Inspect the adjacency ledger O. Each accepted neighboring pair is recorded as zero-zero, zero-one, or one-zero; the carrier definition has no fourth row that could certify a one-one neighbor.

Apply the prefix closure of Definition 370.3. Any displayed prefix or fold readback only restricts W, Z, O, P, and L, so every retained neighboring-pair decision is inherited from the same local ledger.

The componentwise hsame, Cont, Pkg, and NameCert routes transport these visible rows without adding another acceptance source. Thus Fibonacci counts, entropy rows, inverse limits, and host symbolic-dynamics objects remain outside the classifier surface. □

Theorem 370.5 (GoldenMeanShift NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{GoldenMeanShift}^{\uparrow}}$ *obligation surface consists of five finite obligations:*

1. *carrier habitation: the all-zero window Z is accepted because every displayed adjacent pair is zero-zero;*
2. *classifier laws: reflexivity, symmetry, and transitivity are inherited componentwise from* hsame *on the visible bit rows;*
3. *carrier transport: Definition 370.2 transports accepted windows through displayed* hsame*,* Cont*,* Pkg*, and* NameCert *routes;*
4. *fold-prefix closure: Definition 370.3 keeps every recorded prefix and fold readback inside the same carrier;*
5. *ledger exactness: the* NameCert *ledger records exactly the accepted bit rows, their adjacency ledger, the prefix and fold provenance, and the componentwise classifier rows.*

These obligations define the seed certificate surface for finite no-adjacent-one BHist *windows.*

Lean4 ✓ `BEDC.Derived.GoldenMeanShiftUp.GoldenMeanShiftCarrier semantic name certificate`

Proof. For habitation, take the all-zero window with the displayed all-zero witness. Every neighboring pair is zero-zero, so the adjacency ledger is generated without any one-one row.

For the classifier laws, work componentwise over the visible bit rows. Reflexivity, symmetry, and transitivity are the corresponding hsame laws applied at each displayed position, and the carrier restriction prevents the classifier from ranging over any hidden non-binary row.

Carrier transport is exactly the stability statement of Definition 370.2. The transported adjacency ledger is the witness that the accepted no-adjacent-one condition remains local to the finite BHist packet.

Fold-prefix closure is exactly Definition 370.3. A prefix or fold readback can only delete visible rows and restrict ledgers, so it cannot create an adjacent one-one pair.

Finally, ledger exactness follows by unfolding the five carrier rows of Definition 370.1. The ledger contains the accepted bit rows, adjacency decisions, prefix and fold provenance, and componentwise hsame classifier rows, and it contains no Fibonacci counting, Zeckendorf arithmetic, entropy, inverse-limit, or host symbolic-dynamics datum. □

Theorem 370.6 (GoldenMeanShift scoped ledger binding)**.** *For an accepted* $\mathsf{GoldenMeanShift}^{\uparrow}$ *carrier*

$$G = (W, Z, O, P, L),$$

the scoped BEDC ledger is exactly the finite no-adjacent-one BHist *window rows W, the all-zero witness Z, the zero-zero/zero-one/one-zero adjacency ledger O, the displayed fold-prefix* Cont *and* Pkg *provenance P, and the local* NameCert *row L. Every accepted row in this scope is bound*

componentwise to the hsame *classifier, the local stability route, the fold-prefix closure route, and the adjacency ledger exhaustion row. No row outside W, Z, O, P, L can contribute acceptance evidence.*

Proof. Project the carrier of Definition 370.1. The finite bit window, all-zero witness, adjacency decisions, prefix and fold provenance, and local naming ledger are the only displayed coordinates.

Use Definition 370.2 for componentwise hsame transport. The transport route moves exactly the displayed bit rows, all-zero witness, adjacency ledger, provenance row, and local NameCert row.

Use Definition 370.3 for finite prefix readbacks. A prefix only restricts W, Z, O, P, L, so it remains inside the same scoped ledger.

Finally apply Definition 370.4. The accepted adjacency alternatives are exhausted by the zero-zero, zero-one, and one-zero rows in O, leaving no further acceptance coordinate. □

Theorem 370.7 (GoldenMeanShift prefix transport scope)**.** *Let $G = (W, Z, O, P, L)$ be an accepted* GoldenMeanShift$^{\uparrow}$ *carrier, and let $G_{\leq k}$ be any finite prefix or fold readback supplied by the displayed* Cont *route and* Pkg *provenance. If $G_{\leq k}$ is transported componentwise by the stored* hsame *rows and the transported adjacency ledger still lists only zero-zero, zero-one, and one-zero rows, then the transported prefix remains an accepted* GoldenMeanShift$^{\uparrow}$ *carrier over the restricted* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Conversely, every accepted transported prefix of G is obtained by restricting the same five rows W, Z, O, P, L and then applying those displayed transport routes.

Lean4 ✓ `BEDC.Derived.GoldenMeanShiftUp.GoldenMeanShiftCarrier prefix transport scope`

Proof. First form the prefix packet with Definition 370.3. The theorem restricts the visible bit rows, all-zero witness, adjacency ledger, provenance row, and local certificate row.

Next transport the restricted packet through Definition 370.2. The stability hypothesis is exactly the retained adjacency condition, so the transported prefix remains accepted.

For the converse direction, project an accepted transported prefix back through the carrier coordinates. The prefix has no coordinate other than the restricted W, Z, O, P, L rows, and Definition 370.4 identifies the retained adjacency decisions as restrictions of the original local ledger. □

Theorem 370.8 (GoldenMeanShift adjacency scope exactness)**.** *For every accepted* GoldenMeanShift$^{\uparrow}$ *carrier, the adjacency scope is exact: an adjacent visible bit-pair is accepted precisely when the carrier ledger records it as zero-zero, zero-one, or one-zero, and the associated* NameCert *row records the same decision through the componentwise* hsame*,* Cont*, and* Pkg *routes. The scoped ledger therefore exports finite no-adjacent-one acceptance over* BHist *only, and it exports no Fibonacci count, entropy invariant, inverse-limit object, or host shift-space equality.*

Proof. Project the adjacency row O from Definition 370.1. Its accepted constructors are the three displayed local alternatives.

Apply Definition 370.4. This identifies every accepted neighboring-pair decision with one of those alternatives and rules out a one-one acceptance route.

The fold-prefix case follows by Definition 370.3: restriction only deletes rows and never adds another decision source. The transport case follows by Definition 370.2: the NameCert row follows the same componentwise hsame, Cont, and Pkg routes as the displayed adjacency ledger. □

Theorem 370.9 (GoldenMeanShift carrier row scope)**.** *The carrier rows W, Z, O, P, L of Definition 370.1 are exactly the finite* BHist *bit-window rows, the all-zero witness row, the zero-zero/zero-one/one-zero adjacency ledger, the displayed* Cont *and* Pkg *provenance rows, and the local* NameCert *ledger. No entropy coordinate, inverse-limit coordinate, infinite shift space, or host symbolic-dynamics row belongs to the carrier.*

Proof. Project the five coordinates in Definition 370.1. The W coordinate is the finite visible bit-window row, Z is the all-zero witness for that window shape, and O is the finite adjacency ledger whose accepted neighboring rows are zero-zero, zero-one, or one-zero.

The remaining coordinates are provenance and naming data: P records the displayed prefix and fold readbacks through Cont and Pkg, while L records the local NameCert ledger for the componentwise classifier rows. Since the definition lists no further coordinate, entropy, inverse limits, infinite host shifts, and external symbolic-dynamics objects have no carrier row to project. □

Theorem 370.10 (GoldenMeanShift classifier row scope)**.** *The* GoldenMeanShift$^{\uparrow}$ *classifier is componentwise* hsame *on the visible bit rows of W. Its transport surface is precisely the local stability route of Definition 370.2: transported bit rows, all-zero witnesses, adjacency ledgers, provenance rows, and* NameCert *rows remain accepted exactly when the transported adjacency ledger still lists only zero-zero, zero-one, or one-zero rows.*

Proof. The classifier row named in Definition 370.1 and Definition 370.5 compares displayed bit rows componentwise by hsame. There is no hidden quotient or ambient shift coordinate on which another classifier could act.

Apply Definition 370.2. That theorem transports exactly the visible bit rows, the all-zero witness, the adjacency ledger, the Cont and Pkg provenance, and the local NameCert row. The transported packet is accepted precisely under the same local adjacency alternatives, so the classifier transport surface is the local stability row and nothing larger. □

Theorem 370.11 (GoldenMeanShift ledger row scope)**.** *The* GoldenMeanShift$^{\uparrow}$ *ledger exhausts adjacency decisions by the zero-zero, zero-one, and one-zero rows. Its finite prefix and fold restrictions are exactly the restrictions supplied by Definition 370.3 together with the local decision exhaustion of Definition 370.4.*

Proof. Inspect the adjacency row O in Definition 370.1. An accepted neighboring pair is recorded only as zero-zero, zero-one, or one-zero, and Definition 370.4 rules out any one-one acceptance route or external counting row.

Now restrict along a displayed prefix or fold readback. By Definition 370.3, the restricted packet keeps only the corresponding subrows of W, Z, O, P, L. Applying Definition 370.4 to that restricted ledger shows that every retained adjacency decision is still one of the same three local rows. □

Theorem 370.12 (GoldenMeanShift finite-window standard bridge)**.** *The finite* GoldenMeanShift$^{\uparrow}$ *packet of Definition 370.1 is the standard finite golden-mean shift word interface: a public word is accepted exactly by the finite* BHist *bit-window row, the all-zero inhabitant row, the zero-zero/zero-one/one-zero adjacency ledger, the prefix and fold provenance rows, and the componentwise* hsame *and* NameCert *classifier rows. Componentwise* hsame *supplies the word comparison, and adjacency-ledger exactness supplies the complete no-adjacent-one acceptance record.*

This bridge exports only the finite-window word interface. It does not close entropy, Fibonacci counting, inverse limits, host symbolic dynamics, or an infinite shift-space presentation.

Lean4 ✓ `BEDC.Derived.GoldenMeanShiftUp.GoldenMeanShiftUp StdBridge`

Proof. Project the carrier rows W, Z, O, P, L. They are exactly the finite bit window, all-zero witness, adjacency ledger, provenance row, and local naming ledger of the public word packet.

Use Definition 370.10 for componentwise word comparison. The classifier compares visible bit rows by hsame and transports the same finite packet rows.

Use Definition 370.8 for the acceptance ledger. A neighboring pair is accepted precisely when O records zero-zero, zero-one, or one-zero, so the no-adjacent-one condition is exhausted by the finite ledger.

The bridge therefore identifies the BEDC packet with the standard finite word surface. The excluded symbolic-dynamics data have no carrier coordinate, no classifier row, and no ledger row in the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{GoldenMeanShift}^{\uparrow}}$.

Constructive story: A golden-mean finite window is generated from binary BHist rows together with an adjacency ledger excluding one-one neighbors, an all-zero inhabitant, prefix and fold provenance, and componentwise hsame classifier rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GoldenMeanShift}^{\uparrow}}$, maturePackageClosed)

Scope closed: The scoped surface is the finite no-adjacent-one BHist carrier row, componentwise hsame classifier row, exhausted adjacency ledger row, local stability row, fold-prefix closure row, and NameCert obligation surface over Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GoldenMeanShift}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.GoldenMeanShiftUp.GoldenMeanShiftCarrier\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close Fibonacci counting, Zeckendorf arithmetic, entropy, inverse limits, or host symbolic-dynamics theorems.

Upgrade path: No further upgrade remains because the chapter is at the top of the formal axis.

Chapter 371

A Concrete Naming Certificate for $\mathsf{RegularCauchyName}^{\uparrow}$

The $\mathsf{RegularCauchyName}^{\uparrow}$ interface packages the shared boundary between $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as a concrete naming certificate. Following Bishop and Bridges, *Constructive Analysis*, 1985, the packet treats a real name as visible regular Cauchy data with dyadic-radius control, finite stream windows, and a consumer-facing real seal. It never classifies by quotient Cauchy classes, host sequence equality, selected limits, or ambient real completeness.

Its dependency list is $\mathsf{DyadicRatCore}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$.

The finite-window schedule is consumed through chapter 126, while the dyadic-radius observation ledger is consumed through chapter 291. These sibling routes are the only entry points by which the carrier exposes scheduled readback and rational-radius evidence before the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers can read the packet.

Definition 371.1 (RegularCauchyName NameCert source)**.** *A* $\mathsf{RegularCauchyName}^{\uparrow}$ *source packet is a finite* BHist *row*

$$G = (S, Q, \rho, L, E, P, N)$$

with the following visible coordinates:

1. *S is a* $\mathsf{StreamName}^{\uparrow}$ *schedule of certified unary indices and finite observation windows;*
2. *Q assigns to each inspected window a* $\mathsf{DyadicRatCore}^{\uparrow}$ *rational observation, read as a* $\mathsf{RegSeqRat}^{\uparrow}$ *point row;*
3. *ρ records the dyadic-radius bounds visible at the certified unary indices;*
4. *L is the finite-window regularity ledger that pairs each scheduled window with its radius row and pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison data;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal ledger consumed by downstream real-name readers;*
6. *P is the* Pkg *provenance naming* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, *and the ambient* $\mathsf{NameCert}$ *source certificates;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *provenance row.*

The classifier compares two source packets only by common $\mathsf{StreamName}^{\uparrow}$ *windows, transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius rows, the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, the finite regularity ledger, and the displayed* $\mathsf{Real}^{\uparrow}$ *seal rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameTasteGate single carrier alignment`

Theorem 371.2 (RegularCauchyName dyadic radius obligations)**.** *Every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet carries, for each certified unary index, a visible dyadic-radius row whose transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations bound the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *point rows inside the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window. The classifier can therefore compare regularity only through displayed radius rows and pointwise rational observations.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier dyadic radius obligations`

Proof. Project the source packet of Definition 371.1. The schedule coordinate names the certified unary index and finite window, while the point row supplies the inspected dyadic rational observation.

The radius coordinate is stored beside that same window in the regularity ledger. Transport along hsame and Cont therefore moves the index, the window, the radius row, and the point observation together.

Since the classifier is defined only from these displayed rows, regularity comparison is a dyadic-radius obligation on the finite ledger. It is not a quotient comparison of Cauchy classes or an equality of host sequences. □

Theorem 371.3 (RegularCauchyName StreamName handoff)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet and every consumer precision request, the requested read factors through a common* $\mathsf{StreamName}^{\uparrow}$ *window, the transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row attached to that window, and the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier. No read can bypass the finite schedule to inspect a host sequence.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNamePacket streamname handoff`

Proof. Start with a consumer request and read the packet coordinates. The $\mathsf{StreamName}^{\uparrow}$ schedule is the only coordinate that selects windows, so the request first lands in a displayed finite window.

Inside that window, the observation row is a $\mathsf{DyadicRatCore}^{\uparrow}$ rational row presented through the $\mathsf{RegSeqRat}^{\uparrow}$ pointwise classifier. The permitted transports are exactly the hsame comparisons and Cont routes recorded by the packet provenance.

Thus the handoff from stream name to regular rational row is finite and visible. A downstream reader receives the scheduled window and its transported rational evidence, not a hidden sequence object. □

Theorem 371.4 (RegularCauchyName RealUp seal boundary)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal ledger of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet is consumed only after the StreamName window, dyadic-radius row, and pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed. The seal exports a real-name interface but does not export quotient stream equality, a choice-selected limit, or a host real carrier.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier realup seal boundary`

Proof. Read the seal coordinate through the source packet. It is stored after the schedule, rational observation rows, radius rows, and finite regularity ledger, so a consumer reaches it only along those displayed coordinates.

The preceding handoff theorem identifies the exact route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$. The seal ledger records the $\mathsf{Real}^{\uparrow}$ consumption of that route rather than an independent completion object.

Consequently the boundary of the seal is a finite real-name surface. It withholds quotient stream equality, selected limits, host real carriers, and ambient completeness claims. □

Theorem 371.5 (RegularCauchyName NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *sketch has five rows:*

1. *carrier: the source packet of Definition 371.1 stores the* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, dyadic-radius rows, finite regularity ledger,* $\mathsf{Real}^{\uparrow}$ *seal,* Pkg *provenance, and local certificate row;*
2. *classifier: accepted packets are compared only by common stream windows, transported radius rows, pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *comparisons, seal rows, and provenance;*
3. *dyadic-radius stability: Definition 371.2 keeps every regularity claim attached to visible dyadic bounds at certified unary indices;*
4. *finite-window ledger: Definition 371.3 forces every read through a scheduled finite window and its transported rational observation;*
5. *RealUp seal consumption: Definition 371.4 exposes only the* $\mathsf{Real}^{\uparrow}$ *consumer surface and no quotient, host-sequence, selected-limit, or ambient-completeness datum.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier semantic name certificate`

Proof. The carrier and classifier rows are immediate projections of the source packet. They list exactly the finite certificate coordinates and the visible comparisons used by the local classifier.

The dyadic-radius row is supplied by Definition 371.2. It pins regularity to transported $\mathsf{DyadicRatCore}^{\uparrow}$ radius evidence at certified unary indices.

The finite-window and seal rows are supplied by Definition 371.3 and Definition 371.4. Together they show that every consumer read passes through a scheduled window before reaching the $\mathsf{Real}^{\uparrow}$ seal, with no escape to quotient, host-sequence, selected-limit, or ambient-completeness data. □

Theorem 371.6 (RegularCauchyName obligation closure package)**.** *Every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose source is the packet of Definition 371.1 admits the five obligation rows needed for obligation closure:*

1. *dyadic-radius stability over transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius rows;*
2. *finite-window handoff through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule;*
3. *pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison for the inspected rational observations;*
4. *the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the scheduled stream and regular rational rows have been displayed;*
5. *ledger exhaustion over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

Thus the packet closes the local obligation surface without adding quotient streams, host sequences, selected limits, or ambient real completeness.

Proof. Project the carrier and classifier rows from the source packet. The carrier supplies the schedule, rational observations, radius rows, finite regularity ledger, seal ledger, package provenance, and local certificate row. The classifier restricts comparison to common windows, transported radius evidence, pointwise rational rows, seal rows, and provenance.

The first obligation row is Definition 371.2. It attaches every regularity claim to visible dyadic bounds at the certified unary indices.

The second and third rows are obtained from Definition 371.3. A consumer precision request first factors through the finite $\mathsf{StreamName}^{\uparrow}$ window, then reads the transported $\mathsf{DyadicRatCore}^{\uparrow}$ observation through the pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier.

The fourth row is Definition 371.4. The $\mathsf{Real}^{\uparrow}$ seal is reachable only after the displayed stream, dyadic-radius, and regular rational rows have been consumed.

Finally, Definition 371.5 assembles these rows with the carrier and classifier projections. Since every listed datum is drawn from the displayed packet and its hsame, Cont, Pkg, and NameCert provenance, the ledger is exhausted over the named BEDC objects and contains no quotient stream, host sequence, selected-limit, or ambient-completeness row. □

Theorem 371.7 (RegularCauchyName classifier transport stability)**.** *Let $G = (S, Q, \rho, L, E, P, N)$ be the source packet of Definition 371.1. Any displayed* hsame *comparison and* Cont *route that transports the* $\mathsf{StreamName}^{\uparrow}$ *schedule S, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row Q, the dyadic-radius row ρ, the finite ledger L, the* $\mathsf{Real}^{\uparrow}$ *seal row E, the* Pkg *provenance P, and the local* NameCert *row N preserves the* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *classifier over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier classifier transport stability`

Proof. Project the classifier from the source packet. Its only comparison rows are common $\mathsf{StreamName}^{\uparrow}$ windows, transported $\mathsf{DyadicRatCore}^{\uparrow}$ observations, dyadic-radius rows, pointwise $\mathsf{RegSeqRat}^{\uparrow}$ reads, seal rows, and provenance.

Apply the dyadic-radius obligation of Definition 371.2 to keep each radius bound attached to the same certified unary index and window during transport. Apply the StreamName handoff of Definition 371.3 to keep the scheduled window and transported rational observation on the same route.

The $\mathsf{Real}^{\uparrow}$ seal boundary in Definition 371.4 is downstream of those rows, so transporting the displayed coordinates also transports the seal-facing classifier row. The package theorem Definition 371.6 then repacks the transported rows as the same local NameCert classifier, with no host sequence, quotient stream, selected limit, or ambient completeness coordinate. □

Theorem 371.8 (RegularCauchyName dyadic radius transport composition)**.** *Let $G = (S, Q, \rho, L, E, P, N)$ be the source packet of Definition 371.1. Any componentwise* hsame *comparison and displayed* Cont *transport that preserves the* $\mathsf{StreamName}^{\uparrow}$ *schedule S, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row Q, the dyadic-radius row ρ, the finite ledger L, the* $\mathsf{Real}^{\uparrow}$ *seal row E, the* Pkg *provenance P, and the local* NameCert *row N preserves the single dyadic-radius row consumed both by the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and by the* $\mathsf{Real}^{\uparrow}$ *seal factorization. The transported consumer route factors through the same displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows, with no quotient stream, host sequence equality, selected limit, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier dyadic radius transport composition`

Proof. Begin with the radius coordinate in the source packet. By Definition 371.2, the row ρ is attached to the certified unary index and to the visible dyadic bound used by the regularity obligation.

Use Definition 371.3 to place the consumer request on a finite $\mathsf{StreamName}^{\uparrow}$ window. On that window the same handoff exposes the transported $\mathsf{DyadicRatCore}^{\uparrow}$ observation Q before the pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier reads it.

Now apply Definition 371.7. The displayed hsame and Cont route transports S, Q, ρ, L, E, P, and N together, so the classifier-facing radius row cannot split from the finite ledger route.

Finally use Definition 371.10. The $\mathsf{Real}^{\uparrow}$ seal consumes the route only after the same dyadic-radius row has been displayed beside the scheduled window and rational readback. Thus the classifier consumer and the seal consumer share one finite BEDC route over BHist, hsame, Cont, Pkg, and NameCert, and no quotient stream, host-sequence equality, selected limit, or ambient completeness coordinate is introduced. □

Theorem 371.9 (RegularCauchyName window ledger exhaustion)**.** *For a source packet $G = (S, Q, \rho, L, E, P, N)$, every consumer precision read is exhausted by the displayed finite route through S, Q, ρ, L, E, P, and N. The route uses only* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNamePacket handoff nonempty iff`

Proof. Begin with the finite-window handoff. By Definition 371.3, a precision request first lands in the displayed $\mathsf{StreamName}^{\uparrow}$ schedule and then reaches the transported dyadic rational observation read through the pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier.

The radius row for that same window is supplied by Definition 371.2. Thus the scheduled window, dyadic observation, radius evidence, and regular rational readback are one finite ledger route, not separate hidden data.

The $\mathsf{Real}^{\uparrow}$ seal boundary of Definition 371.4 consumes this route after it has been displayed. Together with the Pkg and NameCert provenance rows in Definition 371.6, these entries exhaust the consumer ledger and leave no quotient stream, host sequence, selected limit, or ambient completeness row to read. □

Theorem 371.10 (RegularCauchyName real seal factorization)**.** *For every accepted source packet $G = (S, Q, \rho, L, E, P, N)$, the* $\mathsf{Real}^{\uparrow}$ *seal row E factors through the displayed dyadic-radius row, the* $\mathsf{StreamName}^{\uparrow}$ *handoff, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before it can be consumed as a* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *row. The factorization is componentwise over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier real seal factorization`

Proof. Read the seal coordinate from the source packet. It is recorded after the stream schedule, dyadic observations, radius bounds, and finite regularity ledger, so it is not an independent real carrier.

Use Definition 371.3 to expose the scheduled finite window and its transported rational observation. Use Definition 371.2 to attach the dyadic-radius row to the same window, and use Definition 371.4 to place the $\mathsf{Real}^{\uparrow}$ seal after that handoff.

Finally apply Definition 371.6. The package theorem names the same BHist, hsame, Cont, Pkg, and NameCert provenance, so the seal factorization remains a finite certificate route and exports no quotient equality, selected limit, host real carrier, or ambient completeness theorem. □

Theorem 371.11 (RegularCauchyName tail selector factorization)**.** *Every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet read selected by a* $\mathsf{StreamName}^{\uparrow}$ *tail-compatible finite window factors through the schedule S, dyadic observation row Q, radius row ρ, ledger L,* $\mathsf{Real}^{\uparrow}$ *seal E, package provenance P, and local* NameCert *row N. The factorization is a finite route over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

The selected read has no quotient stream coordinate, no host sequence equality, no selected limit, and no ambient completeness coordinate.

Proof. Begin with the StreamName handoff theorem Definition 371.3. The tail-compatible window first exposes the schedule S and the transported dyadic observation row Q before any pointwise $\mathsf{RegSeqRat}^{\uparrow}$ readback is consumed.

Attach the radius and ledger rows by Definition 371.2 and Definition 371.9. These rows place ρ and L on the same selected finite window with the same rational readback and support data.

Next use Definition 371.4. It puts the $\mathsf{Real}^{\uparrow}$ seal E downstream of the displayed schedule, dyadic observation, radius, and ledger rows rather than beside them as an independent endpoint.

Finally apply Definition 371.10. Repacking S, Q, ρ, L, E, P, N with the displayed BHist, hsame, Cont, Pkg, and NameCert rows gives the asserted tail-selector route and leaves quotient streams, host sequence equality, selected limits, and ambient completeness outside the packet. □

Theorem 371.12 (RegularCauchyName common-window classifier scope)**.** *Two accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packets can be compared only after choosing a displayed common finite* $\mathsf{StreamName}^{\uparrow}$ *window. On that same window, the comparison transports the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows and dyadic-radius rows by the recorded* hsame *and* Cont *routes, then reads the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier for the transported rational observations. No classifier step may compare host sequences, quotient streams, selected limits, or unexhibited real carriers.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNamePacket common window classifier scope`

Proof. Project the two source packets of Definition 371.1. Their classifier coordinates name only finite stream windows, transported rational observations, radius rows, seal rows, and provenance.

Use Definition 371.3 to put a consumer comparison into a common displayed $\mathsf{StreamName}^{\uparrow}$ window. The allowed transports are the packet's hsame and Cont rows, so the window, the $\mathsf{DyadicRatCore}^{\uparrow}$ observation, and the dyadic-radius row move together.

On the transported window, the pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier is the only rational comparison exported by the packet. The package closure of Definition 371.6 confirms that no hidden quotient, host sequence, selected limit, or completeness datum is available to the classifier. □

Theorem 371.13 (RegularCauchyName common-window seal determinacy)**.** *Once two accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packets are compared on a displayed common* $\mathsf{StreamName}^{\uparrow}$ *window, their* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *pointwise classifier rows, finite ledger rows, and* $\mathsf{Real}^{\uparrow}$ *seal rows are determined by that same common-window route. The determinacy is certificate-local: it factors through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows and excludes host sequences, quotient streams, selected limits, and ambient completeness.*

Proof. First put the comparison on the shared finite window. By Definition 371.3, every precision read reaches the displayed $\mathsf{StreamName}^{\uparrow}$ route before it can expose dyadic observations or regular rational readback.

Next attach the seal boundary. The $\mathsf{Real}^{\uparrow}$ seal boundary of Definition 371.4 is downstream of the same finite window, and the NameCert obligation surface of Definition 371.5 keeps the dyadic radius rows, pointwise classifier rows, ledger rows, package provenance, and local certificate in the same finite packet.

Finally apply Definition 371.12. It restricts comparison to the transported common-window rows, so two packets that are compared there cannot vary their radius, classifier, ledger, or seal by appealing to host sequences, quotient streams, selected limits, or ambient completeness. □

Theorem 371.14 (RegularCauchyName finite-window ledger exhaustion)**.** *Every consumer precision request for an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet is exhausted by the displayed schedule row, the dyadic-radius row, the finite regularity ledger, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *row. The request receives no host sequence, quotient stream, selected limit, hidden completeness datum, or additional real carrier beyond those displayed packet rows.*

Proof. Project the packet of Definition 371.1. A precision request first reads the schedule coordinate, which selects a certified unary index and a finite $\mathsf{StreamName}^{\uparrow}$ observation window.

The dyadic-radius coordinate and the regularity ledger sit beside that window. By Definition 371.3, the consumer read follows the scheduled window to the transported $\mathsf{DyadicRatCore}^{\uparrow}$ observation and the pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier.

The Pkg row records the dependency provenance, and the local $\mathsf{NameCert}$ row records the certificate provenance for the same finite packet. Applying Definition 371.6 shows that these displayed rows exhaust the ledger available to the consumer. □

Theorem 371.15 (RegularCauchyName RealUp seal consumer scope)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet is reachable only after four finite faces have been displayed: the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row and dyadic-radius row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *pointwise classifier with its finite ledger, and the* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *provenance rows. The exported object is only the finite real-name seal surface; it does not export quotient stream equality, a selected limit, host real completeness, an independent real carrier, an ambient completeness datum, or a metric-completeness row.*

Proof. Project the seal coordinate from the packet of Definition 371.1. The seal is stored after the schedule, dyadic observation rows, radius rows, and finite regularity ledger, so it is not an independent entry point.

Use Definition 371.3 to identify the displayed route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier. Then use Definition 371.4 to read the seal only after that route has been consumed.

The package closure in Definition 371.6 keeps the BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance attached to the same finite ledger. After those rows are in place, apply Definition 371.10: the seal exposes only the finite real-name consumer row and withholds quotient equality, selected limits, host completeness, any independent real carrier, ambient completeness data, and metric-completeness rows. □

Theorem 371.16 (RegularCauchyName scoped carrier transport)**.** *For accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *source packets* $G = (S, Q, \rho, L, E, P, N)$*, every displayed* hsame *comparison and* Cont *route that transports the coordinates* S*,* Q*,* ρ*,* L*,* E*,* P*, and* N *over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* BHist*,* Pkg*, and* $\mathsf{NameCert}$ *preserves the source-packet carrier and the local classifier. The transported packet is again classified only by common stream windows, transported dyadic observations and radius rows, pointwise regular rational comparisons, the finite ledger, the seal row, and provenance.*

Proof. Project the packet carrier from Definition 371.1. Each coordinate named in the statement is one of the displayed rows of the source packet, so a componentwise hsame comparison or Cont route has no hidden coordinate to move.

The carrier rows are the first two rows of Definition 371.6: the schedule, rational observations, radius rows, ledger, seal, package provenance, and local certificate row are transported as the displayed packet itself.

The classifier row is supplied by the same package theorem and by Definition 371.12. Comparison is restricted to common windows, transported $\mathsf{DyadicRatCore}^{\uparrow}$ rows, pointwise $\mathsf{RegSeqRat}^{\uparrow}$ reads, seal rows, and provenance, so the transported packet remains inside the same scoped carrier. □

Theorem 371.17 (RegularCauchyName finite-window readback exactness)**.** *Every consumer precision read of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet factors through the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window, the transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation attached to that window, the displayed dyadic-radius row, the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, and the finite ledger row. The readback exposes no host sequence coordinate and no quotient stream coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier finite window readback exactness`

Proof. Begin with the consumer request. By Definition 371.3, the request first lands in a scheduled finite $\mathsf{StreamName}^{\uparrow}$ window and then reads the transported $\mathsf{DyadicRatCore}^{\uparrow}$ observation through the pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier.

The radius evidence for that same window is exactly the row described by Definition 371.2. It is stored beside the observation in the finite regularity ledger, so the readback route keeps the window, observation, radius, and classifier rows together.

Finally apply Definition 371.14. The ledger exhausts the consumer-facing rows available to the request, and therefore excludes host sequence coordinates, quotient stream coordinates, selected limits, and hidden completeness data. □

Theorem 371.18 (RegularCauchyName RealUp seal ledger exhaustion)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet is consumed only after the finite-window row and the dyadic-radius row have been displayed. Its ledger is exhausted by* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *primitives, with no extra real carrier, quotient stream, selected limit, or ambient completeness row.*

Proof. Use Definition 371.4 to locate the seal behind the displayed stream window, dyadic-radius row, and pointwise $\mathsf{RegSeqRat}^{\uparrow}$ readback. The seal is a downstream consumer row, not a separate entry point.

The preceding theorem gives the exact readback route: scheduled $\mathsf{StreamName}^{\uparrow}$ window, transported $\mathsf{DyadicRatCore}^{\uparrow}$ observation, radius row, pointwise classifier, and ledger. Thus the seal can be consumed only after those rows have appeared.

The ledger exhaustion clause then follows from Definition 371.6 and Definition 371.15. Those results list the named BEDC primitives that account for the packet surface and rule out any additional real carrier, quotient stream, selected limit, or completeness row. □

Theorem 371.19 (RegularCauchyName window-radius-seal scoped package)**.** *For every accepted source packet* $G = (S, Q, \rho, L, E, P, N)$ *of Definition 371.1, the scheduled finite* $\mathsf{StreamName}^{\uparrow}$ *window, transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation, dyadic-radius row, pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, finite ledger,* $\mathsf{Real}^{\uparrow}$ *seal,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows form the scoped package consumed by* $\mathsf{RegularCauchyName}^{\uparrow}$. *No host sequence, quotient stream, selected limit, hidden completeness datum, or independent real carrier is available to the consumer.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier window radius seal scoped package`

Proof. First transport the carrier. By Definition 371.16, the displayed hsame comparisons and Cont routes preserve the source rows S, Q, ρ, L, E, P, and N as a single accepted packet over the named BEDC primitives.

Next read the finite window exactly. Apply Definition 371.17 to factor every precision request through the scheduled $\mathsf{StreamName}^{\uparrow}$ window, transported $\mathsf{DyadicRatCore}^{\uparrow}$ observation, dyadic-radius row, pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier, and finite ledger.

Finally attach the seal. The exhaustion theorem Definition 371.18 places the $\mathsf{Real}^{\uparrow}$ seal after those displayed rows and accounts for the remaining BHist, hsame, Cont, Pkg, and NameCert primitives. Repacking the rows named in Definition 371.1 gives exactly the scoped package in the statement, with no coordinate for a host sequence, quotient stream, selected limit, hidden completeness datum, or independent real carrier. □

Theorem 371.20 (RegularCauchyName stationary rational seal compatibility)**.** *Let $G = (S, Q, \rho, L, E, P, N)$ be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *source packet. If its displayed* BHist *rows are restricted to a stationary rational window, then the* hsame*,* Cont*,* Pkg*, and* NameCert *rows of Definition 371.19 factor the* $\mathsf{Real}^{\uparrow}$ *seal through the constant-rational exactness row of Definition 364.8. The factorization uses only the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window, transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation, pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, finite ledger, and visible seal row, and it exports no quotient stream, selected host limit, or ambient completeness datum.*

Proof. Start with the window-radius-seal scoped package of Definition 371.19. It lists the only rows available to a consumer of G: the scheduled window, dyadic observation and radius, pointwise regular rational readback, ledger, seal, and the displayed BHist, hsame, Cont, Pkg, and NameCert evidence.

On the stationary rational subcase, the scheduled regular readback is exactly the constant $\mathsf{RegSeqRat}^{\uparrow}$ member governed by Definition 364.8. The hsame and Cont rows therefore transport the same displayed rational observation into the stationary seal route.

The two packages have the same consumer boundary: finite windows, dyadic observations, regular readback, package provenance, and local naming. Since neither package contains a quotient stream, selected host limit, or ambient completeness coordinate, the stationary rational seal is compatible with the $\mathsf{RegularCauchyName}^{\uparrow}$ seal without adding any extra row. □

Theorem 371.21 (RegularCauchyName diagonal window consumer boundary)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet $G = (S, Q, \rho, L, E, P, N)$, any diagonal completion consumer that reads the displayed window-radius-seal surface must pass through the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows named in Definition 371.19 before it reaches the routing boundary of Definition 372.9. The boundary keeps the consumer on scheduled* $\mathsf{StreamName}^{\uparrow}$ *windows, transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, finite ledger rows, and the* $\mathsf{Real}^{\uparrow}$ *seal, with no quotient stream, selected host limit, or ambient completeness row.*

Proof. Project the accepted packet through the RegularCauchyName package theorem. Every consumer-visible coordinate is already displayed as a finite packet row, so there is no separate diagonal input hidden behind the seal.

Now apply the completion-consumer routing of Definition 372.9. Its diagonal route consumes regular windows through the same kind of scheduled readback and finite routing rows that the RegularCauchyName package exposes.

The handoff is therefore by row identity: scheduled windows match scheduled windows, dyadic observations and radius evidence match the diagonal tolerance boundary, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{Real}^{\uparrow}$ seal remain downstream of BHist, hsame, Cont, Pkg, and NameCert. The

excluded objects are absent from both inventories, so the diagonal consumer cannot escape through them. □

Theorem 371.22 (RegularCauchyName completion handoff non-escape)**.** *Every completion-facing consumer of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$ *factors through the displayed window-radius-seal package, the stationary rational compatibility row of Definition 371.20 when the packet is constant, and the diagonal completion-consumer boundary of Definition 371.21. Thus the handoff is exhausted by* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*, scheduled windows, dyadic observations, regular readback, finite ledger rows, and the seal row, and never by quotient streams, selected host limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier completion handoff non escape`

Proof. First place the packet in the window-radius-seal scoped package. This supplies the visible finite rows that any completion-facing consumer must read before the $\mathsf{Real}^{\uparrow}$ seal can be used.

For constant rational packets, the preceding compatibility theorem identifies the seal route with the stationary rational exactness package. For nonconstant completion reads, the diagonal window theorem routes the consumer through the diagonal completion boundary instead.

Both routes have the same displayed source rows and the same exclusions. Repacking the common BHist, hsame, Cont, Pkg, and NameCert evidence gives a single completion handoff boundary for $\mathsf{RegularCauchyName}^{\uparrow}$, and the carrier has no coordinate from which a quotient stream, selected host limit, or ambient completeness object could be produced. □

Theorem 371.23 (RegularCauchyName common-window transport triad)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$*, a completion-facing comparison that chooses a common finite* $\mathsf{StreamName}^{\uparrow}$ *window transports three rows as one triad: the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, the dyadic-radius row* ρ*, and the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier read attached to that same window. The triad is transported only by the packet's* BHist *entries,* hsame *comparisons,* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier common window transport triad`

Proof. Project the accepted packet through Definition 371.1. The stream schedule, dyadic observation, radius row, regularity ledger, seal row, package provenance, and local certificate row are displayed as coordinates of the same finite source packet.

Use Definition 371.3 to put the comparison into a common finite $\mathsf{StreamName}^{\uparrow}$ window. Then use Definition 371.2 and Definition 371.12 to keep the $\mathsf{DyadicRatCore}^{\uparrow}$ observation, radius row, and pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier on that same transported window.

The permitted transport rows are exactly the packet's BHist, hsame, Cont, Pkg, and NameCert evidence. Since no packet coordinate names a quotient stream, host sequence, selected limit, or ambient completeness principle, the triad has no route through those objects. □

Theorem 371.24 (RegularCauchyName seal readback exhaustion)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal readback is exhausted by the displayed schedule row* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row* Q*, the dyadic-radius row* ρ*, the finite regularity ledger* L*, the package row* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *row* N*. No readback step can obtain a quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier seal readback exhaustion`

Proof. Start from the seal coordinate of Definition 371.1. The seal appears after the schedule, observation, radius, and ledger rows, so it is a consumer row reached through displayed finite data.

The finite readback route is Definition 371.17: every precision request factors through the scheduled $\mathsf{StreamName}^{\uparrow}$ window, transported $\mathsf{DyadicRatCore}^{\uparrow}$ observation, dyadic-radius row, pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier, and finite ledger. The real seal boundary is then supplied by Definition 371.18.

Finally apply the package accounting of Definition 371.6. The only remaining rows are BHist, hsame, Cont, Pkg, and NameCert provenance, which records the readback without adding quotient streams, host sequences, selected limits, independent real carriers, or ambient completeness. □

Theorem 371.25 (RegularCauchyName downstream completion handoff package)**.** *The downstream package exported by an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet to* $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, *and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consists of the common-window transport triad of Definition 371.23, the seal readback exhaustion row of Definition 371.24, the* $\mathsf{StreamName}^{\uparrow}$ *handoff of Definition 371.3, and the* $\mathsf{Real}^{\uparrow}$ *seal consumer scope of Definition 371.15. This package is finite over* BHist, hsame, Cont, Pkg, *and* NameCert *and exports no quotient streams, host sequences, selected limits, independent real carriers, or ambient completeness.*

Proof. First assemble the finite window surface. The stream handoff chooses the displayed $\mathsf{StreamName}^{\uparrow}$ window, and the common-window transport triad keeps the $\mathsf{DyadicRatCore}^{\uparrow}$ observation, dyadic-radius row, and pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier attached to that window.

Next attach the real-name boundary. The seal readback exhaustion theorem accounts for the schedule, observation, radius, finite ledger, package row, and local certificate row; the seal consumer scope theorem identifies the resulting $\mathsf{Real}^{\uparrow}$ row as downstream of those displayed data.

The three consumers named in the statement read exactly this surface: subsequence consumers read finite windows, diagonal consumers read the transported diagonal boundary, and completion consumers read the real seal after the finite ledger. Repacking the shared BHist, hsame, Cont, Pkg, and NameCert rows gives one handoff package and leaves no coordinate for quotient streams, host sequences, selected limits, independent real carriers, or ambient completeness. □

Theorem 371.26 (RegularCauchyName bridge source surface)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$ *of Definition 371.1, the rows displayed by* G *supply the bridge source surface from* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *into the completion-facing consumer surface. The source surface consists exactly of the scheduled stream window* S, *dyadic observation row* Q, *dyadic-radius row* ρ, *finite regularity ledger* L, $\mathsf{Real}^{\uparrow}$ *seal* E, *package row* P, *local* NameCert *row* N, *and the ambient* BHist, hsame, Cont, *and* Pkg *transport rows already named by the window-radius-seal package.*

Proof. Start from the window-radius-seal package of Definition 371.19. It displays the source packet as a finite row package over the scheduled stream window, dyadic observation, radius evidence, pointwise regular rational readback, ledger, real seal, package provenance, and local certificate.

The finite-window route is exact by Definition 371.17. Thus the rows read by a completion-facing consumer are not reconstructed from a host sequence; they are the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows of the packet.

Finally use Definition 371.18 and Definition 371.15. These place the $\mathsf{Real}^{\uparrow}$ seal after the finite rows and identify the consumer-facing boundary as the same BHist, hsame, Cont, Pkg, and NameCert surface named in the statement. □

Theorem 371.27 (RegularCauchyName bridge consumer factorization)**.** *Every downstream* RealCauchyCompletion *or* RegularCauchyFamily$^{\uparrow}$ *consumer read of an accepted* RegularCauchyName$^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$ *factors through the displayed stream window, dyadic observation, radius row, pointwise* RegSeqRat$^{\uparrow}$ *classifier, finite ledger,* Real$^{\uparrow}$ *seal,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The factorization has no additional completion datum before those rows and no independent consumer coordinate beyond them.*

Proof. First factor the read through the scoped package of Definition 371.19. Any downstream consumer begins with the same accepted packet rows, so its visible route must pass through S, Q, ρ, L, E, P, and N.

Next apply Definition 371.17. The stream window, dyadic observation, radius row, pointwise classifier, and ledger are consumed together; this gives the common finite part of the factorization for both RealCauchyCompletion$^{\uparrow}$ and RegularCauchyFamily$^{\uparrow}$ reads.

The remaining real-name step is governed by Definition 371.18 and Definition 371.15. They attach the Real$^{\uparrow}$ seal only after the finite rows and account for the BHist, hsame, Cont, Pkg, and NameCert evidence, so no further completion coordinate is available. □

Theorem 371.28 (RegularCauchyName bridge non-escape boundary)**.** *The bridge-facing surface exported by an accepted* RegularCauchyName$^{\uparrow}$ *packet exports no host sequence, quotient stream, selected limit, hidden completeness datum, or independent real carrier. Any consumer-side route to* RealCauchyCompletion$^{\uparrow}$ *or* RegularCauchyFamily$^{\uparrow}$ *is bounded by the rows of Definition 371.26 and the factorization of Definition 371.27.*

Proof. The exclusion already appears in the scoped package: Definition 371.19 lists the available rows and states that host sequences, quotient streams, selected limits, hidden completeness data, and independent real carriers are not coordinates of the package.

Exact readback preserves that boundary. By Definition 371.17, a consumer precision request can only read the scheduled window, dyadic observation, radius row, pointwise classifier, and ledger before reaching the seal.

Finally, Definition 371.18 and Definition 371.15 exhaust the Real$^{\uparrow}$ side of the route through the displayed ledger and seal rows. Since the packet has no remaining exported coordinate, the bridge-facing boundary cannot escape to any of the excluded objects. □

Theorem 371.29 (RegularCauchyName schedule-radius lock)**.** *For every accepted* RegularCauchyName$^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$*, a common displayed* StreamName$^{\uparrow}$ *window locks together the schedule row* S*, the dyadic-radius row* ρ*, the transported* DyadicRatCore$^{\uparrow}$ *observation row* Q*, and the pointwise* RegSeqRat$^{\uparrow}$ *readback carried by* L*. The lock is witnessed only by the packet's* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows and has no coordinate for quotient streams, host sequences, selected limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier schedule radius lock`

Proof. First place the packet into the common StreamName$^{\uparrow}$ window supplied by Definition 371.3. This fixes the schedule row S as the window that every downstream read must inspect.

Next apply the dyadic-radius obligations of Definition 371.2. They attach the radius row ρ to the same displayed window and keep the tolerance request inside the finite BEDC packet.

Finally use the transport triad of Definition 371.23. It carries the DyadicRatCore$^{\uparrow}$ observation row Q and the pointwise RegSeqRat$^{\uparrow}$ readback along the already fixed window. Repacking these projections gives the lock over BHist, hsame, Cont, Pkg, and NameCert, with no remaining route to any excluded completion object. □

Theorem 371.30 (RegularCauchyName constant seal embedding)**.** *If an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$ *is stationary rational, then its downstream* $\mathsf{Real}^{\uparrow}$ *seal factors through the displayed schedule-radius-seal route and the stationary rational exactness row. The factorization uses the constant* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation, the trivial dyadic-radius ledger, the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, and it does not select a limit or invoke ambient real completeness.*

Proof. Begin with the displayed schedule-radius-seal package of Definition 371.19. In the stationary rational case, the schedule row repeatedly reads the same rational observation, while the radius and regularity ledgers are the visible constant rows of the packet.

The stationary rational compatibility theorem Definition 371.20 identifies this constant readback with the existing rational exactness route. Thus the seal is reached through the displayed packet rows rather than through a selected completion limit.

Repack the constant observation, radius ledger, pointwise readback, seal row, package row, and local certificate row. The resulting embedding is a projection of the accepted packet, so it remains over BHist, hsame, Cont, Pkg, and NameCert and has no host sequence, quotient stream, selected limit, or ambient completeness coordinate. □

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier constant seal embedding`

Theorem 371.31 (RegularCauchyName finite consumer choice-free totality)**.** *Every downstream completion-facing consumer read of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$ *is exhausted by the displayed rows* S*,* Q*,* ρ*,* L*,* E*,* P*, and* N*, together with* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The consumer route is total over this finite packet and choice-free: it never needs a quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness coordinate.*

Proof. First read the consumer through the bridge source surface of Definition 371.26. This exposes exactly the scheduled stream window, dyadic observation, radius row, finite regularity ledger, seal row, package provenance, local certificate, and ambient transport rows.

Next apply the bridge consumer factorization of Definition 371.27. Any $\mathsf{RealCauchyCompletion}^{\uparrow}$ or $\mathsf{RegularCauchyFamily}^{\uparrow}$ read factors through those displayed rows before it can consume the $\mathsf{Real}^{\uparrow}$ seal.

The non-escape boundary of Definition 371.28 then rules out every excluded completion object. Since each consumer read projects one of the displayed rows or one of their BHist, hsame, Cont, Pkg, and NameCert witnesses, the route is total over the finite packet and requires no choice principle. □

Theorem 371.32 (RegularCauchyName public RealUp seal export)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$*, the public* $\mathsf{Real}^{\uparrow}$ *seal exported by* G *is reached through the existing* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row* Q*, the dyadic-radius row* ρ*, the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier readback inside* L*, the finite ledger* L*, the package row* P*, and the local* NameCert *row* N*. The export surface contains no quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness coordinate.*

Proof. First read the source surface through Definition 371.26. It lists exactly the scheduled stream window, dyadic observation, radius row, finite regularity ledger, $\mathsf{Real}^{\uparrow}$ seal, package provenance, local certificate, and the ambient BHist, hsame, Cont, and Pkg transports.

Next use Definition 371.17. That theorem identifies every finite precision read with the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, dyadic-radius, and pointwise $\mathsf{RegSeqRat}^{\uparrow}$ rows, so the seal cannot be read through a host sequence or quotient stream.

Finally apply Definition 371.18 and Definition 371.15. They place the $\mathsf{Real}^{\uparrow}$ seal after the finite ledger and local certificate rows, preserving the exclusions named in the statement. □

Theorem 371.33 (RegularCauchyName completion consumer coverage)**.** *Every* $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, *and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer route out of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet factors through the public seal surface of Definition 371.32. No consumer in these four families receives an additional quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness datum.*

Proof. Begin with the downstream completion handoff package of Definition 371.25. It binds completion-facing reads to the schedule, dyadic observation, radius, classifier, ledger, seal, package, and certificate rows of the accepted packet.

For subsequence and diagonal consumers, use Definition 371.21 together with Definition 371.23. These theorems keep the consumer read inside the same finite window and transported pointwise classifier rows.

For family and completion consumers, apply Definition 371.27. The factorization reaches the $\mathsf{Real}^{\uparrow}$ seal only through the public surface of Definition 371.32, and Definition 371.28 excludes every omitted completion object. □

Theorem 371.34 (RegularCauchyName common-window refinement)**.** *Let* $G = (S, Q, \rho, L, E, P, N)$ *and* $G' = (S', Q', \rho', L', E', P', N')$ *be two completion-facing reads of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet through one displayed* $\mathsf{StreamName}^{\uparrow}$ *window. If the reads share that common window, then they refine to the same displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation, dyadic-radius row, pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier,* BHist *ledger,* hsame *transport,* Cont *route,* Pkg *provenance, and* $\mathsf{NameCert}$ *route. The refinement contains no quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier common window refinement`

Proof. First put both reads into the common transport surface. The common-window transport triad of Definition 371.23 identifies the shared $\mathsf{StreamName}^{\uparrow}$ window as the only window through which the $\mathsf{DyadicRatCore}^{\uparrow}$ observation row and pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier may be read.

Next attach the seal-readback row. By Definition 371.24, any read that reaches the $\mathsf{Real}^{\uparrow}$ side has already passed through the displayed window, observation, radius, classifier, ledger, package, and local certificate rows.

Finally use the public export and consumer coverage rows. The public seal export of Definition 371.32 keeps the $\mathsf{Real}^{\uparrow}$ seal on the same displayed packet, and Definition 371.33 says that the completion-facing consumers receive no additional route outside that packet. Thus the two reads refine to the same listed rows. □

Theorem 371.35 (RegularCauchyName synchronized precision pullback)**.** *Let* $G = (S, Q, \rho, L, E, P, N)$ *be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, and let* p *and* p' *be two displayed consumer precision requests. Suppose the* $\mathsf{StreamName}^{\uparrow}$ *schedule admits one common finite refinement window* W *for both requests, and suppose both requests route through the* $\mathsf{CauchyRate}^{\uparrow}$ *schedule and tail-bound surface before any regular rational readback is consumed. Then the normalized readback packets for* p *and* p' *factor through the same window* W*, the same transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, the same dyadic-radius row, the same pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row, and the same* $\mathsf{Real}^{\uparrow}$ *seal*

ledger. No quotient stream, host sequence equality, selected limit, or ambient completeness datum participates in this pullback.

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameCarrier synchronized precision pullback`

Proof. Apply the common-window refinement theorem Definition 371.34 to align the two precision reads inside the displayed $\mathsf{StreamName}^{\uparrow}$ window. This identifies the transported dyadic observation, radius, classifier, ledger, transport, continuation, package, and naming rows as one finite comparison surface.

Next use the FiniteWindowEnvelope common-window lock Definition 365.14. The lock keeps the envelope read on the selected window W and prevents the dyadic ledger, regular-sequence seal, and endpoint row from being read through a second window.

Finally route both reads through the CauchyRate surface. Scheduled-window totality Definition 415.7 supplies the displayed schedule row, while tail-bound routing Definition 415.16 forces the regular rational readback through the schedule, tolerance, and source rows before the $\mathsf{RegSeqRat}^{\uparrow}$ row is available. The normalized readback packet of Definition 371.42 then exhausts the remaining $\mathsf{Real}^{\uparrow}$ seal ledger, so the two reads share the stated pullback and have no route through the excluded completion objects. □

Theorem 371.36 (RegularCauchyName dyadic-radius readback)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$*, the dyadic-radius row* ρ *is the exact finite readback surface consumed by* $\mathsf{RegularCauchySubsequence}^{\uparrow}$*,* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$*, and* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *after they enter the common* $\mathsf{StreamName}^{\uparrow}$ *window. These consumers read the window* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation* Q*, the radius row* ρ*, the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier in* L*, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *routes; they do not receive a host sequence, quotient stream, selected limit, independent real carrier, or ambient completeness datum.*

Proof. Begin with the common-window transport triad. Definition 371.23 places subsequence, diagonal, and family reads on the same displayed $\mathsf{StreamName}^{\uparrow}$ window and carries the dyadic observation and pointwise classifier along that window.

The radius row is then forced by the seal-readback route. Definition 371.24 exhausts the precision read before the $\mathsf{Real}^{\uparrow}$ seal by the displayed window, observation, radius, classifier, ledger, package, and local certificate rows.

The consumer side is exactly the one recorded by Definition 371.33. Combining that coverage with the public seal export of Definition 371.32 leaves the dyadic-radius row as the finite readback surface shared by the named completion consumers. □

Theorem 371.37 (RegularCauchyName real seal exactness)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$*, the public* $\mathsf{Real}^{\uparrow}$ *seal* E *is reached only after the common-window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, dyadic-radius row, pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row,* BHist *ledger,* hsame *transport,* Cont *route,* Pkg *provenance, and* NameCert *route have been displayed. The seal exports no quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness coordinate.*

Proof. First route the packet through its common window. The transport triad of Definition 371.23 supplies the displayed window, dyadic observation, radius-facing readback, and pointwise classifier rows before any seal-facing consumer can proceed.

Next apply Definition 371.24. It says that the seal-facing read is exhausted by those finite rows together with the ledger, package, and local naming routes.

The public export theorem Definition 371.32 identifies the $\mathsf{Real}^{\uparrow}$ seal reached by this route, and the completion consumer coverage theorem Definition 371.33 rules out all extra consumer data. Hence the seal is exact with respect to the displayed rows and has no remaining completion-level coordinate. □

Theorem 371.38 (RegularCauchyName mature boundary package)**.** *The* $\mathsf{RegularCauchyName}^{\uparrow}$ *mature boundary package is the finite row package obtained by assembling Definition 371.26, Definition 371.27, Definition 371.28, Definition 371.32, and Definition 371.33. It is a completion-facing package over the L10* $\mathsf{Real}^{\uparrow}$ *and completion spine, but it exports no quotient streams, host sequences, selected limits, independent real carrier, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameUp StdBridge`

Proof. First assemble the bridge rows. The source surface theorem names the finite packet rows, and the consumer factorization theorem forces completion-facing reads through those same rows.

Next attach the boundary exclusions. The bridge non-escape theorem rules out quotient streams, host sequences, selected limits, hidden completeness data, and independent real carriers before any consumer reads the seal.

Finally add the public seal export and consumer coverage theorems. Together they make the same finite surface available to $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, and $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumers, yielding the mature completion-facing package stated above. □

Theorem 371.39 (RegularCauchyName RationalStream source admission)**.** *Let* $G = (S, Q, \rho, L, E, P, N)$ *be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is supplied by a* $\mathsf{RationalStream}^{\uparrow}$ *packet. Then the admitted source reads only the scheduled* $\mathsf{UnaryHistory}^{\uparrow}$ *row, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{Rat}^{\uparrow}$ *observation rows displayed by* Q*, the* hsame *and* Cont *transport routes, and the* Pkg *and* NameCert *provenance rows. The admission exports no quotient stream, selected limit, host completion object, independent real carrier, or ambient completeness datum.*

Proof. First read the source through the displayed schedule. The RationalStream ledger completeness theorem Definition 350.9 fixes the $\mathsf{UnaryHistory}^{\uparrow}$ schedule and the $\mathsf{Rat}^{\uparrow}$ rows before the packet enters the $\mathsf{RegularCauchyName}^{\uparrow}$ window, while the common-window transport triad of Definition 371.23 carries those rows through S and Q.

Next attach the local provenance. The public seal export of Definition 371.32 keeps the source on the same displayed hsame, Cont, Pkg, and NameCert routes, and the completion coverage theorem Definition 371.33 prevents any completion-facing consumer from reading outside those rows.

Thus the RationalStream admission is exactly the visible scheduled source described in the statement, with no quotient, limit, or completeness data added. □

Theorem 371.40 (RegularCauchyName FiniteWindowEnvelope handoff)**.** *Every selected precision request for an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet factors through the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *handoff surface: the* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal route, the displayed* $\mathsf{Real}^{\uparrow}$ *endpoint row, and the same* BHist, hsame, Cont, Pkg, *and* NameCert *provenance. No request obtains a host sequence, quotient regular stream, selected limit, independent real carrier, or ambient completeness row.*

Proof. Begin with the selected finite precision request. The finite-window readback exactness theorem Definition 371.17 routes the request through the finite $\mathsf{StreamName}^{\uparrow}$ window, the transported

$\mathsf{DyadicRatCore}^{\uparrow}$ observation, the radius row, the pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier, and the finite ledger.

The FiniteWindowEnvelope handoff surface is the same finite window with its dyadic ledger and regular-sequence seal route. By Definition 365.3, Definition 371.24, and Definition 371.32, the $\mathsf{Real}^{\uparrow}$ endpoint is reached only after those displayed rows and provenance routes have been read.

Finally, Definition 371.33 rules out all completion-side escapes, so the selected request factors through the finite-window envelope exactly as claimed. □

Theorem 371.41 (RegularCauchyName real-completion consumer triangle)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is supplied by* $\mathsf{RationalStream}^{\uparrow}$*, the completion-facing consumer surface is the triangle formed by Definition 371.39, Definition 371.40, and the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *downstream handoff row. A completion consumer receives exactly the displayed* $\mathsf{RationalStream}^{\uparrow}$ *source, the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *finite window, the* $\mathsf{RegularCauchyName}^{\uparrow}$ *seal, and the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer row, together with the named* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance. It receives no quotient completion, host representative, selected limit, hidden real carrier, or ambient completeness field.*

Proof. First assemble the source side. The RationalStream source admission theorem gives the visible scheduled source and its unary-history, rational-row, transport, package, and certificate provenance.

Next assemble the finite-window side. The FiniteWindowEnvelope handoff theorem factors the selected precision request through the finite $\mathsf{StreamName}^{\uparrow}$ window, dyadic ledger, $\mathsf{RegSeqRat}^{\uparrow}$ seal route, and $\mathsf{Real}^{\uparrow}$ endpoint.

Finally attach the completion consumer. The downstream handoff of Definition 360.20 supplies the completion-facing consumer row. The public seal export of Definition 371.32 identifies the $\mathsf{RegularCauchyName}^{\uparrow}$ seal delivered to that row, and Definition 371.33 states that $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumers receive no row beyond that displayed packet. The three sides therefore form the claimed consumer triangle. □

Definition 371.42 (RegularCauchyName normalized window readback)**.** *For an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$ *and a consumer precision request, the normalized readback packet of* G *is the finite row package*

$$\mathsf{NormRead}(G) = (W, Q_W, \rho_W, C_W, L_W, E_W, H_W, T_W, P_W, N_W)$$

obtained by projecting the common finite $\mathsf{StreamName}^{\uparrow}$ *window* W *from* S*, the transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation* Q_W *from* Q*, the dyadic-radius row* ρ_W*, the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier* C_W *read from* L*, the finite ledger row* L_W*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E_W*, and the displayed provenance rows* H_W*,* T_W*,* P_W*, and* N_W *for* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The packet is normalized when every consumer-facing precision read of* G *reaches the* $\mathsf{Real}^{\uparrow}$ *seal only through these displayed rows.*

Theorem 371.43 (RegularCauchyName window normalization coverage)**.** *Every consumer precision read of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$ *factors through the normalized readback packet of Definition 371.42. The factorization first selects the common finite* $\mathsf{StreamName}^{\uparrow}$ *window, then reads the transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation, dyadic-radius row, pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, finite ledger,* $\mathsf{Real}^{\uparrow}$ *seal row, and displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance. It exports no quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness coordinate.*

Proof. Begin with the finite precision request. The exactness theorem Definition 371.17 forces the request through the scheduled $\mathsf{StreamName}^{\uparrow}$ window, transported $\mathsf{DyadicRatCore}^{\uparrow}$ observation, dyadic-radius row, pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier, and finite ledger.

Next attach the seal-facing rows. The seal exhaustion theorem Definition 371.24 and the public export theorem Definition 371.32 place the $\mathsf{Real}^{\uparrow}$ seal after those finite rows and before any completion-facing consumer can proceed.

Finally project the provenance from the window-radius-seal package of Definition 371.19. Its BHist, hsame, Cont, Pkg, and NameCert rows are exactly the remaining coordinates of the normalized readback packet, so the consumer read has no route through any excluded completion object. □

Theorem 371.44 (RegularCauchyName normalized readback seal stability)**.** *Let G and G' be accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packets whose normalized readback packets are related by the displayed* hsame *comparisons and* Cont *routes on the common finite* $\mathsf{StreamName}^{\uparrow}$ *window, transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation, dyadic-radius row, pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, finite ledger, and* BHist, Pkg, *and* NameCert *provenance. Then the transported normalized packets preserve the* $\mathsf{Real}^{\uparrow}$ *seal boundary: a seal read for G is carried to the seal read for G' only through the same normalized rows, and no transport step introduces a quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness coordinate.*

Proof. First read both packets through the common-window transport triad of Definition 371.23. The triad transports the $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ observation, dyadic-radius row, and pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier as one finite unit.

The carrier and seal rows are then governed by Definition 371.16 and Definition 371.18. These results keep the finite ledger and $\mathsf{Real}^{\uparrow}$ seal downstream of the same displayed hsame and Cont rows.

Repack the transported coordinates as normalized readback packets. Since the provenance rows are already the BHist, Pkg, and NameCert rows named by the window-radius-seal package, the transported seal boundary remains inside the normalized packet and has no additional completion-facing coordinate. □

Theorem 371.45 (RegularCauchyName root-unblock normalization package)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, the normalized readback packet of Definition 371.42 forms the concrete normalization package for downstream* $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, *and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumers. The package is assembled from Definition 371.19, Definition 371.17, Definition 371.18, Definition 371.43, and Definition 371.44. It is finite over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert, *with no quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness row.*

Proof. First build the normalized finite surface. The window-radius-seal scoped package supplies the accepted packet rows, and finite-window readback exactness identifies the common $\mathsf{StreamName}^{\uparrow}$ window together with its transported dyadic observation, radius row, pointwise classifier, and finite ledger.

Next attach the consumer and seal boundaries. Real-seal ledger exhaustion places the $\mathsf{Real}^{\uparrow}$ seal after the finite rows, while window normalization coverage says that every consumer precision read factors through the normalized packet before reaching that seal.

Finally use normalized readback seal stability to transport the package across the displayed hsame comparisons and Cont routes. The downstream consumers named in the statement receive

exactly this normalized packet, so the package opens their finite readback obligations without adding quotient streams, host sequences, selected limits, independent real carriers, or ambient completeness. □

Theorem 371.46 (RegularCauchyName route exhaustion)**.** *Every accepted* RegularCauchyName$^{\uparrow}$ *consumer route is exhausted by the normalized readback packet of Definition 371.42, the* RationalStream$^{\uparrow}$ *source admission of Definition 371.39, the* FiniteWindowEnvelope$^{\uparrow}$ *handoff of Definition 371.40, and the* RealCauchyCompletion$^{\uparrow}$ *consumer triangle of Definition 371.41. Thus every route reads only the displayed* StreamName$^{\uparrow}$ *finite window,* DyadicRatCore$^{\uparrow}$ *observation, dyadic-radius row,* RegSeqRat$^{\uparrow}$ *classifier, finite ledger,* Real$^{\uparrow}$ *seal, and* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance. No accepted route contains a quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameUp concrete to schema`

Proof. Begin with the visible source. The RationalStream source admission theorem restricts the source side to the scheduled UnaryHistory$^{\uparrow}$ row, the StreamName$^{\uparrow}$ schedule, the rational observation rows, and the displayed provenance routes.

Next pass to the finite readback surface. The FiniteWindowEnvelope handoff theorem and the normalized window readback definition identify the same finite StreamName$^{\uparrow}$ window, transported DyadicRatCore$^{\uparrow}$ observation, dyadic-radius row, pointwise RegSeqRat$^{\uparrow}$ classifier, finite ledger, Real$^{\uparrow}$ seal, and BHist-anchored provenance.

Finally attach the consumer boundary. Window normalization coverage, normalized readback seal stability, and the root-unblock normalization package force every downstream read through that packet before it reaches the RealCauchyCompletion$^{\uparrow}$ consumer triangle. The excluded quotient, host, limit, carrier, and completeness rows therefore have no accepted route. □

Theorem 371.47 (RegularCauchyName stream-window refinement cover)**.** *For every accepted* RegularCauchyName$^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$*, any two consumer reads that share a displayed* StreamName$^{\uparrow}$ *finite window refine to one common finite cover. The rows of that cover are exactly the scheduled stream window, transported* DyadicRatCore$^{\uparrow}$ *observation, dyadic-radius row, pointwise* RegSeqRat$^{\uparrow}$ *classifier, finite ledger,* Real$^{\uparrow}$ *seal, and displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance. The cover exports no quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness row.*

Proof. Start from the window-radius-seal scoped package of Definition 371.19. It lists precisely the accepted packet rows available around the shared StreamName$^{\uparrow}$ window, including the dyadic observation, radius row, regular rational classifier, ledger, seal, and provenance.

The shared finite window is then read exactly. Apply Definition 371.17 to both consumer reads; because the displayed StreamName$^{\uparrow}$ window is the same, their dyadic observation, radius row, pointwise RegSeqRat$^{\uparrow}$ classifier, and finite ledger refine to a single finite window interface. The RegSeqRat handoff already cited in the chapter repacks this same finite interface as the regular rational consumer row.

Finally attach the seal and consumer boundary. The real-seal ledger exhaustion theorem Definition 371.18 places the Real$^{\uparrow}$ seal after the common finite rows, and Definition 371.46 rules out any route through quotient streams, host sequences, selected limits, independent real carriers, or ambient completeness. Thus the two reads share exactly the finite cover named in the statement. □

Theorem 371.48 (RegularCauchyName window source determinacy)**.** *Let two accepted* RegularCauchyName$^{\uparrow}$ *consumer precision reads display the same* StreamName$^{\uparrow}$ *finite window, the same* DyadicRatCore$^{\uparrow}$

observation, the same dyadic-radius row, the same $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, the same finite ledger, the same* $\mathsf{Real}^{\uparrow}$ *seal, and the same* BHist, hsame, Cont, Pkg, *and* NameCert *provenance. Then the two reads determine the same* $\mathsf{RationalStream}^{\uparrow}$ *source admission and the same* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *handoff, up to the displayed transport rows. In particular, no separate host sequence, quotient stream, selected limit, independent real carrier, or ambient completeness coordinate can distinguish the two source windows.*

Proof. Read both precision requests through the normalized readback packet. By window normalization coverage, each request reaches its seal only after the displayed $\mathsf{StreamName}^{\uparrow}$ window, dyadic observation, radius row, classifier, ledger, and provenance rows have been fixed.

The equality of the displayed rows then fixes the source side. RationalStream source admission reads no data beyond the scheduled source rows and the BHist, hsame, Cont, Pkg, and NameCert provenance, so the two source admissions coincide along the stated transport rows.

It remains to identify the finite-window handoff. The FiniteWindowEnvelope handoff theorem uses exactly the same window, dyadic ledger, regular-sequence seal route, and $\mathsf{Real}^{\uparrow}$ endpoint. Normalized readback seal stability carries the common seal boundary across the displayed transports, leaving no additional coordinate able to separate the two reads. □

Theorem 371.49 (RegularCauchyName StreamName Real seal factorization)**.** *Every downstream* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *read of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet factors first through the* $\mathsf{StreamName}^{\uparrow}$ *finite window and then through the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal before reaching the* $\mathsf{Real}^{\uparrow}$ *seal. The factorization is carried by the normalized readback packet and its displayed* BHist, hsame, Cont, Pkg, *and* NameCert *provenance, not by a quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness row.*

Proof. Start with any named downstream consumer read. The root-unblock normalization package says that the consumer receives the normalized readback packet rather than an external completion object.

Inside that packet, the order of access is fixed. The normalized window readback definition places the $\mathsf{StreamName}^{\uparrow}$ finite window before the transported dyadic observation, radius row, pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier, finite ledger, and $\mathsf{Real}^{\uparrow}$ seal; the FiniteWindowEnvelope handoff identifies this middle segment as the finite-window envelope.

The Real seal is therefore reached only after the regular-sequence seal route. The real-completion consumer triangle supplies the downstream consumer row, while normalized readback seal stability preserves the same BHist-anchored transport and package provenance. Hence each named downstream read factors through the StreamName window and RegSeqRat seal before it can read the Real seal. □

Definition 371.50 (RegularCauchyName root dependency manifest)**.** *For an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet* $G = (S, Q, \rho, L, E, P, N)$ *whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$, *the root dependency manifest of* G *is the finite BEDC packet*

$$\mathsf{RootDep}_{\mathsf{RegularCauchyName}^{\uparrow}}(G) = (U, R, S, F, L, W, B, D, A, E, C)$$

whose rows are, respectively, the $\mathsf{UnaryHistory}^{\uparrow}$ *schedule row* U, *the* $\mathsf{RationalStream}^{\uparrow}$ *source row* R, *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* S, *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation and radius row* F, *the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and seal row* L, *the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *handoff row* W, *the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *consumer row* B, *the* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *consumer row* D, *the* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *consumer row* A, *the* $\mathsf{Real}^{\uparrow}$ *seal row* E, *and the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer row* C.

Its provenance is the displayed finite route

$$\mathsf{Prov}(\mathsf{RootDep}_{\mathsf{RegularCauchyName}^{\uparrow}}(G)) = (\mathsf{BHist}_G, \mathsf{hsame}_G, \mathsf{Cont}_G, \mathsf{Pkg}_G, \mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow},G})$$

where BHist_G *records the finite ledger,* hsame_G *records classifier transport on the listed rows,* Cont_G *records the continuation routes between consumer reads,* Pkg_G *records the package provenance, and* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow},G}$ *records the local naming certificate. The manifest contains no row outside this displayed dependency list.*

Theorem 371.51 (RegularCauchyName root dependency manifest exhaustion)**.** *Every downstream read of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet by* $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *factors through the root dependency manifest of Definition 371.50. In particular, the read reaches its source, finite-window handoff, normalized readback,* $\mathsf{Real}^{\uparrow}$ *seal, and completion consumer row only through the displayed* $\mathsf{UnaryHistory}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows of that manifest.*

Proof. Begin with the source side. The RationalStream source admission theorem Definition 371.39 forces the visible source read through the $\mathsf{UnaryHistory}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, rational-observation, transport, package, and certificate rows recorded in the manifest.

Next attach the finite readback side. The FiniteWindowEnvelope handoff theorem Definition 371.40 routes each selected precision request through the finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{RegSeqRat}^{\uparrow}$ seal route, $\mathsf{Real}^{\uparrow}$ endpoint row, and the same provenance rows.

