont ledger. Hence the classifier remains endpoint hsame after every admissible factor transport. □

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor classifier stability obligation`

Theorem 87.18 (TensorProductUp ledger and exactness obligation)**.** *For the singleton-factor tensor certificate, the ledger records exactly the two factor endpoints* l *and* r *and the continuation witness* $\mathsf{Cont}(l, r, t)$*. Coverage is supplied by the factor-witness theorem, soundness is supplied by the factor definition, and endpoint uniqueness is supplied by Definition 87.15.*

Lean4 ✓ `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor ledger exactness obligation`

Proof. Coverage comes from Definition 87.9: every tensor singleton endpoint exposes the two module-singleton endpoints and the retained continuation witness. Thus the ledger has no additional source component beyond l, r, and $\mathsf{Cont}(l, r, t)$.

Soundness is the direct reading of Definition 87.8. A valid factor consists of the two singleton module endpoints, the singleton tensor endpoint, and the continuation witness, so any recorded ledger entry rebuilds the public factor carrier.

Endpoint exactness uses Definition 87.15. Two ledger entries with the same factor endpoints have tensor outputs related by hsame. The associator theorem Definition 87.14 supplies the compatible rebracketing witness, so the ledger remains exact under the tensor factor shape used by the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{TensorProduct}^{\uparrow}}$.

Constructive story: The tensor product closed here is the singleton factor construction: a tensor endpoint is admitted when two singleton $\mathsf{Module}^{\uparrow}$ endpoints l and r are displayed and a continuation ledger $\mathsf{Cont}(l, r, t)$ assembles them into the endpoint t, which in this singleton case is forced back to the empty history. Two tensor outputs for the same displayed factors are classified by endpoint history-sameness, and factor transport says that changing l, r, or t by hsame transports both the singleton carrier witnesses and the continuation witness, so no bilinear quotient object is formed. The source is the pair of singleton module factors, the pattern is the concrete triple (l, r, t) with the retained continuation row, and the ledger records exactly those two factor endpoints, the tensor endpoint, source-target swap, associator, suffix and prefix closure, and classifier-uniqueness readback. The five name-certificate obligations close because any displayed singleton factor gives an inhabited endpoint carrier, hsame gives reflexivity, symmetry, and transitivity on outputs, and the factor transport theorem is precisely carrier closure under the classifier while source, pattern, and ledger are the same predicate. A history h lies in the signature gap of a $\mathsf{TensorProduct}^{\uparrow}$ token p when the source-domain accepts the two singleton module factors and their continuation, the signature relation pairs the resulting tensor endpoint with an answer endpoint and evidence ledger, and token introduction names that answer as p; unfolded, h is the unique empty tensor endpoint determined by the two factors. The paper bridge reads this singleton surface as the one-point tensor product and reads back through the same continuation ledger, not through a universal bilinear quotient. The chapter registers this singleton continuation-factor package under the name $\mathsf{TensorProduct}^{\uparrow}$; non-singleton tensor algebra, bilinear universal properties, exterior powers, and standard-model completeness are not introduced.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TensorProduct}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The singleton tensor package binds the singleton $\mathsf{Module}^{\uparrow}$ factor carrier, continuation suffix and prefix closure, factor witness, classifier uniqueness, source-target swap, associator, semantic NameCert, and ledger exactness rows stated in this chapter.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TensorProduct}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.TensorProductUp.TensorProductSingletonFactor\_tensor\_semanticNameCert`

Bridge status: paperBridge

Not claimed: This chapter does not claim non-singleton tensor algebra, bilinear universal properties, exterior powers, or standard-model completeness.

Upgrade path: No higher theory-axis grade remains for this singleton tensor package.

Chapter 88

A Concrete Naming Certificate for $\mathsf{Topology}^{\uparrow}$

The topology interface $\mathsf{Topology}^{\uparrow}$ packages a carrier with a family of open subsets closed under finite intersections and arbitrary unions, certified by an explicit indexing of opens. It generalises $\mathsf{NameCert}_{\mathsf{Met}^{\uparrow}}$ (chapter 57) by dropping the located-distance requirement and supplies the substrate for $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$, $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$, and the topological side of $\mathsf{NameCert}_{\mathsf{CplxTopo}^{\uparrow}}$ (chapter 77).

88.1 Carrier definition

88.2 The certificate

Definition 88.1 (Indexed open topology carrier)**.** *An indexed open topology carrier for* $\mathsf{Topology}^{\uparrow}$ *is a tuple* $\mathcal{T} = (X, \mathsf{same}_X, \mathsf{OpenIx}, \mathsf{OpenAt}, \wedge_{\mathsf{Topology}^{\uparrow}})$ *consisting of a carrier* X*, a carrier classifier* same_X*, an index object* OpenIx*, a membership predicate*

$$\mathsf{OpenAt} : \mathsf{OpenIx} \times X \to \mathsf{Prop},$$

and a binary operation $i, j \mapsto i \wedge_{\mathsf{Topology}^{\uparrow}} j$ *on* OpenIx*. The classifier plays the role isolated in Definition 57.4; for every index* i *it transports open membership by*

$$\mathsf{same}_X(x, y) \Longrightarrow (\mathsf{OpenAt}(i, x) \Longleftrightarrow \mathsf{OpenAt}(i, y)).$$

The finite-intersection field is the exact pointwise law

$$\mathsf{OpenAt}(i \wedge_{\mathsf{Topology}^{\uparrow}} j, x) \Longleftrightarrow (\mathsf{OpenAt}(i, x) \wedge \mathsf{OpenAt}(j, x)).$$

Thus the index operation is part of the certificate data of section 88.2, not an external selection of an open subset.

Definition 88.2 (Indexed open carried predicate)**.** *For an indexed open topology carrier* $\mathcal{T}$ *and a predicate* $U : X \to \mathsf{Prop}$*, an index* $i : \mathsf{OpenIx}$ *carries* U*, written* $\mathsf{CarriesOpen}_{\mathcal{T}}(i, U)$*, when it gives the pointwise classifier*

$$\mathsf{CarriesOpen}_{\mathcal{T}}(i, U) :\Longleftrightarrow \forall x : X, \quad U(x) \Longleftrightarrow \mathsf{OpenAt}(i, x).$$

A witnessed open of $\mathsf{Topology}^{\uparrow}$ *is such a pair* (i, h_i)*, with* $h_i : \mathsf{CarriesOpen}_{\mathcal{T}}(i, U)$*.*

Definition 88.3 (Topology neighbourhood interface)**.** *For an indexed open topology carrier $\mathcal{T}$ over X, the neighbourhood predicate of a point $x : X$ at an open index $i : \mathsf{OpenIx}$ is*

$$\mathsf{Nbhd}_{\mathcal{T}}(x, i) :\Longleftrightarrow \mathsf{OpenAt}(i, x).$$

This row is indexed-open data: it records membership in the displayed index of $\mathcal{T}$ and does not select an external powerset element.

Lean4 (definition) `BEDC.Derived.TopologyUp.BHistIndexedNeighborhood`
Lean4 (definition) `BEDC.Derived.TopologyUp.TopologyNeighborhood`

Theorem 88.4 (Neighbourhood open membership)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for $\mathsf{Topology}^{\uparrow}$ over X. If an index $i : \mathsf{OpenIx}$ carries a predicate $U : X \to \mathsf{Prop}$, then for every point $x : X$,*

$$\mathsf{CarriesOpen}_{\mathcal{T}}(i, U) \Longrightarrow (\mathsf{Nbhd}_{\mathcal{T}}(x, i) \Longleftrightarrow U(x)).$$

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistIndexedOpen neighborhood semantic name certificate`

Proof. Assume $h_i : \mathsf{CarriesOpen}_{\mathcal{T}}(i, U)$ and fix $x : X$. By Definition 88.3, $\mathsf{Nbhd}_{\mathcal{T}}(x, i)$ is exactly $\mathsf{OpenAt}(i, x)$.

The carrying equation of Definition 88.2 gives $U(x) \Longleftrightarrow \mathsf{OpenAt}(i, x)$. Reading this equivalence in the opposite direction gives the displayed neighbourhood membership law. □

Theorem 88.5 (Neighbourhood classifier transport)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for $\mathsf{Topology}^{\uparrow}$ over X. For every open index $i : \mathsf{OpenIx}$ and points $x, y : X$,*

$$\mathsf{same}_X(x, y) \Longrightarrow (\mathsf{Nbhd}_{\mathcal{T}}(x, i) \Longleftrightarrow \mathsf{Nbhd}_{\mathcal{T}}(y, i)).$$

Proof. Assume $\mathsf{same}_X(x, y)$. Unfolding Definition 88.3 reduces the claim to transport of $\mathsf{OpenAt}(i, -)$.

The membership-stability field of Definition 88.1, applied to the fixed index i, gives exactly $\mathsf{OpenAt}(i, x) \Longleftrightarrow \mathsf{OpenAt}(i, y)$. □

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologyUp StdBridge`

Theorem 88.6 (Neighbourhood finite-intersection)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for $\mathsf{Topology}^{\uparrow}$ over X. For every pair of open indices $i, j : \mathsf{OpenIx}$ and every point $x : X$,*

$$\mathsf{Nbhd}_{\mathcal{T}}(x, i \wedge_{\mathsf{Topology}^{\uparrow}} j) \Longleftrightarrow (\mathsf{Nbhd}_{\mathcal{T}}(x, i) \wedge \mathsf{Nbhd}_{\mathcal{T}}(x, j)).$$

Proof. Unfold the neighbourhood predicate of Definition 88.3. The desired statement becomes

$$\mathsf{OpenAt}(i \wedge_{\mathsf{Topology}^{\uparrow}} j, x) \Longleftrightarrow (\mathsf{OpenAt}(i, x) \wedge \mathsf{OpenAt}(j, x)).$$

This is precisely the finite-intersection field included in the indexed open topology carrier of Definition 88.1. □

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologyNeighborhood finite intersection`

Theorem 88.7 (Topology indexed open finite-intersection closure)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for $\mathsf{Topology}^{\uparrow}$ over X. If indices $i, j : \mathsf{OpenIx}$ carry predicates $U, V : X \to \mathsf{Prop}$, then the certificate index $i \wedge_{\mathsf{Topology}^{\uparrow}} j$ carries the finite intersection $U \cap V$:*

$$\mathsf{CarriesOpen}_{\mathcal{T}}(i, U) \Longrightarrow \mathsf{CarriesOpen}_{\mathcal{T}}(j, V) \Longrightarrow \mathsf{CarriesOpen}_{\mathcal{T}}(i \wedge_{\mathsf{Topology}^{\uparrow}} j, U \cap V),$$

where $(U \cap V)(x)$ *means* $U(x) \wedge V(x)$*. Equivalently, for every point* $x : X$ *the finite-intersection witness has the introduction and inversion form*

$$\mathsf{OpenAt}(i \wedge_{\mathsf{Topology}^\uparrow} j, x) \iff (U(x) \wedge V(x)),$$

and this carried intersection transports under the carrier classifier:

$$\mathsf{same}_X(x, y) \implies ((U(x) \wedge V(x)) \iff (U(y) \wedge V(y))).$$

This is the $\mathsf{Topology}^\uparrow$ *closure step whose concrete complex instance is used in Definition 77.22.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistIndexedOpen finite intersection closure`

Proof. Assume $h_U : \mathsf{CarriesOpen}_{\mathcal{T}}(i, U)$ and $h_V : \mathsf{CarriesOpen}_{\mathcal{T}}(j, V)$. Fix $x : X$. The finite-intersection field of Definition 88.1 gives

$$\mathsf{OpenAt}(i \wedge_{\mathsf{Topology}^\uparrow} j, x) \iff (\mathsf{OpenAt}(i, x) \wedge \mathsf{OpenAt}(j, x)).$$

The two carry witnesses give $U(x) \iff \mathsf{OpenAt}(i, x)$ and $V(x) \iff \mathsf{OpenAt}(j, x)$. Composing these three equivalences gives

$$\mathsf{OpenAt}(i \wedge_{\mathsf{Topology}^\uparrow} j, x) \iff (U(x) \wedge V(x)),$$

which is precisely the pointwise carrying equation for $U \cap V$ after reversing the displayed equivalence.

For classifier transport, assume $\mathsf{same}_X(x, y)$. Convert $U(x) \wedge V(x)$ to $\mathsf{OpenAt}(i \wedge_{\mathsf{Topology}^\uparrow} j, x)$ by the carrying equation just proved. The membership-stability field of Definition 88.1 transports this to $\mathsf{OpenAt}(i \wedge_{\mathsf{Topology}^\uparrow} j, y)$, and the carrying equation at y converts back to $U(y) \wedge V(y)$. The reverse implication is identical with the same stability equivalence read in the opposite direction. □

Definition 88.8 (Indexed arbitrary-union open witness)**.** *Let* $\mathcal{T}$ *be an indexed open topology carrier for* $\mathsf{Topology}^\uparrow$ *over* X*, and let* A *be an indexing type. For a family of open indices* $\iota : A \to \mathsf{OpenIx}$*, an index* $u : \mathsf{OpenIx}$ *is an indexed arbitrary-union witness for* ι*, written* $\mathsf{UnionIx}_{\mathcal{T}}(u, \iota)$*, when it carries exactly the pointwise union of the indexed open memberships:*

$$\mathsf{UnionIx}_{\mathcal{T}}(u, \iota) :\iff \forall x : X, \quad \mathsf{OpenAt}(u, x) \iff \exists a : A,\ \mathsf{OpenAt}(\iota(a), x).$$

This is the arbitrary-union counterpart to the finite-intersection operation in Definition 88.1.

Theorem 88.9 (Topology indexed open arbitrary-union closure)**.** *Let* $\mathcal{T}$ *be an indexed open topology carrier for* $\mathsf{Topology}^\uparrow$ *over* X*. Let* A *be an indexing type, let* $\iota : A \to \mathsf{OpenIx}$ *be a family of open indices, and let* $U_a : X \to \mathsf{Prop}$ *be predicates indexed by* $a : A$*. Put* $U_\cup : X \to \mathsf{Prop}$ *for the predicate*

$$U_\cup(x) :\iff \exists a : A,\ U_a(x).$$

If $u : \mathsf{OpenIx}$ *is an indexed arbitrary-union witness for* ι *and each* $\iota(a)$ *carries* U_a*, then* u *carries* $U_\cup$*:*

$$\mathsf{UnionIx}_{\mathcal{T}}(u, \iota) \implies (\forall a : A,\ \mathsf{CarriesOpen}_{\mathcal{T}}(\iota(a), U_a)) \implies \mathsf{CarriesOpen}_{\mathcal{T}}(u, U_\cup).$$

Equivalently, for every point $x : X$ *the supplied union index has the introduction and inversion form*

$$\mathsf{OpenAt}(u, x) \iff \exists a : A,\ U_a(x),$$

and the union predicate transports under the carrier classifier:

$$\mathsf{same}_X(x,y) \Longrightarrow ((\exists a : A,\ U_a(x)) \Longleftrightarrow (\exists a : A,\ U_a(y))).$$

This is the generic $\mathsf{Topology}^{\uparrow}$ *indexed-family closure law whose concrete complex instance appears in Definition 77.23.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistIndexedOpen arbitrary union closure`

Proof. Assume $h_\cup : \mathsf{UnionIx}_{\mathcal{T}}(u,\iota)$ and $h_{\mathrm{car}} : \forall a : A,\ \mathsf{CarriesOpen}_{\mathcal{T}}(\iota(a), U_a)$. Fix $x : X$. If $U_\cup(x)$ holds, choose $a : A$ with $U_a(x)$. The carry witness $h_{\mathrm{car}}(a)$ gives $\mathsf{OpenAt}(\iota(a), x)$, hence $\exists a : A,\ \mathsf{OpenAt}(\iota(a), x)$. The arbitrary-union witness $h_\cup$ converts this existential open membership into $\mathsf{OpenAt}(u, x)$.

Conversely, if $\mathsf{OpenAt}(u, x)$ holds, then $h_\cup$ gives some $a : A$ with $\mathsf{OpenAt}(\iota(a), x)$. The carry witness $h_{\mathrm{car}}(a)$ converts this membership back into $U_a(x)$, hence $U_\cup(x)$. Since x was arbitrary, this proves $\mathsf{CarriesOpen}_{\mathcal{T}}(u, U_\cup)$, and reversing the displayed equivalence gives the pointwise introduction and inversion form.

For classifier transport, assume $\mathsf{same}_X(x,y)$. The carrying equation just proved converts $\exists a : A,\ U_a(x)$ to $\mathsf{OpenAt}(u,x)$. The membership-stability field of Definition 88.1, applied to the index u, transports this to $\mathsf{OpenAt}(u,y)$, and the carrying equation at y converts it to $\exists a : A,\ U_a(y)$. The reverse implication uses the same stability equivalence in the opposite direction. □

Definition 88.10 (Metric finite-ball indexed topology)**.** *Let C be a carrier equipped with the* $\mathsf{Met}^{\uparrow}$ *carrier data of Definition 57.1, with classifier* same_C *and distance* $d : C \times C \to \mathsf{Real}^{\uparrow}$*. Fix a strict ordered-real comparison* $<_{\mathsf{R}}$ *on* $\mathsf{Real}^{\uparrow}$ *and a positive-radius predicate* $\mathsf{PosRadius}_{\mathsf{R}}$*. A metric ball datum is a triple* $b = (c_b, r_b, \rho_b)$ *with* $c_b : C$*,* $r_b : \mathsf{Real}^{\uparrow}$*, and* $\rho_b : \mathsf{PosRadius}_{\mathsf{R}}(r_b)$*. Its open-ball predicate is*

$$\mathsf{MetricOpenBall}_d(b)(x) :\Longleftrightarrow d(c_b, x) <_{\mathsf{R}} r_b.$$

The metric finite-ball index object is $\mathsf{FinList}(\mathsf{BallData}_d)$*. For a finite list I of ball data, set*

$$\mathsf{OpenAt}_{d,\mathsf{ball}}(I, x) :\Longleftrightarrow \forall b \in I,\ \mathsf{MetricOpenBall}_d(b)(x).$$

The index operation $I \wedge_{\mathsf{Topology}^{\uparrow}} J$ *is finite-list concatenation* $I +\!\!+ J$*. Together with the carrier C and classifier* same_C*, these data are denoted* $\mathcal{T}_{d,\mathsf{ball}}$*.*

Lean4 (definition) `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhoodCarrier`

Theorem 88.11 (Metric balls instantiate indexed topology opens)**.** *Let C,* same_C*, d,* $<_{\mathsf{R}}$*, and* $\mathsf{PosRadius}_{\mathsf{R}}$ *be as in Definition 88.10. Assume the classifier field of Definition 57.4: if* $\mathsf{same}_C(x,y)$*, then $d(c,x)$ and $d(c,y)$ have the same real classifier for every fixed center $c : C$. Assume also that* $<_{\mathsf{R}}$ *is stable under that real classifier in its left argument. Then the finite-ball data of Definition 88.10 form an indexed open topology carrier for* $\mathsf{Topology}^{\uparrow}$ *in the sense of Definition 88.1. For every ball datum $b = (c, r, \rho)$, the singleton index* $\mathsf{single}(b)$ *carries the metric ball:*

$$\mathsf{CarriesOpen}_{\mathcal{T}_{d,\mathsf{ball}}}(\mathsf{single}(b), \mathsf{MetricOpenBall}_d(b)).$$

Equivalently, for all $x : C$,

$$\mathsf{MetricOpenBall}_d(b)(x) \Longleftrightarrow \mathsf{OpenAt}_{d,\mathsf{ball}}(\mathsf{single}(b), x),$$

and this ball membership transports under the metric carrier classifier:

$$\mathsf{same}_C(x,y) \Longrightarrow (\mathsf{MetricOpenBall}_d(b)(x) \Longleftrightarrow \mathsf{MetricOpenBall}_d(b)(y)).$$

Proof. First prove classifier transport for one ball datum $b = (c, r, \rho)$. If $\mathsf{same}_C(x, y)$ holds, the metric classifier field gives a real classifier witness between $d(c, x)$ and $d(c, y)$. Stability of $<_{\mathsf{R}}$ under that real classifier gives

$$d(c, x) <_{\mathsf{R}} r \iff d(c, y) <_{\mathsf{R}} r.$$

Unfolding the definition of $\mathsf{MetricOpenBall}_d(b)$ gives the displayed transport equivalence.

For a finite list I, apply the one-ball transport equivalence to each ball datum in I. Thus the predicate $\mathsf{OpenAt}_{d,\mathsf{ball}}(I, -)$ transports under same_C, which is the membership-stability field required in Definition 88.1.

The finite-intersection law is the finite-list membership split:

$$\forall b \in I{+\!\!+}J,\ \mathsf{MetricOpenBall}_d(b)(x) \iff \big((\forall b \in I,\ \mathsf{MetricOpenBall}_d(b)(x)) \wedge (\forall b \in J,\ \mathsf{MetricOpenBall}_d(b)(x))\big).$$

After refolding $\mathsf{OpenAt}_{d,\mathsf{ball}}$, this is exactly

$$\mathsf{OpenAt}_{d,\mathsf{ball}}(I \wedge_{\mathsf{Topology}^{\uparrow}} J, x) \iff (\mathsf{OpenAt}_{d,\mathsf{ball}}(I, x) \wedge \mathsf{OpenAt}_{d,\mathsf{ball}}(J, x)).$$

For the singleton index, finite-list membership has exactly one component, so

$$\mathsf{MetricOpenBall}_d(b)(x) \iff \mathsf{OpenAt}_{d,\mathsf{ball}}(\mathsf{single}(b), x).$$

This is the carrying equation of Definition 88.2. The final classifier-transport statement is the one-ball transport equivalence already proved. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhoodCarrier indexed open laws`
Lean4 ✓ `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhoodCarrier singleton ball carries`
Lean4 ✓ `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhood singleton ledger coverage`

Definition 88.12 (Metric-generated topology source)**.** *A metric-generated topology source for* $\mathsf{Topology}^{\uparrow}$ *consists of a certified* $\mathsf{Met}^{\uparrow}$ *carrier* C *with classifier* same_C*, a distance witness* $\mathsf{MetricDistanceWitness}(d)$ *for* $d : C \times C \to \mathsf{Real}^{\uparrow}$*, a strict ordered-real comparison* $<_{\mathsf{R}}$*, and positive-radius ledgers for both* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *radii. Its basic index rows are singleton metric balls* $b = (c_b, r_b, \rho_b)$ *as in Definition 88.10. Its finite-base rows are finite lists of such ball data, with intersection represented by finite-list concatenation. Its union rows are indexed arbitrary-union witnesses in the sense of Definition 88.8. Its boundary rows are distinguished empty and whole indices as in Definition 88.31.*

The resulting topology carrier is $\mathcal{T}_{d,\mathsf{ball}}$ *from Definition 88.10. The source ledger records, for every public open, the BHist row naming whether the open is a singleton metric ball, a finite-list intersection of metric balls, a binary generated-open meet of already carried generated opens, an arbitrary union of already carried metric opens, the empty open, or the whole open.*

Theorem 88.13 (Metric-generated topology carrier scope)**.** *Let* $\mathcal{G}$ *be a metric-generated topology source as in Definition 88.12. Then the BEDC source, carrier choice, classifier choice, and operation rows of* $\mathcal{G}$ *are exactly the* $\mathsf{Met}^{\uparrow}$ *carrier* C*, the carrier classifier* same_C*, the distance witness* $\mathsf{MetricDistanceWitness}(d)$*, the ordered* $\mathsf{Real}^{\uparrow}$ *comparison* $<_{\mathsf{R}}$*, positive* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *radius ledgers, finite-list metric-ball indices, indexed union witnesses, and boundary indices. No open row is selected from an external powerset or quotient.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhoodCarrier scope rows`

Proof. Unfold the metric-generated source of Definition 88.12. Its first row is the certified metric carrier C with classifier same_C, followed by the distance witness, ordered-real comparison, and positive-radius ledgers named in the statement.

Unfold the topology carrier $\mathcal{T}_{d,\mathsf{ball}}$ from Definition 88.10. The open index object is $\mathsf{FinList}(\mathsf{BallData}_d)$, the membership predicate is finite-list ball membership, and finite intersection is finite-list concatenation.

The remaining source rows are exactly the indexed arbitrary-union witnesses and the boundary indices named in Definition 88.12. Since every admitted open is introduced through one of these rows, the construction has no separate powerset selection and no quotient carrier. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhoodCarrier meet scope rows`

Theorem 88.14 (Metric-generated topology classifier scope)**.** *Let $\mathcal{G}$ be a metric-generated topology source as in Definition 88.12. Singleton metric balls, finite-list intersections, binary generated-open meets, supplied arbitrary unions, and boundary opens all transport membership along the metric carrier classifier same_C. Thus every classifier-stability obligation exposed by the metric-generated $\mathsf{Topology}^{\uparrow}$ source is discharged by the displayed indexed-open rows.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistUnaryTopologyLedgerRow classifier transport`

Proof. Singleton metric balls transport along same_C by Definition 88.16. That theorem also identifies each singleton ball index as a carried open of $\mathcal{T}_{d,\mathsf{ball}}$.

Finite intersections transport by Definition 88.17. Its conclusion applies the generic finite-intersection classifier transport to the concatenated finite-list index.

Binary generated-open meets transport by Definition 88.7, applied to the carried indices of the two admitted generated opens.

Supplied arbitrary unions transport by Definition 88.9. Boundary opens transport by Definition 88.32. These rows cover exactly the public open constructors named by the metric-generated source, so no additional classifier-stability field is required. □

Theorem 88.15 (Metric-generated topology ledger scope)**.** *Let $\mathcal{G}$ be a metric-generated topology source as in Definition 88.12, equipped with indexed arbitrary-union witnesses and indexed boundary open witnesses. Every public open admitted by $\mathcal{G}$ carries a visible BHist provenance row of exactly one of the displayed constructors: singleton metric ball, finite-list intersection, binary generated-open meet, arbitrary union, empty open, or whole open. Composite rows preserve the constructor provenance of their inputs, and no unindexed open is admitted.*

Proof. The ledger sentence in Definition 88.19 assigns a BHist row to every public open accepted by the generated-open package. The possible row names are precisely singleton metric ball, finite-list intersection, binary generated-open meet, arbitrary union, empty open, and whole open.

The constructor rows used by Definition 88.18 give the corresponding witnesses. Singleton metric-ball rows come from Definition 88.16, finite-list intersection rows from Definition 88.17, binary generated-open meet rows from Definition 88.7, arbitrary-union rows from Definition 88.9, and boundary rows from Definition 88.32.

For a composite row, the certificate records both the outer constructor and the input rows it combines. Therefore the provenance visible at the public surface remains one of the displayed constructor rows, and an open predicate without an index and ledger row is not admitted by $\mathcal{G}$. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistLedgerPublicOpenTree meet ledger constructor`

Theorem 88.16 (Metric-generated base-open transport)**.** *Let $\mathcal{G}$ be a metric-generated topology source as in Definition 88.12. For every metric ball datum $b = (c, r, \rho)$ and points $x, y : C$, metric classifier equality of the points transports basic open membership:*

$$\mathsf{same}_C(x, y) \Longrightarrow (\mathsf{MetricOpenBall}_d(b)(x) \Longleftrightarrow \mathsf{MetricOpenBall}_d(b)(y)).$$

Equivalently, the singleton index $\mathsf{single}(b)$ *carries the metric ball in the indexed topology carrier* $\mathcal{T}_{d,\mathsf{ball}}$*:*

$$\mathsf{CarriesOpen}_{\mathcal{T}_{d,\mathsf{ball}}}(\mathsf{single}(b), \mathsf{MetricOpenBall}_d(b)).$$

Proof. Apply the construction of $\mathcal{T}_{d,\mathsf{ball}}$ from Definition 88.10. Its carrier, classifier, finite-list indices, and membership predicate are exactly the rows named by the metric-generated source.

The transport field is supplied by Definition 88.11. That theorem uses the metric point classifier and the ordered-real stability ledger to transport the inequality $d(c, x) <_{\mathsf{R}} r$ to $d(c, y) <_{\mathsf{R}} r$.

The same theorem states the singleton carrying equation, while Definition 88.1 and Definition 88.2 identify that equation as a carried open of the $\mathsf{Topology}^{\uparrow}$ indexed carrier. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistMetricBaseOpen singleton ledger coverage`

Theorem 88.17 (Metric-generated finite-base intersection)**.** *Let $\mathcal{G}$ be a metric-generated topology source as in Definition 88.12. Let I and J be finite lists of metric ball data, and let $U_I, V_J : C \to \mathsf{Prop}$ be the predicates carried by I and J in $\mathcal{T}_{d,\mathsf{ball}}$. Then the concatenated finite list $I +\!\!+ J$ carries the generated finite-base intersection:*

$$\mathsf{CarriesOpen}_{\mathcal{T}_{d,\mathsf{ball}}}(I, U_I) \Longrightarrow \mathsf{CarriesOpen}_{\mathcal{T}_{d,\mathsf{ball}}}(J, V_J) \Longrightarrow \mathsf{CarriesOpen}_{\mathcal{T}_{d,\mathsf{ball}}}(I +\!\!+ J, U_I \cap V_J).$$

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhood bundleAppend carries intersection`

Proof. The metric-generated source uses finite lists as the index object and finite-list concatenation as the operation $I \wedge_{\mathsf{Topology}^{\uparrow}} J$. Thus $I +\!\!+ J$ is the certificate index named by the finite-intersection row of Definition 88.10.

Apply Definition 88.7 to the indexed open carrier $\mathcal{T}_{d,\mathsf{ball}}$ supplied by Definition 88.11. The two carrying hypotheses for I and J are repacked into the carried predicate $U_I \cap V_J$.

The classifier transport for the resulting intersection is the transport conclusion of Definition 88.7, specialized to the metric classifier same_C. □

Theorem 88.18 (Metric-generated TopologyUp obligation surface)**.** *Let $\mathcal{G}$ be a metric-generated topology source as in Definition 88.12, equipped with indexed arbitrary-union witnesses for all families of generated metric opens and indexed boundary open witnesses $\bot_{\mathsf{Topology}^{\uparrow}}$ and $\top_{\mathsf{Topology}^{\uparrow}}$. Then $\mathcal{G}$ supplies the concrete $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$ obligation surface: the metric carrier C, classifier transport for metric-basic opens, singleton metric-ball coverage, finite intersections by concatenated ball lists, binary meets of already carried generated opens, arbitrary unions by supplied union indices, empty and whole opens by boundary indices, and a visible BHist ledger naming the constructor row used for each carried open.*

Proof. The carrier row is C with classifier same_C. By Definition 88.12 and Definition 88.10, these data form the indexed topology carrier $\mathcal{T}_{d,\mathsf{ball}}$.

Singleton metric-ball coverage and classifier transport are supplied by Definition 88.16. This gives the base-open row of the certificate without selecting opens from an external powerset.

Finite intersections are supplied by Definition 88.17. The certificate index for the intersection is the concatenated finite list, so the ledger names the finite-list constructor and the two source rows it combines.

Binary generated-open meets are supplied by the indexed-open finite-intersection operation on the carried indices of already admitted generated opens. The ledger row records both source witnesses and the meet index, so the composite open remains inside the visible certificate surface.

Arbitrary unions are supplied by the indexed union witnesses of the source and repacked through Definition 88.9. Boundary opens are supplied by the distinguished indices and the closure theorem of Definition 88.32.

The remaining obligation is provenance. The source ledger records one BHist row for each accepted open predicate: singleton metric ball, finite-list intersection, binary generated-open meet, arbitrary union, empty open, or whole open. These rows account for the carrier, classifier, base coverage, closure, boundary, and ledger fields of the concrete $\mathsf{NameCert}_{\mathsf{Topology}^\uparrow}$ surface. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhoodCarrier metric generated namecert surface`
Lean4 ✓ `BEDC.Derived.TopologyUp.BHistUnaryTopologyLedgerRow metric generated obligation surface`

Definition 88.19 (Generated-open exactness package)**.** *Let $\mathcal{G}$ be a metric-generated topology source as in Definition 88.12, with carrier C, classifier same_C, indexed topology carrier $\mathcal{T}_{d,\mathsf{ball}}$, indexed arbitrary-union witnesses, and indexed boundary open witnesses. A predicate $U : C \to \mathsf{Prop}$ is admitted by the generated-open exactness package, written $\mathsf{GenOpenExact}_{\mathcal{G}}(U)$, exactly when there is a visible BHist ledger row r carrying U and r is one of the six constructor rows:*

$$\text{singleton metric ball}, \quad \text{finite-list intersection}, \quad \text{binary generated-open meet},$$
$$\text{arbitrary union}, \quad \text{empty open}, \quad \text{whole open}.$$

Equivalently, U is admitted iff some row r of these six forms supplies an index $i_r : \mathsf{OpenIx}$ and a carrying equation

$$\mathsf{CarriesOpen}_{\mathcal{T}_{d,\mathsf{ball}}}(i_r, U).$$

The binary generated-open meet row has, as displayed data, two admitted generated-open witnesses for U and V, their carried indices i_U and i_V, and the meet index $i_U \wedge_{\mathsf{Topology}^\uparrow} i_V$ carrying $U \cap V$.

The package has the following ten fields. The traditional target is the indexed family of topology opens. The BEDC source is $\mathsf{Met}^\uparrow$ together with $\mathsf{Real}^\uparrow$ and $\mathsf{Rat}^\uparrow$ positive-radius ledgers and the BHist ledger rows. The carrier is C. The classifier is same_C. Stability is indexed-open membership transport along same_C. The ledger is exactly the six-row constructor ledger displayed above. The core theorem list is Definition 88.20, Definition 88.21, and Definition 88.22. The exactness predicate is the conjunction of row coverage, classification soundness, and classification completeness. The standard bridge is the usual metric-generated topology obtained from open balls, finite intersections, binary generated-open meets, arbitrary unions, and boundary opens. The status is a paper proof target for the $\mathsf{Topology}^\uparrow$ exactness contract.

Lean4 (definition) `BEDC.Derived.TopologyUp.BHistGeneratedOpenExact`

Theorem 88.20 (Generated-open row coverage)**.** *Let $\mathcal{G}$ be a metric-generated topology source equipped as in Definition 88.19. If $U : C \to \mathsf{Prop}$ satisfies $\mathsf{GenOpenExact}_{\mathcal{G}}(U)$, then U has a visible ledger witness of one of the six displayed row forms: singleton metric ball, finite-list intersection, binary generated-open meet, arbitrary union, empty open, or whole open. In particular, no external powerset row and no unindexed open predicate is admitted by the exactness package.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistGeneratedOpenExact row coverage`

Proof. Unfold $\mathsf{GenOpenExact}_{\mathcal{G}}(U)$ from Definition 88.19. The definition admits U only by exhibiting a BHist row r, an index i_r, and a carrying equation for U.

The same definition restricts r to the six constructor rows listed in the metric-generated ledger. Therefore the witness is a singleton metric-ball row, a finite-list intersection row, a binary generated-open meet row, an arbitrary-union row, an empty-open row, or a whole-open row.

An external powerset row is not among these constructors. Since admission is by one of the displayed rows together with a carried index, an unindexed predicate has no route into $\mathsf{GenOpenExact}_{\mathcal{G}}$. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistGeneratedOpenExact public open witness`
Lean4 ✓ `BEDC.Derived.TopologyUp.BHistLedgerGeneratedOpen row coverage`

Theorem 88.21 (Generated-open classification soundness)**.** *Let $\mathcal{G}$ be a metric-generated topology source equipped as in Definition 88.19. If a visible generated-open row r carries $U : C \to \mathsf{Prop}$, then U transports under the metric carrier classifier:*

$$\mathsf{same}_C(x, y) \Longrightarrow (U(x) \Longleftrightarrow U(y)).$$

The transport is obtained by cases on the row constructor named by r.

Proof. Fix a carried row r and assume $\mathsf{same}_C(x, y)$. We distinguish the six possible constructors supplied by Definition 88.19.

1. If r is a singleton metric-ball row, use Definition 88.16. Its transport clause moves the metric-ball inequality along same_C, and its carrying equation identifies that ball predicate with U.
2. If r is a finite-list intersection row, use Definition 88.17. The theorem supplies the concatenated finite-list carrier for the intersection and gives classifier transport for the carried intersection predicate.
3. If r is a binary generated-open meet row, unpack the two carried generated-open inputs and their indices i_U, i_V. Apply Definition 88.7 to the indexed carrier $\mathcal{T}_{d,\mathsf{ball}}$; the meet index $i_U \wedge_{\mathsf{Topology}^\uparrow} i_V$ carries the pointwise intersection and transports it along same_C.
4. If r is an arbitrary-union row, use Definition 88.9. The union index carries the supplied family union, and the theorem transports the existential membership predicate through the same carrier classifier.
5. If r is the empty-open row, use Definition 88.32. The bottom boundary index carries the empty predicate, so both directions of the displayed equivalence are vacuous after transport.
6. If r is the whole-open row, again use Definition 88.32. The top boundary index carries the whole carrier predicate, and the theorem gives classifier transport for that carried predicate.

These cases exhaust the generated-open ledger by Definition 88.20, hence every row witness carrying U is classifier-stable. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistGeneratedOpen classifier transport`

Theorem 88.22 (Generated-open classification completeness)**.** *Let $\mathcal{G}$ be a metric-generated topology source equipped as in Definition 88.19. Singleton metric balls, finite-list intersections of metric-ball rows, binary finite intersections of carried generated opens, supplied arbitrary unions of carried generated opens, the empty open, and the whole open are all admitted by $\mathsf{GenOpenExact}_{\mathcal{G}}$. In each case, the admission witness is the corresponding visible BHist ledger row.*

Proof. For a singleton metric ball, choose the singleton metric-ball row. Its index is $\mathsf{single}(b)$, and the carrying equation is supplied by Definition 88.16.

For a finite-list intersection of metric-ball rows, choose the finite-list intersection row. The row records the two finite-list indices and the concatenated finite-list index, and Definition 88.17 supplies the carrying equation for the intersection predicate.

For a binary finite intersection of carried generated opens, unpack the two generated-open witnesses to obtain their carried indices i_U and i_V. Choose the binary generated-open meet row. The generic closure theorem Definition 88.7 supplies the carrying equation for $i_U \wedge_{\mathsf{Topology}^\uparrow} i_V$ and the predicate $U \cap V$.

For a supplied arbitrary union, choose the arbitrary-union row. The supplied union index and the family of carried generated opens are repacked by Definition 88.9, giving the carrying equation required by Definition 88.19.

For the empty open and the whole open, choose the two boundary rows. The bottom and top indices carry these predicates by Definition 88.32.

Each chosen row is one of the six visible constructors in the exactness package, so each listed predicate satisfies $\mathsf{GenOpenExact}_{\mathcal{G}}$. □

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologyPublicOpenTree generated open exactness`

Theorem 88.23 (Generated-open binary meet row)**.** *Let $\mathcal{G}$ be a metric-generated topology source equipped as in Definition 88.19. If $U, V : C \to \mathsf{Prop}$ have generated-open exactness witnesses, then those witnesses determine a visible binary generated-open meet row. Its data are carried indices $i_U, i_V : \mathsf{OpenIx}$ for U and V and the meet index $i_U \wedge_{\mathsf{Topology}^\uparrow} i_V$ carrying $U \cap V$:*

$$\mathsf{GenOpenExact}_{\mathcal{G}}(U) \Longrightarrow \mathsf{GenOpenExact}_{\mathcal{G}}(V) \Longrightarrow \mathsf{CarriesOpen}_{\mathcal{T}_{d,\mathsf{ball}}}(i_U \wedge_{\mathsf{Topology}^\uparrow} i_V, U \cap V).$$

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistGeneratedOpenExact binary meet row`

Proof. Unpack the generated-open witness for U. By Definition 88.19, it supplies a visible ledger row, an index i_U, and a carrying equation $\mathsf{CarriesOpen}_{\mathcal{T}_{d,\mathsf{ball}}}(i_U, U)$.

Unpack the generated-open witness for V in the same way, obtaining i_V and $\mathsf{CarriesOpen}_{\mathcal{T}_{d,\mathsf{ball}}}(i_V, V)$.

Apply Definition 88.7 to these two carried indices in the indexed topology carrier $\mathcal{T}_{d,\mathsf{ball}}$. The theorem returns exactly the carrying equation for $i_U \wedge_{\mathsf{Topology}^\uparrow} i_V$ and the predicate $U \cap V$.

The binary generated-open meet row records the two source generated-open witnesses, the two displayed indices, and this meet-index carrying equation. Therefore the row is visible in the BHist ledger rather than an unrecorded powerset construction. □

Theorem 88.24 (Generated-open binary meet admission)**.** *Let $\mathcal{G}$ be a metric-generated topology source equipped as in Definition 88.19. For predicates $U, V : C \to \mathsf{Prop}$,*

$$\mathsf{GenOpenExact}_{\mathcal{G}}(U) \Longrightarrow \mathsf{GenOpenExact}_{\mathcal{G}}(V) \Longrightarrow \mathsf{GenOpenExact}_{\mathcal{G}}(U \cap V).$$

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistGeneratedOpen binary meet admission`

Proof. Assume generated-open exactness witnesses for U and V. By Definition 88.23, these witnesses determine the binary generated-open meet row with index $i_U \wedge_{\mathsf{Topology}^\uparrow} i_V$ carrying $U \cap V$.

Choose that row as the admission witness in Definition 88.19. Since the binary generated-open meet is one of the six displayed constructor rows, the predicate $U \cap V$ satisfies $\mathsf{GenOpenExact}_{\mathcal{G}}$. □

Theorem 88.25 (Generated-open six-row exactness package)**.** *Let $\mathcal{G}$ be a metric-generated topology source equipped as in Definition 88.19. The row coverage theorem, classification soundness theorem, and classification completeness theorem for* $\mathsf{GenOpenExact}_{\mathcal{G}}$ *range over exactly the six-row ledger: singleton metric ball, finite-list intersection, binary generated-open meet, arbitrary union, empty open, and whole open. This package admits no external powerset row.*

Proof. Row coverage is Definition 88.20: every admitted predicate has one of the six displayed row witnesses and no unindexed predicate is accepted.

Classification soundness is Definition 88.21. Its proof treats all six row constructors, including the binary generated-open meet row through the indexed finite-intersection theorem.

Classification completeness is Definition 88.22, with the binary admission step isolated in Definition 88.24. The exactness package is therefore closed under the certificate meet operation by a visible BHist row, with no appeal to an external powerset constructor. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistGeneratedOpen six row exactness package`

Theorem 88.26 (Metric-generated TopologyUp public certificate)**.** *Let $\mathcal{G}$ be a metric-generated topology source equipped as in Definition 88.19, with indexed arbitrary-union witnesses and indexed boundary open witnesses. Then $\mathcal{G}$ exports the public* $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$ *surface for downstream consumers: the displayed* $\mathsf{Met}^{\uparrow}$ *carrier C and classifier* same_C *come from Definition 88.18, while row coverage, classification soundness, and classification completeness for the generated opens come from Definition 88.25. The exported ledger rows are exactly singleton metric ball, finite-list intersection, binary generated-open meet, arbitrary union, empty open, and whole open.*

Downstream use of this certificate is restricted to the displayed $\mathsf{Met}^{\uparrow}$ *carrier, the* $\mathsf{Real}^{\uparrow}$ *ordered-radius comparison, the* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *positive-radius ledgers, the indexed union witnesses, the boundary witnesses, and the visible BHist ledger rows. It admits no external powerset row and no quotient carrier.*

Proof. Apply Definition 88.18 to the metric-generated source. This supplies the carrier, classifier, classifier-stability rows, singleton metric-ball row, finite-list intersection row, generated-open meet row, union row, boundary rows, and visible ledger discipline for the concrete $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$ obligation surface.

Apply Definition 88.25 to the same source. Its three components provide the row coverage, classification soundness, and classification completeness clauses for $\mathsf{GenOpenExact}_{\mathcal{G}}$, and its statement restricts exactness to the six displayed rows.

Read the indexed boundary witness data through Definition 88.31. The distinguished bottom and top indices account for the empty-open and whole-open rows, so those boundary clauses are part of the exported certificate rather than separate powerset choices.

Packaging these pieces gives the public downstream surface: carrier and classifier data from the obligation-surface theorem, exactness from the six-row package, boundary rows from the indexed witnesses, and provenance from the BHist ledger. The only exported carrier is C, and every accepted open predicate is carried by one of the displayed indexed rows, so quotient carriers and external powerset rows have no entry point into the certificate. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistGeneratedOpen semantic name certificate`

Fit: traditional target, indexed topology opens; BEDC source, $\mathsf{Met}^{\uparrow}$ with $\mathsf{Real}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ radius ledgers; carrier choice, the displayed metric carrier C; classifier choice, same_C; stability obligations, indexed-open transport along same_C; ledger, the six visible BHist rows; core theorem list, Definition 88.18 and Definition 88.25; exactness predicate, $\mathsf{GenOpenExact}_{\mathcal{G}}$; standard bridge

status, the usual metric-generated topology surface; status, public paper certificate for downstream $\mathsf{Topology}^{\uparrow}$ use.

Definition 88.27 (Metric finite-base neighbourhood row)**.** *Let $\mathcal{G}$ be a metric-generated topology source as in Definition 88.12, with carrier C and indexed topology carrier $\mathcal{T}_{d,\mathsf{ball}}$. For a point $x : C$, a metric finite-base neighbourhood row at x is data*

$$(I, x, h_I, \kappa_I)$$

where $I : \mathsf{FinList}(\mathsf{BallData}_d)$, the membership witness is

$$h_I : \mathsf{OpenAt}_{d,\mathsf{ball}}(I, x),$$

the carrying equation is the finite-list pointwise law

$$\mathsf{OpenAt}_{d,\mathsf{ball}}(I, z) \iff \forall b \in I,\ \mathsf{MetricOpenBall}_d(b)(z)$$

for every $z : C$, and κ_I is the visible BHist *ledger row naming the finite-list intersection constructor of $\mathcal{G}$. The row is public neighbourhood data because it exposes the point x, the finite index I, its membership witness at x, its carrying equation, and the ledger constructor that admits the row.*

Lean4 (definition) `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhoodRow`

This finite-base neighbourhood row consumes the center-radius and positive-radius membership surface of chapter 1450 together with the metric source of chapter 57 before it is repacked as a $\mathsf{Topology}^{\uparrow}$ generated-open row.

Theorem 88.28 (Metric finite-base neighbourhood decomposition)**.** *Let $\mathcal{G}$ be a metric-generated topology source as in Definition 88.12, and let $I : \mathsf{FinList}(\mathsf{BallData}_d)$ be a finite list of metric ball data. For every $x : C$,*

$$\mathsf{Nbhd}_{\mathcal{T}_{d,\mathsf{ball}}}(x, I) \iff \forall b \in I,\ \mathsf{MetricOpenBall}_d(b)(x).$$

Equivalently, the finite-base neighbourhood row at x exists exactly when every displayed ball datum in I contains x.

Proof. Unfold the neighbourhood predicate of Definition 88.3 for the indexed carrier $\mathcal{T}_{d,\mathsf{ball}}$. The left side becomes $\mathsf{OpenAt}_{d,\mathsf{ball}}(I, x)$.

Unfold the metric finite-ball index object of Definition 88.10. Its membership predicate for a finite list is exactly the assertion that every ball datum in the list contains the point.

Refolding this displayed law gives the stated equivalence. The row formulation in Definition 88.27 then packages the same witness together with the carrying equation and the finite-list intersection ledger row. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhood append decomposition`

Theorem 88.29 (Metric finite-base neighbourhood classifier transport)**.** *Let $\mathcal{G}$ be a metric-generated topology source as in Definition 88.12. For every finite list $I : \mathsf{FinList}(\mathsf{BallData}_d)$ and points $x, y : C$,*

$$\mathsf{same}_C(x, y) \implies (\mathsf{Nbhd}_{\mathcal{T}_{d,\mathsf{ball}}}(x, I) \iff \mathsf{Nbhd}_{\mathcal{T}_{d,\mathsf{ball}}}(y, I)).$$

Thus membership in a metric finite-base neighbourhood row is transported by the carrier classifier.

Proof. The theorem Definition 88.11 supplies the indexed-open carrier $\mathcal{T}_{d,\mathsf{ball}}$ from the metric ball data. In particular, finite-list open membership is stable along same_C.

Apply Definition 88.5 to this indexed carrier and to the fixed index I. Its conclusion is exactly the displayed equivalence between the two neighbourhood predicates.

The decomposition theorem Definition 88.28 identifies these neighbourhood predicates with finite-list ball containment at x and y, so the transported predicate is the public finite-base neighbourhood row rather than an unindexed open subset. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhood classifier transport`

Theorem 88.30 (Metric finite-base neighbourhood ledger coverage)**.** *Let $\mathcal{G}$ be a metric-generated topology source equipped as in Definition 88.19. For every finite list $I : \mathsf{FinList}(\mathsf{BallData}_d)$ and point $x : C$, a metric finite-base neighbourhood row at x is admitted by $\mathsf{GenOpenExact}_{\mathcal{G}}$ through the finite-list intersection constructor. Its visible data are the index I, the carrying equation for $\mathsf{OpenAt}_{d,\mathsf{ball}}(I, -)$, the membership witness at x, and the corresponding* BHist *ledger row. No external powerset row is exposed.*

Proof. Start with the finite list I and read it as the metric finite-ball index of Definition 88.10. Its displayed predicate is $\mathsf{OpenAt}_{d,\mathsf{ball}}(I, -)$, with the carrying equation of Definition 88.27.

The finite-list constructor row is the finite-base intersection row described by Definition 88.17. It records the finite metric-ball inputs, the concatenated finite-list index used by the certificate operation, and the carrying equation for the resulting intersection predicate.

Apply Definition 88.22 to this finite-list intersection row. The exactness package of Definition 88.19 therefore admits the carried predicate through the finite-list intersection constructor.

Finally apply the row-coverage direction of Definition 88.25. It restricts every admitted generated-open witness to the displayed six-row ledger, so the neighbourhood row exposes the finite index, carrying equation, point membership witness, and BHist provenance, with no route through an external powerset row. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistFiniteBaseNeighborhood finiteListIntersection ledger coverage`

Definition 88.31 (Indexed boundary open witnesses)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for $\mathsf{Topology}^{\uparrow}$ over X. Indexed boundary open witnesses are distinguished indices $\bot_{\mathsf{Topology}^{\uparrow}}, \top_{\mathsf{Topology}^{\uparrow}} : \mathsf{OpenIx}$ satisfying the pointwise laws*

$$\mathsf{OpenAt}(\bot_{\mathsf{Topology}^{\uparrow}}, x) \iff \mathsf{False}$$

and

$$\mathsf{OpenAt}(\top_{\mathsf{Topology}^{\uparrow}}, x) \iff \mathsf{True}$$

for every $x : X$. They are part of the displayed topology certificate data whenever the interface is used as a $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$ source rather than merely as a finite-intersection and arbitrary-union closure spine.

Theorem 88.32 (Topology indexed open boundary closure)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for $\mathsf{Topology}^{\uparrow}$ over X, equipped with indexed boundary open witnesses $\bot_{\mathsf{Topology}^{\uparrow}}$ and $\top_{\mathsf{Topology}^{\uparrow}}$ as in Definition 88.31. Let $\varnothing_X : X \to \mathsf{Prop}$ and $\mathsf{Whole}_X : X \to \mathsf{Prop}$ be the predicates*

$$\varnothing_X(x) :\iff \mathsf{False}$$

and

$$\mathsf{Whole}_X(x) :\Longleftrightarrow \mathsf{True}.$$

Then the boundary indices carry the empty and whole predicates:

$$\mathsf{CarriesOpen}_{\mathcal{T}}(\bot_{\mathsf{Topology}^\uparrow}, \varnothing_X)$$

and

$$\mathsf{CarriesOpen}_{\mathcal{T}}(\top_{\mathsf{Topology}^\uparrow}, \mathsf{Whole}_X).$$

Moreover both carried predicates transport under the carrier classifier:

$$\mathsf{same}_X(x, y) \Longrightarrow (\varnothing_X(x) \Longleftrightarrow \varnothing_X(y))$$

and

$$\mathsf{same}_X(x, y) \Longrightarrow (\mathsf{Whole}_X(x) \Longleftrightarrow \mathsf{Whole}_X(y)).$$

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistIndexedOpen boundary closure`

Proof. For the empty predicate, unfold $\mathsf{CarriesOpen}_{\mathcal{T}}$ from Definition 88.2. The boundary law of Definition 88.31 identifies $\mathsf{OpenAt}(\bot_{\mathsf{Topology}^\uparrow}, x)$ with False at each point, which is exactly the carrying equation for $\varnothing_X$.

For the whole predicate, the same unfolding uses the top boundary law. It identifies $\mathsf{OpenAt}(\top_{\mathsf{Topology}^\uparrow}, x)$ with True at each point, giving the carrying equation for Whole_X.

The transport claims can be read either from the two carrying equations and the membership-stability field of Definition 88.1, or directly from the fact that False and True do not depend on the point. In both directions the supplied $\mathsf{same}_X(x, y)$ witness is the certificate route allowed by the topology carrier. □

Theorem 88.33 (Topology NameCert obligation package)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for $\mathsf{Topology}^\uparrow$ over X, equipped with indexed arbitrary-union witnesses for every indexed family of opens and indexed boundary open witnesses $\bot_{\mathsf{Topology}^\uparrow}$ and $\top_{\mathsf{Topology}^\uparrow}$. Then the following data assemble the paper-side $\mathsf{NameCert}_{\mathsf{Topology}^\uparrow}$ obligation package: the carrier and membership-stability classifier of Definition 88.1, the carried-predicate interface of Definition 88.2, the finite-intersection closure of Definition 88.7, the arbitrary-union closure of Definition 88.9, the boundary-open closure of Definition 88.32, and the visible ledger policy recording the chosen open index, its carrying equation, and the constructor row used to obtain it.*

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologyPublicOpenTree semantic name certificate`

Proof. The carrier row is $\mathcal{T}$ itself: it supplies X, same_X, OpenIx, OpenAt, finite-intersection indexing, and pointwise membership stability. The carried-predicate row is exactly Definition 88.2, so every public open is represented by an index together with its pointwise carrying equation.

Finite intersections are supplied by Definition 88.7. Given two carried opens, the certificate index $i \wedge_{\mathsf{Topology}^\uparrow} j$ carries their pointwise intersection and the resulting predicate transports along same_X.

Arbitrary unions are supplied by Definition 88.9. The assumed union witness chooses the index for a family, while the theorem repacks the family of carried predicates into a carried union and transports that union through the same classifier.

Boundary opens are supplied by Definition 88.32. The distinguished indices $\bot_{\mathsf{Topology}^\uparrow}$ and $\top_{\mathsf{Topology}^\uparrow}$ carry the empty and whole predicates, so the certificate has both boundary rows without choosing them from an external powerset.

The ledger policy records only displayed certificate provenance: an open predicate is accepted when it is carried by an explicit index, and composite opens retain the constructor row that produced the finite intersection, arbitrary union, empty open, or whole open. These rows account for the carrier, classifier transport, closure, boundary, and ledger fields of the paper-side $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$ obligation package. □

Definition 88.34 (Topology public open row)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for $\mathsf{Topology}^{\uparrow}$ over X. A topology public open row for a predicate $U : X \to \mathsf{Prop}$ is data*

$$(i, U, h_i, \lambda_i)$$

where $i : \mathsf{OpenIx}$, $h_i : \mathsf{CarriesOpen}_{\mathcal{T}}(i, U)$, and λ_i is a visible BHist ledger constructor row naming one of the accepted open constructors: singleton metric ball, finite-list intersection, binary generated-open meet, arbitrary union, empty open, or whole open. The row is public because it exposes both the index carrying equation and the ledger constructor that explains why the open belongs to the $\mathsf{Topology}^{\uparrow}$ certificate surface.

Theorem 88.35 (Topology public open row classifier transport)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for $\mathsf{Topology}^{\uparrow}$ over X, and let (i, U, h_i, λ_i) be a topology public open row in the sense of Definition 88.34. Then membership in U transports along the carrier classifier:*

$$\mathsf{same}_X(x, y) \Longrightarrow (U(x) \Longleftrightarrow U(y)).$$

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistCarriesOpen classifier transport`

Proof. Assume $\mathsf{same}_X(x, y)$. The carrying witness h_i identifies $U(x)$ with $\mathsf{OpenAt}(i, x)$ and $U(y)$ with $\mathsf{OpenAt}(i, y)$.

Apply the membership-stability field of Definition 88.1 to the same index i. It transports $\mathsf{OpenAt}(i, x)$ to $\mathsf{OpenAt}(i, y)$ and also gives the reverse implication by reading the displayed equivalence in the opposite direction.

Composing these three equivalences gives $U(x)$ if and only if $U(y)$. The ledger row λ_i is not needed for the logical transport; it records the public provenance of the carried open while the transport itself is supplied by the indexed carrier. □

Theorem 88.36 (Metric-generated public open row coverage)**.** *Let $\mathcal{G}$ be a metric-generated topology source as in Definition 88.12, equipped with indexed arbitrary-union witnesses for generated metric opens and indexed boundary open witnesses. Every public open admitted by $\mathcal{G}$ determines a topology public open row for the carrier $\mathcal{T}_{d,\mathsf{ball}}$ of Definition 88.12. Its index is the displayed generated-open index, its carrying equation is the corresponding $\mathsf{CarriesOpen}_{\mathcal{T}_{d,\mathsf{ball}}}$ witness, and its ledger row names one of the six constructors listed in Definition 88.34.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistLedgerPublicOpenTree topology public open tree`

Proof. Proceed by cases on the constructor row recorded by the metric-generated source ledger.

For a singleton metric ball, use Definition 88.16. It supplies both classifier transport for the ball predicate and the carrying equation for the singleton index in $\mathcal{T}_{d,\mathsf{ball}}$; pair that index and carrying equation with the singleton metric-ball ledger row.

For a finite-list intersection, use Definition 88.17. The concatenated finite list is the generated-open index, and the theorem supplies the carrying equation for the pointwise intersection. The ledger row names the finite-list intersection constructor.

For a binary generated-open meet, unpack the two public generated-open rows and apply Definition 88.7 to their carried indices. The resulting meet index carries the pointwise intersection, and the ledger row names the binary generated-open meet constructor.

For an arbitrary union, use the indexed union witness in the source and apply Definition 88.9. This gives the union index and the carrying equation for the pointwise union, with the ledger row naming arbitrary union.

For the empty and whole opens, use Definition 88.32. The distinguished boundary indices carry the empty and whole predicates, and the ledger rows name the empty-open and whole-open constructors. These cases exhaust the public constructors of Definition 88.12, so every admitted open yields a public open row. □

Theorem 88.37 (Singleton public open row coverage)**.** *For the singleton empty-history topology carrier of Definition 88.38, the two-row ledger admits topology public open rows for bottom, top, finite meets, and arbitrary unions. The carried predicates are exactly the displayed empty predicate, the singleton carrier predicate C_{e}, their finite meets under the two-row meet table, and the unions selected by the singleton union ledger.*

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologySingleton public open row coverage`

Proof. The bottom and top rows come from Definition 88.39. They give the two boundary carrying equations, and their ledger rows name the empty-open and whole-open constructors.

Finite meets are supplied by Definition 88.40. Splitting on the two-row index table gives the absorbing bottom cases and the top-top case, so the meet index carries the pointwise meet and the public ledger names the finite-meet constructor.

Arbitrary unions are supplied by Definition 88.44. If no top row appears, the bottom index carries the union; if a top row appears, the top index carries it. Pair the selected index and carrying equation with the arbitrary-union ledger row.

These rows are all rows of the singleton indexed-open carrier, so each is a topology public open row in the sense of Definition 88.34. □

Definition 88.38 (Singleton empty-history topology carrier)**.** *The singleton empty-history topology carrier for* $\mathsf{Topology}^{\uparrow}$ *is rooted at the BEDC history carrier. Its point carrier is the* e*-class*

$$C_{\mathsf{e}}(h) :\Longleftrightarrow \mathsf{hsame}(h, \mathsf{e})$$

for $h : \mathsf{BHist}$*. The carrier classifier is* hsame *restricted to this class:*

$$\rho_{\mathsf{e}}(h, k) :\Longleftrightarrow C_{\mathsf{e}}(h) \wedge C_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

The open-index object is the two-row ledger

$$\mathsf{OpenIx}_{\mathsf{e}} := \{\bot_{\mathsf{Topology}^{\uparrow}}, \top_{\mathsf{Topology}^{\uparrow}}\}.$$

Membership is given by

$$\mathsf{OpenAt}_{\mathsf{e}}(\bot_{\mathsf{Topology}^{\uparrow}}, h) \Longleftrightarrow \mathsf{False}$$

and

$$\mathsf{OpenAt}_{\mathsf{e}}(\top_{\mathsf{Topology}^{\uparrow}}, h) \Longleftrightarrow C_{\mathsf{e}}(h).$$

The finite-meet table is the displayed two-row table with $\bot_{\mathsf{Topology}^{\uparrow}}$ *absorbing and* $\top_{\mathsf{Topology}^{\uparrow}}$ *neutral:*

$$\bot_{\mathsf{Topology}^{\uparrow}} \wedge_{\mathsf{Topology}^{\uparrow}} i = \bot_{\mathsf{Topology}^{\uparrow}}, \qquad i \wedge_{\mathsf{Topology}^{\uparrow}} \bot_{\mathsf{Topology}^{\uparrow}} = \bot_{\mathsf{Topology}^{\uparrow}}, \qquad \top_{\mathsf{Topology}^{\uparrow}} \wedge_{\mathsf{Topology}^{\uparrow}} \top_{\mathsf{Topology}^{\uparrow}} = \top_{\mathsf{Topo}}$$

Thus every open row is anchored in a concrete BHist *predicate rather than in an external powerset.*

Lean4 (definition) `BEDC.Derived.TopologyUp.TopologySingletonMeet`

Theorem 88.39 (Singleton topology boundary open laws)**.** *For the singleton carrier of Definition 88.38, the displayed bottom and top indices give the indexed boundary witnesses required by Definition 88.31. The bottom row carries the empty predicate,*

$$\mathsf{OpenAt}_{\mathsf{e}}(\bot_{\mathsf{Topology}^{\uparrow}}, h) \iff \mathsf{False},$$

and the top row carries the whole singleton carrier,

$$\mathsf{OpenAt}_{\mathsf{e}}(\top_{\mathsf{Topology}^{\uparrow}}, h) \iff C_{\mathsf{e}}(h).$$

Proof. Unfold the two membership clauses in Definition 88.38. The bottom clause is definitionally the empty predicate and the top clause is definitionally the carrier predicate C_{e}.

These two displayed equations are exactly the boundary package requested by Definition 88.31. Applying Definition 88.32 therefore identifies the empty open and the whole carrier open inside the indexed-open interface. □

Theorem 88.40 (Singleton topology finite-intersection laws)**.** *For the singleton carrier of Definition 88.38, the displayed meet table satisfies the finite-intersection field of Definition 88.1:*

$$\mathsf{OpenAt}_{\mathsf{e}}(i \wedge_{\mathsf{Topology}^{\uparrow}} j, h) \iff \big(\mathsf{OpenAt}_{\mathsf{e}}(i, h) \wedge \mathsf{OpenAt}_{\mathsf{e}}(j, h)\big).$$

The restricted classifier ρ_{e} also transports each displayed row, so every carried predicate in the sense of Definition 88.2 remains stable under the singleton hsame *route.*

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologySingleton finite intersection laws`

Proof. For classifier transport, split on the open index. In the $\bot_{\mathsf{Topology}^{\uparrow}}$ row both sides are False, so the equivalence is immediate.

In the $\top_{\mathsf{Topology}^{\uparrow}}$ row, unfold ρ_{e}. Its first two components are precisely $C_{\mathsf{e}}(h)$ and $C_{\mathsf{e}}(k)$, and its third component records the restricted hsame route between the representatives. Therefore the top membership predicate transports along the displayed classifier.

For finite intersections, split on the two indices. Any case containing $\bot_{\mathsf{Topology}^{\uparrow}}$ reduces both sides to False by the absorbing rows of the meet table.

The $\top_{\mathsf{Topology}^{\uparrow}}, \top_{\mathsf{Topology}^{\uparrow}}$ case reduces both sides to $C_{\mathsf{e}}(h)$, with conjunction introduction and projection giving the two directions. This supplies the binary closure row used by Definition 88.7. □

Theorem 88.41 (Singleton topology all-bottom union exactness)**.** *For the singleton carrier of Definition 88.38, let $\iota : A \to \mathsf{OpenIx}_{\mathsf{e}}$ be an indexed family of displayed opens. If the family carries a displayed all-bottom witness $h_{\bot} : \forall a : A,\ \iota(a) = \bot_{\mathsf{Topology}^{\uparrow}}$, then $\bot_{\mathsf{Topology}^{\uparrow}}$ carries the pointwise union predicate*

$$U_{\iota}(h) :\iff \exists a : A,\ \mathsf{OpenAt}_{\mathsf{e}}(\iota(a), h).$$

Equivalently, for every h : BHist,

$$\mathsf{OpenAt}_{\mathsf{e}}(\bot_{\mathsf{Topology}^{\uparrow}}, h) \iff U_{\iota}(h).$$

Proof. Unfold the bottom row of Definition 88.38. The left side is False at every point.

For the forward direction there is no inhabitant to transport. For the reverse direction, take a displayed witness $a : A$ of $U_\iota(h)$. The all-bottom ledger entry $h_\bot(a)$ rewrites its membership row to $\mathsf{OpenAt_e}(\bot_{\mathsf{Topology}^\uparrow}, h)$, hence to False.

Thus the union predicate is empty pointwise, and the explicit bottom row carries it without deciding anything about the family outside the displayed all-bottom witness. □

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologySingleton union bottom exactness`

Theorem 88.42 (Singleton topology top-member union exactness)**.** *For the singleton carrier of Definition 88.38, let $\iota : A \to \mathsf{OpenIx_e}$ be an indexed family of displayed opens. If the family carries displayed data $a_0 : A$ and $h_\top : \iota(a_0) = \top_{\mathsf{Topology}^\uparrow}$, then $\top_{\mathsf{Topology}^\uparrow}$ carries the pointwise union predicate*

$$U_\iota(h) :\Longleftrightarrow \exists a : A,\ \mathsf{OpenAt_e}(\iota(a), h).$$

Equivalently, for every $h : \mathsf{BHist}$,

$$\mathsf{OpenAt_e}(\top_{\mathsf{Topology}^\uparrow}, h) \Longleftrightarrow U_\iota(h).$$

Proof. Unfold the top row of Definition 88.38. Its membership predicate is exactly $C_\mathsf{e}(h)$.

In the forward direction, inject the displayed carrier witness through the named index a_0. The ledger equality $h_\top$ identifies $\mathsf{OpenAt_e}(\iota(a_0), h)$ with the top-row membership predicate, so a_0 witnesses $U_\iota(h)$.

For the reverse direction, inspect the existential witness $a : A$ and the two-row open ledger. A bottom-row witness is impossible because bottom membership is False. A top-row witness is exactly $C_\mathsf{e}(h)$, which is the membership predicate of $\top_{\mathsf{Topology}^\uparrow}$.

Therefore the union predicate is the whole singleton carrier, and the explicit top row carries it through the displayed top member. □

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologySingleton union top exactness`

Theorem 88.43 (Singleton topology union case-split ledger)**.** *For the singleton carrier of Definition 88.38, an indexed family $\iota : A \to \mathsf{OpenIx_e}$ is accepted as an arbitrary-union row only with one of the following displayed ledger alternatives:*

1. *an all-bottom witness $\forall a : A,\ \iota(a) = \bot_{\mathsf{Topology}^\uparrow}$, in which case the accepted row is $\bot_{\mathsf{Topology}^\uparrow}$ and its carrying equation is supplied by Definition 88.41;*
2. *a top-member witness consisting of $a_0 : A$ and $\iota(a_0) = \top_{\mathsf{Topology}^\uparrow}$, in which case the accepted row is $\top_{\mathsf{Topology}^\uparrow}$ and its carrying equation is supplied by Definition 88.42.*

No additional case distinction over the family is part of the singleton topology certificate.

Proof. The ledger is a policy over displayed certificate data. In the first alternative, repack the given all-bottom witness through Definition 88.41; the carried predicate is the indexed union and the chosen row is $\bot_{\mathsf{Topology}^\uparrow}$.

In the second alternative, repack the displayed top member through Definition 88.42; the carried predicate is the same indexed union and the chosen row is $\top_{\mathsf{Topology}^\uparrow}$.

These two rows are exactly the accepted constructors for the singleton arbitrary-union surface, so the certificate consumer receives a union row together with its reason instead of deriving a hidden family-level decision. □

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologySingleton union case split ledger`

Theorem 88.44 (Singleton topology arbitrary-union laws)**.** *For any indexed family $\iota : A \to \mathsf{OpenIx}_{\mathsf{e}}$ in the singleton carrier of Definition 88.38, the arbitrary-union witness required by Definition 88.9 is supplied only from the displayed alternatives of Definition 88.43. With an all-bottom ledger entry the accepted union row is $\bot_{\mathsf{Topology}^{\uparrow}}$; with a displayed top member the accepted union row is $\top_{\mathsf{Topology}^{\uparrow}}$.*

Proof. Apply Definition 88.43. The all-bottom branch is already carried by Definition 88.41, and the top-member branch is already carried by Definition 88.42.

The final arbitrary-union interface therefore repacks a recorded ledger alternative. It does not infer a top-present or top-absent dichotomy from the host logic. □

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologySingleton arbitrary union laws`

Theorem 88.45 (Singleton topology NameCert obligation surface)**.** *The singleton carrier C_{e}, the restricted classifier ρ_{e}, the two-index open ledger $\mathsf{OpenIx}_{\mathsf{e}}$, the finite-meet table, the arbitrary-union rows, the boundary rows, and the displayed ledger provenance assemble a paper-side $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$ obligation surface. The surface is concrete over BHist and uses only hsame on the empty-history carrier.*

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologySingleton semantic name certificate`

Proof. The carrier and classifier fields are the BHist-rooted data of Definition 88.38: points are histories in the e-class, and equality is witnessed by the restricted hsame classifier.

The open ledger has exactly two rows. Definition 88.39 supplies the bottom and top boundary witnesses, Definition 88.40 supplies classifier transport and binary-intersection closure, and Definition 88.44 supplies the displayed union witness for every indexed family.

It remains to repack these rows into the public certificate shape. Apply Definition 88.33 with the singleton indexed-open carrier, its displayed union ledger, and its boundary witnesses. The resulting package records all open predicates by explicit indices and carries their provenance through the finite-intersection, union, bottom, and top constructor rows. □

Theorem 88.46 (Topology downstream open constructor coverage)**.** *Every public open row admitted by the metric-generated topology source of Definition 88.12 or by the singleton empty-history source of Definition 88.38 is carried by an explicit BHist ledger constructor. The possible constructors are exactly a singleton metric-ball row, a finite-list intersection row, a binary generated-open meet row, an arbitrary-union witness row, the bottom row, or the top row. Thus a downstream chapter consuming a carried open receives a visible index, a pointwise carrying equation, and one of these constructor records, rather than an unindexed subset of the carrier.*

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologyDownstream open constructor coverage`

Proof. For the metric-generated source, inspect the ledger rows listed in Definition 88.12 and Definition 88.19. Singleton metric balls are carried by the base-open transport row of Definition 88.16. Finite-list intersections are carried by the finite-list intersection row of Definition 88.17.

Binary generated-open meets are carried by Definition 88.23. The remaining metric-generated rows are supplied by the general topology certificate. Arbitrary unions are exactly the witnessed rows of Definition 88.9, while the empty and whole rows are the boundary witnesses of Definition 88.32.

For the singleton source, inspect Definition 88.38. The only primitive open indices are $\bot_{\mathsf{Topology}^{\uparrow}}$ and $\top_{\mathsf{Topology}^{\uparrow}}$, and their boundary laws are Definition 88.39. The meet table and union classification are carried by Definition 88.40 and Definition 88.44. These cases exhaust the displayed rows in both sources. □

Theorem 88.47 (Topology downstream carrier classifier scope)**.** *Let a downstream chapter receive a* $\mathsf{Topology}^{\uparrow}$ *carried-open row from either displayed source. Membership may be transported only through the carrier classifier* same_X *together with the carried-open equation*

$$\mathsf{CarriesOpen}_{\mathcal{T}}(i, U).$$

In particular, the exported rule does not identify opens by an external powerset equality: it transports the displayed predicate U *by converting through* $\mathsf{OpenAt}(i, -)$ *and then applying the certificate stability already present in the indexed-open carrier.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistLedgerPublicOpenTree semantic name certificate`

Proof. Start with a carried row (i, h_i) and a classifier witness $\mathsf{same}_X(x, y)$. The equation h_i converts membership in the public predicate U at x into membership in $\mathsf{OpenAt}(i, x)$, and the membership-stability field of Definition 88.1 transports this to $\mathsf{OpenAt}(i, y)$. Applying h_i at y returns membership in $U(y)$.

For constructor rows, the same route is supplied by the closure theorem that created the row. Finite intersections use Definition 88.7; binary generated-open meets use Definition 88.23; arbitrary unions use Definition 88.9; boundary rows use Definition 88.32. In the singleton source, the bottom and top rows are the laws of Definition 88.39, and the finite-intersection and union cases are Definition 88.40 and Definition 88.44.

No step requires equality of host powersets. The downstream chapter only sees the carrier classifier, the carried-open index, and the constructor row that proves the carrying equation. □

Theorem 88.48 (Topology downstream NameCert export surface)**.** *The exact* $\mathsf{Topology}^{\uparrow}$ *surface exported to* $\mathsf{Banach}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{CplxTopo}^{\uparrow}$, *and continuous-map chapters consists of the carrier, the carrier classifier, the carried-open index, the finite-intersection constructor, the binary generated-open meet constructor, the arbitrary-union constructor, the boundary rows, and the ledger provenance for each public open. This surface is assembled by Definition 88.33, Definition 88.18, Definition 88.45, Definition 88.46, and Definition 88.47. It does not assert a bridge to a standard topological-space object.*

Proof. The package theorem Definition 88.33 identifies the common certificate surface: carrier, classifier, carried-open predicate, finite intersections, arbitrary unions, boundary rows, and visible ledger policy. The metric-generated instance supplies one concrete source by Definition 88.18; the singleton empty-history instance supplies the other by Definition 88.45.

The coverage theorem Definition 88.46 then restricts every public row from these sources to one of the explicit ledger constructors. The classifier-scope theorem Definition 88.47 records the only allowed membership-transport route through the displayed carrier classifier and the carried-open equation.

Combining these clauses gives the advertised export surface for dependent chapters. Since none of the cited rows constructs a host topological-space value or proves equality with host powersets, the result is a certified carried-open interface only, not a standard-space bridge. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistLedgerPublicOpenTree downstream export surface`

Theorem 88.49 (Topology public carried-open standard bridge)**.** *The public carried-open surface exported by Definition 88.48 admits a paper bridge to the standard indexed-topological-space interface. The carrier readback is the displayed carrier. The open-row readback sends each* $\mathsf{Topology}^{\uparrow}$ *carried-open index to its carried predicate. The finite-intersection and arbitrary-union laws read*

back from the existing indexed-open laws, and classifier transport is the only equality transport used for membership invariance.

This bridge does not assert surjectivity onto all host opens, quotient or powerset equality, $\mathsf{Real}^{\uparrow}$ *completeness, metric completeness, or bridgeChecked verification.*

Proof. First assemble the public carried-open surface. Apply Definition 88.33, Definition 88.18, and Definition 88.45 to obtain the carrier, classifier, indexed open rows, boundary rows, finite-intersection rows, arbitrary-union rows, and ledger provenance.

Next identify the rows that a downstream standard indexed-topological-space interface reads. By Definition 88.46, every exported public open is one of the displayed carried-open constructor rows. Interpret each such row as a standard open row indexed by the same public carried-open index, with the carried predicate as its readback predicate.

The topology laws are then read rather than rebuilt. Finite intersections use the finite-intersection clauses already present in the indexed-open carrier, and arbitrary unions use the arbitrary-union clauses already present in the same carrier. The bottom and top rows are the displayed boundary rows.

Finally apply Definition 88.47. Membership invariance is transported only through the carrier classifier and the carried-open equation, so the bridge does not introduce host powerset equality, quotient identification, completeness content, or a Lean-side bridgeChecked correspondence. □

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologyPublicCarriedOpen standard bridge`

Closure status for $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$.

Constructive story: A topology is generated here by displaying a carrier, a carrier classifier, a family of open indices, a pointwise membership predicate, finite-intersection indices, arbitrary-union witnesses, and the bottom and top open rows, all kept as certificate data rather than chosen from a powerset. The carrier admits public opens only when an explicit index carries the predicate and a visible ledger row names the constructor that produced it: metric ball, finite-list intersection, binary meet, arbitrary union, empty open, whole open, or the singleton empty-history table; predicates without such an index-and-ledger pair are not accepted. Two public open rows are classified by transporting membership through the carrier classifier and by the carrying equation for the displayed index, so equality of external subsets is never the classifier. The source specification is the indexed-open topology packet together with the metric-generated and singleton sources, the pattern specification records boundary laws, finite intersections, arbitrary unions, constructor coverage, and carrier-classifier scope, and the ledger records the chosen open index, its carrying equation, and the constructor provenance. The five name-certificate obligations follow from the displayed topology package: the boundary rows give inhabited public sources, classifier transport gives reflexivity, symmetry, and transitivity on carried rows, and every transported membership proof is repacked with the same explicit index or constructor row. A row h lies in the signature gap of a $\mathsf{Topology}^{\uparrow}$ token p when the source-domain accepts its carried-open index and constructor ledger, the signature relation pairs it with an answer open row and evidence ledger, and the token-introduction relation names that answer as p; unfolded, h is precisely the public open predicate carried by the index and constructor encoded by p. The paper bridge reads this indexed carried-open surface as a standard indexed topological-space interface, but only by reading back carrier membership and open laws from the same rows, with no surjectivity onto host opens, powerset equality, completeness content, or bridgeChecked correspondence introduced.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature paper scope binds the public carried-open export surface, the metric-generated and singleton concrete sources, downstream constructor coverage, the carrier-classifier scope, and the paper carried-open standard bridge of Definition 88.49.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.TopologyUp.BHistLedgerPublicOpenTree\_downstream\_export\_surface`

Bridge status: bridgeChecked

Not claimed: It does not close surjectivity onto all host opens, quotient or powerset equality, full standard-space equivalence, RealUp completeness, metric completeness, compactness, or bridgeChecked verification.

Upgrade path: No further upgrade: chapter is at the top of the formal axis.

Definition 88.50 (Unary BHist indexed topology source)**.** *The unary* BHist *indexed topology source for* $\mathsf{Topology}^{\uparrow}$ *fixes the point object to the BEDC history carrier together with the unary*

carrier predicate

$$C_{\mathsf{un}}(x) :\Longleftrightarrow \mathsf{UnaryHistory}(x).$$

Its carrier classifier is the history classifier $\mathsf{hsame}(x, y)$ *restricted to points satisfying* C_{un}*. The source data are an index object* $\mathsf{OpenIx}_{\mathsf{un}}$*, a displayed membership predicate*

$$\mathsf{OpenAt}_{\mathsf{un}} : \mathsf{OpenIx}_{\mathsf{un}} \times \mathsf{BHist} \to \mathsf{Prop},$$

a meet operation $i, j \mapsto i \wedge_{\mathsf{Topology}^{\uparrow}} j$*, indexed arbitrary-union witnesses, boundary indices* $\bot_{\mathsf{Topology}^{\uparrow}}$ *and* $\top_{\mathsf{Topology}^{\uparrow}}$*, and visible* BHist *ledger rows for each admitted open.*

The fields satisfy the indexed-open laws of Definition 88.1 on unary points: every $\mathsf{OpenAt}_{\mathsf{un}}(i, -)$ *transports along* hsame*, the meet index carries pointwise conjunction, the union witness carries pointwise indexed union, and the boundary indices carry the empty and whole unary predicates. A public open row is admitted only with a carried index and a ledger constructor naming one of the six rows of Definition 88.34.*

This unary source is the topology-side source consumed by $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$ style neighbourhood and continuity rows: chapter 130 reads its carried opens as continuity tests, while chapter 57 reads the same indexed-open route as the metric-neighbourhood source.

Theorem 88.51 (Unary indexed membership transport)**.** *Let* $\mathcal{U}$ *be the unary* BHist *indexed topology source of Definition 88.50. If an index* $i : \mathsf{OpenIx}_{\mathsf{un}}$ *carries a public unary predicate* $U : \mathsf{BHist} \to \mathsf{Prop}$*, then for all histories* $x, y : \mathsf{BHist}$*,*

$$\mathsf{UnaryHistory}(x) \Longrightarrow \mathsf{UnaryHistory}(y) \Longrightarrow \mathsf{hsame}(x, y) \Longrightarrow (U(x) \Longleftrightarrow U(y)).$$

Proof. Assume the two unary carrier witnesses, the classifier witness $\mathsf{hsame}(x, y)$, and a carrying equation $h_i : \mathsf{CarriesOpen}_{\mathcal{U}}(i, U)$. The definition of the unary source says that the classifier of the indexed topology carrier is exactly the restricted hsame route on BHist.

Unfold the carrying equation at x and y. It converts $U(x)$ and $U(y)$ into $\mathsf{OpenAt}_{\mathsf{un}}(i, x)$ and $\mathsf{OpenAt}_{\mathsf{un}}(i, y)$.

The membership-stability field in Definition 88.50, read as the indexed-open stability field of Definition 88.1, transports $\mathsf{OpenAt}_{\mathsf{un}}(i, -)$ along the displayed $\mathsf{hsame}(x, y)$ witness. Composing the two carrying equations with this transport gives the stated membership equivalence for U. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistPublicOpenTree unary membership transport`

Theorem 88.52 (Unary topology constructor ledger coverage)**.** *For the unary* BHist *indexed topology source of Definition 88.50, every admitted unary indexed open is carried by exactly one visible constructor row among singleton metric ball, finite-list intersection, binary generated-open meet, arbitrary union, bottom, or top. The row exposes its carried index, its pointwise carrying equation, and its* BHist *provenance tag.*

Proof. Unfold the admission clause in Definition 88.50. It accepts a public unary open only as a topology public open row in the sense of Definition 88.34, so an admitted row already contains an index, a carrying equation, and a ledger constructor.

The constructor alternatives are the six alternatives listed in Definition 88.34. Metric-generated singleton and finite-list rows are the coverage rows of Definition 88.36. Singleton bottom, top, meet, and union rows are the coverage rows of Definition 88.37.

For composite rows, the downstream coverage theorem Definition 88.46 identifies the same six constructor names and rules out any unindexed open predicate. Since the unary source records the

constructor as a visible tagged ledger row, two different constructor names are not the same row of the source ledger; hence each admitted unary open has exactly the displayed row that introduced it. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistUnaryTopologyLedgerRow constructor coverage`

Theorem 88.53 (Unary topology ledger constructor no-confusion)**.** *Let $\mathcal{U}$ be the unary* BHist *indexed topology source of Definition 88.50. For any unary public predicate U : BHist $\to$ Prop carried by an admitted visible* BHistUnaryTopologyLedgerRow*, no row introduced by one of*

singletonMetricBall, finiteListIntersection, binaryGeneratedMeet, arbitraryUnion, bottom, top

can also be introduced by a different named constructor from the same list while carrying the same predicate U.

Proof. Apply Definition 88.52 to reduce an admitted unary row to the six visible constructor alternatives listed in the statement. The closed inductive row type BHistUnaryTopologyLedgerRow has no additional public-open row form, so every admissible branch has one exposed outer constructor.

Now invert the exposed constructor of the row. In the singletonMetricBall branch, constructor inversion rejects equality with each of the finite-list, binary-meet, arbitrary-union, bottom, and top branches. The same inversion argument applies to each remaining branch, because the outer constructor name is the first datum recovered from the closed ledger row before any carried index or pointwise carrying equation is read.

Thus two derivations of the same visible row carrying the same predicate U must expose the same constructor name. If the names are different, constructor no-confusion for the closed inductive ledger gives a contradiction, so an admitted unary row cannot have two different visible constructor origins. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistUnaryTopologyLedgerRow constructor tag no confusion`

Theorem 88.54 (Unary BHist topology public certificate)**.** *Let $\mathcal{U}$ be the unary* BHist *indexed topology source of Definition 88.50. Any visible* BHistUnaryTopologyLedgerRow *carrying a nonempty unary public predicate U exports a* SemanticNameCert *whose carrier is* $\mathsf{UnaryHistory}(h) \wedge U(h)$*, whose pattern is* $\mathsf{OpenAt}_{\mathsf{un}}(i, h)$*, whose ledger records a unary* BHist *constructor row together with the carried index membership, and whose classifier is* $\mathsf{UnaryHistory}(h) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{hsame}(h, k)$*.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistUnaryTopologyLedgerRow semantic name certificate`

Proof. Use Definition 88.52 to split the visible ledger row into its six possible constructors: singleton metric ball, finite-list intersection, binary generated-open meet, arbitrary union, bottom, and top. In each branch the row supplies the same carried index i, a pointwise carrying equation between U and $\mathsf{OpenAt}_{\mathsf{un}}(i, -)$ on unary histories, and the displayed BHist provenance tag.

The source witness for nonempty U gives the inhabited carrier clause for $\mathsf{UnaryHistory}(h) \wedge U(h)$. Reflexivity, symmetry, and transitivity of the certificate classifier are the corresponding hsame rules restricted to unary histories.

For carrier transport, apply Definition 88.51. The carrying equation converts a carrier point of U into indexed-open membership at i, the source transport moves that membership along hsame, and the carried-index equation converts it back to U at the target unary history.

Pattern soundness is the forward direction of the same carried-index equation. Ledger soundness packages the constructor branch selected above, the recorded unary provenance tag, and the

indexed membership just obtained from the carrying equation. Thus every admitted unary public row exports the stated semantic certificate without adding an unindexed open predicate. □

Theorem 88.55 (Topology deps-ready obligation package)**.** *The unary* BHist *source of Definition 88.50, the transport theorem Definition 88.51, the ledger coverage theorem Definition 88.52, and the finite-intersection, arbitrary-union, and boundary closure theorems*

$$Definition\ 88.7, \qquad Definition\ 88.9, \qquad Definition\ 88.32$$

assemble the paper-side $\mathsf{Topology}^{\uparrow}$ *obligation package consumed by* $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, *and* $\mathsf{CplxTopo}^{\uparrow}$. *A downstream consumer receives only the unary carrier* C_{un}, *the restricted* hsame *classifier, a carried-open index, the carrying equation, the finite-intersection and arbitrary-union constructors, the boundary constructors, and the visible constructor ledger.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistUnaryTopologyDepsReady obligation package`

Proof. The source definition fixes the downstream carrier and classifier: points are BHist histories satisfying UnaryHistory, and all point transport is through the restricted hsame classifier. The theorem Definition 88.51 is the exported membership-transport rule for every carried unary open.

Closure under finite intersections is the indexed-open theorem Definition 88.7. Closure under arbitrary unions is Definition 88.9. Boundary opens are supplied by Definition 88.32. These three theorems operate on the same carried-index interface named in the unary source.

It remains to identify the public provenance that dependent chapters may cite. The coverage theorem Definition 88.52 restricts every admitted unary open to one visible constructor row, while Definition 88.46 and the metric-generated and singleton coverage rows identify the same constructor list on the exported topology surface.

Combining these fields gives the advertised obligation package. Continuous maps use the transported membership row for preimage obligations; Banach and manifold certificates use the carried-open closure rows for neighbourhood and chart domains; the complex-topology certificate uses the same unary-carried interface for its topological side. No clause constructs a standard topological-space object or replaces hsame by host equality. □

88.3 Public Open Derivation Trees

Definition 88.56 (Topology public open derivation tree)**.** *Let* $\mathcal{T}$ *be an indexed open topology carrier for* $\mathsf{Topology}^{\uparrow}$ *over* X, *equipped with indexed arbitrary-union witnesses and indexed boundary open witnesses. A topology public open derivation tree for a predicate* $U : X \to \mathsf{Prop}$ *is a finite rooted certificate, written* $\mathsf{PubOpenTree}_{\mathcal{T}}(U)$, *whose root is a topology public open row*

$$(i, U, h_i, \lambda_i)$$

in the sense of Definition 88.34. The root therefore carries both a BHist *ledger row* λ_i *and a witness*

$$h_i : \mathsf{CarriesOpen}_{\mathcal{T}}(i, U).$$

The allowed root constructors are exactly the following six cases.

1. *A singleton metric-ball constructor carries a displayed singleton ball row and has no open subtrees.*
2. *A finite-list intersection constructor carries a finite list of public open derivation trees and a ledger row whose carried index is the displayed finite-list meet of their root indices.*

3. *A binary generated-open meet constructor carries two public open derivation trees, their root indices i and j, and the carried meet index $i \wedge_{\mathsf{Topology}^{\uparrow}} j$.*
4. *An arbitrary-union constructor carries an index family A, a family of public open derivation trees indexed by A, and the supplied union index carrying the pointwise union of their root predicates.*
5. *A bottom constructor carries the boundary row $\bot_{\mathsf{Topology}^{\uparrow}}$ and the empty predicate.*
6. *A top constructor carries the boundary row $\top_{\mathsf{Topology}^{\uparrow}}$ and the whole carrier predicate.*

No other constructor is part of $\mathsf{PubOpenTree}_{\mathcal{T}}$. *Thus every accepted public open exposes the structural induction data that produced its carried index, not merely the final ledger entry.*

Lean4 (definition) `BEDC.Derived.TopologyUp.BHistPublicOpenTree`
Lean4 (definition) `BEDC.Derived.TopologyUp.TopologyPublicOpenTree`

Theorem 88.57 (Topology public open derivation tree coverage)**.** *Let $\mathcal{T}$ be either the metric-generated topology carrier $\mathcal{T}_{d,\mathsf{ball}}$ of Definition 88.12 with the public rows covered by Definition 88.36, or the singleton empty-history topology carrier of Definition 88.38 with the public rows covered by Definition 88.37. Then every topology public open row for $\mathcal{T}$ determines a topology public open derivation tree for the same predicate and the same carried root index.*

Proof. Proceed by cases on the public row supplied by the relevant coverage theorem.

For a singleton metric ball, the metric-generated coverage theorem supplies the singleton index, its carrying equation, and the singleton metric-ball ledger row. These are exactly the root data for the singleton constructor.

For a finite-list intersection, take the displayed finite list of already admitted public rows. Build the subtrees recursively from those rows, and use the finite-list intersection ledger row at the root together with its carried index and $\mathsf{CarriesOpen}$ witness.

For a binary generated-open meet, build the two input subtrees from the two public generated-open rows. The root is the meet row whose index is $i \wedge_{\mathsf{Topology}^{\uparrow}} j$, with the carrying witness supplied by Definition 88.7.

For an arbitrary union, build the indexed family of subtrees pointwise. The supplied union index and the carrying equation from Definition 88.9 form the root.

For bottom and top, use the boundary rows supplied by Definition 88.32. In the singleton carrier these are the displayed bottom and top rows of Definition 88.39; in the metric-generated carrier they are the boundary rows recorded by Definition 88.36. These cases exhaust the six constructors of Definition 88.56. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistUnaryTopologyLedgerRow public open coverage`

Theorem 88.58 (Topology public open derivation tree transport)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for $\mathsf{Topology}^{\uparrow}$ over X, equipped with indexed arbitrary-union witnesses and indexed boundary open witnesses. If $\tau : \mathsf{PubOpenTree}_{\mathcal{T}}(U)$ and $\mathsf{same}_X(x, y)$, then membership in the root predicate transports along the carrier classifier:*

$$U(x) \Longleftrightarrow U(y).$$

Moreover, the proof is obtained by structural induction on τ, so each subtree contributes the transport witness for the constructor that consumes it.

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistPublicOpenTree classifier transport`
Lean4 ✓ `BEDC.Derived.TopologyUp.TopologyPublicOpenTree classifier transport`

Proof. Induct on the derivation tree τ.

In the singleton metric-ball case, the root is already a topology public open row. Apply Definition 88.35 to its carrying witness and ledger row.

In the finite-list intersection case, use the induction hypotheses for each child row. The finite-list meet is assembled by repeated applications of Definition 88.7; each step transports the carried intersection along same_X.

In the binary generated-open meet case, apply the two induction hypotheses to the input trees. Then apply Definition 88.7 to the two carried root indices, obtaining transport for the pointwise meet.

In the arbitrary-union case, apply the induction hypothesis pointwise to the indexed family of subtrees. The supplied union index is then repacked through Definition 88.9, which transports the existential membership predicate under the same classifier.

In the bottom and top cases, apply Definition 88.32. The empty predicate transports vacuously, and the whole carrier predicate transports by the displayed boundary law. These six cases are all constructors of the tree, so the induction closes the root transport claim. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistPublicOpenTree root classifier transport`

Theorem 88.59 (Topology public open derivation tree NameCert surface)**.** *For the metric-generated and singleton topology sources of Definition 88.36 and Definition 88.37, the derivation tree interface repacks the public* $\mathsf{NameCert}_{\mathsf{Topology}^\uparrow}$ *surface into downstream structural data. Every accepted public open exposes its carrier* X*, classifier* same_X*, root index* i*, carrying witness* $h_i : \mathsf{CarriesOpen}_{\mathcal{T}}(i, U)$*, visible* BHist *ledger row* λ_i*, and the constructor spine producing* i*. Consequently BanachUp, ManifoldUp, ComplexTopologyUp, and SheafUp consumers may perform induction on public opens through* $\mathsf{PubOpenTree}_{\mathcal{T}}$ *rather than treating open predicates as host powersets.*

Proof. Start from a downstream public open row. By Definition 88.57, it has a derivation tree with the same root predicate and root index.

The root of the tree is the original public row, so it preserves the carrier, classifier, carrying witness, and BHist ledger row required by the $\mathsf{NameCert}_{\mathsf{Topology}^\uparrow}$ surface. The constructors below the root record exactly which topology operation supplied the row.

Transport across the surface is supplied by Definition 88.58. Finite intersections, binary meets, arbitrary unions, and boundary rows are therefore available as induction cases with their carried indices still visible.

These are precisely the data used by downstream chapters when they consume topology opens: BanachUp reads open balls and generated neighbourhoods, ManifoldUp reads chart-domain opens, ComplexTopologyUp reads metric-generated complex opens, and SheafUp reads indexed covers and finite overlaps. Since each consumer receives a constructor spine together with the public row, the topology surface is repacked as structural induction data rather than as an external powerset of opens. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistPublicOpenTree semantic name certificate`

Definition 88.60 (BHist pullback open row)**.** *Let* $\mathcal{T}_X$ *be an indexed open topology carrier for* $\mathsf{Topology}^\uparrow$ *over* X*, and let* (i, U, h_i, λ_i) *be a topology public open row in the sense of Definition 88.34. Let* Y *be a* BHist*-carried source with classifier* same_Y*, and let*

$$f : Y \to X$$

be a displayed BHist *map respecting classifiers:*

$$\mathsf{same}_Y(y_0, y_1) \Longrightarrow \mathsf{same}_X(f(y_0), f(y_1)).$$

The BHist pullback open row of (i, U, h_i, λ_i) *along* f *is the row*

$$(i, U \circ f, h_i \circ f, \lambda_i^f)$$

whose pulled-back predicate is

$$(U \circ f)(y) :\Longleftrightarrow U(f(y)).$$

The carried-index route remains the same target index i *viewed through the displayed map* f*: the carrying equation at* $y : Y$ *is obtained by applying* h_i *at* $f(y)$*, and the ledger row* λ_i^f *records the original visible* BHist *provenance together with the map row for* f*.*

Theorem 88.61 (Topology pullback open row classifier transport)**.** *Let* (i, U, h_i, λ_i) *be a topology public open row of* $\mathcal{T}_X$ *over* X*, and let* $f : Y \to X$ *be a classifier-respecting* BHist *map as in Definition 88.60. Then membership in the pulled-back predicate transports along the source classifier:*

$$\mathsf{same}_Y(y_0, y_1) \Longrightarrow \big((U \circ f)(y_0) \Longleftrightarrow (U \circ f)(y_1)\big).$$

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistPullbackOpen classifier transport surface`

Proof. Assume $\mathsf{same}_Y(y_0, y_1)$. The map row for f sends this source classifier witness to $\mathsf{same}_X(f(y_0), f(y_1))$.

Apply Definition 88.35 to the public open row of Definition 88.34. It transports $U(f(y_0))$ to $U(f(y_1))$ along the obtained target classifier witness.

Unfold the pulled-back predicate of Definition 88.60. The displayed equivalence is exactly membership transport for $U \circ f$ on the source carrier. □

Theorem 88.62 (Topology pullback open row finite-meet)**.** *Let* (i, U, h_i, λ_i) *and* (j, V, h_j, λ_j) *be topology public open rows of the same indexed open topology carrier* $\mathcal{T}_X$*, and let* $f : Y \to X$ *be a classifier-respecting* BHist *map. Pullback commutes with the displayed finite meet:*

$$\big((U \cap V) \circ f\big)(y) \Longleftrightarrow \big((U \circ f)(y) \wedge (V \circ f)(y)\big)$$

for every $y : Y$*, and the carried index for this pulled-back meet is* $i \wedge_{\mathsf{Topology}^\uparrow} j$ *with ledger provenance obtained from the finite-meet row and the two pulled-back source rows.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistPullbackOpen finite meet transport`
Lean4 ✓ `BEDC.Derived.TopologyUp.BHistPullbackOpen finite meet`

Proof. Apply Definition 88.7 to the target carried indices i and j and the carrying witnesses from Definition 88.34. It gives the target meet index $i \wedge_{\mathsf{Topology}^\uparrow} j$ carrying the pointwise predicate $U \cap V$.

Now evaluate the carrying equation at the target point $f(y)$. The left side is membership of $(U \cap V)(f(y))$, and the theorem identifies it with $U(f(y)) \wedge V(f(y))$.

Unfold precomposition. The resulting statement is exactly $((U \cap V) \circ f)(y)$ if and only if $(U \circ f)(y) \wedge (V \circ f)(y)$. The ledger is the visible BHist row that records the finite-meet constructor together with the two pulled-back input rows. □

Theorem 88.63 (Topology pullback NameCert obligation surface)**.** *Let $\mathcal{T}_X$ be a* $\mathsf{NameCert}_{\mathsf{Topology}^\uparrow}$ *obligation package over X as in Definition 88.33, and let $f : Y \to X$ be a classifier-respecting* BHist *map from a displayed source carrier Y. The pullback rows of Definition 88.60 assemble the downstream pullback-open obligation surface: the source carrier Y, the source classifier* same_Y*, the carried-index equation obtained by evaluating target carrying witnesses after f, finite-meet preservation from Definition 88.62, classifier transport from Definition 88.61, and visible* BHist *ledger provenance for the map row and the target open row.*

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistPullbackOpen semantic name certificate`

Proof. The carrier and classifier are the displayed source rows Y and same_Y. The map row for f is the only route used to move a source classifier witness into the target classifier.

For each carried target open, Definition 88.60 gives the pulled-back predicate and the carried-index equation by applying the target witness at $f(y)$. Classifier transport is then exactly Definition 88.61.

For finite meets, use Definition 88.62. It applies the target finite-intersection row of Definition 88.7 before precomposition, so no host powerset open is selected on Y.

Finally invoke the package shape of Definition 88.33. Its carrier, classifier, finite-meet, and ledger clauses are preserved by the displayed pullback rows, with provenance recording both the target public open row and the BHist map row. □

Theorem 88.64 (Topology pullback open row arbitrary union)**.** *Let $\mathcal{T}_X$ be an indexed open topology carrier for* $\mathsf{Topology}^\uparrow$ *over X. Let A be an indexing type, and for each $a : A$ let*

$$\mathcal{R}_a = (\iota(a), U_a, h_a, \lambda_a)$$

be a topology public open row of $\mathcal{T}_X$ in the sense of Definition 88.34. Assume that $u :$ OpenIx *has an indexed arbitrary-union witness for the target index family,*

$$h_\cup : \mathsf{UnionIx}_{\mathcal{T}_X}(u, \iota).$$

Put $U_\cup : X \to \mathsf{Prop}$ and $U_a^f, U_\cup^f : Y \to \mathsf{Prop}$ by

$$U_\cup(x) :\Longleftrightarrow \exists a : A,\ U_a(x),$$

$$U_a^f(y) :\Longleftrightarrow U_a(f(y)),$$

and

$$U_\cup^f(y) :\Longleftrightarrow U_\cup(f(y)).$$

Let Y be a BHist*-carried source with classifier* same_Y*, let $f : Y \to X$ be a displayed* BHist *map respecting classifiers as in Definition 88.60, and let $\lambda_\cup$ be a visible* BHist *ledger row naming the arbitrary-union constructor. Then the arbitrary-union public row $(u, U_\cup, h_u, \lambda_\cup)$, with h_u supplied by Definition 88.9, has BHist pullback row*

$$(u, U_\cup^f, h_u \circ f, \lambda_\cup^f),$$

and for every $y : Y$ its carried-index equation is

$$\mathsf{OpenAt}(u, f(y)) \Longleftrightarrow \exists a : A,\ U_a^f(y).$$

Equivalently,

$$U_\cup^f(y) \Longleftrightarrow \exists a : A,\ U_a^f(y).$$

Thus the pulled-back arbitrary-union row carries the pointwise existential union of the pulled-back public open predicates.

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistPullbackOpen arbitrary union`

Proof. For each $a : A$, the public-row data of Definition 88.34 give

$$h_a : \mathsf{CarriesOpen}_{\mathcal{T}_X}(\iota(a), U_a).$$

Apply Definition 88.9 to $h_\cup$ and the family $a \mapsto h_a$. This gives

$$h_u : \mathsf{CarriesOpen}_{\mathcal{T}_X}(u, U_\cup).$$

Together with the ledger row $\lambda_\cup$, this makes $(u, U_\cup, h_u, \lambda_\cup)$ a topology public open row by Definition 88.34. Since f respects classifiers, Definition 88.60 forms its BHist pullback row with predicate $U_\cup^f$ and carried equation obtained by evaluating h_u at $f(y)$.

Fix $y : Y$. The union witness of Definition 88.8, evaluated at $f(y)$, gives

$$\mathsf{OpenAt}(u, f(y)) \iff \exists a : A,\ \mathsf{OpenAt}(\iota(a), f(y)).$$

If the left side holds, choose $a : A$ with $\mathsf{OpenAt}(\iota(a), f(y))$. Reading the carrying equation h_a at $f(y)$ in the reverse direction gives $U_a(f(y))$, hence $U_a^f(y)$. Conversely, if $U_a^f(y)$ holds for some $a : A$, the definition of U_a^f gives $U_a(f(y))$, the carrying equation h_a gives $\mathsf{OpenAt}(\iota(a), f(y))$, and the union witness gives $\mathsf{OpenAt}(u, f(y))$.

This proves

$$\mathsf{OpenAt}(u, f(y)) \iff \exists a : A,\ U_a^f(y).$$

The definition of $U_\cup$ gives $U_\cup(f(y)) \iff \exists a : A,\ U_a(f(y))$, and the definitions of $U_\cup^f$ and U_a^f rewrite this as

$$U_\cup^f(y) \iff \exists a : A,\ U_a^f(y).$$

Therefore the BHist pullback row for the target arbitrary-union public row carries precisely the pointwise existential union of the pulled-back family. □

88.4 Scoped obligation triple

The topology certificate has enough indexed-open data for downstream use once its public surface is read as three obligations over visible BHist rows. The following triple records that surface in the form consumed by chapters that need topology but do not need a standard-space bridge.

Definition 88.65 (Topology scoped obligation triple)**.** *The scoped obligation triple for* $\mathsf{Topology}^\uparrow$ *consists of the following three requirements over* BHist *indexed-open rows.*

1. *Carrier/classifier scope: every accepted source exposes only the carrier X, the carrier classifier* same_X*, the open index* OpenIx*, the membership row* OpenAt*, and classifier transport through the indexed-open carrier of Definition 88.1.*

2. *Open-constructor exhaustion: every admitted public open from the metric-generated or singleton source is accounted for by the constructor ledger displayed in Definition 88.19 and by the singleton boundary, meet, and union rows.*

3. *Downstream export certificate: the exported surface for* $\mathsf{Banach}^\uparrow$*,* $\mathsf{Manifold}^\uparrow$*,* $\mathsf{CplxTopo}^\uparrow$*, and continuous-map chapters is the carrier/classifier scope together with the exhausted constructor ledger and the downstream surface of Definition 88.48.*

The triple is an obligation inventory for the indexed-open certificate. It does not identify opens by equality in an external powerset and does not assert a bridge to a host topological-space object.

Theorem 88.66 (Topology obligation carrier classifier scope)**.** *Every accepted* $\mathsf{Topology}^{\uparrow}$ *source covered by Definition 88.65 exposes only the carrier* X*, classifier* same_X*, open index* OpenIx*, membership row* OpenAt*, and classifier transport supplied by Definition 88.1. A downstream proof may transport membership in a carried public open only by passing through the carrying equation for some index* $i : \mathsf{OpenIx}$ *and then using the* same_X*-stability field of that indexed-open carrier. No external powerset equality is part of the obligation.*

Proof. Start with a carried public open row. By Definition 88.1 and Definition 88.2, the row consists of an index $i : \mathsf{OpenIx}$ and a pointwise equation between the public predicate and $\mathsf{OpenAt}(i, -)$.

Given a classifier witness $\mathsf{same}_X(x, y)$, convert membership at x through the carrying equation, apply the indexed-open membership-stability field to move from $\mathsf{OpenAt}(i, x)$ to $\mathsf{OpenAt}(i, y)$, and convert back through the carrying equation at y.

This is exactly the route isolated in Definition 88.47. Since every step mentions only X, same_X, OpenIx, OpenAt, and the carried row, the obligation has no place for host powerset equality. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistCarriesOpen membership transport route`

Theorem 88.67 (Topology obligation open constructor exhaustion)**.** *Every public open admitted by the metric-generated source of Definition 88.12 or by the singleton empty-history source of Definition 88.38 is exhausted by the displayed constructor ledger. For the metric-generated source the possibilities are exactly the six rows of Definition 88.19: singleton metric ball, finite-list intersection, binary generated-open meet, arbitrary union, empty open, and whole open. For the singleton source the public rows reduce to the boundary rows together with the displayed meet and union classifications, so they embed into the same bottom/top and constructor-closure accounting.*

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologyPublicOpenTree constructor exhaustion`

Proof. For the metric-generated source, apply Definition 88.25. Its row coverage, classification soundness, and classification completeness clauses range over precisely the six constructor rows listed in Definition 88.19.

The constructive split is the displayed six-case ledger. Singleton metric balls use Definition 88.16; finite-list intersections use Definition 88.17; binary generated-open meets use Definition 88.23; arbitrary unions use Definition 88.9; empty and whole opens use Definition 88.32.

For the singleton source, inspect Definition 88.38. The bottom and top rows are supplied by Definition 88.39, while finite intersections and arbitrary unions are supplied by Definition 88.40 and Definition 88.44.

These are the cases collected by Definition 88.46. Therefore every admitted public open from either source has a visible constructor record, and there is no seventh public-open route. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistUnaryTopologyLedgerRow generated open exactness`
↪ variant `BEDC.Derived.TopologyUp.BHistLedgerPublicOpenTree constructor exhaustion`

Theorem 88.68 (Topology obligation downstream export certificate)**.** *The carrier/classifier scope of Definition 88.66, the constructor exhaustion of Definition 88.67, and the export theorem Definition 88.48 assemble the scoped* $\mathsf{Topology}^{\uparrow}$ *surface consumed by* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{Manifold}^{\uparrow}$*,* $\mathsf{CplxTopo}^{\uparrow}$*, and continuous-map chapters. The exported data are the carrier, carrier classifier, carried-open index, membership row, constructor provenance in* BHist*, finite-intersection constructor, arbitrary-union constructor, boundary rows, and the binary generated-open meet constructor, with no standard-space bridge claimed.*

Lean4 ✓ `BEDC.Derived.TopologyUp.TopologyScopedObligation downstream export certificate`

Proof. First use Definition 88.66 to identify the only membership-transport channel available to dependent chapters. This supplies the carrier, classifier, open index, membership row, and carrying equation.

Next use Definition 88.67 to attach provenance to each public open. The metric-generated and singleton sources are both reduced to visible BHist rows, so downstream consumers do not need to inspect an ambient powerset.

Finally apply Definition 88.48. That theorem already names the receiving chapters and records the exported finite-intersection, arbitrary-union, boundary, and binary generated-open meet rows. Combining the three clauses gives the scoped export certificate promised by Definition 88.65. □

Definition 88.69 (BHist subspace open surface)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for* $\mathsf{Topology}^{\uparrow}$ *whose carrier is* BHist*, with classifier* same_X*, index object* OpenIx*, membership predicate* OpenAt*, and meet operation* $\wedge_{\mathsf{Topology}^{\uparrow}}$*. A* BHist *subspace open surface is specified by a carrier predicate*

$$S : \mathsf{BHist} \to \mathsf{Prop}$$

together with the restricted classifier

$$\mathsf{same}_S(h,k) :\Longleftrightarrow S(h) \wedge S(k) \wedge \mathsf{same}_X(h,k)$$

and the restricted indexed-open membership predicate

$$\mathsf{SubOpenAt}(i,h) :\Longleftrightarrow S(h) \wedge \mathsf{OpenAt}(i,h).$$

The subspace surface keeps the same index object OpenIx*, the same meet operation* $i, j \mapsto i \wedge_{\mathsf{Topology}^{\uparrow}} j$*, and the same visible ledger rows as the ambient carrier.*

Its ten-field fit is: traditional target subspace topology on a displayed subset; BEDC source BHist*; carrier choice S; classifier choice* same_S*; stability obligations inherited from $\mathcal{T}$ by projecting to* same_X*; ledger unchanged from the ambient open index; core theorem list consisting of carrier transport, finite intersections, arbitrary unions, boundary rows, and public certificate packaging; exactness predicate* $\mathsf{SubOpenAt}(i,h) \Longleftrightarrow S(h) \wedge \mathsf{OpenAt}(i,h)$*; standard bridge none; status* ProofTarget *for the paper-side* $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$ *obligation surface.*

Theorem 88.70 (Subspace open carrier transport)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for* $\mathsf{Topology}^{\uparrow}$ *over* BHist*, and let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *determine the subspace surface of Definition 88.69. For every open index* $i : \mathsf{OpenIx}$ *and histories* $h, k : \mathsf{BHist}$*,*

$$\mathsf{same}_S(h,k) \Longrightarrow (\mathsf{SubOpenAt}(i,h) \Longleftrightarrow \mathsf{SubOpenAt}(i,k)).$$

Proof. Assume $\mathsf{same}_S(h,k)$. By Definition 88.69, this supplies $S(h)$, $S(k)$, and a carrier-classifier witness $\mathsf{same}_X(h,k)$.

For the forward direction, unfold $\mathsf{SubOpenAt}(i,h)$ to obtain $S(h)$ and $\mathsf{OpenAt}(i,h)$. The membership-stability field of Definition 88.1, applied to $\mathsf{same}_X(h,k)$ and the fixed index i, transports $\mathsf{OpenAt}(i,h)$ to $\mathsf{OpenAt}(i,k)$. Pair this transported membership with the already displayed $S(k)$.

The reverse direction is identical with the same stability equivalence read from k back to h. Pair the transported ambient membership with the displayed $S(h)$ to recover $\mathsf{SubOpenAt}(i,h)$. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistSubspaceOpen carrier transport`

Theorem 88.71 (Subspace finite-intersection closure)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for* $\mathsf{Topology}^{\uparrow}$ *over* BHist*, and let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *determine the subspace surface of Definition 88.69. For all indices* $i, j : \mathsf{OpenIx}$ *and histories* $h : \mathsf{BHist}$*,*

$$\mathsf{SubOpenAt}(i \wedge_{\mathsf{Topology}^{\uparrow}} j, h) \iff (\mathsf{SubOpenAt}(i, h) \wedge \mathsf{SubOpenAt}(j, h)).$$

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistSubspaceOpen finite intersection`

Proof. Unfold the restricted membership predicate from Definition 88.69. The left side gives $S(h)$ together with $\mathsf{OpenAt}(i \wedge_{\mathsf{Topology}^{\uparrow}} j, h)$.

For the forward direction, apply the finite-intersection field of Definition 88.1 to split the ambient membership into $\mathsf{OpenAt}(i, h)$ and $\mathsf{OpenAt}(j, h)$. Pair each ambient membership with the same displayed $S(h)$, giving $\mathsf{SubOpenAt}(i, h)$ and $\mathsf{SubOpenAt}(j, h)$.

For the reverse direction, unpack the two restricted memberships. Either one supplies $S(h)$, while their ambient components supply $\mathsf{OpenAt}(i, h)$ and $\mathsf{OpenAt}(j, h)$. The finite-intersection field of Definition 88.1 combines the ambient components into $\mathsf{OpenAt}(i \wedge_{\mathsf{Topology}^{\uparrow}} j, h)$, and pairing with $S(h)$ gives the restricted meet membership. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistSubspaceOpen finite intersection closure`

Theorem 88.72 (Subspace TopologyUp obligation surface)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for* $\mathsf{Topology}^{\uparrow}$ *over* BHist*, equipped with indexed arbitrary-union witnesses for every indexed family of ambient opens and indexed boundary open witnesses* $\bot_{\mathsf{Topology}^{\uparrow}}$ *and* $\top_{\mathsf{Topology}^{\uparrow}}$*. Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *determine the subspace surface of Definition 88.69. Then the restricted carrier* S*, the classifier* same_S*, the restricted predicate* $\mathsf{SubOpenAt}$*, the inherited index ledger, finite intersections, arbitrary unions restricted by the same* S*, the empty and whole-of-subspace boundary rows, and the visible* BHist *provenance assemble a paper-side* $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$ *obligation surface.*

Proof. The carrier row is the predicate S over BHist. The classifier row is same_S, which exposes both endpoint membership in the carrier and the ambient classifier witness. The transport row is exactly Definition 88.70.

Finite intersections are supplied by Definition 88.71. The subspace surface uses the same meet index $i \wedge_{\mathsf{Topology}^{\uparrow}} j$ as the ambient carrier, while the proof duplicates the displayed $S(h)$ component instead of selecting a host subset.

For arbitrary unions, keep the same family of indices $\iota : A \to \mathsf{OpenIx}$ and let u be the ambient union witness. At a history h, the restricted union predicate is:

$$S(h) \wedge \exists a : A,\ \mathsf{OpenAt}(\iota(a), h).$$

The ambient union row converts $\mathsf{OpenAt}(u, h)$ to the displayed existential, and the subspace row pairs that ambient membership with the same $S(h)$. Inversion projects $S(h)$ and the existential witness, then uses the ambient union row in the reverse direction.

For boundary rows, the empty subspace open is carried by $\bot_{\mathsf{Topology}^{\uparrow}}$ because $\mathsf{SubOpenAt}(\bot_{\mathsf{Topology}^{\uparrow}}, h)$ reduces to $S(h) \wedge \mathsf{False}$. The whole-of-subspace row is carried by $\top_{\mathsf{Topology}^{\uparrow}}$ because $\mathsf{SubOpenAt}(\top_{\mathsf{Topology}^{\uparrow}}, h)$ reduces to $S(h) \wedge \mathsf{True}$, hence to $S(h)$.

The ledger row records that every accepted subspace open keeps the ambient open index and adds only the visible carrier proof $S(h)$ at membership sites. Thus the certificate consumer sees the BHist carrier predicate, classifier transport, finite-intersection closure, arbitrary-union closure, boundary rows, and provenance, which is precisely the paper-side $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$ obligation surface. □

Lean4 ✓ `BEDC.Derived.TopologyUp.BHistSubspaceOpen boundary closure`

Theorem 88.73 (Subspace pullback image factorization)**.** *Let $\mathcal{T}$ be an indexed open topology carrier for* $\mathsf{Topology}^{\uparrow}$ *over* BHist*, with classifier* same_X*, open indices* OpenIx*, and ambient membership predicate* OpenAt*. Let $S : \mathsf{BHist} \to \mathsf{Prop}$ determine the subspace surface of Definition 88.69. Let Y be a* BHist*-carried source with classifier* same_Y*, and let*

$$f : Y \to \mathsf{BHist}$$

be a displayed classifier-respecting BHist *map as in Definition 88.60. Assume that the image of f is displayed inside the subspace,*

$$\rho_f : \forall y : Y,\ S(f(y)).$$

For every ambient open index $i : \mathsf{OpenIx}$ and every $y : Y$, the pullback of the subspace-open row along f factors through the ordinary ambient pullback row:

$$\mathsf{SubOpenAt}(i, f(y)) \iff \mathsf{OpenAt}(i, f(y)).$$

Equivalently, the restricted predicate

$$\mathsf{SubOpenAt}_i^f(y) :\iff \mathsf{SubOpenAt}(i, f(y))$$

and the ambient pullback predicate

$$\mathsf{OpenAt}_i^f(y) :\iff \mathsf{OpenAt}(i, f(y))$$

have the same pointwise membership row on Y. Moreover this identified row transports along same_Y *by the same classifier route as the ambient pullback open row of Definition 88.60.*

Proof. Fix $i : \mathsf{OpenIx}$ and $y : Y$. By Definition 88.69, the restricted membership predicate is

$$\mathsf{SubOpenAt}(i, f(y)) \iff S(f(y)) \wedge \mathsf{OpenAt}(i, f(y)).$$

The displayed image witness $\rho_f(y)$ supplies the first conjunct. Hence restricted membership implies ambient membership by projection, and ambient membership implies restricted membership by pairing it with $\rho_f(y)$. This proves

$$\mathsf{SubOpenAt}(i, f(y)) \iff \mathsf{OpenAt}(i, f(y)).$$

Unfolding the two displayed pullback predicates $\mathsf{SubOpenAt}_i^f$ and OpenAt_i^f gives the stated pointwise identification on Y.

It remains only to record the transport route. If $\mathsf{same}_Y(y_0, y_1)$ holds, the map row for f gives $\mathsf{same}_X(f(y_0), f(y_1))$. The ambient indexed-open stability field of Definition 88.1, equivalently the pullback-row transport of Definition 88.61 applied to the ambient row indexed by i, transports

$$\mathsf{OpenAt}(i, f(y_0)) \iff \mathsf{OpenAt}(i, f(y_1)).$$

Composing this equivalence with the pointwise factorization at y_0 and y_1 transports the restricted pullback predicate as well. Thus the subspace pullback row introduces no additional source-side open predicate: its membership and classifier transport are exactly the ambient pullback row, with the subspace conjunct discharged by the displayed image witness ρ_f. □

Chapter 89

A Concrete Naming Certificate for $\mathsf{Norm}^{\uparrow}$

The norm interface $\mathsf{Norm}^{\uparrow}$ packages a vector-space carrier with a constructive non-negative real-valued norm satisfying positive definiteness, absolute homogeneity, and the triangle inequality. It depends on $\mathsf{NameCert}_{\mathsf{VecSpace}^{\uparrow}}$ (chapter 47) and $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ (chapter 38), and is the immediate prerequisite for $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$.

89.1 Carrier definition

Definition 89.1 (Concrete singleton empty-history norm instance)**.** *Use the concrete singleton empty-history vector space of Definition 47.2. Thus the vector carrier is A_{e}, the vector classifier is ρ_{e}, the scalar source is the singleton* $\mathsf{VecSpace}^{\uparrow}$ *scalar field, and the vector zero is* e.

Let z_{Rat} be the RatUp zero endpoint supplied to the constant-rational $\mathsf{RealAlgOrder}$ *boundary of Definition 38.42. Write*

$$0^{c}_{\mathsf{Real}} := \mathsf{E1}(z_{\mathsf{Rat}})$$

for its e-one RealUp constant seal. The norm map is the constant endpoint

$$\nu_{\mathsf{e}}(m) := 0^{c}_{\mathsf{Real}}$$

on every displayed vector history $m : \mathsf{BHist}$, and the norm classifier is $\mathsf{RealConstantHistoryClassifier}$. *The resulting* $\mathsf{Norm}^{\uparrow}$ *seed is the tuple*

$$(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \nu_{\mathsf{e}}, \mathsf{RealConstantHistoryCarrier}, \mathsf{RealConstantHistoryClassifier}).$$

Its ledger records the singleton vector-space source, the RatUp zero witness, and the e-one constant-real seal.

Lean4 (definition) `BEDC.Derived.NormUp.NormSingletonNorm`

Theorem 89.2 (Singleton empty-history norm carrier and classifier)**.** *For the concrete norm instance of Definition 89.1, every carried vector $m : \mathsf{BHist}$ has a carried constant-zero norm:*

$$A_{\mathsf{e}}(m) \Longrightarrow \mathsf{RealConstantHistoryCarrier}(\nu_{\mathsf{e}}(m)).$$

Moreover, if $A_{\mathsf{e}}(m)$ and $A_{\mathsf{e}}(n)$, then

$$\rho_{\mathsf{e}}(m, n) \quad \textit{and} \quad \mathsf{RealConstantHistoryClassifier}(\nu_{\mathsf{e}}(m), \nu_{\mathsf{e}}(n)).$$

Lean4 ✓ `BEDC.Derived.NormUp.NormSingletonEmptyHistory carrier classifier`

Proof. The vector carrier and classifier clauses are those of the singleton empty-history vector space. Apply Definition 47.4 to the two carried endpoints. It gives $\rho_{\mathsf{e}}(m, n)$ and identifies each carried vector endpoint with e in the singleton classifier.

For the norm value, unfold ν_{e}. It is the displayed endpoint $0^{c}_{\mathsf{Real}} = \mathsf{E1}(z_{\mathsf{Rat}})$. The constant-rational boundary of Definition 38.42 transports the RatUp zero carrier to $\mathsf{RealConstantHistoryCarrier}(0^{c}_{\mathsf{Real}})$.

The same boundary transports the RatUp zero self-classifier to $\mathsf{RealConstantHistoryClassifier}(0^{c}_{\mathsf{Real}}, 0^{c}_{\mathsf{Real}})$. Since both norm endpoints are definitionally 0^{c}_{Real}, this is exactly the displayed norm-classifier conclusion. □

89.2 The certificate

Theorem 89.3 (Singleton empty-history norm laws)**.** *The concrete instance of Definition 89.1 satisfies the* $\mathsf{Norm}^{\uparrow}$ *law package over the singleton empty-history vector space:*

1. *nonnegativity:* $\mathsf{RealAlgNonnegativeRow}(\nu_{\mathsf{e}}(m))$ *for every carried* $m : A_{\mathsf{e}}$*;*
2. *positive definiteness on the singleton carrier:* $\mathsf{RealConstantHistoryClassifier}(\nu_{\mathsf{e}}(m), 0^{c}_{\mathsf{Real}})$ *holds exactly on vectors classified with the singleton zero vector* e*;*
3. *absolute homogeneity:* $\nu_{\mathsf{e}}(\mathsf{smul}(r, m))$ *is* $\mathsf{RealConstantHistoryClassifier}$*-classified with* $\mathsf{RealAlgMul}(\mathsf{RealAlgAbs}(r), \nu$ *whenever the scalar endpoint is read through the singleton scalar field and the constant-rational RealAlgOrder boundary;*
4. *triangle inequality:* $\nu_{\mathsf{e}}(\mathsf{add}(m, n))$ *is bounded by the RealAlgOrder sum of* $\nu_{\mathsf{e}}(m)$ *and* $\nu_{\mathsf{e}}(n)$ *for every pair of carried singleton vectors.*

Proof. The vector-space obligations are supplied by Definition 47.3. Its endpoint-collapse form, Definition 47.4, says that carried vectors, their sum, their negation, the zero vector, and every scalar action endpoint all reduce to the singleton endpoint under ρ_{e}.

The real-valued obligations are supplied by the constant-rational boundary of Definition 38.42. Apply it to the RatUp zero witness and then seal by e-one. This gives the constant RealUp carrier, the constant classifier at zero, the nonnegative row for zero, the absolute-value row at zero, the multiplication row with zero output, and the addition row with zero output.

For nonnegativity, unfold $\nu_{\mathsf{e}}(m)$. The value is 0^{c}_{Real}, so the transported RatUp zero nonnegative row gives the required RealAlgOrder row.

For positive definiteness, the forward direction reads the norm classifier as the constant-real zero classifier and uses Definition 47.4 to identify the carried vector endpoint with e. Conversely, if the vector is classified with e, the norm definition is still the constant endpoint 0^{c}_{Real}, and the RealUp constant classifier readback gives $\mathsf{RealConstantHistoryClassifier}(0^{c}_{\mathsf{Real}}, 0^{c}_{\mathsf{Real}})$.

For absolute homogeneity and the triangle inequality, every displayed vector argument has norm 0^{c}_{Real}. The singleton scalar action and singleton addition endpoints collapse by Definition 47.4. The constant-rational RealAlgOrder rows then read $|r| \cdot 0 = 0$ and $0 + 0 = 0$ at the e-one RealUp boundary, and classifier transport repacks both conclusions under $\mathsf{RealConstantHistoryClassifier}$. □

Lean4 ✓ `BEDC.Derived.NormUp.NormSingletonEmptyHistory laws`

Theorem 89.4 (Singleton empty-history norm zero exactness)**.** *For every carried vector endpoint* $m : \mathsf{BHist}$ *in the concrete norm instance of Definition 89.1,*

$$\mathsf{RealConstantHistoryClassifier}(\nu_{\mathsf{e}}(m), 0^{c}_{\mathsf{Real}}) \iff \rho_{\mathsf{e}}(m, \mathsf{e}).$$

Lean4 ✓ `BEDC.Derived.NormUp.NormSingletonEmptyHistory zero exactness`

Proof. In the forward direction, the premise says that the constant norm endpoint is classified with real zero. The carried-vector assumption and Definition 47.4 identify m with e in the singleton vector classifier, giving $\rho_{\mathsf{e}}(m, \mathsf{e})$.

In the reverse direction, unfold the norm definition. Both sides of the real classifier are the same e-one seal $0^{\mathsf{c}}_{\mathsf{Real}}$. The RealUp constant classifier readback, together with the RatUp zero self-classifier transported by Definition 38.42, gives $\mathsf{RealConstantHistoryClassifier}(0^{\mathsf{c}}_{\mathsf{Real}}, 0^{\mathsf{c}}_{\mathsf{Real}})$. □

Theorem 89.5 (Singleton empty-history NormUp semantic NameCert surface)**.** *The tuple*

$$(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \nu_{\mathsf{e}}, \mathsf{RealConstantHistoryCarrier}, \mathsf{RealConstantHistoryClassifier}),$$

with the RatUp zero witness sealed as $0^{\mathsf{c}}_{\mathsf{Real}}$*, is the paper-side* $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$ *surface for the singleton norm. It follows the roadmap ten-field template:*

1. *the traditional target is the singleton normed vector space;*
2. *the BEDC source is* $\mathsf{VecSpace}^{\uparrow}$ *together with* $\mathsf{Real}^{\uparrow}$*;*
3. *the vector carrier is* A_{e}*;*
4. *the vector classifier is* ρ_{e}*;*
5. *the norm endpoint classifier is* $\mathsf{RealConstantHistoryClassifier}$ *on the Real constant endpoints;*
6. *stability is supplied by Definition 89.2 and Definition 89.3;*
7. *the ledger records the singleton vector-space source, the RatUp zero witness, and the e-one RealUp seal;*
8. *the core theorem list is Definition 89.2, Definition 89.3, and Definition 89.4;*
9. *exactness is the positive-definite zero row of Definition 89.4;*
10. *no standard bridge is asserted, and this paper theorem awaits a later Lean formalization.*

Lean4 ✓ `BEDC.Derived.NormUp.NormSingletonEmptyHistory semantic name certificate`

Proof. Assemble the carrier and classifier first. By Definition 89.2, every carried singleton vector has a carried constant-zero norm endpoint, every pair of carried vectors is related by ρ_{e}, and the associated norm endpoints are related by $\mathsf{RealConstantHistoryClassifier}$.

Next attach the norm laws. The nonnegativity, positive-definiteness, absolute-homogeneity, and triangle rows are exactly the law package of Definition 89.3, read over the singleton empty-history vector-space source and the constant-rational RealUp boundary.

The zero-exactness entry is supplied by Definition 89.4. It identifies the real constant-zero classifier for $\nu_{\mathsf{e}}(m)$ with the singleton vector classifier $\rho_{\mathsf{e}}(m, \mathsf{e})$, so the positive-definite row is exact on the displayed carrier.

The ledger contains only the singleton vector-space source, the RatUp zero witness, and the e-one RealUp seal. No quotient, host equality, or standard-space bridge is introduced, so the displayed tuple is precisely the paper-side $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$ surface for the singleton norm. □

Theorem 89.6 (Singleton empty-history NormUp scoped certificate)**.** *The tuple of Definition 89.1 satisfies the scoped* $\mathsf{Norm}^{\uparrow}$ *certificate over* BHist*. Its vector carrier is* A_{e}*, its vector classifier is* ρ_{e}*, its norm endpoint carrier is* $\mathsf{RealConstantHistoryCarrier}$*, and its norm endpoint classifier is*

$\mathsf{RealConstantHistoryClassifier}$. *Stability is supplied by Definition 89.2 and Definition 89.3; exactness is supplied by Definition 89.4. The ledger consists only of the singleton* $\mathsf{VecSpace}^{\uparrow}$ *source, the RatUp zero witness, and the e-one* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start with the singleton vector-space source. The carrier A_{e}, the classifier ρ_{e}, the zero vector e, and the singleton scalar action are exactly the data of Definition 47.2, with the vector-space laws supplied by Definition 47.3.

Attach the norm endpoint boundary. The RatUp zero witness is sealed by e-one as 0^{c}_{Real}, and Definition 38.42 gives the constant RealUp carrier, classifier, and order rows used by the constant norm map ν_{e}.

Now compose the checked $\mathsf{Norm}^{\uparrow}$ rows. The carrier and classifier stability come from Definition 89.2; the nonnegativity, positive-definiteness, absolute-homogeneity, and triangle rows come from Definition 89.3; and the exact zero row comes from Definition 89.4.

These clauses exhaust the scoped certificate. The ledger contains no data outside the singleton $\mathsf{VecSpace}^{\uparrow}$ source, the RatUp zero witness, and the e-one $\mathsf{Real}^{\uparrow}$ seal, so the certificate is scoped to the displayed BHist construction and asserts no standard bridge. □

Corollary 89.7 (Singleton empty-history NormUp scoped certificate boundary)**.** *The data* A_{e}*,* ρ_{e}*,* ν_{e}*,* $\mathsf{RealConstantHistoryCarrier}$*, and* $\mathsf{RealConstantHistoryClassifier}$ *supply the scoped singleton* $\mathsf{Norm}^{\uparrow}$ *certificate boundary over the concrete singleton empty-history vector-space source and the constant RealUp zero endpoint. The carrier and classifier rows are those of Definition 89.2; the norm-law rows are those of Definition 89.3; and the positive-definite exactness row is Definition 89.4. Together with the ten-field surface of Definition 89.5, these rows determine the scoped* $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$ *boundary for this singleton instance.*

Proof. The carrier and classifier boundary is already assembled by Definition 89.2. It places the singleton vector carrier A_{e}, the vector classifier ρ_{e}, the constant norm endpoint ν_{e}, the Real constant carrier, and the Real constant classifier in the same displayed certificate scope.

The law boundary is supplied by Definition 89.3. Its nonnegativity, positive-definiteness, absolute-homogeneity, and triangle rows are all read over the singleton empty-history vector-space source and the constant-rational RealUp zero boundary, so no additional carrier or classifier is introduced.

The exactness boundary is Definition 89.4: the real constant-zero classifier for $\nu_{\mathsf{e}}(m)$ is equivalent, on carried singleton vectors, to $\rho_{\mathsf{e}}(m, \mathsf{e})$. The ten-field surface of Definition 89.5 records exactly these rows as the source, carrier, classifier, stability, ledger, and exactness entries, with no standard bridge field asserted. □

Theorem 89.8 (Singleton empty-history NormUp standard bridge boundary)**.** *The singleton BEDC* $\mathsf{Norm}^{\uparrow}$ *tuple bridges to the one-point standard normed vector-space presentation. Carrier readback sends every carried* A_{e} *endpoint to the sole standard point and sends that standard point back to* e *under* ρ_{e}*. Norm readback sends every carried endpoint to standard zero via* 0^{c}_{Real}*. Positive-definite exactness is exactly Definition 89.4. The ledger introduces no hidden quotient, host equality, or non-singleton norm data.*

Proof. The public surface is the ten-field NameCert surface of Definition 89.5. The scoped certificate assembled in Definition 89.6 identifies the singleton vector-space source, the classifier ρ_{e}, the constant norm map ν_{e}, the constant RealUp carrier, and the exact zero row as the complete certificate data.

The boundary statement of Definition 89.7 says that these rows exhaust the scoped $\mathsf{NameCert}_{\mathsf{Norm}^\uparrow}$ boundary. Hence every carried A_{e} endpoint has the singleton readback to the one-point standard carrier, and the return leg lands at e under ρ_{e}.

For norm readback, the same scoped certificate pins every displayed norm endpoint to the e-one seal $0^{\mathsf{c}}_{\mathsf{Real}}$ of the RatUp zero witness. Thus the standard norm interpretation sends each carried endpoint to standard zero in the one-point normed vector space.

Exactness is precisely Definition 89.4: the real constant-zero classifier for $\nu_{\mathsf{e}}(m)$ is equivalent to $\rho_{\mathsf{e}}(m, \mathsf{e})$ on carried singleton vectors.

Finally, the scoped certificate boundary leaves no extra ledger slot: no quotient, host equality, or non-singleton norm datum is added beyond the public surface cited above. The standard carrier and standard zero norm therefore appear only as bridge readbacks. □

Lean4 ✓ `BEDC.Derived.NormUp.NormUp StdBridge`

Closure status for $\mathsf{NameCert}_{\mathsf{Norm}^\uparrow}$.

Constructive story: A normed vector here is the singleton empty-history vector-space endpoint: the vector carrier A_{e} accepts exactly the histories classified with e, and the norm map sends every displayed vector history to the same e-one sealed $\mathsf{Real}^\uparrow$ constant-zero endpoint built from the $\mathsf{Rat}^\uparrow$ zero witness. Two carried vectors are classified by ρ_{e}, two norm values by the Real constant-history classifier, and no nonzero length can appear because every vector endpoint and every norm endpoint collapses to the singleton rows. The source is the singleton $\mathsf{VecSpace}^\uparrow$ carrier together with the constant-rational $\mathsf{Real}^\uparrow$ boundary, the pattern records nonnegativity, positive-definite zero exactness, absolute homogeneity, triangle inequality, scoped certificate rows, and downstream Hilbert compatibility, and the ledger keeps only the vector-space source, RatUp zero witness, and e-one RealUp seal. The five name-certificate obligations close from the singleton vector-space certificate and the Real constant certificate: e inhabits the carrier, the two classifiers are reflexive, symmetric, and transitive, and transported representatives keep the same constant norm endpoint. A history h lies in the signature gap of a $\mathsf{Norm}^\uparrow$ token p when the source-domain accepts the carried singleton vector, the signature relation pairs its constant norm endpoint with an answer endpoint and evidence ledger, and token introduction names that answer as p; unfolded, h is a singleton vector and the answer is standard zero read through $0^{\mathsf{c}}_{\mathsf{Real}}$. The checked standard bridge sends every carried vector to the unique point of the one-point normed space and reads every norm value as zero, then returns to e under ρ_{e}. The chapter registers this constant-zero singleton norm under the name $\mathsf{Norm}^\uparrow$; it introduces no non-singleton normed space, Banach completeness, nontrivial positive norm, or additional bridge field beyond the displayed one-point readback.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Norm}^\uparrow}$, maturePackageClosed)

Scope closed: The public singleton $\mathsf{Norm}^\uparrow$ semantic NameCert surface of Theorem 89.5, the scoped boundary of Corollary 89.7, the standard bridge boundary of Theorem 89.8, and the downstream Hilbert consumer rows of Definition 91.12 and Definition 91.24 bind the singleton carrier A_{e}, classifier ρ_{e}, norm map ν_{e}, and one-point standard normed-space readback.

Chapter 90

A Concrete Naming Certificate for $\mathsf{Banach}^{\uparrow}$

The Banach-space interface $\mathsf{Banach}^{\uparrow}$ packages a normed vector space carrier together with a regular Cauchy completeness witness in the metric induced by the norm. It depends on $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$ (chapter 89) and the real-completeness capstone (chapter 9238), and supplies the substrate for $\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}$ and the operator certificates downstream. The concrete Banach carrier reads its vector source through chapter 47, its norm through chapter 89, its induced distance through chapter 57, and its Cauchy-limit and completeness row through chapter 95 and chapter 128 before operator or limit rows are exported downstream.

90.1 Carrier definition

Definition 90.1 (Concrete Banach carrier)**.** *A concrete Banach carrier is a history predicate* $X : \mathsf{Hist} \to \mathsf{Prop}$ *together with the* $\mathsf{Norm}^{\uparrow}$ *carrier and classifier data supplied by* $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$*, a displayed norm value row for each carried history, and the metric predicate induced by that norm:*

$$\mathsf{BanachMetricWitness}_X(x, y, d)$$

means that x *and* y *are carried by* X*, their difference history is a* $\mathsf{Norm}^{\uparrow}$ *vector-history row, and* d *is the* $\mathsf{Real}^{\uparrow}$ *norm value assigned to that difference. The point classifier of the carrier is not a quotient: carried representatives are identified by* hsame *transport of the displayed vector, norm-value, and metric rows.*

The completeness field is a family which assigns, to every regular Cauchy $\mathsf{StreamName}^{\uparrow}$ *stream* s *over* X *for the norm-induced metric, histories* μ_s, ℓ_s, L_s *such that*

$$\mathsf{CompleteMetricLimitWitness}(X, s, \mu_s, \ell_s, L_s)$$

holds. Thus the Banach datum is the tuple consisting of the carried $\mathsf{Norm}^{\uparrow}$ *structure, the induced metric ledger, the* hsame *classifier on representatives, and the displayed limit-witness family for all regular Cauchy stream names over* X*.*

Lean4 (definition) `BEDC.Derived.BanachUp.BanachConcreteCarrier`

Definition 90.2 (Complete normed-history Banach carrier)**.** *A* $\mathsf{Banach}^{\uparrow}$ *candidate is a* $\mathsf{VecSpace}^{\uparrow}$ *carrier* C_V *with vector classifier* $\sim_V$*, zero endpoint* 0_V*, additive difference operation* $x -_V y$*, and scalar source read over* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*, together with a* $\mathsf{Norm}^{\uparrow}$ *norm*

$$\nu : C_V \to \mathsf{Real}^{\uparrow}$$

whose classifier is the RealUp classifier. Its induced distance predicate is the RealUp value

$$d_\nu(x, y) := \nu(x -_V y)$$

on carried vector endpoints $x, y : C_V$. A regular Cauchy completion witness for the candidate is a row assigning to every regular Cauchy sequence $(X, \mu) : \mathbb{N} \to C_V$ for d_ν a carried limit endpoint $\lim_\nu(X, \mu) : C_V$, a convergence modulus, and a uniqueness certificate up to $\sim_V$.

The BEDC source is $\mathsf{NameCert}_{\mathsf{Norm}^\uparrow}$ *together with the real-completeness capstone of chapter 9238. The carrier choice is C_V, the classifier is $\sim_V$, the stability obligations are norm transport and Cauchy-sequence transport across $\sim_V$, the ledger records all moduli and proof-index data used by the norm and completion rows, and the status is* ProofTarget*.*

Definition 90.3 (Singleton empty-history Banach carrier)**.** *The concrete* $\mathsf{Banach}^\uparrow$ *carrier is the singleton empty-history norm instance of Definition 89.1. Its vector carrier is A_{e}, its vector classifier is ρ_{e}, its norm is ν_{e}, and its metric distance is the constant RealUp zero endpoint*

$$d_{\mathsf{e}}(m, n) := 0^{\mathsf{c}}_{\mathsf{Real}}$$

for all displayed vector histories m, n : BHist*. The metric classifier on all displayed distances is* RealConstantHistoryClassifier*.*

A certified regular Cauchy stream s in this metric is assigned the limit e*. Its convergence witness sends every requested real precision to the same singleton carrier endpoint: each term of s is ρ_{e}-classified with* e*, and each displayed distance to the limit is* RealConstantHistoryClassifier*-classified with $0^{\mathsf{c}}_{\mathsf{Real}}$.*

Theorem 90.4 (Banach singleton carrier semantic NameCert)**.** *The singleton Banach carrier of Definition 90.3, equipped with the classifier which relates two carried histories exactly when their carried rows are present and the histories are* hsame*-classified, forms a* SemanticNameCert *for the singleton Banach surface. Its inhabited carrier is witnessed by* e*; its reflexive, symmetric, and transitive classifier fields are the corresponding* hsame *rows; its carrier transport field is the carrier projection of the classifier triple; and its pattern and ledger soundness fields are identity reads of the carried singleton Banach rows.*

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingletonCarrier semanticNameCert`

Proof. Use Definition 90.3 to read the carried object as the singleton empty-history norm carrier together with its norm-induced empty-distance metric row. The inhabited carrier row is the history e, with its singleton vector row and the MetricDistanceWitness(e, e, e) row supplied by empty-distance exactness.

The classifier row is the carried pair together with hsame. Hence reflexivity, symmetry, and transitivity are the corresponding hsame operations, with the carried rows retained on each side of the comparison. Carrier preservation is projection from the classifier triple: an accepted comparison already contains both endpoint carrier witnesses.

Finally apply Definition 90.13. It identifies the singleton Banach carrier, classifier, norm rows, and constant-zero metric rows. The pattern and ledger soundness clauses therefore read back the same carried singleton rows, with no additional transport beyond the displayed hsame comparison and the empty-distance metric witness. □

Theorem 90.5 (Banach norm-induced metric compatibility)**.** *For the singleton empty-history* $\mathsf{Norm}^\uparrow$ *instance of Definition 89.1, read through the singleton metric carrier and the relation*

MetricDistanceWitness, *the induced Banach metric row is the constant RealUp zero endpoint row. Concretely, for carried vector histories* m, n : BHist, *the Banach distance between* m *and* n *is classified by* 0^{c}_{Real} *exactly when*

$$\rho_{\mathsf{e}}(m, n)$$

holds.

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton metric distance empty iff classifier`

Proof. First identify the singleton vector endpoints. By Definition 89.2, any two carried vectors in the singleton norm instance are related by ρ_{e}, and their constant norm endpoints are related by the RealUp constant-history classifier.

The zero side is exact by Definition 89.4. Thus the displayed norm value of the singleton difference is classified by 0^{c}_{Real} exactly when the underlying vector endpoint is classified with the singleton zero vector.

Finally read the same endpoint row through the metric carrier. The metric row with empty distance is equivalent, by Definition 57.7, to both endpoints being hsame to e. The singleton vector classifier is precisely the collapse relation on those carried endpoints, so the norm-zero row and the empty-distance metric row classify the same pairs m, n. □

Lemma 90.6 (Concrete Banach downstream coverage)**.** *For the concrete* $\mathsf{Banach}^{\uparrow}$ *packet whose complete normed carrier is specified in Definition 90.2 and whose singleton semantic certificate is supplied by Definition 90.4, every accepted local consumer visible before a Hilbert, bounded-operator, or limit export is exhausted by the following displayed Banach rows:*

C_V, $\sim_V$, 0_V, $x -_V y$, ν, $d_\nu(x, y)$, BanachMetricWitness, $\lim_{\nu}$, *modulus*, *uniqueness*, *and the ledger rows.*

In the singleton instance these rows reduce to e, ρ_{e}, ν_{e}, *the constant zero distance* d_{e}, *the* RealConstantHistoryClassifie *row, and the identity pattern and ledger reads of the semantic NameCert. Consequently a request for an anonymous metric row, host normed-space equality, quotient representative, selected limit outside the completion row, compactness argument, choice principle, ordinary non-singleton Banach bridge, or off-packet proof channel is not an accepted consumer of this BEDC packet.*

Proof. Unpack the complete normed carrier in Definition 90.2. Its coordinates are exactly the vector carrier C_V, the classifier $\sim_V$, the zero endpoint 0_V, the difference operation $x -_V y$, the scalar source over $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, the norm ν, and the norm-induced distance

$$d_\nu(x, y) := \nu(x -_V y).$$

The same definition also names the completion surface: for each regular Cauchy stream over d_ν it supplies a carried limit $\lim_\nu$, a convergence modulus, uniqueness up to $\sim_V$, and a ledger containing the norm rows, stream observations, moduli, proof indices, and rational comparison data. Thus a local consumer whose input is the complete normed carrier can only read one of these carrier, metric, completion, or ledger coordinates.

Now specialize this carrier to the singleton surface certified in Definition 90.4. The theorem, together with the transport theorem Definition 90.25, reads the inhabited carrier as e, the classifier fields as the displayed hsame rows, carrier transport as projection from the classifier triple, and pattern and ledger soundness as identity reads of the carried singleton Banach rows. Hence every accepted NameCert consumer is a read of the same singleton carrier, classifier, norm, metric, stream, modulus, limit, or ledger row; there is no additional semantic field through which a different analytic object could enter.

The finite alternatives in the statement are therefore just the possible local read positions of the two cited objects. A carrier or classifier consumer lands in $C_V, \sim_V, 0_V, x -_V y$ and, in the singleton case, in e and ρ_{e}. A metric consumer lands in ν, d_ν, and the displayed BanachMetricWitness row, which becomes ν_{e} and the constant zero distance d_{e}. A completion or limit consumer lands in the regular Cauchy stream row, selected limit, modulus, uniqueness certificate, and ledger rows named by the complete normed carrier, which the singleton semantic certificate reads back by identity.

All excluded alternatives ask for a coordinate not present in this list. An anonymous metric would bypass d_ν and BanachMetricWitness; host equality or quotient representatives would bypass $\sim_V$, ρ_{e}, and hsame; a selected limit outside the completion row would bypass $\lim_\nu$ and its modulus and uniqueness ledger; compactness, choice, an ordinary non-singleton Banach bridge, or an off-packet proof channel would add a proof source not named by either the complete normed carrier or the singleton semantic NameCert. Since acceptance at this local surface is acceptance through those displayed rows, such requests remain outside the BEDC packet. □

Definition 90.7 (Banach root obligation source)**.** *The Banach root obligation source is the paper-side source tuple whose carrier row is the concrete Banach carrier of Definition 90.1. Its distinguished concrete instance is the singleton carrier of Definition 90.3. Its metric row is the norm-induced Banach metric witness of Definition 90.5, and its completion row is the complete-metric interface of Definition 90.39.*

Thus the root source names one surface object: a carried history predicate, the hsame *classifier on representatives, the norm-induced metric ledger, and the regular Cauchy complete-metric witness family read at the Banach surface.*

Theorem 90.8 (Banach root carrier-classifier obligation)**.** *The Banach root obligation source of Definition 90.7 supplies the carried history predicate and the classifier transport field required by the* $\mathsf{NameCert}_{\mathsf{Banach}\uparrow}$ *surface. For the singleton root, the carried predicate is the singleton empty-history carrier, and every accepted classifier comparison transports the displayed carrier, vector, norm, and metric rows.*

Proof. Start with the source tuple of Definition 90.7. Its carrier component is the concrete Banach carrier of Definition 90.1, so the history predicate and the displayed norm rows are already part of the root data.

For classifier transport, apply Definition 90.25. It moves carried representatives, norm rows, induced metric rows, stream observations, modulus histories, limits, and late-observation ledgers componentwise along hsame.

In the singleton root, the carrier and classifier are fixed by Definition 90.3 and Definition 89.2. Hence the transport relation collapses to the singleton carrier comparison while still preserving every displayed Banach row. □

Lean4 ✓ `BEDC.Derived.BanachUp.BanachRoot carrier classifier obligation`

Theorem 90.9 (Banach root norm-metric obligation)**.** *The metric row carried by the Banach root obligation source is exactly the norm-induced metric witness, and this row is stable under the Banach carrier classifier. In the singleton root, the displayed distance between carried histories* $m, n : \mathsf{BHist}$ *is the RealUp zero endpoint row precisely along the singleton classifier comparison* $\rho_{\mathsf{e}}(m, n)$.

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton root norm metric obligation`

Proof. The metric component of the root source is defined to be the norm-induced Banach metric row. Applying Definition 90.5 identifies the singleton instance of this row with the constant RealUp zero endpoint exactly on the singleton classifier comparison.

For a general Banach candidate, apply Definition 90.20. It reads the distance predicate as the norm of a vector difference and supplies the metric laws demanded by the complete-metric surface.

Stability under replacement of representatives is the content of Definition 90.21. The norm values and the induced distances transport across the vector classifier, so the same metric row remains valid after the carrier classifier is applied. □

Theorem 90.10 (Banach root completion obligation)**.** *Every regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *input accepted by the Banach root obligation source has a carried Banach limit. Any two displayed limits for the same accepted input are equal up to the Banach classifier, and in the singleton root this classifier is the singleton empty-history classifier.*

Proof. First read the accepted input through the complete-normed carrier surface. Definition 90.22 supplies the carried limit endpoint, convergence modulus, and uniqueness row for regular Cauchy inputs over the induced metric.

Next place that displayed limit at the NameCert boundary. Apply Definition 90.40; the complete-metric row is accepted only through the Banach metric witness, so the produced package does not leave the root surface.

For uniqueness in the concrete singleton root, apply Definition 90.41. It converts any two Banach-surface complete-metric rows for the same stream into an hsame comparison of limits, and then into the singleton vector classifier ρ_{e}. □

Theorem 90.11 (Banach root NameCert surface)**.** *The Banach root obligation source assembles the paper-side* $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$ *surface. Its fields are the concrete carrier, the* hsame *classifier on carried representatives, the norm-induced metric row, the regular Cauchy completion row, the visible ledger for stream, modulus, limit, norm, distance, and comparison histories, and an absent standard-bridge slot. No ordinary Banach-space bridge is claimed by this root surface.*

Proof. The carrier and classifier fields are supplied by Definition 90.8. They bind the root surface to the carried history predicate and to componentwise hsame transport rather than to an external quotient.

The metric field is supplied by Definition 90.9. It identifies the Banach distance slot with the norm-induced metric witness and records that this row is stable under classifier transport.

The completion field is supplied by Definition 90.10. It turns every accepted regular Cauchy stream into a carried limit and records uniqueness up to the Banach classifier.

The ledger fields are exactly the rows named in Definition 90.7: carrier histories, stream observations, modulus histories, limit histories, norm rows, distance rows, and rational comparison rows. Since the source names no ordinary Banach-space bridge, the standard-bridge row is absent and the root surface is the concrete BEDC obligation package used by downstream Hilbert, topology, and bounded-operator consumers. □

Theorem 90.12 (Banach root downstream coverage)**.** *Every accepted local consumer of the Banach root obligation source of Definition 90.7 is exhausted by the displayed root alternatives: the carrier-classifier obligation of Definition 90.8, the norm-metric obligation of Definition 90.9, and the completion obligation of Definition 90.10. Thus any downstream read factors through the carried history predicate, the* hsame *classifier, the norm-induced metric ledger, the regular Cauchy stream and modulus rows, the carried limit row, the late-distance rows, and the corresponding*

$\mathsf{Rat}^{\uparrow}$ *comparison rows already enumerated by the source. No anonymous metric coordinate, selected representative, quotient limit, ambient completeness proof, or ordinary Banach-space bridge is exported by the root packet.*

Proof. Unfold the source tuple of Definition 90.7. Its carrier row is the concrete Banach carrier, its distinguished instance is the singleton empty-history carrier, its metric row is the norm-induced Banach metric witness, and its completion row is the complete-metric interface. The same definition lists the visible surface data as the carried history predicate, the hsame classifier on representatives, the norm-induced metric ledger, and the regular Cauchy complete-metric witness family read at the Banach surface.

A consumer asking for carrier or classifier data is therefore covered by Definition 90.8. That theorem supplies the carried history predicate and the classifier transport field, and, through Definition 90.25, in the singleton root it identifies the carrier comparison with the singleton empty-history classifier while preserving the displayed vector, norm, and metric rows.

A consumer asking for metric data is covered by Definition 90.9. The metric row is exactly the norm-induced metric witness, stable under the Banach carrier classifier, and in the singleton root the displayed distance is the RealUp zero endpoint row along ρ_{e}. Thus a metric-facing read has no separate anonymous metric slot: it must use the norm-distance ledger already named by the root source.

A consumer asking for completion data is covered by Definition 90.10. By Definition 90.22, every accepted regular Cauchy $\mathsf{StreamName}^{\uparrow}$ input is sent to a carried Banach limit, and any two displayed limits for the same accepted input are equal up to the Banach classifier. In the singleton root that classifier is again the singleton empty-history classifier, so a completion-facing read cannot introduce a second endpoint classifier or quotient limit.

Finally read the assembled surface through Definition 90.11. It records the visible ledger for stream, modulus, limit, norm, distance, and comparison histories, and it also records the absent standard-bridge slot. Since the source tuple has no further coordinate beyond these three obligation alternatives and their displayed ledgers, every accepted downstream local consumer factors through those rows. The excluded alternatives require coordinates not present in the root packet, so they remain outside the BEDC packet. □

90.2 The certificate

Theorem 90.13 (Singleton empty-history Banach carrier and classifier)**.** *For the concrete* $\mathsf{Banach}^{\uparrow}$ *carrier of Definition 90.3, every carried Banach vector is an* A_{e} *vector, every pair of carried Banach vectors is* ρ_{e}*-classified, and every displayed norm or metric distance is classified by* RealConstantHistoryClassifier *at the constant zero RealUp endpoint* 0^{c}_{Real}.

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingletonEmptyHistory carrier classifier`

Proof. The Banach carrier is definitionally the carrier of the singleton empty-history norm instance. Apply Definition 89.2. It supplies the A_{e} carrier row, the ρ_{e} classifier row for carried vectors, and the constant-real classifier row for the norm endpoints.

For the metric row, unfold d_{e}. Both distance endpoints are the same constant 0^{c}_{Real}, so the RealUp constant classifier row already used in Definition 89.2 supplies the displayed distance classification.

The vector endpoint collapse needed by downstream certificates is exactly Definition 47.4; it identifies all carried endpoints with e under ρ_{e}. □

Theorem 90.14 (Singleton empty-history Banach Cauchy completeness)**.** *Every regular Cauchy sequence in the singleton empty-history Banach carrier of Definition 90.3 has the constant limit* e*. For every carried term* s_i *in the sequence, the convergence rows are*

$$\rho_{\mathsf{e}}(s_i, \mathsf{e}) \quad \textit{and} \quad \mathsf{RealConstantHistoryClassifier}(d_{\mathsf{e}}(s_i, \mathsf{e}), 0^c_{\mathsf{Real}}).$$

Proof. The regular Cauchy hypothesis supplies carried terms in the norm carrier. By Definition 89.3, that norm carrier is closed over the singleton vector-space endpoint data and has the constant-zero norm law package.

Apply Definition 47.4 to each carried term s_i and to the singleton endpoint e. This gives $\rho_{\mathsf{e}}(s_i, \mathsf{e})$, so the chosen limit is accepted by the vector classifier without any search over candidate limits.

It remains to verify the metric convergence rows. Unfold d_{e}: every distance to the limit is definitionally 0^c_{Real}. The zero exactness theorem Definition 89.4 supplies the same constant-real zero boundary used by the norm, and the RealUp constant classifier gives $\mathsf{RealConstantHistoryClassifier}(d_{\mathsf{e}}(s_i, \mathsf{e}), 0^c_{\mathsf{Real}})$. □

Lean4 ✓ `BEDC.Derived.CompleteMetricUp.CompleteMetricLimitWitness singleton observation empty distance`

Theorem 90.15 (Singleton empty-history Banach NameCert obligations)**.** *The data of Definition 90.3 instantiate the local* $\mathsf{Banach}^{\uparrow}$ *naming-certificate obligation set: carrier, classifier, norm laws, metric Cauchy completeness, and ledger provenance are all supplied by the singleton empty-history* $\mathsf{Norm}^{\uparrow}$ *package and the constant-limit completeness witness above.*

↪variant `BEDC.Derived.BanachUp.BanachSingletonCarrier semanticNameCert`

Proof. Use Definition 90.13 for the carrier and classifier rows. Its Banach carrier is the same A_{e} carrier as the singleton $\mathsf{Norm}^{\uparrow}$ instance, and its metric classifier is the constant-real classifier on 0^c_{Real}.

Use Definition 89.3 for the norm-law rows and Definition 89.4 for exactness at the zero norm endpoint. These rows are already stated over the displayed ν_{e} norm and the same singleton vector carrier.

Finally, use Definition 90.14 for metric Cauchy completeness. The ledger is inherited from Definition 89.1: singleton vector-space source, RatUp zero witness, e-one constant-real seal, and the explicit constant-limit rule sending certified Cauchy streams to e. □

Theorem 90.16 (Banach regular Cauchy limit witness)**.** *Every regular Cauchy stream carried by the singleton norm-induced Banach metric has a row*

$$\mathsf{CompleteMetricLimitWitness}(C_{\mathsf{e}}, s, \mathsf{e}, \mathsf{e}, L_{\mathsf{e}})$$

whose selected limit is e*, whose modulus history is* e*, and whose late-observation ledgers are the empty-distance rows transported through Definition 90.5.*

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton complete metric limit empty witness`

Proof. Unfold the carried observations of the singleton norm-induced metric. Each observation of the regular Cauchy stream is a carried singleton vector history, hence collapses to e by the singleton vector classifier.

Use the selected singleton limit. The complete-metric singleton construction of Definition 128.3 supplies the carried limit e, the empty modulus, and the convergence ledger with rows $\mathsf{MetricDistanceWitness}(s(n), \mathsf{e}$ for every late observation.

Transport those metric rows back to the norm-induced presentation. By Definition 90.5, the empty-distance metric rows are exactly the rows whose norm endpoint is classified by the constant RealUp zero endpoint. These transported ledgers are the required L_{e} family, so the displayed package is a $\mathsf{CompleteMetricLimitWitness}$ for the singleton Banach stream. □

Theorem 90.17 (Banach limit classifier uniqueness)**.** *For any singleton normed stream s, any two Banach limit witnesses*

$$\mathsf{CompleteMetricLimitWitness}(C_{\mathsf{e}}, s, \mu_0, \ell_0, L_0) \quad \textit{and} \quad \mathsf{CompleteMetricLimitWitness}(C_{\mathsf{e}}, s, \mu_1, \ell_1, L_1)$$

have limits related by $\mathsf{hsame}(\ell_0, \ell_1)$*, and therefore by the singleton vector classifier* $\rho_{\mathsf{e}}(\ell_0, \ell_1)$*.*

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton limit classifier uniqueness`
Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton limit classifier unique`

Proof. Apply Definition 128.6 to the two displayed limit witnesses for the same stream. In the singleton carrier the separated point classifier is empty-history sameness, so the uniqueness conclusion gives $\mathsf{hsame}(\ell_0, \ell_1)$.

It remains to read the same relation as a vector classifier row. Both limits are carried singleton histories in their respective witness rows. Applying Definition 47.4 to the two carried limits collapses them to the singleton endpoint and repacks their hsame relation as $\rho_{\mathsf{e}}(\ell_0, \ell_1)$. □

Corollary 90.18 (Singleton empty-history Banach consumer determinacy)**.** *For the concrete* $\mathsf{Banach}^{\uparrow}$ *object of Definition 90.3, every accepted consumer-facing read of a singleton normed stream s is determined by the finite rows*

$$A_{\mathsf{e}},\ \rho_{\mathsf{e}},\ \nu_{\mathsf{e}},\ d_{\mathsf{e}},\ \mathsf{RealConstantHistoryClassifier}(-, 0^{c}_{\mathsf{Real}}),\ \mathsf{CompleteMetricLimitWitness}(C_{\mathsf{e}}, s, \mu, \ell, L).$$

In particular, any two accepted choices of Banach limit route, vector normal form, distance normal form, or zero-exactness decision for the same displayed singleton stream have the same readback: the limit is classified with e *by* ρ_{e}*, every displayed distance is classified with* 0^{c}_{Real}*, and there is no accepted alternate hidden coordinate or duplicate classifier source for the consumer read.*

Proof. The local admission surface is fixed by Definition 90.15. Its rows are exactly the singleton $\mathsf{Norm}^{\uparrow}$ carrier and classifier, the norm-law and zero-exactness rows, the metric Cauchy-completeness row, and the ledger provenance inherited from the singleton norm certificate. Thus an accepted consumer read can project the displayed A_{e} carrier, the ρ_{e} vector classifier, the constant norm ν_{e}, the constant metric d_{e}, the constant RealUp classifier at 0^{c}_{Real}, and the complete-metric limit-witness row. The certificate provides no separate coordinate for another point classifier, another metric classifier, or another source of limits.

Consider first two accepted limit routes for the same stream s:

$$\mathsf{CompleteMetricLimitWitness}(C_{\mathsf{e}}, s, \mu_0, \ell_0, L_0) \quad \text{and} \quad \mathsf{CompleteMetricLimitWitness}(C_{\mathsf{e}}, s, \mu_1, \ell_1, L_1).$$

By Definition 90.17, the two displayed limits are related by $\mathsf{hsame}(\ell_0, \ell_1)$ and hence by the singleton vector classifier $\rho_{\mathsf{e}}(\ell_0, \ell_1)$. Since both limits are carried by their witness rows, Definition 47.4 collapses each carried endpoint to the singleton endpoint e. Therefore the consumer-facing limit normal form is forced to be the same ρ_{e}-class of e.

For the distance and exactness readbacks, unfold the concrete Banach object. By Definition 90.13, every carried pair is ρ_{e}-classified and every displayed norm or metric endpoint is read by $\mathsf{RealConstantHistoryClassifier}$ at 0^c_{Real}. The metric compatibility theorem Definition 90.5, read with the classifier-transport row Definition 90.25, identifies the empty-distance row with the same ρ_{e} classifier, while Definition 89.4 identifies the zero-norm exactness decision with $\rho_{\mathsf{e}}(m, \mathsf{e})$ for every carried vector endpoint m. Hence the vector normal form, distance normal form, and zero-exactness decision all pass through the same singleton classifier and the same constant RealUp zero row.

Combining these readings, any accepted consumer use factors through the listed finite route. A proposed alternate limit selector, hidden coordinate, or duplicate classifier source would have to supply a carrier, classifier, metric, or exactness row outside the rows fixed by Definition 90.15; such a row is not part of the accepted singleton empty-history $\mathsf{Banach}^{\uparrow}$ surface. □

Theorem 90.19 (Norm-induced metric completeness)**.** *For every concrete Banach carrier X of Definition 90.1, the supplied family of* $\mathsf{CompleteMetricLimitWitness}$ *rows makes the norm-induced metric on X complete: every regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream over X for* $\mathsf{BanachMetricWitness}_X$ *has a carried limit history, an explicit modulus history, and late-observation distance ledgers bounded by each positive* $\mathsf{Rat}^{\uparrow}$ *tolerance.*

Proof. Unfold the carrier tuple in Definition 90.1. A regular Cauchy stream over X is already part of the input shape accepted by the completeness field: its observations are carried by the $\mathsf{Norm}^{\uparrow}$ carrier and its pairwise distance rows are exactly the displayed $\mathsf{BanachMetricWitness}_X$ rows obtained from norm values.

Apply the displayed completeness family to the stream. It returns the modulus history, the carried limit history, and the late-observation ledger family appearing in $\mathsf{CompleteMetricLimitWitness}(X, s, \mu_s, \ell_s, L_s)$. By Definition 128.2, those rows are precisely the complete-metric convergence data for the metric carrier.

The norm side supplies no hidden quotient step. The classifier used at the limit is hsame transport on representatives, so the returned rows remain inside the same BEDC history carrier and are accepted as the completeness witness for the norm-induced metric. □

Theorem 90.20 (Banach norm-induced metric obligations)**.** *For any* $\mathsf{Banach}^{\uparrow}$ *candidate of Definition 90.2, the distance predicate $d_\nu(x, y) = \nu(x -_V y)$ satisfies the* $\mathsf{Met}^{\uparrow}$ *witness obligations on the vector carrier C_V: it is RealUp-valued and non-negative, it is zero exactly on $\sim_V$-classified endpoints, it is symmetric, and it satisfies the triangle inequality*

$$d_\nu(x, z) \leq d_\nu(x, y) + d_\nu(y, z)$$

for carried $x, y, z : C_V$.

Lean4 ✓ `BEDC.Derived.BanachUp.BanachMetricInducedByNorm`

Proof. The RealUp carrier and non-negativity rows are exactly the codomain and non-negativity clauses of the supplied $\mathsf{Norm}^{\uparrow}$ norm. For carried endpoints x and y, the vector-space difference $x -_V y$ is carried by the $\mathsf{VecSpace}^{\uparrow}$ additive stability rows, so applying ν gives a carried RealUp distance.

Zero exactness is the positive-definiteness clause of $\mathsf{Norm}^{\uparrow}$ applied to the difference endpoint $x -_V y$. The vector-space additive inverse and zero laws identify $x -_V y$ with 0_V exactly when $x \sim_V y$, and classifier transport converts this vector statement into the displayed distance-zero statement.

For symmetry, the vector-space inverse law identifies $x -_V y$ with the additive inverse of $y -_V x$. The $\mathsf{Norm}^{\uparrow}$ absolute-homogeneity row for the scalar -1 and the RealUp absolute-value row $|-1| = 1$ show that the two norm values are classified by the RealUp classifier.

For the triangle inequality, use the vector identity $x -_V z \sim_V (x -_V y) +_V (y -_V z)$. Norm transport moves ν across this classifier comparison, and the triangle-inequality row of $\mathsf{Norm}^{\uparrow}$ bounds the right-hand side by $\nu(x -_V y) + \nu(y -_V z)$. This is the required $\mathsf{Met}^{\uparrow}$ triangle row for d_ν. □

Theorem 90.21 (Banach classifier transport obligation)**.** *For any* $\mathsf{Banach}^{\uparrow}$ *candidate of Definition 90.2, if* $x \sim_V x'$ *and* $y \sim_V y'$ *with all four endpoints carried by* C_V*, then the norm values and induced distances transport:*

$$\mathsf{RealClassifier}(\nu(x), \nu(x'))$$

and

$$\mathsf{RealClassifier}(d_\nu(x, y), d_\nu(x', y')).$$

Lean4 ✓ `BEDC.Derived.BanachUp.BanachClassifierTransportObligation`

Proof. The first displayed row is the norm-transport stability obligation contained in the $\mathsf{Norm}^{\uparrow}$ certificate. It reads the vector classifier comparison $x \sim_V x'$ and returns the RealUp classifier comparison between the two norm values.

For the distance row, apply the $\mathsf{VecSpace}^{\uparrow}$ congruence laws to the two input classifier comparisons. They transport additive inverse and addition, giving $x -_V y \sim_V x' -_V y'$ in the vector classifier.

Applying the same norm-transport row to this difference comparison yields $\mathsf{RealClassifier}(\nu(x -_V y), \nu(x' -_V y'))$. Unfolding the definition of d_ν on both sides gives the stated distance transport. □

Theorem 90.22 (Banach regular Cauchy completion obligation)**.** *For any* $\mathsf{Banach}^{\uparrow}$ *candidate of Definition 90.2, every regular Cauchy sequence* $(X, \mu) : \mathbb{N} \to C_V$ *for the induced metric* d_ν *has the supplied limit endpoint* $\lim_\nu(X, \mu) : C_V$*. The endpoint comes with an explicit convergence modulus for* d_ν*, and any two endpoints satisfying the same regular Cauchy limit specification are classified by* $\sim_V$*.*

Proof. The regular Cauchy input contains a carried vector endpoint X_n at each index and a modulus μ witnessing that the distances $d_\nu(X_m, X_n)$ enter every requested positive RealUp tolerance after $\mu(\varepsilon)$. By Definition 90.20, these distances are legitimate $\mathsf{Met}^{\uparrow}$ distances.

The completion row in the carrier definition is then applied directly to (X, μ). It returns the carried endpoint $\lim_\nu(X, \mu)$, the convergence modulus, and the ledger entries recording the modulus calls and the norm rows used to read each distance.

If p and q are two carried endpoints satisfying the same limit specification, the real-completeness capstone supplies uniqueness of the RealUp distance-to-zero limit for the two difference sequences $X_n -_V p$ and $X_n -_V q$. The vector-space subtraction identity rewrites $p -_V q$ through those two tails, and the positive-definiteness row of $\mathsf{Norm}^{\uparrow}$ reflects distance zero back to $p \sim_V q$. □

Theorem 90.23 (Banach zero-sequence limit obligation)**.** *For any* $\mathsf{Banach}^{\uparrow}$ *candidate of Definition 90.2, the constant sequence* $Z_n = 0_V$ *is regular Cauchy for the induced metric* d_ν*, and its supplied completion endpoint is classified with the vector zero:*

$$\lim_\nu(Z, \mu_0) \sim_V 0_V$$

for the constant zero modulus μ_0*.*

Proof. The vector zero endpoint is carried by the $\mathsf{VecSpace}^{\uparrow}$ zero row, so the constant sequence $Z_n = 0_V$ is a sequence in C_V. For any pair of indices, $Z_m -_V Z_n$ is classified with 0_V by the additive identity and inverse laws.

Positive definiteness and norm transport convert that vector zero comparison into RealUp distance zero. Thus every requested tolerance is met by the constant modulus μ_0, and the sequence is regular Cauchy for d_ν.

Apply Definition 90.22 to obtain the completion endpoint and its convergence modulus. The endpoint 0_V itself satisfies the same limit specification by the preceding distance-zero row, so the uniqueness part of the completion obligation classifies $\lim_\nu(Z, \mu_0)$ with 0_V. □

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton zero sequence limit obligation`

Theorem 90.24 (Banach certificate obligation assembly)**.** *The data of a* $\mathsf{Banach}^{\uparrow}$ *candidate in Definition 90.2, together with the four obligation rows of Definition 90.20, Definition 90.21, Definition 90.22, and Definition 90.23, assemble the paper-side* $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$ *obligation set. Its carrier is* C_V*, its classifier is* $\sim_V$*, its metric witness is* d_ν*, its stability rows are vector classifier transport through* ν *and* d_ν*, its ledger is the norm ledger together with all regular Cauchy moduli and proof indices, and its completion row is the supplied* $\lim_\nu$ *operation with uniqueness up to* $\sim_V$*.*

Proof. The carrier and classifier fields are copied from the underlying $\mathsf{VecSpace}^{\uparrow}$ certificate, and the norm field is copied from the supplied $\mathsf{Norm}^{\uparrow}$ certificate. By Definition 90.20, the expression $d_\nu(x, y) = \nu(x -_V y)$ supplies the metric witness expected by $\mathsf{Met}^{\uparrow}$.

The stability fields are the transport rows of Definition 90.21. They show that both norm values and induced distances are invariant under the vector classifier, which is the exact endpoint-respect condition required by the naming certificate.

The completion fields are supplied by Definition 90.22. The special zero row of Definition 90.23 anchors the certificate at the vector zero and records that the completion operation agrees with the vector structure on the constant zero sequence.

Combining these rows gives the ten-field fit: traditional target Banach spaces; BEDC source $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$ plus the RealUp completion capstone; carrier C_V; classifier $\sim_V$; stability norm and distance transport; ledger norm provenance, moduli, and proof indices; core theorem the completion obligation; exactness zero distance iff vector classifier equality; standard bridge ordinary complete normed vector spaces; status $\mathsf{ProofTarget}$. □

Theorem 90.25 (hsame transport of Banach carriers)**.** *Let* X *be a concrete Banach carrier. If carried representatives, norm rows, metric rows, regular Cauchy stream observations, modulus histories, limit histories, and late-observation ledgers are transported componentwise along* hsame*, then the transported package is again a concrete Banach carrier. The transported carrier preserves the* $\mathsf{Norm}^{\uparrow}$ *classifier fields and the complete-metric limit-witness fields.*

Proof. Unpack the Banach carrier as the tuple of Definition 90.1. The first component is the $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$ carrier package, so its carrier, classifier, norm value, and algebraic law rows transport along the given hsame histories by the stability fields of that certificate.

The metric row is induced from the transported norm row. Transport the two endpoints, the displayed difference history, and the $\mathsf{Real}^{\uparrow}$ norm value; then repack these transported ledgers as $\mathsf{BanachMetricWitness}_X$ for the transported representatives.

For the completeness component, apply Definition 128.4. The hypotheses named in the theorem are exactly the transported stream observations, modulus history, limit history, thresholds, distance histories, and $\mathsf{Rat}^{\uparrow}$ comparison rows. The result is a transported $\mathsf{CompleteMetricLimitWitness}(X, s', \mu', \ell', L')$.

Combining the transported norm package, the induced metric row, and the transported complete-metric witness family gives the transported concrete Banach carrier. Since every field was moved by hsame and then repacked componentwise, the norm and limit-witness fields are preserved exactly in the paper-side classifier. □

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton hsame transport package`

Theorem 90.26 (Complete-metric witness exactness for Banach carriers)**.** *For a concrete Banach carrier X, the displayed predicate*

$$\mathsf{CompleteMetricLimitWitness}(X, s, \mu, \ell, L)$$

is exact for regular Cauchy streams over the norm-induced metric. Coverage holds because every accepted regular Cauchy stream receives such a row from the Banach completeness family. Soundness holds because any displayed row contains carried observations, a carried limit, metric-distance rows, and $\mathsf{Rat}^{\uparrow}$ *convergence bounds. Completeness holds because the real-completeness capstone supplies the diagonal regular-Cauchy limit rows consumed by* $\mathsf{NameCert}_{\mathsf{CompleteMetric}^{\uparrow}}$.

Proof. For coverage, start with an accepted regular Cauchy stream over X. The last field of Definition 90.1 assigns the histories μ_s, ℓ_s, L_s and the row $\mathsf{CompleteMetricLimitWitness}(X, s, \mu_s, \ell_s, L_s)$, so the displayed predicate covers the stream.

For soundness, unfold Definition 128.2. A displayed row contains the carried-observation ledger, the explicit modulus, the carried limit, the threshold history for each positive tolerance, and the metric distance and $\mathsf{Rat}^{\uparrow}$ comparison rows for every late observation. Since the metric row is $\mathsf{BanachMetricWitness}_X$, each distance is a norm value of a difference history supplied by $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$.

For completeness of the displayed predicate, use the real-completeness capstone through the $\mathsf{CompleteMetric}^{\uparrow}$ interface. The capstone supplies the diagonal regular-Cauchy limit construction, while Definition 128.5 packages the stream, modulus, limit, metric-distance rows, and rational bounds as a complete-metric witness. Replacing the metric-distance rows by their norm-induced representatives gives the Banach witness without changing the BEDC histories being transported. □

Theorem 90.27 (Banach norm-induced metric row)**.** *Let X be a concrete Banach carrier. For carried histories x, y and a displayed* $\mathsf{Norm}^{\uparrow}$ *difference row with RealUp norm-value endpoint d, the row*

$$\mathsf{BanachMetricWitness}_X(x, y, d)$$

is exactly the metric-distance row consumed by $\mathsf{CompleteMetric}^{\uparrow}$*. If the endpoints, difference history, and RealUp norm value are transported along* hsame*, the transported row is again the same CompleteMetricUp metric-distance row for the transported endpoints.*

Proof. Unfold Definition 90.1. Its metric predicate is defined by the carried endpoints, the displayed $\mathsf{Norm}^{\uparrow}$ difference history, and the RealUp norm value of that difference, so no further quotient or hidden classifier layer is inserted before the CompleteMetricUp metric slot.

The endpoint and difference-history transport clauses are the classifier and carrier stability fields already present in the $\mathsf{Norm}^{\uparrow}$ certificate. They move carried vector histories and their displayed difference rows along hsame without changing the represented BEDC history data.

The RealUp value row transports by the norm-value stability supplied by the same $\mathsf{Norm}^{\uparrow}$ certificate. Repacking the transported endpoints, transported difference row, and transported RealUp value gives $\mathsf{BanachMetricWitness}_X(x', y', d')$, which is precisely the transported CompleteMetricUp distance row. □

Theorem 90.28 (Banach regular Cauchy stream input)**.** *Let X be a concrete Banach carrier. A regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream whose observations are carried by X and whose pairwise distance observations are rows*

$$\mathsf{BanachMetricWitness}_X(s_m, s_n, d_{m,n})$$

is an admissible input for the completeness family in Definition 90.1. Its stream observations, modulus history, pairwise norm-distance rows, and $\mathsf{Rat}^{\uparrow}$ *rational bounds are exactly the CompleteMetricUp regular-Cauchy input shape.*

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton regular cauchy stream input`

Proof. The stream supplies carried observations in X, and each displayed pairwise-distance row is a Banach metric row. By Definition 90.27, each of those rows is already the metric-distance row expected by the CompleteMetricUp interface.

The regular Cauchy modulus is the same history used by CompleteMetricUp: for each positive $\mathsf{Rat}^{\uparrow}$ tolerance it returns the threshold after which all displayed pairwise distances are bounded by that tolerance. The rational-bound ledgers therefore require no reshaping beyond listing them with the stream indices and tolerance history.

Repacking the carried observations, the modulus history, the Banach metric-distance rows, and the $\mathsf{Rat}^{\uparrow}$ comparisons gives precisely the input accepted by the completeness family in Definition 90.1. □

Theorem 90.29 (Banach real-completeness limit consumption)**.** *Let X be a concrete Banach carrier and let s be a regular Cauchy stream admissible by Definition 90.28. When the Phase Real and completion diagonal-limit capstone supplies the regular-Cauchy limit rows for the norm-distance stream, then Definition 128.5 converts the modulus, carried limit ℓ, BanachMetricWitness distance rows, and* $\mathsf{Rat}^{\uparrow}$ *bounds into*

$$\mathsf{CompleteMetricLimitWitness}(X, s, \mu, \ell, L).$$

Proof. First convert the stream into CompleteMetricUp input form by Definition 90.28. This identifies every pairwise Banach distance with the corresponding CompleteMetricUp metric-distance row through Definition 90.27.

The real-completeness capstone supplies the diagonal regular-Cauchy limit rows for the RealUp norm-distance data. These rows provide the carried limit, the convergence modulus, the late-observation distance histories, and the positive $\mathsf{Rat}^{\uparrow}$ comparison bounds demanded by the CompleteMetricUp target.

Apply Definition 128.5 to this modulus, limit, distance ledger, and rational-bound ledger. Since the distance ledger has already been identified with the Banach norm-induced metric row, the resulting witness is $\mathsf{CompleteMetricLimitWitness}(X, s, \mu, \ell, L)$ for the original Banach stream. □

Theorem 90.30 (Banach NameCert obligation package)**.** *The data of Definition 90.1, together with Definition 90.19, Definition 90.25, and Definition 90.26, Definition 90.27, Definition 90.28, and Definition 90.29, assemble the paper-side* $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$ *obligation package. Its fields are the* $\mathsf{Norm}^{\uparrow}$ *carrier, the* hsame *classifier on representatives, the norm-induced metric ledger, the concrete metric-distance rows, the regular Cauchy input shape, the capstone-to-limit consumption row, the complete-metric limit-witness family, the transport stability clauses, the exactness clauses for displayed regular Cauchy limits, and the visible ledger policy inherited from* $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$ *and* $\mathsf{NameCert}_{\mathsf{CompleteMetric}^{\uparrow}}$.

Proof. The carrier field is the predicate $X : \mathsf{Hist} \to \mathsf{Prop}$ equipped with the displayed $\mathsf{Norm}^{\uparrow}$ data and the induced $\mathsf{BanachMetricWitness}_X$ relation of Definition 90.1. The classifier field is hsame transport on representatives, so the certificate compares histories by visible representative transport rather than by a host quotient.

The stability field is supplied by Definition 90.25. It moves the norm rows, metric rows, stream rows, modulus histories, limit histories, and late-observation ledgers componentwise and then repacks them as the same Banach carrier structure.

The completeness and exactness fields are supplied by Definition 90.19 and Definition 90.26. These theorems show that every regular Cauchy stream over the norm-induced metric has a displayed $\mathsf{CompleteMetricLimitWitness}$ row, and that every such row has exactly the carried observations, carried limit, norm-distance rows, and rational comparison bounds demanded by $\mathsf{NameCert}_{\mathsf{CompleteMetric}^{\uparrow}}$.

The concrete witness-row boundary is supplied by Definition 90.27 and Definition 90.28. The first theorem identifies the norm-induced Banach metric row with the CompleteMetricUp distance slot, and the second theorem repacks regular Cauchy streams with Banach distance rows into the input shape expected by the completeness family.

The limit-consumption boundary is supplied by Definition 90.29. It records that the real-completeness capstone rows are consumed through Definition 128.5 to produce the displayed $\mathsf{CompleteMetricLimitWitness}$ row for the Banach stream.

The ledger field is the union of the visible rows already named by $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$ with the stream, modulus, threshold, distance, and comparison rows of $\mathsf{NameCert}_{\mathsf{CompleteMetric}^{\uparrow}}$. The real-completeness capstone supplies the limit construction consumed by the complete-metric side, so all fields of the $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$ obligation package are accounted for constructively. □

Theorem 90.31 (Banach norm-completeness downstream coverage)**.** *For any* $\mathsf{Banach}^{\uparrow}$ *candidate of Definition 90.2, every accepted local consumer of the norm-induced metric completeness surface is exhausted by the displayed finite alternatives in this chapter. A consumer read must factor through one of the following rows: the norm-induced distance row* $d_\nu(x, y) = \nu(x -_V y)$ *of Definition 90.20, the classifier transport row of Definition 90.21, the regular Cauchy completion row of Definition 90.22, the zero-sequence anchor of Definition 90.23, or the assembled NameCert ledger of Definition 90.24. Thus all consumer-visible data are carried endpoints, norm-distance histories, regular Cauchy moduli, convergence moduli, limit endpoints, uniqueness up to* $\sim_V$*, and the ledger rows recording the norm and rational-bound reads. A quotient vector equality, host limit, detached RealUp completion selector, ambient compactness coordinate, countable choice selector, or unlisted metric coordinate is not exported by the* $\mathsf{Banach}^{\uparrow}$ *packet.*

Proof. Start with an accepted local consumer of the norm-induced completeness surface. Since the packet is the one assembled in Definition 90.24, the consumer can inspect only the fields named there: carrier C_V, classifier $\sim_V$, induced metric witness d_ν, stability rows for ν and d_ν, the ledger of orm provenance and regular Cauchy moduli, and the supplied completion operation with uniqueness up to $\sim_V$.

If the consumer reads a distance, the only available distance coordinate is $d_\nu(x, y) = \nu(x -_V y)$. The metric obligations of Definition 90.20 show that this is a legitimate $\mathsf{Met}^{\uparrow}$ row, and Definition 90.21 shows that changing representatives can only transport the same norm value and the same induced distance through the vector classifier. Hence a distance-facing consumer cannot introduce a second metric, a quotient distance, or a host-level endpoint comparison.

If the consumer reads a convergence claim, its input is a regular Cauchy sequence for d_ν. The completion row of Definition 90.22 is then the sole route: it returns the carried endpoint $\lim_\nu(X, \mu)$, an explicit convergence modulus, the ledger entries recording the modulus calls and the norm rows

used to read the distances, and uniqueness of any competing endpoint up to $\sim_V$. The zero-sequence case of Definition 90.23 is the corresponding anchored alternative when the stream is constant at 0_V; it supplies no additional route beyond the same completion and uniqueness rows.

These cases exhaust the assembly theorem. The stability branch is exactly classifier transport, the metric branch is exactly the norm-induced distance, the completion branch is exactly the regular Cauchy limit row, and the anchored branch is the constant-zero instance of that completion row. All remaining entries of the packet are ledger entries recording which norm, modulus, tolerance, and rational-bound rows were consumed. Since the carrier definition and assembly theorem list no coordinate for quotient vector equality, host limits, detached RealUp completion selectors, compactness, choice, or any extra metric, any route requiring one of those data is outside the BEDC packet. □

Theorem 90.32 (Banach complete-metric norm sibling route)**.** *Every* $\mathsf{Banach}^{\uparrow}$ *certificate route consumes the norm carrier of chapter 89, the completion interface of chapter 95, and the complete metric surface of chapter 128 before exporting bounded-linear-operator or limit rows. The Banach packet therefore reaches bounded-linear-operator and limit consumers through a finite ledger factorization, not through an unlisted analytic completeness principle.*

Proof. Read the Banach hub through its child files. The carrier and root NameCert rows expose a normed vector-space source, while the norm-completion certificate identifies the metric distance and regular Cauchy readback rows that the source must carry.

The completion interface is then consumed through the complete-metric NameCert interface. That child file binds the completion read to the complete metric surface before any limit certificate can be projected.

Finally the bounded-linear-operator and limit child files use those same rows as inputs. Their exports are therefore ledger factors over the displayed norm, completion, and complete-metric siblings, not separate claims of analytic completeness. □

Theorem 90.33 (Banach metric-norm completion sibling lattice)**.** *Every public* $\mathsf{Banach}^{\uparrow}$ *read factors through the displayed* $\mathsf{Norm}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows before a bounded-operator, fixed-point, or functional-analysis consumer inspects it. The available route is the norm-induced metric over the Banach carrier, the regular Cauchy stream and modulus surface, the complete-metric limit witness, and the RealUp distance readback recorded by chapter 89, chapter 57, chapter 128, chapter 301, chapter 126, and chapter 38.*

Proof. Read the Banach carrier through the norm-completion certificate. The files `norm_completion_certificate` and `complete_metric_namecert_interface` identify the metric coordinate as the $\mathsf{Norm}^{\uparrow}$-induced RealUp distance and identify accepted regular Cauchy inputs as $\mathsf{StreamName}^{\uparrow}$ observations equipped with displayed modulus and late-distance ledgers.

Next read the limit surface certificate. It exposes the same Banach carrier, stream observations, modulus history, carried limit row, norm-distance ledger, and consumed $\mathsf{CompleteMetric}^{\uparrow}$ witness before any downstream consumer receives a limit or bounded-operator row.

Thus a public Banach read has no independent metric island. Its metric, norm, completion, RegSeqRat, StreamName, and RealUp coordinates are the visible sibling lattice already displayed by the three child files, and all bounded-operator or fixed-point consumers can inspect only that finite route. □

The $\mathsf{Banach}^{\uparrow}$ lattice reads its complete normed source through the $\mathsf{NormedSpace}^{\uparrow}$ rows of chapter 1950 together with the completion-facing metric rows of chapter 128 and chapter 57. Thus a

Banach consumer receives bounded-operator or limit data only after the normed vector carrier, norm-induced distance, regular Cauchy stream, complete-metric limit witness, transport rows, replay rows, provenance, and local naming row have been displayed.

Lemma 90.34 (Banach normed complete-metric lattice anchor)**.** *Every* $\mathsf{Banach}^{\uparrow}$ *bounded-operator, limit, or functional-analysis export first factors through a* $\mathsf{NormedSpace}^{\uparrow}$ *source row and the* $\mathsf{CompleteMetric}^{\uparrow}/\mathsf{Met}^{\uparrow}$ *completion rows before it exposes any Banach-specific conclusion. The route supplies the normed carrier, scalar and additive rows, norm-induced distance, regular Cauchy observation, complete-metric limit witness, transport, replay, provenance, and local* $\mathsf{NameCert}$ *row. It supplies no detached host normed space, anonymous complete metric, selected limit outside the completion row, quotient carrier, or ambient completeness theorem.*

Proof. Read the Banach hub through its normed carrier and completion children. The $\mathsf{NormedSpace}^{\uparrow}$ source supplies the vector, scalar, additive, norm, and classifier rows used by the Banach carrier, while the $\mathsf{Met}^{\uparrow}$ row turns the displayed norm difference into the distance surface consumed by completion.

Next use the $\mathsf{CompleteMetric}^{\uparrow}$ completion interface. Its regular Cauchy stream, modulus, limit, and uniqueness rows are the only route by which the Banach packet can export completed-limit data to later bounded-operator or functional-analysis consumers.

The two source families are therefore jointly load-bearing. A downstream Banach read that omits either the normed-space rows or the complete-metric rows has no displayed coordinate from which to obtain a Banach limit, bounded-operator input, or completion-facing handoff. □

Definition 90.35 (Banach complete-normed template obligations)**.** *The* $\mathsf{Banach}^{\uparrow}$ *complete-normed template is the following ten-field paper target over the concrete carrier of Definition 90.2.*

1. *The traditional target is a complete normed vector space.*
2. *The BEDC source is* $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$ *together with* $\mathsf{CompleteMetricLimitWitness}$ *for the norm-induced metric.*
3. *The carrier is the complete normed* BHist *predicate* C_V*.*
4. *The point classifier is the displayed Banach classifier* $\sim_V$*, routed through* hsame *transport of representatives and ledgers.*
5. *The norm row is* $\nu : C_V \to \mathsf{Real}^{\uparrow}$ *with the RealUp classifier on norm values.*
6. *The metric row is* $d_\nu(x, y) := \nu(x -_V y)$*, displayed as the Banach metric witness consumed by* $\mathsf{CompleteMetric}^{\uparrow}$*.*
7. *Stability consists of norm transport, metric-distance transport, and complete-metric limit transport across the classifier.*
8. *Exactness records zero norm-distance exactly on* $\sim_V$*-classified endpoints and uniqueness of regular Cauchy limits up to* $\sim_V$*.*
9. *The ledger records the norm rows, stream observations, Cauchy moduli, limit rows, metric-distance rows, and* $\mathsf{Rat}^{\uparrow}$ *rational-comparison rows.*
10. *The status is a paper proof target for the* $\mathsf{Banach}^{\uparrow}$ *certificate surface.*

Theorem 90.36 (Banach norm-completion source scope)**.** *For any* $\mathsf{Banach}^{\uparrow}$ *candidate of Definition 90.2, the complete normed carrier supplies exactly the scoped* $\mathsf{Banach}^{\uparrow}$ *source obligations obtained from* $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{MetricDistanceWitness}$*,* $\mathsf{CompleteMetricLimitWitness}$*,*

and hsame. *These obligations are the carrier C_V, classifier $\sim_V$, norm ν, norm-induced metric d_ν, regular Cauchy stream input, completion witness, transport rows, and visible ledger fields named in Definition 90.35.*

Proof. First read the metric row from the norm. Apply Definition 90.20 to obtain the RealUp-valued metric, zero exactness, symmetry, and triangle row for d_ν.

Next read the stream and completion rows. Apply Definition 90.22 to every regular Cauchy $\mathsf{StreamName}^{\uparrow}$ stream for d_ν; the output is the carried limit, the convergence modulus, and uniqueness up to $\sim_V$.

Transport is supplied by Definition 90.25. It moves the carried representatives, norm rows, metric rows, stream observations, modulus histories, limit histories, and rational-comparison ledgers componentwise across hsame.

Finally apply Definition 90.30. Its fields are exactly the carrier, classifier, norm-induced metric, regular Cauchy input, complete-metric witness, transport, exactness, and ledger rows listed above, so the source scope contains no additional Banach obligation. □

Theorem 90.37 (Banach Hilbert downstream substrate)**.** *Let H be a* $\mathsf{Hilbert}^{\uparrow}$ *candidate whose inner-product norm induces the displayed Banach norm ν on the carrier C_V. Then the Banach data consumed by the Hilbert chapter are only the carrier C_V, the classifier $\sim_V$, the norm-induced metric row d_ν, and the* CompleteMetricLimitWitness *family fixed by Definition 90.35. This substrate does not assert Hilbert certificate closure or any operator theorem beyond those rows.*

Proof. Unpack the Hilbert input as an inner-product structure whose displayed norm is the same ν used by the Banach candidate. The Banach carrier and classifier are therefore copied directly as C_V and $\sim_V$.

The metric field required downstream is the norm-induced row. By Definition 90.20, $d_\nu(x, y) = \nu(x -_V y)$ is the metric row over the carried endpoints, and by Definition 90.21 it respects the classifier used by the Hilbert representative surface.

The completeness field is the same family consumed in Definition 90.22. Repack the carried limit endpoint, convergence modulus, uniqueness row, and visible ledger as the complete normed substrate named by the Hilbert chapter.

No inner-product law is inferred from these Banach rows. The Hilbert chapter must still supply the inner-product carrier, sesquilinear rows, positivity, and norm-induction proof at its own surface. □

Theorem 90.38 (Banach bounded-operator source closure)**.** *For* $\mathsf{Banach}^{\uparrow}$ *candidates C, D, the bounded-linear-operator carrier* $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ *of Definition 90.49 is well-scoped over the source and target Banach packages. Its endpoint action, bound row, Lipschitz row, Cauchy-stream transport row, and ledger fields use only the carrier, classifier, norm-induced metric, and completion data of C and D.*

Proof. Begin with the carrier of Definition 90.49. Its hypotheses already name the source and target Banach carriers, their classifiers, their norms, their induced distances, the endpoint map T, the RealUp bound K, and the ledger Λ.

Apply Definition 90.50. The proof reads both distances through Definition 90.20, transports the target difference across linearity of T, and uses the bound row in Λ to obtain the target distance estimate.

Apply Definition 90.51 to a regular Cauchy source stream. The transported observations are carried by D, and the source modulus is converted into a target modulus using the RealUp bound comparison for K.

Finally use Definition 90.72 for componentwise hsame transport of stream observations, modulus histories, candidate limits, distance rows, and rational-comparison ledgers. The resulting operator package preserves the source closure data while landing in the target Banach package, so the bounded-operator carrier is scoped over C and D alone. □

Closure status for $\mathsf{NameCert}_{\mathsf{Banach}^\uparrow}$.

Constructive story: The concrete Banach surface begins with the singleton empty-history norm instance: the only vector endpoint is the empty history, every carried vector is classified with that endpoint, the norm value is the constant $\mathsf{Real}^\uparrow$ zero row, and the induced metric distance between any two carried endpoints is the same zero row. The classifier is the singleton vector classifier routed through hsame and the constant real classifier, so accepted presentations are the same exactly when their vector, norm, metric, stream, modulus, and limit ledgers transport through the displayed rows rather than through a host normed-space equality. The source specification is the consumed $\mathsf{Norm}^\uparrow$ package together with $\mathsf{StreamName}^\uparrow$ regular Cauchy inputs and CompleteMetricLimitWitness rows for the norm-induced metric, while the pattern specification records zero norm-distance exactness, Cauchy completeness with selected limit e, uniqueness of limits up to the singleton classifier, and bounded-operator limit transport over the same source and target Banach rows. The ledger policy keeps the singleton vector-space source, RatUp zero witness, constant-real seal, norm rows, metric-distance rows, Cauchy moduli, late-observation rows, selected limit, and bounded-operator transport evidence visible. The five name-certificate obligations are forced by the singleton: e inhabits the carrier, reflexivity, symmetry, and transitivity come from hsame and the singleton classifier, and carrier closure is projection from any classified comparison because both endpoints already carry the same empty-history package. A history h lies in the signature gap of a $\mathsf{Banach}^\uparrow$ token p when the source-domain accepts it as this complete normed singleton package, the signature relation pairs it with an answer Banach row and evidence ledger, and the token-introduction relation names that answer as p; unfolded, h carries the zero norm, zero metric, and constant-limit data encoded by p. The standard bridge maps the BEDC singleton Banach row to the one-point complete normed vector space and reads the unique standard point back as e, preserving soundness, completeness, and roundtrip classifier rows. The chapter registers this complete-normed singleton construction under the name $\mathsf{Banach}^\uparrow$; non-singleton Banach spaces, Hilbert closure, operator-algebra closure, and checked bridge data are not introduced.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Banach}^\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: The mature paper-side scope binds the singleton SemanticNameCert of Definition 90.4, the complete-normed source obligations of this section, the bounded-operator limit surface of Definition 90.77, and the singleton standard bridge soundness, completeness, and roundtrip rows of Definition 90.80, Definition 90.81, and Definition 90.82.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Banach}^\uparrow}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.BanachUp.BanachSingleton\_standard\_bridge\_soundness`

Bridge status: bridgeChecked

Not claimed: This chapter does not claim bridgeChecked data, ordinary non-singleton Banach spaces, Hilbert closure, or operator-algebra closure.

Upgrade path: No further formal-axis work is recorded; the chapter is at the top formal status.

Definition 90.39 (Banach complete-metric NameCert interface)**.** *For a concrete Banach carrier X of Definition 90.1, a stream name s, a modulus history M, and a displayed limit history ℓ, the Banach complete-metric* NameCert *interface is the predicate*

$$\mathsf{CompleteMetricLimitWitness}(X, s, M, \ell)$$

read over the norm-induced Banach metric rows. Its visible ledger consists of the carrier row X, the carried observations of s, the modulus row M, the carried limit row ℓ, and the late-observation distance ledgers named as $\mathsf{BanachMetricWitness}_X(s(n), \ell, d_{n,\varepsilon})$ *together with the corresponding* $\mathsf{Rat}^\uparrow$ *comparison rows.*

Equivalently, the displayed row

$$\mathsf{CompleteMetricLimitWitness}(X, s, M, \ell, L)$$

is accepted at the Banach surface exactly when every metric-distance component of L is presented by the norm-induced Banach ledger $\mathsf{BanachMetricWitness}_X$ *rather than by an anonymous metric row. Thus the public interface exposes the same carrier X, stream s, modulus M, limit ℓ, and convergence ledgers consumed by* $\mathsf{NameCert}_{\mathsf{CompleteMetric}^\uparrow}$.

Lean4 ✓ BEDC.Derived.CompleteMetricUp.CompleteMetricLimitWitness empty limit rat positive
Lean4 ✓ BEDC.Derived.CompleteMetricUp.CompleteMetricLimitWitness row result alignment

Theorem 90.40 (Banach complete-metric NameCert coupling)**.** *Let X be a concrete Banach carrier, let s be a regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream over the norm-induced metric* $\mathsf{BanachMetricWitness}_X$*, let M be its displayed modulus, and let ℓ be a displayed limit. Carrier transport along* hsame*, together with a displayed Banach-surface row*

$$\mathsf{CompleteMetricLimitWitness}(X, s, M, \ell, L),$$

yields the SemanticNameCert *package for the predicate*

$$\mathsf{CompleteMetricLimitWitness}(X, s, M)$$

on limit histories. The coupling depends on Definition 90.1, Definition 90.25, Definition 90.26, and the complete-metric certificate theorem BEDC.Derived.CompleteMetricUp.CompleteMetricLimitWitness_name_certifi

Lean4 ✓ BEDC.Derived.CompleteMetricUp.CompleteMetricLimitWitness empty modulus observation metric row
Lean4 ✓ BEDC.Derived.CompleteMetricUp.CompleteMetricLimitWitness observation distance deterministic

Proof. Unpack the concrete Banach carrier. Its carrier component supplies the hsame transport operation on carried vector histories, and its norm component identifies each induced distance row with a displayed $\mathsf{BanachMetricWitness}_X$ row.

Next transport the complete-metric data componentwise. Use Definition 90.25 for the stream observations, modulus history, limit history, threshold rows, metric-distance rows, and $\mathsf{Rat}^{\uparrow}$ comparison rows. The result is still a Banach carrier package because the transported metric rows are repacked through the norm-induced ledger.

Now invoke the complete-metric NameCert constructor represented on the Lean side by BEDC.Derived.Complete Its carrier-transport input is the Banach carrier transport just extracted, and its witness input is the displayed row of Definition 90.39.

Finally apply Definition 90.26. It ensures that no metric row has left the Banach surface: every distance ledger used by the complete-metric package is the same norm-distance row displayed as $\mathsf{BanachMetricWitness}_X$. Repacking these rows gives the required SemanticNameCert for $\mathsf{CompleteMetricLimitWitness}(X, s, M)$. □

Theorem 90.41 (Banach singleton limit NameCert uniqueness)**.** *In the singleton empty-history Banach carrier of Definition 90.3, any two Banach-surface complete-metric rows for the same stream,*

$$\mathsf{CompleteMetricLimitWitness}(C_{\mathsf{e}}, s, M_0, \ell_0, L_0) \quad \textit{and} \quad \mathsf{CompleteMetricLimitWitness}(C_{\mathsf{e}}, s, M_1, \ell_1, L_1),$$

have $\mathsf{hsame}(\ell_0, \ell_1)$ *limits. Consequently the two displayed vector limits are classified by the singleton vector classifier $\rho_{\mathsf{e}}(\ell_0, \ell_1)$.*

Lean4 ✓ BEDC.Derived.CompleteMetricUp.CompleteMetricLimitWitness singleton classifier distance

Proof. First read both displayed rows through the interface of Definition 90.39. The carrier predicate is C_{e}, so each limit row is a singleton empty-history endpoint and each metric-distance row is the constant zero Banach metric row.

Apply the complete-metric singleton uniqueness theorem BEDC.Derived.CompleteMetricUp.CompleteMetricLimit to the two rows for the same stream. It returns $\mathsf{hsame}(\ell_0, \ell_1)$ because the complete-metric carrier is the singleton predicate $h \mapsto \mathsf{hsame}(h, \mathsf{e})$.

It remains to read that relation at the vector endpoint surface. The singleton Banach carrier is the singleton norm carrier, so Definition 47.4 converts the two carried limit endpoints and their hsame relation into the classifier row $\rho_{\mathsf{e}}(\ell_0, \ell_1)$. □

Corollary 90.42 (Banach complete-metric interface determinacy)**.** *In the singleton empty-history Banach carrier C_{e} of Definition 90.3, fix a stream name s and fix a displayed Banach complete-metric interface row*

$$\mathsf{CompleteMetricLimitWitness}(C_{\mathsf{e}}, s, M, \ell, L).$$

Every accepted consumer-facing use of this row factors through the same visible interface data: the carrier row C_{e}, the stream observations of s, the modulus row M, the carried limit row ℓ, the late-distance rows in L displayed as

$$\mathsf{BanachMetricWitness}_{C_{\mathsf{e}}}(s(n), \ell, d_{n,\varepsilon}),$$

and the corresponding $\mathsf{Rat}^{\uparrow}$ comparison rows. If a second accepted use for the same stream displays

$$\mathsf{CompleteMetricLimitWitness}(C_{\mathsf{e}}, s, M', \ell', L'),$$

then its limit normal form is the same singleton endpoint, classified by $\rho_{\mathsf{e}}(\ell, \ell')$. Thus the interface admits no alternate hidden metric coordinate, no anonymous distance classifier, and no duplicate endpoint classifier source beyond the rows named in Definition 90.39 and Definition 90.41.

Proof. Unfold the interface of Definition 90.39. An accepted Banach-surface row is not merely a complete-metric row with an unspecified metric component. Its visible ledger consists of the carrier C_{e}, the stream observations of s, the modulus history, the carried limit history, the late-observation distance rows, and the $\mathsf{Rat}^{\uparrow}$ comparison rows. The same definition requires every metric-distance component of the late ledger to be presented as a norm-induced Banach row $\mathsf{BanachMetricWitness}_{C_{\mathsf{e}}}$ rather than as an anonymous metric row. Hence any consumer use of the fixed row must read exactly these displayed coordinates.

For the singleton carrier, Definition 90.3 identifies the vector carrier with the empty-history singleton, the endpoint classifier with ρ_{e}, and the norm-induced metric distance with the constant RealUp zero row. Therefore each accepted distance entry in L has the fixed Banach source $\mathsf{BanachMetricWitness}_{C_{\mathsf{e}}}(s(n), \ell, d_{n,\varepsilon})$, and the only exactness decision available at the complete-metric slot is the one that keeps this norm-induced row at the Banach surface.

Now compare any second accepted use for the same stream. Both displayed rows are Banach-surface complete-metric rows for C_{e}, so Definition 90.41 applies to them. It first gives $\mathsf{hsame}(\ell, \ell')$ and then reads that comparison as the singleton vector classifier $\rho_{\mathsf{e}}(\ell, \ell')$. Thus an alleged alternate limit normal form is already classified by the same singleton endpoint row. Since the interface ledger has no additional carrier coordinate, no extra metric slot, and no classifier other than the displayed singleton classifier, every accepted consumer-facing use factors through the listed finite Banach route. □

90.3 Banach limit surface certificate

Definition 90.43 (Banach limit surface certificate)**.** *For a concrete Banach carrier X of Definition 90.1, a regular $\mathsf{StreamName}^{\uparrow}$ stream s, a displayed modulus history M, a displayed limit*

history ℓ, and a late-distance ledger Λ, the Banach limit surface certificate is the predicate

$$\mathsf{BanachLimitSurface}_X(s, M, \ell, \Lambda).$$

It consists of the carried BHist *stream observations of s, the componentwise* hsame *transport rows for the observations, the modulus history M, and the limit history ℓ, the displayed* $\mathsf{BanachMetricWitness}_X$ *rows in Λ, and the* $\mathsf{CompleteMetricLimitWitness}(X, s, M, \ell, \Lambda)$ *row that consumes those distance rows.*

The ten-field template is fixed as follows. The traditional target is the Banach limit interface for regular Cauchy streams. The BEDC source is $\mathsf{Norm}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *and the* $\mathsf{Real}^{\uparrow}$ *comparison rows used by the displayed norm distances. The carrier is the concrete Banach carrier X. The classifier is* hsame *on carried representatives together with the* RealClassifier *on norm distances. Stability is supplied by Definition 90.21. The ledger records the stream observations, the modulus M, the endpoint ℓ, the norm-distance rows in Λ, and the* $\mathsf{Rat}^{\uparrow}$ *comparison rows.*

The core theorem list is Definition 90.44, Definition 90.45, Definition 90.46, and Definition 90.47. Exactness is the equivalence between the displayed $\mathsf{BanachMetricWitness}_X$ *rows and the* CompleteMetricLimitWitness *rows they feed. The standard bridge field is absent. The status is a paper proof target in* BEDC.Derived.BanachUp.

Theorem 90.44 (Banach limit surface endpoint coverage)**.** *Any displayed row*

$$\mathsf{BanachLimitSurface}_X(s, M, \ell, \Lambda)$$

exposes the carried Banach endpoint X, the carried $\mathsf{StreamName}^{\uparrow}$ *observations of s, the modulus history M, the carried limit history ℓ, every displayed* $\mathsf{BanachMetricWitness}_X$ *distance row in Λ, and the corresponding* $\mathsf{CompleteMetricLimitWitness}(X, s, M, \ell, \Lambda)$ *row.*

Proof. Unfold Definition 90.43. The first displayed fields are exactly the carrier X, the stream observations of s, the modulus history M, and the carried limit history ℓ.

The next displayed fields are the ledger rows. Projecting them gives each $\mathsf{BanachMetricWitness}_X$ distance row in Λ together with the $\mathsf{Rat}^{\uparrow}$ comparison rows attached to the same late-observation entry.

The final displayed field is the consumed complete-metric row. Projecting it gives $\mathsf{CompleteMetricLimitWitness}(X$ with the same carrier, stream, modulus, endpoint, and distance ledger. □

Theorem 90.45 (Banach limit surface classifier transport)**.** *Let* $\mathsf{BanachLimitSurface}_X(s, M, \ell, \Lambda)$ *be displayed. Componentwise* hsame *transport of the stream observations, modulus history, limit endpoint, distance histories, and comparison ledgers preserves the predicate* $\mathsf{BanachLimitSurface}_X$ *for the transported data.*

Proof. Start with the stream and endpoint rows. Apply Definition 90.72 to the transported observations, modulus history, limit history, norm-distance rows, and $\mathsf{Rat}^{\uparrow}$ comparison rows. This keeps the regular Cauchy input and the convergence ledger in the Banach complete-metric shape.

Next transport the norm and distance classifiers. For each carried endpoint comparison in the stream and the candidate limit, use Definition 90.21 to obtain the transported RealClassifier rows for the corresponding norm values and induced distances.

Finally repackage the transported complete-metric row. Apply Definition 90.40 to the transported carrier rows, the transported $\mathsf{BanachMetricWitness}_X$ ledger, and the transported CompleteMetricLimitWitness row. The resulting package is precisely the transported $\mathsf{BanachLimitSurface}_X$ row. □

Theorem 90.46 (Banach limit surface uniqueness)**.** *Let X be a concrete Banach carrier and let s be a regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream over X. If*

$$\mathsf{BanachLimitSurface}_X(s, M_0, \ell_0, \Lambda_0)$$

and

$$\mathsf{BanachLimitSurface}_X(s, M_1, \ell_1, \Lambda_1)$$

are displayed for the same stream, then the carried limit histories are classified by hsame*. In the singleton empty-history carrier this classification is the singleton classifier row $\rho_{\mathsf{e}}(\ell_0, \ell_1)$.*

Proof. First project both surface rows through Definition 90.44. This exposes the two complete-metric rows $\mathsf{CompleteMetricLimitWitness}(X, s, M_0, \ell_0, \Lambda_0)$ and $\mathsf{CompleteMetricLimitWitness}(X, s, M_1, \ell_1, \Lambda_1)$ for the same regular Cauchy stream.

Apply Definition 90.71 to these two rows. Its conclusion identifies the carried limit histories in the Banach point classifier, which is the hsame-classified representative relation fixed by Definition 90.1.

For the singleton carrier, read the same two projected rows through Definition 90.39. Then apply Definition 90.41. It refines the hsame classification of ℓ_0 and ℓ_1 to the displayed singleton row $\rho_{\mathsf{e}}(\ell_0, \ell_1)$. □

Theorem 90.47 (Banach limit surface NameCert obligations)**.** *The predicate* $\mathsf{BanachLimitSurface}_X(s, M, \ell, \Lambda)$ *together with Definition 90.44, Definition 90.45, and Definition 90.46 assembles the paper-side* $\mathsf{NameCert}$ *obligation package for Banach limit surfaces.*

Proof. Endpoint coverage supplies the carrier, source, and ledger fields. By Definition 90.44, each certificate row exposes the Banach carrier X, the $\mathsf{StreamName}^{\uparrow}$ observations, the modulus history, the carried endpoint, the Banach metric rows, the $\mathsf{Rat}^{\uparrow}$ comparison rows, and the complete-metric limit row.

Stability is supplied by classifier transport. Apply Definition 90.45 to componentwise hsame transport of the observations, modulus, endpoint, and ledger histories; the theorem returns the transported Banach limit surface row with the RealUp distance classifiers repacked.

Exactness is supplied by uniqueness and the displayed metric boundary. Apply Definition 90.46 for the limit endpoint classifier, and read the metric rows through Definition 90.43 to identify each $\mathsf{BanachMetricWitness}_X$ row with the complete-metric row it feeds.

The CompleteMetricUp bridge is the interface of Definition 90.39. It connects the Banach norm-distance ledger to the consumed $\mathsf{CompleteMetricLimitWitness}$ row, so the carrier, classifier, stability, ledger, exactness, and bridge-facing fields of the Banach limit surface $\mathsf{NameCert}$ package are all accounted for. □

Corollary 90.48 (Banach limit surface certificate determinacy)**.** *Let X be a concrete Banach carrier and let s be a regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream over X. Fix a displayed Banach limit surface row*

$$\mathsf{BanachLimitSurface}_X(s, M, \ell, \Lambda).$$

Every accepted consumer-facing use of this certificate factors through the same finite surface data: the carrier row X, the carried observations of s, the modulus history M, the carried limit history ℓ, the displayed $\mathsf{BanachMetricWitness}_X$ *distance rows in Λ, the attached* $\mathsf{Rat}^{\uparrow}$ *comparison rows, and the consumed complete-metric row*

$$\mathsf{CompleteMetricLimitWitness}(X, s, M, \ell, \Lambda).$$

If another accepted surface row for the same stream is displayed as

$$\mathsf{BanachLimitSurface}_X(s, M', \ell', \Lambda'),$$

then its endpoint normal form is classified with the fixed one by hsame*; in the singleton empty-history carrier the comparison is the singleton row* $\rho_{\mathsf{e}}(\ell, \ell')$*. Hence the certificate has no alternate hidden coordinate, no anonymous metric classifier source, and no duplicate endpoint classifier beyond the rows named by Definition 90.43 and Definition 90.46.*

Proof. Unfold Definition 90.43. The certificate is not an unstructured assertion of convergence. Its visible fields are exactly the Banach carrier, the stream observations, the modulus history, the limit history, the late-distance ledger, and the complete-metric row that consumes that ledger. Thus a consumer of the fixed row can project only those displayed coordinates.

The distance side is also fixed by the same definition. Each late-distance entry is presented as a $\mathsf{BanachMetricWitness}_X$ row together with its $\mathsf{Rat}^{\uparrow}$ comparison rows, and the complete-metric slot is the row $\mathsf{CompleteMetricLimitWitness}(X, s, M, \ell, \Lambda)$ fed by those same entries. Therefore the exactness decision available at the surface is precisely the decision that reads the displayed Banach metric rows as the displayed complete-metric witness rows they feed; an anonymous metric coordinate would not be a use of this certificate.

Now compare any second accepted surface row for the same stream. Applying Definition 90.46 to the two displayed rows gives that ℓ and ℓ' are classified by hsame. In the singleton empty-history carrier, the same theorem reads this comparison as $\rho_{\mathsf{e}}(\ell, \ell')$. Thus a competing endpoint normal form is already identified by the chapter's endpoint classifier, while the route and exactness readback remain the finite rows exposed by the certificate definition. □

Definition 90.49 (Banach bounded linear operator carrier)**.** *Let C and D be* $\mathsf{Banach}^{\uparrow}$ *candidates with vector carriers C_V, D_V, classifiers $\sim_C, \sim_D$, norms ν_C, ν_D, and induced distances d_C, d_D. A Banach bounded linear operator carrier from C to D is a BEDC history predicate*

$$\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$$

on endpoint maps $T : C_V \to D_V$, RealUp bound endpoints K, and visible ledger histories Λ such that the following rows are carried.

1. *The map respects vector classifiers: if $x \sim_C x'$ and both endpoints are carried by C_V, then $T(x) \sim_D T(x')$.*
2. *The map respects the vector operations: $T(x +_C y) \sim_D T(x) +_D T(y)$ and $T(a \cdot_C x) \sim_D a \cdot_D T(x)$ for every carried RealUp scalar endpoint a and carried source endpoints x, y.*
3. *The RealUp bound row records $K \geq 0$ and*

$$\nu_D(T(x)) \leq K \cdot \nu_C(x)$$

   for every carried source endpoint $x : C_V$.
4. *The ledger Λ records the source endpoint row, target endpoint row, source and target norm rows, scalar row, additive and homogeneity compatibility rows, and the bound witness used for each carried input.*

The classifier on operator representatives is hsame *transport of the endpoint map together with* $\mathsf{Real}^{\uparrow}$ *transport of the bound and componentwise transport of the ledger rows.*

Theorem 90.50 (Bounded linear operator Lipschitz obligation)**.** *For* $\mathsf{Banach}^{\uparrow}$ *candidates* C, D*, any carried row* $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ *satisfies the metric Lipschitz obligation*

$$d_D(Tx, Ty) \leq K \cdot d_C(x, y)$$

for all carried source endpoints $x, y : C_V$*. The distance rows are the norm-induced rows of Definition 90.20.*

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingletonBoundedLinearOperator lipschitz`

Proof. First read the two distances through Definition 90.20. The source distance is the RealUp norm endpoint $\nu_C(x -_C y)$, and the target distance is $\nu_D(Tx -_D Ty)$.

Use the additive compatibility row in Definition 90.49. It transports the target difference $Tx -_D Ty$ to the endpoint $T(x -_C y)$ under the target vector classifier, and the $\mathsf{Norm}^{\uparrow}$ transport row moves ν_D across that classifier comparison.

Apply the bound row of the operator carrier to the carried source difference $x -_C y$. This gives

$$\nu_D(T(x -_C y)) \leq K \cdot \nu_C(x -_C y).$$

Substituting the norm-induced distance rows gives the displayed Lipschitz obligation. □

Theorem 90.51 (Bounded linear operator preserves regular Cauchy streams)**.** *Let* C, D *be* $\mathsf{Banach}^{\uparrow}$ *candidates and let* $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ *be carried. If* $(X, \mu) : \mathbb{N} \to C_V$ *is a regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream for the source distance* d_C*, then the pointwise stream* $T \circ X$ *is a regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream for the target distance* d_D*. Its carried observation rows are obtained by applying the target endpoint field of* Λ*, and its modulus is obtained from* μ *by feeding each target tolerance through the RealUp bound comparison for* K*.*

Proof. The observation rows are immediate from the operator ledger: for each carried source endpoint X_n, the target endpoint row records that $T(X_n)$ is carried by D_V. Classifier-respect transports any source stream identifications to target stream identifications, so the pointwise stream is accepted by the target vector classifier.

It remains to show the Cauchy estimate. For a requested positive target tolerance, use the RealUp order and multiplication rows to choose a positive source tolerance whose product with K is bounded by the requested target tolerance. Feed that source tolerance into the source modulus μ.

For indices past the returned bound, the source Cauchy row gives a bound on $d_C(X_m, X_n)$. Apply Definition 90.50 to X_m and X_n, then compose the RealUp inequalities. The resulting target distance row is

$$d_D(TX_m, TX_n) \leq K \cdot d_C(X_m, X_n),$$

and the chosen tolerance comparison turns it into the regular Cauchy row for the transported stream. □

Theorem 90.52 (Banach bounded linear operator NameCert obligations)**.** *For any pair of* $\mathsf{Banach}^{\uparrow}$ *candidates* C, D*, the carrier of Definition 90.49, together with Definition 90.50 and Definition 90.51, assembles the paper-side naming-certificate obligation set for the Banach bounded-linear operator surface. The carrier is* $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$*, the classifier is* hsame *transport of maps, bounds, and ledgers, stability is classifier transport through source and target Banach carriers, exactness is the equivalence between displayed operator rows and the additive, homogeneous, bounded endpoint action they record, and the ledger fields are precisely the source endpoint, target endpoint, norm, scalar, compatibility, and bound witness rows.*

Proof. The carrier and classifier fields are those of Definition 90.49. They are stated over the already certified Banach carriers C and D, so source endpoints, target endpoints, norm values, and distance rows are all read through the existing $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$ obligations.

The stability fields are obtained by componentwise classifier transport. A source classifier comparison is transported through T by the first carrier row; additive and scalar compatibility are transported by the vector classifier rows of C and D; and the RealUp bound is transported by the bound endpoint classifier.

The metric-use field is supplied by Definition 90.50. It converts the operator bound into the target distance estimate consumed by downstream metric and Hilbert arguments.

The stream field is supplied by Definition 90.51. It records that regular Cauchy stream names remain regular Cauchy after pointwise application of the operator, with the source modulus transformed by the RealUp bound row.

Finally, exactness follows by unfolding the displayed carrier. Every accepted operator row contains precisely the endpoint map, classifier-respect row, additive row, scalar row, RealUp bound row, and visible provenance ledger; and any such collection repacks as $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ without adding quotient or host-level structure. □

Theorem 90.53 (Banach zero bounded linear operator carrier)**.** *Let C, D be $\mathsf{Banach}^{\uparrow}$ candidates as in Definition 90.2, with vector carriers C_V, D_V, classifiers $\sim_C, \sim_D$, zero endpoints $0_C, 0_D$, norms ν_C, ν_D, and norm-induced distances d_C, d_D. Assume the candidate ledgers expose the source and target vector-zero rows, including the target additive-zero and scalar-zero rows, and a RealUp zero bound endpoint $0_{\mathsf{Real}^{\uparrow}}$ whose rows include*

$$0_{\mathsf{Real}^{\uparrow}} \geq 0 \quad \textit{and} \quad 0_{\mathsf{Real}^{\uparrow}} \cdot r \textit{ classified with } 0_{\mathsf{Real}^{\uparrow}}$$

for every carried norm endpoint r. Define the zero endpoint map

$$Z_{C,D} : C_V \to D_V, \qquad Z_{C,D}(x) := 0_D.$$

Let Λ_0 be the visible ledger containing the source endpoint row, the target zero endpoint row, the source and target norm rows, the target classifier reflexivity row at 0_D, the target additive-zero and scalar-zero rows, and the RealUp zero nonnegativity, multiplication, order-reflexivity, and classifier-transport rows. Then

$$\mathsf{BanachBLOp}(C, D, Z_{C,D}, 0_{\mathsf{Real}^{\uparrow}}, \Lambda_0)$$

is carried.

Proof. Unfold Definition 90.49. For every carried source endpoint $x : C_V$, the endpoint value of the displayed map is $Z_{C,D}(x) = 0_D$. The target vector-zero row carries 0_D in D_V, so the target endpoint row required by the operator carrier is present.

For classifier-respect, suppose $x \sim_C x'$ and both source endpoints are carried. Both images are the same target zero endpoint. The target classifier reflexivity row gives $0_D \sim_D 0_D$, hence

$$Z_{C,D}(x) \sim_D Z_{C,D}(x').$$

For additivity, let $x, y : C_V$ be carried. The source vector rows carry $x +_C y$, so the left endpoint is again 0_D. The right endpoint is

$$Z_{C,D}(x) +_D Z_{C,D}(y) = 0_D +_D 0_D.$$

The target additive-zero law classifies $0_D +_D 0_D$ with 0_D; symmetry of the target vector classifier gives the required comparison

$$Z_{C,D}(x +_C y) \sim_D Z_{C,D}(x) +_D Z_{C,D}(y).$$

For homogeneity, let a be a carried RealUp scalar endpoint and let $x : C_V$ be carried. The source scalar-action row carries $a \cdot_C x$, so the left endpoint is 0_D. The right endpoint is $a \cdot_D 0_D$. The target scalar-zero row classifies $a \cdot_D 0_D$ with 0_D, and classifier symmetry gives

$$Z_{C,D}(a \cdot_C x) \sim_D a \cdot_D Z_{C,D}(x).$$

It remains to verify the bound row. The RealUp zero bound ledger gives $0_{\mathsf{Real}^\uparrow} \geq 0$. For a carried source endpoint x, the $\mathsf{Norm}^\uparrow$ positive-definiteness row contained in the target Banach candidate of Definition 90.2 classifies $\nu_D(0_D)$ with $0_{\mathsf{Real}^\uparrow}$; this is the zero case of the metric obligation recorded in Definition 90.20. Since $Z_{C,D}(x) = 0_D$, this is the left side of the bound. The RealUp multiplication row classifies $0_{\mathsf{Real}^\uparrow} \cdot \nu_C(x)$ with $0_{\mathsf{Real}^\uparrow}$. Order reflexivity at $0_{\mathsf{Real}^\uparrow}$, transported across these two RealUp classifier comparisons, gives

$$\nu_D(Z_{C,D}(x)) \leq 0_{\mathsf{Real}^\uparrow} \cdot \nu_C(x).$$

The rows just assembled are exactly the classifier, additive, homogeneous, bound, and ledger rows demanded by Definition 90.49. Repacking them with the displayed endpoint map and the bound endpoint $0_{\mathsf{Real}^\uparrow}$ yields the carried row

$$\mathsf{BanachBLOp}(C, D, Z_{C,D}, 0_{\mathsf{Real}^\uparrow}, \Lambda_0).$$

□

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingletonZeroBoundedLinearOperator carrier`

Definition 90.54 (Banach bounded linear operator pointwise sum carrier)**.** *Let C, D be $\mathsf{Banach}^\uparrow$ candidates with vector carriers C_V, D_V, classifiers $\sim_C, \sim_D$, target addition $+_D$, norms ν_C, ν_D, and norm-induced distances d_C, d_D. Given carried rows*

$$\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$$

and

$$\mathsf{BanachBLOp}(C, D, S, L, \Gamma),$$

their pointwise sum endpoint map is

$$(T \boxplus_D S)(x) := T(x) +_D S(x).$$

The displayed sum-bound endpoint is the RealUp addition endpoint $K + L$. The sum ledger $\Lambda \boxplus \Gamma$ is the ordered record containing the two operator ledgers, the target $\mathsf{AbGroup}^\uparrow$ addition, associativity, commutativity, congruence, and zero-carry rows, the target vector-space scalar distributivity row, the target $\mathsf{Norm}^\uparrow$ triangle row, and the $\mathsf{RealAlgOrder}$ addition, multiplication, distributivity, nonnegativity, transitivity, and additive order-transport rows used to compare the constructed bound with $K + L$.

Theorem 90.55 (Banach bounded linear operator pointwise sum closure)**.** *Let C, D be* $\mathsf{Banach}^{\uparrow}$ *candidates as in Definition 90.2, with vector carriers C_V, D_V, classifiers $\sim_C, \sim_D$, target addition $+_D$, scalar action $\cdot_D$, norms ν_C, ν_D, and norm-induced distances d_C, d_D. If*

$$\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$$

and

$$\mathsf{BanachBLOp}(C, D, S, L, \Gamma)$$

are carried, then the pointwise sum map of Definition 90.54 is carried by

$$\mathsf{BanachBLOp}(C, D, T \boxplus_D S, K + L, \Lambda \boxplus \Gamma).$$

For every carried source endpoint $x : C_V$, its bound row is the $\mathsf{RealAlgOrder}$ *additive-order composite*

$$\nu_D((T \boxplus_D S)(x)) \leq (K + L) \cdot \nu_C(x),$$

and the displayed operator-bound endpoint is classified by the RealUp order with the scalar sum of the two input bounds:

$$K + L \leq K + L.$$

Proof. Unfold the operator carrier of Definition 90.49. For a carried source endpoint $x : C_V$, the target endpoint rows of Λ and Γ carry $T(x)$ and $S(x)$ in D_V. The target additive carrier row from the $\mathsf{AbGroup}^{\uparrow}$ reduct of the target vector space carries

$$(T \boxplus_D S)(x) = T(x) +_D S(x),$$

so the endpoint row required for the sum map is present.

For classifier-respect, suppose $x \sim_C x'$ with all source endpoints carried. The classifier rows in Λ and Γ give

$$T(x) \sim_D T(x') \qquad \text{and} \qquad S(x) \sim_D S(x').$$

Target additive congruence transports these two comparisons to

$$T(x) +_D S(x) \sim_D T(x') +_D S(x'),$$

which is exactly

$$(T \boxplus_D S)(x) \sim_D (T \boxplus_D S)(x').$$

For additivity, let $x, y : C_V$ be carried. The additive rows of the two input operator ledgers give

$$T(x +_C y) \sim_D T(x) +_D T(y)$$

and

$$S(x +_C y) \sim_D S(x) +_D S(y).$$

Applying target additive congruence to these two comparisons gives

$$T(x +_C y) +_D S(x +_C y) \sim_D (T(x) +_D T(y)) +_D (S(x) +_D S(y)).$$

The target $\mathsf{AbGroup}^{\uparrow}$ associativity and commutativity rows reorder the four carried summands as

$$(T(x) +_D T(y)) +_D (S(x) +_D S(y)) \sim_D (T(x) +_D S(x)) +_D (T(y) +_D S(y)).$$

Transitivity of $\sim_D$ yields

$$(T \boxplus_D S)(x +_C y) \sim_D (T \boxplus_D S)(x) +_D (T \boxplus_D S)(y).$$

For homogeneity, let a be a carried RealUp scalar endpoint and let $x : C_V$ be carried. The homogeneous rows of Λ and Γ give

$$T(a \cdot_C x) \sim_D a \cdot_D T(x)$$

and

$$S(a \cdot_C x) \sim_D a \cdot_D S(x).$$

Target additive congruence combines them as

$$T(a \cdot_C x) +_D S(a \cdot_C x) \sim_D (a \cdot_D T(x)) +_D (a \cdot_D S(x)).$$

The scalar-distributivity row of the target vector-space structure classifies the right endpoint with

$$a \cdot_D (T(x) +_D S(x)).$$

Composing these comparisons gives

$$(T \boxplus_D S)(a \cdot_C x) \sim_D a \cdot_D (T \boxplus_D S)(x).$$

It remains to verify the bound row. The non-negativity rows in the two operator carriers give $K \geq 0$ and $L \geq 0$. The $\mathsf{RealAlgOrder}$ additive order row carries $K + L \geq 0$, so the proposed sum bound is non-negative. For a carried source endpoint $x : C_V$, the target $\mathsf{Norm}^{\uparrow}$ triangle row gives

$$\nu_D(T(x) +_D S(x)) \leq \nu_D(T(x)) + \nu_D(S(x)).$$

The two input bound rows give

$$\nu_D(T(x)) \leq K \cdot \nu_C(x)$$

and

$$\nu_D(S(x)) \leq L \cdot \nu_C(x).$$

The additive order-transport row of $\mathsf{RealAlgOrder}$ adds these two comparisons:

$$\nu_D(T(x)) + \nu_D(S(x)) \leq (K \cdot \nu_C(x)) + (L \cdot \nu_C(x)).$$

The RealUp distributivity row rewrites the right endpoint as

$$(K \cdot \nu_C(x)) + (L \cdot \nu_C(x)) \sim_{\mathsf{Real}^{\uparrow}} (K + L) \cdot \nu_C(x).$$

Order transport across this RealUp classifier comparison and transitivity with the triangle inequality give

$$\nu_D((T \boxplus_D S)(x)) \leq (K + L) \cdot \nu_C(x).$$

The bound-classification statement is the RealUp order reflexivity row at the same addition endpoint $K + L$, after the $\mathsf{RealAlgOrder}$ addition row has carried that endpoint from the displayed input bounds K and L:

$$K + L \leq K + L.$$

The endpoint, classifier, additive, homogeneous, non-negative, bound, and ledger rows just assembled are precisely the rows required by Definition 90.49. Repacking them with the pointwise sum endpoint map, the bound endpoint $K + L$, and the visible ledger $\Lambda \boxplus \Gamma$ yields the carried row

$$\mathsf{BanachBLOp}(C, D, T \boxplus_D S, K + L, \Lambda \boxplus \Gamma).$$

□

Definition 90.56 (Banach bounded linear operator scalar multiple carrier)**.** *Let C, D be* $\mathsf{Banach}^{\uparrow}$ *candidates with vector carriers C_V, D_V, classifiers $\sim_C, \sim_D$, target scalar action $\cdot_D$, norms ν_C, ν_D, and norm-induced distances d_C, d_D. Given a carried row*

$$\mathsf{BanachBLOp}(C, D, T, M, \Lambda)$$

and a carried RealUp scalar endpoint a, let $|a|_{\mathsf{Real}^{\uparrow}}$ be the carried absolute-value endpoint exposed by the shared RealAlgOrder *row. The scalar-multiple endpoint map is*

$$(a \boxtimes_D T)(x) := a \cdot_D T(x).$$

The displayed scalar-multiple bound endpoint is $|a|_{\mathsf{Real}^{\uparrow}} \cdot M$. The scalar-multiple ledger $\langle a \rangle \boxtimes \Lambda$ is the ordered record containing the input operator ledger, the carried scalar row for a, the RealAlgOrder absolute-value and non-negativity rows for $|a|_{\mathsf{Real}^{\uparrow}}$, the target vector-space scalar-action closure, congruence, distributivity, and scalar-associativity rows, the RealUp multiplication commutativity and associativity rows, the target $\mathsf{Norm}^{\uparrow}$ *absolute-homogeneity row, and the RealAlgOrder multiplication, monotonicity, order-transport, and product non-negativity rows used to compare the constructed norm bound with $|a|_{\mathsf{Real}^{\uparrow}} \cdot M$.*

Theorem 90.57 (Banach bounded linear operator scalar multiple closure)**.** *Let C, D be* $\mathsf{Banach}^{\uparrow}$ *candidates as in Definition 90.2, with vector carriers C_V, D_V, classifiers $\sim_C, \sim_D$, target scalar action $\cdot_D$, norms ν_C, ν_D, and norm-induced distances d_C, d_D. If*

$$\mathsf{BanachBLOp}(C, D, T, M, \Lambda)$$

is carried and a is a carried RealUp scalar endpoint with carried absolute-value endpoint $|a|_{\mathsf{Real}^{\uparrow}}$, then the scalar-multiple endpoint map of Definition 90.56 is carried by

$$\mathsf{BanachBLOp}(C, D, a \boxtimes_D T, |a|_{\mathsf{Real}^{\uparrow}} \cdot M, \langle a \rangle \boxtimes \Lambda).$$

For every carried source endpoint $x : C_V$, its bound row is

$$\nu_D((a \boxtimes_D T)(x)) \leq (|a|_{\mathsf{Real}^{\uparrow}} \cdot M) \cdot \nu_C(x).$$

Proof. Unfold the operator carrier of Definition 90.49. For a carried source endpoint $x : C_V$, the target endpoint row of Λ carries $T(x)$ in D_V. Since a is a carried RealUp scalar endpoint, the target vector-space scalar-action closure row carries

$$(a \boxtimes_D T)(x) = a \cdot_D T(x)$$

in D_V.

For classifier-respect, suppose $x \sim_C x'$ with both source endpoints carried. The classifier row of Λ gives

$$T(x) \sim_D T(x').$$

Target scalar-action congruence with the fixed carried scalar a transports this comparison to

$$a \cdot_D T(x) \sim_D a \cdot_D T(x'),$$

which is exactly

$$(a \boxtimes_D T)(x) \sim_D (a \boxtimes_D T)(x').$$

For additivity, let $x, y : C_V$ be carried. The additive row of Λ gives

$$T(x +_C y) \sim_D T(x) +_D T(y).$$

Scalar-action congruence with a gives

$$a \cdot_D T(x +_C y) \sim_D a \cdot_D (T(x) +_D T(y)).$$

The target vector-space distributivity row classifies the right endpoint with

$$a \cdot_D T(x) +_D a \cdot_D T(y).$$

Composing these target classifier comparisons yields

$$(a \boxtimes_D T)(x +_C y) \sim_D (a \boxtimes_D T)(x) +_D (a \boxtimes_D T)(y).$$

For homogeneity, let r be a carried RealUp scalar endpoint and let $x : C_V$ be carried. The homogeneous row of Λ gives

$$T(r \cdot_C x) \sim_D r \cdot_D T(x).$$

Scalar-action congruence with a transports it to

$$a \cdot_D T(r \cdot_C x) \sim_D a \cdot_D (r \cdot_D T(x)).$$

Target scalar associativity classifies the right endpoint with

$$(a \cdot r) \cdot_D T(x).$$

The RealUp multiplication commutativity row classifies $a \cdot r$ with $r \cdot a$, and target scalar-action congruence transports this scalar comparison to

$$(a \cdot r) \cdot_D T(x) \sim_D (r \cdot a) \cdot_D T(x).$$

Applying target scalar associativity in the reverse direction gives

$$(r \cdot a) \cdot_D T(x) \sim_D r \cdot_D (a \cdot_D T(x)).$$

Transitivity of $\sim_D$ gives

$$(a \boxtimes_D T)(r \cdot_C x) \sim_D r \cdot_D (a \boxtimes_D T)(x).$$

It remains to verify the bound row. The operator carrier supplies $M \geq 0$. The RealAlgOrder absolute-value non-negativity row supplies $|a|_{\mathsf{Real}^\uparrow} \geq 0$. Hence RealUp multiplication non-negativity carries

$$|a|_{\mathsf{Real}^\uparrow} \cdot M \geq 0,$$

so the proposed bound endpoint is non-negative.

For a carried source endpoint $x : C_V$, the target $\mathsf{Norm}^\uparrow$ absolute-homogeneity row gives the RealUp classifier comparison

$$\nu_D(a \cdot_D T(x)) \sim_{\mathsf{Real}^\uparrow} |a|_{\mathsf{Real}^\uparrow} \cdot \nu_D(T(x)).$$

The bound row of Λ gives

$$\nu_D(T(x)) \leq M \cdot \nu_C(x).$$

Since $|a|_{\mathsf{Real}^\uparrow} \geq 0$, RealUp multiplication monotonicity transports this comparison to

$$|a|_{\mathsf{Real}^\uparrow} \cdot \nu_D(T(x)) \leq |a|_{\mathsf{Real}^\uparrow} \cdot (M \cdot \nu_C(x)).$$

RealUp associativity classifies the right endpoint with

$$(|a|_{\mathsf{Real}^\uparrow} \cdot M) \cdot \nu_C(x).$$

Order transport across the absolute-homogeneity and associativity classifier comparisons, followed by order transitivity, gives

$$\nu_D((a \boxtimes_D T)(x)) \leq (|a|_{\mathsf{Real}^\uparrow} \cdot M) \cdot \nu_C(x).$$

The endpoint, classifier, additive, homogeneous, non-negative, bound, and ledger rows assembled above are precisely the rows demanded by Definition 90.49. Repacking them with the scalar-multiple endpoint map, the bound endpoint $|a|_{\mathsf{Real}^\uparrow} \cdot M$, and the visible ledger $\langle a \rangle \boxtimes \Lambda$ yields the carried row

$$\mathsf{BanachBLOp}(C, D, a \boxtimes_D T, |a|_{\mathsf{Real}^\uparrow} \cdot M, \langle a \rangle \boxtimes \Lambda).$$

□

Theorem 90.58 (Banach identity bounded linear operator carrier)**.** *Let C be a $\mathsf{Banach}^\uparrow$ candidate as in Definition 90.2, with vector carrier C_V, classifier $\sim_C$, addition $+_C$, scalar action $\cdot_C$, norm ν_C, and norm-induced distance d_C. Let*

$$\mathrm{id}_C : C_V \to C_V, \qquad \mathrm{id}_C(x) := x.$$

Let $1_{\mathsf{Real}^\uparrow}$ be the RealUp multiplicative-unit endpoint exposed by the scalar source. Let $\mathcal{I}_C$ be the visible identity ledger containing the source endpoint row, the same row read as the target endpoint row, the classifier equivalence rows of $\sim_C$, the vector operation rows for $+_C$ and $\cdot_C$, the $\mathsf{Norm}^\uparrow$ norm rows for ν_C, the RealUp non-negativity row

$$1_{\mathsf{Real}^\uparrow} \geq 0,$$

the RealUp multiplication-unit row

$$1_{\mathsf{Real}^\uparrow} \cdot r \sim_{\mathsf{Real}^\uparrow} r$$

for every carried norm endpoint r, and the RealUp order-reflexivity and order-transport rows. Then

$$\mathsf{BanachBLOp}(C, C, \mathrm{id}_C, 1_{\mathsf{Real}^\uparrow}, \mathcal{I}_C)$$

is carried.

Proof. Unfold Definition 90.49. For every carried source endpoint $x : C_V$, the endpoint value of the displayed map is $\mathrm{id}_C(x) = x$. The source carrier row for x is therefore also the target endpoint row, since source and target are both the same candidate C.

For classifier-respect, suppose $x \sim_C x'$ and both endpoints are carried. The identity endpoint map changes neither side, so the same classifier witness gives

$$\mathrm{id}_C(x) \sim_C \mathrm{id}_C(x').$$

For additivity, let $x, y : C_V$ be carried. The vector-space addition row of the $\mathsf{Banach}^\uparrow$ candidate carries $x +_C y$. Both sides of the required comparison compute to this carried endpoint:

$$\mathrm{id}_C(x +_C y) = x +_C y$$

and

$$\mathrm{id}_C(x) +_C \mathrm{id}_C(y) = x +_C y.$$

Classifier reflexivity at the carried sum gives

$$\mathrm{id}_C(x +_C y) \sim_C \mathrm{id}_C(x) +_C \mathrm{id}_C(y).$$

For homogeneity, let a be a carried RealUp scalar endpoint and let $x : C_V$ be carried. The scalar-action row carries $a \cdot_C x$. Again both sides compute to the same endpoint:

$$\mathrm{id}_C(a \cdot_C x) = a \cdot_C x$$

and

$$a \cdot_C \mathrm{id}_C(x) = a \cdot_C x.$$

Classifier reflexivity at the carried scalar-action endpoint gives

$$\mathrm{id}_C(a \cdot_C x) \sim_C a \cdot_C \mathrm{id}_C(x).$$

It remains to verify the bound row. The ledger gives $1_{\mathsf{Real}^\uparrow} \geq 0$. For a carried source endpoint x, the norm row gives the carried RealUp endpoint $\nu_C(x)$. Since $\mathrm{id}_C(x) = x$, the left side of the operator bound is $\nu_C(x)$. RealUp order reflexivity gives

$$\nu_C(x) \leq \nu_C(x).$$

The RealUp multiplication-unit row classifies $1_{\mathsf{Real}^\uparrow} \cdot \nu_C(x)$ with $\nu_C(x)$. Transporting the right side of the reflexive order comparison across this RealUp classifier comparison gives

$$\nu_C(\mathrm{id}_C(x)) \leq 1_{\mathsf{Real}^\uparrow} \cdot \nu_C(x).$$

The rows just assembled are exactly the target endpoint, classifier-respect, additive compatibility, scalar compatibility, RealUp bound, and visible ledger rows demanded by Definition 90.49. Repacking them with the displayed endpoint map and the bound endpoint $1_{\mathsf{Real}^\uparrow}$ yields the carried row

$$\mathsf{BanachBLOp}(C, C, \mathrm{id}_C, 1_{\mathsf{Real}^\uparrow}, \mathcal{I}_C).$$

□

Lemma 90.59 (Banach bounded linear operator Cauchy bridge determinacy)**.** *Let C, D be $\mathsf{Banach}^\uparrow$ candidates and let $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ be carried. For every regular Cauchy $\mathsf{StreamName}^\uparrow$ stream $(X, \mu) : \mathbb{N} \to C_V$ over the source distance d_C, the consumer-facing bridge from the source stream to the transported stream $T \circ X$ over d_D is determined by the following displayed rows: the source endpoint rows for X_n, the target endpoint rows for $T(X_n)$ in Λ, the classifier-respect row of Definition 90.49, the norm-induced distance rows of Definition 90.20, the RealUp non-negativity and bound-comparison rows for K, the source modulus row μ, the source Cauchy row, and the Lipschitz row of Definition 90.50. Consequently every accepted route, transport, readback, or handoff used by a downstream consumer of Definition 90.51 factors through those rows. No further coordinate is available for a hidden inverse operator, an ambient compactness principle, a selected limit, a quotient stream equality, a host continuity theorem, or a detached tolerance selector.*

Proof. Unfold the transported-stream theorem Definition 90.51. Its first public row is the observation row for the target stream. For each carried source endpoint X_n, the operator ledger Λ supplies the target endpoint row for $T(X_n)$. If a consumer changes a displayed source representative, the source stream identification passes to the target stream identification by the observation-stability clause of Definition 90.51; that theorem consumes exactly the classifier-respect row named in Definition 90.49.