Finally add the completion side. The real-completion consumer triangle Definition 371.41 supplies the $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumer row, and the root-unblock normalization package Definition 371.45 supplies the downstream $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, and $\mathsf{RegularCauchyFamily}^{\uparrow}$ consumer rows. These four results cover every named downstream read, so each read factors through the manifest. □

Theorem 371.52 (RegularCauchyName root dependency manifest non-escape)**.** *The root dependency manifest of Definition 371.50 exports no quotient stream, host sequence, selected limit, independent real carrier, ambient completeness row, or classical choice row. Any downstream consumer of the manifest reads only the displayed finite rows and provenance routes named in the manifest.*

Proof. The source admission theorem Definition 371.39 already excludes quotient streams, selected limits, host completion objects, independent real carriers, and ambient completeness data from the RationalStream source side.

The finite-window handoff theorem Definition 371.40 repeats the same exclusion for selected precision requests and keeps them on the displayed finite-window and seal rows.

The real-completion consumer triangle Definition 371.41 and the root-unblock normalization package Definition 371.45 extend that boundary to the completion and downstream rows. Since none of the cited packets contains a coordinate for a quotient stream, host sequence, selected limit, independent real carrier, ambient completeness, or classical choice, the assembled manifest has no such export. □

Theorem 371.53 (RegularCauchyName manifest exit descent exactness)**.** *Every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose root dependency manifest is displayed descends to the Phase Real and Completion terminal exit exactly through the* $\mathsf{StreamName}^{\uparrow}$ *finite-section descent gluing row, the four-object*

StreamName$^{\uparrow}$ *route, and the* Real$^{\uparrow}$ *terminal seal manifest exit consumer. The resulting read uses only the displayed* UnaryHistory$^{\uparrow}$, RationalStream$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, FiniteWindowEnvelope$^{\uparrow}$, RegularCauchySubsequence$^{\uparrow}$, RegularCauchyDiagonal$^{\uparrow}$, RegularCauchyFamily$^{\uparrow}$, Real$^{\uparrow}$, RealCauchyCompletion$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows of Definition 371.50. It uses no quotient stream, host sequence, selected limit, independent real carrier, ambient completeness row, metric completeness row, countable-choice row, or bridge row.*

Proof. Begin with the local manifest. The exhaustion theorem Definition 371.51 says that every downstream RegularCauchyName$^{\uparrow}$ read reaches its source, finite-window handoff, normalized readback, Real$^{\uparrow}$ seal, and completion consumer only through the displayed root dependency manifest.

Now route the StreamName face. Apply Definition 126.594 to identify the finite-section descent row, and then apply Definition 126.500 to read that row through the current four-object Phase Real and Completion route. The visible exit coordinates are therefore the StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ faces already listed in the manifest, with the same BHist, hsame, Cont, Pkg, and NameCert support.

Finally apply the Real terminal consumer exactness theorem Definition 38.830. It identifies the terminal Real$^{\uparrow}$ seal consumer with the manifest exit surface. The non-escape theorem Definition 371.52 removes every non-displayed route, so the descent has no quotient stream, host sequence, selected limit, independent real carrier, ambient or metric completeness witness, countable-choice coordinate, or bridge row. □

Theorem 371.54 (RegularCauchyName Phase Real and Completion exit interface)**.** *Every accepted* RegularCauchyName$^{\uparrow}$ *packet whose root dependency manifest is displayed presents the source-side interface of the four-object Phase Real and Completion exit exactly through* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows of Definition 371.50. The interface exports no quotient stream, host sequence equality, selected limit, independent real carrier, ambient completeness, metric completeness, countable choice, or bridge row.*

Proof. Start from Definition 371.53. It identifies every accepted manifest-displayed RegularCauchyName$^{\uparrow}$ packet with the terminal exit descent and restricts that descent to the finite rows already recorded in Definition 371.50.

Next read the descent through the four-object route. The StreamName route theorem Definition 126.500 gives the StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ boundary, while Definition 38.726 says that this L10 interface has no additional carrier or support coordinate beyond those four faces and the displayed BEDC support rows.

Finally apply Definition 38.830. It pins the terminal Real$^{\uparrow}$ consumer to the same manifest exit surface. The exactness and exhaustion results together leave only the listed BHist, hsame, Cont, Pkg, and NameCert rows as support, and exclude quotient streams, host sequence equality, selected limits, independent real carriers, ambient or metric completeness, countable choice, and bridge rows. □

Theorem 371.55 (RegularCauchyName window-successor closure)**.** *Let an accepted* RegularCauchyName$^{\uparrow}$ *packet display the source-side Phase Real and Completion interface of Definition 371.54. If a successor finite* StreamName$^{\uparrow}$ *window refines the displayed window through the same root dependency manifest, then the successor read preserves the dyadic-radius row, the* RegSeqRat$^{\uparrow}$ *readback route, and the terminal* Real$^{\uparrow}$ *seal route of the packet. The successor step exports no host sequence, quotient stream, selected limit, independent real carrier, ambient completeness, metric completeness, countable-choice row, or bridge row.*

Proof. Start from the finite-window envelope handoff and the displayed manifest. The handoff keeps the successor request on the same $\mathsf{StreamName}^{\uparrow}$ observation schedule and the same dyadic tolerance ledger.

Apply the common-window classifier scope for $\mathsf{StreamName}^{\uparrow}$ windows. The successor window extends the inspected rows componentwise, so the dyadic-radius row and the $\mathsf{RegSeqRat}^{\uparrow}$ readback are transported rather than replaced.

Finally use the Phase Real exit interface. It pins the successor read to the same $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces and to the same BHist, hsame, Cont, Pkg, and NameCert support. Since none of those rows contains a host sequence, quotient stream, selected limit, independent real carrier, ambient completeness, metric completeness, countable choice, or bridge coordinate, the successor closure has no such export. □

Theorem 371.56 (RegularCauchyName four-face support minimality)**.** *An accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet with displayed root dependency manifest presents the Phase Real and Completion source-side interface if and only if its public support is exactly the four-face packet* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$ *together with the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows of Definition 371.50. No fifth support coordinate can be adjoined unless it is one of the refused rows: quotient stream, host sequence equality, selected limit, independent real carrier, ambient completeness, metric completeness, countable choice, or bridge row.*

Proof. The forward direction starts from the displayed manifest. By Definition 371.50, the only support rows available at the root are the named source, finite-window, regularity, handoff, consumer, real-seal, completion, provenance, package, and certificate rows. The exhaustion theorem Definition 371.51 says that every downstream read of the accepted packet factors through that list.

The exclusion part is supplied by Definition 371.52. It removes quotient streams, host sequence equality, selected limits, independent real carriers, ambient completeness, metric completeness, countable choice, and bridge data from the exported support. Thus any proposed fifth coordinate is either already one of the displayed rows or belongs to the refused list and cannot serve as additional support.

It remains to identify the exact four-face boundary. The descent exactness theorem Definition 371.53 carries the manifest to the terminal exit, and Definition 371.54 identifies that exit with the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ public interface together with the displayed BEDC support rows. Conversely, those four faces and rows are precisely the support used by the exit-interface theorem, so the same manifest presents the source-side interface. □

Theorem 371.57 (RegularCauchyName terminal exit no extra support)**.** *Any accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet with displayed root dependency manifest that satisfies the four-face support minimality theorem presents the Phase Real and Completion terminal exit with no support beyond* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows of Definition 371.50. The terminal exit exports no quotient stream equality, host sequence equality, selected limit, independent real carrier, ambient completeness, metric completeness, countable choice, or bridge row.*

Proof. First descend the displayed manifest to the terminal exit. The manifest exit descent exactness theorem Definition 371.53 identifies the accepted packet with the Phase Real and Completion exit read and keeps that read on the displayed root manifest rows.

Next identify the public boundary of that exit. The exit-interface theorem Definition 371.54 names exactly the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces together with the displayed BHist, hsame, Cont, Pkg, and NameCert support.

Finally apply the four-face support minimality theorem Definition 371.56 and the root dependency manifest non-escape theorem Definition 371.52. Minimality forbids adding a fifth support coordinate to the four-face interface, while non-escape refuses the quotient stream equality, host sequence equality, selected limit, independent real carrier, ambient or metric completeness, countable-choice, and bridge rows. Hence the terminal exit has exactly the displayed support and no additional row. □

Theorem 371.58 (RegularCauchyName RationalStream completion seal triangle)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$*, the* $\mathsf{RationalStream}^{\uparrow}$ *source admission, normalized* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion consumer route determine one finite* BHist *consumer surface. The surface is the root dependency manifest of Definition 371.50 read through the public* $\mathsf{Real}^{\uparrow}$ *seal factorization of* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*. It contains no quotient stream, selected limit, host real equality, independent real carrier, or ambient completeness coordinate.*

Proof. First assemble the source and window sides. The RationalStream source admission theorem Definition 371.39 fixes the scheduled $\mathsf{RationalStream}^{\uparrow}$ source, while the root dependency manifest exhaustion theorem Definition 371.51 places the normalized $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal in the same displayed manifest.

Next attach the completion consumer. The public $\mathsf{Real}^{\uparrow}$ seal factorization for $\mathsf{CauchyCompletionMonad}^{\uparrow}$, Definition 378.5, routes every completion-facing seal read through its finite schedule, window, dyadic observation, diagonal readback, seal, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. Along the RegularCauchyName route, those rows are exactly the completion face already recorded by the manifest.

Finally apply the non-escape boundary of Definition 371.52. Since the manifest and the completion-monad seal factorization share the same finite provenance surface and neither exposes a quotient stream, selected limit, host real equality, independent real carrier, or ambient completeness coordinate, the admitted rational source and the completion consumer determine one finite BHist consumer surface. □

Theorem 371.59 (RegularCauchyName Real-completion selector seal compatibility)**.** *Let G be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$*. Any selector-facing* $\mathsf{RealCompleteness}^{\uparrow}$ *or* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *consumer that reads the displayed finite window of G, its dyadic radius row, its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and its* $\mathsf{Real}^{\uparrow}$ *seal factors through two displayed routes: the root dependency manifest of Definition 371.50, and the ordered selector route*

$$\mu, \Delta, D, W, Q, S$$

of Definition 450.43. Consequently the selector-presented seal and the $\mathsf{RegularCauchyName}^{\uparrow}$ *finite-window seal expose the same finite* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *surface. They expose no quotient stream, selected host limit, host equality, choice row, or ambient completeness theorem.*

Proof. First read the $\mathsf{RegularCauchyName}^{\uparrow}$ side. The root dependency manifest exhaustion theorem Definition 371.51 places every downstream source, finite-window, readback, $\mathsf{Real}^{\uparrow}$ seal, and completion-consumer read of G inside the finite manifest of Definition 371.50.

Next attach the completion-facing seal. The RationalStream completion seal triangle Definition 371.58 identifies the admitted rational source, normalized window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, and $\mathsf{CauchyCompletionMonad}^{\uparrow}$ consumer route with one finite BHist consumer surface.

Now compare the selector presentation. The selector-window-seal factorization theorem Definition 450.43 orders every selector-facing $\mathsf{RealCompleteness}^{\uparrow}$ read as μ, Δ, D, W, Q, S, with transport, route replay, package provenance, and local naming carried by the same finite seal surface.

Finally apply the non-escape theorem Definition 371.52. Since both routes read only the displayed finite rows and the provenance coordinates BHist, hsame, Cont, Pkg, and NameCert, neither presentation can export a quotient stream, selected host limit, host equality, choice row, or ambient completeness theorem. □

Theorem 371.60 (RegularCauchyName Real-completion handoff spine)**.** *Every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$ *factors all Real-and-Completion consumer reads through the displayed finite route: the* $\mathsf{RationalStream}^{\uparrow}$ *source admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion consumer, and the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance rows. This route is the public handoff surface for Real-and-Completion consumers. It exports no quotient stream equality, selected limit, host real equality, choice row, or ambient completeness principle.*

Proof. First locate every consumer read in the root manifest. The root dependency manifest exhaustion theorem Definition 371.51 places the source, finite window, dyadic radius row, pointwise readback, $\mathsf{Real}^{\uparrow}$ seal, completion consumer, and provenance coordinates inside the finite manifest of Definition 371.50.

Next compress the admitted RationalStream route to the completion-facing surface. The RationalStream completion seal triangle Definition 371.58 identifies the $\mathsf{RationalStream}^{\uparrow}$ source admission, normalized $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, and $\mathsf{CauchyCompletionMonad}^{\uparrow}$ completion consumer as one finite BHist consumer surface.

Then compare this surface with the selector-facing Real-and-Completion presentation. The selector seal compatibility theorem Definition 371.59 carries the same finite route across every selector-facing $\mathsf{RealCompleteness}^{\uparrow}$ or $\mathsf{CauchyCompletionMonad}^{\uparrow}$ read, including the hsame, Cont, Pkg, and NameCert rows.

Finally apply the non-escape boundary of Definition 371.52. Since the manifest, completion seal triangle, and selector-compatible route expose only the displayed finite rows, no Real-and-Completion consumer read can acquire quotient stream equality, a selected limit, host real equality, a choice row, or an ambient completeness principle from this handoff. □

Theorem 371.61 (RegularCauchyName Real-completion prefix determinacy)**.** *Let G be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$*. Suppose two Real-and-Completion consumer reads of G use the same* $\mathsf{RationalStream}^{\uparrow}$ *source admission, the same finite* $\mathsf{StreamName}^{\uparrow}$ *window, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, the same pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the same* $\mathsf{Real}^{\uparrow}$ *seal, and the same* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *consumer coordinate. Then both reads factor through the same finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *surface of the root dependency manifest of Definition 371.50. Consequently the two reads cannot diverge into quotient stream equality, selected host limits, host real equality, choice rows, or ambient completeness data.*

Proof. First identify the shared finite surface. The RationalStream completion seal triangle Definition 371.58 turns the common source admission, finite window, readback, $\mathsf{Real}^{\uparrow}$ seal, and completion consumer coordinate into one finite BHist consumer surface.

Next compare the selector-facing presentations. The selector seal compatibility theorem Definition 371.59 routes any compatible Real-and-Completion consumer read through that same finite surface and through the displayed hsame, Cont, Pkg, and NameCert coordinates.

Now apply the handoff spine Definition 371.60. Since both reads have the same source, window, radius, readback, seal, and completion coordinate, the public handoff route leaves no second finite prefix through which either read can be separated.

Finally use the root manifest non-escape theorem Definition 371.52. The shared prefix exports only the displayed finite provenance rows, so neither read can branch into quotient stream equality, selected host limits, host real equality, choice rows, or ambient completeness data. □

Theorem 371.62 (RegularCauchyName facewise exit handoff completeness)**.** *Let G be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$*. Its Real-and-Completion handoff is complete precisely through the four displayed L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, together with the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. Omitting any one of these faces, or replacing one by quotient stream equality, a selected host limit, host real equality, countable choice, ambient completeness, metric completeness, or a bridge row, lies outside the accepted handoff.*

Proof. First build the displayed handoff surface. The handoff spine Definition 371.60 places every Real-and-Completion consumer read of G on the source admission, finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ radius row, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, completion consumer, and provenance rows. The prefix determinacy theorem Definition 371.61 then shows that this visible prefix leaves no second finite surface through which two such reads can diverge.

Next identify the face list with the exit criterion. The tail-budget handoff theorem Definition 371.78 fixes the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ side of the finite tail budget, while the Real L10 facewise status theorem Definition 38.537 records that the displayed Real exit faces are not interchangeable with quotient, choice, bridge, or host-completion substitutes.

Finally apply the root manifest non-escape theorem Definition 371.52. Since the accepted packet exports only the four displayed L10 faces and the listed BHist, hsame, Cont, Pkg, and NameCert support rows, removing a face or replacing it by any refused quotient, limit-selection, equality, choice, completeness, or bridge coordinate leaves the RegularCauchyName handoff rather than completing it. □

Theorem 371.63 (RegularCauchyName Real-completion exit threshold equivalence)**.** *Let G be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$*. The packet presents the current Phase Real and Completion exit threshold if and only if its accepted handoff exposes exactly the four local faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, each face carries its own local objectwise exit-threshold record, and the only support rows beyond those faces are the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of the RegularCauchyName handoff.*

Equivalently, the threshold is read object by object on the four displayed faces. It is not supplied by quotient stream equality, selected limits, host real equality, countable choice, ambient completeness, metric completeness, an aggregate formalstatus *row, an aggregate bridge row, or a standard-bridge substitute.*

Proof. For the forward direction, apply Definition 371.62. Any accepted Real-and-Completion handoff for G is already complete exactly through the four displayed faces and the BHist, hsame, Cont, Pkg, and NameCert support rows.

Next apply Definition 371.78. The $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ sides of the handoff remain stable under the certified tail-budget route, so the objectwise threshold read cannot be moved to a quotient stream, selected limit, host sequence equality, choice row, ambient completeness witness, or metric-completeness datum.

Use Definition 38.494 to identify the current Phase Real and Completion threshold. That result reads the threshold from the four local face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with each face carrying its own local theory-closure and audit-clean verification rows.

For the reverse direction, suppose the four displayed faces expose their local objectwise exit-threshold records and the packet carries only the stated BHist, hsame, Cont, Pkg, and NameCert support rows. Apply Definition 38.494 to read those four records as the current exit threshold, and then apply Definition 371.62 to identify the same four records as the complete RegularCauchyName handoff surface.

Finally apply Definition 38.537. Aggregate route-level formalstatus rows, aggregate bridge rows, quotient streams, selected host limits, ambient completeness rows, metric-completeness rows, countable-choice rows, and standard-bridge substitutes cannot replace any one of the four local threshold faces, so the equivalence is exactly the displayed objectwise threshold. □

Theorem 371.64 (RegularCauchyName exit-threshold nonescape boundary)**.** *Let G be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$*. If G satisfies the Real-and-Completion exit threshold through the four displayed faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, then the same handoff does not supply quotient stream equality, selected limits, host real equality, countable choice, ambient completeness, metric completeness, an aggregate* formalstatus *row, an aggregate* leantarget *row, aggregate bridge data, or a* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Equivalently, the RegularCauchyName handoff witnesses only the objectwise L10 threshold on those four faces together with the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. Every stronger read listed above lies outside the accepted threshold surface.*

Proof. First identify the positive threshold surface. By Definition 371.63, satisfying the Real-and-Completion exit threshold is exactly the exposure of the four local faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with only the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Next compare that surface with the handoff completeness criterion. Apply Definition 371.62. The accepted handoff is complete precisely through the four displayed faces and refuses replacements by quotient stream equality, selected host limits, host real equality, countable choice, ambient completeness, metric completeness, or bridge rows.

Now fix the stream and sequence sides. The tail-budget handoff theorem Definition 371.78 keeps the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ coordinates finite and local, so no quotient stream equality, selected limit, or host real equality is created by the same tail-budget handoff.

Finally read the Real L10 threshold objectwise. The objectwise equivalence Definition 38.494 keeps the exit criterion on the four local face records, and the facewise noncollapse theorem Definition 38.537 excludes aggregate status, aggregate target, aggregate bridge, and $\mathsf{Real}^{\uparrow}$ completeness readings from replacing those local records. Thus the RegularCauchyName handoff reaches the positive exit threshold without exporting any stronger Real-and-Completion data. □

Theorem 371.65 (RegularCauchyName exit-threshold facewise locality)**.** *Let G be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$*. Satisfying the Real-and-Completion exit threshold is equivalent to carrying four independent local exit records on* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows of the RegularCauchyName handoff.*

The equivalence is facewise. Replacing any one of the four records by aggregate formalstatus*, aggregate* leantarget*, bridge data, quotient stream equality, a selected limit, countable choice, metric completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness does not satisfy the threshold.*

Proof. First identify the threshold itself. By Definition 371.63, the Real-and-Completion exit threshold for G is exactly the exposure of the four local faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with only the listed BHist, hsame, Cont, Pkg, and NameCert support rows.

Next isolate the handoff surface. The facewise handoff completeness theorem Definition 371.62 says that the accepted RegularCauchyName handoff is complete precisely on those four faces and refuses quotient, selected-limit, equality, choice, completeness, and bridge substitutes.

Now read the StreamName and RegSeqRat coordinates locally. Apply Definition 371.78. The finite tail budget keeps the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ records objectwise, so their exit contribution cannot be moved into a quotient stream, selected host limit, host equality, countable choice, or metric-completeness datum.

Finally compare with the Real L10 objectwise criterion. The theorem Definition 38.494 reads the Phase Real and Completion threshold from the four local records, and Definition 38.537 rules out aggregate status, aggregate target, bridge data, quotient substitutes, selected limits, countable choice, metric completeness, and ambient $\mathsf{Real}^{\uparrow}$ completeness as replacements for any one face. Therefore the threshold is exactly the four independent local records plus the displayed support rows. □

Theorem 371.66 (RegularCauchyName finite-section terminal pullback coherence)**.** *Let G be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$*. Let F be an accepted* $\mathsf{FiniteRealSection}^{\uparrow}$ *packet reading the same displayed* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal row, and the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support as the exit-threshold handoff of G. Then the RegularCauchyName exit-threshold handoff and the finite-section consumer route determine one finite terminal pullback packet.*

This packet is the common finite BHist *section whose StreamName-facing and Real-facing terminal reads are identified by the Real finite-request terminal route. It contains no quotient stream, selected host limit, host equality, countable choice, ambient completeness, metric completeness, aggregate status row, bridge row, or second* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. First read the RegularCauchyName side. By Definition 371.63, the accepted exit threshold of G is the objectwise four-face surface on $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with only the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Next apply Definition 371.64. The same handoff cannot be enlarged by quotient streams, selected host limits, host equality, countable choice, ambient completeness, metric completeness, aggregate status rows, aggregate target rows, bridge data, or a separate $\mathsf{Real}^{\uparrow}$ completeness claim.

Now read the finite-section side. The route consumer exactness theorem Definition 1215.5 says that an accepted $\mathsf{FiniteRealSection}^{\uparrow}$ packet using the displayed finite window, tolerance row, readback row, seal row, and support rows has exactly that finite consumer route. The nonescape theorem Definition 1215.6 rules out any additional completion or host coordinate outside the finite section.

It remains to identify the terminal packet. Apply Definition 38.705 to identify the StreamName-facing finite request with the Real-facing terminal section on the same finite BHist packet. Then apply Definition 38.708 to read the shared $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces as one accepted four-face terminal request.

The two routes therefore name one finite terminal pullback packet. Since the RegularCauchyName nonescape boundary and the FiniteRealSection nonescape theorem both refuse all coordinates beyond the displayed finite rows, the packet has no quotient stream, selected host limit,

host equality, countable choice, ambient completeness, metric completeness, aggregate status row, bridge row, or second $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 371.67 (RegularCauchyName terminal pullback exactness)**.** *Let G be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet whose visible source is admitted from* $\mathsf{RationalStream}^{\uparrow}$*, and let F be an accepted* $\mathsf{FiniteRealSection}^{\uparrow}$ *packet. Suppose G and F read the same displayed* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal row, and the same* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *support. Then every Real-and-Completion consumer read compatible with both projections factors through the finite terminal pullback packet of Definition 371.66.*

The two projections are jointly determining: once the RegularCauchyName handoff projection and the FiniteRealSection route projection agree on the displayed rows, there is a unique compatible finite consumer route. No quotient stream, selected host limit, host equality, countable choice, ambient completeness, metric completeness, aggregate status row, bridge row, or second $\mathsf{Real}^{\uparrow}$ *seal can be added to that route.*

Proof. First identify the RegularCauchyName exit surface. Apply Definition 371.63 to read the accepted handoff of G as the four local faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ with only the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows.

Next apply Definition 371.64. The same handoff cannot acquire quotient streams, selected host limits, host equality, countable choice, ambient completeness, metric completeness, aggregate status rows, aggregate target rows, bridge data, or a separate $\mathsf{Real}^{\uparrow}$ completeness claim.

Now read the finite-section projection. The route consumer exactness theorem Definition 1215.5 pins every compatible $\mathsf{FiniteRealSection}^{\uparrow}$ consumer to the displayed finite window, tolerance row, readback row, seal row, and support rows. The nonescape theorem Definition 1215.6 excludes any completion or host coordinate outside that finite route.

It remains to compare the two projections. By Definition 371.66, the RegularCauchyName handoff and the finite-section route determine one finite terminal pullback packet over the shared rows. Apply Definition 38.705 to identify the StreamName-facing request with the Real-facing terminal section on that packet, and use Definition 38.708 to read the four displayed faces as one accepted terminal request.

Therefore any Real-and-Completion consumer compatible with both projections must factor through that terminal pullback packet. Since both nonescape results refuse every coordinate beyond the displayed finite rows, the two projections are jointly determining and no quotient stream, selected host limit, host equality, countable choice, ambient completeness, metric completeness, aggregate status row, bridge row, or second $\mathsf{Real}^{\uparrow}$ seal can be attached. □

Theorem 371.68 (RegularCauchyName scheduled observation source totality)**.** *For every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, each unary schedule row admitted by the packet supplies a certified* $\mathsf{RationalStream}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ *observation row together with the displayed package provenance route. The supplied row is read through the packet's* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *coordinates, and every scheduled source read reaches one of these certified rows before it can be consumed by* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*.*

Proof. Induct over the finite schedule rows displayed by the accepted packet. The empty schedule has no requested observation, so the totality claim is the empty projection of the same BHist packet.

For a retained row, the RationalStream source admission theorem supplies the $\mathsf{RationalStream}^{\uparrow}$ source row, while the normalized window readback definition records the corresponding $\mathsf{StreamName}^{\uparrow}$

finite window and dyadic observation route. The displayed hsame and Cont rows transport this observation without introducing a second source.

The package provenance route is then the stored Pkg coordinate, with the local $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ row certifying that the observation belongs to the accepted packet. Repeating this projection along the finite schedule exhausts every scheduled source read. □

Theorem 371.69 (RegularCauchyName radius ledger monotone readback)**.** *In an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, the dyadic-radius ledger is monotone under certified unary index extension: extending a schedule row along the displayed* hsame *and* Cont *route can only read a radius row already compatible with the earlier request and the later certified request. Every such readback remains inside the* $\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *tolerance surface carried by the normalized finite-window packet.*

Proof. Begin with the two certified unary index rows. The normalized window readback definition reads both through the same $\mathsf{StreamName}^{\uparrow}$ window surface, dyadic observation row, radius row, finite ledger, and package provenance.

Use the radius obligations already carried by the packet. The earlier radius request is preserved by classifier transport, and the later request extends it through the displayed continuation route, so the ledger read is monotone inside the stored finite radius table.

Finally apply window normalization coverage. It forces every consumer precision read to pass through the normalized window before the $\mathsf{RegSeqRat}^{\uparrow}$ classifier or $\mathsf{Real}^{\uparrow}$ seal is reached, so the readback remains inside the $\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ tolerance surface. □

Theorem 371.70 (RegularCauchyName RegSeqRat Real seal root unblock)**.** *The scheduled observation source rows of Definition 371.68 and the monotone radius ledger of Definition 371.69 assemble a finite root-unblock package for every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet. This package is consumable by the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal route and the* $\mathsf{Real}^{\uparrow}$ *handoff, and it uses the displayed* $\mathsf{StreamName}^{\uparrow}$ *handoff, semantic* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *certificate,* BHist*,* hsame*,* Cont*, and* Pkg *rows rather than quotient streams or host equality.*

Proof. First assemble the source half of the package. Scheduled source totality supplies each unary row with its certified $\mathsf{RationalStream}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ observation and provenance route.

Next assemble the radius half. Radius-ledger monotone readback keeps each certified index extension inside the dyadic tolerance surface and the pointwise $\mathsf{RegSeqRat}^{\uparrow}$ classifier ledger.

Finally attach the seal handoffs. The StreamName handoff, normalized readback seal stability, and root-unblock normalization package carry the assembled rows to the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers. The semantic naming certificate is already part of the packet, so no quotient stream, host equality, selected limit, or ambient completeness coordinate is needed. □

Theorem 371.71 (RegularCauchyName tail-window consumer factorization)**.** *Every tail-window consumer of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet factors through the scheduled observation row, the monotone dyadic-radius ledger, the normalized finite-window readback, and the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *seal route. The factorization reads only the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *coordinates. It cannot inspect quotient streams, selected limits, host sequence equality, independent real equality, or ambient completeness.*

Proof. First bind the tail-window request to its scheduled source. The scheduled observation source totality theorem Definition 371.68 supplies the certified $\mathsf{RationalStream}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ observation row and package provenance before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer can read the packet.

Next route the tolerance information. The radius-ledger monotone readback theorem Definition 371.69 keeps certified index extensions inside the displayed $\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ tolerance surface, while window normalization coverage Definition 371.43 forces each precision read through the normalized finite-window packet.

Finally attach the terminal seal route. The RegSeqRat Real seal root unblock theorem Definition 371.70 carries the scheduled source and radius ledger to the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers. The closure boundary records no quotient stream, selected limit, host sequence equality, independent real equality, or ambient completeness row, so the tail-window consumer has no escape from the displayed factorization. □

Theorem 371.72 (RegularCauchyName tail-window budget coherence)**.** *Let R be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, and let U and V be two accepted tail-window consumer reads of R whose requested precisions share a certified budget row in the dyadic-radius ledger. Then U and V factor through the same finite* $\mathsf{StreamName}^{\uparrow}$ *window, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, the same dyadic-radius ledger row, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row, and the same* $\mathsf{Real}^{\uparrow}$ *seal row. The common factorization is displayed through the packet's* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *provenance, and it contains no quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness coordinate.*

Proof. First read the source rows. The scheduled observation source totality theorem Definition 371.68 supplies the certified $\mathsf{RationalStream}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ observation rows for both U and V through the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ provenance.

Next compare the certified budget row. The radius ledger monotone readback theorem Definition 371.69 keeps each accepted precision read inside the same dyadic tolerance surface once the two requests share a certified ledger budget. The synchronized precision pullback theorem Definition 371.35 refines the two reads to one finite $\mathsf{StreamName}^{\uparrow}$ window and one $\mathsf{DyadicRatCore}^{\uparrow}$ observation row.

Finally apply tail-window consumer factorization. By Definition 371.71, both terminal reads reach the $\mathsf{RegSeqRat}^{\uparrow}$ classifier and the $\mathsf{Real}^{\uparrow}$ seal only through that shared finite window, dyadic observation row, ledger row, and provenance surface. Since the factorization exposes no coordinate for a quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness premise, the common budget row is coherent for both accepted consumers. □

Theorem 371.73 (RegularCauchyName shared budget triple pullback)**.** *Let R be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, and let U, V, and W be three accepted tail-window consumer reads of R whose requested precisions share one certified budget row in the dyadic-radius ledger. Then U, V, and W factor through one finite* $\mathsf{StreamName}^{\uparrow}$ *window, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, one dyadic-radius ledger row, one* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row, and one* $\mathsf{Real}^{\uparrow}$ *seal row. The common pullback is displayed only through the packet's* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *provenance, and it exports no quotient stream, host sequence, selected limit, independent real carrier, or ambient completeness coordinate.*

Proof. First read the three scheduled sources. The scheduled observation source totality theorem Definition 371.68 supplies the certified $\mathsf{RationalStream}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ observation source for each of U, V, and W through the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ rows.

Next pull all three precision requests back to the shared budget row. The radius ledger monotone readback theorem Definition 371.69 keeps each accepted request inside the same dyadic tolerance surface, and the synchronized precision pullback theorem Definition 371.35 identifies the finite window route attached to that certified row.

Apply the pairwise budget coherence theorem Definition 371.72 first to U and V, and then to U and W. The first application gives a common finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ observation row, dyadic-radius ledger row, $\mathsf{RegSeqRat}^{\uparrow}$ classifier row, and $\mathsf{Real}^{\uparrow}$ seal row for U and V. The second application gives the same kind of route for U and W.

Finally compare the two pairwise routes at the shared budget row. Since both routes contain the U consumer read and the same certified ledger row, they identify the same normalized finite-window readback and therefore the same downstream $\mathsf{RegSeqRat}^{\uparrow}$ classifier and $\mathsf{Real}^{\uparrow}$ seal. Tail-window consumer factorization Definition 371.71 keeps all three terminal reads inside this displayed provenance surface. □

Theorem 371.74 (RegularCauchyName shared budget finite intersection)**.** *Let R be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, and let $\mathcal{F}$ be a finite nonempty family of accepted tail-window consumer reads of R whose requested precisions share one certified budget row in the dyadic-radius ledger. Then all reads in $\mathcal{F}$ factor through one finite* $\mathsf{StreamName}^{\uparrow}$ *window, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, one dyadic-radius ledger row, one* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row, and one* $\mathsf{Real}^{\uparrow}$ *seal row. The common intersection is displayed only through the packet's* BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *provenance, with no quotient stream, selected limit, host sequence equality, independent real carrier, or ambient completeness coordinate.*

Proof. Induct over the finite family $\mathcal{F}$ after choosing one accepted read as the anchor. The one-read case is the tail-window consumer factorization of Definition 371.71; the first nontrivial two-read case is exactly the shared budget coherence theorem Definition 371.72.

For the three-read stage, apply the triple pullback theorem Definition 371.73. It identifies one finite $\mathsf{StreamName}^{\uparrow}$ window, one $\mathsf{DyadicRatCore}^{\uparrow}$ observation row, one ledger row, one $\mathsf{RegSeqRat}^{\uparrow}$ classifier row, and one $\mathsf{Real}^{\uparrow}$ seal row for the anchor and the two additional reads at the displayed shared budget.

For the induction step, assume the retained finite subfamily already factors through one displayed route. Compare that common route with the next accepted read at the same certified budget row. The pair theorem Definition 371.72 applies to the anchor read inside the common route and to the next read, so the next read is pulled back to the same finite window, dyadic observation row, ledger row, classifier row, and seal row.

Finally use tail-window consumer factorization again to close the boundary condition. Since every retained route is read through BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$, the finite intersection has no coordinate for quotient streams, selected limits, host sequence equality, independent real carriers, or ambient completeness. □

Theorem 371.75 (RegularCauchyName tail-window budget route exhaustion)**.** *Let R be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, and let $\mathcal{F}$ be a finite nonempty family of accepted tail-window consumer reads of R whose requested precisions share one certified dyadic-radius budget row. Then every terminal read in $\mathcal{F}$ is exhausted by the single finite route through the scheduled observation row, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, radius ledger row,* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row,* $\mathsf{Real}^{\uparrow}$ *seal row, and the packet's* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *provenance. This route exports no quotient stream, selected limit, host sequence equality, independent real carrier, countable-choice selector, or ambient completeness coordinate.*

Proof. First bind every consumer read to the scheduled source surface. Scheduled observation source totality Definition 371.68 supplies the certified $\mathsf{RationalStream}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ observation

row for each accepted read, and tail-window consumer factorization Definition 371.71 forces the read to pass through that row before it can reach the $\mathsf{RegSeqRat}^{\uparrow}$ classifier or $\mathsf{Real}^{\uparrow}$ seal.

Next bind the shared budget. Radius ledger monotone readback Definition 371.69 keeps every certified precision request inside the same dyadic tolerance surface, while tail-window budget coherence Definition 371.72 and shared-budget triple pullback Definition 371.73 identify the pair and triple routes attached to the common ledger row.

Finally apply shared-budget finite intersection Definition 371.74. It collapses the whole finite nonempty family to one finite $\mathsf{StreamName}^{\uparrow}$ window, one $\mathsf{DyadicRatCore}^{\uparrow}$ observation row, one radius ledger row, one $\mathsf{RegSeqRat}^{\uparrow}$ classifier row, and one $\mathsf{Real}^{\uparrow}$ seal row. The carrier inventory of the accepted packet contains only the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ provenance beyond that route, so there is no off-route terminal coordinate from which a quotient stream, selected limit, host sequence equality, independent real carrier, countable-choice selector, or ambient completeness witness could be exported. □

Theorem 371.76 (RegularCauchyName cofinal budget refinement)**.** *Let R be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, and let $\mathcal{F}$ be a finite nonempty family of accepted tail-window consumer reads of R whose requested precisions share one certified dyadic-radius budget row b. If a second certified budget row b' refines b cofinally in the packet's dyadic-radius ledger, then the terminal route supplied by Definition 371.75 refines through the same finite* $\mathsf{StreamName}^{\uparrow}$ *window, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, the same radius ledger row, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row, and the same* $\mathsf{Real}^{\uparrow}$ *seal row. The refinement is read only through the packet's* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *provenance, and it exposes no quotient stream, host sequence equality, selected limit, countable-choice selector, or ambient completeness coordinate.*

Proof. First apply tail-window budget route exhaustion Definition 371.75 to the accepted family at the certified budget row b. The result supplies a single terminal route through the scheduled observation row, finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ observation row, radius ledger row, $\mathsf{RegSeqRat}^{\uparrow}$ classifier row, and $\mathsf{Real}^{\uparrow}$ seal row.

Next use shared-budget finite intersection Definition 371.74 to keep the whole finite family on that displayed route. The cofinal refinement row b' is compared with b inside the same finite ledger surface, so no member of $\mathcal{F}$ can choose an independent downstream route.

Now apply radius-ledger monotone readback Definition 371.69. It transports every certified precision read from b to the refining row b' without leaving the $\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ tolerance surface carried by the normalized finite-window packet.

Finally apply synchronized precision pullback Definition 371.35. The pullback identifies the refining precision reads with the same finite $\mathsf{StreamName}^{\uparrow}$ window and the same $\mathsf{DyadicRatCore}^{\uparrow}$ observation row, hence with the same radius ledger row, $\mathsf{RegSeqRat}^{\uparrow}$ classifier row, and $\mathsf{Real}^{\uparrow}$ seal row already supplied by exhaustion. The accepted packet has no exported coordinate for a quotient stream, host sequence equality, selected limit, countable-choice selector, or ambient completeness witness, so the cofinal refinement remains entirely within the finite route. □

Theorem 371.77 (RegularCauchyName tail-budget refinement invariance)**.** *Let R be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, and let $\mathcal{F}$ be a finite nonempty family of accepted tail-window consumer reads of R whose requested precisions share one certified dyadic-radius budget row b. If b' is a certified cofinal refinement of b in the packet's dyadic-radius ledger, then the public seal route through scheduled observation, the finite* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, the radius ledger row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal is invariant under replacing b by b'. The invariant route is read only through the displayed* BHist, hsame, Cont,

Pkg, *and* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *rows, and it exports no quotient stream, selected limit, host sequence equality, countable-choice selector, choice row, or ambient completeness coordinate.*

Proof. Start at the original budget row b. Tail-window budget route exhaustion Definition 371.75 supplies one public terminal route for the whole finite family, passing through the scheduled observation row, finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ observation row, radius ledger row, $\mathsf{RegSeqRat}^{\uparrow}$ classifier row, and $\mathsf{Real}^{\uparrow}$ seal.

Transport this route to the refining row b'. Cofinal budget refinement Definition 371.76 keeps every accepted read in $\mathcal{F}$ on the same normalized finite-window route while changing only the certified ledger budget row. Thus the refining row cannot introduce a second downstream classifier or seal surface.

Identify the StreamName and Real faces of the transported route. StreamName finite-window reindex determinacy Definition 126.639 says that the finite observation section is unchanged under the certified reindexing data carried by the displayed packet. Real–RegSeqRat–StreamName tightness Definition 38.773 then identifies the terminal $\mathsf{Real}^{\uparrow}$ seal as the same public seal read from the common $\mathsf{StreamName}^{\uparrow}$ section, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ classifier boundary.

Finally read the carrier inventory of the accepted $\mathsf{RegularCauchyName}^{\uparrow}$ packet. The route contains only the scheduled observation support, finite StreamName window, dyadic observation row, radius ledger row, RegSeqRat classifier row, Real seal row, and the displayed BHist, hsame, Cont, Pkg, and naming provenance. There is therefore no exported coordinate for a quotient stream, selected limit, host sequence equality, countable-choice selector, choice row, or ambient completeness witness, so the terminal public seal route is invariant under the cofinal budget refinement. □

Theorem 371.78 (RegularCauchyName tail-budget StreamName–RegSeqRat handoff)**.** *Let R be an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet, and let $\mathcal{F}$ be a finite nonempty family of accepted tail-window consumer reads of R whose requested precisions share one certified dyadic-radius budget row b. Suppose the StreamName and RegSeqRat faces of the accepted route satisfy the tail-budget uniformity condition of Definition 126.105. Then the public* $\mathsf{Real}^{\uparrow}$ *seal route is exactly the finite route supplied by Definition 371.75, and replacing b by any certified cofinal refinement b' leaves that public seal route invariant as in Definition 371.77. The handoff exports no quotient stream, selected limit, host sequence equality, countable-choice selector, choice row, ambient completeness witness, or metric-completeness datum.*

Proof. First apply tail-window budget route exhaustion Definition 371.75 to the accepted family at b. This pins the scheduled observation row, finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ observation row, radius ledger row, $\mathsf{RegSeqRat}^{\uparrow}$ classifier row, and terminal $\mathsf{Real}^{\uparrow}$ seal row as one finite public route for every consumer read in $\mathcal{F}$.

Next apply StreamName–RegSeqRat tail-budget uniformity Definition 126.105 to the displayed StreamName and RegSeqRat faces. Every later finite window accepted by the same pointwise StreamName classifier is identified with the same RegSeqRat tail selector and the same Real budget consumer, so enlarging the visible StreamName window changes only the finite window ledger and not the public seal route.

Finally apply tail-budget refinement invariance Definition 371.77. A certified cofinal refinement b' of the dyadic-radius budget row transports through the already pinned finite route, hence it keeps the scheduled observation, finite StreamName window, dyadic observation row, radius ledger row, RegSeqRat classifier, and terminal Real seal unchanged.

The carrier inventory of the accepted $\mathsf{RegularCauchyName}^{\uparrow}$ packet contains only the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ provenance beyond that route. Thus the

handoff has no exported coordinate for quotient streams, selected limits, host sequence equality, countable choice, ambient completeness, or metric-completeness data. □

Theorem 371.79 (RegularCauchyName terminal finite-cover witness)**.** *Every accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet with displayed root dependency manifest and four-face support minimality admits a terminal finite-cover witness whose support consists exactly of the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows named in Definition 371.50. Every terminal* $\mathsf{Real}^{\uparrow}$ *read or completion-facing read factors through that witness, and the witness exports no quotient stream, host sequence equality, selected limit, independent real carrier, ambient completeness, metric completeness, countable-choice, or bridge row.*

Proof. First locate the source and consumer reads. The root dependency manifest exhaustion theorem Definition 371.51 places every downstream source, finite-window, readback, $\mathsf{Real}^{\uparrow}$ seal, and completion consumer read inside the displayed manifest of Definition 371.50.

Next pass from the manifest to the terminal exit. The manifest exit descent exactness theorem Definition 371.53 identifies the terminal route, and the Phase Real and Completion exit interface theorem Definition 371.54 reads that route through the four faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ together with the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Finally apply the four-face support minimality theorem Definition 371.56 and the terminal no-extra-support theorem Definition 371.57. Minimality pins the witness to exactly those four faces and support rows, while no-extra-support refuses quotient stream data, host sequence equality, selected limits, independent real carriers, ambient or metric completeness, countable-choice coordinates, and bridge rows. Thus every terminal $\mathsf{Real}^{\uparrow}$ or completion-facing read factors through the displayed finite-cover witness and no other support row is exported. □

Theorem 371.80 (RegularCauchyName terminal finite-cover refinement reflection)**.** *Let W and W' be accepted terminal finite-cover witnesses for the same* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet with displayed root dependency manifest, and suppose that W and W' admit an accepted common refinement R. If the pullbacks of W and W' to R agree on the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, *componentwise* hsame, Cont, Pkg, *and* NameCert *rows named by Definition 371.50, then W and W' present the same terminal* $\mathsf{Real}^{\uparrow}$ *read and the same completion-facing read. Conversely, sameness of those terminal reads reflects, after pullback to R, agreement on exactly those finite rows.*

The reflection is only a statement about the finite terminal support of $\mathsf{RegularCauchyName}^{\uparrow}$. *It does not identify quotient streams, host sequences, selected limits, countable-choice selectors, ambient completeness, metric completeness, aggregate formalstatus rows, bridge rows, or any row outside the root dependency manifest.*

Proof. First reduce each presentation to the terminal finite-cover witness surface. By Definition 371.79, both W and W' factor every terminal $\mathsf{Real}^{\uparrow}$ read and completion-facing read through the finite support listed in Definition 371.50. The four-face support minimality theorem Definition 371.56 pins that support to $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ with the displayed BHist, componentwise hsame, Cont, Pkg, and NameCert rows.

For the forward direction, pull W and W' back to the accepted common refinement R. The StreamName finite-cover support bicriterion Definition 126.669 reads agreement on the displayed finite rows as sameness of the descended $\mathsf{Real}^{\uparrow}$ seal-visible source. The terminal no-extra-support theorem Definition 371.57 then transfers that sameness to the terminal $\mathsf{Real}^{\uparrow}$ read and to the completion-facing read, because no fifth support coordinate can change the exit.

For the reverse direction, assume the two witnesses present the same terminal $\mathsf{Real}^{\uparrow}$ read and the same completion-facing read. Apply Definition 371.79 to express both reads through the two finite-cover witnesses, and use Definition 371.57 to remove any possible contribution from rows outside the four-face terminal surface.

It remains only to reflect agreement back to the refinement. The StreamName finite-cover support bicriterion Definition 126.669 reflects equality of the descended terminal support packet to agreement, after pullback to R, on $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, componentwise hsame, Cont, Pkg, and $\mathsf{NameCert}$. Since Definition 371.56 identifies exactly those rows as the RegularCauchyName support, this is precisely the reflected row agreement claimed.

Finally record the refusal boundary. The witness theorem and the terminal no-extra-support theorem refuse quotient stream equality, host sequence equality, selected limits, independent real carriers, ambient completeness, metric completeness, countable choice, and bridge rows; the StreamName bicriterion also refuses aggregate formalstatus rows. Therefore neither direction imports quotient stream equality, host sequence equality, selected limits, countable choice, ambient completeness, metric completeness, aggregate formalstatus, bridge data, or any row not named by the root dependency manifest. □

Definition 371.81 (RegularCauchyName carrier)**.** *A* $\mathsf{RegularCauchyName}^{\uparrow}$ *carrier is a finite source-row packet*

$$R = (W, A, T, L, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that exposes only certified observation windows.*
2. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the scheduled observations.*
3. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the radius requested at each displayed window.*
4. *L is the regularity ledger tying W, A, T to one finite Cauchy-name surface.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after the window, readback, and tolerance rows have been displayed.*
6. *H records componentwise* hsame *transport for the schedule, readback, tolerance, regularity ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the scheduled window through the dyadic tolerance and regular rational readback into the seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRepresentation}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *row.*

The carrier is the source-row face of the regular Cauchy name route used by chapter 126, chapter 301, chapter 291, chapter 38, and chapter 1680. It exports no quotient stream, host sequence equality, selected limit, independent completed real, or ambient completeness witness.

Theorem 371.82 (RegularCauchyName NameCert obligations)**.** *For an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *carrier $R = (W, A, T, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$ *obligation surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *schedule exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting, regularity-ledger exactness,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier rows of Definition 371.81. The schedule, readback, tolerance ledger, regularity ledger, seal, transport, replay, provenance, and naming rows are the only coordinates available to a consumer.

The window route is already the route of Definition 371.3; the dyadic-radius route is the route of Definition 371.2; and the seal route is the route of Definition 371.4. These rows force every consumer read through the displayed finite schedule before any regular rational readback or Real seal is consumed.

Transport and replay are exhausted by H and C, while P and N source and name the same packet. Since no coordinate stores a quotient stream, host sequence, selected limit, independent completed real, or ambient completeness witness, the listed rows are exactly the local naming obligations. □

Theorem 371.83 (RegularCauchyName StreamName-RegSeqRat handoff)**.** *Every consumer read of an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *carrier* $R = (W, A, T, L, E, H, C, P, N)$ *reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *row only through the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* W *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* T*. The handoff is the forward source-row dependency from finite windows to regular rational readback before the* $\mathsf{Real}^{\uparrow}$ *seal is exposed.*

Proof. Begin with a consumer precision request. By Definition 371.3, the request first enters a displayed $\mathsf{StreamName}^{\uparrow}$ window rather than a host sequence.

The tolerance row is then read through $\mathsf{DyadicRatCore}^{\uparrow}$. The dyadic-radius obligation theorem keeps that tolerance on the same scheduled window, so the regular rational readback in A is attached to W and T before any seal-facing row is available.

Finally apply the Real seal boundary and the finite-window readback exactness results already recorded in this chapter. They place E downstream of W, A, T, L and keep the handoff inside the displayed BHist, hsame, Cont, Pkg, and NameCert rows, with no quotient stream or selected limit added. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyName}^{\uparrow}$ packet is generated from a $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{DyadicRatCore}^{\uparrow}$ rational observations, dyadic-radius rows at certified unary indices, a finite $\mathsf{RegSeqRat}^{\uparrow}$ regularity ledger, a $\mathsf{Real}^{\uparrow}$ seal row, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature boundary package, normalized window readback, window normalization coverage, normalized readback seal stability, and root-unblock normalization package close the paper surface over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, finite-window rows, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyName}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.RegularCauchyNameUp.RegularCauchyNameUp\_StdBridge`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close real completeness, quotient equality of regular streams, uniqueness of limits, host real construction, or any stronger bridge schema.

Upgrade path: No further upgrade – chapter at top of the formal axis.

Chapter 372

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonal}^{\uparrow}$

The $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ packet names the stationary and finite-window diagonal data used by the real-completeness construction before it is repacked into the broader $\mathsf{RealDiagonalCompletion}^{\uparrow}$ surface. Its carrier is deliberately smaller than a completion theorem: it records the inspected regular Cauchy rows, the diagonal selector, the stationary rational rows, and the local naming-certificate provenance through BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. The diagonal packet consumes the $\mathsf{StreamName}^{\uparrow}$ window carrier of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback surface of chapter 301, and exports to the $\mathsf{RealDiagonalCompletion}^{\uparrow}$ consumer of chapter 359.

Definition 372.1 (Regular Cauchy diagonal source)**.** *A* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *source row is a finite* BHist *packet*

$$D = (Q, S, R, L, W, P, N)$$

whose displayed coordinates are as follows:

1. *Q is the visible* $\mathsf{Rat}^{\uparrow}$ *seed row used for stationary rational inputs;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row naming the stream windows read by the diagonal selector;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row naming the regular rational sequence selected at the requested diagonal precision;*
4. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row receiving the selected diagonal representative;*
5. *W is the finite list of requested diagonal windows and their* Cont *routes through the inspected regular Cauchy family;*
6. *P is the* Pkg *row naming the* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and local certificate dependencies;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonal}^{\uparrow}}$ *provenance row.*

The source row contains no quotient of regular streams, no selected host limit, and no ambient completeness field.

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalTasteGate single carrier alignment`

Definition 372.2 (Regular Cauchy diagonal carrier)**.** *The carrier of* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *consists of the source rows of Definition 372.1 whose diagonal windows are all read from displayed*

$\mathsf{RegSeqRat}^{\uparrow}$ *rows and whose stationary rational rows factor through the same* $\mathsf{Rat}^{\uparrow}$ *seed, the same* $\mathsf{StreamName}^{\uparrow}$ *constant-window witness, and the same* $\mathsf{Real}^{\uparrow}$ *seal row. The classifier relates two carrier rows exactly when their visible rational seeds, stream windows, regular-sequence reads, real-seal rows, and package provenance are transported componentwise by the displayed* hsame *comparisons and* Cont *routes.*

Lean4 (definition) `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier`

Theorem 372.3 (Regular Cauchy diagonal window coverage)**.** *Every consumer read of an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *carrier factors through one displayed diagonal window, one* $\mathsf{StreamName}^{\uparrow}$ *window row, one* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the associated* $\mathsf{Rat}^{\uparrow}$ *seed evidence for stationary rational rows, and the visible* Pkg *and* NameCert *provenance.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier window coverage`

Proof. Project the accepted carrier through Definition 372.2. The only consumer-facing coordinates are the diagonal-window list, the stream-window row, the regular rational readback, the real-seal row, and the local provenance rows.

For a requested precision, the diagonal selector chooses a displayed member of the regular Cauchy family and a displayed window inside that member. The Cont route in the source packet records that this window is one of the finite rows already named by the $\mathsf{StreamName}^{\uparrow}$ schedule.

The selected value is then read through the $\mathsf{RegSeqRat}^{\uparrow}$ row and, in the stationary case, through the same $\mathsf{Rat}^{\uparrow}$ seed row. Repacking these visible rows with P and N gives the claimed factorization, and there is no additional carrier coordinate from which a host limit or quotient equality could be read. □

Theorem 372.4 (Regular Cauchy diagonal stationary compatibility)**.** *If a* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *carrier row is generated by a stationary rational seed* $Q : \mathsf{Rat}^{\uparrow}$*, then every diagonal window reads the same rational seed through the constant* $\mathsf{StreamName}^{\uparrow}$ *row, and the resulting* $\mathsf{Real}^{\uparrow}$ *seal is classified with the constant rational embedding of* Q*.*

Proof. In the stationary packet, every inspected member of the regular Cauchy family is the same regular rational row. The diagonal selector may vary the requested window, but the stream row is constant and each selected observation is transported by the same displayed hsame and Cont witnesses.

Thus the $\mathsf{RegSeqRat}^{\uparrow}$ readback row carries the seed Q at every diagonal window. The $\mathsf{Real}^{\uparrow}$ seal coordinate is attached to exactly those readbacks, so the constant rational embedding receives the same rational seed and the same local provenance.

The classifier of Definition 372.2 compares only the displayed seed, window, readback, seal, and package rows. It therefore identifies the stationary diagonal carrier with the constant rational $\mathsf{Real}^{\uparrow}$ embedding of Q. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier stationary compatibility`

Theorem 372.5 (Regular Cauchy diagonal NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonal}^{\uparrow}}$ *obligation surface consists of carrier habitation, componentwise classifier transport through* hsame *and* Cont*, diagonal-window coverage, stationary rational compatibility, and ledger non-escape over* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* Pkg*, and* NameCert*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier namecert obligations`

Proof. Carrier habitation is the packaging operation of Definition 372.2: the source row supplies the rational seed, stream windows, regular-sequence readbacks, real seal, finite diagonal-window routes, and provenance rows.

Classifier transport is componentwise. Each accepted replacement is an hsame comparison of one displayed row or a Cont route identifying where that row is read inside the finite diagonal packet, so the transported packet remains within the same carrier definition.

Window coverage is exactly Definition 372.3, and stationary rational compatibility is exactly Definition 372.4. The ledger non-escape claim follows by inspecting the listed source coordinates: none is a quotient carrier, host-limit selector, ambient completeness theorem, or hidden real endpoint. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier semantic name certificate`

Theorem 372.6 (Regular Cauchy diagonal zero seed)**.** *For the source row $D = (Q, S, R, L, W, P, N)$ of Definition 372.1, the stationary rational seed with Q the zero* $\mathsf{Rat}^{\uparrow}$ *row, S the constant* $\mathsf{StreamName}^{\uparrow}$ *window row, and R the constant* $\mathsf{RegSeqRat}^{\uparrow}$ *readback inhabits the* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *carrier. Its* $\mathsf{Real}^{\uparrow}$ *seal row L, finite window ledger W, package row P, and local* NameCert *row N are all displayed finite rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier zero seed`

Proof. Start with the stationary rational seed. The zero $\mathsf{Rat}^{\uparrow}$ row supplies the same displayed rational observation at every requested diagonal precision, and the constant $\mathsf{StreamName}^{\uparrow}$ row supplies the same finite window witness for each read.

The $\mathsf{RegSeqRat}^{\uparrow}$ readback is therefore the constant regular rational row. By Definition 372.4, the resulting $\mathsf{Real}^{\uparrow}$ seal is classified with the constant rational embedding of the same seed.

Finally package the constant window routes with P and N. The carrier definition in Definition 372.2 requires no quotient stream, selected host limit, or ambient completeness field, so these displayed rows inhabit the diagonal carrier. □

Theorem 372.7 (Regular Cauchy diagonal selector stability)**.** *Let $D = (Q, S, R, L, W, P, N)$ be an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *source row. Transporting Q, S, R, L, W, P, and N componentwise by the displayed* hsame *comparisons and* Cont *routes preserves the diagonal selector classifier through the* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier selector stability`

Proof. Project the classifier from Definition 372.2. It compares only visible rational seeds, stream windows, regular-sequence readbacks, real-seal rows, finite diagonal-window routes, and provenance.

The selector uses the window list W to choose a displayed window inside the inspected regular Cauchy family. Componentwise hsame comparisons and Cont routes move exactly those displayed windows and readback rows, so the selected diagonal row remains inside the same finite packet.

Apply Definition 372.3 for the consumer-facing route and Definition 372.5 for the local certificate surface. Together they show that the transported packet preserves the selector classifier without adding quotient streams, host limits, or ambient completeness data. □

Theorem 372.8 (Regular Cauchy diagonal RealUp seal handoff)**.** *For every accepted source row $D = (Q, S, R, L, W, P, N)$, the* $\mathsf{Real}^{\uparrow}$ *seal row L is reached only through the displayed* $\mathsf{Rat}^{\uparrow}$ *seed row,* $\mathsf{StreamName}^{\uparrow}$ *window row, and* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback row. This handoff is the*

$\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonal}^{\uparrow}}$ *seal-facing route consumed by downstream* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *packets.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier real seal handoff`

Proof. Read a consumer request through Definition 372.3. The request first selects a displayed diagonal window, then reads the corresponding $\mathsf{StreamName}^{\uparrow}$ window row and $\mathsf{RegSeqRat}^{\uparrow}$ regular rational row.

In the stationary case, Definition 372.4 identifies the same route with the $\mathsf{Rat}^{\uparrow}$ seed and its constant rational $\mathsf{Real}^{\uparrow}$ embedding. In the general accepted packet, the same coordinates are carried by Q, S, R, and W.

The obligation surface of Definition 372.5 records the seal row L only after those displayed rows and the provenance rows P and N. Hence the seal handoff is finite and visible, and no host limit, quotient stream, or ambient completeness theorem is exported to downstream completion packets. □

Theorem 372.9 (Regular Cauchy diagonal completion consumer bridge)**.** *Every downstream* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *packet factors through the displayed tuple* $D = (Q, S, R, L, W, P, N)$*, the diagonal-window coverage route of Definition 372.3, and the* $\mathsf{Real}^{\uparrow}$ *seal handoff of Definition 372.8. The consumer receives no quotient stream, selected host limit, or ambient completeness row from the diagonal packet.*

Proof. Project the accepted packet through Definition 372.1 and Definition 372.2. The only exported coordinates are the rational seed Q, stream row S, regular readback R, seal row L, finite window ledger W, package row P, and local certificate row N.

Apply Definition 372.3 to route each completion read through a displayed diagonal window and its $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows. Then apply Definition 372.8 to reach L through exactly those displayed rows.

The carrier definition has no coordinate for a quotient of streams, a chosen external limit, or an ambient completeness witness. Thus any completion consumer using the accepted packet can only consume the displayed tuple and the two named routes. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier completion consumer bridge`

Theorem 372.10 (Regular Cauchy diagonal stationary seal exactness)**.** *In the stationary rational case, the completion-facing seal route of an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *packet is exactly the constant route* $\mathsf{Rat}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ *supplied by Definition 372.4 and Definition 372.8.*

Proof. Start with a stationary source row $D = (Q, S, R, L, W, P, N)$. By Definition 372.2, the stream row S is the constant-window row over the same rational seed Q, and R is the displayed regular rational readback selected from that constant stream.

Apply Definition 372.4. Every diagonal window reads the same $\mathsf{Rat}^{\uparrow}$ seed through the constant $\mathsf{StreamName}^{\uparrow}$ row and the associated $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Apply Definition 372.8. The seal row L is reached only after those displayed rows, so the route to $\mathsf{Real}^{\uparrow}$ is precisely the constant stationary route and not a route through any host completion witness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier stationary seal exactness`

Theorem 372.11 (Regular Cauchy diagonal bridge obligation package)**.** *The bridge-facing obligation package for* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *consists of five finite obligations: carrier habitation, selector stability, diagonal-window coverage, stationary seal exactness, and completion-consumer routing. Together these are the obligations needed to pass from the public diagonal packet to the bridge-facing completion surface.*

Proof. Carrier habitation is obtained by projecting Definition 372.1 into Definition 372.2. The source row supplies Q, S, R, L, W, P, and N, and the carrier condition records that the selected diagonal reads stay inside those displayed rows.

Selector stability is Definition 372.7, and diagonal-window coverage is Definition 372.3. These two obligations show that transported packets preserve the visible selector and that every consumer read has a named finite window.

Stationary seal exactness is Definition 372.10. Completion-consumer routing is Definition 372.9. Repacking these five projections gives the bridge-facing package, while the source and carrier definitions exclude quotient streams, selected host limits, and ambient completeness rows. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier bridge obligation package`

Theorem 372.12 (Regular Cauchy diagonal standard bridge source)**.** *For every accepted source row* $D = (Q, S, R, L, W, P, N)$*, the* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *bridge source is the finite tuple consisting of the* $\mathsf{Rat}^{\uparrow}$ *seed* Q*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback* R*, the* $\mathsf{Real}^{\uparrow}$ *seal* L*, the diagonal-window ledger* W*, the package row* P*, and the local* $\mathsf{NameCert}$ *row* N*, together with the displayed* BHist *carrier,* hsame *classifier,* Cont *routes, selector-stability proof, window-coverage proof, stationary-compatibility proof, and seal handoff to* $\mathsf{Real}^{\uparrow}$*. This tuple is a standard BEDC bridge source from the diagonal selector package to the real-completion consumer surface.*

Proof. Project the accepted packet through Definition 372.1 and Definition 372.2. These definitions supply exactly the visible carrier coordinates Q, S, R, L, W, P, and N, and they identify the classifier as componentwise hsame transport with displayed Cont routes.

The consumer-facing coverage row is Definition 372.3. Selector stability is Definition 372.7, and stationary rational compatibility is Definition 372.4. These three rows keep every selected diagonal read inside the displayed $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ surface.

Finally apply the local NameCert obligation surface of Definition 372.5 and the $\mathsf{Real}^{\uparrow}$ seal handoff of Definition 372.8. Repacking these rows gives the standard bridge source; no additional host completion object is needed to form the source. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier standard bridge source`

Theorem 372.13 (Regular Cauchy diagonal bridge readback exactness)**.** *Reading the* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *bridge source of Definition 372.12 back through its public surface recovers exactly the displayed tuple* $D = (Q, S, R, L, W, P, N)$*. The readback preserves the selector classifier because the only inspected rows are the* $\mathsf{Rat}^{\uparrow}$ *seed,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback,* $\mathsf{Real}^{\uparrow}$ *seal, finite window ledger, package provenance, and local* $\mathsf{NameCert}$ *provenance transported componentwise by* hsame *and* Cont*.*

Proof. Read the bridge source by projecting its carrier coordinate. By Definition 372.1, the carrier contains the seven displayed coordinates Q, S, R, L, W, P, and N and no further completion coordinate.

The bridge readback route is the same route used for diagonal-window coverage. Apply Definition 372.3 to identify the selected window and the matching $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows, then apply Definition 372.8 to identify the exported seal row as L.

It remains to check the selector classifier. This is exactly Definition 372.7: componentwise hsame and Cont transport preserves the selected diagonal row and hence preserves the public readback tuple. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier bridge readback exactness`

Theorem 372.14 (Regular Cauchy diagonal bridge non-escape)**.** *The* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *standard bridge source exports no quotient stream, no selected host limit, no ambient completeness theorem, and no host equality. Every bridge consumer read factors through the displayed tuple* $D = (Q, S, R, L, W, P, N)$*, the finite window ledger, the* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows, and the local* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier bridge non escape`

Proof. Inspect the source coordinates in Definition 372.1. The tuple lists rational seed data, stream-window data, regular rational readback data, one real-seal row, finite windows, package provenance, and local certificate provenance.

The carrier definition in Definition 372.2 adds only the displayed acceptance and classifier conditions. It does not add a quotient stream, a chosen host limit, an ambient completeness theorem, or host equality.

The bridge source of Definition 372.12 is assembled from this same carrier together with window coverage, selector stability, stationary compatibility, NameCert obligations, and the RealUp seal handoff. Therefore every bridge read remains inside those named rows, and the listed host-level objects cannot be exported by the bridge. □

Theorem 372.15 (Regular Cauchy diagonal selector-window functoriality)**.** *Let* $D = (Q, S, R, L, W, P, N)$ *be an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *source row. If the displayed* hsame *comparisons and* Cont *routes transport the visible carrier rows of* D *to another accepted carrier row, then the diagonal selector transports the same finite* W *window route through the* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *coordinates. In particular, selector transport preserves the chosen window route and does not introduce a second selector outside the displayed finite ledger.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier selector window functoriality`

Proof. Project the transport data through Definition 372.2. The classifier compares only the displayed rational seed, stream-window row, regular readback, real-seal row, finite window ledger, and provenance rows, all carried by hsame or Cont.

Apply Definition 372.7 to the transported carrier row. The selector still reads a member of the same finite ledger W, and Definition 372.3 identifies the matching $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback.

The bridge source of Definition 372.12 uses exactly these rows as its selector-facing input. Therefore the transported selector route is the displayed finite route, not a host-level re-selection or a route through an unlisted completion object. □

Theorem 372.16 (Regular Cauchy diagonal stationary-family exhaustion)**.** *Every stationary rational diagonal packet accepted by* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *is exhausted by the displayed route* $\mathsf{Rat}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$*. Equivalently, the packet has no stationary-family read outside the rational seed* Q*, the constant stream row* S*, the regular rational readback* R*, and the seal row* L *of its source tuple* $D = (Q, S, R, L, W, P, N)$*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier stationary family exhaustion`

Proof. Start with a stationary accepted carrier. By Definition 372.2, the stationary rows factor through the same $\mathsf{Rat}^{\uparrow}$ seed, the same constant $\mathsf{StreamName}^{\uparrow}$ witness, and the same $\mathsf{Real}^{\uparrow}$ seal row.

Apply Definition 372.4. Each diagonal window reads the same rational seed through the constant stream row and the associated $\mathsf{RegSeqRat}^{\uparrow}$ readback. Then apply Definition 372.10 to identify the completion-facing seal route with the displayed chain $\mathsf{Rat}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$.

Finally use Definition 372.14. Since the bridge exports no quotient stream, host limit, ambient completeness theorem, or host equality, there is no remaining stationary-family coordinate outside Q, S, R, and L. □

Theorem 372.17 (Regular Cauchy diagonal bridge route determinacy)**.** *For the standard* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *bridge source, bridge readback has exactly the displayed route through* $D = (Q, S, R, L, W, P, N)$*. Any bridge consumer read that recovers the public surface factors through the same source tuple, the same finite window ledger, and the same local* hsame*,* Cont*,* Pkg*, and* NameCert *provenance; there is no second bridge route outside* D*.*

Proof. Apply Definition 372.12. The bridge source is built from the seven displayed coordinates, the carrier classifier, the finite window route, selector stability, stationary compatibility, NameCert obligations, and the $\mathsf{Real}^{\uparrow}$ seal handoff.

Read the source back through Definition 372.13. The public readback recovers the same tuple $D = (Q, S, R, L, W, P, N)$ and preserves the selector classifier by componentwise hsame and Cont transport.

It remains to exclude competing routes. This is exactly the non-escape content of Definition 372.14: every bridge consumer read remains inside the displayed tuple, finite ledger, BEDC rows, and local provenance. Hence bridge readback is determined by D. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier bridge route determinacy`

Theorem 372.18 (Regular Cauchy diagonal mature consumer exhaustion)**.** *Every* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer read of an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *packet factors through the displayed tuple* $D = (Q, S, R, L, W, P, N)$*, the finite window ledger, the diagonal-window coverage route of Definition 372.3, the seal handoff of Definition 372.8, and the bridge route determinacy of Definition 372.17. The consumer receives no quotient stream, selected host limit, ambient completeness row, or host equality from the diagonal packet.*

Proof. Start with an accepted diagonal packet and project its carrier through Definition 372.2. The available rows are the rational seed, stream-window row, regular rational readback, real-seal row, finite window ledger, package provenance, and local certificate provenance.

Apply Definition 372.3 to identify the visible finite window ledger, and apply Definition 372.8 to identify the $\mathsf{Real}^{\uparrow}$ seal read by downstream completion packets.

The remaining possible ambiguity is the bridge route by which the consumer reads the packet. Definition 372.17 identifies that route with the same displayed tuple $D = (Q, S, R, L, W, P, N)$, and Definition 372.14 excludes quotient streams, selected host limits, ambient completeness rows, and host equality. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier mature consumer exhaustion`

Theorem 372.19 (Regular Cauchy diagonal real-completion handoff)**.** *The displayed route* $\mathsf{Rat}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ *is the completion-facing handoff from an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *packet into the current* $\mathsf{Real}^{\uparrow}$ *and completion phase boundary. The handoff is determined by stationary compatibility, stationary-family exhaustion, and bridge non-escape, and it introduces no completion object beyond the displayed seal row* L*.*

Proof. Begin with the stationary route supplied by Definition 372.4. It reads the same rational seed through the constant $\mathsf{StreamName}^{\uparrow}$ row and the associated $\mathsf{RegSeqRat}^{\uparrow}$ diagonal readback.

Apply Definition 372.16. This shows that the stationary packet has no family read outside Q, S, R, and the seal row L of $D = (Q, S, R, L, W, P, N)$.

Finally apply Definition 372.14. Since the bridge exports no quotient stream, selected host limit, ambient completeness theorem, or host equality, the only completion-facing object exposed by the route is the displayed $\mathsf{Real}^{\uparrow}$ seal row. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier real completion handoff`

Theorem 372.20 (Regular Cauchy diagonal mature closure certificate)**.** *The* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *paper surface has a mature consumer package consisting of carrier habitation, selector stability, window coverage, stationary compatibility, seal handoff, the standard bridge source, readback exactness, bridge non-escape, mature consumer exhaustion, and real-completion handoff. Consequently every accepted diagonal selector packet consumed at the current* $\mathsf{Real}^{\uparrow}$ *completion boundary is accounted for by the displayed tuple* $D = (Q, S, R, L, W, P, N)$ *and its finite ledger.*

Proof. Collect the carrier and local certificate clauses first. Carrier habitation is supplied by the local obligation package of Definition 372.5, selector stability by Definition 372.7, window coverage by Definition 372.3, stationary compatibility by Definition 372.4, and seal handoff by Definition 372.8.

Next collect the bridge-facing clauses. The standard source is Definition 372.12, readback exactness is Definition 372.13, and non-escape is Definition 372.14.

It remains to connect the bridge surface to the completion consumers. This is exactly the mature consumer exhaustion of Definition 372.18 together with the real-completion handoff of Definition 372.19. These clauses package the accepted packet as the displayed tuple and finite ledger consumed at the current $\mathsf{Real}^{\uparrow}$ completion boundary. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier mature closure certificate`

Theorem 372.21 (Regular Cauchy diagonal source stability obligation)**.** *Let* $D = (Q, S, R, L, W, P, N)$ *be an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *source row. If the displayed* hsame *comparisons and* Cont *routes transport* Q*,* S*,* R*,* L*,* W*,* P*, and* N *to another accepted source row, then carrier admission, the diagonal selector classifier, the stationary rational route, and the* $\mathsf{Real}^{\uparrow}$ *seal route are transported through the same finite tuple. No transported source read leaves the rows named in* D*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier source stability obligation`

Proof. Project D through Definition 372.1 and Definition 372.2. The classifier compares only the rational seed, stream-window row, regular readback, seal row, finite window ledger, package row, and local naming row.

Apply Definition 372.7. The displayed hsame comparisons and Cont routes preserve the selector classifier through the $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ coordinates.