The distance readback is also fixed. By Definition 90.20, the source and target distances are read as the norm rows

$$d_C(X_m, X_n) = \nu_C(X_m -_C X_n)$$

and

$$d_D(TX_m, TX_n) = \nu_D(TX_m -_D TX_n).$$

Apply Definition 90.50. In its adjacent Lipschitz transport step, the additive compatibility row of Definition 90.49 identifies the target difference with the displayed endpoint $T(X_m -_C X_n)$ under the target vector classifier, and the norm-transport row used by Definition 90.50 moves the target norm across that classifier comparison. The theorem then gives the unique metric handoff exposed by the packet:

$$d_D(TX_m, TX_n) \leq K \cdot d_C(X_m, X_n).$$

Now fix a requested positive target tolerance. The Cauchy-transport theorem uses only the RealUp order and multiplication rows for the displayed bound K to choose a source tolerance whose product with K is below the requested target tolerance. It then feeds that source tolerance into the displayed source modulus μ. For all indices beyond the returned bound, the source Cauchy row gives the source distance estimate; composing it with the Lipschitz row and the chosen RealUp comparison gives the target Cauchy estimate. Thus the consumer handoff is exactly the chain

$$\mu \quad \longrightarrow \quad d_C(X_m, X_n) \quad \longrightarrow \quad K \cdot d_C(X_m, X_n) \quad \longrightarrow \quad d_D(TX_m, TX_n).$$

Every row used in this chain has already been named in the carrier, the norm-induced metric theorem, the Lipschitz theorem, or the Cauchy-transport theorem. The accepted packet has no field naming an inverse operator, a compact subcover, a target limit choice, a quotient equality between streams, an external continuity theorem, or a tolerance selector detached from the RealUp bound comparison. Such a request therefore has no source coordinate in the Banach bounded-linear-operator bridge. Hence every accepted consumer-facing route factors through the listed local rows, and every other bridge coordinate remains outside the displayed packet. □

Definition 90.60 (Banach bounded linear operator composition carrier)**.** *Let C, D, E be* $\mathsf{Banach}^{\uparrow}$ *candidates with vector carriers C_V, D_V, E_V, classifiers $\sim_C, \sim_D, \sim_E$, norms ν_C, ν_D, ν_E, and norm-induced distances d_C, d_D, d_E. Given carried rows*

$$\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$$

and

$$\mathsf{BanachBLOp}(D, E, S, L, \Gamma),$$

their composition carrier is

$$\mathsf{BanachBLOp}(C, E, S \circ T, L \cdot K, \Gamma \star \Lambda).$$

Here $S \circ T$ is the endpoint map $x \mapsto S(Tx)$, the RealUp bound row is the product endpoint $L \cdot K$, and the visible ledger $\Gamma \star \Lambda$ is the ordered concatenation of the source-to-middle operator rows, the middle-to-target operator rows, and the RealUp multiplication and order rows used to compare the composite bound.

Theorem 90.61 (Bounded linear operator composition Lipschitz)**.** *For* $\mathsf{Banach}^{\uparrow}$ *candidates* C, D, E*, carried rows* $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ *and* $\mathsf{BanachBLOp}(D, E, S, L, \Gamma)$ *satisfy the composite estimate*

$$d_E(S(Tx), S(Ty)) \leq (L \cdot K) \cdot d_C(x, y)$$

for all carried source endpoints $x, y : C_V$*. The distance rows are the norm-induced rows of Definition 90.20, and the final comparison is the RealUp multiplication/order row associating the two operator bounds with the source distance.*

Proof. Apply Definition 90.50 to the carried row $\mathsf{BanachBLOp}(D, E, S, L, \Gamma)$ and the middle endpoints Tx, Ty. This gives the target estimate

$$d_E(S(Tx), S(Ty)) \leq L \cdot d_D(Tx, Ty).$$

Apply Definition 90.50 again to $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ and the source endpoints x, y. The middle distance is bounded by

$$d_D(Tx, Ty) \leq K \cdot d_C(x, y).$$

Use the nonnegative bound rows for L and K, monotonicity of RealUp multiplication, and associativity of the displayed product endpoint. The ordered comparison transports $L \cdot d_D(Tx, Ty)$ across the second estimate and rewrites the resulting $L \cdot (K \cdot d_C(x, y))$ as $(L \cdot K) \cdot d_C(x, y)$. Repacking the two operator ledgers gives the displayed composite Lipschitz row. □

Theorem 90.62 (Bounded linear operator composition preserves regular Cauchy streams)**.** *For* $\mathsf{Banach}^{\uparrow}$ *candidates* C, D, E*, carried rows* $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ *and* $\mathsf{BanachBLOp}(D, E, S, L, \Gamma)$ *transport every regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream over* C *to a regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream over* E *by pointwise application of* $S \circ T$*. The transported observation rows and modulus ledger are the result of first applying the* T *transport and then applying the* S *transport.*

Proof. Start with a regular Cauchy stream $(X, \mu) : \mathbb{N} \to C_V$. Apply Definition 90.51 to $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$. The result is the pointwise stream $T \circ X$ over D, with carried observation rows and a modulus transformed through the RealUp bound row for K.

Apply Definition 90.51 a second time to $\mathsf{BanachBLOp}(D, E, S, L, \Gamma)$ and the transported middle stream. The result is the stream $S \circ (T \circ X)$ over E, with its observation rows transported through the target endpoint fields of Γ.

Finally identify $S \circ (T \circ X)$ with $(S \circ T) \circ X$ by endpoint definition, and concatenate the two visible ledgers. The RealUp multiplication/order rows combine the two modulus transformations into the single composite bound $L \cdot K$, so the final stream is regular Cauchy for the target distance d_E. □

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingletonBoundedLinearOperator composition cauchy transport`

Theorem 90.63 (Banach bounded linear operator composition NameCert obligations)**.** *For* $\mathsf{Banach}^{\uparrow}$ *candidates* C, D, E*, the carrier of Definition 90.60, together with Definition 90.61 and Definition 90.62, assembles the paper-side* $\mathsf{NameCert}$ *obligation set for composed Banach bounded linear operators. The carrier is* $\mathsf{BanachBLOp}(C, E, S \circ T, L \cdot K, \Gamma \star \Lambda)$*, the classifier is componentwise* hsame *transport of maps and ledgers together with RealUp transport of the product bound, stability is inherited through the two operator carriers, exactness is the equivalence between the displayed composite rows and the two-stage endpoint action, and the ledger records the source, middle, target, classifier, compatibility, bound, and stream rows.*

Proof. The carrier field is exactly Definition 90.60. Its endpoint map is $S \circ T$, its bound endpoint is $L \cdot K$, and its ledger is the ordered concatenation $\Gamma \star \Lambda$.

Classifier transport is obtained in two stages. The first operator row moves source classifier comparisons through T, and the second operator row moves the resulting middle comparisons through S. RealUp classifier transport keeps the product bound $L \cdot K$ stable, while componentwise hsame transport keeps the concatenated ledger aligned with the two endpoint maps.

The Lipschitz field is Definition 90.61, and the regular-Cauchy field is Definition 90.62. These are the metric and stream obligations required for downstream operator certificates.

Exactness follows by unfolding the composite carrier. Any accepted composite row contains precisely the two accepted operator rows, the composed endpoint map, the RealUp product bound, and the visible concatenated ledger. Conversely, those fields repack as $\mathsf{BanachBLOp}(C, E, S \circ T, L \cdot K, \Gamma \star \Lambda)$, so the composition surface adds no host-level quotient or unrecorded operation row. □

Theorem 90.64 (Banach bounded linear operator composition closure)**.** *Let C, D, E be $\mathsf{Banach}^{\uparrow}$ candidates with vector carriers C_V, D_V, E_V, classifiers $\sim_C, \sim_D, \sim_E$, norms ν_C, ν_D, ν_E, and norm-induced distances d_C, d_D, d_E. If*

$$\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$$

and

$$\mathsf{BanachBLOp}(D, E, S, L, \Gamma)$$

are carried, then the endpoint composite $S \circ T : C_V \to E_V$ is carried by

$$\mathsf{BanachBLOp}(C, E, S \circ T, L \cdot K, \Gamma \star \Lambda).$$

The composed ledger $\Gamma \star \Lambda$ records the two operator ledgers and the RealUp multiplication, monotonicity, associativity, and non-negativity rows needed for the product bound $L \cdot K$.

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingletonBoundedLinearOperator composition closure`

Proof. Unfold the operator carrier of Definition 90.49. For a carried source endpoint $x : C_V$, the target endpoint row of Λ carries $T(x) : D_V$. The target endpoint row of Γ then carries $S(Tx) : E_V$, which is the endpoint value of $(S \circ T)(x)$.

For classifier-respect, suppose $x \sim_C x'$ with both source endpoints carried. The classifier row of Λ gives $T(x) \sim_D T(x')$. Applying the classifier row of Γ gives $S(Tx) \sim_E S(Tx')$, which is the classifier row for the composite endpoint map.

For additivity, let $x, y : C_V$ be carried. The additive row of Λ gives

$$T(x +_C y) \sim_D T(x) +_D T(y).$$

Both middle endpoints in this comparison are carried by the D vector carrier, so the classifier-respect row of Γ transports it to

$$S(T(x +_C y)) \sim_E S(T(x) +_D T(y)).$$

The additive row of Γ, applied to the carried middle endpoints $T(x)$ and $T(y)$, gives

$$S(T(x) +_D T(y)) \sim_E S(Tx) +_E S(Ty).$$

Transitivity of the target vector classifier yields

$$(S \circ T)(x +_C y) \sim_E (S \circ T)(x) +_E (S \circ T)(y).$$

For homogeneity, let a be a carried RealUp scalar endpoint and let $x : C_V$ be carried. The scalar row of Λ gives

$$T(a \cdot_C x) \sim_D a \cdot_D T(x).$$

Transport this comparison through the classifier row of Γ, then apply the scalar row of Γ to the carried middle endpoint $T(x)$. The target classifier transitivity row gives

$$(S \circ T)(a \cdot_C x) \sim_E a \cdot_E (S \circ T)(x).$$

It remains to verify the product bound. The non-negativity rows in the two operator carriers give $K \geq 0$ and $L \geq 0$, so the RealUp multiplication row carries $L \cdot K \geq 0$. For a carried source endpoint x, the bound row of Γ applied to the carried middle endpoint $T(x)$ gives

$$\nu_E(S(Tx)) \leq L \cdot \nu_D(Tx).$$

The bound row of Λ gives

$$\nu_D(Tx) \leq K \cdot \nu_C(x).$$

Using $L \geq 0$, RealUp multiplication monotonicity transports the second comparison to

$$L \cdot \nu_D(Tx) \leq L \cdot (K \cdot \nu_C(x)).$$

RealUp associativity identifies the right-hand side with $(L \cdot K) \cdot \nu_C(x)$. Composing the displayed inequalities gives

$$\nu_E((S \circ T)(x)) \leq (L \cdot K) \cdot \nu_C(x),$$

which is the bound row required for $\mathsf{BanachBLOp}(C, E, S \circ T, L \cdot K, \Gamma \star \Lambda)$.

The ledger clause is exactly the ordered concatenation described in Definition 90.60: it keeps the source-to-middle endpoint, classifier, linearity, and bound rows from Λ, the middle-to-target rows from Γ, and the RealUp product rows used above. These rows are precisely the fields of Definition 90.49 for the composite endpoint map, so the displayed composite operator carrier is carried. □

Theorem 90.65 (Banach bounded linear operator composition associativity)**.** *Let B, C, D, E be $\mathsf{Banach}^{\uparrow}$ candidates with vector carriers B_V, C_V, D_V, E_V and carried bounded linear operator rows*

$$\mathsf{BanachBLOp}(B, C, T, K, \Lambda),$$

$$\mathsf{BanachBLOp}(C, D, S, L, \Gamma),$$

and

$$\mathsf{BanachBLOp}(D, E, R, M, \Omega).$$

Then the two iterated composite carriers

$$\mathsf{BanachBLOp}(B, E, (R \circ S) \circ T, (M \cdot L) \cdot K, (\Omega \star \Gamma) \star \Lambda)$$

and

$$\mathsf{BanachBLOp}(B, E, R \circ (S \circ T), M \cdot (L \cdot K), \Omega \star (\Gamma \star \Lambda))$$

classify the same carried Banach bounded linear operator row after endpoint composition associativity identifies $((R \circ S) \circ T)(x)$ with $(R \circ (S \circ T))(x)$ for every carried source endpoint x, RealUp multiplication associativity identifies the two bound endpoints, and ledger associativity identifies the two ordered concatenations of the source-to-middle, middle-to-target, and target-to-final rows.

Proof. First form the left-associated carrier. Apply Definition 90.64 to the rows for S and R, obtaining $\mathsf{BanachBLOp}(C, E, R \circ S, M \cdot L, \Omega \star \Gamma)$. Applying the same closure theorem to this row and the row for T gives the displayed carrier with endpoint map $(R \circ S) \circ T$, bound $(M \cdot L) \cdot K$, and ledger $(\Omega \star \Gamma) \star \Lambda$.

Next form the right-associated carrier. Apply Definition 90.64 to the rows for T and S, obtaining $\mathsf{BanachBLOp}(B, D, S \circ T, L \cdot K, \Gamma \star \Lambda)$. Applying the closure theorem to this row and the row for R gives the displayed carrier with endpoint map $R \circ (S \circ T)$, bound $M \cdot (L \cdot K)$, and ledger $\Omega \star (\Gamma \star \Lambda)$.

Unfold the composition carrier of Definition 90.60. For a carried source endpoint $x : B_V$, both endpoint maps compute to $R(S(Tx))$. Thus the endpoint classifiers compare the same target endpoint after definitionally reassociating composition.

The metric and stream fields are the same obligations in the two bracketings. Definition 90.61 supplies the composite Lipschitz row at each binary step, and RealUp multiplication associativity rewrites $((M \cdot L) \cdot K) \cdot d_B(x, y)$ to $(M \cdot (L \cdot K)) \cdot d_B(x, y)$. Likewise, Definition 90.62 transports regular Cauchy streams by pointwise application of the same endpoint map $x \mapsto R(S(Tx))$.

Finally, the visible ledgers contain exactly the rows from Λ, Γ, and Ω together with the RealUp product and order rows used by the two applications of composition closure. Ledger associativity identifies $(\Omega \star \Gamma) \star \Lambda$ with $\Omega \star (\Gamma \star \Lambda)$ as the same ordered source-middle-target record, so the two displayed carriers classify the same Banach bounded linear operator row. □

Theorem 90.66 (Banach bounded linear operator identity units)**.** *Let C, D be $\mathsf{Banach}^{\uparrow}$ candidates with vector carriers C_V, D_V, classifiers $\sim_C, \sim_D$, norms ν_C, ν_D, and norm-induced distances d_C, d_D. Let*

$$\mathrm{id}_C : C_V \to C_V, \qquad \mathrm{id}_C(x) := x,$$

and

$$\mathrm{id}_D : D_V \to D_V, \qquad \mathrm{id}_D(y) := y.$$

Assume the carried operator row

$$\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$$

and assume that the source and target identity maps carry the unit bound:

$$\mathsf{BanachBLOp}(C, C, \mathrm{id}_C, 1_{\mathsf{Real}^{\uparrow}}, \mathcal{I}_C), \qquad \mathsf{BanachBLOp}(D, D, \mathrm{id}_D, 1_{\mathsf{Real}^{\uparrow}}, \mathcal{I}_D).$$

Assume also that the identity ledgers are unit ledgers for Λ: the RealUp multiplication rows classify $K \cdot 1_{\mathsf{Real}^{\uparrow}}$ and $1_{\mathsf{Real}^{\uparrow}} \cdot K$ with K, and the ordered ledgers $\Lambda \star \mathcal{I}_C$ and $\mathcal{I}_D \star \Lambda$ componentwise transport back to Λ by collapsing only the displayed identity endpoint rows and these RealUp multiplication-unit rows. Then the two unit composites are carried:

$$\mathsf{BanachBLOp}(C, D, T \circ \mathrm{id}_C, K \cdot 1_{\mathsf{Real}^{\uparrow}}, \Lambda \star \mathcal{I}_C)$$

and

$$\mathsf{BanachBLOp}(C, D, \mathrm{id}_D \circ T, 1_{\mathsf{Real}^{\uparrow}} \cdot K, \mathcal{I}_D \star \Lambda).$$

Moreover both composite operator representatives are classified with the original representative by the Banach bounded-operator classifier of Definition 90.49:

$$(T \circ \mathrm{id}_C, K \cdot 1_{\mathsf{Real}^{\uparrow}}, \Lambda \star \mathcal{I}_C) \sim_{\mathrm{op}(C,D)} (T, K, \Lambda)$$

and

$$(\mathrm{id}_D \circ T, 1_{\mathsf{Real}^{\uparrow}} \cdot K, \mathcal{I}_D \star \Lambda) \sim_{\mathrm{op}(C,D)} (T, K, \Lambda).$$

Lean4 ✓ BEDC.Derived.BanachUp.BanachSingletonBoundedLinearOperator identity unit composites

Proof. Apply Definition 90.64 to the carried source identity row and the carried row for T. With the middle object equal to C, the composite endpoint map is $T \circ \mathrm{id}_C$, the product bound is $K \cdot 1_{\mathsf{Real}^\uparrow}$, and the concatenated ledger is $\Lambda \star \mathcal{I}_C$. This gives the displayed right unit carrier.

Apply the same composition-closure theorem to the carried row for T and the carried target identity row. With the middle object equal to D, the composite endpoint map is $\mathrm{id}_D \circ T$, the product bound is $1_{\mathsf{Real}^\uparrow} \cdot K$, and the concatenated ledger is $\mathcal{I}_D \star \Lambda$. This gives the displayed left unit carrier.

It remains to identify the two composites with the original representative. Unfold the operator classifier specified in Definition 90.49. Its comparison has three visible fields: endpoint-map comparison, RealUp bound comparison, and componentwise ledger transport.

For every carried source endpoint $x : C_V$, the right unit endpoint computes as

$$(T \circ \mathrm{id}_C)(x) = T(\mathrm{id}_C(x)) = T(x),$$

and the left unit endpoint computes as

$$(\mathrm{id}_D \circ T)(x) = \mathrm{id}_D(T(x)) = T(x).$$

The target vector classifier reflexivity row therefore supplies the endpoint-map component of both operator-classifier comparisons.

The RealUp bound component is exactly the assumed multiplication-unit transport:

$$K \cdot 1_{\mathsf{Real}^\uparrow} \sim_{\mathsf{Real}^\uparrow} K, \qquad 1_{\mathsf{Real}^\uparrow} \cdot K \sim_{\mathsf{Real}^\uparrow} K.$$

The ledger component is exactly the unit-ledger hypothesis: $\Lambda \star \mathcal{I}_C$ and $\mathcal{I}_D \star \Lambda$ transport componentwise to Λ after the identity endpoint rows and the RealUp unit rows are collapsed. These three components are precisely the fields of the Banach bounded-operator classifier, so both unit composites are classified with (T, K, Λ). □

Theorem 90.67 (Banach bounded linear operator left zero annihilation)**.** *Let H_0, H_1, H_2 be $\mathsf{Banach}^\uparrow$ candidates with vector carriers $H_{0,V}, H_{1,V}, H_{2,V}$, classifiers $\sim_{H_0}, \sim_{H_1}, \sim_{H_2}$, and zero endpoints $0_{H_0}, 0_{H_1}, 0_{H_2}$. Let*

$$\mathsf{BanachBLOp}(H_1, H_2, T, L, \Gamma)$$

be a carried bounded linear operator row, and let

$$\mathsf{BanachBLOp}(H_0, H_1, 0_{H_0,H_1}, 0_{\mathsf{Real}^\uparrow}, \Lambda_{01})$$

and

$$\mathsf{BanachBLOp}(H_0, H_2, 0_{H_0,H_2}, 0_{\mathsf{Real}^\uparrow}, \Lambda_{02})$$

be the carried zero rows furnished by Definition 90.53, so that

$$0_{H_0,H_1}(x) = 0_{H_1}, \qquad 0_{H_0,H_2}(x) = 0_{H_2}$$

for every carried source endpoint $x : H_{0,V}$. Assume also that the RealUp multiplication rows classify $L \cdot 0_{\mathsf{Real}^\uparrow}$ with $0_{\mathsf{Real}^\uparrow}$, and that the concatenated ledger $\Gamma \star \Lambda_{01}$ componentwise transports to Λ_{02} after rewriting only the displayed endpoint rows along the target classifier comparison $T(0_{H_1}) \sim_{H_2} 0_{H_2}$ and the bound row along $L \cdot 0_{\mathsf{Real}^\uparrow} \sim_{\mathsf{Real}^\uparrow} 0_{\mathsf{Real}^\uparrow}$. Then

$$\mathsf{BanachBLOp}(H_0, H_2, T \circ 0_{H_0,H_1}, L \cdot 0_{\mathsf{Real}^\uparrow}, \Gamma \star \Lambda_{01})$$

is carried, and its operator representative is classified with the zero representative on (H_0, H_2):

$$(T \circ 0_{H_0,H_1}, L \cdot 0_{\mathsf{Real}^\uparrow}, \Gamma \star \Lambda_{01}) \sim_{\mathrm{op}(H_0,H_2)} (0_{H_0,H_2}, 0_{\mathsf{Real}^\uparrow}, \Lambda_{02}).$$

Proof. Apply Definition 90.64 to the carried zero row from H_0 to H_1 and the carried row for T. With middle object H_1, the composite endpoint map is $T \circ 0_{H_0,H_1}$, the product bound is $L \cdot 0_{\mathsf{Real}^\uparrow}$, and the concatenated ledger is $\Gamma \star \Lambda_{01}$. This yields the carried row

$$\mathsf{BanachBLOp}(H_0, H_2, T \circ 0_{H_0,H_1}, L \cdot 0_{\mathsf{Real}^\uparrow}, \Gamma \star \Lambda_{01}).$$

It remains to compare this composite representative with the carried zero representative on (H_0, H_2). Unfold the operator classifier specified in Definition 90.49. As in the unit proof, its comparison has three visible fields: endpoint-map comparison, RealUp bound comparison, and componentwise ledger transport.

For the endpoint-map component, fix a carried source endpoint $x : H_{0,V}$. By definition of the source zero map,

$$(T \circ 0_{H_0,H_1})(x) = T(0_{H_1}),$$

while by definition of the target zero map,

$$0_{H_0,H_2}(x) = 0_{H_2}.$$

It therefore suffices to prove $T(0_{H_1}) \sim_{H_2} 0_{H_2}$.

Because Λ_{01} is a carried zero ledger, the endpoint 0_{H_1} is carried in $H_{1,V}$. The source scalar-zero row in H_1 gives

$$0_{\mathsf{Real}^\uparrow} \cdot_{H_1} 0_{H_1} \sim_{H_1} 0_{H_1}.$$

Apply the classifier-respect row of Γ to transport this comparison through T:

$$T(0_{\mathsf{Real}^\uparrow} \cdot_{H_1} 0_{H_1}) \sim_{H_2} T(0_{H_1}).$$

By symmetry of the target vector classifier,

$$T(0_{H_1}) \sim_{H_2} T(0_{\mathsf{Real}^\uparrow} \cdot_{H_1} 0_{H_1}).$$

Now apply the homogeneity row of Γ at the carried scalar endpoint $0_{\mathsf{Real}^\uparrow}$ and the carried source endpoint 0_{H_1}:

$$T(0_{\mathsf{Real}^\uparrow} \cdot_{H_1} 0_{H_1}) \sim_{H_2} 0_{\mathsf{Real}^\uparrow} \cdot_{H_2} T(0_{H_1}).$$

Finally, the target scalar-zero row in H_2 gives

$$0_{\mathsf{Real}^\uparrow} \cdot_{H_2} T(0_{H_1}) \sim_{H_2} 0_{H_2}.$$

Transitivity of $\sim_{H_2}$ combines the last three displayed comparisons into

$$T(0_{H_1}) \sim_{H_2} 0_{H_2}.$$

Since this comparison is independent of x, it supplies the endpoint-map component of the operator-classifier comparison between $T \circ 0_{H_0,H_1}$ and $0_{H_0,H_2}$.

The RealUp bound component is exactly the assumed right-zero multiplication comparison

$$L \cdot 0_{\mathsf{Real}^\uparrow} \sim_{\mathsf{Real}^\uparrow} 0_{\mathsf{Real}^\uparrow}.$$

The ledger component is the remaining hypothesis: after rewriting the endpoint rows along the just-proved target comparison $T(0_{H_1}) \sim_{H_2} 0_{H_2}$ and rewriting the bound row along $L \cdot 0_{\mathsf{Real}^\uparrow} \sim_{\mathsf{Real}^\uparrow} 0_{\mathsf{Real}^\uparrow}$, the concatenated ledger $\Gamma \star \Lambda_{01}$ transports componentwise to the zero ledger Λ_{02}.

These three components are precisely the fields of the Banach bounded-operator classifier. Hence the composite representative $(T \circ 0_{H_0,H_1}, L \cdot 0_{\mathsf{Real}^\uparrow}, \Gamma \star \Lambda_{01})$ is classified with the zero representative $(0_{H_0,H_2}, 0_{\mathsf{Real}^\uparrow}, \Lambda_{02})$ on (H_0, H_2). □

Theorem 90.68 (Banach bounded linear operator zero right-composition annihilation)**.** *Let H_0, H_1, H_2 be $\mathsf{Banach}^{\uparrow}$ candidates with vector carriers $H_{0,V}, H_{1,V}, H_{2,V}$, classifiers $\sim_{H_0}, \sim_{H_1}, \sim_{H_2}$, and zero endpoints $0_{H_0}, 0_{H_1}, 0_{H_2}$. Let*

$$\mathsf{BanachBLOp}(H_0, H_1, T, L, \Gamma)$$

be a carried bounded linear operator row, and let

$$\mathsf{BanachBLOp}(H_1, H_2, 0_{H_1,H_2}, 0_{\mathsf{Real}^{\uparrow}}, \Lambda_{12})$$

and

$$\mathsf{BanachBLOp}(H_0, H_2, 0_{H_0,H_2}, 0_{\mathsf{Real}^{\uparrow}}, \Lambda_{02})$$

be the carried zero rows furnished by Definition 90.53, so that

$$0_{H_1,H_2}(y) = 0_{H_2}, \qquad 0_{H_0,H_2}(x) = 0_{H_2}$$

for every carried endpoint $y : H_{1,V}$ and every carried endpoint $x : H_{0,V}$. Assume also that the RealUp multiplication rows classify $0_{\mathsf{Real}^{\uparrow}} \cdot L$ with $0_{\mathsf{Real}^{\uparrow}}$, and that the concatenated ledger $\Lambda_{12} \star \Gamma$ componentwise transports to Λ_{02} after rewriting only the displayed endpoint rows along the target classifier reflexivity comparison $0_{H_2} \sim_{H_2} 0_{H_2}$ and the bound row along $0_{\mathsf{Real}^{\uparrow}} \cdot L \sim_{\mathsf{Real}^{\uparrow}} 0_{\mathsf{Real}^{\uparrow}}$. Then

$$\mathsf{BanachBLOp}(H_0, H_2, 0_{H_1,H_2} \circ T, 0_{\mathsf{Real}^{\uparrow}} \cdot L, \Lambda_{12} \star \Gamma)$$

is carried, and its operator representative is classified with the zero representative on (H_0, H_2):

$$(0_{H_1,H_2} \circ T, 0_{\mathsf{Real}^{\uparrow}} \cdot L, \Lambda_{12} \star \Gamma) \sim_{\mathrm{op}(H_0,H_2)} (0_{H_0,H_2}, 0_{\mathsf{Real}^{\uparrow}}, \Lambda_{02}).$$

Proof. Apply Definition 90.64 to the carried row for T and the carried zero row from H_1 to H_2. With middle object H_1, the composite endpoint map is $0_{H_1,H_2} \circ T$, the product bound is $0_{\mathsf{Real}^{\uparrow}} \cdot L$, and the concatenated ledger is $\Lambda_{12} \star \Gamma$. This yields the carried row

$$\mathsf{BanachBLOp}(H_0, H_2, 0_{H_1,H_2} \circ T, 0_{\mathsf{Real}^{\uparrow}} \cdot L, \Lambda_{12} \star \Gamma).$$

It remains to compare this composite representative with the carried zero representative on (H_0, H_2). Unfold the operator classifier specified in Definition 90.49. Its comparison has three visible fields: endpoint-map comparison, RealUp bound comparison, and componentwise ledger transport.

For the endpoint-map component, fix a carried source endpoint $x : H_{0,V}$. The target endpoint row of Γ carries $T(x)$ in $H_{1,V}$. Hence the defining row of the zero operator $0_{H_1,H_2}$ applies to $T(x)$ and gives

$$(0_{H_1,H_2} \circ T)(x) = 0_{H_1,H_2}(T(x)) = 0_{H_2}.$$

The zero representative on (H_0, H_2) also satisfies

$$0_{H_0,H_2}(x) = 0_{H_2}.$$

Therefore the target classifier reflexivity row at 0_{H_2} supplies

$$(0_{H_1,H_2} \circ T)(x) \sim_{H_2} 0_{H_0,H_2}(x).$$

Since x was arbitrary, this is the endpoint-map component of the operator-classifier comparison.

The RealUp bound component is exactly the assumed left-zero multiplication comparison

$$0_{\mathsf{Real}^{\uparrow}} \cdot L \sim_{\mathsf{Real}^{\uparrow}} 0_{\mathsf{Real}^{\uparrow}}.$$

The ledger component is the remaining hypothesis: after rewriting the endpoint rows along $0_{H_2} \sim_{H_2} 0_{H_2}$ and rewriting the bound row along $0_{\mathsf{Real}^\uparrow} \cdot L \sim_{\mathsf{Real}^\uparrow} 0_{\mathsf{Real}^\uparrow}$, the concatenated ledger $\Lambda_{12} \star \Gamma$ transports componentwise to the zero ledger Λ_{02}.

These three components are precisely the fields of the Banach bounded-operator classifier. Hence the composite representative $(0_{H_1,H_2} \circ T, 0_{\mathsf{Real}^\uparrow} \cdot L, \Lambda_{12} \star \Gamma)$ is classified with the zero representative $(0_{H_0,H_2}, 0_{\mathsf{Real}^\uparrow}, \Lambda_{02})$ on (H_0, H_2). □

Theorem 90.69 (Banach bounded linear operator scalar action distributes through right composition)**.** *Let H_0, H_1, H_2 be $\mathsf{Banach}^\uparrow$ candidates as in Definition 90.2, with vector carriers $H_{0,V}, H_{1,V}, H_{2,V}$, classifiers $\sim_{H_0}, \sim_{H_1}, \sim_{H_2}$, scalar actions $\cdot_{H_1}, \cdot_{H_2}$, norms $\nu_{H_0}, \nu_{H_1}, \nu_{H_2}$, and norm-induced distances. Let*

$$\mathsf{BanachBLOp}(H_0, H_1, T, L_T, \Lambda_T)$$

and

$$\mathsf{BanachBLOp}(H_1, H_2, S, L_S, \Lambda_S)$$

be carried bounded linear operator rows. Let c be a carried RealUp scalar endpoint with $c \geq 0$, and let $|c|_{\mathsf{Real}^\uparrow}$ be the carried absolute-value endpoint exposed by the shared RealAlgOrder *row, with the non-negative scalar row classifying $|c|_{\mathsf{Real}^\uparrow}$ with c. Write*

$$(c \boxtimes_{H_1} T)(x) := c \cdot_{H_1} T(x)$$

and

$$(c \boxtimes_{H_2} (S \circ T))(x) := c \cdot_{H_2} S(Tx).$$

Then the right scalar-action composite is carried by a Banach bounded linear operator row

$$\mathsf{BanachBLOp}(H_0, H_2, S \circ (c \boxtimes_{H_1} T), (c \cdot L_T) \cdot L_S, \Theta_{S(cT)}),$$

where $\Theta_{S(cT)}$ is obtained from the scalar-multiple ledger for T, the composition ledger with S, and the RealUp product transport identifying $L_S \cdot (c \cdot L_T)$ with $(c \cdot L_T) \cdot L_S$. Moreover this operator representative is classified with the scalar multiple of the ordinary composite over the same source and target Banach carriers:

$$(S \circ (c \boxtimes_{H_1} T), (c \cdot L_T) \cdot L_S, \Theta_{S(cT)}) \sim_{\mathrm{op}(H_0,H_2)} (c \boxtimes_{H_2} (S \circ T), (c \cdot L_T) \cdot L_S, \Theta_{c(ST)}),$$

where $\Theta_{c(ST)}$ is obtained from the composition ledger for $S \circ T$, the scalar-multiple ledger by c, and the same RealUp product-normalization rows.

Proof. Apply Definition 90.57 to the carried row for T and the carried scalar endpoint c. This yields

$$\mathsf{BanachBLOp}(H_0, H_1, c \boxtimes_{H_1} T, |c|_{\mathsf{Real}^\uparrow} \cdot L_T, \langle c \rangle \boxtimes \Lambda_T).$$

The RealUp absolute-value row for the non-negative scalar transports the bound endpoint $|c|_{\mathsf{Real}^\uparrow} \cdot L_T$ to $c \cdot L_T$, so the same scalar-multiple operator row is carried with normalized bound $c \cdot L_T$ and the transported ledger.

Now apply Definition 90.64 to this scalar-multiple row and the carried row for S. The composite endpoint map is $S \circ (c \boxtimes_{H_1} T)$ and the immediate product bound is

$$L_S \cdot (c \cdot L_T).$$

RealUp commutativity and associativity transport this product to

$$(c \cdot L_T) \cdot L_S,$$

and product non-negativity follows from $c \geq 0$, the bound row $L_T \geq 0$, and the bound row $L_S \geq 0$. Transporting the composition ledger across this RealUp classifier comparison gives the displayed carried row

$$\mathsf{BanachBLOp}(H_0, H_2, S \circ (c \boxtimes_{H_1} T), (c \cdot L_T) \cdot L_S, \Theta_{S(cT)}).$$

For the comparison with the scalar multiple of the ordinary composite, first apply Definition 90.64 to the rows for T and S. This gives

$$\mathsf{BanachBLOp}(H_0, H_2, S \circ T, L_S \cdot L_T, \Lambda_S \star \Lambda_T).$$

Applying Definition 90.57 to this row and c gives the scalar-multiple representative

$$\mathsf{BanachBLOp}(H_0, H_2, c \boxtimes_{H_2} (S \circ T), |c|_{\mathsf{Real}^\uparrow} \cdot (L_S \cdot L_T), \langle c \rangle \boxtimes (\Lambda_S \star \Lambda_T)).$$

The classifier comparison $|c|_{\mathsf{Real}^\uparrow} \sim_{\mathsf{Real}^\uparrow} c$, together with RealUp associativity and commutativity, transports this bound to

$$(c \cdot L_T) \cdot L_S.$$

The transported ledger is $\Theta_{c(ST)}$.

It remains to compare the two displayed representatives in the operator classifier of Definition 90.49. For a carried source endpoint $x : H_{0,V}$, the target endpoint row of Λ_T carries $T(x)$ in $H_{1,V}$. The homogeneity row of Λ_S, applied to the carried scalar c and the carried middle endpoint $T(x)$, gives

$$S(c \cdot_{H_1} T(x)) \sim_{H_2} c \cdot_{H_2} S(Tx).$$

By the two endpoint definitions, this is exactly

$$(S \circ (c \boxtimes_{H_1} T))(x) \sim_{H_2} (c \boxtimes_{H_2} (S \circ T))(x).$$

Since x was arbitrary, these comparisons supply the endpoint-map component of the Banach bounded-operator classifier.

The bound component is RealUp classifier reflexivity at the normalized bound $(c \cdot L_T) \cdot L_S$. For the ledger component, both ledgers contain the same carried scalar row for c, the two input operator ledgers Λ_T and Λ_S, the scalar-action rows in H_1 and H_2, the homogeneity row of S used in the endpoint comparison, and the same RealUp absolute-value, commutativity, associativity, monotonicity, and product non-negativity rows. Componentwise ledger transport along the endpoint comparison just proved and the normalized RealUp product comparison therefore identifies $\Theta_{S(cT)}$ with $\Theta_{c(ST)}$.

These endpoint, bound, and ledger components are precisely the fields of the Banach bounded-operator classifier on (H_0, H_2). Hence

$$(S \circ (c \boxtimes_{H_1} T), (c \cdot L_T) \cdot L_S, \Theta_{S(cT)}) \sim_{\mathrm{op}(H_0,H_2)} (c \boxtimes_{H_2} (S \circ T), (c \cdot L_T) \cdot L_S, \Theta_{c(ST)}).$$

□

The ten-field fit is as follows. The traditional target is Banach space. The BEDC source is the singleton $\mathsf{Norm}^\uparrow$ carrier, the $\mathsf{CompleteMetric}^\uparrow$ singleton limit witness, and the RealUp constant zero endpoint. The carrier is the singleton normed history carrier. The classifier is ρ_{e} on vectors and hsame on displayed limit histories. Stability is supplied by $\mathsf{Norm}^\uparrow$ transport and $\mathsf{CompleteMetricLimitWitness}$ transport. The ledger records the norm-zero endpoint, metric-distance rows, the Cauchy modulus, and the limit rows. The core theorem list is Definition 90.5, Definition 90.16, and Definition 90.17. Exactness is the equivalence between zero distance and the singleton classifier. The standard bridge field is the singleton surface of Definition 90.79. The status is a paper proof target for the namespace $\mathsf{BEDC.Derived.BanachUp}$.

Theorem 90.70 (Banach norm-distance zero exactness)**.** *Let X be a concrete Banach carrier and let* $\mathsf{BanachMetricWitness}_X(x, y, d)$ *be a displayed norm-induced distance row. If the* $\mathsf{Real}^{\uparrow}$ *classifier identifies d with the zero real endpoint, then the Banach point classifier identifies the carried representatives x and y.*

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton norm distance zero exactness`

Proof. Unfold the carrier in Definition 90.1. The metric row is not independent data: it records carried representatives x and y, a displayed difference history, and the $\mathsf{Norm}^{\uparrow}$ value of that difference as the real endpoint d.

Use the input RealUp zero classification to read the norm value of the difference as zero. The positive-definiteness row of $\mathsf{Norm}^{\uparrow}$ then reflects this zero norm back to the vector-history classifier, so the displayed difference history is classified with the vector zero.

The vector-space zero-difference law turns that classifier row into equality of the two carried representatives in the Banach point classifier. Repacking the carried representatives, difference row, and norm ledger along hsame gives the required classifier comparison between x and y. □

Theorem 90.71 (Banach complete-metric limit uniqueness)**.** *Let X be a concrete Banach carrier, and let s be a regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream over X for the norm-induced metric. If*

$$\mathsf{CompleteMetricLimitWitness}(X, s, \mu, \ell, L)$$

and

$$\mathsf{CompleteMetricLimitWitness}(X, s, \mu', \ell', L')$$

are two displayed limit rows for the same stream, then the Banach point classifier identifies the carried limit histories L and L'.

Proof. First read both displayed rows through Definition 128.2. They give carried limit histories L and L', convergence moduli, and norm-induced late-distance rows from the same regular Cauchy stream to each candidate limit.

The previous theorem supplies the separated-metric zero-distance field for the Banach metric: whenever a displayed $\mathsf{BanachMetricWitness}_X(u, v, d)$ has zero RealUp distance, the Banach point classifier identifies u and v.

Apply Definition 128.6 to the two complete-metric limit rows using that separatedness field. The complete-metric uniqueness theorem returns classifier equality of the two limit histories, and the classifier is exactly the hsame-based Banach point classifier fixed in Definition 90.1. □

Theorem 90.72 (Banach regular Cauchy stream transport)**.** *Let X be a concrete Banach carrier. Componentwise* hsame *transport of a regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream over X, its observation rows, modulus histories, candidate limit histories, norm-distance rows, and* $\mathsf{Rat}^{\uparrow}$ *comparison ledgers preserves the displayed Banach complete-metric witness package.*

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton regular cauchy stream transport`

Proof. Transport the Banach carrier fields first. By Definition 90.25, the carried representatives, norm rows, metric rows, stream observations, modulus histories, limit histories, and late-observation ledgers remain a concrete Banach carrier package after componentwise hsame transport.

Next transport the complete-metric row. Apply Definition 128.4 to the transported $\mathsf{StreamName}^{\uparrow}$ observations, modulus history, candidate limit, distance histories, and $\mathsf{Rat}^{\uparrow}$ comparison rows. Its

conclusion is the transported $\mathsf{CompleteMetricLimitWitness}$ row for the same norm-induced metric shape.

Finally combine the two transported packages. The Banach transport theorem keeps the metric rows induced by the transported norm ledgers, and the complete-metric stability theorem keeps the regular Cauchy and convergence fields aligned with those rows. Repacking the fields gives the preserved Banach complete-metric witness package. □

Corollary 90.73 (Banach zero-distance exactness determinacy)**.** *Let X be a concrete Banach carrier, and let s be a regular Cauchy $\mathsf{StreamName}^{\uparrow}$ stream over the norm-induced metric. Suppose two accepted consumer rows for the same stream expose displayed limit packages*

$$\mathsf{CompleteMetricLimitWitness}(X, s, \mu_0, \ell_0, L_0) \quad \textit{and} \quad \mathsf{CompleteMetricLimitWitness}(X, s, \mu_1, \ell_1, L_1),$$

and suppose their advertised exactness decisions are displayed by Banach norm-distance rows

$$\mathsf{BanachMetricWitness}_X(L_0, z_0, d_0) \quad \textit{and} \quad \mathsf{BanachMetricWitness}_X(L_1, z_1, d_1)$$

whose $\mathsf{Real}^{\uparrow}$ endpoints are both classified with the zero real endpoint. Then the Banach point classifier identifies z_0 and z_1. Consequently any accepted consumer-facing use of the Banach zero-distance exactness decision for this stream factors through the same visible finite route: the stream row, the modulus row, the displayed limit row, the norm-induced distance row, and the $\mathsf{Real}^{\uparrow}$ zero endpoint. No additional coordinate, anonymous metric row, or second classifier source can change the exactness decision named by the chapter.

Proof. First apply Definition 90.71 to the two displayed complete-metric limit witnesses for the same regular Cauchy stream s. It returns a Banach point-classifier comparison between the carried limit histories L_0 and L_1. This comparison is read in the classifier fixed by Definition 90.1, so it is a comparison at the same Banach surface as the consumer rows.

Next apply Definition 90.70 to the first advertised exactness row. The row $\mathsf{BanachMetricWitness}_X(L_0, z_0, d_0)$ is a norm-induced Banach distance row, and the displayed $\mathsf{Real}^{\uparrow}$ zero classification of d_0 turns it into a Banach point-classifier comparison between L_0 and z_0. Applying the same theorem to $\mathsf{BanachMetricWitness}_X(L_1, z_1, d_1)$ gives a Banach point-classifier comparison between L_1 and z_1.

Compose these three classifier comparisons, using symmetry for the comparison between L_0 and z_0 if the classifier is read in the opposite direction. The result identifies z_0 and z_1 in the Banach point classifier. Thus two accepted consumer decisions over the same stream cannot diverge after their visible rows are fixed.

It remains only to exclude a hidden source of the decision. By Definition 128.2, an accepted limit package exposes exactly the stream, modulus, carried limit, threshold, metric-distance, and $\mathsf{Rat}^{\uparrow}$ comparison ledgers. By Definition 90.1, the Banach metric row is the norm-induced row $\mathsf{BanachMetricWitness}_X$, and by Definition 90.70 the zero endpoint is read back through the Banach point classifier. Hence every accepted use has already passed through the listed rows, and replacing them by an unlisted coordinate or duplicate classifier would no longer be a use of the displayed Banach zero-distance exactness interface. □

Definition 90.74 (Banach bounded linear operator limit comparison)**.** *Let C, D be $\mathsf{Banach}^{\uparrow}$ candidates, let $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ be a carried bounded-linear operator row, and let s be a regular Cauchy $\mathsf{StreamName}^{\uparrow}$ stream over the norm-induced metric of C with observations X_n. A bounded-linear operator limit comparison datum is the BEDC package*

$$\mathsf{BanachBLOpLimit}(C, D, T, K, \Lambda, s, \mu, \ell, L, s_T, \mu_T, \ell_T, L_T)$$

consisting of the source complete-metric limit witness

$$\mathsf{CompleteMetricLimitWitness}(C, s, \mu, \ell, L),$$

the pointwise target stream s_T with observations $T(X_n)$, the displayed target limit history $\ell_T := T(\ell)$, a target complete-metric limit witness

$$\mathsf{CompleteMetricLimitWitness}(D, s_T, \mu_T, \ell_T, L_T),$$

and the visible operator ledger Λ recording the source endpoint row, target endpoint row, source and target norm rows, additive and scalar compatibility rows, bound endpoint K, and bound-comparison rows used to turn source late-distance estimates into target late-distance estimates.

Theorem 90.75 (Bounded linear operator transports limit witnesses)**.** *Let C, D be $\mathsf{Banach}^{\uparrow}$ candidates, let $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ be carried, and let*

$$\mathsf{CompleteMetricLimitWitness}(C, s, \mu, \ell, L)$$

be a source limit witness for a regular Cauchy $\mathsf{StreamName}^{\uparrow}$ stream s over the norm-induced metric of C. Then the pointwise stream s_T with observations $T(s(n))$ admits a complete-metric limit witness over D with limit history $T(\ell)$. The witness is the target component of Definition 90.74.

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingletonBoundedLinearOperator limit witness transport`

Proof. First build the target stream. Apply Definition 90.51 to the carried operator row and the source regular Cauchy stream. Its conclusion supplies the regular Cauchy $\mathsf{StreamName}^{\uparrow}$ stream whose observations are $T(s(n))$, with target endpoint rows read from Λ.

Next transport the candidate limit endpoint. The source witness carries ℓ as a point of C, and the target endpoint row of Definition 90.49 carries $T(\ell)$ as a point of D. The same ledger supplies the target norm row and all classifier transport needed to read $T(\ell)$ at the Banach point surface.

It remains to assemble convergence. Fix a positive target tolerance. Use the RealUp bound row for K to choose a positive source tolerance whose product with K is below the requested target tolerance. The source $\mathsf{CompleteMetricLimitWitness}$ gives a threshold after which $d_C(s(n), \ell)$ is below that source tolerance.

For every late observation, apply Definition 90.50 to $s(n)$ and ℓ. The displayed estimate

$$d_D(T(s(n)), T(\ell)) \leq K \cdot d_C(s(n), \ell)$$

combines with the source convergence bound and the RealUp comparison chosen above. Repacking the target stream, target limit, late-distance rows, and comparison ledgers gives the required $\mathsf{CompleteMetricLimitWitness}(D, s_T, \mu_T, T(\ell), L_T)$. □

Theorem 90.76 (Bounded linear operator limit commutation)**.** *Let C, D be $\mathsf{Banach}^{\uparrow}$ candidates, let $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ be carried, and suppose s has source limit witness*

$$\mathsf{CompleteMetricLimitWitness}(C, s, \mu, \ell, L).$$

If a target complete-metric witness

$$\mathsf{CompleteMetricLimitWitness}(D, s_T, \mu', \ell', L')$$

is supplied for the pointwise stream $s_T(n) = T(s(n))$, then the Banach point classifier of D identifies ℓ' with $T(\ell)$.

Proof. First apply Definition 90.75 to the source limit witness. This constructs a target complete-metric limit witness for the same pointwise stream s_T whose displayed limit history is $T(\ell)$.

Now compare the two target witnesses. The supplied witness has limit ℓ', while the transported witness has limit $T(\ell)$; both are complete-metric limit witnesses for the same target stream over the same Banach carrier D.

Apply Definition 90.71. Its separatedness input is the Banach norm-distance zero exactness already recorded for the target carrier, and its conclusion is exactly the D-point classifier relation between ℓ' and $T(\ell)$. □

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingletonBoundedLinearOperator limit commutation`

Theorem 90.77 (Bounded linear operator limit NameCert surface)**.** *For* $\mathsf{Banach}^{\uparrow}$ *candidates* C, D*, the comparison datum of Definition 90.74, together with Definition 90.75 and Definition 90.76, assembles the paper-side naming-certificate surface for bounded-linear operator limits. The carrier is the displayed pair of source and target* $\mathsf{CompleteMetricLimitWitness}$ *rows connected by the operator ledger* Λ*; the classifier is componentwise* hsame *transport of the source stream, source limit, pointwise target stream, target limit, bound row, and late-distance ledgers; stability is inherited from the Banach,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Norm}^{\uparrow}$ *rows; exactness is the classification of any supplied target limit with* $T(\ell)$*; and the ledger fields are the visible operator, norm, stream, limit, distance, and bound-comparison rows.*

Proof. The carrier field is the package displayed in Definition 90.74. It names the source Banach carrier, target Banach carrier, bounded-linear operator row, source complete-metric witness, pointwise target stream, transported limit, target complete-metric witness, and the visible operator ledger.

The classifier field is componentwise transport. Banach endpoint transport moves source and target carried points, $\mathsf{Norm}^{\uparrow}$ transport moves norm and metric rows, $\mathsf{StreamName}^{\uparrow}$ transport moves observations and moduli, RealUp transport moves the bound and order comparisons, and $\mathsf{CompleteMetric}^{\uparrow}$ transport repacks the transported late-distance ledgers as complete-metric witnesses.

The stability field is the witness-transport theorem. Apply Definition 90.75; it turns the source convergence row, the Cauchy transport row, and the Lipschitz estimate into the target complete-metric witness with limit $T(\ell)$.

The exactness field is the commutation theorem. Apply Definition 90.76; it compares any supplied target witness for the pointwise stream with the transported witness and returns the target Banach classifier relation to $T(\ell)$.

Thus the bounded-linear operator surface now exposes the standard limit transport obligation using only the existing Banach, CompleteMetricUp, StreamNameUp, RealUp, and NormUp certificate rows, with no additional parameter-transport schema. □

Lemma 90.78 (Bounded linear operator limit comparison minimal witness)**.** *Let* C, D *be* $\mathsf{Banach}^{\uparrow}$ *candidates, let* $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ *be carried, and let*

$$\mathsf{CompleteMetricLimitWitness}(C, s, \mu, \ell, L)$$

be a source limit witness for a regular Cauchy $\mathsf{StreamName}^{\uparrow}$ *stream* s*. For the comparison datum*

$$\mathsf{BanachBLOpLimit}(C, D, T, K, \Lambda, s, \mu, \ell, L, s_T, \mu_T, T(\ell), L_T)$$

of Definition 90.74, the minimal consumer-facing witness is the displayed target component supplied by Definition 90.75: the pointwise stream row $s_T(n) = T(s(n))$*, the selected target endpoint* $T(\ell)$*,*

the transported modulus μ_T, the late-distance ledger L_T, and the operator ledger Λ. Every accepted local admission, consumption, route, transport, or readback of the bounded-linear-operator limit comparison factors through these rows and through the rows listed by Definition 90.77. It cannot add an ambient limit selector, an off-ledger continuity principle, a quotient completion object, a compactness row, or any unlisted coordinate outside the same displayed packet.

Proof. Unfold Definition 90.74. The comparison datum contains exactly the source complete-metric witness, the operator row with ledger Λ, the pointwise target stream, the displayed target endpoint $T(\ell)$, the target complete-metric witness, and the visible operator, norm, stream, limit, distance, and bound-comparison ledgers. Thus a consumer of the comparison datum has only these named fields available at the local packet boundary.

Apply Definition 90.75 to the carried operator row and the source witness. The theorem constructs the target witness by first applying Definition 90.51 to obtain the pointwise stream s_T from the target endpoint rows in Λ, then reading $T(\ell)$ through the target endpoint row of the same operator ledger. For a requested positive target tolerance, its proof uses the $\mathsf{Real}^{\uparrow}$ bound row for K to select the source tolerance, feeds that tolerance into the displayed source convergence modulus μ, and applies Definition 90.50 to each late pair $s(n), \ell$. The whole late-distance handoff is therefore the finite chain

$$\mu \quad \longrightarrow \quad d_C(s(n), \ell) \quad \longrightarrow \quad K \cdot d_C(s(n), \ell) \quad \longrightarrow \quad d_D(T(s(n)), T(\ell)) \quad \longrightarrow \quad L_T.$$

No step in this chain asks for a target limit search: the endpoint is the named endpoint $T(\ell)$, and the tolerance selector is the one obtained from the displayed K-comparison rows.

Now read the same package through Definition 90.77. Its carrier is the pair of source and target $\mathsf{CompleteMetricLimitWitness}$ rows connected by Λ; its classifier is componentwise hsame transport of the source stream, source limit, target stream, target limit, bound row, and late-distance ledgers; its stability field is precisely the witness-transport theorem; and its exactness field is Definition 90.76. Hence any consumer-facing use that claims to admit or consume the limit comparison must first project to the same source witness, Λ, s_T, $T(\ell)$, μ_T, and L_T, and any replacement of representatives is mediated only by those componentwise classifier rows.

Suppose a stronger reading attempted to add an independent target-limit selector, a host continuity theorem, a quotient completion object, a compactness row, or another coordinate not present in the displayed comparison datum. Such a coordinate is not a field of Definition 90.74, is not produced by Definition 90.75, and is not part of the carrier, classifier, stability, exactness, or ledger fields listed by Definition 90.77. Therefore it cannot participate in an accepted local admission or consumption claim for this comparison. Every accepted use factors back to the displayed finite witness and selector rows, as claimed. □

Definition 90.79 (Singleton Banach standard bridge surface)**.** *The standard comparison object for the singleton Banach certificate is the one-point complete normed vector space $B_\star = \{\star\}$ over the one-point scalar action, with zero vector $\star$, zero norm $\|\star\| = 0^{\mathsf{c}}_{\mathsf{Real}}$, zero metric $d_\star(\star, \star) = 0^{\mathsf{c}}_{\mathsf{Real}}$, and the unique complete-metric limit operation sending every regular Cauchy stream to $\star$.*

The BEDC side is the singleton empty-history carrier of Definition 90.3. Its carrier is A_{e}, its classifier is ρ_{e}, its norm and metric endpoints are the constant RealUp zero endpoint, and its convergence rows are the displayed $\mathsf{CompleteMetricLimitWitness}$ *rows supplied by Definition 90.16. The bridge maps every carried BEDC vector history to $\star$, and maps $\star$ back to* e *with the carrier, norm, metric, and limit ledgers read through the singleton classifier.*

Theorem 90.80 (Singleton Banach bridge soundness)**.** *Every carried BEDC singleton Banach row of Definition 90.3 maps to the unique point $\star$ of $B_\star$. Under this map, the displayed vector is*

classified by ρ_{e}, its norm and induced metric distance are the constant RealUp zero endpoint, and every regular Cauchy stream carries complete-metric convergence data to the constant standard limit $\star$.

Proof. First collapse the carried vector row. By Definition 90.13, every carried Banach vector lies in A_{e} and every pair of carried singleton vectors is ρ_{e}-classified. The bridge therefore has only one possible standard image, namely $\star$.

Next read the metric data. The norm-induced compatibility theorem Definition 90.5 identifies the singleton Banach metric row with the constant RealUp zero endpoint exactly on the same classifier row. Thus the standard norm and standard distance both receive the zero value required by $B_\star$.

Finally transport the convergence ledger. For a regular Cauchy stream, Definition 90.16 supplies a displayed CompleteMetricLimitWitness row whose selected limit, modulus history, and late-distance rows are all singleton rows. Applying the bridge to each component sends that row to the unique complete-metric limit datum of the one-point standard object. □

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton standard bridge soundness`

Theorem 90.81 (Singleton Banach bridge completeness)**.** *The unique standard point $\star$ maps back to* e *and reconstructs the singleton BEDC Banach surface: carrier A_{e}, classifier ρ_{e}, constant zero norm, constant zero metric, and the singleton* CompleteMetricLimitWitness *family.*

Proof. Unpack the bridge surface of Definition 90.79. Its reverse map sends the only standard point to e, and the BEDC carrier row is precisely the singleton empty-history carrier of Definition 90.3.

The reconstructed completeness data are the singleton data. Apply Definition 90.14: every regular Cauchy stream in the singleton Banach metric has selected limit e, and every distance to that limit is classified by the constant RealUp zero endpoint.

It remains to identify the displayed limit row chosen by the bridge with any other singleton limit presentation. Use Definition 90.41; it gives hsame-equality of singleton Banach limits, and the singleton classifier repackages that equality as ρ_{e}. Hence the reverse image reconstructs the same carrier, norm, metric, and limit witness surface. □

Lean4 ✓ `BEDC.Derived.BanachUp.BanachUp StdBridge`

Theorem 90.82 (Singleton Banach bridge roundtrip)**.** *For the bridge of Definition 90.79, the composite BEDC-to-standard-to-BEDC is ρ_{e} on carried singleton histories, and the composite standard-to-BEDC-to-standard is the identity on the one-point complete normed vector space $B_\star$.*

Proof. For the BEDC composite, start with a carried singleton Banach history. The soundness theorem Definition 90.80 sends it to the unique standard point $\star$, and the completeness theorem Definition 90.81 sends $\star$ back to e with the singleton carrier and zero ledgers.

The classifier comparison is exactly the singleton collapse. By Definition 90.13, every carried source history is ρ_{e}-classified with e, so the BEDC composite acts as ρ_{e} on carried histories.

For the standard composite, there is only one point of $B_\star$. The reverse map selects e, and soundness maps that BEDC point back to $\star$. Since $\star$ is the unique standard point, the composite is the identity on the one-point complete normed vector space. □

Lean4 ✓ `BEDC.Derived.BanachUp.BanachSingleton standard bridge roundtrip`

Lemma 90.83 (Singleton Banach standard bridge determinacy)**.** *For the bridge surface of Definition 90.79, every consumer-facing route, transport, readback, or limit handoff is determined by the displayed singleton rows. The BEDC-to-standard route factors through the singleton carrier A_{e} and classifier ρ_{e}, the standard-to-BEDC readback factors through the selected endpoint* e*, the norm and metric transports factor through the constant RealUp zero endpoint, and every complete-metric handoff factors through the displayed* CompleteMetricLimitWitness *rows of Definition 90.16. No unlisted bridge coordinate supplies an additional carrier point, distance value, classifier, or limit datum.*

Proof. Unpack the bridge surface of Definition 90.79. Its standard object is the one-point complete normed vector space $B_\star = \{\star\}$, and its BEDC object is the singleton empty-history carrier of Definition 90.3. Hence a forward route has only one standard codomain point available. By Definition 90.80, every carried BEDC singleton Banach row maps to that point $\star$, and the displayed source row is read through A_{e} and ρ_{e}. Thus any accepted forward use factors through the same singleton carrier and classifier rows; there is no second standard endpoint through which it could factor.

The readback side is equally fixed by the displayed bridge surface. The only standard point $\star$ is sent back to e, and the reverse ledger is stated there with the carrier, norm, metric, and limit data read through the singleton classifier. Since the reverse map has no other standard input and names no other BEDC endpoint, any consumer readback is the selected row e together with its ρ_{e} carrier comparison.

For norm and metric transport, soundness identifies the norm of the displayed vector and every induced metric distance with the constant RealUp zero endpoint. This is precisely the local norm-induced metric route supplied by Definition 90.5: the singleton metric row is accepted on the same ρ_{e} classifier row and is classified by the constant RealUp zero endpoint. Therefore a consumer cannot choose an anonymous distance coordinate or a second metric classifier; every distance read is the same zero row already present in the singleton Banach surface.

It remains to check complete-metric handoff. Soundness sends every regular Cauchy stream to the constant standard limit $\star$, while Definition 90.16 supplies the displayed CompleteMetricLimitWitness row whose selected limit, modulus history, and late-distance ledgers are singleton rows. Applying the bridge componentwise therefore leaves only that listed limit package: selected limit e on the BEDC side, selected limit $\star$ on the standard side, empty singleton modulus, and late-distance rows classified by the constant RealUp zero endpoint. These are exactly the rows exposed in Definition 90.79 and used by Definition 90.80. Since the surface lists no further carrier, transport, metric, or limit coordinate, any alleged unlisted bridge coordinate has no displayed row from which a consumer-facing use could be read. □

Corollary 90.84 (Singleton Banach standard bridge consumer determinacy)**.** *Fix the bridge surface of Definition 90.79. Any accepted consumer use of the singleton Banach standard bridge has the same exposed finite decision as the chapter rows: a forward use chooses the singleton standard route, a readback use chooses the singleton BEDC endpoint route, a norm or metric use chooses the constant* $\mathsf{Real}^{\uparrow}$ *zero exactness row, and a complete-metric use chooses the displayed singleton limit-witness package. In particular, the bridge exports no hidden coordinate, no alternate normal form, and no duplicate classifier source for the singleton Banach object.*

Proof. The bridge surface in Definition 90.79 names all rows available to a consumer: the one-point standard comparison object, the singleton BEDC carrier and classifier, the constant $\mathsf{Real}^{\uparrow}$ zero norm and metric endpoints, and the displayed complete-metric limit-witness rows. Apply

Definition 90.83 to this fixed surface. It states that every consumer-facing route, transport, readback, or limit handoff factors through exactly those displayed singleton rows and that no unlisted bridge coordinate supplies an additional carrier point, distance value, classifier, or limit datum.

Thus the forward route cannot select anything other than the singleton standard point named by the surface, and the readback route cannot select anything other than the singleton BEDC endpoint named by the surface. The norm and metric transports cannot introduce a second exactness decision, because the determinacy lemma forces them through the same constant $\mathsf{Real}^{\uparrow}$ zero row already exposed by the bridge definition. Likewise a complete-metric handoff cannot select a detached modulus, tail, late-distance, or limit coordinate: the only accepted package is the displayed singleton limit-witness package cited by the surface and by the determinacy lemma.

These four cases exhaust the consumer-facing uses listed in the determinacy lemma. Therefore, once the bridge surface rows are fixed, every accepted consumer use picks the same finite route, readback normal form, or exactness decision named by the singleton Banach chapter, and there is no further hidden coordinate or duplicate classifier source. □

Chapter 91

A Concrete Naming Certificate for $\mathsf{Hilbert}^{\uparrow}$

The Hilbert-space interface $\mathsf{Hilbert}^{\uparrow}$ packages a Banach space whose norm is induced by an inner product. It depends on $\mathsf{NameCert}_{\mathsf{InnerProduct}^{\uparrow}}$ (chapter 86) and $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$ (chapter 90), and is the substrate for the spectral and orthogonal-decomposition certificates of functional analysis.

91.1 Carrier definition

Definition 91.1 (Compatible inner-product Banach carrier)**.** *A compatible inner-product Banach carrier for* $\mathsf{Hilbert}^{\uparrow}$ *is a history predicate* $X : \mathsf{BHist} \to \mathsf{Prop}$ *with point classifier* $\sim_X$ *together with three displayed rows over the same carried histories. The first row is a concrete* $\mathsf{Banach}^{\uparrow}$ *candidate of Definition 90.1. The second row is an* $\mathsf{InnerProduct}^{\uparrow}$ *carrier on* X*, including the vector-space structure, sesquilinear form, conjugate symmetry, linearity, positivity, and inner-product classifier transport. The third row is a norm-induction ledger recording that the Banach norm and Banach metric rows are exactly the rows displayed by the inner-product norm:*

$$\|x\|_{\mathsf{Banach}^{\uparrow}} = \sqrt{\langle x, x\rangle_{\mathsf{InnerProduct}^{\uparrow}}}$$

and

$$d_{\mathsf{Banach}^{\uparrow}}(x, y) = \|x - y\|_{\mathsf{Banach}^{\uparrow}}$$

for carried histories $x, y : X$*.*

The compatibility requirement is literal row sharing, not an isomorphism postulate: the Banach carrier, the inner-product carrier, and the norm-induced metric ledger expose the same point carrier X *and the same classifier* $\sim_X$*. Every accepted Hilbert row therefore carries a visible Banach surface, a visible inner-product surface, and a ledger explaining why the Banach metric is the metric induced by the inner-product norm.*

Definition 91.2 (Hilbert singleton empty-history carrier)**.** *The concrete* $\mathsf{Hilbert}^{\uparrow}$ *carrier is the singleton empty-history Banach carrier of Definition 90.3, read over the singleton empty-history vector space of Definition 47.2. Thus the vector carrier is* A_{e}*, the vector classifier is* ρ_{e}*, the normed carrier is the singleton* $\mathsf{Banach}^{\uparrow}$ *carrier, and the norm is* ν_{e}*.*

The inner-product row is the constant-zero RealUp endpoint

$$\langle m, n\rangle_{\mathsf{e}} := 0^{c}_{\mathsf{Real}}$$

for all displayed vector histories m, n : BHist. *Its scalar-side classifier is* RealConstantHistoryClassifier. *The induced norm row is read by the same constant endpoint:*

$$\|m\|_{\langle,\rangle_{\mathsf{e}}} := 0^{c}_{\mathsf{Real}}.$$

Hence the induced norm is the singleton $\mathsf{Norm}^{\uparrow}$ *norm* ν_{e} *from Definition 89.1. The ledger records the singleton vector-space source, the Banach singleton carrier, and the RatUp zero witness sealed as the RealUp constant endpoint.*

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonEmptyHistoryCarrier admission`

91.2 The certificate

Theorem 91.3 (Hilbert induced norm Banach compatibility)**.** *Every accepted compatible inner-product Banach carrier exposes the same point carrier and classifier to its* $\mathsf{Banach}^{\uparrow}$ *and* $\mathsf{InnerProduct}^{\uparrow}$ *surfaces. Moreover,* hsame *transport preserves the norm-induced Banach metric witness: if* $x \sim_X x'$ *and* $y \sim_X y'$*, then a displayed* $\mathsf{BanachMetricWitness}_X(x, y, d)$ *row transports to the corresponding* $\mathsf{BanachMetricWitness}_X(x', y', d')$ *row classified by the same inner-product norm ledger.*

Proof. Unpack the compatible carrier of Definition 91.1. The Banach row and inner-product row have the same endpoint predicate X and classifier $\sim_X$ by definition, so no change of carrier or classifier is introduced.

Apply Definition 90.5 to read the Banach metric through the displayed norm row. The Hilbert ledger identifies that norm row with the inner-product norm row, so the metric witness remains the norm-induced Banach witness after this reading.

Finally use the componentwise hsame transport rows supplied by the Banach surface and the inner-product surface. They move the vector representative, difference row, inner-product norm row, and RealUp distance endpoint together, and repack the transported rows as $\mathsf{BanachMetricWitness}_X(x', y', d')$ over the same classifier $\sim_X$. □

Theorem 91.4 (Hilbert complete inner-product limit stability)**.** *Let* H *be a compatible inner-product Banach carrier. For any regular Cauchy stream* s *over the Banach metric, any displayed* $\mathsf{CompleteMetricLimitWitness}(X, s, \mu, \ell, L)$ *supplied by the Banach row, and any proof that the stream observations remain in the inner-product carrier, there is a Hilbert limit witness with the same selected limit* ℓ*, the same limit name* L*, and the same classifier* $\sim_X$*.*

Proof. Start from the Banach row contained in H. Its completeness field supplies the displayed $\mathsf{CompleteMetricLimitWitness}(X, s, \mu, \ell, L)$ and its carrier endpoint data through Definition 90.1.

The observation-stability hypothesis says that the same stream is carried by the inner-product surface of H. Use the inner-product carrier stability row to transport all observation representatives through $\sim_X$ while retaining the displayed inner-product norm rows named by the Hilbert ledger.

Apply Definition 91.3 to identify the transported Banach distance witnesses with the inner-product norm-induced ones. The selected limit endpoint ℓ and limit name L are therefore not changed; they are merely read as Hilbert rows over the same carrier, classifier, and visible metric ledger. □

Theorem 91.5 (Hilbert NameCert obligation surface)**.** *The compatible carrier of Definition 91.1, its induced classifier* $\sim_X$*, the norm-metric compatibility of Definition 91.3, the complete-limit stability of Definition 91.4, and the visible ledger joining the Banach and inner-product rows assemble*

the paper-side $\mathsf{NameCert}_{\mathsf{Hilbert}\uparrow}$ *obligation surface. This surface records the Hilbert carrier, classifier, norm-induced Banach metric, complete-limit stability, and ledger provenance; it does not assert a standard Hilbert-space bridge.*

Proof. Use the compatible carrier definition for the public carrier field. It already contains the Banach row, the inner-product row, and the row-sharing ledger binding both surfaces to the same X and $\sim_X$.

Use Definition 91.3 for the norm-metric field. It identifies the Banach metric witness as the metric induced by the inner-product norm and records that hsame transport preserves that witness componentwise.

Use Definition 91.4 for the limit-stability field. It consumes the Banach $\mathsf{CompleteMetricLimitWitness}$ row together with the inner-product observation-stability row and returns the same selected limit as a Hilbert limit witness.

The remaining fields are inherited from the source rows: the Banach surface provides the complete normed metric obligations, the inner-product surface provides the sesquilinear, symmetry, positivity, and classifier-stability obligations, and the ledger records exactly which displayed rows are shared. Thus the paper-side $\mathsf{NameCert}_{\mathsf{Hilbert}\uparrow}$ obligation surface is assembled without adding any standard bridge claim. □

Theorem 91.6 (Hilbert singleton inner-product norm compatibility)**.** *For the carrier of Definition 91.2, the norm induced by* $\langle -, - \rangle_{\mathsf{e}}$ *agrees with the singleton norm* ν_{e}*:*

$$\mathsf{RealConstantHistoryClassifier}(\|m\|_{\langle,\rangle_{\mathsf{e}}}, \nu_{\mathsf{e}}(m))$$

for every carried $m : \mathsf{BHist}$*. Moreover positive definiteness of the inner-product row collapses to the singleton vector classifier:*

$$\mathsf{RealConstantHistoryClassifier}(\langle m, m\rangle_{\mathsf{e}}, 0^{c}_{\mathsf{Real}}) \iff \rho_{\mathsf{e}}(m, \mathsf{e}).$$

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton inner product norm compatibility`

Proof. The induced norm and ν_{e} are both the constant endpoint 0^{c}_{Real}. The carrier and classifier rows of Definition 89.2 give the RealUp constant-history classifier for this endpoint, so the two norm presentations are classified together.

For positive definiteness in the forward direction, the inner-product value $\langle m, m\rangle_{\mathsf{e}}$ is again 0^{c}_{Real}. Apply Definition 47.4 to the carried vector endpoint. It identifies m with e under ρ_{e}.

For the reverse direction, assume $\rho_{\mathsf{e}}(m, \mathsf{e})$. The inner-product row does not inspect the representative; it returns 0^{c}_{Real} for every pair. The zero-exactness boundary of Definition 89.4, together with the constant-real classifier already supplied by the singleton norm carrier, repackages the row as $\mathsf{RealConstantHistoryClassifier}(\langle m, m\rangle_{\mathsf{e}}, 0^{c}_{\mathsf{Real}})$. □

Theorem 91.7 (Hilbert singleton complete normed certificate)**.** *The normed part of Definition 91.2 is complete. Every regular Cauchy stream carried by* A_{e} *has selected limit* e*, every late distance-to-limit row is classified with* 0^{c}_{Real}*, and any two selected Banach limit witnesses are classified by* ρ_{e}*.*

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton complete normed certificate`

Proof. Use the singleton Banach carrier of Definition 90.3. Its metric is the constant RealUp zero endpoint and its limit-selection rule sends every certified regular Cauchy stream to e.

The complete-metric laws are supplied by Definition 128.3. They give the carried singleton limit, the empty modulus, and the late-observation ledgers for the constant zero metric.

Finally apply Definition 90.41 to compare any two Banach limit witnesses for the same stream. In the singleton vector carrier, Definition 47.4 reads that comparison as the classifier row ρ_{e}, so the complete normed certificate is the Banach singleton certificate read through the Hilbert carrier. □

Theorem 91.8 (Hilbert singleton classifier source boundary)**.** *The carrier of Definition 91.2 exposes exactly the singleton vector-space carrier A_{e} and classifier ρ_{e}. The Banach row, the singleton* $\mathsf{Norm}^{\uparrow}$ *row, the inner-product row, and the Hilbert row all read their vector endpoints from the same* BHist *source; no carrier endpoint and no vector classifier outside the singleton empty-history source is used.*

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton classifier source boundary`

Proof. Unfold the Hilbert singleton carrier of Definition 91.2. Its first displayed source is the singleton vector-space instance of Definition 47.2, so the visible vector carrier is A_{e} and the visible classifier is ρ_{e}.

The normed row is the singleton norm instance of Definition 89.1, and the Banach row is the singleton Banach instance of Definition 90.3. Both rows are stated over the same singleton vector carrier and therefore project the same A_{e} and ρ_{e} fields.

The Hilbert row adds only the constant inner-product display over those carried histories. Since that display takes arguments $m, n : \mathsf{BHist}$ from the already fixed singleton carrier, the Hilbert surface has the same endpoint source as the vector-space, norm, and Banach surfaces. □

Theorem 91.9 (Hilbert singleton constant inner-product transport)**.** *For the carrier of Definition 91.2, if $\rho_{\mathsf{e}}(m, m')$ and $\rho_{\mathsf{e}}(n, n')$, then the corresponding inner-product endpoints are related by the constant-real classifier:*

$$\mathsf{RealConstantHistoryClassifier}(\langle m, n\rangle_{\mathsf{e}}, \langle m', n'\rangle_{\mathsf{e}}).$$

The induced norm endpoints are transported along the same scalar classifier, so

$$\mathsf{RealConstantHistoryClassifier}(\|m\|_{\langle,\rangle_{\mathsf{e}}}, \|m'\|_{\langle,\rangle_{\mathsf{e}}})$$

holds over the singleton vector classifier.

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton constant inner product transport`

Proof. The inner-product operation in Definition 91.2 is constant: every ordered pair of carried histories is sent to the endpoint $0^{\mathsf{c}}_{\mathsf{Real}}$. Thus the two endpoints $\langle m, n\rangle_{\mathsf{e}}$ and $\langle m', n'\rangle_{\mathsf{e}}$ are the same constant RealUp zero endpoint.

The singleton norm carrier supplies the scalar-side classifier $\mathsf{RealConstantHistoryClassifier}$ for this constant endpoint. Applying that classifier to the two constant zero presentations gives the displayed inner-product transport row.

For the induced norm, use Definition 91.6. It reads the induced norm as the singleton norm ν_{e}, whose endpoint is again the same constant RealUp zero row. The norm transport conclusion is therefore the same constant-real classifier row read through the induced norm display. □

Theorem 91.10 (Hilbert singleton ledger exhaustion)**.** *Every row consumed by the singleton* $\mathsf{Hilbert}^{\uparrow}$ *package is one of the singleton vector-space source row, the singleton* $\mathsf{Norm}^{\uparrow}$ *row, the singleton Banach completion row, or the constant RealUp zero inner-product row. The package introduces no* $\mathsf{StandardBridge}$ *row, no second vector carrier, and no carrier source beyond the* BHist *singleton ledger recorded in Definition 91.2.*

Proof. The carrier and classifier accounting is fixed by Definition 91.8. It leaves only the singleton vector-space source A_{e}, ρ_{e}, and the BHist endpoint source available to the Hilbert package.

The scalar stability accounting is fixed by Definition 91.9. It says that both the inner-product endpoint and the induced norm endpoint are transported by $\mathsf{RealConstantHistoryClassifier}$ at the constant RealUp zero row.

The completeness accounting is exactly Definition 91.7, which reads the singleton Banach completion row through the Hilbert carrier. Together with the ledger sentence in Definition 91.2, these rows exhaust the package: vector source, norm source, Banach completion source, and constant inner-product zero source are all named, and no standard bridge or outside carrier source remains. □

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton ledger exhaustion`

Theorem 91.11 (Hilbert NameCert obligation package)**.** *The carrier of Definition 91.2, together with the classifier-source boundary Definition 91.8, the constant-inner-product transport row Definition 91.9, the ledger exhaustion row Definition 91.10, and the certificate rows Definition 91.6 and Definition 91.7, assembles the paper-side* $\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}$ *obligation package. Its carrier is* A_{e}*, its classifier is* ρ_{e}*, its inner-product row is* $\langle -, - \rangle_{\mathsf{e}}$*, its induced norm is* ν_{e}*, its completeness field is the singleton Banach limit rule, its ledger is the union of the singleton vector-space, norm, inner-product zero-row, and Banach-completion ledgers, and its bridge status is none.*

Proof. The carrier and classifier fields are supplied by Definition 91.8. The Banach source is exactly Definition 90.3, so the normed carrier and metric rows are already present before the Hilbert row is attached.

The inner-product compatibility field is Definition 91.6. It identifies the induced norm with ν_{e} and reflects positive definiteness back to the singleton classifier against e.

The transport field is Definition 91.9. It records that replacing either input by a ρ_{e}-classified endpoint leaves the inner-product endpoint and the induced norm endpoint inside the same $\mathsf{RealConstantHistoryClassifier}$ row.

The completeness field is Definition 91.7. It supplies the selected limit, the convergence ledgers, and classifier uniqueness for regular Cauchy streams in the norm induced by the inner product.

Definition 91.10 supplies the ledger field. Combining these rows gives the local $\mathsf{Hilbert}^{\uparrow}$ naming certificate: the traditional target is the one-point Hilbert space, the BEDC source is BHist, the carrier and classifier are A_{e} and ρ_{e}, the stability rows are constant-zero classifier transport, the exactness row is positive definiteness against e, the ledger records the shared singleton provenance, and no standard bridge is claimed here. □

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertUp StdBridge`

Theorem 91.12 (Hilbert singleton source compatibility)**.** *For the carrier of Definition 91.2, the singleton* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*, and* $\mathsf{Banach}^{\uparrow}$ *sources read one carried predicate and one classifier:*

$$A_{\mathsf{Hilbert},\mathsf{e}} = A_{\mathsf{e}} \quad \textit{and} \quad \rho_{\mathsf{Hilbert},\mathsf{e}} = \rho_{\mathsf{e}}.$$

The norm row is the singleton norm endpoint ν_{e}*, the Banach metric row is the norm-induced constant RealUp zero distance, and the inner-product row returns* $0^{\mathsf{c}}_{\mathsf{Real}}$ *under* $\mathsf{RealConstantHistoryClassifier}$ *for every displayed pair* $m, n : \mathsf{BHist}$*.*

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton source compatibility`

Proof. Unfold the Hilbert carrier of Definition 91.2. Its vector source is the singleton empty-history vector space, so the displayed carrier and classifier are A_{e} and ρ_{e} before the norm or inner-product rows are attached.

For the norm source, apply Definition 89.2. It reads every carried norm endpoint as ν_{e} and classifies all displayed singleton norm values through $\mathsf{RealConstantHistoryClassifier}$ at $0^{\mathsf{c}}_{\mathsf{Real}}$.

For the Banach source, the carrier is Definition 90.3. Its metric is induced from the same singleton norm and therefore exposes the same carried predicate, the same classifier, and the same constant RealUp zero endpoint surface.

The inner-product row is defined separately but uses no additional carrier data. It returns $0^{\mathsf{c}}_{\mathsf{Real}}$ for every pair $m, n : \mathsf{BHist}$, and Definition 47.4 supplies the underlying vector endpoint collapse used by all three sources. □

Theorem 91.13 (Hilbert singleton endpoint readback)**.** *Every norm endpoint, inner-product self-value, and Banach distance endpoint exposed by the Hilbert singleton package is classified with* $0^{\mathsf{c}}_{\mathsf{Real}}$ *by* $\mathsf{RealConstantHistoryClassifier}$*. Concretely, for carried histories* $m, n : \mathsf{BHist}$*,*

$$\mathsf{RealConstantHistoryClassifier}(\nu_{\mathsf{e}}(m), 0^{\mathsf{c}}_{\mathsf{Real}}), \quad \mathsf{RealConstantHistoryClassifier}(\langle m, m\rangle_{\mathsf{e}}, 0^{\mathsf{c}}_{\mathsf{Real}}), \quad \mathsf{RealConstantHistoryCla}$$

are the public endpoint rows of the package.

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton endpoint readback`

Proof. The norm endpoint row is the zero-exactness surface of Definition 89.4. On the singleton carrier, the only accepted vector endpoint is classified with e, so the norm value is read as $0^{\mathsf{c}}_{\mathsf{Real}}$ by the constant-real classifier.

The inner-product self-value is handled by Definition 91.6. It identifies the induced norm with ν_{e} and states that the diagonal inner-product row is classified with the constant RealUp zero endpoint exactly at the singleton vector classifier boundary.

The Banach distance endpoint comes from Definition 90.3. Its metric row is the norm-induced singleton distance, and Definition 90.13 reads every displayed distance as the same constant RealUp zero endpoint. □

Definition 91.14 (Hilbert singleton projection witness)**.** *For the carrier of Definition 91.2, a Hilbert singleton projection witness from a carried endpoint* m *to a projected endpoint* p *is the concrete tuple*

$$(A_{\mathsf{e}}(m), A_{\mathsf{e}}(p), \rho_{\mathsf{e}}(p, \mathsf{e}), \mathsf{RealConstantHistoryClassifier}(\|m-p\|_{\langle,\rangle_{\mathsf{e}}}, 0^{\mathsf{c}}_{\mathsf{Real}}), \mathsf{RealConstantHistoryClassifier}(\langle m-p, p\rangle_{\mathsf{e}}, 0^{\mathsf{c}}_{\mathsf{Real}}$$

The first two entries record that both endpoints are carried by the singleton empty-history carrier, the third entry fixes the concrete projected endpoint ledger, the fourth entry is the constant RealUp zero readback for the induced norm, and the fifth entry is the constant inner-product row against the projected endpoint.

Lean4 (definition) `BEDC.Derived.HilbertUp.HilbertSingletonProjectionWitness`

Theorem 91.15 (Hilbert singleton projection existence)**.** *Every carried endpoint* m *of Definition 91.2 admits a Hilbert singleton projection witness with projected endpoint* e*.*

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection existence`

Proof. First read the Hilbert carrier through Definition 91.12. The endpoint m is carried by A_{e}, and the projected endpoint e is carried by the same singleton source and classified with itself by ρ_{e}.

Next use Definition 91.13. It identifies the induced norm endpoint exposed by the Hilbert singleton package with the constant RealUp zero endpoint under $\mathsf{RealConstantHistoryClassifier}$.

Finally apply Definition 91.9. The inner-product row is constant at 0^{c}_{Real}, so $\langle m - \mathsf{e}, \mathsf{e}\rangle_{\mathsf{e}}$ is classified with the same constant RealUp zero endpoint. These rows are exactly the tuple required by Definition 91.14. □

Theorem 91.16 (Hilbert singleton projection idempotence)**.** *If p is the projected endpoint in a Hilbert singleton projection witness for m, then the Hilbert singleton projection witness for p has projected endpoint e, and this endpoint is classified with p by ρ_{e}.*

Proof. Unpack the witness of Definition 91.14. One of its displayed rows is $\rho_{\mathsf{e}}(p, \mathsf{e})$, so the projected endpoint is already fixed at the singleton empty-history representative.

Apply Definition 47.4 to the carried endpoint p. The singleton carrier has no second vector endpoint, so the endpoint used by the projection witness of p is again e.

Combining the displayed row $\rho_{\mathsf{e}}(p, \mathsf{e})$ with this singleton collapse gives the idempotence claim: projecting the projected endpoint does not leave the ρ_{e}-class of p. □

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection witness idempotent`

Theorem 91.17 (Hilbert singleton projection orthogonal zero)**.** *Let p be the projected endpoint in a Hilbert singleton projection witness for m. For every carried endpoint n of Definition 91.2, the residual inner-product row is classified with 0^{c}_{Real}:*

$$\mathsf{RealConstantHistoryClassifier}(\langle m - p, n\rangle_{\mathsf{e}}, 0^{c}_{\mathsf{Real}}).$$

Proof. The inner-product operation in Definition 91.2 is constant at 0^{c}_{Real} for every displayed pair of carried histories. Thus the residual row $\langle m - p, n\rangle_{\mathsf{e}}$ does not depend on the representatives m, p, or n.

Use Definition 91.13 to read this displayed inner-product endpoint through the Hilbert singleton package. The scalar classifier is $\mathsf{RealConstantHistoryClassifier}$, and its endpoint is the constant RealUp zero endpoint.

The witness assumption supplies the carried projected endpoint and the $\rho_{\mathsf{e}}(p, \mathsf{e})$ row from Definition 91.14. Hence the residual inner-product row is the same constant-zero row after the projection ledger is unpacked. □

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection orthogonal zero`

Theorem 91.18 (Hilbert singleton projection uniqueness)**.** *Let s be an accepted regular Cauchy stream in the Hilbert singleton carrier. Any two Hilbert singleton limit or projection witnesses for s are identified by ρ_{e}. Consequently they project to the same Banach limit, the same singleton $\mathsf{Norm}^{\uparrow}$ zero endpoint, and the same inner-product zero row.*

Proof. First read each Hilbert limit witness through the complete normed field of Definition 91.7. This places the limit witnesses on the Banach singleton surface for the same accepted regular Cauchy stream.

Apply Definition 90.41 to the two Banach-surface rows. It identifies their displayed limits first by hsame and then by the singleton vector classifier ρ_{e}.

For a projection witness, use Definition 91.14 to read the projected endpoint as a carried singleton endpoint with displayed row $\rho_{\mathsf{e}}(p, \mathsf{e})$. Then apply Definition 91.16. It says that the projection branch remains in the same ρ_{e}-class after projecting again.

Finally use Definition 91.12. The Hilbert carrier, the normed carrier, and the Banach carrier all expose the same classifier surface, so the ρ_{e} comparison just obtained is simultaneously the Banach limit comparison, the NormUp zero-endpoint comparison, and the inner-product row comparison. The endpoint readback is the constant RealUp zero row supplied by Definition 91.13. □

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection uniqueness`

Theorem 91.19 (Hilbert singleton limit inner-product carrier)**.** *Let s be an accepted regular Cauchy stream in the Hilbert singleton carrier, and let ℓ : BHist be the selected complete-limit witness exposed by the Hilbert singleton package. Then ℓ is carried by A_{e}, the classifier ρ_{e} classifies ℓ with e, and the inner-product row of the limit is the constant RealUp zero endpoint:*

$$\mathsf{RealConstantHistoryClassifier}(\langle \ell, \ell \rangle_{\mathsf{e}}, 0^{c}_{\mathsf{Real}}).$$

Proof. First use the complete normed field of Definition 91.7. It reads the accepted Hilbert Cauchy stream as the Banach singleton completion problem and places its selected limit witness on the Banach limit row.

Apply Definition 90.41 to the selected Banach limit row. Since the Banach singleton carrier and classifier are A_{e} and ρ_{e}, the selected witness is classified with e by ρ_{e}.

Finally transport the same witness back through Definition 91.12. The Hilbert and Banach surfaces share the carrier and classifier, while Definition 91.13 reads the diagonal inner-product value as the constant RealUp zero endpoint. □

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton limit inner product carrier`

Theorem 91.20 (Hilbert singleton norm-induced metric classifier)**.** *For carried histories m, n : BHist on the Hilbert singleton carrier, the Banach metric endpoint $d_{\mathsf{e}}(m, n)$, the induced-norm endpoint $\|m - n\|_{\langle,\rangle_{\mathsf{e}}}$, and the constant endpoint 0^{c}_{Real} are classified by $\mathsf{RealConstantHistoryClassifier}$. Consequently the metric classifier on the singleton Hilbert carrier is exactly the norm-induced classifier obtained from the constant inner product.*

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton norm induced metric classifier`

Proof. Begin with Definition 91.6. It identifies the norm induced by the constant inner product with the singleton norm ν_{e} on every carried history.

Next apply Definition 91.3. The Banach distance row attached to the singleton Hilbert package is the distance induced by that same norm, so $d_{\mathsf{e}}(m, n)$ and $\|m - n\|_{\langle,\rangle_{\mathsf{e}}}$ name the same endpoint surface for the classifier.

It remains to read the endpoint. By Definition 91.13, the norm endpoint, the inner-product endpoint, and the Banach metric endpoint are all classified by $\mathsf{RealConstantHistoryClassifier}$ at 0^{c}_{Real}. □

Theorem 91.21 (Hilbert singleton semantic NameCert surface)**.** *The singleton carrier A_{e}, classifier ρ_{e}, constant inner-product row, induced norm row, complete-limit row, norm-induced metric classifier, projection uniqueness row, and ledger exhaustion row together form the concrete paper-side SemanticNameCert surface for $\mathsf{Hilbert}^{\uparrow}$. This surface does not assert a standard bridge; it records the singleton Hilbert certificate inside the BEDC BHist and NameCert interfaces.*

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection semantic name certificate`

Proof. Start from Definition 91.11. It assembles the carrier, classifier, vector source, scalar source, norm source, Banach source, and Hilbert inner-product source into the Hilbert singleton obligation package.

The complete-limit carrier row is supplied by Definition 91.19. The metric row is the norm-induced classifier of Definition 91.20.

Projection determinacy is exactly Definition 91.18, and the remaining certificate ledger is exhausted by Definition 91.10. These rows give the paper-side SemanticNameCert surface for $\mathsf{Hilbert}^{\uparrow}$ while leaving any standard bridge claim outside the singleton certificate. □

Theorem 91.22 (Hilbert singleton universal orthogonality)**.** *For any carried histories $m, n : \mathsf{BHist}$ in the singleton Hilbert carrier, the inner-product endpoint is the constant RealUp zero row:*

$$\mathsf{RealConstantHistoryClassifier}(\langle m, n\rangle_{\mathsf{e}}, 0^{c}_{\mathsf{Real}}).$$

Thus every carried pair is orthogonal under the singleton Hilbert classifier.

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton universal orthogonality`

Proof. By Definition 91.2, every carried history is the public singleton endpoint. Hence the displayed pair has no separate source data beyond the unique e endpoint.

Apply Definition 91.9. The constant inner-product row transports every accepted pair to the same $\mathsf{RealConstantHistoryClassifier}$ value at 0^{c}_{Real}.

Finally, Definition 91.13 identifies that endpoint with the public Hilbert readback row. This is precisely the singleton orthogonality classifier for the carried pair. □

Theorem 91.23 (Hilbert singleton parallelogram collapse)**.** *For carried histories $m, n : \mathsf{BHist}$ in the singleton Hilbert carrier, the parallelogram law surface over the singleton vector-space operations collapses to the constant RealUp zero endpoint. The four norm rows*

$$\nu_{\mathsf{e}}(m+n), \quad \nu_{\mathsf{e}}(m-n), \quad \nu_{\mathsf{e}}(m), \quad \nu_{\mathsf{e}}(n)$$

are all classified with 0^{c}_{Real} by $\mathsf{RealConstantHistoryClassifier}$, so both sides of the Hilbert parallelogram identity are read through the same constant-real row.

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton parallelogram collapse`

Proof. First use Definition 91.12. It places the Hilbert carrier, the singleton vector carrier, and the singleton norm carrier on one shared ρ_{e} source surface.

The vector operations are collapsed by Definition 47.4. Therefore $m+n$, $m-n$, m, and n all expose the unique carried endpoint of the singleton vector space.

Apply Definition 89.3 to those four carried endpoints. Each displayed norm is classified with the constant RealUp zero endpoint, and Definition 91.13 reads these norm rows inside the Hilbert package. The two parallelogram sides therefore have the same classifier row. □

Theorem 91.24 (Hilbert singleton projection boundary)**.** *The public projection boundary of the singleton Hilbert package selects e for every carried input pair. The selected endpoint is classified by ρ_{e}, and the projection readback agrees simultaneously with the Banach limit row, the singleton $\mathsf{Norm}^{\uparrow}$ row, and the constant inner-product zero row.*

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection boundary`

Proof. Apply Definition 91.18 to the public projection witnesses for the carried inputs. Since the Hilbert carrier has only the singleton endpoint, uniqueness identifies every selected endpoint by ρ_{e}.

The complete normed certificate in Definition 91.7 places that selection on the Banach singleton surface. Through Definition 91.12, the same source comparison is also the singleton $\mathsf{Norm}^{\uparrow}$ comparison.

It remains to read the Hilbert geometry row. By Definition 91.22, the inner-product component of the selected pair is the constant RealUp zero row. Hence the projection boundary agrees with the Banach limit row, the NormUp zero row, and the orthogonality row at the same selected endpoint. □

Definition 91.25 (Hilbert singleton orthogonal projection row)**.** *The concrete orthogonal-projection row over the Hilbert singleton carrier is the map*

$$\pi_{\mathsf{e}}(h) := \mathsf{e}.$$

Its ledger surface is the carrier A_{e} of Definition 91.2, the classifier ρ_{e}, the singleton norm row ν_{e}, the constant zero inner-product row $\langle -, - \rangle_{\mathsf{e}}$, and the Banach singleton completion row of Definition 90.3. The row therefore selects the unique carried endpoint e *and records every norm, distance, and inner-product readback through* $\mathsf{RealConstantHistoryClassifier}$ *at* 0^{c}_{Real}.

Theorem 91.26 (Hilbert singleton projection carried endpoint)**.** *For every carried $h : \mathsf{BHist}$ in the Hilbert singleton carrier, the projection endpoint $\pi_{\mathsf{e}}(h)$ is carried, the classifier row $\rho_{\mathsf{e}}(h, \pi_{\mathsf{e}}(h))$ holds, and the norm, distance, and inner-product endpoints exposed by this projection row are classified with 0^{c}_{Real}. Concretely,*

$$\mathsf{RealConstantHistoryClassifier}(\nu_{\mathsf{e}}(\pi_{\mathsf{e}}(h)), 0^{c}_{\mathsf{Real}}), \quad \mathsf{RealConstantHistoryClassifier}(d_{\mathsf{e}}(h, \pi_{\mathsf{e}}(h)), 0^{c}_{\mathsf{Real}}), \quad \mathsf{RealConstantHis}$$

are the endpoint rows carried by $\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}$.

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection carried endpoint`
Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton projection carried endpoint`

Proof. Unfold Definition 91.25. The projection endpoint is definitionally e, and Definition 91.2 identifies e as the carried endpoint of the Hilbert singleton carrier.

The classifier claim follows from Definition 91.12. The Hilbert carrier, NormUp carrier, and Banach carrier expose the same singleton classifier ρ_{e}, so every carried h is compared with the selected endpoint e by the same row.

For the endpoint readbacks, apply Definition 91.13. It classifies the singleton norm endpoint, the Banach distance endpoint, and the inner-product row through $\mathsf{RealConstantHistoryClassifier}$ at 0^{c}_{Real}. Since $\pi_{\mathsf{e}}(h)$ is e, the residual row is one of the displayed singleton inner-product rows. □

Theorem 91.27 (Hilbert singleton projection idempotence)**.** *For every carried $h : \mathsf{BHist}$ in the Hilbert singleton carrier,*

$$\rho_{\mathsf{e}}(\pi_{\mathsf{e}}(\pi_{\mathsf{e}}(h)), \pi_{\mathsf{e}}(h))$$

holds. Moreover the residual inner-product row

$$\langle \pi_{\mathsf{e}}(h) - \pi_{\mathsf{e}}(\pi_{\mathsf{e}}(h)), \pi_{\mathsf{e}}(h) \rangle_{\mathsf{e}}$$

is classified with 0^{c}_{Real} by $\mathsf{RealConstantHistoryClassifier}$.

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection idempotence`

Proof. Unfold the projection row twice. Both $\pi_{\mathsf{e}}(h)$ and $\pi_{\mathsf{e}}(\pi_{\mathsf{e}}(h))$ are the selected endpoint e.

The classifier statement is therefore the singleton reflexive comparison inside ρ_{e}, using the common carrier and classifier surface of Definition 91.12.

The residual inner-product expression has only singleton endpoints. Apply Definition 91.13, which reads every displayed inner-product endpoint in this package as the constant RealUp zero endpoint. □

Theorem 91.28 (Hilbert singleton projection-residual zero package)**.** *For every carried $h : \mathsf{BHist}$ in the Hilbert singleton carrier, set $p := \pi_{\mathsf{e}}(h)$ and $p' := \pi_{\mathsf{e}}(p)$. Then the projected endpoints are classified by*

$$\rho_{\mathsf{e}}(p', p).$$

Moreover the norm endpoints of p, of p', and of the residual display $h - p$ are classified with 0^c_{Real}:

$$\mathsf{RealConstantHistoryClassifier}(\nu_{\mathsf{e}}(p), 0^c_{\mathsf{Real}})$$

$$\mathsf{RealConstantHistoryClassifier}(\nu_{\mathsf{e}}(p'), 0^c_{\mathsf{Real}})$$

$$\mathsf{RealConstantHistoryClassifier}(\|h - p\|_{\langle,\rangle_{\mathsf{e}}}, 0^c_{\mathsf{Real}})$$

The residual inner-product rows used by the projection ledger are also classified with 0^c_{Real}:

$$\mathsf{RealConstantHistoryClassifier}(\langle h - p, p\rangle_{\mathsf{e}}, 0^c_{\mathsf{Real}})$$

$$\mathsf{RealConstantHistoryClassifier}(\langle p - p', p\rangle_{\mathsf{e}}, 0^c_{\mathsf{Real}})$$

$$\mathsf{RealConstantHistoryClassifier}(\langle h - p, p'\rangle_{\mathsf{e}}, 0^c_{\mathsf{Real}})$$

Thus the singleton projection row packages idempotence, zero norm readback, and zero orthogonal residual as one reusable projection obligation.

Proof. Unfold Definition 91.25. The projection sends every carried endpoint to e, so both p and p' are the selected endpoint of the Hilbert singleton carrier. The carried endpoint row is supplied by Definition 91.26.

Apply Definition 91.27. It gives the displayed classifier $\rho_{\mathsf{e}}(p', p)$ and reads the idempotence residual inner-product row $\langle p - p', p\rangle_{\mathsf{e}}$ as the constant RealUp zero endpoint.

For the norm endpoints, use Definition 91.13 for p and p' and use Definition 91.32 for the residual display. Since every displayed endpoint lies on the singleton carrier, each norm row is classified with 0^c_{Real}.

Finally apply Definition 91.22 to the carried singleton endpoints appearing in the residual ledger. It classifies the rows $\langle h - p, p\rangle_{\mathsf{e}}$ and $\langle h - p, p'\rangle_{\mathsf{e}}$ with 0^c_{Real}, completing the projection-residual zero package. □

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection residual zero package`

Theorem 91.29 (Hilbert singleton orthogonal projection NameCert surface)**.** *The row of Definition 91.25, together with Definition 91.12, Definition 91.13, Definition 91.26, Definition 91.27, and Definition 91.18, forms the paper-side singleton orthogonal-projection obligation surface for $\mathsf{NameCert}_{\mathsf{Hilbert}\uparrow}$. Its carrier is A_{e}, its classifier is ρ_{e}, its selected projection is π_{e}, its endpoint ledger is the zero norm, distance, and inner-product row, and its completeness source is the Banach singleton completion row. This surface asserts only the singleton projection obligation and does not claim a general projection theorem or a standard bridge.*

Proof. The carrier and classifier fields are fixed by Definition 91.12. They identify the Hilbert singleton carrier with A_{e} and its comparison row with ρ_{e}.

The concrete projection field is Definition 91.25. The carried endpoint and zero endpoint readbacks are supplied by Definition 91.26; these are the NameCert rows that state the projection lives on the singleton Hilbert surface.

Idempotence is supplied by Definition 91.27. It records that projecting the selected endpoint again returns the same ρ_{e}-class and that the residual inner-product row remains classified with 0^{c}_{Real}.

The uniqueness field is Definition 91.18. It compares any two limit or projection witnesses by ρ_{e}, so the selected projection row is the unique singleton endpoint in the certificate surface. The endpoint classification used by all these rows is Definition 91.13, and the completion source is Definition 90.3. □

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonOrthogonalProjection namecert surface`

Theorem 91.30 (Hilbert singleton projection standard bridge)**.** *The public singleton projection surface of Definition 91.29 bridges conservatively to the one-point Hilbert space. Under this bridge, the carrier A_{e} maps to the unique point, the classifier ρ_{e} maps to equality on that point, the projection π_{e} maps to the identity projection, and the Banach distance, NormUp norm, and inner-product rows map to the zero metric, zero norm, and zero inner product.*

Proof. The source side is the public singleton surface. Its carrier and classifier are fixed by Definition 91.12, so the only standard carrier compatible with the displayed row is the one-point Hilbert space, and ρ_{e} reads as equality on its unique point.

The projection row is fixed by Definition 91.26. Since the carried endpoint is the unique endpoint, Definition 91.27 identifies applying π_{e} again with the same endpoint, and Definition 91.18 prevents a second projection value. Thus the standard interpretation of π_{e} is the identity projection on the one-point Hilbert space.

It remains to read the scalar rows. The endpoint readback theorem Definition 91.13 identifies every displayed norm endpoint with 0^{c}_{Real}, while Definition 91.29 packages the Banach singleton distance, NormUp norm, and inner-product rows as the zero metric, zero norm, and zero inner product. These identifications give a conservative paper-side standard bridge for the singleton projection surface only. □

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection standard bridge`

Theorem 91.31 (Hilbert singleton orthogonal complement collapse)**.** *For the carrier of Definition 91.2, any displayed vector endpoint orthogonal to the singleton carried surface is classified by ρ_{e} with e. Conversely, every carried endpoint has the zero inner-product row against every carried endpoint:*

$$\mathsf{RealConstantHistoryClassifier}(\langle m, n\rangle_{\mathsf{e}}, 0^{c}_{\mathsf{Real}})$$

for carried histories $m, n : \mathsf{BHist}$. Thus the displayed orthogonal complement of the singleton carrier collapses to the singleton endpoint.

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton orthogonal complement collapse`

Proof. First identify the source surface. By Definition 91.12, the Hilbert carrier, the singleton vector-space carrier, and the Banach carrier all expose the same predicate A_{e} and classifier ρ_{e}.

Now apply Definition 47.4. Any displayed vector endpoint on this singleton vector-space surface is therefore classified by ρ_{e} with e; there is no separate vector endpoint available for an orthogonal-complement row.

For the converse direction, take carried endpoints $m, n : \mathsf{BHist}$. Definition 91.22 reads their inner-product endpoint as 0^{c}_{Real} under $\mathsf{RealConstantHistoryClassifier}$, so every carried endpoint is orthogonal to every other carried endpoint in the singleton Hilbert display. □

Theorem 91.32 (Hilbert singleton projection-residual decomposition)**.** *Let s be an accepted regular Cauchy stream in the Hilbert singleton carrier, and let p be a Hilbert singleton projection witness for its carried endpoint. Then p decomposes the endpoint into its unique ρ_{e}-classified projection plus a residual whose inner-product row is orthogonal to the singleton carrier and whose norm endpoint is 0^{c}_{Real}.*

Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingletonProjection residual decomposition`
Lean4 ✓ `BEDC.Derived.HilbertUp.HilbertSingleton projection residual decomposition`

Proof. Use Definition 91.18 to read the projection witness against the complete singleton Hilbert surface. Any other limit or projection witness for the same accepted stream is identified with p by ρ_{e}.

The projection component is therefore the singleton endpoint classified by ρ_{e} with e. The complete normed certificate Definition 91.7 supplies the matching Banach limit row and the norm-induced constant RealUp zero endpoint.

It remains to identify the residual row. Since both the carried endpoint and the projection component lie on the singleton carrier, Definition 91.22 classifies the inner-product row of the residual comparison with 0^{c}_{Real}.

Definition 91.31 then collapses the residual endpoint itself to the singleton classifier. Its norm endpoint is read back as 0^{c}_{Real} by the complete normed certificate, so the projection plus residual display is the unique singleton decomposition with zero orthogonal residual. □

Closure status for $\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}$**.**

Constructive story: A Hilbert object in this concrete closure is the same singleton carrier A_{e} seen simultaneously as Banach, normed, and inner-product data, with all three surfaces sharing the classifier ρ_{e} and the same empty-history endpoint. The inner product is the constant RealUp zero row, the induced norm is the singleton $\mathsf{Norm}^{\uparrow}$ norm, the Banach metric and completion rows are the singleton completion rows, and the projection map sends every carried endpoint back to e, so any non-singleton endpoint or separate closed-subspace carrier is excluded. The source is the compatible Banach-plus-inner-product package, the pattern records norm-induced metric compatibility, complete-limit stability, endpoint readback, projection existence, projection idempotence, uniqueness, orthogonal residual decomposition, and universal zero orthogonality, and the ledger keeps the Banach surface, NormUp zero row, constant inner-product row, selected projection endpoint, and residual rows aligned. The five name-certificate obligations close because e inhabits A_{e}, ρ_{e} supplies reflexivity, symmetry, and transitivity, and the compatibility rows transport Banach metric, norm, inner-product, limit, and projection witnesses along the same classifier. A history h lies in the signature gap of a $\mathsf{Hilbert}^{\uparrow}$ token p when the source-domain accepts the singleton compatible carrier and projection row, the signature relation pairs it with a projected answer endpoint and evidence ledger, and token introduction names that answer as p; unfolded, h is carried by A_{e} and the answer is the ρ_{e}-class of e with zero norm and zero residual inner product. The paper bridge reads the package as the one-point Hilbert space and reads back its unique point, zero norm, zero inner product, and projection endpoint through the same singleton rows. The chapter registers this singleton projection package under the name $\mathsf{Hilbert}^{\uparrow}$; arbitrary Hilbert spaces, arbitrary closed-subspace projections, spectral theory, and checked bridge verification are not introduced.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The Hilbert surface is closed for the singleton projection NameCert package: carrier A_{e}, classifier ρ_{e}, projection endpoint π_{e}, Banach singleton completion row, NormUp zero row, constant inner-product zero row, residual decomposition rows, and the one-point standard bridge of Definition 91.30.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.HilbertUp.HilbertSingletonProjection\_semantic\_name\_certificate`

Bridge status: bridgeChecked
Not claimed: It does not close arbitrary Hilbert spaces, arbitrary closed-subspace projections, or spectral theory.
Upgrade path: no further upgrade – chapter at top of formal axis.

Measure consumers route through the calculus and integral sibling surface of chapter 3632; the dependency path is carried by `parts/concrete_instances/measure/probability_integral_dependency_route` below together with the adjacent probability-integral rows.

Chapter 92

A Concrete Naming Certificate for $\mathsf{Measure}^{\uparrow}$

The measure interface $\mathsf{Measure}^{\uparrow}$ packages a carrier with a constructive σ-additive non-negative real-valued set function on a designated σ-algebra of measurable subsets. It depends on $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ (chapter 38) and supplies the substrate for the integral certificate $\mathsf{NameCert}_{\mathsf{Integral}^{\uparrow}}$ (chapter 123).

The same carrier surface supplies the finite event-algebra rows and $\mathsf{Real}^{\uparrow}$-valued mass rows consumed by $\mathsf{ProbSpace}^{\uparrow}$ in chapter 184, with the real endpoints classified through chapter 38.

92.1 Carrier definition

Definition 92.1 (MeasureUp carrier surface)**.** *A* $\mathsf{Measure}^{\uparrow}$ *carrier surface is a tuple*

$$(\mathsf{MCarrier}, \sim_M, \mathcal{A}, \mu, \sim_R)$$

with the following rows. The carrier row is a predicate $\mathsf{MCarrier} : \mathsf{BHist} \to \mathsf{Prop}$*. The classifier row* $h \sim_M k$ *is a NameCert-style classifier on carried histories in the sense of Definition 9.7. The measurable-subset row* $\mathcal{A}(h, E)$ *assigns to each carried history* h *a designated family of measurable subsets* E *of its event object. The measure row* $\mu_h(E)$ *assigns to every* $\mathcal{A}(h, E)$ *a* $\mathsf{Real}^{\uparrow}$ *endpoint classified by the* $\mathsf{Real}^{\uparrow}$ *classifier* $\sim_R$ *of Definition 38.9.*

Carrier transport is part of the surface: if $\mathsf{MCarrier}(h)$*,* $h \sim_M k$*, and* $\mathcal{A}(h, E)$*, then the transported event row is read in the* k*-fiber, and the corresponding measure values compare under* $\sim_R$*.*

Definition 92.2 (MeasureUp countable-additivity row)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier surface as in Definition 92.1, the countable-additivity row fixes, for every carried history* h*, a sequence* $E : \mathbb{N} \to \mathcal{P}(h)$ *satisfying:*

1. *each* E_n *is measurable,* $\mathcal{A}(h, E_n)$*;*
2. *the sequence is pairwise disjoint in the* h*-fiber;*
3. *the union event* $\bigcup_{n:\mathbb{N}} E_n$ *is supplied as a measurable row of* $\mathcal{A}(h, -)$*;*
4. *there is a countable* $\mathsf{Real}^{\uparrow}$ *sum endpoint* $\sum_{n=0}^{\infty} \mu_h(E_n)$*;*
5. *the head-tail readback compares this endpoint with* $\mu_h(E_0) + \sum_{n=0}^{\infty} \mu_h(E_{n+1})$ *under* $\sim_R$*;*
6. *pointwise* $\sim_R$*-classification of the summands transports to* $\sim_R$*-classification of the two countable sum endpoints.*

The row asserts the sigma-additivity comparison

$$\mu_h\left(\bigcup_{n:\mathbb{N}} E_n\right) \sim_R \sum_{n=0}^{\infty} \mu_h(E_n).$$

Theorem 92.3 (Measure carrier classifier obligations)**.** *Every* $\mathsf{Measure}^{\uparrow}$ *carrier surface supplies the NameCert-style reflexivity, symmetry, and transitivity rows for* $\sim_M$ *on carried histories, and it transports* $\mathsf{MCarrier}$*, measurable rows, and measure comparisons along that classifier.*

Proof. Unpack the carrier surface of Definition 92.1. Its classifier row is required to be a carrier naming certificate in the sense of Definition 9.7, so reflexivity, symmetry, transitivity, and carrier transport are projections of that row.

The measurable-subset and measure rows are indexed by carried histories. The surface states that a classifier comparison between carried histories re-reads the event row in the target fiber and compares the corresponding $\mathsf{Real}^{\uparrow}$ measure values. Applying that transport clause gives exactly the displayed carrier, classifier, and measure-stability obligations. □

Theorem 92.4 (Measure sigma-algebra obligations)**.** *For every* $\mathsf{Measure}^{\uparrow}$ *carrier surface, the designated measurable family* $\mathcal{A}(h, -)$ *is closed under the empty event, binary union, countable union, and complement rows used by the measure certificate whenever* $\mathsf{MCarrier}(h)$ *holds.*

Proof. Fix a carried history h. The measurable-subset row in Definition 92.1 is the designated sigma-algebra family for the h-fiber, so its certificate clauses give the empty event and complement rows.

The same sigma-algebra row supplies finite binary union as the two-term case of its closure data, and it supplies countable union for every measurable sequence. These are the exact rows consumed by the sigma-additivity comparison in Definition 92.2. □

Theorem 92.5 (Measure RealUp sum scope)**.** *The countable-additivity comparison of Definition 92.2 is scoped only to the* $\mathsf{Real}^{\uparrow}$ *classifier stability of Definition 38.9 and to the additive* $\mathsf{AbGroup}^{\uparrow}$ *zero, unit, and congruence rows cited from Definition 42.1. It does not assert an independent construction of real analysis outside those rows.*

Proof. Unpack the countable-additivity row. Its endpoint is a $\mathsf{Real}^{\uparrow}$ countable sum, and every comparison involving that endpoint is stated under the classifier $\sim_R$ from Definition 38.9.

The two measure consequences below use this endpoint only through head-tail readback, pointwise classifier stability, sigma-additivity, and the additive $\mathsf{AbGroup}^{\uparrow}$ rows of Definition 42.1. Thus the scope of the row is exactly the named classifier and additive certificate surface, with no extra analytic closure claim. □

Definition 92.6 (MeasureUp carrier obligation inventory)**.** *A* $\mathsf{Measure}^{\uparrow}$ *carrier is a* BHist *package whose rows expose the constructive measure-space data needed by the certificate. Its ten-field inventory is:*

1. *traditional target: a constructive measure space;*
2. *BEDC source:* $\mathsf{Real}^{\uparrow}$*, the additive* $\mathsf{AbGroup}^{\uparrow}$ *row for* $\mathsf{Real}^{\uparrow}$ *addition, and countable StreamName-style measurable families of chapter 126;*
3. *carrier choice: a* BHist *package containing a sample/event carrier, a* σ*-algebra predicate* $\mathcal{A}$*, a* $\mathsf{Real}^{\uparrow}$*-valued map* μ*, and rows for the empty event, binary union, countable union, and complement/relative difference;*

4. *classifier choice: componentwise* hsame *on the carrier package, together with the* $\mathsf{Real}^{\uparrow}$ *classifier on measure values;*
5. *stability obligations: carrier transport, measurable-set transport, μ-congruence, complement/relative-difference transport, σ-additivity, and head-tail readback for countable sums;*
6. *ledger: event rows, relative-difference rows, measurable sequence rows, and countable-sum rows;*
7. *core theorem list: empty set zero, finite disjoint-union additivity, relative-difference additivity, and countable disjoint additivity;*
8. *exactness predicate: measurable package coverage, soundness, and completeness;*
9. *standard bridge: absent at this paper site;*
10. *status: paper obligation surface.*

The countable-family row is read through StreamName finite observations and the $\mathsf{Real}^{\uparrow}$ *endpoint classifier, not through a host-level sequence primitive.*

Definition 92.7 (Measure classifier specification)**.** *For two* $\mathsf{Measure}^{\uparrow}$ *carriers M and N as in Definition 92.1, the public classifier $M \sim_{\mathsf{Measure}^{\uparrow}} N$ consists of shared event-carrier sameness and endpoint agreement. Shared event-carrier sameness says that an event witness of M and an event witness of N classify the same displayed event precisely when their BHist presentations are related by the displayed* hsame *transport rows and their measurable witnesses transport between the two displayed measurable families. Endpoint agreement says that, for every such shared measurable event, the endpoints $\mu_M(E)$ and $\mu_N(E')$ compare through* RealConstantHistoryClassifier *and hence through the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. The classifier does not assert quotient equality or host set equality; it only records the public event witness, measurable witness, and* $\mathsf{Real}^{\uparrow}$ *endpoint rows visible in the carrier ledger.*

Lean4 (definition) `BEDC.Derived.MeasureUp.MeasureClassifierSpecification`

Theorem 92.8 (Measure carrier transport obligation)**.** *Let $\mathcal{M}$ be a* $\mathsf{Measure}^{\uparrow}$ *certificate surface as in Definition 92.15. If $h, k : \mathsf{BHist}$ satisfy $\mathsf{MeasCode}(h)$ and $h \sim_M k$, then $\mathsf{MeasCode}(k)$. Moreover, every displayed row attached to the carried measure code, namely the measurable-family row, σ-algebra rows, complement/relative-difference row,* $\mathsf{Real}^{\uparrow}$ *endpoint map, σ-additivity row, head-tail row, and countable-sum classifier row, may be read at k after transporting its carrier proof along $h \sim_M k$.*

Proof. The carrier part is the transport field of the core $\mathsf{NameCert}(\mathsf{MeasCode}, \sim_M)$ in the surface. Apply it to the carried proof at h and the classifier comparison $h \sim_M k$.

The remaining rows are fields of the same certificate surface indexed by the carried measure code. Once the carrier proof has been moved from h to k, the row projections are read with that transported proof. No quotient or host equality of histories is used; the only movement is along the displayed NameCert classifier. □

Theorem 92.9 (MeasureUp carrier-classifier obligation)**.** *For the* $\mathsf{Measure}^{\uparrow}$ *sigma-algebra carrier surface of Definition 92.14, the carrier slots are exactly the displayed* BHist *rows for measurable events, empty event, binary union, countable union, complement/relative-difference, disjoint sequence readback,* $\mathsf{Real}^{\uparrow}$ *measure values, hidden measurable-set membership, and countable-sum witnesses. The classifier slots are exactly componentwise* hsame *on those rows, together with the* $\mathsf{Real}^{\uparrow}$ *classifier on measure endpoints. Transport along the classifier carries each carrier slot to the corresponding slot of the target presentation.*

Proof. Read the ten fields of Definition 92.14. The carrier entries are the rows named in the carrier, stability, and ledger clauses, and no additional carrier row is listed by the exactness clause.

For transport, project the componentwise hsame witness at each visible row. The event rows move by their own history-sameness components, and the measure-value rows move by first projecting the endpoint comparison and then using $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ to read it as a $\mathsf{Real}^\uparrow$ classifier comparison.

The ledger rows are repacked after the visible rows move. Since exactness says that every hidden membership, relative-difference, or countable-sum witness is attached to one of the displayed rows, transporting the visible row also transports the only ledger entry that can justify it. □

Theorem 92.10 (Measure constant-empty sigma-additive row)**.** *Let $\mathcal{M}$ be a $\mathsf{Measure}^\uparrow$ certificate surface as in Definition 92.15. Define $E_n := \varnothing$ for every $n : \mathbb{N}$. Then $E_\bullet$ is a measurable sequence, it is pairwise disjoint, its countable union is $\varnothing$, and the σ-additivity row gives the comparison*

$$\mu(\varnothing) \sim_R \Sigma_\mu(E_\bullet).$$

This is the sigma-additive input used by Definition 92.25.

Proof. The σ-algebra rows of the surface include the empty-event row, so each E_n is measurable. Pairwise disjointness is immediate because both sides of every pairwise intersection are the empty predicate.

The countable union of the constant-empty sequence is again the empty predicate. The countable-union row therefore identifies the union endpoint required by the σ-additivity row with $\varnothing$.

Apply the σ-additivity row to this measurable pairwise-disjoint sequence and its displayed union. The resulting comparison is precisely $\mu(\varnothing) \sim_R \Sigma_\mu(E_\bullet)$. □

Theorem 92.11 (MeasureUp sigma-additivity obligation)**.** *For the $\mathsf{Measure}^\uparrow$ sigma-algebra carrier surface of Definition 92.14, the sigma-additivity row classifies the value of a countable disjoint union by the displayed countable $\mathsf{Real}^\uparrow$ sum. Concretely, for every pairwise-disjoint measurable sequence $E_\bullet$ with countable union U, the certificate supplies*

$$\mu(U) \sim_R \Sigma_\mu(E_\bullet).$$

The same row supplies the measurable-sequence, disjointness, union, head-tail, and $\mathsf{Real}^\uparrow$ endpoint hypotheses consumed by Definition 92.25 and Definition 92.26.

Proof. Project the sigma-additivity row from the carrier surface and apply it to the displayed measurable sequence $E_\bullet$, its pairwise-disjointness witness, and its countable-union row U. The projected conclusion is exactly the $\mathsf{Real}^\uparrow$ classifier comparison between $\mu(U)$ and $\Sigma_\mu(E_\bullet)$.

For the empty-zero theorem, specialize $E_\bullet$ to the constant empty sequence. The empty-event, countable-union, disjointness, and head-tail rows are precisely the hypotheses required there.

For the finite disjoint-union theorem, specialize $E_\bullet$ to the sequence with first terms A and B and empty tail. Binary-union closure supplies the visible union row, while countable-union and head-tail readback supply the countable sum whose first two summands are $\mu(A)$ and $\mu(B)$. □

Theorem 92.12 (Measure countable-sum classifier stability obligation)**.** *Let $\mathcal{M}$ be a $\mathsf{Measure}^\uparrow$ certificate surface as in Definition 92.15. Let $E_\bullet$ and $F_\bullet$ be measurable sequences. If every index satisfies $\mu(E_n) \sim_R \mu(F_n)$ through the $\mathsf{Real}^\uparrow$ classifier, then their countable endpoints satisfy*

$$\Sigma_\mu(E_\bullet) \sim_R \Sigma_\mu(F_\bullet).$$

In particular, the all-empty tail used in Definition 92.25 and the shifted empty tail used in Definition 92.26 transport to the same countable $\mathsf{Real}^{\uparrow}$ *sum.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureZeroBHistPrefix classifier stability`

Proof. The countable-sum classifier row is part of the certificate surface. Feed it the two measurable sequences and the pointwise $\mathsf{Real}^{\uparrow}$ classifier comparison of their measure endpoints.

For the all-empty tail, the pointwise comparison is reflexivity of $\sim_R$ at each endpoint $\mu(\varnothing)$. For the shifted finite-union tail, every shifted term is the empty event, so the same reflexive pointwise comparison applies after reading the sequence definition at each index.

Thus both downstream arguments may replace a syntactically shifted empty countable sum by the canonical all-empty countable sum using only classifier transport, not host-level equality of sums. □

Theorem 92.13 (MeasureUp ledger exactness obligation)**.** *For the* $\mathsf{Measure}^{\uparrow}$ *sigma-algebra carrier surface of Definition 92.14, the ledger contains exactly the empty-event, binary-union, countable-union, complement/relative-difference, disjointness, measure-value, and countable-sum rows. Every hidden measurable-set membership witness, every relative-difference witness, and every countable-sum witness is attached to one of those displayed rows, and no external choice object or quotient object is part of the ledger.*

Proof. Unpack the ledger and exactness clauses of Definition 92.14. The ledger clause lists only hidden measurable-set membership witnesses, relative-difference witnesses, and countable-sum witnesses, and the surrounding carrier and stability clauses list the visible rows to which those witnesses may attach.

Exactness is visible row exhaustion. Therefore every ledger witness must be read through the empty-event, binary-union, countable-union, complement/relative-difference, disjointness, measure-value, or countable-sum row that exposes it.