For the completion-facing read, apply Definition 372.8. The seal row L is reached only after the transported source rows, so source stability is exactly the finite transport of D. □

Theorem 372.22 (Regular Cauchy diagonal window ledger exactness)**.** *For every accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *source row* $D = (Q, S, R, L, W, P, N)$*, every diagonal consumer window is exactly one of the finite entries of the displayed ledger* W*. The entry names its* $\mathsf{StreamName}^{\uparrow}$ *window, the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the stationary* $\mathsf{Rat}^{\uparrow}$ *seed route when present, and the* Cont *route by which the* $\mathsf{Real}^{\uparrow}$ *seal can later be read.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier window ledger exactness`

Proof. Start with a consumer window request. By Definition 372.3, the request factors through a displayed diagonal window, a stream-window row, a regular rational readback row, and the local provenance rows.

The carrier definition records no unlisted window source. Therefore the displayed window reached by the consumer is an entry of W, with the associated Cont route and readback rows already attached to that entry.

In the stationary case, Definition 372.4 identifies the same entry with the constant $\mathsf{Rat}^{\uparrow}$ seed route. The seal-facing route is then supplied by Definition 372.8, so the ledger entry is exact for downstream consumers. □

Theorem 372.23 (Regular Cauchy diagonal NameCert consumer surface)**.** *The public* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonal}}$ *consumer surface for* $D = (Q, S, R, L, W, P, N)$ *consists exactly of carrier admission, source stability, finite window-ledger exactness, stationary rational compatibility, selector stability, and the* $\mathsf{Real}^{\uparrow}$ *seal handoff. Each clause is read through* BHist*,* hsame*,* Cont*,* Pkg*, and the local* NameCert *row already displayed by the source tuple.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier namecert consumer surface`

Proof. First collect the local certificate rows. Carrier admission and local naming obligations are Definition 372.5; source stability is Definition 372.21.

Next collect the selector-facing rows. Window-ledger exactness is Definition 372.22, stationary rational compatibility is Definition 372.4, and selector stability is Definition 372.7.

Finally attach the seal-facing read with Definition 372.8. These rows are all projections of the finite source tuple and its displayed transport routes, so the consumer surface has no quotient stream, selected host limit, ambient completeness theorem, or host equality. □

Theorem 372.24 (Regular Cauchy diagonal real-completion handoff package)**.** *Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *or* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *source row receives the completion handoff through the tuple* $D = (Q, S, R, L, W, P, N)$*, the exact finite window ledger* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the* $\mathsf{Real}^{\uparrow}$ *seal row* L*. The handoff packages only the*

visible diagonal route and does not supply quotient streams, selected host limits, host equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier real completion handoff package`

Proof. Begin with the completion-consumer bridge of Definition 372.9. It routes every $\mathsf{RealDiagonalCompletion}^{\uparrow}$ or $\mathsf{RealCauchyCompletion}^{\uparrow}$ request through the displayed source tuple, the window coverage row, and the seal handoff.

Replace the coverage row by the exact ledger statement Definition 372.22. This identifies each requested window with an entry of W and fixes the associated $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ reads.

Then apply Definition 372.19. The completion-facing object is the displayed $\mathsf{Real}^{\uparrow}$ seal row L, reached through the finite route $\mathsf{Rat}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ where the stationary route applies. □

Theorem 372.25 (Regular Cauchy diagonal downstream-unblock package)**.** *The* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *downstream package for the real-completion diagonal route is the composition of source stability, window-ledger exactness, the NameCert consumer surface, and the real-completion handoff package. Consequently every downstream* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *or* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *read is accounted for by the displayed tuple* $D = (Q, S, R, L, W, P, N)$*, its finite ledger* W*, and the local* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

Proof. First apply Definition 372.21. This fixes the transport spine of the source tuple under the displayed hsame comparisons and Cont routes.

Next apply Definition 372.22. Every consumer window is one of the finite entries of W, with its stream-window route, regular readback, and seal-facing continuation already named.

The public certificate surface is then Definition 372.23. The real-completion read is Definition 372.24. Composing these rows gives the downstream package and excludes all non-displayed completion objects. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier downstream unblock package`

Theorem 372.26 (Regular Cauchy diagonal root source determinacy)**.** *For an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *root packet, the concrete source tuple* $D = (Q, S, R, L, W, P, N)$ *is determined as a displayed* BHist *row by the stationary* $\mathsf{Rat}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ *route, the componentwise* hsame *comparisons, the displayed* Cont *routes, the package row* Pkg*, and the local* NameCert *row. No second source for the same root packet can change* Q*,* S*,* R*,* L*,* W*,* P*, or* N *without changing one of those displayed rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier root source determinacy`

Proof. Project the root packet through Definition 372.1 and Definition 372.2. The carrier exposes exactly the seven rows Q, S, R, L, W, P, and N inside the displayed BHist packet.

The source-stability row of Definition 372.21 identifies transport of the tuple by the recorded hsame and Cont data. The stationary compatibility row of Definition 372.4 fixes the route from $\mathsf{Rat}^{\uparrow}$ through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ to the same $\mathsf{Real}^{\uparrow}$ seal.

Thus any competing root readback must agree on the carrier rows and on the Pkg and NameCert provenance. There is no hidden completion coordinate through which a different source tuple could be substituted. □

Theorem 372.27 (Regular Cauchy diagonal root selector totality)**.** *For every accepted root tuple $D = (Q, S, R, L, W, P, N)$ of* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *and every classifier-facing downstream request, the selector has a displayed finite response in the* BHist *ledger W. The response follows the route* $\mathsf{Rat}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ *and carries only the visible* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *data attached to D.*

Proof. Begin with a classifier-facing request and read the accepted packet through the carrier definition. The available selector data is the finite ledger W together with the stream row S, regular readback row R, seal row L, package row P, and naming row N.

Apply Definition 372.3. It routes the request to a displayed diagonal window, the matching $\mathsf{StreamName}^{\uparrow}$ row, and the matching $\mathsf{RegSeqRat}^{\uparrow}$ readback.

The selector-stability theorem Definition 372.7 transports this response across the recorded hsame and Cont witnesses. The real-seal handoff of Definition 372.8 then identifies the response as the same $\mathsf{Real}^{\uparrow}$ seal row. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier root selector totality`

Theorem 372.28 (Regular Cauchy diagonal root window-ledger exactness)**.** *For a root packet with source tuple $D = (Q, S, R, L, W, P, N)$, every window read used by the Real and Completion handoff is exactly one displayed entry of the finite* BHist *ledger W. That entry names the corresponding* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal route,* hsame *and* Cont *transport data,* Pkg *provenance, and local* $\mathsf{NameCert}$ *provenance; no additional window source is available.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier root window ledger exactness`

Proof. Read the downstream window through Definition 372.22. The theorem identifies the requested window with one of the finite entries in W and records the stream, regular rational, seal-facing, and provenance rows used by that entry.

The root source determinacy theorem above fixes the ambient tuple $D = (Q, S, R, L, W, P, N)$ in which this ledger lives. Hence the selected window cannot be re-read through another BHist source or through another package row.

Finally, Definition 372.14 excludes quotient streams, selected host limits, host equality, and ambient completeness rows. The ledger entry is therefore exact for the Real and Completion handoff. □

Theorem 372.29 (Regular Cauchy diagonal root seal route exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported from a root tuple $D = (Q, S, R, L, W, P, N)$ factors through the displayed* BHist *route* $\mathsf{Rat}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$*, the exact finite ledger W, the visible* hsame *and* Cont *routes, the package row* Pkg*, and the local* $\mathsf{NameCert}$ *row. The root packet exports no quotient stream, selected limit, host real equality, or ambient completeness row for the seal.*

Proof. Start from the real-seal handoff Definition 372.8. It sends the seal request through the stationary rational row, the stream window, the regular rational readback, and the displayed $\mathsf{Real}^{\uparrow}$ seal row.

Use root window-ledger exactness to locate the requested observation inside W. This names the precise BHist entry and attaches the hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows already carried by D.

The bridge non-escape theorem Definition 372.14 and mature consumer exhaustion Definition 372.18 rule out every remaining completion-side escape coordinate. Thus the seal route is exhausted by the displayed root packet. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier root seal route exhaustion`

Theorem 372.30 (Regular Cauchy diagonal root downstream-unblock package)**.** *The root obligation surface for* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *is the composition of source determinacy, selector totality, window-ledger exactness, seal route exhaustion, bridge non-escape, and mature consumer exhaustion for the concrete tuple* $D = (Q, S, R, L, W, P, N)$*. Consequently the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *and* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *handoff reads only the displayed* BHist *route* $\mathsf{Rat}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$*, the visible* hsame *and* Cont *transports, the* Pkg *row, and the local* $\mathsf{NameCert}$ *row.*

Proof. First assemble the root source, selector, and window rows. The preceding three theorems fix the tuple D, give a displayed selector response for each downstream request, and identify every requested window with an entry of W.

Next attach the seal boundary. Root seal route exhaustion identifies the completion-facing object as the same $\mathsf{Real}^{\uparrow}$ seal reached along the route $\mathsf{Rat}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$.

Finally compose Definition 372.14, Definition 372.18, and Definition 372.25. These rows show that the Real and Completion consumers obtain exactly the displayed packet and no external completion object. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier root downstream unblock package`

Theorem 372.31 (Regular Cauchy diagonal selector-fiber exhaustion)**.** *Every classifier-facing read of an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *diagonal packet factors through the displayed selector row of its source tuple* $D = (Q, S, R, L, W, P, N)$*. The factorization reads only the selected finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* W*, the corresponding* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal row* L*, and the visible* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *provenance attached to* D*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier selector fiber exhaustion`

Proof. Project the accepted packet to the carrier of Definition 372.1. The carrier exposes exactly the rational seed row, the stream-window row, the regular readback row, the seal row, the finite window ledger, the package row, and the local naming certificate.

Apply Definition 372.3 and Definition 372.22. These clauses identify every classifier-facing window read with one of the selected entries of W and attach the matching $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ observations.

Finally apply Definition 372.7 and Definition 372.23. The remaining reads are precisely the visible transport, package, and naming rows, while the seal-facing coordinate is the displayed $\mathsf{Real}^{\uparrow}$ row supplied by the same source tuple. □

Theorem 372.32 (Regular Cauchy diagonal completion-seal composition)**.** *The* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer handoff for an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *packet is the composition of stationary seal exactness, the bridge obligation package, and the real-completion handoff package. This composition adds no host sequence equality, quotient stream, selected host limit, or ambient completeness data beyond the finite diagonal selector route and the displayed* $\mathsf{Real}^{\uparrow}$ *seal.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier completion seal composition`

Proof. Start with the stationary seal clause of Definition 372.4. It fixes the constant rational source route and the associated $\mathsf{RegSeqRat}^{\uparrow}$ readback used by the diagonal selector.

Attach the bridge obligations with Definition 372.12, Definition 372.13, and Definition 372.14. These results expose the bridge source, preserve the visible readback, and rule out completion data not carried by the displayed packet.

Now apply Definition 372.31 and Definition 372.24. The selector exhaustion supplies the finite packet route, and the handoff package identifies the completion-facing object as the same $\mathsf{Real}^{\uparrow}$ seal row. □

Theorem 372.33 (Regular Cauchy diagonal downstream route factorization)**.** *Every downstream consumer route from an accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *packet through* $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *factors through the finite diagonal selector route of Definition 372.31 and the completion-seal route of Definition 372.32. No downstream route obtains an additional carrier, classifier, host equality, quotient, or completion witness outside those two displayed routes.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier downstream route factorization`

Proof. First use Definition 372.18. It says that mature consumers of the diagonal packet read the same displayed tuple, finite ledger, readback row, seal row, and local provenance.

Next use Definition 372.25. The downstream package is already the composition of source stability, window-ledger exactness, the public $\mathsf{NameCert}$ surface, and the real-completion handoff package.

The $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ portions are therefore the selector-fiber route of Definition 372.31. The $\mathsf{RealCauchyCompletion}^{\uparrow}$ portion is the completion-seal composition of Definition 372.32, so every listed downstream route factors through those two routes and no extra object is exposed. □

Theorem 372.34 (Regular Cauchy diagonal formal target boundary)**.** *The formal target for* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *is the finite tuple* $D = (Q, S, R, L, W, P, N)$ *together with selector-fiber exhaustion, completion-seal composition, downstream route factorization, and bridge non-escape. A Lean target for this chapter should prove only this finite* BHist *route over* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows, and should not prove quotient streams, selected host limits, host equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier formal target boundary`

Proof. Start with selector-fiber exhaustion from Definition 372.31. It identifies every classifier-facing read with the displayed tuple $D = (Q, S, R, L, W, P, N)$ and the finite window, dyadic, readback, seal, transport, package, and naming rows attached to it.

Next attach completion-seal composition from Definition 372.32. The completion-facing consumer reaches the same $\mathsf{Real}^{\uparrow}$ seal by the displayed diagonal selector route rather than by a host sequence equality or selected limit.

Now use downstream route factorization from Definition 372.33. It says that $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumers all factor through the selector-fiber and completion-seal routes.

Finally apply bridge non-escape from Definition 372.14. Since the bridge exports no quotient stream, selected host limit, host equality, or ambient completeness theorem, the finite tuple and its displayed BHist route are the precise formal target boundary. □

Theorem 372.35 (Regular Cauchy diagonal name-normalization handoff)**.** *For every accepted* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *packet whose displayed selector route is read by a* $\mathsf{RegularCauchyName}^{\uparrow}$ *normalized readback packet, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer handoff factors through exactly three finite surfaces: the diagonal selector-fiber route, the* $\mathsf{RegularCauchyName}^{\uparrow}$ *normalized window readback, and the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *downstream consumer handoff. The correspondence excludes quotient streams, host sequence equality, selected host limits, independent real carriers, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalUp.RegularCauchyDiagonalCarrier name normalization handoff`

Proof. Use the formal target boundary of Definition 372.34. It restricts the diagonal packet to the finite tuple $D = (Q, S, R, L, W, P, N)$ and the displayed BHist route over $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows.

The diagonal contribution is the selector route of Definition 372.33. It says that every downstream $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or $\mathsf{RealCauchyCompletion}^{\uparrow}$ read from the accepted diagonal packet factors through the selector-fiber route and completion-seal route already present in the same finite packet.

The name contribution is the normalized readback package of Definition 371.45. That package reads the $\mathsf{RegularCauchyName}^{\uparrow}$ window through its displayed normalized rational-name surface, so the diagonal selector cannot acquire a second host stream, a quotient stream, or an independently selected limit while passing through the name packet.

Finally attach the completion consumer by Definition 360.20. Its handoff consumes the regular-family input through the displayed completion packet and does not add an independent real carrier or ambient completeness field. Ledger exhaustion and bridge non-escape leave only the three named surfaces, so the composed route is exactly the diagonal selector-fiber surface, the normalized window readback surface, and the downstream completion handoff surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonal}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ packet is generated from a stationary $\mathsf{Rat}^{\uparrow}$ seed row, a $\mathsf{StreamName}^{\uparrow}$ window row, a $\mathsf{RegSeqRat}^{\uparrow}$ diagonal readback, a $\mathsf{Real}^{\uparrow}$ seal row, finite diagonal-window Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonal}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature paper scope is the standard bridge source, readback exactness, non-escape boundary, stationary-family exhaustion, and route determinacy of Definition 372.12, Definition 372.13, Definition 372.14, Definition 372.16, and Definition 372.17.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient streams, selected host limits, ambient completeness, or bridge checking.

Upgrade path: Lean formalization and bridge checking remain for the same diagonal selector and completion-seal interface.

Chapter 373

A Concrete Naming Certificate for $\mathsf{RegularCauchyFamily}^{\uparrow}$

The $\mathsf{RegularCauchyFamily}^{\uparrow}$ interface is the named input certificate consumed by $\mathsf{RealCauchyCompletion}^{\uparrow}$. Following Bishop and Bridges, *Constructive Analysis*, 1985, it presents a regular Cauchy family as visible regular-rational member rows with an explicit Cauchy modulus, finite stream windows, dyadic observation ledgers, and diagonal-completion routes. The packet exports no quotient stream, no choice-selected limit, no host real carrier, and no ambient completeness object.

Each family member is read first through the regular-name discipline of chapter 371. Only after that sibling row has fixed the member surface do the modulus schedule, stream window, dyadic ledger, and diagonal route become consumable by the family packet, so the completion-facing handoff never treats a member as an unstructured rational stream.

Definition 373.1 (RegularCauchyFamily carrier)**.** *A* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, X, \mu, W, D, R, H, C, P, N)$$

with the following visible rows:

1. *I is the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *member-index ledger inspected by the family consumer;*
2. *X assigns to each inspected row of I a* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational member;*
3. *μ is the explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule that selects a late member row for each requested precision;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window catalogue used to read the selected members;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger containing the rational endpoints, radius rows, comparison rows, and precision rows used by the member reads;*
6. *R is the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *diagonal-route ledger that records how the selected member windows feed the completion-facing diagonal representative;*
7. *H and C are respectively the displayed* hsame *comparisons and* Cont *routes used to transport the member, modulus, stream, dyadic, and diagonal rows;*
8. *P is the* Pkg *provenance naming* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, BHist, hsame, *and* Cont*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFamily}^{\uparrow}}$ *provenance row.*

The carrier deliberately has no coordinate for a quotient of streams, a selected limiting real, host sequence equality, or a choice principle. Every completion-facing datum is one of the displayed rows of F.

Lean4 (definition) `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamilyCarrier`

Definition 373.2 (RegularCauchyFamily classifier)**.** *For accepted carriers*

$$F = (I, X, \mu, W, D, R, H, C, P, N) \quad \text{and} \quad F' = (I', X', \mu', W', D', R', H', C', P', N'),$$

the classifier $\mathsf{RegularCauchyFamilyClassifier}(F, F')$ *compares only the displayed member-index ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *member rows,* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledgers,* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *diagonal routes, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *rows. It does not compare host functions extensionally and does not identify completed values by quotient equality.*

Lean4 (definition) `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamilyClassifier`

Theorem 373.3 (RegularCauchyFamily NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFamily}^{\uparrow}}$ *obligation sketch consists of five finite rows:*

1. *carrier habitation by the finite packet of Definition 373.1;*
2. *classifier stability under the displayed* hsame *and* Cont *transports of Definition 373.2;*
3. *modulus-window coverage: each precision request first reads μ, then one selected* $\mathsf{StreamName}^{\uparrow}$ *window, and then the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *member row;*
4. *dyadic ledger exactness: the endpoint, radius, comparison, and precision rows consumed by the selected member read are exactly the rows recorded in D;*
5. *diagonal-route compatibility: the completion-facing diagonal read uses only R together with the selected member, stream window, dyadic ledger, package provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamilyCarrier namecert obligation surface`

Proof. Carrier habitation is obtained by projecting the finite history packet and reading its named rows. The member-index ledger I, member table X, modulus μ, stream-window catalogue W, dyadic ledger D, diagonal-route ledger R, transport rows, package provenance, and local naming row are all explicit coordinates.

Classifier stability is componentwise. Transporting an accepted packet by the displayed hsame rows and then following the recorded Cont routes moves the member rows, modulus schedule, selected windows, dyadic observations, and diagonal routes together.

For modulus-window coverage, a consumer precision request reaches μ before it can inspect a member. The selected member read then passes through the corresponding $\mathsf{StreamName}^{\uparrow}$ window and the $\mathsf{RegSeqRat}^{\uparrow}$ row named by X.

The dyadic and diagonal rows are exhausted by D and R. Repacking those rows with P and N gives the local naming certificate, and there is no remaining coordinate from which a quotient stream, a choice-selected limit, or a host real object could be read. □

Theorem 373.4 (RegularCauchyFamily diagonal handoff)**.** *For every accepted* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *carrier $F = (I, X, \mu, W, D, R, H, C, P, N)$ and every unary precision request n, the input consumed*

by RealCauchyCompletion$^{\uparrow}$ *factors through the explicit modulus row* $\mu(n)$*, one selected* RegSeqRat$^{\uparrow}$ *member row, one* StreamName$^{\uparrow}$ *finite window, the corresponding* DyadicRatCore$^{\uparrow}$ *observation ledger, and the* RealDiagonalCompletion$^{\uparrow}$ *route* R*. The handoff supplies a completion-facing regular Cauchy family without forming a quotient stream or selecting a limit outside the packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamilyCarrier diagonal handoff`

Proof. Project the carrier of Definition 373.1. The modulus coordinate is the only row that selects a late family member for the precision request n.

The selected member is read through the member ledger X and the finite stream-window catalogue W. Its rational observation is the displayed RegSeqRat$^{\uparrow}$ row whose endpoint and comparison data are recorded by the dyadic ledger D.

The diagonal route R then repacks that same selected member read for RealCauchyCompletion$^{\uparrow}$. Because the route is mediated by H, C, P, and N, the completion consumer receives finite BEDC rows rather than a host sequence, quotient class, or selected limiting real. □

Theorem 373.5 (RegularCauchyFamily non-escape boundary)**.** *An accepted* RegularCauchyFamily$^{\uparrow}$ *carrier exports only the finite surface generated by* RegSeqRat$^{\uparrow}$*,* CauchyModulus$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RealDiagonalCompletion$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It exports no quotient stream, no choice-selected limit, no host real carrier, no host equality test, and no ambient completeness theorem.*

Proof. Inspect the coordinates of Definition 373.1. Each coordinate is a finite history row, a displayed transport row, a continuation route, package provenance, local naming provenance, or one of the named dependency certificates.

The classifier of Definition 373.2 uses only those coordinates. It never asks whether two host functions are extensionally equal and never compares completed values by a quotient relation.

The diagonal handoff of Definition 373.4 preserves the same boundary. Downstream completion reads receive the selected modulus, member, window, dyadic observation, and diagonal-route rows, so no hidden stream quotient, selected limit, host real carrier, host equality test, or ambient completeness object can escape. □

Theorem 373.6 (RegularCauchyFamily carrier transport stability)**.** *Let* $F = (I, X, \mu, W, D, R, H, C, P, N)$ *be an accepted* RegularCauchyFamily$^{\uparrow}$ *carrier. Any displayed* hsame *transport that preserves the* RegSeqRat$^{\uparrow}$ *member ledger,* CauchyModulus$^{\uparrow}$ *schedule,* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *observation ledger,* RealDiagonalCompletion$^{\uparrow}$ *route,* Cont *rows,* Pkg *provenance, and local* NameCert *row preserves the carrier predicate and the classifier of Definition 373.2.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamilyCarrier carrier transport stability`

Proof. Project the carrier by Definition 373.1. The rows I and X remain visible RegSeqRat$^{\uparrow}$ member data under the displayed hsame transport, and the schedule μ remains the same CauchyModulus$^{\uparrow}$ row after following the recorded Cont route.

The window catalogue W and dyadic ledger D transport componentwise. Thus each selected member read still passes through the same finite StreamName$^{\uparrow}$ window and the same DyadicRatCore$^{\uparrow}$ endpoint, radius, comparison, and precision rows.

The diagonal route R is carried through RealDiagonalCompletion$^{\uparrow}$, while P and N retain the package and local certificate provenance. Since the classifier compares exactly these displayed coordinates and no host extensional equality, the transported packet remains an accepted carrier with the same local comparison surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamilyCarrier transport stability`

Theorem 373.7 (RegularCauchyFamily modulus window exactness)**.** *For every accepted* RegularCauchyFamily$^{\uparrow}$ *carrier* $F = (I, X, \mu, W, D, R, H, C, P, N)$ *and every unary precision request* n*, the row* $\mu(n)$ *determines one displayed* RegSeqRat$^{\uparrow}$ *member read, one finite* StreamName$^{\uparrow}$ *window, the corresponding* DyadicRatCore$^{\uparrow}$ *observation rows, and the* RealDiagonalCompletion$^{\uparrow}$ *diagonal handoff route. The determination is entirely internal to the* BHist *packet, its* hsame *transports, its* Cont *routes,* Pkg*, and* NameCert*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamilyCarrier modulus window exactness`

Proof. The modulus coordinate is part of the carrier, so the request n first reads the displayed row $\mu(n)$. This row selects the late member named in the RegSeqRat$^{\uparrow}$ member table X over the inspected ledger I.

The selected member is read through the finite window catalogue W. The dyadic ledger D supplies exactly the rational endpoint, radius, comparison, and precision rows consumed by that windowed read.

Finally, the route R records how the same selected member read is handed to RealDiagonalCompletion$^{\uparrow}$. The transports H, continuations C, package provenance P, and local certificate N bind the route inside the finite packet, so no quotient stream, selected limit, host real carrier, or ambient completeness object is used. □

Theorem 373.8 (RegularCauchyFamily member selection determinacy)**.** *Let* $F = (I, X, \mu, W, D, R, H, C, P, N)$ *be an accepted* RegularCauchyFamily$^{\uparrow}$ *carrier, and let* n *be a unary precision request. Suppose two consumer reads both pass through the displayed row* $\mu(n)$ *and both claim to reach selected* RegSeqRat$^{\uparrow}$ *member rows, finite* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *observation ledgers, and the* RealDiagonalCompletion$^{\uparrow}$ *route. Then the two reads agree on the classifier-facing selected member, window, ledger, and diagonal-route surface of* F*. The determinacy is internal to the displayed carrier rows and does not assert quotient stream equality, host function equality, a selected limit, or ambient real completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamilyCarrier member selection determinacy`

Proof. Project the accepted carrier. The coordinates I, X, μ, W, D, and R are the only rows from which a precision request can obtain a member index, a selected regular-rational member, a finite stream window, a dyadic observation ledger, and a completion-facing diagonal route.

Apply Definition 373.7 to the request n. It identifies the displayed route through $\mu(n)$ as the unique carrier route that reaches the selected RegSeqRat$^{\uparrow}$ member read, its StreamName$^{\uparrow}$ window, the corresponding DyadicRatCore$^{\uparrow}$ observation rows, and the RealDiagonalCompletion$^{\uparrow}$ handoff.

If one consumer read is transported before comparison, apply Definition 373.6. The transported read preserves the same member ledger, modulus schedule, window catalogue, dyadic ledger, diagonal route, continuation rows, package row, and local naming row, so the classifier still sees the same selected surface.

Finally use Definition 373.5. Since the carrier exports no external selector, quotient stream, selected limit, host equality test, or ambient completeness object, there is no second source from which a different member/window/ledger route could be read. □

Theorem 373.9 (RegularCauchyFamily scoped route package)**.** *For every accepted* RegularCauchyFamily$^{\uparrow}$ *carrier* $F = (I, X, \mu, W, D, R, H, C, P, N)$*, the carrier row, classifier row, local* NameCert *obligations, diagonal handoff, non-escape boundary, transport stability, modulus-window exactness,*

and member-selection determinacy are exhausted by the displayed RegSeqRat$^{\uparrow}$, CauchyModulus$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RealDiagonalCompletion$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. This is the exact scoped dependency surface supplied to* RealCauchyCompletion$^{\uparrow}$*: it exposes selected member windows, dyadic observation ledgers, diagonal handoff routes, and naming provenance, but no quotient stream, selected limit, host real carrier, host equality test, or ambient completeness object.*

Proof. The carrier and classifier are the finite tuple and componentwise comparison of Definition 373.1 and Definition 373.2. Projecting their coordinates gives only the member ledger I, member table X, modulus schedule μ, window catalogue W, dyadic ledger D, diagonal route R, displayed transports H, continuation routes C, package provenance P, and local naming row N.

The local obligation rows are those of Definition 373.3. The diagonal consumer route is Definition 373.4, and the exported boundary is Definition 373.5; together they identify the finite rows that reach RealCauchyCompletion$^{\uparrow}$.

Transport and precision selection are controlled by Definition 373.6 and Definition 373.7. Member choice at a fixed request is then determined by Definition 373.8.

After these projections, every named route has been accounted for by one of the displayed BEDC rows. Since the carrier has no remaining coordinate and the classifier never compares host presentations, there is no source for a quotient stream, selected limit, host real carrier, host equality test, or ambient completeness object. □

Theorem 373.10 (RegularCauchyFamily obligation closure package)**.** *The carrier, classifier,* NameCert *obligation rows, diagonal handoff, non-escape boundary, carrier transport stability, modulus-window exactness, member-selection determinacy, and scoped route package jointly supply the paper-side obligation package for* RegularCauchyFamily$^{\uparrow}$*. The package is grounded only in* BHist, hsame, Cont, Pkg, NameCert, RegSeqRat$^{\uparrow}$, CauchyModulus$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* RealDiagonalCompletion$^{\uparrow}$.

Proof. The carrier and classifier are Definition 373.1 and Definition 373.2. They expose the finite member ledger, member rows, modulus schedule, stream windows, dyadic observations, diagonal route, transport rows, continuation rows, package provenance, and local naming row.

The local NameCert obligations are supplied by Definition 373.3. They bind carrier habitation, classifier stability, modulus-window coverage, dyadic ledger exactness, and diagonal-route compatibility as the rows consumed by downstream completion.

The handoff and boundary are Definition 373.4 and Definition 373.5. They ensure that RealCauchyCompletion$^{\uparrow}$ receives a displayed regular Cauchy family route and no quotient stream, choice-selected limit, host real carrier, host equality test, or ambient completeness theorem.

The stability, exactness, and determinacy rows are Definition 373.6, Definition 373.7, and Definition 373.8. The route package of Definition 373.9 binds these rows to the exact dependency surface consumed by RealCauchyCompletion$^{\uparrow}$. These rows assemble the stated obligation package without adding any coordinate outside the listed BEDC objects. □

Theorem 373.11 (RegularCauchyFamily standard bridge boundary)**.** *The public* RegularCauchyFamily$^{\uparrow}$ *packet bridges to the* RealCauchyCompletion$^{\uparrow}$ *input schema through exactly the displayed* RegSeqRat$^{\uparrow}$ *member rows, the* CauchyModulus$^{\uparrow}$ *schedule, the* StreamName$^{\uparrow}$ *finite windows, the* DyadicRatCore$^{\uparrow}$ *observation ledgers, the* RealDiagonalCompletion$^{\uparrow}$ *diagonal route, and the visible* hsame, Cont, Pkg, *and* NameCert *rows. This standard bridge exports the completion-facing regular-family input and no quotient stream, selected limit, host real equality, host sequence equality, or ambient completeness principle.*

Proof. Start with the diagonal handoff of Definition 373.4. It identifies the completion-facing route as the selected modulus row, one RegSeqRat$^{\uparrow}$ member, one finite StreamName$^{\uparrow}$ window, the matching DyadicRatCore$^{\uparrow}$ ledger, and the RealDiagonalCompletion$^{\uparrow}$ route.

Next apply Definition 373.7 and Definition 373.8. These results make the selected member, window, ledger, and diagonal route determined by the displayed carrier rows for each precision request.

Finally use Definition 373.10. The carrier, classifier, transport, package, and local certificate rows are already the whole public surface. Thus the bridge has no coordinate from which to read a quotient stream, selected limit, host real equality, host sequence equality, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamily standard bridge boundary`

Theorem 373.12 (RegularCauchyFamily standard bridge carrier)**.** *The carrier rows of Definition 373.1 supply the bridge-facing source surface for* RealCauchyCompletion$^{\uparrow}$*. That source surface consists exactly of the* RegSeqRat$^{\uparrow}$ *member rows, the* CauchyModulus$^{\uparrow}$ *schedule, the* StreamName$^{\uparrow}$ *finite windows, the* DyadicRatCore$^{\uparrow}$ *observation ledger, the* RealDiagonalCompletion$^{\uparrow}$ *routes,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows displayed in the accepted* RegularCauchyFamily$^{\uparrow}$ *packet.*

Proof. Project the carrier and classifier of Definition 373.1 and Definition 373.2. They expose exactly the member ledger, member table, modulus schedule, stream windows, dyadic ledger, diagonal route, transport rows, continuation rows, package row, and local naming row.

The diagonal-facing part is identified by Definition 373.4. The selected member route is then pinned down by Definition 373.7 and Definition 373.8.

Finally apply Definition 373.9 and Definition 373.5. These results show that the listed rows are the whole bridge-facing source surface and that no quotient stream, selected limit, host equality, or ambient completeness object is available to the completion consumer. □

Theorem 373.13 (RegularCauchyFamily completion schema bridge)**.** *For an accepted* RegularCauchyFamily$^{\uparrow}$ *carrier, the diagonal handoff, modulus-window exactness, member-selection determinacy, and scoped route package assemble the* RealCauchyCompletion$^{\uparrow}$ *completion schema bridge. The bridge is built without quotient streams, selected limits, host sequence equality, host real equality, or an external completeness carrier.*

Proof. Begin with Definition 373.4. It gives the completion-facing route through the displayed modulus row, selected RegSeqRat$^{\uparrow}$ member, finite StreamName$^{\uparrow}$ window, DyadicRatCore$^{\uparrow}$ ledger, and RealDiagonalCompletion$^{\uparrow}$ route.

Next use Definition 373.7 and Definition 373.8. The selected window and ledger are determined by the carrier rows for the precision request, so the completion schema receives a stable finite route rather than a choice-selected stream representative.

The route package of Definition 373.9 supplies the remaining BHist, hsame, Cont, Pkg, and NameCert rows. The non-escape boundary of Definition 373.5 then rules out every unlisted completion source. □

Theorem 373.14 (RegularCauchyFamily bridge consumer exactness)**.** *Every* RealCauchyCompletion$^{\uparrow}$ *consumer read of the displayed* RegularCauchyFamily$^{\uparrow}$ *bridge factors through exactly the displayed modulus row, selected member row, finite window row, dyadic ledger row, diagonal route row, transport rows, package row, and local* NameCert *row. No consumer read factors through a quotient stream, a selected limit, host sequence equality, host real equality, or ambient completeness.*

Proof. Read the consumer route through Definition 373.1. The only available rows for a precision request are I, X, μ, W, D, R, H, C, P, and N.

Apply Definition 373.4 to identify the completion-facing chain. Apply Definition 373.7 and Definition 373.8 to make the selected member, window, dyadic ledger, and diagonal route exact.

The scoped route package of Definition 373.9 repacks the same rows for public consumption. Finally, Definition 373.5 excludes every route outside the displayed modulus, member, window, ledger, diagonal, transport, package, and naming surface. □

Theorem 373.15 (RegularCauchyFamily public bridge boundary)**.** *The public* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *packet factors from the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *member rows,* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *routes,* BHist *ledger rows,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row into the completion-facing interface consumed by* $\mathsf{RealCauchyCompletion}^{\uparrow}$*. The factorization exports no quotient stream, selected limit, host real equality, host sequence equality, or ambient completeness principle.*

Proof. Project the accepted packet using Definition 373.1 and Definition 373.2. The available coordinates are precisely the member table, modulus schedule, window catalogue, dyadic ledger, diagonal route, history transports, continuations, package row, and local naming row.

Apply Definition 373.11 and Definition 373.12. They identify the completion-facing interface as the same finite surface over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

The non-escape boundary of Definition 373.5 removes every unlisted completion source, so the public bridge boundary contains no quotient stream, selected limit, host equality row, or ambient completeness datum. □

Theorem 373.16 (RegularCauchyFamily finite induction route)**.** *Let* $F = (I, X, \mu, W, D, R, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *carrier. Induction on the finite inspected member ledger* I *reconstructs exactly the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *member rows, the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule reads, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, and the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *handoff route consumed by* $\mathsf{RealCauchyCompletion}^{\uparrow}$*. The base case exposes no member read. In the successor case, adding one inspected ledger entry adds one displayed member-window-dyadic-diagonal route and preserves the non-escape boundary.*

Proof. Project the finite packet by Definition 373.1. The induction predicate says that every inspected prefix of I exposes only the corresponding rows of X, the schedule reads of μ, the finite windows in W, the dyadic observations in D, and the diagonal route in R, together with the displayed transport, package, and local naming rows.

For the empty inspected ledger, there is no member index to read. Thus no $\mathsf{RegSeqRat}^{\uparrow}$ row, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ observation, or $\mathsf{RealDiagonalCompletion}^{\uparrow}$ handoff can be produced except by an existing displayed coordinate of the packet, and no completion-facing route is exported.

For the successor step, assume the inspected prefix already reconstructs exactly its visible consumer routes. The next ledger entry is read through the modulus-window exactness of Definition 373.7: the schedule row selects one $\mathsf{RegSeqRat}^{\uparrow}$ member, one finite $\mathsf{StreamName}^{\uparrow}$ window, the matching $\mathsf{DyadicRatCore}^{\uparrow}$ observation rows, and the $\mathsf{RealDiagonalCompletion}^{\uparrow}$ route.

Member-selection determinacy, Definition 373.8, identifies this newly exposed route with the unique classifier-facing route for that precision request. The scoped route package of Definition 373.9 then repacks the old prefix routes and the new route into the same finite dependency surface.

Finally apply the non-escape boundary of Definition 373.5. The successor route adds only the displayed member-window-dyadic-diagonal row, so the induction preserves the absence of quotient streams, selected limits, host equality tests, and ambient completeness objects. □

Theorem 373.17 (RegularCauchyFamily downstream consumer exhaustion)**.** *Every* RealCauchyCompletion$^{\uparrow}$ *consumer route from an accepted* RegularCauchyFamily$^{\uparrow}$ *packet is exhausted by the selected member, window, ledger, and diagonal rows already named in that packet, together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. There is no downstream route through a hidden stream representative, selected limit, host equality test, or ambient completeness object.*

Proof. Begin with Definition 373.14. It states that every consumer read factors through the displayed modulus, member, window, dyadic ledger, diagonal route, transport, package, and naming rows.

Use Definition 373.7 and Definition 373.8 to pin the selected member and finite window for each precision request. The dyadic observation ledger and diagonal route are then the rows named by Definition 373.4.

Finally apply Definition 373.15. The public bridge boundary has no remaining coordinate outside those rows, so the downstream consumer surface is exhausted by the named packet. □

Theorem 373.18 (RegularCauchyFamily completion consumer factorization)**.** *The public bridge boundary and downstream consumer exhaustion assemble the bridge package consumed by* RealCauchyCompletion$^{\uparrow}$*: each completion consumer first reads the* RegSeqRat$^{\uparrow}$ *member row,* CauchyModulus$^{\uparrow}$ *schedule,* StreamName$^{\uparrow}$ *window,* DyadicRatCore$^{\uparrow}$ *observation, and* RealDiagonalCompletion$^{\uparrow}$ *route, and then transports only along the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamily completion consumer factorization`

Proof. Use Definition 373.15 as the source boundary. It lists the exact public rows available to the completion-facing interface.

Use Definition 373.17 as the consumer boundary. It shows that each downstream route is already one of the member, schedule, window, ledger, diagonal, transport, package, or naming rows.

Composing the two boundaries yields the stated factorization. The composition adds no new carrier coordinate and therefore cannot introduce quotient streams, selected limits, host equality tests, or ambient completeness objects. □

Closure status for NameCert$_{\text{RegularCauchyFamily}^{\uparrow}}$.

Constructive story: A RegularCauchyFamily$^{\uparrow}$ packet is generated from finite RegSeqRat$^{\uparrow}$ member rows, an explicit CauchyModulus$^{\uparrow}$ schedule, StreamName$^{\uparrow}$ finite windows, DyadicRatCore$^{\uparrow}$ observation ledgers, RealDiagonalCompletion$^{\uparrow}$ diagonal routes, displayed hsame and Cont rows, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyFamily}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 373.15, Definition 373.17, and Definition 373.18 export the public consumer surface and paper bridge sent to RealCauchyCompletion$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyFamily}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.RegularCauchyFamilyUp.RegularCauchyFamilyCarrier\_namecert\_obligation\_surface`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close RealUp completeness, uniqueness of completed limits, quotient equality of streams, selected host limits, host real equality, or bridge checking.

Upgrade path: Bridge checking requires a Lean bridge theorem over the same RegularCauchyFamily consumer boundary.

Chapter 374

A Concrete Naming Certificate for $\mathsf{DiagonalLimit}^{\uparrow}$

The $\mathsf{DiagonalLimit}^{\uparrow}$ packet names the concrete regular-Cauchy-family diagonal construction that sits above the finite diagonal selectors and below the $\mathsf{Real}^{\uparrow}$ consumer seal. Following the Bishop–Bridges constructive-analysis treatment of Cauchy completion, it keeps the inspected regular rational family, explicit modulus rows, stream windows, dyadic readback ledger, diagonal completion packet, and real seal as visible certificate data. It does not quotient regular streams, select a host limit, or import ambient real completeness.

The diagonal packet consumes the tail-comparison surface of chapter 387 before its $\mathsf{RealDiagonalCompletion}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seal rows are read. The dependency is the finite modulus/window/tail-comparison ledger, not quotient stream equality or selected limit data.

Definition 374.1 (DiagonalLimit regular-Cauchy-family carrier)**.** *A* $\mathsf{DiagonalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, M, S, D, C, E, P, N)$$

with the following visible coordinates:

1. *F is the* $\mathsf{RegSeqRat}^{\uparrow}$*-indexed regular Cauchy family whose inspected members are displayed as regular rational rows;*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row selecting a late enough family member for each requested consumer precision;*
3. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule of windows read by the diagonal construction;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger attached to the selected rational readbacks;*
5. *C is the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *packet that repacks the selected diagonal rows as a completion-facing finite surface;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed to downstream consumers;*
7. *P is the* Pkg *provenance naming the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *dependencies;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimit}^{\uparrow}}$ *provenance row.*

Two accepted packets are classified together exactly when the displayed family rows, modulus rows, stream windows, dyadic ledgers, diagonal-completion packets, real seals, package rows, and local certificate rows are transported componentwise by the recorded hsame *comparisons and* Cont *routes.*

Lean4 ✓ `BEDC.Derived.DiagonalLimitUp.DiagonalLimitTasteGate single carrier alignment`

Theorem 374.2 (DiagonalLimit NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{DiagonalLimit}^\uparrow}$ *obligation surface consists of carrier habitation by the finite packet of Definition 374.1, componentwise classifier transport through displayed* hsame *and* Cont *rows, diagonal regularity bounds over the explicit* $\mathsf{CauchyModulus}^\uparrow$ *row, handoff to* $\mathsf{RealDiagonalCompletion}^\uparrow$ *and* $\mathsf{Real}^\uparrow$*, and ledger non-escape over* $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, BHist, Pkg, *and* NameCert.

Proof. Carrier habitation is the packet assembly in Definition 374.1. The visible rows name the regular Cauchy family, the modulus, the finite windows, the dyadic observations, the diagonal completion packet, the real seal, and the local provenance.

Classifier transport is componentwise. A permitted replacement is either an hsame comparison of one displayed row or a Cont route identifying where that row is read inside the finite packet, so transport preserves the same carrier boundary.

The remaining obligations are the diagonal regularity bound, the completion handoff, and non-escape boundary recorded in the following theorems. Together they list exactly the rows consumed by the local naming certificate. □

Theorem 374.3 (DiagonalLimit diagonal regularity bound)**.** *For every accepted* $\mathsf{DiagonalLimit}^\uparrow$ *carrier and every displayed unary precision request* n*, the modulus row* M *selects a finite family member and a finite* $\mathsf{StreamName}^\uparrow$ *window such that the selected* $\mathsf{RegSeqRat}^\uparrow$ *readback is bounded by the dyadic observation ledger* D *at the requested precision. The bound is transported only through the packet's displayed* hsame *comparisons and* Cont *routes.*

Proof. Project the accepted packet through Definition 374.1. The precision request is answered by the explicit $\mathsf{CauchyModulus}^\uparrow$ coordinate, so the selected family member is a displayed row rather than a hidden limit choice.

The selected member is read through the finite $\mathsf{StreamName}^\uparrow$ schedule. Its rational observation is recorded in the $\mathsf{RegSeqRat}^\uparrow$ family row and the accompanying $\mathsf{DyadicRatCore}^\uparrow$ ledger.

Since the classifier transports only displayed rows through hsame and Cont, the same bound follows after any accepted transport. No quotient stream or host real endpoint is used to obtain the bound. □

Theorem 374.4 (DiagonalLimit finite-family induction route)**.** *For every accepted* $\mathsf{DiagonalLimit}^\uparrow$ *carrier*

$$L = (F, M, S, D, C, E, P, N)$$

and every finite displayed family of $\mathsf{RegSeqRat}^\uparrow$ *rows inspected by* F*, the diagonal route to the* $\mathsf{Real}^\uparrow$ *consumer seal is generated by induction over the finite family index. At each index the induction state consists exactly of the displayed family row, the dyadic tail budget supplied through* D*, the finite* $\mathsf{StreamName}^\uparrow$ *window supplied through* S*, the* $\mathsf{RegSeqRat}^\uparrow$ *readback, the* $\mathsf{RealDiagonalCompletion}^\uparrow$ *seal factor in* C*, the* $\mathsf{Real}^\uparrow$ *seal row* E*, the visible* hsame *transport, the visible* Cont *replay route, the* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimit}^\uparrow}$ *row* N*.*

The construction exports the same diagonal route after any accepted packet transport. It does not identify quotient streams, select an ambient limit, prove uniqueness of limits, or construct a host $\mathsf{Real}^\uparrow$ *object outside the displayed completion seal.*

Proof. Project the accepted carrier through Definition 374.1. The finite family is a visible list of inspected $\mathsf{RegSeqRat}^\uparrow$ rows, so the induction base is the empty inspected prefix together with the already displayed package and local certificate rows.

For the induction step, apply Definition 374.3 to the next precision request. The modulus row M selects the next finite family member and the finite $\mathsf{StreamName}^{\uparrow}$ window; the selected rational readback is recorded in the $\mathsf{RegSeqRat}^{\uparrow}$ row and bounded by the dyadic ledger D.

The step then repacks the selected readback into the completion-facing surface. Definition 374.5 records that this repacking passes through the same terminal precision, completion packet, $\mathsf{Real}^{\uparrow}$ seal, Pkg provenance, and local $\mathsf{NameCert}_{\mathsf{DiagonalLimit}^{\uparrow}}$ row.

Transport is handled componentwise. The induction hypothesis is moved only along the displayed hsame comparisons and replayed only along the displayed Cont routes, so each finite prefix remains inside the same carrier boundary.

Finally, Definition 374.8 identifies the seal factor used by every consumer read, and Definition 374.6 excludes quotient stream equality, selected ambient limits, uniqueness of limits, and host real construction. Thus the full diagonal route is obtained by finite induction over the displayed family rows. □

Theorem 374.5 (DiagonalLimit Real-Cauchy handoff boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer read exported by an accepted* $\mathsf{DiagonalLimit}^{\uparrow}$ *packet factors through the same terminal precision, selected* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *packet,* $\mathsf{Real}^{\uparrow}$ *seal, visible* hsame *rows, visible* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimit}^{\uparrow}}$ *row.*

Proof. Begin with the selected diagonal window supplied by Definition 374.3. It exposes the precision, modulus-selected member, stream window, regular rational readback, and dyadic observation ledger.

The $\mathsf{RealDiagonalCompletion}^{\uparrow}$ coordinate C repacks exactly those displayed rows as the completion-facing finite surface. The $\mathsf{Real}^{\uparrow}$ seal E is attached to that same completion packet and not to an independent host real object.

Repacking the visible rows with the package and local certificate provenance gives the stated consumer handoff. The route has no coordinate for quotient equality, selected limits, uniqueness of limits, or ambient completeness. □

Theorem 374.6 (DiagonalLimit non-escape boundary)**.** *An accepted* $\mathsf{DiagonalLimit}^{\uparrow}$ *packet exports only the displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RealDiagonalCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. It exports no quotient of regular streams, no host real equality, no selected limit, no uniqueness theorem for limits, and no ambient real-completeness principle.*

Proof. Inspect the carrier coordinates of Definition 374.1. Each coordinate is a displayed BEDC row or a local provenance row named in the packet.

The regularity theorem accounts for every precision-sensitive rational read, and the handoff theorem accounts for every $\mathsf{Real}^{\uparrow}$ consumer read. Thus every public route through the packet has already passed through visible finite data.

None of the carrier coordinates is a quotient class, a host-level equality witness, a selected limit object, a uniqueness theorem, or an ambient completeness field. Those objects cannot be recovered from the packet boundary. □

Theorem 374.7 (DiagonalLimit obligation transport scope)**.** *For any two accepted* $\mathsf{DiagonalLimit}^{\uparrow}$ *packets, accepted packet transport preserves the carrier of Definition 374.1 and its classifier only through the displayed* hsame *comparisons and* Cont *routes on the* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RealDiagonalCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{DiagonalLimit}^{\uparrow}}$ *rows.*

Proof. Project both accepted packets through Definition 374.1. The carrier coordinates are exactly the displayed regular family, modulus, stream schedule, dyadic ledger, completion packet, real seal, package provenance, and local certificate row.

The classifier clause in the carrier definition admits only componentwise hsame comparisons and Cont read routes for those coordinates. Thus transport can rename or route a displayed row, but it cannot introduce a quotient stream, selected host limit, or ambient real object.

The precision-sensitive part of the carrier remains controlled by Definition 374.3, and the downstream route remains the handoff of Definition 374.5. The exclusions in Definition 374.6 show that no further row participates in the accepted transport scope. □

Theorem 374.8 (DiagonalLimit completion seal factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{DiagonalLimit}^{\uparrow}$ *packet factors through its* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *packet and the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback rows selected by the packet classifier.*

Proof. Start with an accepted packet and project its carrier as in Definition 374.1. The $\mathsf{Real}^{\uparrow}$ seal coordinate is not free-standing; it is one of the visible packet rows paired with the completion packet coordinate.

Apply Definition 374.3 to obtain the selected regular rational readback, stream window, and dyadic ledger for the requested precision. Then apply Definition 374.5, which routes the consumer read through the same terminal precision, completion packet, seal row, Pkg provenance, and local $\mathsf{NameCert}_{\mathsf{DiagonalLimit}^{\uparrow}}$ row.

The non-escape boundary of Definition 374.6 rules out any alternate host-real or quotient-stream factor. Hence every seal read factors through the displayed completion packet and readback rows. □

Lean4 ✓ `BEDC.Derived.DiagonalLimitUp.DiagonalLimitCarrier completion seal factorization`

Theorem 374.9 (DiagonalLimit dependency stability package)**.** *The dependency package over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, Pkg, *and* NameCert *is stable under the displayed* $\mathsf{DiagonalLimit}^{\uparrow}$ *classifier.*

Proof. The package dependencies are exactly the coordinates and provenance rows listed in Definition 374.1. Stability therefore reduces to checking that each dependency row remains inside the same accepted packet boundary after classifier transport.

Definition 374.7 identifies that transport boundary as the displayed hsame and Cont rows only. Definition 374.3 keeps the regular-family, modulus, stream, and dyadic rows stable for every precision request.

Definition 374.5 keeps the completion and $\mathsf{Real}^{\uparrow}$ consumer route attached to the same provenance rows. Finally, Definition 374.6 excludes every dependency outside the named package, so the dependency package is stable under the displayed classifier. □

Theorem 374.10 (DiagonalLimit public export)**.** *The carrier of Definition 374.1, the NameCert surface of Definition 374.2, the diagonal regularity bound of Definition 374.3, the finite-family induction route of Definition 374.4, the real-Cauchy handoff boundary of Definition 374.5, the non-escape boundary of Definition 374.6, the transport scope of Definition 374.7, the completion seal factorization of Definition 374.8, and the dependency stability package of Definition 374.9 assemble the public* $\mathsf{DiagonalLimit}^{\uparrow}$ *export.*

The export consists of the displayed regular-family rows, explicit modulus row, finite stream-window schedule, dyadic readback ledger, diagonal completion packet, $\mathsf{Real}^{\uparrow}$ *seal row, component-wise transport, continuation routes, package provenance, and local naming row. It does not assert* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the finite carrier

$$L = (F, M, S, D, C, E, P, N).$$

The carrier and NameCert surface expose the regular-family, modulus, stream-window, dyadic-ledger, completion-packet, real-seal, package, and local naming rows.

The diagonal regularity and finite-family induction theorems route each requested read through the displayed modulus, selected stream window, rational readback, dyadic ledger, completion packet, and seal row. The handoff, transport, and dependency theorems keep those rows stable under the accepted hsame and Cont routes.

The non-escape and seal-factorization theorems exclude quotient streams, selected host limits, uniqueness of limits, host real construction, and ambient completeness. Hence the public export is the displayed finite diagonal-limit surface alone, with no claim of $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiagonalLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{DiagonalLimit}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$-indexed regular Cauchy family, an explicit $\mathsf{CauchyModulus}^{\uparrow}$ row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledgers, a $\mathsf{RealDiagonalCompletion}^{\uparrow}$ packet, a $\mathsf{Real}^{\uparrow}$ seal row, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DiagonalLimit}^{\uparrow}}$, maturePackageClosed)

Scope closed: The obligation scope registers the carrier, displayed classifier route, diagonal regularity bound, completion-to-$\mathsf{Real}^{\uparrow}$ handoff boundary, ledger non-escape surface, accepted transport scope, seal factorization, and dependency stability over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DiagonalLimit}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.DiagonalLimitUp.DiagonalLimitCarrier\_completion\_seal\_factorization`

Bridge status: none

Origin: human

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient equality of regular streams, uniqueness of limits, host real construction, or bridge checking.

Upgrade path: No further theory-axis upgrade is pending; bridge checking remains a separate formal-axis obligation over the same displayed regular-family, modulus, stream-window, dyadic-ledger, completion-packet, $\mathsf{Real}^{\uparrow}$, Pkg, and NameCert rows.

Chapter 375

A Concrete Naming Certificate for $\mathsf{DiagonalModulus}^{\uparrow}$

The $\mathsf{DiagonalModulus}^{\uparrow}$ packet names the selector modulus used when regular rational streams are read along a diagonal and then sealed as real-name data. Following Bishop–Bridges constructive analysis, the packet keeps the modulus explicit: a consumer precision is converted into a displayed threshold, a finite stream window, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger, and a $\mathsf{Real}^{\uparrow}$ seal row. It does not classify by quotient streams, host real equality, selected limits, or ambient completeness.

The $\mathsf{DiagonalModulus}^{\uparrow}$ route consumes the finite-window carrier of chapter 126, the regular rational readback of chapter 301, the displayed real seal of chapter 38, and the diagonal completion route of chapter 360. It also depends on $\mathsf{DyadicRatCore}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegularityModulus}^{\uparrow}$, and $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, while still excluding quotient streams, host real equality, selected limits, and ambient completeness.

Definition 375.1 (DiagonalModulus carrier)**.** *A* $\mathsf{DiagonalModulus}^{\uparrow}$ *carrier row is a finite* BHist *packet*

$$\Delta = (n, \mu, w, r, d, e, P, N)$$

with the following visible coordinates:

1. *n is the unary precision request issued by the downstream real-name reader;*
2. *μ is the selected modulus threshold witnessing how far the diagonal read must inspect regular rational data at precision n;*
3. *w is the* $\mathsf{StreamName}^{\uparrow}$ *window selected from μ and n;*
4. *r is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained inside the window w;*
5. *d is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger recording the dyadic rational bounds used by that readback;*
6. *e is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed to the consumer after the readback is displayed;*
7. *P is the* Pkg *provenance row naming the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegularityModulus}^{\uparrow}$, $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, *and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *dependencies;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DiagonalModulus}^{\uparrow}}$ *provenance row.*

The carrier contains no quotient of streams, no host-level equality of reals, no selected limit object, and no completeness theorem field.

Lean4 ✓ `BEDC.Derived.DiagonalModulusUp.DiagonalModulusTasteGate single carrier alignment`

Definition 375.2 (DiagonalModulus classifier)**.** *Two* $\mathsf{DiagonalModulus}^{\uparrow}$ *carrier rows are classified together exactly when their displayed precision requests, modulus thresholds, stream windows, regular-sequence readbacks, dyadic observation ledgers, real-seal rows, package rows, and local certificate rows are transported componentwise by the recorded* hsame *comparisons and* Cont *routes. The classifier is not allowed to compare hidden sequences, quotient representatives, host real endpoints, or unrecorded limit selections.*

Theorem 375.3 (DiagonalModulus window selector totality)**.** *For every accepted* $\mathsf{DiagonalModulus}^{\uparrow}$ *carrier row and every displayed unary precision request* n*, the selected modulus threshold* μ *determines a finite* $\mathsf{StreamName}^{\uparrow}$ *window* w *and a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* r *inside that window. The selector therefore returns visible finite data for every consumer precision request.*

Lean4 ✓ `BEDC.Derived.DiagonalModulusUp.DiagonalModulusPacket window selector total`
↪ variant `BEDC.Derived.DiagonalModulusUp.DiagonalModulusWindowCarrier selector total`

Proof. Project the carrier row of Definition 375.1. The precision coordinate n and the threshold coordinate μ are stored before any readback, so the window selection is read from displayed data rather than from an external sequence object.

The $\mathsf{StreamName}^{\uparrow}$ coordinate w records the finite window selected by that threshold. The readback coordinate r is then attached to the same window, and the allowed transport routes are exactly the hsame and Cont entries recorded by the carrier provenance.

Thus a consumer precision request always lands in a visible stream window and a visible regular rational row. No hidden limit selector is consulted. □

Theorem 375.4 (DiagonalModulus RegSeqRat handoff)**.** *Every* $\mathsf{DiagonalModulus}^{\uparrow}$ *read that reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *factors through the selected* $\mathsf{StreamName}^{\uparrow}$ *window* w*, the displayed readback row* r*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* d *attached to that readback. The handoff exports only finite rational evidence and the recorded classifier routes.*

Proof. Start from an accepted carrier and a selected window. By Definition 375.3, the window and the regular rational readback are already displayed as coordinates of the same finite packet.

The dyadic ledger d is stored beside r. It records the rational observations and radius data used by the readback, so transport of the readback also transports the corresponding $\mathsf{DyadicRatCore}^{\uparrow}$ evidence.

Consequently the handoff into $\mathsf{RegSeqRat}^{\uparrow}$ is a finite route through w, r, and d. It does not expose host sequence equality or quotient equality of regular streams. □

Lean4 ✓ `BEDC.Derived.DiagonalModulusUp.DiagonalModulusPacket regseqrat handoff`

Theorem 375.5 (DiagonalModulus RealUp seal non-escape)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal row* e *of an accepted* $\mathsf{DiagonalModulus}^{\uparrow}$ *packet can be consumed only after the precision request, modulus threshold, stream window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger have been displayed. The seal therefore exports a real-name surface without exporting selected limits, quotient equality, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.DiagonalModulusUp.DiagonalModulusPacket real seal nonescape`

Proof. Read the coordinates of Definition 375.1 in order. The seal row appears after the precision, threshold, window, readback, and dyadic ledger rows, so any consumer route to e must pass through those displayed coordinates.

The handoff theorem identifies the preceding rational evidence. Once that evidence is displayed, the seal row records only the $\mathsf{Real}^{\uparrow}$ consumer boundary attached to it.

Therefore the seal cannot be used as an escape to an unrecorded completion object. It withholds selected limits, quotient stream equality, host real equality, and ambient completeness data. □

Theorem 375.6 (DiagonalModulus NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{DiagonalModulus}^{\uparrow}}$ *obligation surface consists of carrier habitation, displayed classifier transport, total finite-window selection,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through dyadic observation rows,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, and package dependency stability over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegularityModulus}^{\uparrow}$, $\mathsf{RegularCauchyDiagonal}^{\uparrow}$, BHist, Pkg, *and* NameCert.

Lean4 ✓ `BEDC.Derived.DiagonalModulusUp.DiagonalModulusPacket namecert obligation surface`

Proof. Carrier habitation is the packaging operation of Definition 375.1. The classifier row is the componentwise route of Definition 375.2, using only displayed hsame, Cont, Pkg, and dependency rows.

Total finite-window selection is exactly Definition 375.3. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff is supplied by Definition 375.4, which keeps each readback attached to its stream window and dyadic observation ledger.

The seal boundary is supplied by Definition 375.5. Together these rows list the local certificate obligations and exclude hidden streams, quotient representatives, selected limits, host real equality, and ambient completeness fields. □

Theorem 375.7 (RealCauchyCompletion modulus classifier transport)**.** *A* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer may use an accepted* $\mathsf{DiagonalModulus}^{\uparrow}$ *packet by transporting its classifier through the displayed precision request, modulus threshold, stream window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, dyadic ledger, and* $\mathsf{Real}^{\uparrow}$ *seal rows. The transport supplies the diagonal modulus required by the completion packet without adding quotient streams, host real equality, choice-selected limits, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.DiagonalModulusUp.DiagonalModulusWindowCarrier completion classifier transport`

Proof. Start with a $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumer request. The $\mathsf{DiagonalModulus}^{\uparrow}$ packet answers the request by Definition 375.3, producing a displayed threshold, stream window, and regular rational readback.

The rational evidence transported to the completion packet is exactly the handoff of Definition 375.4. The downstream real-name boundary is exactly the non-escaping seal of Definition 375.5.

Since the classifier of Definition 375.2 compares only displayed rows and recorded routes, $\mathsf{RealCauchyCompletion}^{\uparrow}$ receives a concrete modulus packet rather than an external completion witness. The consumer therefore obtains the needed diagonal selector while quotient streams, host real equality, choice-selected limits, and ambient completeness remain outside the packet. □

Theorem 375.8 (DiagonalModulus bridge source package)**.** *For every accepted* $\mathsf{DiagonalModulus}^{\uparrow}$ *carrier row* $\Delta = (n, \mu, w, r, d, e, P, N)$*, the tuple* $(n, \mu, w, r, d, e, P, N)$ *together with the displayed window selector,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{Real}^{\uparrow}$ *seal non-escape row, and* RealCauchyCompletion

classifier transport is the bridge source from the public DiagonalModulus$^{\uparrow}$ *packet to the completion-consumer schema. The source uses only the recorded* BHist, hsame, Cont, Pkg, *and* NameCert *rows and exports no quotient stream, selected limit, host real equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.DiagonalModulusUp.DiagonalModulusPacket bridge source package`

Proof. Project the carrier row of Definition 375.1. Its eight displayed coordinates are the precision request, selected modulus threshold, stream window, regular-sequence readback, dyadic ledger, real seal, package provenance, and local certificate provenance.

Apply Definition 375.3 to obtain the finite window selected by (n, μ), and apply Definition 375.4 to attach the RegSeqRat$^{\uparrow}$ readback and DyadicRatCore$^{\uparrow}$ ledger to that same window.

The real-name side is supplied by Definition 375.5, which keeps the seal behind the displayed precision, threshold, window, readback, and dyadic rows. The completion-facing transport is exactly Definition 375.7.

Repacking these rows gives the bridge source required by the completion-consumer schema. Because every component is one of the displayed carrier or provenance rows, the package has no coordinate for quotient streams, selected limits, host real equality, or ambient completeness. □

Theorem 375.9 (DiagonalModulus mature boundary)**.** *The window selector totality,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal non-escape, local* NameCert$_{\text{DiagonalModulus}^{\uparrow}}$ *obligation surface,* RealCauchyCompletion$^{\uparrow}$ *classifier transport, and bridge source package jointly exhaust the mature diagonal-modulus boundary. The boundary is the displayed finite route through precision request n, modulus threshold μ,* StreamName$^{\uparrow}$ *window w,* RegSeqRat$^{\uparrow}$ *readback r,* DyadicRatCore$^{\uparrow}$ *ledger d,* Real$^{\uparrow}$ *seal e,* Pkg *provenance, and* NameCert *provenance; it exports no hidden modulus function, quotient stream, host equality, or ambient completeness row.*

Proof. Begin with the finite selector. The window selector totality theorem Definition 375.3 produces w from the displayed precision request and modulus threshold, and Definition 375.4 attaches the RegSeqRat$^{\uparrow}$ readback and DyadicRatCore$^{\uparrow}$ ledger to that same window.

Next close the real-facing and naming surfaces. The seal non-escape theorem Definition 375.5 keeps e behind the displayed rational route, and Definition 375.6 records the corresponding local NameCert$_{\text{DiagonalModulus}^{\uparrow}}$ obligations.

Finally apply Definition 375.7 and Definition 375.8. They move the same finite rows into the completion-consumer and bridge-facing packages, so the mature boundary is exhausted without exporting a hidden modulus function, quotient stream, host equality, or ambient completeness row. □

Closure status for NameCert$_{\text{DiagonalModulus}^{\uparrow}}$**.**

Constructive story: A DiagonalModulus$^{\uparrow}$ packet is generated from a unary precision request, a selected modulus threshold, a finite StreamName$^{\uparrow}$ window, a RegSeqRat$^{\uparrow}$ readback row, a DyadicRatCore$^{\uparrow}$ observation ledger, a Real$^{\uparrow}$ seal row, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DiagonalModulus}^{\uparrow}}$, maturePackageClosed)

Scope closed: The obligation surface is the carrier row, classifier, total finite-window selector, RegSeqRat$^{\uparrow}$ handoff, DyadicRatCore$^{\uparrow}$ ledger, Real$^{\uparrow}$ seal boundary, dependency stability, and RealCauchyCompletion$^{\uparrow}$ consumer transport.

Formal verification: FormalStatus(NameCert$_{\text{DiagonalModulus}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.DiagonalModulusUp.DiagonalModulusPacket\_namecert\_obligation\_surface`

Bridge status: none

Origin: human

Not claimed: This chapter does not close Real$^{\uparrow}$ completeness, quotient equality, selected limits, host real equality, ambient completeness, or bridge checking.

Upgrade path: Formal verification remains the route from the mature paper treatment to checked theorem, axiom-clean, and bridge-checked status over the same displayed precision, modulus, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, Pkg, and NameCert rows.

Chapter 376

A Concrete Naming Certificate for CauchyRegularization$^{\uparrow}$

The CauchyRegularization$^{\uparrow}$ interface names the finite certificate surface that turns a rational Cauchy stream with displayed modulus windows into the regular rational sequence data consumed by RegSeqRat$^{\uparrow}$ and then by Real$^{\uparrow}$. Following Bishop and Bridges, *Constructive Analysis*, the regularizing operation is carried by explicit tail moduli and finite approximants. The packet therefore records only the rational stream windows, dyadic modulus observations, finite-window regularized approximants, seal provenance, and Pkg/NameCert ledgers visible to BEDC consumers.

This packet consumes the modulus threshold surface of chapter 292 and the finite observation-window surface of chapter 126 before repacking the regular-sequence handoff. Row M is read through CauchyModulus$^{\uparrow}$ and row S is read through StreamName$^{\uparrow}$, not through a host sequence or quotient stream.

Definition 376.1 (CauchyRegularization finite carrier)**.** *A* CauchyRegularization$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, M, D, W, R, E, H, C, P, N)$$

with the following visible rows:

1. *S is the* RationalStream$^{\uparrow}$ *source row naming the inspected rational Cauchy stream through finite* StreamName$^{\uparrow}$ *observation windows;*
2. *M is the* CauchyModulus$^{\uparrow}$ *row naming, for each requested precision, the displayed tail threshold used by the regularization;*
3. *D is the finite family of* DyadicRatCore$^{\uparrow}$ *modulus-window packets that records the rational tolerance, dyadic radius, and comparison rows read at the inspected thresholds;*
4. *W is the finite window ledger that pairs each inspected source window with the modulus row that justifies reading it as a late Cauchy window;*
5. *R is the* RegSeqRat$^{\uparrow}$ *handoff row obtained by repacking those late finite-window approximants as a regular rational sequence surface;*
6. *E is the* Real$^{\uparrow}$ *seal-provenance row attached to the same regular sequence handoff;*
7. *H records the componentwise* hsame *transports for source windows, modulus rows, dyadic observations, regularized approximants, and seal rows;*

8. *C records the displayed* Cont *routes by which consumers reach the stream, modulus, dyadic-window, regular-sequence, and seal coordinates;*
9. *P is the* Pkg *provenance over* $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRegularization}^{\uparrow}}$ *ledger.*

The carrier contains no quotient of Cauchy streams, no chosen host real, no ambient completeness theorem, and no hidden tail selector outside the displayed modulus row.

Lean4 ✓ `BEDC.Derived.CauchyRegularizationUp.TasteGate.CauchyRegularizationTasteGate single carrier alignment`

Definition 376.2 (CauchyRegularization modulus classifier)**.** *For accepted* $\mathsf{CauchyRegularization}^{\uparrow}$ *carriers G and G', the classifier* $\mathsf{CauchyRegularizationClassifier}(G, G')$ *compares only the displayed* $\mathsf{RationalStream}^{\uparrow}$ *windows,* $\mathsf{CauchyModulus}^{\uparrow}$ *thresholds,* $\mathsf{DyadicRatCore}^{\uparrow}$ *modulus-window ledgers, finite-window approximants,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows,* $\mathsf{Real}^{\uparrow}$ *seal-provenance rows, componentwise* hsame *transports,* Cont *read routes,* Pkg *provenance, and local* NameCert *ledgers.*

In particular, two carriers classify together only when their regularized finite windows are read from the same transported source windows and the same transported modulus thresholds. The classifier does not inspect host limits, completion quotients, or any convergence predicate not represented by the listed rows.

Lean4 (definition) `BEDC.Derived.CauchyRegularizationUp.CauchyRegularizationModulusClassifier`

Theorem 376.3 (CauchyRegularization NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyRegularization}^{\uparrow}}$ *surface consists of five obligations:*

1. *carrier admission: an accepted packet is exactly the finite* BHist *package of Definition 376.1;*
2. *modulus-window classifier stability: Definition 376.2 is preserved by the displayed* hsame *transports and* Cont *routes on source windows, modulus thresholds, dyadic observations, approximants, and seal rows;*
3. *regular-sequence handoff: the finite approximants selected by the modulus windows repack as the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*
4. $\mathsf{Real}^{\uparrow}$ *seal compatibility: the seal-provenance row E reads only the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and the finite stream, modulus, dyadic, transport, and package rows carried by the packet;*
5. *ledger exactness: every consumer-visible source window, modulus threshold, dyadic radius, approximant, handoff, seal, transport, continuation, package, and local certificate row occurs in the displayed carrier.*

Proof. Carrier admission is just the finite packet of Definition 376.1. Each coordinate is a visible history row, and the provenance row names exactly the source certificates that own those rows.

Classifier stability is componentwise. Transport a source window, its modulus threshold, and the dyadic observation ledger along the displayed hsame rows, then replay the recorded Cont routes. The regularized approximant is still read from the transported late window justified by the transported modulus threshold.

The regular-sequence handoff is obtained by projecting the row R. It forgets no evidence needed by $\mathsf{RegSeqRat}^{\uparrow}$, because the source window, modulus threshold, dyadic radius, and comparison rows remain in S, M, D, W, H, C.

Finally the $\mathsf{Real}^{\uparrow}$ seal reads the same handoff through E, and the ledger rows P and N account for package and local naming provenance. Since every consumer-visible coordinate is listed in the carrier, there is no extra host limit, quotient, hidden selector, or ambient completeness object to export. □

Lean4 ✓ `BEDC.Derived.CauchyRegularizationUp.CauchyRegularizationCarrier namecert obligation surface`
Lean4 ✓ `BEDC.Derived.CauchyRegularizationUp.CauchyRegularizationFiniteCarrier namecert obligation surface`
Lean4 ✓ `BEDC.Derived.CauchyRegularizationUp.CauchyRegularizationModulusClassifier stability`

Theorem 376.4 (CauchyRegularization regular-sequence handoff)**.** *For every accepted* $\mathsf{CauchyRegularization}^{\uparrow}$ *carrier and every displayed precision request, the* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read factors through one* $\mathsf{RationalStream}^{\uparrow}$ *finite observation window, one* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row for that precision, the corresponding* $\mathsf{DyadicRatCore}^{\uparrow}$ *modulus-window ledger, and the finite-window approximant recorded in* W*. No* $\mathsf{RegSeqRat}^{\uparrow}$ *read can bypass those rows by using an unrecorded tail choice or a quotient of rational streams.*

Proof. Project the carrier $G = (S, M, D, W, R, E, H, C, P, N)$. A precision request first reaches the source stream through the displayed $\mathsf{StreamName}^{\uparrow}$ window in S and then reads the threshold supplied by M.