Since the ten-field surface names only BHist rows, hsame, $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, and the additive $\mathsf{AbGroup}^{\uparrow}$ row, there is no remaining slot in which an external choice object or quotient object could be stored. □

Definition 92.14 (MeasureUp sigma-algebra carrier surface)**.** *The* $\mathsf{Measure}^{\uparrow}$ *sigma-algebra carrier surface is the following ten-field BEDC package.*

1. *traditional target: a constructive measure space whose measurable predicates form a* σ*-algebra and whose measure map takes values in* $\mathsf{Real}^{\uparrow}$*;*
2. *BEDC source:* BHist *presentations, the certificate* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*, and the additive* $\mathsf{AbGroup}^{\uparrow}$ *row on real histories;*
3. *carrier: a* BHist *package exposing measurable-event rows for the empty event, binary union, countable union, complement/relative-difference, disjoint sequence readback, and* $\mathsf{Real}^{\uparrow}$ *measure values;*
4. *classifier: componentwise* hsame *on the package rows, with the* $\mathsf{Real}^{\uparrow}$ *classifier applied to the visible measure endpoints;*
5. *stability rows: transport for the empty event, binary union, countable union, complement/relative-difference, disjoint sequence readback, and* $\mathsf{Real}^{\uparrow}$ *measure values;*
6. *ledger rows: hidden measurable-set membership witnesses, relative-difference witnesses, and countable-sum witnesses attached to the visible rows they justify;*

7. *core theorem list: Definition 92.25, Definition 92.26, and Definition 92.102;*
8. *exactness: visible row exhaustion, meaning every measurable-set, disjointness, relative-difference, value, and countable-sum witness consumed by the certificate is attached to one of the displayed rows;*
9. *standard bridge: no* StandardBridge *is asserted at this paper site;*
10. *status: paper-side target for the* $\mathsf{Measure}^{\uparrow}$ *NameCert obligation package.*

Lean4 (definition) `BEDC.Derived.MeasureUp.MeasureSigmaAlgebraCarrierSurface`

Definition 92.15 (MeasureUp certificate surface)**.** *A* $\mathsf{Measure}^{\uparrow}$ *certificate surface over the BEDC history substrate consists of the following data.*

1. *a carrier predicate* $\mathsf{MeasCode} : \mathsf{BHist} \to \mathsf{Prop}$ *for histories that present measure codes;*
2. *a classifier* $\sim_M : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *and a core* $\mathsf{NameCert}(\mathsf{MeasCode}, \sim_M)$*, so membership in* $\mathsf{MeasCode}$ *transports along* $\sim_M$ *by the* $\mathsf{NameCert}$ *transport field;*
3. *a designated measurable-family predicate* $\mathsf{MeasFam}$ *on predicates* $E : \mathsf{BHist} \to \mathsf{Prop}$*, stable under the displayed classifier and under* hsame *on the endpoint histories that present the same event;*
4. *a* $\mathsf{Real}^{\uparrow}$*-valued endpoint map* μ *from measurable predicates to their measure endpoints, with equality of measurable presentations transported through the* $\mathsf{Real}^{\uparrow}$ *classifier* $\sim_R$ *of Definition 38.9;*
5. *a countable-sum endpoint* $\Sigma_\mu(E_\bullet)$ *for each measurable sequence* $E_\bullet : \mathbb{N} \to (\mathsf{BHist} \to \mathsf{Prop})$*;*
6. σ*-algebra rows asserting* $\mathsf{MeasFam}(\varnothing)$*, binary-union closure for disjoint measurable pairs, countable-union closure for measurable sequences, and complement/relative-difference closure for displayed inclusions of measurable events in the same carried fiber;*
7. *a* σ*-additivity row: whenever* $E_\bullet$ *is a pairwise-disjoint measurable sequence with countable union* U*, the comparison* $\mu(U) \sim_R \Sigma_\mu(E_\bullet)$ *holds;*
8. *a head-tail readback row: for every measurable sequence* $E_\bullet$*, the endpoint* $\Sigma_\mu(E_\bullet)$ *is classified with* $\mu(E_0) + \Sigma_\mu(E_{\bullet+1})$ *by the* $\mathsf{Real}^{\uparrow}$ *additive operation;*
9. *a countable-sum classifier row: pointwise classifier equality of measurable sequences transports their countable endpoints through* $\sim_R$*.*

The dependencies of the surface are exactly the BEDC objects named above: $\mathsf{NameCert}$ *supplies carrier and classifier transport;* BHist *supplies the visible code substrate;* hsame *and* Cont *supply history sameness and continuation discipline for event presentations;* $\mathsf{Real}^{\uparrow}$ *supplies the codomain classifier; and the additive* $\mathsf{AbGroup}^{\uparrow}$ *row of Definition 42.1 supplies the addition, zero, congruence, and cancellation laws used by the displayed measure consequences.*

Lean4 (definition) `BEDC.Derived.MeasureUp.MeasureCertificateSurface`

Definition 92.16 (Measure complement and relative-difference row)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *certificate surface as in Definition 92.15, the complement/relative-difference row is the displayed carrier row with the following fields. Whenever* A *and* B *are measurable events in the same carried fiber and the public event readback displays* $B \subseteq A$*, the row supplies a measurable event* $A \setminus B$ *in that fiber. It also supplies a disjointness witness between* B *and* $A \setminus B$*, a binary-union readback classifying* $B \cup (A \setminus B)$ *as* A*, and a* $\mathsf{Real}^{\uparrow}$ *endpoint row for* $\mu(A \setminus B)$*.*

The same row is stable under the public $\mathsf{Measure}^{\uparrow}$ *classifier. If componentwise* hsame *transports the carried fiber, the event presentations, and the inclusion witness from one package to another, the*

relative-difference event, its measurable witness, its disjointness witness, its binary-union readback, and its measure endpoint transport to the corresponding target package. The endpoint movement is read through the $\mathsf{Real}^{\uparrow}$ *classifier* $\sim_R$ *supplied by Definition 38.9.*

Lean4 (definition) `BEDC.Derived.MeasureUp.MeasureComplementDifferenceRow`

Theorem 92.17 (Measure root NameCert carrier and classifier)**.** *The root* $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ *surface has carrier face* $\mathsf{MeasCode}$ *and classifier face* $\sim_M$ *exactly as displayed in Definition 92.14 and Definition 92.15. Its visible event rows are the empty-event, binary-union, countable-union, complement/relative-difference, disjoint-sequence readback, and countable-sum endpoint rows of those definitions, and its endpoint classifier rows are read through the* $\mathsf{Real}^{\uparrow}$ *classifier* $\sim_R$*. The root face does not assert a quotient of measure codes and does not identify host event predicates by ambient set equality.*

Proof. Project the carrier list of Definition 92.14. The third, fourth, fifth, sixth, and eighth fields name the displayed measure-code carrier, the componentwise classifier, the event-row stability data, the ledger rows, and the visible-row exactness requirement.

Next project Definition 92.15. Its first two clauses name $\mathsf{MeasCode}$, $\sim_M$, and the core $\mathsf{NameCert}(\mathsf{MeasCode}, \sim_M)$ transport field. Its event-family, endpoint, countable-sum, σ-algebra, σ-additivity, head-tail, and countable-sum classifier clauses supply the visible rows and the $\mathsf{Real}^{\uparrow}$ endpoint classifier.

The statement follows by reading these projections as the root public face: transport is the $\mathsf{NameCert}$ transport field, while quotienting of codes and ambient host set equality never appear among the displayed fields. □

Theorem 92.18 (Measure root NameCert stability and exactness)**.** *For the root* $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ *surface, Definition 92.9, Definition 92.12, Definition 92.11, and Definition 92.13 supply, respectively, componentwise transport of the carrier rows, classifier stability of countable-sum endpoints,* σ*-additive classification of disjoint countable unions, and visible ledger exhaustion for every witness consumed by the root surface.*

Proof. Start with Definition 92.9. It transports the displayed empty, binary-union, countable-union, complement/relative-difference, disjoint-readback, and endpoint rows componentwise along the public $\mathsf{Measure}^{\uparrow}$ classifier.

The countable endpoint row is stable by Definition 92.12. This keeps the $\mathsf{Real}^{\uparrow}$ endpoint classifier compatible with pointwise transport of measurable sequences.

The σ-additive classifier row is supplied by Definition 92.11: pairwise-disjoint measurable sequences with displayed union U classify $\mu(U)$ against the countable endpoint assigned to the sequence.

Finally Definition 92.13 states that the membership, relative-difference, disjointness, value, and countable-sum witnesses consumed by the surface are exactly the witnesses attached to the visible rows. These four rows therefore give the stability and exactness face of the root package. □

Theorem 92.19 (Measure root downstream boundary)**.** *The downstream public boundary of the root* $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ *surface is exactly the collection exposed by Definition 92.27, Definition 92.59, and Definition 92.60. These are precisely the rows consumed by* $\mathsf{ProbSpace}^{\uparrow}$*,* $\mathsf{Integral}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*, with no additional host carrier, quotient relation, or unlisted ledger witness exported to those chapters.*

Proof. Project Definition 92.27. It packages the carrier, classifier, stability, exactness, nonnegative value, monotone inclusion, and measure consequence rows as the public $\mathsf{Measure}^{\uparrow}$ substrate.

The probability boundary is the one isolated by Definition 92.59. It exposes the total event normalization and the finite-additivity rows used by $\mathsf{ProbSpace}^{\uparrow}$, while keeping the remaining measure witnesses inside the named package.

The integral and functional-analysis boundary is the one isolated by Definition 92.60. It exposes measurable event membership, nonnegative endpoints, monotone inclusion, relative-difference rows, and countable-sum rows to $\mathsf{Integral}^{\uparrow}$ and $\mathsf{FunctionalAnalysis}^{\uparrow}$. Together these projections give exactly the downstream boundary stated above. □

92.2 The certificate

Theorem 92.20 (Measure carrier and classifier stability)**.** *Let M and N be $\mathsf{Measure}^{\uparrow}$ carriers as in Definition 92.1, related by the classifier of Definition 92.7. If E is a displayed event of M, E' is a displayed event of N, and the event presentations satisfy $\mathsf{hsame}(E, E')$, then the measurable witness for E in $\mathcal{A}_M$ transports to a measurable witness for E' in $\mathcal{A}_N$. Moreover the visible measure endpoints satisfy*

$$\mu_M(E) \sim_R \mu_N(E')$$

through $\mathsf{RealConstantHistoryClassifier}$ *and the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9.*

Proof. The shared event-carrier component of Definition 92.7 is exactly the transport rule for displayed event witnesses. Apply it to the $\mathsf{hsame}(E, E')$ comparison to move the event witness and its measurable row from M to N.

The endpoint component of the classifier reads the two ledger endpoints attached to the transported measurable event. Since the carrier specification records the event witness, measurable witness, and $\mathsf{Real}^{\uparrow}$ endpoint in the same visible ledger, the endpoint comparison is the displayed $\mathsf{RealConstantHistoryClassifier}$ row.

Finally, Definition 38.9 identifies that row as a valid $\mathsf{Real}^{\uparrow}$ classifier comparison. No quotient of event codes and no host equality of subsets is introduced. □

Theorem 92.21 (MeasureUp classifier stability obligations)**.** *For a $\mathsf{Measure}^{\uparrow}$ carrier with inventory Definition 92.6, componentwise* hsame *of carrier packages transports every row named by the inventory. In particular, if two packages are componentwise* hsame*, then measurable membership in $\mathcal{A}$, the $\mathsf{Real}^{\uparrow}$-valued measure rows for μ, the σ-algebra closure rows, and the $\mathsf{Real}^{\uparrow}$ classifier on μ-values are preserved across the transport.*

Proof. Unpack the carrier inventory. The event carrier, the measurable predicate, the measure map, and the empty, binary-union, countable-union, and complement/relative-difference rows are separate components of the same BHist package.

Componentwise hsame supplies a transport witness for each component. Applying the measurable-set component transports membership in $\mathcal{A}$, and applying the closure-row components transports the empty, binary-union, and countable-union witnesses. The same componentwise projection transports the relative-difference event, its inclusion readback, its disjointness witness, and its binary-union readback.

It remains to identify the value rows. The μ-congruence component sends transported measurable events to transported $\mathsf{Real}^{\uparrow}$ values, and the $\mathsf{Real}^{\uparrow}$ classifier of Definition 38.9 composes those comparisons inside the codomain. Hence the classifier on μ-values is stable under the same componentwise carrier transport. □

Theorem 92.22 (MeasureUp sigma-additive certificate obligations)**.** *For a $\mathsf{Measure}^{\uparrow}$ carrier with inventory Definition 92.6, a $\mathsf{Measure}^{\uparrow}$ certificate consists of the following rows:*

1. *empty-event membership* $\varnothing \in \mathcal{A}$*;*
2. *binary disjoint-union closure in* $\mathcal{A}$*;*
3. *countable disjoint-union closure in* $\mathcal{A}$ *for StreamName-style measurable families;*
4. *complement/relative-difference closure for displayed inclusions* $B \subseteq A$ *of measurable events in the same carried fiber;*
5. σ*-additivity into the* $\mathsf{Real}^{\uparrow}$ *countable-sum classifier;*
6. *classifier-stable head-tail readback for those countable sums.*

With these rows, Definition 92.25 and Definition 92.26 are consequences of the certificate package, and the displayed relative-difference row supplies the finite difference readback of Definition 92.102.

Proof. The first row gives the all-empty measurable sequence used for the zero law. The countable disjoint-union row identifies its union as the empty event, and the σ-additivity row compares $\mu(\varnothing)$ with the associated $\mathsf{Real}^{\uparrow}$ countable sum.

Head-tail readback splits that sum into its head and tail. The classifier stability theorem transports the tail back to the original all-empty sum, and the additive $\mathsf{AbGroup}^{\uparrow}$ row then cancels the repeated summand exactly as in Definition 92.25.

For the finite disjoint-union law, use the measurable sequence whose first two terms are the given disjoint events and whose remaining terms are empty. Binary closure supplies measurability of $A \cup B$, countable closure supplies the same event as the countable union, and σ-additivity compares its measure with the corresponding countable sum.

Two applications of head-tail readback expose the first two summands. The empty tail is classified as 0_R by the zero law, and the additive $\mathsf{AbGroup}^{\uparrow}$ row removes that unit. The resulting comparison is the statement of Definition 92.26.

For displayed inclusions $B \subseteq A$, the complement/relative-difference row supplies the measurable event $A \setminus B$, the disjointness of B and $A \setminus B$, and the binary-union readback to A. Feeding those rows into finite disjoint-union additivity gives the finite difference comparison. □

Theorem 92.23 (Measure finite-support countable readback)**.** *Let* M *be a* $\mathsf{Measure}^{\uparrow}$ *carrier as in Definition 92.1. Let* $E_\bullet$ *be a pairwise-disjoint measurable sequence such that* $E_n = \varnothing$ *for every* $n \geq 2$*. Write*

$$S := \Sigma_\mu(E_\bullet), \qquad T := \Sigma_\mu(E_{\bullet+1}), \qquad U := \Sigma_\mu(E_{\bullet+2}).$$

If the carrier supplies classifier-stable head-tail readback, pointwise countable-sum stability, and the additive $\mathsf{AbGroup}^{\uparrow}$ *row of Definition 42.1 with zero* 0_R*, then*

$$S \sim_R \mu(E_0) + \mu(E_1).$$

Proof. Apply the head-tail row to the original sequence. It gives $S \sim_R \mu(E_0) + T$. Apply the same row to the shifted sequence. It gives $T \sim_R \mu(E_1) + U$.

It remains to read back the empty tail. Let $F_n := \varnothing$ for all n. Since $E_{n+2} = \varnothing$ by hypothesis, pointwise countable-sum stability gives $U \sim_R \Sigma_\mu(F_\bullet)$. The constant-empty σ-additivity row identifies $\mu(\varnothing)$ with $\Sigma_\mu(F_\bullet)$, and Definition 92.25 identifies $\mu(\varnothing)$ with 0_R.

Transport this comparison through the additive congruence supplied by Definition 42.1. The right-unit law then reads $\mu(E_1) + U$ as $\mu(E_1)$, and a final congruence step reads $\mu(E_0) + T$ as $\mu(E_0) + \mu(E_1)$. □

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureZeroBHistPrefix finite support countable readback`

Theorem 92.24 (Measure certificate obligation threshold)**.** *A* $\mathsf{Measure}^{\uparrow}$ *NameCert obligation threshold is reached by the following paper-side data: a carrier satisfying Definition 92.1, a classifier satisfying Definition 92.7, the stability row of Definition 92.20, the finite-support countable readback row of Definition 92.23, the empty-set-zero theorem Definition 92.25, and the finite disjoint-union additivity theorem Definition 92.26. These data provide the carrier transport, classifier transport, σ-additive readback, zero endpoint, binary additivity, and visible ledger rows required by the public* $\mathsf{Measure}^{\uparrow}$ *certificate surface.*

Proof. The carrier and classifier definitions supply the public surface: event witnesses, measurable witnesses, endpoint rows, and classifier movement are all visible BHist and $\mathsf{Real}^{\uparrow}$ rows. The stability theorem is the transport field of the surface, with endpoint movement discharged by Definition 38.9.

The finite-support theorem turns the countable-sum row into the binary readback needed by finite disjoint union. The empty-set-zero theorem supplies the additive zero endpoint, and the additive $\mathsf{AbGroup}^{\uparrow}$ row of Definition 42.1 supplies the congruence and unit laws used in that readback.

Finally, Definition 92.26 packages these rows into the displayed binary additivity clause. The cancellation step used by the zero endpoint is exactly the group row cited in Definition 41.114, so the threshold is assembled from visible certificate fields rather than from external set equality. □

Theorem 92.25 (Measure empty set is zero)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let $\mathcal{A}$ be its designated σ-algebra, let μ be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write $x \sim_R y$ for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Suppose $\varnothing \in \mathcal{A}$, and suppose the* $\mathsf{Measure}^{\uparrow}$ *certificate supplies σ-additivity for every pairwise-disjoint measurable sequence, together with classifier-stable head-tail readback for the resulting countable* $\mathsf{Real}^{\uparrow}$ *sum. If the target* $\mathsf{Real}^{\uparrow}$ *addition is carried by its additive* $\mathsf{AbGroup}^{\uparrow}$ *row with zero 0_R, then*

$$\mu(\varnothing) \sim_R 0_R.$$

Proof. Let $E_n := \varnothing$ for every $n : \mathbb{N}$. The hypothesis $\varnothing \in \mathcal{A}$ makes every E_n measurable. The sequence is pairwise disjoint, and its union is again $\varnothing$.

Let S be the countable $\mathsf{Real}^{\uparrow}$ sum $\sum_{n=0}^{\infty} \mu(E_n)$. The σ-additivity row gives

$$\mu(\varnothing) \sim_R S.$$

The head-tail row for this sum gives

$$S \sim_R \mu(E_0) + \sum_{n=1}^{\infty} \mu(E_n).$$

Since $E_0 = \varnothing$, the first summand is $\mu(\varnothing)$. The tail sequence $(E_{n+1})_{n\geq 0}$ is pointwise the same empty sequence as $(E_n)_{n\geq 0}$, so countable-sum classifier stability gives

$$\sum_{n=1}^{\infty} \mu(E_n) \sim_R S.$$

Composing this with the σ-additivity comparison and transporting the right summand through addition yields

$$S \sim_R \mu(\varnothing) + \mu(\varnothing).$$

Composing once more with $\mu(\varnothing) \sim_R S$ gives

$$\mu(\varnothing) \sim_R \mu(\varnothing) + \mu(\varnothing).$$

By symmetry, $\mu(\varnothing) + \mu(\varnothing) \sim_R \mu(\varnothing)$.

The additive $\mathsf{AbGroup}^{\uparrow}$ row described in Definition 42.1 gives the group hypotheses for $+$ and 0_R. Applying Definition 41.114 with $a = \mu(\varnothing)$ and $b = \mu(\varnothing)$ forces the right summand to the additive unit, yielding $\mu(\varnothing) \sim_R 0_R$. □

Theorem 92.26 (Measure finite disjoint-union additivity)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $A, B \in \mathcal{A}$ *be disjoint, and let* $A \cup B$ *be the measurable binary union supplied by the* σ*-algebra row. Suppose* $\varnothing \in \mathcal{A}$*, and suppose the* $\mathsf{Measure}^{\uparrow}$ *certificate supplies* σ*-additivity for every pairwise-disjoint measurable sequence, together with classifier-stable head-tail readback and pointwise classifier stability for the resulting countable* $\mathsf{Real}^{\uparrow}$ *sums. If the target* $\mathsf{Real}^{\uparrow}$ *addition is carried by its additive* $\mathsf{AbGroup}^{\uparrow}$ *row with zero* 0_R*, then*

$$\mu(A \cup B) \sim_R \mu(A) + \mu(B).$$

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureFiniteDisjointUnion additivity`

Proof. Define a measurable sequence by $E_0 := A$, $E_1 := B$, and $E_n := \varnothing$ for every $n \geq 2$. Each term is measurable because $A, B, \varnothing \in \mathcal{A}$. The sequence is pairwise disjoint: the only nonempty pair to check is A against B, and this is the displayed disjointness hypothesis. Its countable union is exactly $A \cup B$.

Let

$$S := \sum_{n=0}^{\infty} \mu(E_n), \qquad T := \sum_{n=0}^{\infty} \mu(E_{n+1}), \qquad U := \sum_{n=0}^{\infty} \mu(E_{n+2}).$$

The σ-additivity row gives

$$\mu(A \cup B) \sim_R S.$$

The first head-tail readback gives

$$S \sim_R \mu(E_0) + T,$$

hence $S \sim_R \mu(A) + T$. The second head-tail readback gives

$$T \sim_R \mu(E_1) + U,$$

hence $T \sim_R \mu(B) + U$.

It remains to identify the empty tail. Let $F_n := \varnothing$ for every n, and let $S_\varnothing := \sum_{n=0}^{\infty} \mu(F_n)$. Since $E_{n+2} = F_n$ for every n, pointwise classifier stability of the countable sum gives

$$U \sim_R S_\varnothing.$$

Applying σ-additivity to the all-empty sequence gives $\mu(\varnothing) \sim_R S_\varnothing$, while Definition 92.25 gives $\mu(\varnothing) \sim_R 0_R$. By symmetry and transitivity of the $\mathsf{Real}^{\uparrow}$ classifier, $S_\varnothing \sim_R 0_R$, and therefore

$$U \sim_R 0_R.$$

The additive $\mathsf{AbGroup}^{\uparrow}$ row of Definition 42.1 supplies addition congruence and the right-unit law. Transporting $U \sim_R 0_R$ through addition gives

$$\mu(B) + U \sim_R \mu(B) + 0_R \sim_R \mu(B),$$

so $T \sim_R \mu(B)$. Transporting this comparison through addition with the fixed left summand $\mu(A)$ gives

$$\mu(A) + T \sim_R \mu(A) + \mu(B).$$

Composing this with $S \sim_R \mu(A) + T$ and with $\mu(A \cup B) \sim_R S$ yields the displayed classification. □

Theorem 92.27 (MeasureUp NameCert obligation package)**.** *The rows displayed in Definition 92.14, together with the classifier transport of Definition 92.9, the complement transport of Definition 92.100, the sigma-additivity classification of Definition 92.11, the ledger exactness of Definition 92.13, the nonnegative value obligation of Definition 92.98, the monotone measurable inclusion row of Definition 92.99, and the measure consequence theorems Definition 92.25, Definition 92.26, Definition 92.102, Definition 92.28, Definition 92.29, Definition 92.30, Definition 92.31, Definition 92.32, Definition 92.33, and Definition 92.34, form the* $\mathsf{Measure}^{\uparrow}$ *NameCert obligation package. This package is the measure substrate consumed by* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureNamecertObligationPackage`

Proof. Start with the carrier surface and project its visible event, value, stability, and ledger rows. Repack those projections as the carrier and classifier side of the $\mathsf{Measure}^{\uparrow}$ certificate.

The carrier-classifier obligation supplies componentwise transport for every displayed row, including the complement/relative-difference row. The complement-row transport theorem makes that projection available under the public classifier. The sigma-additivity obligation supplies the countable-union classification needed by the measure consequences, while the ledger exactness obligation identifies all hidden witnesses with their visible rows.

Finally include the nonnegative value row, the measurable-inclusion monotonicity row, and the empty-zero, finite disjoint-union, relative-difference, null-event neutral, symmetric finite-readback, empty-union, zero-tail, finite three-support, and triple disjoint-union consequence theorems as the core theorem rows of the package. The downstream chapters named in the statement consume only this package surface: $\mathsf{Integral}^{\uparrow}$ uses the measurable event, nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum rows, $\mathsf{ProbSpace}^{\uparrow}$ uses the empty and disjoint-union rows, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ uses the $\mathsf{Real}^{\uparrow}$ value classifier and additive compatibility rows. □

Theorem 92.28 (Measure null event addition neutral)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* E *be a measurable event, let* $\varnothing$ *be the empty measurable event, and let* 0_R *be the additive unit in the* $\mathsf{Real}^{\uparrow}$ *additive* $\mathsf{AbGroup}^{\uparrow}$ *row. Then the finite measure endpoint satisfies both neutral readbacks*

$$\mu(E) + \mu(\varnothing) \sim_R \mu(E)$$

and

$$\mu(\varnothing) + \mu(E) \sim_R \mu(E).$$

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureCountableZeroTail canonical`

Proof. Definition 92.25 gives $\mu(\varnothing) \sim_R 0_R$ from the all-empty countable disjoint family. The $\mathsf{Real}^{\uparrow}$ classifier transport row carries this comparison through addition with the fixed endpoint $\mu(E)$.

For the right neutral readback, additive congruence gives $\mu(E) + \mu(\varnothing) \sim_R \mu(E) + 0_R$. The right-unit row of the additive $\mathsf{AbGroup}^{\uparrow}$ structure then gives $\mu(E) + 0_R \sim_R \mu(E)$, and transitivity of $\sim_R$ composes the two comparisons.

For the left neutral readback, the same transport gives $\mu(\varnothing) + \mu(E) \sim_R 0_R + \mu(E)$. The left-unit row of the additive $\mathsf{AbGroup}^{\uparrow}$ structure gives $0_R + \mu(E) \sim_R \mu(E)$, so transitivity gives the displayed comparison. □

Theorem 92.29 (Measure finite disjoint-union symmetric readback)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* A *and* B *be disjoint measurable events, and let* $A \cup B$ *be the measurable binary union row. If the ordered finite readback gives*

$$\mu(A \cup B) \sim_R \mu(A) + \mu(B),$$

then the symmetric readback also holds:

$$\mu(A \cup B) \sim_R \mu(B) + \mu(A).$$

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureZeroBHistClassifier empty union comm`

Proof. Apply Definition 92.26 to the displayed disjoint measurable pair. This supplies the ordered comparison $\mu(A \cup B) \sim_R \mu(A) + \mu(B)$ from empty-zero, head-tail readback, and finite-support countable additivity.

The additive commutativity row of the $\mathsf{Real}^{\uparrow}$ additive $\mathsf{AbGroup}^{\uparrow}$ surface gives $\mu(A) + \mu(B) \sim_R \mu(B) + \mu(A)$. Transitivity of the $\mathsf{Real}^{\uparrow}$ classifier composes the ordered finite readback with this commutativity row and gives the symmetric readback. □

Theorem 92.30 (Measure empty-union right unit)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $A \in \mathcal{A}$*, and let* $A \cup \varnothing$ *be the measurable binary union row supplied by the* σ*-algebra row. Suppose* $\varnothing \in \mathcal{A}$*, and suppose the* $\mathsf{Measure}^{\uparrow}$ *certificate supplies the sigma-additivity, head-tail, and countable-sum stability rows used in Definition 92.26. If the target* $\mathsf{Real}^{\uparrow}$ *addition is carried by its additive* $\mathsf{AbGroup}^{\uparrow}$ *row with zero* 0_R*, then*

$$\mu(A \cup \varnothing) \sim_R \mu(A).$$

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureEmptyUnion right unit`

Proof. The events A and $\varnothing$ are disjoint, and the displayed binary union row is measurable. Apply Definition 92.26 with $B = \varnothing$ to obtain

$$\mu(A \cup \varnothing) \sim_R \mu(A) + \mu(\varnothing).$$

By Definition 92.25, $\mu(\varnothing) \sim_R 0_R$. Addition congruence in the additive $\mathsf{AbGroup}^{\uparrow}$ row transports the right summand to 0_R, and the right-unit law gives $\mu(A) + 0_R \sim_R \mu(A)$. Transitivity of $\sim_R$ yields the displayed comparison. □

Theorem 92.31 (Measure disjoint-union symmetric readback)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $A, B \in \mathcal{A}$ *be disjoint, and let* $A \cup B$ *be the measurable binary union supplied by the* σ*-algebra row. Suppose* $\varnothing \in \mathcal{A}$*, and suppose the* $\mathsf{Measure}^{\uparrow}$ *certificate supplies the sigma-additivity, head-tail, and countable-sum stability rows used in Definition 92.26. If the target* $\mathsf{Real}^{\uparrow}$ *addition is carried by its additive* $\mathsf{AbGroup}^{\uparrow}$ *row, then*

$$\mu(A \cup B) \sim_R \mu(B) + \mu(A).$$

Proof. Apply Definition 92.26 to the disjoint measurable pair A, B. This gives

$$\mu(A \cup B) \sim_R \mu(A) + \mu(B).$$

The additive $\mathsf{AbGroup}^{\uparrow}$ row supplies commutativity for $+$. Hence $\mu(A)+\mu(B) \sim_R \mu(B)+\mu(A)$, and composing the two comparisons gives the stated symmetric readback. □

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureZeroBHistClassifier union symmetry`

Theorem 92.32 (Measure countable zero tail canonical)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, write* 0_R *for the additive zero in the target* $\mathsf{Real}^{\uparrow}$ *row, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $F_\bullet$ *be the constant-empty measurable sequence* $F_n := \varnothing$*. Suppose* $\varnothing \in \mathcal{A}$*, the sequence is read by the* σ*-additivity row of Definition 92.10, the countable-sum classifier is stable under pointwise* $\sim_R$*-classification, and the target* $\mathsf{Real}^{\uparrow}$ *addition is carried by the additive* $\mathsf{AbGroup}^{\uparrow}$ *row of Definition 42.1. Then the canonical countable endpoint of the all-empty sequence is classified with zero:*

$$\Sigma_\mu(F_\bullet) \sim_R 0_R.$$

Proof. Apply the σ-additivity row to the all-empty measurable sequence. Its countable union is the empty event, so the row gives a classifier comparison between $\mu(\varnothing)$ and $\Sigma_\mu(F_\bullet)$.

The zero endpoint theorem Definition 92.25 classifies $\mu(\varnothing)$ with 0_R. The $\mathsf{Real}^{\uparrow}$ classifier fields from Definition 38.9 compose the two comparisons and orient the result toward the countable endpoint.

Countable-sum classifier stability makes this endpoint independent of the chosen constant-empty presentation. The additive $\mathsf{AbGroup}^{\uparrow}$ row supplies the zero endpoint used by the comparison, so the all-empty countable sum has the canonical classification displayed above. □

Theorem 92.33 (Measure finite three-support countable readback)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, write* 0_R *for the additive zero in the target* $\mathsf{Real}^{\uparrow}$ *row, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $E_\bullet$ *be a pairwise-disjoint measurable sequence such that* $E_n = \varnothing$ *for every* $n \geq 3$*. Suppose the* $\mathsf{Measure}^{\uparrow}$ *certificate supplies* σ*-additivity for pairwise-disjoint measurable sequences, classifier-stable head-tail readback and pointwise classifier stability for the resulting countable* $\mathsf{Real}^{\uparrow}$ *sums, and the target* $\mathsf{Real}^{\uparrow}$ *addition is carried by its additive* $\mathsf{AbGroup}^{\uparrow}$ *row. Then*

$$\Sigma_\mu(E_\bullet) \sim_R (\mu(E_0) + \mu(E_1)) + \mu(E_2).$$

Proof. Let

$$S := \Sigma_\mu(E_\bullet), \qquad T := \Sigma_\mu(E_{\bullet+1}), \qquad U := \Sigma_\mu(E_{\bullet+2}), \qquad V := \Sigma_\mu(E_{\bullet+3}).$$

Apply head-tail readback to the original sequence, to the once-shifted sequence, and to the twice-shifted sequence. These comparisons classify S with $\mu(E_0) + T$, classify T with $\mu(E_1) + U$, and classify U with $\mu(E_2) + V$.

The three-shifted tail is the all-empty sequence by the support hypothesis. Pointwise countable-sum stability transports V to the canonical empty-sequence endpoint, and Definition 92.32 classifies that endpoint with 0_R.

Use additive congruence from Definition 42.1 to transport the comparison $V \sim_R 0_R$ through the third head-tail equation. The right-unit law reads $\mu(E_2) + 0_R$ as $\mu(E_2)$, so $U \sim_R \mu(E_2)$.

Transport this comparison through the second and first head-tail equations. Associativity from the additive $\mathsf{AbGroup}^{\uparrow}$ row rewrites $\mu(E_0) + (\mu(E_1) + \mu(E_2))$ as $(\mu(E_0) + \mu(E_1)) + \mu(E_2)$, giving the displayed classification. □

Theorem 92.34 (Measure triple disjoint-union additivity)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $A, B, C \in \mathcal{A}$ *be pairwise disjoint. Suppose the measurable binary-union rows display* $A \cup B \in \mathcal{A}$ *and* $(A \cup B) \cup C \in \mathcal{A}$*, and suppose*

the $\mathsf{Measure}^{\uparrow}$ *certificate supplies* σ*-additivity for pairwise-disjoint measurable sequences, classifier-stable head-tail readback and pointwise classifier stability for the resulting countable* $\mathsf{Real}^{\uparrow}$ *sums, and the target* $\mathsf{Real}^{\uparrow}$ *addition is carried by its additive* $\mathsf{AbGroup}^{\uparrow}$ *row. Then*

$$\mu((A \cup B) \cup C) \sim_R (\mu(A) + \mu(B)) + \mu(C).$$

Proof. Define $E_0 := A$, $E_1 := B$, $E_2 := C$, and $E_n := \varnothing$ for every $n \geq 3$. The displayed measurable rows make each term measurable, and pairwise disjointness of A, B, C is the only nonempty disjointness check.

The countable union of this sequence is the displayed event $(A \cup B) \cup C$. Applying σ-additivity gives a classifier comparison between $\mu((A \cup B) \cup C)$ and $\Sigma_\mu(E_\bullet)$.

The finite three-support readback theorem Definition 92.33 classifies $\Sigma_\mu(E_\bullet)$ with $(\mu(E_0) + \mu(E_1)) + \mu(E_2)$. Substituting the three displayed heads and composing the $\mathsf{Real}^{\uparrow}$ classifier comparisons gives the claimed triple disjoint-union additivity. □

Theorem 92.35 (Measure two-step finite-additivity package)**.** *The* $\mathsf{Measure}^{\uparrow}$ *finite-additivity readback surface consists of the empty-zero row, null-event neutrality, ordered binary disjoint-union additivity, and symmetric binary disjoint-union additivity. Its fit is the following ten-field package:*

1. *traditional target: finite additive measure readback;*
2. *BEDC source:* $\mathsf{Measure}^{\uparrow} + \mathsf{Real}^{\uparrow} + \mathsf{AbGroup}^{\uparrow}$*;*
3. *carrier: measurable* BHist *event rows;*
4. *classifier: the endpoint classifier* $\sim_R$*;*
5. *stability: classifier transport and additive congruence;*
6. *ledger: empty-event, binary-union, and countable-tail rows;*
7. *core theorem list: Definition 92.25, Definition 92.28, Definition 92.26, and Definition 92.29;*
8. *exactness: visible finite support readback;*
9. *standard bridge: absent at this paper site;*
10. *status: paper target.*

Proof. Project the empty measurable event, binary-union row, countable disjoint-family row, head-tail countable-sum row, endpoint classifier, and additive $\mathsf{AbGroup}^{\uparrow}$ rows from Definition 92.27.

The empty-zero row is exactly Definition 92.25. The two null-event neutrality rows are Definition 92.28, obtained by transporting empty-zero through additive congruence and then applying the left and right unit laws.

For a disjoint measurable pair, the ordered binary readback is Definition 92.26. Composing that ordered readback with additive commutativity gives Definition 92.29. These four rows are precisely the finite support surface required by downstream $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ consumers. □

Theorem 92.36 (Measure triple disjoint-union associativity)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9, and write* $X \sim_M Y$ *for the public event classifier of Definition 92.7. Let* $A, B, C \in \mathcal{A}$ *be pairwise disjoint displayed events in one carried fiber. Let* U_{AB} *be the displayed binary union* $A \cup B$*, let* U_{BC} *be the displayed binary union* $B \cup C$*, let* U_L *be the displayed binary union* $U_{AB} \cup C$*, and let* U_R *be the displayed binary union* $A \cup U_{BC}$*. Assume*

the binary-union rows unfold membership by disjunction in the displayed fiber, and assume the hypotheses of Definition 92.26 for the disjoint pairs A, B, B, C, U_{AB}, C, and A, U_{BC}. If the target $\mathsf{Real}^{\uparrow}$ *addition is carried by its additive* $\mathsf{AbGroup}^{\uparrow}$ *row, then the two bracketed finite unions are classifier-equal as measurable events,*

$$U_L \sim_M U_R,$$

and their measure endpoints are classifier-equal,

$$\mu(U_L) \sim_R \mu(U_R).$$

Proof. First compare the displayed event rows. For any point of the carried fiber, the membership readback for U_L unfolds to

$$(x \in A \vee x \in B) \vee x \in C,$$

while the membership readback for U_R unfolds to

$$x \in A \vee (x \in B \vee x \in C).$$

The two implications are obtained by cases on the displayed disjunctions: from the left display, either the first summand gives $x \in A$ or $x \in B$, or the second summand gives $x \in C$; from the right display, either $x \in A$, or the right summand gives $x \in B$ or $x \in C$. Thus the two binary-union presentations have the same public membership readback. The measurable witnesses transport along this readback, so the event component of Definition 92.7 gives

$$U_L \sim_M U_R.$$

Pairwise disjointness of A, B, C also gives the two compound disjointness witnesses needed below. If a point lies in both U_{AB} and C, the membership readback for U_{AB} puts it in A or in B, contradicting the corresponding pairwise disjointness with C. Hence U_{AB} and C are disjoint. Similarly, if a point lies in both A and U_{BC}, the membership readback for U_{BC} puts it in B or in C, contradicting the corresponding pairwise disjointness with A. Hence A and U_{BC} are disjoint.

Apply Definition 92.26 to A and B:

$$\mu(U_{AB}) \sim_R \mu(A) + \mu(B).$$

Apply the same theorem to U_{AB} and C:

$$\mu(U_L) \sim_R \mu(U_{AB}) + \mu(C).$$

Addition congruence in the additive $\mathsf{AbGroup}^{\uparrow}$ row transports the first comparison through the left summand of the second comparison, giving

$$\mu(U_{AB}) + \mu(C) \sim_R (\mu(A) + \mu(B)) + \mu(C).$$

By transitivity of $\sim_R$,

$$\mu(U_L) \sim_R (\mu(A) + \mu(B)) + \mu(C).$$

Apply Definition 92.26 to B and C:

$$\mu(U_{BC}) \sim_R \mu(B) + \mu(C).$$

Apply the same theorem to A and U_{BC}:

$$\mu(U_R) \sim_R \mu(A) + \mu(U_{BC}).$$

Addition congruence transports the comparison for U_{BC} through the fixed left summand $\mu(A)$, so

$$\mu(A) + \mu(U_{BC}) \sim_R \mu(A) + (\mu(B) + \mu(C)).$$

The additive associativity row of Definition 42.1 classifies

$$\mu(A) + (\mu(B) + \mu(C)) \sim_R (\mu(A) + \mu(B)) + \mu(C).$$

Composing these comparisons yields

$$\mu(U_R) \sim_R (\mu(A) + \mu(B)) + \mu(C).$$

Finally, symmetry and transitivity of the $\mathsf{Real}^{\uparrow}$ classifier compose the two readbacks to the common endpoint $(\mu(A) + \mu(B)) + \mu(C)$. Therefore

$$\mu(U_L) \sim_R \mu(U_R).$$

□

Definition 92.37 (Measure four-support sequence surface)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, a four-support sequence surface consists of measurable events* $E_0, E_1, E_2, E_3 \in \mathcal{A}$*, a pairwise-disjoint measurable sequence* $E_\bullet$*, and the empty event* $\varnothing \in \mathcal{A}$ *such that*

$$E_\bullet(0) = E_0, \qquad E_\bullet(1) = E_1, \qquad E_\bullet(2) = E_2, \qquad E_\bullet(3) = E_3$$

and $E_\bullet(n) = \varnothing$ *for every* $n \geq 4$*. The surface records only the displayed event rows, their pairwise-disjointness witnesses, the countable-union row, the countable* $\mathsf{Real}^{\uparrow}$ *sum endpoint* $\Sigma_\mu(E_\bullet)$*, and the head-tail readback rows supplied by the* $\mathsf{Measure}^{\uparrow}$ *certificate.*

Theorem 92.38 (Measure four-support countable readback)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, write* 0_R *for the additive zero in the target* $\mathsf{Real}^{\uparrow}$ *row, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $E_\bullet$ *be a four-support sequence surface in the sense of Definition 92.37. Suppose the* $\mathsf{Measure}^{\uparrow}$ *certificate supplies* σ*-additivity for pairwise-disjoint measurable sequences, classifier-stable head-tail readback and pointwise classifier stability for the resulting countable* $\mathsf{Real}^{\uparrow}$ *sums, and the target* $\mathsf{Real}^{\uparrow}$ *addition is carried by its additive* $\mathsf{AbGroup}^{\uparrow}$ *row. Then*

$$\Sigma_\mu(E_\bullet) \sim_R (((\mu(E_0) + \mu(E_1)) + \mu(E_2)) + \mu(E_3)).$$

Proof. Let $F_\bullet$ be the shifted sequence $F_n := E_\bullet(n+1)$. The four-support surface makes $F_0 = E_1$, $F_1 = E_2$, $F_2 = E_3$, and $F_n = \varnothing$ for every $n \geq 3$, so $F_\bullet$ is a finite three-support sequence with the same measurable and pairwise-disjoint rows.

Apply head-tail readback to $E_\bullet$. It classifies $\Sigma_\mu(E_\bullet)$ with $\mu(E_0) + \Sigma_\mu(F_\bullet)$.

Apply Definition 92.33 to $F_\bullet$. This classifies the shifted endpoint with $(\mu(E_1) + \mu(E_2)) + \mu(E_3)$, using countable zero-tail exactness at the three-shifted tail and the additive unit rows of $\mathsf{Real}^{\uparrow}$.

Transport the shifted comparison through the first summand by additive congruence. Associativity in the additive $\mathsf{AbGroup}^{\uparrow}$ row rewrites $\mu(E_0) + ((\mu(E_1) + \mu(E_2)) + \mu(E_3))$ first as $(\mu(E_0) + (\mu(E_1) + \mu(E_2))) + \mu(E_3)$ and then as $((\mu(E_0) + \mu(E_1)) + \mu(E_2)) + \mu(E_3)$. Transitivity of $\sim_R$ composes these classifier comparisons and gives the displayed endpoint. □

Theorem 92.39 (Measure quadruple disjoint-union additivity)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $A, B, C, D \in \mathcal{A}$ *be pairwise disjoint. Suppose the measurable binary-union rows display* $A \cup B \in \mathcal{A}$*,* $(A \cup B) \cup C \in \mathcal{A}$*, and* $((A \cup B) \cup C) \cup D \in \mathcal{A}$*, and suppose the* $\mathsf{Measure}^{\uparrow}$ *certificate supplies* σ*-additivity for pairwise-disjoint measurable sequences, classifier-stable head-tail readback and pointwise classifier stability for the resulting countable* $\mathsf{Real}^{\uparrow}$ *sums, and the target* $\mathsf{Real}^{\uparrow}$ *addition is carried by its additive* $\mathsf{AbGroup}^{\uparrow}$ *row. Then*

$$\mu(((A \cup B) \cup C) \cup D) \sim_R (((\mu(A) + \mu(B)) + \mu(C)) + \mu(D)).$$

Proof. Define $E_0 := A$, $E_1 := B$, $E_2 := C$, $E_3 := D$, and $E_n := \varnothing$ for every $n \geq 4$. The displayed measurable rows make each term measurable, and pairwise disjointness of A, B, C, D is the only nonempty disjointness check.

The countable union of this sequence is the displayed event $((A \cup B) \cup C) \cup D$. Applying σ-additivity gives a classifier comparison between $\mu(((A \cup B) \cup C) \cup D)$ and $\Sigma_\mu(E_\bullet)$.

The four-support readback theorem Definition 92.38 classifies $\Sigma_\mu(E_\bullet)$ with $((\mu(E_0) + \mu(E_1)) + \mu(E_2)) + \mu(E_3)$. Substituting the four displayed heads and composing the $\mathsf{Real}^{\uparrow}$ classifier comparisons gives the claimed quadruple disjoint-union additivity. □

Theorem 92.40 (Measure four-support analysis consumer package)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, the four-support analysis package consumed by probability partitions, simple-integral rectangles, and functional-analysis positive decompositions has exactly these visible rows:*

1. *four displayed measurable event rows* E_0, E_1, E_2, E_3 *with pairwise disjointness witnesses;*
2. *the countable empty-tail sequence surface of Definition 92.37;*
3. *the four-support countable endpoint classification of Definition 92.38;*
4. *the displayed quadruple disjoint-union measure row of Definition 92.39.*

The package exposes no host set equality, no quotient event carrier, and no extra $\mathsf{Real}^{\uparrow}$ *operation beyond the additive* $\mathsf{AbGroup}^{\uparrow}$ *associativity, unit, congruence, and classifier-transitivity rows used in those four visible rows.*

Proof. Project the displayed event rows, empty-tail sequence, countable-union row, head-tail readback rows, and $\mathsf{Real}^{\uparrow}$ endpoint classifier from the $\mathsf{Measure}^{\uparrow}$ certificate. Project additive associativity, unit, congruence, and classifier transitivity from the target $\mathsf{Real}^{\uparrow}$ additive $\mathsf{AbGroup}^{\uparrow}$ surface.

The countable endpoint row is Definition 92.38. The public finite union row is Definition 92.39. These two rows use only the four displayed event entries, the empty tail, and the listed additive $\mathsf{Real}^{\uparrow}$ structure.

Probability partitions, simple-integral rectangles, and positive decompositions read the same rows: they need four visible measurable pieces, their classified measure endpoints, the bracketed finite sum, and the displayed disjoint-union endpoint. Since every step is phrased through measurable-event witnesses and $\mathsf{Real}^{\uparrow}$ classifier comparisons, no host set equality or quotient event carrier is introduced. □

92.3 Continuity from below row

Theorem 92.41 (Measure monotone partial-union chain)**.** *Let* M *be a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, with designated measurable family* $\mathcal{A}$*, measure map* μ*, and event classifier* $\sim_M$*. Let* $E_\bullet$ *be a displayed increasing measurable sequence in one carried* BHist *fiber: every* E_n *is in* $\mathcal{A}$*,*

and the public event readback displays $E_n \subseteq E_{n+1}$. Then the $\mathsf{Measure}^{\uparrow}$ *sigma-algebra and relative-difference rows supply measurable finite partial unions P_n and pairwise disjoint measurable layers D_n such that*

$$D_0 = E_0, \qquad D_{n+1} = E_{n+1} \setminus E_n, \qquad P_n \sim_M E_n.$$

Moreover P_n is classified as the displayed disjoint union $D_0 \sqcup \cdots \sqcup D_n$, and the public monotone row classifies $\mu(E_n) \leq_R \mu(E_{n+1})$ for every n.

Proof. Start with $D_0 := E_0$ and $P_0 := E_0$. The displayed measurability of E_0 gives both rows, and the classifier comparison $P_0 \sim_M E_0$ is reflexivity of the $\mathsf{Measure}^{\uparrow}$ event classifier.

For the successor step, apply Definition 92.101 to the displayed inclusion $E_n \subseteq E_{n+1}$. It supplies the measurable layer $D_{n+1} := E_{n+1} \setminus E_n$, its disjointness from E_n, and the binary-union readback

$$E_n \sqcup D_{n+1} \sim_M E_{n+1}.$$

Use the induction readback $P_n \sim_M E_n$ to transport this binary-union row from E_n to P_n. The sigma-algebra binary-union row then supplies $P_{n+1} := P_n \sqcup D_{n+1}$ as a measurable event, classified with E_{n+1} by the composed event classifier comparison.

The disjointness of the accumulated layers follows by induction from the displayed chain: earlier layers lie inside E_n by the previous partial-union readback, while the new layer is disjoint from E_n. Finally apply Definition 92.99 to each displayed inclusion $E_n \subseteq E_{n+1}$ to obtain $\mu(E_n) \leq_R \mu(E_{n+1})$. □

Theorem 92.42 (Measure continuity from below package)**.** *Let M be a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1. For a displayed increasing measurable sequence $E_\bullet$, let $D_0 := E_0$ and $D_{n+1} := E_{n+1} \setminus E_n$ be the measurable disjoint layers supplied by Definition 92.41. If $U := \bigcup_{n:\mathbb{N}} E_n$ is the countable-union row of the same measurable sequence, then the σ-additivity row classifies*

$$\mu(U) \sim_R \Sigma_\mu(D_\bullet).$$

For every finite prefix, the finite disjoint-union readback classifies

$$\Sigma_\mu(D_0, \ldots, D_n) \sim_R \mu(E_n),$$

where the left endpoint denotes the visible finite-support countable sum associated to the first $n+1$ layers and an empty tail.

Proof. Apply Definition 92.41 to obtain the layer sequence $D_\bullet$, the partial unions P_n, and the classifier readbacks $P_n \sim_M E_n$. The same theorem gives pairwise disjointness of the layers and measurability of every layer.

The countable union of the layers is classified with the countable union $U := \bigcup_n E_n$: every layer lies in the corresponding E_n, and every element visible in some E_n lies in the finite partial union $D_0 \sqcup \cdots \sqcup D_n$ by the partial-union readback. This is an event classifier comparison, not a host-level equality of subsets.

Apply the σ-additivity row of Definition 92.22 to the pairwise-disjoint measurable sequence $D_\bullet$. It gives the comparison between the measure of the displayed countable union of the layers and $\Sigma_\mu(D_\bullet)$, and event-classifier transport carries the left endpoint to $\mu(U)$.

For a fixed n, apply finite disjoint-union additivity along the visible binary-union tree for $P_n = D_0 \sqcup \cdots \sqcup D_n$. The finite-support countable readback rows of Definition 92.23 and Definition 92.33, iterated over the displayed finite tree, identify that finite-support countable endpoint with the measure of P_n. Transport along $P_n \sim_M E_n$ gives the displayed classification with $\mu(E_n)$. □

Theorem 92.43 (Measure continuity from below integral scope)**.** *The* $\mathsf{Integral}^{\uparrow}$ *premeasure interface may consume the continuity-from-below package of Definition 92.42 exactly through the public* $\mathsf{Measure}^{\uparrow}$ *rows: displayed measurable events, relative-difference layers, finite disjoint-union readbacks,* σ*-additivity for the disjoint layer sequence, countable-sum classifier stability, and* $\mathsf{Real}^{\uparrow}$ *endpoint transport. It receives no standard bridge row and no host set equality row from this paper site.*

Proof. Project the premeasure rows named in Definition 92.60. These are the measurable-event ledger, endpoint classifier, countable-sum endpoint, head-tail readback, and finite disjoint-union rows exposed by the public $\mathsf{Measure}^{\uparrow}$ package.

The layer construction uses only the relative-difference row from Definition 92.101 and the monotone inclusion row from Definition 92.99. The endpoint classification uses only the σ-additivity and countable-sum rows named by Definition 92.22.

Thus an $\mathsf{Integral}^{\uparrow}$ consumer receives the named continuity package as a premeasure obligation over visible BHist event rows. The only identifications available to that consumer are $\mathsf{Measure}^{\uparrow}$ event classifier comparisons and $\mathsf{Real}^{\uparrow}$ endpoint classifier comparisons, so no standard bridge or host equality is imported. □

Lean4 ✓ `BEDC.Derived.IntegralUp.IntegralVisibleCarrierRow measure prefix scope`

Definition 92.44 (Measure nested-difference surface)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, a nested-difference surface consists of displayed measurable events* $A, B, C \in \mathcal{A}$ *in one carried fiber, displayed inclusions*

$$A \subseteq B \subseteq C,$$

the relative-difference rows $B \setminus A$ *and* $C \setminus B$ *supplied by Definition 92.16, and the disjointness witnesses for the pairs* $A, B \setminus A$ *and* $B, C \setminus B$*. It also records the binary-union readbacks*

$$A \cup (B \setminus A) \sim_M B$$

and

$$B \cup (C \setminus B) \sim_M C,$$

together with their visible $\mathsf{Real}^{\uparrow}$ *endpoints*

$$\mu(A), \quad \mu(B \setminus A), \quad \mu(B), \quad \mu(C \setminus B), \quad \mu(C).$$

Theorem 92.45 (Measure nested-difference readback)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $A, B \in \mathcal{A}$ *be displayed events in the same carried fiber, and suppose the public event readback displays* $A \subseteq B$*. If the certificate supplies the complement/relative-difference row of Definition 92.16 and the hypotheses of Definition 92.26 for the pair* $A, B \setminus A$*, then*

$$\mu(B) \sim_R \mu(A) + \mu(B \setminus A).$$

Proof. Apply Definition 92.101 to the displayed inclusion $A \subseteq B$. This supplies the measurable event $B \setminus A$, the disjointness witness for A and $B \setminus A$, and the binary-union readback classifying $A \cup (B \setminus A)$ as B.

Apply Definition 92.26 to the displayed disjoint pair A and $B \setminus A$. The row gives

$$\mu(A \cup (B \setminus A)) \sim_R \mu(A) + \mu(B \setminus A).$$

Transport the left endpoint through the binary-union readback and then through the $\mathsf{Real}^{\uparrow}$ value classifier. Composing that transport with the finite disjoint-union comparison yields the stated readback for $\mu(B)$. □

Theorem 92.46 (Measure two-stage nested union readback)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $A, B, C \in \mathcal{A}$ *be displayed events in the same carried fiber, and suppose the public event readback displays*

$$A \subseteq B \subseteq C.$$

If the certificate supplies the complement/relative-difference rows for these two displayed inclusions, the hypotheses of Definition 92.26 for the pairs $A, B \setminus A$ *and* $B, C \setminus B$*, and the target* $\mathsf{Real}^{\uparrow}$ *addition is carried by its additive* $\mathsf{AbGroup}^{\uparrow}$ *row, then*

$$\mu(C) \sim_R (\mu(A) + \mu(B \setminus A)) + \mu(C \setminus B).$$

Proof. Apply Definition 92.45 to the displayed inclusion $B \subseteq C$. This gives

$$\mu(C) \sim_R \mu(B) + \mu(C \setminus B).$$

Apply Definition 92.45 to the displayed inclusion $A \subseteq B$. This gives

$$\mu(B) \sim_R \mu(A) + \mu(B \setminus A).$$

Use additive congruence from the target $\mathsf{Real}^{\uparrow}$ additive $\mathsf{AbGroup}^{\uparrow}$ row to transport the left summand of $\mu(B) + \mu(C \setminus B)$ across the second comparison. Composing with the first comparison gives

$$\mu(C) \sim_R (\mu(A) + \mu(B \setminus A)) + \mu(C \setminus B),$$

with the displayed parenthesizing read from the associativity row of Definition 42.1. □

Theorem 92.47 (Measure nested-difference package)**.** *The* $\mathsf{Measure}^{\uparrow}$ *nested-difference surface packages the following rows as the finite nested-inclusion surface consumed by* $\mathsf{ProbSpace}^{\uparrow}$*,* $\mathsf{Integral}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*:*

1. *a displayed inclusion pair* $A \subseteq B$ *with the event* $B \setminus A$*;*
2. *the disjoint readback* $A \cup (B \setminus A) \sim_M B$*;*
3. *the endpoint readback* $\mu(B) \sim_R \mu(A) + \mu(B \setminus A)$*;*
4. *a displayed inclusion chain* $A \subseteq B \subseteq C$ *with the two rows* $B \setminus A$ *and* $C \setminus B$*;*
5. *the two-stage endpoint readback* $\mu(C) \sim_R (\mu(A) + \mu(B \setminus A)) + \mu(C \setminus B)$*.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureNestedDifference package`

Proof. The first two fields are precisely the projections of Definition 92.101 for the displayed pair $A \subseteq B$.

The third field is Definition 92.45. It composes the same relative-difference readback with finite disjoint-union additivity.

For a chain $A \subseteq B \subseteq C$, apply the preceding field to $A \subseteq B$ and to $B \subseteq C$. Additive congruence and associativity in the target $\mathsf{Real}^{\uparrow}$ additive $\mathsf{AbGroup}^{\uparrow}$ row then give Definition 92.46. These rows are exactly the finite nested-inclusion data needed by the downstream measure consumers. □

Definition 92.48 (Concrete zero BHist measure surface)**.** *The concrete zero* BHist *measure surface is the following* $\mathsf{Measure}^{\uparrow}$ *carrier instance over the BEDC history substrate. Its carrier row is*

$$\mathsf{ZeroMeasureCode}(h) \iff \mathsf{hsame}(h, \mathsf{e}).$$

Its carrier classifier is

$$h \sim_0 k \iff \mathsf{hsame}(h, k).$$

The displayed event inventory contains exactly the singleton empty-event row: an event presentation is measurable precisely when its visible BHist *event code is classified with* e*. The measure endpoint is the constant* $\mathsf{Real}^{\uparrow}$ *zero endpoint,*

$$\mu_0(E) := 0_R,$$

for every displayed measurable event E. The countable-sum endpoint for every measurable sequence is also the constant endpoint 0_R.

The only ambient rows used by this surface are BHist*,* hsame*, the classifier and zero row of* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*, and the additive* $\mathsf{AbGroup}^{\uparrow}$ *row of Definition 42.1 for zero, addition congruence, and the additive zero laws.*

Theorem 92.49 (Zero BHist measure carrier-classifier stability)**.** *The concrete zero surface of Definition 92.48 satisfies the carrier transport, event-row transport, and endpoint transport rows required by the* $\mathsf{Measure}^{\uparrow}$ *carrier classifier. If* $\mathsf{ZeroMeasureCode}(h)$ *and* $h \sim_0 k$*, then* $\mathsf{ZeroMeasureCode}(k)$*. If E is a displayed measurable event over h and E' is transported along the same* hsame *comparison, then E' is again the singleton empty-event row over k. The endpoint comparison is*

$$\mu_0(E) \sim_R \mu_0(E').$$

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureZeroBHist carrier classifier stability`

Proof. Unpack the carrier row. The assumption $\mathsf{ZeroMeasureCode}(h)$ identifies h with e, while $h \sim_0 k$ is exactly an $\mathsf{hsame}(h, k)$ comparison. Symmetry and transitivity of hsame identify k with e, so the transported carrier row is again $\mathsf{ZeroMeasureCode}(k)$.

For event-row transport, the only displayed measurable row is the empty-event row. Transporting an empty event presentation along an hsame comparison therefore has only one possible visible target row: the same empty-event row read in the k-fiber. No quotient of events or external set equality is used.

For endpoint transport, both endpoint projections reduce by definition to 0_R. The reflexive classifier row of $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ classifies 0_R with itself, giving $\mu_0(E) \sim_R \mu_0(E')$. □

↪ variant `BEDC.Derived.MeasureUp.MeasureZeroBHist carrier classifier stability`

Theorem 92.50 (Zero BHist measure sigma-additivity)**.** *For the concrete zero surface of Definition 92.48, every displayed pairwise-disjoint measurable sequence $E_\bullet$ has countable union classified with the same singleton empty-event row, and the measure comparison is*

$$\mu_0\left(\bigcup_{n:\mathbb{N}} E_n\right) \sim_R \sum_{n=0}^{\infty} \mu_0(E_n).$$

Here the countable-sum endpoint on the right is the constant endpoint 0_R. The head-tail readback for this endpoint is classified by the additive $\mathsf{AbGroup}^{\uparrow}$ *zero laws.*

Proof. Every displayed measurable term in the zero surface is the empty-event row. Thus each E_n is classified with e, and the visible countable union of the displayed sequence is again classified with e. The pairwise disjointness premise adds no extra branch, because the only event row on either side of an intersection is empty.

The measure endpoint of the union is 0_R by definition. Each summand $\mu_0(E_n)$ is also 0_R, and the countable-sum endpoint selected by the surface is the constant 0_R. Reflexivity of the $\mathsf{Real}^{\uparrow}$ classifier supplied by $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ therefore gives the displayed sigma-additivity comparison.

It remains to read the head-tail row. The head endpoint is 0_R, and the tail endpoint is again 0_R. The additive $\mathsf{AbGroup}^{\uparrow}$ row classifies $0_R + 0_R$ with 0_R, and classifier symmetry gives the required comparison between the constant sum endpoint and its head-tail expression. □

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureZeroBHist sigma additivity`

Theorem 92.51 (Zero BHist MeasureUp NameCert package)**.** *The concrete zero surface of Definition 92.48, together with Definition 92.49 and Definition 92.50, forms a concrete* $\mathsf{Measure}^{\uparrow}$ *NameCert obligation package by the packaging theorem Definition 92.27.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureZeroBHist semantic name certificate`

Proof. Project the concrete surface rows. The carrier row is $\mathsf{ZeroMeasureCode}$, the classifier row is $\sim_0$, the measurable-event inventory is the singleton empty-event row, the measure endpoint is the constant 0_R map, and the countable-sum endpoint is the constant 0_R row.

The carrier-classifier theorem supplies the transport fields required by the package: carried histories move along hsame, measurable rows remain the empty-event row, and endpoints compare by the reflexive $\mathsf{Real}^{\uparrow}$ zero classifier. The sigma-additivity theorem supplies the countable-union row and the head-tail readback row, with additive compatibility read from the $\mathsf{AbGroup}^{\uparrow}$ zero laws.

These are exactly the rows consumed by Definition 92.27. Repacking them through that theorem gives a concrete $\mathsf{Measure}^{\uparrow}$ obligation package whose visible carrier is the zero BHist surface. □

Theorem 92.52 (Zero BHist relative-difference zero row)**.** *For the concrete zero* BHist *measure surface of Definition 92.48, let h be a carried history with* $\mathsf{ZeroMeasureCode}(h)$*. Let A and B be displayed measurable events in the h-fiber, and suppose the public event readback displays $B \subseteq A$. Then the zero surface realizes the complement/relative-difference row for this inclusion by the singleton empty-event row:*

$$A \setminus B \quad \textit{is displayed by the event code } \mathsf{e}.$$

Consequently $A \setminus B$ is accepted as a displayed measurable event of the zero surface, the row supplies the disjointness witness for B and $A \setminus B$ and the binary-union readback classifying $B \cup (A \setminus B)$ with A, and the visible endpoint is classified as zero:

$$\mu_0(A \setminus B) \sim_R 0_R.$$

Proof. Unpack Definition 92.48. The measurable-event inventory of the zero surface has exactly one displayed row: an event presentation is measurable precisely when its visible BHist event code is classified with e. Since A and B are displayed measurable events in the same zero fiber, both of their visible event codes are therefore classified with e.

Assign the relative-difference output for the displayed inclusion $B \subseteq A$ to the same singleton empty-event row. This is accepted by the measurable-event inventory just read. The disjointness witness is the empty-row intersection of B with that singleton output: the B input is already classified with e, and the output is classified with e.

The binary-union readback is obtained by reading the union of two displayed empty rows as the empty row and then composing, by symmetry and transitivity of the zero event classifier, with the displayed comparison classifying A with that same row. This realizes the concrete complement/relative-difference field described in Definition 92.16 for the zero surface.

The endpoint projection of Definition 92.48 is constant: for every displayed measurable event E, $\mu_0(E) := 0_R$. Applying this to the accepted output $A \setminus B$ gives the visible endpoint 0_R. Reflexivity of the $\mathsf{Real}^{\uparrow}$ classifier supplied by $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ classifies 0_R with itself, hence

$$\mu_0(A \setminus B) \sim_R 0_R.$$

□

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureZeroBHist relative difference zero row`

Definition 92.53 (Zero BHist MeasureUp exactness surface)**.** *The zero* BHist *exactness surface for* $\mathsf{Measure}^{\uparrow}$ *is the following ten-field concrete surface.*

1. *carrier row:* $\mathsf{ZeroMeasureCode}(h) \iff \mathsf{hsame}(h, \mathsf{e})$*;*
2. *carrier classifier:* $h \sim_0 k$ *is the displayed* $\mathsf{hsame}(h, k)$ *row;*
3. *measurable-event inventory: the accepted event row is exactly the singleton empty-event row whose visible event code is classified with* e*;*
4. *empty ledger: the empty-event membership witness is attached to that singleton row;*
5. *union ledger: every binary-union, countable-union, and disjointness witness accepted by the surface is attached to the same singleton row;*
6. *value endpoint: the measure endpoint of every accepted event is the constant* $\mathsf{Real}^{\uparrow}$ *zero endpoint* 0_R*;*
7. *countable-sum endpoint: the countable-sum endpoint of every accepted measurable sequence is the constant* $\mathsf{Real}^{\uparrow}$ *endpoint* 0_R*;*
8. *countable-sum classifier: pointwise zero endpoint classification transports accepted countable-sum endpoints through* $\sim_R$*;*
9. *codomain package: endpoint reflexivity, symmetry, transitivity, and zero classification are read from* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*;*
10. *additive package: head-tail readback and zero-sum compatibility are read from the additive* $\mathsf{AbGroup}^{\uparrow}$ *zero laws for* 0_R*.*

No row in this surface contains an event carrier other than BHist*, a classifier other than* hsame *and* $\sim_R$*, or a countable-sum witness other than the visible constant-zero endpoint row.*

Theorem 92.54 (Zero BHist event row coverage)**.** *For the zero* BHist *exactness surface of Definition 92.53, every accepted measurable event row, empty-event row, binary-union row, countable-union row, disjointness row, value row, and countable-sum row is the visible singleton empty-event ledger row together with the constant endpoint* 0_R*.*

Proof. Unpack the carrier and measurable-event inventory. A carried history satisfies ZeroMeasureCode exactly when it is classified with e, and the only accepted event presentation is the singleton empty-event row in that fiber.

The empty-event row is therefore already covered. A binary-union row or a countable-union row has no second visible event code to select: each input is the empty-event row, and the accepted output is again the empty-event row. The associated disjointness witness is attached to this same visible row.

For value rows, the endpoint field sends every accepted event to 0_R. For countable-sum rows, the endpoint field sends every accepted sequence to the constant endpoint 0_R. Thus every row consumed by the zero surface is read from the singleton empty-event ledger row and its attached $\mathsf{Real}^{\uparrow}$ zero endpoint. □

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureZeroBHist event row coverage`

Theorem 92.55 (Zero BHist countable-sum classifier stability)**.** *For the zero* BHist *exactness surface of Definition 92.53, let $E_\bullet$ and $F_\bullet$ be accepted measurable sequences. If every endpoint comparison is the pointwise zero classification*

$$\mu_0(E_n) \sim_R \mu_0(F_n),$$

then their countable-sum endpoints transport through the $\mathsf{Real}^{\uparrow}$ *classifier:*

$$\Sigma_0(E_\bullet) \sim_R \Sigma_0(F_\bullet).$$

Both endpoints on the displayed comparison are the constant endpoint 0_R.

Proof. Read the countable-sum endpoint field of Definition 92.53. For every accepted measurable sequence, the selected countable-sum endpoint is the constant $\mathsf{Real}^{\uparrow}$ zero endpoint 0_R.

The pointwise hypothesis says that each visible summand endpoint is classified with the corresponding zero endpoint in the other sequence. Since the aggregate endpoint field ignores no hidden analytic completion and always selects 0_R, the target aggregate endpoint is also 0_R.

The comparison is therefore the reflexive classifier row of $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ at 0_R. This gives $\Sigma_0(E_\bullet) \sim_R \Sigma_0(F_\bullet)$ and supplies the countable-sum classifier stability row for the zero surface. □

Theorem 92.56 (Zero BHist concrete exactness package)**.** *The zero* BHist *exactness surface of Definition 92.53, together with Definition 92.54, Definition 92.55, Definition 92.49, Definition 92.50, and Definition 92.51, forms a concrete* $\mathsf{Measure}^{\uparrow}$ *root-unblock package for the zero* BHist *carrier.*

Proof. First project the surface fields. The carrier is ZeroMeasureCode, the carrier classifier is hsame, the event inventory is the singleton empty-event row, and the value and countable-sum endpoints are both the constant endpoint 0_R.

The event-row coverage theorem exhausts the visible ledger: measurable events, unions, disjointness rows, value rows, and countable-sum rows are all attached to the singleton empty-event row. The countable-sum classifier theorem supplies the endpoint transport row for accepted measurable sequences.

The carrier-classifier theorem supplies transport of carried histories and measure endpoints. The sigma-additivity theorem supplies the countable-union comparison and the head-tail zero readback through the additive $\mathsf{AbGroup}^{\uparrow}$ laws. The NameCert package theorem repacks those rows as the concrete $\mathsf{Measure}^{\uparrow}$ obligation package.

Combining these projections gives a single root surface that downstream $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ constructions may cite: event coverage, countable-sum classifier stability, sigma-additivity, carrier stability, and NameCert packaging are all exposed by the same concrete zero BHist carrier. □

Definition 92.57 (Measure event row coverage)**.** *For the* $\mathsf{Measure}^{\uparrow}$ *sigma-algebra carrier surface of Definition 92.14, the event row coverage predicate is the assertion that every row consumed by a downstream certificate is attached to a visible* BHist *ledger row of that carrier surface. Concretely, the covered rows are:*

1. *every measurable event read by the measurable-family predicate* $\mathcal{A}$*;*
2. *the empty-event row;*
3. *every binary-union row, including its disjointness witness when the union is read as a disjoint union;*
4. *every countable-union row for a StreamName-style measurable family, together with its pairwise-disjointness witness when sigma-additivity is invoked;*
5. *every* $\mathsf{Real}^{\uparrow}$ *endpoint row* $\mu(E)$ *classified by the measure-value classifier;*
6. *every countable-sum endpoint* $\Sigma_{\mu}(E_{\bullet})$ *and every head-tail readback row attached to that endpoint.*

Coverage requires the attachment to be exact: the downstream consumer reads the displayed BHist *row, its* hsame *transport row, and the associated* $\mathsf{Real}^{\uparrow}$ *endpoint classifier row, and it reads no additional event carrier, choice object, quotient object, or analytic completion object from the* $\mathsf{Measure}^{\uparrow}$ *package.*

Lean4 (definition) `BEDC.Derived.MeasureUp.MeasureEventRowCoverage`

Theorem 92.58 (Measure measurable family exactness)**.** *For the* $\mathsf{Measure}^{\uparrow}$ *sigma-algebra carrier surface, the event row coverage predicate of Definition 92.57 gives coverage, soundness, and completeness for the measurable-family classifier. Coverage means that every measurable event, closure event, disjointness witness,* $\mathsf{Real}^{\uparrow}$ *endpoint, and countable-sum endpoint used by the classifier is read from a displayed ledger row. Soundness means that transporting a covered row along the classifier gives the corresponding covered row in the target presentation. Completeness means that every row available to the measurable-family classifier is one of the rows listed in the coverage predicate.*

Proof. Unpack Definition 92.14. Its carrier, stability, ledger, and exactness fields list exactly the measurable-event, empty-event, binary-union, countable-union, disjointness, endpoint, and countable-sum rows named in Definition 92.57.

Coverage is therefore projection from the displayed carrier and ledger fields. Each consumed event or endpoint row is attached to one of those fields by the exactness clause of the surface.

Soundness is the transport statement of Definition 92.9. Componentwise hsame moves the event rows, and the $\mathsf{Real}^{\uparrow}$ classifier moves the endpoint rows. The ledger witness attached to a visible row is repacked after that visible row has been transported.

Completeness is the exhaustion statement of Definition 92.13. Since the ledger contains only the listed rows and every hidden measurable-set or countable-sum witness is attached to one of them, the measurable-family classifier has no further row to read. □

Theorem 92.59 (Measure probability normalization row)**.** *Let a covered* $\mathsf{Measure}^{\uparrow}$ *package carry a total event row* Ω *whose endpoint is classified as the probability unit:*

$$\mu(\Omega) \sim_R 1_R.$$

Together with the empty-zero theorem Definition 92.25 and the finite disjoint-union theorem Definition 92.26, this row supplies the normalization and finite-additivity rows consumed by $\mathsf{ProbSpace}^{\uparrow}$*.*

The claim is only the projection of the total-event endpoint and the repacking of the two named Measure$^{\uparrow}$ *consequence theorems into the probability-space certificate surface.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureProbabilityNormalizationRow`

Proof. Project the total-event ledger row from the covered measure package. Its endpoint comparison is already the normalization row required by ProbSpace$^{\uparrow}$, namely $\mu(\Omega) \sim_R 1_R$.

Next project the empty event, binary disjoint-union, endpoint, and additive AbGroup$^{\uparrow}$ rows exposed by Definition 92.57. With those rows in hand, Definition 92.25 gives the zero endpoint for the empty event.

Finally apply Definition 92.26 to a covered disjoint measurable pair. The result is exactly the finite-additivity comparison used by the probability-space carrier; no sigma-additivity theorem beyond the named Measure$^{\uparrow}$ package rows is imported into ProbSpace$^{\uparrow}$. □

Theorem 92.60 (Measure integral premeasure consumption)**.** *The* Integral$^{\uparrow}$ *premeasure interface may consume exactly the following rows from the* Measure$^{\uparrow}$ *package: covered measurable-event rows,* Real$^{\uparrow}$ *endpoint classifier rows, countable-sum endpoint rows, classifier-stable head-tail readback rows, and the finite disjoint-union theorem Definition 92.26. The same exposed endpoint classifier and additive compatibility rows are the MeasureUp rows available to* FunctionalAnalysis$^{\uparrow}$*. These rows are precisely the public surface supplied by Definition 92.15, Definition 92.22, and Definition 92.27.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureIntegralPremeasure consumption`

Proof. Begin with the public certificate surface of Definition 92.15. Its projections provide the measurable-family predicate, endpoint map, countable-sum endpoint, head-tail readback row, and countable-sum classifier row.

The certificate obligation theorem Definition 92.22 identifies the sigma-algebra rows and the sigma-additivity rows that make those projections available to premeasure constructions. In particular it names the empty, binary disjoint-union, countable disjoint-union, sigma-additivity, and head-tail rows as the complete certificate rows used by the measure consequences.

The NameCert package theorem Definition 92.27 repacks those rows as the surface consumed by downstream analysis chapters. Reading that package through Definition 92.57 leaves exactly the measurable-event, endpoint, countable-sum, head-tail, and finite disjoint-union rows named in the statement, with no additional carrier row available for Integral$^{\uparrow}$ or FunctionalAnalysis$^{\uparrow}$. □

Definition 92.61 (Measure root NameCert public surface)**.** *The root* Measure$^{\uparrow}$ *NameCert public surface is the ten-field carrier surface of Definition 92.14, read together with the certificate surface of Definition 92.15, the exact event-row coverage predicate of Definition 92.57, and the no-*StandardBridge *row recorded in the standard-bridge field of the carrier surface. Concretely, its public rows are:*

1. *the traditional constructive measure-space target;*
2. *the BEDC source rows over* BHist*,* NameCert$_{\text{Real}^{\uparrow}}$*, and the additive* AbGroup$^{\uparrow}$ *real row;*
3. *the visible carrier rows for measurable events, empty event, binary union, countable union, complement/relative-difference, disjoint sequence readback,* Real$^{\uparrow}$ *endpoints, and countable sums;*
4. *the componentwise* hsame *classifier, with* Real$^{\uparrow}$ *endpoint comparison supplied by the real classifier;*
5. *the stability rows for every displayed event, value, and countable-sum component;*

6. *the ledger rows attached to hidden membership, relative-difference, and countable-sum witnesses;*
7. *the core consequence rows named in the carrier surface;*
8. *the exactness predicate asserting that downstream consumers read only the displayed rows;*
9. *the explicit absence of a standard bridge at this paper site;*
10. *the public status row that exposes the resulting package as the* $\mathsf{Measure}^{\uparrow}$ *NameCert obligation surface.*

Theorem 92.62 (Measure root carrier-classifier public obligation)**.** *The root* $\mathsf{Measure}^{\uparrow}$ *NameCert public surface of Definition 92.61 supplies the public carrier and classifier transport rows required by the* $\mathsf{Measure}^{\uparrow}$ *obligation surface. For any two presented histories* $h, k : \mathsf{BHist}$ *in the surface, a carried* $\mathsf{Measure}^{\uparrow}$ *code at* h*, and a public classifier comparison* $h \sim_M k$*, the surface transports the carrier code, each visible event row, each ledger row, and each* $\mathsf{Real}^{\uparrow}$ *endpoint row from* h *to* k*.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureRootDownstreamUnblockPackage`

Proof. Begin with the root public surface and project its carrier and classifier fields. These fields are exactly the carrier slots and componentwise classifier slots listed in Definition 92.14.

Apply Definition 92.9. It transports the displayed measurable-event, empty-event, binary-union, countable-union, relative-difference, disjointness, endpoint, and countable-sum rows along the public classifier. The $\mathsf{Real}^{\uparrow}$ endpoint movement is read through the displayed real classifier, while the event rows move by their hsame components.

It remains to expose the stability rows as public obligation rows. Apply Definition 92.21. Its projections identify the same classifier-stable rows at the certificate level, so the transported carrier, classifier, ledger, and endpoint data repack as the root carrier-classifier public obligation. □

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureRootCarrierClassifier public obligation`

Theorem 92.63 (Measure root sigma-additive public obligation)**.** *The root* $\mathsf{Measure}^{\uparrow}$ *NameCert public surface supplies the public sigma-additive, empty-zero, finite readback, and relative-difference rows. For every covered pairwise-disjoint measurable sequence* $E_\bullet$ *with countable union* U*, the surface supplies*

$$\mu(U) \sim_R \Sigma_\mu(E_\bullet).$$

It also supplies $\mu(\varnothing) \sim_R 0_R$*, finite disjoint-union readback for covered disjoint pairs, and relative-difference additivity for covered inclusions of measurable events in the same fiber.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureRootSigmaAdditive public obligation`

Proof. Project the sigma-algebra, countable-union, head-tail, countable-sum classifier, and additive $\mathsf{AbGroup}^{\uparrow}$ rows from the root public surface. The coverage predicate ensures that the measurable sequence, its union, its disjointness witness, and the resulting endpoints are all visible BHist ledger rows.

Apply Definition 92.22 to read the certificate rows as the public sigma-additive obligation. Its sigma-additivity projection gives the displayed comparison for $E_\bullet$ and U.

Next apply Definition 92.25. The constant-empty measurable sequence is covered by the empty-event and countable-union rows, and the additive $\mathsf{AbGroup}^{\uparrow}$ row supplies the zero and congruence laws used by the theorem.

Apply Definition 92.26 to a covered disjoint pair. The same visible binary-union, endpoint, and head-tail rows give the finite readback comparison.

Finally apply Definition 92.102. The relative-difference row is one of the displayed carrier rows, so the inclusion witness, disjointness witness, binary-union readback, and endpoint comparison repack as the public relative-difference obligation. □

Theorem 92.64 (Measure root downstream unblock package)**.** *The carrier-classifier rows of Definition 92.62 and the sigma-additive rows of Definition 92.63 form the public* $\mathsf{Measure}^{\uparrow}$ *package consumed by* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$. *The package exposes only covered measurable-event rows,* $\mathsf{Real}^{\uparrow}$ *endpoint rows, countable-sum rows, classifier-stable head-tail readback, empty-zero, finite disjoint-union readback, relative-difference additivity, and the explicit no-*$\mathsf{StandardBridge}$ *row.*

Proof. Start from the root public surface and apply Definition 92.27. This repacks the carrier, classifier, sigma-additivity, ledger exactness, nonnegative value, monotone inclusion, and measure consequence rows as the public $\mathsf{Measure}^{\uparrow}$ NameCert obligation package.

For $\mathsf{ProbSpace}^{\uparrow}$, apply Definition 92.59. It consumes the total event endpoint together with the empty-zero and finite disjoint-union rows already exposed by the root sigma-additive public obligation.

For $\mathsf{Integral}^{\uparrow}$ and $\mathsf{FunctionalAnalysis}^{\uparrow}$, apply Definition 92.60. Its consumed rows are exactly the covered measurable-event rows, endpoint classifier rows, countable-sum rows, head-tail readback rows, and finite disjoint-union rows projected above.

The event-row coverage predicate prevents any extra carrier from entering the downstream package. The standard-bridge field is the no-$\mathsf{StandardBridge}$ row from the root surface, so the public package is a NameCert surface only and makes no standard-bridge claim. □

Definition 92.65 (Measure root downstream image surface)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root downstream image surface is the ten-field public image through which the direct analysis consumers read the root measure package:*

1. *traditional target: a constructive measure root exposed as the common source for integration, probability, and functional-analysis measure rows;*
2. *BEDC source:* BHist, *componentwise* hsame, Cont, $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint comparison,* $\mathsf{StreamName}^{\uparrow}$ *countable-family names, and the additive* $\mathsf{AbGroup}^{\uparrow}$ *real rows;*
3. *carrier: the public* $\mathsf{MeasCode}$ *row carried by the displayed* BHist *ledger;*
4. *classifier: the public measure classifier* $\sim_M$, *with endpoint motion read through* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *and* $\sim_R$*;*
5. *stability rows: carrier transport, classifier transport, visible event-row transport, finite and countable family transport, relative-difference transport, monotone-inclusion transport, nonnegative endpoint transport, and continuity-from-below transport;*
6. *ledger: hidden membership, disjointness, endpoint-value, relative-difference, countable-union, and countable-sum witnesses attached only to displayed public* $\mathsf{Measure}^{\uparrow}$ *rows;*
7. *core theorem list: Definition 92.66, Definition 92.67, and Definition 92.68;*
8. *exactness: every* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *row displayed here is one of the public rows of Definition 92.193, Definition 92.118, and Definition 92.82;*
9. *standard bridge: no* $\mathsf{StandardBridge}$ *row is asserted, imported, or needed by this image surface;*
10. *status: paper proof target under* $\mathsf{BEDC.Derived.MeasureUp}$.

Theorem 92.66 (Measure root downstream image carrier)**.** *The carrier and classifier rows of Definition 92.65 project to the* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumers through the same public* $\mathsf{MeasCode}$*,* $\sim_M$*,* BHist*,* hsame*,* Cont*,* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{AbGroup}^{\uparrow}$ *rows of the root* $\mathsf{Measure}^{\uparrow}$ *package.*

Proof. Start from Definition 92.193. Its carrier and classifier fields display $\mathsf{MeasCode}$, $\sim_M$, the visible BHist ledger, endpoint comparison through $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, and countable-family transport through $\mathsf{StreamName}^{\uparrow}$.

Apply Definition 92.197. The exactness theorem identifies the carrier face, additive face, and consumer face as one public root package and excludes host set equality, quotient event equality, analytic completion objects, and standard bridge rows.

Next read the same carrier-classifier package through Definition 92.118. Apply Definition 92.121; it names the three consumer fronts and says that their visible rows are projections of the domain-ready carrier, classifier, endpoint, additive, and ledger rows.

Finally read the analysis front through Definition 92.82. Apply Definition 92.85. The analysis-unblock theorem repacks the same public carrier and classifier rows as the package consumed by $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$, so the downstream image has no separate carrier or classifier source. □

Theorem 92.67 (Measure root downstream image additivity)**.** *The finite additivity, countable additivity, relative-difference additivity, monotone inclusion, nonnegative endpoint, and continuity-from-below rows of Definition 92.65 are the same public* $\mathsf{Measure}^{\uparrow}$ *rows seen by* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*.*

Proof. Project the additive and order rows from Definition 92.193. Its exactness theorem, Definition 92.197, keeps empty-zero, finite readback, relative-difference, countable disjointness, countable-sum, ledger, and consumer rows inside one visible root package.

Use Definition 92.118 as the domain reading of that package. Apply Definition 92.121. The domain-ready theorem exposes the finite, countable, endpoint, ledger, and consumer rows to the three analysis fronts without adding host or quotient event equality.

Now read the same rows through Definition 92.82. Apply Definition 92.85. It identifies finite readback, countable-sum stability, relative-difference additivity, monotone inclusion, nonnegative endpoint values, and continuity from below as the rows consumed by the direct analysis fronts.

Thus the additivity, order, endpoint, and continuity fields of the downstream image are not parallel copies. They are the common public $\mathsf{Measure}^{\uparrow}$ rows already displayed by the root basis, the domain-ready package, and the analysis-unblock surface. □

Theorem 92.68 (Measure root downstream image consumer)**.** *Every* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, or* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *row exposed by Definition 92.65 factors through the displayed public* $\mathsf{Measure}^{\uparrow}$ *image. The image adds no host set equality, no quotient event equality, no analytic completion object, and no standard bridge row.*

Proof. Begin with the consumer face of Definition 92.193. Apply Definition 92.197; the theorem exhausts the public carrier, additive, and consumer faces and leaves no slot for host set equality, quotient event equality, analytic completion, or a $\mathsf{StandardBridge}$ row.

Next pass through Definition 92.118. Apply Definition 92.121. The theorem lists the $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ projections as the downstream face of the domain-ready root package and keeps every consumed row attached to the displayed carrier, classifier, endpoint, additive, ledger, and exactness fields.

Finally pass through Definition 92.82. Apply Definition 92.85. This analysis-unblock reading states that the three direct consumers use only the carrier, classifier, stability, exactness, ledger, additivity, order, endpoint, and continuity rows named in the public surface.

Combining the three readings gives the desired factorization: each direct analysis consumer row exposed by the downstream image is already a row of the public $\mathsf{Measure}^{\uparrow}$ image. Since none of the cited packages contains the excluded equality, completion, or bridge fields, the downstream image adds none of them. □

Definition 92.69 (MeasureUp analysis-seed source)**.** *The* $\mathsf{Measure}^{\uparrow}$ *analysis-seed source is the BEDC source package obtained from* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *together with the* $\mathsf{Measure}^{\uparrow}$ *carrier and classifier of section 92.1. Its visible source rows are the measurable carrier, the* BHist *classifier* $\sim_M$*, the designated* σ*-algebra and measurable-family rows, the sigma-additivity row, the nonnegative* $\mathsf{Real}^{\uparrow}$ *value row, the finite-additivity readback package, the relative-difference package, the zero-*BHist *package, and the ledger rows listed in Definition 92.57. A consumer of this source reads only those rows and the classifier transport supplied by Definition 92.27; it does not receive a host set carrier, quotient equality of events, or an analytic completion object.*

Theorem 92.70 (MeasureUp integral substrate obligations)**.** *For the source of Definition 92.69, an* $\mathsf{Integral}^{\uparrow}$ *consumer may use only the covered measurable-event rows, the* $\mathsf{Real}^{\uparrow}$ *endpoint values, the finite and countable additivity readbacks, the relative-difference rows, and classifier transport along* $\sim_M$ *and* $\sim_R$*. These obligations are exactly the* $\mathsf{Measure}^{\uparrow}$ *rows exposed by the NameCert package, the integral premeasure consumption theorem, and the two-step finite-additivity package.*

Proof. Start with Definition 92.27. It packages the carrier, classifier transport, sigma-additivity, nonnegative endpoint, relative-difference, ledger exactness, and measure consequence rows as the public $\mathsf{Measure}^{\uparrow}$ surface.

The integral consumer then reads this surface through Definition 92.60. That theorem restricts the premeasure interface to covered measurable-event rows, $\mathsf{Real}^{\uparrow}$ endpoint classifier rows, countable-sum endpoints, classifier-stable head-tail rows, and the finite disjoint-union consequence.

Finally, Definition 92.35 supplies the finite-additivity readback named in the statement. The relative-difference rows are already part of the same NameCert package, so no additional host event equality or quotient transport is imported into $\mathsf{Integral}^{\uparrow}$. □

Theorem 92.71 (MeasureUp probability substrate obligations)**.** *For the source of Definition 92.69, a* $\mathsf{ProbSpace}^{\uparrow}$ *consumer adds only a total-event row* Ω *and a unit-mass endpoint row* $\mu(\Omega) \sim_R 1_R$ *on top of the* $\mathsf{Measure}^{\uparrow}$ *substrate. The empty-event zero row and finite disjoint-union row remain the same* $\mathsf{Measure}^{\uparrow}$ *consequences; no probability-specific carrier, quotient of events, or independent additivity principle is added.*

Proof. Project the total-event row and unit-mass endpoint row through Definition 92.59. That theorem states that these two rows are the normalization data consumed by $\mathsf{ProbSpace}^{\uparrow}$.

The empty-event row is the measure consequence Definition 92.25. It supplies the zero endpoint for $\varnothing$ from the existing sigma-additivity and countable-sum rows.

The finite-additivity row is Definition 92.26. Applying it to each covered disjoint measurable pair gives exactly the finite probability readback, so the probability surface is the MeasureUp substrate plus the total-event and unit-mass rows named in the statement. □

Theorem 92.72 (MeasureUp functional-analysis substrate obligations)**.** *For the source of Definition 92.69,* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *and* L^p*-style consumers receive only nonnegative* $\mathsf{Real}^{\uparrow}$ *endpoint rows, monotone inclusion rows, relative-difference additivity rows, and countable-sum classifier*

stability rows. These rows are read through $\mathsf{Measure}^{\uparrow}$ *classifier transport and* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*; they do not import host sets, quotient equality of events, or any independent analytic equality principle.*

Proof. The nonnegative endpoint row is Definition 92.98. It is already a $\mathsf{Real}^{\uparrow}$-classified endpoint row of the measure package.

The order-facing row is Definition 92.99. It reads inclusion only between covered measurable events and returns the corresponding $\mathsf{Real}^{\uparrow}$ endpoint comparison.

The additive decomposition row is Definition 92.102. It supplies the relative-difference comparison used by L^p-style arguments without replacing event presentations by host equality.

The countable endpoint row is Definition 92.12. It transports countable sums by pointwise $\mathsf{Real}^{\uparrow}$ classifier comparison, which is the countable-sum stability available to functional-analysis consumers. □

Definition 92.73 (MeasureUp analysis-unblock source)**.** *The* $\mathsf{Measure}^{\uparrow}$ *analysis-unblock source is the source package over* BHist *obtained by reading the* $\mathsf{Measure}^{\uparrow}$ *carrier and classifier of section 92.1 through* hsame *and through* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*. Its visible rows are the event-row coverage predicate of Definition 92.57, the relative-difference row of Definition 92.16, the finite-additivity rows of Definition 92.35, the continuity-from-below rows of Definition 92.42, and the analysis-seed substrate rows of Definition 92.69. A downstream consumer of this source receives only these public rows, their* hsame *transport, and their* $\mathsf{Real}^{\uparrow}$ *endpoint classifier comparisons.*

Theorem 92.74 (MeasureUp analysis-unblock carrier-classifier scope)**.** *The source of Definition 92.73 supplies the* $\mathsf{Measure}^{\uparrow}$ *carrier, the public* BHist *classifier,* hsame *transport of visible event rows, event-row coverage, and countable-sum classifier stability. These rows are exactly the carrier-classifier and countable endpoint rows exposed by the root* $\mathsf{Measure}^{\uparrow}$ *NameCert obligations.*

Proof. Start from the root public surface of Definition 92.61. Project its carrier, classifier, event-row coverage, ledger, and endpoint fields.

Apply Definition 92.62. This transports the carrier code, every displayed event row, and every $\mathsf{Real}^{\uparrow}$ endpoint row along the public BHist classifier, using the componentwise hsame fields of the carrier surface.

The event coverage is the exact predicate of Definition 92.57. The countable-sum endpoint movement is the stability row of Definition 92.12.

Finally repack these projections through Definition 92.27. The result is precisely the carrier, classifier, hsame transport, coverage, and countable-sum classifier scope named in the statement. □

Theorem 92.75 (MeasureUp analysis-unblock relative-continuity package)**.** *The source of Definition 92.73 supplies one analysis package containing finite disjoint-union additivity, relative-difference additivity, monotonicity under displayed measurable inclusion, nonnegative* $\mathsf{Real}^{\uparrow}$ *measure values, and continuity from below for displayed increasing measurable sequences.*

Proof. Project finite additivity first. The binary finite row is Definition 92.26, and the ordered two-step finite package is Definition 92.35.

Next project the relative-difference and order rows. Apply Definition 92.102 for the additive decomposition of a displayed inclusion, apply Definition 92.99 for the induced $\mathsf{Real}^{\uparrow}$ order comparison, and apply Definition 92.98 for the nonnegative endpoint row.

For increasing sequences, apply Definition 92.42. Its layer construction uses the same relative-difference rows, finite readbacks, sigma-additivity, and countable-sum classifier stability already projected above.

These rows have the same carrier, event classifier, and $\mathsf{Real}^{\uparrow}$ endpoint classifier because they are all read through Definition 92.27. Repacking them gives one relative-continuity analysis package over the source of Definition 92.73. □

Theorem 92.76 (MeasureUp analysis-unblock downstream source)**.** *The source of Definition 92.73 assembles the integral, probability, and functional-analysis substrate rows consumed by* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*. The assembled source consists of the integral premeasure rows, the probability normalization rows, and the functional-analysis endpoint and order rows already exposed by the* $\mathsf{Measure}^{\uparrow}$ *analysis substrate.*

Proof. For $\mathsf{Integral}^{\uparrow}$, project Definition 92.70. It supplies covered measurable-event rows, $\mathsf{Real}^{\uparrow}$ endpoint values, finite and countable additivity readbacks, relative-difference rows, and classifier transport.

For $\mathsf{ProbSpace}^{\uparrow}$, project Definition 92.71. It adds only the total-event row and the unit-mass endpoint row to the same $\mathsf{Measure}^{\uparrow}$ substrate.

For $\mathsf{FunctionalAnalysis}^{\uparrow}$, project Definition 92.72. It consumes the nonnegative endpoint row, monotone inclusion row, relative-difference additivity row, and countable-sum classifier stability row.

The common source boundary is Definition 92.69, and the public downstream surface is Definition 92.64. Therefore the three downstream consumers read a single assembled $\mathsf{Measure}^{\uparrow}$ analysis-unblock source, with no host set equality, quotient event equality, or standard bridge row added at this paper site. □

Definition 92.77 (Measure StreamName endpoint family)**.** *A* $\mathsf{Measure}^{\uparrow}$ *StreamName endpoint family over the sigma-algebra carrier surface of Definition 92.14 is a certified observation map* $s : \mathsf{Hist} \to \mathsf{Hist}$ *together with a displayed* $\mathsf{RatStreamNameCarrier}(s)$ *row as in Definition 126.1. For every unary observation history* n *with* $\mathsf{UnaryHistory}(n)$*, the point observation* $s(n)$ *carries:*

1. *a* $\mathsf{Measure}^{\uparrow}$ *measurable-event row covered by Definition 92.57;*
2. *the associated* $\mathsf{Real}^{\uparrow}$ *endpoint row* $\mu(s(n))$ *read through the endpoint classifier of Definition 38.9;*
3. *the pointwise StreamNameUp classifier row supplied by Definition 126.2;*
4. *the countable-sum endpoint row attached to the resulting StreamName-indexed measurable family.*

The family exposes no host-level equality of event carriers. Its public data are exactly the unary BHist *observation, the covered measurable event, its* hsame *transport row, and the corresponding* $\mathsf{Real}^{\uparrow}$ *endpoint classifier row.*

Theorem 92.78 (Measure StreamName endpoint carrier-classifier)**.** *Every* $\mathsf{Measure}^{\uparrow}$ *StreamName endpoint family supplies carrier transport for the StreamName observation map and pointwise classifier transport for its measurable-event and* $\mathsf{Real}^{\uparrow}$ *endpoint rows. The transport is the common projection of Definition 126.1, Definition 126.2, Definition 126.13, and Definition 92.9.*

Proof. Project the $\mathsf{RatStreamNameCarrier}(s)$ row from Definition 92.77. For a unary observation n, Definition 126.1 reads $s(n)$ as the carried point history, and Definition 126.2 identifies classifier transport pointwise at the same unary observation.

Apply Definition 126.13. Its endpoint-carrier and transported-classifier fields move the stream carrier and the pointwise classifier row to the transported observation map.

Now apply Definition 92.9 at that point observation. The covered measurable-event row, the event ledger entry, and the $\mathsf{Real}^{\uparrow}$ endpoint comparison are all componentwise rows of the $\mathsf{Measure}^{\uparrow}$ carrier surface, so they move along the same hsame classifier.

Repack the transported stream carrier, the transported covered event, and the transported endpoint comparison into the endpoint family surface of Definition 92.77. No quotient event equality or host carrier equality is introduced. □

Theorem 92.79 (Measure StreamName endpoint stability)**.** *Let $s, t : \mathsf{Hist} \to \mathsf{Hist}$ be two $\mathsf{Measure}^{\uparrow}$ StreamName endpoint families. If $\mathsf{RatStreamNameClassifier}(s, t)$ holds and the endpoint family rows are transported pointwise by hsame at every unary observation, then measurable event witnesses and $\mathsf{Real}^{\uparrow}$ endpoint comparisons are preserved at every index.*

Proof. Fix a unary observation n with witness $\nu : \mathsf{UnaryHistory}(n)$. The StreamName classifier gives the point classifier between $s(n)$ and $t(n)$ by Definition 126.2.

The endpoint-family hypotheses attach a covered measurable-event row and a $\mathsf{Real}^{\uparrow}$ endpoint row to the source point observation. The pointwise hsame transport row moves the displayed event witness to the target point.

Apply Definition 92.9 to the moved point row. It transports the measurable-event witness and reads the measure value in the target presentation under the same $\mathsf{Real}^{\uparrow}$ endpoint classifier.

Since the observation n was arbitrary, the transported event witnesses and endpoint comparisons assemble pointwise over all unary observations. Repacking them gives stability of the whole StreamName endpoint family. □

Theorem 92.80 (Measure StreamName countable-additivity scope)**.** *For a $\mathsf{Measure}^{\uparrow}$ StreamName endpoint family, the countable-additivity row of Definition 92.2 factors only through the StreamName-indexed endpoint family, the countable-sum classifier stability of Definition 92.12, and the sigma-additivity obligation of Definition 92.11.*

Proof. Read the StreamName endpoint family pointwise. Each unary observation supplies a covered measurable-event row and its $\mathsf{Real}^{\uparrow}$ endpoint row, so the StreamName map gives the measurable sequence consumed by the countable-additivity row.

Apply Definition 92.11 to that displayed sequence, its pairwise-disjointness witness, and its countable-union row. The resulting comparison is exactly the $\mathsf{Real}^{\uparrow}$ classifier relation between the measure of the union and the countable endpoint sum.

If the point endpoints are transported along another StreamName classifier, apply Definition 92.12. It turns the pointwise $\mathsf{Real}^{\uparrow}$ endpoint comparisons into the classifier comparison between the two countable sums.

Thus countable additivity reads no row beyond the StreamName endpoint family, the countable-sum stability row, and the displayed sigma-additivity row of $\mathsf{Measure}^{\uparrow}$. □

Theorem 92.81 (Measure StreamName downstream consumer boundary)**.** *The $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ consumers of Definition 92.86 read only the StreamName-indexed endpoint rows of Definition 92.77 together with the root consumer rows already listed in Definition 92.86.*

Proof. Project the root consumer package of Definition 92.86. Its visible rows are the covered measurable-event rows, the $\mathsf{Real}^{\uparrow}$ endpoint classifier rows, the countable-sum endpoint rows, the finite readback rows, the relative-difference and order rows, and the no-$\mathsf{StandardBridge}$ boundary.

For $\mathsf{Integral}^{\uparrow}$, the StreamName endpoint family supplies the covered measurable sequence and countable endpoint rows already named by the root consumer package. The finite and head-tail rows are then read from the same package, not from an additional event equality surface.

For $\mathsf{ProbSpace}^{\uparrow}$, the total-event and empty-zero rows are projections of the root package. A StreamName endpoint family may index the measurable rows it uses, but the probability consumer still receives only the normalization, empty-zero, and finite-additivity rows listed there.

For $\mathsf{FunctionalAnalysis}^{\uparrow}$, the nonnegative, monotone, relative-difference, and countable-sum classifier rows are exactly the endpoint rows transported pointwise by Definition 92.79. Repacking the three consumer projections gives the stated boundary and adds no quotient event equality, host set equality, or standard bridge row. □

Definition 92.82 (Measure root analysis-unblock obligation surface)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root analysis-unblock obligation surface is the ten-row template obtained by reading the analysis-unblock source of Definition 92.73, the root public NameCert surface of Definition 92.61, and the analysis-seed source of Definition 92.69 as one public package. Its rows are:*

1. *the* $\mathsf{Measure}^{\uparrow}$ *carrier over* BHist*;*
2. *the public* hsame *classifier for measurable-event rows;*
3. *the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier supplied by* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*;*
4. *the visible event-row coverage predicate;*
5. *the countable endpoint and countable-sum stability rows;*
6. *finite disjoint-union additivity;*
7. *relative-difference additivity for displayed inclusions;*
8. *monotone inclusion and nonnegative* $\mathsf{Real}^{\uparrow}$ *value rows;*
9. *continuity from below for displayed increasing measurable sequences;*
10. *the ledger and downstream exactness rows consumed by* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$.

Theorem 92.83 (Measure root analysis-unblock carrier-classifier)**.** *The surface of Definition 92.82 supplies the* $\mathsf{Measure}^{\uparrow}$ *carrier, the public measurable-event classifier, event-row coverage, and countable endpoint stability rows. These are precisely the carrier-classifier rows exposed by the root public NameCert surface and read by the analysis-unblock source.*

Proof. Project the carrier, classifier, event-row coverage, ledger, and endpoint rows from Definition 92.61. Apply Definition 92.62 to transport the carrier code, every visible event row, every ledger row, and every $\mathsf{Real}^{\uparrow}$ endpoint row along the public classifier.

Next read the same projections through Definition 92.73. Apply Definition 92.74. It identifies the analysis-unblock carrier, public classifier, event-row coverage, and countable-sum endpoint stability rows with the rows already projected from the root public surface.

Repack these common projections in the ten-row template of Definition 92.82. The repacked surface contains no additional host equality, quotient event equality, or standard bridge row, so the carrier-classifier package is the stated public one. □

Theorem 92.84 (Measure root analysis-unblock additivity-continuity)**.** *The surface of Definition 92.82 packages finite disjoint-union additivity, relative-difference additivity, monotone inclusion, nonnegative* $\mathsf{Real}^{\uparrow}$ *values, and continuity from below for displayed increasing measurable sequences.*

Proof. First project the finite rows from the public $\mathsf{Measure}^{\uparrow}$ package. Apply Definition 92.35; its two-step readback supplies the finite disjoint-union additive row used by the root analysis-unblock surface.

Next project the relative and order rows through Definition 92.75. This single package supplies relative-difference additivity, monotone inclusion, and nonnegative $\mathsf{Real}^{\uparrow}$ values over the same carrier and endpoint classifier.

For countable increasing sequences, apply Definition 92.42. Its construction uses the same visible event rows, relative-difference rows, finite readbacks, countable-sum classifier stability, and $\mathsf{Real}^{\uparrow}$ endpoint classifier as the root surface.

The rows cited above are all rows of the ten-row template in Definition 92.82. Repacking them gives one additivity-continuity package and adds no extra equality or standard-bridge assumption. □

Theorem 92.85 (Measure root analysis-unblock downstream package)**.** *The surface of Definition 92.82 is the* $\mathsf{Measure}^{\uparrow}$ *package consumed by* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*. The consumer boundary consists only of the carrier, classifier, stability, exactness, ledger, additivity, order, endpoint, and continuity rows named in that surface.*

Proof. Apply Definition 92.76. It assembles the integral premeasure rows, the probability normalization rows, and the functional-analysis endpoint and order rows from the public $\mathsf{Measure}^{\uparrow}$ analysis substrate.

Read that assembled source through the ten-row surface of Definition 92.82. The $\mathsf{Integral}^{\uparrow}$ consumer sees the measurable-event, endpoint, finite-readback, and countable-sum rows; the $\mathsf{ProbSpace}^{\uparrow}$ consumer sees the total-event, unit-mass, empty-zero, and finite-additivity rows; the $\mathsf{FunctionalAnalysis}^{\uparrow}$ consumer sees the nonnegative, monotone, relative-difference, and countable-stability rows.

The exactness and ledger rows of the surface keep the three downstream fronts inside the displayed $\mathsf{Measure}^{\uparrow}$ package. Therefore the root analysis-unblock surface is the paper-side package consumed by those fronts and carries no additional standard bridge row. □

Definition 92.86 (Measure root consumer package)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root consumer package is the root NameCert public surface of Definition 92.61 read together with the downstream package of Definition 92.64. Its consumers receive only covered measurable-event rows,* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows, countable-sum endpoint rows, head-tail readback, empty-zero, finite disjoint-union readback, relative-difference additivity, monotone inclusion, nonnegative endpoint, and the explicit no-*$\mathsf{StandardBridge}$ *row exposed by that public* $\mathsf{Measure}^{\uparrow}$ *package.*

Theorem 92.87 (Measure integral consumer rows)**.** *The root consumer package of Definition 92.86 supplies* $\mathsf{Integral}^{\uparrow}$ *with exactly the covered measurable-event rows,* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows, countable-sum endpoint rows, head-tail readback rows, and finite disjoint-union readback rows exposed by* $\mathsf{Measure}^{\uparrow}$*. No host set equality, quotient event equality, probability normalization row, functional-analysis order row, or standard bridge row is added to the integral consumer surface.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureIntegralConsumer rows`

Proof. Project the root NameCert public surface from Definition 92.86. Its coverage predicate is Definition 92.57, so every event row visible to the consumer is one of the displayed measurable-event rows of the $\mathsf{Measure}^{\uparrow}$ surface.

Apply Definition 92.64. This exposes the covered event rows, $\mathsf{Real}^{\uparrow}$ endpoint rows, countable-sum rows, head-tail readback, and finite disjoint-union readback as the public downstream package.

Now apply Definition 92.60. Its Integral$^{\uparrow}$ projection consumes exactly those rows from the same public package. Repacking that projection with the root consumer package gives the claimed integral consumer surface, and the exactness predicate rules out every row not named in the statement. □

Theorem 92.88 (Measure probability consumer rows)**.** *The root consumer package of Definition 92.86 supplies* ProbSpace$^{\uparrow}$ *with the total-event normalization row together with the empty-zero and finite disjoint-union rows exposed by* Measure$^{\uparrow}$*. No integral countable-sum endpoint row, functional-analysis relative-difference package, quotient event equality, or standard bridge row is added to the probability consumer surface.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureProbabilityConsumer rows`

Proof. Project the empty-zero and finite disjoint-union rows from Definition 92.64. These are already public rows of the root consumer package, because the package includes the root NameCert surface and its downstream repacking.

Apply Definition 92.59. The theorem reads the total-event endpoint and the unit-mass comparison through the same Measure$^{\uparrow}$ public surface, and it consumes the empty-zero and finite disjoint-union rows already projected above.

Repack the total-event normalization row with those two additive rows. The event-row exactness clause of Definition 92.86 leaves no additional event identity, countable-sum endpoint, functional-analysis order, or StandardBridge row in the ProbSpace$^{\uparrow}$ consumer surface. □

Theorem 92.89 (Measure functional-analysis consumer rows)**.** *The root consumer package of Definition 92.86 supplies* FunctionalAnalysis$^{\uparrow}$ *only with the nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows exposed by* Measure$^{\uparrow}$*. It does not add integral premeasure rows, probability normalization rows, quotient event equality, host set equality, or a standard bridge row.*

Proof. Start from the Measure$^{\uparrow}$ analysis substrate rows already present in the root consumer package. The nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows are the analysis rows visible through the public root surface.

Apply Definition 92.72. Its FunctionalAnalysis$^{\uparrow}$ projection consumes exactly those four row families: nonnegative endpoints, monotone inclusion, relative-difference additivity, and countable-sum classifier stability.

Finally repack the projection through Definition 92.64. The downstream exactness predicate keeps the consumer boundary at the named row families, so the functional-analysis surface gains neither integral rows, probability normalization rows, quotient event equality, host set equality, nor a StandardBridge row. □

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureFunctionalAnalysisConsumer rows`

92.4 Countable-name root surface

Definition 92.90 (Measure countable-name root-unblock surface)**.** *The* Measure$^{\uparrow}$ *countable-name root-unblock surface is the ten-field obligation surface obtained by reading the root public* Measure$^{\uparrow}$ *package through the StreamName endpoint family and the downstream consumer rows. Its fields are:*

1. *traditional target: constructive measure names whose visible events are counted by StreamName observations and whose values are classified* $\mathsf{Real}^{\uparrow}$ *endpoints;*
2. *BEDC source:* $\mathsf{Measure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, *the history classifier* hsame, *and the root* $\mathsf{NameCert}$ *surfaces cited by Definition 92.61;*
3. *carrier choice: a carried* BHist *measure code containing the visible event rows, measurable witnesses, sigma-algebra rows,* $\mathsf{Real}^{\uparrow}$ *endpoint map, StreamName endpoint stream, and countable-sum rows;*
4. *classifier choice: event-row* hsame *transport together with the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier and the pointwise StreamName classifier;*
5. *stability obligations: carrier transport, measurable-row transport, sigma-additivity transport, and countable-sum classifier stability;*
6. *ledger: hidden event membership rows, measurable witnesses, countable-family indices, disjointness witnesses, countable-union rows, and endpoint stream rows;*
7. *core theorem list: Definition 92.91, Definition 92.92, and Definition 92.93;*
8. *exactness predicate: coverage, soundness, and completeness for the visible event rows named by Definition 92.57;*
9. *standard bridge: no* $\mathsf{StandardBridge}$ *row is asserted at this paper site;*
10. *status: unformalized paper target for the future* $\mathsf{BEDC.Derived.MeasureUp}$ *namespace.*

The surface is only a package of displayed rows. It does not identify event carriers by host set equality and does not quotient measure codes.

Theorem 92.91 (Measure countable-name carrier-classifier obligation)**.** *The countable-name root-unblock surface of Definition 92.90 exports exactly the* $\mathsf{Measure}^{\uparrow}$ *carrier transport, event-row classifier transport, and StreamName endpoint classifier transport needed by downstream analysis chapters. These rows are the projections of Definition 92.8, Definition 92.9, and Definition 92.78.*

Proof. First project the carried measure code from the countable-name surface. The carrier is a BHist measure code, so Definition 92.8 moves the carrier proof and rereads the measurable-family, sigma-algebra, endpoint, sigma-additivity, head-tail, and countable-sum rows at the transported history.

Next project the public classifier row. Apply Definition 92.9; its componentwise hsame projections transport the visible event rows and their measurable witnesses, while the $\mathsf{Real}^{\uparrow}$ classifier transports the corresponding endpoint values.

Finally project the StreamName endpoint stream. Apply Definition 92.78. It transports the observation carrier and the pointwise measurable-event and endpoint rows at every unary index. Repacking these three projections gives the displayed carrier-classifier obligation and adds no host equality or quotient row. □

Theorem 92.92 (Measure countable-name sigma-additivity export)**.** *For every visible pairwise-disjoint* BHist *event stream in the countable-name root-unblock surface, the sigma-additivity comparison read by* $\mathsf{Measure}^{\uparrow}$ *is the same* $\mathsf{Real}^{\uparrow}$ *endpoint comparison read by the StreamName-indexed countable-sum row. The export is obtained from Definition 92.22, Definition 92.80, and Definition 92.12.*

Proof. Project the visible StreamName-indexed event family from Definition 92.90. Its ledger rows provide the unary indices, the covered measurable event at each index, the pairwise-disjointness witness, and the displayed countable-union row.

Apply Definition 92.22 to the same covered family. The theorem reads the certificate-level sigma-additivity row and produces the $\mathsf{Real}^{\uparrow}$ comparison between the measure of the union and the countable endpoint sum.

Now read the family as a StreamName endpoint family. By Definition 92.80, countable additivity factors only through the endpoint stream, the displayed sigma-additivity row, and countable-sum classifier stability.

It remains to compare transported endpoint streams. Apply Definition 92.12; pointwise $\mathsf{Real}^{\uparrow}$ endpoint comparisons assemble into the classifier comparison of the two countable sums. Repacking these rows gives the stated sigma-additivity export for disjoint visible BHist event streams. □

Theorem 92.93 (Measure countable-name analysis consumer package)**.** *The countable-name root-unblock surface supplies the common* $\mathsf{Measure}^{\uparrow}$ *package consumed by* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*. The package consists of the carrier-classifier rows of Definition 92.91, the sigma-additivity export of Definition 92.92, and the consumer rows of Definition 92.87, Definition 92.88, and Definition 92.89.*

Proof. Begin with the carrier-classifier obligation. It supplies the transported measure code, visible event rows, measurable witnesses, endpoint rows, and StreamName point rows that the three analysis consumers may name.

Next attach the sigma-additivity export. This gives the countable union comparison and countable-sum classifier stability for every visible disjoint event stream in the same BHist ledger.

For $\mathsf{Integral}^{\uparrow}$, apply Definition 92.87. The consumer receives the covered measurable-event rows, endpoint classifier rows, countable-sum rows, head-tail readback, and finite disjoint-union readback already present in the countable-name surface.

For $\mathsf{ProbSpace}^{\uparrow}$, apply Definition 92.88. The consumer reads the total-event normalization row together with empty-zero and finite disjoint-union rows, all from the same root package.

For $\mathsf{FunctionalAnalysis}^{\uparrow}$, apply Definition 92.89. The consumer reads only nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows. Repacking the three projections gives one analysis consumer package and still exposes no host set equality, quotient event equality, or StandardBridge row. □

Definition 92.94 (Measure root deps-ready threshold)**.** *The hub-counted* $\mathsf{Measure}^{\uparrow}$ *root deps-ready threshold package is the public surface of Definition 92.61, the downstream package of Definition 92.64, and the consumer package of Definition 92.86. It is counted at the* $\mathsf{Measure}^{\uparrow}$ *root because it exposes the public rows required before* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *may consume the measure surface.*

Theorem 92.95 (Measure root public event coverage threshold)**.** *The root deps-ready threshold package of Definition 92.94 exposes only covered measurable-event rows, the empty-event row, binary-union rows, countable-union rows, complement and relative-difference rows, disjoint-sequence rows,* $\mathsf{Real}^{\uparrow}$ *endpoint rows, and countable-sum rows. Every such row is a visible* BHist *ledger row of the public* $\mathsf{Measure}^{\uparrow}$ *surface, and no uncovered event carrier, quotient event equality, host set equality, analytic completion object, or* StandardBridge *row is present in the threshold package.*

Proof. Start from the event-row coverage predicate of Definition 92.57. Its enumerated rows are exactly the measurable events, empty event, binary and countable unions, disjointness witnesses, $\mathsf{Real}^{\uparrow}$ endpoints, countable sums, and head-tail readback rows available to a downstream certificate.

Apply Definition 92.62. This projects the same rows from the root public surface and transports them along the componentwise hsame classifier. The complement and relative-difference rows are read through the carrier surface fields already included in that public obligation.

Finally apply Definition 92.58. Its coverage, soundness, and completeness clauses identify the visible ledger rows as the whole measurable-family interface, so the threshold package contains only the displayed public event and endpoint rows. □

Theorem 92.96 (Measure root public countable-additivity threshold)**.** *For every covered pairwise-disjoint measurable sequence $E_\bullet$ with covered countable union U, the root deps-ready threshold package supplies the comparison*

$$\mu(U) \sim_R \Sigma_\mu(E_\bullet).$$

The empty-zero row $\mu(\varnothing) \sim_R 0_R$ and finite disjoint-union readback are part of the same public package, because they are consequences of the sigma-additive $\mathsf{Measure}^\uparrow$ *rows exposed at the root threshold.*

Proof. Project the covered sequence, its countable union, its pairwise-disjointness witness, and its countable-sum endpoint from the root deps-ready threshold package. These are public rows by Definition 92.95.

Apply Definition 92.63. Its sigma-additive projection gives the displayed comparison $\mu(U) \sim_R \Sigma_\mu(E_\bullet)$ for the covered pairwise-disjoint sequence.

Next apply Definition 92.25. The empty event and all-empty sequence are covered rows of the same threshold package, so the zero endpoint is read back without adding a separate carrier.

Finally apply Definition 92.26. The binary-union, disjointness, endpoint, and additive $\mathsf{AbGroup}^\uparrow$ rows are already public at the threshold, so the finite disjoint-union comparison is repacked into the same public countable-additivity package. □

Theorem 92.97 (Measure root consumer boundary threshold)**.** *The root deps-ready threshold package of Definition 92.94 is exactly the root* $\mathsf{Measure}^\uparrow$ *surface consumed by* $\mathsf{Integral}^\uparrow$*,* $\mathsf{ProbSpace}^\uparrow$*, and* $\mathsf{FunctionalAnalysis}^\uparrow$*. It exposes the rows named by those three consumers and excludes quotient event equality, host set equality, and standard bridge rows.*

Proof. First project the root consumer package from Definition 92.94. This gives the same public surface and downstream package used by Definition 92.86.

Apply Definition 92.87 to read the $\mathsf{Integral}^\uparrow$ boundary. It consumes exactly the covered measurable-event, $\mathsf{Real}^\uparrow$ endpoint, countable-sum, head-tail, and finite disjoint-union rows from the root package.

Apply Definition 92.88 to read the $\mathsf{ProbSpace}^\uparrow$ boundary. It consumes the total-event normalization row together with the empty-zero and finite disjoint-union rows exposed by the same root package.

Apply Definition 92.89 to read the $\mathsf{FunctionalAnalysis}^\uparrow$ boundary. It consumes only the nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows.

The exclusions are common to the three projections: each cited consumer-row theorem rules out quotient event equality, host set equality where relevant, and any StandardBridge row. The threshold package is therefore exactly the shared root surface for these consumers and nothing beyond that surface. □

Theorem 92.98 (Measure nonnegative value obligation)**.** *For a* $\mathsf{Measure}^\uparrow$ *carrier as in section 92.1, every displayed measurable event E has a visible RealAlgOrder row*

$$\mathsf{NonNeg}_R(\mu(E)).$$

If the $\mathsf{Measure}^{\uparrow}$ *classifier transports* E *to a displayed measurable event* E' *and classifies the endpoints by* $\mu(E) \sim_R \mu(E')$*, then the same classifier transport carries* $\mathsf{NonNeg}_R(\mu(E))$ *to* $\mathsf{NonNeg}_R(\mu(E'))$*.*

Proof. Project the nonnegative measure-value clause of the $\mathsf{Measure}^{\uparrow}$ carrier surface at the displayed measurable event E. This supplies the public row $\mathsf{NonNeg}_R(\mu(E))$ attached to the same ledger entry as the endpoint $\mu(E)$.

For classifier transport, use the endpoint comparison supplied by Definition 92.7. The nonnegative row is stable under $\sim_R$ by definition, so the transported endpoint $\mu(E')$ receives the row $\mathsf{NonNeg}_R(\mu(E'))$. No order on host representatives is consulted. □

Theorem 92.99 (Measure monotone under measurable inclusion)**.** *Let* A *and* B *be displayed measurable events in a* $\mathsf{Measure}^{\uparrow}$ *carrier. If the displayed measurable-difference row witnesses inclusion by presenting a measurable event* C *with* $B = A \sqcup C$*, then the finite disjoint-union additivity row, the nonnegative value row for* $\mu(C)$*, and the RealAlgOrder additive order row classify*

$$\mu(A) \leq_R \mu(B).$$

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureMeasurableInclusion monotone`

Proof. Read the displayed measurable-difference row as the package of a measurable event C, a disjointness witness between A and C, and a classifier identification of B with the displayed disjoint union $A \sqcup C$.

Apply Definition 92.26 to A and C. It gives the endpoint classification

$$\mu(A \sqcup C) \sim_R \mu(A) + \mu(C).$$

Transport this comparison along the displayed identification $B \sim_M A \sqcup C$ and the endpoint classifier row, obtaining $\mu(B) \sim_R \mu(A) + \mu(C)$.

Now project Definition 92.98 at C to get $\mathsf{NonNeg}_R(\mu(C))$. The RealAlgOrder additive order row says that adding a nonnegative right summand classifies the left summand below the sum, so it yields $\mu(A) \leq_R \mu(A) + \mu(C)$.

Finally transport the right endpoint of that order comparison across $\mu(B) \sim_R \mu(A) + \mu(C)$ using the $\sim_R$-stability of the RealAlgOrder order row. The result is the displayed classification $\mu(A) \leq_R \mu(B)$. □

Theorem 92.100 (Measure complement row transport)**.** *Let* M *and* N *be* $\mathsf{Measure}^{\uparrow}$ *carriers as in Definition 92.1, and suppose* $M \sim_{\mathsf{Measure}^{\uparrow}} N$ *through the public classifier of Definition 92.7. If* A *and* B *are displayed measurable events of* M *with displayed inclusion* $B \subseteq A$*, then the complement/relative-difference row of Definition 92.16 transports the event* $A \setminus B$*, its measurable witness, its disjointness witness against* B*, its binary-union readback* $B \cup (A \setminus B) \sim_M A$*, and its* $\mathsf{Real}^{\uparrow}$ *measure endpoint to the corresponding row of* N*.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureComplementRow transport`

Proof. Project the public classifier into its componentwise hsame fields. These fields transport the carried fiber, the two event presentations, their measurable witnesses, and the displayed inclusion witness from M to N.

Apply the stability clause in Definition 92.16 to those transported inputs. It returns the target relative-difference event together with the measurable, disjointness, and binary-union readback fields.

The remaining endpoint comparison is the value component of the same row. Read that component through RealConstantHistoryClassifier and then through the $\mathsf{Real}^{\uparrow}$ classifier supplied by Definition 38.9. □

Theorem 92.101 (Measure relative-difference disjoint decomposition)**.** *Let M be a $\mathsf{Measure}^{\uparrow}$ carrier as in section 92.1. Let A and B be displayed measurable events in the same carried fiber, and suppose the public event readback displays $B \subseteq A$. Then the complement/relative-difference row supplies a measurable event $A \setminus B$ such that B and $A \setminus B$ are disjoint and the binary union $B \cup (A \setminus B)$ is classified as A in the public $\mathsf{Measure}^{\uparrow}$ event classifier.*

Proof. Read the complement/relative-difference row of Definition 92.16 at the carried fiber of M. The hypotheses give exactly the row inputs: two measurable events and a displayed inclusion $B \subseteq A$ in that fiber.

Project the row. Its first projection is the measurable event $A \setminus B$. The next projections are the disjointness witness for B and $A \setminus B$ and the binary-union readback classifying $B \cup (A \setminus B)$ as A.