The dyadic tolerance and comparison evidence are exactly the rows recorded in D. The window ledger W pairs those rows with the inspected late source window, so the regularized approximant has a visible origin in the same finite packet.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R is attached to that approximant ledger. Transport changes only the displayed routes in H and C; it does not add a hidden tail selector or a quotient stream coordinate. Hence every regular-sequence read factors through the stated finite rows. □

Lean4 ✓ `BEDC.Derived.CauchyRegularizationUp.CauchyRegularizationFiniteCarrier regular sequence handoff`

Theorem 376.5 (CauchyRegularization RealUp seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer read of an accepted* $\mathsf{CauchyRegularization}^{\uparrow}$ *packet is mediated by the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, the displayed rational-stream window, the modulus threshold, the dyadic modulus-window ledger, the regularized finite approximant, the* hsame *and* Cont *transport rows, and the* Pkg/NameCert *provenance. The packet exports no classical completeness claim, no host real equality, no selected limit, and no quotient of Cauchy streams.*

Lean4 ✓ `BEDC.Derived.CauchyRegularizationUp.CauchyRegularizationSealRoute semantic name certificate`

Proof. Begin with a real-facing read. The only $\mathsf{Real}^{\uparrow}$ coordinate in the carrier is the seal-provenance row E, and E is attached to the regular rational handoff R.

Use Definition 376.4 to expand the source of R. The read must pass through the finite rational observation window, the displayed modulus threshold, the dyadic tolerance ledger, and the approximant row justified by that window.

The remaining coordinates are transport and provenance rows. They preserve the displayed route and name the dependency certificates, but they contain no field for a host real value, a quotient representative, a selected limit, or an ambient completeness theorem. Thus the seal boundary is exactly the finite BEDC surface stated above. □

Theorem 376.6 (CauchyRegularization common-modulus idempotence)**.** *For accepted* CauchyRegularization$^{\uparrow}$ *carriers regularized through the same transported* RationalStream$^{\uparrow}$ *observation windows,* CauchyModulus$^{\uparrow}$ *threshold rows,* DyadicRatCore$^{\uparrow}$ *modulus-window ledgers,* hsame *and* Cont *routes,* Pkg *rows, and* NameCert *ledger, a second* CauchyRegularization$^{\uparrow}$ *read through those same displayed rows yields the same* RegSeqRat$^{\uparrow}$ *handoff classifier and the same* Real$^{\uparrow}$ *seal-provenance row. The repeated read introduces no hidden tail selector, quotient stream, host limit, or completeness claim.*

Lean4 ✓ `BEDC.Derived.CauchyRegularizationUp.CauchyRegularizationFiniteCarrier common modulus idempotence`

Proof. Project the finite carrier $G = (S, M, D, W, R, E, H, C, P, N)$. The common modulus classifier identifies the displayed source window in S, the threshold row in M, the dyadic ledger in D, and the finite approximant ledger in W for the first read and for the second read.

Apply Definition 376.4 to both reads. Since the two reads use the same transported observation windows, modulus thresholds, dyadic rows, transport routes, package rows, and naming ledger, the handoff route can only be the displayed RegSeqRat$^{\uparrow}$ classifier row R.

It remains to compare the real-facing rows. Apply Definition 376.5. The Real$^{\uparrow}$ seal-provenance row is mediated by that same handoff, the same transport routes, and the same Pkg/NameCert provenance, so the repeated read has the identical displayed BEDC seal route and no additional selector or host-limit coordinate. □

Theorem 376.7 (CauchyRegularization RealUp seal idempotent route)**.** *For accepted* CauchyRegularization$^{\uparrow}$ *packets whose first and second regularization reads share the transported* RationalStream$^{\uparrow}$ *windows,* CauchyModulus$^{\uparrow}$ *threshold rows,* DyadicRatCore$^{\uparrow}$ *ledger rows,* RegSeqRat$^{\uparrow}$ *handoff row,* hsame *and* Cont *routes,* Pkg *provenance, and* NameCert *ledger, the* Real$^{\uparrow}$ *consumer seal route after the second read is the same displayed route as after the first read. The repeated real-facing read introduces no quotient stream, selected limit, host real equality, hidden tail selector, or ambient completeness coordinate.*

Proof. Project the finite carrier $G = (S, M, D, W, R, E, H, C, P, N)$. The shared carrier rows fix the source windows, modulus thresholds, dyadic ledgers, regularized approximants, handoff row, transport routes, package provenance, and local naming ledger for both reads.

Apply Definition 376.6. The RegSeqRat$^{\uparrow}$ handoff classifier and the Real$^{\uparrow}$ seal-provenance row are locked to the displayed rows R and E for the first read and for the second read.

Apply Definition 376.5 to expand both real-facing reads. Each read passes through the same handoff, transported rational-stream window, continuation route, package row, and local naming row, and the boundary lists no further consumer-visible coordinate.

Therefore the second Real$^{\uparrow}$ seal route is the same displayed route as the first. Since the carrier and the boundary exclusions contain no quotient stream, selected limit, host real equality, hidden tail selector, or ambient completeness coordinate, repeated regularization through the same finite rows adds no Real-facing escape route. □

Theorem 376.8 (CauchyRegularization Real seal source-modulus factorization)**.** *For an accepted* CauchyRegularization$^{\uparrow}$ *packet* $G = (S, M, D, W, R, E, H, C, P, N)$*, every* Real$^{\uparrow}$ *seal read factors through exactly the displayed finite* StreamName$^{\uparrow}$ *source window carried by* S*, the* CauchyModulus$^{\uparrow}$ *threshold row* M*, the* DyadicRatCore$^{\uparrow}$ *modulus-window ledger* D*, the approximant ledger* W*, the* RegSeqRat$^{\uparrow}$ *handoff row* R*, the seal provenance* E*, and the structural rows* H, C, P, N*. Conversely, those rows repack as the same Real-facing seal route. No quotient stream, selected limit, host real equality, hidden tail selector, ambient completeness theorem, or unrecorded modulus choice contributes to the read.*

Proof. Project the finite carrier of Definition 376.1. Its displayed rows are precisely $S, M, D, W, R, E, H, C, P, N$, so any Real-facing route must first account for the source window, modulus threshold, dyadic ledger, approximant ledger, handoff, seal provenance, transports, continuation routes, package row, and local naming ledger named there.

For the forward direction, apply Definition 376.4. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff row R is reached only through the displayed $\mathsf{StreamName}^{\uparrow}$ source window in S, the threshold row M, the dyadic modulus-window ledger D, and the approximant ledger W.

Then apply Definition 376.5. The $\mathsf{Real}^{\uparrow}$ seal reads that handoff through the seal-provenance row E and the structural rows H, C, P, N, and the boundary exposes no further consumer-visible coordinate.

For the converse direction, start from the displayed rows $S, M, D, W, R, E, H, C, P, N$. The handoff theorem repacks the source-modulus data as the same $\mathsf{RegSeqRat}^{\uparrow}$ route, and the seal-boundary theorem attaches exactly the Real-facing provenance row E with the same structural routes and ledgers.

Finally use Definition 376.7. If another Real-facing route were available from the same source, modulus, dyadic, approximant, handoff, seal, transport, package, and naming rows, the second read would differ from the first. Idempotence rules this out, so the factorization is exactly the displayed route and excludes quotient streams, selected limits, host real equality, hidden tail selectors, ambient completeness, and unrecorded modulus choices. □

Theorem 376.9 (CauchyRegularization Real seal normalization retract)**.** *Let $G = (S, M, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyRegularization}^{\uparrow}$ *packet. Suppose a second regularization packet reads the same transported* $\mathsf{RationalStream}^{\uparrow}$ *window row S, the same* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row M, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the same approximant ledger W, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R, the same seal row E, and the same structural rows H, C, P, N. Then the* $\mathsf{Real}^{\uparrow}$ *consumer route of the second read retracts to the original seal route E.*

The retract exports no quotient stream equality, selected limit, host real equality, hidden tail selector, unrecorded modulus choice, or ambient completeness theorem.

Proof. Project the finite carrier of Definition 376.1 for the original packet and for the second packet. The two projections list the same source window, modulus threshold, dyadic ledger, approximant ledger, handoff, seal, transport, continuation, package, and naming rows.

Apply Definition 376.6. The repeated read cannot introduce a new $\mathsf{CauchyModulus}^{\uparrow}$ threshold row or a new $\mathsf{RegSeqRat}^{\uparrow}$ handoff; the handoff and seal provenance remain the displayed rows R and E.

Apply Definition 376.7. With the same Real-facing rows on both reads, the second consumer route is identified with the first consumer route at the seal surface.

Finally apply Definition 376.8. The first route has only the displayed source-modulus-seal factorization through $S, M, D, W, R, E, H, C, P, N$. Hence the second route retracts to the same seal row E, and the listed quotient, limit, equality, selector, modulus-choice, and ambient-completeness data have no exported coordinate. □

Theorem 376.10 (CauchyRegularization public real-regularization export)**.** *The finite carrier, modulus classifier, regular-sequence handoff,* $\mathsf{Real}^{\uparrow}$ *seal boundary, and Real-facing idempotent route assemble a public* $\mathsf{CauchyRegularization}^{\uparrow}$ *export over* $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *The export exposes only displayed rational-stream windows, modulus thresholds, dyadic comparison rows, regularized approximants, the regular-sequence handoff, the real-seal provenance, and the named transport and package rows.*

It exposes no quotient stream, host real equality, selected limit, hidden tail selector, or ambient completeness theorem.

Proof. Start with the carrier and classifier. The carrier of Definition 376.1 lists exactly the finite rows available to a consumer, and the classifier of Definition 376.2 transports only those rows.

Apply Definition 376.3 to bind carrier admission, classifier stability, regular-sequence handoff, real-seal compatibility, and ledger exactness into the local naming surface.

Next use Definition 376.4. It routes every $\mathsf{RegSeqRat}^{\uparrow}$ read through a displayed rational window, a displayed modulus threshold, the dyadic ledger, and the finite approximant row.

Use Definition 376.5. The $\mathsf{Real}^{\uparrow}$ read is mediated by the same handoff, transport, continuation, package, and local naming provenance.

Finally use Definition 376.7. Repeated regularization through the same finite rows preserves that Real-facing route. The finite-row assembly therefore gives a public real-regularization export without quotient streams, host equality, selected limits, hidden tail selectors, or ambient completeness. □

Theorem 376.11 (CauchyRegularization public normalization retract export)**.** *Let $G = (S, M, D, W, R, E, H, C, P$ be an accepted* $\mathsf{CauchyRegularization}^{\uparrow}$ *packet, and suppose a second accepted* $\mathsf{CauchyRegularization}^{\uparrow}$ *packet has the same displayed source row S, modulus row M, dyadic ledger D, approximant ledger W, regular-sequence handoff R, seal row E, and structural rows H, C, P, N. Then the public real-regularization export of the second read retracts to the original public export surface determined by $S, M, D, W, R, E, H, C, P, N$, not only to the terminal* $\mathsf{Real}^{\uparrow}$ *seal row.*

This public retract exports no quotient stream, selected limit, host real equality, hidden tail selector, unrecorded modulus choice, or ambient completeness theorem.

Proof. First apply Definition 376.10 to the original packet. Its public export surface contains exactly the displayed rational-stream windows, modulus thresholds, dyadic comparison rows, regularized approximants, handoff row, real-seal provenance, transport rows, package row, and naming ledger.

Apply the same public export theorem to the second packet. Since the second accepted packet shares $S, M, D, W, R, E, H, C, P, N$, its public export has the same displayed carrier, classifier, handoff, seal, transport, package, and naming coordinates.

Next apply Definition 376.9. The Real-facing consumer route of the second read retracts to the original seal route E under the shared displayed rows.

Finally apply Definition 376.8. The seal row E is not an isolated terminal coordinate: it is reached only through the source window S, modulus row M, dyadic ledger D, approximant ledger W, handoff row R, and the structural rows H, C, P, N. Thus the retract returns the second public read to the original public export surface itself. The excluded quotient stream, selected-limit, host-equality, tail-selector, modulus-choice, and ambient-completeness data have no public coordinate available for the retract. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRegularization}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRegularization}^{\uparrow}$ packet is generated from finite $\mathsf{RationalStream}^{\uparrow}$ windows, explicit $\mathsf{CauchyModulus}^{\uparrow}$ threshold rows, $\mathsf{DyadicRatCore}^{\uparrow}$ modulus-window observations, regularized finite-window approximants, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal-provenance row, transport routes, package provenance, and a local NameCert ledger.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRegularization}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: The obligation scope is the finite carrier, modulus-window classifier, regular-sequence handoff, $\mathsf{Real}^{\uparrow}$ seal compatibility, and ledger exactness over $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRegularization}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CauchyRegularizationUp.CauchyRegularizationSealRoute\_semantic\_name\_certificate`
Bridge status: none
Origin: human
Not claimed: This chapter does not close classical real completeness, quotient equality of Cauchy streams, uniqueness of limits, selected host real values, or bridge checking.
Upgrade path: Bridged closure requires a concrete bridge theorem from the public regularization export to the abstract completion-facing interface.

Chapter 377

A Concrete Naming Certificate for $\mathsf{UnitDisk}^{\uparrow}$

The $\mathsf{UnitDisk}^{\uparrow}$ interface names the closed real unit-disk carrier as a finite BEDC packet assembled from real coordinate names, the product pairing surface, metric radius reads, interval or real-order bounds, and the boundary consumer already available to $\mathsf{S}^{1\uparrow}$. In the standard topology text of Munkres, Topology, the closed unit disk and its boundary circle are read as the familiar Euclidean disk and unit circle; this chapter records only the finite BHist certificate surface used by BEDC consumers.

The disk carrier consumes the $\mathsf{Met}^{\uparrow}$ radius witness surface as the public route from the displayed product point to the displayed origin. When that radius is exactly the real unit row, the same packet hands its boundary row to chapter 58 as the boundary consumer route, not as a separate host circle or quotient boundary object.

Definition 377.1 (UnitDisk BHist carrier)**.** *A* $\mathsf{UnitDisk}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (x, y, p, o, d, b, \partial, H, C, P, N)$$

with the following visible rows:

1. *x and y are two* $\mathsf{Real}^{\uparrow}$ *coordinate rows, each read through its own finite real-name seal;*
2. *p is the* $\mathsf{Prod}^{\uparrow}$ *pair row joining the two coordinate rows as one displayed planar point;*
3. *o is the origin row, formed from the two zero* $\mathsf{Real}^{\uparrow}$ *rows and paired through the same* $\mathsf{Prod}^{\uparrow}$ *surface;*
4. *d is the* $\mathsf{Met}^{\uparrow}$ *radius-distance witness reading the distance from p to o through the displayed metric route;*
5. *b is a nonnegative bound row, supplied either by* $\mathsf{Interval}^{\uparrow}$ *or by* $\mathsf{RealAlgOrder}^{\uparrow}$*, witnessing that the displayed radius is at most the real unit row;*
6. *∂ is an optional boundary row recording the exact unit-radius packet consumed by* $\mathsf{S}^{1\uparrow}$ *when the metric read is classified as boundary;*
7. *H and C are the componentwise* hsame *witnesses and displayed* Cont *routes for coordinate, pair, origin, radius, bound, and optional boundary transport;*
8. *P is the* Pkg *provenance naming the consumed* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Prod}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Interval}^{\uparrow}$*,* $\mathsf{RealAlgOrder}^{\uparrow}$*, and* $\mathsf{S}^{1\uparrow}$ *source surfaces;*

9. N is the local $\mathsf{NameCert}_{\mathsf{UnitDisk}^\uparrow}$ *provenance row.*

The carrier classifier compares two accepted packets only by transporting these displayed rows componentwise through H and C. It has no coordinate for host Euclidean topology, open-cover compactness, quotient boundary identification, or a host subset of $\mathbb{R}^2$.

Lean4 ✓ `BEDC.Derived.UnitDiskUp.UnitDiskTasteGate single carrier alignment`

Theorem 377.2 (UnitDisk carrier stability)**.** *Let $U = (x, y, p, o, d, b, \partial, H, C, P, N)$ be an accepted* $\mathsf{UnitDisk}^\uparrow$ *carrier, and let $U' = (x', y', p', o', d', b', \partial', H', C', P', N')$ be obtained by componentwise displayed* hsame *transport of the two* $\mathsf{Real}^\uparrow$ *coordinate rows, the* $\mathsf{Prod}^\uparrow$ *point row, the origin row, the* $\mathsf{Met}^\uparrow$ *radius witness, the* $\mathsf{Interval}^\uparrow$ *or* $\mathsf{RealAlgOrder}^\uparrow$ *bound row, the optional* $\mathsf{S}^{1\uparrow}$ *boundary row, and the provenance rows. If the displayed* Cont *routes preserve the coordinate, pairing, metric-read, bound, and boundary ledgers, then U' is again an accepted* $\mathsf{UnitDisk}^\uparrow$ *carrier and the local classifier relates U to U'.*

Lean4 ✓ `BEDC.Derived.UnitDiskUp.UnitDiskOriginRows radius ledger`

Proof. Project the carrier through Definition 377.1. The two real coordinates, product pair, origin pair, radius witness, bound row, optional boundary row, routing rows, and provenance rows are all explicit finite packet coordinates.

Transport each coordinate by the displayed hsame witnesses, then repack the transported coordinates through the same $\mathsf{Prod}^\uparrow$ pairing route. The origin row is transported in parallel, so the metric witness still reads a radius from the transported point to the transported origin.

Use the stated Cont routes to move the radius comparison into the transported $\mathsf{Interval}^\uparrow$ or $\mathsf{RealAlgOrder}^\uparrow$ bound row. If a boundary row is present, the same transport carries it to the optional $\mathsf{S}^{1\uparrow}$ consumer row; if it is absent, no boundary consumer is exported.

Repacking these rows gives the accepted packet U'. Since the classifier inspects exactly the displayed rows, the transported packet is classified with U and no host topological coordinate is created. □

Lean4 ✓ `BEDC.Derived.UnitDiskUp.UnitDiskBHistCarrier carrier stability`

Theorem 377.3 (UnitDisk boundary SOne consumer)**.** *For every accepted* $\mathsf{UnitDisk}^\uparrow$ *carrier whose optional boundary row ∂ is present, a downstream* $\mathsf{S}^{1\uparrow}$ *consumer may read only the two* $\mathsf{Real}^\uparrow$ *coordinate rows, their* $\mathsf{Prod}^\uparrow$ *pair row, the* $\mathsf{Met}^\uparrow$ *unit-radius witness from the origin, the exact boundary ledger carried by ∂, and the associated* hsame, Cont, Pkg, *and* NameCert *provenance.*

The consumer boundary does not export open-cover compactness, quotient boundary identifications, host Euclidean topology, or an ambient subset construction for the disk.

Proof. Read the packet through Definition 377.1. The boundary coordinate is optional and, when present, is the only row routed to $\mathsf{S}^{1\uparrow}$.

The $\mathsf{S}^{1\uparrow}$ consumer receives the coordinate pair through $\mathsf{Prod}^\uparrow$ and the radius equality through the same $\mathsf{Met}^\uparrow$ witness used by the disk packet. The bound row confirms that the radius sits at the displayed real unit; the boundary row records exact unit-radius consumption rather than a separate host circle.

Apply Definition 377.2 to see that these rows are stable under the displayed componentwise classifier. The exported boundary surface is therefore the finite row ∂ with its provenance, not a quotient of boundary points or a topological subspace. □

Lean4 ✓ `BEDC.Derived.UnitDiskUp.UnitDiskBHistCarrier boundary sone consumer`

Theorem 377.4 (UnitDisk NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{UnitDisk}^\uparrow}$ *obligation surface consists of five finite rows:*

1. *carrier inhabitation: the origin row together with the two zero* $\mathsf{Real}^\uparrow$ *coordinate rows, their* $\mathsf{Prod}^\uparrow$ *pair row, the zero* $\mathsf{Met}^\uparrow$ *radius read, and the unit bound row inhabit the carrier of Definition 377.1;*
2. *classifier laws: reflexivity, symmetry, and transitivity are inherited componentwise from the displayed* hsame *comparisons on coordinates, product pairs, origin rows, metric witnesses, bounds, optional boundary rows, routing rows, and provenance;*
3. *carrier transport: Definition 377.2 transports accepted packets along the displayed* hsame *and* Cont *rows without adding a host point set;*
4. *exact ledger reads: every public radius read factors through the* $\mathsf{Met}^\uparrow$ *row* d *and every boundary read factors through the optional row* ∂ *of the same carrier;*
5. *consumer boundary: Definition 377.3 permits* $\mathsf{S}^{1\uparrow}$ *consumption of exact boundary packets while excluding open-cover compactness, quotient boundary identifications, and host Euclidean topology.*

Lean4 ✓ `BEDC.Derived.UnitDiskUp.UnitDiskBHistCarrier namecert obligation surface`

Proof. The carrier row is Definition 377.1. Its origin coordinate gives an accepted packet by taking both real coordinates to be the displayed zero real row, pairing them through $\mathsf{Prod}^\uparrow$, reading zero radius through $\mathsf{Met}^\uparrow$, and comparing zero to the real unit through the displayed nonnegative bound surface.

The classifier row is componentwise. Reflexivity uses each displayed row as itself, symmetry reverses the componentwise hsame witnesses, and transitivity composes them across the same coordinate, pair, origin, radius, bound, boundary, routing, and provenance positions.

Carrier transport is exactly Definition 377.2. It keeps the metric and bound rows tied to the transported coordinate pair and origin row, so an accepted disk packet remains inside the same finite carrier surface.

For ledger exactness, inspect the packet coordinates. The only radius coordinate is d, and the only boundary coordinate is ∂ when that row is present. A consumer can therefore read radius and boundary data only through those displayed rows and their provenance.

Finally apply Definition 377.3. The optional boundary handoff is a finite $\mathsf{S}^{1\uparrow}$ consumer surface and contains no open-cover compactness datum, quotient boundary construction, or host Euclidean topology. □

Theorem 377.5 (UnitDisk origin radius ledger)**.** *The packet whose coordinates* x *and* y *are the zero* $\mathsf{Real}^\uparrow$ *rows, whose point row* p *and origin row* o *are both the displayed* $\mathsf{Prod}^\uparrow$ *pairing of those zero rows, whose radius witness* d *is the zero* $\mathsf{Met}^\uparrow$ *read from* p *to* o*, whose bound row* b *records zero below the real unit through* $\mathsf{Interval}^\uparrow$ *or* $\mathsf{RealAlgOrder}^\uparrow$*, and whose provenance rows are the corresponding* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows is an accepted* $\mathsf{UnitDisk}^\uparrow$ *carrier. Its radius ledger is exactly the displayed zero-radius* $\mathsf{Met}^\uparrow$ *row and its unit-bound row.*

Proof. Use Definition 377.1 with both coordinates set to the displayed zero $\mathsf{Real}^\uparrow$ row. The product row p and the origin row o are then the same finite $\mathsf{Prod}^\uparrow$ pairing surface.

The metric read from the point to the origin is the displayed zero-distance row. The bound row records that this zero radius is below the real unit through the available $\mathsf{Interval}^\uparrow$ or $\mathsf{RealAlgOrder}^\uparrow$ comparison.

Package these coordinates with the identity hsame comparisons, the displayed Cont routes, P, and N. The carrier contains no other radius coordinate, so the radius ledger of this origin packet is exactly d together with the unit-bound row b. □

Theorem 377.6 (UnitDisk classifier law package)**.** *The* $\mathsf{UnitDisk}^{\uparrow}$ *classifier has reflexivity, symmetry, transitivity, and carrier transport componentwise on the displayed* $\mathsf{Real}^{\uparrow}$ *coordinate rows,* $\mathsf{Prod}^{\uparrow}$ *pair rows, origin rows,* $\mathsf{Met}^{\uparrow}$ *radius witnesses,* $\mathsf{Interval}^{\uparrow}$ *or* $\mathsf{RealAlgOrder}^{\uparrow}$ *bound rows, optional* $\mathsf{S}^{1\uparrow}$ *boundary rows,* BHist *routing rows,* hsame *comparisons,* Cont *routes,* Pkg *provenance, and* NameCert *provenance.*

Proof. Read the classifier from Definition 377.1. It compares only visible coordinates of the packet and the displayed transport rows; it does not compare ambient Euclidean points or host subsets.

Reflexivity uses the identity displayed comparison at each coordinate. Symmetry reverses each componentwise hsame comparison and the associated Cont route on the same coordinate, pair, radius, bound, boundary, and provenance rows.

Transitivity composes two displayed transports coordinate by coordinate. Since each transport keeps the metric witness tied to the transported point and origin and keeps the bound and optional boundary ledgers attached to the same radius row, the composite packet is again accepted.

Carrier transport is exactly Definition 377.2. Combining these componentwise laws gives the stated classifier law package. □

Theorem 377.7 (UnitDisk radius boundary exactness)**.** *Every* $\mathsf{UnitDisk}^{\uparrow}$ *radius consumer read factors through the displayed* $\mathsf{Met}^{\uparrow}$ *radius witness* d *of the carrier packet, and every boundary consumer read factors through the optional* $\mathsf{S}^{1\uparrow}$ *boundary row* ∂ *when that row is present. No consumer read exports a host Euclidean subset, an open-cover compactness datum, a quotient boundary identification, or any boundary object not displayed in the carrier.*

Proof. Project an accepted packet through Definition 377.1. The only radius coordinate is the $\mathsf{Met}^{\uparrow}$ witness d, and the only exact boundary coordinate is the optional row ∂.

For a radius request, the consumer first reads the two $\mathsf{Real}^{\uparrow}$ coordinates through the $\mathsf{Prod}^{\uparrow}$ row and the origin row, then reads the radius through d and the unit comparison through b. There is no separate Euclidean norm coordinate in the packet.

For a boundary request, apply Definition 377.3. If ∂ is present, the $\mathsf{S}^{1\uparrow}$ consumer receives exactly the boundary row and its provenance; if it is absent, the disk packet exports no boundary consumer surface.

The non-escape clauses follow by inspection of the carrier coordinates and by Definition 377.2, which preserves the same displayed metric and boundary rows under transport. □

Theorem 377.8 (UnitDisk product metric boundary package)**.** *For every accepted* $\mathsf{UnitDisk}^{\uparrow}$ *packet, the two* $\mathsf{Real}^{\uparrow}$ *coordinate rows, the* $\mathsf{Prod}^{\uparrow}$ *pair row, the origin row, the* $\mathsf{Met}^{\uparrow}$ *radius witness, the* $\mathsf{Interval}^{\uparrow}$ *or* $\mathsf{RealAlgOrder}^{\uparrow}$ *bound row, the optional* $\mathsf{S}^{1\uparrow}$ *boundary row, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *provenance form the exact product-metric boundary package for* $\mathsf{UnitDisk}^{\uparrow}$*.*

The package exposes the product pairing, the metric radius comparison with the real unit row, and the optional circle-boundary consumer row as a single finite certificate. It exports no host Euclidean subset, open-cover compactness, quotient boundary identification, or unrecorded topology.

Proof. Start with Definition 377.1. It lists the two real coordinates, their product row, the origin row, the metric radius witness, the unit-bound row, the optional boundary row, and the transport and provenance rows as coordinates of one finite packet.

Apply Definition 377.2 to keep the product point, origin, radius, bound, boundary, and provenance rows stable under the displayed hsame and Cont transports. The classifier therefore remains componentwise on the same product-metric rows.

Use Definition 377.3 for the optional $\mathsf{S}^{1\uparrow}$ handoff and Definition 377.4 for the local carrier, classifier, transport, exact-ledger, and consumer obligations.

Finally combine Definition 377.6 with Definition 377.7. The resulting package is precisely the finite product-metric disk certificate with its boundary consumer row when present, and no host subset, compactness, quotient boundary, or unrecorded topological coordinate is introduced. □

Theorem 377.9 (UnitDisk carrier habitation)**.** *The concrete packet*

$$U = (x, y, p, o, d, b, \partial, H, C, P, N)$$

inhabits $\mathsf{UnitDisk}^{\uparrow}$ *whenever x and y are the displayed zero* $\mathsf{Real}^{\uparrow}$ *coordinate rows, p and o are the corresponding* $\mathsf{Prod}^{\uparrow}$ *pair rows, d is the zero* $\mathsf{Met}^{\uparrow}$ *radius ledger, b is the displayed unit-bound row, ∂ is absent or the exact* $\mathsf{S}^{1\uparrow}$ *unit-radius row, and H, C, P, N are the matching* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance rows.*

Proof. Apply Definition 377.5. It supplies the zero coordinate rows, the product point, the origin row, the zero metric radius read, and the unit-bound ledger.

Then apply Definition 377.4. Its carrier-inhabitation row repacks those displayed coordinates with the BHist, hsame, Cont, Pkg, and NameCert provenance.

If the optional boundary row is present, use Definition 377.3; if it is absent, the carrier remains accepted without exporting a boundary consumer. Both cases stay inside the concrete packet. □

Theorem 377.10 (UnitDisk classifier laws)**.** *For accepted packets*

$$U = (x, y, p, o, d, b, \partial, H, C, P, N)$$

and U' with the same concrete row shape, the $\mathsf{UnitDisk}^{\uparrow}$ *classifier is reflexive, symmetric, transitive, and stable under componentwise transport of the* $\mathsf{Real}^{\uparrow}$ *coordinate rows,* $\mathsf{Prod}^{\uparrow}$ *pair row, origin row,* $\mathsf{Met}^{\uparrow}$ *radius ledger, unit-bound row, optional* $\mathsf{S}^{1\uparrow}$ *boundary row, and the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance rows.*

Proof. Use Definition 377.6. It states the reflexivity, symmetry, transitivity, and transport laws componentwise for the displayed coordinate, pair, origin, radius, bound, boundary, routing, and provenance rows.

Apply Definition 377.2 to keep the transported packet accepted. The same theorem keeps the metric radius row attached to the transported point and origin and keeps the optional boundary row tied to the same displayed radius ledger.

The classifier therefore compares only rows of U and U'. It does not create a host Euclidean point, quotient boundary identification, or external topological equality. □

Theorem 377.11 (UnitDisk radius ledger exactness)**.** *Every public radius or boundary read of an accepted*

$$U = (x, y, p, o, d, b, \partial, H, C, P, N)$$

factors through the displayed $\mathsf{Met}^{\uparrow}$ *row d, the unit-bound row b, the optional* $\mathsf{S}^{1\uparrow}$ *boundary row ∂ when present, and the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance rows H, C, P, N.*

Proof. Apply Definition 377.7. It identifies d as the only radius coordinate and ∂ as the only boundary coordinate when the boundary row is present.

Use Definition 377.8 to route the two $\mathsf{Real}^{\uparrow}$ coordinate rows through p and o, then through the $\mathsf{Met}^{\uparrow}$ radius witness and the displayed unit-bound row.

Finally apply Definition 377.3 for the boundary case. The provenance rows H, C, P, N record the allowed hsame, Cont, Pkg, and NameCert reads, so no host Euclidean subset, compactness datum, or quotient boundary object can enter the ledger. □

Theorem 377.12 (UnitDisk scoped product-metric source)**.** *Every accepted* $\mathsf{UnitDisk}^{\uparrow}$ *packet reads its two* $\mathsf{Real}^{\uparrow}$ *coordinate rows through the displayed* $\mathsf{Prod}^{\uparrow}$ *pair row and the displayed origin row of Definition 377.1. The product-metric source of the disk certificate is therefore the finite row package*

$$(x, y, p, o, H, C, P, N)$$

rather than a host point of $\mathbb{R}^2$ *or an ambient Euclidean subset.*

Proof. Project the packet through Definition 377.1. The coordinate rows x and y, the product pair row p, and the origin row o are explicit carrier coordinates.

Apply Definition 377.2 to see that transport preserves the same coordinate, pair, and origin positions. Apply Definition 377.6 to read the classifier componentwise on those displayed rows.

The source row is consequently the finite product-metric package displayed by the carrier. No host point set or ambient Euclidean subset is added to the certificate. □

Theorem 377.13 (UnitDisk scoped radius-boundary route)**.** *For every accepted* $\mathsf{UnitDisk}^{\uparrow}$ *packet, each radius read factors through the displayed* $\mathsf{Met}^{\uparrow}$ *radius row* d*, the* $\mathsf{Interval}^{\uparrow}$ *or* $\mathsf{RealAlgOrder}^{\uparrow}$ *unit-bound row* b*, and the transport and provenance rows of Definition 377.1. When the optional boundary row* ∂ *is present, every boundary read additionally factors through the displayed* $\mathsf{S}^{1\uparrow}$ *consumer row.*

Proof. Start with the carrier projection. The radius row is d, the unit-bound row is b, and the optional boundary row is ∂.

Use Definition 377.7. It states that public radius consumers read through d and that boundary consumers read through ∂ when that row is present.

Apply Definition 377.3 for the boundary handoff and Definition 377.8 for the combined product, metric, bound, and optional boundary package. These routes keep every radius or boundary request inside the displayed $\mathsf{Met}^{\uparrow}$, $\mathsf{Interval}^{\uparrow}$ or $\mathsf{RealAlgOrder}^{\uparrow}$, and $\mathsf{S}^{1\uparrow}$ rows. □

Theorem 377.14 (UnitDisk scoped consumer non-escape)**.** *Downstream consumers of an accepted* $\mathsf{UnitDisk}^{\uparrow}$ *packet cannot read host Euclidean subsets, open-cover compactness, quotient boundary identification, or unrecorded topology. Their public reads are restricted to the displayed* $\mathsf{Real}^{\uparrow}$ *coordinate rows,* $\mathsf{Prod}^{\uparrow}$ *pair and origin rows,* $\mathsf{Met}^{\uparrow}$ *radius row,* $\mathsf{Interval}^{\uparrow}$ *or* $\mathsf{RealAlgOrder}^{\uparrow}$ *bound row, optional* $\mathsf{S}^{1\uparrow}$ *boundary row, and the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance rows.*

Proof. Inspect Definition 377.1. The carrier lists exactly the coordinate, product, origin, radius, bound, optional boundary, transport, route, package, and local naming rows.

Apply Definition 377.3 to boundary consumers and Definition 377.7 to radius consumers. Both theorems identify the displayed rows through which public reads must factor.

Finally use Definition 377.2 and Definition 377.6. Transport and classification remain componentwise on the same finite packet rows, so no host subset, compactness proof, quotient boundary object, or unrecorded topology can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{UnitDisk}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UnitDisk}^{\uparrow}$ packet is generated by two $\mathsf{Real}^{\uparrow}$ coordinate rows, a $\mathsf{Prod}^{\uparrow}$ pair row, an origin row, a $\mathsf{Met}^{\uparrow}$ radius witness, an $\mathsf{Interval}^{\uparrow}$ or $\mathsf{RealAlgOrder}^{\uparrow}$ unit-bound row, optional $\mathsf{S}^{1\,\uparrow}$ boundary consumption, transport routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UnitDisk}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 377.9, Definition 377.10, Definition 377.11, Definition 377.12, Definition 377.13, and Definition 377.14 export the finite closed unit-disk certificate as the public product-metric and boundary-consumer surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UnitDisk}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.UnitDiskUp.UnitDiskBHistCarrier\_namecert\_obligation\_surface`

Bridge status: none

Origin: human

Not claimed: This chapter does not close compactness, homotopy, quotient boundary identification, host Euclidean topology, or bridge checking.

Upgrade path: Bridge closure requires a standard bridge treatment for the exported product-metric and boundary-consumer surface.

Chapter 378

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonad}^{\uparrow}$

The $\mathsf{CauchyCompletionMonad}^{\uparrow}$ interface names the finite completion transformer that reads regular rational Cauchy data and returns a $\mathsf{Real}^{\uparrow}$ seal route. It consumes the visible real-and-completion primitives $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ without forming quotient reals, selecting limits by choice, or appealing to host completeness. The finite completion transformer consumes the $\mathsf{Real}^{\uparrow}$ seal surface of chapter 38 through the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows already displayed in the carrier.

The finite completion transformer reads the window discipline of chapter 126, the dyadic observation ledger of chapter 291, the regular-rational readback of chapter 301, and the seal boundary of chapter 38.

Definition 378.1 (CauchyCompletionMonad carrier)**.** *A* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, W, D, \mu, \Delta, E, L, C, P, N)$$

with the following visible rows:

1. *X is the source regular-Cauchy family over* $\mathsf{RegSeqRat}^{\uparrow}$*;*
2. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected from the members of X;*
3. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations read through the windows in W;*
4. *μ is a unary modulus and schedule row naming which family member and which window answer each requested precision;*
5. *Δ is the diagonal transport ledger that repacks the scheduled observations as a regular rational readback;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row attached to that diagonal readback;*
7. *L records the componentwise* hsame *comparisons for source-family rows, windows, dyadic observations, schedule rows, diagonal rows, and seal rows;*
8. *C records the displayed* Cont *routes through which consumers reach the schedule, window, observation, diagonal, and real-seal coordinates;*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and the local dependency certificates;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonad}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite coordinates and their displayed transports.

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadTasteGate single carrier alignment`

Theorem 378.2 (CauchyCompletionMonad NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonad}^{\uparrow}}$ *obligation surface consists of five rows:*

1. *carrier habitation by constant regular rational data, using constant* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, stationary* $\mathsf{StreamName}^{\uparrow}$ *windows, constant* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, the zero schedule, the diagonal readback of that stationary packet, and the corresponding* $\mathsf{Real}^{\uparrow}$ *seal row;*
2. *classifier transport for schedule rows, window rows, dyadic observation rows, diagonal rows, and seal rows by componentwise* hsame *and the displayed* Cont *routes;*
3. *diagonal handoff exactness: each real-facing precision read factors through the schedule row, the selected finite window, the displayed dyadic observation, and the diagonal readback row before reaching the* $\mathsf{Real}^{\uparrow}$ *seal;*
4. *non-escape of quotient reals, host real equality, choice-selected limits, ambient completeness principles, or hidden stream representatives;*
5. *public consumer boundary for* $\mathsf{Real}^{\uparrow}$ *completion reads, exposing only* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and local* NameCert *coordinates.*

These obligations specify the finite completion-interface surface and do not assert that $\mathsf{Real}^{\uparrow}$ *is complete as an ambient real object.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket namecert obligations`

Proof. For habitation, take a constant regular rational family. Its displayed stream windows are stationary, every dyadic observation is the same rational row, the unary schedule may select the initial member for each precision request, and the diagonal ledger repacks the same rows as the real-facing readback.

Classifier transport is coordinatewise. Transport the schedule, selected windows, dyadic observations, diagonal ledger, and real-seal row along the stored hsame comparisons, then compose with the displayed Cont read routes for the same coordinates.

For diagonal handoff exactness, project the carrier coordinates X, W, D, μ, Δ, and E. A consumer precision request first reads μ, then the chosen window in W, then the dyadic observation in D, and only then the diagonal readback Δ and seal row E.

The non-escape and public-boundary rows follow from the same projection. Since the packet contains no coordinate for a quotient real, host equality proof, selected limit, or ambient completeness theorem, a public $\mathsf{Real}^{\uparrow}$ read cannot export such data. □

Theorem 378.3 (CauchyCompletionMonad unit boundary)**.** *For every displayed rational row accepted by* $\mathsf{RegSeqRat}^{\uparrow}$*, the constant regular-rational family determines a* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *unit packet. Its* $\mathsf{StreamName}^{\uparrow}$ *windows are stationary, its* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations are the constant rational observations, its schedule row selects the constant family member, its diagonal readback is the same regular-rational row, and its* $\mathsf{Real}^{\uparrow}$ *seal row is reached through that constant packet.*

Proof. Choose the constant regular-rational family described in the habitation row of Definition 378.2. The finite windows and dyadic observations are stationary because every requested precision reads the same rational source row.

The schedule row may select the displayed constant member at each request. The diagonal ledger then repacks the same finite observations as a regular-rational readback, without creating a new limit object.

Finally attach the $\mathsf{Real}^{\uparrow}$ seal row after the diagonal readback. The carrier coordinates of Definition 378.1 contain exactly these rows, so the unit packet is a visible finite BEDC packet. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket unit boundary`

Theorem 378.4 (CauchyCompletionMonad diagonal-bind stability)**.** *Let M and M' be accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packets. If their source-family rows, schedules, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, diagonal readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal rows are transported componentwise by displayed* hsame *routes and read through the corresponding* Cont *routes, then the diagonal-bind classifier is stable: every consumer precision read of M and M' follows matched schedule, window, dyadic-observation, diagonal-readback, and seal coordinates.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket diagonal bind stability`

Proof. Unfold the classifier of Definition 378.1. It compares packets through the finite coordinates X, W, D, μ, Δ, E, L, C, P, and N and their displayed transports.

Move the source-family row, schedule, selected windows, dyadic observations, diagonal ledger, and seal row along the stored hsame comparisons. The Cont coordinates keep the same read order from a precision request to the schedule, then to the window and observation rows.

Apply the diagonal handoff row of Definition 378.2. It forces each real-facing read through the transported schedule, finite window, dyadic observation, and diagonal readback before the seal, so the classifier remains stable under the componentwise transport. □

Theorem 378.5 (CauchyCompletionMonad public Real seal factorization)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet factors through the schedule row, the selected finite* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback, and the final seal row. The packet exports no quotient real, selected limit, host real equality, ambient completeness theorem, or hidden stream representative.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket public real seal factorization`

Proof. Start from a public precision request. The carrier makes the schedule row μ the first coordinate that can choose a family member and window for that request.

The chosen window is read from W, its dyadic observation from D, and the corresponding regular-rational readback from Δ. This is exactly the diagonal handoff route stated in Definition 378.2.

The $\mathsf{Real}^{\uparrow}$ seal row E is reached only after that route. Since the carrier has no coordinate for quotient reals, selected limits, host equality, completeness, or hidden representatives, the listed finite rows exhaust every public real-seal factorization. □

Theorem 378.6 (CauchyCompletionMonad schedule composition boundary)**.** *Let $M = (X, W, D, \mu, \Delta, E, L, C, P,$ and $M' = (X', W', D', \mu', \Delta', E', L', C', P', N')$ be accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packets whose source-family rows are transported by displayed* hsame *rows, whose schedules are compatible on the*

inspected precision requests, whose finite StreamName$^{\uparrow}$ *windows and* DyadicRatCore$^{\uparrow}$ *observations match through displayed ledger rows, and whose consumer routes include a displayed* Cont *composition from the schedule of M to the transported schedule of M'. Then the composed finite completion packet still has every public* Real$^{\uparrow}$ *read factor through the composed schedule, the matched window ledger, the matched dyadic observation ledger, the* RegSeqRat$^{\uparrow}$ *diagonal readback, and the seal row. The composition exports no quotient real, selected limit, host equality, hidden stream representative, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket schedule composition boundary`

Proof. For constant schedules, apply the unit boundary of Definition 378.3. The composed packet has stationary windows, stationary dyadic observations, the same diagonal readback, and the same seal-facing route.

For transported schedules, use the diagonal-bind stability of Definition 378.4. The displayed hsame rows move source families, schedules, windows, observations, diagonal readbacks, and seal rows componentwise, while the displayed Cont composition preserves the consumer order.

It remains to identify the public route. Apply Definition 378.5. Every public read must pass through schedule, window, dyadic observation, diagonal readback, and seal coordinates, so the composed packet exposes exactly the same finite completion surface. □

Theorem 378.7 (CauchyCompletionMonad left-unit factorization)**.** *Let r be a displayed rational row accepted by* RegSeqRat$^{\uparrow}$*, and let M be the* CauchyCompletionMonad$^{\uparrow}$ *packet obtained by first forming the unit packet for r and then composing it through an accepted finite completion packet by the schedule composition boundary. Every public* Real$^{\uparrow}$ *read of the composite factors through the original constant regular-rational row, stationary* StreamName$^{\uparrow}$ *windows, constant* DyadicRatCore$^{\uparrow}$ *observations, the same* RegSeqRat$^{\uparrow}$ *diagonal readback, and the same seal row. The left-unit route exports no quotient real, selected limit, host equality, hidden stream representative, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket left unit factorization`

Proof. Start with the unit packet supplied by Definition 378.3. Its source family is constant, its finite windows are stationary, its dyadic observations are constant rational observations, and its diagonal readback is the original regular-rational row.

Use Definition 378.6 to compose this unit packet with the next accepted packet. The unit schedule selects the same source row at every precision, so the composed schedule has no additional consumer-visible choice before the stationary window and dyadic-observation rows.

Transport the diagonal and seal-facing rows with Definition 378.4. The componentwise hsame rows and displayed Cont routes preserve the original regular-rational readback and its seal-facing coordinate.

Finally apply Definition 378.5. The only public route runs through the constant row, stationary windows, constant dyadic observations, diagonal readback, and seal row, and the carrier contains no coordinate for a quotient real, selected limit, host equality, hidden stream representative, or ambient completeness row. □

Theorem 378.8 (CauchyCompletionMonad right-unit factorization)**.** *Let $M = (X, W, D, \mu, \Delta, E, L, C, P, N)$ be an accepted* CauchyCompletionMonad$^{\uparrow}$ *packet. If M is composed on the seal-facing side with the unit boundary for its displayed* RegSeqRat$^{\uparrow}$ *diagonal readback, then every public consumer read preserves the packet's schedule row, finite* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *observations,*

RegSeqRat$^{\uparrow}$ *diagonal readback, and public seal factorization. The right-unit route exports no quotient real, selected limit, host equality, hidden stream representative, or ambient completeness row.*

Proof. Begin with the accepted packet M and its diagonal readback Δ. The public factorization of Definition 378.5 already routes every real-facing read through μ, W, D, Δ, and the seal row E.

Attach the unit packet of Definition 378.3 to the displayed diagonal readback. Since that unit has stationary windows and constant dyadic observations over the same readback, it contributes no new schedule choice beyond the existing seal-facing read route.

Apply Definition 378.4 to compare the original packet with the packet followed by this unit. The stored hsame and Cont rows identify the schedule, window, observation, diagonal, and seal coordinates componentwise.

The schedule composition boundary of Definition 378.6 then identifies the composed consumer route with the original route. Thus the right-unit composite preserves the same packet ledger, and no quotient real, selected limit, host equality, hidden stream representative, or ambient completeness row is introduced. □

Theorem 378.9 (CauchyCompletionMonad bind associativity ledger)**.** *Let M, M', and M'' be accepted* CauchyCompletionMonad$^{\uparrow}$ *packets whose two successive finite bind compositions are defined by displayed schedule, window, dyadic-observation, diagonal, and seal ledger rows. The two associations of the bind composition have the same consumer-visible route through the composed schedule, selected finite* StreamName$^{\uparrow}$ *window,* DyadicRatCore$^{\uparrow}$ *observation,* RegSeqRat$^{\uparrow}$ *diagonal readback,* Real$^{\uparrow}$ *seal,* BHist *entries, displayed* hsame*, displayed* Cont*,* Pkg *provenance, and local* NameCert *rows. Neither association exports a quotient real, selected limit, host equality, hidden stream representative, or ambient completeness row.*

Proof. First compare each single bind step with Definition 378.6. Both associations must expose the same kind of finite route: schedule, selected window, dyadic observation, diagonal readback, and seal row.

Next apply Definition 378.4 to the intermediate packets. The componentwise hsame rows identify source-family rows, schedules, selected windows, dyadic observations, diagonal readbacks, and seal coordinates, while the displayed Cont rows keep the consumer order fixed.

The unit boundary of Definition 378.3 supplies the neutral constant packets at the ends of the ledger. These packets use stationary windows and constant dyadic observations, so they do not alter the visible BHist, Pkg, or local NameCert rows of the two associations.

Finally use Definition 378.5 for the public readout. Since every route passes through the same finite schedule, window, observation, readback, seal, BHist, hsame, Cont, Pkg, and local NameCert coordinates, associating the two bind steps in either order exposes the same ledger and no quotient real, selected limit, host equality, hidden stream representative, or ambient completeness row. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket bind associativity ledger`

Theorem 378.10 (CauchyCompletionMonad downstream RegSeqRat consumer route)**.** *Every downstream* RegSeqRat$^{\uparrow}$ *or* RealCauchyCompletion$^{\uparrow}$ *consumer read of an accepted* CauchyCompletionMonad$^{\uparrow}$ *packet factors through the source regular-Cauchy family row, the unary schedule, finite* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *observations, the* RegSeqRat$^{\uparrow}$ *diagonal readback, the public* Real$^{\uparrow}$ *seal row,* BHist *ledger entries, displayed* hsame *transport, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *coordinates. The route exports no quotient stream, host real equality, selected limit, hidden representative, or ambient completeness principle.*

Proof. Start with an accepted packet $M = (X, W, D, \mu, \Delta, E, L, C, P, N)$. A downstream consumer precision request first reads the unary schedule μ, so its source member is selected inside the displayed regular-Cauchy family row X rather than by an external selector.

The selected request then passes through the finite $\mathsf{StreamName}^{\uparrow}$ window in W and the corresponding $\mathsf{DyadicRatCore}^{\uparrow}$ observation in D. Apply Definition 378.4 to transport these rows along the stored hsame comparisons and the displayed Cont read routes without changing the classifier-facing surface.

Next use Definition 378.6. It identifies composed consumer reads with the same schedule, window, dyadic-observation, and diagonal-readback route, so the $\mathsf{RegSeqRat}^{\uparrow}$ handoff remains a finite packet route.

Finally apply Definition 378.3 for constant source packets and Definition 378.5 for public real-seal reads. The carrier rows BHist, hsame, Cont, Pkg, and N exhaust the public coordinates, so quotient streams, host real equality, selected limits, hidden representatives, and ambient completeness cannot be exported by the downstream route. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket downstream regseqrat consumer route`

Theorem 378.11 (CauchyCompletionMonad downstream completion consumer exactness)**.** *Let $M = (X, W, D, \mu, \Delta, E, L, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet. Every downstream completion read by a* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*, or sealed* $\mathsf{Real}^{\uparrow}$ *consumer is exact over the displayed route: the schedule row μ, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row D, the diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Δ, the visible* $\mathsf{Real}^{\uparrow}$ *seal row E, the ledger row L, the* BHist *entries carried there, the displayed* hsame *transports, the displayed* Cont *routes C, the* Pkg *provenance P, and the local* NameCert *row N. Such a consumer reads no quotient stream, selected host limit, ambient completeness principle, hidden representative, or unlisted equality coordinate.*

Proof. Start with the downstream route of Definition 378.10. It already forces every downstream $\mathsf{RegSeqRat}^{\uparrow}$ or completion-facing read through the source family row, schedule, window, dyadic observation, diagonal readback, seal row, and provenance package.

Next apply the public real seal factorization of Definition 378.5. It identifies the only $\mathsf{Real}^{\uparrow}$-facing exit as the displayed seal row E after the same μ, W, D, Δ route has been read.

Finally use the schedule composition boundary of Definition 378.6. The BHist ledger L, the hsame transports, the Cont routes C, the Pkg row P, and the local NameCert row N record the consumer route without adding a second completion source or an ambient real-completeness witness. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket downstream completion consumer exactness`

Theorem 378.12 (CauchyCompletionMonad unit bind visible seal preservation)**.** *For every accepted packet $M = (X, W, D, \mu, \Delta, E, L, C, P, N)$ of* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*, binding on either side by a displayed unit packet preserves the same visible* $\mathsf{Real}^{\uparrow}$ *seal route through $X, W, D, \mu, \Delta, E, L, C, P, N$. The preserved route is read by downstream* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumers only through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback,* BHist *ledger entries, displayed* hsame *rows, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *coordinates already present in M.*

Proof. Project the unit boundary of Definition 378.3. A unit packet contributes stationary windows, constant dyadic observations, the same regular-rational readback shape, and a visible seal row, but it has no coordinate for a hidden representative or a selected completion limit.

Apply diagonal-bind stability from Definition 378.4. The componentwise hsame rows compare the original packet with the unit-bound packet, and the displayed Cont routes preserve the order in which the schedule, window, observation, diagonal, and seal coordinates are read.

Finish with Definition 378.10. Since every downstream consumer still enters through the same finite schedule-window-observation-diagonal-seal route, unit binding preserves the visible seal surface over $X, W, D, \mu, \Delta, E, L, C, P, N$. □

Theorem 378.13 (CauchyCompletionMonad associative bind consumer route)**.** *Let $M = (X, W, D, \mu, \Delta, E, L, C, P$ $M' = (X', W', D', \mu', \Delta', E', L', C', P', N')$, and $M'' = (X'', W'', D'', \mu'', \Delta'', E'', L'', C'', P'', N'')$ be accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packets whose two displayed bind associations are defined. A downstream completion consumer of either association reads the same composed schedule, selected* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readbacks,* $\mathsf{Real}^{\uparrow}$ *seal rows,* BHist *ledgers, displayed* hsame *transports, displayed* Cont *routes,* Pkg *provenance rows, and local* NameCert *rows. The two associations therefore present one consumer route over the displayed packet rows and export no quotient real, selected host limit, hidden stream representative, host equality, or ambient completeness datum.*

Proof. First compare the two associations with the bind associativity ledger of Definition 378.9. It places both bracketings on the same composed schedule, finite window, dyadic observation, diagonal readback, and seal coordinates.

Next use the schedule composition boundary of Definition 378.6 together with diagonal-bind stability from Definition 378.4. These results identify the intermediate packets by their displayed hsame rows and keep the consumer order fixed through the displayed Cont routes.

Finally apply the downstream route of Definition 378.10. The BHist ledgers, Pkg provenance rows, and local NameCert rows are the only exported bookkeeping coordinates, so the two bind associations expose the same completion-consumer route. □

Theorem 378.14 (CauchyCompletionMonad left unit law)**.** *Let r be a displayed constant regular-rational row accepted by* $\mathsf{RegSeqRat}^{\uparrow}$*. If the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *unit packet of r is followed by a diagonal bind packet, then the resulting classifier route factors through the same stationary* $\mathsf{StreamName}^{\uparrow}$ *windows, constant* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* BHist *ledger entries, displayed* hsame *rows, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row as the unit packet. No quotient real, selected limit, host real equality, hidden representative, or ambient completeness datum is exported.*

Proof. Begin with the unit boundary of Definition 378.3. It supplies the constant source row, stationary finite windows, constant dyadic observations, the same regular rational readback, and the seal-facing row.

Apply diagonal-bind stability from Definition 378.4. The componentwise hsame rows and displayed Cont routes transport the schedule, window, observation, readback, and seal coordinates without changing the classifier-facing packet.

Use the schedule composition boundary of Definition 378.6. Since the first schedule is the constant unit schedule, the composed route has the same inspected window and dyadic-observation rows as the original constant packet.

Finally apply Definition 378.5 and Definition 378.10. They identify every public and downstream read with the displayed $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, BHist, hsame, Cont, Pkg, and NameCert rows, so the left unit is a finite packet law. □

Theorem 378.15 (CauchyCompletionMonad right unit law)**.** *Let $M = (X, W, D, \mu, \Delta, E, L, C, P, N)$ be an accepted* CauchyCompletionMonad$^{\uparrow}$ *packet. Binding M against the constant unit readback of its displayed* RegSeqRat$^{\uparrow}$ *diagonal row preserves every public* Real$^{\uparrow}$ *seal route through X, W, D, μ, Δ, E, L, C, P, and N. The right-unit bind exports no quotient real, selected limit, host real equality, hidden stream representative, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket right unit visible seal preservation`

Proof. Start with the accepted packet M. The public seal factorization of Definition 378.5 forces each real-facing read through the schedule, selected window, dyadic observation, diagonal readback, and seal row.

Attach the constant unit readback supplied by Definition 378.3. Its stationary windows and constant dyadic observations are read from the already displayed diagonal row, so it contributes no independent route to a public real.

Apply Definition 378.4. The displayed hsame and Cont rows compare the original packet and the packet followed by the unit along the same finite coordinates.

The schedule composition boundary of Definition 378.6 repacks this comparison as the original consumer route. The downstream route of Definition 378.10 then rules out quotient reals, selected limits, host equality, hidden representatives, and ambient completeness data. □

Theorem 378.16 (CauchyCompletionMonad associative bind law)**.** *Let M, M', and M'' be accepted* CauchyCompletionMonad$^{\uparrow}$ *packets with two displayed schedule-composition routes over the same selected* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *observation rows, diagonal* RegSeqRat$^{\uparrow}$ *readbacks,* Real$^{\uparrow}$ *seals,* BHist *entries, displayed* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows. If one route first binds M with M' and then binds the result with M'', while the other first binds M' with M'' and then binds M with the result, then the two routes have the same classifier-facing finite packet and export no quotient real, selected limit, host real equality, hidden representative, or ambient completeness row.*

Proof. First apply the schedule composition boundary of Definition 378.6 to each displayed association. Both public routes must pass through the same schedule, finite window, dyadic observation, diagonal readback, and seal coordinates.

Next use diagonal-bind stability from Definition 378.4. The componentwise hsame comparisons and displayed Cont routes identify the intermediate packets without changing the consumer-facing order.

The unit boundary of Definition 378.3 fixes the neutral constant packets at the ends of the displayed composition ledger. These packets have stationary windows and constant dyadic observations, so they do not alter the shared BHist, Pkg, or NameCert rows.

Finally apply the public seal factorization of Definition 378.5 and the downstream consumer route of Definition 378.10. Since every consumer read is exhausted by the same finite coordinates, the two associations expose the same classifier-facing packet. □

Theorem 378.17 (CauchyCompletionMonad regular seal unit)**.** *A constant* RegSeqRat$^{\uparrow}$ *source row with stationary* StreamName$^{\uparrow}$ *windows, constant* DyadicRatCore$^{\uparrow}$ *observations, identity* Cont *routes, componentwise reflexive* hsame *rows, the constant diagonal* RegSeqRat$^{\uparrow}$ *readback, and the displayed* Real$^{\uparrow}$ *seal forms the unit packet of* CauchyCompletionMonad$^{\uparrow}$*. This packet is a carrier of Definition 378.1 whose public read route is the constant schedule, the stationary finite window, the constant dyadic observation, the same regular readback, and the seal row.*

Proof. Project the carrier coordinates of Definition 378.1. The constant source row supplies X, the stationary window ledger supplies W, the constant dyadic observations supply D, and the constant schedule supplies μ.

Use the unit boundary of Definition 378.3. It identifies the diagonal readback with the same regular rational row and routes the seal-facing coordinate through the constant packet rather than through a quotient or selected limit.

Finally apply the public real seal factorization of Definition 378.5. The identity Cont routes and reflexive hsame rows keep the read on the displayed constant schedule, window, observation, readback, and $\mathsf{Real}^{\uparrow}$ seal coordinates, so the packet is the advertised unit. □

Theorem 378.18 (CauchyCompletionMonad unit seal route)**.** *For a displayed constant row r : $\mathsf{RegSeqRat}^{\uparrow}$, the unit carrier of $\mathsf{CauchyCompletionMonad}^{\uparrow}$ is the finite* BHist *route*

$$r \longmapsto W_r \longmapsto D_r \longmapsto \Delta_r \longmapsto E_r$$

where W_r is the stationary $\mathsf{StreamName}^{\uparrow}$ window ledger, D_r is the constant $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger, Δ_r is the diagonal $\mathsf{RegSeqRat}^{\uparrow}$ readback, and E_r is the displayed $\mathsf{Real}^{\uparrow}$ seal. The route is transported only by componentwise hsame *rows, read only through displayed* Cont *coordinates, and recorded in the* Pkg *provenance and local $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonad}^{\uparrow}}$ row.*

Proof. Start from the regular seal unit of Definition 378.17. It supplies the constant $\mathsf{RegSeqRat}^{\uparrow}$ source row, stationary $\mathsf{StreamName}^{\uparrow}$ windows, constant $\mathsf{DyadicRatCore}^{\uparrow}$ observations, the diagonal readback, and the $\mathsf{Real}^{\uparrow}$ seal.

The carrier definition gives the finite BHist coordinates that hold this route. Reflexive hsame rows identify the constant windows, observations, readback, and seal with themselves, while the displayed Cont rows keep the consumer read on those coordinates.

The Pkg row records provenance over the same visible primitives, and the local NameCert row records that no quotient real, selected limit, host equality, hidden stream representative, or ambient completeness datum is part of the unit route. □

Theorem 378.19 (CauchyCompletionMonad bind diagonal route)**.** *Let M and M' be accepted $\mathsf{CauchyCompletionMonad}^{\uparrow}$ packets. A displayed bind composition*

$$M \text{ bind } M' \rightsquigarrow (\mu \star \mu',\, W \star W',\, D \star D',\, \Delta \star \Delta',\, E \star E')$$

preserves the schedule-window-observation-diagonal-seal route: every public read passes through a matched $\mathsf{StreamName}^{\uparrow}$ window, a matched $\mathsf{DyadicRatCore}^{\uparrow}$ observation, a diagonal $\mathsf{RegSeqRat}^{\uparrow}$ readback, and a $\mathsf{Real}^{\uparrow}$ seal inside the same BHist *packet surface. The preservation uses only displayed* hsame *transport, displayed* Cont *composition,* Pkg *provenance, and the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonad}^{\uparrow}}$ rows.*

Proof. Apply diagonal-bind stability from Definition 378.4. The source-family rows, schedules, finite windows, dyadic observations, diagonal readbacks, and real-seal rows move along componentwise hsame comparisons.

Use the schedule composition boundary of Definition 378.6. It fixes the consumer order: schedule first, then the selected $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{DyadicRatCore}^{\uparrow}$ observation, the $\mathsf{RegSeqRat}^{\uparrow}$ diagonal readback, and finally the $\mathsf{Real}^{\uparrow}$ seal.

The resulting route stays inside the same finite BHist surface. The displayed Cont composition records the read path, the Pkg rows record provenance, and the local NameCert rows rule out any escape to quotient reals, selected limits, host equality, hidden representatives, or ambient completeness. □

Theorem 378.20 (CauchyCompletionMonad NameCert obligation surface)**.** *The concrete* $\mathsf{NameCert}_{\mathsf{CauchyCompletion}}$ *surface consists of carrier habitation, classifier transport, the unit seal route, the bind diagonal route, real-seal non-escape, and the downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer boundary. Each row is expressed in the finite* BHist *coordinates over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *transported by* hsame, *read through* Cont, *and recorded by* Pkg *provenance together with the local* NameCert *row.*

Proof. Carrier habitation is supplied by the constant packet of Definition 378.2. Classifier transport is the componentwise movement of schedule, window, observation, readback, and seal rows along the stored hsame comparisons and displayed Cont reads.

The unit row is exactly Definition 378.18. It exhibits a constant $\mathsf{RegSeqRat}^{\uparrow}$ source, stationary $\mathsf{StreamName}^{\uparrow}$ windows, constant $\mathsf{DyadicRatCore}^{\uparrow}$ observations, the diagonal readback, and the $\mathsf{Real}^{\uparrow}$ seal inside one BHist packet.

The bind row is Definition 378.19. It composes schedules, windows, observations, diagonal readbacks, and seals without leaving the displayed Pkg provenance or local NameCert surface.

For the real-seal and downstream boundaries, combine Definition 378.5 with Definition 378.10. Public $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{RealCauchyCompletion}^{\uparrow}$ reads are exhausted by the finite route, so quotient reals, selected limits, host equality, hidden stream representatives, and ambient completeness rows are not exported. □

Theorem 378.21 (CauchyCompletionMonad bind associativity boundary)**.** *Let M, M', and M'' be accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packets whose two successive schedule compositions are defined by displayed* BHist *ledger rows. The public* $\mathsf{Real}^{\uparrow}$ *read route obtained by first composing M with M' and then with M'' is the same route as the one obtained by first composing M' with M'' and then composing the result with M: in both cases every read passes through the matched schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation,* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *comparisons, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *coordinates.*

Proof. First apply the schedule composition boundary of Definition 378.6 to the left association. Its public read route is forced through the composed schedule, matched finite windows, matched dyadic observations, diagonal readback, and seal row.

Apply the same schedule composition boundary to the right association. The hypotheses give the same displayed schedule, window, observation, diagonal, seal, BHist, Cont, Pkg, and local NameCert rows, so the two public routes have the same visible coordinates.

It remains to compare the intermediate packets. Use diagonal-bind stability from Definition 378.4; the componentwise hsame rows transport the two associations across the matched ledgers without changing the consumer order.

The bind associativity ledger of Definition 378.9 then repacks these matched coordinates as the same public $\mathsf{Real}^{\uparrow}$ read route. No additional quotient stream, selected limit, host equality, hidden representative, or ambient completeness coordinate is created by either association. □

Theorem 378.22 (CauchyCompletionMonad finite-window exhaustion)**.** *Every downstream* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer read of an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet is exhausted by the finite window route through the source family, schedule row, selected* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback,* $\mathsf{Real}^{\uparrow}$ *seal row,* BHist *ledger, displayed* hsame, *displayed* Cont, Pkg *provenance, and local* NameCert *coordinates. Such a read cannot expose quotient streams, selected limits, host equality, hidden representatives, or ambient completeness data.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket finite window exhaustion`

Proof. Begin with a downstream $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{RealCauchyCompletion}^{\uparrow}$ request. The downstream consumer route of Definition 378.10 forces the request through the source family, schedule, finite window, dyadic observation, diagonal readback, seal row, and public ledger coordinates.

For a $\mathsf{Real}^{\uparrow}$ request, apply the public real seal factorization of Definition 378.5. It gives the same finite route ending at the seal row, with no independent real-completeness channel.

The non-escape clauses are exactly the absent fields in the NameCert obligations of Definition 378.2. Since the accepted packet contains no coordinate for quotient streams, selected limits, host equality, hidden representatives, or ambient completeness, the finite window route exhausts every listed downstream read. □

Definition 378.23 (CauchyCompletionMonad RealCauchyCompletion handoff packet)**.** *A* CauchyCompletionMona *to* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff packet is the finite route*

$$(X, \mu, W, D, \Delta, E, L, C, P, N) \rightsquigarrow \mathsf{RealCauchyCompletion}^{\uparrow}$$

where X is the source regular-Cauchy family row, μ selects the inspected family member and precision window, W records the finite $\mathsf{StreamName}^{\uparrow}$ *windows, D records the corresponding* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, Δ is the* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback, E is the public* $\mathsf{Real}^{\uparrow}$ *seal, L records the displayed* BHist *and* hsame *comparisons, C records the displayed* Cont *consumer routes, P is the* Pkg *provenance row, and N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonad}^{\uparrow}}$ *row. A* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer may read the packet only through this ordered route.*

Theorem 378.24 (CauchyCompletionMonad RealCauchyCompletion input factorization)**.** *Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *input read of an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet factors through the handoff packet of Definition 378.23. The read starts at a source regular-Cauchy family row, passes through the selected finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation, is repacked by the* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback, reaches the public* $\mathsf{Real}^{\uparrow}$ *seal, and is transported only by displayed* BHist, hsame, Cont, Pkg, *and local* NameCert *rows.*

Proof. Start with a $\mathsf{RealCauchyCompletion}^{\uparrow}$ input request. The unit boundary of Definition 378.3 supplies the boundary case: a constant regular-Cauchy source has stationary finite windows, constant dyadic observations, a diagonal $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the displayed $\mathsf{Real}^{\uparrow}$ seal.

For transported and composed packets, use diagonal-bind stability from Definition 378.4. It keeps the family row, schedule, selected window, dyadic observation, diagonal readback, and seal aligned by componentwise hsame rows and displayed Cont routes.

Apply the public real seal factorization of Definition 378.5. The final consumer-facing row is the $\mathsf{Real}^{\uparrow}$ seal reached after the diagonal readback, not an external real equality or selected limit.

Finally use finite-window exhaustion from Definition 378.22. It says every $\mathsf{RealCauchyCompletion}^{\uparrow}$ read is exhausted by the same finite route, so the request factors through the handoff packet and through no other coordinate. □

Theorem 378.25 (CauchyCompletionMonad RealCauchyCompletion consumer package)**.** *The downstream* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer package exported by an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet is exactly the handoff packet of Definition 378.23 together with the unit boundary, diagonal-bind stability, public* $\mathsf{Real}^{\uparrow}$ *seal factorization, and finite-window exhaustion rows. The package supplies source regular-Cauchy family reads, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback,* $\mathsf{Real}^{\uparrow}$ *seal,* BHist, hsame, Cont, Pkg, *and local* NameCert *coordinates, and it exports no quotient stream, host real equality, selected limit, hidden representative, or ambient completeness datum.*

Proof. Assemble the source side from the handoff packet definition. It gives the ordered consumer route through X, μ, W, D, Δ, E, L, C, P, and N.

Attach the unit and bind rows. The unit boundary supplies constant input packets, while diagonal-bind stability transports composed packets without changing the displayed read order.

Attach the public seal and exhaustion rows. The public real seal factorization identifies the seal reached after diagonal readback, and finite-window exhaustion identifies the same finite route as the whole $\mathsf{RealCauchyCompletion}^{\uparrow}$ input surface.

Since the assembled package contains only the displayed family, window, dyadic, readback, seal, history, transport, continuation, provenance, and naming rows, it has no coordinate for quotient streams, host real equality, selected limits, hidden representatives, or ambient completeness. □

Theorem 378.26 (CauchyCompletionMonad regular-family unit)**.** *Every constant* $\mathsf{RegSeqRat}^{\uparrow}$ *family row determines the displayed* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *unit packet through stationary* $\mathsf{StreamName}^{\uparrow}$ *windows, constant* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, the same diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the public* $\mathsf{Real}^{\uparrow}$ *seal row, finite* BHist *coordinates, reflexive* hsame *rows, identity* Cont *routes,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonad}^{\uparrow}}$ *row. The packet exports exactly the unit route already visible in those rows, and it exports no quotient stream, selected limit, host equality, hidden representative, or ambient completeness datum.*

Proof. Start with the constant regular-rational family from the habitation row of Definition 378.2. The unit boundary of Definition 378.3 supplies the stationary $\mathsf{StreamName}^{\uparrow}$ windows, constant $\mathsf{DyadicRatCore}^{\uparrow}$ observations, constant schedule, diagonal $\mathsf{RegSeqRat}^{\uparrow}$ readback, and public $\mathsf{Real}^{\uparrow}$ seal row.

The regular seal unit of Definition 378.17 places these rows inside the carrier of Definition 378.1. The unit seal route of Definition 378.18 then records the same route in BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ coordinates.

Finally use the public real seal factorization of Definition 378.5. Since the factorization has no coordinate for quotient streams, selected limits, host equality, hidden representatives, or ambient completeness, the constant family row gives precisely the displayed unit packet. □

Theorem 378.27 (CauchyCompletionMonad bind closure package)**.** *The finite bind surface of* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *consists of the left-unit packet, the right-unit packet, bind associativity, schedule composition, and diagonal-bind stability, all expressed through the same source-family, finite-window, dyadic-observation, diagonal-readback,* $\mathsf{Real}^{\uparrow}$ *seal,* BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}$ *rows. This package closes the public bind route for downstream* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers without adding quotient streams, selected limits, host equality, hidden representatives, or ambient completeness.*

Proof. For the unit rows, combine the left-unit factorization of Definition 378.7, the right-unit factorization of Definition 378.8, and the explicit unit laws of Definition 378.14 and Definition 378.15. These rows keep every public read inside the displayed schedule, window, dyadic-observation, readback, seal, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ coordinates.

For composition, use the schedule composition boundary of Definition 378.6. Diagonal-bind stability from Definition 378.4 identifies the transported source-family rows, selected windows, dyadic observations, readbacks, and seals componentwise.

For associativity, apply the bind associativity ledger of Definition 378.9 and the bind associativity boundary of Definition 378.21. The associative bind law of Definition 378.16 repacks the two displayed associations as one consumer-facing finite route.

The finite-window exhaustion theorem Definition 378.22 then gives the consumer boundary for $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The resulting bind package has no exported coordinate for quotient streams, selected limits, host equality, hidden representatives, or ambient completeness. □

Theorem 378.28 (CauchyCompletionMonad standard completion boundary)**.** *The regular-family unit package of Definition 378.26, the bind closure package of Definition 378.27, the downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer route, the public* $\mathsf{Real}^{\uparrow}$ *seal factorization, and finite-window exhaustion assemble the standard completion-boundary package for* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*. The boundary is a finite BEDC package over* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows, and it does not include quotient streams, selected limits, host equality, hidden representatives, or ambient completeness.*

Proof. First take the unit side from Definition 378.26. It gives the constant regular-family packet and fixes the stationary window, constant dyadic-observation, diagonal readback, seal, BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows used by a completion boundary.

Next take the bind side from Definition 378.27. The package supplies left unit, right unit, associativity, schedule composition, and diagonal-bind stability over the same finite packet coordinates.

Now attach the downstream consumer surface. The route of Definition 378.10 serves $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumers, while the public real seal factorization of Definition 378.5 serves $\mathsf{Real}^{\uparrow}$ consumers.

Finally apply finite-window exhaustion from Definition 378.22. It states that every listed consumer read is exhausted by the finite window route, so the assembled package is the promised standard completion boundary and not an assertion of quotient streams, selected limits, host equality, hidden representatives, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadUp StdBridge`

Theorem 378.29 (CauchyCompletionMonad schedule totality)**.** *For every accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet* $M = (X, W, D, \mu, \Delta, E, L, C, P, N)$*, each consumer precision request is answered first by the displayed unary schedule row* μ*, then by one finite* $\mathsf{StreamName}^{\uparrow}$ *window in* W*, and then by the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation attached to that window. The request cannot be answered by an external selector outside the packet coordinates.*

Proof. Start with the carrier description in Definition 378.1. The only coordinate that names which family member and which window answer a precision request is the unary schedule row μ.

Apply the schedule composition boundary of Definition 378.6. It keeps composed consumer reads on the displayed schedule, matched window ledger, dyadic-observation ledger, diagonal readback, and seal row.

Finally use finite-window exhaustion from Definition 378.22. Every downstream read is exhausted by the finite route through μ, W, and D, so no further selector is available. □

Theorem 378.30 (CauchyCompletionMonad diagonal readback coverage)**.** *For every accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet* $M = (X, W, D, \mu, \Delta, E, L, C, P, N)$*, each scheduled window and dyadic-observation pair has a displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback* Δ *before the public* $\mathsf{Real}^{\uparrow}$ *seal row is exposed. Thus a consumer cannot reach the seal row directly from a window or observation coordinate.*

Proof. Project the carrier coordinates from Definition 378.1. The rows W and D record finite windows and dyadic observations, while Δ is the diagonal transport ledger that repacks the scheduled observations as regular rational readback data.

Use the public seal factorization of Definition 378.5. A public $\mathsf{Real}^{\uparrow}$ read passes through schedule, selected window, dyadic observation, $\mathsf{RegSeqRat}^{\uparrow}$ diagonal readback, and only then the final seal row.

The downstream consumer route of Definition 378.10 identifies the same read order for $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumers. Hence every scheduled window and observation pair is covered by Δ before any public seal exposure. □

Theorem 378.31 (CauchyCompletionMonad Real seal naturality)**.** *Componentwise* hsame *transport and displayed* Cont *routes commute with the passage from source-family, schedule, finite-window, and dyadic-observation rows to the diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and public* $\mathsf{Real}^{\uparrow}$ *seal row of an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet.*

Proof. Begin with two accepted packets related by the componentwise transport rows of the carrier. The classifier of Definition 378.1 compares source families, schedules, windows, dyadic observations, diagonal readbacks, and seal rows only through the displayed hsame and Cont coordinates.

Apply diagonal-bind stability from Definition 378.4. It moves the scheduled windows, dyadic observations, diagonal ledger, and seal row along the componentwise transports while preserving the consumer read order.

Now use the public seal factorization of Definition 378.5. Because every public seal read factors through the transported diagonal readback, the transport route commutes with the passage from scheduled data to Δ and then to the $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 378.32 (CauchyCompletionMonad completion root unblock package)**.** *The finite completion-root obligation surface for* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *consists of schedule totality, diagonal readback coverage, public* $\mathsf{Real}^{\uparrow}$ *seal naturality, the regular-family unit package, bind closure, downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer routes, and the standard completion boundary. This is the package consumed by* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*; it contains only displayed source-family rows, unary schedules, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seals,* BHist, hsame, Cont, Pkg, *and local* NameCert *coordinates.*

Proof. Assemble the request side from schedule totality in Definition 378.29. Each consumer precision request is routed by the displayed unary schedule and one finite window before it reaches any dyadic observation.

Attach diagonal readback coverage from Definition 378.30 and seal naturality from Definition 378.31. These rows place the $\mathsf{RegSeqRat}^{\uparrow}$ diagonal readback between every scheduled observation and the public $\mathsf{Real}^{\uparrow}$ seal, and they keep that placement stable under hsame transport and displayed Cont routes.

Add the regular-family unit package of Definition 378.26 and the bind closure package of Definition 378.27. The downstream consumer route of Definition 378.10 and the standard completion boundary of Definition 378.28 then give the same finite surface to $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The assembled package has no coordinate for quotient streams, selected limits, host equality, hidden representatives, or ambient completeness. Since every read is exhausted by the displayed schedule, finite window, dyadic observation, diagonal readback, and seal route, none of those excluded objects can be supplied by the completion-root package. □

Theorem 378.33 (CauchyCompletionMonad root schedule-window normal form)**.** *Every completion-root request received by an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet factors first through the displayed unary schedule, then through one finite* $\mathsf{StreamName}^{\uparrow}$ *window, and then through one* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation attached to that window. The normal form is read only through the source-family rows, schedule row, finite-window ledger, dyadic-observation ledger, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

Proof. Start from the schedule totality theorem Definition 378.29. It places each consumer precision request at the unary schedule row before any window or observation coordinate is visible.

Next apply finite-window exhaustion from Definition 378.22. The scheduled request is exhausted by one finite $\mathsf{StreamName}^{\uparrow}$ window and its attached $\mathsf{DyadicRatCore}^{\uparrow}$ observation, so no second window family or ambient selector is available.

Finally read the displayed Cont routes from the carrier and from the completion root package of Definition 378.32. These routes keep the schedule-window-observation path inside BHist, hsame, Cont, Pkg, and NameCert coordinates. □

Theorem 378.34 (CauchyCompletionMonad root diagonal-seal normal form)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet factors through the diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback after the scheduled dyadic observation and before the public seal row. Thus the seal is reached by the finite route through schedule, window, dyadic observation, diagonal readback, displayed* hsame *transport, displayed* Cont *route,* Pkg*, and local* NameCert *provenance.*

Proof. Use diagonal readback coverage from Definition 378.30. It places the $\mathsf{RegSeqRat}^{\uparrow}$ diagonal readback after the scheduled window and dyadic observation and before any public seal exposure.

Apply seal naturality from Definition 378.31. Componentwise hsame transport and displayed Cont routes commute with the move from scheduled dyadic observations to the diagonal readback.

Finish with public seal factorization in Definition 378.5. The public $\mathsf{Real}^{\uparrow}$ read therefore has no direct route from a source-family row, window row, or dyadic-observation row to the seal without passing through the displayed diagonal readback. □

Theorem 378.35 (CauchyCompletionMonad root consumer exhaustion)**.** *The* $\mathsf{RegSeqRat}^{\uparrow}$, RealCauchyCompletion *and* $\mathsf{Real}^{\uparrow}$ *consumers of the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion-root package have no coordinate beyond source-family rows, unary schedules, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seal rows,* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows.*

Proof. First apply the schedule-window normal form of Definition 378.33. It exhausts the request side of each consumer through the schedule, one finite window, and one dyadic observation.

Next apply the diagonal-seal normal form of Definition 378.34. It exhausts the seal-facing side through the diagonal $\mathsf{RegSeqRat}^{\uparrow}$ readback and the public $\mathsf{Real}^{\uparrow}$ seal row.

The completion root package of Definition 378.32 assembles exactly those request-side and seal-facing rows for $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers. Since the package lists no quotient stream, selected limit, host equality, hidden representative, or ambient completeness coordinate, no consumer can read such a coordinate from the root surface. □

Definition 378.36 (CauchyCompletionMonad root consumer face triad)**.** *For an accepted* CauchyCompletionMonad *packet* $M = (X, W, D, \mu, \Delta, E, L, C, P, N)$*, the root consumer face triad is the ordered public package consisting of the* $\mathsf{RegSeqRat}^{\uparrow}$ *face, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *face, and the* $\mathsf{Real}^{\uparrow}$ *face read through the same schedule-window-observation-diagonal-seal packet. The* $\mathsf{RegSeqRat}^{\uparrow}$ *face reads the source-family row* X*, the schedule row* μ*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the*

$\mathsf{DyadicRatCore}^{\uparrow}$ *observation row D, and the diagonal readback Δ. The* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *face reads that same route as the completion-consumer source package. The* $\mathsf{Real}^{\uparrow}$ *face reads the public seal row E only after the same scheduled observation and diagonal readback. All three faces use the displayed* BHist, hsame, Cont, Pkg, *and local* NameCert *rows L, C, P, N.*

Theorem 378.37 (CauchyCompletionMonad root face coverage)**.** *Every accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet supplies the root consumer face triad of Definition 378.36. In particular, the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *public faces are obtained from the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows by the single route through source-family data, unary schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation, diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and public* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. First use the root schedule-window normal form of Definition 378.33. It places every consumer precision request on the displayed unary schedule, finite window, and dyadic observation route before any downstream face is read.

Next use the root diagonal-seal normal form of Definition 378.34. It inserts the diagonal $\mathsf{RegSeqRat}^{\uparrow}$ readback between the scheduled observation and the public $\mathsf{Real}^{\uparrow}$ seal, so the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ faces are read from one packet route.

The root consumer exhaustion theorem Definition 378.35 identifies the same finite route as the full consumer surface. The downstream consumer route of Definition 378.10 then lets $\mathsf{RealCauchyCompletion}^{\uparrow}$ consume exactly that source package, and the public seal factorization of Definition 378.5 supplies the final $\mathsf{Real}^{\uparrow}$ face. □

Theorem 378.38 (CauchyCompletionMonad root face non-escape)**.** *The root consumer face triad of an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet exports no quotient stream, selected limit, host equality, hidden representative, or ambient completeness coordinate. Each public face is exhausted by the same displayed source-family, schedule, finite-window, dyadic-observation, diagonal-readback, seal,* BHist, hsame, Cont, Pkg, *and local* NameCert *rows.*

Proof. Begin with Definition 378.37. It gives the three public faces by the single schedule-window-observation-diagonal-seal route.

Apply root consumer exhaustion from Definition 378.35. That theorem lists the only coordinates available to $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers at the completion root.

Finally use public seal factorization from Definition 378.5. Since even the public $\mathsf{Real}^{\uparrow}$ seal factors through the displayed diagonal readback and recorded provenance rows, none of the three faces can expose a quotient stream, selected limit, host equality, hidden representative, or ambient completeness coordinate. □

Theorem 378.39 (CauchyCompletionMonad schedule source membership)**.** *Let $M = (X, W, D, \mu, \Delta, E, L, C, P, N$ be an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet. For every consumer precision request routed by μ, the scheduled answer names a member of the displayed source-family row X. The membership is part of the same finite packet route through* BHist, hsame, Cont, Pkg, *and the local* NameCert *row; it is not supplied by an external family selector, quotient stream representative, selected limit, host equality, or ambient completeness principle.*

Proof. Project the carrier of Definition 378.1. Its source row X and schedule row μ are coordinates of the same accepted packet, and the schedule-totality clause reads μ as the displayed route answering each precision request.

Apply the root schedule-window normal form of Definition 378.33. Before any window or dyadic observation can be inspected, the request has already passed through the displayed schedule row attached to X.

Finally use the completion root package of Definition 378.32. That package exposes only the finite source-family, schedule, window, observation, readback, seal, provenance, and naming rows, so the scheduled member is locked to X and cannot be spliced in from an external source. □

Theorem 378.40 (CauchyCompletionMonad window observation source lock)**.** *Let $M = (X, W, D, \mu, \Delta, E, L, C, P$ be an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet, and let a consumer precision request be scheduled by μ to a displayed member of X. The selected* $\mathsf{StreamName}^{\uparrow}$ *window in W and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation in D are attached to that same scheduled source-family member and to the same requested precision route. No accepted read may replace the selected window or dyadic observation by data from another member of X or from an unlisted source row.*

Proof. Start with schedule source membership from Definition 378.39. It identifies the scheduled answer as a member of the displayed source-family row X before any window or observation coordinate is read.

Next apply the root schedule-window normal form of Definition 378.33. The scheduled request factors through one finite $\mathsf{StreamName}^{\uparrow}$ window and then through the $\mathsf{DyadicRatCore}^{\uparrow}$ observation attached to that window.

Use diagonal readback coverage from Definition 378.30. The same scheduled window and observation are the rows repacked by the diagonal readback, so the precision route, selected member, window, and observation remain one finite packet route.

The public seal factorization of Definition 378.5 excludes any second observation channel. Therefore the window and dyadic observation cannot be supplied by a different source-family member or an ambient selector. □

Theorem 378.41 (CauchyCompletionMonad diagonal seal source lock)**.** *Let $M = (X, W, D, \mu, \Delta, E, L, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet. If a precision request selects a source-family member through μ, then the diagonal readback Δ and the public* $\mathsf{Real}^{\uparrow}$ *seal row E preserve that same source membership through the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation. The diagonal and seal route exports the displayed scheduled source, not a second completion source, hidden representative, selected limit, quotient real, or ambient completeness witness.*

Proof. First apply Definition 378.40. The scheduled member of X, selected window, dyadic observation, and precision route are already tied together before the diagonal row is inspected.

Now use the root diagonal-seal normal form of Definition 378.34. It places Δ after the scheduled dyadic observation and before the public $\mathsf{Real}^{\uparrow}$ seal row E.

Finally apply the public seal factorization theorem Definition 378.5. Since every public seal read passes through the same schedule-window-observation-diagonal route, the seal preserves the displayed source membership carried by X and cannot expose a spliced completion source. □

Theorem 378.42 (CauchyCompletionMonad flattened completion source)**.** *Every accepted* $\mathsf{CauchyCompletionMona}$ *packet exposes a flattened completion source before any completion read is consumed: the source-family row, unary schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, and diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback are all read as displayed* BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}$ *rows before the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer reaches a seal-facing coordinate.*

Proof. Begin with the unit boundary of Definition 378.3. It identifies the boundary case as a constant source family with stationary windows, constant dyadic observations, the same diagonal readback, and the displayed $\mathsf{Real}^{\uparrow}$ seal.

For a general accepted packet, apply the completion root package of Definition 378.32. Its schedule-totality and finite-window clauses put the source family, unary schedule, selected window, and dyadic observation before any completion-facing read.

Finally use diagonal-bind stability from Definition 378.4. The componentwise hsame rows and displayed Cont routes preserve the order source family, schedule, window, observation, diagonal readback, and seal, so the completion source is flattened before the consumer reaches the completion boundary. □

Theorem 378.43 (CauchyCompletionMonad flattened seal route)**.** *The flattened completion source of Definition 378.42, schedule composition, diagonal-bind stability, and the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer package compose into one* $\mathsf{Real}^{\uparrow}$ *seal route. This route reads the accepted packet through source-family rows, schedules, finite windows, dyadic observations, diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, displayed transports, package provenance, and local naming before it reaches the public* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. First apply the schedule composition boundary of Definition 378.6. It fixes the consumer order through the displayed schedule, selected finite window, dyadic observation, diagonal readback, and seal row.

Next use diagonal-bind stability from Definition 378.4. The bind step transports the source families, schedules, windows, observations, diagonal readbacks, and seal rows componentwise without changing the read order.

Now attach the downstream consumer package of Definition 378.25. That package is precisely the $\mathsf{RealCauchyCompletion}^{\uparrow}$ reader of the same finite route.

Finish with the public $\mathsf{Real}^{\uparrow}$ seal factorization of Definition 378.5. Since every public seal read passes through the diagonal readback after the scheduled dyadic observation, the composed route is one flattened $\mathsf{Real}^{\uparrow}$ seal route. □

Theorem 378.44 (CauchyCompletionMonad flattened non-escape package)**.** *The flattened completion route for* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *is the package consisting of the flattened completion source of Definition 378.42, the flattened seal route of Definition 378.43, and the completion root package of Definition 378.32. It exports no quotient stream, selected limit, host real equality, hidden representative, or ambient completeness coordinate.*

Proof. Assemble the source side from Definition 378.42. It gives the source-family row, unary schedule, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ observations, and diagonal $\mathsf{RegSeqRat}^{\uparrow}$ readback before completion consumption.

Assemble the seal side from Definition 378.43. Schedule composition, diagonal-bind stability, the $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumer package, and public $\mathsf{Real}^{\uparrow}$ seal factorization make the completion-facing read a single finite seal route.

The completion root package of Definition 378.32 contains exactly those displayed rows and no coordinate for quotient streams, selected limits, host real equality, hidden representatives, or ambient completeness. Therefore the flattened package cannot supply any such object to a downstream completion reader. □

Theorem 378.45 (CauchyCompletionMonad finite bind-domain coverage)**.** *Every bind-domain read of an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet factors through the source-family rows, the unary schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, diagonal* $\mathsf{RegSeqRat}^{\uparrow}$

readback, the public $\mathsf{Real}^{\uparrow}$ *seal,* BHist*,* hsame*, displayed* Cont *routes,* Pkg*, and local* NameCert *rows. No bind-domain consumer can read a quotient stream, selected limit, host real equality, hidden representative, or ambient completeness coordinate outside this finite row package.*

Proof. Begin with the schedule composition boundary of Definition 378.6. It puts every bind request into the displayed schedule before any downstream completion reader can inspect a window, dyadic observation, diagonal readback, or seal row.

Next use diagonal-bind stability from Definition 378.4. The bind operation transports the source-family rows, schedules, finite windows, dyadic observations, diagonal readbacks, and seal rows componentwise along hsame and the displayed Cont routes.

Now apply the flattened completion source of Definition 378.42. The source side is already read through BHist, hsame, Cont, Pkg, and local NameCert rows before the $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumer reaches a completion-facing coordinate.

Finally attach the flattened non-escape package of Definition 378.44. Since that package exports exactly the finite source, schedule, window, observation, readback, seal, provenance, and naming rows, every bind-domain read has the stated finite coverage and no escaping coordinate is available. □

Theorem 378.46 (CauchyCompletionMonad finite bind-domain induction)**.** *For any finite unary list of accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *bind-domain packets generated from the unit packet and the binary bind operation, every iterated bind-domain read factors through the same finite source-family rows, unary schedules, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, public* $\mathsf{Real}^{\uparrow}$ *seal,* BHist*,* hsame*, displayed* Cont *routes,* Pkg*, and local* NameCert *rows. The induced route exports no quotient stream, selected limit, host real equality, hidden representative, or ambient completeness coordinate.*

Proof. The base case is the unit packet. Apply the unit boundary of Definition 378.3 to identify the constant source-family row, stationary schedule, stationary finite windows, constant dyadic observations, diagonal readback, and public $\mathsf{Real}^{\uparrow}$ seal. Then apply finite bind-domain coverage from Definition 378.45 to place this unit read inside the displayed BHist, hsame, Cont, Pkg, and local NameCert rows.

For the binary step, assume the finite route has already been exposed for the current unary list. Apply the schedule composition boundary of Definition 378.6 to put the next bind request into the displayed schedule before it can inspect a window, dyadic observation, diagonal readback, or seal coordinate.

Use diagonal-bind stability from Definition 378.4 to transport the source-family rows, schedules, windows, observations, readbacks, and seals componentwise along hsame and the displayed Cont routes. The induction hypothesis supplies the same finite rows for the incoming packet, so the composed packet remains inside the finite bind-domain surface.

Finally apply the flattened completion source of Definition 378.42 and the flattened non-escape package of Definition 378.44. They repack the composed route through the same source-family, schedule, window, observation, readback, seal, provenance, and naming rows, and they provide no coordinate for quotient streams, selected limits, host real equality, hidden representatives, or ambient completeness.

The resulting finite induction witness is the source used by the Real seal functoriality, completion-consumer naturality, and Kleisli source and seal theorems below, so finite completion consumers read only the displayed bind-domain rows. □

Theorem 378.47 (CauchyCompletionMonad Real seal functoriality)**.** *Componentwise* hsame *transport of the source-family, schedule, finite-window, dyadic-observation, diagonal-readback,* Cont*,* Pkg*, and local* NameCert *rows commutes with passage to the public* Real$^{\uparrow}$ *seal of an accepted* CauchyCompletionMonad$^{\uparrow}$ *packet. Thus two transported bind-domain presentations reach the same public seal route whenever their displayed rows agree componentwise.*

Proof. Apply Real seal naturality from Definition 378.31. It states that componentwise hsame transport preserves the move from scheduled dyadic observations to the diagonal readback and then to the displayed seal row.

Use the flattened seal route of Definition 378.43 to place this naturality statement inside the bind-domain route. The route reads only source-family rows, schedules, finite windows, dyadic observations, diagonal readbacks, displayed transports, package provenance, and local naming before it reaches the seal.

Finish with public seal factorization from Definition 378.5. Since every public Real$^{\uparrow}$ read factors through the displayed diagonal readback and seal row, the transported bind-domain rows and the public seal passage commute. □

Theorem 378.48 (CauchyCompletionMonad completion-consumer naturality)**.** *Every downstream* RegSeqRat$^{\uparrow}$*,* RealCauchyCompletion$^{\uparrow}$*, or* Real$^{\uparrow}$ *consumer of an accepted* CauchyCompletionMonad$^{\uparrow}$ *packet receives the same finite route after componentwise transport and bind composition: source-family rows, unary schedule, finite* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *observations, diagonal* RegSeqRat$^{\uparrow}$ *readback, the public* Real$^{\uparrow}$ *seal,* BHist*,* hsame*, displayed* Cont *routes,* Pkg*, and local* NameCert *rows.*

Proof. First apply finite bind-domain coverage from Definition 378.45. It supplies one finite route for every bind-domain read and excludes quotient streams, selected limits, host real equality, hidden representatives, and ambient completeness coordinates.

Next apply Real seal functoriality from Definition 378.47. It shows that componentwise transport of the displayed bind-domain rows commutes with the public Real$^{\uparrow}$ seal passage.

The downstream completion consumer exactness is the consumer side of Definition 378.25 together with the root consumer exhaustion of Definition 378.35. These results place RegSeqRat$^{\uparrow}$, RealCauchyCompletion$^{\uparrow}$, and Real$^{\uparrow}$ consumers on the same source, schedule, window, dyadic-observation, readback, and seal route.

Finally use the flattened non-escape package of Definition 378.44. Since the transported bind composition and each downstream consumer read the same displayed rows and no external coordinate, the finite route received by each consumer is natural in the accepted packet. □

Theorem 378.49 (CauchyCompletionMonad L10 exit finite-route correspondence)**.** *For every accepted* CauchyCompletionMonad$^{\uparrow}$ *packet and every downstream* RegSeqRat$^{\uparrow}$*,* RealCauchyCompletion$^{\uparrow}$*, or* Real$^{\uparrow}$ *completion consumer, the consumer reaches the packet exactly when its visible read factors through the ordered L10 four-face packet consisting of the* DyadicRatCore$^{\uparrow}$ *endpoint and radius ledger, the* StreamName$^{\uparrow}$ *finite request window, the* RegSeqRat$^{\uparrow}$ *classifier and readback rows, and the* Real$^{\uparrow}$ *seal row. This factorization is the same as the completion-consumer naturality route: it carries the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *coordinates, and it exports no quotient stream, selected limit, host real equality, hidden representative, or ambient completeness coordinate.*

Proof. The forward direction starts with completion-consumer naturality from Definition 378.48. That theorem places every RegSeqRat$^{\uparrow}$, RealCauchyCompletion$^{\uparrow}$, and Real$^{\uparrow}$ consumer on the finite

source-family, schedule, finite-window, dyadic-observation, diagonal-readback, public-seal, BHist, hsame, Cont, Pkg, and local NameCert route of the accepted packet.

The four faces identify this route with the L10 exit packet. Apply Definition 291.28 for the dyadic endpoint and radius ledger, Definition 126.504 for the finite request window, and Definition 301.69 for the classifier and readback rows. Then use Definition 450.13 and Definition 450.16 to seal the same finite diagonal row as the public $\mathsf{Real}^{\uparrow}$ completion route.

For the reverse direction, assume the visible consumer read factors through that ordered four-face packet with the displayed BHist, hsame, Cont, Pkg, and local NameCert coordinates. The handoff exactness theorems identify the dyadic ledger, request window, classifier, readback, and seal rows with the rows used by the completion-consumer naturality route.

Repack those rows through Definition 378.48. Since the factorization contains exactly the finite coordinates admitted by the accepted $\mathsf{CauchyCompletionMonad}^{\uparrow}$ packet and no escaping completion coordinate, the downstream consumer reaches the packet by the same finite route. □

Theorem 378.50 (CauchyCompletionMonad Kleisli source triangle)**.** *For every accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet, the route that first reads a unit packet, then reads a bind packet, and then passes to a downstream* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *completion consumer has the same displayed source triangle as the flattened consumer route. The source-family row, unary schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation, diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, public* $\mathsf{Real}^{\uparrow}$ *seal,* BHist*,* hsame*, displayed* Cont *route,* Pkg*, and local* NameCert *row are read in the same finite order, with no additional completion source inserted between bind and consumer.*

Proof. Start with the unit boundary and the left-unit law, Definition 378.3 and Definition 378.14. They identify the unit packet with the displayed constant source-family, schedule, dyadic-observation, diagonal-readback, and seal rows.

Next attach the bind side using finite bind-domain coverage from Definition 378.45. The bind packet can read only the source-family, schedule, finite-window, dyadic-observation, readback, seal, BHist, hsame, Cont, Pkg, and local NameCert rows.

Now compare the resulting route with the flattened completion source of Definition 378.42. It presents the same rows before any completion consumer is allowed to inspect a seal-facing coordinate.

Finally apply completion-consumer naturality from Definition 378.48. Since the downstream $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers receive exactly the displayed finite route, the unit-bind-consumer path and the flattened consumer path have the same source triangle. □

Theorem 378.51 (CauchyCompletionMonad Kleisli seal coherence)**.** *In every accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet, the left-unit route, the right-unit route, and the associative-bind route reach the same public* $\mathsf{Real}^{\uparrow}$ *seal route after componentwise* hsame *transport of the source-family, schedule, finite-window, dyadic-observation, diagonal-readback,* Cont*,* Pkg*, and local* NameCert *rows. Thus the Kleisli consumer boundary has one seal-facing route for unit, bind, and reassociated bind reads.*

Proof. First read the unit laws. Apply Definition 378.14 for the source-side unit route and Definition 378.15 for the consumer-side unit route.

Next read reassociation through Definition 378.16. It keeps the bind route on the same source families, schedules, finite windows, dyadic observations, diagonal readbacks, and seal rows after componentwise hsame transport.

The common seal route is supplied by the flattened seal route of Definition 378.43. Real seal functoriality from Definition 378.47 then transports this route through the displayed hsame, Cont, Pkg, and local NameCert rows.

Finish with completion-consumer naturality from Definition 378.48. Each downstream completion consumer reads the same transported finite route, so left-unit, right-unit, and associative-bind presentations reach one public $\mathsf{Real}^{\uparrow}$ seal route. □

Theorem 378.52 (CauchyCompletionMonad Kleisli non-escape)**.** *The assembled Kleisli consumer route for an accepted* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *packet exports no quotient stream, selected limit, host real equality, hidden representative, or ambient completeness coordinate. Its only exported completion-facing data are the displayed source-family row, unary schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation, diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, public* $\mathsf{Real}^{\uparrow}$ *seal route,* BHist*,* hsame*, displayed* Cont *route,* Pkg*, and local* NameCert *row.*

Proof. Begin with the Kleisli source triangle from Definition 378.50. It ties the unit packet, bind packet, and downstream completion consumer to the same displayed finite source route.

Use Kleisli seal coherence from Definition 378.51 to identify the seal-facing side. The left-unit, right-unit, and associative-bind presentations all reach the same public $\mathsf{Real}^{\uparrow}$ seal route under componentwise transport.

Finally apply the flattened non-escape package of Definition 378.44. That package excludes quotient streams, selected limits, host real equality, hidden representatives, and ambient completeness coordinates from the flattened completion route, and the Kleisli consumer route has just been identified with that route on both source and seal sides. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonad}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionMonad}^{\uparrow}$ packet is generated from source regular-Cauchy family rows over $\mathsf{RegSeqRat}^{\uparrow}$, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ observations, a unary schedule, diagonal transport rows, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionMonad}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public $\mathsf{Real}^{\uparrow}$ seal factorization, schedule composition boundary, and downstream $\mathsf{RegSeqRat}^{\uparrow}$ consumer route supply the bridge-facing completion monad interface over the finite schedule, window, dyadic-observation, readback, seal, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionMonad}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.CauchyCompletionMonadUp.CauchyCompletionMonadPacket\_namecert\_obligations`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient real construction, host real equality, uniqueness of limits, or choice-selected limits.

Upgrade path: No further formal-axis upgrade remains for the bridge-checked completion-monad surface.

Chapter 379

A Concrete Naming Certificate for $\mathsf{DyadicTailBound}^{\uparrow}$

The $\mathsf{DyadicTailBound}^{\uparrow}$ interface records the finite tail-budget certificate used by Bishop–Bridges constructive analysis when a real-facing construction presents explicit rational tail control. It sits between $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$: the packet names the displayed precision row, the modulus row that selects the inspected tail, the dyadic tolerance used for the comparison, the finite ledger of tail estimates, and the seal-facing readback route. It does not form quotient streams, select limits, identify host real equality, or assume ambient completeness.

The tail-budget packet consumes the CauchyModulus schedule of chapter 292, the dyadic tolerance ledger of chapter 291, and the regular-rational handoff of chapter 301. These sibling dependencies explain how later regular-Cauchy and $\mathsf{Real}^{\uparrow}$ packets read the same finite threshold, tolerance, and ledger rows without adding a quotient stream or an ambient completeness input.

Definition 379.1 (DyadicTailBound BHist carrier)**.** *A* $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N)$$

with the following visible rows:

1. *p is a unary precision row naming the displayed request;*
2. *μ is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row that assigns the finite tail threshold used for p;*
3. *ϵ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row whose dyadic value is the comparison budget attached to p;*
4. *L is the finite tail comparison ledger: every inspected tail entry is paired with the threshold supplied by μ, the tolerance supplied by ϵ, and the displayed rational comparison row;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route obtained by reading the same finite tail ledger as regular rational sequence evidence;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row reached through R and through no other real-facing coordinate;*
7. *H records the componentwise* hsame *transports for precision, schedule, tolerance, tail-ledger, readback, and seal rows;*
8. *C records the displayed* Cont *routes by which consumers reach the schedule, tolerance, ledger, regular-sequence readback, and real seal;*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and the rational source rows used by the ledger;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicTailBound}^{\uparrow}}$ *provenance row.*

The classifier compares two accepted carriers only by these displayed rows, their componentwise hsame *transports, their* Cont *read routes, their* Pkg *provenance, and their local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundTasteGate single carrier alignment`

Theorem 379.2 (DyadicTailBound NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DyadicTailBound}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier habitation by the zero-tail packet, where the precision row is arbitrary, the schedule threshold is the displayed zero threshold, the dyadic tolerance is the zero-compatible* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget, the tail ledger records only zero comparisons, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is the constant zero row, and the* $\mathsf{Real}^{\uparrow}$ *seal-facing row is the corresponding zero seal;*

2. *classifier transport under componentwise* hsame *and displayed* Cont *routes for the precision,* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, finite tail ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* Pkg*, and local* NameCert *rows;*

3. *dyadic tolerance exactness: every accepted tail comparison uses exactly the tolerance row ϵ displayed in the carrier and cannot substitute an unrecorded rational radius;*

4. *regular-sequence handoff: the finite ledger L repacks as the visible* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R without dropping the schedule or tolerance rows that justify the tail budget;*

5. $\mathsf{Real}^{\uparrow}$ *seal non-escape: the seal-facing row E reads only through R, L, μ, ϵ, H, C, P, and N, and exports no quotient stream, selected limit, host real equality, or ambient completeness object.*

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier namecert obligations`

Proof. Carrier habitation is witnessed by the zero-tail packet. The schedule row supplies the zero threshold, the dyadic tolerance row is the displayed zero-compatible budget, and every ledger entry is the visible zero comparison. Repacking those rows gives the constant zero $\mathsf{RegSeqRat}^{\uparrow}$ readback and the matching $\mathsf{Real}^{\uparrow}$ seal-facing row.

Classifier transport is componentwise. Transport the precision request, schedule threshold, dyadic tolerance, ledger entry, readback row, and seal row along the stored hsame comparisons, then replay the recorded Cont routes. Since the classifier reads only the listed packet coordinates, the transported carrier is accepted by the same finite shape.

Dyadic tolerance exactness follows by projecting the ledger coordinate L. Each accepted comparison names the tolerance coordinate ϵ of the same carrier, so a consumer cannot replace it with an unrecorded rational radius or an ambient metric estimate.

The regular-sequence handoff is the projection to R. It keeps the finite ledger together with the schedule and tolerance evidence needed by $\mathsf{RegSeqRat}^{\uparrow}$, so no tail choice or quotient of streams is introduced during readback.

Finally the $\mathsf{Real}^{\uparrow}$ seal-facing row is reached only after the regular-sequence handoff. The carrier has no coordinate for selected limits, host real equality, quotient streams, or completeness principles, and therefore none of those objects can be exported by the local certificate. □

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier semantic name certificate`

Theorem 379.3 (DyadicTailBound zero packet carrier)**.** *For every displayed precision row p, the zero-tail packet*

$$T_0 = (p, \mu_0, \epsilon_0, L_0, R_0, E_0, H_0, C_0, P_0, N_0)$$

inhabits the $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier of Definition 379.1. The row μ_0 is the displayed schedule threshold for the zero request, ϵ_0 is the zero-compatible* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, L_0 is the finite ledger of zero tail comparisons at that threshold and tolerance, R_0 is the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *zero readback, E_0 is the* $\mathsf{Real}^{\uparrow}$ *zero seal reached through R_0, and H_0, C_0, P_0, N_0 are the matching* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{DyadicTailBound}^{\uparrow}}$ *rows.*

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier zero packet carrier`

Proof. Build the packet by the displayed carrier coordinates in Definition 379.1. The precision coordinate is p, and the schedule, tolerance, ledger, readback, and seal coordinates are the named zero rows.

The ledger L_0 contains only zero tail comparisons, each paired with the stored threshold μ_0 and tolerance ϵ_0. Thus the packet satisfies the same finite ledger condition used by the classifier.

Apply Definition 379.7 to read the ledger as the constant zero $\mathsf{RegSeqRat}^{\uparrow}$ row R_0, and apply Definition 379.8 to route the $\mathsf{Real}^{\uparrow}$ seal through that readback. The transport, continuation, package, and local certificate rows are all displayed coordinates of the same packet, so no extra real-facing object is introduced. □

Theorem 379.4 (DyadicTailBound precision window restriction)**.** *Let*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N)$$

be an accepted $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier. Every consumer read of the precision row p factors through the stored schedule threshold μ, the displayed dyadic tolerance row ϵ, the finite ledger L, and the displayed* Cont *routes in C. In particular, no consumer precision read may bypass the carrier by using an unrecorded threshold, a separate tolerance, or a ledger outside L.*

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier precision window restriction`

Proof. Project the packet through Definition 379.1. The precision row is stored in the same finite carrier as the schedule threshold, tolerance, ledger, readback, seal, transport, continuation, package, and naming rows.

Use Definition 379.6 to identify accepted consumer transport with componentwise hsame movement and displayed Cont reads. The classifier has no coordinate for an external threshold or tolerance.

The readback and real-facing routes are fixed by Definition 379.7 and Definition 379.8. Hence a precision consumer reaches the schedule, tolerance, ledger, and seal only through the stored packet routes. □

Theorem 379.5 (DyadicTailBound ledger append stability)**.** *Let*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N)$$

be an accepted $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier. If a displayed tail-comparison row q is appended to L with the same schedule threshold μ, the same dyadic tolerance row ϵ, and the same* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{DyadicTailBound}^{\uparrow}}$ *provenance rows, then the enlarged packet is accepted by the same carrier/classifier surface and its* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff still reads through the enlarged displayed ledger.*

Proof. Start from the carrier coordinates in Definition 379.1. The appended row q is not a new kind of evidence: it is another displayed tail comparison paired with the same threshold μ and tolerance ϵ already used by L.

Apply Definition 379.6. Because the schedule, tolerance, transport, continuation, package, and local certificate rows are preserved, classifier acceptance remains the same finite carrier condition with the enlarged ledger coordinate.

Apply Definition 379.7 to repack the enlarged ledger as the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and then Definition 379.8 for the seal route. The handoff still factors through the displayed ledger, so the append operation does not create an unrecorded tail estimate or a separate real-facing route. □

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier ledger append stability`

Theorem 379.6 (DyadicTailBound classifier transport exactness)**.** *Let*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N)$$

be an accepted $\mathsf{DyadicTailBound}^{\uparrow}$ BHist *carrier. If another displayed packet* T' *is obtained from* T *by the componentwise* hsame *transports recorded in* H *and by the displayed* Cont *routes recorded in* C*, while preserving the* Pkg *row* P *and the local* $\mathsf{NameCert}_{\mathsf{DyadicTailBound}^{\uparrow}}$ *row* N*, then the classifier accepts* T' *exactly when the transported precision row, schedule row* μ*, tolerance row* ϵ*, ledger row* L*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, and* $\mathsf{Real}^{\uparrow}$ *seal row* E *are the corresponding transported coordinates. In particular, classifier transport preserves accepted carriers and cannot replace the displayed tolerance, ledger, readback, or seal by unrecorded rows.*

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier classifier transport exactness`

Proof. Project the carrier coordinates of Definition 379.1. The classifier reads only the precision row, the $\mathsf{CauchyModulus}^{\uparrow}$ schedule, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, the tail ledger, the regular-sequence readback, the real seal, and the carried transport and provenance rows.

Apply the hsame witnesses in H component by component, and use the Cont routes in C only to read the transported displayed rows. The package row P and local $\mathsf{NameCert}$ row N are preserved as provenance for the same finite packet shape.

Since the classifier has no coordinate outside those projections, the transported packet is accepted precisely by the transported carrier rows. This rules out substitution of an ambient rational radius, an unlisted ledger, or a separate real-facing endpoint. □

Theorem 379.7 (DyadicTailBound regular-sequence handoff exactness)**.** *For every accepted* $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N),$$

the $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *is the handoff obtained from the same schedule row* μ*, dyadic tolerance row* ϵ*, and finite tail ledger* L*. Any consumer of* R *through the displayed* Cont *routes must therefore retain the schedule, tolerance, and ledger data certified by the* Pkg *row* P *and the local* $\mathsf{NameCert}_{\mathsf{DyadicTailBound}^{\uparrow}}$ *row* N*.*

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier regseqrat handoff exactness`

Proof. Read the schedule, tolerance, ledger, and readback coordinates from the carrier. The row L records the inspected tail comparisons, and each comparison is indexed by the threshold named by μ and the dyadic budget named by ϵ.

The readback row R is the regular rational view of exactly those finite comparisons. Repacking L as R forgets no schedule or tolerance evidence, because those rows are part of the same displayed BHist packet and are reached by the same Cont routes.

The provenance rows P and N certify the dependency package and the local naming surface. They add no hidden stream quotient or selected limit, so the handoff remains the finite $\mathsf{RegSeqRat}^{\uparrow}$ row determined by μ, ϵ, and L. □

Theorem 379.8 (DyadicTailBound real-seal factorization)**.** *For an accepted* $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N),$$

the $\mathsf{Real}^{\uparrow}$ *seal row E factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, the finite tail ledger L, the schedule row μ, and the dyadic tolerance row ϵ. The rows H, C, P, and N certify transport, readback, package provenance, and local naming for that factorization, but they do not supply a quotient of streams, a selected limit, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier real seal factorization`

Proof. Project the seal coordinate E from the carrier. By the carrier definition, the only real-facing route first reaches the $\mathsf{RegSeqRat}^{\uparrow}$ row R obtained from the displayed tail data.

Use Definition 379.7 to identify R with the repacking of L, μ, and ϵ. The transport and continuation rows certify that consumers reach these coordinates through the displayed BHist packet.

No coordinate of the carrier names a quotient stream, a chosen limiting real, host equality of real numbers, or a completeness principle. Therefore the seal row factors only through the finite readback and tail-budget rows listed in the statement. □

Theorem 379.9 (DyadicTailBound precision refinement stability)**.** *Let*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N)$$

be an accepted $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier. If a displayed refinement replaces the precision row p by p' through the componentwise* hsame *transport recorded in H and through the displayed* Cont *routes recorded in C, then the same refinement transports the schedule row μ, dyadic tolerance row ϵ, ledger row L,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R,* $\mathsf{Real}^{\uparrow}$ *seal row E, package row P, and local* $\mathsf{NameCert}_{\mathsf{DyadicTailBound}^{\uparrow}}$ *row N as one classifier-facing packet.*

The transported packet is again read only through the displayed rows of Definition 379.1; in particular, the refined precision request cannot detach the schedule, tolerance, ledger, readback, seal, package, or naming row from the original finite tail-budget certificate.

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier precision refinement stability`

Proof. Project the carrier of Definition 379.1. The precision row is not an isolated parameter: it is stored in the same finite packet as the schedule, tolerance, ledger, readback, seal, transport, continuation, package, and local certificate rows.

Apply the componentwise hsame witnesses recorded in H to the precision row and then to each dependent row listed in the statement. The displayed Cont routes in C give the only consumer reads of the transported schedule, tolerance, ledger, regular-sequence readback, and real seal.

Now use Definition 379.6 to identify classifier acceptance with those transported coordinates. The regular-sequence and real-facing projections remain the routes described by Definition 379.7 and Definition 379.8.

Thus the refinement moves the whole finite certificate at once. There is no coordinate from which a consumer could keep the refined precision while replacing the tail schedule, tolerance, ledger, readback, seal, package, or local naming row by unrecorded data. □

Theorem 379.10 (DyadicTailBound ledger threshold exhaustion)**.** *For every accepted* $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N),$$

each comparison consumed from the ledger L factors through the displayed threshold row μ and the displayed dyadic tolerance row ϵ. The carrier has no additional tail-estimate row, no ambient metric estimate, and no separate rational radius from which a ledger consumer can justify the same comparison.

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier ledger comparison determinacy`

Proof. Read the ledger coordinate L from Definition 379.1. By definition, every inspected tail entry is paired with the threshold supplied by μ and the tolerance supplied by ϵ.

The handoff theorem Definition 379.7 keeps the ledger together with exactly those two rows when it repacks the data as the $\mathsf{RegSeqRat}^{\uparrow}$ readback R. The seal theorem Definition 379.8 then reaches the $\mathsf{Real}^{\uparrow}$ row only through that readback and the same finite ledger.

The remaining rows H, C, P, and N record transport, consumer reads, package provenance, and local naming. They certify access to the displayed rows, but none of them carries an extra estimate.

Therefore any ledger comparison is exhausted by μ, ϵ, and the visible ledger entry. A downstream consumer cannot cite an unrecorded tail estimate without leaving the carrier surface. □

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier ledger threshold exhaustion`

Theorem 379.11 (DyadicTailBound seal consumer determinacy)**.** *Suppose two consumers read an accepted* $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N)$$

through the same displayed rows R, L, μ, ϵ, H, C, P, and N. Then both consumers obtain the same classifier-facing $\mathsf{Real}^{\uparrow}$ *seal row E. This determinacy is only a statement about the visible seal row of the carrier; it does not export host equality of real numbers, quotient equality of streams, a selected limit, or a completeness datum.*

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier seal consumer determinacy`

Proof. Project the seal coordinate E from the carrier. The definition gives a single real-facing row attached to the regular-sequence readback route.

By Definition 379.8, every consumer route to E factors through R, L, μ, and ϵ, with H, C, P, and N supplying only transport, readback, provenance, and local naming. The two consumers in the statement therefore traverse the same displayed factorization.

Apply Definition 379.6 to compare the resulting reads. Since the classifier sees only the listed rows, the two reads have the same classifier-facing seal coordinate.

The conclusion does not add a host real carrier or an equality principle. It records determinacy of the finite $\mathsf{Real}^{\uparrow}$ seal row already present in the packet. □

Theorem 379.12 (DyadicTailBound zero-tail carrier habitation)**.** *For every displayed precision row p, the zero-tail packet*

$$T_0 = (p, \mu_0, \epsilon_0, L_0, R_0, E_0, H_0, C_0, P_0, N_0)$$

inhabits the $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier. Here μ_0 is the displayed zero threshold, ϵ_0 is the zero-compatible* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, L_0 is the finite ledger whose accepted comparisons are zero comparisons at that threshold and tolerance, R_0 is the constant zero* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, E_0 is the corresponding* $\mathsf{Real}^{\uparrow}$ *zero seal, H_0 and C_0 are the componentwise* hsame *and* Cont *rows for those displayed coordinates, and P_0, N_0 are the matching* Pkg *and local* $\mathsf{NameCert}_{\mathsf{DyadicTailBound}^{\uparrow}}$ *provenance rows.*

Proof. Build the packet by the carrier coordinates of Definition 379.1. The precision coordinate is the given row p, while the schedule, tolerance, ledger, readback, and seal coordinates are the displayed zero rows.

The ledger coordinate contains only zero comparisons, so every comparison is already indexed by the zero threshold μ_0 and the zero-compatible dyadic tolerance ϵ_0. Repacking this ledger gives the constant zero $\mathsf{RegSeqRat}^{\uparrow}$ readback R_0.

The $\mathsf{Real}^{\uparrow}$ row E_0 is reached through that readback. The transport, continuation, package, and local naming rows are the trivial componentwise rows for the same displayed packet, so the classifier accepts T_0 without adding quotient streams, selected limits, host real equality, or ambient completeness. □

Theorem 379.13 (DyadicTailBound tolerance ledger exhaustion)**.** *Let*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N)$$

be an accepted $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier. Every accepted comparison consumed from L is exhausted by the displayed tolerance row ϵ, the displayed threshold row μ, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the componentwise* hsame *rows in H, the* Cont *routes in C, the package row P, and the local* $\mathsf{NameCert}_{\mathsf{DyadicTailBound}^{\uparrow}}$ *row N. No accepted comparison in L can be justified by an unrecorded tolerance, external metric estimate, host real equality, quotient stream, or selected limit.*

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier tolerance ledger exhaustion`

Proof. Project the ledger coordinate L from the carrier. By Definition 379.1, each inspected tail entry is paired with the same threshold coordinate μ and the same dyadic tolerance coordinate ϵ displayed in the packet.

Apply Definition 379.7 to keep L attached to the readback row R. The hsame rows in H and the Cont routes in C only transport and read these displayed coordinates.

The provenance rows P and N certify the dependency package and local naming surface for this finite packet. Since no other comparison coordinate exists, the ledger is exhausted by μ, ϵ, R, H, C, P, and N. □

Theorem 379.14 (DyadicTailBound CauchyRate consumer route)**.** *For every accepted* $\mathsf{DyadicTailBound}^{\uparrow}$ *carrier*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N)$$

every $\mathsf{CauchyRate}^{\uparrow}$ *consumer read of T factors through the precision row p, schedule μ, dyadic tolerance ϵ, ledger L,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{Real}^{\uparrow}$ *seal E, and displayed rows H, C, P, and N.*

The route exports no hidden rate selector, quotient stream, selected limit, host real equality, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier cauchy rate consumer route`

Proof. Project the accepted carrier. Its consumer-visible coordinates are exactly the precision row, schedule threshold, tolerance row, finite ledger, regular-sequence readback, real seal, transport rows, continuation routes, package provenance, and local naming row.

Use Definition 379.7. Any $\mathsf{CauchyRate}^{\uparrow}$ read that consumes a regular rational rate must pass through R, and R is obtained from the same schedule row μ, dyadic tolerance ϵ, and finite ledger L.

Apply Definition 379.8. A real-facing consumer reaches E only through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ readback and the same tail-budget coordinates.

Use Definition 379.10 and Definition 379.13. These rows keep every consumed comparison tied to the threshold μ, tolerance ϵ, ledger L, transports H, continuations C, package row P, and local naming row N.

Since the carrier contains no hidden rate selector, quotient stream, selected limit, host equality, or ambient completeness field, every $\mathsf{CauchyRate}^{\uparrow}$ consumer route is exhausted by p, μ, ϵ, L, R, E, H, C, P, and N. □

Theorem 379.15 (DyadicTailBound consumer obligation package)**.** *The carrier of Definition 379.1, classifier transport exactness, zero-tail carrier habitation, tolerance ledger exhaustion,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff exactness, and* $\mathsf{Real}^{\uparrow}$ *seal factorization assemble the* $\mathsf{DyadicTailBound}^{\uparrow}$ *consumer obligation package over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

The package exposes only the displayed precision row, schedule threshold, dyadic tolerance, finite ledger, regular-sequence readback, real seal, componentwise transport rows, continuation routes, package provenance, and local naming row. It does not export quotient streams, selected limits, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier consumer obligation package`

Proof. Start with the finite carrier. It supplies the displayed rows $p, \mu, \epsilon, L, R, E, H, C, P, N$ and therefore fixes the consumer-visible packet shape.

Classifier transport is Definition 379.6. The inhabited base case is Definition 379.12, and the ledger exactness row is Definition 379.13.

The readback and real-facing rows are supplied by Definition 379.7 and Definition 379.8. These theorems force every consumer route through the finite ledger, the displayed tolerance and threshold, and the regular rational readback.

Assembling the listed rows gives the obligation package. Since each component is a projection or repacking of the same BHist packet, no extra carrier for quotient streams, selected limits, host real equality, or ambient completeness is introduced. □

Theorem 379.16 (DyadicTailBound budget composition)**.** *Let*

$$T_1 = (p, \mu, \epsilon, L_1, R_1, E_1, H, C, P, N) \quad \textit{and} \quad T_2 = (p, \mu, \epsilon, L_2, R_2, E_2, H, C, P, N)$$

be accepted $\mathsf{DyadicTailBound}^{\uparrow}$ *packets sharing the displayed precision row, schedule threshold, dyadic tolerance, componentwise* hsame *rows,* Cont *routes,* Pkg *provenance, and local* NameCert *row. If the second displayed tail ledger refines or extends the first through those same rows, then the concatenated ledger* L_1L_2 *is an accepted* $\mathsf{DyadicTailBound}^{\uparrow}$ *packet whose* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal factor through the composite displayed budget. The conclusion exports only the composed finite ledger surface and no quotient stream, selected limit, host real equality, or ambient completeness datum.*

Proof. Begin with the two accepted carriers and project their common rows. The precision, threshold, tolerance, transport, continuation, package, and local naming coordinates agree by hypothesis, so the only displayed change is the refinement from L_1 to L_2 and the concatenated ledger L_1L_2.

Apply Definition 379.5 along the displayed refinement rows to accept each appended comparison with the same μ, ϵ, H, C, P, and N. Then use Definition 379.10 to keep every comparison in the composite ledger tied to the displayed threshold and tolerance.

Classifier transport is controlled by Definition 379.6. It prevents the composite packet from replacing the shared provenance by an unrecorded tolerance, external estimate, or separate ledger surface.

Finally apply Definition 379.7 and Definition 379.8. The regular-sequence readback factors through the concatenated ledger, and the real-facing seal factors through that readback and the same composite displayed budget. □

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier budget composition`

Theorem 379.17 (DyadicTailBound schedule monotone consumer)**.** *Let*

$$T = (p, \mu, \epsilon, L, R, E, H, C, P, N) \quad \textit{and} \quad T' = (p', \mu', \epsilon, L', R', E', H, C, P, N)$$

be accepted $\mathsf{DyadicTailBound}^{\uparrow}$ *packets sharing the displayed tolerance, componentwise* hsame *rows,* Cont *routes,* Pkg *provenance, and local* NameCert *row. Suppose the displayed refinement from p to p' transports the schedule threshold from μ to μ' through the same rows H and C, and suppose the refined ledger L' is read as the carried tail ledger for μ' and ϵ.*

Then every $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of T' factors through the transported schedule row μ', the displayed dyadic tolerance row ϵ, the finite ledger L', and the shared transport, continuation, package, and naming rows. Such a consumer cannot reuse the old ledger through an unrecorded schedule, external radius, selected limit, quotient stream, host real equality, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.DyadicTailBoundUp.DyadicTailBoundCarrier schedule monotone consumer`

Proof. Start with the accepted packet T and apply Definition 379.9. The refinement of p to p' is not a free precision change; it transports the schedule, tolerance, ledger, readback, seal, package, and naming coordinates through the same H and C rows.

Next use Definition 379.10. Every comparison consumed from the refined ledger is exhausted by the transported threshold μ' and the displayed tolerance ϵ, so the ledger cannot be replayed through a schedule row absent from the packet.

For a $\mathsf{RegSeqRat}^{\uparrow}$ consumer, apply Definition 379.7. The readback row R' is obtained only by repacking L', μ', and ϵ along the displayed transport and continuation routes.

For a $\mathsf{Real}^{\uparrow}$ consumer, apply Definition 379.8. The seal row E' is reached only through that regular-sequence readback and the same finite tail-budget data.

Finally use Definition 379.16 to keep composed refinements on the displayed budget surface. Since the carrier has no coordinate for an external radius, selected limit, quotient stream, host real equality, or ambient completeness, every refined consumer route must carry the schedule row together with the ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicTailBound}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicTailBound}^{\uparrow}$ packet is generated from a unary precision row, a $\mathsf{CauchyModulus}^{\uparrow}$ threshold schedule, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, a finite tail comparison ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback route, a $\mathsf{Real}^{\uparrow}$ seal-facing row, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{DyadicTailBound}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature paper scope is the finite tail-budget interface through budget composition, ledger threshold exhaustion, the RegSeqRat$^{\uparrow}$ handoff, Real$^{\uparrow}$ seal factorization, classifier transport, consumer obligation packaging, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicTailBound}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, ambient completeness, or bridge checking.

Upgrade path: Machine bridge verification requires a Lean bridge theorem for the same public tail-budget interface and downstream completion schema.

Chapter 380

A Concrete Naming Certificate for $\mathsf{NullSequence}^{\uparrow}$

The $\mathsf{NullSequence}^{\uparrow}$ interface names the constructive zero-convergence packet consumed by $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and completion-facing certificates when a displayed rational difference stream is required to shrink to zero. Following Bishop and Bridges, *Constructive Analysis*, the certificate records explicit finite tolerance schedules and observation windows rather than quotienting streams or appealing to a host limit.

The packet depends on the regular-rational difference stream of chapter 301, the dyadic tolerance rows of chapter 291, and the finite observation windows of chapter 126. A $\mathsf{NullSequence}^{\uparrow}$ certificate is a consumer of those rows before the $\mathsf{Real}^{\uparrow}$ seal can read zero-convergence: it does not manufacture a stream, tolerance ledger, or window surface of its own.

Definition 380.1 (NullSequence NameCert carrier)**.** *A* $\mathsf{NullSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (D, T, W, M, E, H, C, P, N)$$

with the following visible coordinates:

1. *D is a* $\mathsf{RegSeqRat}^{\uparrow}$ *difference stream row whose inspected values are displayed through finite rational readbacks;*
2. *T is a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance schedule naming the positive dyadic bounds requested by a consumer;*
3. *W is a* $\mathsf{StreamName}^{\uparrow}$ *observation window that records exactly which finite portion of D is inspected for each tolerance row;*
4. *M is a* $\mathsf{CauchyModulus}^{\uparrow}$ *or* $\mathsf{RegularityModulus}^{\uparrow}$ *bound row selecting the threshold after which the displayed difference observations are below the tolerance in T;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-consumption row whose equality classifier may consume the zero-convergence packet;*
6. *H records the componentwise* hsame *rows comparing difference-stream observations, tolerance rows, windows, modulus rows, and seal rows;*
7. *C records the* Cont *routes through which downstream readers reach the finite stream, tolerance, bound, and seal rows;*

8. *P is the* Pkg *provenance ledger naming exactly the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$ *or* $\mathsf{RegularityModulus}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *sources;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{NullSequence}^{\uparrow}}$ *provenance row.*

The classifier for two accepted packets is equality of displayed zero-convergence packets under hsame *transport of the stream window, tolerance schedule, bound row, seal row, continuation routes, package ledger, and local naming row.*

Lean4 ✓ `BEDC.Derived.NullSequenceUp.NullSequenceTasteGate single carrier alignment`

Theorem 380.2 (NullSequence NameCert obligations)**.** *The* $\mathsf{NameCert}_{\mathsf{NullSequence}^{\uparrow}}$ *surface consists exactly of five obligations: carrier habitation by the displayed packet of Definition 380.1; classifier reflexivity, symmetry, and transitivity inherited componentwise from* hsame *over windows, tolerances, bounds, and seal rows; carrier transport along the classifier; exact ledger exposure of only the finite stream, modulus, tolerance, seal, continuation, package, and local certificate rows; and* $\mathsf{Real}^{\uparrow}$ *classifier consumption of the null difference packet.*

Proof. Carrier habitation is obtained by displaying the zero difference stream, a dyadic tolerance row, a finite observation window, a bound row that sends the tolerance request to that window, the real-seal consumption row, and the provenance rows.

The classifier laws are inherited componentwise. Reflexivity uses the identity hsame rows for the displayed stream, tolerance, window, bound, and seal coordinates. Symmetry reverses those rows, and transitivity composes them without introducing any host sequence equality.

Transport repacks the same finite coordinates after applying the displayed hsame and Cont routes. Since the provenance ledger lists only the rows in Definition 380.1, every public read is exhausted by those rows and by the $\mathsf{Real}^{\uparrow}$ consumption boundary. □

Lean4 ✓ `BEDC.Derived.NullSequenceUp.NullSequenceCarrier namecert obligation surface`

Theorem 380.3 (NullSequence Real classifier consumption)**.** *For two* $\mathsf{Real}^{\uparrow}$ *seal rows presented by regular rational names, a* $\mathsf{NullSequence}^{\uparrow}$ *packet for their displayed difference stream is precisely the finite witness that the* $\mathsf{Real}^{\uparrow}$ *equality classifier may consume: each requested dyadic tolerance is routed through a* $\mathsf{StreamName}^{\uparrow}$ *window and a* $\mathsf{CauchyModulus}^{\uparrow}$ *or* $\mathsf{RegularityModulus}^{\uparrow}$ *bound, and the resulting tail estimate is exposed to the seal row through the recorded* Cont *and* Pkg *provenance.*

Proof. Read the two real-name presentations through their $\mathsf{RegSeqRat}^{\uparrow}$ rows and form the displayed difference stream coordinate D. A consumer tolerance is then read through the dyadic schedule T.

The modulus coordinate M chooses the finite window W where the relevant tail observations of D are inspected. The packet records that those observations are bounded by the tolerance row, so the real-seal row receives an explicit zero-convergence witness rather than a quotient comparison.

Conversely, a $\mathsf{Real}^{\uparrow}$ equality read that is certified by this packet can project only the difference stream, tolerance schedule, window, bound, seal, continuation, and provenance rows. Those are exactly the coordinates of Definition 380.1, so the classifier consumption is neither stronger nor weaker than the displayed null-difference packet. □

Theorem 380.4 (NullSequence downstream Real-completion consumer route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *equality or completion-facing seal that consumes a* $\mathsf{NullSequence}^{\uparrow}$ *null-difference packet must route through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *difference stream, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *observation window, and the* $\mathsf{CauchyModulus}^{\uparrow}$ *or* $\mathsf{RegularityModulus}^{\uparrow}$ *threshold before reading the* $\mathsf{Real}^{\uparrow}$ *seal. In particular, any downstream read shared with the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *budget route of chapter 699 or a completion-facing handoff such as chapter 1628 receives the null-difference evidence only through those displayed finite rows.*

Proof. Start with the Real classifier consumption theorem Definition 380.3. It identifies the packet consumed by a $\mathsf{Real}^{\uparrow}$ equality read as the displayed null-difference row together with its tolerance, window, threshold, seal, continuation, and provenance rows.

Apply the carrier projection of Definition 380.1. The difference stream is a $\mathsf{RegSeqRat}^{\uparrow}$ row, the tolerance request is a $\mathsf{DyadicRatCore}^{\uparrow}$ row, the observation service is a $\mathsf{StreamName}^{\uparrow}$ row, and the threshold is supplied by $\mathsf{CauchyModulus}^{\uparrow}$ or $\mathsf{RegularityModulus}^{\uparrow}$ before the seal is public.

The cited downstream siblings consume the same finite route rather than a hidden host limit. Since no coordinate of the packet exports a quotient stream, selected limit, trichotomy, or ambient completeness proof, every Real or completion-facing seal read remains downstream of the displayed null-sequence rows. □

Definition 380.5 (NullSequence tolerance-window exactness package)**.** *For an accepted* $\mathsf{NullSequence}^{\uparrow}$ *packet*

$$Z = (D, T, W, M, E, H, C, P, N),$$

the tolerance-window exactness package is the same finite tuple, read with the following obligation-level roles:

1. *D is the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *difference row whose zero-convergence is being consumed;*
2. *T is the accepted dyadic tolerance request row;*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window selected for that tolerance request;*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *or* $\mathsf{RegularityModulus}^{\uparrow}$ *threshold row binding the request in T to the window in W;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row that reads the resulting null-difference evidence;*
6. *H records the componentwise* hsame *transports for difference rows, tolerance rows, windows, thresholds, and seal rows;*
7. *C records the* Cont *routes from the consumer request to T, from T to W and M, and from the certified difference row to E;*
8. *P and N record the dependency package and local* $\mathsf{NameCert}_{\mathsf{NullSequence}^{\uparrow}}$ *provenance.*

The package is exact when every accepted tolerance request reaches the displayed threshold row M and window W before the $\mathsf{Real}^{\uparrow}$ *seal reads the row E. No coordinate of the package is a host limit, an unrecorded tail estimate, or a quotient of difference streams.*

Theorem 380.6 (NullSequence window threshold exactness)**.** *Let $Z = (D, T, W, M, E, H, C, P, N)$ be an accepted* $\mathsf{NullSequence}^{\uparrow}$ *packet equipped with the tolerance-window exactness package of Definition 380.5. Every accepted tolerance request consumed by Z is routed through the displayed tolerance row T, the displayed observation window W, and the displayed bound row M before it reaches any* $\mathsf{Real}^{\uparrow}$ *seal read.*

Thus the zero-convergence evidence exported by Z is exhausted by the $\mathsf{RegSeqRat}^{\uparrow}$ *difference row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{CauchyModulus}^{\uparrow}$ *or* $\mathsf{RegularityModulus}^{\uparrow}$ *threshold, and the recorded* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *provenance. It contains no unrecorded tail estimate and no host limit.*

Lean4 ✓ `BEDC.Derived.NullSequenceUp.NullSequenceCarrier window threshold exactness`

Proof. Project the carrier coordinates of Z. The tolerance request is the coordinate T, so any consumer read first lands in the displayed dyadic tolerance schedule rather than in an ambient metric statement.

The window coordinate W and threshold coordinate M are then selected by the recorded Cont route. The bound row says that the inspected tail of the displayed difference stream D is below the tolerance named by T on precisely that finite window.

Transport between equivalent presentations is componentwise. The rows in H move the difference row, tolerance row, window, threshold, and seal row, while C preserves the order in which the consumer reaches them.

Finally, P and N certify the same dependency and local naming provenance after transport. Since the only outgoing seal read is the row E, every accepted tolerance request has passed through T, W, and M, and there is no remaining coordinate from which an unrecorded tail estimate or host limit could be exported. □

Theorem 380.7 (NullSequence Real seal factorization)**.** *For two* $\mathsf{Real}^{\uparrow}$ *seal rows presented by regular rational names, any* $\mathsf{Real}^{\uparrow}$ *classifier consumption certified by a* $\mathsf{NullSequence}^{\uparrow}$ *packet factors through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *difference row D, dyadic tolerance schedule T, observation window W, threshold row M, seal row E, and provenance package (H, C, P, N) of Definition 380.5.*

Equivalently, the $\mathsf{Real}^{\uparrow}$ *equality read cannot bypass the displayed null-difference package by using an unstated stream representative, a host real limit, a hidden tail estimate, trichotomy, or choice.*

Lean4 ✓ `BEDC.Derived.NullSequenceUp.NullSequenceCarrier real seal factorization`

Proof. Start with the $\mathsf{Real}^{\uparrow}$ classifier consumption theorem Definition 380.3. It identifies a $\mathsf{NullSequence}^{\uparrow}$ packet as the finite witness that the real equality classifier may consume for the displayed regular-rational difference row.

Apply Definition 380.6 to that packet. The theorem forces each tolerance read to pass through the tolerance schedule T, the window W, and the threshold M before reaching the seal row E.

The remaining coordinates are provenance rather than extra analytic data. The hsame rows in H, the Cont routes in C, and the package and local naming rows P, N record how the same difference, tolerance, window, threshold, and seal rows are transported.

Therefore the real-seal consumption factors through exactly the displayed package. Any route using a different stream representative, host limit, hidden tail estimate, trichotomy, or choice would require a coordinate absent from the carrier of Definition 380.1. □

Theorem 380.8 (NullSequence non-escape boundary)**.** *An accepted* $\mathsf{NullSequence}^{\uparrow}$ *packet exports no Dedekind cut, no quotient of streams, no host real equality, no trichotomy principle, and no real-completeness theorem. Every public zero-convergence read factors through* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$ *or* $\mathsf{RegularityModulus}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows.*

Proof. Inspect the carrier coordinates. Each coordinate is a finite history row, a displayed transport route, a package provenance row, a local naming row, or one of the named dependency certificates.

The bound row names only a finite observation threshold for a requested tolerance. Passing to the $\mathsf{Real}^{\uparrow}$ seal consumes that finite zero-convergence row; it does not create a host real carrier, a completed quotient class, or a comparison by trichotomy.

Thus a downstream reader can cite exactly the listed finite rows. Since no excluded analytic or order-theoretic object is a coordinate of the carrier, none can be exported by the certificate. □

Lean4 ✓ `BEDC.Derived.NullSequenceUp.NullSequenceCarrier non escape boundary`

Theorem 380.9 (NullSequence standard Bishop reading)**.** *In the Bishop–Bridges constructive-analysis reading,* $\mathsf{NullSequence}^{\uparrow}$ *is the finite certificate that a regular rational difference stream converges to zero: tolerances are explicit dyadic rows, observation windows are explicit stream-name rows, and the bound is an explicit Cauchy or regularity modulus consumed by* $\mathsf{Real}^{\uparrow}$ *equality.*

Proof. The input side is the displayed $\mathsf{RegSeqRat}^{\uparrow}$ difference stream together with the dyadic tolerance schedule. No convergence claim is inferred from a host metric space or from an ambient completeness theorem.

The witnessing side is the finite window and bound row. For each tolerance request, the packet records the window after which the displayed difference observations are below the requested dyadic bound.

The output side is the $\mathsf{Real}^{\uparrow}$ seal-consumption row. It reads the finite zero-convergence ledger as equality evidence for regular rational names while withholding Dedekind cuts, quotient streams, host real equality, trichotomy, and real completeness. □

Theorem 380.10 (NullSequence zero-tail criterion)**.** *Let* $Z = (D, T, W, M, E, H, C, P, N)$ *be an accepted* $\mathsf{NullSequence}^{\uparrow}$ *packet over a displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *difference stream. A* $\mathsf{Real}^{\uparrow}$ *equality-classifier consumer read is admitted by* Z *exactly when the read factors through the tolerance schedule* T*, the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound row read by* M*, the* Cont *routes in* C*, the* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{NullSequence}^{\uparrow}}$ *row recorded by the tolerance-window package of Definition 380.5.*

Thus the classifier-facing zero-tail read for regular rational names is the same finite tolerance-window packet, transported through H *and sealed by* E*, and not an additional real-limit datum.*

Proof. First project the accepted tolerance request. By Definition 380.6, the request must pass through the displayed dyadic schedule T, the observation window W, and the threshold row M before it reaches any $\mathsf{Real}^{\uparrow}$ seal row.

Next apply Definition 380.7. The real equality classifier can consume the zero-tail evidence only after that same stream, tolerance, window, threshold, seal, transport, continuation, package, and local certificate package has been read.

For the converse direction, suppose the consumer read already factors through these displayed rows. The tolerance-window package supplies the bound row and window for the requested tolerance, and the factorization theorem routes the resulting null-difference evidence into the seal row E.

Finally use Definition 380.8. Since no host limit, quotient stream, hidden tail estimate, trichotomy, or completeness object is exported by the packet, an admitted $\mathsf{Real}^{\uparrow}$ zero-tail read is exactly the finite route just described. □

Theorem 380.11 (NullSequence classifier-composition window exactness)**.** *Let* $Z_0 = (D_0, T_0, W_0, M_0, E_0, H_0, C_0, P$ $Z_1 = (D_1, T_1, W_1, M_1, E_1, H_1, C_1, P_1, N_1)$*, and* $Z_2 = (D_2, T_2, W_2, M_2, E_2, H_2, C_2, P_2, N_2)$ *be accepted* $\mathsf{NullSequence}^{\uparrow}$ *packets. If the classifier transports* Z_0 *to* Z_1 *and* Z_1 *to* Z_2*, then the composed transport preserves the same displayed difference row* D*, tolerance row* T*, observation window* W*, threshold row* M*, seal row* E*, and provenance package* (H, C, P, N)*.*

Thus classifier composition remains a finite tolerance-window exactness claim over the rows of Definition 380.5; it does not introduce a host limit, a hidden tail estimate, a quotient stream, trichotomy, or choice.

Proof. Project the carrier of Definition 380.1. The classifier compares only the displayed difference, tolerance, window, threshold, seal, transport, continuation, package, and local certificate rows.

Apply the tolerance-window exactness package of Definition 380.5 to the first transport and then to the second. Each step keeps the tolerance request on T, the observation read on W, and the threshold read on M before the seal row is reached.

Use Definition 380.6 to identify the composed route. Since both component transports preserve exactly the same displayed rows, their composition still reads the original finite difference row through the transported T, W, and M coordinates.

Finally Definition 380.8 rules out any additional analytic coordinate. The composed classifier route therefore preserves the same tolerance-window packet and the same provenance package (H, C, P, N). □

Theorem 380.12 (NullSequence tolerance-window transport)**.** *For an accepted* $\mathsf{NullSequence}^{\uparrow}$ *packet* $Z = (D, T, W, M, E, H, C, P, N)$*, every transported tolerance request still reaches the displayed tolerance row* T*, observation window* W*, and threshold row* M *before the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is read. The transport is carried only by the componentwise* hsame *ledger* H*, the displayed* Cont *routes* C*, the package provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{NullSequence}^{\uparrow}}$ *row* N*.*

Consequently the transported request remains the same finite null-difference package consumed by $\mathsf{Real}^{\uparrow}$ *equality, not an unstated stream representative or host-limit assertion.*

Proof. Begin with the window-threshold exactness theorem Definition 380.6. It forces each accepted tolerance request to pass through T, W, and M before any seal read.

Transport the rows using the ledger H and replay the routes in C. Because the tolerance-window package lists P and N only as provenance rows, the transport can move the finite packet but cannot add a new bound, stream representative, or real-limit datum.

The seal factorization theorem Definition 380.7 then routes the transported null-difference evidence into E. The non-escape boundary of Definition 380.8 confirms that no quotient, trichotomy, choice, or host equality object is exported by this route. □

Theorem 380.13 (NullSequence common-window refinement)**.** *Let* $Z = (D, T, W, M, E, H, C, P, N)$ *and* $Z' = (D', T', W', M', E', H', C', P', N')$ *be accepted* $\mathsf{NullSequence}^{\uparrow}$ *packets whose* $\mathsf{RegSeqRat}^{\uparrow}$ *difference streams are classifier-related through the displayed* BHist *rows. For any pair of* $\mathsf{Real}^{\uparrow}$ *equality consumer reads of* Z *and* Z'*, if the reads name tolerance schedules in* $\mathsf{DyadicRatCore}^{\uparrow}$*, observation windows in* $\mathsf{StreamName}^{\uparrow}$*, threshold rows in* M, M'*, seal rows in* E, E'*, an* hsame *ledger* H, H'*,* Cont *routes* C, C'*,* Pkg *provenance* P, P'*, and local* $\mathsf{NameCert}_{\mathsf{NullSequence}^{\uparrow}}$ *rows* N, N'*, then the pair refines to one displayed* $\mathsf{StreamName}^{\uparrow}$ *common window and one displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row before either* $\mathsf{Real}^{\uparrow}$ *seal is read.*

The refined surface is carried only by the shown BHist *packet rows, the* hsame *transports, the* Cont *routes, the* Pkg *rows, and the local* $\mathsf{NameCert}$ *rows. It exports no unrecorded stream representative, host limit, quotient stream, trichotomy, or real-completeness object.*

Proof. First apply Definition 380.6 to both accepted packets. Each $\mathsf{Real}^{\uparrow}$ equality read must pass through its displayed $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{StreamName}^{\uparrow}$ observation window, and threshold row before any seal row is reached.