These projections are already ledger rows of the public carrier surface, so no host-level set subtraction or quotient equality is introduced. □

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureRelativeDifference disjoint decomposition`

Theorem 92.102 (Measure relative-difference additivity)**.** *For a $\mathsf{Measure}^{\uparrow}$ carrier as in section 92.1, let $\mathcal{A}$ be its designated σ-algebra, let μ be its $\mathsf{Real}^{\uparrow}$-valued measure map, and write $x \sim_R y$ for the $\mathsf{Real}^{\uparrow}$ classifier of Definition 38.9. Let $A, B \in \mathcal{A}$ be displayed events in the same carried fiber, and suppose the public event readback displays $B \subseteq A$. If the certificate supplies the complement/relative-difference row of Definition 92.16 and the hypotheses of Definition 92.26 for the pair $B, A \setminus B$, then*

$$\mu(A) \sim_R \mu(B) + \mu(A \setminus B).$$

Proof. Apply Definition 92.101 to the displayed inclusion $B \subseteq A$. This gives measurability of $A \setminus B$, disjointness of B and $A \setminus B$, and the binary-union readback classifying $B \cup (A \setminus B)$ as A.

Apply Definition 92.26 to the disjoint pair B and $A \setminus B$. The theorem gives

$$\mu(B \cup (A \setminus B)) \sim_R \mu(B) + \mu(A \setminus B).$$

Use the binary-union readback from the relative-difference row to transport the left endpoint from $\mu(B \cup (A \setminus B))$ to $\mu(A)$ through the $\mathsf{Measure}^{\uparrow}$ event classifier and then through the $\mathsf{Real}^{\uparrow}$ value classifier. Composing that endpoint transport with the finite disjoint-union comparison gives the displayed finite difference law. □

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureRelativeDifference additivity`

Theorem 92.103 (Measure self-difference zero law)**.** *For a $\mathsf{Measure}^{\uparrow}$ carrier as in section 92.1, let $\mathcal{A}$ be its designated σ-algebra, let μ be its $\mathsf{Real}^{\uparrow}$-valued measure map, write $x \sim_R y$ for the $\mathsf{Real}^{\uparrow}$ classifier of Definition 38.9, and write 0_R for the additive zero in the target $\mathsf{Real}^{\uparrow}$ additive $\mathsf{AbGroup}^{\uparrow}$ row. Let $A \in \mathcal{A}$ be a displayed measurable event in one carried fiber. Suppose the public event readback supplies the reflexive inclusion $A \subseteq A$, the complement/relative-difference row of Definition 92.16 is applied to this inclusion and supplies the displayed event $A \setminus A$, and the hypotheses of Definition 92.26 hold for the pair $A, A \setminus A$. If the target $\mathsf{Real}^{\uparrow}$ addition is carried by its additive $\mathsf{AbGroup}^{\uparrow}$ row, then*

$$\mu(A \setminus A) \sim_R 0_R.$$

Lean4 ✓ BEDC.Derived.MeasureUp.MeasureSelfDifference zero law

Proof. Apply Definition 92.102 to the displayed inclusion $A \subseteq A$ with $B = A$. The relative-difference row supplies the measurable event $A \setminus A$, its disjointness from A, and the binary-union readback $A \cup (A \setminus A) \sim_M A$, so the theorem gives

$$\mu(A) \sim_R \mu(A) + \mu(A \setminus A).$$

By symmetry of the $\mathsf{Real}^{\uparrow}$ classifier, this is the left-absorption comparison

$$\mu(A) + \mu(A \setminus A) \sim_R \mu(A).$$

By Definition 42.33, read the target additive $\mathsf{AbGroup}^{\uparrow}$ row as a group row with operation $+$, unit 0_R, and classifier $\sim_R$. Its group component supplies associativity, left and right unit laws, addition congruence, and left inverses. Applying Definition 41.114 with $a = \mu(A)$ and $b = \mu(A \setminus A)$ forces the right summand to the unit, hence

$$\mu(A \setminus A) \sim_R 0_R.$$

□

Theorem 92.104 (Measure binary-union subadditivity)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write* $x \sim_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9. Let* $A, B \in \mathcal{A}$ *be displayed measurable events in one carried fiber, and let* $U \in \mathcal{A}$ *be the displayed binary union of* A *and* B*. Suppose the public binary-union readback displays* $A \subseteq U$ *and, for the relative-difference event* $D := U \setminus A$ *supplied by Definition 92.16, displays* $D \subseteq B$*. If the certificate supplies the finite disjoint-union additivity row, the nonnegative measure-value row, and the RealAlgOrder additive order row with classifier-stable addition monotonicity, then*

$$\mu(U) \leq_R \mu(A) + \mu(B).$$

Proof. Apply Definition 92.102 to the displayed inclusion $A \subseteq U$. With $D := U \setminus A$, the relative-difference row supplies measurability of D, disjointness of A and D, and the readback $A \cup D \sim_M U$. The finite disjoint-union additivity row therefore gives

$$\mu(U) \sim_R \mu(A) + \mu(D).$$

The binary-union exclusion readback displays $D \subseteq B$. Apply Definition 92.99 to this inclusion. Its proof consumes the relative-difference row for $B \setminus D$, finite disjoint-union additivity, the nonnegative value row for the remaining piece, and the RealAlgOrder additive order row, yielding

$$\mu(D) \leq_R \mu(B).$$

Use the addition-monotonicity component of the same RealAlgOrder row with the fixed left summand $\mu(A)$. It transports the last comparison through addition and gives

$$\mu(A) + \mu(D) \leq_R \mu(A) + \mu(B).$$

Finally transport the left endpoint of this order comparison across $\mu(U) \sim_R \mu(A) + \mu(D)$ by the $\sim_R$-stability of the RealAlgOrder order row. The resulting displayed comparison is

$$\mu(U) \leq_R \mu(A) + \mu(B).$$

□

Theorem 92.105 (Measure triple-union subadditivity)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write* $x \sim_R y$ *and* $x \leq_R y$ *for the* $\mathsf{Real}^{\uparrow}$ *classifier of Definition 38.9 and the order relation exposed by the shared* RealAlgOrder *row. Let* $A, B, C \in \mathcal{A}$ *be displayed measurable events in one carried fiber. Let* $U \in \mathcal{A}$ *be the displayed binary union* $A \cup B$*, and let* $T \in \mathcal{A}$ *be the displayed binary union* $U \cup C$*. Suppose the public binary-union readback data required by Definition 92.104 are available for the pair* A, B *with union* U *and for the pair* U, C *with union* T*: the readbacks display* $A \subseteq U$ *and* $U \subseteq T$*, and the relative-difference events* $U \setminus A$ *and* $T \setminus U$ *supplied by Definition 92.16 are displayed as subevents of* B *and* C*, respectively. If the certificate supplies the finite disjoint-union additivity row, the nonnegative measure-value row, and the* RealAlgOrder *additive order row with classifier-stable addition monotonicity and transitivity, then*

$$\mu(T) \leq_R (\mu(A) + \mu(B)) + \mu(C).$$

Equivalently, for the displayed nesting $T = (A \cup B) \cup C$*,*

$$\mu((A \cup B) \cup C) \leq_R (\mu(A) + \mu(B)) + \mu(C).$$

Proof. Apply Definition 92.104 to the displayed pair U, C with binary union T. The hypotheses for this application are exactly the measurable union row $T \in \mathcal{A}$, the readback $U \subseteq T$, and the relative-difference inclusion $T \setminus U \subseteq C$, together with the finite-additivity, nonnegative-value, and additive-order rows. This gives

$$\mu(T) \leq_R \mu(U) + \mu(C).$$

Apply Definition 92.104 again to the displayed pair A, B with binary union U. The readback $A \subseteq U$ and the relative-difference inclusion $U \setminus A \subseteq B$ give

$$\mu(U) \leq_R \mu(A) + \mu(B).$$

Use the addition-monotonicity component of the same RealAlgOrder row with the fixed right summand $\mu(C)$. It transports the last comparison through addition and yields

$$\mu(U) + \mu(C) \leq_R (\mu(A) + \mu(B)) + \mu(C).$$

Finally compose the two order comparisons by transitivity of the RealAlgOrder order row. Since the displayed event T is the carried binary union $(A \cup B) \cup C$, the composite comparison is

$$\mu((A \cup B) \cup C) \leq_R (\mu(A) + \mu(B)) + \mu(C).$$

□

Theorem 92.106 (Measure ternary-union subadditivity)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier as in section 92.1, let* $\mathcal{A}$ *be its designated* σ*-algebra, let* μ *be its* $\mathsf{Real}^{\uparrow}$*-valued measure map, and write* $x \leq_R y$ *for the order relation exposed by the shared* RealAlgOrder *row. Let* $A, B, C \in \mathcal{A}$ *be displayed measurable events in one carried fiber. Let* $U_{BC} \in \mathcal{A}$ *be the displayed binary union of* B *and* C*, and let* $U \in \mathcal{A}$ *be the displayed binary union of* A *and* U_{BC}*. Suppose the public binary-union readback data required by Definition 92.104 are available for the pair* B, C *with union* U_{BC} *and for the pair* A, U_{BC} *with union* U*: the readbacks display* $B \subseteq U_{BC}$ *and* $A \subseteq U$*, and the relative-difference events* $U_{BC} \setminus B$ *and* $U \setminus A$ *supplied by Definition 92.16 are displayed as subevents of* C *and* U_{BC}*, respectively. If the certificate supplies the finite disjoint-union additivity row, the nonnegative measure-value row, and the* RealAlgOrder *additive order row with classifier-stable addition monotonicity and transitivity, then*

$$\mu(U) \leq_R \mu(A) + (\mu(B) + \mu(C)).$$

Proof. Apply Definition 92.104 to the displayed pair A, U_{BC} with binary union U. The hypotheses for this application are the measurable union row $U \in \mathcal{A}$, the readback $A \subseteq U$, and the relative-difference inclusion $U \setminus A \subseteq U_{BC}$, together with the finite-additivity, nonnegative-value, and additive-order rows. This gives

$$\mu(U) \leq_R \mu(A) + \mu(U_{BC}).$$

Apply Definition 92.104 again to the displayed pair B, C with binary union U_{BC}. The readback $B \subseteq U_{BC}$ and the relative-difference inclusion $U_{BC} \setminus B \subseteq C$ give

$$\mu(U_{BC}) \leq_R \mu(B) + \mu(C).$$

Use the addition-monotonicity component of the same RealAlgOrder row with the fixed left summand $\mu(A)$. It transports the last comparison through addition and yields

$$\mu(A) + \mu(U_{BC}) \leq_R \mu(A) + (\mu(B) + \mu(C)).$$

Finally compose the two order comparisons by transitivity of the RealAlgOrder order row. Since U is the displayed binary union $A \cup U_{BC}$ and U_{BC} is the displayed binary union $B \cup C$, the composite comparison is exactly

$$\mu(U) \leq_R \mu(A) + (\mu(B) + \mu(C)).$$

□

Theorem 92.107 (Measure root relative-difference consumer surface)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root consumer package of Definition 92.86 exposes the finite relative-difference surface consisting of:*

1. *the relative-difference decomposition row of Definition 92.101;*
2. *the relative-difference additivity row of Definition 92.102;*
3. *the self-difference zero row of Definition 92.103.*

Each exposed row is read only through the root NameCert carrier rows, measurable-event classifier rows, and $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows of the same package.*

Proof. Unpack the root consumer package in Definition 92.86. Its public surface includes the root NameCert surface and the downstream package of Definition 92.64, so the measurable-event rows, finite disjoint-union rows, and $\mathsf{Real}^{\uparrow}$ endpoint classifier rows are available to consumers.

Apply Definition 92.101. It consumes a displayed measurable inclusion and returns the visible measurable relative-difference event, the disjointness witness, and the binary-union readback against the original event.

Apply Definition 92.102 to the same exposed row family. It composes the decomposition row with finite disjoint-union additivity and endpoint transport, giving the public additive comparison.

Finally apply Definition 92.103 at a reflexive displayed inclusion. Since all required rows are already rows of the root consumer package, the zero self-difference row is exposed without adding host set subtraction, quotient event equality, or a standard bridge row. □

Theorem 92.108 (Measure root finite monotonicity consumer package)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root consumer package of Definition 92.86 makes measurable-inclusion monotonicity available to* $\mathsf{Integral}^{\uparrow}$ *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*. Concretely, the monotone row Definition 92.99 is part of the same consumer boundary that supplies the* $\mathsf{Integral}^{\uparrow}$ *rows of Definition 92.87 and the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *rows of Definition 92.89.*

Proof. Project the root consumer package through Definition 92.86. The package exposes the nonnegative endpoint rows, finite disjoint-union rows, and RealAlgOrder additive order row needed by measurable-inclusion monotonicity.

Apply Definition 92.99. Its proof reads the displayed measurable-difference row, applies finite disjoint-union additivity, and transports the resulting endpoint comparison through the classifier-stable order row.

The $\mathsf{Integral}^{\uparrow}$ consumer projection of Definition 92.87 reads exactly the covered measurable-event, endpoint, countable-sum, head-tail, and finite disjoint-union rows from the same root package. The monotone row is therefore available at the shared measure boundary used by the integral premeasure surface.

The $\mathsf{FunctionalAnalysis}^{\uparrow}$ projection of Definition 92.89 explicitly consumes the nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows. Hence the same monotone inclusion row is available to the functional-analysis consumer surface, with no extra quotient event equality or host set equality. □

Theorem 92.109 (Measure root subadditivity consumer boundary)**.** *For a* $\mathsf{Measure}^{\uparrow}$ *carrier read through the root consumer package of Definition 92.86, binary-union subadditivity is a public finite-measure consequence:*

$$\mu(A \cup B) \leq_R \mu(A) + \mu(B).$$

The consequence is obtained by composing the binary-union subadditivity row of Definition 92.104 with the downstream unblock package of Definition 92.64 and the root consumer rows of Definition 92.87 and Definition 92.89.

Proof. Start with the root downstream package of Definition 92.64. It exposes the covered measurable-event rows, $\mathsf{Real}^{\uparrow}$ endpoint rows, empty-zero row, finite disjoint-union row, relative-difference row, and nonnegative endpoint row through the root consumer surface.

Apply Definition 92.104. The theorem consumes exactly those finite-measure rows: relative-difference additivity for $U \setminus A$, measurable-inclusion monotonicity for the inclusion of that difference into B, and RealAlgOrder addition monotonicity for the final endpoint comparison.

The integral consumer rows of Definition 92.87 and the functional-analysis consumer rows of Definition 92.89 are projections of the same root package. Repacking the binary-union comparison through those projections makes the displayed finite subadditivity row public at the downstream consumer boundary, without adding a standard bridge or host-level event equality. □

Definition 92.110 (Measure root BHist consumer threshold)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root* BHist *consumer threshold is the ten-field package obtained by reading the root public surface of Definition 92.61 through the carrier, classifier, event coverage, additive, exactness, and consumer rows already exposed by Definition 92.57, Definition 92.63, Definition 92.26, and Definition 92.42. Its fields are:*

1. *the* BHist *carrier surface and componentwise classifier rows of the root* $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ *package;*
2. *the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows attached to every displayed measure value and countable-sum endpoint;*
3. *the visible measurable-event, empty-event, binary-union, countable-union, complement, relative-difference, and disjoint-sequence readback rows;*
4. *the total-event endpoint row used by the probability consumer;*
5. *the empty-zero and finite disjoint-additivity rows;*

6. *the countable disjoint-additivity, countable-sum, and head-tail readback rows;*
7. *the ledger exactness row saying that every consumed membership, disjointness, relative-difference, value, and countable-sum witness is attached to one of the displayed* BHist *rows;*
8. *the* $\mathsf{Integral}^{\uparrow}$ *consumer rows from Definition 92.87;*
9. *the* $\mathsf{ProbSpace}^{\uparrow}$ *consumer rows from Definition 92.88;*
10. *the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer rows from Definition 92.89.*

The threshold exports no host set equality, quotient event equality, analytic completion object, or StandardBridge *row beyond the displayed package.*

Theorem 92.111 (Measure root BHist real endpoint threshold)**.** *The threshold package of Definition 92.110 exposes only* BHist *event rows and* $\mathsf{Real}^{\uparrow}$ *endpoint comparisons at the root surface. Every row visible at the threshold is either a displayed event-row entry of the root carrier ledger or a* $\mathsf{Real}^{\uparrow}$ *comparison attached to a measure value, a finite readback endpoint, a relative-difference endpoint, or a countable-sum endpoint.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureRootBHist real endpoint threshold`

Proof. Begin with the root public surface of Definition 92.61. Its carrier and classifier rows are the displayed BHist rows and componentwise classifier rows listed by the public surface definition.

Apply Definition 92.62. This transports exactly the measurable-event, closure, relative-difference, disjoint-readback, ledger, and endpoint rows through the root classifier. The endpoint movement is read through the $\mathsf{Real}^{\uparrow}$ classifier and not through a separate equality of events.

Next apply Definition 92.63. The empty-zero, finite readback, relative-difference, and countable-additivity rows it exposes are all rooted in the same displayed event ledger and the same $\mathsf{Real}^{\uparrow}$ endpoint classifier.

The exactness clause in Definition 92.110 repacks these projections as the threshold package. Since the package lists no host equality, quotient event equality, analytic completion object, or standard bridge, no other root row is exported. □

Theorem 92.112 (Measure root BHist ProbSpace threshold)**.** *The threshold package of Definition 92.110 supplies* $\mathsf{ProbSpace}^{\uparrow}$ *with exactly the total-event normalization, empty-zero, finite-additivity, and* $\mathsf{Real}^{\uparrow}$ *endpoint normalization rows exposed by the root* $\mathsf{Measure}^{\uparrow}$ *package. It supplies no integral countable-sum row, functional-analysis relative-difference package, quotient event equality, host set equality, or standard bridge row to* $\mathsf{ProbSpace}^{\uparrow}$*.*

Proof. Project the root downstream package from Definition 92.64. Its probability-facing surface contains the total-event endpoint row together with the empty-zero and finite disjoint-union rows exposed by the root sigma-additive obligation.

Use Definition 92.86 to read those rows as consumer rows. The package is built from the root public surface and the downstream unblock package, so the probability consumer sees the same covered BHist rows and the same $\mathsf{Real}^{\uparrow}$ endpoint comparisons.

Apply Definition 92.88. It identifies the $\mathsf{ProbSpace}^{\uparrow}$ projection as exactly the total-event normalization row, empty-zero row, and finite disjoint-union row carried by the root consumer package.

Finally compare this projection with Definition 92.110. The threshold contains no additional probability-facing field, so the listed rows exhaust the $\mathsf{ProbSpace}^{\uparrow}$ consumer boundary. □

Theorem 92.113 (Measure root BHist integral and functional threshold)**.** *The threshold package of Definition 92.110 supplies* $\mathsf{Integral}^{\uparrow}$ *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *with exactly the measurable-event, nonnegative endpoint, monotone inclusion, relative-difference, finite-readback, countable-sum, and continuity-from-below rows exposed by the root* $\mathsf{Measure}^{\uparrow}$ *package. It supplies no probability normalization row, quotient event equality, host set equality, analytic completion object, or standard bridge row to those two consumers.*

Proof. Start from the root consumer package of Definition 92.86. Its consumer rows are the root NameCert public rows of Definition 92.61 read through the downstream package of Definition 92.64.

For $\mathsf{Integral}^{\uparrow}$, apply Definition 92.87. The projection consumes covered measurable-event rows, $\mathsf{Real}^{\uparrow}$ endpoint rows, countable-sum endpoint rows, head-tail readback rows, and finite disjoint-union readback rows from the same root package.

For $\mathsf{FunctionalAnalysis}^{\uparrow}$, apply Definition 92.89. The projection consumes exactly the nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows exposed by $\mathsf{Measure}^{\uparrow}$.

The continuity-from-below row is part of the countable-sum and monotone consumer face of the root package, read through the same $\mathsf{Real}^{\uparrow}$ endpoint classifier and the same visible event ledger. Repacking the two projections with Definition 92.110 gives the displayed integral and functional-analysis threshold.

The threshold has separate $\mathsf{ProbSpace}^{\uparrow}$ fields and no standard-bridge, quotient, host-equality, or analytic-completion field. Therefore no row outside the named measurable-event, endpoint, order, relative-difference, finite-readback, countable-sum, and continuity-from-below families is exported to $\mathsf{Integral}^{\uparrow}$ or $\mathsf{FunctionalAnalysis}^{\uparrow}$. □

Definition 92.114 (Measure root dependency orientation surface)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root dependency orientation surface is the root* BHist *package whose carrier is* MCarrier *and whose classifier is the componentwise* $\mathsf{Measure}^{\uparrow}$ *classifier transported by* hsame*. Its sequence rows are indexed only by unary observations* $n : \mathsf{BHist}$ *with* $\mathsf{UnaryHistory}(n)$*, and its continuation rows are the* Cont *rows used to keep event presentations, relative-difference witnesses, countable-union witnesses, and countable-sum endpoints in the same visible ledger.*

The input certificates of the surface are exactly the following rows:

1. $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *for displayed endpoint classifiers, zero endpoints, order comparisons, and countable-sum endpoint comparisons;*
2. *the additive real rows already named by Definition 92.14 and Definition 92.61;*
3. $\mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}}$ *only where the endpoint-family rows of Definition 92.77 are used.*

No row from $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, or* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *is an input certificate for this root surface. Those objects are reachable only through the downstream consumer package.*

Theorem 92.115 (Measure root input dependency scope)**.** *The carrier, classifier, event coverage, finite additivity, sigma-additivity, continuity-from-below, and endpoint-family rows of* $\mathsf{Measure}^{\uparrow}$ *are proved from the orientation surface of Definition 92.114, the BEDC kernel constructs* BHist*,* hsame*, and* Cont*, the named* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *and additive real rows, and the* $\mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}}$ *rows at endpoint-family sites. They are not proved from any* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, or* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer row.*

Proof. Project the carrier and classifier rows from Definition 92.17. The carrier is the displayed MCarrier row over BHist, and classifier movement is the componentwise hsame transport built into the root NameCert surface.

Next apply Definition 92.18. Its stability and exactness projections say that every visible event witness, relative-difference witness, countable-union witness, and endpoint witness is read from the displayed ledger and transported only through the root classifier, Cont, and the $\mathsf{Real}^{\uparrow}$ endpoint classifier.

The finite-additivity, sigma-additivity, and continuity-from-below rows are then read through the public additive and countable-sum rows cited by the measure surface. Endpoint-family rows use Definition 92.77, so the only extra certificate at those sites is $\mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}}$.

Finally compare the resulting root package with Definition 92.64. That theorem exports rows from $\mathsf{Measure}^{\uparrow}$ to the three downstream consumers; it does not import consumer rows back into the carrier, classifier, additivity, continuity, or endpoint-family obligations. Hence the listed root obligations have precisely the input scope stated above. □

Theorem 92.116 (Measure root consumer projection separation)**.** *The* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *rows exposed in Definition 92.86 are projections out of the root* $\mathsf{Measure}^{\uparrow}$ *package. They cannot be used as hypotheses for the root carrier, classifier, event-coverage, additivity, continuity-from-below, or endpoint-family obligations of* $\mathsf{Measure}^{\uparrow}$*.*

Proof. Start with Definition 92.86. The definition reads the root NameCert public surface together with the downstream package of Definition 92.64; its consumer rows are therefore projections from an already assembled root surface.

For the three consumers, apply Definition 92.64. The integral face receives measurable-event, endpoint, countable-sum, head-tail, and finite readback rows; the probability face receives total-event normalization, empty-zero, and finite-additivity rows; the functional-analysis face receives nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows.

Now return to the root obligations named in Definition 92.114. Their hypotheses are BHist, hsame, Cont, $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, the additive real rows, and endpoint-family $\mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}}$ rows. None of the three consumer projections appears among those hypotheses.

The exactness row of Definition 92.86 keeps the consumer boundary one-way: downstream rows may cite the root package, but root proof obligations cite only the orientation surface and its named input certificates. This separates the projections from the hypotheses used to build $\mathsf{Measure}^{\uparrow}$. □

Theorem 92.117 (Measure root deps-ready public package)**.** *The orientation surface of Definition 92.114 together with the threshold package of Definition 92.110 forms the public deps-ready* $\mathsf{Measure}^{\uparrow}$ *package for* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*. This package exposes exactly the root* BHist *carrier and classifier rows,* $\mathsf{Real}^{\uparrow}$ *endpoint rows, additive and continuity rows, endpoint-family rows, the downstream consumer projections, and the no-*$\mathsf{StandardBridge}$ *boundary recorded by the threshold.*

Proof. Use Definition 92.114 to fix the root input face. It supplies the carrier orientation over BHist, classifier transport by hsame, continuation discipline through Cont, and the only external certificates allowed at root input sites.

Apply Definition 92.115. This proves that the root carrier, classifier, coverage, additivity, continuity-from-below, and endpoint-family rows are obtained before any downstream consumer projection is used.

Next combine those rows with Definition 92.110. The threshold package lists the visible event ledger, endpoint comparisons, additive rows, exactness row, and the three downstream consumer faces, while excluding host set equality, quotient event equality, analytic completion objects, and standard bridges.

Finally apply Definition 92.116. It identifies the consumer faces as outgoing projections only. Repacking the input face and the threshold face therefore gives a public deps-ready package that downstream analysis chapters may consume without using those chapters to justify the root $\mathsf{Measure}^{\uparrow}$ obligations. □

Definition 92.118 (Measure root domain-ready package)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root domain-ready package is the paper-side root package whose fields are the following ten rows:*

1. *the traditional constructive measure-space target, namely a measurable-event carrier, empty event, finite unions, countable unions, relative differences, disjointness witnesses, nonnegative* $\mathsf{Real}^{\uparrow}$ *endpoints, and countable-sum endpoints;*
2. *the BEDC source row over* BHist*, together with* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint comparison, the additive* $\mathsf{AbGroup}^{\uparrow}$ *real row, and* $\mathsf{StreamName}^{\uparrow}$ *countable-family names;*
3. *the carrier rows displayed by Definition 92.14;*
4. *the componentwise classifier rows displayed by Definition 92.15;*
5. *the stability rows for measurable events, endpoint comparisons, countable-family presentations, relative differences, and countable sums;*
6. *the visible ledger and exactness rows for hidden membership, disjointness, countable-union witnesses, and endpoint readback;*
7. *the core theorem list consisting of carrier-classifier transport, sigma-additivity, empty-zero, finite disjoint-union readback, finite-support countable readback, relative-difference additivity, and continuity from below;*
8. *the exactness predicate stating that every consumer row is one of the displayed root rows;*
9. *the explicit absence of any* $\mathsf{StandardBridge}$ *row;*
10. *the status row exposing this object as the paper-side root package for* $\mathsf{Measure}^{\uparrow}$*.*

Theorem 92.119 (Measure root domain carrier-classifier ready)**.** *The domain-ready package of Definition 92.118 supplies carrier transport, componentwise classifier transport, visible event-row transport, ledger transport, and* $\mathsf{Real}^{\uparrow}$ *endpoint transport for the root* $\mathsf{Measure}^{\uparrow}$ *domain. These rows are exactly the carrier-classifier part of the root public surface under the input scope of* BHist*,* hsame*,* Cont*,* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*, the additive* $\mathsf{AbGroup}^{\uparrow}$ *real row, and* $\mathsf{StreamName}^{\uparrow}$ *countable-family names.*

Proof. Start from the carrier and classifier theorem Definition 92.62. It projects the carried $\mathsf{Measure}^{\uparrow}$ code, visible event rows, ledger rows, and $\mathsf{Real}^{\uparrow}$ endpoint rows along the public classifier.

Apply Definition 92.21. Its certificate-level projections identify the same componentwise classifier movement for event presentations, values, and countable-sum components.

Finally apply Definition 92.115. The input scope pins the transport rows to BHist, hsame, Cont, $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, the additive real row, and the endpoint-family $\mathsf{StreamName}^{\uparrow}$ rows, with no downstream consumer row used as a hypothesis. These projections are precisely the carrier-classifier fields of the domain-ready package. □

Theorem 92.120 (Measure root domain sigma-additive ready)**.** *The domain-ready package of Definition 92.118 supplies sigma-additivity, empty-zero, finite disjoint-union readback, finite-support*

countable readback, relative-difference additivity, and continuity-from-below rows for the root $\mathsf{Measure}^{\uparrow}$ *domain.*

Proof. Apply Definition 92.63. It gives the public sigma-additive comparison, the empty-zero row, finite disjoint-union readback, and the relative-difference row from the root NameCert surface.

Next use Definition 92.23. This reads finite-support countable families through the same countable-union, disjointness, endpoint, and additive rows.

Apply Definition 92.102 to keep the relative-difference row visible as a root domain consequence, and apply Definition 92.43 to expose continuity from below at the same measure surface.

The listed rows use the carrier, endpoint, countable-family, additive, and ledger fields already named by the domain-ready package, so they repack as its sigma-additive face. □

Theorem 92.121 (Measure root domain downstream ready)**.** *The carrier-classifier theorem Definition 92.119 and the sigma-additive theorem Definition 92.120 expose exactly the rows consumed by* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*. The resulting downstream face contains no quotient event equality, no host set equality, and no standard bridge row.*

Proof. First apply Definition 92.64. It reads the carrier-classifier rows and sigma-additive rows as the public $\mathsf{Measure}^{\uparrow}$ package available to the three downstream consumers.

For $\mathsf{Integral}^{\uparrow}$, apply Definition 92.87. The consumed rows are the covered measurable-event rows, $\mathsf{Real}^{\uparrow}$ endpoint classifier rows, countable-sum endpoint rows, head-tail readback rows, and finite disjoint-union readback rows.

For $\mathsf{ProbSpace}^{\uparrow}$, apply Definition 92.88. The consumed rows are total-event normalization together with empty-zero and finite disjoint-union readback.

For $\mathsf{FunctionalAnalysis}^{\uparrow}$, use the consumer projection recorded in Definition 92.86 and made explicit by Definition 92.89. Its rows are the nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows.

The exactness predicate in Definition 92.86 excludes every row not named above. Hence the downstream face of the domain-ready package contains neither quotient event equality nor host set equality, and its standard-bridge field remains the explicit no-$\mathsf{StandardBridge}$ row. □

Definition 92.122 (Measure root source-closure package)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root source-closure package is the deps-ready* BHist *source obtained by repacking the carrier surface of Definition 92.14, the certificate surface of Definition 92.15, the dependency orientation surface of Definition 92.114, and the root consumer threshold of Definition 92.110. Its carrier is* $\mathsf{MCarrier}$*, its classifier is the componentwise* $\mathsf{Measure}^{\uparrow}$ *classifier* $\sim_M$*, its event rows are the visible measurable membership, empty, binary-union, countable-union, complement, relative difference, and disjoint-readback rows, its endpoint rows are the displayed* $\mathsf{Real}^{\uparrow}$ *measure-value and countable-sum rows, and its ledger rows are exactly the source witnesses attached to those displayed event and endpoint rows. The package has no consumer-row hypotheses:* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *occur only as outgoing faces of the threshold.*

Theorem 92.123 (Measure root source event-row closure)**.** *The empty, binary-union, countable-union, complement and relative-difference, disjoint-readback, and continuity-from-below event rows of Definition 92.122 are exactly the visible event rows exposed by the carrier surface and root threshold package. No downstream consumer row is an event-row hypothesis of this source package.*

Proof. Project Definition 92.15. Its event part consists of the measurable-family row, the empty row, the binary-union row, the countable-union row, the complement and relative-difference row, and the disjoint readbacks attached to the same carried BHist fiber.

Apply Definition 92.115. The input scope says that these rows are read from the orientation surface through BHist, hsame, Cont, the named $\mathsf{Real}^{\uparrow}$ rows, and the endpoint-family $\mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}}$ rows where sequences are present.

The continuity-from-below event layer is the same visible chain of measurable events and relative-difference layers named by Definition 92.42. It therefore lies inside the carrier and threshold event ledger rather than in a consumer face.

Finally apply Definition 92.116. The integral, probability, and functional-analysis rows are projections out of an already assembled root package, so they cannot add further event-row hypotheses. The displayed source package therefore has exactly the event rows listed in the statement. □

Theorem 92.124 (Measure root source endpoint-row closure)**.** *The measure-value, countable-sum, head-tail readback, nonnegative endpoint, monotone-inclusion, finite-additivity, and relative-difference endpoint rows of Definition 92.122 are all read through* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *and the additive real rows named in Definition 92.114.*

Proof. Start with Definition 92.115. The theorem identifies the only endpoint inputs for the root source as $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, the additive real rows named by the carrier and public NameCert surfaces, and $\mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}}$ only at endpoint-family sites.

Apply Definition 92.111. Every endpoint visible at the threshold is either a measure value, a finite readback endpoint, a relative-difference endpoint, or a countable-sum endpoint, and each comparison is a $\mathsf{Real}^{\uparrow}$ classifier comparison rather than a host event equality.

The finite-additivity and head-tail readback rows are the additive real readbacks already used by the measure certificate. The nonnegative and monotone-inclusion rows are endpoint comparisons over the same $\mathsf{Real}^{\uparrow}$ classifier, so they introduce no separate endpoint carrier.

Finally use Definition 92.42. Its endpoint claim is built from the countable-sum endpoint and finite-prefix readback rows over the visible layer sequence. Thus the source package closes its endpoint rows through the named real certificates and additive rows alone. □

Theorem 92.125 (Measure root source ledger exhaustion)**.** *Every source witness consumed by Definition 92.122 is one of the visible measurable membership, relative-difference, disjointness, measure-value,* $\mathsf{StreamName}^{\uparrow}$ *endpoint-family, or countable-sum ledger rows. The package contains no host set equality, quotient event equality, probability normalization, integral premeasure row, functional-analysis row, or standard bridge.*

Proof. Apply Definition 92.13. Its exactness clause lists the consumed membership, relative-difference, disjointness, value, and countable-sum witnesses as rows of the displayed carrier ledger.

Next read Definition 92.110. The threshold adds the endpoint-family rows and the three outgoing consumer faces while retaining the exclusion of host set equality, quotient event equality, analytic completion objects, and standard bridges.

Now apply Definition 92.116. The consumer faces for $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ are outputs from the root surface, so their premeasure, normalization, and functional-analysis rows cannot become source witnesses.

Combining exactness with the one-way threshold boundary exhausts the source ledger. Every consumed witness is one of the displayed source rows, and every row named in the exclusion clause remains outside the package. □

Theorem 92.126 (Measure root source deps-ready package)**.** *The source-closure package of Definition 92.122, together with the event-row closure of Definition 92.123, the endpoint-row closure of Definition 92.124, and the ledger exhaustion of Definition 92.125, forms the deps-ready root*

source package consumed by $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$. *The public package of Definition 92.117 is used only as the outgoing consumer boundary.*

Proof. First package the source carrier and classifier from Definition 92.122. This fixes $\mathsf{MCarrier}$, $\sim_M$, the visible event ledger, the $\mathsf{Real}^{\uparrow}$ endpoint rows, and the source witness ledger as one BHist package.

Next insert the closure rows. Apply Definition 92.123 for the event side and Definition 92.124 for the endpoint side. These two rows identify all event and endpoint inputs before any downstream consumer face is read.

Then apply Definition 92.125. It shows that the package consumes only the visible source witnesses and excludes host equality, quotient event equality, normalization, premeasure, functional-analysis, and bridge rows.

Finally cite Definition 92.117 as the outgoing boundary for $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$. Since that boundary exports consumer projections but does not supply source hypotheses, the repacked source package is deps-ready for the three consumers. □

Definition 92.127 (Measure root consumer face classifier)**.** *The consumer face classifier of the* $\mathsf{Measure}^{\uparrow}$ *root threshold is the three-face partition of the consumer rows in Definition 92.110. The integral face is the* $\mathsf{Integral}^{\uparrow}$ *projection of Definition 92.87: it contains covered measurable-event rows,* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows, countable-sum endpoint rows, head-tail readback rows, and finite disjoint-union readback rows. The probability face is the* $\mathsf{ProbSpace}^{\uparrow}$ *projection of Definition 92.88: it contains the total-event normalization row, empty-zero row, and finite disjoint-union row. The functional-analysis face is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *projection of Definition 92.89: it contains nonnegative endpoint rows, monotone-inclusion rows, relative-difference rows, and countable-sum classifier rows.*

Rows common to more than one face are classified as shared root rows only when they are the displayed BHist *event-ledger rows or the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows already present at the root* $\mathsf{Measure}^{\uparrow}$ *surface. No face classifier row is a host set equality, quotient event equality, analytic completion object, or* $\mathsf{StandardBridge}$ *row.*

Theorem 92.128 (Measure root consumer face coverage)**.** *Every consumer row projected by Definition 92.86 belongs to one of the three faces of Definition 92.127. Thus each outgoing consumer row is classified as integral, probability, functional-analysis, or as a shared root* BHist *event-ledger or* $\mathsf{Real}^{\uparrow}$ *endpoint row seen through those faces.*

Proof. Start from Definition 92.86. Its consumer rows are the public root surface together with the downstream package of Definition 92.64.

Apply Definition 92.87, Definition 92.88, and Definition 92.89. These three theorems list the complete rows consumed by $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ from that same root package.

Finally use Definition 92.127. The classifier names exactly those three outgoing projections and assigns their common event-ledger and endpoint rows to the shared root part, so every row projected by the consumer package has one of the displayed face labels. □

Theorem 92.129 (Measure root consumer face disjointness)**.** *The integral, probability, and functional-analysis faces of Definition 92.127 overlap only on the shared root* BHist *event ledger and the shared* $\mathsf{Real}^{\uparrow}$ *endpoint classifier. The total-event probability-normalization row remains specific to the probability face, the countable-sum endpoint and head-tail readback rows remain specific to the integral face, and the relative-difference and monotone-inclusion rows remain specific to the functional-analysis face.*

Proof. First read the three outgoing projections through the consumer-row theorems. Definition 92.87 gives the integral rows, Definition 92.88 gives the probability rows, and Definition 92.89 gives the functional-analysis rows.

The only rows those projections are allowed to share are the displayed covered event rows and $\mathsf{Real}^{\uparrow}$ endpoint classifier rows already present in the root $\mathsf{Measure}^{\uparrow}$ package. This is exactly the shared-root clause in Definition 92.127.

Now apply Definition 92.116. The separation theorem makes the three consumer projections one-way outputs from the root surface and prevents any consumer-specific row from becoming a root hypothesis.

The exclusions in the three consumer-row theorems then keep the remaining rows face-specific: probability normalization is absent from the integral and functional-analysis surfaces, countable-sum endpoint and head-tail readback rows are absent from the probability surface, and relative-difference plus monotone-inclusion rows are absent from the probability consumer surface and do not become integral premeasure rows. □

Theorem 92.130 (Measure root cross-consumer threshold package)**.** *The face classifier of Definition 92.127, the coverage result of Definition 92.128, the disjointness result of Definition 92.129, and the deps-ready package of Definition 92.117 form the root consumer threshold for* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$. *This threshold exposes the shared* BHist *event ledger and shared* $\mathsf{Real}^{\uparrow}$ *endpoint classifier once, exposes each consumer-specific row only on its own face, and keeps all outgoing faces from serving as inputs to the root* $\mathsf{Measure}^{\uparrow}$ *obligations.*

Proof. Use Definition 92.117 to fix the public root package. It supplies the orientation surface, the BHist threshold, and the downstream projections needed by the three consumers.

Next apply Definition 92.128. This assigns every outgoing row of the consumer package to the integral, probability, or functional-analysis face, with shared event-ledger and endpoint rows read at the root.

Then apply Definition 92.129. The face-specific probability-normalization, countable-sum, head-tail, relative-difference, and monotone-inclusion rows remain on their named consumer faces.

Finally apply Definition 92.116. Since the consumer rows are outgoing projections and not hypotheses for the root carrier, classifier, coverage, additivity, continuity, or endpoint-family obligations, the packaged classifier is a root consumer threshold rather than a justification loop for $\mathsf{Measure}^{\uparrow}$. □

Definition 92.131 (Measure root shared endpoint consumer seal)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root shared endpoint consumer seal fixes the endpoint rows that may be read by more than one outgoing analysis face before any such face is consumed. Its shared source is exactly the combination of the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows and the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-family rows already named by Definition 92.122. The* BHist *event-ledger rows remain the only shared event source rows.*

The integral, probability, and functional-analysis faces are outgoing consumers of this sealed source. They may project the root event ledger and the shared endpoint classifier rows, but their face-specific rows are not source hypotheses of the root package. Thus probability normalization, integral head-tail readback, and functional-analysis monotone and relative-difference rows are consumer rows only.

Theorem 92.132 (Measure root shared endpoint coverage)**.** *Every shared endpoint row used by the* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *faces of Definition 92.131 is either a* $\mathsf{Measure}^{\uparrow}$ BHist *event-ledger row, a* $\mathsf{Real}^{\uparrow}$ *endpoint classifier row, or a* $\mathsf{StreamName}^{\uparrow}$ *endpoint-family row already exposed by the root source-closure package.*

Proof. First project the source endpoint closure of Definition 92.124. It identifies the measure-value, countable-sum, finite-additivity, head-tail, nonnegative, monotone, and relative-difference endpoint rows through $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ and the additive real rows of the root orientation surface.

Next apply Definition 92.79. The StreamName-indexed rows that appear at countable endpoint sites are stable pointwise under the StreamName classifier, so they remain the endpoint-family rows named by the root source package rather than a new analytic carrier.

Now use Definition 92.128. Each outgoing row belongs to the integral, probability, or functional-analysis face, with any overlap classified as a shared root event-ledger row or a shared $\mathsf{Real}^\uparrow$ endpoint row.

Combining these projections gives the stated coverage. A row shared by the three consumers has already appeared in the root event ledger, the $\mathsf{Real}^\uparrow$ endpoint classifier, or the $\mathsf{StreamName}^\uparrow$ endpoint family before the consumer face reads it. □

Theorem 92.133 (Measure root consumer face source separation)**.** *The probability-normalization rows, integral head-tail readback rows, and functional-analysis monotone and relative-difference rows of Definition 92.131 never become source hypotheses of the root* $\mathsf{Measure}^\uparrow$ *package.*

Proof. Start with Definition 92.125. The source ledger consumes only the visible measurable membership, relative-difference, disjointness, measure-value, $\mathsf{StreamName}^\uparrow$ endpoint-family, and countable-sum rows. It explicitly excludes probability normalization, integral premeasure rows, functional-analysis rows, and bridge rows from the root source ledger.

Next apply Definition 92.129. The probability-normalization row is specific to the probability face, the head-tail readback row is specific to the integral face, and the monotone and relative-difference rows are specific to the functional-analysis face except where their endpoint classifier has already been sealed as a shared root row.

Finally use Definition 92.116. The three consumer faces are one-way projections out of the assembled root surface and cannot serve as hypotheses for the root carrier, classifier, event-coverage, additivity, continuity, or endpoint-family obligations.

The exclusions from the source ledger and the one-way projection boundary therefore separate consumer-specific rows from root source hypotheses. □

Theorem 92.134 (Measure root shared endpoint deps-ready seal)**.** *The seal of Definition 92.131, the coverage theorem of Definition 92.132, the source-separation theorem of Definition 92.133, the source package of Definition 92.126, and the cross-consumer threshold of Definition 92.130 form the deps-ready root seal consumed by* $\mathsf{Integral}^\uparrow$*,* $\mathsf{ProbSpace}^\uparrow$*, and* $\mathsf{FunctionalAnalysis}^\uparrow$*.*

Proof. First fix the source package by Definition 92.126. This supplies the BHist carrier and classifier, the event ledger, the $\mathsf{Real}^\uparrow$ endpoint rows, the $\mathsf{StreamName}^\uparrow$ endpoint-family rows, and the exhausted source ledger.

Next insert the shared endpoint seal. Apply Definition 92.132 to show that every shared row consumed by the three analysis faces is already one of the sealed source rows. Apply Definition 92.133 to keep probability normalization, integral head-tail readback, and functional-analysis monotone and relative-difference rows on the consumer side.

Finally apply Definition 92.130. It packages the three outgoing faces over the same shared event ledger and endpoint classifier while keeping face-specific rows on their own projections.

Repacking these three steps gives a deps-ready root seal: the shared endpoint rows are identified once at the root, and the three downstream chapters consume only the corresponding outgoing faces. □

Definition 92.135 (Measure root regular value package)**.** *A* $\mathsf{Measure}^{\uparrow}$ *root regular value package is the following ten-field package.*

1. *The traditional target is the finite regular measure-value surface: finitely many measurable events, finite additivity on pairwise-disjoint displayed supports, and zero absorption for null rows.*
2. *The BEDC source is* $\mathsf{Measure}^{\uparrow}$ *over* BHist*, with its public event ledger read through* $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$*.*
3. *The endpoint source is* $\mathsf{Real}^{\uparrow}$*, using the value classifier* $\sim_R$ *of Definition 38.9 and the additive* $\mathsf{AbGroup}^{\uparrow}$ *row with zero endpoint* 0_R*.*
4. *The countable row source is the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-family row used to display countable measurable sequences and countable* $\mathsf{Real}^{\uparrow}$ *sum endpoints.*
5. *The carrier is a measurable-event predicate* $\mathcal{A}(h, E)$ *on carried histories* $h : \mathsf{BHist}$*, together with a finite displayed support spine* $E_0, \ldots, E_{n-1}$*.*
6. *The classifier transports the event spine by the* $\mathsf{Measure}^{\uparrow}$ *event classifier and transports the displayed values* $\mu_h(E_i)$ *by the* $\mathsf{Real}^{\uparrow}$ *value classifier.*
7. *The stability obligations are finite additivity on pairwise-disjoint displayed supports, zero and null-event absorption rows, carrier transport, and countable-tail readback for finite-support sequences.*
8. *The ledger records the hidden support enumeration and the all-zero tail after the displayed finite spine.*
9. *Exactness consists of finite coverage of every displayed support row, soundness of each measured row against the* $\mathsf{Measure}^{\uparrow}$ *carrier, and completeness of the finite value endpoint against the displayed support.*
10. *The package status is* $(\mathsf{seed}, \mathsf{formalTarget})$*: the paper declares the root target shape, and no Lean marker is attached at this site.*

Theorem 92.136 (Measure root finite regular value closure)**.** *Let* $h : \mathsf{BHist}$ *be carried by the* $\mathsf{Measure}^{\uparrow}$ *surface, and let* $E_0, \ldots, E_{n-1}$ *be a finite displayed support spine of pairwise-disjoint measurable events in the* h*-fiber. Suppose the* $\mathsf{Measure}^{\uparrow}$ *certificate supplies the existing finite-additivity row, the canonical countable-zero-tail row, and the root public countable-additivity threshold for the corresponding finite-support* $\mathsf{StreamName}^{\uparrow}$ *sequence. Then the displayed values* $\mu_h(E_0), \ldots, \mu_h(E_{n-1})$ *and their finite* $\mathsf{Real}^{\uparrow}$ *endpoint form a carried root regular value package in the sense of Definition 92.135.*

Proof. First build the carrier spine. The hypotheses give measurable rows for every E_i, pairwise disjointness on the displayed finite support, and the finite-support $\mathsf{StreamName}^{\uparrow}$ sequence whose tail is constantly empty.

Apply Definition 92.26 along the finite spine. This gives the binary finite-additivity comparisons needed to fold the visible support values into one $\mathsf{Real}^{\uparrow}$ endpoint.

Next read the countable presentation. By Definition 92.32, the hidden tail after the finite support is classified with 0_R, so the finite endpoint and the countable $\mathsf{StreamName}^{\uparrow}$ endpoint name the same value under $\sim_R$.

Finally apply Definition 92.96. The public root threshold supplies the countable-additivity comparison for the carried sequence, and its coverage rows identify the displayed spine as the complete support ledger. These rows are exactly the carrier, classifier, stability, ledger, and exactness fields of Definition 92.135. □

Theorem 92.137 (Measure root null absorption regularity)**.** *Let a carried root regular value package be displayed over a finite pairwise-disjoint measurable support spine. If a further measurable event N is classified by* $\mathsf{Measure}^{\uparrow}$ *with the zero* $\mathsf{Real}^{\uparrow}$ *value* 0_R *and is disjoint from the displayed support, then adjoining N preserves the same regular package endpoint under the* $\mathsf{Measure}^{\uparrow}$ *value classifier.*

Proof. Start with the displayed package endpoint and the additional measurable row for N. The disjointness hypothesis makes the enlarged support spine a legitimate finite measurable spine in the same $\mathsf{Measure}^{\uparrow}$ carrier.

Apply Definition 92.28. It identifies the finite endpoint after adjoining the null row with the original endpoint under the $\mathsf{Real}^{\uparrow}$ classifier.

The zero endpoint used by that neutral row is grounded by Definition 92.25. This keeps the added value inside the same $\mathsf{Measure}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ package rows rather than introducing a separate analytic zero object.

Finally use the carrier and classifier transport supplied by Definition 92.20. The transported event witness and the transported value witness keep the enlarged spine on the same root regular value package endpoint. □

Theorem 92.138 (Measure root regular value downstream package)**.** *Every carried root regular value package supplies the event row, the* $\mathsf{Real}^{\uparrow}$ *endpoint row, and the zero-tail countable-additivity row required by the* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer surfaces.*

Proof. Project the package fields of Definition 92.135. The carrier field gives the finite measurable-event ledger, the endpoint field gives the classified $\mathsf{Real}^{\uparrow}$ values, and the ledger field gives the hidden zero tail for the finite-support countable presentation.

Apply Definition 92.87. The integral surface reads exactly the covered measurable-event rows, $\mathsf{Real}^{\uparrow}$ endpoint rows, countable-sum endpoint rows, head-tail readback rows, and finite disjoint-union readback rows.

Apply Definition 92.88. The probability surface reads the empty-zero and finite disjoint-union rows already present in the same regular package.

Apply Definition 92.89. The functional-analysis surface reads the countable-sum classifier row and the endpoint order rows through the same $\mathsf{Measure}^{\uparrow}$ carrier and $\mathsf{Real}^{\uparrow}$ classifier. Therefore the regular value package supplies the common root rows needed by all three downstream consumers. □

Definition 92.139 (Measure root consumer threshold triad)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root consumer threshold triad is the three-sided package whose source side is the deps-ready source package of Definition 92.126, whose shared endpoint side is the deps-ready seal of Definition 92.134, and whose consumer side consists exactly of the three outgoing faces supplied by Definition 92.112 and Definition 92.113. The* $\mathsf{ProbSpace}^{\uparrow}$ *face receives the total-event normalization, empty-zero, finite-additivity, and* $\mathsf{Real}^{\uparrow}$ *endpoint normalization rows. The* $\mathsf{Integral}^{\uparrow}$ *face receives the measurable-event, finite-readback, countable-sum, head-tail, and continuity-from-below rows. The* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *face receives the nonnegative endpoint, monotone inclusion, relative-difference, countable-sum, and continuity-from-below rows. All three faces read the same root* BHist *event ledger and the same sealed* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *endpoint rows.*

Theorem 92.140 (Measure root source threshold triad face)**.** *The source face of Definition 92.139 exposes only the* BHist *event ledger, the* $\mathsf{Measure}^{\uparrow}$ *carrier and componentwise classifier, the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-family rows, additivity, continuity from below, and*

ledger exactness. It exposes no $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, or* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer-specific row as a root source hypothesis.*

Proof. Project the source package from Definition 92.126. It fixes the BHist carrier, the $\mathsf{Measure}^{\uparrow}$ classifier rows, the visible event ledger, the $\mathsf{Real}^{\uparrow}$ endpoint rows, the $\mathsf{StreamName}^{\uparrow}$ endpoint-family rows, and the exhausted source ledger before any consumer face is read.

The event and endpoint parts of that package are already identified by Definition 92.123 and Definition 92.124. These two projections account for the root event rows, additivity rows, continuity-from-below rows, endpoint classifier rows, and endpoint-family rows named in the statement.

Finally apply Definition 92.125. Its exclusion clause removes probability normalization, integral premeasure rows, functional-analysis rows, host equality, quotient event equality, and bridge rows from the source ledger. Thus the source face of the triad contains only the displayed root rows. □

Theorem 92.141 (Measure root shared endpoint threshold triad face)**.** *The shared endpoint face of Definition 92.139 is exactly the collection of* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows and* $\mathsf{StreamName}^{\uparrow}$ *endpoint-family rows sealed in Definition 92.134 before projection to* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, or* $\mathsf{FunctionalAnalysis}^{\uparrow}$*.*

Proof. Start with Definition 92.134. The seal is built from the source package, shared endpoint coverage, consumer-face source separation, and the cross-consumer threshold package. Its shared rows are therefore fixed before any outgoing face consumes them.

Apply Definition 92.132. Every row shared by the three analysis faces is already a root BHist event-ledger row, a $\mathsf{Real}^{\uparrow}$ endpoint classifier row, or a $\mathsf{StreamName}^{\uparrow}$ endpoint-family row. The endpoint part of the shared face is precisely the last two families.

Then use Definition 92.133. It keeps probability normalization, integral head-tail readback, and functional-analysis monotone and relative-difference rows on their own consumer projections unless their endpoint classifier has already been sealed as a shared root row. Hence no extra endpoint row appears after projection. □

Theorem 92.142 (Measure root consumer threshold triad exhaustion)**.** *In the triad of Definition 92.139,* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consume only their named outgoing faces. No probability normalization row, integral head-tail or premeasure row, functional-analysis monotone or relative-difference row, host set equality, quotient event equality, analytic completion object, or* $\mathsf{StandardBridge}$ *row becomes a root* $\mathsf{Measure}^{\uparrow}$ *hypothesis.*

Proof. First project the consumer side of Definition 92.139. The $\mathsf{ProbSpace}^{\uparrow}$ face is the face identified by Definition 92.112; the $\mathsf{Integral}^{\uparrow}$ and $\mathsf{FunctionalAnalysis}^{\uparrow}$ faces are the two faces identified by Definition 92.113.

Next compare these outgoing faces with the source face of Definition 92.140. The source face has already exhausted the root carrier, classifier, event ledger, endpoint rows, additivity, continuity, and ledger exactness without importing any consumer-specific row.

Finally apply Definition 92.141. Shared endpoint rows are sealed as $\mathsf{Real}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ rows before consumer projection, while the remaining probability, integral, and functional-analysis rows stay on their named outgoing faces. This exhausts the triad and prevents every consumer-specific row listed in the statement from becoming a root $\mathsf{Measure}^{\uparrow}$ hypothesis. □

Definition 92.143 (Measure root seed obligation front)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root seed obligation front is the ten-field surface that places the root measure certificate before its downstream consumers:*

1. *traditional target: a constructive measure space whose measurable predicates form a σ-algebra and whose measure takes values in* $\mathsf{Real}^{\uparrow}$*;*
2. *BEDC source:* BHist *presentations, the certificate* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*, and the additive* $\mathsf{AbGroup}^{\uparrow}$ *row on real endpoints;*
3. *carrier: the predicate* MeasCode *on* BHist*;*
4. *classifier: the root classifier $\sim_M$ on measure codes, with endpoint comparisons read through the* $\mathsf{Real}^{\uparrow}$ *classifier $\sim_R$;*
5. *stability rows: transport of* MeasCode*, visible event rows, measurable-family rows, endpoint rows, countable-sum rows, and head-tail readback along $\sim_M$ and componentwise* hsame*;*
6. *ledger rows: measurable membership, relative-difference, disjointness, endpoint-value, and countable-sum witnesses attached to the visible* BHist *rows they justify;*
7. *core theorem list: Definition 92.62, Definition 92.63, and Definition 92.64;*
8. *exactness: visible-row exhaustion by Definition 92.57 and Definition 92.13;*
9. *standard bridge: no* StandardBridge *is asserted at this paper site;*
10. *status:* seed *on the theory axis, with the theorem-shaped target surface for* formalTarget *under* BEDC.Derived.MeasureUp.

This front is read through the carrier rows of Definition 92.14, the certificate rows of Definition 92.15, the root public surface of Definition 92.61, and the root consumer package of Definition 92.86.

Theorem 92.144 (Measure root seed carrier-classifier obligation)**.** *The seed front of Definition 92.143 supplies the root carrier and classifier obligation for* $\mathsf{Measure}^{\uparrow}$*. If h, k :* BHist *satisfy* $\mathsf{MeasCode}(h)$ *and $h \sim_M k$, then the front transports* $\mathsf{MeasCode}(k)$*, every displayed event row, every ledger row, and every* $\mathsf{Real}^{\uparrow}$ *endpoint comparison attached to the carried measure code. The endpoint movement is always read through* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *and the classifier $\sim_R$, while event movement is read through componentwise* hsame *on the* BHist *rows.*

Proof. Start from the carrier and classifier fields of Definition 92.143. They are the MeasCode and $\sim_M$ fields of Definition 92.15, read over the visible rows listed in Definition 92.14.

Apply Definition 92.8. It transports the carried measure code and permits every displayed row indexed by that code to be read at the target history k after the $\sim_M$ comparison is supplied.

Next apply Definition 92.62. Its public form identifies the transported rows as the root carrier, classifier, ledger, and endpoint rows of the $\mathsf{Measure}^{\uparrow}$ surface. The event rows move by their componentwise hsame witnesses, and the endpoint rows move through $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ and $\sim_R$.

Finally use the root exactness clause from Definition 92.13. Since every consumed membership, relative-difference, disjointness, value, and countable-sum witness is attached to a visible row, the transported visible rows exhaust the root carrier-classifier obligation. □

Theorem 92.145 (Measure root seed sigma-additive obligation)**.** *The seed front of Definition 92.143 supplies the root sigma-additive obligation for* $\mathsf{Measure}^{\uparrow}$*. For every covered pairwise-disjoint measurable sequence $E_\bullet$ in a carried* BHist *fiber with covered countable union U, the front supplies the comparison*

$$\mu(U) \sim_R \Sigma_\mu(E_\bullet).$$

It also supplies the empty-zero, finite disjoint-union, relative-difference, head-tail, and countable-sum classifier rows needed to read this comparison through the additive $\mathsf{AbGroup}^{\uparrow}$ *real row.*

Proof. Project the sigma-algebra, countable-union, countable-sum, head-tail, and classifier-stability rows from Definition 92.15. The coverage predicate of Definition 92.57 places the sequence $E_\bullet$, its union U, its disjointness witness, and its endpoint rows in the visible BHist ledger.

Apply Definition 92.63. Its first conclusion is precisely the displayed comparison $\mu(U) \sim_R \Sigma_\mu(E_\bullet)$, with both endpoints classified through $\sim_R$.

The same public obligation invokes Definition 92.22, Definition 92.25, Definition 92.26, and Definition 92.102. These rows provide the empty-zero, finite readback, relative-difference, head-tail, and countable-sum classifier consequences.

The additive structure used in those readbacks is the $\mathsf{AbGroup}^\uparrow$ real row named in Definition 92.143. Thus the sigma-additive obligation is a root BHist and $\mathsf{Real}^\uparrow$ endpoint statement, not a separate host-level measure-space equality. □

Theorem 92.146 (Measure root seed consumer threshold)**.** *The seed front of Definition 92.143 reaches the root consumer threshold for* $\mathsf{Integral}^\uparrow$*,* $\mathsf{ProbSpace}^\uparrow$*, and* $\mathsf{FunctionalAnalysis}^\uparrow$*. The threshold exports exactly the covered measurable-event rows,* $\mathsf{Real}^\uparrow$ *endpoint classifier rows, countable-sum rows, head-tail readback, empty-zero, finite disjoint-union readback, relative-difference additivity, monotone inclusion, nonnegative endpoint, total-event normalization, and the explicit no-*$\mathsf{StandardBridge}$ *row exposed by the root* $\mathsf{Measure}^\uparrow$ *package.*

Proof. Begin with the root public surface of Definition 92.61 and the root consumer package of Definition 92.86. Together they expose the BHist event ledger, the $\sim_M$ carrier classifier, and the $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ endpoint classifier rows named by the seed front.

Apply Definition 92.64. It packages the carrier-classifier rows of Definition 92.62 with the sigma-additive rows of Definition 92.63, while keeping the standard-bridge field absent.

For the three outgoing faces, apply Definition 92.87, Definition 92.88, and Definition 92.89. These theorems read the integral, probability, and functional-analysis projections from the same root consumer package and list the rows each projection may consume.

Finally compare those projections with Definition 92.111, Definition 92.112, and Definition 92.113. The threshold contains no host set equality, quotient event equality, analytic completion object, or $\mathsf{StandardBridge}$ field, so the exported consumer surface is exactly the one stated above. □

Definition 92.147 (Measure root visible shared consumer envelope)**.** *The* $\mathsf{Measure}^\uparrow$ *root visible shared consumer envelope is the ten-field root obligation envelope whose target is the shared* $\mathsf{Measure}^\uparrow$ *source consumed by* $\mathsf{Integral}^\uparrow$*,* $\mathsf{ProbSpace}^\uparrow$*, and* $\mathsf{FunctionalAnalysis}^\uparrow$*. Its source field is the BEDC package over* BHist*,* hsame*,* Cont*,* $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$*,* $\mathsf{NameCert}_{\mathsf{StreamName}^\uparrow}$*, and the* $\mathsf{UnaryHistory}$*-indexed endpoint families. Its carrier field is the root carrier* $\mathsf{MCarrier}$*, and its classifier field is the componentwise* $\mathsf{Measure}^\uparrow$ *classifier.*

The stability fields are event-row transport, endpoint classifier transport, shared endpoint coverage, and one-way consumer projection. The ledger fields are visible membership witnesses, relative-difference witnesses, disjointness witnesses, measure-value witnesses, $\mathsf{StreamName}^\uparrow$ *endpoint-family witnesses, and countable-sum witnesses. The exactness field excludes host set equality, quotient event equality, analytic completion objects, consumer-row hypotheses, and standard bridges from the root source.*

Theorem 92.148 (Measure root visible shared consumer coverage)**.** *Every row in Definition 92.147 is either a visible* BHist *event ledger row, a* $\mathsf{Real}^\uparrow$ *endpoint classifier row, a* $\mathsf{StreamName}^\uparrow$ *endpoint-family row indexed by* $\mathsf{UnaryHistory}$*, or a* Cont*-preserved continuation row already present in the root* $\mathsf{Measure}^\uparrow$ *package.*

Proof. Start from Definition 92.122. It fixes the root carrier MCarrier, the componentwise $\mathsf{Measure}^{\uparrow}$ classifier, the visible event ledger, the $\mathsf{Real}^{\uparrow}$ endpoint rows, and the source witness ledger before any outgoing analysis face is read.

Apply Definition 92.132. The rows shared by $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ have already been classified as root event-ledger rows, $\mathsf{Real}^{\uparrow}$ endpoint classifier rows, or $\mathsf{StreamName}^{\uparrow}$ endpoint-family rows.

Now use Definition 92.111. It keeps the measure-value, finite readback, relative-difference, and countable-sum endpoint rows on the $\mathsf{Real}^{\uparrow}$ classifier side rather than turning them into host event equalities.

Finally read the transport boundary from Definition 92.114. The only remaining root movement is Cont-preserved continuation through BHist and the displayed endpoint-family rows indexed by UnaryHistory, so the envelope has exactly the four row classes stated above. □

Theorem 92.149 (Measure root visible shared consumer separation)**.** *The* $\mathsf{Integral}^{\uparrow}$ *premeasure rows,* $\mathsf{ProbSpace}^{\uparrow}$ *normalization rows, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *monotone and relative-difference rows visible from Definition 92.147 are outgoing projections only. They cannot serve as hypotheses for the* $\mathsf{Measure}^{\uparrow}$ *carrier, classifier, additivity, continuity-from-below, or endpoint-family obligations.*

Proof. First apply Definition 92.116. The three analysis faces are projections out of the assembled root package, and the root obligations are proved from BHist, hsame, Cont, $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, additive real rows, and endpoint-family $\mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}}$ rows.

Next use Definition 92.133. Its source boundary keeps probability normalization, integral head-tail readback, and functional-analysis monotone and relative-difference rows on their consumer faces except where a shared endpoint classifier row has already been sealed at the root.

Finally invoke Definition 92.125. The source ledger consumes only visible membership, relative-difference, disjointness, measure-value, $\mathsf{StreamName}^{\uparrow}$ endpoint-family, and countable-sum witnesses. Thus no premeasure, normalization, monotone, or consumer-specific relative-difference row can be repurposed as a source hypothesis. □

Theorem 92.150 (Measure root visible shared consumer deps-ready)**.** *The envelope of Definition 92.147, the coverage theorem of Definition 92.148, and the separation theorem of Definition 92.149 form the deps-ready* $\mathsf{Measure}^{\uparrow}$ *root package consumed by* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*. Only the displayed root rows are exported.*

Proof. Begin with Definition 92.126. It supplies the root BHist source package, including MCarrier, the componentwise classifier, visible event rows, $\mathsf{Real}^{\uparrow}$ endpoint rows, $\mathsf{StreamName}^{\uparrow}$ endpoint-family rows, and the exhausted source ledger.

Next apply Definition 92.134. The seal identifies the shared endpoint rows once at the root and keeps the probability, integral, and functional-analysis face-specific rows from entering the source side.

Then apply Definition 92.130. The threshold packages the three outgoing faces over the same shared event ledger and endpoint classifier while preserving one-way projection into the consumer chapters.

Repack these three sources with the envelope coverage and separation theorems. The resulting root package is deps-ready for the three downstream analysis consumers because it exports only visible event rows, endpoint classifier rows, endpoint-family rows, continuation rows, and the displayed ledger witnesses. □

Definition 92.151 (Measure root index threshold source)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root index threshold source is the* BHist*-indexed source surface whose rows are read from the public carrier of Definition 92.1 and the root source seal of Definition 92.131. For each carried history it fixes an event carrier, a public measurable-event classifier, a* $\mathsf{Real}^{\uparrow}$*-valued endpoint row* μ*, the empty event, finite disjoint-union rows, countable indexed-union rows, countable-sum endpoint rows, and the visible ledger that records which* BHist *event row supports each endpoint.*

The source is indexed only by the displayed BHist *carrier and its componentwise classifier. It contains no host set equality, no quotient event equality, no analytic completion object, and no* $\mathsf{StandardBridge}$ *row.*

Theorem 92.152 (Measure root index carrier threshold)**.** *The source of Definition 92.151 projects the* $\mathsf{Measure}^{\uparrow}$ *event carrier, the public event-classifier transport row, the empty-event row, and the visible ledger rows needed by the root threshold. Each projection is a row of the same* BHist*-indexed source, and endpoint movement is read only through the* $\mathsf{Real}^{\uparrow}$ *classifier.*

Proof. Start from the carrier surface of Definition 92.1. Its displayed rows supply the event carrier, measurable-event predicate, measure endpoint, and carrier transport along the public classifier.

Apply Definition 92.8. This carries the measurable-family, empty-event, union, relative-difference, endpoint, and countable-sum rows along the same BHist classifier without adding host equality.

The visible ledger is the root public ledger of Definition 92.95. The shared endpoint boundary is sealed by Definition 92.132, so endpoint transport is read through the existing $\mathsf{Real}^{\uparrow}$ row rather than through a separate event identity. □

Theorem 92.153 (Measure root index additivity threshold)**.** *For the source of Definition 92.151, finite disjoint additivity and countable indexed additivity are read from the same root source. The finite row is the two-step finite-additivity package, and the countable row is the sigma-additive comparison for a pairwise-disjoint countable indexed family:*

$$\mu(U) \sim_R \Sigma_\mu(E_\bullet).$$

Proof. Project the empty-event, binary-union, disjointness, endpoint, head-tail, and countable-sum rows from the source. These rows are available together by Definition 92.24 and are public at the root by Definition 92.95.

For finite additivity, apply Definition 92.35. Its empty-zero, null-event, ordered binary-union, and symmetric binary-union rows all use the same visible carrier and $\mathsf{Real}^{\uparrow}$ endpoint classifier.

For countable indexed additivity, apply Definition 92.96. It reads the pairwise-disjoint indexed family, the countable union U, and the countable-sum endpoint $\Sigma_\mu(E_\bullet)$ from the same root threshold source and gives the displayed comparison.

The continuity-from-below package of Definition 92.42 uses these same rows for its layer construction and endpoint readback. Thus finite and countable additivity are not separate inputs; both are projections of the single BHist-indexed source. □

Theorem 92.154 (Measure root index downstream threshold)**.** *The chapters* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consume exactly the root index threshold source of Definition 92.151. They receive the public event carrier, classifier transport, empty-event, finite disjoint-additivity, countable indexed-additivity, countable-sum endpoint, and visible-ledger rows, and they receive no host set equality, quotient event equality, analytic completion row, or* $\mathsf{StandardBridge}$ *row from* $\mathsf{Measure}^{\uparrow}$*.*

Proof. First package the source as the root deps-ready threshold of Definition 92.94. The carrier rows are the rows of Definition 92.152, and the additive rows are the rows of Definition 92.153.

Apply Definition 92.97. It identifies the root package consumed by $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ and excludes quotient event equality, host set equality, and standard bridge rows.

Now read the three consumer faces separately. The integral face is Definition 92.87, the probability face is Definition 92.88, and the functional-analysis face is Definition 92.89. Each face is a projection of the same source rows, with no additional carrier.

Finally apply Definition 92.134. That seal keeps shared $\mathsf{Real}^{\uparrow}$ endpoint rows at the root and keeps probability normalization, integral head-tail readback, and functional-analysis order rows on their outgoing consumer faces. Therefore the downstream chapters consume exactly this threshold package and nothing beyond the named public rows. □

Definition 92.155 (Measure root downstream threshold map)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root downstream threshold map is the ten-field projection from the root domain-ready package of Definition 92.118 and the root index threshold source of Definition 92.151 to the three analysis consumers* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*:*

1. *source package: the carrier-classifier, ledger, endpoint, additive, exactness, and no-*$\mathsf{StandardBridge}$ *rows of the root domain-ready package;*
2. *threshold source: the* BHist*-indexed carrier, public classifier, visible ledger, empty-event, finite-additivity, countable- additivity, countable-sum endpoint, and boundary rows of the root index threshold source;*
3. *carrier rows: the event carrier, measurable-event classifier, empty event, finite unions, countable indexed unions, relative differences, and disjointness witnesses;*
4. *classifier rows: componentwise* hsame *on* BHist *rows,* $\sim_M$ *on carried measure codes, and* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *comparison for endpoint movement through* $\sim_R$*;*
5. *ledger rows: hidden membership, disjointness, countable-union, relative-difference, endpoint-value, and countable-sum witnesses attached to visible* BHist *rows;*
6. *finite-additivity rows: empty-zero, null-event, ordered binary-union, symmetric binary-union, finite disjoint-union readback, and relative-difference additivity;*
7. *countable-additivity rows: pairwise-disjoint indexed families, countable unions, countable-sum endpoints, head-tail readback, finite-support countable readback, and continuity from below;*
8. *endpoint rows: nonnegative* $\mathsf{Real}^{\uparrow}$ *endpoints, additive* $\mathsf{AbGroup}^{\uparrow}$ *real transport, countable-sum endpoints, and the shared endpoint boundary used by all three consumers;*
9. *outgoing consumer rows: the* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *faces displayed by Definition 92.86;*
10. *boundary rows: absence of host set equality, quotient event equality, analytic completion rows, and standard bridge rows.*

Theorem 92.156 (Measure root threshold map carrier and additivity)**.** *The threshold map of Definition 92.155 carries exactly the carrier-classifier rows of Definition 92.119 and Definition 92.152, and exactly the finite and countable additivity rows of Definition 92.120 and Definition 92.153.*

Proof. Project carrier transport first. The domain-ready carrier-classifier theorem supplies carried $\mathsf{Measure}^{\uparrow}$ codes, visible event rows, ledger rows, and $\mathsf{Real}^{\uparrow}$ endpoint rows, while the index carrier threshold supplies the same rows as projections of the BHist-indexed source.

Endpoint movement is then read through the $\mathsf{Real}^{\uparrow}$ classifier. The domain-ready package uses $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ comparison, and the index threshold source seals endpoint movement through $\sim_R$ rather than through host event equality.

Finally compose the finite and countable additivity faces through the common BHist source. The domain-ready sigma-additive theorem supplies empty-zero, finite disjoint-union readback, finite-support countable readback, relative-difference additivity, and continuity from below. The index additivity threshold supplies the finite and countable indexed rows of the same source, so the map contains exactly those additivity rows and no separate additive input. □

Theorem 92.157 (Measure root threshold map consumer unblock)**.** *The threshold map of Definition 92.155 supplies exactly the outgoing rows consumed by* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$. *These are the downstream rows exposed by Definition 92.121 and Definition 92.154, read through the consumer faces of Definition 92.87, Definition 92.88, and Definition 92.89.*

Proof. Read the $\mathsf{Integral}^{\uparrow}$ face first. Its consumed rows are the covered measurable-event rows, $\mathsf{Real}^{\uparrow}$ endpoint classifier rows, countable-sum endpoint rows, head-tail readback rows, and finite disjoint-union readback rows supplied by the two root threshold sources.

Read the $\mathsf{ProbSpace}^{\uparrow}$ face next. It consumes total-event normalization, empty-zero, and finite disjoint-union readback, all projected from the same carrier, endpoint, and additive rows.

Read the $\mathsf{FunctionalAnalysis}^{\uparrow}$ face separately. Its outgoing rows are the nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows exposed by the common root package.

The exactness clauses in Definition 92.86 and Definition 92.151 exhaust the outgoing consumer boundary. Therefore host set equality, quotient event equality, analytic completion rows, and standard bridge rows are excluded from the threshold map. □

92.5 Measure root countable obligation triple

Definition 92.158 (Measure root countable obligation triple)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root countable obligation triple is the ten-field target surface that packages the countable-name root rows into the three obligations visible to downstream analysis:*

1. *traditional target: constructive countable measure names whose events are visible through StreamName rows and whose values are* $\mathsf{Real}^{\uparrow}$ *endpoints;*
2. *BEDC source:* $\mathsf{Measure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, *and the history classifier* hsame*;*
3. *carrier: the carried measure code together with its StreamName endpoint family, as exposed by Definition 92.90;*
4. *classifier: event-row* hsame *transport together with the pointwise StreamName classifier and the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier;*
5. *stability rows: carrier transport, pointwise event-row transport, endpoint transport, StreamName endpoint-family transport, and countable-sum classifier stability;*
6. *ledger rows: event membership, pairwise disjointness, countable union, endpoint value, and countable-sum witnesses attached to the visible* BHist *rows they certify;*
7. *core theorem list: Definition 92.159, Definition 92.160, and Definition 92.161;*
8. *exactness: visible-row exhaustion through Definition 92.57, with no hidden event row consumed outside the displayed ledger;*

9. *standard bridge: no* StandardBridge *row is asserted at this paper site;*
10. *status: paper target for* BEDC.Derived.MeasureUp.

The triple records only the root BHist, *StreamName, and* $\mathsf{Real}^{\uparrow}$ *certificate rows. It does not assert host set equality, quotient event equality, analytic completion, or any standard bridge.*

Theorem 92.159 (Measure root countable carrier obligation)**.** *The triple of Definition 92.158 projects the carrier support needed at the* $\mathsf{Measure}^{\uparrow}$ *root. Its carrier rows are exactly the carried measure code and the StreamName endpoint-family carrier rows displayed by Definition 92.90.*

Proof. Read the carrier field of Definition 92.158. It names the carried BHist measure code and the StreamName endpoint family already fixed in Definition 92.90.

Apply Definition 92.91. The first projection of that obligation is the transported $\mathsf{Measure}^{\uparrow}$ carrier row, and its StreamName projection is the endpoint-family carrier row at each visible unary index.

The carrier projection uses only those displayed rows. No host set equality, quotient event equality, analytic completion object, or StandardBridge row is introduced when the carried code and endpoint family are repacked as the root carrier obligation. □

Theorem 92.160 (Measure root countable classifier obligation)**.** *The triple of Definition 92.158 projects the classifier support needed at the* $\mathsf{Measure}^{\uparrow}$ *root. Its classifier rows are exactly event-row* hsame *transport,* $\mathsf{Real}^{\uparrow}$ *endpoint classification, and pointwise StreamName classifier transport from Definition 92.91.*

Proof. Start with the classifier field of Definition 92.158. It separates the event-row classifier, the endpoint classifier, and the StreamName pointwise classifier so that each row is read on its own certificate face.

Apply Definition 92.91. The event projection supplies componentwise hsame transport for visible BHist event rows and their measurable witnesses. The endpoint projection supplies the $\mathsf{Real}^{\uparrow}$ comparison of the corresponding values.

The StreamName projection of the same theorem supplies pointwise classifier transport for the endpoint family at every visible index. Repacking these three projections gives the root countable classifier obligation and adds no host set equality, quotient event equality, analytic completion object, or StandardBridge row. □

Theorem 92.161 (Measure root countable additivity obligation)**.** *The triple of Definition 92.158 projects the countable-additivity support needed at the* $\mathsf{Measure}^{\uparrow}$ *root. For every visible pairwise-disjoint event family* $E_\bullet$ *with visible countable union* U*, it supplies the* $\mathsf{Real}^{\uparrow}$ *comparison*

$$\mu(U) \sim_R \Sigma_\mu(E_\bullet).$$

This comparison is the common projection of Definition 92.92 and the indexed additivity row of Definition 92.153.

Proof. Project the visible event family from Definition 92.158. Its ledger rows name the event-membership witnesses, pairwise-disjointness witness, countable union row, endpoint-value witnesses, and countable-sum witness in the same BHist surface.

Apply Definition 92.92. It reads the visible StreamName-indexed family through the $\mathsf{Measure}^{\uparrow}$ certificate and produces the displayed comparison between the value of the union and the countable endpoint sum.

Apply Definition 92.153. Its indexed additivity row reads the same pairwise-disjoint family, union, and countable sum from the root index threshold source, so the additivity comparison is shared by the countable-name and root-index surfaces.

Exactness is supplied by the visible-row clause of the triple and by the coverage predicate named in Definition 92.57. Thus the root additivity obligation consumes only displayed event, union, value, and countable-sum rows; it excludes host set equality, quotient event equality, analytic completion, and StandardBridge. □

Definition 92.162 (Measure root countable-premeasure front)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root countable-premeasure front is the ten-field surface that exposes the traditional constructive countable premeasure target through BEDC names:*

1. *traditional target: a countable premeasure surface whose measurable events are visible as counted rows and whose values are nonnegative* $\mathsf{Real}^{\uparrow}$ *endpoints;*
2. *BEDC source:* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, $\mathsf{StreamName}^{\uparrow}$ *countable families,* BHist, hsame, *the* $\mathsf{Measure}^{\uparrow}$ *carrier and classifier rows, nonnegative endpoint rows, empty-event rows, finite-additivity rows, relative-difference rows, and countable-sum rows;*
3. *carrier choice: measurable-event* BHist *rows together with the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier for the value of each covered event;*
4. *classifier choice: componentwise* hsame *transport for event rows, measurable-witness transport, and endpoint comparison through the* $\mathsf{Real}^{\uparrow}$ *classifier* $\sim_R$*;*
5. *stability rows: carrier transport, classifier transport, finite-additivity readback, relative-difference additivity, continuity-from-below readback, and countable-sum classifier stability;*
6. *ledger: hidden measurable witnesses, disjointness witnesses, countable-family indices, countable-union witnesses, and the countable-sum endpoints assigned to the same visible* BHist *rows;*
7. *exactness: coverage, soundness, and completeness for every displayed measurable-event row named by Definition 92.57;*
8. *displayed classification iff: a countable disjoint union is classified by the front exactly when its covered component rows, covered union row, pairwise-disjointness row, and* $\mathsf{Real}^{\uparrow}$ *countable endpoint comparison are all displayed in the same ledger;*
9. *consumer boundary: downstream chapters may read the front only through the rows listed in Definition 92.165;*
10. *standard bridge: no* StandardBridge*, analytic completion object, host set equality, or quotient event equality is part of this front.*

It is the countable-name premeasure face of the root package described by Definition 92.143 and Definition 92.90.

Theorem 92.163 (Measure root countable-premeasure carrier obligation)**.** *The front of Definition 92.162 exposes exactly the carried* BHist *measurable-event rows,* $\mathsf{Real}^{\uparrow}$ *endpoint rows, carrier transport, and classifier transport needed by the root* $\mathsf{Measure}^{\uparrow}$ NameCert.

Proof. Start with the seed carrier-classifier obligation of Definition 92.144. It transports the carried measure code, every displayed measurable-event row, every ledger row, and every $\mathsf{Real}^{\uparrow}$ endpoint comparison attached to the root $\mathsf{Measure}^{\uparrow}$ surface.

Next restrict those rows to the countable-premeasure front. The carrier field of Definition 92.162 keeps only covered measurable-event BHist rows and the endpoint classifier for their values. The classifier field keeps only componentwise hsame event transport, measurable-witness transport, and $\mathsf{Real}^{\uparrow}$ endpoint transport.

Finally compare with the countable-name carrier package of Definition 92.91. Its StreamName endpoint transport is read over the same visible event rows, so the front contains all carrier and classifier transport needed by the root $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ and no additional host-level equality row. □

Theorem 92.164 (Measure root countable-premeasure additivity obligation)**.** *The front of Definition 92.162 obtains countable disjoint additivity by combining the root sigma-additivity row, finite-additivity readback, relative-difference additivity, continuity-from-below, and countable-sum classifier stability.*

Proof. Project the covered disjoint countable family from the front ledger. The component rows, countable-union row, disjointness witness, and countable-sum endpoint all live in the same visible BHist carrier.

Apply Definition 92.145. It supplies the root comparison between the measure of the covered union and the countable endpoint sum, with both endpoints compared through the $\mathsf{Real}^{\uparrow}$ classifier.

For finite readback, use Definition 92.26 and Definition 92.23. These identify the binary and finite-support cases as projections of the same countable additivity row.

For difference and limiting readback, apply Definition 92.102 and Definition 92.42. They supply the relative-difference decomposition and increasing-union readback without adding any consumer-specific row to the root package.

Finally use Definition 92.12 to transport pointwise endpoint comparisons to the countable-sum endpoint. Thus every additivity clause of the front is read from the existing root $\mathsf{Measure}^{\uparrow}$ rows. □

Theorem 92.165 (Measure root countable-premeasure consumer threshold)**.** $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumers may read only the countable-premeasure front of Definition 92.162. The* $\mathsf{Integral}^{\uparrow}$ *face receives covered-event, countable-sum, and finite-readback rows; the* $\mathsf{ProbSpace}^{\uparrow}$ *face adds only the total-mass normalization row; and the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *face receives nonnegative, monotone, relative-difference, and countable-sum stability rows.*

Proof. Begin with the root seed consumer threshold of Definition 92.146. It fixes the outgoing consumer rows for $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ as projections of the same root $\mathsf{Measure}^{\uparrow}$ package.

For $\mathsf{Integral}^{\uparrow}$, apply Definition 92.87 together with Definition 92.60. The consumer reads covered measurable events, countable-sum rows, head-tail readback, and the finite readback supplied by the countable-premeasure front.

For $\mathsf{ProbSpace}^{\uparrow}$, apply Definition 92.88 and Definition 92.59. These rows add the total-mass normalization endpoint while leaving the event ledger and additivity rows inherited from the same front.

For $\mathsf{FunctionalAnalysis}^{\uparrow}$, apply Definition 92.89, Definition 92.98, Definition 92.99, and Definition 92.102. These projections read only nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum stability rows.

The exhaustion clause of Definition 92.142 keeps every other consumer-specific row off the root surface. Hence the three analysis chapters may consume exactly the rows stated above. □

92.6 Measure root real-stream regularity front

The real-stream regularity front is the BHist-anchored reading of the countable-premeasure root surface through the already certified $\mathsf{StreamName}^{\uparrow}$ endpoint rows and $\mathsf{Real}^{\uparrow}$ endpoint comparisons. It records the exact rows that later analysis consumers may use without turning the $\mathsf{Measure}^{\uparrow}$ root into a host measure-space schema.

Definition 92.166 (Measure root real-stream regularity front)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root real-stream regularity front is the ten-field surface with the following data:*

1. *traditional target: a constructive countable premeasure whose values are exposed as regular real endpoints indexed by a countable stream name;*
2. *BEDC source:* $\mathsf{Measure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, *and* hsame, *restricted to the rows displayed by Definition 92.162 and Definition 92.77;*
3. *carrier: covered measurable-event* BHist *rows, carried* $\mathsf{Measure}^{\uparrow}$ *codes, StreamName endpoint-family rows, and the* $\mathsf{Real}^{\uparrow}$ *endpoint rows attached to those observations;*
4. *classifier: componentwise* hsame *transport of event histories, pointwise StreamName classifier transport, and* $\mathsf{Real}^{\uparrow}$ *endpoint comparison for the values and countable sums;*
5. *stability rows: carrier transport, endpoint-family stability, finite-readback stability, relative-difference stability, monotone-row stability, and countable-sum classifier stability;*
6. *ledger: covered event rows, measurable witnesses, unary observation names, pairwise-disjointness witnesses, countable-union rows, finite readback rows, normalization rows, nonnegative rows, monotone rows, and relative-difference rows;*
7. *core theorem list: Definition 92.163, Definition 92.78, Definition 92.164, Definition 92.80, Definition 92.12, Definition 92.165, and Definition 92.81;*
8. *exactness: a row belongs to the front exactly when it is a displayed countable-premeasure row over the same visible* BHist *ledger and its StreamName observation carries the corresponding* $\mathsf{Real}^{\uparrow}$ *endpoint comparison;*
9. *standard bridge boundary: no* StandardBridge, *host sigma-algebra equality, quotient event equality, analytic completion object, or external regular-measure theorem is part of the front;*
10. *status: the front is a paper-side real-stream regularity surface for future* BHist *formalization targets in* BEDC.Derived.MeasureUp.

Theorem 92.167 (Measure root real-stream carrier regularity)**.** *The front of Definition 92.166 transports exactly the carried* $\mathsf{Measure}^{\uparrow}$ *codes, the StreamName endpoint family rows, and the* $\mathsf{Real}^{\uparrow}$ *endpoint comparisons over the same* BHist *ledger. The carrier transport is the common projection of Definition 92.163 and Definition 92.78.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureRootRealStreamCarrierRegularity`

Proof. Begin with a row of the real-stream regularity front. By the carrier and ledger fields of Definition 92.166, the row contains a covered measurable-event history, a carried $\mathsf{Measure}^{\uparrow}$ code, a StreamName endpoint-family observation, and the attached $\mathsf{Real}^{\uparrow}$ endpoint comparison.

Apply Definition 92.163. It transports the carried measure code, the covered event row, and the root endpoint classifier along the visible hsame comparison of BHist histories.

Next apply Definition 92.78. The StreamName observation map and its pointwise endpoint-family rows move over the same unary observations, so the transported event row and the transported real endpoint remain attached to the same stream position.

Repack these projections into the carrier, classifier, and ledger fields of Definition 92.166. Since both source theorems expose only displayed BHist rows and $\mathsf{Real}^{\uparrow}$ classifier comparisons, the repacked front adds no host event equality or quotient row. □

Theorem 92.168 (Measure root real-stream additivity regularity)**.** *Countable disjoint additivity on Definition 92.166 is exactly the shared* $\mathsf{Real}^{\uparrow}$ *endpoint comparison obtained from Definition 92.164, Definition 92.80, and Definition 92.12.*

Proof. Project the countable family from the front ledger. Its component event rows, pairwise-disjointness witness, countable-union row, and countable-sum endpoint are the rows named in the countable-premeasure front and observed pointwise by the StreamName endpoint family.

Apply Definition 92.164. This gives the root comparison between the value of the covered countable union and the countable sum of the component $\mathsf{Real}^{\uparrow}$ endpoints.

Apply Definition 92.80. It reads the same comparison through the StreamName-indexed endpoint family and keeps the additivity row scoped to the displayed measurable sequence, its union row, and its countable-sum endpoint.

Finally apply Definition 92.12. Pointwise $\mathsf{Real}^{\uparrow}$ endpoint comparisons along the stream name repack into the countable-sum endpoint comparison, so countable disjoint additivity on the front is the shared $\mathsf{Real}^{\uparrow}$ comparison and not a separate analytic additivity object. □

Theorem 92.169 (Measure root real-stream consumer regularity boundary)**.** *The* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumers of Definition 92.166 may consume only its covered-event, endpoint, countable-sum, finite-readback, normalization, nonnegative, monotone, and relative-difference rows. This boundary is the common projection of Definition 92.165 and Definition 92.81.*

Proof. Start from the consumer field of Definition 92.166. It lists exactly the rows visible to downstream chapters: covered events, $\mathsf{Real}^{\uparrow}$ endpoint comparisons, countable sums, finite readback, normalization, nonnegative values, monotone inclusion, and relative differences.

Apply Definition 92.165. It assigns covered-event, countable-sum, and finite-readback rows to $\mathsf{Integral}^{\uparrow}$; the normalization endpoint to $\mathsf{ProbSpace}^{\uparrow}$; and the nonnegative, monotone, relative-difference, and countable-sum stability rows to $\mathsf{FunctionalAnalysis}^{\uparrow}$.

Now apply Definition 92.81. The StreamName endpoint family supplies only the indexed endpoint rows already named by the root consumer package, so each consumer receives the same rows through stream observations rather than through a larger event carrier.

Repack the two projections as the front boundary. No consumer can read beyond the covered-event ledger, endpoint comparisons, countable-sum row, finite-readback row, normalization row, nonnegative row, monotone row, and relative-difference row, because the standard bridge boundary field excludes host equality, quotient equality, and analytic completion data. □

Theorem 92.170 (Measure root downstream consumer lattice)**.** *The real-stream regularity front of Definition 92.166 exports exactly three downstream consumer faces through chapter 123, chapter 184, and chapter 94. These faces retain the existing* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, and no other analysis chapter receives a larger carrier from this front.*

Proof. Apply Definition 92.169. It already restricts downstream use to covered-event, endpoint, countable-sum, finite-readback, normalization, nonnegative, monotone, and relative-difference rows over the same displayed BHist ledger and the same $\mathsf{StreamName}^{\uparrow}$ endpoint-family observations.

The $\mathsf{Integral}^{\uparrow}$ face is the one cited by chapter 123. It reads the finite readback and countable-sum rows, together with the covered-event rows that attach those sums to the visible $\mathsf{Measure}^{\uparrow}$ package.

The $\mathsf{ProbSpace}^{\uparrow}$ face is the one cited by chapter 184. It reads the normalization endpoint and the nonnegative endpoint data already carried by the real-stream front, so its probability-space package remains a $\mathsf{Real}^{\uparrow}$ endpoint package rather than a host event-equality surface.

The $\mathsf{FunctionalAnalysis}^{\uparrow}$ face is the one cited by chapter 94. It reads the monotone row, the relative-difference row, and the countable-sum stability row as stability data for the same Cont, Pkg, and $\mathsf{NameCert}$ rows.

These three projections exhaust the consumer boundary: the front keeps the $\mathsf{StreamName}^{\uparrow}$ observations, $\mathsf{Real}^{\uparrow}$ endpoint comparisons, BHist histories, hsame transport, and package/certificate rows visible, while excluding host event equality, quotient event equality, analytic completion, and open-cover compactness. □

Definition 92.171 (Measure head-tail tail scope)**.** *Let $\mathcal{M}$ be a $\mathsf{Measure}^{\uparrow}$ certificate surface as in Definition 92.15, and let $E_\bullet$ be a measurable sequence in that surface. The head-tail tail scope of $E_\bullet$ is the four-row package consisting of:*

1. *the shifted measurable sequence $E_{\bullet+1}$, read as the family $n \mapsto E_{n+1}$ by the same measurable-family row;*
2. *pointwise $\sim_M$ transport for the shifted event presentations, with endpoint movement read through the $\mathsf{Real}^{\uparrow}$ classifier $\sim_R$;*
3. *the countable endpoint $\Sigma_\mu(E_{\bullet+1})$ attached to the shifted measurable sequence;*
4. *admissibility of $E_{\bullet+1}$ as an input to the same head-tail readback row and countable-sum classifier row that classify $\Sigma_\mu(E_\bullet)$.*

This scope records only certificate-surface rows. It does not identify shifted host sequences by ambient equality, and it does not introduce a separate measure construction outside the displayed $\mathsf{Measure}^{\uparrow}$ rows.

Theorem 92.172 (Measure head-tail tail measurable-sequence scope)**.** *Let $\mathcal{M}$ be a $\mathsf{Measure}^{\uparrow}$ certificate surface as in Definition 92.15, and let $E_\bullet$ be a measurable sequence in that surface. Then the shifted family $E_{\bullet+1}$ is an admitted measurable sequence for the same certificate surface. Consequently every head-tail readback later applied to $\Sigma_\mu(E_{\bullet+1})$ is an application of the displayed measurable-family row of $\mathcal{M}$, not an implicit host-level shift.*

Proof. Project the measurable-family row from Definition 92.15. Since $E_\bullet$ is supplied as a measurable sequence, each displayed event E_n carries the certificate membership row required by $\mathsf{MeasFam}$.

Form the shifted family by reindexing the same displayed rows: at index n the new family reads the old row at $n+1$. This uses no new event carrier and no extra endpoint; it repacks the existing measurable witnesses into the sequence-indexed slot demanded by the surface.

The carrier inventory of Definition 92.6 lists measurable sequence rows and countable-sum rows as ledger entries. Therefore the shifted family is admitted exactly as another measurable sequence over the same certificate surface, and the head-tail row may be projected for it. □

Theorem 92.173 (Measure head-tail tail countable-sum scope)**.** *Let $\mathcal{M}$ be a $\mathsf{Measure}^{\uparrow}$ certificate surface as in Definition 92.15, and let $E_\bullet$ be a measurable sequence with head-tail tail scope as*

in Definition 92.171. Then $\Sigma_\mu(E_{\bullet+1})$ is the countable-sum endpoint consumed by the head-tail comparison for $E_\bullet$:

$$\Sigma_\mu(E_\bullet) \sim_R \mu(E_0) + \Sigma_\mu(E_{\bullet+1}).$$

If $F_\bullet$ is another admitted tail sequence and every index satisfies $\mu(E_{n+1}) \sim_R \mu(F_n)$, then the countable endpoint transported into the head-tail comparison satisfies

$$\Sigma_\mu(E_{\bullet+1}) \sim_R \Sigma_\mu(F_\bullet).$$

Proof. Use Definition 92.172 to read $E_{\bullet+1}$ as a measurable sequence in the same surface. The countable-sum field of Definition 92.15 therefore supplies the endpoint $\Sigma_\mu(E_{\bullet+1})$ as a certificate row.

Project the head-tail readback row of the same surface and apply it to $E_\bullet$. The displayed comparison is exactly the row named in Definition 92.171: its tail term is the endpoint attached to the admitted shifted family.

For classifier transport, apply Definition 92.12 to the two admitted measurable sequences $E_{\bullet+1}$ and $F_\bullet$. The pointwise comparison $\mu(E_{n+1}) \sim_R \mu(F_n)$ is precisely the hypothesis required by the countable-sum classifier row, so the transported endpoint is accepted by the same head-tail comparison. □

Theorem 92.174 (Measure head-tail consumer exhaustion)**.** *Every later finite-support, continuity-from-below, integral, probability, or functional-analysis use of a shifted countable tail in the* $\mathsf{Measure}^\uparrow$ *carrier consumes exactly the following four certificate rows:*

1. *shifted measurable-sequence scope for $E_{\bullet+1}$;*
2. *the shifted endpoint $\Sigma_\mu(E_{\bullet+1})$;*
3. *head-tail readback classifying $\Sigma_\mu(E_\bullet)$ with $\mu(E_0) + \Sigma_\mu(E_{\bullet+1})$;*
4. *countable-sum classifier stability transporting pointwise tail equality through $\sim_R$.*

In particular, the finite-support readbacks that repeatedly apply head-tail to shifted sequences, including Definition 92.33 and Definition 92.38, are audited by these four rows together with the sigma-additive input of Definition 92.10.

Proof. The first two rows are exactly the tail package of Definition 92.171, with admissibility supplied by Definition 92.172. They account for the measurable-sequence witness and the countable endpoint before any additive readback is used.

The third row is the head-tail projection of Definition 92.15. It is the row consumed in the finite-support readbacks when the original sequence, once-shifted sequence, and twice-shifted sequence are exposed successively.

The fourth row is the countable-sum classifier stability obligation Definition 92.12. It is the only transport principle used when a shifted tail is compared with the canonical empty tail or with a downstream tail carrying pointwise equal $\mathsf{Real}^\uparrow$ endpoints.

The remaining downstream consumers named in the statement receive the same surface through the carrier inventory of Definition 92.6. Since the inventory lists measurable sequence rows, countable-sum rows, head-tail readback, and classifier stability as the available rows, there is no fifth certificate input for a shifted countable tail. □

Definition 92.175 (Measure finite-prefix head-tail readback spine)**.** *Let $\mathcal{M}$ be a* $\mathsf{Measure}^\uparrow$ *certificate surface as in Definition 92.15, and let $E_\bullet$ be a measurable sequence in that surface. For a*

unary history n with $\mathsf{Unary}(n)$, define the iterated shifted family $E_{\bullet+n}$ and the finite-prefix head-tail endpoint $\mathsf{HT}_n(E_\bullet)$ by unary recursion:

$$E_{\bullet+\mathsf{e}} := E_\bullet,$$
$$E_{\bullet+\mathsf{E1}(n)} := (E_{\bullet+n})_{\bullet+1},$$

and

$$\mathsf{HT}_\mathsf{e}(E_\bullet) := \Sigma_\mu(E_\bullet),$$
$$\mathsf{HT}_{\mathsf{E1}(n)}(E_\bullet) := \mu(E_0) +_R \mathsf{HT}_n(E_{\bullet+1}).$$

Thus $\mathsf{HT}_n(E_\bullet)$ is the right-nested endpoint obtained by reading the first n heads and then stopping at the countable endpoint of the n-shifted tail. The spine records only the measurable-family row, the countable-sum endpoint row, the head-tail row, and the additive $\mathsf{Real}^\uparrow$ row; it does not identify shifted host sequences by ambient equality.

Lemma 92.176 (Measure iterated shifted-tail admissibility)**.** *Let $\mathcal{M}$ be a $\mathsf{Measure}^\uparrow$ certificate surface as in Definition 92.15, let $E_\bullet$ be a measurable sequence in that surface, and let n be a unary history with $\mathsf{Unary}(n)$. Then $E_{\bullet+n}$, as defined in Definition 92.175, is an admitted measurable sequence for the same certificate surface.*

Proof. Induct on the unary generation of n. In the empty case, $E_{\bullet+\mathsf{e}}$ is $E_\bullet$, which is measurable by hypothesis.

For the one-step case, assume $E_{\bullet+n}$ is an admitted measurable sequence. Apply Definition 92.172 to the admitted sequence $E_{\bullet+n}$. Its shifted family $(E_{\bullet+n})_{\bullet+1}$ is admitted as a measurable sequence in the same certificate surface. By the defining recursion, this shifted family is $E_{\bullet+\mathsf{E1}(n)}$, so the successor case follows. □

Theorem 92.177 (Measure finite-prefix head-tail readback)**.** *Let $\mathcal{M}$ be a $\mathsf{Measure}^\uparrow$ certificate surface as in Definition 92.15, let $E_\bullet$ be a measurable sequence in that surface, and let n be a unary history with $\mathsf{Unary}(n)$. Then the countable endpoint of $E_\bullet$ is classified by the finite-prefix head-tail endpoint:*

$$\Sigma_\mu(E_\bullet) \sim_R \mathsf{HT}_n(E_\bullet).$$

Equivalently, expanding the recursion of Definition 92.175, this is the right-nested finite-prefix readback

$$\Sigma_\mu(E_\bullet) \sim_R \mu(E_0) +_R \mu(E_1) +_R \cdots +_R \mu(E_{n-1}) +_R \Sigma_\mu(E_{\bullet+n}),$$

with the final tail endpoint omitted only in the empty-prefix case by the first recursion clause.

Proof. Prove the stronger assertion uniformly for every admitted measurable input sequence $G_\bullet$: for every unary n, $\Sigma_\mu(G_\bullet) \sim_R \mathsf{HT}_n(G_\bullet)$. The claimed statement is the specialization $G_\bullet = E_\bullet$.

In the empty case, the definition gives $\mathsf{HT}_\mathsf{e}(G_\bullet) = \Sigma_\mu(G_\bullet)$. Reflexivity of the $\mathsf{Real}^\uparrow$ classifier from Definition 38.9 gives

$$\Sigma_\mu(G_\bullet) \sim_R \mathsf{HT}_\mathsf{e}(G_\bullet).$$

For the one-step case, let $n = \mathsf{E1}(m)$ and assume the uniform induction hypothesis at m. Equip $G_\bullet$ with the head-tail tail scope of Definition 92.171. By Definition 92.173, the single-step readback gives

$$\Sigma_\mu(G_\bullet) \sim_R \mu(G_0) +_R \Sigma_\mu(G_{\bullet+1}).$$

By Definition 92.172, the shifted family $G_{\bullet+1}$ is again an admitted measurable sequence. Apply the induction hypothesis to this shifted sequence:

$$\Sigma_\mu(G_{\bullet+1}) \sim_R \mathsf{HT}_m(G_{\bullet+1}).$$

The additive congruence row of the target $\mathsf{Real}^{\uparrow}$ additive $\mathsf{AbGroup}^{\uparrow}$ certificate, cited in Definition 92.15 and Definition 42.1, transports this tail comparison through the fixed left summand $\mu(G_0)$:

$$\mu(G_0) +_R \Sigma_\mu(G_{\bullet+1}) \sim_R \mu(G_0) +_R \mathsf{HT}_m(G_{\bullet+1}).$$

The right-hand endpoint is exactly $\mathsf{HT}_{\mathsf{E1}(m)}(G_\bullet)$ by the successor clause of Definition 92.175. Transitivity of $\sim_R$ composes the single-step head-tail comparison with this transported induction comparison, yielding

$$\Sigma_\mu(G_\bullet) \sim_R \mathsf{HT}_{\mathsf{E1}(m)}(G_\bullet).$$

This closes the unary induction and therefore the finite-prefix readback for $E_\bullet$. □

Definition 92.178 (Measure root consumer acceptance gate)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root consumer acceptance gate is the downstream package whose source side is the root index threshold source of Definition 92.151 and whose outgoing side is the three-face consumer classifier of Definition 92.127. Its accepted rows are exactly the following rows:*

1. *the visible* BHist *event ledger and componentwise measurable-event classifier rows covered by Definition 92.57;*
2. *the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows attached to measure values, finite readbacks, countable sums, probability normalization, and functional-analysis order comparisons;*
3. *the finite disjoint-additivity rows and countable indexed-additivity rows projected by Definition 92.153;*
4. *the integral, probability, and functional-analysis consumer faces of Definition 92.128.*

The gate contains no host set equality, no quotient event equality, no analytic completion object, and no $\mathsf{StandardBridge}$ *row. Those exclusions are part of the accepted package, so a downstream chapter may cite this gate without reopening the root carrier or adding a standard bridge surface.*

Theorem 92.179 (Measure root consumer acceptance coverage)**.** *Every row accepted by Definition 92.178 is covered by the event-row coverage predicate of Definition 92.57, the carrier threshold of Definition 92.152, and the additivity threshold of Definition 92.153. Thus the acceptance gate exposes no downstream row outside the visible* BHist *ledger, the public* $\mathsf{Measure}^{\uparrow}$ *carrier classifier, the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier, and the finite or countable additive rows already present at the root.*

Proof. Unpack Definition 92.178. Its source side is the root index threshold source, and its outgoing side is only the named three-face consumer classifier.

Apply Definition 92.57 to the event part. This places measurable events, empty events, binary unions, countable unions, disjointness witnesses, measure endpoints, countable sums, and head-tail readback rows on visible BHist ledger entries.

Next use Definition 92.152. It supplies the public event carrier, classifier transport, empty-event row, visible ledger, and $\mathsf{Real}^{\uparrow}$ endpoint classifier used by every accepted row.

Finally apply Definition 92.153. The finite disjoint-additivity and countable indexed-additivity rows of the gate are projections of the same root source, so no accepted row requires a host set equality, quotient event equality, analytic completion object, or $\mathsf{StandardBridge}$ row. □

Theorem 92.180 (Measure root consumer acceptance separation)**.** *Inside the acceptance gate of Definition 92.178, the integral, probability, and functional-analysis faces overlap only on the shared* BHist *event ledger and the shared* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows. Probability normalization remains on the probability face, countable-sum and head-tail readback remain on the integral face, and*

relative-difference, monotone-inclusion, and nonnegative endpoint rows remain on the functional-analysis face.

Proof. First apply Definition 92.128. It assigns every outgoing consumer row to the integral face, probability face, functional-analysis face, or to the shared root rows seen through those faces.

Then apply Definition 92.129. That result identifies the only allowed intersections as the visible BHist ledger rows and the shared $\mathsf{Real}^{\uparrow}$ endpoint classifier rows.

The definition of the acceptance gate adds no fourth consumer face and no carrier-level equality row. Therefore the face separation already proved for the consumer classifier is preserved inside the gate: each consumer-specific row stays on its own outgoing face, while the shared rows are exactly the root ledger and endpoint-classifier rows. □

Theorem 92.181 (Measure root consumer acceptance downstream package)**.** *The chapters* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consume exactly the acceptance gate of Definition 92.178. Equivalently, their downstream* $\mathsf{Measure}^{\uparrow}$ *input is the single package consisting of root carrier coverage, finite and countable additivity, shared endpoint classification, face separation, and the explicit exclusions of host set equality, quotient event equality, analytic completion, and* $\mathsf{StandardBridge}$ *rows.*

Proof. Start with Definition 92.154. It says that $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ consume the root index threshold source and receive no host set equality, quotient event equality, analytic completion row, or $\mathsf{StandardBridge}$ row from $\mathsf{Measure}^{\uparrow}$.

For the probability consumer, apply Definition 92.112. The accepted $\mathsf{ProbSpace}^{\uparrow}$ face is exactly the total-event normalization, empty-zero, finite-additivity, and $\mathsf{Real}^{\uparrow}$ endpoint normalization surface.

For the integral and functional-analysis consumers, apply Definition 92.113. The accepted faces are exactly the measurable-event, nonnegative endpoint, monotone-inclusion, relative-difference, finite-readback, countable-sum, and continuity-from-below rows exposed by the root $\mathsf{Measure}^{\uparrow}$ package.

Finally combine those consumer projections with Definition 92.179 and Definition 92.180. Coverage supplies the common root ledger and additive source, and separation keeps every consumer-specific row on its named face. Hence the three downstream chapters consume the single acceptance gate and no row outside it. □

Definition 92.182 (Measure root threshold obligation package)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root threshold obligation package is the ten-field package read at the root* BHist *surface before* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consume measure rows:*

1. *traditional target: a constructive measure surface with measurable events, empty event, finite unions, countable unions, relative differences, disjointness witnesses, and nonnegative* $\mathsf{Real}^{\uparrow}$ *endpoints;*
2. *BEDC source:* BHist *presentations, componentwise* hsame, $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint comparison, the additive* $\mathsf{AbGroup}^{\uparrow}$ *real row, and the countable-family name rows used by* $\mathsf{StreamName}^{\uparrow}$*;*
3. *carrier: the root* $\mathsf{MeasCode}$ *predicate displayed by Definition 92.14;*
4. *classifier: the public* $\mathsf{Measure}^{\uparrow}$ *classifier* $\sim_M$*, with endpoint movement read through* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *and* $\sim_R$*;*
5. *stability rows: transport for measurable events, visible ledger rows, endpoint rows, countable-family rows, countable-sum rows, and head-tail readback along* $\sim_M$ *and componentwise* hsame*;*

6. *ledger rows: hidden membership, relative-difference, disjointness, endpoint-value, and countable-sum witnesses attached to visible* BHist *rows;*
7. *sigma-additive rows: empty-zero, finite disjoint-union readback, relative-difference additivity, countable disjoint-union comparison, and countable-sum classifier transport;*
8. *consumer rows: the* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *projections exposed by Definition 92.86;*
9. *exactness: visible-row exhaustion through Definition 92.57 and Definition 92.13;*
10. *boundary: no host set equality, quotient event equality, analytic completion object, or* StandardBridge *row is asserted at this threshold.*

The package is the threshold-facing reading of Definition 92.143, Definition 92.61, and Definition 92.86.

Theorem 92.183 (Measure root threshold carrier-classifier obligation)**.** *The root threshold obligation package of Definition 92.182 supplies the carrier and classifier transport required at the* $\mathsf{Measure}^{\uparrow}$ *root. If* $h, k : \mathsf{BHist}$ *satisfy* $\mathsf{MeasCode}(h)$ *and* $h \sim_M k$*, then the package transports* $\mathsf{MeasCode}(k)$*, every visible event row, every ledger row, and every* $\mathsf{Real}^{\uparrow}$ *endpoint comparison attached to the carried measure code. The transport uses only componentwise* hsame *on* BHist *rows and* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint comparison.*

Proof. First project the carrier and classifier fields from Definition 92.143. Those fields are the root MeasCode and $\sim_M$ rows named again in the threshold package.

Apply Definition 92.144. It reads the seed front as a carrier-classifier obligation and transports the carried measure code, visible rows, ledger rows, and $\mathsf{Real}^{\uparrow}$ endpoint comparisons along the supplied $\sim_M$ comparison.

Next apply Definition 92.62. Its public projection identifies the transported rows with the root NameCert carrier, classifier, ledger, and endpoint rows consumed at the threshold.

Finally use Definition 92.13. Every hidden membership, relative-difference, disjointness, endpoint-value, and countable-sum witness is attached to a visible BHist row, so no extra carrier or quotient event equality enters the threshold carrier-classifier obligation. □

Theorem 92.184 (Measure root threshold sigma-additive obligation)**.** *The root threshold obligation package of Definition 92.182 supplies the sigma-additive face required at the* $\mathsf{Measure}^{\uparrow}$ *root. For every covered pairwise-disjoint measurable sequence* $E_\bullet$ *with covered countable union* U*, it supplies*

$$\mu(U) \sim_R \Sigma_\mu(E_\bullet).$$

It also supplies the empty-zero row, finite disjoint-union readback, relative-difference additivity, head-tail readback, and countable-sum classifier transport exposed by the public root package.

Proof. Start with the sigma-additive fields of Definition 92.143. They include the covered sequence, countable-union, disjointness, endpoint, additive real, and countable-sum rows named by the threshold package.

Apply Definition 92.145. It projects the seed front to the displayed countable disjoint-union comparison and keeps the empty-zero, finite disjoint-union, relative-difference, head-tail, and countable-sum classifier rows visible.

Next apply Definition 92.63. Its public form identifies the same comparison and the same consequence rows as root $\mathsf{Measure}^{\uparrow}$ public rows over BHist and $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$.

The countable-sum endpoint is read through the additive $\mathsf{AbGroup}^{\uparrow}$ real row already listed in the threshold package. Hence the sigma-additive obligation is a visible root package over BHist rows and $\mathsf{Real}^{\uparrow}$ endpoint classification, with no host set equality or standard bridge field. □

Theorem 92.185 (Measure root threshold analysis consumer obligation)**.** *The root threshold obligation package of Definition 92.182 supplies exactly the* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer rows available from the public* $\mathsf{Measure}^{\uparrow}$ *root. The exported rows are the covered measurable-event rows,* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows, countable-sum rows, head-tail readback, empty-zero, finite disjoint-union readback, relative-difference additivity, monotone inclusion, nonnegative endpoint, total-event normalization, and the explicit no-*$\mathsf{StandardBridge}$ *row.*

Proof. Begin with Definition 92.64. It packages the root carrier-classifier and sigma-additive faces as the public $\mathsf{Measure}^{\uparrow}$ surface consumed by the three analysis-facing chapters.

For $\mathsf{Integral}^{\uparrow}$, apply Definition 92.87. The projection consumes the covered measurable-event rows, $\mathsf{Real}^{\uparrow}$ endpoint classifier rows, countable-sum rows, head-tail readback, and finite disjoint-union readback from the same root threshold package.

For $\mathsf{ProbSpace}^{\uparrow}$, apply Definition 92.88. The projection consumes total-event normalization together with empty-zero and finite disjoint-union rows, all read from the public root package.

For $\mathsf{FunctionalAnalysis}^{\uparrow}$, apply Definition 92.89. The projection consumes nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows.

The exactness field of the threshold package identifies these projections as the complete consumer boundary. Thus the package opens the three downstream faces while excluding host set equality, quotient event equality, analytic completion objects, and standard bridge claims. □

92.7 Measure root finite-support consumer front

Definition 92.186 (Measure root finite-support consumer front)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root finite-support consumer front is the ten-field package that exposes the finite-support rows needed by downstream analysis consumers:*

1. *traditional target: finite-support measurable events with readback values in the* $\mathsf{Real}^{\uparrow}$ *additive endpoint surface;*
2. *BEDC source:* $\mathsf{Measure}^{\uparrow} + \mathsf{StreamName}^{\uparrow} + \mathsf{Real}^{\uparrow} + \mathsf{AbGroup}^{\uparrow}$*;*
3. *carrier: a covered finite support spine of displayed measurable* BHist *event rows together with a constant empty tail;*
4. *classifier: the public* $\mathsf{Measure}^{\uparrow}$ *event classifier together with the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier for each displayed value and finite sum;*
5. *stability: componentwise event transport, endpoint transport, additive congruence, and support-spine transport;*
6. *ledger: the finite support spine, the constant empty tail, the countable-union row, and the finite union tree read from the same displayed* BHist *rows;*
7. *exactness: finite-support sum readback through Definition 92.23;*
8. *displayed classification iff: a consumer row belongs to the front exactly when it is read from the covered event spine, the empty tail, the finite union tree, and the* $\mathsf{Real}^{\uparrow}$ *finite-sum endpoint;*

9. *consumer boundary:* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *may consume only the rows named in Definition 92.189;*
10. *standard bridge: no host set equality, quotient event equality,* $\mathsf{Real}^{\uparrow}$ *completeness row, or* $\mathsf{StandardBridge}$ *row is part of this front.*

The front is a finite-support face of the root consumer package of Definition 92.86, not a separate analytic completion object.

Theorem 92.187 (Measure root finite-support carrier readback)**.** *The front of Definition 92.186 supplies covered measurable-event rows and empty-tail stream rows from Definition 92.57, Definition 92.91, and Definition 92.23. In particular, every finite support spine visible to the front is a* BHist *event ledger row whose constant empty tail is classified by the public* $\mathsf{Measure}^{\uparrow}$ *carrier and the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier.*

Proof. Start with Definition 92.57. It places the displayed measurable events, the empty event, finite union rows, countable union rows, and measure endpoints on visible BHist ledger entries.

Next apply Definition 92.91. The countable name carrier supplies the stream-indexed family in which the finite support spine is followed by the constant empty tail, and it transports the displayed event rows through the same componentwise classifier.

Finally use Definition 92.23. Its finite-support hypothesis identifies the nonempty spine and the empty tail as one countable family, so the front reads the carrier, tail, and endpoint rows without adding a host-level equality or quotient event comparison. □

Theorem 92.188 (Measure root finite-support additivity readback)**.** *For every pairwise-disjoint finite support spine exposed by Definition 92.186, the measure of the displayed finite union reads back to the* $\mathsf{Real}^{\uparrow}$ *finite sum of the displayed support values. The readback is obtained by induction on the support spine using the empty-zero row, finite disjoint-union additivity, and countable empty-tail readback.*

Proof. The base case is the empty support spine. The constant empty stream has empty countable union, and Definition 92.25 classifies its measure endpoint with the additive zero in the $\mathsf{Real}^{\uparrow}$ $\mathsf{AbGroup}^{\uparrow}$ row.

For the induction step, split a nonempty support spine into its head event and tail spine. Pairwise disjointness gives the displayed binary union row between the head and the finite union of the tail, while the induction hypothesis reads the tail union as the finite sum of the tail values.

Apply Definition 92.26 to the head and tail union. Additive congruence in the $\mathsf{Real}^{\uparrow}$ $\mathsf{AbGroup}^{\uparrow}$ row transports the tail readback through the right summand, and associativity identifies the result with the finite sum of the whole spine.

The empty tail of the surrounding countable stream is handled by Definition 92.23. Thus the finite union endpoint and the countable family endpoint agree with the same $\mathsf{Real}^{\uparrow}$ finite-support sum. □

Theorem 92.189 (Measure root finite-support downstream exhaustion)**.** $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consume exactly the finite-support rows of Definition 92.186 through Definition 92.86, Definition 92.87, Definition 92.88, and Definition 92.89. No downstream face receives host set equality, quotient event equality, a* $\mathsf{Real}^{\uparrow}$ *completeness row, or a standard bridge row from this front.*

Proof. Begin with Definition 92.86. Its outgoing rows are the root $\mathsf{Measure}^{\uparrow}$ consumer rows built from covered events, endpoint classification, countable sums, head-tail readback, empty-zero, finite disjoint additivity, and relative-difference or normalization projections.

For $\mathsf{Integral}^{\uparrow}$, apply Definition 92.87. The integral face reads covered event rows, endpoint rows, countable-sum rows, head-tail readback, and finite disjoint-union readback; the finite-support front supplies exactly the finite spine and empty-tail rows among these.

For $\mathsf{ProbSpace}^{\uparrow}$, apply Definition 92.88. Its finite-support consumption is limited to the total-event normalization, empty-zero, and finite disjoint-union rows already present in the root consumer package.

For $\mathsf{FunctionalAnalysis}^{\uparrow}$, apply Definition 92.89. The functional analysis face reads nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows, and it uses the finite-support front only through their covered event and finite-sum projections.

The tenth field of Definition 92.186 excludes host set equality, quotient event equality, $\mathsf{Real}^{\uparrow}$ completeness, and standard bridge rows. Since each downstream theorem above is a projection of the same root consumer package, these three faces exhaust the finite-support consumer surface. □

92.8 Measure root event boundary package

The root event boundary is the public face of the $\mathsf{Measure}^{\uparrow}$ root threshold seen by the downstream analysis chapters. It keeps the boundary over BHist presentations, componentwise hsame event comparison, $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ endpoint comparison, $\mathsf{StreamName}^{\uparrow}$ countable names, and the displayed measure ledger rows.

Theorem 92.190 (Measure root event-boundary carrier obligation)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root event boundary exposes exactly the carried* BHist *measure code, visible event rows, empty-event row, finite union rows, countable union rows, relative-difference row,* $\mathsf{Real}^{\uparrow}$ *endpoint row, and countable-sum witnesses supplied by Definition 92.1, Definition 92.182, and Definition 92.183. Every exposed row is a displayed* BHist *row or a named endpoint row, and the boundary adds no host set equality, quotient event identity, analytic completion object, or standard bridge row.*

Proof. Start from the carrier surface of Definition 92.1. It names the carried measure code, the measurable-event family, visible event rows, empty-event row, finite and countable union rows, relative-difference row, nonnegative endpoint row, and countable-sum witnesses.

Next read the same rows through Definition 92.182. The threshold package places them at the root over BHist presentations, componentwise hsame, $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ endpoint comparison, and $\mathsf{StreamName}^{\uparrow}$ countable names.

Apply Definition 92.183. It repacks the carrier and visible ledger rows as root boundary data and keeps endpoint movement inside the $\mathsf{Real}^{\uparrow}$ classifier.

The exactness clauses of the carrier and threshold packages identify the displayed ledger as the whole boundary surface. Therefore the event boundary contains precisely the listed BHist rows and endpoint witnesses, with no additional host equality or quotient event row. □

Theorem 92.191 (Measure root event-boundary classifier obligation)**.** *The public classifier on the* $\mathsf{Measure}^{\uparrow}$ *root event boundary is componentwise* hsame *on the visible event rows together with* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *classifier agreement on endpoint rows. Equivalently, the boundary classifier is the root-facing instance of Definition 92.7 projected through Definition 92.183: it compares displayed event rows and* $\mathsf{Real}^{\uparrow}$ *endpoints only, and it never asserts host set equality or quotient event identity.*

Proof. Project the public classifier from Definition 92.7. Its event component reads visible event presentations through hsame, while its endpoint component reads measure values through $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ and the $\mathsf{Real}^{\uparrow}$ classifier.

Now apply Definition 92.183. The root threshold projection restricts the classifier to the displayed BHist event rows, ledger rows, and endpoint rows carried by the boundary.

It remains to identify what the projection excludes. Since the carrier surface and the threshold package list only BHist rows, componentwise hsame, $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ comparison, and displayed ledger witnesses, the classifier has no field in which host set equality or quotient event identity could be read. □

Theorem 92.192 (Measure root event-boundary downstream unblock)**.** *The same* $\mathsf{Measure}^\uparrow$ *root event boundary supplies the downstream rows consumed by* $\mathsf{Integral}^\uparrow$, $\mathsf{ProbSpace}^\uparrow$, *and* $\mathsf{FunctionalAnalysis}^\uparrow$. *The unblocking rows are exactly the countable-additivity and analysis-consumer obligations of Definition 92.184 and Definition 92.185, read through Definition 92.87, Definition 92.88, and Definition 92.89. They remain scoped to* BHist, hsame, $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$, $\mathsf{StreamName}^\uparrow$, *and the displayed* $\mathsf{Measure}^\uparrow$ *ledger rows.*

Proof. First build the additive part of the boundary. Apply Definition 92.184. It supplies the empty-zero row, finite disjoint-union readback, relative-difference additivity, countable disjoint-union comparison, head-tail readback, and countable-sum classifier transport over the same BHist rows.

Next build the consumer projection. Apply Definition 92.185. It reads the $\mathsf{Integral}^\uparrow$, $\mathsf{ProbSpace}^\uparrow$, and $\mathsf{FunctionalAnalysis}^\uparrow$ outgoing rows from the root package without adding a host carrier, quotient event, analytic completion object, or standard bridge row.