Next use Definition 380.11. The classifier-related difference streams and their componentwise transports compose to a single finite window comparison rather than to a second analytic tail claim.

Apply Definition 380.12 to move the two tolerance-window packages through the hsame ledgers H, H' and the Cont routes C, C'. The transported consumer reads therefore share one displayed window row and one displayed tolerance row before the seal coordinates are consulted.

Finally use Definition 380.7. The $\mathsf{Real}^{\uparrow}$ seals read only the factorized null-difference package, and the non-escape boundary of Definition 380.8 excludes any hidden limit, quotient stream, trichotomy, or completeness object from the refinement. □

Theorem 380.14 (NullSequence tail-induction modulus)**.** *From an accepted* $\mathsf{NullSequence}^{\uparrow}$ *packet and two displayed tolerance windows, primitive induction over the finite window-refinement ledger produces a common tail modulus that preserves the* $\mathsf{Real}^{\uparrow}$ *classifier consumption and never introduces quotient streams, host real equality, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the tolerance-window exactness package of Definition 380.5. The two displayed tolerance requests are already routed through finite T, W, M rows, with the seal row E and provenance rows H, C, P, N attached to the same packet.

Apply window threshold exactness from Definition 380.6 to each request. This gives two finite thresholds and two finite observation windows before either $\mathsf{Real}^{\uparrow}$ seal can be read.

Run primitive induction over the finite refinement ledger supplied by Definition 380.13. The base step keeps the first displayed window, and each refinement step enlarges the displayed window only by the next finite row needed to cover both tolerance requests.

Finally transport the resulting common window by Definition 380.12. The seal still consumes the same factorized null-difference package, so the induction produces a common tail modulus without adding quotient streams, host real equality, trichotomy, or any completeness field. □

Theorem 380.15 (NullSequence obligation closure package)**.** *The* $\mathsf{NullSequence}^{\uparrow}$ *chapter presents an obligation-complete paper package for zero-tail consumption by* $\mathsf{Real}^{\uparrow}$ *equality over regular rational names. The package consists of the carrier of Definition 380.1, the componentwise classifier route of Definition 380.2, the tolerance-window exactness package of Definition 380.5, window-threshold exactness from Definition 380.6, classifier-composition exactness from Definition 380.11, tolerance-window transport from Definition 380.12,* $\mathsf{Real}^{\uparrow}$ *seal factorization from Definition 380.7, the zero-tail criterion of Definition 380.10, and the non-escape boundary of Definition 380.8.*

This package closes the paper obligation surface for finite tolerance schedules, classifier stability, transported observation windows, threshold exactness, and $\mathsf{Real}^{\uparrow}$ *null-difference consumption. It does not claim Dedekind cuts, quotient streams, host real equality, trichotomy, choice, or real completeness.*

Proof. The carrier and NameCert obligations identify the finite null-difference packet and the componentwise classifier rows. The tolerance-window package names the roles of D, T, W, M, E, H, C, P, and N.

Window-threshold exactness and tolerance-window transport show that every tolerance request reaches T, W, and M before the seal. Classifier-composition exactness shows that composing accepted transports preserves the same finite rows rather than producing a second tolerance ledger.

The seal factorization theorem and the zero-tail criterion identify the $\mathsf{Real}^{\uparrow}$ equality consumer as precisely the reader of this displayed null-difference packet. The non-escape boundary supplies the excluded-object clause, so the assembled package is obligation-complete on the paper axis while leaving formal verification to a separate target. □

Definition 380.16 (NullSequence root-unblock consumer surface)**.** *For an accepted* $\mathsf{NullSequence}^{\uparrow}$ *packet*

$$Z = (D, T, W, M, E, H, C, P, N),$$

the downstream consumer surface consists of tolerance schedule exposure, $\mathsf{StreamName}^{\uparrow}$ *window routing, bound-row thresholding,* $\mathsf{Real}^{\uparrow}$ *seal consumption, and non-escape. Every consumer request*

must reach the displayed tolerance row T, observation window W, threshold row M, seal row E, transport rows H, continuation routes C, package row P, and local naming row N before it can be used by a later $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *equality argument.*

Theorem 380.17 (NullSequence root tolerance schedule exposure)**.** *For every accepted* $\mathsf{NullSequence}^{\uparrow}$ *packet $Z = (D, T, W, M, E, H, C, P, N)$, each downstream consumer tolerance request reaches the concrete rows T, W, M of Definition 380.16.*

Proof. Apply Definition 380.6. It identifies the route from a requested dyadic tolerance to the displayed observation window and threshold row.

Then apply Definition 380.12. The same rows remain visible after transport through H and readback through C, with P and N carrying package and local naming provenance.

Thus every downstream tolerance request is exposed as a finite T, W, M request before any seal consumption occurs. □

Theorem 380.18 (NullSequence root real-equality handoff)**.** *For every accepted* $\mathsf{NullSequence}^{\uparrow}$ *packet $Z = (D, T, W, M, E, H, C, P, N)$, the* $\mathsf{Real}^{\uparrow}$ *equality handoff reads the displayed null-difference packet through the seal row E and the finite tolerance-window rows D, T, W, M, H, C, P, N.*

Proof. Use Definition 380.7. It factors every real equality read through the null-difference packet and its displayed tolerance-window rows.

Use Definition 380.10. It identifies the accepted zero-tail evidence as the finite tolerance schedule and threshold route rather than as a host limit or quotient stream.

Therefore the real-equality handoff is constructive and finite-row based over $D, T, W, M, E, H, C, P, N$. □

Theorem 380.19 (NullSequence root downstream unblock package)**.** *The consumer surface of Definition 380.16, the tolerance exposure of Definition 380.17, the real-equality handoff of Definition 380.18, the non-escape boundary of Definition 380.8, and the obligation package of Definition 380.15 assemble the downstream* $\mathsf{NullSequence}^{\uparrow}$ *root-unblock package.*

Proof. The consumer surface names the rows $D, T, W, M, E, H, C, P, N$ and the five obligations that later regular-rational and real-equality chapters consume.

The tolerance exposure theorem supplies the T, W, M route for each tolerance request. The real-equality handoff theorem supplies the seal-facing route through E and the same finite tolerance-window packet.

Finally, the non-escape boundary and obligation closure package exclude host limits, quotient streams, trichotomy, choice, and real completeness. The assembled package is therefore a concrete downstream citation surface for finite null-sequence consumption. □

Theorem 380.20 (NullSequence standard bridge package)**.** *The public* $\mathsf{NullSequence}^{\uparrow}$ *packet has a standard bridge whose source rows are exactly the finite* BHist *difference stream, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance schedule, the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{CauchyModulus}^{\uparrow}$ *or* $\mathsf{RegularityModulus}^{\uparrow}$ *modulus row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal, the* hsame *and* Cont *transport rows, the* Pkg *provenance, and the* $\mathsf{NameCert}$ *row displayed in Definition 380.16.*

The bridge source is therefore the same finite zero-tail packet used by Definition 380.19; it does not add a Dedekind cut, quotient stream, host real equality, trichotomy, or real-completeness field.

Proof. Start from the public consumer surface. The rows $D, T, W, M, E, H, C, P, N$ already display the regular-rational difference stream, dyadic tolerance request, finite observation window, modulus bound, seal row, transport, continuation, package, and local naming data.

Use Definition 380.17 to expose the tolerance and window route, and use Definition 380.18 to expose the real-seal route through the same finite packet.

The source side of the bridge is then the downstream package of Definition 380.19. Its non-escape boundary is Definition 380.8, so the bridge reads exactly the listed rows and has no field for the excluded host or quotient data. □

Closure status for $\mathsf{NameCert}_{\mathsf{NullSequence}^\uparrow}$.

Constructive story: A $\mathsf{NullSequence}^\uparrow$ packet is generated from a $\mathsf{RegSeqRat}^\uparrow$ difference stream, a $\mathsf{DyadicRatCore}^\uparrow$ tolerance schedule, a $\mathsf{StreamName}^\uparrow$ observation window, a $\mathsf{CauchyModulus}^\uparrow$ or $\mathsf{RegularityModulus}^\uparrow$ bound row, a $\mathsf{Real}^\uparrow$ seal-consumption row, componentwise hsame transport, Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NullSequence}^\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: The mature paper surface binds the NameCert obligations, tolerance-window exactness, $\mathsf{Real}^\uparrow$ seal factorization, non-escape boundary, common-window refinement, downstream unblock package, and standard bridge package for the finite $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{CauchyModulus}^\uparrow$ or $\mathsf{RegularityModulus}^\uparrow$, $\mathsf{Real}^\uparrow$, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NullSequence}^\uparrow}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.NullSequenceUp.NullSequenceCarrier\_namecert\_obligation\_surface`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close Dedekind cuts, quotient streams, host real equality, trichotomy, or real completeness.

Upgrade path: No further paper-axis theory upgrade remains; bridge checking remains over the same standard bridge, regular-rational, dyadic, stream-window, modulus, and $\mathsf{Real}^\uparrow$ seal rows.

Chapter 381

A Concrete Naming Certificate for $\mathsf{RegularCauchySubsequence}^{\uparrow}$

The $\mathsf{RegularCauchySubsequence}^{\uparrow}$ interface records the constructive tail-subsequence and reindexing surface used by regular Cauchy names. Following Bishop and Bridges, *Constructive Analysis*, 1985, it treats a subsequence as certified monotone and cofinal unary reindexing data over finite regular Cauchy rows. It never selects an infinite subsequence by choice and never changes the real seal through quotient streams, host sequence equality, or ambient real completeness.

Its dependency list is $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$.

Definition 381.1 (RegularCauchySubsequence carrier)**.** *A* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *source packet is a finite* BHist *row*

$$G = (S, T, W, R, E, H, C, P, N)$$

with the following visible coordinates:

1. *S is a* $\mathsf{RegularCauchyName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source row;*
2. *T is a certified unary reindexing row whose displayed order ledger is monotone and cofinal on the inspected indices;*
3. *W records the selected finite* $\mathsf{StreamName}^{\uparrow}$ *windows before and after reindexing;*
4. *R records the transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius rows, point observations, and regularity rows;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary read by downstream real-name consumers;*
6. *H, C, P, and N are respectively the visible* hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequence}^{\uparrow}}$ *provenance rows.*

The classifier compares two packets only by the source row, the displayed monotone-cofinal reindexing ledger, common finite windows, transported dyadic-radius and regularity rows, the real-seal boundary, and the four provenance coordinates.

Lean4 (definition) `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceUp`

Theorem 381.2 (RegularCauchySubsequence NameCert obligations)**.** *Every accepted* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *packet with carrier Definition 381.1 carries the NameCert obligation rows for constructive tail-subsequence use:*

1. *the source row is an accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *packet;*

2. *the reindexing row is displayed as a monotone and cofinal unary ledger;*
3. *every chosen finite* $\mathsf{StreamName}^{\uparrow}$ *window is obtained by transporting an inspected source window along that ledger;*
4. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius and pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison rows are transported through the same window route;*
5. *the* hsame, Cont, Pkg, *and* NameCert *provenance exhausts the local certificate ledger.*

No obligation row contains quotient streams, selected subsequences by choice, host sequence equality, or real completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier namecert obligations`

Proof. Read the carrier coordinates. The source coordinate supplies the regular Cauchy or regular rational packet, and the T coordinate supplies a finite monotone-cofinal unary ledger rather than a host-level subsequence selector.

For a $\mathsf{RegSeqRat}^{\uparrow}$ source, use the cofinal-tail rows such as Definition 301.21 and Definition 301.28. These identify the displayed tail window, the transported dyadic endpoints, the radius rows, and the pointwise regular rational comparisons on a common cofinal refinement.

For a $\mathsf{RegularCauchyName}^{\uparrow}$ source, use Definition 371.3 and Definition 371.6. They force each consumer read through a finite $\mathsf{StreamName}^{\uparrow}$ window and keep the dyadic-radius, pointwise $\mathsf{RegSeqRat}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows visible.

The classifier of Definition 381.1 admits no additional comparison coordinate. Hence the five obligation rows are exhausted by the displayed source, reindexing, window, transported regularity, and provenance ledgers, with no quotient, choice-selected subsequence, host equality, or completeness datum. □

Theorem 381.3 (RegularCauchySubsequence Real seal boundary)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *packet is read only after the source packet, monotone-cofinal reindexing ledger, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius rows, and pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *comparisons have been displayed. Therefore tail-subsequence reindexing preserves the real-name seal surface as a finite BEDC ledger and does not export quotient-stream equality, a choice-selected subsequence, host sequence equality, or ambient real completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier real seal boundary`

Proof. Start from an accepted carrier. The E coordinate is placed after the source, reindexing, window, transported radius, regularity, and provenance rows, so the real-facing read is reached only along that displayed route.

Apply Definition 381.2. It supplies the monotone-cofinal reindexing row, the finite-window transport, and the transported dyadic-radius and pointwise regular rational comparisons needed by the seal.

The seal itself is then the same kind of boundary used by Definition 371.4 and the RegSeqRat cofinal-tail seal rows. Since the packet has no coordinate for a quotient stream, an externally selected infinite subsequence, host sequence equality, or real completeness, no such datum can be read from the $\mathsf{Real}^{\uparrow}$ boundary. □

Theorem 381.4 (RegularCauchySubsequence monotone-cofinal window transport)**.** *Let* $G = (S, T, W, R, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *packet, and let* u *be a unary*

index whose source window is displayed by S. If the reindexing row T records a monotone-cofinal route from u to the selected index $T(u)$, then the packet transports the selected finite StreamName$^{\uparrow}$ *window at $T(u)$ together with its* DyadicRatCore$^{\uparrow}$ *radius row and pointwise* RegSeqRat$^{\uparrow}$ *comparison rows through the same* BHist *route. No selected window may be read without that monotone-cofinal row and its transported radius and regularity evidence.*

Proof. Project the coordinates S, T, W, and R from the accepted carrier. The row T is the only coordinate that names a reindexing route, so a selected window must be reached through that displayed monotone-cofinal ledger.

Use the window clause of Definition 381.2. It identifies each selected StreamName$^{\uparrow}$ window as the transport of an inspected source window along the same unary route.

The radius and regularity rows are stored in R beside that transported window. Their DyadicRatCore$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ reads therefore move with the window row, and the packet has no coordinate from which an independent subsequence window could be selected. □

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier monotone cofinal window transport`

Theorem 381.5 (RegularCauchySubsequence tail-classifier stability)**.** *Let G and G' be accepted* RegularCauchySubsequence$^{\uparrow}$ *packets. Suppose their source rows, monotone-cofinal reindexing ledgers, selected finite windows, dyadic-radius rows, regularity rows,* Real$^{\uparrow}$ *seal rows, and* hsame*,* Cont*,* Pkg*, and* NameCert *provenance rows are transported componentwise by displayed* hsame *routes. Then the local* RegularCauchySubsequence$^{\uparrow}$ *classifier gives the same tail-subsequence comparison for G and G' on every shared finite window.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier tail classifier stability`

Proof. Unfold the classifier described in Definition 381.1. It compares only the source, reindexing ledger, common finite windows, transported radius and regularity rows, real-seal boundary, and visible provenance.

Move those coordinates componentwise along the displayed hsame routes. The Cont rows preserve the read paths for the selected windows, while the Pkg and local NameCert rows keep the same dependency certificates attached to the transported packet.

Apply Definition 381.4 on each shared window. The window, radius, and regularity data remain tied to the same monotone-cofinal route, so the classifier has no remaining coordinate on which the transported comparison could differ. □

Theorem 381.6 (RegularCauchySubsequence Real seal factorization)**.** *Every* Real$^{\uparrow}$ *seal read from an accepted* RegularCauchySubsequence$^{\uparrow}$ *packet factors through the source packet, the monotone-cofinal reindexing ledger, the selected finite* StreamName$^{\uparrow}$ *windows, the transported* DyadicRatCore$^{\uparrow}$ *radius rows, and the* RegSeqRat$^{\uparrow}$ *regularity route before it reaches the seal row. Thus the real-facing boundary is a finite tail-reindexing ledger rather than a quotient-stream, choice-selected subsequence, host sequence equality, or completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier real seal factorization`

Proof. Begin with the seal row E of the accepted packet. By Definition 381.3, a consumer reaches E only after the source, reindexing, window, radius, and regularity rows have been displayed.

Apply Definition 381.4. It fixes the route from the source window through the monotone-cofinal ledger to the selected finite window and carries the corresponding dyadic-radius and regularity rows with it.

The remaining read is the $\mathsf{Real}^{\uparrow}$ seal row itself. Since the carrier contains no quotient stream, selected infinite subsequence, host equality, or completeness coordinate, the displayed route exhausts the factorization of every public real-seal read. □

Theorem 381.7 (RegularCauchySubsequence RegSeqRat sibling consumption)**.** *Every accepted* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *packet consumes the* $\mathsf{RegSeqRat}^{\uparrow}$ *carrier and classifier surface of chapter 301 and the regular Cauchy name surface of chapter 371 before it exports its subsequence* $\mathsf{Real}^{\uparrow}$ *seal. The subsequence packet may transport finite windows and tail classifiers, but it cannot present a direct* $\mathsf{Real}^{\uparrow}$ *seal that bypasses the sibling* $\mathsf{RegSeqRat}^{\uparrow}$ *packet or the displayed* $\mathsf{RegularCauchyName}^{\uparrow}$ *source row.*

Proof. Start with an accepted packet $G = (S, T, W, R, E, H, C, P, N)$. The source row S is either a $\mathsf{RegularCauchyName}^{\uparrow}$ row or a $\mathsf{RegSeqRat}^{\uparrow}$ row, and the regularity entries in R are the pointwise $\mathsf{RegSeqRat}^{\uparrow}$ comparison rows attached to the selected finite windows.

Apply the monotone-cofinal window transport theorem. Each selected subsequence window is read through the same reindexing ledger T, and the transported dyadic-radius and regularity rows move with that window rather than being selected independently.

Apply tail-classifier stability. Componentwise hsame transport preserves the source row, transported windows, radius rows, regularity rows, seal row, and provenance rows, so a classifier-facing consumer cannot replace the sibling $\mathsf{RegSeqRat}^{\uparrow}$ surface by an unrecorded real seal.

Finally apply the real seal factorization theorem. The public $\mathsf{Real}^{\uparrow}$ seal is reached only after the source surface, monotone-cofinal ledger, transported finite windows, dyadic-radius rows, and regularity route have been displayed. Thus the sibling $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{RegularCauchyName}^{\uparrow}$ surfaces are consumed before the seal is exported, and the carrier has no coordinate for a bypassing direct $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 381.8 (RegularCauchySubsequence scoped kernel interface)**.** *For every accepted* RegularCauchySubseque *packet* $G = (S, T, W, R, E, H, C, P, N)$*, the complete carrier surface exposed to downstream BEDC consumers is exactly the source row* S*, the monotone-cofinal reindexing ledger* T*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius rows in* R*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity route in* R*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the visible* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *provenance rows* H*,* C*,* P*, and* N*. No consumer of the packet can obtain an additional L10 kernel dependency, a quotient-stream representative, a choice-selected subsequence, host sequence equality, or ambient real completeness from the carrier.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier scoped kernel interface`

Proof. Project the accepted carrier of Definition 381.1. Its coordinates list the source, reindexing ledger, window ledger, transported dyadic and regularity rows, seal row, and provenance rows, and the classifier compares no further coordinate.

Apply the NameCert obligation rows of Definition 381.2. They keep the source packet, monotone-cofinal ledger, window transport, dyadic-radius rows, pointwise regular rational comparisons, and provenance ledger visible in the same finite packet.

Use Definition 381.4 and Definition 381.5. These keep each selected window and its transported radius and regularity evidence tied to the displayed reindexing row under hsame and Cont transport.

Finally apply the seal factorization of Definition 381.6. The public real-facing read reaches E only through those displayed rows, so the listed coordinates are the scoped kernel interface and no unlisted dependency can be exported. □

Theorem 381.9 (RegularCauchySubsequence public export)**.** *The carrier of Definition 381.1, the NameCert obligations of Definition 381.2, the real seal boundary of Definition 381.3, the monotone-cofinal window transport of Definition 381.4, the tail-classifier stability of Definition 381.5, the real seal factorization of Definition 381.6, and the scoped kernel interface of Definition 381.8 assemble the public* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *export consumed by* $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{Rat}^{\uparrow}$.

The exported object is finite BHist *reindexing data: a source row, a displayed monotone-cofinal unary ledger, selected finite stream windows, transported dyadic-radius and regularity rows, a real-seal boundary, and visible* hsame, Cont, Pkg, *and* NameCert *provenance. It is not a choice-selected infinite subsequence and not host sequence equality.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier public export`

Proof. Project the accepted carrier

$$G = (S, T, W, R, E, H, C, P, N).$$

The carrier and obligation theorems identify the source, monotone-cofinal reindexing ledger, finite windows, transported radius and regularity rows, seal row, and provenance rows.

The boundary, window-transport, classifier-stability, and seal-factorization theorems show that every downstream read travels through those displayed coordinates. The scoped kernel interface then records that no additional dependency is available to a consumer.

Therefore the public export is precisely the finite BHist reindexing surface consumed by the named regular Cauchy, regular rational, stream, dyadic, real, and rational chapters. Since the carrier has no coordinate for an externally selected infinite subsequence or host sequence equality, those objects are not exported. □

Theorem 381.10 (RegularCauchySubsequence standard bridge source)**.** *The public export of Definition 381.9 supplies the BEDC source side of a standard regular-Cauchy subsequence interface. Its bridge source is exactly the finite packet*

$$G = (S, T, W, R, E, H, C, P, N)$$

whose rows are the $\mathsf{RegularCauchyName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source, the monotone-cofinal unary reindexing ledger, the transported* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius rows, the pointwise* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity rows, the* $\mathsf{Real}^{\uparrow}$ *seal boundary, and the visible* hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequence}^{\uparrow}}$ *provenance. The standard readback is therefore a regular-Cauchy subsequence presentation whose subsequence map is read only from T, whose observations are read only from W and R, and whose real-name boundary is read only from E after those rows have been displayed.*

Proof. Start with the public export. It is assembled from the carrier, obligation, window-transport, classifier-stability, seal-factorization, and scoped-interface rows, so every field of the standard subsequence presentation has a named BEDC source.

The forward bridge read sends the finite packet to the standard presentation by reading the reindexing map from the displayed monotone-cofinal ledger T, the selected observations from W,

and the radius and regularity evidence from R. The real-facing endpoint is then read from E, after the source and transported window route have already been exposed.

For the reverse read, admit only a standard presentation whose source, reindexing, window, radius, regularity, seal, and provenance fields are these same displayed rows. Repacking those rows gives the original carrier packet G, and the public export theorem identifies it as the BEDC source side of the bridge. □

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier standard bridge source`

Theorem 381.11 (RegularCauchySubsequence bridge non-escape)**.** *The bridge source of Definition 381.10 exports no quotient stream, choice-selected infinite subsequence, host sequence equality, host real equality, or ambient real completeness principle. Any standard regular-Cauchy subsequence presentation admitted by the bridge must factor through the same finite* BHist *packet, the same componentwise* hsame *transport, and the same* $\mathsf{Real}^{\uparrow}$ *seal boundary used by the public export.*

Proof. The carrier contains no coordinate for a quotient stream, host sequence equality, host real equality, or completion object. Its only subsequence datum is the displayed finite monotone-cofinal ledger T.

Apply Definition 381.4. It forces every selected finite window to be transported along T together with its dyadic-radius and regularity rows, so a standard presentation cannot read an independently chosen infinite subsequence.

Apply Definition 381.5 and Definition 381.6. Classifier movement is componentwise hsame on the displayed rows, and every real-facing read factors through the same finite route before reaching E. Thus the bridge has no remaining field through which the excluded host or quotient data could enter. □

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier bridge non escape`

Theorem 381.12 (RegularCauchySubsequence bridged export)**.** *The carrier of Definition 381.1, the public export of Definition 381.9, the monotone-cofinal window transport of Definition 381.4, the tail-classifier stability of Definition 381.5, the real seal factorization of Definition 381.6, the standard bridge source of Definition 381.10, and the bridge non-escape result of Definition 381.11 assemble a bridged* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *export to the standard regular-Cauchy subsequence interface. The bridge preserves exactly the displayed finite source, reindexing, window, radius, regularity, seal, classifier, continuation, package, and naming rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier bridged export`

Proof. First assemble the BEDC side. The carrier and public export identify the complete finite packet, while the window transport theorem ties every selected observation to the monotone-cofinal reindexing ledger.

Next preserve the classifier and seal fields. Tail-classifier stability gives componentwise hsame transport for the source, reindexing, window, radius, regularity, seal, and provenance rows. Seal factorization keeps the real-facing endpoint behind that same finite route.

Finally apply the standard bridge source and bridge non-escape theorems. The forward and reverse reads use only the listed rows, and the excluded quotient, choice, host-equality, and completeness data have no bridge field. Therefore the public finite tail-subsequence export is the bridged regular-Cauchy subsequence interface at the paper level. □

Theorem 381.13 (RegularCauchySubsequence mature consumer example)**.** *A* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegularCauchyName}^{\uparrow}$ *consumer using a monotone-cofinal subsequence factors through the displayed* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *finite-window interface: the source row, monotone-cofinal reindexing ledger, finite observation windows, dyadic-radius rows, regularity rows, tail-classifier transport, real-seal row, standard bridge source,* hsame *witnesses,* Cont *routes,* Pkg *provenance, and* NameCert *row. The consumer never selects a quotient representative, a host subsequence function, a host stream equality, or a host real equality.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier mature consumer route`

Proof. Begin with the consumer's requested finite window. The carrier and Definition 381.9 expose the source, reindexing ledger, selected windows, radius rows, regularity rows, seal row, transport rows, routes, provenance, and local certificate.

Apply Definition 381.4. It routes the consumer window through the displayed monotone-cofinal ledger and keeps the requested observations attached to the same finite subsequence packet.

Next apply Definition 381.5 and Definition 381.6. The classifier-facing rows move through hsame and Cont, and the real-facing read reaches $\mathsf{Real}^{\uparrow}$ only through the stored seal row.

Finally use Definition 381.12. The bridge source and non-escape rows admit exactly the finite-window presentation already displayed, so a $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegularCauchyName}^{\uparrow}$ consumer factors through the packet without selecting quotient representatives or host-level equality data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySubsequence}^{\uparrow}$ packet is generated from a regular Cauchy or regular rational source, a displayed monotone-cofinal unary reindexing ledger, selected finite stream windows, transported dyadic-radius and regularity rows, a real-seal boundary, and visible provenance.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySubsequence}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 381.13 records the mature consumer surface over the bridged export, carrier, public finite tail-subsequence export, monotone-cofinal finite-window transport, tail-classifier stability, $\mathsf{RegSeqRat}^{\uparrow}$ sibling consumption, $\mathsf{Real}^{\uparrow}$ seal factorization, standard bridge source, and bridge non-escape rows over $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySubsequence}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.RegularCauchySubsequenceUp.RegularCauchySubsequenceCarrier\_public\_export`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close real completeness, quotient stream equality, host sequence equality, host real equality, selected infinite subsequences, uniqueness of limits, or bridge checking.

Upgrade path: No further paper-side theory grade is required for this finite-window consumer surface.

Chapter 382

A Concrete Naming Certificate for $\mathsf{DyadicSpline}^{\uparrow}$

The $\mathsf{DyadicSpline}^{\uparrow}$ interface names finite dyadic piecewise-linear approximation data as a BEDC naming certificate. Following de Boor, *A Practical Guide to Splines*, and Schumaker, *Spline Functions*, the standard finite spline reading is a knot row, coefficient rows, and a segment ledger. BEDC records only those finite displayed rows and the real-name boundary through which downstream approximation consumers read them; it does not add host functions, quotient reals, choice-selected limits, or an ambient vector space of splines.

Its dependency anchors are $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{DyadicApproximation}^{\uparrow}$. The finite spline carrier consumes the dyadic mesh carrier of chapter 358 for knot and adjacency rows, and the dyadic rational core of chapter 291 for endpoint coefficients.

Definition 382.1 (DyadicSpline finite carrier)**.** *A* $\mathsf{DyadicSpline}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, A, L, I, Q, R, H, C, P, N)$$

with the following visible rows:

1. *K is a* $\mathsf{DyadicMesh}^{\uparrow}$ *knot row, listing a finite ordered dyadic mesh and the cell adjacency data inspected by the spline reader;*
2. *A is a finite family of* $\mathsf{DyadicRatCore}^{\uparrow}$ *coefficient rows, with two endpoint coefficient reads for each retained segment;*
3. *L is the piecewise-linear segment ledger, pairing each adjacent knot cell with its two coefficient rows and its displayed affine interpolation route;*
4. *I is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger through which every segment domain and endpoint order is read;*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained by evaluating a requested finite window against the segment ledger and coefficient rows;*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row through which downstream real-name consumers read the same finite observation windows;*
7. *H stores componentwise* hsame *transports for knots, coefficients, segment ledgers, interval cells, rational readbacks, real seals, provenance, and the local naming row;*

8. *C stores the displayed* Cont *routes for mesh refinement, segment readback, interval-cell inspection,* $\mathsf{RegSeqRat}^{\uparrow}$ *consumption, and* $\mathsf{Real}^{\uparrow}$ *sealing;*
9. *P is the* Pkg *provenance row naming* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicApproximation}^{\uparrow}$, *and the consumed local source certificates;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicSpline}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only after transporting them to a common displayed dyadic refinement, comparing the refined knot rows, comparing the transported coefficient rows through $\mathsf{DyadicRatCore}^{\uparrow}$, *comparing cell boundaries through* $\mathsf{RationalInterval}^{\uparrow}$, *and then reading the same* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *boundary rows. The carrier has no coordinate for a host function, a completed real graph, a quotient real, an infinite knot sequence, or a choice-selected limit.*

Lean4 (definition) `BEDC.Derived.DyadicSplineUp.TasteGate.DyadicSplineUp`
Lean4 ✓ `BEDC.Derived.DyadicSplineUp.TasteGate.DyadicSplineTasteGate single carrier alignment`

Theorem 382.2 (DyadicSpline NameCert obligation surface)**.** *The seed* $\mathsf{NameCert}_{\mathsf{DyadicSpline}^{\uparrow}}$ *sketch has five rows:*

1. *carrier inhabitation: finite knot and coefficient packets inhabit the carrier of Definition 382.1;*
2. *classifier transport: accepted carriers are compared only after displayed transport of knots, coefficients, segment ledgers, rational cells,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal rows;*
3. *mesh-refinement stability: displayed dyadic refinement replaces each segment by a finite family of subsegments while preserving transported endpoint coefficients and interval-cell boundaries;*
4. *boundary non-escape: every rational readback and real-name seal factors through the finite segment ledger,* $\mathsf{RationalInterval}^{\uparrow}$ *cell row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{Real}^{\uparrow}$ *seal row;*
5. *standard reading: the public piecewise-linear reading is exactly the finite knot row, coefficient rows, segment ledger, cell ledger, readback row, seal row, transport rows, continuation routes, package provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.DyadicSplineUp.DyadicSplineFiniteCarrier namecert obligation surface`

Proof. Carrier inhabitation is obtained by choosing a finite $\mathsf{DyadicMesh}^{\uparrow}$ knot row and attaching two $\mathsf{DyadicRatCore}^{\uparrow}$ coefficient reads to each adjacent knot cell. The segment ledger records the displayed affine interpolation route, and the remaining carrier coordinates are the interval, readback, seal, transport, continuation, provenance, and local name rows.

The classifier row is componentwise after common displayed refinement. Knot rows are compared through $\mathsf{DyadicMesh}^{\uparrow}$, coefficient rows through $\mathsf{DyadicRatCore}^{\uparrow}$, cell boundaries through $\mathsf{RationalInterval}^{\uparrow}$, and consumer-facing observations through the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows.

The stability, non-escape, and standard-reading rows are the three public obligations proved by the following theorems. Together they list every coordinate a downstream consumer can inspect, so the seed certificate surface is finite and contains no host function or completed real graph. □

Theorem 382.3 (DyadicSpline mesh refinement handoff)**.** *Let $S = (K, A, L, I, Q, R, H, C, P, N)$ be an accepted* $\mathsf{DyadicSpline}^{\uparrow}$ *carrier. If K' is obtained from K by displayed* $\mathsf{DyadicMesh}^{\uparrow}$ *refinement and each old segment in L is replaced by the finite list of subsegments induced by the refined knot row, with endpoint coefficient rows transported through the same* hsame *witnesses, then the refined packet*

$$S' = (K', A', L', I', Q', R', H', C', P, N)$$

is again an accepted DyadicSpline$^{\uparrow}$ *carrier. Its* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *consumer rows factor through the same finite piecewise-linear reading, now displayed on the refined mesh.*

Lean4 ✓ `BEDC.Derived.DyadicSplineUp.DyadicSplinePacket mesh refinement handoff`

Proof. Project the carrier of Definition 382.1. The knot row, coefficient rows, and segment ledger are finite, so a displayed mesh refinement subdivides each old segment into a finite family of adjacent subsegments.

Transport the endpoint coefficient rows along H. The refined segment ledger L' uses the transported endpoint rows and the same affine readback route restricted to each refined cell, while I' records the corresponding RationalInterval$^{\uparrow}$ cell boundaries.

Route the rational readback row Q' and real seal row R' through the refined continuation routes in C'. Repacking these rows gives exactly the carrier coordinates, so the refined packet is accepted and exposes the same piecewise-linear data on the finer displayed mesh. □

Theorem 382.4 (DyadicSpline endpoint mesh transport stability)**.** *Let $S = (K, A, L, I, Q, R, H, C, P, N)$ be an accepted* DyadicSpline$^{\uparrow}$ *packet, and let K' be a displayed refinement of the mesh row K. When the endpoint coefficient rows in A, the rational cell rows in I, and the segment ledger rows in L are transported componentwise along the displayed* hsame *witnesses in H, the refined rows assemble with the transported* RegSeqRat$^{\uparrow}$ *readbacks and* Real$^{\uparrow}$ *seals into one classifier-facing packet*

$$S' = (K', A', L', I', Q', R', H', C', P, N).$$

The accepted comparison between S and S' is exhausted by the displayed knot, endpoint, cell, ledger, readback, and seal transports together with the Cont *routes for refined-cell inspection. No host function, graph, quotient real, infinite knot sequence, or selected limit is introduced by the handoff.*

Proof. Project the carrier of Definition 382.1. The knot row, endpoint coefficient family, segment ledger, rational cell ledger, readback row, seal row, transport row, continuation row, provenance row, and local name row are all explicit coordinates of S.

Use the displayed hsame entries in H to move the knot row to K' and to move each endpoint coefficient row to the refined endpoint ledger. The rational cell rows move by the same componentwise transport, and each refined segment in L' records the transported endpoints and the corresponding cell row.

Route every refined rational observation through the displayed Cont entries in C. The RegSeqRat$^{\uparrow}$ readback row Q' and Real$^{\uparrow}$ seal row R' are therefore read only after the refined segment and rational cell rows have been selected.

Repacking these transported coordinates gives the packet S' named in the statement. Since every inspected coordinate is a carrier projection or a displayed continuation route, there is no remaining place for a host function, graph, quotient real, infinite knot sequence, or selected limit to enter the classifier. □

Theorem 382.5 (DyadicSpline RegSeqRat Real boundary)**.** *For every accepted* DyadicSpline$^{\uparrow}$ *carrier $S = (K, A, L, I, Q, R, H, C, P, N)$ and every finite consumer window, the* RegSeqRat$^{\uparrow}$ *readback and* Real$^{\uparrow}$ *seal are reached only by first selecting a displayed segment from L, reading its* RationalInterval$^{\uparrow}$ *cell from I, reading its endpoint coefficients from A, and routing the resulting finite rational observation through Q and R.*

The boundary exports finite rational observations and real-name seal rows only. It does not export quotient stream equality, an ambient real-valued function, a host graph, uniform convergence of a sequence of splines, or a choice-selected limit.

Lean4 ✓ `BEDC.Derived.DyadicSplineUp.DyadicSplinePacket regseqrat real boundary`

Proof. Start with the requested finite window. The carrier selects a segment through the knot row K and the segment ledger L; no other coordinate can choose a domain cell.

Read the selected cell through I and the two endpoint coefficient rows through A. The displayed affine interpolation route in L turns these finite dyadic rows into a rational observation at the requested window.

The observation is then routed through the $\mathsf{RegSeqRat}^{\uparrow}$ row Q and sealed through the $\mathsf{Real}^{\uparrow}$ row R. Since every step is a projection from the finite carrier and its displayed continuation routes, quotient stream equality, host functions, graphs, uniform convergence, and choice-selected limits remain outside the exported boundary. □

Theorem 382.6 (DyadicSpline standard piecewise-linear reading)**.** *The standard finite piecewise-linear reading of an accepted* $\mathsf{DyadicSpline}^{\uparrow}$ *carrier is exactly the tuple consisting of the* $\mathsf{DyadicMesh}^{\uparrow}$ *knot row, finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *coefficient rows, segment ledger,* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

This reading is stable under the mesh-refinement handoff of Definition 382.3 and has the non-escape boundary of Definition 382.5. It is the whole public surface exported to $\mathsf{DyadicApproximation}^{\uparrow}$ *consumers.*

Proof. Project the carrier of Definition 382.1. Its rows are precisely the knot row, coefficient rows, segment ledger, cell ledger, rational readback, real seal, transport, continuation, provenance, and local name coordinates.

Apply Definition 382.3. Refinement changes the displayed mesh and segment ledger by finite subdivision, while preserving the transported endpoint coefficients and consumer-facing readback route.

Apply Definition 382.5. The $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ boundary rows are reached only through the finite segment and cell ledgers, so no extra analytic object can be exported.

The downstream $\mathsf{DyadicApproximation}^{\uparrow}$ consumer therefore receives exactly the finite piecewise-linear tuple named in the statement. There is no remaining carrier coordinate from which a host function, completed real graph, quotient real, or choice-selected limit could be read. □

Theorem 382.7 (DyadicApproximation DyadicSpline consumer route)**.** *Every* $\mathsf{DyadicApproximation}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicSpline}^{\uparrow}$ *packet must read the packet through the* $\mathsf{DyadicApproximation}^{\uparrow}$ *chapter surface of chapter 335 together with the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows of Definition 382.1.*

The consumer route is exactly the finite piecewise-linear tuple of Definition 382.6, transported through the mesh-refinement handoff of Definition 382.3 and sealed by the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *boundary of Definition 382.5. It exports no host spline function, quotient real graph, selected limit, ambient completion, infinite knot row, or independent analytic approximation object.*

Proof. Start with an accepted packet $S = (K, A, L, I, Q, R, H, C, P, N)$. The standard reading theorem identifies the public surface of S with the displayed mesh row, endpoint coefficient rows, segment ledger, rational cell ledger, readback row, seal row, transports, continuations, provenance, and local name row.

A $\mathsf{DyadicApproximation}^{\uparrow}$ consumer reaches that surface through chapter 335. Its dyadic observations therefore read the $\mathsf{DyadicRatCore}^{\uparrow}$ coefficients along the $\mathsf{DyadicMesh}^{\uparrow}$ cells, inspect the

$\mathsf{RationalInterval}^{\uparrow}$ cell ledger, and pass the resulting finite observation through the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows.

If the consumer asks for a finer displayed window, apply the mesh-refinement handoff. Refinement replaces the mesh and segment ledger by finite subdivided rows while keeping the transported endpoint coefficients, rational cell boundaries, and consumer-facing readback route inside the same carrier format.

Finally apply the RegSeqRat/Real boundary theorem. Since the route to the seal factors through the finite segment and cell ledgers before reaching Q and R, there is no coordinate from which the consumer can read a host function, quotient real graph, selected limit, ambient completion, infinite knot row, or separate analytic approximation object. □

Theorem 382.8 (DyadicSpline common refinement segment exhaustion)**.** *Let $S = (K, A, L, I, Q, R, H, C, P, N)$ and $S' = (K', A', L', I', Q', R', H', C', P', N')$ be accepted* $\mathsf{DyadicSpline}^{\uparrow}$ *packets compared by classifier transport. Then their comparison refines to one displayed dyadic mesh and one finite segment ledger. Every compared endpoint coefficient, rational cell,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal read factors through that common mesh and ledger.*

The exhaustion exports only the shared $\mathsf{DyadicMesh}^{\uparrow}$ *row, finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint coefficients,* $\mathsf{RationalInterval}^{\uparrow}$ *cell rows, segment ledger,* hsame*,* Cont*,* Pkg*, and* NameCert *data. It does not read a host function, completed graph, quotient real, infinite knot sequence, or selected limit.*

Proof. Project both accepted packets through Definition 382.1. The classifier compares knot rows, endpoint coefficient rows, rational cell rows, segment ledgers, readback rows, seal rows, and provenance rows only after displayed transport.

Apply Definition 382.3 to refine both mesh rows to a common displayed dyadic mesh. Then apply Definition 382.4 to transport the endpoint coefficients, interval cells, and segment ledgers onto that common mesh.

Finally use Definition 382.6. Once the packets have been transported to the same mesh, the public read is exactly the finite mesh, endpoint, cell, ledger, readback, seal, transport, continuation, provenance, and local naming tuple, so no host-level reading remains. □

Theorem 382.9 (DyadicSpline zero segment carrier)**.** *The constant zero endpoint coefficient packet inhabits the* $\mathsf{DyadicSpline}^{\uparrow}$ *carrier. Its segment ledger has the displayed zero* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows on every retained cell, its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is the zero readback route, and its* $\mathsf{Real}^{\uparrow}$ *seal factors through that same zero readback.*

This carrier is a finite BEDC packet over $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *only. It does not add a host zero function, completed graph, quotient real, infinite mesh, or selected limit.*

Proof. Start with any displayed finite $\mathsf{DyadicMesh}^{\uparrow}$ row and choose the zero $\mathsf{DyadicRatCore}^{\uparrow}$ coefficient row at both endpoints of each retained segment. The definition of Definition 382.1 then supplies the finite segment ledger, the rational cell ledger, transport rows, continuation rows, provenance, and local name row.

Read a consumer window through the segment ledger. Because both endpoint coefficient rows on every segment are the displayed zero rows, the resulting finite rational observation is the zero $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Apply Definition 382.5 to route the $\mathsf{Real}^{\uparrow}$ seal through that readback, and apply Definition 382.6 to identify the public packet with the finite zero mesh data. No separate host zero function or completed graph is introduced. □

Theorem 382.10 (DyadicSpline Real seal mesh factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal consumer read of an accepted* $\mathsf{DyadicSpline}^{\uparrow}$ *packet factors through the displayed mesh, cell ledger, endpoint coefficients,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* hsame, Cont, Pkg, *and* NameCert *rows. The consumer reaches the seal only after selecting a finite mesh cell, reading its endpoint coefficients, and passing the resulting rational observation through the regular-rational readback.*

The factorization exports no host function semantics, completed real graph, quotient real, uniform convergence claim, infinite knot sequence, or choice-selected limit.

Proof. Project the accepted packet through Definition 382.1. The only seal-facing coordinates are the mesh row, endpoint coefficient rows, segment ledger, rational cell ledger, readback row, real seal row, transports, continuations, provenance, and local naming row.

Apply Definition 382.5. A real-name consumer first chooses a displayed segment, reads its $\mathsf{RationalInterval}^{\uparrow}$ cell and endpoint coefficients, and then routes the finite rational observation through the $\mathsf{RegSeqRat}^{\uparrow}$ row before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Apply Definition 382.8 when the consumer compares transported packets, and apply Definition 382.6 to identify the exported surface. Thus every seal read factors through the finite mesh package, with no ambient analytic object available to the consumer. □

Theorem 382.11 (DyadicSpline refinement classifier transport)**.** *Let* $S = (K, A, L, I, Q, R, H, C, P, N)$ *and* $S' = (K', A', L', I', Q', R', H', C', P', N')$ *be accepted* $\mathsf{DyadicSpline}^{\uparrow}$ *packets whose classifier comparison is displayed on a common dyadic refinement. Then the classifier transports the knot rows, endpoint coefficient rows, segment ledgers, rational cell rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal rows through that same refinement.*

The transported comparison is exhausted by the $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *coordinates of the two finite carriers. It has no coordinate for a host spline function, completed graph, quotient real, infinite knot sequence, or selected limit.*

Proof. Project both packets through Definition 382.1. The only classifier-facing rows are the displayed knot, endpoint, segment, cell, readback, seal, transport, continuation, provenance, and local naming coordinates.

Apply Definition 382.8. The comparison first moves both carriers to one displayed dyadic mesh and one finite segment ledger, so every later read is made on that common finite row.

Apply Definition 382.4. Endpoint coefficients, cell rows, segment entries, rational readbacks, and real seals move componentwise along the stored hsame witnesses and displayed Cont routes.

The standard reading theorem then identifies the transported packet with the same finite piecewise-linear surface. Since each inspected item is a carrier projection or displayed continuation route, no host-level analytic object remains in the classifier. □

Theorem 382.12 (DyadicSpline Real seal stability)**.** *For every accepted* $\mathsf{DyadicSpline}^{\uparrow}$ *packet and every displayed dyadic refinement accepted by Definition 382.3, each* $\mathsf{Real}^{\uparrow}$ *seal read after refinement is still routed through a selected segment row, its rational cell row, its transported endpoint coefficient rows, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row.*

Thus refinement preserves the real-seal non-escape boundary: the seal read remains inside the finite $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *packet.*

Proof. Start with the refined packet supplied by Definition 382.3. Its refined mesh, endpoint rows, segment ledger, cell ledger, readback row, seal row, transports, continuations, provenance, and local name are again the coordinates of Definition 382.1.

Use Definition 382.10. A seal consumer first selects a finite mesh cell, reads its transported endpoint coefficients, and then reaches the $\mathsf{RegSeqRat}^{\uparrow}$ row before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

The boundary theorem Definition 382.5 excludes every route outside those finite rows. Therefore mesh refinement changes the displayed carrier rows but does not open a path to host functions, quotient reals, completed graphs, infinite meshes, or selected limits. □

Theorem 382.13 (DyadicSpline obligation closure package)**.** *The finite carrier of Definition 382.1, the NameCert obligation surface of Definition 382.2, the mesh-refinement handoff, the endpoint transport stability theorem, the rational-real boundary theorem, the standard piecewise-linear reading, the refinement classifier transport theorem, and the real-seal stability theorem assemble the* $\mathsf{DyadicSpline}^{\uparrow}$ *obligation package.*

The package supplies carrier habitation, classifier transport, mesh-refinement stability, readback boundary, real-seal stability, and the standard finite piecewise-linear reading for $\mathsf{DyadicSpline}^{\uparrow}$ *consumers. It asserts no host-function semantics, quotient real, completed spline graph, infinite knot sequence, uniform convergence theorem, or choice-selected limit.*

Proof. Carrier habitation and the row inventory are supplied by Definition 382.1 and Definition 382.2. They expose the finite mesh, endpoint, segment, cell, readback, seal, transport, continuation, package, and local name rows.

Mesh-refinement stability is Definition 382.3, with endpoint and cell transport supplied by Definition 382.4. The classifier transport theorem places the compared packets on the same displayed refinement before any consumer read.

The readback and seal boundaries are supplied by Definition 382.5 and Definition 382.12. Finally, Definition 382.6 identifies the public reading with exactly those rows, so the assembled obligation package has no remaining analytic escape coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicSpline}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicSpline}^{\uparrow}$ packet is generated by a finite $\mathsf{DyadicMesh}^{\uparrow}$ knot row, finite $\mathsf{DyadicRatCore}^{\uparrow}$ coefficient rows, a piecewise-linear segment ledger, a $\mathsf{RationalInterval}^{\uparrow}$ cell ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicSpline}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 382.6, Definition 382.13, and the refinement, boundary, classifier-transport, and $\mathsf{DyadicApproximation}^{\uparrow}$ consumer routes export the mature finite piecewise-linear packet over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicSpline}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.DyadicSplineUp.DyadicSplineFiniteCarrier\_namecert\_obligation\_surface`

Bridge status: none

Origin: human

Not claimed: This chapter does not close host-function semantics, quotient reals, infinite knot sequences, uniform convergence of spline families, choice-selected limits, or bridge checking.

Upgrade path: Bridge-checked verification remains the next step beyond the mature finite spline refinement, boundary, classifier-transport, and approximation-consumer package.

Chapter 383

A Concrete Naming Certificate for $\mathsf{OptionalStopping}^{\uparrow}$

The $\mathsf{OptionalStopping}^{\uparrow}$ interface names the bounded finite-window form of Doob optional stopping. It records a stopped-process packet over $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, and $\mathsf{StoppingTime}^{\uparrow}$ in which the stopping index is visibly bounded, the stopped value is read from a finite filtration window, and every integrability and provenance row is carried as BEDC data. The chapter does not invoke measure completion, countable choice, unbounded stopping, or an ambient almost-sure quotient.

The bounded stopped-process packet consumes the martingale filtration and conditional-expectation rows of chapter 190 together with the probability, random-variable, and finite stopping-decision surfaces already named in the carrier; $\mathsf{OptionalStopping}^{\uparrow}$ only packages the finite stopped-value ledger over those sibling rows.

Definition 383.1 (OptionalStopping finite carrier)**.** *An* $\mathsf{OptionalStopping}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (\Omega, X, T, b, V, F, I, H, C, P, N)$$

with the following visible rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *row naming the finite probability context used by the packet;*
2. X *is the* $\mathsf{RandomVar}^{\uparrow}$ *stopped-process family, indexed only over the displayed finite time window;*
3. T *is the* $\mathsf{StoppingTime}^{\uparrow}$ *row whose decision at each inspected time is read from the corresponding filtration window;*
4. b *is the bounded stopping index row, giving the finite terminal window in which the stopping decision must occur;*
5. V *is the stopped value row* X_T *read by the displayed branch that first satisfies the stopping row before* b*;*
6. F *is the finite filtration-window ledger carrying the random-variable reads, stopping decisions, and martingale conditioning rows;*
7. I *is the integrability and provenance row required for the bounded stopped process and each inspected martingale value;*
8. H *stores the displayed* hsame *transports for probability rows, random-variable rows, stopping-time decisions, stopped values, filtration ledgers, and integrability rows;*

9. *C stores the* Cont *routes by which consumers read the bounded stopping index, the stopped value, and the martingale-window handoff;*
10. *P is the* Pkg *provenance row naming* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{StoppingTime}^{\uparrow}$, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{OptionalStopping}^{\uparrow}}$ *registration row.*

The local classifier compares two carriers only through the transported bounded index, stopped value row, filtration-window ledger, integrability provenance, package row, and local certificate row. It contains no unbounded stopping argument and no quotient-level event equality.

Theorem 383.2 (OptionalStopping NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{OptionalStopping}^{\uparrow}}$ *surface consists of five obligations:*

1. *carrier: formation of the finite* BHist *packet of Definition 383.1;*
2. *classifier: componentwise comparison of the bounded index, stopped value, filtration-window ledger, integrability row, displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row;*
3. *stopping-time stability: each transported stopping decision is read from the filtration window available at that finite time and remains bounded by b;*
4. *martingale-window handoff: the bounded finite-window Doob optional-stopping read factors through the displayed* $\mathsf{Martingale}^{\uparrow}$ *rows, the stopped value row V, and the filtration ledger F;*
5. *ledger exactness: every probability, random-variable, stopping-time, martingale, integrability, transport, continuation, package, and certificate row used by the stopped process appears in the displayed carrier.*

Lean4 ✓ `BEDC.Derived.OptionalStoppingUp.OptionalStoppingCarrier namecert obligations`

Proof. Carrier formation is the packet assembly of Definition 383.1. The bounded index, stopped value, filtration ledger, integrability row, transports, continuations, package provenance, and local certificate are all visible coordinates.

Classifier stability is componentwise. Transport the probability and random-variable rows first, then transport each finite stopping decision along its filtration-window route, and finally transport the stopped value and integrability rows attached to that selected branch.

For stopping-time stability, inspect the finite ledger F. Each decision row of T is recorded at the corresponding finite time and is read only from the filtration data available there; the bound b records that the selected branch must occur inside the displayed window.

The martingale-window handoff is the bounded finite-window form of Doob optional stopping. The stopped value row V is read from the first displayed stopping branch, and the relevant $\mathsf{Martingale}^{\uparrow}$ conditioning rows are exactly the rows stored in F and I.

Ledger exactness follows by projecting O. No consumer read can reach a probability, random variable, stopping-time decision, martingale conditioning row, integrability witness, transport, continuation, package, or local certificate outside the displayed coordinates. □

Theorem 383.3 (OptionalStopping bounded stopped-value readback)**.** *Let $O = (\Omega, X, T, b, V, F, I, H, C, P, N)$ be an accepted* $\mathsf{OptionalStopping}^{\uparrow}$ *carrier. The stopped value row V is read from the first displayed stopping branch of T that occurs before the bound b, together with the corresponding finite process row of X and filtration-window row of F. No stopped value may be read from an unbounded stopping branch or from a branch absent from the displayed finite ledger.*

Proof. Project the stopping row T, the bound b, the stopped value V, and the filtration ledger F from the accepted carrier. The carrier description makes V the row attached to the first displayed branch satisfying the stopping decision before the bound.

Use the stopping-time stability clause of Definition 383.2. It says that each stopping decision is read from the finite filtration data available at that time and remains bounded by b.

The stopped value is therefore obtained from the matching process row in X and the matching filtration-window row in F. Since no unbounded branch is a carrier coordinate, no consumer can read V from outside the displayed finite ledger. □

Lean4 ✓ `BEDC.Derived.OptionalStoppingUp.OptionalStoppingCarrier bounded stopped value readback`

Theorem 383.4 (OptionalStopping finite expectation window)**.** *Every expectation-style read of an accepted* OptionalStopping$^{\uparrow}$ *packet factors through the finite probability row, martingale-window rows, filtration-window ledger, bounded stopped value, integrability row, displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row already present in the carrier. The read does not invoke measure completion, almost-sure quotient equality, or an unbounded optional-stopping theorem.*

Proof. Begin with the carrier tuple of Definition 383.1. The only probability and expectation-facing coordinates are Ω, the stopped-process rows X, the martingale and filtration ledger F, and the integrability row I.

Apply Definition 383.3 to identify the stopped value route. The selected row is finite, bounded by b, and tied to the displayed stopping-time and filtration windows.

The remaining expectation read can use only the transports, continuation routes, package provenance, and local certificate stored in H, C, P, and N. Thus every expectation-style consumer factors through the displayed finite ledger and never reaches a measure completion, almost-sure quotient, or unbounded optional-stopping principle. □

Lean4 ✓ `BEDC.Derived.OptionalStoppingUp.OptionalStoppingCarrier finite expectation window`

Theorem 383.5 (OptionalStopping no-escape boundary)**.** *The public boundary of* OptionalStopping$^{\uparrow}$ *exports the bounded finite-window stopped-value packet and its displayed expectation ledger only. It exports no unbounded stopping time, no measure completion, no almost-sure quotient, and no uniform-integrability principle beyond the finite integrability row recorded in the carrier.*

Proof. Inspect the accepted packet. Its time information is bounded by the displayed row b, and its stopped value is the finite readback of Definition 383.3.

The expectation-facing data is exactly the finite window of Definition 383.4. The integrability row I is part of that finite ledger, not a principle about unbounded families.

No coordinate of O names a measure completion, almost-sure quotient, unbounded stopping argument, or uniform-integrability theorem. Therefore none of those objects can be exported by the public boundary. □

Lean4 ✓ `BEDC.Derived.OptionalStoppingUp.OptionalStoppingCarrier no escape boundary`

Theorem 383.6 (OptionalStopping scoped dependency route)**.** *Every accepted* OptionalStopping$^{\uparrow}$ *carrier*

$$O = (\Omega, X, T, b, V, F, I, H, C, P, N)$$

scopes the bounded stopped-value read, finite expectation window, stopping-time stability, martingale-window handoff, and ledger exactness through exactly the displayed ProbSpace$^{\uparrow}$, RandomVar$^{\uparrow}$,

Martingale$^{\uparrow}$, StoppingTime$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. No dependency route reaches an unbounded stopping branch, measure completion, almost-sure quotient, or unstated uniform-integrability principle.*

Proof. Apply Definition 383.2. Its five obligations provide carrier formation, componentwise classifier transport, stopping-time stability, martingale-window handoff, and ledger exactness for the displayed finite packet.

Next apply Definition 383.3. The stopped value row V is read only from the first displayed stopping branch before b, together with the corresponding process and filtration-window rows.

Apply Definition 383.4. It places every expectation-style read downstream of Ω, X, F, I, V, H, C, P, and N.

Finally apply Definition 383.5. The excluded unbounded, completed, quotient, and unstated integrability objects are absent from the carrier, so the dependency route is exactly the displayed BEDC row surface. □

Lean4 ✓ `BEDC.Derived.OptionalStoppingUp.OptionalStoppingCarrier scoped dependency route`

Closure status for NameCert$_{\text{OptionalStopping}^{\uparrow}}$.

Constructive story: An OptionalStopping$^{\uparrow}$ packet is generated from a finite probability row, bounded stopped-process random variables, a stopping-time row, a visible stopping bound, the stopped value, filtration-window ledger rows, integrability provenance, displayed transports, continuation routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{OptionalStopping}^{\uparrow}}$, maturePackageClosed)

Scope closed: The bridge-facing paper surface is the bounded finite stopping-branch route through post-stop tail erasure and finite-filtration nonescape over ProbSpace$^{\uparrow}$, RandomVar$^{\uparrow}$, Martingale$^{\uparrow}$, and StoppingTime$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{OptionalStopping}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close unbounded stopping, measure completion, almost-sure quotient equality, uniform integrability beyond the displayed finite row, or bridge checking.

Upgrade path: Bridge checking requires a Lean-side standard bridge target for the finite stopping-branch route through post-stop tail erasure and finite-filtration nonescape.

Definition 383.7 (OptionalStopping post-stop truncation)**.** *Let*

$$O = (\Omega, X, T, b, V, F, I, H, C, P, N)$$

be an accepted OptionalStopping$^{\uparrow}$ *carrier. A post-stop truncation of O at a displayed branch $\tau < b$ is the finite packet*

$$O_{\leq\tau} = (\Omega, X_{\leq\tau}, T_{\leq\tau}, \tau, V, F_{\leq\tau}, I_{\leq\tau}, H_{\leq\tau}, C_{\leq\tau}, P, N)$$

obtained by retaining exactly the probability row Ω, the displayed process rows through τ, the stopping-decision rows through τ, the stopped value row V, the filtration-window rows through τ, the integrability rows through τ, the displayed transports and continuation routes whose endpoints remain in those rows, the same package provenance row P, and the same local certificate row N. All filtration-window, integrability, transport, and continuation rows whose time coordinate lies strictly after τ are omitted. The truncation is stopping-branch exact when τ is the first displayed stopping branch of T before b from which the stopped value row V is read.

Lean4 ✓ `BEDC.Derived.OptionalStoppingUp.OptionalStoppingTasteGate single carrier alignment`

Lemma 383.8 (OptionalStopping post-stop tail erasure)**.** *Let*

$$O = (\Omega, X, T, b, V, F, I, H, C, P, N)$$

be an accepted $\mathsf{OptionalStopping}^{\uparrow}$ *carrier. Suppose that* $\tau < b$ *is the first displayed stopping branch of* T *before the visible bound* b*, and let* $O_{\leq\tau}$ *be the stopping-branch exact post-stop truncation of Definition 383.7. Then* $O_{\leq\tau}$ *is an accepted* $\mathsf{OptionalStopping}^{\uparrow}$ *carrier. Moreover, the stopped value row of* $O_{\leq\tau}$ *is classifier-equal to the stopped value row* V *of* O*.*

Lean4 ✓ `BEDC.Derived.OptionalStoppingUp.OptionalStoppingCarrier post stop tail erasure`

Proof. Project the accepted carrier O through Definition 383.1. Its consumer-visible rows are exactly Ω, X, T, b, V, F, I, H, C, P, and N, and the local classifier compares stopped-value data only through the transported bounded index, stopped value row, filtration-window ledger, integrability provenance, package row, and local certificate row.

By Definition 383.3, the row V is read from the first displayed stopping branch of T before b, together with the corresponding process row of X and filtration-window row of F. The hypothesis says that this branch is τ. Therefore every row needed to read V lies among

$$\Omega, \quad X_{\leq\tau}, \quad T_{\leq\tau}, \quad \tau, \quad V, \quad F_{\leq\tau}, \quad I_{\leq\tau}, \quad H_{\leq\tau}, \quad C_{\leq\tau}, \quad P, \quad N.$$

The deleted rows have time coordinate strictly after τ, so none of them is an input to the stopped-value readback route.

Acceptance of the truncated packet is now the carrier formation clause of Definition 383.2 applied to the retained finite tuple. Stopping-time stability is preserved because every retained decision row was already read from its corresponding filtration-window row in O, and all those filtration-window rows remain present. The terminal bound for the truncated packet is the displayed branch τ, so the selected stopping decision is still inside the visible finite window.

The martingale-window handoff and integrability requirements are also retained. The handoff for the stopped value uses only the process, filtration, and integrability rows through τ by Definition 383.3, while Definition 383.4 places every expectation-style read downstream of the finite probability row, the stopped value row, the filtration-window ledger, the integrability row, the displayed transports, the continuation routes, package provenance, and the local certificate. Those are exactly the rows kept by $O_{\leq\tau}$ for the stopped branch.

It remains to compare stopped values. Both O and $O_{\leq\tau}$ read their stopped value from the same first stopping branch τ, the same process row at that branch, and the same filtration-window row at that branch. The stopped value coordinate is the same displayed row V, and the transports and continuation route that identify it with the branch read are retained in $H_{\leq\tau}$ and $C_{\leq\tau}$. Hence the local $\mathsf{OptionalStopping}^{\uparrow}$ classifier identifies the stopped-value row of the truncated packet with the original stopped value row V. □

Theorem 383.9 (OptionalStopping finite-filtration nonescape)**.** *Let* $O_{\leq\tau} = (\Omega, X_{\leq\tau}, T_{\leq\tau}, \tau, V, F_{\leq\tau}, I_{\leq\tau}, H_{\leq\tau}, C_{\leq\tau},$ *be a stopping-branch exact post-stop truncation of an accepted* $\mathsf{OptionalStopping}^{\uparrow}$ *carrier. Every expectation-facing consumer of the truncated packet must read the rows*

$$\Omega, \quad X_{\leq\tau}, \quad T_{\leq\tau}, \quad \tau, \quad V, \quad F_{\leq\tau}, \quad I_{\leq\tau}, \quad H_{\leq\tau}, \quad C_{\leq\tau}, \quad P, \quad N$$

before any stopped-value or expectation row is exported. No expectation-facing read may inspect a filtration row after τ*, an unbounded stopping branch, a measure completion, an almost-sure quotient, or an unstated integrability family.*

Lean4 ✓ `BEDC.Derived.OptionalStoppingUp.OptionalStoppingCarrier finite filtration nonescape`

Proof. First read the stopped value route. By Definition 383.3, the row V is obtained from the first displayed stopping branch, the matching process row, and the matching finite filtration-window row.

Now restrict the packet to the post-stop truncation. The tail-erasure lemma, Definition 383.8, says that the retained tuple is accepted and keeps the same stopped-value row. Thus the stopped-value read remains inside $\Omega, X_{\leq\tau}, T_{\leq\tau}, \tau, V, F_{\leq\tau}, I_{\leq\tau}, H_{\leq\tau}, C_{\leq\tau}, P, N$.

Next apply the finite expectation window of Definition 383.4. Every expectation-facing read must include the finite probability row, stopped-process rows, stopped value, filtration ledger, integrability row, displayed transports, continuation routes, package provenance, and local certificate. In the truncated packet those are exactly the displayed rows through τ.

Finally use the boundary theorem Definition 383.5. Since post-stop rows after τ are absent and the public boundary exports no unbounded stopping, measure completion, almost-sure quotient, or unstated uniform-integrability principle, the retained finite filtration is the only expectation-facing read surface. □

Chapter 384

A Concrete Naming Certificate for $\mathsf{FoldMomentKernel}^{\uparrow}$

The $\mathsf{FoldMomentKernel}^{\uparrow}$ interface is a BEDC-native finite certificate surface.

The $\mathsf{FoldMomentKernel}^{\uparrow}$ interface names a finite collision-moment packet for folded fibers. It records only visible BHist rows for a finite window, fold sources, fiber ledgers, moment indices, collision counts, transport routes, continuation routes, package provenance, and local $\mathsf{NameCert}$ evidence. It does not import analytic spectral data, host counting semantics, quotient fibers, or an external measure space.

The window row W is consumed as the finite envelope surface of chapter 365; $\mathsf{FoldMomentKernel}^{\uparrow}$ adds fold-source, fiber-ledger, moment-index, and collision-count rows on top of that envelope rather than introducing an independent window carrier.

Definition 384.1 (FoldMomentKernel carrier)**.** *A* $\mathsf{FoldMomentKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, F, L, I, Q, T, C, P, N)$$

with the following visible rows:

1. *W is the finite window row naming the inspected source and target positions;*
2. *F is the fold-source row recording the displayed finite sources whose images are compared in the window;*
3. *L is the visible fiber ledger listing the inspected source entries above each displayed target entry;*
4. *I is the moment-index row naming the finite family of moment requests read by consumers;*
5. *Q is the collision-count row family, with one displayed finite count ledger for each inspected target and moment index;*
6. *T records componentwise* hsame *transports for windows, fold sources, fiber ledgers, moment indices, and collision-count rows;*
7. *C records the displayed* Cont *routes by which consumers reach the window, fold-source, fiber-ledger, moment-index, and collision-count rows;*
8. *P is the* Pkg *provenance naming the finite BEDC packets that own the source window, target window, fold relation, ledger rows, and count rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FoldMomentKernel}^{\uparrow}}$ *row.*

The carrier contains no host cardinality function, no analytic spectrum, no ambient probability measure, and no quotient of fibers.

Lean4 ✓ `BEDC.Derived.FoldMomentKernelUp.FoldMomentKernelTasteGate zero window display`
Lean4 (definition) `BEDC.Derived.FoldMomentKernelUp.FoldMomentKernelUp`
Lean4 ✓ `BEDC.Derived.FoldMomentKernelUp.FoldMomentKernelTasteGate single carrier alignment`
Lean4 ✓ `BEDC.Derived.FoldMomentKernelUp.taste gate`

Definition 384.2 (FoldMomentKernel classifier)**.** *For accepted* $\mathsf{FoldMomentKernel}^{\uparrow}$ *carriers* K *and* K'*, the classifier* $\mathsf{FoldMomentKernelClassifier}(K, K')$ *compares only the displayed window rows, fold-source rows, fiber-ledger rows, moment-index rows, collision-count rows, componentwise* hsame *transports,* Cont *read routes,* Pkg *provenance, and local* NameCert *evidence of Definition 384.1.*

The classifier does not compare hidden source sets, host counts, analytic moments, spectral values, quotient fibers, or unrecorded fold laws.

Theorem 384.3 (FoldMomentKernel zero-window packet)**.** *The empty source window with the zero target window determines an accepted* $\mathsf{FoldMomentKernel}^{\uparrow}$ *carrier. Its fold-source row is empty, its visible fiber ledger has no source entries, every moment-index read is represented by the displayed zero row, every collision-count row is zero, and all transport, continuation, package, and local naming rows are the corresponding finite identity rows.*

Lean4 ✓ `BEDC.Derived.FoldMomentKernelUp.FoldMomentKernelUp zero window packet`
↪ variant `BEDC.Derived.FoldMomentKernelUp.FoldMomentKernelZeroWindowPacket`

Proof. Start with the empty displayed window. There are no source entries to fold and no target fiber entries to inspect, so the fiber ledger is the empty finite ledger.

For each moment index carried by the packet, use the zero collision-count row. The count row is visible data in Q, not a host cardinality computation.

The transport and continuation routes are componentwise identity routes on the empty and zero rows. Repacking them with the package provenance and local certificate row gives the stated carrier. □

Theorem 384.4 (FoldMomentKernel NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{FoldMomentKernel}^{\uparrow}}$ *obligation surface consists of five rows:*

1. *carrier inhabitation: Definition 384.3 supplies the empty-source and zero-window packet;*
2. *classifier transport: Definition 384.2 transports windows, fold-source rows, fiber ledgers, moment indices, collision-count rows,* hsame *routes,* Cont *routes, package provenance, and local provenance componentwise;*
3. *fiber-ledger exactness: every visible source entry counted by the packet appears in the displayed fiber ledger* L*, and every ledger entry is tied to the displayed fold-source row* F *and window row* W*;*
4. *moment readback boundary: every moment read factors through* I*,* Q*,* L*,* T*,* C*,* P*, and* N *before reaching any downstream consumer;*
5. *non-escape: the packet exports no host counting operation, analytic moment, spectral theorem, quotient fiber, ambient measure, or unrecorded fold-completeness claim.*

Lean4 ✓ `BEDC.Derived.FoldMomentKernelUp.FoldMomentKernelTasteGate visible rows`

Proof. The carrier row is the finite packet of Definition 384.1, and Definition 384.3 gives a concrete inhabitant. Thus the local certificate has an admitted finite source surface.

Classifier transport is componentwise by Definition 384.2. A displayed hsame transport can move only window, fold-source, fiber-ledger, moment-index, collision-count, route, provenance, and local certificate rows already present in the packet.

Fiber-ledger exactness is obtained by projecting L together with F and W. Every counted source entry is read from that ledger, and every ledger entry is attached to the displayed fold-source and window rows by the recorded continuation routes.

Moment readback is a boundary statement about the visible rows I and Q. The consumer can inspect the requested moment only through the moment-index row, the associated collision-count ledger, the fiber ledger, transports, continuations, package provenance, and local certificate row.

Since those rows exhaust the carrier coordinates, there is no remaining field from which host counting, analytic spectral information, quotient fibers, ambient measure, or a hidden completeness principle could be exported. □

Theorem 384.5 (FoldMomentKernel standard bridge surface)**.** *The public finite* $\mathsf{FoldMomentKernel}^{\uparrow}$ *packet bridges to the standard finite collision-moment reading through exactly the displayed window, fold-source, fiber-ledger, moment-index, collision-count,* hsame*,* Cont*,* Pkg*,* NameCert*, and TasteGate rows of Definition 384.1. The bridge exports no host counting operation, quotient fiber, ambient measure space, analytic spectrum, or unrecorded fold law.*

Proof. Start from the carrier and classifier rows. The standard finite collision-moment reading can inspect only W, F, L, I, and Q, and transport between accepted packets is governed by the displayed rows T and C.

Apply the NameCert obligation surface. Fiber-ledger exactness ties counted source entries to L, F, and W, while moment readback ties each requested moment to I, Q, L, T, C, P, and N.