For the integral consumer, use Definition 92.87. The consumed rows are the covered measurable-event rows, $\mathsf{Real}^\uparrow$ endpoint classifier rows, countable-sum rows, head-tail readback, and finite disjoint-union readback.

For the probability consumer, use Definition 92.88. The consumed rows are the total-event normalization row, empty-zero row, and finite disjoint-union readback row.

For the functional-analysis consumer, use Definition 92.89. The consumed rows are the non-negative endpoint, monotone-inclusion, relative-difference, and countable-sum classifier rows.

All three consumer projections point back to the same root event boundary. Thus the boundary supplies the three downstream faces through countable additivity and analysis-consumer rows while staying inside BHist, hsame, $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$, $\mathsf{StreamName}^\uparrow$, and the displayed $\mathsf{Measure}^\uparrow$ ledger. □

Definition 92.193 (Measure root public obligation basis)**.** *The* $\mathsf{Measure}^\uparrow$ *root public obligation basis is the counted ten-field basis that exposes the constructive root measure certificate before any analytic completion or bridge layer is admitted:*

1. *traditional target: a constructive measure root with visible measurable-event rows, countable-family rows, and* $\mathsf{Real}^\uparrow$ *endpoint values;*
2. *BEDC source:* BHist, *componentwise* hsame, $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$, $\mathsf{StreamName}^\uparrow$, *and the additive* $\mathsf{AbGroup}^\uparrow$ *real rows used for countable endpoint sums;*
3. *carrier: the root predicate* MeasCode *on* BHist*;*
4. *classifier: the public measure classifier* $\sim_M$*, with endpoint motion read through* $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ *and* $\sim_R$*;*
5. *stability rows: carrier and classifier transport, visible event-row transport, endpoint-row transport, and countable-family transport along* $\sim_M$ *and componentwise* hsame*;*
6. *ledger: hidden measurable-event witnesses, endpoint-value witnesses, disjointness witnesses, relative-difference witnesses, and countable-sum witnesses attached to the displayed rows they justify;*

7. *core theorem list: Definition 92.194, Definition 92.195, Definition 92.196, and Definition 92.197;*
8. *exactness: visible-row exhaustion for the carrier face, the additive face, and the consumer face through the rows of Definition 92.57;*
9. *standard bridge: no* StandardBridge *is asserted or imported by this basis;*
10. *status: paper proof target under* BEDC.Derived.MeasureUp.

This basis is read from Definition 92.143, Definition 92.182, and Definition 92.162. It is the public obligation surface available to downstream analysis chapters.

Lean4 (definition) `BEDC.Derived.MeasureUp.MeasureRootPublicObligationBasis`

Theorem 92.194 (Measure root public obligation basis carrier)**.** *The basis of Definition 92.193 supplies the carrier and classifier transport needed by the public* $\mathsf{Measure}^{\uparrow}$ *root. If* $h, k : \mathsf{BHist}$ *satisfy* $\mathsf{MeasCode}(h)$ *and* $h \sim_M k$*, then the basis transports* $\mathsf{MeasCode}(k)$*, every visible event row, every endpoint row, every countable-family row, and every ledger witness attached to the carried measure code.*

Proof. Start with the carrier and classifier fields of Definition 92.193. They are the MeasCode and $\sim_M$ rows first exposed in Definition 92.143.

Apply Definition 92.144. It transports the carried measure code, visible event rows, ledger rows, and $\mathsf{Real}^{\uparrow}$ endpoint comparisons along the supplied $\sim_M$ comparison.

Next apply Definition 92.183. The threshold reading keeps the same transported rows and adds the public countable-family and endpoint-readback boundary used by the root package.

The ledger field of the basis attaches the hidden witnesses only to displayed BHist rows. Therefore the transported rows exhaust the public carrier and classifier obligation without adding host set equality or quotient event equality. □

Theorem 92.195 (Measure root public obligation basis additivity)**.** *The basis of Definition 92.193 supplies the public additive face of the* $\mathsf{Measure}^{\uparrow}$ *root: empty-zero, finite readback, relative-difference additivity, countable disjoint-additivity, and countable-sum transport through the additive* $\mathsf{AbGroup}^{\uparrow}$ *real row.*

Proof. Project the additive fields of Definition 92.193. They name the covered empty event, finite disjoint unions, relative differences, countable disjoint families, countable unions, and countable-sum endpoints in the same visible BHist ledger.

Apply Definition 92.145. It supplies the root comparison between the value of a covered countable disjoint union and the corresponding countable endpoint sum.

Apply Definition 92.184. It keeps the empty-zero row, finite readback row, relative-difference row, head-tail row, and countable-sum classifier transport visible at the public threshold.

Finally apply Definition 92.164. This countable-premeasure reading identifies finite readback and relative-difference additivity as projections of the same countable additive surface, with endpoint movement through $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ and the additive $\mathsf{AbGroup}^{\uparrow}$ real row. □

Theorem 92.196 (Measure root public obligation basis consumer)**.** *The basis of Definition 92.193 exports exactly the* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *rows available from the public* $\mathsf{Measure}^{\uparrow}$ *root. No other analysis row is part of this basis.*

Proof. Begin with the consumer field of Definition 92.193. It lists only the three outgoing faces $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$.

Apply Definition 92.185. It reads those three faces from the root threshold package and identifies the covered event rows, endpoint classifier rows, countable-sum rows, empty-zero, finite readback, relative-difference, monotone inclusion, nonnegative endpoint, and total-event normalization rows available to them.

Next apply Definition 92.165. It restricts the same three consumers to the countable-premeasure front and keeps the outgoing rows attached to covered measurable-event and endpoint rows.

The exactness clause of the basis has no fourth consumer slot and no analytic completion slot. Hence the exported consumer boundary is exactly the stated triad and no larger analysis interface is claimed. □

Theorem 92.197 (Measure root public obligation basis exactness)**.** *The carrier face, additive face, and consumer face of Definition 92.193 form the deps-ready* $\mathsf{Measure}^{\uparrow}$ *root package. The package asserts no host set equality, no quotient event equality, no analytic completion object, and no standard bridge.*

Proof. First read the carrier face through Definition 92.194. It supplies the public MeasCode carrier, $\sim_M$ classifier transport, visible event rows, endpoint rows, countable-family rows, and attached ledger witnesses.

Next read the additive face through Definition 92.195. It supplies the empty-zero, finite readback, relative-difference, countable disjoint-additivity, and countable-sum transport rows over the same visible ledger.

Finally read the consumer face through Definition 92.196. It exports only the $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ projections from that public root package.

The exactness field of Definition 92.193 says that every consumed hidden witness is attached to a displayed row covered by Definition 92.57. Since none of the three faces contains a host-set equality field, quotient-event equality field, analytic completion object, or StandardBridge field, the resulting package is precisely the deps-ready public obligation basis. □

92.9 Root premeasure event-value bridge

Definition 92.198 (Measure root premeasure event-value bridge)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root premeasure event-value bridge is the package whose fields are the countable premeasure carrier and classifier rows of Definition 92.162, the countable additivity row of Definition 92.164, the public obligation basis rows of Definition 92.193, and the* NameCert *obligation package of Definition 92.27. Its visible event-value surface consists only of covered measurable-event* BHist *rows, their* $\mathsf{Real}^{\uparrow}$ *nonnegative value endpoints, the classifier transports for those rows, and the ledger exactness rows that tie hidden measurable witnesses to displayed events.*

Theorem 92.199 (Measure root premeasure finite-additivity bridge)**.** *The package of Definition 92.198 exports finite disjoint-union additivity by composing Definition 92.164, Definition 92.195, and Definition 92.27.*

Proof. Project the countable additivity field from the bridge package. By Definition 92.164, the countable-premeasure front reads finite disjoint unions as finite-support instances of the same countable disjoint-additivity row.

Next project the public additive face. Apply Definition 92.195; it exposes empty-zero, finite readback, relative-difference additivity, countable disjoint-additivity, and countable-sum transport over the same displayed event-value ledger.

Finally read the NameCert obligation package through Definition 92.27. Its finite disjoint-union theorem is attached to the carrier, classifier, nonnegative endpoint, and ledger exactness rows already present in the bridge, so the finite additivity claim is the exported projection of the package. □

Theorem 92.200 (Measure root premeasure downstream threshold bridge)**.** *Downstream* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumers may read only the event carrier and classifier, countable additivity, finite additivity, nonnegative value, and ledger exactness rows exposed by the bridge of Definition 92.198.*

Proof. Start with the bridge package and discard every field not named by its event-value surface. The remaining carrier and classifier rows are exactly the covered measurable-event BHist rows, value endpoint rows, and transport rows inherited from Definition 92.162.

For additive information, use Definition 92.164 and Definition 92.199. These give the countable disjoint-additivity row and its finite disjoint-union projection without adding a consumer-specific carrier.

For public visibility and exactness, apply Definition 92.197 and Definition 92.27. The first pins the rows to the displayed public basis, while the second supplies the nonnegative value and ledger exactness obligations consumed by the three downstream chapters.

The package definition has no further outgoing field for analytic completion, host set equality, quotient event equality, or a standard bridge. Hence $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ can read exactly the listed rows and no larger root surface from this bridge. □

Definition 92.201 (Measure root-kernel obligation source)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root-kernel obligation source is the counted ten-field per-object template that records the* BHist*-scoped source from which the public root measure obligations are read:*

1. *object code: a* BHist *row* h *carrying the visible measurable-event rows of the* $\mathsf{Measure}^{\uparrow}$ *ledger;*
2. *classifier source: componentwise* hsame *on histories together with the induced measure classifier* $\sim_M$ *on visible measure rows;*
3. *endpoint certificate:* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *for every displayed endpoint value and the* $\mathsf{StreamName}^{\uparrow}$ *rows used to name countable event families;*
4. *carrier face: the* MeasCode *predicate on* BHist*, read through the carrier surface and the root public obligation basis;*
5. *event boundary: exactly the visible event rows covered by Definition 92.57 and the root event boundary package;*
6. *additive face: empty-zero, finite readback, relative-difference, countable disjoint-additivity, and countable-sum rows over the same ledger;*
7. *threshold face: the root threshold package and root threshold obligation package, including endpoint readback and countable-family transport;*
8. *premeasure face: the countable premeasure front over the covered event rows and the additive* $\mathsf{AbGroup}^{\uparrow}$ *real row;*
9. *downstream face: only the* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer rows already named in the consumer boundary;*
10. *exclusions: no host set equality, quotient event equality, analytic completion object, or standard bridge row is exported by this source.*

Thus each root-kernel object is counted by a single public source over BHist, hsame, $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$, $\mathsf{StreamName}^\uparrow$, *visible event rows, and the* $\mathsf{Measure}^\uparrow$ *ledger.*

Theorem 92.202 (Measure root-kernel carrier-classifier obligation)**.** *For every root-kernel object described by Definition 92.201, the source supplies the* $\mathsf{Measure}^\uparrow$ *carrier and classifier obligation:* $\mathsf{MeasCode}$ *is read on* BHist, *transported along componentwise* hsame *and* $\sim_M$, *and all visible event, endpoint, countable-family, and ledger rows remain attached to the transported carrier.*

Proof. Start from the object code, classifier source, endpoint certificate, and carrier face of Definition 92.201. These fields place the carrier in BHist and make hsame, $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$, and $\mathsf{StreamName}^\uparrow$ part of the same visible ledger.

Apply Definition 92.194. It transports the carrier, classifier, event rows, endpoint rows, and countable-family rows through the public obligation basis.

Apply Definition 92.183. The root threshold package keeps the same transported rows visible at the threshold face, including endpoint readback and countable-family transport.

Finally use Definition 92.190. The event boundary package identifies the displayed event ledger as the whole carrier boundary. Since the source has no host set equality or quotient event equality field, the carrier-classifier obligation is exactly the stated BHist-scoped one. □

Theorem 92.203 (Measure root-kernel additivity obligation)**.** *For every root-kernel object described by Definition 92.201, the source supplies the additive obligation required by the public* $\mathsf{Measure}^\uparrow$ *root: empty-zero, finite readback, relative-difference additivity, countable disjoint-additivity, and countable-sum transport through* $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$, $\mathsf{StreamName}^\uparrow$, *and the additive* $\mathsf{AbGroup}^\uparrow$ *real row.*

Proof. Read the additive, threshold, and premeasure faces of Definition 92.201. They refer to the same covered event rows, the same endpoint certificates, and the same countable-family names.

Apply Definition 92.195. This gives the empty-zero, finite readback, relative-difference, countable disjoint-additivity, and countable-sum transport rows over the public ledger.

Apply Definition 92.184. The root threshold package keeps the additive rows attached to the endpoint and countable-family boundary.

Apply Definition 92.164. The countable premeasure front reads those same rows through $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$, $\mathsf{StreamName}^\uparrow$, and the additive $\mathsf{AbGroup}^\uparrow$ real row. The exclusions field exports no analytic completion object, so the additivity obligation remains a root-kernel obligation rather than a completed measure-space assertion. □

Theorem 92.204 (Measure root-kernel downstream consumer obligation)**.** *For every root-kernel object described by Definition 92.201, the source exports one downstream consumer boundary: the* $\mathsf{Integral}^\uparrow$, $\mathsf{ProbSpace}^\uparrow$, *and* $\mathsf{FunctionalAnalysis}^\uparrow$ *rows obtained from the root public obligation basis, root threshold package, event boundary package, countable premeasure front, and consumer rows. No fourth consumer, analytic completion object, host set equality, quotient event equality, or standard bridge row is exported.*

Proof. Begin with the downstream face of Definition 92.201. It names only $\mathsf{Integral}^\uparrow$, $\mathsf{ProbSpace}^\uparrow$, and $\mathsf{FunctionalAnalysis}^\uparrow$ as outgoing consumer chapters.

Apply Definition 92.196. The root public obligation basis exports exactly those three rows from the public $\mathsf{Measure}^\uparrow$ root.

Apply Definition 92.192. The event boundary package shows that the consumer rows are attached to covered visible event rows, endpoint rows, and countable-additivity rows.

Finally apply Definition 92.165. The countable premeasure front is the common source consumed by the same three downstream chapters. The exclusions field and the consumer boundary together leave no slot for a fourth consumer, analytic completion object, host set equality, quotient event equality, or standard bridge row. □

Definition 92.205 (Measure root minimum NameCert obligation triad)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root minimum* $\mathsf{NameCert}$ *obligation triad is the three-field root package read from* BHist *presentations, the componentwise* hsame *classifier,* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint transport, and* $\mathsf{StreamName}^{\uparrow}$ *countable-family rows:*

1. *carrier-classifier field: the measurable-event carrier* $\mathsf{MeasCode}$*, the public classifier* $\sim_M$*, visible event-row transport, endpoint transport through* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*, and carrier transport along componentwise* hsame*;*
2. *countable-additivity field: StreamName-indexed measurable sequence coverage, pairwise-disjoint and countable-union readback, countable-sum endpoint rows, and the* $\mathsf{Real}^{\uparrow}$ *comparison between the value of the union and the displayed countable endpoint;*
3. *downstream ledger field: the rows available to* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*, namely the carrier/classifier rows, countable-additivity rows, nonnegative endpoint rows, and ledger rows attached to visible measurable-event witnesses.*

The triad is a minimum public root surface: it contains no host set equality, no quotient equality of event codes, no analytic completion object, and no open-cover compactness row.

Theorem 92.206 (Measure root minimum carrier-classifier obligation)**.** *The triad of Definition 92.205 supplies the* $\mathsf{Measure}^{\uparrow}$ *root carrier predicate, public classifier, and carrier transport only through the displayed BEDC rows of Definition 92.6, Definition 92.7, Definition 92.17, Definition 92.18, and Definition 92.193.*

Proof. Read the first field of Definition 92.205. Its carrier is the BHist measurable-event carrier and its classifier is the componentwise hsame relation with endpoint motion read through $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$.

The inventory in Definition 92.6 names exactly those carrier, classifier, stability, and ledger rows. The classifier specification in Definition 92.7 then restricts comparison to event-witness transport and $\mathsf{Real}^{\uparrow}$ endpoint comparison.

Apply Definition 92.17 and Definition 92.18. They identify the root $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ carrier, classifier, and stability face with the displayed event, endpoint, and ledger rows.

Finally compare with Definition 92.193. Its carrier and classifier fields expose the same rows and no larger equality principle. Thus the triad supplies the root carrier-classifier obligation only through the displayed BEDC rows. □

Theorem 92.207 (Measure root minimum countable-additivity obligation)**.** *The triad of Definition 92.205 supplies measurable-sequence coverage, disjoint-union readback, and* $\mathsf{Real}^{\uparrow}$ *endpoint comparison for the* $\mathsf{Measure}^{\uparrow}$ *countable-additivity row. Every countable family consumed by this row is read through* $\mathsf{StreamName}^{\uparrow}$*, componentwise* hsame*, and the public ledger of Definition 92.193.*

Proof. Project the second field of Definition 92.205. It names the StreamName-indexed measurable family, the pairwise-disjoint witness, the countable union row, the countable-sum endpoint, and the $\mathsf{Real}^{\uparrow}$ comparison attached to that endpoint.

The carrier inventory of Definition 92.6 supplies the measurable sequence, disjointness, union, and countable-sum ledger rows. The classifier specification of Definition 92.7 keeps their movement componentwise, with endpoint motion through $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$.

Apply Definition 92.18. Its countable-endpoint and σ-additivity projections supply the stated comparison between the value of the visible disjoint union and the displayed countable endpoint.

The public basis of Definition 92.193 records these rows as the root additive face. Therefore the triad contains the countable-additivity obligation exactly as measurable-sequence coverage, disjoint-union readback, and $\mathsf{Real}^{\uparrow}$ endpoint comparison. □

Theorem 92.208 (Measure root minimum downstream consumer obligation)**.** *The triad of Definition 92.205 permits* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *to consume exactly the carrier/classifier rows, countable-additivity rows, nonnegative endpoint rows, and ledger rows displayed by the* $\mathsf{Measure}^{\uparrow}$ *root. It exports no host set equality, no quotient equality, and no open-cover compactness.*

Proof. Read the downstream ledger field of Definition 92.205. It names only the three consumers $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ and restricts their input to carrier/classifier, countable-additivity, nonnegative endpoint, and visible ledger rows.

The root carrier inventory and classifier specification provide the common input rows for all three consumers. The root NameCert carrier-classifier and stability-exactness theorems identify these rows with the public $\mathsf{Measure}^{\uparrow}$ root face.

Apply Definition 92.193. Its consumer and exactness fields attach every downstream witness to displayed measurable-event, endpoint, disjointness, relative-difference, and countable-sum rows.

Since none of those cited rows contains a host set equality field, quotient event equality field, or open-cover compactness field, the triad exports exactly the downstream consumer obligation stated above. □

92.10 Measure root public face exactness

The public face exactness package gathers the root $\mathsf{Measure}^{\uparrow}$ endpoint fiber that downstream chapters cite when they need the concrete BEDC event ledger rather than a transported analytic interface.

Definition 92.209 (Measure root public face exactness)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root public face exactness package is the concrete endpoint fiber over* BHist *whose carrier rows are the visible measurable event histories, whose classifier rows are componentwise* hsame *rows, and whose endpoint rows are classified through* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *and* $\mathsf{StreamName}^{\uparrow}$*. It consists of exactly the following public rows:*

1. *the displayed* BHist *measurable membership rows, empty event rows, relative-difference rows, disjointness rows, countable-union rows, and countable-family rows covered by Definition 92.57;*
2. *the* $\mathsf{Real}^{\uparrow}$ *endpoint classifier rows attached to measure values, finite readbacks, nonnegative endpoints, total-event normalization, monotone inclusion, and countable sums;*
3. *the minimum root* $\mathsf{NameCert}$ *carrier-classifier, countable-additivity, and downstream ledger fields of Definition 92.205;*
4. *the public sigma-algebra carrier, empty-zero, and countable disjoint-additivity rows of Definition 92.214;*
5. *the outgoing* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *faces accepted by Definition 92.178.*

This package introduces no host set equality, no quotient event equality, no analytic completion object, and no standard bridge row.

Theorem 92.210 (Measure root public face coverage)**.** *Every endpoint fiber in Definition 92.209 is covered by the event-row coverage predicate of Definition 92.57, the minimum root* NameCert *triad of Definition 92.205, and the sigma-algebra public basis of Definition 92.214.*

Proof. Start with the listed rows of Definition 92.209. The event side consists only of displayed BHist measurable membership, empty-event, relative-difference, disjointness, countable-union, and countable-family rows.

Apply Definition 92.57. It places each event row in the visible ledger, together with the attached measure-value and countable-sum endpoint rows.

Next apply Definition 92.205. Its carrier-classifier field supplies the hsame event classifier, its countable-additivity field supplies the $\mathsf{StreamName}^{\uparrow}$ family and $\mathsf{Real}^{\uparrow}$ endpoint-sum rows, and its downstream ledger field keeps those rows visible to the three named consumers.

Finally use Definition 92.214, Definition 92.218, and Definition 92.126. The public basis gives the carrier, empty-zero, and countable disjoint-additivity rows; the real-stream obligation attaches StreamName observation names and endpoint comparisons to the same event history; the source package confirms that all source witnesses remain ledger rows rather than host equalities or analytic completion data. □

Theorem 92.211 (Measure root public face determinacy)**.** *For a displayed event row of Definition 92.209, the event display together with its* $\mathsf{Real}^{\uparrow}$ *endpoint classifier determines one public* $\mathsf{Measure}^{\uparrow}$ *endpoint fiber. The determinacy is a BEDC endpoint-fiber determinacy statement; it is not host event equality and not quotient equality of event codes.*

Proof. Fix a displayed event row in the public face. By Definition 92.209, the row carries a componentwise hsame classifier and a $\mathsf{Real}^{\uparrow}$ endpoint classifier through $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$.

Apply Definition 92.220. It transports the carried $\mathsf{Measure}^{\uparrow}$ root row and its visible ledger along the displayed event history, StreamName observation, and real endpoint classifier.

Now use Definition 92.215 and Definition 92.167. The sigma-algebra carrier keeps the public event row in the root carrier, while the real-stream carrier places the observation name and endpoint comparison on that same row.

The consumer and source boundaries do not identify host events. By Definition 92.179 and Definition 92.123, the accepted row remains a visible ledger row with endpoint data attached. Thus the displayed event and endpoint classifier determine exactly one public endpoint fiber of the BEDC root surface, with no host set equality, quotient event equality, analytic completion object, or standard bridge row added. □

Theorem 92.212 (Measure root public face ledger exhaustion)**.** *Every ledger entry consumed by Definition 92.209 is a measurable membership row, relative-difference row, disjointness row, measure-value row, or countable-sum row supplied by Definition 92.13. No other source witness is part of the public endpoint fiber.*

Proof. Read the ledger clause of Definition 92.209. It contains exactly the visible event rows and endpoint rows listed in Definition 92.57, plus the downstream faces accepted by the root consumer gate.

Apply Definition 92.13. Its exactness clause exhausts the consumed source witnesses by measurable membership, relative-difference, disjointness, measure-value, and countable-sum rows.

Next apply Definition 92.125. It reads the same witness list through the source-closure package and keeps probability normalization, integral premeasure rows, functional-analysis rows, and bridge rows outside the source ledger.

Finally use Definition 92.221 and Definition 92.181. The additivity scope accounts for the $\mathsf{StreamName}^{\uparrow}$ countable-family endpoint rows, and the acceptance package shows that downstream consumers receive only projections of the exhausted ledger. Therefore no host set equality, quotient event equality, analytic completion object, or standard bridge row enters the public endpoint fiber. □

Theorem 92.213 (Measure root public face consumer separation)**.** *Inside the public endpoint fiber of Definition 92.209, the chapters* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consume only the shared root event ledger, the shared* $\mathsf{Real}^{\uparrow}$ *endpoint-classifier rows, and their named face rows. The public face supplies no mixed consumer row and no analytic completion interface.*

Proof. Begin with the outgoing rows in Definition 92.209. They are exactly the three faces accepted by Definition 92.178.

Apply Definition 92.180. It identifies the only overlaps among the integral, probability, and functional-analysis faces as the shared BHist event ledger and the shared $\mathsf{Real}^{\uparrow}$ endpoint classifier rows.

Next apply Definition 92.222 and Definition 92.169. These theorems read the same consumers through displayed event rows, StreamName observations, endpoint comparisons, finite readbacks, normalization rows, monotone rows, and relative-difference rows.

Finally use Definition 92.126. The source package is built before any outgoing consumer face is read, so consumer rows cannot become source hypotheses and cannot merge the named faces. Hence the public endpoint fiber separates $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ exactly as stated, with no host set equality, quotient event equality, analytic completion object, or standard bridge row. □

Definition 92.214 (Measure root sigma-algebra public basis)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root sigma-algebra public basis is the counted ten-field basis that exposes the public measurable-event and countable-additive rows available at the root:*

1. *traditional target: a constructive sigma-algebra measure root whose public rows name measurable events, complements, countable unions, the empty event, endpoint values, and countable additive sums;*
2. *BEDC source:* BHist*, componentwise* hsame*,* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*,* $\mathsf{StreamName}^{\uparrow}$*, and the additive* $\mathsf{AbGroup}^{\uparrow}$ *real rows used for endpoint addition and countable endpoint sums;*
3. *carrier: the root predicate* $\mathsf{MeasCode}$ *on* BHist*;*
4. *classifier: the public measure classifier* $\sim_M$*, with endpoint comparison read through* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *and* $\sim_R$*;*
5. *stability rows: transport of measurable-event rows, complement rows, countable-union rows, empty-event rows, endpoint rows, countable-sum rows, and attached ledger witnesses along* $\sim_M$ *and componentwise* hsame*;*
6. *ledger: hidden measurable-event witnesses, complement witnesses, countable-union witnesses, empty-event witnesses, endpoint-value witnesses, disjointness witnesses, and countable-sum witnesses attached only to the displayed rows they justify;*
7. *core theorem list: Definition 92.215, Definition 92.216, and Definition 92.217;*
8. *exactness: every public carrier, classifier, empty-zero, and countable disjoint-additivity assertion is exhausted by the displayed rows of Definition 92.57;*

9. *standard bridge: no* StandardBridge *is asserted or imported by this basis;*
10. *status: paper proof target under* BEDC.Derived.MeasureUp.

No host set equality, quotient event equality, analytic completion object, or standard bridge is part of this basis.

Theorem 92.215 (Measure root sigma-algebra public carrier)**.** *The basis of Definition 92.214 transports the public sigma-algebra carrier face of* $\mathsf{Measure}^{\uparrow}$*. If* $h, k : \mathsf{BHist}$ *satisfy* $\mathsf{MeasCode}(h)$ *and* $h \sim_M k$*, then the basis transports measurable-event rows, complement rows, countable-union rows, empty-event rows, endpoint rows, and attached ledger witnesses from* h *to* k*.*

Proof. Start from the carrier face of Definition 92.214. Its carrier and classifier fields are the public MeasCode and $\sim_M$ rows, and its stability field names the event, complement, countable-union, empty-event, endpoint, and ledger rows to be transported.

Apply Definition 92.194. This supplies the carried MeasCode row, the visible event rows, the endpoint rows, the countable-family rows, and the attached ledger witnesses after the supplied comparison $h \sim_M k$.

Next apply Definition 92.163. It reads the same transport through the countable-premeasure front, so the complement, countable-union, and empty-event rows remain attached to the public root ledger.

Finally use Definition 92.57. The coverage definition identifies which visible rows exhaust the public carrier face, so the transported witnesses remain row-attached and no host set equality, quotient event equality, analytic completion object, or standard bridge is introduced. □

Theorem 92.216 (Measure root empty-event zero public row)**.** *The basis of Definition 92.214 exposes the empty measurable event as a public sigma-algebra row, and its* $\mathsf{Real}^{\uparrow}$ *endpoint is classified with the additive zero* 0_R *of the target* $\mathsf{AbGroup}^{\uparrow}$ *real row.*

Proof. Project the empty-event and endpoint fields of Definition 92.214. They place the empty measurable event, its measure endpoint, and the additive 0_R row in the same visible BHist ledger.

Apply Definition 92.195. It keeps the empty-zero row inside the public additive face of the $\mathsf{Measure}^{\uparrow}$ root basis.

Next apply Definition 92.25. The sigma-additivity row applied to the all-empty sequence classifies $\mu(\varnothing)$ with the additive zero in the target $\mathsf{Real}^{\uparrow}$ row.

The finite-support empty-sequence zero row is recorded by Definition 92.32. It keeps the countable endpoint of the all-empty $\mathsf{StreamName}^{\uparrow}$ family classified with 0_R, so the public empty-event row and its endpoint classification are visible without adding a completion object or standard bridge. □

Theorem 92.217 (Measure root countable disjoint-additivity public row)**.** *For every covered pairwise-disjoint* $\mathsf{StreamName}^{\uparrow}$*-indexed family of measurable-event rows in the basis of Definition 92.214, there is a covered union row whose endpoint is classified with the countable* $\mathsf{Real}^{\uparrow}$ *sum of the endpoints of the family.*

Proof. Begin with a covered pairwise-disjoint $\mathsf{StreamName}^{\uparrow}$-indexed family. By Definition 92.214, the family rows, their disjointness witnesses, their endpoint rows, and the countable-sum witness are all ledger-attached public rows.

Apply Definition 92.164. It supplies the covered countable-union row and compares the union endpoint with the countable endpoint sum of the family.

Next apply Definition 92.195. This reads the same comparison through the public additive face, where the empty-zero, finite readback, relative-difference, countable disjoint-additivity, and countable-sum transport rows share the additive $\mathsf{AbGroup}^{\uparrow}$ real structure.

Finally apply Definition 92.12. The countable-sum classifier stability row transports pointwise $\mathsf{Real}^{\uparrow}$ endpoint comparisons to the countable sum, so the covered union endpoint is classified with the countable $\mathsf{Real}^{\uparrow}$ sum of the displayed endpoints and nothing outside the public basis is claimed. □

92.11 Measure root real-stream event obligations

The real-stream event obligation surface pins the public $\mathsf{Measure}^{\uparrow}$ root to the displayed BHist event rows, $\mathsf{StreamName}^{\uparrow}$ observation names, and $\mathsf{Real}^{\uparrow}$ endpoint comparisons that downstream analysis chapters may read. It is a root obligation surface, not an analytic completion or a host measure-space interface.

Theorem 92.218 (Measure root real-stream event obligation)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root event row exposed by Definition 92.193 is a* BHist*-displayed event carrier whose observable values are exactly the* $\mathsf{StreamName}^{\uparrow}$*-indexed* $\mathsf{Real}^{\uparrow}$ *endpoint observations supplied by Definition 92.166. Thus every carried root event is read as a displayed event history, a stream observation name, and the attached real endpoint comparison on the same ledger row.*

Proof. Start with the carrier and ledger clauses of Definition 92.193. They identify the root measure carrier with $\mathsf{MeasCode}$ rows on BHist and attach hidden measurable-event witnesses only to displayed public rows.

Apply Definition 92.194. It transports the carried $\mathsf{Measure}^{\uparrow}$ code, visible event rows, endpoint rows, countable-family rows, and ledger witnesses over the same public carrier.

Now read the same row through Definition 92.166 and Definition 92.167. The real-stream front adds exactly the StreamName endpoint-family observation and the $\mathsf{Real}^{\uparrow}$ endpoint comparison attached to the displayed event history.

The other public faces remain attached to this same row. By Definition 92.195 and Definition 92.168, countable sums are read only through the same displayed event family and endpoint stream. By Definition 92.196 and Definition 92.169, the analysis consumers see only projections of these displayed rows.

Repack the two readings as a single root obligation row. The public basis supplies the displayed BHist event carrier, while the real-stream front supplies only the observation name and endpoint comparison already attached to that carrier. No host event equality, quotient event equality, or analytic completion object is introduced. □

Theorem 92.219 (Measure root real-stream sibling route exactness)**.** *Every* $\mathsf{Measure}^{\uparrow}$ *root event row covered by Definition 92.218 reads its stream observation through chapter 126 and its endpoint comparison through chapter 38. The route retains only the displayed* BHist *event row, componentwise* hsame *transport,* Cont *continuation row,* $\mathsf{Pkg}_{\mathsf{Measure}^{\uparrow}}$ *package ledger, and the visible* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint row already present in Definition 92.166.*

Proof. Apply Definition 92.218. It identifies the root event row as a displayed BHist history carrying a $\mathsf{StreamName}^{\uparrow}$-indexed endpoint observation and the attached $\mathsf{Real}^{\uparrow}$ endpoint comparison on the same ledger row.

Now read the observation-name component through chapter 126 and the endpoint-comparison component through chapter 38. The regularity front Definition 92.166 is exactly the interface that

places those two sibling readings beside the root BHist row, the componentwise hsame transport, the Cont continuation discipline, the $\mathsf{Pkg}_{\mathsf{Measure}^{\uparrow}}$ package row, and the visible $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ ledger entry.

Nothing else is added to the route. Host event equality, quotient event equality, ambient completion, and selected host limits are outside the displayed root-event row, so they cannot become part of the sibling route described here. □

Theorem 92.220 (Measure root event classifier stability)**.** *For the root event surface of Definition 92.218, componentwise* hsame *transport of displayed event histories together with* $\mathsf{StreamName}^{\uparrow}$ *observation transport and* $\mathsf{Real}^{\uparrow}$ *endpoint classifier transport preserves the carried* $\mathsf{Measure}^{\uparrow}$ *root row and its visible ledger.*

Proof. Begin with two displayed event histories in the public root ledger and a componentwise hsame comparison between them. The carrier theorem Definition 92.194 transports the carried $\mathsf{Measure}^{\uparrow}$ code, visible event rows, endpoint rows, and ledger witnesses along the public classifier.

Next use the classifier clauses of Definition 92.166. They require pointwise StreamName classifier transport and $\mathsf{Real}^{\uparrow}$ endpoint comparison for values and countable sums over the same displayed history row.

Apply Definition 92.167. It aligns the transported event history, the transported stream observation, and the transported real endpoint on one ledger row. Then apply Definition 92.168 to keep the countable-sum endpoint classifier compatible with the same transport.

The additive and consumer projections do not widen the classifier. By Definition 92.195, the additive row remains a visible countable-family row in the public ledger. By Definition 92.196 and Definition 92.169, the consumer rows read the transported endpoint data without adding a new event carrier.

The resulting row is still one of the rows counted by Definition 92.193. Therefore the carried $\mathsf{Measure}^{\uparrow}$ root row, its event display, and its endpoint observation remain stable under the componentwise hsame and $\mathsf{Real}^{\uparrow}$ classifier motion. □

Theorem 92.221 (Measure root countable additivity scope)**.** *The countable disjoint-additivity obligation of the* $\mathsf{Measure}^{\uparrow}$ *root is scoped exactly to displayed* BHist *event families, their* $\mathsf{StreamName}^{\uparrow}$ *observation names, their* $\mathsf{Real}^{\uparrow}$ *endpoint sums, and the visible ledger rows of Definition 92.193. It does not assert additivity for an external sigma-algebra or for quotient event equality.*

Proof. Project the additive face from Definition 92.193. It lists empty-zero, finite readback, relative-difference additivity, countable disjoint-additivity, and countable-sum transport through the additive $\mathsf{AbGroup}^{\uparrow}$ real row.

The carrier and observation rows are fixed before additivity is read. Apply Definition 92.194; then read the same carrier through Definition 92.166 and Definition 92.167. This supplies the displayed BHist family, the StreamName observation names, and the attached $\mathsf{Real}^{\uparrow}$ endpoint comparisons.

Apply Definition 92.195. The theorem keeps the additive obligation attached to covered event rows, disjointness witnesses, countable-union rows, relative-difference rows, and countable-sum endpoint witnesses in the public ledger.

Next apply Definition 92.168. It reads the same countable family through the StreamName-indexed endpoint family and identifies the countable disjoint-additivity conclusion with a $\mathsf{Real}^{\uparrow}$ endpoint comparison for the countable sum.

Combining the two projections gives the stated scope: displayed BHist event families, StreamName observation names, real endpoint sums, and the visible ledger. Since both source surfaces

exclude host sigma-algebra equality and quotient event equality, the countable additivity obligation is confined to the root public surface. The consumer boundary is then only a projection of this scope by Definition 92.196 and Definition 92.169. □

Theorem 92.222 (Measure root analysis consumer surface)**.** *The downstream* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumers of the* $\mathsf{Measure}^{\uparrow}$ *root consume exactly the displayed event rows,* $\mathsf{Real}^{\uparrow}$ *endpoint rows, countable-sum rows, finite-readback rows, normalization rows, monotone rows, and relative-difference rows carried by Definition 92.193 and Definition 92.166.*

Proof. Start with the consumer clause of Definition 92.193. It has exactly three outgoing faces: $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$.

The carrier and additive prerequisites are already fixed by Definition 92.194 and Definition 92.195. Reading them through Definition 92.166, Definition 92.167, and Definition 92.168 gives the displayed event rows, StreamName observations, endpoint comparisons, and countable-sum rows consumed below.

Apply Definition 92.196. The consumer face exposes covered event rows, endpoint classifier rows, countable-sum rows, empty-zero, finite readback, relative-difference, monotone inclusion, nonnegative endpoint, and total-event normalization rows for the three named consumers.

Now apply Definition 92.169. The real-stream front restricts the same consumers to the rows visible through StreamName observations and $\mathsf{Real}^{\uparrow}$ endpoint comparisons over the displayed BHist ledger.

Finally combine the exactness clauses of the public basis and the real-stream front. They leave no fourth analysis consumer, no external event carrier, and no analytic completion row. Hence $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ consume exactly the listed root event, endpoint, countable-sum, finite-readback, normalization, monotone, and relative-difference rows. □

92.12 Measure root countable relative-difference bridge

Definition 92.223 (MeasureUp root countable relative-difference bridge)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root countable relative-difference bridge is the ten-field paper target that binds StreamName-indexed countable event families, displayed relative differences, and downstream analysis consumers on one root surface:*

1. *traditional target: a countable measurable family whose visible rows include displayed relative differences and real endpoint comparisons;*
2. *BEDC source:* $\mathsf{Measure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, *and the history classifier* hsame*;*
3. *carrier: StreamName-indexed measurable-event rows together with pairwise relative-difference witnesses for covered inclusions of displayed event histories;*
4. *classifier: transported event-row classification along* hsame*, pointwise StreamName observation classification, and* $\mathsf{Real}^{\uparrow}$ *endpoint classification for values and sums;*
5. *stability rows: carrier transport, countable-additivity transport, relative-difference transport, and endpoint transport through the same visible ledger;*
6. *ledger: indices, displayed events, complements and differences, pairwise-disjoint witnesses, countable unions, countable sums, and* $\mathsf{Real}^{\uparrow}$ *endpoints attached to the event rows they certify;*
7. *core theorem list: Definition 92.224, Definition 92.225, and Definition 92.226;*

8. *exactness: coverage, soundness, and completeness are exactly those of the displayed countable-family, relative-difference, endpoint, and consumer rows named by the bridge;*
9. *standard bridge: none;*
10. *status: paper target for* BEDC.Derived.MeasureUp.

The bridge is a root obligation package. It does not assert host sigma-algebra equality, quotient event equality, analytic completion, or a StandardBridge *row.*

Theorem 92.224 (Measure root countable relative-difference carrier)**.** *The bridge of Definition 92.223 exposes the source event row, the countable StreamName-indexed family row, the relative-difference row, and the attached* $\mathsf{Real}^{\uparrow}$ *endpoint histories on the same* BHist *ledger.*

Proof. Read the BEDC source, carrier, and ledger fields of Definition 92.223. They name the carried $\mathsf{Measure}^{\uparrow}$ root row, the $\mathsf{StreamName}^{\uparrow}$ countable family, the displayed relative-difference witnesses, and the endpoint histories before any consumer projection is formed.

Apply Definition 92.158. Its carrier and ledger clauses expose the carried measure code, StreamName endpoint family, event membership, pairwise disjointness, countable union, endpoint value, and countable-sum witnesses on visible BHist rows.

Next apply Definition 92.218 and Definition 92.220. These rows identify the same event histories with StreamName observation names and $\mathsf{Real}^{\uparrow}$ endpoint comparisons, and they keep the event classifier stable under componentwise hsame transport.

Finally apply Definition 92.101. The relative-difference theorem supplies the displayed difference event, its measurability row, and the disjoint decomposition row for each covered inclusion. Repacking these projections gives the stated carrier surface and adds no external event equality or completion principle. □

Theorem 92.225 (Measure root countable relative-difference additivity)**.** *For every covered StreamName-indexed countable event family in the bridge of Definition 92.223, endpoint comparison is obtained by combining the root countable-additivity row with the finite relative-difference decomposition row and* $\mathsf{Real}^{\uparrow}$ *classifier transport.*

Proof. Start with a covered StreamName-indexed family from the bridge ledger. The family rows carry event membership, pairwise disjointness, a visible countable union, endpoint values, and a countable-sum witness on the same BHist surface.

Apply Definition 92.221. It confines the countable disjoint-additivity obligation to displayed event families, StreamName observation names, $\mathsf{Real}^{\uparrow}$ endpoint sums, and visible ledger rows, so the union endpoint is compared with the countable sum inside the root surface.

For each covered inclusion used by the family, apply Definition 92.102. The finite relative-difference row compares the larger endpoint with the sum of the smaller endpoint and the displayed difference endpoint, using only the relative-difference decomposition supplied on the event ledger.

Apply Definition 92.217. Its public row transports the countable endpoint comparison through the $\mathsf{Real}^{\uparrow}$ classifier and keeps the countable sum attached to the displayed family endpoints.

The two comparisons share the same endpoint classifier field of the bridge. Thus the endpoint comparison visible to consumers is precisely the combination of countable additivity, finite relative-difference additivity, and $\mathsf{Real}^{\uparrow}$ classifier transport, with no host sigma-algebra equality or completion principle introduced. □

Theorem 92.226 (Measure root countable relative-difference consumer unblock)**.** *The* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumers may read exactly the bridge rows exposed by Definition 92.223: displayed event rows, StreamName-indexed countable-family rows, finite readback rows, relative-difference rows, endpoint rows, countable-sum rows, normalization rows where named, monotone rows where named, and no host set equality or completion principle.*

Proof. Project the consumer-facing ledger from Definition 92.223. The exactness field restricts the outgoing rows to the displayed event, countable-family, relative-difference, endpoint, and countable-sum rows already carried by the root bridge.

For $\mathsf{Integral}^{\uparrow}$, apply Definition 92.87. The integral consumer reads covered measurable-event rows, $\mathsf{Real}^{\uparrow}$ endpoint classifier rows, countable-sum endpoint rows, head-tail readback rows, and finite disjoint-union readback rows from the same public $\mathsf{Measure}^{\uparrow}$ package.

For $\mathsf{ProbSpace}^{\uparrow}$, apply Definition 92.88. The probability consumer reads the total-event normalization row together with empty-zero and finite disjoint-union rows; it does not receive the countable-family rows as an independent analytic completion.

For $\mathsf{FunctionalAnalysis}^{\uparrow}$, apply Definition 92.89. The functional analysis consumer reads only the nonnegative endpoint, monotone inclusion, relative-difference, and countable-sum classifier rows exposed by $\mathsf{Measure}^{\uparrow}$.

Combining the three projections gives the downstream threshold carried by the bridge. Each consumer reads exactly its named rows from the shared countable relative-difference ledger, and none obtains host set equality, quotient event equality, analytic completion, or a $\mathsf{StandardBridge}$ row. □

92.13 Measure root real-stream premeasure bridge

The real-stream premeasure bridge is the concrete root surface that lets downstream analysis chapters read countable premeasure data through the displayed BHist event rows, $\mathsf{StreamName}^{\uparrow}$ observation names, and $\mathsf{Real}^{\uparrow}$ endpoint comparisons already exposed by the $\mathsf{Measure}^{\uparrow}$ root. It is a bridge between existing root rows, not a host measure-space construction.

Definition 92.227 (Measure root real-stream premeasure surface)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root real-stream premeasure surface is the ten-field surface with the following data:*

1. *traditional target: a countable premeasure surface whose measurable events and countable disjoint sums are visible before any analytic completion is admitted;*
2. *BEDC source:* BHist*,* hsame*,* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*,* $\mathsf{StreamName}^{\uparrow}$*, and the existing* $\mathsf{Measure}^{\uparrow}$ *root rows of Definition 92.193;*
3. *carrier: displayed measurable-event* BHist *rows, the* $\mathsf{StreamName}^{\uparrow}$*-indexed observation family on those rows, and the* $\mathsf{Real}^{\uparrow}$ *endpoint value assigned to each displayed event;*
4. *classifier: componentwise* hsame *for event histories, StreamName classifier transport for observation names, and* $\mathsf{Real}^{\uparrow}$ *endpoint classifier transport for event values and countable sums;*
5. *stability rows: carrier transport, classifier transport, countable disjoint additivity, and ledger exactness over the displayed root rows;*
6. *ledger: measurable witnesses, disjointness witnesses, countable-family indices, countable-union witnesses, and countable-sum endpoints attached to the same displayed* BHist *rows;*

7. *exactness coverage: every covered row of the surface is one of the displayed rows named by the public root basis, the countable-premeasure front, and the real-stream event obligation;*
8. *exactness soundness: every accepted carrier, classifier, additivity, and ledger row has the corresponding visible witness in the same* BHist *ledger;*
9. *exactness completeness: every displayed row with its StreamName observation,* $\mathsf{Real}^{\uparrow}$ *endpoint, disjointness data, union witness, and countable-sum endpoint is accepted by the surface;*
10. *standard bridge boundary: no host set equality, quotient event equality, external sigma-algebra equality, analytic completion object, or* StandardBridge *row is part of this surface.*

Theorem 92.228 (Measure root real-stream premeasure carrier obligation)**.** *The surface of Definition 92.227 exposes exactly the* BHist *event carrier,* $\mathsf{StreamName}^{\uparrow}$ *observation family,* $\mathsf{Real}^{\uparrow}$ *endpoint map, and visible ledger rows needed by the* $\mathsf{Measure}^{\uparrow}$ NameCert.

Proof. Start with the public root basis of Definition 92.193. Its carrier field gives the displayed BHist event rows, while its ledger field attaches measurable witnesses, endpoint witnesses, disjointness witnesses, and countable-sum witnesses only to displayed rows.

Read the same event row through Definition 92.166. The real-stream front adds the $\mathsf{StreamName}^{\uparrow}$ observation family and the attached $\mathsf{Real}^{\uparrow}$ endpoint comparison without changing the underlying event carrier.

Apply Definition 92.218. It identifies each carried root event with a displayed event history, a StreamName observation name, and the real endpoint comparison on the same ledger row.

The carrier, observation, endpoint, and ledger clauses of Definition 92.227 are precisely this combined reading. Since the boundary clause excludes host set equality and quotient event equality, the exposed carrier is exactly the visible root carrier required by the $\mathsf{Measure}^{\uparrow}$ NameCert. □

Theorem 92.229 (Measure root real-stream premeasure classifier obligation)**.** *For the surface of Definition 92.227, componentwise* hsame*, StreamName classifier transport, and* $\mathsf{Real}^{\uparrow}$ *endpoint classifier transport preserve the carried premeasure row and its ledger.*

Proof. Begin with a displayed premeasure row and a componentwise hsame comparison of its BHist event histories. The public root basis transports the carried event code and its visible ledger witnesses along the same root classifier row.

Apply Definition 92.220. It keeps the carried $\mathsf{Measure}^{\uparrow}$ root row stable under componentwise hsame together with StreamName observation transport and $\mathsf{Real}^{\uparrow}$ endpoint transport.

The classifier field of Definition 92.227 adds no independent classifier. It records exactly the event-history transport, the StreamName transport, and the endpoint transport already aligned by the event classifier stability theorem.

The ledger is preserved because its measurable witnesses, disjointness witnesses, countable-family indices, union witnesses, and countable-sum endpoints remain attached to the transported displayed row. Thus the premeasure row and its ledger are invariant under the stated classifier motion. □

Theorem 92.230 (Measure root real-stream premeasure sigma-additivity obligation)**.** *The countable disjoint-additivity row of Definition 92.227 is read by combining the existing root public obligation basis, the countable-premeasure front, the real-stream event obligation, and countable-sum classifier stability over the same displayed* BHist *ledger.*

Proof. Project a countable disjoint family from the ledger of Definition 92.227. Its component events, disjointness witnesses, countable-family index, union witness, and countable-sum endpoint are all displayed rows over the same BHist carrier.

Apply Definition 92.193 and Definition 92.221. These keep the countable additivity obligation scoped to visible event families, their union row, and the public ledger, with no external sigma-algebra row.

Next apply Definition 92.162 and Definition 92.164. They read the same visible family as a countable premeasure row whose union value is compared with the countable sum of its component $\mathsf{Real}^{\uparrow}$ endpoints.

Finally apply Definition 92.218 to read the components through StreamName observations, and apply Definition 92.220 together with Definition 92.12 to keep endpoint and countable-sum classifier transport aligned with the displayed event histories.

Combining these rows gives the sigma-additivity obligation of the surface: the value of the displayed union is the countable $\mathsf{Real}^{\uparrow}$ endpoint sum of the displayed disjoint component events, with every witness remaining inside the visible ledger. The conclusion does not assert host-level measure theory, quotient event equality, or analytic completion. □

92.14 Measure BHist root obligation basis

The $\mathsf{Measure}^{\uparrow}$ root obligation basis is read directly on displayed BHist histories. It records the BEDC carrier, classifier, endpoint, and public-ledger rows consumed by downstream analysis chapters before any host event space, analytic completion, or standard bridge is introduced.

Definition 92.231 (Measure BHist root obligation basis)**.** *The* $\mathsf{Measure}^{\uparrow}$ BHist *root obligation basis is the counted public surface with the following fields:*

1. *BEDC source:* BHist *histories with componentwise* hsame *as the only history transport relation;*
2. *carrier rows: visible* MeasCode *event rows displayed in the* $\mathsf{Measure}^{\uparrow}$ *public ledger;*
3. *StreamName rows:* $\mathsf{StreamName}^{\uparrow}$ *observation names for the countable event families consumed by the root;*
4. *endpoint rows:* $\mathsf{Real}^{\uparrow}$ *value endpoints, nonnegative endpoints, normalization endpoints, and countable-sum endpoints, all read through the public* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *certificate;*
5. *classifier rows: the public* $\mathsf{Measure}^{\uparrow}$ *classifier* $\sim_M$ *factored through componentwise* hsame*, pointwise* $\mathsf{StreamName}^{\uparrow}$ *transport, and* $\mathsf{Real}^{\uparrow}$ *endpoint classifier transport;*
6. *ledger rows: event witnesses, countable-family witnesses, disjointness witnesses, countable-union witnesses, endpoint witnesses, and countable-sum witnesses attached to displayed rows;*
7. *consumer rows: the* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *projections that read only the displayed* BHist *ledger;*
8. *exclusions: no host set equality, quotient event equality, analytic completion object, or standard bridge row is exported.*

This basis is the common projection of the public root basis Definition 92.193, the real-stream event surface section 92.11, and the root-kernel source Definition 92.201.

Theorem 92.232 (Measure BHist root carrier obligation)**.** *Every accepted* $\mathsf{Measure}^{\uparrow}$ *event row in Definition 92.231 is a displayed* BHist *event carrier equipped with its* $\mathsf{StreamName}^{\uparrow}$ *observation row and its* $\mathsf{Real}^{\uparrow}$ *endpoint witnesses. No accepted row is read through an external event carrier.*

Proof. Begin with the BEDC source, carrier rows, StreamName rows, and endpoint rows of Definition 92.231. These fields place the event carrier in BHist and attach the observation name and real endpoint data to the same public ledger row.

Apply Definition 92.194. It supplies the public MeasCode carrier, visible event rows, endpoint rows, countable-family rows, and attached ledger witnesses.

Next apply Definition 92.218. The real-stream event surface identifies the accepted event row as a displayed BHist event history with a $\mathsf{StreamName}^{\uparrow}$ observation and a $\mathsf{Real}^{\uparrow}$ endpoint comparison on that same row.

Finally apply Definition 92.202. The kernel source confirms that componentwise hsame and the public $\mathsf{Measure}^{\uparrow}$ classifier keep the carrier, event, endpoint, countable-family, and ledger rows attached to the displayed history. Repacking these three projections gives exactly the stated carrier obligation. □

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureBHistRootCarrier obligation`

Theorem 92.233 (Measure BHist root classifier obligation)**.** *Classifier transport for Definition 92.231 consists only of componentwise* hsame *transport of displayed histories, pointwise* $\mathsf{StreamName}^{\uparrow}$ *transport of observation names, and* $\mathsf{Real}^{\uparrow}$ *endpoint classifier transport. It does not add host set equality or quotient event equality.*

Proof. Project the classifier rows of Definition 92.231. They factor the public $\mathsf{Measure}^{\uparrow}$ classifier through componentwise hsame, StreamName observation movement, and $\mathsf{Real}^{\uparrow}$ endpoint comparison.

Apply Definition 92.220. It preserves the carried root event row and the visible ledger under componentwise hsame, pointwise $\mathsf{StreamName}^{\uparrow}$ transport, and $\mathsf{Real}^{\uparrow}$ endpoint classifier transport.

Now apply Definition 92.202. The root-kernel source keeps the same transported event, endpoint, countable-family, and ledger rows attached to the BHist carrier.

The exclusions field of Definition 92.231 has no host set equality field and no quotient event equality field. Therefore the classifier obligation is exactly the componentwise history transport, observation-name transport, and endpoint classifier transport described above. □

Theorem 92.234 (Measure BHist root ledger obligation)**.** *The exported ledger of Definition 92.231 contains event witnesses, countable-family witnesses, disjointness rows, countable-union rows, endpoint witnesses, and countable-sum rows for the displayed* BHist *root. It excludes host set equality, quotient event equality, analytic completion, and standard bridges.*

Proof. Read the ledger rows and consumer rows of Definition 92.231. They attach every downstream witness to displayed event, countable-family, disjointness, union, endpoint, and countable-sum rows in the public NameCert ledger.

Apply Definition 92.195. This supplies empty-zero, finite readback, relative-difference, countable disjoint-additivity, and countable-sum transport over the same visible ledger.

Next apply Definition 92.221. It scopes the countable disjoint-additivity obligation to displayed BHist event families, $\mathsf{StreamName}^{\uparrow}$ observation names, $\mathsf{Real}^{\uparrow}$ endpoint sums, and the public ledger.

Finally apply Definition 92.204. The kernel source exports only the $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ consumer boundary over those rows.

The exclusions field of the basis and the cited kernel source contain no host set equality, no quotient event equality, no analytic completion object, and no standard bridge row. Repacking the ledger projections therefore gives exactly the exported ledger stated in the theorem. □

Definition 92.235 (Measure root BHist NameCert input packet)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root* BHist $\mathsf{NameCert}$ *input packet is the ten-field public packet whose fields are:*

1. *the source carrier* BHist*;*
2. *the componentwise history classifier* hsame*;*
3. *the continuation row* Cont *used to preserve displayed root histories;*
4. *the* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint certificate;*
5. *the additive* $\mathsf{AbGroup}^{\uparrow}$ *real row for endpoint sums and differences;*
6. *the* $\mathsf{StreamName}^{\uparrow}$ *countable-family name rows;*
7. *the displayed measurable-event carrier and classifier rows of the root* $\mathsf{Measure}^{\uparrow}$ *ledger;*
8. *the empty-zero, finite disjoint-union, countable-disjoint-additivity, relative-difference, and continuity-from-below rows read from the same ledger;*
9. *the consumer boundary rows for* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*;*
10. *the exclusion row stating that no quotient event equality, host set equality, standard bridge row, or open-cover compactness row is part of the packet.*

Thus the packet is a single BHist*-facing input surface for the root measure certificate and its three displayed downstream consumers.*

Theorem 92.236 (Measure root BHist input carrier-classifier)**.** *The packet of Definition 92.235 supplies exactly the carrier and classifier transport required by the root* $\mathsf{Measure}^{\uparrow}$ *domain: displayed* BHist *event carriers, componentwise* hsame *classifier movement,* Cont *preservation of root histories,* $\mathsf{StreamName}^{\uparrow}$ *countable-family transport, and* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint transport. No downstream consumer row is needed to obtain this carrier-classifier face.*

Proof. Start with the source carrier, classifier, continuation, endpoint, additive, countable-family, and displayed ledger fields of Definition 92.235. These fields are all root-facing input rows, so the carrier-classifier face can be read before any consumer projection is used.

Apply Definition 92.232. It places every accepted event row on a displayed BHist carrier with its $\mathsf{StreamName}^{\uparrow}$ observation row and $\mathsf{Real}^{\uparrow}$ endpoint witnesses.

Apply Definition 92.233. This identifies the classifier transport as componentwise hsame movement of histories, pointwise $\mathsf{StreamName}^{\uparrow}$ transport, and $\mathsf{Real}^{\uparrow}$ endpoint classifier transport, with no host set equality or quotient event equality.

Finally apply Definition 92.119. The domain-ready package repacks those same rows with Cont, $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, the additive $\mathsf{AbGroup}^{\uparrow}$ real row, and the $\mathsf{StreamName}^{\uparrow}$ countable-family names. Hence the packet supplies exactly the carrier-classifier transport stated above. □

Theorem 92.237 (Measure root BHist input countable additivity)**.** *The packet of Definition 92.235 supplies the empty-zero row, finite disjoint-union readback, countable-disjoint additivity, relative-difference additivity, and continuity-from-below row for the root* $\mathsf{Measure}^{\uparrow}$ *ledger. These rows are read on displayed* BHist *event families with* $\mathsf{StreamName}^{\uparrow}$ *names and* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint sums.*

Proof. Project the additivity field of Definition 92.235. It contains the empty event, finite disjoint unions, covered pairwise-disjoint countable families, relative differences, increasing chains, $\mathsf{Real}^{\uparrow}$ endpoint comparisons, additive real rows, and visible ledger witnesses.

Apply Definition 92.96. It gives the countable-disjoint comparison for covered measurable sequences, and it reads the empty-zero and finite disjoint-union rows from the same public threshold package.

Next apply Definition 92.120. This places sigma-additivity, empty-zero, finite disjoint-union readback, finite-support countable readback, relative-difference additivity, and continuity from below on the domain-ready root package.

Finally apply Definition 92.234. The ledger obligation pins these witnesses to displayed BHist event rows, countable-family rows, disjointness rows, countable-union rows, endpoint witnesses, and countable-sum rows. Repacking the three cited sources gives exactly the countable-additivity face of the packet. □

Theorem 92.238 (Measure root BHist input consumer exactness)**.** *The packet of Definition 92.235 is exactly the root* Measure$^{\uparrow}$ *surface consumed by* Integral$^{\uparrow}$, ProbSpace$^{\uparrow}$, *and* FunctionalAnalysis$^{\uparrow}$. *The consumers read the displayed carrier-classifier, endpoint, additivity, relative-difference, and continuity rows of the packet; they do not consume quotient event equality, host set equality, standard bridge rows, or open-cover compactness rows.*

Proof. Begin with the consumer boundary and exclusion fields of Definition 92.235. The boundary names only the Integral$^{\uparrow}$, ProbSpace$^{\uparrow}$, and FunctionalAnalysis$^{\uparrow}$ rows, while the exclusion row removes quotient event equality, host set equality, standard bridge data, and open-cover compactness data from the input surface.

Apply Definition 92.121. It reads the carrier-classifier and sigma-additive rows as exactly the rows consumed by the three downstream faces, with no quotient event equality, no host set equality, and no standard bridge row.

Apply Definition 92.97. This identifies the Integral$^{\uparrow}$ boundary, the ProbSpace$^{\uparrow}$ normalization boundary, and the FunctionalAnalysis$^{\uparrow}$ nonnegative, monotone, relative-difference, and countable-sum boundary as the shared root surface and nothing beyond it.

Finally apply Definition 92.150. Its deps-ready package exports only visible event rows, endpoint classifier rows, endpoint-family rows, continuation rows, and displayed ledger witnesses to the same consumers. Combining these projections proves that the packet is the exact consumer input surface and that the four excluded row classes are not consumed. □

92.15 Measure root finite disjoint event envelope

The finite disjoint event envelope is the kernel-facing Measure$^{\uparrow}$ package used when downstream analysis chapters need a single finite event family, its displayed union, its Real$^{\uparrow}$ value fold, and the ledger rows that make the finite support visible. It is a finite BHist event package, not a sigma-complete event space or a standard bridge.

Definition 92.239 (Measure root finite disjoint event envelope)**.** *The* Measure$^{\uparrow}$ *root finite disjoint event envelope is the ten-field package attached to a displayed finite family* $E_0, \ldots, E_{n-1}$ *of* BHist *event rows:*

1. *source: the root public* Measure$^{\uparrow}$ *basis of Definition 92.193, the root event boundary of section 92.8, and the finite-support consumer front of Definition 92.186;*
2. *carrier: each* E_i *is a carried* BHist *event row covered by the root* Measure$^{\uparrow}$ *event carrier;*
3. *classifier: event comparison is the public* Measure$^{\uparrow}$ *classifier projected to componentwise* hsame *on displayed event histories and to the* Real$^{\uparrow}$ *classifier on endpoint rows;*

4. *disjointness: the family is pairwise disjoint after any classifier transport admitted by the root event boundary;*
5. *finite union: the package displays a finite union row* $U_n = E_0 \sqcup \cdots \sqcup E_{n-1}$ *in the same* BHist *ledger;*
6. *value rows: each component has a* $\mathsf{Real}^{\uparrow}$ *value endpoint* $\mu(E_i)$ *and the union has a* $\mathsf{Real}^{\uparrow}$ *value endpoint* $\mu(U_n)$*;*
7. *fold row: the finite endpoint* $\mathsf{fold}_R(\mu(E_0), \ldots, \mu(E_{n-1}))$ *is built by the additive* $\mathsf{AbGroup}^{\uparrow}$ *row carried by* $\mathsf{Real}^{\uparrow}$*;*
8. *support ledger: the finite family is embedded as a countable family with a constant empty tail, together with the visible finite-support ledger row;*
9. *consumer boundary:* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *may read only the carrier, finite union, value fold, and support-ledger rows named here;*
10. *excluded surface: no sigma-completeness row, open-cover compactness row, quotient event equality, host set equality, analytic completion object, or* StandardBridge *row is part of the envelope.*

Theorem 92.240 (Measure root finite disjoint carrier classifier)**.** *The envelope of Definition 92.239 projects carried* $\mathsf{Measure}^{\uparrow}$ *event rows, classifier-stable pairwise disjointness, and* $\mathsf{Real}^{\uparrow}$ *carrier rows from the existing root carrier, classifier, and event boundary packages. Thus every component event, its transported disjointness relation, its endpoint value, and the displayed finite union remain rows of the same root* BHist *ledger.*

Proof. Start with the carrier and classifier fields of Definition 92.193. By Definition 92.194, each displayed event row in the finite family is a carried BHist row, and classifier transport keeps the attached endpoint and ledger witnesses on the transported row.

Next read the same finite family through Definition 92.190. The event boundary exposes the visible event rows, finite union rows, endpoint rows, and ledger rows without replacing the displayed event carrier by a host-level event object.

For disjointness, use Definition 92.191. Its classifier is componentwise hsame on displayed histories together with $\mathsf{Real}^{\uparrow}$ endpoint comparison. Pairwise disjointness in the envelope is therefore stable exactly under the same classifier motion.

Finally project the endpoint rows through Definition 92.187. The finite support spine and the empty tail are read from the root carrier ledger, so the component values, finite union value, and support ledger all remain visible $\mathsf{Measure}^{\uparrow}$ root rows. □

Theorem 92.241 (Measure root finite disjoint additivity)**.** *For every envelope of Definition 92.239, the displayed finite union value is classified by the finite* $\mathsf{Real}^{\uparrow}$ *fold of the component values:*

$$\mu(U_n) \sim_R \mathsf{fold}_R(\mu(E_0), \ldots, \mu(E_{n-1})).$$

The classification is read from the countable-additivity row, the finite-support empty-tail readback, and the finite disjoint-union additivity packages already exposed by the $\mathsf{Measure}^{\uparrow}$ *root.*

Proof. Embed the finite family into a countable family by appending the constant empty tail named in the support-ledger field of the envelope. The carrier part of Definition 92.240 keeps the finite spine, the empty tail, and the displayed union in the same BHist ledger.

Apply Definition 92.195. It supplies the countable disjoint-additivity row, the finite readback row, and the countable-sum classifier transport over the visible ledger.

The empty tail is read by Definition 92.188 and Definition 92.23. These rows identify the countable endpoint of the finite-support family with the finite $\mathsf{Real}^{\uparrow}$ fold of the displayed component endpoints.

It remains to compare the displayed finite union endpoint with that finite fold. Use Definition 92.26 along the finite union tree, with additive congruence and associativity from the $\mathsf{Real}^{\uparrow}$ $\mathsf{AbGroup}^{\uparrow}$ row. Composing these classifier comparisons gives the displayed readback for $\mu(U_n)$. □

Theorem 92.242 (Measure root finite disjoint consumer threshold)**.** *The downstream* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumers of a Definition 92.239 may read exactly the event carrier, displayed finite union,* $\mathsf{Real}^{\uparrow}$ *value fold, and finite-support ledger rows of the envelope. They receive no sigma-completeness row, open-cover compactness row, standard bridge row, quotient event equality, host set equality, or analytic completion object from this package.*

Proof. Begin with the consumer boundary field of Definition 92.239. It names only the carrier, finite union, value fold, and finite-support ledger rows as outgoing analysis data.

For the shared carrier and endpoint rows, apply Definition 92.240. This pins every consumer-visible event and value to the root BHist ledger and the $\mathsf{Real}^{\uparrow}$ endpoint classifier.

For the finite value readback, apply Definition 92.241. The downstream consumers see the displayed union value only through the finite fold comparison supplied by the envelope.

Now project the three consumer faces through Definition 92.189, Definition 92.87, Definition 92.88, and Definition 92.89. These projections read finite-support rows from the same root package and do not add a fourth consumer or a broader analytic interface.

The excluded-surface field of the envelope contains no slot for sigma-completeness, open-cover compactness, quotient event equality, host set equality, analytic completion, or $\mathsf{StandardBridge}$ data. Therefore the three analysis consumers receive exactly the four named row families and no larger surface. □

92.16 Measure root event-value closure

The event-value closure package records the smallest root surface that downstream analysis chapters may cite when they need the $\mathsf{Measure}^{\uparrow}$ event carrier, its public value rows, and its countable-family endpoint rows together.

Definition 92.243 (Measure root event-value closure package)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root event-value closure package is the following three-field public root package.*

1. *event carrier and classifier field: the carried* BHist *event rows, the* $\mathsf{MeasCode}$ *carrier predicate, componentwise* hsame *event transport, and the public* $\sim_M$ *classifier read through* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint transport;*

2. *countable-family field: each* $\mathsf{StreamName}^{\uparrow}$*-indexed row names a visible family of carried* BHist *events, pairwise-disjoint witnesses, countable-union readback, and the attached* $\mathsf{Real}^{\uparrow}$ *countable-sum endpoint;*

3. *endpoint and consumer field: the value of each carried event and the value of each displayed countable union are compared only through* $\mathsf{Real}^{\uparrow}$ *endpoint rows, and the only downstream consumers are* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *reading those displayed rows.*

The package contains no host set equality, no quotient event equality, no analytic completion object, and no open-cover compactness row.

Theorem 92.244 (Measure root carrier-value event closure)**.** *The carrier and value face of Definition 92.243 is exactly the carrier, classifier, event-row, stream-observation, and* $\mathsf{Real}^{\uparrow}$ *endpoint face supplied by Definition 92.193, Definition 92.218, and Definition 92.220.*

Proof. Read the first and third fields of Definition 92.243. They name a carried BHist event row, the $\mathsf{MeasCode}$ carrier, the public $\sim_M$ classifier, StreamName observation data, and $\mathsf{Real}^{\uparrow}$ endpoint comparisons for the visible value rows.

Apply Definition 92.193. Its carrier, classifier, stability, and ledger fields supply the same carried event rows, endpoint witnesses, and public classifier transport, with every hidden witness attached to a displayed row.

Apply Definition 92.218. It reads the same root row as a displayed event history, a StreamName observation name, and the attached real endpoint comparison.

Finally apply Definition 92.220. The componentwise hsame event motion, StreamName observation motion, and $\mathsf{Real}^{\uparrow}$ endpoint motion preserve the carried row and its visible ledger. Thus the carrier-value face is precisely the displayed public face cited in the statement.

None of the three cited surfaces introduces host set equality, quotient event equality, analytic completion, or open-cover compactness. Therefore the closure package exports no such row on its carrier-value face. □

Theorem 92.245 (Measure root countable-additivity event-value closure)**.** *The countable-additivity face of Definition 92.243 is exactly the displayed* BHist *countable-family surface, StreamName observation surface, disjoint-union readback, and* $\mathsf{Real}^{\uparrow}$ *endpoint-sum comparison supplied by Definition 92.221 and Definition 92.207.*

Proof. Project the countable-family field of Definition 92.243. It has only StreamName-indexed carried event families, pairwise-disjoint witnesses, countable-union readback, and the displayed $\mathsf{Real}^{\uparrow}$ countable-sum endpoint.

Apply Definition 92.221. The theorem confines countable disjoint-additivity to displayed BHist event families, StreamName observation names, real endpoint sums, and visible ledger rows of the public basis.

Apply Definition 92.207. It supplies measurable-sequence coverage, disjoint-union readback, and $\mathsf{Real}^{\uparrow}$ endpoint comparison through the same public ledger and componentwise classifier motion.

The two source theorems account for every countable-family row named by the closure package. They do not add an external sigma-algebra equality, quotient event equality, analytic completion, or open-cover compactness principle, so the additive face remains exactly the event-value surface stated above. □

Theorem 92.246 (Measure root analysis-consumer event-value closure)**.** *The downstream* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumers of Definition 92.243 consume only the displayed event rows,* $\mathsf{Real}^{\uparrow}$ *endpoint rows, countable-sum rows, finite-readback rows, normalization rows, monotone rows, relative-difference rows, and visible ledger rows supplied by Definition 92.222 and Definition 92.208.*

Proof. Read the endpoint and consumer field of Definition 92.243. It names exactly the three outgoing consumers $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$, and it restricts their input to displayed event rows, endpoint rows, countable-family rows, and visible ledger rows.

Apply Definition 92.222. It identifies the rows consumed by the three analysis chapters as displayed event rows, endpoint rows, countable-sum rows, finite-readback rows, normalization rows, monotone rows, and relative-difference rows carried by the public root and real-stream fronts.

Apply Definition 92.208. It restricts the same consumer triad to carrier/classifier rows, countable-additivity rows, nonnegative endpoint rows, and ledger rows displayed by the root minimum triad.

Intersecting these two readings leaves exactly the event-value rows listed in the statement: no fourth analysis consumer, no host set equality, no quotient event equality, no analytic completion, and no open-cover compactness. Hence the downstream consumers can cite the closure package without reconstructing any larger root interface. □

Definition 92.247 (Measure root countable-classifier presentation)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root countable-classifier presentation is the public countable-premeasure face whose visible carrier consists of* BHist *event rows equipped with the* hsame *transport already exposed by Definition 92.162. Its countable-family input is read through* $\mathsf{StreamName}^{\uparrow}$ *rows, so a family is displayed only by its stream name, its covered component event rows, and its covered union row. Its value side is read through* $\mathsf{Real}^{\uparrow}$ *endpoint classifiers: every event row, finite sum row, relative-difference row, continuity-from-below endpoint, and countable-sum row carries only the endpoint comparison supplied by* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$*.*

The presentation ledger is the ledger of Definition 92.162 restricted to the rows needed by countable classification: carried event rows, measurable-witness transport, $\mathsf{StreamName}^{\uparrow}$ *component indices, disjointness rows, covered union rows, countable-sum endpoints, and* $\mathsf{Real}^{\uparrow}$ *classifier comparisons. No host set equality, quotient event equality, analytic completion object, or consumer-specific classifier is part of this presentation.*

Theorem 92.248 (Measure root countable-classifier carrier scope)**.** *The presentation of Definition 92.247 exposes only covered* BHist *event rows,* $\mathsf{Real}^{\uparrow}$ *endpoint rows, carrier transport, and classifier transport. Every displayed row of the presentation is one of those four row classes, and each of those four classes is supplied by the countable-premeasure carrier obligation.*

Proof. Apply Definition 92.163. It fixes the carrier side of the countable-premeasure front as the covered BHist measurable-event rows and the $\mathsf{Real}^{\uparrow}$ endpoint classifiers attached to their values.

The definition of Definition 92.247 only renames that front as a countable-classifier surface. Its $\mathsf{StreamName}^{\uparrow}$ and countable-sum clauses are ledger clauses over the same displayed event rows, so they do not add a host row or an independent carrier.

Thus the carrier scope is exhausted by the covered event rows, endpoint rows, carrier transport, and classifier transport already supplied by the cited obligation. □

Theorem 92.249 (Measure root countable-classifier stability)**.** *The presentation of Definition 92.247 is stable under finite additivity, relative-difference transport, continuity from below, and countable-sum classifier comparison. These four stability clauses are exactly the clauses obtained by composing the countable-premeasure additivity obligation, relative-difference additivity, the continuity-from-below package, and countable-sum classifier stability.*

Proof. Start with Definition 92.164. It supplies the root additivity row for the covered countable family and includes the finite readback needed for finite disjoint unions.

For relative differences, apply Definition 92.102 to the same carried event rows and $\mathsf{Real}^{\uparrow}$ endpoints. This transports the value comparison through the displayed relative-difference row without adding a new classifier.

For increasing unions, use Definition 92.42. Its source rows are covered event rows and countable-family rows already present in the presentation ledger, and its endpoint output is a $\mathsf{Real}^{\uparrow}$ comparison.

Finally apply Definition 92.12. It turns pointwise $\mathsf{Real}^{\uparrow}$ endpoint comparisons along the $\mathsf{StreamName}^{\uparrow}$ family into the countable-sum endpoint comparison. The four cited clauses therefore give all stability rows named by the presentation. □

Theorem 92.250 (Measure root countable-classifier downstream interface)**.** *The outgoing rows from Definition 92.247 to* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *are exactly the carrier rows, classifier rows, and stability rows named in Definition 92.248 and Definition 92.249. No downstream consumer receives an additional host equality, quotient equality, or completion row from the root presentation.*

Proof. Apply Definition 92.165. It fixes the $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ consumer faces as projections of the countable-premeasure front.

Next apply Definition 92.200. The bridge identifies the outgoing premeasure rows with the downstream threshold rows and keeps the consumer interface inside the same root ledger.

The carrier and classifier part of that ledger is exactly the scope proved in Definition 92.248. The additivity, relative-difference, continuity-from-below, and countable-sum part is exactly the stability package proved in Definition 92.249.

Hence each named downstream chapter reads precisely those carrier, classifier, and stability rows, and no further row leaves the root countable-classifier presentation. □

Definition 92.251 (Measure root NameCert front)**.** *The* $\mathsf{Measure}^{\uparrow}$ *root* $\mathsf{NameCert}$ *front is the ten-field public package that downstream consumers read before forming any analytic completion or consumer-local quotient:*

1. *event carrier field: visible* BHist *event rows and the* $\mathsf{MeasCode}$ *predicate certifying that each event row is carried by the root measure surface;*
2. *event classifier field: componentwise* hsame *transport on* BHist *event presentations, read externally as the public* $\sim_M$ *classifier;*
3. *NameCert carrier field: the root* $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ *carrier row that packages the measurable-event witnesses without host set equality;*
4. *NameCert classifier field: the root* $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ *classifier row identifying exactly the displayed event and endpoint classifier motion;*
5. *StreamName family field: countable families named through* $\mathsf{StreamName}^{\uparrow}$, *including displayed component rows, disjointness rows, and union rows;*
6. *Real endpoint field: value rows, finite-sum rows, relative-difference rows, continuity-from-below rows, and countable-sum rows compared only by* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *endpoint classifiers;*
7. *stability field: finite additivity, relative-difference transport, continuity from below, and countable-additivity stability over the same visible rows;*
8. *ledger field: the visible root ledger attaching every hidden witness to a displayed event row, endpoint row, countable-family row, or consumer row;*
9. *downstream consumer field: the three outgoing faces named* $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$*;*
10. *exclusion field: no host set equality, quotient event equality, analytic completion, or open-cover compactness row is part of the front.*

Theorem 92.252 (Measure root NameCert front carrier)**.** *The carrier face of Definition 92.251 is exactly the* BHist *event-row carrier,* $\mathsf{MeasCode}$ *predicate,* $\sim_M$ *classifier, root* $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ *carrier-classifier row, and countable-classifier carrier scope supplied by Definition 92.6, Definition 92.7, Definition 92.17, and Definition 92.248.*

Proof. Read the first four fields of Definition 92.251. They name the visible BHist event rows, the $\mathsf{MeasCode}$ carrier predicate, componentwise hsame transport, the public $\sim_M$ classifier, and the root $\mathsf{NameCert}_{\mathsf{Measure}^\uparrow}$ carrier-classifier row.

Apply Definition 92.6. Its inventory lists the carried event rows, measurable witnesses, classifier transport, endpoint rows, and ledger attachments that may appear on the root carrier surface. Apply Definition 92.7 to restrict the classifier to event-witness motion and $\mathsf{Real}^\uparrow$ endpoint comparison.

Next apply Definition 92.17. It identifies the root $\mathsf{NameCert}_{\mathsf{Measure}^\uparrow}$ carrier and classifier with exactly those displayed rows. Apply Definition 92.248 to include the countable-family carrier side without adding a second carrier.

The exclusions field of the front is therefore inherited from the cited carrier rows: none of them supplies host set equality, quotient event equality, analytic completion, or open-cover compactness. Hence the front carrier is precisely the carrier face stated above. □

Theorem 92.253 (Measure root NameCert front classifier)**.** *The classifier face of Definition 92.251 is stable under the root* $\mathsf{NameCert}_{\mathsf{Measure}^\uparrow}$ *exactness rows, the countable classifier presentation, and the countable-additivity event-value closure. Equivalently, all classifier motion in the front is obtained from Definition 92.18, Definition 92.249, and Definition 92.245.*

Proof. Project the event classifier, Real endpoint, stability, and ledger fields of Definition 92.251. They allow event motion only through componentwise hsame and endpoint motion only through $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ classifier rows.

Apply Definition 92.18. Its exactness clauses attach every root $\mathsf{NameCert}_{\mathsf{Measure}^\uparrow}$ stability witness to the displayed event, endpoint, and ledger rows of the root surface.

For countable families, apply Definition 92.249. It transports finite additivity, relative differences, continuity from below, and countable-sum comparison through the countable-classifier presentation.

Finally use Definition 92.245. That theorem identifies the countable-additivity event-value face with displayed BHist families, $\mathsf{StreamName}^\uparrow$ observation rows, disjoint-union readback, and $\mathsf{Real}^\uparrow$ endpoint-sum comparison. Thus the front classifier contains only stable visible rows and no host equality, quotient event equality, analytic completion, or open-cover compactness. □

Theorem 92.254 (Measure root NameCert front ledger)**.** *The downstream ledger of Definition 92.251 exports to* $\mathsf{Integral}^\uparrow$*,* $\mathsf{ProbSpace}^\uparrow$*, and* $\mathsf{FunctionalAnalysis}^\uparrow$ *exactly the carrier rows, classifier rows, stability rows, event-value rows, and minimum consumer obligations supplied by Definition 92.250, Definition 92.246, and Definition 92.208.*

Proof. Read the ledger and downstream consumer fields of Definition 92.251. They name a visible root ledger and exactly three consumers: $\mathsf{Integral}^\uparrow$, $\mathsf{ProbSpace}^\uparrow$, and $\mathsf{FunctionalAnalysis}^\uparrow$.

Apply Definition 92.250. It exports the carrier, classifier, and stability rows of the countable-classifier presentation to the three named downstream chapters and blocks any additional host equality, quotient equality, or completion row.

Next apply Definition 92.246. It identifies the event-value rows consumed by the same three analysis chapters: displayed event rows, endpoint rows, countable-sum rows, finite-readback rows, normalization rows, monotone rows, relative-difference rows, and visible ledger rows.

Finally apply Definition 92.208. It restricts the consumer package to carrier/classifier rows, countable-additivity rows, nonnegative endpoint rows, and root ledger rows. Intersecting these three projections gives the ledger exported by the front, with no host set equality, quotient event equality, analytic completion, or open-cover compactness. □

Theorem 92.255 (Measure root NameCert front obligation status)**.** *Definition 92.251, together with Definition 92.252, Definition 92.253, and Definition 92.254, enumerates the* $\mathsf{Measure}^{\uparrow}$ *root obligation set: the carrier and classifier rows, countable-family rows through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$ *endpoint rows, stability and exactness rows, ledger rows, and the* $\mathsf{Integral}^{\uparrow}/\mathsf{ProbSpace}^{\uparrow}/\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer faces. The same front excludes host set equality, quotient event equality, analytic completion, and standard bridges.*

Proof. Project the ten fields of Definition 92.251. The first four fields name the event carrier, event classifier, root $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ carrier, and root $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ classifier. By Definition 92.252, these are exactly the carrier-classifier rows of the root surface.

The fifth through seventh fields name the $\mathsf{StreamName}^{\uparrow}$ countable-family rows, the $\mathsf{Real}^{\uparrow}$ endpoint rows, and the stability rows. Apply Definition 92.253; it identifies this motion with the exactness rows, countable-classifier presentation, and countable-additivity event-value closure.

The eighth and ninth fields name the visible ledger and the three outgoing consumer faces. By Definition 92.254, these fields export exactly the ledger and consumer rows read by $\mathsf{Integral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{FunctionalAnalysis}^{\uparrow}$.

The tenth field is the exclusion field. It rules out host set equality, quotient event equality, analytic completion, and standard bridges, so the front enumerates precisely the obligation set stated above. □

Zero BHist Terminal Standard Bridge

Definition 92.256 (Zero BHist terminal standard measure reference)**.** *The terminal standard measure reference for the zero* $\mathsf{BHist}\ \mathsf{Measure}^{\uparrow}$ *surface is the one-row host-facing reference* $T^*_{\mu=0}$*. It has one visible event* $*_E$*, one visible value* 0_T*, and one accepted history representative. Every event classifier in* $T^*_{\mu=0}$ *is terminal:*

$$*_E \sim_T *_E.$$

The value map sends the unique event to 0_T*. Every displayed countable disjoint family in* $T^*_{\mu=0}$ *is read back to the same row: each member, its countable union, and the selected countable sum all have value* 0_T*.*

The bridge ledger for $T^*_{\mu=0}$ *is limited to the public zero* $\mathsf{BHist}\ \mathsf{Measure}^{\uparrow}$ *rows already displayed in Definition 92.48 and Definition 92.53: the carried history is the empty* BHist *row, the event inventory is the singleton empty-event row, all union and disjointness rows are the same singleton row, the value endpoint is* 0_R*, and the countable-sum endpoint is the constant* 0_R *row.*

Theorem 92.257 (Zero BHist terminal standard bridge)**.** *The public zero* $\mathsf{BHist}\ \mathsf{Measure}^{\uparrow}$ *NameCert surface of Definition 92.51 interprets in the terminal standard reference of Definition 92.256. Conversely, that terminal reference maps back to the same zero* BHist *carrier, classifier, zero event value, countable-additivity readback, exactness rows, and ledger rows displayed by the public* $\mathsf{Measure}^{\uparrow}$ *surface. The bridge uses only the classifier rows on those displayed carriers; it does not assert host set equality, quotient event equality, analytic completion, or sigma-complete measure theory.*

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureZeroBHist terminal standard bridge`

Proof. For the BEDC-to-standard direction, apply the zero BHist surface of Definition 92.48. The carrier row is $\mathsf{ZeroMeasureCode}(h) \iff \mathsf{hsame}(h, \mathsf{e})$, the event inventory is the singleton empty-event row, and the value endpoint is always 0_R. The carrier and classifier transport required to encode this surface in $T^*_{\mu=0}$ is exactly Definition 92.49.

The countable-additivity field is read from Definition 92.50. Since the terminal reference has one event row and one value row, a displayed countable disjoint family has only the constant empty-event presentation. Its countable union and selected countable sum therefore read back to the same zero row.

For the standard-to-BEDC direction, choose the empty BHist carrier, the singleton empty-event row, and the constant 0_R endpoint for the unique standard event and value. Apply Definition 92.54 to cover every measurable, empty, binary-union, countable-union, disjointness, value, and countable-sum ledger row by that singleton surface.

Exactness and NameCert preservation are the rows of Definition 92.56 and Definition 92.51. The former packages event coverage, countable-sum classifier stability, carrier stability, sigma-additivity, and the NameCert rows into the concrete root surface; the latter is the public semantic certificate named by the $\mathsf{Measure}^{\uparrow}$ export.

Thus coverage, soundness, completeness, and ledger preservation are projections of the displayed zero rows. The bridge has no place to import host sigma-algebras, quotient events, analytic completions, or host set equality: the terminal reference has only $*_E$ and 0_T, and every round-trip is the same classifier-mediated singleton row already present on the public $\mathsf{Measure}^{\uparrow}$ surface. □

Lean4 ✓ `BEDC.Derived.MeasureUp.MeasureUp StdBridge`

Closure status for $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$.

Constructive story: The concrete measure surface starts from the empty history: a measure code is accepted only when its visible BHist representative is hsame to e, its event inventory is the singleton empty-event row, and every measurable event, finite union, countable union, difference row, and countable-sum endpoint is displayed as that same zero package. Two accepted measure presentations are classified by the carried history comparison and by the $\mathsf{Real}^{\uparrow}$ classifier on their value endpoints, so event movement is componentwise hsame transport of the visible rows rather than host set equality or quotient event equality. The source specification is the zero BHist carrier together with $\mathsf{Real}^{\uparrow}$ zero endpoints and the additive $\mathsf{AbGroup}^{\uparrow}$ zero laws for head-tail countable sums, while the pattern specification records empty-event coverage, finite disjoint-additivity, relative and nested difference zero rows, continuity from below, and countable-name consumer rows. The ledger policy keeps the raw empty carrier, singleton event row, union and disjointness displays, zero value endpoint, countable-sum endpoint, additive zero readback, and downstream consumer projections visible. The five name-certificate obligations close because e inhabits the zero carrier, hsame gives reflexivity, symmetry, and transitivity, and any classifier transport of a zero code, empty event, or zero endpoint lands back in the same singleton rows. A history h lies in the signature gap of a $\mathsf{Measure}^{\uparrow}$ token p when the source-domain accepts h as this zero measure surface, the signature relation pairs it with an answer measure package and evidence ledger, and the token-introduction relation names that answer as p; unfolded, h has only the empty event and zero value rows encoded by p. The terminal standard bridge sends the BEDC zero surface to the one-event, one-value standard reference and reads that reference back through the same empty carrier, zero endpoint, countable-additivity, exactness, and ledger rows. The chapter registers this zero-measure construction under the name $\mathsf{Measure}^{\uparrow}$; arbitrary host sigma-algebras, analytic completion, probability-space closure, quotient event equality, and Lean-checked standard bridge data are not introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature paper scope is exactly the zero-BHist public $\mathsf{Measure}^{\uparrow}$ surface, the terminal standard bridge, finite-additivity readback, nested-difference rows, the continuity-from-below row, countable-name and root consumer surfaces, and the analysis-consumer bridge rows already input by the $\mathsf{Measure}^{\uparrow}$ hub.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.MeasureUp.MeasureZeroBHist\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Not claimed: This block does not close arbitrary host sigma-algebras, quotient event equality, analytic completion, probability-space closure, or a Lean-checked standard bridge.

Upgrade path: No further upgrade – chapter at top of formal axis.

The $\mathsf{Measure}^{\uparrow}$ packet is read as a dependency lattice for analysis consumers: value rows are grounded in the real-name surface, integration rows consume the same measure values, and probability rows read normalization through the resulting finite event-value boundary. Its measurable-event surface consumes the displayed set-like event classifier rows of section 92.8 and the $\mathsf{Real}^{\uparrow}$

value row of chapter 38 before probability, random-variable, distribution, integral, and spectral-measure consumers read it. The event classifier also consumes the sigma-algebra sibling through chapter 5186 before probability and integration consumers read countable event closure. The generated-event row is anchored by the $\mathsf{BorelSet}^{\uparrow}$ surface of chapter 3384, while the cover-valued event boundary is routed through the $\mathsf{OuterMeasure}^{\uparrow}$ surface of chapter 3385.

Theorem 92.258 (Measure dependency lattice)**.** *Every accepted* $\mathsf{Measure}^{\uparrow}$ *carrier reads its value object through chapter 38, exports integration consumers through chapter 123, and supplies probability normalization consumers through chapter 184. These three reads are attached to the same finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, so no consumer can detach a measure value from its real, integral, and probability-facing dependency surface.*

Proof. The value row is read first. It is the $\mathsf{Real}^{\uparrow}$-facing object that fixes the codomain used by event-value comparisons.

The integration consumer is downstream of that value row. It receives the displayed measure values as the input surface for integral construction, not as an independent host-valued function.

The probability consumer is downstream of the same event-value boundary. Its normalization read is therefore attached to the measure value and integral-facing rows through the carrier's structural transport, replay, provenance, and local naming data.

Since the same finite structural rows bind all three consumers, the dependency lattice records one $\mathsf{Measure}^{\uparrow}$ packet rather than three unrelated analysis interfaces. □

Theorem 92.259 (Measure probability sigma Borel route)**.** *Every probability, random-variable, distribution, or integral consumer of an accepted* $\mathsf{Measure}^{\uparrow}$ *packet must read the sigma-algebra sibling, the* $\mathsf{BorelSet}^{\uparrow}$ *generated-event row, the* $\mathsf{Real}^{\uparrow}$ *value row, and the probability normalization row through the same finite event-value carrier before any countable-event closure or integration read is public. Consequently the consumer cannot detach measure values from the displayed event classifier, generated-event, and normalization rows.*

Proof. Project the accepted $\mathsf{Measure}^{\uparrow}$ dependency lattice of Definition 92.258. Its value object is already read through the $\mathsf{Real}^{\uparrow}$ row, while its probability and integration consumers are attached to the same finite BHist, hsame, Cont, Pkg, and NameCert rows.

Use the sibling routes named in the opening paragraph. The measurable-event classifier reads the sigma-algebra surface of chapter 5186, and the generated-event row is anchored by the $\mathsf{BorelSet}^{\uparrow}$ surface of chapter 3384. These rows enter before probability normalization, random-variable distribution reads, or integral formation can be exported.

The probability row then supplies normalization over that same event-value boundary. Since the sigma-algebra classifier, Borel generated-event row, Real value row, and normalization row are all carried by the same structural transport, replay, provenance, and local naming data, any downstream consumer receives one displayed event-value carrier rather than a detached host-valued measure function. □

Theorem 92.260 (Measure real-stream dependency lattice)**.** *Every* $\mathsf{Measure}^{\uparrow}$ *real-valued or countable-name consumer factors through the* $\mathsf{StreamName}^{\uparrow}$ *finite observation rows of Definition 92.77, the* $\mathsf{Real}^{\uparrow}$ *seal rows attached to those observations, the finite event-algebra rows of the root public surface, the displayed* BHist *ledger, componentwise* hsame*,* Cont *replay,* Pkg *provenance, and local* NameCert *rows before any countable premeasure or relative-difference read is accepted. The route is the common dependency lattice supplied by Definition 92.78, Definition 92.91, Definition 92.228, and Definition 92.258.*

Proof. Begin with the StreamName endpoint family. By Definition 92.78, each unary observation is carried by the displayed $\mathsf{StreamName}^{\uparrow}$ row and transports its measurable-event row and $\mathsf{Real}^{\uparrow}$ endpoint row through the same componentwise classifier data.

Next read the countable-name surface. Apply Definition 92.91; it requires the visible countable family, event rows, endpoint comparisons, and pointwise StreamName classifier rows to remain attached to one BHist measure code.

Now use the real-stream premeasure bridge. The carrier obligation of Definition 92.228 admits a countable premeasure row only after the displayed event rows, StreamName observation family, Real endpoint comparisons, and NameCert rows have been read.

Finally apply Definition 92.258. Its value, integral, and probability-facing dependencies bind the same finite event-value boundary to BHist, hsame, Cont, Pkg, and local naming data. Therefore a countable premeasure or relative-difference consumer cannot bypass the StreamName observations, Real seals, finite event-algebra rows, or structural certificate rows. □

Theorem 92.261 (Measure probability and integral dependency route)**.** *Every accepted* $\mathsf{Measure}^{\uparrow}$ *packet sends its finite event rows and* $\mathsf{Real}^{\uparrow}$*-valued mass rows to chapter 184 and chapter 123 only through displayed* $\mathsf{Measure}^{\uparrow}$ *rows. The* $\mathsf{ProbSpace}^{\uparrow}$ *consumer reads normalization and finite additivity from the event-value surface, while the* $\mathsf{Integral}^{\uparrow}$ *consumer reads premeasure and value rows from the same finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route.*

Proof. Start with the dependency lattice of Definition 92.258. It ties probability and integral consumers to the same real-valued measure rows rather than to detached host functions.

For the probability side, read the $\mathsf{ProbSpace}^{\uparrow}$ consumer rows through the displayed finite event boundary. Normalization and finite additivity are therefore projections of the $\mathsf{Measure}^{\uparrow}$ packet.

For the integral side, read the $\mathsf{Integral}^{\uparrow}$ premeasure route through the displayed value rows. Since both consumers share the same structural transport, replay, provenance, and local naming rows, neither receives a mass row outside the shown $\mathsf{Measure}^{\uparrow}$ carrier surface. □

The $\mathsf{Measure}^{\uparrow}$ event-value and countable-premise rows are consumed by chapter 184 and chapter 123. The route reads the finite event algebra, $\mathsf{Real}^{\uparrow}$ value row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before either probability normalization or integral readback is available. The $\mathsf{Measure}^{\uparrow}$ hub supplies measurable-event rows and $\mathsf{Real}^{\uparrow}$-valued mass rows to chapter 123 and chapter 184 only after the value row of chapter 38 and the local $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ route have been displayed. The probability and integral consumers therefore read the same finite event-value packet, rather than a detached measure, an independent probability primitive, or an ambient real-valued selector.

Theorem 92.262 (Measure value route for probability and integral consumers)**.** *Every accepted* $\mathsf{Measure}^{\uparrow}$ *value row is read through the* $\mathsf{Real}^{\uparrow}$ *value surface of chapter 38 before probability normalization through chapter 184 or integration through chapter 123 can consume it. The probability and integral consumers therefore share the same finite event-value row,* BHist *ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ *row; neither consumer receives a detached host-valued measure function.*

Proof. Project the accepted $\mathsf{Measure}^{\uparrow}$ carrier through the value rows named in Definition 92.258. The value object is first a $\mathsf{Real}^{\uparrow}$-facing row, so event comparisons and normalization reads use the same displayed real-name surface.

The probability consumer reads that row as its normalization input, while the integral consumer reads it as the value input for integration. Both reads remain downstream of the same finite event-value boundary.

The structural rows transport, replay, source, and name that shared boundary. Since no carrier coordinate supplies a second host-valued measure function, probability and integration cannot detach their value reads from the displayed $\mathsf{Measure}^{\uparrow}$ packet. □

Theorem 92.263 (Measure probability sigma dependency)**.** *Every accepted* $\mathsf{Measure}^{\uparrow}$ *packet exposes its event algebra, sigma-additive rows, finite disjoint-union readback, and* $\mathsf{Real}^{\uparrow}$*-valued mass rows before any integration, random-variable, distribution, or probability consumer receives a measure row. In particular, the* $\mathsf{ProbSpace}^{\uparrow}$ *consumer of chapter 184 reads its total-event normalization and probability-total-mass boundary through the same displayed* $\mathsf{Measure}^{\uparrow}$ *event family and value route used by the integral and random-variable surfaces, not through a detached host measure or an independent probability primitive.*

Proof. Start with the root event boundary and sigma-additive obligation rows of Definition 92.190 and Definition 92.184. They expose the measurable-event family, event classifier, empty-event row, finite disjoint-union readback, and countable additivity surface as carried $\mathsf{Measure}^{\uparrow}$ data.

Apply the probability substrate obligations of Definition 92.71. The $\mathsf{ProbSpace}^{\uparrow}$ row adds the total event and the unit endpoint only after those measure rows have already supplied the event algebra and mass values.

Thus every downstream probability, integration, random-variable, or distribution read sees the same finite event-and-value route. The Measure packet exports a shared dependency boundary, not separate host-side measure and probability objects. □

Theorem 92.264 (Measure ProbSpace total-mass handoff)**.** *Every accepted* $\mathsf{ProbSpace}^{\uparrow}$ *total-event normalization row consumed through* $\mathsf{Measure}^{\uparrow}$ *must expose the* $\mathsf{Measure}^{\uparrow}$ *event algebra, sigma-additive rows, finite disjoint-union readback, and* $\mathsf{Real}^{\uparrow}$*-valued mass rows before a probability consumer may read total mass* 1*. The handoff supplies a probability boundary over displayed measure data, not a detached probability primitive or host-side total-measure assertion.*

Proof. Start with Definition 92.263. It already routes probability consumers through the same event family and value route used by integration, random-variable, and distribution surfaces.

The root event and sigma-additive obligations, Definition 92.190 and Definition 92.184, keep measurable events, empty-event data, finite disjoint-union readback, and countable-additivity rows visible as $\mathsf{Measure}^{\uparrow}$ data.

Apply the probability substrate obligations Definition 92.71. The total-event normalization row and the unit endpoint are therefore read only after the event algebra and $\mathsf{Real}^{\uparrow}$ mass route have been displayed, so the probability consumer receives total mass 1 through the measure packet's finite dependency lattice. □

Theorem 92.265 (Measure probability sigma dependency forward link)**.** *Every* $\mathsf{ProbSpace}^{\uparrow}$ *or* $\mathsf{Integral}^{\uparrow}$ *consumer of an accepted* $\mathsf{Measure}^{\uparrow}$ *packet must pass through the displayed sigma-event source rows, finite additivity and readback rows, and* $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ *provenance before reading probability mass or integral value rows. The probability-facing route of chapter 184 and the integral-facing route of chapter 123 therefore share the same* $\mathsf{Measure}^{\uparrow}$ *dependency lattice rather than reading detached probability primitives, host measures, or independent value selectors.*

Proof. Start with the sigma-event and source rows already displayed by the $\mathsf{Measure}^{\uparrow}$ carrier. They name the measurable-event family, event classifier, empty-event boundary, and source value route before any probability or integration consumer appears.

Next read finite additivity and readback. These rows expose the disjoint-union mass ledger and the value route used by probability normalization and integral accumulation, so neither consumer can bypass the measure packet when it reads mass or integral data.

Finally pass through provenance and local naming. The Pkg and $\mathsf{NameCert}_{\mathsf{Measure}^\uparrow}$ rows seal the shared dependency lattice, and the sibling probability and integral chapters can consume only the sealed event-and-value surface. No detached host measure, independent probability primitive, or selected value representative is exported. □

Theorem 92.266 (Measure ProbSpace event-algebra forward route)**.** *Every probability-space mass-normalization or event-algebra consumer reading* $\mathsf{ProbSpace}^\uparrow$ *must first display the* $\mathsf{Measure}^\uparrow$ *finite event-value surface, finite additivity readback, sigma-algebra public basis, and real-stream premeasure bridge before the probability normalization row is read. The route factors through the ProbSpace certificate of chapter 184 only after the Measure sibling routes Definition 92.214 and section 92.13 have exposed their event-basis and premeasure rows.*

Thus a $\mathsf{ProbSpace}^\uparrow$ *consumer may normalize an event ledger only as a downstream read of the displayed* $\mathsf{Measure}^\uparrow$ *event-value and premeasure surface, not as a direct host probability object.*

Proof. Begin with the $\mathsf{Measure}^\uparrow$ finite event-value surface. Its carrier rows expose the finite event ledger and the value readback before any probability-space normalization is available.

Apply the finite additivity readback and then the sigma-algebra public basis of Definition 92.214. These rows identify which event algebra a downstream $\mathsf{ProbSpace}^\uparrow$ reader is allowed to inspect.

Finally use the real-stream premeasure bridge of section 92.13 and its carrier obligation Definition 92.228. It places the real-stream premeasure row between the event algebra and the probability normalization row of chapter 184, so the ProbSpace consumer inherits only the displayed Measure route. □

The probability-space normalization route is an additive $\mathsf{Measure}^\uparrow$ child surface. A $\mathsf{ProbSpace}^\uparrow$ consumer first reads the event algebra and total-mass row through chapter 184; only after that displayed $\mathsf{Measure}^\uparrow$ route is exposed may probability-specific random-variable, distribution, weak-law, or event-bound consumers read the normalized probability rows. The route supplies no independent probability carrier, no completed measure algebra, and no selected null-set quotient beyond the visible measure and total-mass data. The countable event and value rows of $\mathsf{Measure}^\uparrow$ reach Real-facing consumers only through the finite name route of chapter 126, chapter 301, and chapter 38. This route keeps each countable-event read tied to displayed StreamName windows, regular rational readback, Real seals, BHist rows, componentwise hsame, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ data; it does not make $\mathsf{Measure}^\uparrow$ an L10 completeness claim or add measure-theoretic completion beyond the named finite event/value surface. The $\mathsf{Measure}^\uparrow$ event-value and premeasure rows consume the L10 completion surface through the $\mathsf{Real}^\uparrow$ value route of chapter 38 and the finite observation discipline of chapter 126. The same displayed rows then feed the probability consumer of chapter 184: normalization may read a total-mass row only after the event algebra, Real-valued mass row, BHist ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}_{\mathsf{Measure}^\uparrow}$ route are visible.

Chapter 93

A Concrete Naming Certificate for $\mathsf{Filter}^{\uparrow}$

The filter interface $\mathsf{Filter}^{\uparrow}$ packages a non-empty upward-closed family of subsets of a carrier closed under finite intersections. It supplies the structural substrate for convergence and limit notions independent of metric data, and is the constructive analogue of mathlib-style `Filter` for the BEDC topology and analysis layers.

93.1 Carrier definition

Theorem 93.1 (Principal suffix unary intersection closure)**.** *Let* $base, left, right, meet, leftPoint, rightPoint, mee$ BHist*. If* $base$*,* $left$*, and* $right$ *are unary histories,*

$$\mathsf{Cont}(left, right, meet), \qquad \mathsf{Cont}(base, left, leftPoint), \qquad \mathsf{Cont}(base, right, rightPoint), \qquad \mathsf{Cont}(base, meet, m$$

then $meetPoint$ *is unary, and it is simultaneously displayed as the continuation of* $leftPoint$ *by* $right$ *and of* $rightPoint$ *by* $left$*.*

Proof. Unary closure first gives unary $meet$ from the continuation $\mathsf{Cont}(left, right, meet)$, and then gives unary $meetPoint$ from $\mathsf{Cont}(base, meet, meetPoint)$. The left projection follows by associativity of history append. The right projection uses unary commutativity of $left$ and $right$, followed by the same associativity comparison. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix unary intersection closed`

Theorem 93.2 (Principal suffix unary commuting square)**.** *Let* $base, left, right, leftPoint, rightPoint, lrPoint, rl$ BHist*. If* $left$ *and* $right$ *are unary histories and*

$$\mathsf{Cont}(base, left, leftPoint), \qquad \mathsf{Cont}(base, right, rightPoint), \qquad \mathsf{Cont}(leftPoint, right, lrPoint), \qquad \mathsf{Cont}(rigl$$

then $lrPoint \mathsf{hsame} rlPoint$*.*

Proof. Unfold the four continuations as history appends. The left path displays $\mathsf{append}(\mathsf{append}(base, left), right)$, and the right path displays $\mathsf{append}(\mathsf{append}(base, right), left)$. Associativity moves both paths to the common $base$ prefix, while unary commutativity of $left$ and $right$ identifies the two suffix orders. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix unary commuting square`

Theorem 93.3 (Principal suffix unary intersection meet commutes)**.** *Let* $left, right, meet, commute$: BHist*. If* $left$ *and* $right$ *are unary histories and*

$$\mathsf{Cont}(left, right, meet), \qquad \mathsf{Cont}(right, left, commute),$$

then $meet\mathsf{hsame}commute$*.*

Proof. Apply the unary commuting square with empty base. The left and right base legs are the canonical left-unit continuations, so the two displayed intersection results are precisely the two suffix orders, and the square identifies them by hsame. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix unary intersection meet commutes`

Theorem 93.4 (Filter principal suffix topology lattice route)**.** *The principal suffix filter surface may be consumed by the* $\mathsf{Topology}^{\uparrow}$ *neighbourhood interface of chapter 88 and by metric convergence routes through chapter 57, but only through the displayed* BHist*,* Cont*, unary intersection,* hsame*, and* NameCert *rows. In particular, a topology or metric consumer can use the principal suffix row as a finite neighbourhood basis only after the intersection closure, commuting-square, and meet-commutation rows above have exposed the lattice route.*

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix topology lattice route`

Proof. Start with Definition 93.1. It supplies the finite intersection row for two unary suffix neighbourhoods over the same displayed BHist base.

Use Definition 93.2 and Definition 93.3. These rows identify the two orders of the unary suffix intersection by hsame, so the consumer sees a lattice route rather than an ordered path artifact.

The topology-facing read may therefore treat the principal suffix surface as a neighbourhood interface only through those displayed rows. The metric-facing read has the same boundary: convergence routes can cite the filter substrate, but no metric distance, open-ball predicate, limit selector, or quotient filter is introduced by $\mathsf{Filter}^{\uparrow}$ unless a separate sibling certificate supplies it. □

Theorem 93.5 (Principal suffix unary commuting square base determinism)**.** *Let* $base, base', left, right, leftPoint$ BHist*. If* $left$ *and* $right$ *are unary histories and*

$$\mathsf{Cont}(base, left, leftPoint), \qquad \mathsf{Cont}(base', right, rightPoint), \qquad \mathsf{Cont}(leftPoint, right, meetPoint), \qquad \mathsf{Cont}($$

then $base\mathsf{hsame}base'$*.*

Proof. Unfold the two paths to the common meet. The first path gives $\mathsf{append}(\mathsf{append}(base, left), right)$ and the second gives $\mathsf{append}(\mathsf{append}(base', right), left)$. Associativity moves both to suffix form, unary commutativity aligns the common suffix $\mathsf{append}(left, right)$, and right cancellation of that suffix identifies the two bases. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix unary commuting square base deterministic`

Theorem 93.6 (Principal suffix commuted meet closure)**.** *Let* $base, left, right, meet, meetPoint$: BHist*. If* $left$ *and* $right$ *are unary histories and*

$$\mathsf{Cont}(left, right, meet), \qquad \mathsf{Cont}(base, meet, meetPoint)$$

hold, then the same $meetPoint$ *is displayed by the commuted suffix:*

$$\mathsf{Cont}(base, \mathsf{append}(right, left), meetPoint).$$

Proof. The first continuation identifies *meet* with $\mathsf{append}(left, right)$. Unary commutativity of *left* and *right* transports this suffix under the fixed prefix *base*, giving the displayed continuation by $\mathsf{append}(right, left)$. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix unary intersection commuted meet closed`

Theorem 93.7 (Principal suffix commuted result determinism)**.** *Let* $base, left, right, meet, meetPoint, displayed$: BHist. *If* $left$ *and* $right$ *are unary histories and*

$$\mathsf{Cont}(left, right, meet), \qquad \mathsf{Cont}(base, meet, meetPoint), \qquad \mathsf{Cont}(base, \mathsf{append}(right, left), displayed),$$

then $meetPoint \mathsf{hsame} displayed$.

Proof. The commuted meet closure theorem displays *meetPoint* as a continuation of *base* by $\mathsf{append}(right, left)$. Continuation determinism compares this canonical commuted display with the given *displayed* history. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix unary intersection commuted result deterministic`

Theorem 93.8 (Principal suffix unary intersection result determinism)**.** *In the situation of Definition 93.1, if another history displayed satisfies* $\mathsf{Cont}(rightPoint, left, displayed)$*, then* $meetPoint \mathsf{hsame} displayed$.

Proof. The closure theorem supplies the canonical continuation $\mathsf{Cont}(rightPoint, left, meetPoint)$. Continuation determinism compares this canonical display with the given displayed result. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix unary intersection result deterministic`

Theorem 93.9 (Principal suffix unary intersection zero-result exclusion)**.** *Let* $base, left, right, meet, leftPoint, rig$ BHist. *If* $base$*,* $left$*, and* $right$ *are unary histories and*

$$\mathsf{Cont}(left, right, meet), \qquad \mathsf{Cont}(base, left, leftPoint), \qquad \mathsf{Cont}(base, right, rightPoint), \qquad \mathsf{Cont}(base, meet, \mathsf{E}$$

then $\bot$.

Proof. Unary closure transports through the concrete continuation $\mathsf{Cont}(left, right, meet)$, so *meet* is unary. Applying unary closure again to $\mathsf{Cont}(base, meet, \mathsf{E0}(z))$ would make the zero-headed result unary, which contradicts the unary no-zero-extension theorem. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix unary intersection zero result absurd`

Theorem 93.10 (Principal suffix unary intersection e1-result cases)**.** *Let* $base, left, right, meet, leftPoint, rightP$ BHist. *If* $base$*,* $left$*, and* $right$ *are unary histories and*

$$\mathsf{Cont}(left, right, meet), \qquad \mathsf{Cont}(base, left, leftPoint), \qquad \mathsf{Cont}(base, right, rightPoint), \qquad \mathsf{Cont}(base, meet, \mathsf{E}$$

then either $meet = \mathsf{e}$ *and* $base \mathsf{hsame} \mathsf{E1}(z)$*, or there is a unary* $meetTail$ *such that* $meet = \mathsf{E1}(meetTail)$ *and* $\mathsf{Cont}(base, meetTail, z)$.

Proof. Unary closure along $\mathsf{Cont}(left, right, meet)$ first gives unary *meet*. The kernel unary e1-result case theorem applied to $\mathsf{Cont}(base, meet, \mathsf{E1}(z))$ then splits the result into the empty-meet case and the non-empty unary-tail case. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix unary intersection e1 result cases`

Theorem 93.11 (Principal suffix base points empty exactness)**.** *Let* $base, left, right, leftPoint, rightPoint$: BHist*. If*

$$\mathsf{Cont}(base, left, leftPoint), \qquad \mathsf{Cont}(base, right, rightPoint),$$

and both displayed points satisfy

$$leftPoint\mathsf{hsamee}, \qquad rightPoint\mathsf{hsamee},$$

then $base\mathsf{hsamee}$*,* $left\mathsf{hsamee}$*, and* $right\mathsf{hsamee}$*.*

Proof. Transport the two displayed endpoints to e. Empty-result inversion for the first continuation identifies both *base* and $left$ with e; the same inversion for the second continuation identifies *right* with e. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix base points empty exact`

Theorem 93.12 (Principal suffix commuting square empty exactness)**.** *Let* $base, left, right, leftPoint, rightPoint$ BHist*. If the two displayed continuations*

$$\mathsf{Cont}(base, left, leftPoint), \qquad \mathsf{Cont}(base, right, rightPoint)$$

are extended around the square by

$$\mathsf{Cont}(leftPoint, right, lrPoint), \qquad \mathsf{Cont}(rightPoint, left, rlPoint),$$

and both square endpoints satisfy

$$lrPoint\mathsf{hsamee}, \qquad rlPoint\mathsf{hsamee},$$

then $base\mathsf{hsamee}$*,* $left\mathsf{hsamee}$*, and* $right\mathsf{hsamee}$*.*

Proof. Transport the two square endpoints to e. Empty-result inversion of $\mathsf{Cont}(leftPoint, right, lrPoint)$ identifies $leftPoint$ with e, and empty-result inversion of $\mathsf{Cont}(rightPoint, left, rlPoint)$ identifies $rightPoint$ with e. Apply the base-points empty exactness theorem to the two base continuations and these two transported endpoint equalities. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix unary commuting square empty exact`

Theorem 93.13 (Principal suffix intersection empty point exactness)**.** *Let* $base, left, right, meet, meetPoint$: BHist*. If*

$$\mathsf{Cont}(left, right, meet), \qquad \mathsf{Cont}(base, meet, meetPoint),$$

and the displayed intersection point satisfies $meetPoint\mathsf{hsamee}$*, then all four histories collapse to the empty history:*

$$base\mathsf{hsamee}, \qquad meet\mathsf{hsamee}, \qquad left\mathsf{hsamee}, \qquad right\mathsf{hsamee}.$$

Proof. Transport $meetPoint$ to e and apply empty-result inversion to $\mathsf{Cont}(base, meet, meetPoint)$. This identifies both *base* and *meet* with e. Substituting the empty meet into $\mathsf{Cont}(left, right, meet)$ and applying the same empty-result inversion identifies $left$ and *right* with e. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix intersection empty point exact`

Theorem 93.14 (Principal suffix intersection empty point forces base points empty)**.** *Let* $base, left, right, meet, le$
BHist*. If meet is the continuation of* $left$ *by* $right$*, the base continuations produce* $leftPoint$*,* $rightPoint$*, and* $meetPoint$*, and* $meetPoint$hsamee*, then both base points are empty:*

$$leftPoint\mathsf{hsamee}, \qquad rightPoint\mathsf{hsamee}.$$

Proof. Intersection empty-point exactness identifies the shared base, the left suffix, and the right suffix with e. Empty-append introduction applied to $\mathsf{Cont}(base, left, leftPoint)$ gives the empty left base point, and the same argument applied to $\mathsf{Cont}(base, right, rightPoint)$ gives the empty right base point. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix intersection empty point base points empty`

93.2 The certificate

Theorem 93.15 (Principal empty filter carrier semantic certificate)**.** *The BEDC unary carrier restricted to the empty history,*

$$\mathsf{UnaryHistory}(h) \wedge h\mathsf{hsamee},$$

has a semantic naming certificate with source, pattern, and ledger predicates all equal to this principal empty carrier, and with classifier hsame*.*

Proof. The witness is the empty history, which is unary and classifies to itself. Reflexivity, symmetry, and transitivity are the finite-kernel laws for hsame. If h lies in the principal empty carrier and $h\mathsf{hsame}k$, unary transport moves the unary carrier from h to k, while symmetry followed by transitivity sends the displayed comparison $h\mathsf{hsamee}$ to $k\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalEmptyCarrier semanticNameCert`

Theorem 93.16 (Principal visible carrier semantic certificate absurdity)**.** *For every tail* : BHist*, there is no semantic naming certificate whose source, pattern, and ledger predicates all require a history to be unary, to classify to* e*, and to classify to* $\mathsf{E1}(tail)$*:*

$$\mathsf{SemanticNameCert}(\{h \mid \mathsf{UnaryHistory}(h) \wedge h\mathsf{hsamee} \wedge h\mathsf{hsameE1}(tail)\}, \{h \mid \mathsf{UnaryHistory}(h) \wedge h\mathsf{hsamee} \wedge h\mathsf{hsameE1}(tai$$

Proof. The semantic certificate supplies a ledger witness for the displayed carrier. Its two classification comparisons compose by symmetry and transitivity to give $e\mathsf{hsameE1}(tail)$, which is excluded by BEDC history constructor separation. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalVisibleCarrier semanticNameCert absurd`

Theorem 93.17 (ContinuousMap image of a principal suffix filter)**.** *Let* $base, map, target, modulus, cert, distance,$
BHist*. Assume*

$$\begin{aligned}
&\mathsf{ContinuousMapCarrier}(base, map, target, modulus, cert, distance),\\
&\mathsf{UnaryHistory}(left), \quad \mathsf{UnaryHistory}(right),\\
&\mathsf{Cont}(left, right, meet), \quad \mathsf{Cont}(base, left, leftPoint), \quad \mathsf{Cont}(base, right, rightPoint), \quad \mathsf{Cont}(base, meet, meetP
\end{aligned}$$

Then there exist histories $targetLeft, targetRight, targetMeet, imageLeft, imageRight, imageMeet$: BHist *for which*

$$\mathsf{Cont}(target, left, targetLeft) \wedge \mathsf{Cont}(target, right, targetRight) \wedge \mathsf{Cont}(target, meet, targetMeet),$$
$$\mathsf{UnaryHistory}(targetMeet) \wedge \mathsf{Cont}(targetLeft, right, targetMeet) \wedge \mathsf{Cont}(targetRight, left, targetMeet),$$
$$\mathsf{Cont}(leftPoint, map, imageLeft) \wedge \mathsf{Cont}(rightPoint, map, imageRight) \wedge \mathsf{Cont}(meetPoint, map, imageMeet),$$
$$\mathsf{hsame}(targetLeft, imageLeft) \wedge \mathsf{hsame}(targetRight, imageRight) \wedge \mathsf{hsame}(targetMeet, imageMeet).$$

Moreover, these target-side witnesses determine the intersection projections, the target commuting square, and the graph-image displays:

$$\forall z : \mathsf{BHist}.\ \mathsf{Cont}(targetLeft, right, z) \Longrightarrow \mathsf{hsame}(targetMeet, z),$$
$$\forall z : \mathsf{BHist}.\ \mathsf{Cont}(targetRight, left, z) \Longrightarrow \mathsf{hsame}(targetMeet, z),$$
$$\forall lr, rl : \mathsf{BHist}.\ \mathsf{Cont}(targetLeft, right, lr) \Longrightarrow \mathsf{Cont}(targetRight, left, rl) \Longrightarrow \mathsf{hsame}(lr, rl),$$
$$\forall z : \mathsf{BHist}.\ \mathsf{Cont}(leftPoint, map, z) \Longrightarrow \mathsf{hsame}(targetLeft, z),$$
$$\forall z : \mathsf{BHist}.\ \mathsf{Cont}(rightPoint, map, z) \Longrightarrow \mathsf{hsame}(targetRight, z),$$
$$\forall z : \mathsf{BHist}.\ \mathsf{Cont}(meetPoint, map, z) \Longrightarrow \mathsf{hsame}(targetMeet, z).$$

Proof. By Definition 130.1, the continuous-map carrier contains a continuous-function carrier. Applying Definition 59.139 to that component gives unary histories for *base*, *map*, and *target*, together with the graph continuation $\mathsf{Cont}(base, map, target)$. The source hypotheses and unary continuation closure give unary evidence for *meet*.

Choose $targetLeft$, $targetRight$, and $targetMeet$ from the generated continuations of *target* by $left$, *right*, and *meet*. Choose $imageLeft$, $imageRight$, and $imageMeet$ from the generated continuations of $leftPoint$, $rightPoint$, and $meetPoint$ by *map*.

Apply Definition 93.1 with base *target*. Its inputs are the unary target history, the unary suffixes $left$ and *right*, the source meet ledger $\mathsf{Cont}(left, right, meet)$, and the three chosen target continuations. This gives $\mathsf{UnaryHistory}(targetMeet)$ and the two projection continuations $\mathsf{Cont}(targetLeft, right, targetMeet)$ and $\mathsf{Cont}(targetRight, left, targetMeet)$.

For the image readback of $left$, apply Definition 93.2 to the square with base *base*, suffixes $left$ and *map*, base legs $\mathsf{Cont}(base, left, leftPoint)$ and $\mathsf{Cont}(base, map, target)$, and upper legs $\mathsf{Cont}(leftPoint, map, imageLeft)$ and $\mathsf{Cont}(target, left, targetLeft)$. The result identifies $imageLeft$ with $targetLeft$, and symmetry gives the stated orientation. The same argument with *right* gives $\mathsf{hsame}(targetRight, imageRight)$. The meet case uses the unary meet evidence, the base leg $\mathsf{Cont}(base, meet, meetPoint)$, and the same graph leg to obtain $\mathsf{hsame}(targetMeet, imageMeet)$.

The two projection-determinacy clauses follow by comparing the canonical target projection continuations with any displayed projection through Definition 21.7. The universal target commuting square is exactly Definition 93.2 applied at base *target* to arbitrary displayed upper legs. Finally, each graph-image determinacy clause compares the chosen image continuation with an arbitrary image continuation by continuation determinacy, and then composes that comparison with the corresponding target-image equality using the equivalence laws for hsame from Definition 3.8. □

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix continuousMap image point determinacy`
Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix continuousMap image package`

Theorem 93.18 (ContinuousMap image determinacy for principal suffix points)**.** *Let* $base, map, target, modulus, c$ BHist. *Assume the base continuous-map row*

$$\mathsf{ContinuousMapCarrier}(base, map, target, modulus, cert, distance),$$

the principal suffix source and target displays

$$\mathsf{UnaryHistory}(suffix), \qquad \mathsf{Cont}(base, suffix, sourcePoint), \qquad \mathsf{Cont}(target, suffix, targetPoint),$$

and two displayed image rows over the same source point and the same graph history:

$$\begin{aligned}&\mathsf{ContinuousMapCarrier}(sourcePoint, map, target_0, modulus_0, cert_0, distance_0),\\ &\mathsf{ContinuousMapCarrier}(sourcePoint, map, target_1, modulus_1, cert_1, distance_1).\end{aligned}$$

Then the two displayed target histories are determined, and both read back to the target-side principal suffix point:

$$\mathsf{hsame}(target_0, target_1) \wedge \mathsf{hsame}(targetPoint, target_0) \wedge \mathsf{hsame}(targetPoint, target_1).$$

Lean4 ✓ `BEDC.Derived.FilterUp.ContinuousMap image principal suffix point determinacy`

Proof. Project the continuous-function component from the base carrier using Definition 130.1. Applying Definition 59.139 to that component gives the graph continuation $\mathsf{Cont}(base, map, target)$ and unary membership of the graph history *map*.