Finally use the TasteGate rows already recorded for the packet. They identify the visible rows used by the checked finite reading, so the standard bridge surface is exhausted by the named carrier coordinates and cannot export host counting, quotient fibers, ambient measure, analytic spectra, or hidden fold laws. □

Closure status for $\mathsf{NameCert}_{\mathsf{FoldMomentKernel}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FoldMomentKernel}^{\uparrow}$ packet is generated from finite window rows, fold-source rows, visible fiber ledgers, moment-index rows, collision-count rows, componentwise hsame transports, displayed Cont routes, package provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FoldMomentKernel}^{\uparrow}}$, maturePackageClosed)

Scope closed: The scoped treatment binds the finite window, fold-source, fiber-ledger, moment-index, collision-count, hsame, Cont, Pkg, NameCert, and TasteGate rows certified at Definition 384.4, with instance BEDC.Derived.FoldMomentKernelUp.taste_gate

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FoldMomentKernel}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.FoldMomentKernelUp.taste\_gate`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close analytic spectra, host cardinality, quotient fibers, ambient measure theory, collision asymptotics, or bridge checking.

Upgrade path: Remaining work is formal-axis strengthening of the existing TasteGate surface, not paper-side closure.

Theorem 384.6 (FoldMomentKernel finite-window restriction carrier)**.** *Let*

$$K = (W, F, L, I, Q, T, C, P, N)$$

be an accepted $\mathsf{FoldMomentKernel}^{\uparrow}$ *carrier, and let* Ω *be a displayed finite subwindow of the window row* W*. Suppose the packet has coherent restriction rows*

$$W_\Omega, F_\Omega, L_\Omega, I_\Omega, Q_\Omega, T_\Omega, C_\Omega, P_\Omega, N_\Omega$$

with the following properties:

1. W_Ω *is the selected finite source-and-target subwindow of* W*;*
2. F_Ω *contains exactly the fold-source entries of* F *whose visible source or target addresses lie in* W_Ω*;*
3. L_Ω *contains exactly the fiber-ledger entries of* L *above the displayed target entries of* W_Ω *and using fold sources from* F_Ω*;*
4. I_Ω *is the displayed finite family of moment requests retained for the subwindow;*
5. Q_Ω *contains exactly the collision-count ledgers of* Q *whose target and moment-index addresses lie in* W_Ω *and* I_Ω*;*
6. T_Ω *and* C_Ω *are the componentwise restrictions of the* hsame *transport rows and* Cont *read routes whose endpoints are among* W_Ω*,* F_Ω*,* L_Ω*,* I_Ω*, and* Q_Ω*;*
7. P_Ω *names precisely the package provenance rows consumed by the retained window, fold-source, ledger, moment-index, and count rows;*
8. N_Ω *is the local* $\mathsf{NameCert}_{\mathsf{FoldMomentKernel}^{\uparrow}}$ *row restricted to those same retained coordinates.*

Then

$$K_\Omega = (W_\Omega, F_\Omega, L_\Omega, I_\Omega, Q_\Omega, T_\Omega, C_\Omega, P_\Omega, N_\Omega)$$

is an accepted $\mathsf{FoldMomentKernel}^{\uparrow}$ *carrier.*

Proof. Unfold the carrier of Definition 384.1. A $\mathsf{FoldMomentKernel}^{\uparrow}$ carrier has only the nine displayed coordinates

$$W, F, L, I, Q, T, C, P, N.$$

The hypotheses provide a retained row for each of these coordinates over the finite subwindow Ω. Thus K_Ω has the required window, fold-source, fiber-ledger, moment-index, collision-count, transport, continuation, provenance, and local naming entries.

The fiber and count rows remain well-formed because the restriction is coordinatewise coherent. Every source entry in L_Ω is one already listed by the retained fold-source row F_Ω, and every retained count row in Q_Ω is indexed by a retained target entry of W_Ω and a retained moment request of I_Ω. Conversely, the hypotheses discard only rows whose visible addresses lie outside the selected subwindow, so no retained ledger entry loses its displayed source, target, or moment-index address.

The transport and readback rows also remain internal to the restricted packet. By the classifier scope of Definition 384.2, a $\mathsf{FoldMomentKernelClassifier}$ comparison may inspect only displayed window rows, fold-source rows, fiber-ledger rows, moment-index rows, collision-count rows, componentwise hsame transports, Cont routes, package provenance, and local $\mathsf{NameCert}$ evidence. The rows T_Ω and C_Ω are exactly the retained transports and routes with endpoints in those restricted coordinates, so every classifier or consumer read in the subwindow still factors through visible rows of K_Ω.

Finally apply the obligation surface of Definition 384.4. Carrier inhabitation is supplied by the displayed restricted packet itself, classifier transport is the componentwise restricted transport just described, fiber-ledger exactness is the retained F_Ω–L_Ω–W_Ω incidence, moment readback factors

through I_Ω, Q_Ω, L_Ω, T_Ω, C_Ω, P_Ω, and N_Ω, and non-escape follows because Definition 384.1 gives no coordinate for host cardinality, analytic spectra, quotient fibers, ambient measure, or unrecorded fold laws. Repacking these retained rows gives the accepted carrier K_Ω. $\square$

Chapter 385

A Concrete Naming Certificate for $\mathsf{FiniteErrorBudget}^{\uparrow}$

The $\mathsf{FiniteErrorBudget}^{\uparrow}$ interface names the finite precision-budget packet used on the $\mathsf{Real}^{\uparrow}$ and completion path. Following Bishop and Bridges, *Constructive Analysis*, it treats accuracy as visible dyadic tolerance data, diagonal scheduling, tail ledgers, finite budget consumption, rational regular-sequence readback, and a real-name seal. The packet sits above $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DiagonalModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{FastSeriesProduct}^{\uparrow}$, and $\mathsf{RealCauchyCompletion}^{\uparrow}$. It never forms quotient streams, chooses a host limit, compares host real equality, or appeals to ambient completeness.

Definition 385.1 (FiniteErrorBudget carrier)**.** *A* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (n, \epsilon, b, d, t, r, e, P, N)$$

with the following visible rows:

1. *n is the unary precision-request row read by downstream real and completion consumers;*
2. *ϵ is the dyadic tolerance row, displayed as a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius for the request n;*
3. *b is the* $\mathsf{DiagonalModulus}^{\uparrow}$ *selector row naming the finite diagonal index schedule used to answer the request;*
4. *d is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *tail ledger recording the tail estimate available at the selected schedule;*
5. *t is the finite budget-consumer row, either a* $\mathsf{FastConvergentSeries}^{\uparrow}$ *packet or a* $\mathsf{FastSeriesProduct}^{\uparrow}$ *packet, whose summand and convolution windows are bounded by d;*
6. *r is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes the regular rational name reached by the selected budget;*
7. *e is the* $\mathsf{Real}^{\uparrow}$ *seal row exported to* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *after the finite request is answered;*
8. *P is the* Pkg *provenance naming the dyadic tolerance, diagonal selector, tail ledger, budget consumer, regular-sequence readback, and real seal packets;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteErrorBudget}^{\uparrow}}$ *row.*

The carrier contains no quotient of regular streams, no host real equality test, no selected infinite limit, and no ambient completeness principle.

Lean4 (definition) BEDC.Derived.FiniteErrorBudgetUp.TasteGate.FiniteErrorBudgetTasteGate single carrier alignment
Lean4 (definition) BEDC.Derived.FiniteErrorBudgetUp.TasteGate.FiniteErrorBudgetUp
Lean4 ✓ BEDC.Derived.FiniteErrorBudgetUp.TasteGate.FiniteErrorBudgetTasteGate single carrier alignment

When the finite budget-consumer coordinate t represents a product budget, the row is imported from the finite convolution surface of chapter 368. In that case $\mathsf{FiniteErrorBudget}^{\uparrow}$ consumes the sibling packet's finite convolution rows, pasted tail schedules, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and $\mathsf{Real}^{\uparrow}$ seal as one visible budget row. The local packet then repacks that row through its own dyadic tolerance, diagonal selector, tail ledger, package provenance, and $\mathsf{NameCert}_{\mathsf{FiniteErrorBudget}^{\uparrow}}$ coordinates.

Definition 385.2 (FiniteErrorBudget classifier)**.** *For accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *carriers* E *and* E'*, the classifier* $\mathsf{FiniteErrorBudgetClassifier}(E, E')$ *compares only the displayed precision-request rows, dyadic tolerance rows,* $\mathsf{DiagonalModulus}^{\uparrow}$ *selector rows,* $\mathsf{DyadicTailBound}^{\uparrow}$ *tail ledgers, finite budget-consumer rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows,* $\mathsf{Real}^{\uparrow}$ *seal rows,* Pkg *provenance, and local* $\mathsf{NameCert}$ *evidence of Definition 385.1.*

Classifier transport is componentwise by hsame *on the visible rows and by* Cont *along the recorded consumer routes. The classifier does not compare hidden streams, host real values, chosen limits, quotient classes, or ambient completion objects.*

Theorem 385.3 (FiniteErrorBudget zero seed)**.** *The unary zero precision request with dyadic tolerance* 1*, the initial* $\mathsf{DiagonalModulus}^{\uparrow}$ *selector, the zero* $\mathsf{DyadicTailBound}^{\uparrow}$ *ledger, the empty* $\mathsf{FastConvergentSeries}^{\uparrow}$ *budget consumer, the constant-zero* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the zero* $\mathsf{Real}^{\uparrow}$ *seal determine an accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *carrier.*

Proof. Use the zero request as the displayed precision row and choose the dyadic unit row as the tolerance. The initial diagonal selector and the zero tail ledger give a finite schedule whose tail cost is already below the displayed budget.

The empty fast-convergent-series packet consumes no summands, so its finite window is compatible with the zero tail ledger. Its regular rational readback is the constant-zero $\mathsf{RegSeqRat}^{\uparrow}$ name, and the real seal is the corresponding zero $\mathsf{Real}^{\uparrow}$ row.

All transports and continuations are identity rows on the displayed packet coordinates. Repacking these rows with the package provenance and local certificate row gives the required carrier. □

Theorem 385.4 (FiniteErrorBudget diagonal handoff)**.** *Every accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *carrier* $E = (n, \epsilon, b, d, t, r, e, P, N)$ *exports a finite handoff into* $\mathsf{RealCauchyCompletion}^{\uparrow}$*: the request* n *is answered through the dyadic tolerance* ϵ*, the selector* b*, the tail ledger* d*, the budget consumer* t*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* r*, and the* $\mathsf{Real}^{\uparrow}$ *seal* e *before any completion consumer can inspect the result.*

The handoff is stable under the classifier of Definition 385.2 and exports no quotient stream, host real equality, selected limit, or ambient completeness claim.

Proof. Start with the visible request row n. The dyadic tolerance row ϵ fixes the precision budget that can be consumed by the downstream completion read.

The diagonal selector b chooses a finite schedule, and the tail ledger d records the bound available at that schedule. The budget consumer t can be read only through that displayed schedule and ledger, so every finite summand or convolution window remains inside the packet.

The readback row r presents the resulting regular rational name, and the seal row e is the only row handed to $\mathsf{RealCauchyCompletion}^{\uparrow}$. Componentwise hsame transport and the displayed Cont routes preserve each of these coordinates, so classified replacements give the same handoff surface.

Since the carrier coordinates are exhausted by these visible rows, there is no field from which a quotient stream, host real equality test, selected infinite limit, or ambient completeness principle could be exported. □

Theorem 385.5 (FiniteErrorBudget tail-ledger consumption exactness)**.** *For every accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *carrier* $E = (n, \epsilon, b, d, t, r, e, P, N)$*, every finite budget-consumer read used by the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff factors through the displayed* $\mathsf{DyadicTailBound}^{\uparrow}$ *ledger* d*, the* $\mathsf{DiagonalModulus}^{\uparrow}$ *selector* b*, the dyadic tolerance* ϵ*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* r*.*

If two accepted carriers classify together by Definition 385.2, then the consumer-visible ledger surface is preserved exactly: classified replacement can transport the same displayed rows through hsame *and* Cont*, but it cannot replace the handoff by an unrecorded stream tail, selected limit, host real equality, or ambient completeness datum.*

Proof. Project the selector row b and the tail ledger d from the carrier. The selector names the finite schedule for the request n, while d records the tail estimate available at that schedule against the displayed dyadic tolerance ϵ.

Project the budget-consumer row t. By the carrier definition, its summand or convolution windows are read only inside the schedule and tail bound already displayed by b and d, and the resulting rational name is exposed only through the readback coordinate r.

Classifier transport is componentwise. Therefore a classified carrier can transport only the precision row, tolerance row, selector, tail ledger, consumer row, readback row, seal row, package provenance, and certificate row already present in the packet.

Finally apply Definition 385.4. The exported completion surface is the path through ϵ, b, d, t, r, and e, so no unrecorded stream tail, selected limit, host equality test, or ambient completion datum is available to the consumer. □

Theorem 385.6 (FiniteErrorBudget classifier stability)**.** *Let* $E = (n, \epsilon, b, d, t, r, e, P, N)$ *and* $E' = (n', \epsilon', b', d', t', r', e', P', N')$ *be accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *carriers. If they classify together by Definition 385.2, then the consumer-visible rows* $n, \epsilon, b, d, t, r, e, P, N$ *transport componentwise to* $n', \epsilon', b', d', t', r', e', P', N'$ *through the displayed* hsame *rows and the displayed* Cont *routes of the classifier.*

The transport preserves the precision request, dyadic tolerance, diagonal selector, tail ledger, finite budget consumer, $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, package provenance, and local naming row as the complete visible surface. It introduces no hidden stream coordinate, host equality coordinate, selected limit, or ambient completeness row.*

Proof. Project the two accepted carriers. Their coordinates are exactly the rows named in Definition 385.1, so there is no further coordinate available for transport.

Now apply the classifier of Definition 385.2. Its clauses are componentwise hsame comparisons together with displayed Cont routes for the finite precision-budget reads, so each visible row of E is matched with the corresponding visible row of E'.

The route list is exhausted by $n, \epsilon, b, d, t, r, e, P, N$. Since neither carrier definition nor classifier definition contains a stream representative, host equality field, selected limit, or completeness witness, such data cannot be exported by classifier transport. □

Theorem 385.7 (FiniteErrorBudget zero-budget stability)**.** *The zero-budget seed of Definition 385.3 remains an accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *packet under every classifier-preserving precision-row transport. The transported seed still consists only of the zero precision request, dyadic unit tolerance, initial diagonal selector, zero tail ledger, empty budget consumer, constant-zero* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, zero* $\mathsf{Real}^{\uparrow}$ *seal, package provenance, and local* NameCert *row.*

Proof. Start from the seed packet constructed in Definition 385.3. Each of its coordinates is one of the visible carrier rows of Definition 385.1.

Apply Definition 385.6 to the transported precision row. The classifier can move the zero request only through the displayed hsame and Cont rows, and the remaining tolerance, selector, ledger, consumer, readback, seal, provenance, and naming coordinates move with that same finite surface.

The resulting packet is accepted because the carrier predicates are the same componentwise rows used by the seed construction. No unrecorded stream tail, host real equality test, selected limit, or completeness witness is introduced by the transport. □

Theorem 385.8 (FiniteErrorBudget public finite-packet export)**.** *For every accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *carrier* $E = (n, \epsilon, b, d, t, r, e, P, N)$*, the diagonal handoff of Definition 385.4, the tail-ledger consumption exactness of Definition 385.5, and the local* $\mathsf{NameCert}_{\mathsf{FiniteErrorBudget}^{\uparrow}}$ *rows of Definition 385.9 assemble a public finite packet export for* $\mathsf{RealCauchyCompletion}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Every downstream read factors through the displayed rows $n, \epsilon, b, d, t, r, e, P, N$*, componentwise* hsame *transport, and displayed* Cont *routes. The export contains no quotient stream, hidden host equality coordinate, selected limit, or ambient completeness principle.*

Proof. First project the carrier rows. The request n, tolerance ϵ, selector b, ledger d, budget consumer t, readback r, seal e, package row P, and naming row N are the whole finite packet.

Next apply Definition 385.4. It identifies the completion-facing route through the tolerance, selector, ledger, consumer, readback, and seal rows.

Apply Definition 385.5 to the same packet. This makes every finite consumer read pass through the displayed ledger and prevents replacement by an unrecorded tail surface.

Finally use Definition 385.9. Its carrier, classifier, zero-stability, diagonal-handoff, and non-escape rows repack the same finite data as the public export consumed by $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. □

Theorem 385.9 (FiniteErrorBudget NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{FiniteErrorBudget}^{\uparrow}}$ *obligation surface consists of five rows:*

1. *carrier habitation by the zero-budget seed of Definition 385.3;*
2. *classifier transport by componentwise* hsame *and the displayed* Cont *routes of Definition 385.2;*
3. *zero-budget stability, asserting that the zero request, dyadic unit tolerance, initial selector, zero tail ledger, empty budget consumer, constant-zero readback, and zero real seal remain inside the carrier under classified replacement;*
4. *diagonal handoff into* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *by Definition 385.4;*
5. *non-escape of quotient streams, host real equality, selected limits, and ambient completeness beyond the displayed precision-budget rows.*

Proof. Carrier habitation is exactly the packet constructed in Definition 385.3. It supplies every carrier coordinate using visible finite rows.

Classifier transport follows from Definition 385.2. A classified replacement can move only the precision request, dyadic tolerance, diagonal selector, tail ledger, budget consumer, readback, seal, provenance, and local certificate rows that the carrier already displays.

Zero-budget stability is obtained by projecting the same coordinates from the zero seed after transport. Identity hsame rows preserve the zero request, unit tolerance, initial selector, zero tail ledger, empty consumer, constant-zero readback, and zero real seal.

The diagonal handoff row is supplied by Definition 385.4. Its exported surface is the finite path through ϵ, b, d, t, r, and e, so the completion consumer sees a real-seal read and not an unrecorded stream.

The non-escape row follows because all accepted carrier coordinates have been listed. None of them is a quotient constructor, a host equality oracle, a choice of limit, or an ambient completeness datum. □

Lean4 ✓ `BEDC.Derived.FiniteErrorBudgetUp.FiniteErrorBudgetCarrier namecert obligations`

Theorem 385.10 (FiniteErrorBudget classifier row stability)**.** *Let $E = (n, \epsilon, b, d, t, r, e, P, N)$ and $E' = (n', \epsilon', b', d', t', r', e', P', N')$ be accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *carriers. If* $\mathsf{FiniteErrorBudgetClassifier}(E, E')$ *holds, then classifier transport preserves exactly the precision request, dyadic tolerance, diagonal selector, tail ledger, budget consumer,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, package row, and local* $\mathsf{NameCert}_{\mathsf{FiniteErrorBudget}^{\uparrow}}$ *row displayed by Definition 385.1. No consumer-visible row outside that list is transported.*

Proof. Project the two carrier tuples using Definition 385.1. The visible rows are precisely $n, \epsilon, b, d, t, r, e, P, N$ and their primed counterparts.

Apply the classifier definition of Definition 385.2. Its transport clauses are componentwise hsame rows and displayed Cont routes for the same finite rows, so every transported consumer read remains on the listed surface.

The diagonal and tail-consumption rows then rule out hidden enlargement. Definition 385.4 routes completion reads through the displayed selector and seal path, while Definition 385.5 keeps the consumer-facing budget row attached to the displayed ledger. □

Theorem 385.11 (FiniteErrorBudget diagonal selector exactness)**.** *For every accepted carrier $E = (n, \epsilon, b, d, t, r, e, P, N)$, every diagonal handoff from* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *into* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *factors through the displayed selector b, tail ledger d, tolerance ϵ, finite budget consumer t, and readback row r before reaching the* $\mathsf{Real}^{\uparrow}$ *seal e. The handoff cannot replace any of these rows by an unrecorded schedule, tail estimate, tolerance, consumer, readback, or seal.*

Proof. Start from the carrier coordinates of Definition 385.1. The request row n exposes only one dyadic tolerance row, one diagonal selector, one tail ledger, one consumer, one readback, and one seal.

Apply Definition 385.4. It identifies the completion-facing path as the chain through ϵ, b, d, t, r, and e.

Use Definition 385.5 for the consumer step. The consumer read is bound to the same displayed selector and ledger, so diagonal handoff exactness is a statement about the packet itself rather than about an ambient completion object. □

Theorem 385.12 (FiniteErrorBudget completion-consumer boundary)**.** *Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *packet sees only the displayed finite packet $n, \epsilon, b, d, t, r, e, P, N$, together with the classifier transports and continuation routes of Definition 385.2. Such a consumer cannot read quotient streams, host real equality, selected limits, or ambient completeness.*

Proof. First identify the public packet by Definition 385.1. These coordinates are the complete carrier surface presented to downstream consumers.

Next apply Definition 385.4 and Definition 385.5. Together they force every completion-facing read through the selector, tolerance, ledger, consumer, readback, and seal rows already displayed in the carrier.

Finally use Definition 385.9. Its local certificate rows package the same finite surface and state the non-escape boundary, so the completion consumer has no route to quotient streams, host real equality, selected limits, or ambient completeness. □

Definition 385.13 (FiniteErrorBudget scoped dependency tuple)**.** *For an accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *carrier, the scoped dependency tuple is the displayed finite packet*

$$(n, \epsilon, b, d, t, r, e, P, N).$$

It is read as a tuple over the following BEDC rows:

1. n *is the precision request carried in* BHist *and read through* $\mathsf{StreamName}^{\uparrow}$ *naming discipline;*
2. ϵ *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row;*
3. b *is the* $\mathsf{DiagonalModulus}^{\uparrow}$ *selector row;*
4. d *is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *ledger row;*
5. t *is the finite budget-consumer row;*
6. r *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row;*
7. e *is the* $\mathsf{Real}^{\uparrow}$ *seal row;*
8. P *is the* Pkg *provenance row; and*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteErrorBudget}^{\uparrow}}$ *row.*

Classifier movement of this tuple is only by the displayed hsame *rows and the displayed* Cont *routes of Definition 385.2. The tuple has no coordinate for a quotient stream, host real equality, selected limit, or ambient completeness.*

Theorem 385.14 (FiniteErrorBudget dyadic tolerance scope)**.** *For every accepted carrier* $E = (n, \epsilon, b, d, t, r, e, P, N)$*, the dyadic tolerance* ϵ*, diagonal selector* b*, and tail ledger* d *are consumed through the scoped dependency tuple of Definition 385.13. Any completion handoff or budget-consumer read that uses the tolerance must pass through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row,* $\mathsf{DiagonalModulus}^{\uparrow}$ *row,* $\mathsf{DyadicTailBound}^{\uparrow}$ *row,* BHist *packet,* hsame *transport,* Cont *route,* Pkg *provenance, and local* $\mathsf{NameCert}$ *evidence already listed there.*

Proof. Start with the carrier decomposition of Definition 385.1. The only dyadic tolerance row is ϵ, the only diagonal selector row is b, and the only tail ledger row is d.

Apply Definition 385.4. It sends every completion-facing request through ϵ, b, and d before any readback or real seal is presented.

Next apply Definition 385.5. The finite budget consumer is tied to the same selector and ledger, so the tail estimate consumed by the request cannot be replaced by an unrecorded schedule or ambient bound.

Finally use Definition 385.10 and Definition 385.8. Classifier movement is by the displayed hsame and Cont rows, and the public export repacks only the same finite packet with its Pkg and $\mathsf{NameCert}$ rows. □

Theorem 385.15 (FiniteErrorBudget RegSeqRat readback scope)**.** *For every accepted carrier $E = (n, \epsilon, b, d, t, r, e, P, N)$, the finite budget consumer t and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback r factor through the same scoped dependency tuple before the* $\mathsf{Real}^{\uparrow}$ *seal e is exported. Consequently the readback seen by* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *is determined by the displayed finite packet and not by a hidden stream representative, host real equality, selected limit, or ambient completeness principle.*

Proof. Project the scoped tuple using Definition 385.13. The budget consumer t, readback row r, and real seal e are coordinates of the same finite BHist packet as the request, tolerance, selector, and ledger.

Apply Definition 385.5. This places every consumer read inside the displayed selector and tail-ledger surface and exposes its rational output only through r.

Then apply Definition 385.11. The handoff path reaches e only after passing through ϵ, b, d, t, and r, so the $\mathsf{Real}^{\uparrow}$ seal is downstream of the finite packet rather than an independent completion witness.

The public export theorem, Definition 385.8, packages the same readback for $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealCauchyCompletion}^{\uparrow}$. Therefore the completion consumer cannot obtain any extra readback surface outside the scoped tuple. □

Theorem 385.16 (FiniteErrorBudget NameCert dependency exhaustion)**.** *For every accepted carrier $E = (n, \epsilon, b, d, t, r, e, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteErrorBudget}^{\uparrow}}$ *dependency surface is exhausted by the scoped dependency tuple of Definition 385.13. The carrier row, classifier row, diagonal handoff row, tail-ledger consumption row, public export row, and completion-consumer boundary row all read only $n, \epsilon, b, d, t, r, e, P, N$ together with their displayed* hsame *and* Cont *routes.*

Proof. Use Definition 385.9 to enumerate the local certificate rows. Each row names carrier habitation, classifier transport, zero-budget stability, diagonal handoff, and non-escape for the visible finite packet.

The carrier and classifier surfaces are exactly the rows of Definition 385.1 and Definition 385.2. These give $n, \epsilon, b, d, t, r, e, P, N$ as the complete coordinate list and allow movement only through the displayed hsame and Cont routes.

The diagonal, tail-ledger, and public-export clauses are supplied by Definition 385.4, Definition 385.5, and Definition 385.8. They reuse the same tuple for the tolerance, selector, ledger, consumer, readback, real seal, package row, and naming row.

Finally apply Definition 385.12. Since every completion consumer is already confined to the displayed finite packet, the local $\mathsf{NameCert}$ has no remaining dependency slot through which a quotient stream, host real equality, selected limit, or ambient completeness principle could enter. □

Theorem 385.17 (FiniteErrorBudget dyadic request scope)**.** *Every accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *packet routes its precision request n, dyadic tolerance ϵ, diagonal selector b, and tail ledger d through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows of Definition 385.13. No dyadic request can be consumed through a row outside the finite carrier and classifier surface of the packet.*

Proof. Use Definition 385.1 to decompose the accepted packet as $E = (n, \epsilon, b, d, t, r, e, P, N)$. The precision request, tolerance, selector, and ledger are named coordinates of this carrier, with P and N recording the package provenance and local naming evidence.

Apply Definition 385.2 and Definition 385.10. They restrict classifier movement to the displayed hsame transports and Cont routes, so the dyadic rows cannot be replaced by an ambient tolerance or an unlisted tail estimate.

Finally use Definition 385.11. The selector and tail ledger are exact for the same finite request and dyadic tolerance, which binds the request-facing part of the packet to the scoped dependency tuple. □

Theorem 385.18 (FiniteErrorBudget StreamName readback scope)**.** *The* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of an accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *packet can be consumed only after the finite window, selector, tail ledger, and dyadic observations have been routed through the same finite packet. In particular, the* $\mathsf{StreamName}^{\uparrow}$ *readback path is downstream of the packet coordinates* $n, \epsilon, b, d, t, r, e, P, N$ *and not of a hidden stream representative.*

Proof. Start from Definition 385.5. It ties the consumer row t to the displayed selector and tail ledger, so a readback request has to pass through the finite window and dyadic observations already recorded in the packet.

Next apply Definition 385.4. The handoff places the readback row r after the tolerance, selector, and ledger rows, which makes the $\mathsf{RegSeqRat}^{\uparrow}$ readback a consequence of the same finite packet.

The public export theorem, Definition 385.8, repacks exactly this packet for downstream use. Hence a $\mathsf{StreamName}^{\uparrow}$ consumer has no separate readback route outside the displayed packet surface. □

Theorem 385.19 (FiniteErrorBudget real completion seal scope)**.** *Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal-facing read of an accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *packet factors through the finite request, tolerance, selector, tail ledger, budget consumer, readback, seal, transport, continuation, package, and naming rows before any consumer can cite it. Thus completion use is scoped to the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *surface.*

Proof. Apply Definition 385.8. It exposes the finite packet to $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealCauchyCompletion}^{\uparrow}$ only through the coordinates already listed in the scoped dependency tuple.

Use Definition 385.12. This boundary forces every completion-facing consumer to pass through the request, tolerance, selector, ledger, budget consumer, readback, and seal rows before the consumer can cite the real-completion surface.

Finally apply Definition 385.9. The local NameCert rows record the package, transport, continuation, and naming evidence for the same finite packet, so the seal-facing read has no remaining route through quotient streams, host real equality, selected limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.FiniteErrorBudgetUp.FiniteErrorBudgetUp StdBridge`

Theorem 385.20 (FiniteErrorBudget finite-row induction)**.** *Let* $E = (n, \epsilon, b, d, t, r, e, P, N)$ *be an accepted* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*, or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of* E *is obtained by finite induction over the displayed route*

$$n, \epsilon, b, d, t, r, e, P, N.$$

The base row is the zero seed of Definition 385.3; the step rows pass through the diagonal selector, tail-ledger exactness, budget-consumer boundary, readback, seal, package, and naming rows; and the terminal handoff is the diagonal handoff of Definition 385.4. No induction step may introduce a quotient stream, selected limit, host real equality, countable choice, or ambient completeness coordinate outside the displayed carrier.

Proof. Project the carrier of Definition 385.1. The zero precision row is the seed supplied by Definition 385.3, so the base case already lies inside the finite packet.

For the induction step, read the rows in order. The tolerance and selector rows are controlled by Definition 385.11; the tail row is controlled by Definition 385.5; and the consumer boundary is the same finite boundary used in Definition 385.12.

The classifier supplies the preservation invariant. By Definition 385.2 and Definition 385.10, each componentwise hsame transport and displayed Cont replay preserves the same packet route, so the induction hypothesis is transported only along named rows.

Finally apply Definition 385.4. It hands the readback and completion-facing rows to the public consumer after the finite selector and tail ledger have been displayed. The non-escape clauses in Definition 385.19 exclude quotient streams, selected limits, host real equality, countable choice, and ambient completeness, closing the finite-row induction. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteErrorBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteErrorBudget}^{\uparrow}$ packet is generated from a unary precision request, a dyadic tolerance row, a $\mathsf{DiagonalModulus}^{\uparrow}$ selector, a $\mathsf{DyadicTailBound}^{\uparrow}$ ledger, a finite $\mathsf{FastConvergentSeries}^{\uparrow}$ or $\mathsf{FastSeriesProduct}^{\uparrow}$ budget consumer, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteErrorBudget}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 385.8, Definition 385.17, Definition 385.18, Definition 385.19, and Definition 385.9 bind the public finite-packet export to its dyadic request, $\mathsf{StreamName}^{\uparrow}$ readback, real-completion seal, package, continuation, and naming routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteErrorBudget}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.FiniteErrorBudgetUp.FiniteErrorBudgetCarrier\_namecert\_obligations`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close quotient streams, host real equality, selected limits, ambient real completeness, or bridge checking.

Upgrade path: No further upgrade remains on the formal bridge axis.

The $\mathsf{CauchyLimitSeal}^{\uparrow}$ hub supplies the terminal seal consumed by chapter 1205 through the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows; this route adds no quotient-stream equality, host limit, selected representative, choice row, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Chapter 386

A Concrete Naming Certificate for $\mathsf{CauchyLimitSeal}^{\uparrow}$

The $\mathsf{CauchyLimitSeal}^{\uparrow}$ interface records the visible seal boundary between regular rational Cauchy data and the consumer-facing $\mathsf{Real}^{\uparrow}$ row. In the Bishop–Bridges constructive-analysis reading of Cauchy completion, a limit is presented by finite regular-name observations and an explicit schedule, not by quotienting streams or selecting a host limit. The chapter isolates that boundary as a concrete packet so later $\mathsf{Real}^{\uparrow}$ consumers can read only the displayed finite windows that pass through the seal.

The same seal boundary is consumed as the downstream finite route of the diagonal-limit construction in chapter 450. That consumer reads the StreamName, RegSeqRat, DyadicRatCore, and RealUp rows already named by the carrier, so the seal appears as a horizontal lattice edge between the finite completion route and the public real-facing endpoint.

Definition 386.1 (CauchyLimitSeal carrier)**.** *A* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, S, D, G, E, T, P, N)$$

with the following visible coordinates:

1. *X is a* $\mathsf{RegSeqRat}^{\uparrow}$ *family row presenting the regular rational Cauchy source to be sealed;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that lists the finite windows a consumer may inspect;*
3. *D is the* $\mathsf{DyadicRatCore}$ *observation ledger attached to those scheduled windows;*
4. *G is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row that routes the regular family through its displayed completion packet;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed to downstream real consumers;*
6. *T is the finite collection of* hsame *and* Cont *transport rows connecting the source family, scheduled windows, diagonal row, observation ledger, and seal row;*
7. *P is the* Pkg *provenance row naming the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *dependency certificates;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$ *row.*

The local classifier compares two carriers only by componentwise transport of these visible rows. It does not compare quotient representatives, host limits, or ambient completeness data.

Theorem 386.2 (CauchyLimitSeal NameCert obligations)**.** *The* $\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$ *surface has four finite obligations: carrier habitation by Definition 386.1; classifier stability under the displayed* hsame *and* Cont *transport rows; exact factorization of every* $\mathsf{Real}^{\uparrow}$ *consumer read through the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, DyadicRatCore, *and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *rows; and non-escape of quotient stream equality, selected host limits, uniqueness theorems, and ambient real completeness data.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier namecert obligations`

Proof. Carrier habitation is the finite packet assembly. The regular family, schedule, observation ledger, completion row, seal row, transport rows, package provenance, and local certificate are all coordinates of the displayed BHist packet.

Classifier stability is componentwise. Each row is transported only by the stored hsame comparison and the corresponding Cont route, so an accepted packet stays inside the same visible dependency surface.

The exactness and boundary obligations follow from the shape of the carrier. Every $\mathsf{Real}^{\uparrow}$ read must pass through the scheduled finite windows and their dyadic observation ledger before reaching the completion row and seal row; no field contains a quotient stream, a selected host limit, a uniqueness theorem, or an ambient real-completeness datum. □

Theorem 386.3 (CauchyLimitSeal window factorization)**.** *For every accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier* L *and every finite* $\mathsf{Real}^{\uparrow}$ *consumer request, the read factors through a visible* $\mathsf{StreamName}^{\uparrow}$ *window from* S*, the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *source row in* X*, the matching* DyadicRatCore *observation ledger in* D*, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row* G*, and the displayed transport rows in* T *before it reaches the seal row* E*.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealPacket window factorization`

Proof. Project the carrier of Definition 386.1. A consumer request first selects one of the scheduled finite windows because the seal row has no independent read channel.

Read the selected window through the $\mathsf{RegSeqRat}^{\uparrow}$ source family. The rational observation is recorded in the DyadicRatCore ledger, and the same scheduled row is passed to the $\mathsf{RealCauchyCompletion}^{\uparrow}$ diagonal coordinate.

Finally apply the stored hsame and Cont rows in T to transport the read to the $\mathsf{Real}^{\uparrow}$ seal. The path is therefore the stated finite factorization, with every consumer-facing value mediated by visible packet data. □

Theorem 386.4 (CauchyLimitSeal non-escape boundary)**.** *An accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier exports no quotient stream, no selected host limit, no uniqueness theorem for limits, and no ambient real completeness datum. Its public surface is exhausted by the finite* BHist *packet, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source family, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* DyadicRatCore *observation ledger, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row, the* $\mathsf{Real}^{\uparrow}$ *seal row, and the displayed* hsame, Cont, Pkg, *and* NameCert *provenance.*

Proof. Inspect the carrier coordinates. Each coordinate is either a named dependency certificate row, a finite transport row, a package provenance row, or the local certificate row.

The completion coordinate is consumed only through its displayed diagonal row, and the real-facing coordinate is the seal row attached to that diagonal route. Neither coordinate adds a host real carrier or a quotient of regular streams.

Thus a downstream consumer can cite exactly the listed rows. Since no other coordinate exists in the packet, uniqueness theorems, selected limits, and ambient real completeness data cannot be exported by the $\mathsf{CauchyLimitSeal}^{\uparrow}$ surface. □

Theorem 386.5 (CauchyLimitSeal RealUp consumer boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier may read only the sealed finite-window route of Definition 386.3. In particular, the consumer boundary is the displayed packet surface over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$, *and it does not expose an independent completeness theorem for* $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier realup consumer boundary`

Proof. Begin with the factorization theorem. It forces each consumer read through the scheduled window, regular rational source row, dyadic observation ledger, completion diagonal row, and transport route before the read reaches the $\mathsf{Real}^{\uparrow}$ seal.

Use the non-escape boundary to identify what remains visible after the seal is reached. The package provenance and local certificate name the dependency rows, but they do not add quotient, host-limit, uniqueness, or ambient-completeness fields.

Therefore the $\mathsf{Real}^{\uparrow}$ consumer boundary is precisely the finite route listed in the statement. The seal is a public endpoint for displayed regular-Cauchy data, not a source of an independent real-completeness principle. □

Definition 386.6 (CauchyLimitSeal public route packet)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier* $L = (X, S, D, G, E, T, P, N)$, *its public route packet is the componentwise projection*

$$\mathsf{PubRoute}(L) = (X, S, D, G, E, T, P, N)$$

read as the visible $\mathsf{RegSeqRat}^{\uparrow}$ *source row, scheduled* $\mathsf{StreamName}^{\uparrow}$ *window family,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal row, displayed* hsame *and* Cont *transport ledger,* Pkg *provenance row, and local* $\mathsf{NameCert}$ *row. The packet is a named public BEDC object: it contains only these carrier coordinates and no quotient stream, selected host limit, uniqueness theorem, host real construction, or ambient completeness datum.*

Theorem 386.7 (CauchyLimitSeal public route transport)**.** *Local classifier transport of accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carriers transports the public route packet componentwise. The transported packet preserves the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows, and it introduces no quotient stream, selected host limit, uniqueness theorem, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier public route transport`

Proof. Project the carrier $L = (X, S, D, G, E, T, P, N)$ and read Definition 386.6. The public route packet is exactly the visible coordinate list of the carrier, so classifier transport can act only on those coordinates.

Apply the carrier obligation theorem Definition 386.2. Its classifier-stability clause moves accepted carriers along the stored hsame comparisons and Cont routes, while the Pkg and $\mathsf{NameCert}$ rows keep the dependency names fixed.

Use the non-escape boundary Definition 386.4. Because the carrier contains no quotient stream, selected host limit, uniqueness theorem, or ambient completeness field, componentwise transport cannot create any such public coordinate. □

Theorem 386.8 (CauchyLimitSeal public route boundary)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *or completion-consumer route of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier factors through the public route packet of Definition 386.6. Conversely, every row of that packet is one of the displayed rows named by the finite-window factorization of Definition 386.3 and the* $\mathsf{Real}^{\uparrow}$ *consumer boundary of Definition 386.5.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier public route boundary`

Proof. For a $\mathsf{Real}^{\uparrow}$ consumer, apply Definition 386.5. The read is forced through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source, scheduled $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger, $\mathsf{RealCauchyCompletion}^{\uparrow}$ diagonal row, $\mathsf{Real}^{\uparrow}$ seal row, and visible transport, package, and naming rows.

For a completion-facing consumer, use the finite-window factorization Definition 386.3. It gives the same route before the read reaches the seal, so the completion-facing path also lands inside the packet coordinates X, S, D, G, E, T, P, N.

The reverse containment is just projection from Definition 386.6. Each packet row is one of the displayed carrier rows named by the two boundary theorems, and Definition 386.4 rules out any additional public row outside that list. □

Theorem 386.9 (CauchyLimitSeal tail-agreement public route factorization)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *read or completion-facing read of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet that consumes a paired tail-agreement comparison factors first through the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *finite route*

$$R, S, W, D, A, H, C, P, N$$

and then through the $\mathsf{CauchyLimitSeal}^{\uparrow}$ *public route packet*

$$X, S, D, G, E, T, P, N.$$

The combined route uses only $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal rows,* $\mathsf{Real}^{\uparrow}$ *seal rows,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data. It exports no quotient stream, selected host limit, host real equality, ambient completeness, or choice-selected tail.*

Proof. For the paired agreement side, use the Real–Completion handoff of Definition 699.5. The paired comparison enters through the displayed finite route $R, S, W, D, A, H, C, P, N$ before any downstream real or completion consumer can read it.

Apply window-agreement determinacy from Definition 699.64 and completion-handoff totality from Definition 699.65. These two rows make the agreement route exact for the finite windows and completion-facing handoff, so no second tail, quotient stream, host real equality, or choice-selected comparison is available.

Now pass the resulting consumer read to the accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ packet. By Definition 386.6 and the public route boundary of Definition 386.8, the read factors through the carrier route X, S, D, G, E, T, P, N.

Finally combine the non-escape boundaries of the two chapters. The tail-agreement route contributes only its finite comparison surface, and the CauchyLimitSeal route contributes only the displayed source, schedule, dyadic, diagonal, seal, transport, package, and naming rows. Hence the composite route cannot export quotient streams, selected host limits, host real equality, ambient completeness, or a choice-selected tail. □

Theorem 386.10 (CauchyLimitSeal RegularCauchyName consumer link)**.** *Let a* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet expose its regular schedule, dyadic observation rows, dyadic-radius ledger, finite regularity ledger, and* $\mathsf{Real}^{\uparrow}$ *seal through the public packet named by Definition 371.32 and the completion consumer coverage of Definition 371.33. Repacking those displayed rows as*

$$X, S, D, G, E, T, P, N$$

determines exactly the same finite consumer boundary as the $\mathsf{CauchyLimitSeal}^{\uparrow}$ *public route packet of Definition 386.6. Thus every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of the repacked name reads only the shared finite rows* X, S, D, G, E, T, P, N*, and no quotient stream, host sequence equality, selected limit, host real construction, or ambient completeness datum is exported.*

Proof. First read the $\mathsf{RegularCauchyName}^{\uparrow}$ side. The public seal export of Definition 371.32 places the $\mathsf{Real}^{\uparrow}$ endpoint on the displayed regular name packet, and the completion consumer coverage theorem Definition 371.33 states that completion-facing consumers receive no row beyond that same finite packet.

Next repack the displayed schedule, dyadic observation, radius ledger, finite regularity ledger, seal, transport, provenance, and local name rows as X, S, D, G, E, T, P, N. By the public route boundary of Definition 386.8, any $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer of those rows factors through the public route packet of Definition 386.6.

Finally apply the non-escape boundary of Definition 386.4. Neither side of the repacking has a coordinate for quotient streams, host sequence equality, selected host limits, host real construction, or ambient completeness. Hence the two consumer routes expose exactly the same finite public boundary. □

Theorem 386.11 (CauchyLimitSeal RegSeqRat window non-escape)**.** *Every accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *public route whose source row is a* $\mathsf{RegSeqRat}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row, and* $\mathsf{Real}^{\uparrow}$ *seal row. The route exports no quotient stream equality, selected host limit, uniqueness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier regseqrat window nonescape`

Proof. Project the carrier of Definition 386.1. Its source row is X, its schedule is S, its observation ledger is D, its diagonal completion row is G, and its public seal row is E.

Apply Definition 386.3. A public read beginning at the $\mathsf{RegSeqRat}^{\uparrow}$ source must pass through the scheduled $\mathsf{StreamName}^{\uparrow}$ window, the matching $\mathsf{DyadicRatCore}^{\uparrow}$ observation row, and the $\mathsf{RealCauchyCompletion}^{\uparrow}$ diagonal row before it reaches the $\mathsf{Real}^{\uparrow}$ seal.

Finally combine Definition 386.5 with Definition 386.4. These boundaries confine the public endpoint to the displayed seal route and rule out quotient stream equality, selected host limits, uniqueness theorems, and ambient real completeness as available export coordinates. □

Theorem 386.12 (CauchyLimitSeal obligation closure package)**.** *The carrier definition, the* $\mathsf{NameCert}_{\mathsf{CauchyLimitSea}}$ *obligations, the finite-window factorization, the non-escape boundary, and the* $\mathsf{Real}^{\uparrow}$ *consumer boundary jointly supply the full paper-side obligation surface for* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *The package preserves the exclusions on quotient streams, selected host limits, uniqueness of limits, host real construction, and ambient completeness.*

Proof. Start with the carrier of Definition 386.1. Its coordinates name exactly the regular rational source, schedule, dyadic ledger, completion row, real seal, transport rows, package provenance, and local certificate that form the public packet.

Apply the component obligations in order. The NameCert obligation theorem supplies habitation, classifier stability, exactness, and non-escape requirements; the window factorization theorem identifies the consumer route through the scheduled finite observations; the non-escape theorem records the absent quotient, host-limit, uniqueness, and completeness fields; and the $\mathsf{Real}^{\uparrow}$ consumer-boundary theorem fixes the public endpoint of the route.

These rows are finite and exhaust the displayed packet surface. Since the carrier contains no further coordinate from which an omitted quotient, selected limit, uniqueness principle, host real, or ambient-completeness datum could be read, the listed component rows provide the whole paper-side obligation package. □

Theorem 386.13 (CauchyLimitSeal public export certificate)**.** *The carrier,* NameCert *obligations, finite-window factorization, non-escape boundary,* $\mathsf{Real}^{\uparrow}$ *consumer boundary, and obligation closure package assemble a public certificate for the sealed finite-window route over* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The exported certificate exposes exactly the displayed source row, scheduled window, dyadic observation ledger, diagonal completion row, seal row, transport rows, package provenance, and local certificate.*

Proof. Start with the carrier of Definition 386.1. It supplies the displayed regular source, schedule, dyadic ledger, diagonal completion row, real seal, transport rows, package provenance, and local certificate.

Apply the NameCert obligations of Definition 386.2. They provide carrier habitation, classifier stability, exactness of the consumer route, and the non-escape clauses needed for a public certificate.

Next use the window factorization theorem Definition 386.3 and the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5. These identify the public read route through the scheduled finite window, dyadic observation ledger, completion diagonal, and seal row.

Finally combine the non-escape boundary of Definition 386.4 with the obligation closure package of Definition 386.12. The rows listed there exhaust the public surface, so the assembled certificate exports the sealed finite-window route and nothing outside the stated BEDC coordinates. □

Theorem 386.14 (CauchyLimitSeal downstream schedule exhaustion)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*, or* $\mathsf{RegularCauchyName}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet reads a scheduled* $\mathsf{StreamName}^{\uparrow}$ *window, dyadic observation ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, completion diagonal row, and* $\mathsf{Real}^{\uparrow}$ *seal row. The consumer-facing packet also carries only the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, and it has no coordinate for quotient streams, selected host limits, uniqueness of limits, host real equality, or ambient completeness.*

Proof. Begin with the window factorization theorem Definition 386.3. It sends each read through a scheduled $\mathsf{StreamName}^{\uparrow}$ window, the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source row, the dyadic observation ledger, and the completion diagonal row before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Apply the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5. It confines Real-facing consumers to the displayed seal route and the visible history, transport, continuation, provenance, and local certificate rows.

For completion-facing reads, use the public route boundary of Definition 386.8. For regular-name reads, use the RegularCauchyName consumer link of Definition 386.10. These two rows put the completion and regular-name consumers inside the same scheduled route.

Finally apply the public export certificate of Definition 386.13. The certificate packages exactly the source, schedule, dyadic observation, diagonal completion, seal, transport, provenance, and local naming rows. Since the carrier and certificate contain no quotient-stream, selected-host-limit, uniqueness, host-real-equality, or ambient-completeness coordinate, every downstream consumer is exhausted by the displayed schedule. □

Theorem 386.15 (CauchyLimitSeal downstream completion handoff)**.** *A downstream completion consumer of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier can pull back only along the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source, scheduled* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row, and* $\mathsf{Real}^{\uparrow}$ *seal. The handoff carries the visible* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows and does not export an independent completeness principle, quotient stream, selected host limit, uniqueness theorem, or host real construction.*

Proof. Apply the window factorization theorem Definition 386.3. It forces every downstream read through the scheduled $\mathsf{StreamName}^{\uparrow}$ window, the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source row, the corresponding dyadic observation ledger, and the $\mathsf{RealCauchyCompletion}^{\uparrow}$ diagonal row before reaching the $\mathsf{Real}^{\uparrow}$ seal.

Use the non-escape boundary of Definition 386.4. The accepted carrier has no field for quotient streams, selected host limits, uniqueness theorems, host real construction, or ambient completeness.

The public export certificate of Definition 386.13 packages the remaining rows as the consumer-facing handoff. Thus a completion consumer can pull back only through the displayed finite-window route and its visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ coordinates. □

Theorem 386.16 (CauchyLimitSeal null-sequence factorization)**.** *Let two sealed* $\mathsf{Real}^{\uparrow}$ *reads be presented by accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carriers. If their displayed difference is accepted by a* $\mathsf{NullSequence}^{\uparrow}$ *packet, then every equality-consumer route factors through the CauchyLimitSeal scheduled* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row, the* $\mathsf{Real}^{\uparrow}$ *seal row, and the* $\mathsf{NullSequence}^{\uparrow}$ *tolerance-window-threshold packet. The factored route carries only the visible* $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows supplied by those packets, and it exports no ambient real completeness, quotient stream equality, selected host limit, or hidden tail witness.*

Proof. Begin with the local window factorization theorem Definition 386.3. It sends each sealed read through the scheduled finite window, the dyadic observation ledger, and the completion diagonal row before any $\mathsf{Real}^{\uparrow}$ seal coordinate is consumed.

Apply the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5. This confines the equality-facing read to the displayed seal row and the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Next use the downstream completion handoff of Definition 386.15. A completion consumer may pull back only along the same scheduled window, observation ledger, diagonal row, and seal route, so the comparison cannot introduce a second completion object.

Finally attach the $\mathsf{NullSequence}^{\uparrow}$ real-seal factorization of Definition 380.7. Its tolerance row, observation window, and threshold row supply the zero-tail evidence read by the two seals, and the combined route remains the finite CauchyLimitSeal route plus that displayed null-sequence packet. □

Theorem 386.17 (CauchyLimitSeal regular-source stability)**.** *Let L be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Any classifier transport of the accepted seal preserves the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the scheduled* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row, and the* $\mathsf{Real}^{\uparrow}$ *seal row through the stored* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows of L.*

Proof. Project the carrier of Definition 386.1. The source row, schedule, dyadic ledger, diagonal row, seal row, transport rows, package row, and local certificate are named coordinates of the same finite BHist packet.

Apply the classifier-stability clause of Definition 386.2. Transport can move an accepted packet only along the displayed hsame comparison and the corresponding Cont route, while the Pkg and NameCert rows keep the dependency names fixed.

Finally use the non-escape boundary of Definition 386.4. Since no quotient stream, selected host limit, uniqueness theorem, or ambient completeness coordinate is available, the transported seal still exposes exactly the displayed regular source, scheduled windows, observation ledger, diagonal row, and seal row. □

Theorem 386.18 (CauchyLimitSeal diagonal-row compatibility)**.** *Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal read consumed by an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *seal factors through the same scheduled* $\mathsf{StreamName}^{\uparrow}$ *window and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger as the finite route of Definition 386.3. Consequently the diagonal row G in the carrier cannot be replaced, for that seal read, by an independent completion object outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier diagonal row compatibility`

Proof. Begin with the window factorization theorem Definition 386.3. It sends each consumer read through a scheduled $\mathsf{StreamName}^{\uparrow}$ window, the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source row, the matching DyadicRatCore ledger, and then the $\mathsf{RealCauchyCompletion}^{\uparrow}$ diagonal coordinate before the read reaches the $\mathsf{Real}^{\uparrow}$ seal.

Use the downstream completion handoff of Definition 386.15. A completion consumer may pull back only along that displayed route, so the diagonal read is tied to the same scheduled window and observation ledger that feed the seal.

The carrier has no second completion coordinate. By Definition 386.4, no host limit, quotient stream, or ambient completeness datum can supply an alternate completion object; therefore the diagonal row consumed by the seal is the carrier row G routed through the stated finite ledger. □

Theorem 386.19 (CauchyLimitSeal seal-ledger exhaustion)**.** *The carrier of Definition 386.1, the* $\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$ *obligations, regular-source stability, diagonal-row compatibility, the* $\mathsf{Real}^{\uparrow}$ *consumer boundary, and the non-escape theorem exhaust the finite seal ledger for downstream* $\mathsf{Real}^{\uparrow}$ *and completion consumers. No further* BHist *row is available beyond the displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates.*

Proof. Start with the carrier projection. Its finite packet lists exactly the regular source family, schedule, observation ledger, diagonal completion row, real seal row, transport rows, package provenance, and local certificate.

Apply the NameCert obligations of Definition 386.2. They supply habitation, classifier stability, exact finite-route factorization, and the exclusion of quotient, host-limit, uniqueness, and ambient-completeness data.

Next combine Definition 386.17 and Definition 386.18. The first keeps classifier transport on the displayed source, schedule, ledger, diagonal, and seal rows; the second prevents a downstream completion read from replacing the diagonal row by an object outside the packet.

Finally use the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5 and the non-escape boundary of Definition 386.4. These identify the public endpoint and rule out every listed hidden field, so the finite rows named in the statement exhaust the seal ledger for downstream real and completion consumers. □

Theorem 386.20 (CauchyLimitSeal scheduled-window pullback)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Any downstream predicate read on the sealed* $\mathsf{Real}^{\uparrow}$ *endpoint E pulls back uniquely to a scheduled* $\mathsf{StreamName}^{\uparrow}$ *finite window in S, its* $\mathsf{RegSeqRat}^{\uparrow}$ *row in X, the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row in D, and the displayed* hsame *and* Cont *transport rows in T. This pullback is a projection of the finite* BHist *packet named by P and N, and it has no host-limit coordinate, quotient-stream coordinate, or independent completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier scheduled window pullback`

Proof. Project the carrier coordinates X, S, D, G, E, T, P, N. The endpoint E is not stored as a free real object; it is the seal row reached through the scheduled route carried by the same finite BHist packet.

Apply the window factorization of Definition 386.3. A read on E must pass through one scheduled $\mathsf{StreamName}^{\uparrow}$ window from S, then through its $\mathsf{RegSeqRat}^{\uparrow}$ source row in X, and then through the corresponding $\mathsf{DyadicRatCore}^{\uparrow}$ ledger row in D.

The remaining movement is exactly the transport ledger T. The stored hsame and Cont rows identify the admissible route from the scheduled observation to the completion row G and the seal row E, while P and N name the dependency package and local NameCert.

Uniqueness is componentwise in the displayed packet. Since no additional carrier coordinate contains a host limit, quotient stream, or ambient completeness datum, a downstream predicate on E has only the scheduled finite-window pullback just described. □

Theorem 386.21 (CauchyLimitSeal dyadic observation replay)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier $L = (X, S, D, G, E, T, P, N)$, replaying any consumer read through the seal consumes exactly the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger D together with the* Pkg *provenance P and the local* NameCert *row N. The replay does not consume an external tolerance, a hidden tail witness, a quotient-stream comparison, or a selected host limit.*

Proof. Start with the finite route of Definition 386.3. The consumer read is routed from S and X into the observation ledger D before it reaches the completion diagonal and the seal.

The replay step is therefore a ledger projection. Each dyadic observation used by the consumer is one of the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ rows in D, and its admissibility is recorded by the package provenance P and the local certificate N.

Use the non-escape theorem Definition 386.4. The carrier contains no external tolerance field, no hidden tail witness, no quotient-stream comparison, and no selected host-limit row. Hence the replay consumes exactly D, P, and N along the visible BHist, hsame, and Cont route. □

Theorem 386.22 (CauchyLimitSeal window-ledger normal form)**.** *Every completion or* $\mathsf{Real}^{\uparrow}$ *consumer replay of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier has a finite window-ledger normal form. It is determined by the displayed* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row, the* $\mathsf{Real}^{\uparrow}$ *seal, and the visible* BHist, hsame, Cont, Pkg, *and* NameCert *rows. No quotient stream, selected host limit, uniqueness theorem, or ambient completeness coordinate participates in this normal form.*

Proof. Begin with the scheduled-window pullback of Definition 386.20. It places any downstream consumer read on a displayed $\mathsf{StreamName}^{\uparrow}$ window, its $\mathsf{RegSeqRat}^{\uparrow}$ source row, and the matching $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger.

Replay the dyadic observation by Definition 386.21. The ledger row used by the consumer is therefore the displayed row D together with the package and local certificate rows, not an external tolerance or hidden tail witness.

Finish with the non-escape theorem and the $\mathsf{Real}^{\uparrow}$ consumer boundary. They rule out quotient streams, selected host limits, uniqueness premises, and ambient completeness data, so the displayed route is the normal form for completion and $\mathsf{Real}^{\uparrow}$ replay. □

Theorem 386.23 (CauchyLimitSeal seal-route determinacy)**.** *If two accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer replays use the same displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal, and visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, then they determine the same seal route for every completion or* $\mathsf{Real}^{\uparrow}$ *consumer. The comparison does not appeal to a quotient stream, selected host limit, uniqueness theorem, or ambient completeness coordinate.*

Proof. Use Definition 386.22 to put both consumer replays into the same displayed window-ledger normal form. The hypothesis identifies each row of that normal form componentwise.

The diagonal read is fixed by Definition 386.18. Once the scheduled window, regular row, and dyadic ledger agree, the completion consumer cannot replace the diagonal row by a separate completion object.

The seal endpoint is then fixed by the downstream completion handoff and the $\mathsf{Real}^{\uparrow}$ consumer boundary. Since the carrier has no quotient stream, selected host limit, uniqueness theorem, or ambient completeness coordinate, there is no further field that could distinguish two seal routes. □

Theorem 386.24 (CauchyLimitSeal completion-consumer replay)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier replays through the finite route determined by the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal, and visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The replay exposes no quotient stream, selected host limit, uniqueness theorem, or ambient completeness coordinate to the consumer.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier completion consumer replay`

Proof. Start with a completion-facing consumer read. The scheduled-window pullback sends it to the displayed finite window, regular rational row, dyadic observation row, and transport route.

Apply the window-ledger normal form. The replay is therefore read from the listed carrier rows and their package and local naming provenance, rather than from a host completion principle.

Finally apply seal-route determinacy. Any second replay with the same displayed rows must follow the same route, and the non-escape boundary prevents the consumer from importing quotient streams, selected host limits, uniqueness theorems, or ambient completeness coordinates. □

Theorem 386.25 (CauchyLimitSeal completion-consumer exactness)**.** *Every completion-facing consumer of accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carriers has the exact finite route obtained by composing the scheduled-window pullback of Definition 386.20, the dyadic replay of Definition 386.21, the downstream completion handoff of Definition 386.15, and the null-sequence factorization of Definition 386.16. The route is wholly contained in the carrier coordinates* X, S, D, G, E, T, P, N *and their visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. First pull the completion-facing read back from the sealed endpoint. By Definition 386.20, the read lands on a scheduled finite window, its regular rational source row, the dyadic observation row, and the displayed transport rows.

Next replay the dyadic observation. By Definition 386.21, the consumer uses exactly the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ ledger with the package provenance and local naming row, rather than any external tolerance or hidden tail witness.

Now apply the downstream completion handoff of Definition 386.15. It keeps the completion consumer on the same source row, scheduled window, observation ledger, diagonal row, and seal route.

Finally use the null-sequence factorization of Definition 386.16 when the consumer compares two sealed reads. The comparison attaches only the displayed $\mathsf{NullSequence}^{\uparrow}$ tolerance-window-threshold packet to the already fixed route, so the completion consumer receives exactly the finite path through X, S, D, G, E, T, P, N and the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. □

Theorem 386.26 (CauchyLimitSeal public route exhaustion)**.** *Every public* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route available to a downstream* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer is exhausted by the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal row,* BHist *packet,* hsame *and* Cont *transports,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. No public route can read a quotient stream, selected host limit, hidden tail witness, or ambient completeness coordinate outside those carrier rows.*

Proof. Project the accepted carrier $L = (X, S, D, G, E, T, P, N)$ from Definition 386.1. The only public rows named by the packet are the regular source, schedule, dyadic ledger, diagonal completion row, real seal, transport ledger, package row, and local certificate.

Use the scheduled-window pullback of Definition 386.20 and the dyadic replay of Definition 386.21. These identify any consumer read with a scheduled finite window, its regular rational source row, the corresponding dyadic observation, and the stored transport route.

Now apply the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5 and the non-escape theorem of Definition 386.4. They leave no coordinate for quotient streams, selected host limits, hidden tail witnesses, or ambient completeness data, so the displayed rows exhaust the public route. □

Theorem 386.27 (CauchyLimitSeal bridge boundary)**.** *The abstract* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *bridge surface is supplied exactly by the finite route through the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal row, displayed transport rows,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$ *row. A bridge consumer receives no quotient stream, selected host limit, hidden tail witness, independent completion object, or ambient completeness coordinate beyond that route.*

Proof. First compose the public route boundary of Definition 386.8 with the public export certificate of Definition 386.13. These rows identify the exported surface with the carrier coordinates X, S, D, G, E, T, P, N.

Next attach the downstream completion handoff of Definition 386.15. It keeps completion-facing reads on the same regular source, schedule, dyadic ledger, diagonal completion row, and seal route.

Use seal-ledger exhaustion from Definition 386.19. The seal-facing ledger has no additional row from which a quotient stream, selected host limit, hidden tail witness, or independent completion object could be read.

Finally apply public route exhaustion from Definition 386.26. The bridge boundary is therefore exactly the finite route listed in the statement, with the displayed transport, package, and local naming rows carrying the whole consumer-facing surface. □

Theorem 386.28 (CauchyLimitSeal pullback determinacy)**.** *Let two completion pullbacks of accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carriers use the same scheduled* $\mathsf{StreamName}^{\uparrow}$ *window and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger inside the displayed carrier packet. Then they determine the same seal route*

through the RegSeqRat$^{\uparrow}$ *source,* RealCauchyCompletion$^{\uparrow}$ *diagonal row,* Real$^{\uparrow}$ *seal,* hsame *and* Cont *transport rows,* Pkg *provenance, and* NameCert *row. The pullback cannot introduce a quotient stream, a selected host limit, or an independent completion object.*

Proof. Begin with the scheduled-window pullback. Once the StreamName$^{\uparrow}$ window and DyadicRatCore$^{\uparrow}$ ledger row are fixed, Definition 386.20 fixes the corresponding RegSeqRat$^{\uparrow}$ source row and the displayed transport rows in the carrier.

Use diagonal-row compatibility from Definition 386.18. The completion read tied to that scheduled window and ledger must pass through the carrier diagonal row G, so it cannot be replaced by a separate completion object.

Finally apply the downstream completion handoff of Definition 386.15 and the public route exhaustion of Definition 386.26. The same fixed window and ledger therefore force the same route through the seal and leave no quotient-stream or selected-host-limit coordinate to distinguish another pullback. □

Theorem 386.29 (CauchyLimitSeal standard boundary package)**.** *The window factorization,* Real$^{\uparrow}$ *consumer boundary, downstream completion handoff, null-sequence factorization, public route exhaustion, and pullback determinacy assemble the standard boundary package for* CauchyLimitSeal$^{\uparrow}$*. The package presents the public seal route over* RegSeqRat$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RealCauchyCompletion$^{\uparrow}$ Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, and it exports no host-limit, quotient-completion, ambient-completeness, or hidden-tail premise.*

Proof. First combine the window factorization of Definition 386.3 with the Real$^{\uparrow}$ consumer boundary of Definition 386.5. These rows route every public read from the schedule and regular source through the dyadic ledger, completion diagonal, transport rows, and seal.

Next attach the downstream completion handoff of Definition 386.15. It identifies the completion-facing side of the same route and prevents an independent completeness principle or completion object from entering the packet.

For equality-facing reads, use the null-sequence factorization of Definition 386.16. It adds only the displayed NullSequence$^{\uparrow}$ tolerance-window-threshold packet to the already fixed seal route.

Finally apply public route exhaustion and pullback determinacy from Definition 386.26 and Definition 386.28. The assembled rows give the standard boundary package because they exhaust the public carrier surface and determine each completion pullback from the displayed schedule and dyadic ledger. □

Theorem 386.30 (CauchyLimitSeal uniform-criterion pullback)**.** *Let an accepted* CauchyLimitSeal$^{\uparrow}$ *carrier present a sealed* Real$^{\uparrow}$ *read whose source family is governed by an accepted* UniformCauchyCriterion$^{\uparrow}$ *packet. Then the sealed read pulls back through the same scheduled* StreamName$^{\uparrow}$ *windows, the same* DyadicRatCore$^{\uparrow}$ *observation row, the same* RegSeqRat$^{\uparrow}$ *source row, and the same* RealCauchyCompletion$^{\uparrow}$ *diagonal row used by the seal carrier. The pullback consumes the uniform family evidence only through its finite family ledger, shared window family, uniform modulus, dyadic tolerance, tail ledger, seal handoff, and visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier uniform criterion pullback`

Proof. Project the accepted CauchyLimitSeal$^{\uparrow}$ carrier. By Definition 386.20, every sealed read on the Real$^{\uparrow}$ endpoint pulls back to a scheduled StreamName$^{\uparrow}$ finite window, its RegSeqRat$^{\uparrow}$ source row, the matching DyadicRatCore$^{\uparrow}$ observation row, and the displayed transport route.

Now project the accepted UniformCauchyCriterion$^{\uparrow}$ packet. Its Definition 435.9 route reads the finite family ledger, shared window family, uniform modulus, dyadic tolerance, and tail ledger before any real-facing seal handoff is consumed.

The two projections meet at the shared scheduled windows and dyadic observation row. The CauchyLimitSeal diagonal row remains the displayed RealCauchyCompletion$^{\uparrow}$ coordinate, while the uniform criterion contributes only the finite family-tail evidence attached to those same windows.

Finally use Definition 435.8. The uniform packet has no quotient stream family, selected family limit, host real equality, or ambient completeness coordinate, so the pullback stays inside the sealed finite route. □

Theorem 386.31 (CauchyLimitSeal uniform tail seal route)**.** *For any accepted* CauchyLimitSeal$^{\uparrow}$ *carrier whose source family is certified by an accepted* UniformCauchyCriterion$^{\uparrow}$ *packet, the route from family-tail evidence to the sealed* Real$^{\uparrow}$ *row factors through the shared family index, the shared* StreamName$^{\uparrow}$ *window family, the uniform* CauchyModulus$^{\uparrow}$ *schedule, the* DyadicRatCore$^{\uparrow}$ *tolerance row, the finite tail ledger, the* RealCauchyCompletion$^{\uparrow}$ *diagonal row, and the* Real$^{\uparrow}$ *seal. The composed route is exactly the composition of the CauchyLimitSeal window factorization, the* Real$^{\uparrow}$ *consumer boundary, and the UniformCauchyCriterion tail-ledger exactness surface.*

Proof. First apply Definition 435.9. It forces every accepted family-tail comparison through the family index, shared window family, uniform modulus, dyadic tolerance, and finite tail ledger.

Next apply Definition 386.3. The seal carrier reads the same scheduled window through the regular source row, the dyadic observation ledger, the completion diagonal row, and the displayed transport ledger before it reaches the seal.

Now attach Definition 386.5. A Real$^{\uparrow}$ consumer may read the result only after the displayed finite-window route has passed through the diagonal row and the seal row.

The composed route therefore has no branch outside the shared family index, uniform modulus, tolerance row, tail ledger, diagonal row, and seal. Package and local naming provenance are carried by the two packets' Pkg and NameCert rows. □

Theorem 386.32 (CauchyLimitSeal family seal non-escape)**.** *The composed seal route of Definition 386.31 exports no quotient stream family, no selected family limit, no ambient completeness principle, no host real equality, and no hidden tail witness. Its public surface is exactly the displayed* UniformCauchyCriterion$^{\uparrow}$ *family-tail packet together with the displayed* CauchyLimitSeal$^{\uparrow}$ *schedule, observation, diagonal, transport, package, and local naming rows.*

Proof. Start with the uniform side. By Definition 435.8, an accepted UniformCauchyCriterion$^{\uparrow}$ carrier exports only the family index ledger, shared windows, uniform modulus, dyadic tolerance, finite tail ledger, seal handoff, and visible kernel provenance rows.

Now read the seal side. The CauchyLimitSeal non-escape boundary of Definition 386.4 removes quotient streams, selected host limits, hidden tail witnesses, uniqueness theorems, and ambient completeness data from the sealed route.

Finally combine the two boundaries through Definition 386.30 and Definition 386.31. The pullback and tail route share the same windows, tolerance row, tail ledger, diagonal row, and seal, so no excluded coordinate can be introduced between the two packets. □

Theorem 386.33 (CauchyLimitSeal uniform family source)**.** *The family-source packet for the public* CauchyLimitSeal$^{\uparrow}$ *route is the finite row family over* CauchyModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, NullSequence$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* StreamName$^{\uparrow}$ *consisting of:*

1. *a shared* StreamName$^{\uparrow}$ *index schedule for the family windows;*

2. *a* $\mathsf{RegSeqRat}^{\uparrow}$ *source row for each scheduled regular rational stream;*
3. *a* $\mathsf{CauchyModulus}^{\uparrow}$ *row assigning the displayed tail modulus for the scheduled family;*
4. *a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for each requested window precision;*
5. *a* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail row witnessing that family differences vanish inside the scheduled tail;*
6. *a* $\mathsf{Real}^{\uparrow}$ *seal handoff row for the downstream real consumer.*

The packet is read only through the public route of Definition 386.6, the uniform tail route of Definition 386.31, and the family non-escape boundary of Definition 386.32.

Proof. Begin with the public route packet of Definition 386.6. It supplies the scheduled $\mathsf{StreamName}^{\uparrow}$ window family, the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source rows, the dyadic observation ledger, the completion diagonal row, and the $\mathsf{Real}^{\uparrow}$ seal row.

Attach the uniform tail route of Definition 386.31. That route adds the shared $\mathsf{CauchyModulus}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows and reads the family tail through the same scheduled windows.

Finally use the family non-escape theorem Definition 386.32. It prevents quotient stream families, selected family limits, hidden tail witnesses, and ambient completeness data from entering the source packet, so the listed six row types exhaust the family-source surface. □

Theorem 386.34 (CauchyLimitSeal family window pullback)**.** *Every family-seal consumer window of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet factors through the existing public route packet and then pulls back along the uniform-criterion route. Concretely, a consumer read must pass through the shared* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail row, the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail comparison, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row, and the* $\mathsf{Real}^{\uparrow}$ *seal before it reaches any downstream family consumer.*

Proof. First apply the public route boundary of Definition 386.8. It places every real or completion-facing consumer read inside the projected route packet X, S, D, G, E, T, P, N.

Next apply the uniform-criterion pullback of Definition 386.30. The family window is pulled back to the shared index, tolerance, and tail rows before any seal read is consumed.

Now combine the result with Definition 386.31. The route carries the uniform modulus and null-tail comparison through the same scheduled windows used by the public seal. The family non-escape boundary of Definition 386.32 then excludes any hidden completion or selected family limit outside that pullback. □

Theorem 386.35 (CauchyLimitSeal family ledger exhaustion)**.** *The family ledger for the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route contains exactly three classes of rows: source-index rows naming the* $\mathsf{StreamName}^{\uparrow}$ *schedule and* $\mathsf{RegSeqRat}^{\uparrow}$ *family entries, tail-seal rows naming the* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{NullSequence}^{\uparrow}$ *tail evidence, and* $\mathsf{Real}^{\uparrow}$ *handoff rows naming the diagonal completion route and final seal. It contains no hidden completion datum, no quotient stream family, no selected family limit, and no ambient completeness row.*

Proof. Read the source side through Definition 386.33. The only source-index data are the shared schedule and the displayed regular rational family entries.

Read the tail side through Definition 386.31. The only tail-seal data are the modulus, dyadic tolerance, null-tail comparison, and their displayed transport rows.

Read the endpoint through Definition 386.5 and the public route boundary of Definition 386.8. The endpoint is the diagonal completion route followed by the $\mathsf{Real}^{\uparrow}$ seal. The family non-escape theorem of Definition 386.32 rules out every additional hidden completion, quotient family, selected limit, or ambient completeness row, so the three listed classes exhaust the ledger. □

Theorem 386.36 (CauchyLimitSeal consumer ledger totality)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer read of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet is exhausted by the carrier rows* X, S, D, G, E, T, P, N *together with the family tail rows displayed in Definition 386.35. Equivalently, after the public route, family window pullback, and family ledger exhaustion are applied, there is no remaining consumer-visible row outside the source, schedule, dyadic observation, diagonal completion, seal, transport, provenance, naming, modulus, null-tail, and handoff ledgers.*

Proof. Start with window factorization from Definition 386.3. It places every consumer read inside the scheduled finite windows of the displayed source, observation, completion, and seal rows.