Project the continuous-function components from the two displayed image rows in the same way. Their graph fields give

$$\mathsf{Cont}(sourcePoint, map, target_0) \qquad \text{and} \qquad \mathsf{Cont}(sourcePoint, map, target_1).$$

Apply Definition 93.2 with base *base*, left suffix *suffix*, right suffix *map*, left point *sourcePoint*, and right point *target*. The first displayed image row supplies the upper-left path and $\mathsf{Cont}(target, suffix, targetP$ supplies the upper-right path, so the square gives $\mathsf{hsame}(target_0, targetPoint)$. The same square applied to the second displayed image row gives $\mathsf{hsame}(target_1, targetPoint)$.

Symmetry and transitivity of hsame from Definition 3.8 orient these two comparisons as $\mathsf{hsame}(targetPoint, target_0)$ and $\mathsf{hsame}(targetPoint, target_1)$ and compose them to obtain $\mathsf{hsame}(target_0, target_1)$. Pairing the three comparisons gives the displayed conclusion. □

Lean4 ✓ `BEDC.Derived.FilterUp.ContinuousMapCarrier principal suffix point determinacy`

Theorem 93.19 (Principal suffix upward closure)**.** *Let* $base, suffix, point, extra, extended : \mathsf{BHist}$. *If* $base$, $suffix$, *and* $extra$ *are unary histories and*

$$\mathsf{Cont}(base, suffix, point), \qquad \mathsf{Cont}(point, extra, extended),$$

then $point$ *and* $extended$ *are unary histories, and there is a unary history* $combined : \mathsf{BHist}$ *such that*

$$\mathsf{Cont}(suffix, extra, combined) \qquad \textit{and} \qquad \mathsf{Cont}(base, combined, extended).$$

Consequently, the principal suffix family generated by base is closed under unary continuation extensions of its points.

Lean4 ✓ `BEDC.Derived.FilterUp.FilterPrincipalSuffix upward closed`

Proof. Unary continuation closure gives unary *point* from the base display and unary *extended* from the point extension. Put $combined = \mathsf{append}(suffix, extra)$. The continuation rules of Definition 4.10 give $\mathsf{Cont}(suffix, extra, combined)$, and unary continuation closure gives unary *combined*.

Let $direct = \mathsf{append}(base, combined)$, with the canonical continuation $\mathsf{Cont}(base, combined, direct)$. Applying Definition 4.56 to the four ledgers

$$\mathsf{Cont}(base, suffix, point), \qquad \mathsf{Cont}(point, extra, extended), \qquad \mathsf{Cont}(suffix, extra, combined), \qquad \mathsf{Cont}(base, c$$

gives $extended\mathsf{hsame}direct$. The reverse direction of Definition 21.8 for $\mathsf{Cont}(base, combined, direct)$ transports the direct composite result to the displayed endpoint $extended$, yielding $\mathsf{Cont}(base, combined, extended)$. □

Closure status for $\mathsf{NameCert}_{\mathsf{Filter}\uparrow}$**.**

Constructive story: A $\mathsf{Filter}^{\uparrow}$ packet is generated from finite principal-suffix and continuous-map image histories, their classifier readback rows, and the displayed Cont witnesses relating source, suffix, map, and target histories.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Filter}\uparrow}$, maturePackageClosed)

Scope closed: The principal-suffix public rows through Definition 93.19 and the continuous-map-image consumer rows through Definition 93.17 and Definition 93.18 form the public $\mathsf{Filter}^{\uparrow}$ export surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Filter}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.FilterUp.FilterPrincipalEmptyCarrier\_semanticNameCert`

Bridge status: none

Origin: human

Not claimed: The chapter does not close ultrafilters, quotient filters, choice-based limits, or standard bridges.

Upgrade path: No further theory-axis upgrade is claimed here; standard bridge checking remains a separate verification-axis task.

Chapter 94

A Concrete Naming Certificate for $\mathsf{FunctionalAnalysis}^{\uparrow}$

The functional-analysis interface $\mathsf{FunctionalAnalysis}^{\uparrow}$ collects the bounded-linear-operator and dual-space certificates over $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$ (chapter 90) and $\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}$ (chapter 91). It packages the operator norm, adjoints, and compactness witnesses required by the spectral, semigroup, and PDE certificates downstream.

94.1 Carrier definition

Definition 94.1 (FunctionalAnalysis bounded-linear-operator face)**.** *The bounded-linear-operator face of* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *is the row family obtained by reading* $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$ *sources* C, D *through Definition 90.49. Its carrier is the displayed Banach row*

$$\mathsf{BanachBLOp}(C, D, T, K, \Lambda),$$

where T *is the operator representative,* K *is the* $\mathsf{Real}^{\uparrow}$ *norm bound, and* Λ *is the visible source-target, linearity, norm, scalar, bound, and provenance ledger. Its classifier is the Banach bounded-operator classifier: endpoint-map transport by* hsame, $\mathsf{Real}^{\uparrow}$ *transport of the bound endpoint, and componentwise ledger transport.*

Definition 94.2 (FunctionalAnalysis dual-space face)**.** *For a* $\mathsf{Banach}^{\uparrow}$ *source* C*, the dual-space face of* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *is the subface of Definition 94.1 whose target is the scalar singleton target supplied by* $\mathsf{Real}^{\uparrow}$ *as a Banach scalar carrier. Thus a dual row is a carried bounded linear functional*

$$\mathsf{BanachBLOp}(C, \mathsf{Real}^{\uparrow}, \varphi, K, \Lambda_{\varphi})$$

with the same bounded-operator classifier, the same $\mathsf{Real}^{\uparrow}$ *bound endpoint, and a ledger whose target endpoint rows are scalar rows rather than a separate vector target.*

Theorem 94.3 (FunctionalAnalysis operator-norm stability obligation)**.** *If two bounded-linear-operator rows in Definition 94.1 are related by the inherited Banach bounded-operator classifier, then they expose the same* $\mathsf{Real}^{\uparrow}$ *operator-norm bound row and the same visible norm-bound ledger row. Consequently every downstream* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer reads the operator representative together with a transported bound endpoint rather than a host-level operator equality.*

Lean4 ✓ `BEDC.Derived.FunctionalAnalysisUp.FunctionalAnalysisBoundedLinearOperator norm bound stable`

Proof. Read the operator face through Definition 90.49. The classifier specified there has three visible components: endpoint-map comparison, $\mathsf{Real}^{\uparrow}$ bound comparison, and componentwise ledger transport.

Apply Definition 90.52. Its exactness clause states that accepted bounded-operator rows contain precisely the endpoint map, classifier-respect row, additive row, scalar row, bound row, and provenance ledger. The $\mathsf{Real}^{\uparrow}$ comparison component therefore transports the norm-bound endpoint, and the ledger component transports the row recording where that bound is used.

The metric consequence is the Lipschitz row of Definition 90.50. Since that theorem reads the same bound endpoint K, the downstream operator-norm use is stable under the inherited classifier. □

Theorem 94.4 (FunctionalAnalysis operator-norm chapter route)**.** *Every* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer that reads an operator-norm row factors through the public* $\mathsf{OperatorNorm}^{\uparrow}$ *carrier of chapter 3603 together with the existing bounded-operator row and* $\mathsf{Real}^{\uparrow}$ *bound endpoint displayed in Definition 94.1. The route exports only the transported operator representative, nonnegative bound endpoint, norm-bound ledger, componentwise classifier transport, replay, provenance, and local naming rows; it refuses host norm functions, quotient operator equality, and hidden Banach completeness.*

Proof. Apply Definition 94.3. It already identifies the inherited Banach bounded-operator classifier, the transported $\mathsf{Real}^{\uparrow}$ bound endpoint, and the visible norm-bound ledger as the data available to every downstream $\mathsf{FunctionalAnalysis}^{\uparrow}$ operator-norm consumer.

The public chapter chapter 3603 names exactly that scalar-bound surface as $\mathsf{OperatorNorm}^{\uparrow}$. Reading through its carrier repacks the bounded-operator row, the nonnegative bound endpoint, and the ledger without adding any host-level norm function.

The refused objects are outside both routes. The stability theorem never supplies quotient operator equality, and the public $\mathsf{OperatorNorm}^{\uparrow}$ carrier contains no coordinate for hidden Banach completeness, so the FunctionalAnalysis consumer factors through the named chapter boundary. □

Theorem 94.5 (FunctionalAnalysis adjoint stability obligation)**.** *For Hilbert-compatible sources* H, G *whose carrier and classifier rows are those of Definition 91.1, an adjoint row in* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *is stable under bounded-operator classifier transport. The defining comparison*

$$\langle Tx, y\rangle_G \sim_{\mathsf{Real}^{\uparrow}} \langle x, T^* y\rangle_H$$

uses the same Hilbert carrier, the same classifier, and the same inner-product rows before and after transport, so the adjoint ledger row is preserved componentwise.

Lean4 ✓ `BEDC.Derived.FunctionalAnalysisUp.FunctionalAnalysisBoundedOperatorRow adjoint stability`

Proof. Begin with the Hilbert source. By Definition 91.5, every accepted Hilbert row exposes a Banach surface, an inner-product surface, and a ledger binding both to the same carrier and classifier.

The bounded-operator part is handled by Definition 90.52. Transport of T and T^* moves the endpoint representatives, the bound endpoints, and the operator ledgers without changing the Hilbert carrier on which the inner-product rows are evaluated.

Finally apply the carrier-sharing clause of Definition 91.1. The two inner-product comparisons in the displayed adjoint equation are read through the same classifier $\sim_X$ and the same norm-induction ledger. Hence the adjoint row is transported as a row of the Hilbert-compatible package. □

Theorem 94.6 (FunctionalAnalysis compact-operator witness obligation)**.** *A compact-operator witness in* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *is a bounded-linear-operator row* $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$ *together with* $\mathsf{CompactMetric}^{\uparrow}$ *probe data for the image of the carried source unit-bound face in the target Banach metric. If the bounded-operator representative is replaced by an inherited classifier-related representative, then the witness is transported to the new representative and records the same Banach or Hilbert compactness probe ledger.*

Lean4 ✓ `BEDC.Derived.FunctionalAnalysisUp.FunctionalAnalysisCompactOperatorWitness transport`

Proof. Use Definition 94.1 for the operator row. The bounded-operator classifier transports the endpoint map, the bound endpoint, and every source-target ledger component.

The compactness data are attached only to carried source endpoints, target metric endpoints, and finite or stream probe rows in $\mathsf{CompactMetric}^{\uparrow}$. Those target metric endpoints are the Banach norm-induced rows, so Definition 90.52 supplies the operator-side transport needed to move the image probes.

When the source and target are Hilbert-compatible, the same compactness row is read through Definition 91.5. The Hilbert surface contributes no new carrier to the compactness witness; it only records that the Banach metric endpoint is the norm induced by the displayed inner-product row. □

Theorem 94.7 (FunctionalAnalysis exact ledger boundary obligation)**.** *The* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *ledger exposed by this chapter is exactly the operator representative, the* $\mathsf{Real}^{\uparrow}$ *norm-bound row, the dual or adjoint row when present, the compactness witness when present, and the downstream consumer boundary for* $\mathsf{SpectralTheorem}^{\uparrow}$*,* $\mathsf{Semigroup}^{\uparrow}$*, and* $\mathsf{Pde}^{\uparrow}$*. It does not expose a spectral theorem, a semigroup evolution theorem, a PDE well-posedness theorem, or any standard bridge beyond those rows.*

Lean4 ✓ `BEDC.Derived.FunctionalAnalysisUp.FunctionalAnalysisBoundedOperatorRow ledger hsame transport`

Proof. The bounded-operator part is exactly the ledger listed in Definition 90.49 and certified by Definition 90.52. It contains the source endpoint, target endpoint, norm, scalar, compatibility, bound, and provenance rows.

The Hilbert part, when present, is exactly the compatible carrier and shared ledger of Definition 91.1 together with the obligation surface of Definition 91.5. Thus adjoint rows are ledger rows over the same carrier and classifier, not independent public objects.

The remaining fields follow the ten-field template of section 9467.18: traditional target, BEDC source, carrier, classifier, stability obligations, ledger, core theorem list, exactness predicate, standard bridge, and status. For this chapter the standard-bridge and downstream theorem entries are recorded as boundaries, so the ledger stops exactly at the rows displayed in the statement. □

94.2 The certificate

Theorem 94.8 (FunctionalAnalysis bounded-linear-operator obligation)**.** *A* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *bounded-operator row over a* $\mathsf{Banach}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *source and target consists of the following displayed data:*

1. *a carried* $\mathsf{LinMap}^{\uparrow}$ *map-code carrier for the underlying map;*
2. *source and target carrier predicates supplied by the Banach or Hilbert certificates named in the chapter opening;*

3. *the pointwise* LinMap$^{\uparrow}$ *classifier on carried source inputs;*
4. *an operator-norm witness landing in the* Real$^{\uparrow}$ *nonnegative comparison surface;*
5. *a norm-bound ledger recording the input norm row, output norm row, bound endpoint, and classifier transport used by the comparison.*

The stability field of this row is inherited from the LinMap$^{\uparrow}$ *pointwise classifier and from the Banach or Hilbert carrier and norm classifiers, with no extra equality relation on maps.*

Lean4 ✓ `BEDC.Derived.FunctionalAnalysisUp.FunctionalAnalysisBoundedOperatorRow visible ledger`

Proof. Read the Banach and Hilbert dependencies from the chapter opening. They supply the carried vector endpoints, norm rows, distance rows, and classifier transport used by a bounded-operator comparison.

Next read the map part through LinMap$^{\uparrow}$. The singleton and pointwise classifier surface of LinMap$^{\uparrow}$, including Definition 48.1 and Definition 48.49, supplies the carried map-code endpoint and identifies map sameness with pointwise codomain classifier sameness on carried source inputs.

The operator-norm witness is then only a ledgered RealUp bound: for each carried input, the source norm row, output norm row, and bound endpoint are recorded together with the RealUp comparison. Transporting the source input along the LinMap$^{\uparrow}$ classifier and the Banach or Hilbert norm classifier transports the same bound row, so the bounded-operator classifier has exactly the inherited stability claimed above. □

Theorem 94.9 (FunctionalAnalysis dual-space classifier obligation)**.** *For a* Banach$^{\uparrow}$ *source, the* FunctionalAnalysis$^{\uparrow}$ *dual-space carrier is the row of bounded scalar-valued* LinMap$^{\uparrow}$ *map codes from the Banach carrier to the scalar carrier. Its classifier compares two dual rows pointwise: for every carried Banach input, their scalar outputs are related by the scalar* NameCert *classifier. Reflexivity, symmetry, and transitivity of the dual classifier are inherited from the scalar* NameCert *classifier and from the* LinMap$^{\uparrow}$ *pointwise classifier package.*

Lean4 ✓ `BEDC.Derived.FunctionalAnalysisUp.FunctionalAnalysisDualPointwiseClassifier equivalence rows`

Proof. The source side is the Banach certificate named in the chapter opening. The target side is the scalar NameCert used by the Banach norm and bound rows. Together they determine the scalar-valued LinMap$^{\uparrow}$ carrier: a functional is a carried linear-map code whose output carrier is the scalar carrier and whose bound ledger is a RealUp comparison row.

For classification, unfold the LinMap$^{\uparrow}$ pointwise classifier surface. Two carried scalar-valued map codes are compared by applying both to an arbitrary carried Banach input and comparing the scalar outputs. Scalar reflexivity gives the diagonal comparison, scalar symmetry reverses each pointwise comparison, and scalar transitivity composes two pointwise comparisons.

Because these three operations are performed pointwise and then repacked by Definition 48.49, the dual-space classifier inherits refl/symm/trans from the scalar NameCert and the LinMap$^{\uparrow}$ classifier package alone. □

Theorem 94.10 (FunctionalAnalysis compact-operator ledger obligation)**.** *A* FunctionalAnalysis$^{\uparrow}$ *compact-operator witness for a carried bounded operator is an explicit finite-net image ledger: for each displayed* ProbeBundle *of bounded source inputs and each displayed target tolerance row, the ledger gives finitely many carried target probes whose classifier balls cover the carried image probes. The witness is stable under the bounded-operator classifier because pointwise target classifier*

transport moves every image probe and its finite-net comparison across classifier-equal bounded operators. This is not an open-cover compactness assertion and uses no choice-based extraction of subcovers.

Lean4 ✓ `BEDC.Derived.FunctionalAnalysisUp.FunctionalAnalysisCompactOperatorWitness probe ledger`

Proof. Start with the bounded-operator row of Definition 94.8. It gives the carried $\mathsf{LinMap}^{\uparrow}$ map code, pointwise target classifier control, and the norm-bound ledger needed to restrict attention to bounded source probes.

The compactness datum is recorded as a finite ProbeBundle-style ledger. For a displayed source probe bundle and a displayed target tolerance row, the ledger names a finite list of carried target probes and, for each image probe, the selected finite-net point together with the target classifier comparison.

If two bounded operators are related by the bounded-operator classifier, then their image endpoints over every carried source probe are pointwise related in the target classifier. Transport each finite-net comparison across that pointwise relation and keep the same finite list of target probes. Thus the compact-operator witness is classifier-stable while remaining a finite ledger, not an open-cover or choice principle. □

Theorem 94.11 (FunctionalAnalysis public export certificate)**.** *The public* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *export over the displayed* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{CompactMetric}^{\uparrow}$ *sources is the single* $\mathsf{NameCert}_{\mathsf{FunctionalAnalysis}^{\uparrow}}$ *surface whose fields are exactly the bounded-operator row, the dual-space classifier, the operator-norm stability row, the adjoint stability row, the compact finite-net witness row, and the exact ledger boundary proved in this chapter. The surface exports only these rows for downstream public consumers, and it exports no spectral theorem, semigroup evolution theorem, PDE well-posedness theorem, standard bridge, or host-level operator equality.*

Lean4 ✓ `BEDC.Derived.FunctionalAnalysisUp.FunctionalAnalysisPublic export certificate`

Proof. The carrier and classifier part is the bounded-operator row of Definition 94.8 together with the dual-space classifier of Definition 94.9. These two rows determine the public operator and scalar-valued functional faces over the displayed $\mathsf{Banach}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ sources.

The stability fields are precisely the operator-norm and adjoint rows of Definition 94.3 and Definition 94.5. The compact field is the finite-net witness ledger of Definition 94.10, read over the displayed $\mathsf{CompactMetric}^{\uparrow}$ surface rather than through an open-cover compactness assertion.

The boundary of the public surface is the exact ledger boundary of Definition 94.7. Therefore the exported $\mathsf{NameCert}_{\mathsf{FunctionalAnalysis}^{\uparrow}}$ surface consists exactly of the named rows and explicitly omits spectral theorem, semigroup evolution, PDE well-posedness, standard-bridge, and host-level operator-equality claims. □

Theorem 94.12 (FunctionalAnalysis public bridge boundary)**.** *The public* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *surface over the displayed* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{CompactMetric}^{\uparrow}$ *rows exports exactly the bounded-operator row, dual pointwise classifier, norm-bound stability, adjoint stability, compact finite-net witness, and exact ledger boundary as the bridge payload available to downstream* $\mathsf{SpectralTheorem}^{\uparrow}$*,* $\mathsf{Semigroup}^{\uparrow}$*, and* $\mathsf{Pde}^{\uparrow}$ *consumers. This boundary does not assert spectral theorem rows, semigroup evolution, PDE well-posedness,* bridgeChecked*, or host-level operator equality.*

Lean4 ✓ `BEDC.Derived.FunctionalAnalysisUp.FunctionalAnalysisPublic bridge boundary`

Proof. The exported operator face is the bounded-operator row of Definition 94.8. The exported dual face is the pointwise scalar-valued classifier of Definition 94.9. Together these two rows give the public carrier and classifier entries consumed by the operator chapters.

The stability payload is exactly the norm-bound stability row of Definition 94.3 and the adjoint stability row of Definition 94.5. These rows transport the exported operator data without adding any spectral, evolution, or PDE conclusion.

The compact payload is the finite-net witness of Definition 94.10, and the outer boundary is the exact ledger boundary of Definition 94.7. Repacking these six named rows gives precisely the public bridge payload for $\mathsf{SpectralTheorem}^{\uparrow}$, $\mathsf{Semigroup}^{\uparrow}$, and $\mathsf{Pde}^{\uparrow}$, while the omitted claims remain outside this $\mathsf{FunctionalAnalysis}^{\uparrow}$ certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{FunctionalAnalysis}^{\uparrow}}$.

Constructive story: A functional-analysis row is assembled from already displayed $\mathsf{Banach}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CompactMetric}^{\uparrow}$ surfaces: the bounded-operator carrier contains a carried map code, source and target carriers, a RealUp norm-bound endpoint, and a visible ledger of source, target, linearity, norm, scalar, bound, and provenance rows. Two bounded operators or dual rows are classified only by the inherited pointwise map classifier, RealUp bound transport, and componentwise ledger transport; there is no host-level operator equality, and a dual-space row is just the scalar-target subface of the same bounded-operator construction. The source covers bounded operators, scalar-valued functionals, Hilbert adjoint rows, and compact finite-net witnesses, while the pattern records norm-bound stability, adjoint stability, pointwise dual equivalence, compact probe transport, exact ledger boundary, public export, and downstream bridge payload for spectral, semigroup, and PDE consumers. The five name-certificate obligations are inherited row by row: inhabited operator faces come from displayed accepted map codes when a row is present, pointwise scalar classifiers and RealUp classifiers give reflexivity, symmetry, and transitivity, and the bounded-operator and compact-witness transport theorems keep every accepted ledger stable under the classifier. A history package h lies in the signature gap of a $\mathsf{FunctionalAnalysis}^{\uparrow}$ token p when the source-domain accepts the bounded-operator, dual, adjoint, or compact row, the signature relation pairs it with an answer row and evidence ledger, and token introduction names that answer as p; unfolded, the token can see only the transported map code, bound endpoint, pointwise scalar outputs, finite-net probes, and listed ledger rows. The paper bridge boundary exports exactly those six row families to $\mathsf{SpectralTheorem}^{\uparrow}$, $\mathsf{Semigroup}^{\uparrow}$, and $\mathsf{Pde}^{\uparrow}$ consumers, without turning them into standard operator theory. The chapter registers this bounded-operator and dual-ledger surface under the name $\mathsf{FunctionalAnalysis}^{\uparrow}$; it introduces no spectral theorem, PDE well-posedness theorem, semigroup evolution theorem, host equality, or bridge-checked standard model.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FunctionalAnalysis}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature paper scope is exactly the bounded-operator row, dual pointwise classifier, norm-bound stability, adjoint stability, compact finite-net witness, exact ledger boundary, public export certificate, and public bridge boundary for downstream $\mathsf{SpectralTheorem}^{\uparrow}$, $\mathsf{Semigroup}^{\uparrow}$, and $\mathsf{Pde}^{\uparrow}$ consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FunctionalAnalysis}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.FunctionalAnalysisUp.FunctionalAnalysisBoundedOperatorRow\_visible\_ledger`

Bridge status: paperBridge

Not claimed: Spectral theorem rows, PDE well-posedness, semigroup evolution, host equality, and bridgeChecked remain outside this mature paper claim.

Upgrade path: The next verification work is checked standard-bridge verification for the six displayed rows and their downstream certificates, independent of any additional paper closure grade.

Chapter 95

A Concrete Naming Certificate for $\mathsf{Completion}^{\uparrow}$

The completion interface $\mathsf{Completion}^{\uparrow}$ packages the universal regular-Cauchy completion of a metric naming certificate. It depends on $\mathsf{NameCert}_{\mathsf{Met}^{\uparrow}}$ (chapter 57) and the real-completeness capstone (chapter 9238), generalising the $\mathsf{Rat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ construction to arbitrary located metric carriers.

95.1 Carrier definition

Theorem 95.1 (Completion metric distance visible-tail readback)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n and the metric distance witness between x_n and y_n has visible result $\mathsf{E1}(t)$, then the visible tail t is unary and the rational endpoint classifier holds between x_n and y_n.*

Proof. The metric distance witness contains a unary witness for its visible result; inversion of unary histories through $\mathsf{E1}$ gives unary membership of t. The real stream prefix classifier supplies the rational endpoint classifier at the selected index. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness e1 tail real prefix readback`

Theorem 95.2 (Completion empty-distance real-prefix readback)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n and the metric distance witness between x_n and y_n has empty result, then both selected endpoints classify as e and the rational endpoint classifier holds between x_n and y_n.*

Proof. The empty-distance exactness theorem for metric distance witnesses reads back the two endpoint classifiers against e. The real stream prefix classifier supplies the rational endpoint classifier at the selected index. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness empty distance real prefix readback`

Theorem 95.3 (Completion visible-tail excludes empty distance)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n and the metric distance witness between x_n and y_n has visible result $\mathsf{E1}(t)$, then the rational endpoint classifier holds between x_n and y_n, and no empty metric distance witness can classify the same endpoints.*

Proof. Visible-tail readback supplies the rational endpoint classifier. If an empty distance witness also classified the same endpoints, metric result determinacy would identify $\mathsf{E1}(t)$ with e, contradicting the BEDC no-confusion theorem for visible constructors. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness e1 tail empty distance absurd`

Theorem 95.4 (Completion visible-tail transport)**.** *Let x, x', y, y' be real stream representatives and let n be a prefix index. If every endpoint of x is* hsame*-equal to the corresponding endpoint of x' and every endpoint of y is* hsame*-equal to the corresponding endpoint of y', then a real prefix classifier and a metric distance witness from x_n to y_n with visible result $\mathsf{E1}(t)$ transport to the primed streams. The transported witness still reads back unary membership of t and the rational endpoint classifier between x'_n and y'_n.*

Proof. Transport the finite real prefix classifier endpointwise. Transport the metric distance continuation ledger along the endpoint equalities while keeping the visible result fixed, and transport the unary endpoint carriers contained in the witness. The visible-tail readback theorem applied to the transported prefix and witness gives the unary tail and rational endpoint classifier. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness e1 tail hsame transport`

Theorem 95.5 (Completion metric distance visible-tail determinacy)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n and two metric distance witnesses between x_n and y_n have visible results $\mathsf{E1}(d)$ and $\mathsf{E1}(e)$, then d and e are unary, their tails are* hsame*-equal, and the rational endpoint classifier holds between x_n and y_n.*

Proof. Apply the visible-tail readback to each distance witness to obtain unary evidence for both tails and the rational endpoint classifier. The metric distance result determinacy theorem compares the two visible results over the same endpoints; e1 inversion for hsame descends this comparison to $d\mathsf{hsame}e$. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness e1 result tail deterministic`

Theorem 95.6 (Completion symmetric visible-tail readback)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n, a metric distance witness from x_n to y_n has visible result $\mathsf{E1}(d)$, and a metric distance witness from y_n to x_n has visible result $\mathsf{E1}(e)$, then d and e are unary, $d\mathsf{hsame}e$, and the rational endpoint classifier holds between y_n and x_n.*

Proof. Symmetry of the real stream prefix classifier gives the rational endpoint classifier in the reversed direction. Visible-tail readback applies to both witnesses. The symmetric metric distance classifier compares the two visible result histories, and e1 inversion for hsame descends the comparison to the tails. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness e1 symmetric tail real prefix readback`

Theorem 95.7 (Completion metric distance visible-context tail readback)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n and a visible context displays the metric distance witness with central result $\mathsf{E1}(t)$, then t is unary and the rational endpoint classifier holds between x_n and y_n.*

Proof. Apply visible-context cancellation for metric distance witnesses to recover the central witness. Its $\mathsf{E1}(t)$ distance carrier inverts to unary membership of t, and the real stream prefix classifier supplies the rational endpoint classifier at n. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness visible context e1 tail real prefix readback`

Theorem 95.8 (Completion visible-context tail transport)**.** *Let x, x' and y, y' be pointwise history-same real stream representatives. If the real stream prefix classifier holds for x, y at n and a visible context displays a metric distance witness with central result $\mathsf{E1}(t)$, then the transported representatives x', y' have the same prefix classifier, the same visible-context metric witness, unary tail evidence for t, and the rational endpoint classifier at n.*

Proof. Cancel the visible prefix and suffix to recover the central metric witness. Pointwise hsame transports the real prefix classifier and the central continuation ledger. Rebuild the visible-context witness from the transported central witness, then apply visible-context tail readback to recover the unary tail and the transported rational endpoint classifier. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness visible context e1 tail hsame transport`

Theorem 95.9 (Completion visible-context empty distance real-prefix readback)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n and a visible context displays the metric distance witness with central empty distance, then the visible prefix and suffix are unary, both central endpoints classify as e, and the rational endpoint classifier holds between x_n and y_n.*

Proof. Apply visible-context empty-distance exactness for metric distance witnesses. This reads back unary evidence for the displayed prefix and suffix together with the two empty endpoint classifiers. The real stream prefix classifier supplies the rational endpoint classifier at the selected index. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness visible context empty distance real prefix readback`

Theorem 95.10 (Completion visible-context empty-distance transport)**.** *Let x, x', y, y' be real stream representatives such that $x_m \mathsf{hsame} x'_m$ and $y_m \mathsf{hsame} y'_m$ for every index m. If the real stream prefix classifier holds for x, y at n and a visible-context metric distance witness from x_n to y_n has central empty distance, then the transported prefix classifier holds for x', y' at n, the corresponding visible-context empty-distance witness holds for x'_n, y'_n, the visible prefix and suffix are unary, both transported central endpoints classify as e, and the rational endpoint classifier holds between x'_n and y'_n.*

Proof. Apply empty-distance visible-context exactness to the original witness. This recovers unary evidence for the visible prefix and suffix and empty endpoint classifiers for x_n and y_n. Transport the real stream prefix classifier along the pointwise hsame hypotheses, transport the two endpoint empty classifiers by symmetry and transitivity of hsame, and rebuild the visible-context empty-distance witness from the transported data. The transported real prefix classifier supplies the rational endpoint classifier at the selected index. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness visible context empty distance hsame transport`

Theorem 95.11 (Completion visible-context symmetric tail readback)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n, a visible-context metric distance witness from x_n to y_n has central result* $\mathsf{E1}(d)$*, and a visible-context metric distance witness from y_n to x_n has central result* $\mathsf{E1}(e)$*, then d and e are unary,* $d\mathsf{hsame}e$*, and the rational endpoint classifier holds between y_n and x_n.*

Proof. Apply visible-context exactness to both displayed distance witnesses. This recovers the two central metric distance witnesses with visible results $\mathsf{E1}(d)$ and $\mathsf{E1}(e)$. The symmetric visible-tail readback theorem then extracts both unary tails, compares them by hsame, and reads back the reversed rational endpoint classifier. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness visible context e1 symmetric tail real prefix readback`

Theorem 95.12 (Completion metric distance visible-context tail determinacy)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n and two visible contexts display metric distance witnesses with central results* $\mathsf{E1}(d)$ *and* $\mathsf{E1}(e)$*, then d and e are unary,* $d\mathsf{hsame}e$*, and the rational endpoint classifier holds between x_n and y_n.*

Proof. Apply visible-context tail readback to both displayed witnesses to obtain unary membership for each tail and the rational endpoint classifier. Visible metric result determinacy compares the two displayed central $\mathsf{E1}$ results, and $\mathsf{E1}$ inversion for hsame descends the comparison to $d\mathsf{hsame}e$. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness visible context e1 tail deterministic`

Theorem 95.13 (Completion prefix-independent visible-context tail determinacy)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n and two visible contexts, possibly with different left and right context histories, display metric distance witnesses with central results* $\mathsf{E1}(d)$ *and* $\mathsf{E1}(e)$*, then d and e are unary,* $d\mathsf{hsame}e$*, and the rational endpoint classifier holds between x_n and y_n.*

Proof. Visible-context tail readback applies to both displayed witnesses and supplies the two unary tail witnesses together with the rational endpoint classifier. Prefix-independent metric result determinacy compares the displayed central $\mathsf{E1}$ results across the two contexts. Inverting $\mathsf{E1}$ under hsame descends the comparison to $d\mathsf{hsame}e$. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness visible context e1 prefix independent tail deterministic`

Theorem 95.14 (Completion prefix-independent visible-context symmetric tail readback)**.** *Let x and y be real stream representatives and let n be a prefix index. If the real stream prefix classifier holds at n, a visible-context metric distance witness from x_n to y_n has central result* $\mathsf{E1}(d)$*, and an independently contextualized visible metric distance witness from y_n to x_n has central result* $\mathsf{E1}(e)$*, then d and e are unary,* $d\mathsf{hsame}e$*, and the rational endpoint classifier holds between y_n and x_n.*

Proof. Visible-context tail readback applies to the first displayed witness, while symmetry of the real stream prefix classifier supplies the readback direction for the second witness. The prefix-independent symmetric metric classifier compares the two displayed $\mathsf{E1}$ results, and $\mathsf{E1}$ inversion for hsame descends the comparison to the tails. □

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness visible context e1 prefix independent symmetric tail readback`

95.2 The certificate

Theorem 95.15 (Concrete CompletionUp naming certificate)**.** *The* Completion$^{\uparrow}$ *chapter carries a concrete naming-certificate boundary for the universal regular-Cauchy completion of a metric naming certificate. The certificate has the following ten fields.*

1. *The traditional target is the universal regular-Cauchy completion associated to* $\mathsf{NameCert}_{\mathsf{Met}^{\uparrow}}$.
2. *The BEDC source is* BHist *equipped with* RealStreamPrefixClassifier*,* MetricDistanceWitness*, and the supplied real-completeness capstone data.*
3. *The carrier consists of completion candidates, namely regular Cauchy point-name streams modulo the pointwise* hsame *transport already used by the readback rows.*
4. *The classifier reads pointwise metric-distance tolerance through the real-prefix classifier at a selected prefix index.*
5. *Stability is supplied by the checked visible-tail, empty-distance, transport, symmetry, determinacy, and prefix-independent readback theorems listed in this chapter.*
6. *The ledger records the selected prefix index, the visible left and right contexts, the metric-distance witness, the Cauchy modulus, and the limit candidate.*
7. *The core theorem is this certificate boundary, which repacks the carrier, classifier, stability, ledger, and exactness clauses for* Completion$^{\uparrow}$.
8. *Exactness is finite-prefix distance readback together with limit uniqueness under the classifier.*
9. *The standard bridge slot is carried by the conservative completion bridge, so this certificate exposes the paper-side boundary consumed by* CompleteMetric$^{\uparrow}$ *and* CompactMetric$^{\uparrow}$ *without asserting that bridge here.*
10. *The certificate status is* ProofTarget.

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness semanticNameCert`

Proof. Endpoint coverage comes from the two direct real-prefix readback rows. Apply Definition 95.1 for visible E1 distance results, equivalently the checked `CompletionMetricDistanceWitness_e1_tail_re` row, and apply Definition 95.2 for empty results, equivalently the checked `CompletionMetricDistanceWitness_em` row. These two cases cover the finite-prefix distance readback used by the classifier.

Carrier and classifier transport are the two hsame transport rows. Use Definition 95.4 for ordinary visible tails and Definition 95.8 for contextualized tails. The empty contextual case is carried by Definition 95.10, so the selected prefix index and its visible contexts can be moved along pointwise representative equality.

Symmetry and uniqueness are read from the symmetric and deterministic rows. Apply Definition 95.5, Definition 95.6, Definition 95.11, and Definition 95.12 to compare all visible distance tails attached to the same finite-prefix classifier data.

Context-insensitive readback is supplied by the prefix-independent visible-context rows. Apply Definition 95.13 and Definition 95.14 to remove dependence on the chosen visible left and right contexts. The Cauchy modulus and limit candidate are then ledger fields, while limit uniqueness is the exactness condition read through the same classifier.

This is not a one-theorem variant of any checked row: its conclusion packages the source, carrier, classifier, stability obligations, ledger, exactness predicate, and downstream bridge slots into one Completion$^{\uparrow}$ certificate boundary. □

Theorem 95.16 (Completion carrier obligation)**.** *The* Completion$^{\uparrow}$ *carrier obligation is the BEDC finite-prefix regular-Cauchy point-name packet over* BHist, RealStreamPrefixClassifier, MetricDistanceWitness, *Cauchy modulus data, visible-context transport, and* Pkg *provenance. Its carrier row consists only of displayed point-name streams, selected prefix indices, finite distance-readback rows, visible left and right contexts, modulus rows, limit-candidate ledger rows, and package provenance.*

The obligation contains no quotient real, no host real equality, no choice-selected limit, and no representative selected outside the displayed finite-prefix packet.

Lean4 ✓ `BEDC.Derived.CompletionUp.CompletionCarrier obligation`

Proof. Read the carrier and ledger fields of Definition 95.15. The source is BHist equipped with the real-prefix classifier, metric-distance witness rows, Cauchy modulus data, visible contexts, and package provenance. These are exactly the finite coordinates named in the carrier statement.

The readback rows are supplied by Definition 95.1 and Definition 95.2. The visible-context coordinates are transported by Definition 95.4, Definition 95.8, and Definition 95.10.

The deterministic and prefix-independent rows of Definition 95.15 show that the carrier is exhausted by those finite-prefix coordinates. Since no cited row introduces a quotient type, host real equality, or choice-selected limit, none is part of the carrier obligation. □

Theorem 95.17 (Completion classifier stability obligation)**.** *The* Completion$^{\uparrow}$ *classifier is stable under displayed* hsame *and* Cont *transport of the selected prefix, visible left and right contexts, metric-distance witness, Cauchy modulus, and limit-candidate ledger. After transport, the classifier still reads only the transported real-prefix distance result, the transported visible-context rows, the transported modulus row, the transported limit-candidate row, and the transported* Pkg *provenance.*

The stability obligation introduces no quotient real equality, no host real equality, no completion point outside the packet, and no choice-selected representative.

Proof. Begin with the carrier rows named in Definition 95.16. A displayed hsame route moves the selected prefix and the visible contexts, while the displayed Cont routes preserve the finite readback boundary consumed by the classifier.

Apply Definition 95.4 to the ordinary visible tail and Definition 95.8 to the contextualized visible tail. For the empty contextual distance row, apply Definition 95.10.

The transported classifier remains deterministic by Definition 95.5 and Definition 95.12. Prefix-independent visible-context readback is supplied by Definition 95.13 and Definition 95.14.

Thus the transported classifier has the same finite-prefix inventory as the original packet. The proof never passes through a quotient type, host real equality, an external completion point, or a choice-selected representative. □

Theorem 95.18 (Completion ledger exactness obligation)**.** *Every public* Completion$^{\uparrow}$ *consumer read factors through the selected prefix index, real-prefix readback, metric-distance witness, visible-context transport, Cauchy modulus, limit-candidate row, and* Pkg *provenance displayed in the* Completion$^{\uparrow}$ *packet. The exactness ledger has no further public coordinate.*

In particular, a consumer cannot read a quotient real, host real equality, choice-selected limit, or representative outside the finite-prefix regular-Cauchy point-name packet.

Proof. Project a public consumer read through the ten-field boundary of Definition 95.15. The carrier field supplies the selected prefix and point-name packet, while the classifier field supplies the real-prefix distance readback through MetricDistanceWitness.

The visible-context rows are exactly the rows transported by Definition 95.8 and Definition 95.10. The ordinary and empty readback cases are exactly Definition 95.1 and Definition 95.2.

Use the determinacy and prefix-independent rows cited in Definition 95.15 to rule out any second public read path for the same displayed prefix data. The Cauchy modulus, limit-candidate row, and package provenance are ledger coordinates, so they are readable only as the displayed rows of that packet.

Therefore every public read factors through the listed finite-prefix coordinates. No step creates a quotient real, host real equality, choice-selected limit, or hidden representative. □

Closure status for $\mathsf{NameCert}_{\mathsf{Completion}\uparrow}$.

Constructive story: A completion packet is generated by regular-Cauchy point-name streams, real-prefix readback rows, metric-distance witnesses, visible-context transport, prefix-independent determinacy, Cauchy modulus data, and limit-candidate ledger rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Completion}\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: Definition 95.15, Definition 95.16, Definition 95.17, and Definition 95.18 export the concrete completion certificate, carrier obligation, classifier stability obligation, and ledger exactness obligation as the public finite-prefix completion surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Completion}\uparrow}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CompletionUp.CompletionMetricDistanceWitness\_semanticNameCert`

Bridge status: none

Origin: human

Not claimed: This chapter does not claim completeness of arbitrary metric spaces, quotient reals, choice-selected limits, open-cover compactness, or standard bridge verification.

Upgrade path: No paper-side theory-axis upgrade remains; formal bridge checking is tracked only on the verification axis.

Chapter 96

A Concrete Naming Certificate for $\mathsf{Manifold}^{\uparrow}$

The manifold interface $\mathsf{Manifold}^{\uparrow}$ packages a topological carrier with a finite atlas of charts into $(\mathsf{Real}^{\uparrow})^n$ whose transition maps are constructively smooth. It depends on $\mathsf{NameCert}_{\mathsf{Topology}^{\uparrow}}$ (chapter 88) and the real-analytic certificate (chapter 74), and supplies the substrate for the bundle and de Rham certificates.

96.1 Carrier definition

Definition 96.1 (Charted manifold carrier)**.** *A charted* $\mathsf{Manifold}^{\uparrow}$ *carrier package over a* $\mathsf{Topology}^{\uparrow}$ *source is a tuple*

$$\mathcal{M} = (X, \mathcal{T}, A, \mathsf{Dom}, \mathsf{domIx}, \mathsf{chart}, \mathsf{coord}, \mathsf{Trans})$$

with the following displayed data. The point carrier is a predicate $X : \mathsf{BHist} \to \mathsf{Prop}$ *on BEDC histories, and* $\mathcal{T}$ *is an indexed open topology carrier for* X *in the sense of Definition 88.1. The atlas index family* A *is finite. For every* $a : A$*, the chart-domain predicate* $\mathsf{Dom}_a : X \to \mathsf{Prop}$ *is carried by a witnessed open* $\mathsf{domIx}(a) : \mathsf{OpenIx}$*:*

$$\mathsf{CarriesOpen}_{\mathcal{T}}(\mathsf{domIx}(a), \mathsf{Dom}_a).$$

The chart map chart_a *sends a point* x *with* $\mathsf{Dom}_a(x)$ *to a finite list of coordinate histories*

$$\mathsf{coord}_a(x) = (r_1, \ldots, r_{n(a)})$$

whose entries satisfy the $\mathsf{Real}^{\uparrow}$ *carrier and are classified by the* $\mathsf{Real}^{\uparrow}$ *classifier under replacement of* x *along the topology carrier classifier.*

For every overlap row $a, b : A$ *and every point* x *lying in* $\mathsf{Dom}_a \cap \mathsf{Dom}_b$*, the ledger includes a transition entry*

$$\mathsf{Trans}_{a,b}(x) : \mathsf{coord}_a(x) \longmapsto \mathsf{coord}_b(x)$$

whose source and target coordinate lists are finite $\mathsf{Real}^{\uparrow}$ *histories and whose local transport row is certified by the* $\mathsf{RealAnalytic}^{\uparrow}$ *boundary of Definition 74.29. Thus the manifold carrier does not add a new equality principle: point sameness is the topology carrier classifier, coordinate sameness is the* $\mathsf{Real}^{\uparrow}$ *classifier, and overlap smoothness is ledgered by supplied real-analytic rows.*

Lean4 (definition) `BEDC.Derived.ManifoldUp.ManifoldChartedCarrier`

Definition 96.2 (Chart-atlas manifold carrier)**.** *A chart-atlas manifold carrier for* $\mathsf{Manifold}^{\uparrow}$ *is a predicate* $\mathsf{ManAtlasPkg}(P)$ *on* BHist *packages* P *whose fields are the following rows.*

1. *The traditional target is a finite-atlas topological manifold.*
2. *The BEDC source is* $\mathsf{Topology}^{\uparrow}$ *together with* $\mathsf{Real}^{\uparrow}$ *coordinate histories and real-analytic transition rows from chapter 74.*
3. *The carrier row contains a topological carrier history* M *with its* $\mathsf{Topology}^{\uparrow}$ *certificate, a finite chart-index history* I*, chart-domain predicates* Dom_i *on* M*, chart maps* $\varphi_i : \mathsf{Dom}_i \to (\mathsf{Real}^{\uparrow})^{n_i}$*, and overlap transition ledgers* Trans_{ij} *for each chart pair* i, j*.*
4. *The classifier row is componentwise* hsame *on* M*, on* I*, on every chart-domain row, on every chart-map row, and on every transition ledger.*
5. *The stability row says that componentwise* hsame *transport of those fields carries* $\mathsf{ManAtlasPkg}$ *packages to* $\mathsf{ManAtlasPkg}$ *packages.*
6. *The ledger records topology rows, real-coordinate rows, overlap rows, and constructively smooth transition certificates for each nonempty chart overlap.*
7. *The standard bridge row is absent: this carrier names the BEDC obligation surface and does not assert an external manifold equivalence.*

Equivalently, $\mathsf{ManAtlasPkg}(P)$ *is the ten-field* $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ *source object whose public carrier is the finite chart atlas over* M*, whose classifier is the displayed componentwise* hsame *classifier, and whose visible ledger is the topology-coordinate-overlap ledger just listed.*

Theorem 96.3 (ManifoldUp chart cover coverage)**.** *For every package* P *with* $\mathsf{ManAtlasPkg}(P)$ *and every carried point history* x *in the underlying* $\mathsf{Topology}^{\uparrow}$ *carrier, the visible atlas ledger exhibits a chart index* i *together with the displayed chart-domain row* $\mathsf{Dom}_i(x)$*.*

Proof. Unpack $\mathsf{ManAtlasPkg}(P)$ by Definition 96.2. The carrier row says that x is a BHist point carried by the same $\mathsf{Topology}^{\uparrow}$ carrier that supports every chart domain.

The visible atlas ledger is part of the charted source object. Its chart-cover row is indexed by the finite chart history and states that every carried point is displayed in at least one domain row.

Project the cover witness for x. The projection returns a chart index i and the corresponding membership evidence $\mathsf{Dom}_i(x)$, both living in the same $\mathsf{Topology}^{\uparrow}$ carrier row as x. □

Theorem 96.4 (ManifoldUp chart domain carrier transport)**.** *Let* P *be a package with* $\mathsf{ManAtlasPkg}(P)$*. If carried point histories* x *and* y *are related by the* $\mathsf{Topology}^{\uparrow}$ *carrier classifier and* $\mathsf{Dom}_i(x)$ *holds for a displayed chart-domain row, then* $\mathsf{Dom}_i(y)$ *holds after transporting the row along the classifier.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage chart domain carrier transport`

Proof. The chart-domain row Dom_i is an indexed-open witness supplied by the $\mathsf{Topology}^{\uparrow}$ part of Definition 96.2. Its membership predicate is therefore classified by the same carrier comparison as the underlying topological points.

Apply the carrier classifier to the evidence that x and y are the same carried point for the topology row. The indexed-open stability clause transports membership in Dom_i from x to y.

The transported domain row is still the displayed row for chart i, because the chart classifier is componentwise hsame on chart-domain histories. Thus the transported membership is exactly $\mathsf{Dom}_i(y)$. □

Theorem 96.5 (ManifoldUp atlas transition composition)**.** *Let P be a package with* $\mathsf{ManAtlasPkg}(P)$*. For chart indices i, j, k and a carried point history x lying in the three displayed domains, the overlap transition from i to k is witnessed by composing the supplied* $\mathsf{RealAnalytic}^{\uparrow}$ *transition ledgers from i to j and from j to k on the common overlap.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage transition composition scope`
Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage transition append readback`

Proof. Unpack the transition rows of Definition 96.2. The hypotheses $\mathsf{Dom}_i(x)$, $\mathsf{Dom}_j(x)$, and $\mathsf{Dom}_k(x)$ place x in both overlaps (i, j) and (j, k).

Project the two visible ledgers Trans_{ij} and Trans_{jk}. Each supplies a coordinate-change history between finite $\mathsf{Real}^{\uparrow}$ windows together with a $\mathsf{RealAnalytic}^{\uparrow}$ local transition certificate on its overlap.

Compose the coordinate histories at the shared j-coordinates. The $\mathsf{RealAnalytic}^{\uparrow}$ local transition row is closed under this displayed composition boundary, so the composed history carries a real-analytic certificate on the triple-overlap row.

Record the composed certificate as the transition witness from i to k on the common overlap. This witness is the atlas-transition composition required by the $\mathsf{Manifold}^{\uparrow}$ ledger. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage transition composition target`
Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage transition composition readback`

Theorem 96.6 (ManifoldUp chart-domain intersection open)**.** *Let P be a package with* $\mathsf{ManAtlasPkg}(P)$*. For chart indices i, j, the* $\mathsf{Topology}^{\uparrow}$ *index* $\mathsf{domIx}(i) \wedge_{\mathsf{Topology}^{\uparrow}} \mathsf{domIx}(j)$ *carries the overlap predicate*

$$x \longmapsto \mathsf{Dom}_i(x) \wedge \mathsf{Dom}_j(x)$$

on the underlying topological carrier.

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage chart domain intersection open`

Proof. Unpack $\mathsf{ManAtlasPkg}(P)$ by Definition 96.2. The carrier row exposes the common $\mathsf{Topology}^{\uparrow}$ carrier and, for every chart index, a displayed open index $\mathsf{domIx}(-)$ carrying the corresponding chart-domain predicate.

Project the two rows $\mathsf{CarriesOpen}_{\mathcal{T}}(\mathsf{domIx}(i), \mathsf{Dom}_i)$ and $\mathsf{CarriesOpen}_{\mathcal{T}}(\mathsf{domIx}(j), \mathsf{Dom}_j)$. They live over the same carrier because both chart domains are fields of the same atlas package.

Apply Definition 88.7 to these two carried opens. The resulting finite-intersection index is $\mathsf{domIx}(i) \wedge_{\mathsf{Topology}^{\uparrow}} \mathsf{domIx}(j)$, and its pointwise readback is exactly the displayed conjunction of the two chart-domain memberships. □

Theorem 96.7 (ManifoldUp overlap transition source carried)**.** *Let P be a package with* $\mathsf{ManAtlasPkg}(P)$*. Every displayed transition row* Trans_{ij} *is sourced on the carried open overlap supplied by Definition 96.6 and exposes finite* $\mathsf{Real}^{\uparrow}$ *source and target coordinate rows* $\mathsf{coord}_i(x)$ *and* $\mathsf{coord}_j(x)$*.*

Proof. Fix the chart pair i, j and unpack the transition ledger of Definition 96.2. The ledger row for Trans_{ij} is indexed by the same chart-domain predicates Dom_i and Dom_j that appear in the carrier row.

Use Definition 96.6 to replace the informal pairwise overlap by the explicit carried-open index $\mathsf{domIx}(i) \wedge_{\mathsf{Topology}^{\uparrow}} \mathsf{domIx}(j)$. Thus the source predicate for the transition is not a hidden set-theoretic intersection; it is the $\mathsf{Topology}^{\uparrow}$ certificate carrying $\mathsf{Dom}_i(x) \wedge \mathsf{Dom}_j(x)$.

Project the coordinate fields from the same atlas package. The source list $\mathsf{coord}_i(x)$ and target list $\mathsf{coord}_j(x)$ are finite lists of $\mathsf{Real}^{\uparrow}$ histories, and the transition row records the real-analytic certificate between those two finite coordinate rows on the carried overlap. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage transition source readback`

Theorem 96.8 (ManifoldUp triple-overlap composition scope)**.** *Let P be a package with* $\mathsf{ManAtlasPkg}(P)$*. For chart indices i, j, k, the triple-overlap predicate*

$$x \longmapsto \mathsf{Dom}_i(x) \wedge \mathsf{Dom}_j(x) \wedge \mathsf{Dom}_k(x)$$

is carried by iterating the $\mathsf{Topology}^{\uparrow}$ *finite-intersection index, and this carried triple overlap is the scoped source on which Definition 96.5 composes the two real-analytic transition ledgers.*

Proof. First build the pairwise overlap for i and j using Definition 96.6. This gives a $\mathsf{Topology}^{\uparrow}$ carried-open index for $\mathsf{Dom}_i(x) \wedge \mathsf{Dom}_j(x)$ over the package carrier.

Project the chart-domain row for k from Definition 96.2. Apply Definition 88.7 to the carried pairwise overlap and the carried open Dom_k. The resulting iterated index carries the displayed triple conjunction, with the parenthesizing read through the pointwise conjunction witness.

Now restrict the transition ledgers Trans_{ij} and Trans_{jk} to this carried triple overlap. The source and target coordinate rows are finite $\mathsf{Real}^{\uparrow}$ lists by Definition 96.7, and the shared j-coordinate row is exposed on the same carried source.

Only after this source has been carried, apply Definition 96.5. Its composition witness therefore lives on the explicit $\mathsf{Topology}^{\uparrow}$ triple-overlap certificate, not on an implicit common-overlap predicate. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldScopedBoundaryPackage reassociated source`
Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldScopedBoundaryPackage pair transition closure`

Definition 96.9 (Singleton empty-chart manifold package)**.** *Let the BEDC manifold carrier be the singleton history predicate*

$$C_{\mathsf{e}}(h) \quad \Longleftrightarrow \quad \mathsf{hsame}(h, \mathsf{e})$$

on BHist*. Its carrier classifier is* hsame *restricted to C_{e}: two carried histories classify when they are internally the same, and the carrier side conditions are transported along* hsame*.*

The topology surface is the inherited indexed $\mathsf{Topology}^{\uparrow}$ *boundary surface on this carrier. The distinguished top index carries C_{e} itself, and the distinguished bottom index carries the empty predicate. The membership ledger records the chosen history, its C_{e} witness, the classifier row, and the boundary open witness supplied by* $\mathsf{Topology}^{\uparrow}$*.*

The atlas has one chart χ_{e}. Its domain is the top open of the displayed topology surface. Its target is the constant zero endpoint of $\mathsf{Real}^{\uparrow}$*, read through the real-analytic local constant stream boundary. For every carried h, the chart value is the same constant endpoint, and the chart ledger records* BHist*,* $\mathsf{UnaryHistory}$*,* hsame*,* Cont*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and the* $\mathsf{RealAnalytic}^{\uparrow}$ *constant-map boundary.*

Thus the singleton package supplies the following ten certificate rows:

1. *the traditional target is a one-point smooth manifold;*
2. *the BEDC source is* BHist *with* e *as the displayed point;*
3. *the carrier choice is C_{e};*
4. *the classifier choice is* hsame *restricted to C_{e};*
5. *the stability obligations are carrier transport, top-domain transport, bottom-domain exclusion, chart-value transport, and transition transport;*

6. *the ledger is the history, unary-history row, classifier row, continuation row, topology boundary row, real constant endpoint row, and real-analytic constant-map row;*
7. *the core theorem list is carrier topology scope, chart coverage, transition smoothness, and the assembled* $\mathsf{Manifold}^{\uparrow}$ *obligation package;*
8. *the exactness predicate says every chart-domain witness is exactly a* C_{e} *witness and every transition witness is the sole self-overlap row;*
9. *the standard bridge is absent;*
10. *the status is paper-side obligation target.*

96.2 Atlas Obligation Inventory

Definition 96.10 (Manifold atlas obligation inventory)**.** *The atlas obligation inventory for* $\mathsf{ManAtlasPkg}$ *is the ten-field* $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ *template whose rows are fixed as follows.*

1. *The traditional target is a finite-atlas manifold: a topological carrier equipped with finitely many chart domains, chart maps into finite* $(\mathsf{Real}^{\uparrow})$ *coordinate windows, and transition data on visible overlaps.*
2. *The BEDC source is* BHist *together with the already named* $\mathsf{Topology}^{\uparrow}$ *carrier surface, the* $\mathsf{Real}^{\uparrow}$ *coordinate rows, and the* $\mathsf{RealAnalytic}^{\uparrow}$ *local transition rows.*
3. *The carrier is the predicate* $\mathsf{ManAtlasPkg}(P)$ *of Definition 96.2 on package histories* P*.*
4. *The classifier is componentwise* hsame *on the topological carrier, the finite chart-index history, chart-domain rows, chart-map rows, coordinate histories, and transition ledgers.*
5. *The stability field consists of transport of the carrier, chart domains, chart maps, coordinate rows, and transition ledgers along those componentwise* hsame *witnesses.*
6. *The ledger records the* $\mathsf{Topology}^{\uparrow}$ *carried-open rows, finite intersection rows for pairwise and triple overlaps,* $\mathsf{Real}^{\uparrow}$ *coordinate rows, and* $\mathsf{RealAnalytic}^{\uparrow}$ *certificates for each displayed transition.*
7. *The core theorem list is Definition 96.3, Definition 96.4, Definition 96.6, Definition 96.7, Definition 96.8, Definition 96.5, Definition 96.18, Definition 96.21, Definition 96.22, and Definition 96.23.*
8. *Exactness is visible-atlas readback: every accepted carrier, classifier, domain, coordinate, overlap, transition, and coherence row is one of the displayed rows of* $\mathsf{ManAtlasPkg}$*.*
9. *The standard bridge row is absent.*
10. *The boundary package is the scoped surface of Definition 96.41, with field coverage supplied by Definition 96.42.*

Lean4 (definition) `BEDC.Derived.ManifoldUp.ManifoldAtlasObligationInventory`

Theorem 96.11 (Manifold atlas carrier-classifier obligation)**.** *For every atlas package history* P*, the carrier and classifier slots of the inventory in Definition 96.10 are fixed by Definition 96.2: the carrier slot is exactly* $\mathsf{ManAtlasPkg}(P)$*, and the classifier slot is componentwise* hsame *on the displayed carrier, chart-index, chart-domain, chart-map, coordinate, and transition-ledger rows.*

Proof. Unpack the inventory definition. Its carrier row names $\mathsf{ManAtlasPkg}(P)$ and points back to Definition 96.2, so there is no second carrier predicate to choose.

Unpack Definition 96.2. The classifier row there is componentwise hsame on the same topological carrier history, finite chart-index history, chart-domain rows, chart-map rows, and transition ledger rows that appear in the inventory.

The two projections therefore read the same BHist package fields in the same order. Carrier equality is definitional readback of ManAtlasPkg, and classifier equality is componentwise readback of the displayed hsame witnesses. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage classifier transport`

Theorem 96.12 (Manifold atlas chart-domain transition obligation)**.** *For every package P satisfying* $\mathsf{ManAtlasPkg}(P)$*, the inventory of Definition 96.10 supplies the chart-cover, domain-transport, pairwise-overlap, triple-overlap, and transition-ledger obligations from the existing* $\mathsf{Manifold}^{\uparrow}$ *theorem surface.*

Proof. The chart-cover row is Definition 96.3. It projects, for each carried point history in the $\mathsf{Topology}^{\uparrow}$ carrier, a finite chart index and a displayed chart-domain witness.

The domain-transport row is Definition 96.4. It transports membership in a displayed chart domain along the $\mathsf{Topology}^{\uparrow}$ carrier classifier, with the chart-domain row itself compared by componentwise hsame.

The pairwise overlap row is Definition 96.6, and the transition source row is Definition 96.7. Together they turn each displayed overlap into a carried $\mathsf{Topology}^{\uparrow}$ finite intersection with finite $\mathsf{Real}^{\uparrow}$ source and target coordinate rows.

The triple-overlap and transition-ledger rows are Definition 96.8, Definition 96.5, and Definition 96.18. These rows provide the iterated finite-intersection source, the $\mathsf{RealAnalytic}^{\uparrow}$ composition witness, and componentwise hsame stability for the visible transition ledger. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage transition closure`

Theorem 96.13 (Manifold atlas NameCert exactness obligation)**.** *Every package satisfying the inventory of Definition 96.10 and the scoped boundary of Definition 96.41 has visible-atlas exactness: its public* $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ *fields are exactly the carrier, classifier, stability, ledger, theorem-list, exactness, and absent-bridge rows listed in the inventory, with no additional chart, coordinate, overlap, or transition row outside the displayed* ManAtlasPkg *surface.*

Proof. First project the carrier and classifier by Definition 96.11. The public carrier is ManAtlasPkg, and the public classifier is the componentwise hsame row over the displayed atlas fields.

Next project the chart, domain, overlap, and transition obligations by Definition 96.12. These projections account for the chart cover, domain transport, pairwise overlap, triple overlap, transition composition, and transition-ledger stability rows.

Now apply Definition 96.41. Its exactness row accepts only the visible chart cover, domain, coordinate, overlap, transition, and coherence rows of ManAtlasPkg, and its standard bridge row is absent.

Finally apply Definition 96.42. The scoped field coverage theorem says that the visible fields are precisely the carrier, componentwise classifier, chart cover, domain transport, overlap sources, transition-ledger stability, and coherence rows already named above. Hence the ledger is exhausted by the inventory and no hidden atlas field remains. □

96.3 The certificate

Theorem 96.14 (Manifold chart endpoint coverage)**.** *For a charted carrier package $\mathcal{M}$ as in Definition 96.1, every displayed chart row exposes the following endpoint data:*

1. *the underlying* $\mathsf{Topology}^{\uparrow}$ *carrier row* $X(x)$ *and the classifier* same_X *supplied by* $\mathcal{T}$*;*
2. *the witnessed open row* $\mathsf{CarriesOpen}_{\mathcal{T}}(\mathsf{domIx}(a), \mathsf{Dom}_a)$ *for the chart domain;*
3. *the finite* $\mathsf{Real}^{\uparrow}$ *coordinate output* $\mathsf{coord}_a(x) = (r_1, \ldots, r_{n(a)})$*;*
4. *the visible atlas ledger entry recording* a*,* $\mathsf{domIx}(a)$*,* x*, and the coordinate list.*

Proof. Unfold the charted carrier package of Definition 96.1. The first fields are exactly the predicate X on BHist and the indexed open topology carrier $\mathcal{T}$, so the $\mathsf{Topology}^{\uparrow}$ carrier and classifier are obtained by projection.

For a fixed atlas index a, the same unfolding exposes the domain predicate Dom_a, the chosen open index $\mathsf{domIx}(a)$, and the carrying equation for that open. This is the chart-domain open witness required by the certificate.

Finally project the chart map field. Its output is already a finite list of $\mathsf{Real}^{\uparrow}$ coordinate histories, and the atlas index plus open index are retained in the package ledger. No quotient or hidden atlas representative is introduced, so the displayed tuple is the visible readback of the chart row. □

Theorem 96.15 (Manifold transition classifier stability)**.** *Let $\mathcal{M}$ be a charted carrier package. Suppose $x, y : \mathsf{BHist}$ are carried points with $\mathsf{same}_X(x, y)$, and suppose the atlas domains Dom_a and Dom_b carry x through their witnessed open indices. Then the overlap transition row $\mathsf{Trans}_{a,b}(x)$ transports to the corresponding row at y using:*

1. *the topology carrier classifier and membership-stability field of Definition 88.1;*
2. *the two carrying equations for* $\mathsf{CarriesOpen}_{\mathcal{T}}(\mathsf{domIx}(a), \mathsf{Dom}_a)$ *and* $\mathsf{CarriesOpen}_{\mathcal{T}}(\mathsf{domIx}(b), \mathsf{Dom}_b)$*;*
3. *the* $\mathsf{Real}^{\uparrow}$ *classifier on each coordinate of* $\mathsf{coord}_a(-)$ *and* $\mathsf{coord}_b(-)$*;*
4. *the supplied* $\mathsf{RealAnalytic}^{\uparrow}$ *local transport rows from Definition 74.29.*

Consequently the transported source and target coordinate lists represent the same overlap transition in the atlas ledger.

Proof. Begin with the topology side. The carrying equation for $\mathsf{domIx}(a)$ converts $\mathsf{Dom}_a(x)$ into $\mathsf{OpenAt}(\mathsf{domIx}(a), x)$. The membership-stability field of Definition 88.1, applied to $\mathsf{same}_X(x, y)$, transports this open membership to y, and the same carrying equation converts it back to $\mathsf{Dom}_a(y)$.

Repeat the identical argument for b. This supplies the transported overlap witness $\mathsf{Dom}_a(y) \wedge \mathsf{Dom}_b(y)$, so the transition ledger has the same atlas indices at the transported point.

Project the coordinate fields from Definition 96.1. Their stability clauses give coordinatewise $\mathsf{Real}^{\uparrow}$ classifier witnesses from $\mathsf{coord}_a(x)$ to $\mathsf{coord}_a(y)$ and from $\mathsf{coord}_b(x)$ to $\mathsf{coord}_b(y)$.

The transition row itself is one of the real-analytic rows supplied at the boundary of Definition 74.29. Apply that row to the transported overlap witness and the coordinatewise $\mathsf{Real}^{\uparrow}$ classifier witnesses. The result is the transition row at y, classified by the same visible atlas ledger entry. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton transition classifier stability`

Theorem 96.16 (Manifold charted NameCert surface)**.** *A charted carrier package $\mathcal{M}$ as in Definition 96.1, together with Definition 96.14 and Definition 96.15, assembles the paper-side* $\mathsf{NameCert}_{\mathsf{Manifold}^\uparrow}$ *obligation surface. Its fields are the* BHist *point carrier X, the* $\mathsf{Topology}^\uparrow$ *classifier* same_X*, the finite atlas ledger, chart-domain open witnesses, finite* $\mathsf{Real}^\uparrow$ *coordinate outputs, overlap-transition stability rows, and an explicit statement that no standard bridge is claimed.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage semanticNameCert`

Proof. Unfold the NameCert template fields against Definition 96.1. The traditional target is a charted manifold, the BEDC source is BHist equipped with the topology carrier $\mathcal{T}$ and the finite atlas data, the carrier is X, and the classifier is same_X.

Endpoint coverage supplies the public readback rows: each chart exposes its carried point, witnessed open domain, finite coordinate output, and atlas ledger entry. These are exactly the carrier, source, and ledger fields needed by the certificate surface.

Transition classifier stability supplies the stability field. It transports overlap rows along the topology classifier, uses the two chart-domain carrying equations to keep the point inside both domains, and then invokes the $\mathsf{Real}^\uparrow$ and $\mathsf{RealAnalytic}^\uparrow$ rows for coordinate and smooth-transition transport.

The exactness policy is visible-ledger exactness: a manifold chart row is accepted only through the displayed atlas index, open witness, coordinate output, and transition row. The standard bridge field is absent, so the assembled surface is a BEDC paper-side NameCert obligation package rather than a bridge to an external manifold library. □

Theorem 96.17 (Manifold chart-transition classifier stability)**.** *Let P and Q be* BHist *packages. Suppose* $\mathsf{ManAtlasPkg}(P)$ *holds and the data of P and Q are related componentwise by* hsame*: the topological carrier histories are* hsame*, the finite chart-index histories are* hsame*, corresponding chart-domain rows are* hsame*, corresponding chart-map rows are* hsame*, and corresponding real-analytic transition ledgers are* hsame*. Then* $\mathsf{ManAtlasPkg}(Q)$ *holds.*

Proof. Unpack $\mathsf{ManAtlasPkg}(P)$ using Definition 96.2. The package supplies the $\mathsf{Topology}^\uparrow$ carrier row for M, the finite chart-index row, all chart-domain and chart-map rows, and the overlap transition ledgers.

Transport the topological carrier by the supplied hsame comparison of the carrier histories. Transport the finite chart-index row in the same way. For each chart index, transport the domain predicate and the chart-map row by the componentwise hsame hypotheses.

For each chart pair, transport the real-coordinate transition ledger and the constructively smooth transition certificate by the corresponding real-analytic hsame row. Repack the transported topology, chart, map, overlap, and smoothness rows. These are exactly the fields required by Definition 96.2 for $\mathsf{ManAtlasPkg}(Q)$. □

Theorem 96.18 (ManifoldUp transition ledger stability)**.** *Let P and Q be* BHist *packages. Suppose* $\mathsf{ManAtlasPkg}(P)$ *holds and the atlas rows of P and Q are related componentwise by* hsame*: the carrier histories, finite chart-index histories, indexed-open domain rows, coordinate histories, and real-analytic transition ledgers are all related. Then the transition ledger of P transports to a transition ledger for Q.*

Proof. Start with a displayed transition row of P for chart indices i, j. It contains the overlap membership boundary, the coordinate-change history, and the $\mathsf{RealAnalytic}^\uparrow$ local transition certificate.

Transport the two chart-domain rows by componentwise hsame. The $\mathsf{Topology}^{\uparrow}$ indexed-open membership stability clause transports the overlap predicate because it is the conjunction of the two transported domain memberships.

Transport the source and target coordinate histories by their componentwise hsame rows. The real-analytic transport boundary then carries the local transition certificate across the transported coordinate histories.

Repack the transported overlap, coordinate-change history, and real-analytic certificate. The result is the corresponding transition ledger row for Q. □

Theorem 96.19 (Manifold atlas overlap coverage)**.** *Every carried atlas package P with* $\mathsf{ManAtlasPkg}(P)$ *exposes, for each chart pair i, j in its finite chart-index history, a domain-overlap row*

$$\mathsf{Overlap}_{ij}(x) :\Longleftrightarrow \mathsf{Dom}_i(x) \wedge \mathsf{Dom}_j(x)$$

on the topological carrier and the corresponding constructively smooth $\mathsf{Real}^{\uparrow}$ *transition ledger from φ_i-coordinates to φ_j-coordinates on that overlap.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage pairwise overlap readback`

Proof. Unpack the carried atlas package by Definition 96.2. The finite chart-index row gives the admissible chart pairs, while the chart-domain rows give the two predicates Dom_i and Dom_j over the same topological carrier.

For a fixed pair i, j, form the overlap row by conjunction of the two domain memberships. The topology ledger records the carrier support of both domains, so the overlap row is a predicate on the same topological carrier M.

The package ledger contains, for this same pair, the transition row Trans_{ij}. Its real-coordinate part records the source and target $\mathsf{Real}^{\uparrow}$ coordinate histories, and its real-analytic part records the constructively smooth transition certificate on the displayed overlap. Project these two ledger components to obtain the claimed coverage row. □

Definition 96.20 (Manifold transition coherence ledger)**.** *For a carried atlas package P with* $\mathsf{ManAtlasPkg}(P)$*, the transition coherence ledger is the sub-ledger of* $\mathsf{ManAtlasPkg}(P)$ *whose rows are indexed by one, two, and three chart names in the finite chart-index history. It contains the following displayed entries.*

1. *For every chart i, the row* $\mathsf{IdTrans}_i$ *is carried on the self-overlap* $\mathsf{Overlap}_{ii}$ *supplied by* $\mathsf{Topology}^{\uparrow}$ *and classifies the transition* Trans_{ii} *by the identity coordinate history row on φ_i.*
2. *For every chart pair i, j, the row* $\mathsf{InvTrans}_{ij}$ *is carried on the overlap transported between* $\mathsf{Overlap}_{ij}$ *and* $\mathsf{Overlap}_{ji}$ *by the* $\mathsf{Topology}^{\uparrow}$ *overlap rows, and classifies the two composites* $\mathsf{Trans}_{ji} \circ \mathsf{Trans}_{ij}$ *and* $\mathsf{Trans}_{ij} \circ \mathsf{Trans}_{ji}$ *by the corresponding* IdTrans *rows.*
3. *For every chart triple i, j, k, the row* $\mathsf{Cocycle}_{ijk}$ *is carried on the triple-overlap predicate*

$$\mathsf{Dom}_i(x) \wedge \mathsf{Dom}_j(x) \wedge \mathsf{Dom}_k(x),$$

and classifies $\mathsf{Trans}_{jk} \circ \mathsf{Trans}_{ij}$ *and* Trans_{ik} *by the same real-analytic transition row from φ_i-coordinates to φ_k-coordinates.*

Each entry is a visible ledger row over $\mathsf{Topology}^{\uparrow}$ *carried-overlap transport,* $\mathsf{Real}^{\uparrow}$ *coordinate histories, and the real-analytic classifier rows already exposed by the atlas package.*

Lean4 (definition) `BEDC.Derived.ManifoldUp.ManifoldTransitionCoherenceLedger`

Theorem 96.21 (Manifold overlap identity transition)**.** *Every carried atlas package P with* $\mathsf{ManAtlasPkg}(P)$ *exposes, for each chart i, a self-overlap transition row* Trans_{ii} *on* $\mathsf{Overlap}_{ii}$*. This row is classified by* $\mathsf{IdTrans}_i$ *in the transition coherence ledger, so its coordinate action is the identity real-coordinate row on φ_i over the carried self-overlap.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldTransitionCoherenceLedger identity transition readback`
Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton overlap identity transition`
Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldTransitionCoherenceLedger identity transition empty`
Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldTransitionCoherenceLedger identity transition`

Proof. Unpack $\mathsf{ManAtlasPkg}(P)$ by Definition 96.2. The finite chart-index row admits the pair (i, i), and Definition 96.19 identifies the carried domain as $\mathsf{Dom}_i(x) \wedge \mathsf{Dom}_i(x)$ on the underlying $\mathsf{Topology}^{\uparrow}$ carrier.

Project the self row from Definition 96.20. Its source and target coordinate histories are both the displayed list $\varphi_i(x)$, transported through the same carried-overlap row.

The real-analytic classifier component of $\mathsf{IdTrans}_i$ is the identity coordinate row. Repacking that classifier with the self-overlap transport gives the displayed Trans_{ii} transition classified as the identity on φ_i. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldTransitionCoherenceLedger identity transition boundary`

Theorem 96.22 (Manifold overlap inverse transition)**.** *Every carried atlas package P with* $\mathsf{ManAtlasPkg}(P)$ *exposes, for each chart pair i, j, inverse transition rows on the carried overlap. The composite* $\mathsf{Trans}_{ji} \circ \mathsf{Trans}_{ij}$ *is classified by* $\mathsf{IdTrans}_i$ *on the i-coordinate overlap, and the composite* $\mathsf{Trans}_{ij} \circ \mathsf{Trans}_{ji}$ *is classified by* $\mathsf{IdTrans}_j$ *on the j-coordinate overlap.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton transition inverse boundary`
Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton overlap inverse transition`

Proof. Unpack the two pairwise overlap rows using Definition 96.19. The row for (i, j) carries $\mathsf{Dom}_i(x) \wedge \mathsf{Dom}_j(x)$, while the row for (j, i) carries the same two domain memberships in the reversed order.

Use the $\mathsf{Topology}^{\uparrow}$ carried-overlap transport to identify those two overlap readbacks. This gives a common domain on which both transition ledgers can be composed without changing the carried point or the chart-domain witnesses.

Project $\mathsf{InvTrans}_{ij}$ from Definition 96.20. Its real-analytic classifier rows state exactly that the two displayed composites classify to the relevant identity rows. Together with Definition 96.21, these projected rows give the two claimed inverse identities on the carried overlap. □

Theorem 96.23 (Manifold triple-overlap cocycle)**.** *Every carried atlas package P with* $\mathsf{ManAtlasPkg}(P)$ *exposes, for each chart triple i, j, k, a cocycle row on the carried triple overlap. On that overlap,* $\mathsf{Trans}_{jk} \circ \mathsf{Trans}_{ij}$ *and* Trans_{ik} *are classified by the same real-analytic transition row from φ_i-coordinates to φ_k-coordinates.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton coherence rows empty`

Proof. Start from the three pairwise overlap rows supplied by Definition 96.19. Their $\mathsf{Topology}^{\uparrow}$ domain components restrict to the same carried triple-overlap predicate $\mathsf{Dom}_i(x) \wedge \mathsf{Dom}_j(x) \wedge \mathsf{Dom}_k(x)$.

Transport the pairwise transition ledgers to this common triple-overlap domain. The source of Trans_{ij} is the φ_i coordinate row, its target is the φ_j row, and the source of Trans_{jk} is the same φ_j row after $\mathsf{Real}^{\uparrow}$ coordinate-history transport.

Project $\mathsf{Cocycle}_{ijk}$ from Definition 96.20. Its real-analytic classifier component identifies the composite $\mathsf{Trans}_{jk} \circ \mathsf{Trans}_{ij}$ with the direct transition Trans_{ik} as the same transition row from φ_i to φ_k. Repacking that classifier with the common carried-overlap domain gives the displayed cocycle obligation. □

Theorem 96.24 (ManifoldUp transition-coherence exhaustion)**.** *For every carried atlas package P with $\mathsf{ManAtlasPkg}(P)$, every row of the transition coherence ledger of Definition 96.20 is one of the displayed one-chart identity rows, two-chart inverse-composite rows, or three-chart cocycle rows. In each case its source is a carried $\mathsf{Topology}^{\uparrow}$ overlap or triple-overlap, its endpoints are finite $\mathsf{Real}^{\uparrow}$ coordinate histories, and its classifier is the real-analytic transition row already exposed by the atlas ledger.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldTransitionCoherenceLedger exhaustion`

Proof. Unpack the transition coherence ledger of Definition 96.20. Its indexing data is the finite chart-index history carried by $\mathsf{ManAtlasPkg}(P)$, so each ledger row has one chart name, an ordered chart pair, or an ordered chart triple as its visible index.

In the one-index case, the row is $\mathsf{IdTrans}_i$. Apply Definition 96.21. The source is the self-overlap $\mathsf{Overlap}_{ii}$ carried by $\mathsf{Topology}^{\uparrow}$, the two endpoints are the same finite $\mathsf{Real}^{\uparrow}$ coordinate history φ_i, and the classifier is the identity real-analytic transition row exposed in the atlas ledger.

In the two-index case, the row is $\mathsf{InvTrans}_{ij}$. Apply Definition 96.22. The source is the carried overlap transported between $\mathsf{Overlap}_{ij}$ and $\mathsf{Overlap}_{ji}$, the endpoints are the finite coordinate histories φ_i and φ_j, and the two composites classify through the identity rows already exposed by the atlas transition ledger.

In the three-index case, the row is $\mathsf{Cocycle}_{ijk}$. Apply Definition 96.23. The source is the carried triple-overlap predicate, the endpoints are the finite coordinate histories φ_i, φ_j, and φ_k, and the composite transition and direct transition are classified by the same real-analytic row from φ_i to φ_k.

These three cases exhaust the constructors displayed in Definition 96.20. Repack the resulting carrier, endpoint, and classifier witnesses through Definition 96.25 to obtain the advertised $\mathsf{Manifold}^{\uparrow}$ ledger boundary. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldScopedBoundaryPackage transition coherence rows`

Theorem 96.25 (Manifold name-certificate obligation surface)**.** *The carrier definition of Definition 96.2, together with Definition 96.17 and Definition 96.19, Definition 96.21, Definition 96.22, and Definition 96.23, assembles the paper-side $\mathsf{Manifold}^{\uparrow}$ obligation surface. The surface consists of a topological carrier, a finite chart atlas, chart classifier stability, overlap coverage, transition-smoothness rows, identity transitions, inverse transition composites, triple-overlap cocycles, and no standard bridge row.*

Proof. The carrier definition supplies the named source object: $\mathsf{Topology}^{\uparrow}$ rows for the base carrier, $\mathsf{Real}^{\uparrow}$ coordinate rows for chart targets, finite chart-index data, chart domains, chart maps, and transition ledgers.

Definition 96.17 supplies the classifier-stability obligation for the whole package, because every public field is transported by the componentwise hsame classifier specified in the carrier definition.

Definition 96.19 supplies the overlap and transition-smoothness obligations. The absence of a standard bridge is already part of the carrier definition.

It remains to account for atlas compatibility. The coherence ledger of Definition 96.20 records the self, reversed-pair, and triple-overlap rows. The identity row is exposed by Definition 96.21; the inverse composite rows are exposed by Definition 96.22; and the triple-overlap cocycle row is exposed by Definition 96.23.

These rows use the same $\mathsf{Topology}^{\uparrow}$ carried-overlap transport, the same $\mathsf{Real}^{\uparrow}$ coordinate histories, and the same real-analytic classifier ledger as the pairwise transition rows. Repacking them with the carrier, classifier, and stability fields gives exactly the $\mathsf{Manifold}^{\uparrow}$ paper obligation surface listed in the theorem statement. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasSurfaceClassifier endpoints`
Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldAtlasPackage semantic name certificate`

Theorem 96.26 (Manifold name-certificate obligation threshold)**.** *The carrier definition of Definition 96.2, together with Definition 96.3, Definition 96.4, Definition 96.5, and Definition 96.18, assembles the paper-side* $\mathsf{Manifold}^{\uparrow}$ $\mathsf{NameCert}$ *obligation threshold. The threshold consists of the carrier, classifier, chart cover, chart-domain transport, transition composition, transition-ledger stability, and the visible atlas ledger.*

Proof. The carrier definition supplies the named source object: $\mathsf{Topology}^{\uparrow}$ rows for the base carrier, $\mathsf{Real}^{\uparrow}$ coordinate rows for chart targets, finite chart-index data, indexed-open chart domains, coordinate histories, and transition ledgers.

Definition 96.3 supplies the cover obligation by projecting, for every carried point, an index and domain membership from the visible atlas ledger.

Definition 96.4 supplies the classifier boundary for chart-domain membership. The same componentwise hsame classifier transports the carrier, domains, coordinate histories, and ledger rows named in the definition.

Definition 96.5 supplies the atlas composition obligation, and Definition 96.18 supplies stability of the visible transition ledger under transported chart rows. The absence of a standard bridge is already part of the carrier definition, so the assembled object is exactly the $\mathsf{Manifold}^{\uparrow}$ $\mathsf{NameCert}$ obligation threshold listed in the theorem statement. □

96.4 Chart Coordinate Transport

Definition 96.27 (ManifoldUp chart-coordinate transport row)**.** *Let P be a* BHist *package with* $\mathsf{ManAtlasPkg}(P)$*, let i be a chart index in the finite atlas history, and let x, y be carried points of the underlying* $\mathsf{Topology}^{\uparrow}$ *carrier. A chart-coordinate transport row for P, i, x, y consists of the following displayed data.*

1. *A chart-domain witness* $\mathsf{Dom}_i(x)$ *and a* $\mathsf{Topology}^{\uparrow}$ *classifier witness carrying x to y.*
2. *The transported chart-domain witness* $\mathsf{Dom}_i(y)$ *in the same indexed-open row.*
3. *A finite* $\mathsf{Real}^{\uparrow}$ *coordinate history $\varphi_i(x) = (r_1, \ldots, r_{n_i})$ exposed by the chart map at x.*
4. *A finite* $\mathsf{Real}^{\uparrow}$ *coordinate history $\varphi_i(y) = (s_1, \ldots, s_{n_i})$ exposed by the same chart map at y.*
5. *For each coordinate slot a in the finite chart output, a* $\mathsf{Real}^{\uparrow}$ *classifier witness relating r_a and s_a.*

Equivalently, the row is the visible coordinate-transport projection of $\mathsf{ManAtlasPkg}(P)$ *along a* $\mathsf{Topology}^{\uparrow}$ *carrier comparison: it records the chart index, the transported chart-domain membership, the two finite coordinate outputs, and the coordinatewise real classifiers.*

Lean4 (definition) `BEDC.Derived.ManifoldUp.ManifoldChartCoordinateTransportRow`

Theorem 96.28 (ManifoldUp chart-coordinate carrier transport)**.** *Let* P *be a* BHist *package with* $\mathsf{ManAtlasPkg}(P)$*. If* i *is a displayed chart index,* x *and* y *are carried points related by the* $\mathsf{Topology}^{\uparrow}$ *carrier classifier, and* $\mathsf{Dom}_i(x)$ *holds, then there exists a chart-coordinate transport row for* P, i, x, y*.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton chart coordinate carrier transport`

Proof. Unpack $\mathsf{ManAtlasPkg}(P)$ by Definition 96.2. The atlas carrier supplies the finite chart-index history, the indexed-open chart-domain row Dom_i, the chart map φ_i, and the finite $\mathsf{Real}^{\uparrow}$ coordinate histories read by that chart map on its domain.

Apply Definition 96.4 to the given $\mathsf{Topology}^{\uparrow}$ classifier witness between x and y. This transports the domain evidence $\mathsf{Dom}_i(x)$ to the displayed membership $\mathsf{Dom}_i(y)$ without changing the chart index or leaving the inherited topological carrier.

Evaluate the same chart-map row at the two displayed domain witnesses. The atlas classifier row is componentwise on chart maps and real-coordinate histories, so each coordinate in $\varphi_i(x)$ is related to the corresponding coordinate in $\varphi_i(y)$ by the $\mathsf{Real}^{\uparrow}$ classifier. These projections are exactly the fields of Definition 96.27. □

Theorem 96.29 (ManifoldUp chart-coordinate classifier determinacy)**.** *Let* P *be a* BHist *package with* $\mathsf{ManAtlasPkg}(P)$*, let* i *be a displayed chart index, and let* x, y *be carried points related by the* $\mathsf{Topology}^{\uparrow}$ *carrier classifier. Any two chart-coordinate transport rows for the same* P, i, x, y *have coordinate outputs that are coordinatewise classified by the* $\mathsf{Real}^{\uparrow}$ *classifier at both endpoints, and their endpoint comparison witnesses classify the same finite coordinate pairs.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldChartCoordinateTransportRow coordinate determinacy`
Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton chart coordinate classifier determinacy`

Proof. Both rows project from the same atlas package and the same chart index. By Definition 96.2, the chart-domain row and chart-map row are components of the visible $\mathsf{ManAtlasPkg}$ ledger, not separate set-level choices.

At the source endpoint, the two rows evaluate the same chart map on the same displayed domain membership $\mathsf{Dom}_i(x)$. The componentwise classifier for chart-map histories therefore relates their finite coordinate outputs by the $\mathsf{Real}^{\uparrow}$ classifier in every coordinate slot.

At the transported endpoint, both rows use Definition 96.4 with the same $\mathsf{Topology}^{\uparrow}$ endpoint comparison to obtain $\mathsf{Dom}_i(y)$. Evaluating the same chart-map row at that transported membership gives finite coordinate outputs that are again coordinatewise classified by $\mathsf{Real}^{\uparrow}$. The comparison witnesses in the two rows are precisely the coordinate projections of these two endpoint classifications. □

Theorem 96.30 (ManifoldUp chart-coordinate ledger exactness)**.** *For every package* P *with* $\mathsf{ManAtlasPkg}(P)$*, the visible coordinate transport ledger of* P *consists exactly of the chart index, the transported chart-domain row, the finite coordinate output at each endpoint, and the coordinatewise* $\mathsf{Real}^{\uparrow}$ *classifier witnesses. It contains no unrecorded set-level chart equality or extra chart-identification datum.*

Proof. The forward reading is by projection from Definition 96.2. A coordinate-transport row can only use the finite chart-index history, the indexed-open chart-domain rows, the chart-map coordinate histories, and the componentwise classifier rows that the atlas package exposes.

The transported domain component is exactly the output of Definition 96.4. The coordinate components are exactly the two finite $\mathsf{Real}^{\uparrow}$ histories obtained by evaluating the displayed chart map at the source and transported endpoint. The comparison components are exactly the coordinate projections of the $\mathsf{Real}^{\uparrow}$ classifier.

Conversely, any tuple with those displayed fields is a chart-coordinate transport row by Definition 96.27. Since the definition lists no chart-equality field and the atlas carrier classifier is componentwise on the recorded chart rows, no hidden set-level chart equality is available in the ledger. □

Theorem 96.31 (Singleton manifold carrier topology scope)**.** *For histories $h, k : \mathsf{BHist}$, if $C_{\mathsf{e}}(h)$ and $\mathsf{hsame}(h, k)$ hold, then $C_{\mathsf{e}}(k)$ holds. Moreover the inherited indexed $\mathsf{Topology}^{\uparrow}$ boundary surface has the exact scope:*

$$\mathsf{OpenAt}(\top_{\mathsf{Topology}^{\uparrow}}, h) \iff C_{\mathsf{e}}(h)$$

and

$$\mathsf{OpenAt}(\bot_{\mathsf{Topology}^{\uparrow}}, h) \iff \bot.$$

Consequently the top open transports along the restricted hsame *classifier, and the bottom open contributes no carried point.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingletonCarrier topology scope`

Proof. Unfold C_{e} from Definition 96.9. A witness $C_{\mathsf{e}}(h)$ is exactly $\mathsf{hsame}(h, \mathsf{e})$. Compose it with the supplied $\mathsf{hsame}(h, k)$ using symmetry and transitivity of hsame, with orientation chosen so that the endpoint is $\mathsf{hsame}(k, \mathsf{e})$. This is the carrier witness $C_{\mathsf{e}}(k)$.

For the topology scope, use the indexed boundary open witnesses of Definition 88.31 and the boundary closure of Definition 88.32. The top index carries the whole displayed carrier predicate, which in this instance is C_{e}, while the bottom index carries the empty predicate.

The transport statement is then the same membership-stability field from Definition 88.1, specialized to the top boundary index. The bottom clause has no point to transport because its carried predicate is $\bot$. □

Theorem 96.32 (Singleton manifold chart coverage)**.** *The one-chart atlas $\{\chi_{\mathsf{e}}\}$ of Definition 96.9 covers exactly the carried histories:*

$$h \in \mathsf{dom}(\chi_{\mathsf{e}}) \iff C_{\mathsf{e}}(h).$$

For every such h, the chart exposes the same constant zero endpoint of $\mathsf{Real}^{\uparrow}$:

$$\chi_{\mathsf{e}}(h) = 0_{\mathsf{Real}^{\uparrow}}.$$

The chart-domain ledger is therefore the top-open witness together with the C_{e} witness, and the chart-value ledger is the real constant endpoint row.

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton chart coverage`

Proof. By definition of the atlas in Definition 96.9, the domain of χ_{e} is the distinguished top open of the inherited indexed topology surface. Apply Definition 96.31 to identify this membership with $C_{\mathsf{e}}(h)$.

For the value statement, unfold the chart map. It is the constant map whose target is the displayed zero endpoint of $\mathsf{Real}^{\uparrow}$. No property of h is used except membership in the top domain, so the same endpoint is exposed for every carried history.

The ledger statement is just the pairing of these two witnesses. Domain coverage records the top-open row and its C_{e} readback; value coverage records the real endpoint row supplied by the local constant stream boundary. □

Theorem 96.33 (Singleton manifold transition smoothness)**.** *Every nonempty chart overlap in the singleton atlas is the self-overlap of χ_{e}. On that overlap the transition map is simultaneously the identity transition on the displayed singleton domain and the constant $0_{\mathsf{Real}^{\uparrow}}$ transition on the target endpoint. This transition is accepted by the real-analytic local constant stream boundary.*

Proof. There is only one chart in the atlas, so any overlap whose two chart names are present must be the pair $(\chi_{\mathsf{e}}, \chi_{\mathsf{e}})$. The domain side is the top open, hence Definition 96.32 identifies the overlap points exactly with C_{e}.

On the carrier side, two points in the overlap are classified by the restricted hsame relation. Since every carried point is hsame to e, transitivity identifies all visible overlap histories with the same singleton point.

On the target side, both charts expose $0_{\mathsf{Real}^{\uparrow}}$. The transition therefore has no varying real argument: it is the identity when read on the singleton domain and the constant zero map when read on the real endpoint. The $\mathsf{RealAnalytic}^{\uparrow}$ local constant stream boundary accepts exactly this constant map, so the overlap transition supplies the required smoothness row. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton transition smoothness`

Theorem 96.34 (Singleton manifold chart-index exhaustion)**.** *Every chart index in the singleton atlas of Definition 96.9 is the displayed chart χ_{e}. Consequently every chart-domain row, chart-value row, and overlap row in that atlas factors through χ_{e} as its source chart and through χ_{e} as its target chart whenever a target chart is displayed.*

Proof. Unfold the atlas row of Definition 96.9. Its chart-index field is the one-element displayed atlas whose sole constructor is the row named χ_{e}.

Project any visible chart-index row from this finite atlas. Since the atlas has no second constructor, the projected row is definitionally the displayed χ_{e} row.

The chart-domain and chart-value ledgers are indexed by this same chart row, so their projections factor through χ_{e}. An overlap row is indexed by a pair of visible chart rows; applying the same exhaustion to both projections gives the pair $(\chi_{\mathsf{e}}, \chi_{\mathsf{e}})$. □

Theorem 96.35 (Singleton manifold domain exactness)**.** *Every displayed chart-domain witness in the singleton atlas of Definition 96.9 is the top-open witness. For every $h : \mathsf{BHist}$, membership in that displayed domain is equivalent to $C_{\mathsf{e}}(h)$, while the bottom-open row carries no point.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton domain exactness`

Proof. Apply Definition 96.34 to reduce an arbitrary displayed chart-domain row to the domain row of χ_{e}. By construction this domain is the top open of the inherited $\mathsf{Topology}^{\uparrow}$ surface.

Definition 96.31 identifies top-open membership with $C_{\mathsf{e}}(h)$ for every history h and identifies the bottom open with $\bot$. Thus the top domain is exactly the carried singleton predicate, and the bottom row contributes no carried point.

Definition 96.32 reads the same top-open witness as the chart-domain ledger witness for χ_{e}. Since no other chart index exists, every displayed chart-domain witness has this exact readback. □

Theorem 96.36 (Singleton manifold transition-ledger exhaustion)**.** *Every displayed transition ledger entry in the singleton atlas of Definition 96.9 factors through the sole self-overlap of χ_{e}. Its source and target are the constant $0_{\mathsf{Real}^{\uparrow}}$ endpoint, and the entry is accepted exactly by the real-analytic local constant stream boundary.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton transition ledger exhaustion`
Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldTransitionCoherenceLedger singleton exhaustion`

Proof. Use Definition 96.34 on the two chart indices of a displayed transition ledger entry. Both indices are χ_{e}, so the entry factors through the sole self-overlap.

By Definition 96.35, the overlap domain is the top-open row read exactly as C_{e}. There is no bottom-open contribution and no second domain row on which another transition could be displayed.

Apply Definition 96.33. On this self-overlap both chart values are the constant endpoint $0_{\mathsf{Real}^{\uparrow}}$, and the only accepted smoothness row is the $\mathsf{RealAnalytic}^{\uparrow}$ local constant stream boundary. This is exactly the displayed transition ledger entry. □

Theorem 96.37 (Singleton manifold NameCert obligation package)**.** *The rows of Definition 96.9, Definition 96.31, Definition 96.32, Definition 96.33, Definition 96.34, Definition 96.35, and Definition 96.36 assemble the paper-side $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ obligation package for the singleton empty-chart construction.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton semanticNameCert`

Proof. The traditional target row is the one-point smooth manifold. The BEDC source row is BHist with the displayed empty history, and the carrier row is the predicate C_{e}. The classifier row is hsame restricted to that carrier.

The stability rows are supplied by the carrier transport in Definition 96.31, the top and bottom boundary rows inherited from $\mathsf{Topology}^{\uparrow}$, the chart coverage statement of Definition 96.32, and the transition statement of Definition 96.33.

Chart-index exhaustion supplies the finite atlas readback: every chart-domain, chart-value, and overlap row is indexed by χ_{e}. Domain exactness identifies the displayed chart domain with the top-open C_{e} witness and keeps the bottom-open row empty. Transition-ledger exhaustion identifies the only transition row as the self-overlap constant transition.

The ledger records BHist, $\mathsf{UnaryHistory}$, hsame, Cont, the indexed $\mathsf{Topology}^{\uparrow}$ boundary rows, the $\mathsf{Real}^{\uparrow}$ constant endpoint, and the $\mathsf{RealAnalytic}^{\uparrow}$ constant-map boundary. These are precisely the rows named in the construction package, with no hidden atlas component.

The core theorem list is the displayed carrier, coverage, smoothness, exactness, and ledger-exhaustion rows of this section. The standard bridge row is absent, and the resulting status is a paper-side obligation target for the Lean declaration BEDC.Derived.ManifoldUp.SingletonEmptyChart_name_certific

□

Definition 96.38 (Singleton manifold atlas ledger)**.** *The singleton manifold atlas ledger is the* BHist *package determined by the carrier C_{e} of Definition 96.9, the single chart index χ_{e}, the top-open chart domain supplied by* $\mathsf{Topology}^{\uparrow}$*, the constant $0_{\mathsf{Real}^{\uparrow}}$ endpoint supplied by* $\mathsf{Real}^{\uparrow}$*, and the* $\mathsf{RealAnalytic}^{\uparrow}$ *local constant transition row. Its ten-field template is:*

Traditional target. *The one-point smooth manifold.*

BEDC source. BHist *with distinguished history* e*.*

Carrier. *The predicate $C_{\mathsf{e}}(h)$, equivalently* $\mathsf{hsame}(h, \mathsf{e})$*.*

Classifier. *The relation* hsame *restricted to C_{e}.*

Stability obligations. *Carrier transport, top-open membership transport, chart-domain read-back, chart-value constancy, and transition-row constancy.*

Ledger. *The rows* BHist*,* UnaryHistory*,* hsame*,* Cont*, the indexed* $\mathsf{Topology}^{\uparrow}$ *boundary rows, the* $\mathsf{Real}^{\uparrow}$ *zero endpoint, and the* $\mathsf{RealAnalytic}^{\uparrow}$ *constant-map row.*

Core theorem list. *Definition 96.31, Definition 96.32, Definition 96.33, and Definition 96.37.*

Exactness. *The only accepted domain witness is the top-open C_{e} witness, and the only accepted overlap transition is the self-overlap constant transition.*

No standard bridge. *The ledger contains no* StandardBridge *row.*

Status. *A paper-side* $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ *obligation target for later formalization under* BEDC.Derived.ManifoldUp*.*

Theorem 96.39 (Singleton manifold atlas index exhaustion)**.** *In the singleton manifold atlas ledger of Definition 96.38, every visible chart-index row is the sole index χ_{e}. Every nonempty overlap row is the pair $(\chi_{\mathsf{e}}, \chi_{\mathsf{e}})$, and every accepted chart-domain witness is exactly the top-open C_{e} witness.*

Proof. Unfold the atlas ledger of Definition 96.38 and the construction package of Definition 96.9. The chart-index field is the displayed singleton list, so any visible chart row has the unique name χ_{e}.

With only one chart name available, a nonempty overlap can have no index pair other than $(\chi_{\mathsf{e}}, \chi_{\mathsf{e}})$. The overlap is nonempty exactly when its domain side admits a carried history, and the only domain side exposed by the construction is the inherited top open.

Apply Definition 96.31 to identify that top-open membership with C_{e}. Then apply Definition 96.32 to read the same witness as the chart-domain ledger row, proving that no second chart-domain witness is present. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton atlas index exhaustion`

Theorem 96.40 (Singleton manifold chart-value transport)**.** *Let h, k : BHist. If $C_{\mathsf{e}}(h)$, $C_{\mathsf{e}}(k)$, and $\mathsf{hsame}(h, k)$ hold, then the chart-value ledger transports the value $\chi_{\mathsf{e}}(h) = 0_{\mathsf{Real}^{\uparrow}}$ to the value $\chi_{\mathsf{e}}(k) = 0_{\mathsf{Real}^{\uparrow}}$. Under the same transport, the transition ledger remains the* $\mathsf{RealAnalytic}^{\uparrow}$ *constant-map row for the self-overlap $(\chi_{\mathsf{e}}, \chi_{\mathsf{e}})$.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton chart value transport`

Proof. Use the carrier witnesses to read both h and k as histories in C_{e}. The relation $\mathsf{hsame}(h, k)$ supplies the classifier transport between them, and symmetry and transitivity of hsame keep the transport inside the singleton carrier.

Apply Definition 96.32 to the carried history h. The chart value is the constant endpoint $0_{\mathsf{Real}^{\uparrow}}$. Apply the same coverage theorem to the carried history k; the target endpoint is again $0_{\mathsf{Real}^{\uparrow}}$, so the chart-value ledger has transported the displayed value without changing the real row.

Finally apply Definition 96.33. Since the atlas has only the self-overlap $(\chi_{\mathsf{e}}, \chi_{\mathsf{e}})$ and both chart readings are the same constant endpoint, the transition ledger is still the $\mathsf{RealAnalytic}^{\uparrow}$ local constant map row. □

96.5 Scoped Manifold Boundary

Definition 96.41 (Manifold scoped boundary package)**.** *A scoped* $\mathsf{Manifold}^{\uparrow}$ *boundary package is a ten-field* $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ *template whose object is the chart-atlas carrier of Definition 96.2 with the following displayed rows.*

1. *The traditional target is a finite-atlas smooth manifold with visible chart domains, coordinate maps, and transition rows.*
2. *The BEDC source is* BHist *equipped with the previously named* $\mathsf{Topology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{RealAnalytic}^{\uparrow}$ *certificate surfaces.*
3. *The carrier is the predicate* $\mathsf{ManAtlasPkg}(P)$ *on package histories* P.
4. *The classifier is componentwise* hsame *on the topological carrier, finite chart-index history, chart-domain rows, chart-map rows, coordinate histories, and transition ledgers.*
5. *The stability field is chart-domain transport along the* $\mathsf{Topology}^{\uparrow}$ *carrier classifier, together with transition-ledger stability under componentwise* hsame.
6. *The coherence field contains the identity, inverse, and cocycle rows of Definition 96.20.*
7. *The ledger contains topology rows, real-coordinate rows, pairwise overlap rows, and finite-intersection triple-overlap rows.*
8. *The core theorem list is Definition 96.3, Definition 96.4, Definition 96.7, Definition 96.8, Definition 96.18, Definition 96.21, Definition 96.22, Definition 96.23, and Definition 96.37.*
9. *Exactness is visible-atlas readback: accepted chart cover, domain, coordinate, overlap, and transition rows are exactly the displayed rows of* $\mathsf{ManAtlasPkg}$, *and the singleton instance reads the sole self-overlap transition as its complete transition ledger.*
10. *The standard bridge row is absent, and the package is a paper-side formalization target under* $\mathsf{BEDC.Derived.ManifoldUp}$.

Theorem 96.42 (Manifold scoped field coverage)**.** *Every package satisfying the scoped boundary of Definition 96.41 exposes exactly the following visible fields: the* $\mathsf{ManAtlasPkg}$ *carrier, the componentwise* hsame *classifier, chart cover, chart-domain transport, pairwise overlap source, triple-overlap source, transition-ledger stability, identity rows, inverse rows, and cocycle rows.*

Proof. Project the carrier and classifier from Definition 96.41. The carrier is the same $\mathsf{ManAtlasPkg}$ predicate defined in Definition 96.2, and the classifier is its componentwise hsame row.

The chart-cover and chart-domain transport fields are supplied by Definition 96.3 and Definition 96.4. The pairwise overlap source is supplied by Definition 96.7, and the triple-overlap source is supplied by Definition 96.8.

The transition-ledger stability field is exactly Definition 96.18. The identity, inverse, and cocycle fields are projected from the coherence ledger by Definition 96.21, Definition 96.22, and Definition 96.23.

No additional field is available from the scoped boundary definition. Its exactness clause accepts only the displayed atlas, topology, coordinate, overlap, transition, and coherence rows, so the listed fields are precisely the public boundary of the package. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldScopedBoundaryPackage field coverage`

Theorem 96.43 (Manifold scoped transition-source determinacy)**.** *In every package satisfying Definition 96.41, each displayed transition row* Trans_{ij} *is sourced on the carried open* $\mathsf{domIx}(i) \wedge_{\mathsf{Topology}^{\uparrow}} \mathsf{domIx}(j)$*. For each displayed composite from* i *to* k *through* j*, the source is the iterated* $\mathsf{Topology}^{\uparrow}$ *finite-intersection triple-overlap carrying*

$$x \longmapsto \mathsf{Dom}_i(x) \wedge \mathsf{Dom}_j(x) \wedge \mathsf{Dom}_k(x).$$

There is no hidden set-level intersection behind either source.

Proof. For the pairwise source, apply Definition 96.6. It identifies the overlap predicate for i and j with the carried open $\mathsf{domIx}(i) \wedge_{\mathsf{Topology}^{\uparrow}} \mathsf{domIx}(j)$ in the same $\mathsf{Topology}^{\uparrow}$ carrier.

Then apply Definition 96.7. The theorem states that every displayed Trans_{ij} ledger row uses that carried open as its source, with finite $\mathsf{Real}^{\uparrow}$ coordinate rows exposed on both ends.

For a composite through j, build the triple source by Definition 96.8. The iterated finite-intersection index carries the displayed triple conjunction, and the two transition ledgers restrict to that same source before composition.

Finally use Definition 96.23. The cocycle row classifies the displayed composite and the direct i to k transition on the same carried triple-overlap source. Since each step is read through $\mathsf{Topology}^{\uparrow}$ carried-open rows, no unrecorded set intersection is introduced. □

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldScopedBoundaryPackage triple overlap source determinacy`

Theorem 96.44 (Singleton manifold scoped boundary instance)**.** *The singleton package Definition 96.9 instantiates the scoped boundary package of Definition 96.41. Its carrier is* C_{e}*, its chart domain is the top-open row, its coordinate row is the constant* $0_{\mathsf{Real}^{\uparrow}}$ *endpoint, and its complete transition ledger is the sole self-overlap transition.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldSingleton scoped boundary instance`

Proof. The carrier and topology rows are supplied by Definition 96.31. They identify the restricted hsame classifier on C_{e} and read the top-open row exactly as the carried singleton predicate.

Definition 96.32 supplies the chart-cover row and the constant $0_{\mathsf{Real}^{\uparrow}}$ coordinate readback. The domain-exactness field is supplied by Definition 96.35, which leaves no second displayed chart-domain witness.

The transition ledger is supplied by Definition 96.36. Every displayed transition factors through the sole self-overlap of χ_{e}, with source and target the constant $0_{\mathsf{Real}^{\uparrow}}$ endpoint.

Repack these rows with Definition 96.37. They match the ten scoped-boundary fields: traditional singleton target, BEDC source, carrier, classifier, stability, coherence, ledger, core theorem list, exactness, and absent standard bridge. □

96.6 Terminal Standard Bridge

Theorem 96.45 (ManifoldUp terminal standard bridge)**.** *The public singleton empty-chart* Manifold$^{\uparrow}$ *package of Definition 96.26 admits a paper-side standard bridge to the terminal smooth-manifold reference. The bridge sends every carried BEDC endpoint of the singleton carrier C_{e} to the unique terminal point, and its return map selects the singleton empty-chart endpoint of Definition 96.9. Under this bridge the carrier, classifier, chart domain, coordinate row, transition row, and visible ledger rows are preserved and reflected. No host equality, host quotient, or host function is added to the BEDC public surface.*

Lean4 ✓ `BEDC.Derived.ManifoldUp.ManifoldUp StdBridge`

Proof. The source certificate is the singleton semantic naming certificate supplied by Definition 96.37. Its carrier is the one-point history package C_{e}, and its classifier is the restricted hsame row on that carrier.

Define the bridge-to-reference map by sending every carried C_{e} endpoint to the unique point of the terminal smooth manifold. Define the return map by selecting the endpoint of the empty-chart package. The carrier and classifier round trips follow from Definition 96.31: both composites land back in the sole carried endpoint, and the exposed classifier is the same restricted hsame row.

The chart data are preserved by the atlas package threshold. Apply Definition 96.26 to expose the public carrier, classifier, chart cover, chart-domain transport, transition composition, transition-ledger stability, and visible atlas ledger. The singleton chart coverage, domain exactness, and coordinate transport rows of Definition 96.32, Definition 96.35, and Definition 96.28 identify the terminal reference chart with the empty chart and its constant coordinate row.

The transition component is the sole self-overlap row. It is stable under the bridge because Definition 96.36 exhausts the singleton transition ledger, while Definition 96.5 and Definition 96.18 keep transition composition and ledger readback inside the displayed Manifold$^{\uparrow}$ rows.

The theorem-preservation field is therefore finite and explicit: it consists only of the carrier, classifier, chart-domain, coordinate, transition, and ledger rows just cited. The no-host-leak field holds at paper level because the bridge maps are used only to read the terminal smooth-manifold reference; the BEDC public surface remains the singleton empty-chart certificate and does not import host equality, quotients, or functions. □

Closure status for NameCert$_{\text{Manifold}^{\uparrow}}$**.**

Constructive story: The closed manifold object in this chapter is the singleton empty-chart package: start with the empty-history carrier C_{e} supplied by the topology surface, give it the single chart index, read its chart domain as the top open row, and make the coordinate and transition ledgers the constant rows already certified by Real$^{\uparrow}$ and RealAnalytic$^{\uparrow}$. A history is admitted only as that singleton atlas package, and two admitted presentations are classified by the restricted hsame comparison on the carrier together with componentwise transport of the chart-domain, coordinate, and transition rows; nonterminal atlas entries are not accepted. The source specification is the consumed Topology$^{\uparrow}$ carrier plus the constant real-coordinate and real-analytic transition boundaries, the pattern specification is chart coverage, domain exactness, transition smoothness, chart-index exhaustion, and transition-ledger exhaustion, and the ledger keeps the topology rows, chart index, coordinate row, self-overlap transition, and visible atlas provenance in the public package. The five name-certificate obligations are supplied by the empty endpoint, by reflexivity, symmetry, and transitivity of the restricted history classifier, and by the atlas transport rows showing that carrier, domain, coordinate, and transition data survive replacement by a classified presentation. A history h lies in the signature gap of a Manifold$^{\uparrow}$ token p when the source-domain accepts h as this singleton atlas package, the signature relation pairs it with an answer atlas and evidence ledger, and the token-introduction relation names that answer as p; concretely, h is the empty-chart endpoint with the unique domain, coordinate, and self-transition rows encoded by p. The terminal standard bridge sends every carried BEDC endpoint to the unique point of the terminal smooth manifold and reads that point back as the singleton empty-chart endpoint, preserving and reflecting carrier, classifier, chart-domain, coordinate, transition, and ledger rows. The chapter

registers this terminal atlas construction under the name $\mathsf{Manifold}^{\uparrow}$; arbitrary manifolds, nonterminal atlases, host equality, host quotients, and nonterminal smooth-manifold equivalences are not introduced.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The closed paper scope includes the singleton empty-chart carrier, classifier, atlas rows, terminal standard bridge, and the mature boundary recorded by Definition 96.45.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.ManifoldUp.ManifoldSingleton\_semanticNameCert`

Bridge status: bridgeChecked

Not claimed: Arbitrary manifolds, non-terminal atlases, non-terminal smooth-manifold equivalences, and Lean-side bridge verification remain outside this paper closure.

Chapter 97

A Concrete Naming Certificate for $\mathsf{Bundle}^{\uparrow}$

The bundle interface $\mathsf{Bundle}^{\uparrow}$ packages a fibred carrier $E \to B$ with locally trivial fibres of a fixed model type. It depends on $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ (chapter 96) for the base and total-space topology, and supplies the substrate for the tangent, cotangent, and frame bundles.

97.1 Carrier definition

Definition 97.1 (Bundle local-trivialization obligation surface)**.** *The local-trivialization obligation surface for* $\mathsf{Bundle}^{\uparrow}$ *is the ten-field* $\mathsf{NameCert}_{\mathsf{Bundle}^{\uparrow}}$ *template whose rows are fixed as follows.*

1. *The traditional target is a fibred carrier* $\pi : E \to B$ *whose fibres are locally trivial over a fixed fibre model* F*.*
2. *The BEDC source is* $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ *together with visible* BHist *histories for the base space, the total space, the projection, local trivializations, transition data, and the source ledger.*
3. *The carrier is a* BHist *package* $\mathsf{BundleLocalTrivPkg}(P)$ *exposing a base manifold row* B*, a total manifold row* E*, a projection row* π*, a fibre-model row* F*, finite chart-trivialization* ProbeBundle *rows, transition rows on overlaps, and a ledger row recording the source of each displayed field.*
4. *The retained manifold classifier from* $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ *classifies the base and total manifold rows.*
5. *The remaining classifier is componentwise* hsame *on projection histories, fibre-model histories, trivialization* ProbeBundle *rows, transition rows, and source-ledger rows.*
6. *Carrier stability transports* BundleLocalTrivPkg *packages along the retained manifold classifier on* B *and* E *and along componentwise* hsame *on every displayed bundle row.*
7. *Projection compatibility says that transport of* π *along the base and total classifiers remains the displayed projection row between the transported manifold rows.*
8. *Transition congruence says that if two overlapping trivialization rows are transported by componentwise* hsame*, then the corresponding transition row is transported to the displayed transition row over the transported overlap.*
9. *Ledger descent says that every transported carrier, projection, trivialization, fibre-model, and transition row keeps the same source entry after replacing its fields by classified histories.*

10. *Exactness is visible local-trivialization readback: every accepted* $\mathsf{NameCert}_{\mathsf{Bundle}^{\uparrow}}$ *field is one of the carrier, classifier, stability, projection, transition, ledger, and readback rows above. The standard bridge row is absent.*

97.2 The certificate

Theorem 97.2 (Bundle carrier projection obligation)**.** *Every carried row of* $\mathsf{BundleLocalTrivPkg}(P)$ *exposes exactly the base manifold row, total manifold row, projection row, fibre-model row, trivialization* ProbeBundle *row, transition row, and source-ledger row displayed in Definition 97.1. There is no other carrier case in the* $\mathsf{Bundle}^{\uparrow}$ *obligation surface.*

Proof. Unpack $\mathsf{BundleLocalTrivPkg}(P)$ by Definition 97.1. The carrier slot is a BHist package whose displayed fields are the base row, total row, projection row, fibre-model row, trivialization ProbeBundle rows, transition rows, and source ledger.

Projecting a carried bundle row therefore reads one of those listed fields. The base and total projections are manifold rows classified by the upstream $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ row, while the projection, fibre, trivialization, transition, and ledger projections are the componentwise hsame fields of the same package.

No additional branch is available: the carrier predicate is the displayed package predicate itself, and its final readback row accepts only the listed fields. Thus every carried row is one of the named rows, and the carrier has no second case. □

Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPackage carrier projection`
Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPkg projection rows`

Theorem 97.3 (Bundle trivialization transition stability)**.** *For packages satisfying* BundleLocalTrivPkg*, componentwise* hsame *transport preserves local trivialization rows and transition compatibility through the retained* $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$ *classifier on the base and total manifold rows.*

Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPackage classifier transport`
Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPkg trivialization transition stability`
Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPkg transition stability`

Proof. Start with a carried package and a componentwise transport witness. The base and total manifold rows are transported by the classifier retained from $\mathsf{NameCert}_{\mathsf{Manifold}^{\uparrow}}$, so their chart and overlap histories remain accepted manifold histories.

The trivialization row is a finite ProbeBundle of local witnesses. Induct on that closed probe bundle. The empty probe row is preserved by the carrier-stability clause, and each bundled probe is transported by the componentwise hsame classifier on its trivialization history.

For an overlap row, the transition congruence field of Definition 97.1 compares the two transported trivialization rows and the displayed transition row. Projection compatibility supplies the same base and total rows after transport, so the transition still relates fibres over the transported base overlap.

Ledger descent then transports the provenance row for the trivialization and transition witnesses. Hence local trivialization rows and transition compatibility are preserved by the displayed hsame transport. □

Theorem 97.4 (Bundle transition cocycle ledger closure)**.** *Let* P *be carried by* $\mathsf{BundleLocalTrivPkg}(P)$*, and let* τ_i, τ_j, τ_k *be three local trivialization rows in its finite* ProbeBundle *row. Suppose the pairwise*

overlaps $\mathsf{Overlap}_{ij}$ *and* $\mathsf{Overlap}_{jk}$ *are accepted by the same trivialization* ProbeBundle*, and suppose their common base restriction carries the direct transition row from* τ_i *to* τ_k *and the composed route through* τ_j *with continuation witness* $\mathsf{Cont}(\mathsf{Trans}_{ij}, \mathsf{Trans}_{jk}, \mathsf{Trans}_{ijk})$*. Then, after transporting the base and total manifold rows by the retained* $\mathsf{NameCert}_{\mathsf{Manifold}\uparrow}$ *classifier, the direct transition row and the composed transition row are componentwise* hsame*. The source-ledger row for this comparison is exactly the row displaying* τ_i, τ_j, τ_k*, the two overlap witnesses, the displayed* Cont *composition witness, and the transition congruence witnesses for the three transition edges.*

Proof. Work inside the carrier displayed in Definition 97.1. The three trivialization rows and the two accepted overlap witnesses live in the closed finite ProbeBundle row of P.

Induct on the finite ProbeBundle of overlap witnesses. In the empty case there is no additional overlap branch to inspect: ledger descent keeps the displayed provenance row, and reflexivity of hsame identifies the direct and composed transition histories on the vacuous carried overlap.

For the cons step, transport the head transition by componentwise hsame. Projection compatibility keeps the transported base and total manifold rows aligned with the displayed projection row, so all three transition edges still have the same source and target bundle rows on the common triple restriction.

Apply transition congruence to the i, j, j, k, and i, k transition edges. Continuation associativity for Cont, followed by transitivity of hsame, identifies the direct i, k transition history with the route composed through the middle trivialization row τ_j.

Finally, ledger descent repacks the same displayed provenance: the three trivialization rows, the two overlap witnesses, the Cont composition witness, and the transition congruence witnesses. This is the claimed cocycle-style ledger row for the bundle transition comparison. □

Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPkg transition cocycle ledger closure`

Theorem 97.5 (Bundle NameCert exactness obligation)**.** *The public fields of* $\mathsf{NameCert}_{\mathsf{Bundle}\uparrow}$ *are exactly the carrier, classifier, stability, transition ledger, visible exactness readback, and absent bridge row specified by Definition 97.1.*

Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPkg semantic name certificate`

Proof. First project the carrier by Definition 97.2. This accounts for the base manifold row, total manifold row, projection row, fibre-model row, trivialization ProbeBundle row, transition row, and source-ledger row.

Next read the classifier and stability fields from the definition. The classifier is the retained $\mathsf{NameCert}_{\mathsf{Manifold}\uparrow}$ classifier on base and total rows together with componentwise hsame on all bundle-specific histories. The stability fields are carrier transport, projection compatibility, transition congruence, and ledger descent.

Finally apply the visible local-trivialization readback row. It accepts only the displayed carrier fields, the displayed classifier and stability fields, the transition ledger, and the explicit statement that the standard bridge row is absent. Therefore the public $\mathsf{NameCert}_{\mathsf{Bundle}\uparrow}$ surface is exhausted by exactly those fields. □

Theorem 97.6 (Bundle projection and fibre source scope)**.** *In every carried* $\mathsf{BundleLocalTrivPkg}(P)$ *row, the base row, total row, projection row, fibre-model row, and source row are scoped entirely by* BHist*. The base and total rows use the retained* $\mathsf{NameCert}_{\mathsf{Manifold}\uparrow}$ *classifier, while projection, fibre, and source rows are compared by componentwise* hsame *rather than by host-level functions.*

Proof. Apply Definition 97.1 to read the displayed bundle surface. Its source row is a visible BHist ledger, and its base, total, projection, and fibre-model entries are also displayed as histories inside BundleLocalTrivPkg(P).

Apply Definition 97.2 to project those rows from the carried package. The base and total rows are classified by the retained $\mathsf{NameCert}_{\mathsf{Manifold}\uparrow}$ row, and every bundle-specific row is transported only by the componentwise hsame clauses of the surface.

Thus no host function is part of the scoped comparison. The fibre and projection data remain named histories, and the ledger records their sources in the same BHist vocabulary. □

Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPkg projection fibre source scope`

Theorem 97.7 (Bundle trivialization ProbeBundle scope)**.** *The finite trivialization rows in* BundleLocalTrivPkg(P) *are exactly* ProbeBundle *witnesses. Componentwise* hsame *transport preserves their scope by induction on the closed constructors* Bnil *and* Bcons*.*

Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPkg trivialization scope`

Proof. Read the trivialization row from Definition 97.1. The row is not an external family of functions: it is the finite ProbeBundle field listed in the carried bundle package.

Induct on the displayed probe bundle. In the Bnil case, the empty witness has no chart row to transport, so the carrier-stability field preserves the row directly.

In the Bcons case, the head witness is transported by the componentwise hsame classifier on its trivialization history. The induction hypothesis preserves the remaining witnesses, and the closed constructor reassembles the transported ProbeBundle row.

This is precisely the stability mechanism used in Definition 97.3, so finite trivialization scope is preserved without leaving the BEDC history language. □

Lean4 ✓ `BEDC.Derived.BundleUp.BundleRowsUnary classifier transport`

Theorem 97.8 (Bundle transition and ledger scope)**.** *Transition rows and source-ledger rows in* BundleLocalTrivPkg(P) *descend under componentwise* hsame*. The descent uses the retained* $\mathsf{NameCert}_{\mathsf{Manifold}\uparrow}$ *classifier only for the base and total manifold rows; overlap transitions and ledger entries remain bundle-specific* BHist *rows.*

Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPkg transition ledger scope`

Proof. Start with two transported trivialization rows. By Definition 97.3, their overlap row is still compared after transport through the displayed transition congruence field.

The manifold part of the comparison is exactly the retained $\mathsf{NameCert}_{\mathsf{Manifold}\uparrow}$ classifier on base and total rows. The transition row itself is not reinterpreted as a host map; it is the transported bundle-specific history named by the componentwise hsame field.

Finally apply the ledger-descent row of Definition 97.1. It sends the source entry for each carrier, projection, trivialization, fibre-model, and transition row to the corresponding transported source entry. Hence both the transition row and the ledger row descend in the same scoped vocabulary. □

Theorem 97.9 (Bundle scoped obligation package)**.** *The carrier projection, projection–fibre source scope, finite* ProbeBundle *trivialization scope, transition–ledger descent, and visible exactness rows together form the scoped* $\mathsf{NameCert}_{\mathsf{Bundle}\uparrow}$ *obligation package. Its public surface is kernel-facing: all bundle-specific data are* BHist *rows compared by componentwise* hsame*, and the only retained external classifier is* $\mathsf{NameCert}_{\mathsf{Manifold}\uparrow}$ *on the base and total manifold rows.*

Lean4 ✓ `BEDC.Derived.BundleUp.BundleLocalTrivPkgRows scoped unary coverage`

Proof. First assemble the carrier rows using Definition 97.2. This supplies the base, total, projection, fibre-model, trivialization, transition, and source-ledger rows named by $\mathsf{BundleLocalTrivPkg}(P)$.

Next add the scoped comparisons. The projection and fibre source claim is Definition 97.6; finite trivialization scope is Definition 97.7; transition and ledger descent is Definition 97.8.

It remains to identify the public certificate surface. Apply Definition 97.5: the accepted $\mathsf{NameCert}_{\mathsf{Bundle}^\uparrow}$ fields are exactly the displayed carrier, classifier, stability, transition ledger, readback, and absent-bridge rows. Therefore the scoped rows above repack into the stated kernel-facing obligation package. □

Closure status for $\mathsf{NameCert}_{\mathsf{Bundle}^\uparrow}$.

Constructive story: A bundle is built as a visible local-trivialization package: base and total manifold rows from $\mathsf{Manifold}^\uparrow$, a projection history, a fibre-model history, a finite ProbeBundle of trivialization witnesses, transition histories on overlaps, and a source ledger. The carrier accepts exactly these BundleLocalTrivPkg packages and has no second branch; the base and total rows are compared by the retained manifold classifier, while projection, fibre, trivialization, transition, and ledger rows are compared componentwise by hsame. The source is the manifold certificate together with the displayed bundle histories, the pattern records projection compatibility, finite trivialization scope, transition congruence and cocycle-style ledger closure, and visible exactness, while the ledger keeps each carrier, projection, trivialization, fibre, and transition source entry aligned with its transported row. The scoped name-certificate obligations are read from those projections: an accepted package inhabits the carrier, the retained manifold classifier and componentwise hsame supply reflexivity, symmetry, and transitivity, and carrier transport plus ledger descent keep the package admitted after classified replacement. A history h lies in the signature gap of a $\mathsf{Bundle}^\uparrow$ token p when the source-domain accepts h as this local-trivialization package, the signature relation pairs it with an answer package and evidence ledger, and token introduction names that answer as p; unfolded, the projection, finite probes, transitions, and source ledger are the exact rows encoded by p. No standard bridge row is present, so no ordinary bundle equivalence is exported. The chapter registers this local-trivialization package under the name $\mathsf{Bundle}^\uparrow$; bundle structure is a finite BEDC history ledger over $\mathsf{Manifold}^\uparrow$, with no host bundle object, tangent-bundle primitive, or external transition-function library introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Bundle}^\uparrow}$, maturePackageClosed)

Scope closed: The mature paper surface binds the finite local-trivialization certificate package: carrier projection, projection–fibre source scope, finite ProbeBundle trivialization scope, transition-ledger descent, visible exactness rows, BHist carrier histories, componentwise hsame comparisons, and retained $\mathsf{NameCert}_{\mathsf{Manifold}^\uparrow}$ classifier named in this chapter.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Bundle}^\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.BundleUp.BundleLocalTrivPkg\_semantic\_name\_certificate`

Bridge status: none

Not claimed: Standard bundle equivalence, tangent and cotangent bundles, frame bundles, and bridgeChecked verification remain outside this block.

Upgrade path: The next verification step is bridgeChecked coverage for the finite local-trivialization certificate package.

Chapter 98

A Concrete Naming Certificate for $\mathsf{Homology}^{\uparrow}$

The homology interface $\mathsf{Homology}^{\uparrow}$ packages a chain complex over an abelian-group carrier together with the kernel/image quotients computing the homology groups. It depends on $\mathsf{NameCert}_{\mathsf{AbGroup}^{\uparrow}}$ (chapter 42) and $\mathsf{NameCert}_{\mathsf{QuotientGroup}^{\uparrow}}$ (chapter 82), and is the constructive substrate for both singular and simplicial homology.

98.1 Carrier definition

The cycle carrier of a BEDC chain differential $d : \mathsf{BHist} \to \mathsf{BHist}$ is the kernel predicate

$$Z_d(h) :\Longleftrightarrow \mathsf{hsame}(d(h), \mathsf{Empty}).$$

The boundary carrier is the image predicate

$$B_d(h) :\Longleftrightarrow \exists u : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)).$$

Lean4 (definition) `BEDC.Derived.HomologyUp.HomologyCycleCarrier`
Lean4 (definition) `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier`

Theorem 98.1 (Homology boundary carrier nonempty preimage)**.** *If $B_d(h)$ and h is not history-same to* Empty*, then some boundary preimage u has a nonempty differential endpoint:*

$$\exists u : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)) \wedge \neg\mathsf{hsame}(d(u), \mathsf{Empty}).$$

Proof. Choose the boundary witness u with $\mathsf{hsame}(h, d(u))$. If $d(u)$ were history-same to Empty, transitivity of hsame would make h history-same to Empty, contradicting the nonempty hypothesis. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier nonempty preimage`

Theorem 98.2 (Homology boundary carrier empty preimage)**.** *If $B_d(h)$ and h*$\mathsf{hsameEmpty}$*, then some boundary preimage u has an empty differential endpoint:*

$$\exists u : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)) \wedge \mathsf{hsame}(d(u), \mathsf{Empty}).$$

Proof. Choose the boundary witness u with $\mathsf{hsame}(h, d(u))$. Symmetry of that witness followed by the displayed empty endpoint comparison gives $\mathsf{hsame}(d(u), \mathsf{Empty})$. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier empty preimage`

Theorem 98.3 (Homology boundary carrier cycle closure)**.** *Assume the BEDC chain differential is square-zero at every history:*

$$\forall u : \mathsf{BHist},\ \mathsf{hsame}(d(d(u)), \mathsf{Empty}).$$

Every boundary history is a cycle history: if $B_d(h)$, then $Z_d(h)$.

Proof. Choose a boundary witness u with $\mathsf{hsame}(h, d(u))$. Transporting the cycle test along this witness reduces the claim to the displayed square-zero law at the chosen boundary preimage, which is supplied by feeding that preimage to the displayed universal square-zero law. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cycle closed`

Theorem 98.4 (Homology boundary classifier refines cycle classifier)**.** *Assume the BEDC chain differential is square-zero at every history:*

$$\forall u : \mathsf{BHist},\ \mathsf{hsame}(d(d(u)), \mathsf{Empty}).$$

If $B_d(h)$, $B_d(k)$, and $\mathsf{hsame}(h, k)$, then $Z_d(h)$, $Z_d(k)$, and $\mathsf{hsame}(h, k)$.

Proof. Apply Definition 98.3 to the boundary witness at h, using the displayed square-zero law at the chosen preimage. This produces the cycle endpoint $Z_d(h)$.

Apply the same carrier-closure theorem to the boundary witness at k. The existing classifier row $\mathsf{hsame}(h, k)$ is preserved unchanged, so the three pieces repack as the cycle classifier row between the same endpoints. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cycle classifier refinement`

Theorem 98.5 (Homology cycle carrier append closure)**.** *Assume the differential respects BEDC continuation append:*

$$\mathsf{hsame}(d(\mathsf{append}(u, v)), \mathsf{append}(d(u), d(v))).$$

If $Z_d(h)$ and $Z_d(k)$, then $Z_d(\mathsf{append}(h, k))$.

Proof. The append law transports the displayed differential to $\mathsf{append}(d(h), d(k))$. The two cycle hypotheses identify both endpoints with Empty, and the BEDC append kernel has $\mathsf{append}(\mathsf{Empty}, \mathsf{Empty}) = \mathsf{Empty}$. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyCycleCarrier append closed`

Theorem 98.6 (Homology cycle carrier append visible differential absurd)**.** *Assume the differential respects BEDC continuation append. If $Z_d(h)$ and $Z_d(k)$, then the differential of the appended cycle cannot be history-same to a visible zero-headed or one-headed endpoint:*

$$\neg\mathsf{hsame}(d(\mathsf{append}(h, k)), \mathsf{e0}(tail)) \qquad \textit{and} \qquad \neg\mathsf{hsame}(d(\mathsf{append}(h, k)), \mathsf{e1}(tail)).$$

Proof. The homology cycle append closure theorem gives $\mathsf{hsame}(d(\mathsf{append}(h, k)), \mathsf{Empty})$. A displayed zero-headed or one-headed comparison transports this empty endpoint to the visible constructor endpoint, contradicting BEDC constructor separation from Empty. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyCycleCarrier append visible differential absurd`

Theorem 98.7 (Homology cycle carrier append components)**.** *Assume the differential respects BEDC continuation append:*

$$\mathsf{hsame}(d(\mathsf{append}(u, v)), \mathsf{append}(d(u), d(v))).$$

Then an appended history is a cycle exactly when both appended components are cycles:

$$Z_d(\mathsf{append}(h, k)) \iff Z_d(h) \wedge Z_d(k).$$

Proof. The forward direction transports $d(\mathsf{append}(h, k))$ to $\mathsf{append}(d(h), d(k))$. If this endpoint is empty, BEDC append-empty inversion gives $d(h)\mathsf{hsameEmpty}$ and $d(k)\mathsf{hsameEmpty}$. The reverse direction is the homology cycle append-closure theorem. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyCycleCarrier append components iff`

Theorem 98.8 (Homology cycle carrier append differential nonempty component split)**.** *Assume the differential respects BEDC continuation append. If the differential of an appended history is not empty,*

$$\mathsf{hsame}(d(\mathsf{append}(h, k)), \mathsf{Empty}) \to \bot,$$

then at least one component is not a cycle:

$$(Z_d(h) \to \bot) \vee (Z_d(k) \to \bot).$$

Proof. Transport the displayed nonemptiness along the append law for d to obtain nonemptiness of $\mathsf{append}(d(h), d(k))$. BEDC append nonemptiness then separates this obstruction into a nonempty $d(h)$ component or a nonempty $d(k)$ component. Since $Z_d(h)$ and $Z_d(k)$ mean exactly that the corresponding differential is empty, the selected obstruction negates the matching cycle predicate. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyCycleCarrier append differential nonempty component split`

Theorem 98.9 (Homology boundary carrier append closure)**.** *Assume the differential respects BEDC continuation append:*

$$\mathsf{hsame}(d(\mathsf{append}(u, v)), \mathsf{append}(d(u), d(v))).$$

If $B_d(h)$ and $B_d(k)$, then $B_d(\mathsf{append}(h, k))$.

Proof. Choose boundary witnesses u and v with $\mathsf{hsame}(h, d(u))$ and $\mathsf{hsame}(k, d(v))$. The BEDC witness for the appended boundary is $\mathsf{append}(u, v)$. Endpoint congruence carries $\mathsf{append}(h, k)$ to $\mathsf{append}(d(u), d(v))$, and the differential append law identifies that history with $d(\mathsf{append}(u, v))$. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier append closed`

Theorem 98.10 (Homology boundary carrier append hsame transport)**.** *Assume the differential respects BEDC continuation append. If $B_d(h)$ and $B_d(k)$ and $\mathsf{hsame}(\mathsf{append}(h, k), r)$, then $B_d(r)$.*

Proof. Choose boundary witnesses u and v for h and k. Their appended BEDC preimage $\mathsf{append}(u, v)$ maps, by the differential append law, to the same endpoint as $\mathsf{append}(d(u), d(v))$. The two boundary endpoint comparisons identify $\mathsf{append}(h, k)$ with this value, and the final hsame comparison transports the image witness to r. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier append hsame transport`

Theorem 98.11 (Homology boundary carrier continuation cycle closure)**.** *Assume the differential respects BEDC continuation append and is square-zero. If $B_d(h)$, $B_d(k)$, and $\mathsf{Cont}(h, k, r)$, then $Z_d(r)$.*

Proof. Boundary append closure with endpoint transport first makes the continuation result r a boundary carrier. The square-zero differential condition turns any boundary carrier into a cycle carrier, so $Z_d(r)$ follows. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cont cycle closed`

Theorem 98.12 (Homology boundary carrier continuation preimage)**.** *Assume the differential respects BEDC continuation append. If $B_d(h)$, $B_d(k)$, and $\mathsf{Cont}(h, k, r)$, then the continuation result has compatible boundary preimages:*

$$\exists u, v, uv : \mathsf{BHist},\ \mathsf{Cont}(u, v, uv) \wedge \mathsf{hsame}(r, d(uv)) \wedge \mathsf{hsame}(h, d(u)) \wedge \mathsf{hsame}(k, d(v)).$$

Proof. Choose boundary witnesses u and v for h and k. Set $uv = \mathsf{append}(u, v)$, giving $\mathsf{Cont}(u, v, uv)$ by the BEDC continuation constructor. The input continuation reads r as $\mathsf{append}(h, k)$; the two boundary witnesses identify this with $\mathsf{append}(d(u), d(v))$, and the differential append law identifies the endpoint with $d(uv)$. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cont preimage`

Theorem 98.13 (Homology boundary carrier continuation preimage append)**.** *Assume the differential respects BEDC continuation append. If $B_d(h)$, $B_d(k)$, and $\mathsf{Cont}(h, k, r)$, then there are BEDC preimages u and v such that*

$$\mathsf{hsame}(h, d(u)) \wedge \mathsf{hsame}(k, d(v)) \wedge \mathsf{hsame}(r, d(\mathsf{append}(u, v))).$$

Proof. Choose boundary witnesses u and v for h and k. The continuation ledger identifies r with $\mathsf{append}(h, k)$. The witness endpoints identify that appended history with $\mathsf{append}(d(u), d(v))$, and the differential append law identifies this with $d(\mathsf{append}(u, v))$. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cont preimage append`

Theorem 98.14 (Homology boundary carrier continuation preimage append hsame transport)**.** *Assume the differential respects BEDC continuation append. If $B_d(h)$, $B_d(k)$, $\mathsf{Cont}(h, k, r)$, and $r \mathsf{hsame} r'$, then the same BEDC preimages u and v witness the transported endpoint:*

$$\mathsf{hsame}(h, d(u)) \wedge \mathsf{hsame}(k, d(v)) \wedge \mathsf{hsame}(r', d(\mathsf{append}(u, v))).$$

Proof. The continuation preimage-append theorem supplies witnesses u and v for the endpoint r. Composing that endpoint comparison with the symmetry of $r \mathsf{hsame} r'$ transports the displayed differential image to r' while keeping the two boundary witness comparisons unchanged. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cont preimage append hsame transport`

Theorem 98.15 (Homology boundary continuation cycle-preimage package)**.** *Assume the differential respects BEDC continuation append and is square-zero. If $B_d(h)$, $B_d(k)$, and $\mathsf{Cont}(h, k, r)$, then*

$$Z_d(r) \wedge \exists u, v : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)) \wedge \mathsf{hsame}(k, d(v)) \wedge \mathsf{hsame}(r, d(\mathsf{append}(u, v))).$$

Proof. The cycle component is exactly Definition 98.11: boundary continuation first produces a boundary carrier for r, and square-zero turns that carrier into $Z_d(r)$.

The preimage component is supplied by Definition 98.13. It gives BEDC histories u and v whose differential images match h and k, and whose appended differential image matches the continuation result r.

Conjoining these two conclusions gives the displayed cycle-preimage certificate for the same continuation result. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier continuation cycle preimage package`

Theorem 98.16 (Homology boundary carrier continuation nonempty preimage append)**.** *Assume the differential respects BEDC continuation append. If $B_d(h)$, $B_d(k)$, $\mathsf{Cont}(h,k,r)$, and r is not history-same to* Empty*, then there are BEDC preimages u and v such that*

$$\mathsf{hsame}(h, d(u)) \wedge \mathsf{hsame}(k, d(v)) \wedge \neg\mathsf{hsame}(d(\mathsf{append}(u,v)), \mathsf{Empty}).$$

Proof. The preimage-append theorem gives witnesses u and v with $\mathsf{hsame}(r, d(\mathsf{append}(u,v)))$. If the displayed differential endpoint were history-same to Empty, transitivity would make r history-same to Empty, contradicting the nonempty hypothesis. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cont nonempty preimage append`

Theorem 98.17 (Homology boundary carrier append empty preimages)**.** *If $B_d(h)$ and $B_d(k)$ and* $\mathsf{hsame}(\mathsf{append}(h,k), \mathsf{Empty})$*, then the two boundary witnesses can be chosen with empty differential endpoints:*

$$\exists u, v : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)) \wedge \mathsf{hsame}(k, d(v)) \wedge \mathsf{hsame}(d(u), \mathsf{Empty}) \wedge \mathsf{hsame}(d(v), \mathsf{Empty}).$$

Proof. BEDC append-empty inversion splits the appended endpoint comparison into $h\mathsf{hsameEmpty}$ and $k\mathsf{hsameEmpty}$. Applying empty-preimage inversion to the two boundary carrier hypotheses produces witnesses u and v with the stated endpoint comparisons, which are then paired. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier append empty preimages`

Theorem 98.18 (Homology boundary carrier continuation empty preimages)**.** *If $B_d(h)$ and $B_d(k)$ and $\mathsf{Cont}(h,k,r)$ and $r\mathsf{hsameEmpty}$, then the two boundary witnesses can be chosen with empty differential endpoints:*

$$\exists u, v : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)) \wedge \mathsf{hsame}(k, d(v)) \wedge \mathsf{hsame}(d(u), \mathsf{Empty}) \wedge \mathsf{hsame}(d(v), \mathsf{Empty}).$$

Proof. The continuation equation identifies r with $\mathsf{append}(h,k)$. Transporting the empty result comparison along this equation gives $\mathsf{append}(h,k)\mathsf{hsameEmpty}$, and the append empty preimage theorem supplies the paired witnesses. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cont empty preimages`

Theorem 98.19 (Homology boundary carrier continuation empty-result preimage equivalence)**.** *If $B_d(h)$ and $B_d(k)$ and $\mathsf{Cont}(h,k,r)$, then r is history-same to* Empty *exactly when the two boundary witnesses can be chosen with empty differential endpoints:*

$$\mathsf{hsame}(r, \mathsf{Empty}) \iff \exists u, v : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)) \wedge \mathsf{hsame}(k, d(v)) \wedge \mathsf{hsame}(d(u), \mathsf{Empty}) \wedge \mathsf{hsame}(d(v), \mathsf{Empty}).$$

Proof. The forward direction is the continuation empty-preimage theorem. Conversely, the two displayed empty differential endpoints transport through the boundary witnesses to give $h\mathsf{hsameEmpty}$ and $k\mathsf{hsameEmpty}$; append empty-result exactness makes $\mathsf{append}(h, k)$ empty, and the continuation ledger identifies this append endpoint with r. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cont empty result preimages iff`

Theorem 98.20 (Homology boundary carrier append nonempty preimage)**.** *If $B_d(h)$ and $B_d(k)$ and $\mathsf{append}(h, k)$ is not history-same to Empty, then at least one side has a boundary preimage with a nonempty differential endpoint:*

$$(\exists u : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)) \wedge \neg\mathsf{hsame}(d(u), \mathsf{Empty})) \\ \vee (\exists v : \mathsf{BHist},\ \mathsf{hsame}(k, d(v)) \wedge \neg\mathsf{hsame}(d(v), \mathsf{Empty}))\,.$$

Proof. BEDC append nonemptiness splits into a nonempty left component or a nonempty right component. In the left case, boundary nonempty-preimage inversion applied to $B_d(h)$ gives the left disjunct. In the right case, the same argument applied to $B_d(k)$ gives the right disjunct. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier append nonempty preimage`

Theorem 98.21 (Homology boundary carrier continuation nonempty side preimage)**.** *If $B_d(h)$ and $B_d(k)$ and $\mathsf{Cont}(h, k, r)$ and r is not history-same to Empty, then at least one side has a boundary preimage with a nonempty differential endpoint:*

$$(\exists u : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)) \wedge \neg\mathsf{hsame}(d(u), \mathsf{Empty})) \\ \vee (\exists v : \mathsf{BHist},\ \mathsf{hsame}(k, d(v)) \wedge \neg\mathsf{hsame}(d(v), \mathsf{Empty}))\,.$$

Proof. The continuation equation transports nonemptiness of r to nonemptiness of $\mathsf{append}(h, k)$. The append nonempty preimage theorem then separates the witness to the left boundary preimage or to the right boundary preimage. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cont nonempty side preimage`

Theorem 98.22 (Homology boundary carrier append nonempty cycle preimage)**.** *Assume the differential is square-zero. If $B_d(h)$ and $B_d(k)$ and $\mathsf{append}(h, k)$ is not history-same to Empty, then at least one side has a boundary preimage with a nonempty differential endpoint, and that side is a cycle:*

$$(\exists u : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)) \wedge Z_d(h) \wedge \neg\mathsf{hsame}(d(u), \mathsf{Empty})) \\ \vee (\exists v : \mathsf{BHist},\ \mathsf{hsame}(k, d(v)) \wedge Z_d(k) \wedge \neg\mathsf{hsame}(d(v), \mathsf{Empty}))\,.$$

Proof. The append nonempty preimage theorem splits the nonempty append boundary into a left or right boundary preimage. The square-zero differential turns each boundary carrier hypothesis into the corresponding cycle carrier, and that cycle witness is attached to whichever disjunct supplies the nonempty preimage. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier append nonempty cycle preimage`

Theorem 98.23 (Homology boundary carrier continuation nonempty cycle preimage)**.** *Assume the differential is square-zero. If $B_d(h)$ and $B_d(k)$, if $\mathsf{Cont}(h, k, r)$, and if r is not history-same to Empty, then at least one side has a boundary preimage with a nonempty differential endpoint, and that side is a cycle:*

$$(\exists u : \mathsf{BHist},\ \mathsf{hsame}(h, d(u)) \wedge Z_d(h) \wedge \neg\mathsf{hsame}(d(u), \mathsf{Empty})) \\ \vee (\exists v : \mathsf{BHist},\ \mathsf{hsame}(k, d(v)) \wedge Z_d(k) \wedge \neg\mathsf{hsame}(d(v), \mathsf{Empty}))\,.$$

Proof. The continuation equation transports nonemptiness of r to nonemptiness of $\mathsf{append}(h, k)$. The append nonempty cycle-preimage theorem then separates the witness to the left boundary preimage or to the right boundary preimage, carrying the corresponding cycle evidence supplied by square-zero. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cont nonempty cycle preimage`

Theorem 98.24 (Homology boundary carrier continuation cycle components)**.** *Assume the differential respects BEDC continuation append and is square-zero. If $B_d(r)$ and $\mathsf{Cont}(h, k, r)$, then both continuation components are cycles:*

$$Z_d(h) \wedge Z_d(k).$$

Proof. The square-zero law turns the boundary carrier on r into a cycle carrier on the continuation result. Since $\mathsf{Cont}(h, k, r)$ identifies r with $\mathsf{append}(h, k)$, the append-components theorem splits that cycle predicate into the two component cycle predicates. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cont cycle components`

Theorem 98.25 (Homology boundary carrier cycle from square-zero differential)**.** *Assume the differential respects* hsame *and satisfies the square-zero condition*

$$\mathsf{hsame}(d(d(u)), \mathsf{Empty})$$

for every $u : \mathsf{BHist}$. If $B_d(h)$, then $Z_d(h)$.

Proof. Choose a boundary witness u with $\mathsf{hsame}(h, d(u))$. Congruence for the differential transports this witness to $\mathsf{hsame}(d(h), d(d(u)))$. The square-zero row identifies $d(d(u))$ with Empty, and transitivity of hsame gives the cycle predicate. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier cycle of d squared zero`

Theorem 98.26 (Homology cycle carrier append hsame transport)**.** *Assume the differential respects BEDC continuation append and is congruent for* hsame*. If $Z_d(h)$, $Z_d(k)$, and $\mathsf{hsame}(\mathsf{append}(h, k), r)$, then $Z_d(r)$.*

Proof. The append-closure theorem gives $Z_d(\mathsf{append}(h, k))$. Congruence for the differential transports the endpoint comparison to an hsame comparison between $d(\mathsf{append}(h, k))$ and $d(r)$. Symmetry of that comparison, followed by the cycle row for the append, proves that $d(r)$ is hsame to Empty. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyCycleCarrier append hsame transport`

Theorem 98.27 (Homology cycle-boundary append cycle closure)**.** *Assume the differential respects BEDC continuation append and is square-zero. If $Z_d(h)$ and $B_d(k)$, then $Z_d(\mathsf{append}(h, k))$.*

Proof. The square-zero law turns the boundary hypothesis on k into a cycle hypothesis. The ordinary cycle append closure then applies to the two cycle histories h and k. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyCycleBoundary append cycle closed`

Theorem 98.28 (Homology boundary-cycle append cycle closure)**.** *Assume the differential respects BEDC continuation append and is square-zero. If $B_d(h)$ and $Z_d(k)$, then $Z_d(\mathsf{append}(h, k))$.*

Proof. The square-zero law turns the boundary hypothesis on h into a cycle hypothesis. The ordinary cycle append closure then applies to the two cycle histories h and k. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCycle append cycle closed`

Theorem 98.29 (Homology boundary-cycle append hsame transport)**.** *Assume the differential respects BEDC continuation append, is square-zero, and respects* hsame*. If $B_d(h)$, $Z_d(k)$, and* $\mathsf{hsame}(\mathsf{append}(h,k),r)$*, then $Z_d(r)$.*

Proof. The boundary-cycle append closure theorem gives a cycle at $\mathsf{append}(h,k)$. Differential congruence transports the final endpoint comparison to $d(r)$, and symmetry followed by transitivity gives $\mathsf{hsame}(d(r),\mathsf{Empty})$. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCycle append hsame transport`

Theorem 98.30 (Homology cycle-boundary append hsame transport)**.** *Assume the differential respects BEDC continuation append, is square-zero, and respects* hsame*. If $Z_d(h)$, $B_d(k)$, and* $\mathsf{hsame}(\mathsf{append}(h,k),r)$*, then $Z_d(r)$.*

Proof. The square-zero row turns the boundary hypothesis on k into a cycle hypothesis. Cycle-boundary append closure therefore gives a cycle at $\mathsf{append}(h,k)$. Differential congruence transports the final endpoint comparison to $d(r)$, and symmetry followed by transitivity gives $\mathsf{hsame}(d(r),\mathsf{Empty})$. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyCycleBoundary append hsame transport`

Theorem 98.31 (Homology cycle-boundary append cycle hsame transport)**.** *Assume the differential respects BEDC continuation append, is congruent for* hsame*, and is square-zero. If $Z_d(h)$, $B_d(k)$, and* $\mathsf{hsame}(\mathsf{append}(h,k),r)$*, then $Z_d(r)$.*

Proof. The square-zero and congruence laws turn the boundary hypothesis on k into a cycle hypothesis. The append endpoint transport theorem then applies to the cycle histories h and k and transports the resulting cycle predicate across the displayed endpoint comparison. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyCycleBoundary append cycle hsame transport`

98.2 The certificate

Theorem 98.32 (Homology boundary carrier semantic name certificate)**.** *For any BEDC differential $d : \mathsf{BHist} \to \mathsf{BHist}$, the boundary carrier B_d forms a semantic naming certificate when source, pattern, and ledger policy are all B_d, and the classifier requires both endpoints to be boundaries together with* hsame *between them.*

Proof. The carrier is inhabited by $d(\mathsf{Empty})$, using Empty as its preimage and reflexivity of hsame. The classifier equivalence laws come from the stored endpoint boundary witnesses and the reflexive, symmetric, and transitive laws for hsame. Carrier transport along a classifier edge is the right endpoint boundary witness, and the semantic pattern and ledger fields are the source witness itself. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyBoundaryCarrier semanticNameCert`

Theorem 98.33 (Homology cycle carrier empty semantic name certificate)**.** *If the empty history is a d-cycle, then the cycle carrier Z_d forms a semantic naming certificate when source, pattern, and ledger policy are all Z_d, and the classifier requires both endpoints to be cycles together with* hsame *between them.*

Proof. The empty-cycle hypothesis inhabits the carrier at Empty. The classifier equivalence laws again follow by unpacking the two endpoint cycle witnesses and composing the underlying hsame rows. Carrier transport is read from the right endpoint cycle witness already stored in the classifier, and the semantic pattern and ledger fields are identities on the source witness. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyCycleCarrier empty semanticNameCert`

Theorem 98.34 (Homology singleton cycle semantic name certificate)**.** *Let the singleton cycle carrier contain exactly the BEDC histories h*hsameBHist.Empty*. Let its classifier require both endpoints to lie in that carrier and require h*hsame*k. This classifier is a semantic naming certificate for the carrier used simultaneously as source, pattern, and ledger policy.*

Proof. The carrier is inhabited by BHist.Empty through reflexivity of hsame. Classifier reflexivity, symmetry, and transitivity are obtained by unpacking the two endpoint-carrier witnesses and composing the underlying hsame proofs. Carrier transport along a classifier edge is the right endpoint carrier witness already stored in the classifier. The semantic pattern and ledger fields are the source witness itself. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologySingletonCycle semanticNameCert`

Theorem 98.35 (Homology singleton cycle standard bridge boundary)**.** *The singleton-cycle semantic certificate of Definition 98.34 supplies the paper-side standard bridge boundary for the exported* Homology$^{\uparrow}$ *cycle interface. The BEDC source is* BHist *with* hsame*, the carrier is the singleton cycle carrier, the classifier is endpoint carriage together with* hsame*, the ledger is the source witness, and the standard readback is the one-cycle trivial homology object.*

Proof. Project the semantic certificate of Definition 98.34. Its source, pattern, and ledger policy are all the singleton cycle carrier, and its classifier stores the two endpoint-carrier witnesses together with the hsame comparison.

Read the source as BHist equipped with hsame. The carrier is inhabited by BHist.Empty, so the standard readback is the one-cycle object whose only accepted cycle endpoint is the singleton empty-history class.

The ledger field is the source witness itself, and transport along the classifier uses the right endpoint-carrier witness. Repacking these rows gives the standard bridge boundary for the exported singleton-cycle Homology$^{\uparrow}$ interface. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyUp StdBridge`

Closure status for NameCert$_{\text{Homology}^{\uparrow}}$**.**

Constructive story: The exported homology surface is the singleton cycle cut out of a displayed chain differential: a history is carried when it is history-same to BHist.Empty, while the surrounding cycle and boundary rows explain how general predicates $Z_d(h)$ and $B_d(h)$ would be read through differential endpoints and preimages. The carrier therefore accepts the empty cycle and excludes nonempty endpoints for this exported object; its classifier stores the two endpoint-carrier witnesses together with hsame(h, k), rather than forming a boundary quotient or homology class. The source, pattern, and ledger policy are all the singleton cycle predicate, with the wider pattern rows recording boundary-to-cycle closure under square-zero, append closure, continuation preimages, and transport along hsame. The five name-certificate obligations are immediate on this surface: BHist.Empty inhabits the carrier, hsame gives reflexivity, symmetry, and transitivity, and classifier transport returns the right endpoint's stored carrier witness. A history h lies in the signature gap of a Homology$^{\uparrow}$

token p when the source-domain accepts h as the singleton cycle, the signature relation pairs it with an answer cycle and the source witness as evidence ledger, and token introduction names that answer as p; unfolded, h is history-same to the empty history and matches the one-cycle endpoint encoded by p. The paper bridge reads this singleton certificate as the trivial one-cycle homology object, with the ledger still being the same source witness and without exporting a quotient by boundaries. The chapter registers this singleton-cycle construction under the name Homology$^{\uparrow}$; the homology interface here is a checked kernel/image boundary over histories, with no arbitrary chain complex library, boundary quotient carrier, or derived-functor primitive introduced.

Theory closure: TheoryGate(NameCert$_{\text{Homology}\uparrow}$, maturePackageClosed)

Scope closed: The mature surface binds the singleton-cycle semantic certificate, cycle and boundary carrier readbacks, continuation preimage package, append and Cont transport rows, and the final hsame transport theorem.

Formal verification: FormalStatus(NameCert$_{\text{Homology}\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.HomologyUp.HomologySingletonCycle\_semanticNameCert`

Bridge status: bridgeChecked

Not claimed: General homology theory: arbitrary chain complexes, boundary/image quotients, chain maps, exact sequences, long exact sequences, singular or simplicial homology, and derived functors.

Theorem 98.36 (Homology cycle carrier hsame transport)**.** *Assume the differential is stable under history-sameness:*

$$\forall u, v : \mathsf{BHist},\ \mathsf{hsame}(u, v) \to \mathsf{hsame}(d(u), d(v)).$$

If $Z_d(h)$ and $\mathsf{hsame}(h, k)$, then $Z_d(k)$.

Proof. By section 98.1, $Z_d(h)$ is the endpoint comparison $\mathsf{hsame}(d(h), \mathsf{Empty})$. Applying the displayed stability row to $\mathsf{hsame}(h, k)$ gives $\mathsf{hsame}(d(h), d(k))$. Symmetry of hsame gives $\mathsf{hsame}(d(k), d(h))$, and transitivity with the cycle endpoint gives $\mathsf{hsame}(d(k), \mathsf{Empty})$. By the same carrier definition, this is $Z_d(k)$. □

Lean4 ✓ `BEDC.Derived.HomologyUp.HomologyCycleCarrier hsame transport`

Chapter 99

A Concrete Naming Certificate for Cohomology$^{\uparrow}$

The cohomology interface $\mathsf{Cohomology}^{\uparrow}$ packages a cochain complex with the dual kernel/image quotients computing cohomology groups. It depends on $\mathsf{NameCert}_{\mathsf{Homology}^{\uparrow}}$ (chapter 98) and supplies the structural substrate for de Rham, sheaf, and Čech cohomology certificates.

99.1 Carrier definition

Theorem 99.1 (Cohomology cocycle axis right cancel)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame*. If the shifted history $h \cdot axis$ is a d-cocycle, then h is a d-cocycle.*

Proof. Append preservation rewrites the shifted differential as $\mathsf{append}(d(h), d(axis))$. BEDC append-empty inversion reads the left component back from the empty appended history, giving $d(h)\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle axis right cancel`

Theorem 99.2 (Cohomology cocycle axis left cancel)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame*. If the shifted history $axis \cdot h$ is a d-cocycle, then h is a d-cocycle.*

Proof. Append preservation rewrites the shifted differential as $\mathsf{append}(d(axis), d(h))$. BEDC append-empty inversion reads the right component back from the empty appended history, giving $d(h)\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle axis left cancel`

Theorem 99.3 (Cohomology cocycle axis context cancel)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame*. If the two-sided shifted history $left \cdot (h \cdot right)$ is a d-cocycle, then h is a d-cocycle.*

Proof. Apply left-axis cancellation to the outer context. This recovers the right-axis shifted cocycle for $h \cdot right$. Applying right-axis cancellation to that shifted cocycle gives $d(h)\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle axis context cancel`

Theorem 99.4 (Cohomology cocycle bilateral axis cancel)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame*. If the doubly shifted history $(leftAxis \cdot h) \cdot rightAxis$ is a d-cocycle, then h is a d-cocycle.*

Proof. Right-axis cancellation removes the trailing $rightAxis$ from the displayed cocycle and yields a cocycle on $leftAxis \cdot h$. Left-axis cancellation then removes the leading $leftAxis$ and gives the core cocycle condition on h. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle axis bilateral cancel`

Theorem 99.5 (Cohomology cocycle append closure)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame*, and let the fixed cohomology axis satisfy $d(axis)\mathsf{hsamee}$. If the shifted histories $h \cdot axis$ and $k \cdot axis$ are d-cocycles, then the shifted append $(h \cdot k) \cdot axis$ is also a d-cocycle.*

Proof. Apply append preservation to the two shifted cocycle hypotheses. Append-empty inversion gives $d(h)\mathsf{hsamee}$ and $d(k)\mathsf{hsamee}$, since the axis derivative is empty. Append preservation for $h \cdot k$ then makes $d(h \cdot k)$ empty, and one final append-preservation step with the same axis gives the displayed shifted cocycle. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle append closed`

Theorem 99.6 (Cohomology cocycle prepend axis closure)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame*, and let the fixed cohomology axis satisfy $d(axis)\mathsf{hsamee}$. If the shifted histories $axis \cdot h$ and $axis \cdot k$ are d-cocycles, then the shifted append $axis \cdot (h \cdot k)$ is also a d-cocycle.*

Proof. Append preservation rewrites the two shifted cocycle hypotheses as empty append histories $\mathsf{append}(d(axis), d(h))$ and $\mathsf{append}(d(axis), d(k))$. Append-empty inversion extracts $d(h)\mathsf{hsamee}$ and $d(k)\mathsf{hsamee}$. The core append closure makes $d(h \cdot k)$ empty, and the axis cocycle row then rebuilds the displayed left-axis cocycle through the append law. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle prepend axis closed`

Theorem 99.7 (Cohomology cocycle append hsame transport)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame *and be congruent for* hsame*, and let the fixed cohomology axis satisfy $d(axis)\mathsf{hsamee}$. If the shifted histories $h \cdot axis$ and $k \cdot axis$ are d-cocycles and $\mathsf{hsame}((h \cdot k) \cdot axis, r)$, then r is a d-cocycle.*

Proof. The append closure theorem gives the cocycle predicate for $(h \cdot k) \cdot axis$. Congruence for d transports the endpoint comparison to the corresponding differential histories, and symmetry plus transitivity of hsame carries the cocycle predicate to r. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle append hsame transport`

Theorem 99.8 (Cohomology cocycle mixed-axis append hsame transport)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame *and be congruent for* hsame*. If $h \cdot axis$ and $axis \cdot k$ are d-cocycles, and if $h \cdot k\mathsf{hsame}r$, then r is a d-cocycle.*

Proof. Right-axis cancellation extracts the core cocycle for h, and left-axis cancellation extracts the core cocycle for k. Core append closure then gives the cocycle for $h \cdot k$. Congruence for d transports this cocycle across the displayed hsame comparison to r. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle mixed axis append hsame transport`

Theorem 99.9 (Cohomology cocycle core append closure)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame*. If h and k are d-cocycles in the core history sense, then their append $h \cdot k$ is also a d-cocycle.*

Proof. Convert the two core cocycle hypotheses to empty equalities for $d(h)$ and $d(k)$. Append-empty introduction makes $d(h) \cdot d(k)$ empty. Append preservation transports this empty result back to $d(h \cdot k)$. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle append core closed`

Theorem 99.10 (Cohomology cocycle continuation hsame transport)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame *and be congruent for* hsame*. If* $\mathsf{Cont}(h, k, r)$*, the histories h and k are d-cocycles, and* $\mathsf{hsame}(r, s)$*, then s is a d-cocycle.*

Proof. Continuation identifies r with $h \cdot k$. Core append closure gives $d(h \cdot k)\mathsf{hsamee}$ from the two endpoint cocycle hypotheses. The $\mathsf{hsame}(r, s)$ comparison is transported through d, and symmetry plus transitivity carries the cocycle witness to s. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle continuation hsame transport`

Theorem 99.11 (Cohomology cocycle continuation context cancel)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame *and respect* hsame *on histories. If* $\mathsf{Cont}(left, h, mid)$ *and* $\mathsf{Cont}(mid, right, r)$ *compose a two-sided context around h, then any d-cocycle on r restricts to a d-cocycle on h.*

Proof. The two continuation ledgers identify r with $(left \cdot h) \cdot right$. Associativity rewrites this as $left \cdot (h \cdot right)$, and congruence for d transports the cocycle witness to that reassociated context. Axis context cancellation then removes the visible left and right factors. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle continuation context cancel`

Theorem 99.12 (Cohomology cocycle continuation context empty iff)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame*. If* $\mathsf{Cont}(left, h, mid)$ *and* $\mathsf{Cont}(mid, right, r)$ *compose a two-sided continuation context, then r is a d-cocycle exactly when the three exposed components $left$, h, and $right$ are d-cocycles:*

$$d(r)\mathsf{hsamee} \iff d(left)\mathsf{hsamee} \ \wedge \ d(h)\mathsf{hsamee} \ \wedge \ d(right)\mathsf{hsamee}.$$

Proof. The two continuation ledgers identify r with $(left \cdot h) \cdot right$. Append-empty equivalence first splits the outer append into the cocycle on $left \cdot h$ and the cocycle on $right$, and then splits $left \cdot h$ into the two cocycles on $left$ and h. Conversely, core append closure combines $left$ with h and then combines that result with $right$. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle continuation context empty iff`

Theorem 99.13 (Cohomology cocycle continuation context e1 boundary empty absurd)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame*. If* $\mathsf{Cont}(left, h, mid)$ *and* $\mathsf{Cont}(mid, right, r)$ *form a two-sided continuation context, any visible* E1 *boundary among $d(left)$, $d(h)$, and $d(right)$ contradicts $d(r)\mathsf{hsamee}$.*

Proof. The continuation-context empty equivalence decomposes $d(r)\mathsf{hsamee}$ into empty witnesses for $d(left)$, $d(h)$, and $d(right)$. In each visible boundary case, symmetry and transitivity give an E1 history hsamee, forbidden by constructor disjointness. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle continuation context e1 boundary empty absurd`

Theorem 99.14 (Cohomology cocycle core append hsame transport)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame *and respect* hsame *on histories. If* h *and* k *are core* d*-cocycles and* $\mathsf{hsame}(h \cdot k, r)$*, then* r *is a* d*-cocycle.*

Proof. Core append closure first gives $d(h \cdot k)\mathsf{hsamee}$. The displayed endpoint comparison transports through d, and symmetry followed by transitivity carries the cocycle predicate to r. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle core append hsame transport`

Theorem 99.15 (Cohomology cocycle append empty equivalence)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame*. For histories* $h, k : \mathsf{BHist}$*, the appended history* $h \cdot k$ *is a* d*-cocycle exactly when both* h *and* k *are* d*-cocycles:*

$$d(h \cdot k)\mathsf{hsamee} \iff d(h)\mathsf{hsamee} \ \wedge \ d(k)\mathsf{hsamee}.$$

Proof. Append preservation transports the displayed cocycle on $h \cdot k$ to the empty appended history $\mathsf{append}(d(h), d(k))$, and BEDC append-empty inversion splits this into the two component cocycle equations. Conversely, the core append closure theorem combines the two component cocycles into the appended cocycle. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle append empty iff`

Theorem 99.16 (Cohomology cocycle continuation axis context cancel)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame*. If* $\mathsf{Cont}(h, k, r)$ *and the two-sided contextual history* $left \cdot (r \cdot right)$ *is a* d*-cocycle, then both* h *and* k *are* d*-cocycles:*

$$d(h)\mathsf{hsamee} \ \wedge \ d(k)\mathsf{hsamee}.$$

Proof. The continuation witness identifies r with $h \cdot k$. Axis-context cancellation removes the surrounding histories from the contextual cocycle and gives $d(h \cdot k)\mathsf{hsamee}$. Append-empty equivalence then splits this core cocycle into the two component cocycle rows for h and k. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle continuation axis context cancel`

Theorem 99.17 (Cohomology cocycle continuation axis context closure)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame *and respect* hsame*. If* $\mathsf{Cont}(h, k, r)$ *and* $left$*,* h*,* k*, and* $right$ *are* d*-cocycles, then the two-sided contextual continuation history* $left \cdot (r \cdot right)$ *is a* d*-cocycle.*

Proof. Core append closure first combines the cocycles on h and k. Congruence for d transports the continuation comparison to a cocycle on r. Applying core append closure to r with $right$, and then to $left$ with that result, gives the displayed two-sided contextual cocycle. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle continuation axis context closed`

Theorem 99.18 (Cohomology visible left boundary excludes appended cycle)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame*. If* $d(h)$ *has visible boundary* $\mathsf{E1}(t)$*, then the appended history* $h \cdot k$ *cannot be a* d*-cocycle:*

$$d(h)\mathsf{hsameE1}(t) \Longrightarrow d(h \cdot k)\mathsf{hsamee} \Longrightarrow \bot.$$

Proof. Append preservation transports the appended cocycle to $\mathsf{append}(d(h), d(k))\mathsf{hsamee}$. Append-empty inversion then forces $d(h)\mathsf{hsamee}$. Together with the visible boundary hypothesis this identifies $\mathsf{E1}(t)$ with e, contradicting BEDC constructor no-confusion. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle append left e1 boundary empty absurd`

Theorem 99.19 (Cohomology visible left boundary excludes appended cycle)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame*. If* $d(h)$ *is* hsame *to either* $\mathsf{E0}(t)$ *or* $\mathsf{E1}(t)$*, then* $d(h \cdot k)\mathsf{hsamee}$ *is impossible.*

Proof. Append preservation and append-empty inversion force $d(h)\mathsf{hsamee}$; either visible constructor case contradicts BEDC constructor no-confusion. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle append left visible boundary empty absurd`

Theorem 99.20 (Cohomology visible right boundary excludes appended cycle)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame*. If* $d(k)$ *has visible boundary* $\mathsf{E1}(t)$*, then the appended history* $h \cdot k$ *cannot be a* d*-cocycle:*

$$d(k)\mathsf{hsameE1}(t) \Longrightarrow d(h \cdot k)\mathsf{hsamee} \Longrightarrow \bot.$$

Proof. Append preservation transports the appended cocycle to $\mathsf{append}(d(h), d(k))\mathsf{hsamee}$. Append-empty inversion then forces $d(k)\mathsf{hsamee}$. Together with the visible boundary hypothesis this identifies $\mathsf{E1}(t)$ with e, contradicting BEDC constructor no-confusion. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle append right e1 boundary empty absurd`

Theorem 99.21 (Cohomology cocycle left-shift append empty equivalence)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame*. For histories* $axis, h, k : \mathsf{BHist}$*, the left-shifted appended history* $axis \cdot (h \cdot k)$ *is a* d*-cocycle exactly when the axis and both tail components are* d*-cocycles:*

$$d(axis \cdot (h \cdot k))\mathsf{hsamee} \quad \Longleftrightarrow \quad d(axis)\mathsf{hsamee} \ \wedge \ d(h)\mathsf{hsamee} \ \wedge \ d(k)\mathsf{hsamee}.$$

Proof. Apply append-empty equivalence to split the left axis from the tail $h \cdot k$. Apply the same equivalence again to split the tail into h and k. The converse first rebuilds the tail cocycle and then rebuilds the left-shifted cocycle. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle left shift append empty iff`

Theorem 99.22 (Cohomology cocycle core append transport)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame *and be congruent for* hsame*. If* h *and* k *are core* d*-cocycles and* $h \cdot k\mathsf{hsame}r$*, then* r *is also a* d*-cocycle.*

Proof. Core append closure gives $d(h \cdot k)\mathsf{hsamee}$. Congruence for d transports the comparison $h \cdot k\mathsf{hsame}r$ to the differential histories, and symmetry plus transitivity carries the cocycle predicate to r. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle append core hsame transport`

Theorem 99.23 (Cohomology cocycle axis context append closure)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame*, and let* $left$ *and* $right$ *be* d*-cocycles. If the two-sided shifted histories* $left \cdot (h \cdot right)$ *and* $left \cdot (k \cdot right)$ *are* d*-cocycles, then the two-sided shifted append* $left \cdot ((h \cdot k) \cdot right)$ *is also a* d*-cocycle.*

Proof. Two-sided context cancellation applied to the two hypotheses gives core cocycles for h and k. Core append closure makes $h \cdot k$ a core cocycle. Append preservation with the right context, then with the left context, combines these three cocycle rows into the displayed two-sided shifted cocycle. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle axis context append closed`

Theorem 99.24 (Cohomology cocycle axis context append hsame transport)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame *and be congruent for* hsame*, and let $left$ and $right$ be d-cocycles. If $left \cdot (h \cdot right)$ and $left \cdot (k \cdot right)$ are d-cocycles and*

$$\mathsf{hsame}(left \cdot ((h \cdot k) \cdot right), r),$$

then r is a d-cocycle.

Proof. The two-sided context append closure theorem gives the cocycle predicate for $left \cdot ((h \cdot k) \cdot right)$. Congruence for d transports the final hsame comparison to the differential histories, and symmetry followed by transitivity carries the cocycle predicate to r. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle axis context append hsame transport`

Theorem 99.25 (Cohomology cocycle left-shift append closure)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame*, and let the fixed cohomology axis satisfy $d(axis)$*hsamee*. If the shifted histories $axis \cdot h$ and $axis \cdot k$ are d-cocycles, then the shifted append $axis \cdot (h \cdot k)$ is also a d-cocycle.*

Proof. Apply left-axis cancellation to the two shifted cocycle hypotheses to obtain core cocycles for h and k. Core append closure gives a cocycle for $h \cdot k$. Append preservation for $axis \cdot (h \cdot k)$ then combines the empty axis differential with this core cocycle and yields the displayed left-shifted cocycle. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle left shift append closed`

Theorem 99.26 (Cohomology cocycle left-shift append hsame transport)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame *and be congruent for* hsame*, and let the fixed cohomology axis satisfy $d(axis)$*hsamee*. If the shifted histories $axis \cdot h$ and $axis \cdot k$ are d-cocycles and* hsame$(axis \cdot (h \cdot k), r)$*, then r is a d-cocycle.*

Proof. The left-shift append closure theorem gives the cocycle predicate for $axis \cdot (h \cdot k)$. Congruence for d transports the displayed endpoint comparison to the differential histories, and symmetry followed by transitivity of hsame carries the cocycle predicate to r. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle left shift append hsame transport`

Theorem 99.27 (Cohomology cocycle prepend hsame transport)**.** *Let $d : \mathsf{BHist} \to \mathsf{BHist}$ preserve append up to* hsame *and be congruent for* hsame*, and let the fixed cohomology axis satisfy $d(axis)$*hsamee*. If the shifted histories $axis \cdot h$ and $axis \cdot k$ are d-cocycles and* hsame$(axis \cdot (h \cdot k), r)$*, then r is a d-cocycle.*

Proof. The left-shift append closure theorem gives the cocycle predicate for $axis \cdot (h \cdot k)$. Congruence for d transports the endpoint comparison to differentials, and symmetry plus transitivity of hsame carries the cocycle predicate to r. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle prepend hsame transport`

99.2 The certificate

Definition 99.28 (Cohomology cocycle predicate)**.** *For a BEDC cohomology differential* $d : \mathsf{BHist} \to \mathsf{BHist}$*, write*

$$C_d(h) :\Longleftrightarrow d(h)\mathsf{hsamee}.$$

Lean4 (definition) `BEDC.Derived.CohomologyUp.CohomologyCocycle`

Lemma 99.29 (Cohomology cocycle hsame transport)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *respect* hsame*. If* $C_d(h)$ *and* $\mathsf{hsame}(h, k)$*, then* $C_d(k)$*.*

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle hsame transport`

Proof. By the respect-hsame hypothesis on d, $\mathsf{hsame}(h, k)$ implies $\mathsf{hsame}(d(h), d(k))$. Symmetry of that comparison, followed by the cocycle row $d(h)\mathsf{hsamee}$, gives $d(k)\mathsf{hsamee}$. □

Theorem 99.30 (Cohomology cocycle predicate semantic name certificate)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame *and respect* hsame*. Fix* $axis : \mathsf{BHist}$ *with* $C_d(axis)$*. Then the cocycle predicate* C_d*, used simultaneously as source, pattern, and ledger, with classifier* hsame*, carries a semantic naming certificate:*

$$\mathsf{SemanticNameCert}(C_d, C_d, C_d, \mathsf{hsame}).$$

Its cohomology stability witnesses are the bilateral axis-cancel row of Definition 99.4 and the append-closure row of Definition 99.5.

Proof. The source is inhabited by the chosen axis cocycle. The classifier fields in Definition 9.7 are the finite-kernel reflexivity, symmetry, and transitivity laws for hsame. Carrier transport for the core certificate is Definition 99.29. Therefore C_d with classifier hsame forms the core $\mathsf{NameCert}(C_d, \mathsf{hsame})$.

Since source, pattern, and ledger are all the same predicate C_d, both semantic soundness maps are identity maps on a source witness. The stability component from Definition 9.4 is supplied within the same predicate: Definition 99.4 descends a two-sided axis-shifted cocycle to the unshifted cocycle, and Definition 99.5 composes two shifted cocycle witnesses along a cocycle axis. These fields populate the five roles of Definition 9.6 with source C_d, pattern C_d, ledger C_d, and classifier hsame. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle predicate semanticNameCert`

Theorem 99.31 (Cohomology cocycle semantic name certificate)**.** *Let* $d : \mathsf{BHist} \to \mathsf{BHist}$ *preserve append up to* hsame*. The cocycle predicate* $h \mapsto d(h)\mathsf{hsamee}$*, used simultaneously as source, pattern, and ledger policy, forms a semantic naming certificate whose classifier compares histories by* $d(h)\mathsf{hsame}d(k)$*.*

Proof. Append preservation at e, e identifies $d(\mathsf{e})$ with $\mathsf{append}(d(\mathsf{e}), d(\mathsf{e}))$. BEDC right-unit exactness for append therefore forces $d(\mathsf{e})\mathsf{hsamee}$, giving the carrier witness. The classifier fields are reflexivity, symmetry, and transitivity of hsame on the displayed differential histories. Carrier transport composes the symmetric classifier witness with the source cocycle predicate, and the pattern and ledger policies are the same cocycle predicate. □

Lean4 ✓ `BEDC.Derived.CohomologyUp.CohomologyCocycle semanticNameCert`

Closure status for $\mathsf{NameCert}_{\mathsf{Cohomology}\uparrow}$.

Constructive story: A cohomology cocycle is generated by a displayed cochain differential d on histories: a history h is admitted exactly when the differential endpoint $d(h)$ is history-same to e. Histories whose differential does not collapse to the empty endpoint are excluded, and the classifier compares admitted histories by the differential endpoints, asking whether $d(h)$ and $d(k)$ are hsame rather than quotienting by coboundaries. The source, pattern, and ledger policy are all the cocycle predicate, with the pattern rows spelling out right, left, and bilateral axis cancellation, append closure along a cocycle axis, and transport through continuation and hsame contexts. The name-certificate obligations are supplied by the append-preservation proof that makes e a cocycle, by reflexivity, symmetry, and transitivity of hsame on displayed differential histories, and by carrier transport that composes the classifier witness with the source cocycle witness. A history h lies in the signature gap of a Cohomology$^{\uparrow}$ token p when the source-domain accepts h as a cocycle, the signature relation pairs it with an answer cocycle and evidence ledger, and token introduction names that answer as p; concretely, the differential of h is empty and its differential endpoint is classified with the endpoint encoded by p. The paper bridge boundary keeps this as a cocycle predicate over the displayed cochain differential, not as an external coboundary quotient or cohomology group. The chapter registers this cocycle-predicate construction under the name Cohomology$^{\uparrow}$; all visible information remains in differential endpoints, axis rows, and ledgers, with no cup product, sheaf complex, spectral sequence, or host quotient primitive introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Cohomology}\uparrow}$, maturePackageClosed)

Scope closed: The public cocycle SemanticNameCert over the displayed cochain differential is exported with carrier, classifier transport, and pattern/ledger policies equal to the cocycle predicate.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Cohomology}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.CohomologyUp.CohomologyCocycle\_semanticNameCert`

Bridge status: paperBridge

Not claimed: General cohomology theory: arbitrary cochain complexes, coboundary quotients, cup products, de Rham cohomology, sheaf cohomology, Čech cohomology, or spectral sequences.

Upgrade path: No further theory-axis upgrade is claimed in this chapter; any bridgeChecked uplift is a separate verification-axis step.

Chapter 100

A Concrete Naming Certificate for $\mathsf{Padic}^{\uparrow}$

The p-adic interface $\mathsf{Padic}^{\uparrow}$ packages the carrier of regular Cauchy sequences over $\mathsf{NameCert}_{\mathsf{Rat}^{\uparrow}}$ (chapter 37) under the p-adic absolute value, indexed by a prime p from $\mathsf{NameCert}_{\mathsf{Prime}^{\uparrow}}$ (chapter 64). It is the non-archimedean sibling of $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ (chapter 38).

100.1 Carrier definition

Definition 100.1 (Prime scale over unary multiplication)**.** *For histories p, e, r, the predicate* $\mathsf{PadicPrimeScale}(p, e, r)$ *holds when p is a* $\mathsf{Prime}^{\uparrow}$*-prime and r is the unary multiplication result of p by the exponent e.*

Lean4 (definition) `BEDC.Derived.PadicUp.PadicPrimeScale`

Theorem 100.2 (Prime scale unary components)**.** *If* $\mathsf{PadicPrimeScale}(p, e, r)$*, then the prime base p, exponent e, and result r are all unary histories.*

Proof. The scale predicate consists of a $\mathsf{NatPrime}(p)$ witness and a $\mathsf{NatMul}(p, e, r)$ witness. The prime witness supplies the unary carrier field for p. The unary multiplication witness supplies the unary field for e, and together with the unary field for p, supplies the unary field for the result r. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale unary components`

Theorem 100.3 (Prime scale commutes with the exponent)**.** *If p and q are unary histories, and* $\mathsf{PadicPrimeScale}(p, q, r)$ *and* $\mathsf{PadicPrimeScale}(q, p, s)$ *both hold, then r*hsame*s.*

Proof. Each prime-scale witness contains a concrete NatMul field. The commutativity theorem for unary multiplication applies to those two fields and identifies the two scale results up to hsame. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale prime exponent comm hsame`

Theorem 100.4 (Prime scale totality)**.** *If p is a* $\mathsf{Prime}^{\uparrow}$*-prime and e is a unary history, then some unary history r realizes* $\mathsf{PadicPrimeScale}(p, e, r)$*.*

Proof. The prime witness contains the unary carrier field for p. Unary multiplication totality applied to this carrier and to the exponent carrier produces a unary result r together with the $\mathsf{NatMul}(p, e, r)$ witness. Pairing the original prime witness with that multiplication witness is precisely $\mathsf{PadicPrimeScale}(p, e, r)$. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale total`

Theorem 100.5 (Prime scale exists uniquely)**.** *If p is a $\mathsf{Prime}^{\uparrow}$-prime and e is a unary history, then there is a history r with $\mathsf{PadicPrimeScale}(p, e, r)$, and every other such scale result is* hsame-*equal to r.*

Proof. Prime-scale totality supplies a concrete result witness. Any competing prime-scale result has the same prime base and exponent in its NatMul field, so unary multiplication functionality identifies the two result histories. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale exists unique`

Theorem 100.6 (Prime scale empty result exactness)**.** *If $\mathsf{PadicPrimeScale}(p, e, r)$, then r*hsamee *exactly when e*hsamee*.*

Proof. The forward direction uses the $\mathsf{Prime}^{\uparrow}$ prime field to rule out $p$hsamee, then applies the empty-result exactness theorem for NatMul with a nonempty multiplicand. The reverse direction identifies the exponent with e, so the zero constructor of NatMul identifies the result with e. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale empty result iff empty exponent`

Lemma 100.7 (Prime scale successor exponent inversion)**.** *If $\mathsf{PadicPrimeScale}(p, \mathsf{E1}(q), r)$, then there is a predecessor result n with $\mathsf{PadicPrimeScale}(p, q, n)$ and $\mathsf{Cont}(n, p, r)$.*

Proof. The scale witness contains the prime field for p and a multiplication witness $\mathsf{NatMul}(p, \mathsf{E1}(q), r)$. Successor inversion for unary multiplication extracts the predecessor product n and the continuation $\mathsf{Cont}(n, p, r)$. Reusing the same prime field packages the predecessor as a prime-scale witness. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale succ exponent inversion`

Theorem 100.8 (Prime scale positive-exponent continuation readback)**.** *If the exponent e is unary, not history-same as* e*, and $\mathsf{PadicPrimeScale}(p, e, r)$ holds, then e has a unary tail t and the scale result is obtained from a predecessor scale by one continuation with the prime base:*

$$\exists t, n.\ \mathsf{Unary}(t) \wedge e = \mathsf{E1}(t) \wedge \mathsf{PadicPrimeScale}(p, t, n) \wedge \mathsf{Cont}(n, p, r).$$

Proof. The unary nonempty exponent has a one-headed tail. After substituting that tail into the scale witness, successor-exponent inversion for PadicPrimeScale exposes the predecessor scale and the continuation from the predecessor result by p. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale positive exponent cont readback`

Theorem 100.9 (Prime scale successor exponent factorization)**.** *A successor-exponent prime scale $\mathsf{PadicPrimeScale}(p, \mathsf{E1}(q), r)$ holds exactly when some predecessor result n carries $\mathsf{PadicPrimeScale}(p, q, n)$ and a continuation $\mathsf{Cont}(n, p, r)$.*

Proof. The forward direction is successor-exponent inversion. Conversely, the predecessor scale gives the prime field and a concrete $\mathsf{NatMul}(p, q, n)$ witness; the successor constructor for NatMul, applied to $\mathsf{Cont}(n, p, r)$, rebuilds the scale over $\mathsf{E1}(q)$. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale succ exponent factorization iff`

Lemma 100.10 (Prime scale exponent-result cases)**.** *Every* $\mathsf{PadicPrimeScale}(p, e, r)$ *witness is either the empty exponent case, with* $e\mathsf{hsame}e$ *and* $r\mathsf{hsame}e$*, or a successor exponent case: there are histories* e_0 *and* r_0 *such that* $e = \mathsf{E1}(e_0)$*,* $\mathsf{PadicPrimeScale}(p, e_0, r_0)$*, and* $\mathsf{Cont}(r_0, p, r)$*.*

Proof. Apply the exponent-result case split for the underlying $\mathsf{NatMul}(p, e, r)$ field. In the successor branch, the same prime witness for p packages the predecessor multiplication witness as a predecessor prime-scale witness. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale exponent result cases`

Theorem 100.11 (Prime scale successor predecessor uniqueness)**.** *If* $\mathsf{PadicPrimeScale}(p, \mathsf{E1}(q), r)$*, then there is a predecessor result* n *with* $\mathsf{PadicPrimeScale}(p, q, n)$ *and* $\mathsf{Cont}(n, p, r)$*, and every other predecessor scale over* q *is history-same to* n*.*

Proof. Successor-exponent inversion supplies the predecessor result n, its prime-scale witness over q, and the continuation witness into r. Any competing predecessor scale over the same base p and exponent q has a second $\mathsf{NatMul}(p, q, -)$ field. Unary multiplication functionality, using the unary carrier field of the prime witness, identifies the two predecessor histories. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale succ exponent predecessor unique`

Theorem 100.12 (Prime scale unit exponent reads back to the prime)**.** *If* $\mathsf{PadicPrimeScale}(p, \mathsf{E1}(\mathsf{e}), result)$ *holds, then the scale result is history-same to the prime base:*

$$result\mathsf{hsame}p.$$

Proof. Successor-exponent inversion extracts a predecessor result over the empty exponent and a continuation from that predecessor through p to *result*. Empty-result exactness for prime scales identifies the predecessor with e. Comparing the displayed continuation with the left-unit continuation for p identifies *result* with p. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale unit exponent result prime hsame`

Theorem 100.13 (Prime scale append continuation closure)**.** *If* $\mathsf{PadicPrimeScale}(p, w, n)$*,* $\mathsf{PadicPrimeScale}(p, q, e)$*, and* $\mathsf{Cont}(n, e, r)$*, then* $\mathsf{PadicPrimeScale}(p, \mathsf{append}(w, q), r)$*.*

Proof. Both scale witnesses share the same prime field for p. The multiplication fields are concrete NatMul derivations, so append continuation closure for NatMul, applied to the supplied continuation witness, gives the scale witness for the appended exponent. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append cont closure`

Theorem 100.14 (Padic natural multiplication append exponent decomposition)**.** *For unary histories* d, w, q*, any multiplication witness over the appended exponent decomposes into multiplication witnesses over the two exponent factors and a continuation between their results:*

$$\mathsf{NatMul}(d, \mathsf{append}(w, q), r) \quad \Longrightarrow \quad \exists n, e.\ \mathsf{NatMul}(d, w, n) \wedge \mathsf{NatMul}(d, q, e) \wedge \mathsf{Cont}(n, e, r).$$

Proof. Induct on the unary right exponent q. For the empty exponent, take the left result to be the displayed result r and the right result to be e. In the one-headed case, successor inversion for NatMul extracts the previous product over $\mathsf{append}(w, q)$ and the final continuation by d. The induction hypothesis decomposes the previous product into left and right results; composing its continuation with the final continuation and using append associativity gives the required continuation from the left result to the successor right product. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicNatMul append exponent decomposition`

Theorem 100.15 (Prime scale append factorization)**.** *For unary exponent histories w, q, a prime scale over the appended exponent is exactly a pair of prime-scale factor results linked by continuation:*

$$\mathsf{PadicPrimeScale}(p, \mathsf{append}(w, q), r) \iff \exists n, e.\ \mathsf{PadicPrimeScale}(p, w, n) \wedge \mathsf{PadicPrimeScale}(p, q, e) \wedge \mathsf{Cont}(n, e, r).$$

Proof. The forward direction applies append-exponent decomposition to the NatMul field of the scale witness and reattaches the common prime field to both factor multiplications. The reverse direction is precisely prime-scale append continuation closure applied to the two factor scales and their continuation row. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append factorization iff`

Theorem 100.16 (Prime scale append exponent decomposition)**.** *For unary histories w, q, any prime scale over the appended exponent decomposes into prime-scale witnesses over the two exponent factors and a continuation between their results:*

$$\mathsf{PadicPrimeScale}(p, \mathsf{append}(w, q), r) \implies \exists n, e.\ \mathsf{PadicPrimeScale}(p, w, n) \wedge \mathsf{PadicPrimeScale}(p, q, e) \wedge \mathsf{Cont}(n, e, r).$$

Proof. The scale witness contains the shared prime field for p and a concrete $\mathsf{NatMul}(p, \mathsf{append}(w, q), r)$ field. Append-exponent decomposition for NatMul splits that multiplication field into factor multiplications and a continuation. Reusing the same prime field with each factor multiplication gives the two displayed prime-scale witnesses. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append exponent decomposition`

Theorem 100.17 (Prime scale append successor right factorization)**.** *For unary histories w and q, a prime scale over $\mathsf{append}(w, \mathsf{E1}(q))$ is exactly a left prime-scale result over w, a predecessor right prime-scale result over q, a one-step continuation by the prime base, and the final continuation from the left result:*

$$\mathsf{PadicPrimeScale}(p, \mathsf{append}(w, \mathsf{E1}(q)), r) \iff \exists n, e, s.\ \mathsf{PadicPrimeScale}(p, w, n) \wedge \mathsf{PadicPrimeScale}(p, q, e) \wedge \mathsf{Cont}(e, p, s)$$

Proof. The forward direction first applies append-exponent decomposition with the right factor $\mathsf{E1}(q)$. The right factor scale is then inverted by the successor-exponent factorization theorem, producing the predecessor scale over q and its continuation by p. Conversely, rebuild the right successor scale from the predecessor row and then apply append continuation closure with the final continuation row. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append succ right exponent factorization iff`

Theorem 100.18 (Prime scale append successor left factorization)**.** *For unary histories w and q, a prime scale over $\mathsf{append}(\mathsf{E1}(w), q)$ is exactly a predecessor left prime-scale result over w, a one-step continuation by the prime base, a right prime-scale result over q, and the final continuation from the successor left result:*

$$\mathsf{PadicPrimeScale}(p, \mathsf{append}(\mathsf{E1}(w), q), r) \iff \exists n, e, s.\ \mathsf{PadicPrimeScale}(p, w, n) \wedge \mathsf{Cont}(n, p, s) \wedge \mathsf{PadicPrimeScale}(p, q, e$$

Proof. Apply append-exponent decomposition to the scale over $\mathsf{append}(\mathsf{E1}(w), q)$. The left factor is then inverted by the successor-exponent factorization theorem, producing the predecessor scale over w and the continuation by p. Conversely, rebuild the left successor scale from that predecessor row and apply append continuation closure with the right scale and final continuation. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append succ left exponent factorization iff`

Theorem 100.19 (Prime scale append unit right factorization)**.** *For unary w, a prime scale over* $\mathsf{append}(w, \mathsf{E1}(\mathsf{e}))$ *is exactly a left prime-scale result over w followed by continuation with the prime base:*

$$\mathsf{PadicPrimeScale}(p, \mathsf{append}(w, \mathsf{E1}(\mathsf{e})), r) \iff \exists n.\, \mathsf{PadicPrimeScale}(p, w, n) \wedge \mathsf{Cont}(n, p, r).$$

Proof. The forward direction decomposes the appended exponent and then applies the unit exponent readback theorem, replacing the right factor result by the prime base. Conversely, the empty exponent scale gives the unit successor scale by the successor factorization theorem, and append continuation closure combines it with the left scale and the displayed continuation. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append unit right factorization iff`

Theorem 100.20 (Prime scale append unit right predecessor uniqueness)**.** *For unary w, every prime scale over* $\mathsf{append}(w, \mathsf{E1}(\mathsf{e}))$ *exposes a predecessor scale* $\mathsf{PadicPrimeScale}(p, w, n)$ *and a continuation* $\mathsf{Cont}(n, p, r)$*, and the predecessor is unique up to* hsame *among prime-scale results over w:*

$$\mathsf{PadicPrimeScale}(p, \mathsf{append}(w, \mathsf{E1}(\mathsf{e})), r) \implies \exists n.\, \mathsf{PadicPrimeScale}(p, w, n) \wedge \mathsf{Cont}(n, p, r) \wedge \forall other.\, \mathsf{PadicPrimeScale}(p,$$

Proof. The append-unit-right factorization extracts the predecessor scale and the continuation by the prime base. Uniqueness is the functional property of the underlying natural multiplication field of $\mathsf{PadicPrimeScale}(p, w, n)$. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append unit right predecessor unique`

Theorem 100.21 (Prime scale append unit right result readback)**.** *For unary w, if n is a prime-scale result over w and r is a prime-scale result over* $\mathsf{append}(w, \mathsf{E1}(\mathsf{e}))$*, then r reads back to appending the prime base to n:*

$$\mathsf{PadicPrimeScale}(p, w, n) \wedge \mathsf{PadicPrimeScale}(p, \mathsf{append}(w, \mathsf{E1}(\mathsf{e})), r) \Rightarrow r \mathsf{hsameappend}(n, p).$$

Proof. The append-unit-right predecessor theorem extracts a predecessor scale $\mathsf{PadicPrimeScale}(p, w, pred)$ with continuation $\mathsf{Cont}(pred, p, r)$. Predecessor uniqueness identifies $pred$ with the displayed result n up to hsame, and continuation respects that endpoint comparison against the canonical continuation $\mathsf{Cont}(n, p, \mathsf{append}(n, p))$. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append unit right result hsame`

Theorem 100.22 (Prime scale append unit left factorization)**.** *For unary q, a prime scale over* $\mathsf{append}(\mathsf{E1}(\mathsf{e}), q)$ *is exactly a prime-scale result over q preceded by continuation from the prime base:*

$$\mathsf{PadicPrimeScale}(p, \mathsf{append}(\mathsf{E1}(\mathsf{e}), q), r) \iff \exists e.\, \mathsf{PadicPrimeScale}(p, q, e) \wedge \mathsf{Cont}(p, e, r).$$

Proof. Decompose the appended exponent into a unit left factor and the displayed right factor. The unit-exponent readback identifies the left scale result with the prime base, leaving the continuation $\mathsf{Cont}(p, e, r)$. Conversely, construct the unit scale from the empty exponent scale and combine it with the displayed right scale by append continuation closure. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append unit left factorization iff`

Theorem 100.23 (Prime scale append unit left predecessor uniqueness)**.** *For unary q, every prime scale over* $\mathsf{append}(\mathsf{E1}(\mathsf{e}), q)$ *exposes a right-factor scale* $\mathsf{PadicPrimeScale}(p, q, e)$ *and a continuation* $\mathsf{Cont}(p, e, r)$*, and the right-factor result is unique up to* hsame *among prime-scale results over q:*

$$\mathsf{PadicPrimeScale}(p, \mathsf{append}(\mathsf{E1}(\mathsf{e}), q), r) \Longrightarrow \exists e.\, \mathsf{PadicPrimeScale}(p, q, e) \wedge \mathsf{Cont}(p, e, r) \wedge \forall other.\, \mathsf{PadicPrimeScale}(p, q,$$

Proof. The append-unit-left factorization extracts the right-factor scale and the continuation from the prime base. Uniqueness is the functional property of the underlying natural multiplication field of $\mathsf{PadicPrimeScale}(p, q, e)$. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append unit left predecessor unique`

Theorem 100.24 (Prime scale append unit left result readback)**.** *For unary q, if* $\mathsf{PadicPrimeScale}(p, q, e)$ *and* $\mathsf{PadicPrimeScale}(p, \mathsf{append}(\mathsf{E1}(\mathsf{e}), q), r)$ *hold, then the appended-exponent result reads back to the continuation result* $\mathsf{append}(p, e)$*:*

$$\mathsf{PadicPrimeScale}(p, q, e) \wedge \mathsf{PadicPrimeScale}(p, \mathsf{append}(\mathsf{E1}(\mathsf{e}), q), r) \Rightarrow r\mathsf{hsameappend}(p, e).$$

Proof. The append-unit-left predecessor theorem extracts a right-factor result *pred* with $\mathsf{PadicPrimeScale}(p, q, pred)$ and continuation $\mathsf{Cont}(p, pred, r)$. The uniqueness clause identifies *pred* with the displayed scale result e. Continuation respect for hsame compares the extracted continuation with the canonical continuation $\mathsf{Cont}(p, e, \mathsf{append}(p, e))$. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append unit left result hsame`

Theorem 100.25 (Prime scale append unit left result nonempty)**.** *For unary q, if* $\mathsf{PadicPrimeScale}(p, q, e)$ *and* $\mathsf{PadicPrimeScale}(p, \mathsf{append}(\mathsf{E1}(\mathsf{e}), q), r)$ *hold, then the appended unit-left scale result cannot be empty:*

$$\mathsf{PadicPrimeScale}(p, q, e) \wedge \mathsf{PadicPrimeScale}(p, \mathsf{append}(\mathsf{E1}(\mathsf{e}), q), r) \wedge r\mathsf{hsamee} \Longrightarrow \bot.$$

Proof. Read back the unit-left predecessor as a right-factor scale result *pred* and a continuation $\mathsf{Cont}(p, pred, r)$. If $r$hsamee, continuation empty-result inversion forces both p and *pred* to be empty. The uniqueness clause identifies *pred* with the displayed right-factor result e, and the empty-result iff for $\mathsf{PadicPrimeScale}(p, q, e)$ reads this back to the right exponent. The prime-base empty contradiction applied to p closes the case. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append unit left result not empty`

Lemma 100.26 (Prime scale append continuation result functional)**.** *Under the hypotheses of Definition 100.13, any other* PadicPrimeScale *result over the same appended exponent is history-same to the continuation result.*

Proof. The closure theorem constructs the prime-scale witness for the continuation result. Its multiplication field and the multiplication field of the other scale witness have the same prime base and appended exponent, so NatMul functionality identifies the two results. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append cont result functional`

Theorem 100.27 (Prime scale two unit exponents give prime square)**.** *If* $\mathsf{PadicPrimeScale}(p, \mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e})), r$ *holds, then the result is history-same to the square append of the prime base:*

$$result\mathsf{hsameappend}(p, p).$$

Proof. The unit-exponent scale theorem constructs $\mathsf{PadicPrimeScale}(p, \mathsf{E1}(\mathsf{e}), p)$ for each of the two exponent factors. The concrete continuation $\mathsf{Cont}(p, p, \mathsf{append}(p, p))$ closes these two scales under append continuation. The resulting scale witness has the same prime base and appended exponent as the given witness, so NatMul functionality identifies the displayed results. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append unit exponents result square hsame`

Theorem 100.28 (Prime scale two unit exponents have nonempty result)**.** *If* $\mathsf{PadicPrimeScale}(p, \mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e}$ *holds, then* $result\mathsf{hsamee}$ *is impossible.*

Proof. The square readback identifies $result$ with $\mathsf{append}(p, p)$. If $result\mathsf{hsamee}$, append empty inversion forces $p\mathsf{hsamee}$. But the prime witness contains a strict unary prefix from $\mathsf{E1}(\mathsf{e})$ to p; transporting the final continuation to the empty endpoint forces its nonempty tail to be empty, a contradiction. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append unit exponents result not empty`

Theorem 100.29 (Prime scale append factor results unique)**.** *Let* $\mathsf{PadicPrimeScale}(p, w, n)$ *and* $\mathsf{PadicPrimeScale}(p, q, e)$ *be linked by* $\mathsf{Cont}(n, e, r)$*. If* $\mathsf{PadicPrimeScale}(p, w, n_2)$ *and* $\mathsf{PadicPrimeScale}(p, q, e_2)$ *are linked by* $\mathsf{Cont}(n_2, e_2, r_2)$*, then the factor results and continuation results are history-same:*

$$n\mathsf{hsame}n_2 \wedge e\mathsf{hsame}e_2 \wedge r\mathsf{hsame}r_2.$$

Proof. Functionality of NatMul identifies the two results over the left factor exponent w and separately identifies the two results over the right factor exponent q. Continuation respect for hsame transports those two factor identifications across the displayed continuations and identifies the two composite results. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append factor results unique`

Theorem 100.30 (Prime scale append factor results commute)**.** *Let* $\mathsf{PadicPrimeScale}(p, w, n)$ *and* $\mathsf{PadicPrimeScale}(p, q, e)$ *hold. If the two factor results are linked by both continuation orders* $\mathsf{Cont}(n, e, r)$ *and* $\mathsf{Cont}(e, n, s)$*, then the continuation results satisfy* $r\mathsf{hsame}s$*.*

Proof. The scale witnesses expose unary carriers for the two factor results n and e. Unary append commutativity identifies $\mathsf{append}(n, e)$ with $\mathsf{append}(e, n)$, and the two displayed continuation ledgers identify r and s with those append histories. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append factor results comm hsame`

Theorem 100.31 (Prime scale append totality)**.** *If* p *is a* $\mathsf{Prime}^{\uparrow}$*-prime and* w, q *are unary histories, then there is a history* r *such that* $\mathsf{PadicPrimeScale}(p, \mathsf{append}(w, q), r)$*. Moreover* r *is obtained from scale witnesses for* w *and* q *by a continuation witness.*

Proof. Totality for NatMul supplies histories n and e with $\mathsf{PadicPrimeScale}(p, w, n)$ and $\mathsf{PadicPrimeScale}(p, q, e)$, using the unary field of the prime witness for p. The concrete continuation $\mathsf{Cont}(n, e, \mathsf{append}(n, e))$ then feeds Definition 100.13, producing the scale witness for $\mathsf{append}(w, q)$ together with the displayed factor witnesses. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append total`

Theorem 100.32 (Prime scale appended empty result split)**.** *Under the hypotheses of Definition 100.13, the result history satisfies* $r\mathsf{hsamee}$ *exactly when both exponent factors satisfy* $w\mathsf{hsamee}$ *and* $q\mathsf{hsamee}$*.*

Proof. The closure theorem first supplies a prime-scale witness for $\mathsf{append}(w, q)$ with result r. Empty-result exactness for prime scales reduces $r\mathsf{hsamee}$ to $\mathsf{append}(w, q)\mathsf{hsamee}$, and append empty-result exactness splits that condition into the two factor witnesses. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append empty result empty factors iff`

Theorem 100.33 (Prime scale append factor empty alignment)**.** *Under the hypotheses of Definition 100.13, the two factor results and the composite continuation result are all empty exactly when the two exponent factors are empty:*

$$n\mathsf{hsamee} \wedge e\mathsf{hsamee} \wedge r\mathsf{hsamee} \iff w\mathsf{hsamee} \wedge q\mathsf{hsamee}.$$

Proof. Prime-scale empty-result exactness identifies $n\mathsf{hsamee}$ with $w\mathsf{hsamee}$ and $e\mathsf{hsamee}$ with $q\mathsf{hsamee}$. The appended empty-result split identifies $r\mathsf{hsamee}$ with the same two exponent factor conditions, so the three result-side empty witnesses align exactly with the two empty exponent factors. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append factor empty alignment iff`

Theorem 100.34 (Prime scale appended empty factor result readback)**.** *Under the hypotheses of Definition 100.13, an empty left exponent factor identifies the continuation result with the right factor result, and an empty right exponent factor identifies the continuation result with the left factor result.*

Proof. Prime-scale empty-result exactness turns the empty exponent factor into an empty factor result. The continuation ledger is then compared with the corresponding left-unit or right-unit continuation by Cont stability under hsame. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append empty factor result hsame`

Theorem 100.35 (Prime scale visible exponent nonempty result)**.** *Under the hypotheses of Definition 100.32, if the left exponent factor is* $e0(tail)$ *or* $e1(tail)$*, then the continuation result cannot satisfy* $r\mathsf{hsamee}$*.*

Proof. Assume $r\mathsf{hsamee}$. The appended empty-result split forces the left exponent factor to satisfy empty sameness. This contradicts the no-confusion theorem for $e0(tail)$ in the first case and for $e1(tail)$ in the second case. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append visible exponent result nonempty`

Theorem 100.36 (Prime scale visible right exponent nonempty result)**.** *Under the hypotheses of Definition 100.32, if the right exponent factor is* $e0(tail)$ *or* $e1(tail)$*, then the continuation result cannot satisfy* $r\mathsf{hsamee}$*.*

Proof. Assume $r\mathsf{hsamee}$. The appended empty-result split forces the right exponent factor to satisfy empty sameness. This contradicts the no-confusion theorem for $e0(tail)$ in the first case and for $e1(tail)$ in the second case. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale append visible right exponent result nonempty`

Theorem 100.37 (Prime scale visible exponent result nonempty)**.** *For histories* $p, result, tail$: BHist*, if* $\mathsf{PadicPrimeScale}(p, e0(tail), result)$ *or* $\mathsf{PadicPrimeScale}(p, e1(tail), result)$ *holds, then* $result\mathsf{hsamee}$ *is impossible.*

Proof. Empty-result exactness for prime scales transports $result\mathsf{hsamee}$ back to the visible exponent. The two cases contradict no-confusion for $e0(tail)$ and for $e1(tail)$ against e. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale visible exponent result nonempty`

Theorem 100.38 (Prime scale empty exponent result)**.** *If* $\mathsf{NatPrime}(p)$ *and* $e\mathsf{hsamee}$*, then* $\mathsf{PadicPrimeScale}(p, e, \mathsf{e})$*.*

Proof. Transport the exponent along $e\mathsf{hsamee}$. The zero constructor of NatMul multiplies the prime base by the empty exponent and returns e, while the same prime witness supplies the prime-scale carrier field. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale empty exponent result empty`

Theorem 100.39 (First prime scale at unit exponent)**.** *The first prime, the unit exponent, and the first-prime result form a concrete* $\mathsf{Padic}^{\uparrow}$ *prime scale:*

$$\mathsf{PadicPrimeScale}(\mathsf{E1}(\mathsf{E1}(\mathsf{e})), \mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{E1}(\mathsf{e}))).$$

Proof. Pair the first-prime field from Definition 64.103 with the concrete unit-exponent multiplication witness from Definition 64.104. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale first prime unit exponent result`

100.2 The certificate

Theorem 100.40 (Padic prime-scale result semantic name certificate)**.** *If* p *is a* $\mathsf{Prime}^{\uparrow}$ *prime and* e *is a unary exponent, then the result carrier* $r \mapsto \mathsf{PadicPrimeScale}(p, e, r)$ *forms a semantic naming certificate with* hsame *as classifier.*

Proof. Prime-scale totality supplies an inhabited result carrier. Reflexivity, symmetry, and transitivity of the classifier are exactly the corresponding BEDC hsame laws on result histories. Carrier transport along hsame is obtained by identifying the two result histories and reusing the concrete prime-scale witness. The source, pattern, and ledger predicates are the same result carrier. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale result semanticNameCert`

Theorem 100.41 (Prime scale at unit exponent reads back the prime)**.** *For every history* p*, if* $\mathsf{NatPrime}(p)$*, then* $\mathsf{PadicPrimeScale}(p, \mathsf{E1}(\mathsf{e}), p)$*.*

Proof. The prime witness supplies the unary carrier field for p required by Definition 64.1. The zero multiplication constructor gives $\mathsf{NatMul}(p, \mathsf{e}, \mathsf{e})$. The left-unit part of Definition 21.12 supplies the continuation $\mathsf{Cont}(\mathsf{e}, p, p)$. Applying the successor constructor of Definition 64.1 therefore yields $\mathsf{NatMul}(p, \mathsf{E1}(\mathsf{e}), p)$. Pairing this multiplication witness with the given prime witness is exactly $\mathsf{PadicPrimeScale}(p, \mathsf{E1}(\mathsf{e}), p)$ by Definition 100.1. □

Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale unit exponent prime`
Lean4 ✓ `BEDC.Derived.PadicUp.PadicPrimeScale unit exponent result prime`

Table 100.1: Constructive-boundary decomposition of the p-adic external scope.

Scope item	Status	Evidence or footprint
$\mathbb{Z}_p$ ring and completeness	BEDC reconstructed constructive kernel	The ring surface is carried by `BEDC.Derived.PadicUp.ZpInt_comm_ring_laws`; completeness is carried by `BEDC.Derived.PadicUp.ZpInt_complete`.
$\mathbb{Q}_p$ valued field: field, valuation, norm, ultrametric comparison	BEDC reconstructed constructive kernel	The field/valuation/completeness summary is `BEDC.Derived.PadicUp.QpInt_valued_field`; its valuation, norm, multiplicative valuation, lower-bound additivity, and strong unequal-valuation addition rows are exposed through `BEDC.Derived.PadicUp.QpValuationCore`.
Hensel existence and uniqueness	BEDC reconstructed constructive kernel	Existence, lift, and uniqueness are carried by `BEDC.Derived.PadicUp.henselRoot_is_root`, `BEDC.Derived.PadicUp.henselRoot_lifts`, `BEDC.Derived.PadicUp.henselRoot_unique`, and `BEDC.Derived.PadicUp.henselRoot_unique_of_data`.
FTA: fundamental theorem of arithmetic / unique factorisation used by p-adic valuations	BEDC reconstructed constructive kernel	The arithmetic extraction and uniqueness surface is carried by `BEDC.Derived.PrimeUp.factorize`, `BEDC.Derived.PrimeUp.factorization_unique_perm`, and `BEDC.Derived.PrimeUp.IntegerPrimeFactorization`.
mathlib `PadicInt`/`Padic` quotient-completion objects and standard Real-valued norm interpretation	measured/refused classical boundary	This row is outside the BEDC kernel because the reference corpus uses quotient and classical comparison infrastructure. Footprint: `PadicInt`, `Padic`, `Real`; measured/refused dependencies `Classical.choice`, `Quot.sound`, and `propext`.
Global product formula and classical absolute-value package	measured/refused classical boundary	This row is outside the local $\mathsf{Padic}^{\uparrow}$ constructive kernel because it requires the archimedean `Real` side plus global product quantification over places. Footprint: `Real`, absolute values, place product; measured/refused dependencies `Classical.choice`, `Quot.sound`, and `propext`.

Theorem 100.42 (Padic external-scope constructive-boundary exhaustion)**.** *For the declared mathlib p-adic scope consisting of $\mathbb{Z}_p$ ring and completeness, $\mathbb{Q}_p$ valued-field structure with val-*

uation, norm, and ultrametric comparison, Hensel existence and uniqueness, FTA as unique-factorisation arithmetic used by p-adic valuations, mathlib `PadicInt/Padic` *quotient-completion objects with their standard Real-valued norm reading, and the global product-formula package, Table 100.1 exhausts the scope as*

$$S_{\text{padic}} = S_{\text{BEDC kernel}} \sqcup S_{\text{measured/refused classical boundary}}.$$

There is no hidden third region in this declared scope.

Proof. The first four rows of Table 100.1 name the BEDC constructive kernel: the $\mathbb{Z}_p$ ring and completeness rows, the $\mathbb{Q}_p$ field/valuation/norm/completeness summary, the Hensel existence-and-uniqueness rows, and the FTA / unique-factorisation arithmetic used by valuation reads. The last two rows name the refused classical boundary: the quotient-completion `PadicInt/Padic` objects with their Real-valued norm reading, and the global product-formula package with its archimedean and all-places footprint. These rows are pairwise classified by their status column, and the scope sentence lists exactly these six items. □

Closure status for $\mathsf{NameCert}_{\mathsf{Padic}^\uparrow}$.

Constructive story: The p-adic surface closed here is the prime-scale result row: choose a displayed $\mathsf{Prime}^\uparrow$ history p, choose a unary exponent e, and admit exactly those result histories r that the unary multiplication witness displays as p multiplied by e. The classifier on accepted results is hsame of the result history, so two scale computations name the same result only when multiplication determinacy identifies their displayed endpoints, while non-prime bases, non-unary exponents, and histories not produced by the scale predicate are excluded. The source, pattern, and ledger are all read from the same prime-scale package: the source fixes the prime and exponent, the pattern records unary components, totality, unique result, successor and append inversion, unit-exponent readback, and factorization rows, and the ledger keeps the underlying NatPrime, NatMul, UnaryHistory, Cont, append, and hsame witnesses visible. Prime-scale totality supplies a carried result, the hsame laws give reflexivity, symmetry, and transitivity, and transport along hsame repacks the same concrete multiplication witness, so the five name-certificate obligations close without a valuation field. A history h lies in the signature gap of a $\mathsf{Padic}^\uparrow$ token p_0 when the source-domain accepts the selected prime and exponent, the signature relation pairs a scale result with an answer history and evidence ledger, and the token-introduction relation names that answer as p_0; unfolded, h is the unique unary product of the prime base by the exponent encoded in the token. The chapter registers this prime-scale result certificate under the name $\mathsf{Padic}^\uparrow$; it does not introduce p-adic Cauchy completion, valuation algebra, field laws, or a standard bridge.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Padic}^\uparrow}$, maturePackageClosed)

Scope closed: The mature surface binds the prime-scale carrier, totality, uniqueness, successor and append inversion, unit-exponent readback, append factorization, hsame transport, semantic certificate, and downstream number-theory consumer examples to the BHist, NatPrime, NatMul, UnaryHistory, Cont, append, and hsame primitives cited in the chapter proofs.

External correspondence: ExternalCorrespondenceStatus($\mathsf{NameCert}_{\mathsf{Padic}^\uparrow}$, calibratedReconstruction)

External reference: mathlib v4.x p-adic corpus, commit `PIN-MATHLIB-COMMIT`.

Reconstruction scope: $\mathbb{Z}_p$ ring and completeness; $\mathbb{Q}_p$ valued field with field, valuation, norm, and ultrametric comparison; Hensel existence and uniqueness; FTA as unique-factorisation arithmetic used by p-adic valuations; mathlib `PadicInt/Padic` quotient-completion objects and standard Real-valued norm reading; global product formula.

Boundary exhaustion: Table 100.1

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Padic}^\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.PadicUp.PadicPrimeScale\_result\_semanticNameCert`

Bridge status: none

Not claimed: This does not close p-adic Cauchy completion, valuation algebra, field laws, the standard bridge, or RealUp-like completeness.

Upgrade path: No further theory-axis upgrade remains; bridge verification is recorded separately when the standard bridge target is present.

Chapter 101

A Concrete Naming Certificate for $\mathsf{Adele}^{\uparrow}$

The adele interface $\mathsf{Adele}^{\uparrow}$ packages the restricted product of $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ and $\mathsf{NameCert}_{\mathsf{Padic}^{\uparrow}}$ over all primes p. It depends on $\mathsf{NameCert}_{\mathsf{Padic}^{\uparrow}}$ (chapter 100) and supplies the global object on which automorphic and L-function certificates are built.

101.1 Carrier definition

Definition 101.1 (Adele history carrier)**.** *For a history h, the predicate* $\mathsf{AdeleHistoryCarrier}(h)$ *holds when there are histories r, p, e, s such that r is a constant real history,* $\mathsf{PadicPrimeScale}(p, e, s)$ *holds, and*

$$\mathsf{hsame}(h, \mathsf{append}(r, s)).$$

Lean4 (definition) `BEDC.Derived.AdeleUp.AdeleHistoryCarrier`

Theorem 101.2 (Adele history carrier nonempty)**.** *If* $\mathsf{AdeleHistoryCarrier}(h)$ *holds, then h is not internally the same as* e.

Proof. Unpack the carrier into its constant real endpoint, p-adic scale endpoint, and append witness. If $h\mathsf{hsamee}$, the append witness identifies the appended real and scale endpoints with e, so append-empty exactness makes the real endpoint empty. The constant real endpoint is one-sealed, and empty cannot be internally the same as a one-sealed history. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier not empty`

Theorem 101.3 (Adele carrier continuation result nonempty)**.** *If* $\mathsf{AdeleHistoryCarrier}(h)$ *holds,* $\mathsf{Cont}(h, k, r)$ *holds, and* $r\mathsf{hsamee}$*, then contradiction follows.*

Proof. Transport the continuation result along $r\mathsf{hsamee}$ to a continuation with empty result. The empty-result inversion theorem for Cont forces the source endpoint h to be e. This contradicts the nonempty theorem for the adele history carrier. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier cont result nonempty`

Theorem 101.4 (Adele right carrier continuation result nonempty)**.** *If* $\mathsf{AdeleHistoryCarrier}(k)$ *holds,* $\mathsf{Cont}(h, k, r)$ *holds, and* $r\mathsf{hsamee}$*, then contradiction follows.*

Proof. Transport the continuation result along $r\mathsf{hsamee}$ to a continuation with empty result. The empty-result inversion theorem for Cont forces the right endpoint k to be e, contradicting the nonempty theorem for the adele history carrier. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier cont right result nonempty`

Theorem 101.5 (Adele appended right carrier continuation result nonempty)**.** *If* $\mathsf{AdeleHistoryCarrier}(k)$ *holds,* $\mathsf{Cont}(h, \mathsf{append}(p, k), r)$ *holds, and* $r\mathsf{hsamee}$*, then contradiction follows.*

Proof. Transport the continuation result along $r\mathsf{hsamee}$ to a continuation with empty result. The empty-result inversion theorem for Cont forces $\mathsf{append}(p, k)\mathsf{hsamee}$. Empty append inversion recovers $k\mathsf{hsamee}$, contradicting the nonempty theorem for the adele history carrier. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier cont append right result nonempty`

Theorem 101.6 (Adele real-padic e1 real nonempty scale result package)**.** *For histories* r, p, e, s : BHist*, if* r *is a rational-history carrier and* $\mathsf{PadicPrimeScale}(p, \mathsf{e1}(e), s)$ *holds, then the real component* $\mathsf{e1}(r)$ *is a real constant-history carrier and the padic scale result is not history-same as* e*:*

$$\mathsf{RatHistoryCarrier}(r) \wedge \mathsf{PadicPrimeScale}(p, \mathsf{e1}(e), s) \Longrightarrow \mathsf{RealConstantHistoryCarrier}(\mathsf{e1}(r)) \wedge (\mathsf{hsame}(s, \mathsf{e}) \to \bot).$$

The real component is certified by the $\mathsf{Real}^{\uparrow}$ $e1$ *readback theorem from the rational carrier. The padic component uses the empty-result iff for* $\mathsf{Padic}^{\uparrow}$ *scale: an empty result would force* $\mathsf{hsame}(\mathsf{e1}(e), \mathsf{e})$*, which is excluded by the BEDC history constructor separation.*

Proof. Apply the real constant-history $e1$ iff to the rational carrier witness for r. For the padic result, assume $\mathsf{hsame}(s, \mathsf{e})$. The padic empty-result iff turns this into $\mathsf{hsame}(\mathsf{e1}(e), \mathsf{e})$, contradicting the BEDC $e1$-versus-empty separation theorem. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleRealPadic e1 real nonempty scale result package`

Theorem 101.7 (Adele carrier from the first-prime unit scale)**.** *For any rational-history carrier tail* r*, the history formed by appending the one-sealed real component to the concrete first-prime unit scale result is an adele-history carrier:*

$$\mathsf{RatHistoryCarrier}(r) \Longrightarrow \mathsf{AdeleHistoryCarrier}(\mathsf{append}(\mathsf{E1}(r), \mathsf{E1}(\mathsf{E1}(\mathsf{e})))).$$

Proof. The real component is a constant real history by the $e1$ readback theorem for rational carriers. The padic component is the concrete first-prime unit scale from Definition 100.39. The final carrier equality is reflexive history sameness for the displayed append history. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier first prime unit scale`

Theorem 101.8 (Adele visible scale result carrier and nonempty result)**.** *For histories* r, p, e, s : BHist*, if* $\mathsf{RealConstantHistoryCarrier}(r)$ *and* $\mathsf{PadicPrimeScale}(p, \mathsf{e1}(e), s)$ *hold, then the appended history* $\mathsf{append}(r, s)$ *is an adele-history carrier and the visible scale result is not history-same as* e*:*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(r, s)) \wedge (\mathsf{hsame}(s, \mathsf{e}) \to \bot).$$

Proof. Use $r, p, \mathsf{e1}(e), s$ as the four carrier witnesses for the appended adele history. The append witness is reflexive history sameness. If $s\mathsf{hsamee}$, the p-adic empty-result iff forces $\mathsf{hsame}(\mathsf{e1}(e), \mathsf{e})$, contradicting the BEDC separation of one-sealed histories from e. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier visible scale result nonempty`

Theorem 101.9 (Adele visible zero-scale result carrier and nonempty result)**.** *For histories* r, p, e, s : BHist*, if* RealConstantHistoryCarrier(r) *and* PadicPrimeScale$(p, \mathsf{E0}(e), s)$ *hold, then the appended history* append(r, s) *is an adele-history carrier and the visible zero-scale result is not history-same as* e*:*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(r, s)) \wedge (\mathsf{hsame}(s, \mathsf{e}) \to \bot).$$

Proof. Use $r, p, \mathsf{E0}(e), s$ as the four carrier witnesses for the appended adele history. The append witness is reflexive history sameness. If $s$hsamee, the p-adic empty-result iff forces hsame$(\mathsf{E0}(e), \mathsf{e})$, contradicting the BEDC separation of zero-headed histories from e. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier visible zero scale result nonempty`

Theorem 101.10 (Adele prime-swap scale readback)**.** *Let* $real, p, q, r, s$: BHist*. If* $real$ *is a constant real-history carrier and the two swapped prime scales* PadicPrimeScale(p, q, r) *and* PadicPrimeScale(q, p, s) *hold, then both appended real-padic histories are adele-history carriers and they are history-same:*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(real, r)) \wedge \mathsf{AdeleHistoryCarrier}(\mathsf{append}(real, s)) \wedge \mathsf{hsame}(\mathsf{append}(real, r), \mathsf{append}(real, s)).$$

Proof. Use the displayed real component and the two displayed prime-scale witnesses as the adele carrier payloads. The p-adic scale results are identified by prime-exponent commutativity for PadicPrimeScale, and applying the fixed real append context to that hsame identifies the two adele histories. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier prime swap scale readback`

Theorem 101.11 (Adele visible scale continuation nonempty package)**.** *For histories* r, p, e, s, k, out : BHist*, if* RealConstantHistoryCarrier(r)*,* PadicPrimeScale$(p, \mathsf{e1}(e), s)$*, and* Cont$(\mathsf{append}(r, s), k, out)$ *hold, then*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(r, s)) \wedge (\mathsf{hsame}(s, \mathsf{e}) \to \bot) \wedge (\mathsf{hsame}(out, \mathsf{e}) \to \bot).$$

Proof. The visible scale theorem supplies both the adele-history carrier for append(r, s) and the nonempty scale endpoint s. Feeding that carrier and the displayed continuation into the adele continuation-result theorem gives the nonempty output endpoint. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier visible scale cont nonempty package`

Theorem 101.12 (Adele visible zero-scale continuation nonempty package)**.** *For histories* r, p, e, s, k, out : BHist*, if* RealConstantHistoryCarrier(r)*,* PadicPrimeScale$(p, \mathsf{e0}(e), s)$*, and* Cont$(\mathsf{append}(r, s), k, out)$ *hold, then*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(r, s)) \wedge (\mathsf{hsame}(s, \mathsf{e}) \to \bot) \wedge (\mathsf{hsame}(out, \mathsf{e}) \to \bot).$$

Proof. The visible zero-scale theorem supplies both the adele-history carrier for append(r, s) and the nonempty scale endpoint s. Feeding that carrier and the displayed continuation into the adele continuation-result theorem gives the nonempty output endpoint. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier visible zero scale cont nonempty package`

Theorem 101.13 (Adele e1 real append carrier is nonempty)**.** *For histories* $realTail, p, exponent, result$: BHist*, if* RealConstantHistoryCarrier(e1($realTail$)) *and* PadicPrimeScale($p, exponent, result$) *hold, then the appended real-padic history is an adele-history carrier and cannot be history-same as* e*:*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(\mathsf{e1}(realTail), result)) \wedge (\mathsf{hsame}(\mathsf{append}(\mathsf{e1}(realTail), result), \mathsf{e}) \to \bot).$$

Proof. Use the displayed one-sealed real component, p, *exponent*, and *result* as the four witnesses for the adele carrier. If the append were empty, append-empty exactness would force $\mathsf{e1}(realTail)\mathsf{hsamee}$, contradicting BEDC constructor separation. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier e1 real append nonempty`

Theorem 101.14 (Adele visible scale append is not empty)**.** *For histories* r, p, e, s : BHist*, if* RealConstantHistoryCarrier(r) *and* PadicPrimeScale($p, \mathsf{e1}(e), s$) *hold, then the appended visible scale history is not history-same as* e*:*

$$\mathsf{hsame}(\mathsf{append}(r, s), \mathsf{e}) \to \bot.$$

Proof. Assume the appended history is empty. Append-empty exactness makes the scale result s empty. The p-adic empty-result iff then forces $\mathsf{hsame}(\mathsf{e1}(e), \mathsf{e})$, contradicting the BEDC separation of one-sealed histories from e. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier visible scale append not empty`

Theorem 101.15 (Adele empty scale real readback)**.** *Let* $real, p, result$: BHist*. If real is a constant real-history carrier and* PadicPrimeScale($p, \mathsf{e}, result$) *holds, then* append($real, result$) *is an adele-history carrier and*

$$\mathsf{append}(real, result)\mathsf{hsame}real.$$

Proof. The padic empty-result iff identifies *result* with e because the exponent is e. The adele carrier uses the displayed real component, prime, empty exponent, scale result, and reflexive append witness. The readback to *real* follows from the identified empty scale result and append-right unit. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier empty scale real readback`

Theorem 101.16 (Adele unit scale real-prime readback)**.** *Let* $real, p, result$: BHist*. If real is a constant real-history carrier and* PadicPrimeScale($p, \mathsf{E1}(\mathsf{e}), result$) *holds, then* append($real, result$) *is an adele-history carrier and*

$$\mathsf{append}(real, result)\mathsf{hsameappend}(real, p).$$

Proof. Use the displayed real component, prime base, unit exponent, and scale result as the four witnesses for the adele carrier. The prime-scale unit-exponent readback identifies *result* with p; applying append congruence under the fixed real component gives the displayed real-prime readback. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier unit scale real prime readback`

Theorem 101.17 (Adele unit-left scale continuation readback)**.** *Let* $real, p, q, result$: BHist*. If real is a constant real-history carrier, q is unary, and* PadicPrimeScale(p, append($\mathsf{E1}(\mathsf{e}), q$), $result$) *holds, then* append($real, result$) *is an adele-history carrier and*

$$\exists e.\, \mathsf{PadicPrimeScale}(p, q, e) \wedge \mathsf{Cont}(p, e, result).$$

Proof. The adele carrier uses the displayed real component, prime base, appended unit-left exponent, and scale result. The continuation readback is exactly the unit-left prime-scale append factorization applied to the unary right exponent. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier unit left scale cont readback`

Theorem 101.18 (Adele unit-left scale append readback)**.** *Let* $real, p, q, result : \mathsf{BHist}$*. If* $real$ *is a constant real-history carrier,* q *is unary, and* $\mathsf{PadicPrimeScale}(p, \mathsf{append}(\mathsf{E1}(\mathsf{e}), q), result)$ *holds, then* $\mathsf{append}(real, result)$ *is an adele-history carrier and*

$$\exists e.\, \mathsf{PadicPrimeScale}(p, q, e) \wedge \mathsf{append}(real, result)\mathsf{hsameappend}(real, \mathsf{append}(p, e)).$$

Proof. The adele carrier uses the displayed real component, prime base, appended unit-left exponent, and scale result. The unit-left prime-scale factorization extracts a right-factor result e with $\mathsf{Cont}(p, e, result)$; reading that continuation as the append endpoint and applying the fixed real append context gives the displayed real-padic readback. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier unit left scale append readback`

Theorem 101.19 (Adele unit-right scale continuation readback)**.** *Let* $real, p, w, result : \mathsf{BHist}$*. If* $real$ *is a constant real-history carrier,* w *is unary, and* $\mathsf{PadicPrimeScale}(p, \mathsf{append}(w, \mathsf{E1}(\mathsf{e})), result)$ *holds, then* $\mathsf{append}(real, result)$ *is an adele-history carrier and*

$$\exists n.\, \mathsf{PadicPrimeScale}(p, w, n) \wedge \mathsf{Cont}(n, p, result).$$

Proof. The adele carrier uses the displayed real component, prime base, appended unit-right exponent, and scale result. The continuation readback is exactly the unit-right prime-scale append factorization applied to the unary left exponent. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier unit right scale cont readback`

Theorem 101.20 (Adele unit-right scale append readback)**.** *Let* $real, p, w, result : \mathsf{BHist}$*. If* $real$ *is a constant real-history carrier,* w *is unary, and* $\mathsf{PadicPrimeScale}(p, \mathsf{append}(w, \mathsf{E1}(\mathsf{e})), result)$ *holds, then* $\mathsf{append}(real, result)$ *is an adele-history carrier and*

$$\exists n.\, \mathsf{PadicPrimeScale}(p, w, n) \wedge \mathsf{append}(real, result)\mathsf{hsameappend}(real, \mathsf{append}(n, p)).$$

Proof. The adele carrier uses the displayed real component, prime base, appended unit-right exponent, and scale result. The unit-right prime-scale factorization extracts a left-factor result n with $\mathsf{Cont}(n, p, result)$; reading that continuation as the append endpoint and applying the fixed real append context gives the displayed real-padic readback. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier unit right scale append readback`

Theorem 101.21 (Adele real-stream prefix visible scale carrier)**.** *Let* $x, y : \mathbb{N} \to \mathsf{BHist}$ *be real stream representatives whose visible left stream is unary at every index. If* $\mathsf{RealStreamPrefixClassifier}(x, y, m+n)$ *holds,* $x(n)\mathsf{hsameE1}(\mathsf{E1}(d))$*,* $y(n)\mathsf{hsameE1}(i)$*, and the concrete first-prime* p*-adic scale* $\mathsf{PadicPrimeScale}(\mathsf{E1}(\mathsf{E1}(\mathsf{e}))$ *holds, then* $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ *holds and*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(\mathsf{E1}(\mathsf{E1}(d)), r)).$$

Proof. The add-left prefix projection recovers the classifier at index n. The visible real-pair readback at that prefix identifies the displayed $\mathsf{E1}(\mathsf{E1}(d))$ endpoint as a rational denominator carrier, hence as a constant real-history carrier. Combining that real component with the stored first-prime p-adic scale and reflexive history sameness of the displayed append endpoint gives the adele carrier. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleRealStreamPrefix visible scale carrier`

Theorem 101.22 (Adele long-prefix visible scale carrier)**.** *Let $x, y : \mathbb{N} \to \mathsf{BHist}$ be real stream representatives. If $\mathsf{RealStreamPrefixClassifier}(x, y, m+n)$ holds, $x(n)\mathsf{hsameE1}(\mathsf{E1}(d))$, $y(n)\mathsf{hsameE1}(i)$, and the concrete first-prime p-adic scale $\mathsf{PadicPrimeScale}(\mathsf{E1}(\mathsf{E1}(\mathsf{e})), e, r)$ holds, then $\mathsf{RealStreamPrefixClassifier}(x, y,$ holds and*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(\mathsf{E1}(\mathsf{E1}(d)), r)).$$

Proof. Induct on m through the recursive finite-prefix classifier to descend from $m+n$ to n. At the selected index, the displayed one-extension endpoints read back through the rational stream-prefix classifier: the left displayed tail is unary, hence $\mathsf{E1}(d)$ is a rational-history carrier and $\mathsf{E1}(\mathsf{E1}(d))$ is a constant real-history carrier. Combining this real component with the stored first-prime p-adic scale and reflexive sameness of the appended endpoint gives the adele-history carrier. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleRealStreamPrefix long prefix visible scale carrier`

Theorem 101.23 (Adele long-prefix visible p-adic scale carrier)**.** *Let $x, y : \mathbb{N} \to \mathsf{BHist}$ be real stream representatives. If $\mathsf{RealStreamPrefixClassifier}(x, y, m+n)$ holds, $x(n)\mathsf{hsameE1}(\mathsf{E1}(d))$, $y(n)\mathsf{hsameE1}(i)$, and $\mathsf{PadicPrimeScale}(p, e, r)$ holds, then $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ holds and*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(\mathsf{E1}(\mathsf{E1}(d)), r)).$$

Proof. Induct on m through the finite-prefix classifier to descend from $m+n$ to n. The visible one-extension pair at index n reads back a unary denominator tail, so $\mathsf{E1}(d)$ is a rational-history carrier and $\mathsf{E1}(\mathsf{E1}(d))$ is a constant real-history carrier. The arbitrary displayed p-adic scale supplies the non-real component of the adele carrier, and reflexive history sameness identifies the displayed append endpoint. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleRealStreamPrefix long prefix visible padic scale carrier`

Theorem 101.24 (Adele long-prefix visible unit-scale readback)**.** *Let $x, y : \mathbb{N} \to \mathsf{BHist}$ be real stream representatives. If $\mathsf{RealStreamPrefixClassifier}(x, y, m+n)$ holds, $x(n)\mathsf{hsameE1}(\mathsf{E1}(d))$, $y(n)\mathsf{hsameE1}(i)$, and the displayed p-adic unit scale $\mathsf{PadicPrimeScale}(p, \mathsf{E1}(\mathsf{e}), r)$ holds, then $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ holds,*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(\mathsf{E1}(\mathsf{E1}(d)), r)),$$

and the appended adele endpoint reads back to the displayed prime endpoint:

$$\mathsf{append}(\mathsf{E1}(\mathsf{E1}(d)), r)\mathsf{hsameappend}(\mathsf{E1}(\mathsf{E1}(d)), p).$$

Proof. Induct on m through the finite-prefix classifier to descend from $m + n$ to n. The visible endpoints at index n recover a unary denominator tail, hence $\mathsf{E1}(d)$ is a rational-history carrier and $\mathsf{E1}(\mathsf{E1}(d))$ is a constant real-history carrier. The unit-exponent prime-scale readback identifies r with p, and applying the fixed real append context gives the displayed adele endpoint readback. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleRealStreamPrefix long prefix visible unit scale readback`

Theorem 101.25 (Adele long-prefix visible scale result is not empty)**.** *Let* $x, y : \mathbb{N} \to \mathsf{BHist}$ *be real stream representatives. If* $\mathsf{RealStreamPrefixClassifier}(x, y, m + n)$ *holds,* $x(n)\mathsf{hsameE1}(\mathsf{E1}(d))$*,* $y(n)\mathsf{hsameE1}(i)$*, and the concrete first-prime* p*-adic visible scale* $\mathsf{PadicPrimeScale}(\mathsf{E1}(\mathsf{E1}(\mathsf{e})), \mathsf{E1}(e), r)$ *holds, then* $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ *holds,*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(\mathsf{E1}(\mathsf{E1}(d)), r)),$$

and the visible scale result is not history-same as e*:*

$$\mathsf{hsame}(r, \mathsf{e}) \to \bot.$$

Proof. Induct on m through the prefix classifier to descend from $m + n$ to n. The selected one-extension endpoints read back to a unary denominator tail, hence to a rational carrier and then to the constant real-history carrier $\mathsf{E1}(\mathsf{E1}(d))$. The visible p-adic scale theorem packages this real component with the displayed scale and separates the scale result from e. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleRealStreamPrefix long prefix visible scale result nonempty`

Theorem 101.26 (Adele long-prefix visible zero-scale result is not empty)**.** *Let* $x, y : \mathbb{N} \to \mathsf{BHist}$ *be real stream representatives. If* $\mathsf{RealStreamPrefixClassifier}(x, y, m+n)$ *holds,* $x(n)\mathsf{hsameE1}(\mathsf{E1}(d))$*,* $y(n)\mathsf{hsameE1}(i)$*, and the concrete first-prime* p*-adic visible zero scale* $\mathsf{PadicPrimeScale}(\mathsf{E1}(\mathsf{E1}(\mathsf{e})), \mathsf{E0}(e), r)$ *holds, then* $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ *holds,*

$$\mathsf{AdeleHistoryCarrier}(\mathsf{append}(\mathsf{E1}(\mathsf{E1}(d)), r)),$$

and the visible zero-scale result is not history-same as e*:*

$$\mathsf{hsame}(r, \mathsf{e}) \to \bot.$$

Proof. Induct on m through the prefix classifier to descend from $m + n$ to n. The selected one-extension endpoints read back to a unary denominator tail, hence to a rational carrier and then to the constant real-history carrier $\mathsf{E1}(\mathsf{E1}(d))$. The visible zero-scale theorem packages this real component with the displayed p-adic scale and separates the scale result from e. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleRealStreamPrefix long prefix visible zero scale result nonempty`

Theorem 101.27 (Adele long-prefix visible scale continuation result is not empty)**.** *Let* $x, y : \mathbb{N} \to \mathsf{BHist}$ *be real stream representatives. If* $\mathsf{RealStreamPrefixClassifier}(x, y, m+n)$ *holds,* $x(n)\mathsf{hsameE1}(\mathsf{E1}(d))$*,* $y(n)\mathsf{hsameE1}(i)$*, and the concrete first-prime* p*-adic visible scale* $\mathsf{PadicPrimeScale}(\mathsf{E1}(\mathsf{E1}(\mathsf{e})), \mathsf{E1}(e), r)$ *holds, then every continuation out of the appended visible scale endpoint has a non-empty result:*

$$\mathsf{Cont}(\mathsf{append}(\mathsf{E1}(\mathsf{E1}(d)), r), k, out) \Longrightarrow \mathsf{hsame}(out, \mathsf{e}) \to \bot.$$

Proof. The long-prefix visible scale result theorem supplies an adele-history carrier for $\mathsf{append}(\mathsf{E1}(\mathsf{E1}(d)), r)$. Applying the adele carrier continuation-result nonemptiness theorem to the displayed continuation rules out $out\mathsf{hsame}\mathsf{e}$. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleRealStreamPrefix long prefix visible scale cont result nonempty`

Theorem 101.28 (Adele long-prefix visible scale append is not empty)**.** *Under the hypotheses of Definition 101.22, the appended visible scale endpoint is not history-same as* e*:*

$$\mathsf{hsame}(\mathsf{append}(\mathsf{E1}(\mathsf{E1}(d)), r), \mathsf{e}) \to \bot.$$

Proof. The long-prefix visible scale carrier theorem supplies the adele-history carrier for the displayed append endpoint. Adele-history carriers cannot be history-same as e, so the assumed empty append endpoint is impossible. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleRealStreamPrefix long prefix visible scale append not empty`

Theorem 101.29 (Real–padic empty-result split)**.** *Let the two real coordinates be displayed as endpoint histories* $\mathsf{E1}(d)$ *and* $\mathsf{E1}(e)$*, and let two p-adic prime-scale factors* $\mathsf{PadicPrimeScale}(p, w, n)$ *and* $\mathsf{PadicPrimeScale}(p, q, r)$ *be linked by* $\mathsf{Cont}(n, r, out)$*. Then out*hsame*e exactly when the real endpoint payloads are rational carriers and both p-adic exponent factors satisfy w*hsame *and q*hsame*.*

Proof. The endpoint theorem for $\mathsf{RealConstantHistoryCarrier}$ reads $\mathsf{E1}(d)$ and $\mathsf{E1}(e)$ back to rational-carrier payloads. The p-adic append empty-result theorem applies to the two prime-scale factors and the continuation witness, splitting *out*hsamee into the two empty exponent conditions. Combining these independent readbacks gives the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleRealPadic e1 append empty padic result iff`

Theorem 101.30 (Adele constant-slice carrier transport)**.** *Let* $\mathsf{AdeleConstantSliceCarrier}(h)$ *mean that histories* d, p, e, r *exist with*

$$\mathsf{hsame}(h, \mathsf{E1}(d)) \ \wedge \ \mathsf{RatHistoryCarrier}(d) \ \wedge \ \mathsf{PadicPrimeScale}(p, e, r).$$

If $h\mathsf{hsame}h'$ *and* $\mathsf{AdeleConstantSliceCarrier}(h)$*, then* $\mathsf{AdeleConstantSliceCarrier}(h')$*.*

Proof. Unpack the constant-slice witnesses d, p, e, r. The rational endpoint and the p-adic scale witnesses are unchanged. Symmetry and transitivity of hsame move the displayed $\mathsf{E1}(d)$ endpoint from h to h'. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleConstantSliceCarrier hsame transport`

101.2 The certificate

Theorem 101.31 (Adele history-carrier semantic name certificate)**.** *The adele history carrier forms a semantic naming certificate with* hsame *as classifier, using the same adele carrier as source, pattern, and ledger policy.*

Proof. A rational tail $\mathsf{E1}(\mathsf{e})$ supplies the constant-real side, and the first-prime unit scale supplies the p-adic side, so the adele carrier is inhabited by the displayed append endpoint from Definition 101.7. The classifier laws are the BEDC hsame equivalence laws. For carrier transport, unpack an adele witness into its real component, prime, exponent, result, and append comparison; composing that comparison with the symmetric endpoint hsame moves the same witnesses to the target history. Pattern and ledger soundness are identity maps on the carrier predicate. □

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier semanticNameCert`

Theorem 101.32 (Adele visible-scale append result hsame transport)**.** *For histories* a, a', s : BHist*, if a is an adele-history carrier, the append endpoint* $\mathsf{append}(a, s)$ *is not history-same as* e*, and a*hsame*a′, then the same visible scale s has a nonempty append endpoint over a′:*

$$\mathsf{AdeleHistoryCarrier}(a) \wedge (\mathsf{hsame}(\mathsf{append}(a, s), \mathsf{e}) \to \bot) \wedge a\mathsf{hsame}a' \Longrightarrow \mathsf{hsame}(\mathsf{append}(a', s), \mathsf{e}) \to \bot.$$

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleHistoryCarrier visible scale append result hsame transport`

Proof. The carrier premise fixes the source endpoint in the adele layer. Let H be the nonempty premise for $\mathsf{append}(a, s)$ and let $\alpha : a\mathsf{hsame}a'$. By the reverse direction of Definition 4.50, applied with the reflexive right-context comparison $s\mathsf{hsame}s$, the endpoint comparison α gives

$$\mathsf{hsame}(\mathsf{append}(a, s), \mathsf{append}(a', s)).$$

If $\mathsf{append}(a', s)\mathsf{hsame}e$, transitivity of hsame carries this empty comparison back to $\mathsf{append}(a, s)\mathsf{hsame}e$, contradicting H. □

Theorem 101.33 (Adele mature treatment)**.** *The displayed Adele carrier exports a mature BEDC treatment of the public* $\mathsf{Adele}^{\uparrow}$ *certificate surface. Its semantic* NameCert *is the certificate of Definition 101.31; its visible-scale and long-prefix readbacks are the* BHist *rows carried by the real constant-slice, p-adic scale, append nonempty-result, and prefix readback theorems above; and its ClassField and Automorphic consumers may cross the boundary only through* BHist*,* hsame*, and* Cont*. This treatment does not assert a standard-model bridge.*

Lean4 ✓ `BEDC.Derived.AdeleUp.AdeleUp StdBridge`

Proof. Start with the Adele carrier constructed from the real constant-slice row and the first-prime p-adic scale row. The nonempty append-result theorem gives the visible scale, while the long-prefix readback rows identify the finite history prefixes available to public consumers.

Next apply the semantic certificate of Definition 101.31. It binds the carrier, classifier, source, pattern, and ledger rows to BHist, hsame, and Cont without adding an ambient adele object.

Finally use the hsame transport theorem for visible-scale append results. Transport preserves the same carried rows across history-same endpoints, so a ClassField or Automorphic consumer receives only the displayed BEDC rows. Since no standard-model comparison is introduced in these steps, the mature treatment is paper-side only on the bridge axis. □

Closure status for $\mathsf{NameCert}_{\mathsf{Adele}^{\uparrow}}$**.**

Constructive story: An adele history is built by putting a constant real history beside a p-adic prime-scale result: the carrier accepts a history h when some real component r, prime row p, exponent row e, and scale result s exist with h history-equal to $\mathsf{append}(r, s)$. The real side is read from the $\mathsf{Real}^{\uparrow}$ constant-stream surface, the p-adic side from $\mathsf{Padic}^{\uparrow}$ prime scaling, and empty or malformed scale results are excluded by the same constructor-separation and non-emptiness rows used by the upstream certificates. Two adeles are classified by hsame on the appended history, while transport unpacks the real component, prime, exponent, scale result, and append comparison and moves that same witness package across the endpoint comparison. The source, pattern, and ledger are all the adele carrier predicate: the source accepts exactly these real-padic append packages, the pattern records non-emptiness, unit-scale, empty-scale, prime-swap, and continuation readback rows, and the ledger keeps the hidden real, prime, exponent, scale, and append witnesses aligned with the visible endpoint. Because a rational tail supplies a constant real component and the first-prime unit scale supplies the p-adic component, the carrier is inhabited; because hsame is reflexive, symmetric, and transitive and carrier transport repacks the same witnesses, the five name-certificate obligations follow. A history h lies in the signature gap of an $\mathsf{Adele}^{\uparrow}$ token p_0 when the source-domain accepts this appended real-padic row, the signature relation pairs it with an answer adele and evidence ledger, and token introduction names the answer as p_0; unfolded, its constant real part and prime-scale part are exactly the components encoded by p_0. The chapter registers this real-padic append construction under the name $\mathsf{Adele}^{\uparrow}$; it is a BEDC restricted-product surface with no product formula, automorphic theory, analytic continuation, or standard-model bridge introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Adele}^{\uparrow}}$, maturePackageClosed)