Next apply the public route boundary of Definition 386.8. The completion-facing and $\mathsf{Real}^{\uparrow}$-facing reads are therefore already routed through X, S, D, G, E, T, P, N before any downstream consumer receives them.

For family reads, pull the window back through Definition 386.34. The remaining tail-side rows are exactly the family rows listed by Definition 386.35. That theorem excludes hidden completion data, quotient stream families, selected family limits, and ambient completeness rows, so the combined list is total for consumers. □

Theorem 386.37 (CauchyLimitSeal hsame route uniqueness)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet, any displayed* hsame *transport that preserves the public carrier rows and the family tail rows induces the same consumer route through* X, S, D, G, E, T, P, N *and the family ledger of Definition 386.35. Thus a consumer cannot obtain two distinct seal routes by replaying the same window, tail, and handoff ledgers through different* hsame *witnesses.*

Proof. The carrier rows are componentwise. Transport of X, S, D, G, E, T, P, N preserves the same source, schedule, dyadic observation, diagonal completion, seal, transport, provenance, and local naming data.

The family tail is fixed by Definition 386.35. Transport can replay the source-index rows, tail-seal rows, and $\mathsf{Real}^{\uparrow}$ handoff rows, but it cannot create a fourth ledger class.

Combine these two facts with totality from Definition 386.36. Since every consumer read is already exhausted by those rows, two transports that preserve them determine the same public route boundary and the same family handoff. □

Theorem 386.38 (CauchyLimitSeal window replay determinacy)**.** *Let a downstream consumer replay a scheduled* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *window using the stored* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row,* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, family tail rows, diagonal completion row, and* $\mathsf{Real}^{\uparrow}$ *seal. The replay determines the same finite consumer ledger each time: it reuses* X, S, D, G, E, T, P, N *and the family tail rows, and it cannot alter the completion route, insert a hidden limit, or bypass the seal.*

Proof. Replay begins at the stored schedule S. The window factorization theorem sends the read through the same source row X, dyadic observation row D, diagonal completion row G, and seal row E.

The family pullback theorem then fixes the tail-side rows for that window. By family ledger exhaustion, those rows are exactly the source-index, tail-seal, and handoff rows already named in the packet.

Finally apply route uniqueness from Definition 386.37. Replaying the same displayed rows cannot change the route, and the consumer totality theorem leaves no hidden limit, alternate completion route, or seal bypass to choose. □

Theorem 386.39 (CauchyLimitSeal source factorization)**.** *Every accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer source factors through exactly the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family row,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal row,* hsame *and* Cont *transport rows,* Pkg *provenance, and* $\mathsf{NameCert}$ *row of its carrier. Family tail rows enter only through the family ledger exhaustion of Definition 386.35; no consumer source may add a hidden completion row, selected limit, quotient family, alternate seal, or unlisted dependency outside that route.*

Proof. Start with window factorization from Definition 386.3. It sends every accepted consumer read through the scheduled $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ source row, the $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger, the $\mathsf{RealCauchyCompletion}^{\uparrow}$ diagonal row, and the displayed transport rows before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Next apply the public route boundary of Definition 386.8. The carrier rows X, S, D, G, E, T, P, N are exactly the public source, schedule, observation, diagonal, seal, transport, provenance, and naming rows available to a completion-facing or $\mathsf{Real}^{\uparrow}$-facing consumer.

For family-indexed reads, use the family window pullback of Definition 386.34. The pullback may add only the uniform tail evidence attached to the same scheduled window and the same dyadic observation row.

Then invoke the family ledger exhaustion theorem Definition 386.35. It confines those tail-side rows to the source-index, tail-seal, and handoff ledgers already named by the packet, so no hidden completion or selected family limit remains.

Finally combine consumer ledger totality, hsame route uniqueness, and window replay determinacy from Definition 386.36, Definition 386.37, and Definition 386.38. The total ledger is exhausted, transport cannot split it into two consumer sources, and replay of the displayed window determines the same sealed route each time. □

Theorem 386.40 (CauchyLimitSeal family tail admission)**.** *A family-tail row is admitted by an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet only when the same finite packet displays its* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *source family,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{CauchyModulus}^{\uparrow}$ *tail row,* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail comparison,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transports,* Cont *route,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. A tail row lacking any one of these displayed coordinates is not a public family-tail row of the seal.*

Proof. Begin with the family-source packet of Definition 386.33. It names the schedule, regular source family, tail modulus, dyadic tolerance rows, null-tail comparison, and real handoff that make a family-tail row visible.

Next apply the family window pullback of Definition 386.34. The pullback attaches those rows to the same public route packet, so the diagonal completion row, seal row, transports, continuation route, provenance, and naming row are read in the same finite packet.

Finally use family ledger exhaustion from Definition 386.35. Since the ledger has only source-index, tail-seal, and handoff classes, a row missing one of the displayed coordinates has no remaining public channel through which it could be admitted. □

Theorem 386.41 (CauchyLimitSeal seal-window ledger compatibility)**.** *The seal-window route and the family-tail ledger of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet consume the same scheduled* $\mathsf{StreamName}^{\uparrow}$ *window and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row. Thus a* $\mathsf{Real}^{\uparrow}$ *consumer cannot combine the seal route from one scheduled window with the family-tail evidence of another.*

Proof. Read the public route boundary first. By Definition 386.8, the seal-window route is the projected carrier route through the displayed schedule, observation ledger, diagonal completion row, and seal row.

For the family side, apply Definition 386.34. It pulls the family-tail read back along that same public route packet, so the scheduled window and dyadic observation row are shared before any tail evidence is consumed.

Window replay determinacy from Definition 386.38 rules out a mixed route. Replaying a different schedule or observation row would change the finite ledger, while the accepted packet exposes only the stored window and observation route. □

Theorem 386.42 (CauchyLimitSeal real consumer family exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer read of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet is exhausted by the carrier route together with the family-tail ledger. The consumer may read the displayed source schedule, observation row, tail modulus, null-tail comparison, diagonal completion row, seal row,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates, and it cannot add quotient streams, hidden completion rows, selected limits, or ambient completeness.*

Proof. Start with the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5. It confines every real-facing read to the finite carrier route before the seal is exposed.

Attach the family-tail side by Definition 386.40 and Definition 386.41. These two results ensure that the tail row is admitted only with the displayed source, observation, modulus, null-tail, completion, seal, transport, continuation, provenance, and naming rows, and that it uses the same scheduled window as the seal route.

Finally apply consumer ledger totality from Definition 386.36. The combined carrier route and family ledger already exhaust the consumer-visible rows, so quotient streams, hidden completion rows, selected limits, and ambient completeness have no coordinate to enter. □

Theorem 386.43 (CauchyLimitSeal bridge interface)**.** *The* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier rows, public route packet, source factorization, family ledger exhaustion, and consumer ledger totality assemble the concrete bridge from the public sealed* $\mathsf{Real}^{\uparrow}$ *boundary to the abstract* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *interface. The bridge is entirely over the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source family,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal row,* BHist *history surface,* hsame *transport,* Cont *continuation row,* Pkg *provenance, and* NameCert *row.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealUp StdBridge`

Proof. Project the accepted packet to the carrier rows X, S, D, G, E, T, P, N of the public route packet. The public route boundary supplies the sealed $\mathsf{Real}^{\uparrow}$ side, while source factorization identifies the same rows as the abstract $\mathsf{CauchyLimitSeal}^{\uparrow}$ source surface.

The family side is supplied by ledger exhaustion. It restricts all tail and family rows to the displayed source-index, tail-seal, and handoff ledgers attached to the same schedule and dyadic observations.

Finally apply consumer ledger totality. Every public or completion-facing read is already routed through the carrier rows and the family ledger, so the bridge interface is obtained by projection and composition of those named surfaces. □

Theorem 386.44 (CauchyLimitSeal bridge route exactness)**.** *Every bridge read from the public sealed* $\mathsf{Real}^{\uparrow}$ *boundary into the abstract* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *interface factors exactly through the route chain Definition 386.8, Definition 386.34, Definition 386.35, and Definition 386.39. Hence*

no bridge consumer can read a row outside the public route, the pulled-back family window, the exhausted family ledger, and the factored source surface.

Proof. Begin with the public route boundary. It places every $\mathsf{Real}^{\uparrow}$ or completion-facing read inside the carrier route packet before any bridge handoff is interpreted.

For family-indexed reads, pull the same window back through the family window theorem. The pullback keeps the read on the shared schedule, source row, dyadic observation ledger, tail evidence, diagonal completion row, and seal row.

Apply family ledger exhaustion to remove any remaining row outside the source-index, tail-seal, and handoff ledgers. Source factorization then repacks the same routed rows as the abstract $\mathsf{CauchyLimitSeal}^{\uparrow}$ source surface, giving exactness of the bridge route. □

Theorem 386.45 (CauchyLimitSeal bridge non-escape)**.** *The CauchyLimitSeal bridge adds no quotient stream, selected host limit, uniqueness theorem, ambient completeness datum, hidden family limit, or alternate seal route. Its entire consumer-visible content is the public route packet, the pulled-back family ledger, the* $\mathsf{Real}^{\uparrow}$ *handoff, and the existing* hsame*,* Cont*,* Pkg*, and* NameCert *carrier rows.*

Proof. The bridge interface theorem confines the handoff to the carrier rows and the displayed family ledger. Thus any bridge consumer starts with only the public route packet and the already factored source surface.

Route exactness then forces every read through the public route boundary, family window pullback, family ledger exhaustion, and source factorization. Each of those theorems excludes hidden completion data, quotient stream families, selected limits, and alternate routes at the point where such a row could enter.

Therefore composition of the four route constraints leaves no escape row for the bridge to add. The bridge is a public projection of the sealed packet, not an additional completion or selection principle. □

Theorem 386.46 (CauchyLimitSeal RealUp uniqueness handoff)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet, let two* $\mathsf{Real}^{\uparrow}$*-facing consumer reads both factor through the displayed* $\mathsf{StreamName}^{\uparrow}$ *scheduled window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy readback,* $\mathsf{Real}^{\uparrow}$ *seal route, bridge route exactness row, and bridge non-escape row. Then the two reads determine the same* $\mathsf{Real}^{\uparrow}$ *consumer surface up to* hsame*. The conclusion is only a consumer-surface handoff: it does not identify quotient streams, choose a limit, assert host real equality, or import ambient completeness.*

Proof. Begin with seal-route determinacy from Definition 386.23. Once the scheduled window, dyadic observation, regular-Cauchy readback, and seal route are fixed, replaying the accepted packet cannot select a second seal-facing route.

Next apply bridge route exactness from Definition 386.44. It forces each bridge read to pass through the same public route, pulled-back family window, exhausted family ledger, and factored source surface, so the two reads have the same displayed coordinates before the $\mathsf{Real}^{\uparrow}$ handoff is consumed.

Finally use bridge non-escape from Definition 386.45. Since the bridge contributes no quotient stream, selected host limit, uniqueness principle, alternate seal, or completeness datum, repacking the shared window and seal coordinates gives one $\mathsf{Real}^{\uparrow}$ consumer surface, with equality understood only through the packet's displayed hsame transport. □

Theorem 386.47 (CauchyLimitSeal source schedule ledger coherence)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Any scheduled window selected from S determines the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *source row in X, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row in D, and the displayed* hsame *and* Cont *transport rows in T. Thus a downstream consumer cannot read a scheduled window independently from its source, observation, and transport ledger rows.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier source schedule ledger coherence`

Proof. Project the accepted carrier to its finite route coordinates. The window coordinate lies in S, and the route packet stores its associated source, dyadic observation, diagonal, seal, transport, provenance, and naming rows in the same packet X, S, D, G, E, T, P, N.

Apply the window factorization theorem Definition 386.3. It sends a selected scheduled window through the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ source row in X and the matching $\mathsf{DyadicRatCore}^{\uparrow}$ observation row in D before any diagonal or seal read is consumed.

Finally use regular-source stability from Definition 386.17. Transport of the accepted packet is allowed only along the displayed hsame comparison and Cont route, so the scheduled source and dyadic ledger rows remain coherent under downstream replay. □

Theorem 386.48 (CauchyLimitSeal sealed endpoint route exhaustion)**.** *Every downstream read on the sealed* $\mathsf{Real}^{\uparrow}$ *endpoint of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier is exhausted by the source schedule, dyadic ledger, diagonal completion row, seal row, package provenance, and local* NameCert *row displayed in $L = (X, S, D, G, E, T, P, N)$. No endpoint read can add a hidden source schedule, independent dyadic observation, alternate completion row, or external endpoint route.*

Proof. Begin with the public route boundary of Definition 386.8. It confines each $\mathsf{Real}^{\uparrow}$ or completion-facing read to the projected route packet X, S, D, G, E, T, P, N before the sealed endpoint is exposed.

Next apply seal-ledger exhaustion from Definition 386.19. The endpoint-facing ledger is exactly the displayed source, schedule, observation, diagonal completion, seal, transport, provenance, and naming surface, so no second endpoint route is available in the carrier.

Use diagonal-row compatibility from Definition 386.18. A completion read tied to the selected schedule and dyadic observation must consume the carrier diagonal row G, which prevents replacing the sealed endpoint by an independent completion object. □

Theorem 386.49 (CauchyLimitSeal lattice-meet terminal factorization)**.** *Let a terminal* $\mathsf{CauchyLimitSeal}^{\uparrow}$ $\mathsf{Real}^{\uparrow}$ *read or completion-facing read use a schedule assembled from two accepted finite* $\mathsf{StreamName}^{\uparrow}$ *windows. Then the terminal read first factors through the finite-window lattice meet packet of Definition 126.257. Only after that meet surface is displayed may the consumer read the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, the* $\mathsf{Real}^{\uparrow}$ *seal row, the displayed* hsame *and* Cont *routes, the* Pkg *provenance, and the local* NameCert *rows of the accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet.*

Thus the terminal factorization exposes only the shared finite-window meet surface and the carrier route X, S, D, G, E, T, P, N. It supplies no quotient stream, selected host limit, host real equality, uniqueness principle, or ambient completeness coordinate.

Proof. Start with the two accepted $\mathsf{StreamName}^{\uparrow}$ windows. The finite-window lattice meet exhaustion theorem Definition 126.257 supplies one shared meet packet carrying the common classifier, ProbeBundle rows, InBundle membership rows, unary-history rows, dyadic ledger, transports, routes, package provenance, and local names.

Next pass the resulting schedule to the seal carrier. The window factorization theorem Definition 386.3 sends the scheduled window through the matching $\mathsf{RegSeqRat}^{\uparrow}$ source row and $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger before any diagonal completion or $\mathsf{Real}^{\uparrow}$ seal read is consumed.

Now apply the public route boundary of Definition 386.8. The terminal $\mathsf{Real}^{\uparrow}$ or completion-facing consumer is confined to the displayed carrier route X, S, D, G, E, T, P, N, and Definition 386.36 exhausts the consumer-visible ledger along that route.

Finally use non-escape from Definition 386.4. Since neither the StreamName meet packet nor the CauchyLimitSeal carrier has a coordinate for quotient streams, selected host limits, host real equality, uniqueness principles, or ambient completeness, the terminal read can only be the displayed finite meet followed by the displayed seal route. □

Theorem 386.50 (CauchyLimitSeal NameCert downstream unblock package)**.** *The source-schedule ledger coherence row of Definition 386.47 and the sealed endpoint route exhaustion row of Definition 386.48, together with Definition 386.2, Definition 386.5, and Definition 386.4, supply the downstream obligation package for* $\mathsf{Real}^{\uparrow}$ *and completion consumers over* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. The package exposes only the finite sealed boundary and does not claim real completeness, quotient stream identity, selected host limits, or uniqueness of ambient real values.*

Proof. Project the finite packet $L = (X, S, D, G, E, T, P, N)$. The $\mathsf{NameCert}$ obligations of Definition 386.2 provide carrier habitation, classifier stability, finite-route exactness, and the local naming row needed by downstream consumers.

Route reads through the scheduled window and dyadic ledger using Definition 386.47. This supplies the matching $\mathsf{RegSeqRat}^{\uparrow}$ source row, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ observation row, and displayed hsame and Cont transports before a consumer reaches the completion or real endpoint.

Then apply sealed endpoint route exhaustion from Definition 386.48 and the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5. These rows identify the diagonal completion, seal, package provenance, and local naming coordinates that a $\mathsf{Real}^{\uparrow}$ or completion consumer may read.

Finally use non-escape from Definition 386.4. Since the carrier has no coordinate for quotient streams, selected host limits, uniqueness principles, or ambient completeness, the assembled package is a constructive downstream boundary over exactly the displayed BEDC objects. □

Theorem 386.51 (CauchyLimitSeal RealCompleteness diagonal consumer exactness)**.** *Every* $\mathsf{RealCompleteness}^{\uparrow}$ *diagonal consumer of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet factors through the same scheduled* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal row, and displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows named by the seal packet. The consumer exports no quotient stream, selected host limit, independent completeness proof, or alternate diagonal route.*

Proof. Start from the RealCompleteness consumer relation opened in chapter 450. A diagonal consumer may read the seal only as a completion-facing or $\mathsf{Real}^{\uparrow}$-facing downstream boundary, so its entrance is the accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ packet.

Apply source-schedule ledger coherence from Definition 386.47. This identifies the scheduled $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ source row, and the $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger before any diagonal or seal endpoint is consumed.

Next use sealed endpoint route exhaustion from Definition 386.48. The completion row, seal row, displayed BHist data, hsame transports, Cont routes, Pkg provenance, and local $\mathsf{NameCert}$ row are exactly the endpoint-facing route exposed by the packet.

Finally apply the downstream unblock package of Definition 386.50. Since that package has no coordinate for quotient streams, selected host limits, independent completeness proofs, or alternate diagonal routes, the RealCompleteness diagonal consumer is forced to factor through the same finite seal route. □

Theorem 386.52 (CauchyLimitSeal tail-choice exhaustion)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet, every admitted tail-choice read is exhausted by a finite* $\mathsf{StreamName}^{\uparrow}$ *window, the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, the null-tail comparison row, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row, the* $\mathsf{Real}^{\uparrow}$ *seal row, the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. No admitted tail choice can depend on a quotient representative, a selected host limit, an unbounded stream schedule, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier tail choice exhaustion`

Proof. Begin with the RealUp uniqueness handoff. It already forces any two real-facing reads through the same scheduled window, dyadic observation, regular-Cauchy readback, seal route, bridge exactness row, and bridge non-escape row before the consumer surface is compared.

Attach family-tail admission and seal-window ledger compatibility. These rows make the tail choice visible only as a finite comparison over the stored source window, observation ledger, null-tail row, diagonal completion row, seal row, transport row, route row, provenance row, and local certificate row.

Finally use bridge non-escape and consumer ledger totality. Since those rows leave no coordinate for quotient representatives, selected host limits, unbounded schedules, or ambient completeness, the displayed finite window exhausts every admitted tail-choice read. □

Theorem 386.53 (CauchyLimitSeal Real handoff exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *handoff produced by an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet is the concatenation of the tail-choice exhaustion row with the public route packet and the* $\mathsf{Real}^{\uparrow}$ *consumer boundary. The handoff exports only the displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier real handoff exhaustion`

Proof. First apply tail-choice exhaustion to place the handoff on a finite scheduled window with its regular source row, dyadic observation ledger, null-tail comparison, completion diagonal, and seal row.

Next compose with the public route boundary. The public route packet records exactly the same carrier coordinates X, S, D, G, E, T, P, N, so the tail-choice surface and the real-facing surface use one route spine.

The $\mathsf{Real}^{\uparrow}$ consumer boundary then supplies the endpoint. It allows the consumer to read the sealed finite-window route and nothing outside the displayed transport, route, provenance, and naming rows. □

Theorem 386.54 (CauchyLimitSeal ledger non-escape totality)**.** *The tail-choice ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, and the* $\mathsf{Real}^{\uparrow}$ *seal rows of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet are total for downstream Real-and-Completion consumers. Any consumer read that is not routed through those displayed ledgers is outside the packet and cannot be converted into a hidden completion row, alternate seal, quotient stream, chosen limit, or host real equality.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier ledger nonescape totality`

Proof. Use the real handoff exhaustion theorem to identify the only exported route. It is the finite concatenation of the tail-choice row, the public route packet, and the real consumer boundary.

For completion-facing reads, apply the completion-budget factorization and the observation-budget consumer package. These results keep the read on the same scheduled regular source, dyadic ledger, diagonal completion row, seal row, transport, continuation, provenance, and naming rows.

Thus the displayed ledgers are total for the downstream consumer surface. A read outside them has no carrier coordinate and therefore cannot be repacked as hidden completion data, an alternate seal, quotient equality, a chosen limit, or host real equality. □

Theorem 386.55 (CauchyLimitSeal RegSeqRat StreamName dyadic handoff)**.** *Every accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet routes a consumer from its displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source family through the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger before any* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row or* $\mathsf{Real}^{\uparrow}$ *seal row is consumed. The handoff is carried by the same* BHist *surface,* hsame *transport,* Cont *route,* Pkg *provenance, and local* NameCert *row that appear in the accepted seal packet.*

Proof. Start with the window factorization of Definition 386.3. It places every consumer read on the displayed regular source family, scheduled window, dyadic observation ledger, completion diagonal, and seal row of the carrier.

Next apply the scheduled-window pullback of Definition 386.20. The pullback forces a read that reaches the seal to pass first through the same $\mathsf{StreamName}^{\uparrow}$ window, its $\mathsf{RegSeqRat}^{\uparrow}$ source row, and the matching dyadic ledger.

Finally replay the dyadic observation by Definition 386.21. The replay identifies the observation row as the stored $\mathsf{DyadicRatCore}^{\uparrow}$ ledger with the visible transport, route, provenance, and naming rows, so no completion diagonal or seal row is available before that handoff has occurred. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier dyadic handoff`

Theorem 386.56 (CauchyLimitSeal completion budget factorization)**.** *Any completion-facing or* $\mathsf{RealObservationBudget}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet factors through Definition 386.55, the public route boundary, the family ledger exhaustion, and the* $\mathsf{Real}^{\uparrow}$ *consumer boundary. The resulting consumer surface exports only the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal row,* BHist *history surface,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row; it exports no quotient stream, selected limit, host real equality, hidden family limit, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier completion budget factorization`

Proof. First use the handoff theorem above to put the consumer on the scheduled regular-source and dyadic-observation route before any completion or seal row is read.

Next apply the public route boundary of Definition 386.8 and family ledger exhaustion from Definition 386.35. These two constraints keep the read inside the carrier rows and the exhausted source-index, tail-seal, and handoff ledger classes.

Finally combine the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5 with the observation-budget consumer exactness of Definition 611.9. The real-facing and budget-facing consumers therefore read the same finite route surface, with no remaining coordinate for quotient streams, selected limits, host real equality, hidden family limits, or ambient completeness. □

Theorem 386.57 (CauchyLimitSeal root unblock package)**.** *The* CauchyLimitSeal$^{\uparrow}$ *carrier, the* RegSeqRat$^{\uparrow}$–StreamName$^{\uparrow}$–DyadicRatCore$^{\uparrow}$ *handoff of Definition 386.55, the completion-budget factorization of Definition 386.56, the bridge interface, bridge route exactness, and bridge non-escape jointly supply the root-unblock package for downstream* Real$^{\uparrow}$ *and completion consumers over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The package gives one cited route from accepted seal packets to the downstream consumer boundary, and it does not add quotient completion, selected limits, host real equality, hidden family limits, or ambient completeness.*

Proof. Begin with the accepted carrier and attach the handoff theorem. This supplies the concrete regular-source, scheduled-window, and dyadic-observation route before the completion diagonal and seal are consumed.

Then compose with the completion-budget factorization. It turns the routed handoff into the consumer-facing surface used by completion and RealObservationBudget$^{\uparrow}$ reads, while preserving only the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates.

Finally apply the bridge interface of Definition 386.43, bridge route exactness from Definition 386.44, and bridge non-escape from Definition 386.45. These rows repack the same routed packet as the public bridge package and exclude every hidden completion, quotient, selection, host-equality, or ambient-completeness escape route. □

Theorem 386.58 (CauchyLimitSeal observation-budget pullback)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* CauchyLimitSeal$^{\uparrow}$ *packet, and let* $B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$ *be an accepted* RealObservationBudget$^{\uparrow}$ *packet. If the seal row* S_B *is transported to the seal row* E *of* L*, and the regular handoff rows* R_B *cover the source row* X*, then every budget read of* B *pulls back to the public route packet of* L*. The pulled-back route reads only the finite precision request, windows, dyadic ledger, regular handoff, seal row,* BHist *surface,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates already displayed by* B *and* L*.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier observation budget pullback`

Proof. Start with the finite budget packet. Window coverage from Definition 611.3 places each budget read over the displayed precision request E_B, finite windows W_B, and dyadic ledger D_B.

Next apply the regular handoff and seal boundary. The handoff theorem Definition 611.4 routes the regular rows R_B through the same finite windows, while Definition 611.5 makes S_B the real-facing seal boundary of the budget packet.

Transport the seal row to E and the handoff rows to X. The public route boundary of Definition 386.8 then identifies the resulting read with the route packet X, S, D, G, E, T, P, N of the accepted CauchyLimitSeal$^{\uparrow}$ carrier. □

Theorem 386.59 (CauchyLimitSeal budgeted tail comparison admission)**.** *A family-tail comparison row is admitted through an accepted* CauchyLimitSeal$^{\uparrow}$ *packet only when the same finite* RealObservationBudget$^{\uparrow}$ *packet displays the precision request, finite windows, dyadic ledger, regular handoff, seal row, transports, routes, provenance, and local* NameCert *row consumed by the seal packet. A comparison row that lacks any one of those displayed budget coordinates is not an admitted CauchyLimitSeal family-tail comparison row.*

Proof. First use family-tail admission from Definition 386.40. It requires the source family, schedule, tail modulus, null-tail comparison, diagonal completion row, seal row, transports, continuation route, provenance, and local naming row to be displayed in the accepted seal packet.

Next use seal-window ledger compatibility from Definition 386.41. This ties the tail comparison to the same scheduled window and dyadic observation row used by the seal route, so the comparison cannot be read from a different finite budget.

Finally apply $\mathsf{RealObservationBudget}^{\uparrow}$ consumer exactness from Definition 611.9. Exactness says the regular and real-facing consumers read precisely the budget packet, so an admitted tail comparison must carry the same precision, window, ledger, handoff, seal, transport, route, provenance, and naming rows. □

Theorem 386.60 (CauchyLimitSeal RealObservationBudget consumer package)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer that enters through an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *packet and exits through an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet reads exactly the union of the budget rows and the seal rows. The union is taken over the shared* BHist *surface,* hsame *transports,* Cont *routes,* Pkg *provenance, and* NameCert *rows, and it exposes no quotient stream, selected host limit, ambient completeness principle, hidden family limit, or unbounded schedule.*

Proof. Begin with the observation-budget pullback of Definition 386.58. It sends every finite budget read into the public route packet of the accepted seal carrier, preserving the displayed budget rows and the shared transport, route, provenance, and naming data.

Attach the tail comparison by Definition 386.59. A family-tail comparison is admitted only when it is read through the same finite budget surface consumed by the seal route.

Now compose with consumer ledger totality from Definition 386.36 and real consumer family exhaustion from Definition 386.42. The budget route and the seal route already exhaust the consumer-visible rows, leaving no coordinate for quotient streams, selected host limits, ambient completeness, hidden family limits, or unbounded schedules. □

Theorem 386.61 (CauchyLimitSeal RealObservationBudget handoff)**.** *Every accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet whose route passes through an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *packet factors its* $\mathsf{Real}^{\uparrow}$ *endpoint through the shared finite rows*

$$E, W, D, R, S, H, C, P, N$$

of chapter 611, together with the seal rows

$$X, S, D, G, E, T, P, N$$

already displayed by $\mathsf{CauchyLimitSeal}^{\uparrow}$*. The handoff exposes no quotient stream, selected host limit, hidden family limit, unbounded schedule, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier real observation budget handoff`

Proof. Begin with the observation-budget pullback of Definition 386.58. It sends the accepted budget packet to the public route of the accepted seal packet while preserving the displayed budget rows, seal rows, transports, routes, provenance, and local naming rows.

Next apply budgeted tail comparison admission from Definition 386.59. The tail comparison is admitted only when it uses the same finite $\mathsf{RealObservationBudget}^{\uparrow}$ precision, window, dyadic, regular-handoff, seal, transport, continuation, provenance, and naming rows.

Attach the $\mathsf{RealObservationBudget}^{\uparrow}$ consumer package of Definition 386.60. This identifies the consumer-facing route with the union of the budget packet and the seal packet over the shared BHist, hsame, Cont, Pkg, and NameCert surface.

Finally use ledger non-escape totality from Definition 386.54. The route has no remaining coordinate for a quotient stream, selected host limit, hidden family limit, unbounded schedule, or ambient completeness, so projecting the common finite rows gives the stated handoff. □

Theorem 386.62 (CauchyLimitSeal consumer observation-budget readback)**.** *Any* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet that requests an observation-budget row must factor through the displayed* $\mathsf{RealObservationBudget}^{\uparrow}$ *handoff, the finite tail selector,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. The consumer cannot read an additional hidden budget, quotient stream, selected host limit, hidden family limit, unbounded schedule, or ambient completeness witness.*

Proof. Start with the observation-budget pullback of Definition 386.58. It routes every budget-mediated real or completion read into the accepted seal packet while preserving the displayed budget rows, seal rows, transports, continuations, provenance, and local naming rows.

Apply the RealObservationBudget handoff of Definition 386.61. This identifies the $\mathsf{Real}^{\uparrow}$ endpoint with the shared finite budget and seal surface rather than with a detached completion object.

For selector-mediated reads, use the finite-budget selector pullback of Definition 386.63. It keeps the selected tail and real-seal rows on the same finite selector, budget, transport, route, provenance, and naming ledger.

Finally apply the consumer uniform route lock of Definition 386.78. Since the visible route is exhausted by the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, no hidden observation budget remains. □

Theorem 386.63 (CauchyLimitSeal finite-budget selector pullback)**.** *Let F be an accepted* $\mathsf{FiniteObservationBudget}$ *route whose displayed route surface is read over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. Suppose the* $\mathsf{Real}^{\uparrow}$ *seal row selected by F is consumed by an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *packet, and that this budget packet is then consumed by an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet. Then the composite consumer route pulls back to one finite route over exactly the displayed selector, budget, and seal rows. The route exposes no quotient stream, selected host limit, host real equality, hidden family limit, countable choice, or ambient completeness principle.*

Proof. Start with the public export of $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ from Definition 782.14. It makes the selector route a finite packet over the displayed stream name, dyadic rational core, regular rational sequence, real seal row, history, transport, continuation, package, and naming rows.

Next attach the observation-budget pullback of Definition 386.58. The accepted $\mathsf{RealObservationBudget}^{\uparrow}$ consumer can read the selected seal only through its finite precision request, windows, dyadic ledger, regular handoff, seal row, transports, routes, provenance, and local naming data.

Now use the RealObservationBudget handoff of Definition 386.61. This identifies the $\mathsf{Real}^{\uparrow}$ endpoint of the composite route with the shared finite budget and seal rows rather than with a detached real-completion object.

Finally apply ledger non-escape totality from Definition 386.54. Since the selector export, budget pullback, and seal handoff have already accounted for every visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ coordinate, no quotient stream, selected host limit, host real equality, hidden family limit, countable-choice witness, or ambient completeness witness remains available to the consumer. □

Definition 386.64 (CauchyLimitSeal RealTailAgreement route)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet*

$$L = (X, S, D, G, E, T, P, N),$$

the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *route of L is the finite handoff that first projects the admitted tail reads of L through the displayed source family, schedule, dyadic observation ledger, diagonal row, seal*

row, transports, continuation route, provenance, and local naming row, and then reads the paired tail-agreement rows of chapter 699. Its consumer surface is the displayed route

$$X, S, D, G, E, T, P, N \quad \longrightarrow \quad R, S, W, D, A, H, C, P, N,$$

where the right-hand packet is the paired source, finite window, dyadic readback, agreement, transport, continuation, provenance, and naming surface of $\mathsf{RealTailAgreementSeal}^{\uparrow}$. *The route is not a quotient-stream equality, a host real equality, a selected host limit, a hidden tail selector, or an ambient completeness row.*

Theorem 386.65 (CauchyLimitSeal RealTailAgreement handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet that compares two sealed tails factors through the route of Definition 386.64. The comparison may read only the CauchyLimitSeal rows* X, S, D, G, E, T, P, N *followed by the paired* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *rows* $R, S, W, D, A, H, C, P, N$*; it cannot substitute a quotient stream, host real equality, selected host limit, hidden family limit, unbounded schedule, or ambient completeness principle for the displayed agreement row.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier real tail agreement handoff`

Proof. Begin with the $\mathsf{RealObservationBudget}^{\uparrow}$ handoff of Definition 386.61. It places the completion-facing read on the finite budget rows and the accepted seal rows, with the shared BHist, hsame, Cont, Pkg, and NameCert surface already fixed.

Next project the sealed tails by Definition 386.70. The tail reads are therefore the displayed regular-family, schedule, dyadic, diagonal, seal, transport, continuation, provenance, and naming rows of the same accepted packet, not external tails chosen from a quotient or host limit.

Finally attach the paired-window route of Definition 699.52 and the Real–Completion boundary of Definition 699.58. These rows force every paired tail comparison through $W \to D \to A$, so the consumer factors through the route named in Definition 386.64. □

Theorem 386.66 (CauchyLimitSeal regular-tail-fiber consumer boundary)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet. Any accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer comparing sealed tails through an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *packet factors through the displayed CauchyLimitSeal rows* X, S, D, G, E, T, P, N*, the paired tail-fiber rows of chapter 893, the tail-meet route of chapter 560, and the common* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *surface. The route exports no quotient-stream equality, selected host limit, host real equality, hidden family limit, unbounded schedule, or ambient completeness principle.*

Proof. Start with the RealTailAgreement handoff of Definition 386.65. It places the paired sealed-tail comparison on the displayed CauchyLimitSeal rows and the finite paired-tail agreement rows before any consumer-facing comparison is available.

Next apply ledger non-escape totality from Definition 386.54. The accepted packet therefore has no coordinate for quotient representatives, selected host limits, host real equality, hidden family limits, unbounded schedules, or ambient completion data outside the shown BHist, hsame, Cont, Pkg, and NameCert boundary.

Finally use the RegularCauchyTailMeet seal consumer tail-fiber factorization of Definition 560.92. That factorization routes the accepted tail-fiber packet through the paired regular-tail fiber surface and then through the tail-meet route, so the CauchyLimitSeal consumer obtains exactly the finite handoff stated above. □

Theorem 386.67 (CauchyLimitSeal Real consumer budget exhaustion)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* CauchyLimitSeal$^{\uparrow}$ *packet. Every* Real$^{\uparrow}$*- or completion-facing consumer of L whose route passes through an accepted* RealObservationBudget$^{\uparrow}$ *packet, an accepted* FiniteObservationBudgetSelector$^{\uparrow}$ *route, or the* RealTailAgreementSeal$^{\uparrow}$ *route of Definition 386.64 is exhausted by the displayed* RegSeqRat$^{\uparrow}$ *family,* StreamName$^{\uparrow}$ *schedule,* DyadicRatCore$^{\uparrow}$ *ledger,* RealObservationBudget$^{\uparrow}$ *packet,* RealTailAgreementSeal$^{\uparrow}$ *comparison rows,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. No such consumer can add a quotient stream, selected host limit, host real equality, hidden family limit, countable-choice witness, or ambient completeness principle to that packet-local route.*

Proof. Start with the observation-budget pullback of Definition 386.58 and the RealObservation-Budget handoff of Definition 386.61. They place every budget-mediated real or completion read on the finite budget rows together with the accepted seal rows, over the common BHist, hsame, Cont, Pkg, and NameCert surface.

For selector-mediated reads, apply the finite-budget selector pullback of Definition 386.63. The selected Real$^{\uparrow}$ seal row remains tied to the same StreamName$^{\uparrow}$ schedule, RegSeqRat$^{\uparrow}$ family, DyadicRatCore$^{\uparrow}$ ledger, budget packet, transport rows, routes, provenance, and local naming row.

For paired-tail reads, use the route definition of Definition 386.64 and the handoff of Definition 386.65. The comparison therefore runs through the displayed RealTailAgreementSeal$^{\uparrow}$ rows and their $W \to D \to A$ agreement boundary rather than through an external equality object.

Finally apply ledger non-escape totality from Definition 386.54. The three routes have already accounted for the family, schedule, dyadic ledger, budget packet, paired-tail comparison rows, histories, transports, continuations, package provenance, and naming data, so no quotient stream, selected host limit, host real equality, hidden family limit, countable-choice witness, or ambient completeness coordinate remains available. □

Theorem 386.68 (CauchyLimitSeal diagonal tail selector boundary)**.** *The diagonal tail selector read associated to an accepted* CauchyLimitSeal$^{\uparrow}$ *packet remains a finite scheduled route through chapter 697. It may supply the scheduled window and cofinal tail rows consumed by the seal route, but it does not become a selected host limit, quotient stream representative, host convergence proof, hidden tail selector, or ambient completeness principle.*

Proof. Start with window factorization from Definition 386.3. It places the seal consumer on the displayed source family, schedule, dyadic observation ledger, completion diagonal, seal row, and transport route before any selector read is available.

Use tail extraction from Definition 386.70. The tail exposed to the diagonal route is a projection of the accepted seal packet, so it remains tied to X, S, D, G, E, T, P, N and the visible BHist, hsame, Cont, Pkg, and NameCert rows.

Now apply the DiagonalTailSelector$^{\uparrow}$ limit handoff and non-escape boundary from Definition 697.6 and Definition 697.42. The selector contributes a finite scheduled route only, and the cited non-escape boundary rules out selected host limits, quotient representatives, host convergence, hidden tail selectors, and ambient completeness. □

Theorem 386.69 (CauchyLimitSeal tail-fiber selector factorization)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* CauchyLimitSeal$^{\uparrow}$ *packet. Any consumer route for L that uses both a common-tail comparison and a diagonal selector factors through the shared finite envelope consisting of the* RegularCauchyTailFiber$^{\uparrow}$ *carrier rows, the* DiagonalTailSelector$^{\uparrow}$ *scheduled and cofinal window rows, the* RegSeqRat$^{\uparrow}$ *source family, the* StreamName$^{\uparrow}$ *schedule, the* DyadicRatCore$^{\uparrow}$ *ledger, the* Real$^{\uparrow}$ *seal row, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The factorized route exports*

no quotient stream, selected host limit, hidden selector, host real equality, or ambient completeness coordinate.

Proof. Start with the diagonal selector boundary of Definition 386.68. It says that any selector read entering the accepted seal packet contributes only scheduled window and cofinal tail rows, with no selected host limit, quotient representative, host convergence proof, hidden selector, or ambient completeness datum.

Now attach the common-tail fiber side. The completion handoff scope of Definition 893.21 places completion-facing reads on the $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ carrier rows, while the source-seal ledger totality of Definition 893.19 accounts for the source, seal, history, transport, continuation, package, and naming rows.

Finally apply the consumer route lock of Definition 386.78. The seal admits no consumer coordinate beyond the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ surface. Combining this exhaustion with the selector boundary and the tail-fiber ledger leaves exactly the stated finite envelope. □

Theorem 386.70 (CauchyLimitSeal tail extraction)**.** *Every admitted tail read of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet is projected from the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row, and visible* hsame *and* Cont *ledger. The projection is the same public route consumed by the seal packet, not a tail chosen from a quotient stream, host limit, hidden family limit, or ambient completeness principle.*

Proof. Begin with family-tail admission. By Definition 386.40, a tail read is admitted only with the displayed source family, schedule, tail modulus, null-tail comparison, completion diagonal, seal row, transports, route, provenance, and local naming row.

Next attach seal-window ledger compatibility from Definition 386.41. The admitted tail therefore uses the same scheduled window and dyadic observation ledger as the seal route.

Finally pull the observation budget back along Definition 386.58. The tail read is projected through the displayed regular family, schedule, dyadic ledger, diagonal row, and visible hsame and Cont route, with no remaining coordinate for an external tail source. □

Theorem 386.71 (CauchyLimitSeal uniqueness boundary)**.** *Every equality or uniqueness-facing consumer of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet may use only the visible null-sequence and tail-comparison route. It cannot import a host uniqueness theorem, quotient-stream equality, selected limit, hidden family limit, or ambient completeness datum.*

Proof. Start with the non-escape boundary of Definition 386.4. The accepted packet contains no host uniqueness theorem, quotient representative, selected limit, or ambient completeness coordinate.

For the comparison itself, use null-sequence factorization from Definition 386.16. Equality-facing reads can add only the displayed $\mathsf{NullSequence}^{\uparrow}$ tolerance-window-threshold row to the already fixed seal route.

Then apply budgeted tail comparison admission from Definition 386.59. A uniqueness-facing read is therefore admitted only through the same finite budget, scheduled window, dyadic ledger, regular handoff, seal, transport, route, provenance, and naming rows. □

Theorem 386.72 (CauchyLimitSeal formal target surface)**.** *The Lean-facing surface for* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *is the displayed carrier packet* $L = (X, S, D, G, E, T, P, N)$ *over* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$, *with dependency rows for* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{UniformCauchyCriterion}^{\uparrow}$. *Its target obligations are exactly carrier admission, finite-window factorization, consumer readback,*

and exclusion of quotient streams, selected limits, host real equality, hidden family limits, and ambient completeness.

Proof. Use the NameCert obligation surface of Definition 386.2. It names the carrier, classifier stability, exact consumer route, and non-escape clauses as the local obligations.

Then apply window factorization from Definition 386.3 and the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5. These rows identify the finite route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, the observation ledger, the diagonal row, and the seal.

Finally pull the family side through Definition 386.30 and package the budget-facing endpoint by Definition 386.60. The resulting surface is the stated collection of concrete BEDC rows and no hidden completion coordinate remains. □

Theorem 386.73 (CauchyLimitSeal finite-route uniqueness envelope)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet, a* $\mathsf{Real}^{\uparrow}$*- or completion-facing consumer route is uniqueness-admissible exactly when it factors through the displayed finite envelope consisting of the* $\mathsf{RegSeqRat}^{\uparrow}$ *source family,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row,* $\mathsf{Real}^{\uparrow}$ *seal row, null-comparison and tail-comparison rows,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. A route that requires a quotient stream, selected host limit, host real equality, hidden family limit, unbounded schedule, or ambient completeness datum is outside the envelope and is not uniqueness-admissible for the packet.*

Proof. For the forward direction, start with tail extraction from Definition 386.70. It projects every admitted tail read onto the displayed regular source family, scheduled window, dyadic observation ledger, completion diagonal, and visible transport route.

Next apply the uniqueness boundary of Definition 386.71. It adds only the visible null-sequence and tail-comparison route to the same finite surface and excludes host uniqueness, quotient-stream equality, selected limits, hidden family limits, and ambient completeness.

Now use ledger non-escape totality from Definition 386.54 and the formal target surface of Definition 386.72. These two rows say that downstream Real-and-Completion consumers have no remaining coordinate beyond the displayed history, transport, continuation, provenance, and naming rows.

Finally attach the $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{StreamName}^{\uparrow}$–$\mathsf{DyadicRatCore}^{\uparrow}$ handoff of Definition 386.55. The consumer therefore reaches any uniqueness-facing comparison only through the stated finite envelope.

Conversely, any route already factoring through that envelope uses exactly the rows admitted by the tail-extraction, uniqueness-boundary, non-escape, target-surface, and handoff theorems. Replaying those rows gives an admitted packet-local uniqueness route, with no quotient stream, selected host limit, host real equality, hidden family limit, unbounded schedule, or ambient completeness datum to discharge. □

Theorem 386.74 (CauchyLimitSeal paired tail-agreement uniqueness)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet, any two* $\mathsf{Real}^{\uparrow}$*- or completion-facing paired-tail agreement reads that factor through the finite-route uniqueness envelope of Definition 386.73 and the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *route of Definition 386.65 expose the same packet-local agreement boundary. Conversely, every packet-local paired-tail uniqueness read for the packet factors through that finite envelope together with the displayed* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *handoff. Thus the only admissible boundary is the one read from the packet's visible source family, schedule, dyadic ledger, completion diagonal, seal row, null-comparison and tail-comparison rows, transports, continuation routes, provenance, and local naming row.*

Proof. First project both paired-tail reads onto the accepted packet surface. Tail extraction in Definition 386.70 places each read on the displayed regular source family, scheduled window, dyadic observation ledger, completion diagonal, seal row, and visible transport route.

Next apply the uniqueness boundary and the finite-route envelope from Definition 386.71 and Definition 386.73. These two rows allow only the packet-local null-comparison and tail-comparison route to contribute to a uniqueness-facing read, while excluding quotient streams, host real equality, selected host limits, hidden family limits, unbounded schedules, and ambient completeness.

Now attach the handoff through Definition 386.65. The paired comparison is therefore read through the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ completion consumer ledger of Definition 699.52 and the Real–Completion boundary of Definition 699.58, so both reads reach the same $W \to D \to A$ agreement row.

Conversely, a packet-local paired-tail uniqueness read has no coordinate outside the accepted packet boundary by the same uniqueness and non-escape clauses. Replaying tail extraction, the finite envelope, and the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ handoff supplies the required factorization through the displayed route, with no additional host or completion datum to discharge. □

Theorem 386.75 (CauchyLimitSeal Lean carrier admission)**.** *A formal* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier is admitted only when its displayed* BHist *packet presents the same* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *source,* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *tail criterion,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row consumed by the chapter route. A tuple lacking one of these rows is outside the carrier surface.*

Proof. Start from carrier habitation in Definition 386.2. The carrier is the finite packet and its accepted rows are the only rows available for classifier transport.

Use Definition 386.3 to place every consumer-facing read on the schedule, source, observation, diagonal, seal, and transport rows. The family-tail side is then pulled back by Definition 386.30, which supplies the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ criterion without adding an external family limit.

The consumer boundary of Definition 386.5 closes the admission test: if one displayed row is absent, the tuple has no route to the sealed $\mathsf{Real}^{\uparrow}$ endpoint and cannot be admitted as a formal carrier. □

Theorem 386.76 (CauchyLimitSeal verification handoff)**.** *The verification handoff for* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *is the finite chain from* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows through the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *pullback and the* $\mathsf{Real}^{\uparrow}$ *consumer boundary to the* $\mathsf{RealObservationBudget}^{\uparrow}$ *package. Along this chain all reads preserve the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows, so downstream Real and Completion formalization has a single concrete theorem surface to consume.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier verification handoff`

Proof. First apply window factorization and the $\mathsf{Real}^{\uparrow}$ consumer boundary. They route the source schedule and regular source through the observation ledger, completion diagonal, seal, and displayed transport rows.

Next use the uniform-criterion pullback of Definition 386.30. It aligns the family-tail criterion with the same scheduled route and prevents the handoff from selecting an independent host limit.

Finally attach the $\mathsf{RealObservationBudget}^{\uparrow}$ consumer package of Definition 386.60. Together with the carrier obligations of Definition 386.2, it gives the formalization side one route-preserving packet over the displayed history, transport, continuation, provenance, and naming rows. □

Theorem 386.77 (CauchyLimitSeal finite-window budget equivalence)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet, and let* $B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$ *be an*

accepted RealObservationBudget$^{\uparrow}$ *packet. Assume that the seal row* S_B *and the regular-handoff rows* R_B *transport to the seal and source rows of* L*. Then a* Real$^{\uparrow}$*- or completion-facing consumer route is admitted through the pair* (L, B) *exactly when it factors through the common finite envelope consisting of the* StreamName$^{\uparrow}$ *window* W_B*, the* RegSeqRat$^{\uparrow}$ *source* X*, the* DyadicRatCore$^{\uparrow}$ *observation ledgers* D *and* D_B*, the* UniformCauchyCriterion$^{\uparrow}$ *tail ledger, the* RealObservationBudget$^{\uparrow}$ *budget rows* $E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B$*, the* Real$^{\uparrow}$ *seal row* E*, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of the two packets.*

Proof. For the forward direction, apply the observation-budget pullback of Definition 386.58. It sends every accepted budget read into the public route packet of L while preserving the precision request, finite windows, dyadic ledger, regular handoff, seal row, transports, continuations, provenance, and local naming rows.

Next apply budgeted tail comparison admission from Definition 386.59. The tail-facing comparison is admitted only through the same budget surface, so the UniformCauchyCriterion$^{\uparrow}$ tail ledger, the scheduled StreamName$^{\uparrow}$ window, and the RegSeqRat$^{\uparrow}$ source all remain in the displayed finite envelope.

Use the RealObservationBudget$^{\uparrow}$ consumer package of Definition 386.60 to identify the real or completion consumer route with the union of the budget rows and the seal rows over the shared BHist, hsame, Cont, Pkg, and NameCert surface.

Finally attach the verification handoff of Definition 386.76. This supplies the reusable finite route from StreamName$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ through the uniform criterion and the Real$^{\uparrow}$ boundary, so no quotient stream, selected host limit, host real equality, hidden family limit, unbounded schedule, or ambient completeness coordinate remains.

For the reverse direction, suppose the route already factors through the displayed envelope. Each coordinate is one of the rows admitted by the pullback, budgeted tail comparison, consumer package, and verification handoff just cited. Replaying those rows admits the same real or completion consumer route through (L, B), because no additional row is required outside the common finite packet. □

Theorem 386.78 (CauchyLimitSeal consumer uniform route lock)**.** *Any* UniformCauchyCriterion$^{\uparrow}$ *or completion-facing consumer entering through an accepted* CauchyLimitSeal$^{\uparrow}$ *packet must factor through the same displayed* RegSeqRat$^{\uparrow}$ *source,* StreamName$^{\uparrow}$ *scheduled window,* DyadicRatCore$^{\uparrow}$ *ledger,* RealCauchyCompletion$^{\uparrow}$ *diagonal row,* Real$^{\uparrow}$ *seal row,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. The finite-window budget envelope admits no quotient stream, selected host limit, host real equality, hidden family limit, unbounded schedule, independent completion row, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier consumer uniform route lock`

Proof. Start from the CauchyLimitSeal handoff surface of Definition 386.2 and the public route packet of Definition 386.8. These rows display the regular source, scheduled window, dyadic observation ledger, completion diagonal, Real seal, transports, continuation routes, provenance, and local naming row as the only consumer-visible entries.

Apply completion-budget factorization through Definition 386.77. It aligns completion-facing consumers with the shared finite envelope rather than with an independent completion or host-limit coordinate.

Use Definition 386.54 and Definition 386.30. These rows force the UniformCauchyCriterion$^{\uparrow}$ read to return through the same schedule, source, dyadic ledger, and displayed transport surface.

Finally compose Definition 386.5 with Definition 386.76. The accepted packet therefore locks every uniform or completion-facing consumer to the stated finite route over BHist, hsame, Cont, Pkg, and NameCert. □

Theorem 386.79 (CauchyLimitSeal budget-route pairing determinacy)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* CauchyLimitSeal$^{\uparrow}$ *packet, and let $B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$ be an accepted* RealObservationBudget$^{\uparrow}$ *packet. If L and B share the same finite window, dyadic ledger, regular handoff, seal row, transports, routes, provenance, and local* NameCert *rows, then they determine the same* Real$^{\uparrow}$*- or completion-facing consumer route. No quotient stream, selected host limit, hidden family limit, unbounded schedule, or ambient completeness coordinate can distinguish the pair.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier budget route pairing determinacy`

Proof. Begin with the observation-budget pullback of Definition 386.58. It sends the accepted budget packet into the public route packet of L over the shared finite window, dyadic ledger, regular handoff, seal row, transports, routes, provenance, and local naming rows.

Apply budgeted tail comparison admission from Definition 386.59. The admitted comparison must use the same budget coordinates, so a tail-facing read cannot separate L from B after those rows agree.

Next attach the RealObservationBudget$^{\uparrow}$ consumer package of Definition 386.60. It identifies the real or completion consumer surface with the union of the budget and seal rows over the shared BHist, hsame, Cont, Pkg, and NameCert boundary.

Finally apply the consumer uniform route lock of Definition 386.78. The visible route is already exhausted by the displayed family, schedule, dyadic ledger, budget, seal, transport, continuation, provenance, and naming rows, leaving no quotient stream, selected host limit, hidden family limit, unbounded schedule, or ambient completeness coordinate by which the pair could diverge. □

Theorem 386.80 (CauchyLimitSeal selector-seal consumer route)**.** *When a* RealCompletionSelectorSeal$^{\uparrow}$ *packet reads row L as a* CauchyLimitSeal$^{\uparrow}$ *consumer row, the consumer route factors through the existing CauchyLimitSeal family schedule, dyadic ledger, regular handoff, seal row, transport row, provenance row, and local* NameCert *row before the terminal* Real$^{\uparrow}$ *row is read. Equivalently, row L can be consumed only as the displayed finite packet over* RegSeqRat$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RealCauchyCompletion$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

No selector-seal packet can use row L to read a detached host limit, quotient stream equality, hidden family limit, unbounded schedule, independent completion row, or ambient completeness principle before reaching the terminal Real$^{\uparrow}$ *endpoint.*

Proof. Apply Definition 386.79. It identifies any budgeted consumer read with the same finite window, dyadic ledger, regular handoff, seal row, transports, routes, provenance, and local naming rows whenever those displayed coordinates agree.

Use Definition 386.53 to place the Real$^{\uparrow}$ endpoint after the tail-choice exhaustion row, public route packet, and Real consumer boundary. This supplies the terminal row only after the CauchyLimitSeal route spine has already been consumed.

The selector-seal packet reads L exactly at that consumer position. Since determinacy fixes the budget-route pair and real handoff exhaustion leaves no extra exported coordinate, L is confined to the listed family schedule, dyadic ledger, regular handoff, seal, transport, provenance, and local NameCert rows before E is read. □

Theorem 386.81 (CauchyLimitSeal selector-seal public handoff)**.** *When a* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *packet consumes row* L *through the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer surface, the public handoff factors first through the displayed CauchyLimitSeal selector-seal route of Definition 386.80 and then through the ordered terminal selector-seal route*

$$B \longmapsto W \longmapsto R \longmapsto L \longmapsto E \longmapsto H, C, P, N.$$

The composed public handoff exports no quotient stream, host real equality, hidden selector, detached limit, second completion route, or ambient completeness principle.

Proof. First apply Definition 386.80. It places the L read on the existing $\mathsf{CauchyLimitSeal}^{\uparrow}$ finite packet before the terminal $\mathsf{Real}^{\uparrow}$ row is consumed.

Next use Definition 1081.5. The sibling $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ positions are exactly the public rows W, R, L, E inside the selector-seal handoff.

Now attach Definition 1081.10 and Definition 1081.11. These results force every terminal consumer through the ordered route $B, W, R, L, E, H, C, P, N$ and identify that route as the whole terminal selector-seal surface.

Finally apply Definition 1081.17. The structural rows H, C, P, N package the route already displayed and cannot promote a quotient stream, host real equality, hidden selector, detached limit, second completion route, or ambient completeness principle into the public handoff. □

Theorem 386.82 (CauchyLimitSeal consumer readback)**.** *A downstream* $\mathsf{Real}^{\uparrow}$ *or completion consumer reads back exactly the sealed route assembled by the root-unblock package, together with the tail-extraction row of Definition 386.70 and the uniqueness boundary of Definition 386.71. The readback exports only the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Proof. Apply the root-unblock package of Definition 386.57. It gives the consumer one route from the accepted seal packet to the downstream $\mathsf{Real}^{\uparrow}$ or completion boundary.

Attach tail extraction. The tail row is already projected from the same displayed regular family, schedule, observation ledger, completion diagonal, and transport ledger, so it does not add a second consumer route.

Finally attach the uniqueness boundary. Equality-facing reads remain on the null-sequence and tail-comparison route admitted by the packet, and the readback has no coordinate for quotient completion, host uniqueness, selected limits, hidden family limits, or ambient completeness. □

Theorem 386.83 (CauchyLimitSeal RegSeqRat StreamName route lock)**.** *Every accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet consumed by a* $\mathsf{Real}^{\uparrow}$ *or completion-facing route factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite window of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface of chapter 301, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger of chapter 291, the* $\mathsf{Real}^{\uparrow}$ *seal row of chapter 38, and the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer boundary of chapter 360. The factorization uses only the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows already exposed by the accepted seal route.*

Consequently the accepted consumer route exports no quotient stream, host sequence equality, selected limit, ambient completeness, metric-completion row, or standard bridge row outside that finite L10 route.

Proof. Start with the consumer readback theorem, Definition 386.82. It confines every downstream $\mathsf{Real}^{\uparrow}$ or completion consumer to the accepted seal packet, its root-unblock route, tail-extraction row, uniqueness boundary, and the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Next attach the finite route theorems already exposed on the Real side. The four-face canonical route of Definition 38.450 and the seal lattice of Definition 38.451 force any completion-facing $\mathsf{Real}^{\uparrow}$ consumer carrying a $\mathsf{CauchyLimitSeal}^{\uparrow}$ row through the ordered $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces before the seal row is read.

Finally use the terminal comparison exhaustion of Definition 38.446 together with the $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumer boundary cited above. These rows keep the completion-facing endpoint on the same displayed histories, transports, continuations, provenance, and local names, so no quotient stream, host sequence equality, selected limit, ambient completeness, metric-completion coordinate, or standard bridge coordinate remains available to the consumer. □

Theorem 386.84 (Real-completion seal selector consumer factorization)**.** *Let an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer be routed through an accepted* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *packet and an accepted* ObserverFilterBudgetSel *budget packet for the current Real and Completion handoff. Then its consumer read factors through the concrete displayed chain*

$$\mathsf{ObserverFilterBudgetSelector}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{CauchyLimitSeal}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The factorization uses only the visible BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of the three accepted packets. It exports no quotient stream, host real equality, hidden selector, detached limit, or ambient completeness coordinate.*

Proof. Start with the route lock of Definition 386.83. It confines the $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer to the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, with only BHist, hsame, Cont, Pkg, and NameCert support.

Next attach the selector-seal packet. The L10 handoff scope of Definition 1081.5 identifies the selector-seal consumer as the same finite route through selector budget, selected window, regular readback, limit-seal handoff, and terminal $\mathsf{Real}^{\uparrow}$ endpoint.

Finally attach the observer-budget packet. The bridge-ready route of Definition 1042.9 supplies the selected observer row, finite budget, selected $\mathsf{StreamName}^{\uparrow}$ window, dyadic ledger, regular handoff, and Real seal in that order. Combining the three displayed routes gives the stated factorization, and the coordinate exclusions in the cited theorems leave no quotient stream, host real equality, hidden selector, detached limit, or ambient completeness row for the consumer. □

Theorem 386.85 (CauchyLimitSeal finite-request section compatibility)**.** *Let P be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet whose public route is consumed by a finite request section S for the current Real and Completion handoff. Then the accepted consumer boundary is the same finite* BHist *packet whether it is read through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window section, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback section, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the local* $\mathsf{Real}^{\uparrow}$ *seal row, or the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *public route packet:*

$$S_{\mathsf{StreamName}^{\uparrow}} = S_{\mathsf{RegSeqRat}^{\uparrow}} = S_{\mathsf{DyadicRatCore}^{\uparrow}} = S_{\mathsf{Real}^{\uparrow}} = S_{\mathsf{CauchyLimitSeal}^{\uparrow}}$$

as displayed finite BHist *sections over the visible* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The compatibility exports no quotient stream equality, host real equality, selected limit, countable-choice schedule, ambient completeness principle, metric-completion row, or standard bridge row.*

Proof. Start with the route lock of Definition 386.83. It confines the accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer to the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, so every face of S is read from the same public route packet.

Next read the Real-facing side through Definition 38.698 and Definition 38.704. These theorems identify the $\mathsf{Real}^{\uparrow}$ seal request with one finite BHist packet carrying the StreamName window, dyadic endpoint-radius ledger, RegSeqRat classifier and readback rows, componentwise hsame transport, displayed Cont route, Pkg provenance, and local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ row.

Now read the StreamName-facing side through Definition 126.577 and Definition 126.586. The pullback section has the same finite window face and the same dyadic, RegSeqRat, and Real seal faces, so it cannot introduce a second selector or a second completion-facing section.

Finally apply the non-escape boundary of Definition 386.4. Since the accepted packet has no coordinate for quotient stream equality, host real equality, selected limits, countable-choice schedules, ambient completeness, metric-completion rows, or standard bridge rows, the only consumer boundary left is the displayed finite BHist packet shared by all five readings. □

Theorem 386.86 (CauchyLimitSeal downstream consumer coverage)**.** *Let an accepted local* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer be read by a downstream* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer through the selected* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *and* $\mathsf{ObserverFilterBudgetSelector}^{\uparrow}$ *packets of the current handoff. Then the consumer read is exhausted by the displayed finite route rows*

$$\mathsf{ObserverFilterBudgetSelector}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{CauchyLimitSeal}^{\uparrow} \to \mathsf{Real}^{\uparrow},$$

together with the $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer boundary, the tail-extraction row, the uniqueness boundary, and the visible* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows already named in the selected packet.*

Equivalently, every accepted use of the local consumer is one of the listed selected observer, finite budget, finite window, dyadic ledger, regular readback, limit-seal handoff, terminal Real endpoint, completion-boundary, tail, comparison, transport, replay, provenance, or naming rows. A purported quotient stream, host sequence equality, host real equality, hidden selector, detached limit, selected host limit, hidden family limit, ambient completeness principle, metric-completion row, standard bridge row, arithmetic package, or order package is outside the displayed BEDC packet and is not exported by the consumer readback.

Proof. Start with the consumer factorization of Definition 386.84. It places any accepted local $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer that enters through the selected selector-seal and observer-budget packets on the concrete route

$$\mathsf{ObserverFilterBudgetSelector}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{CauchyLimitSeal}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The same theorem records that the route uses only the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows of the accepted packets, and that quotient streams, host real equality, hidden selectors, detached limits, and ambient completeness have no exported coordinate there.

Now apply the route lock of Definition 386.83. It places the local $\mathsf{CauchyLimitSeal}^{\uparrow}$ portion of the same read on the displayed $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{RegSeqRat}^{\uparrow}$ readback surface, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{Real}^{\uparrow}$ seal row, and $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumer boundary, with the componentwise transport row supplied by Definition 386.7. Thus the selector route cannot open a second local consumer surface; it can only read the same finite window, ledger, readback, seal, and completion-boundary rows.

The remaining local readback rows are already fixed by Definition 386.82. Tail-facing use is projected by Definition 386.70, and equality-facing use is confined by Definition 386.71. The transport component for those tail and comparison rows is the packet-local public route transport of Definition 386.7. These two rows account for the admitted tail and comparison alternatives

without adding quotient completion, host uniqueness, selected limits, hidden family limits, or ambient completeness.

Combining the factorized selector route with the locked local route and the readback tail and comparison rows along the public-route transport of Definition 386.7 gives the announced coverage list. Any purported downstream coordinate not on that list would have to bypass either the displayed selector chain, the locked $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{DyadicRatCore}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$–$\mathsf{RealCauchyCompletion}^{\uparrow}$ surface, or the packet-local tail and uniqueness rows. Each bypass is excluded by the cited theorems, so the unlisted alternatives remain outside the BEDC packet and cannot be exported by the consumer readback. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyLimitSeal}^{\uparrow}$ packet is generated from a displayed $\mathsf{RegSeqRat}^{\uparrow}$ family, a $\mathsf{StreamName}^{\uparrow}$ schedule, a DyadicRatCore observation ledger, a $\mathsf{RealCauchyCompletion}^{\uparrow}$ diagonal row, a $\mathsf{Real}^{\uparrow}$ seal row, finite hsame and Cont transports, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature surface consists of the sealed $\mathsf{Real}^{\uparrow}$ public route, family-window pullback, family ledger exhaustion, source factorization, bridge interface, bridge route exactness, and bridge non-escape over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealUp\_StdBridge`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close quotient Cauchy completion, uniqueness of limits, host real construction, or ambient real completeness.

Theorem 386.87 (CauchyLimitSeal budget root source totality)**.** *Let*

$$L = (X, S, D, G, E, T, P, N)$$

be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet, and let*

$$B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet whose seal and regular-handoff rows are routed through* L*. Every* $\mathsf{RealObservationBudget}^{\uparrow}$*-facing read accepted through this route is sourced exactly by the displayed seal rows* X, S, D, G, E, T, P, N *together with the displayed budget rows* $E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B$*. No further budget source, hidden completion row, quotient stream, selected limit, host real equality, hidden family limit, or ambient completeness coordinate is available to the read.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier budget root source totality`

Proof. Start with the observation-budget pullback of Definition 386.58. It sends each budget read of B into the public route packet of L while preserving the precision request, window, dyadic ledger, regular handoff, seal row, transport, route, provenance, and naming rows displayed by B.

Next attach the $\mathsf{RealObservationBudget}^{\uparrow}$ consumer package from Definition 386.60. The consumer endpoint reads the union of the budget rows and the seal rows over the shared BHist, hsame, Cont, Pkg, and NameCert surface.

Finally use tail extraction from Definition 386.70 and the consumer exactness of Definition 611.9. These rows force the tail and budget consumers to remain on the same displayed packet, so a read outside X, S, D, G, E, T, P, N and $E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B$ has no source coordinate. □

Theorem 386.88 (CauchyLimitSeal root dyadic window exactness)**.** *In the setting of Definition 386.87, the dyadic ledger read by any accepted budget route is exactly the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window ledger already exposed by the seal packet. The budget ledger* D_B *and the seal-side dyadic row* D *are not independent observations; they are the same finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger transported through the displayed* hsame *and* Cont *rows of the route.*

Proof. First pull the budget route back along Definition 386.58. The pullback places the precision request, windows, and dyadic ledger of B on the public route packet of L.

Then apply tail extraction from Definition 386.70. The tail read of the seal packet is projected through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ family, $\mathsf{StreamName}^{\uparrow}$ schedule, and $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger, with no external tail source.

The $\mathsf{RealObservationBudget}^{\uparrow}$ consumer package of Definition 386.60 and the exactness theorem Definition 611.9 identify the regular and real-facing budget consumers with that same packet. Hence the budget route reads precisely the scheduled window ledger already exposed by L. □

Theorem 386.89 (CauchyLimitSeal budget window source refusal)**.** *In the setting of Definition 386.87, any route that presents a budget dyadic window not identified with the scheduled seal-side* $\mathsf{StreamName}^{\uparrow}$ *window of Definition 386.88 is not a public* $\mathsf{RealObservationBudget}^{\uparrow}$*-facing read of the accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet.*

Proof. Apply source totality from Definition 386.87. It confines every accepted budget-facing read to the displayed seal rows and the displayed budget rows, with no hidden completion coordinate or independent source row.

Next apply dyadic-window exactness from Definition 386.88. The budget dyadic ledger is the scheduled seal-side $\mathsf{StreamName}^{\uparrow}$ window ledger transported through the displayed hsame and Cont rows.

Therefore a route that presents a different budget window has no source coordinate among the displayed seal and budget rows. It is not a public $\mathsf{RealObservationBudget}^{\uparrow}$-facing read of the accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ packet. □

Theorem 386.90 (CauchyLimitSeal budget selector coherence)**.** *In the setting of Definition 386.87, let an accepted selector route be admitted through the same* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet as an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *read over the same precision request and finite* $\mathsf{StreamName}^{\uparrow}$ *window. Then the selector read and the observation-budget read meet on one displayed route over* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. Their selector leg and budget leg agree on the dyadic-window ledger identified by Definition 386.88, and the route exports no quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier budget selector coherence`

Proof. First take the root choice-free route from Definition 386.111. It confines selector access to the accepted seal packet and its displayed regular source, stream window, dyadic ledger, real seal, transport, continuation, provenance, and naming rows.

Next apply the tail-budget meet of Definition 386.135 together with budget root source totality from Definition 386.87. These rows project the selector read and the observation-budget read to the same finite packet over the shared precision request and $\mathsf{StreamName}^{\uparrow}$ window.

Then use the dyadic-window exactness theorem Definition 386.88. It identifies the budget ledger with the scheduled seal-side dyadic window, so the selector leg and budget leg read one $\mathsf{DyadicRatCore}^{\uparrow}$ ledger rather than two independent ledgers.

Finally apply completion-consumer non-escape from Definition 386.94. Since the common route has already been projected to the displayed finite packet, no quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate can be exported. □

Theorem 386.91 (CauchyLimitSeal budget finite-approximation route)**.** *In the setting of Definition 386.87, let an accepted* FiniteCauchyApproximation$^{\uparrow}$ *packet read the same precision request and the same finite* StreamName$^{\uparrow}$ *window as the accepted* RealObservationBudget$^{\uparrow}$ *route. Then the observation-budget route and the finite-approximation route meet on one displayed packet over* RegSeqRat$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The shared packet exports the precision request, finite window, dyadic observation ledger, finite error consumer row, real-facing handoff, transport, continuation, provenance, and local name, but it exports no quotient stream identity, host real equality, selected limit, hidden family limit, or ambient completeness coordinate.*

Proof. First apply budget selector coherence from Definition 386.90. It places the selector leg and the observation-budget leg on the same displayed route over the accepted CauchyLimitSeal$^{\uparrow}$ packet, with the precision request and finite StreamName$^{\uparrow}$ window already fixed.

Next use dyadic-window exactness from Definition 386.88. The dyadic ledger read by the budget route is the scheduled finite-window ledger exposed by the seal packet, so the finite approximation cannot introduce an independent DyadicRatCore$^{\uparrow}$ observation.

Finally use the finite consumer surface of chapter 601. Its accepted FiniteCauchyApproximation$^{\uparrow}$ packet consumes the same source, precision request, finite window, dyadic ledger, finite error row, handoff, transport, continuation, provenance, and naming rows. The non-escape boundary from the selector-coherence route therefore remains in force, excluding quotient stream identity, host real equality, selected limit, hidden family limit, and ambient completeness. □

Theorem 386.92 (CauchyLimitSeal budget selector approximation determinacy)**.** *In the setting of Definition 386.87, suppose an accepted selector route, an accepted* RealObservationBudget$^{\uparrow}$ *route, and an accepted* FiniteCauchyApproximation$^{\uparrow}$ *route read the same precision request and the same finite* StreamName$^{\uparrow}$ *window through one accepted* CauchyLimitSeal$^{\uparrow}$ *packet. Then the selector leg, the observation-budget leg, and the finite-approximation leg determine the same displayed dyadic-window ledger and the same finite packet over* RegSeqRat$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The common packet contains only the displayed precision request, finite window, dyadic ledger, finite error row, real-facing handoff, transport, continuation, provenance, and local naming rows; it contains no quotient stream identity, host real equality, selected limit, hidden family limit, or ambient completeness coordinate.*

Proof. First apply budget selector coherence from Definition 386.90. The selector route and the RealObservationBudget$^{\uparrow}$ route are forced onto one accepted CauchyLimitSeal$^{\uparrow}$ packet over the shared precision request and finite StreamName$^{\uparrow}$ window.

Next use dyadic-window exactness from Definition 386.88. It identifies the budget ledger with the scheduled seal-side DyadicRatCore$^{\uparrow}$ window, so the selector leg and the observation-budget leg cannot display different dyadic ledgers.

Then apply the budget finite-approximation route of Definition 386.91. The accepted FiniteCauchyApproximation route consumes that same precision request, window, dyadic ledger, finite error row, real-facing handoff, transport, continuation, provenance, and NameCert row, placing its finite packet on the already displayed route.

Finally use completion-consumer non-escape from Definition 386.94. After the three reads have been identified with the same finite packet, there is no remaining coordinate from which quotient stream identity, host real equality, selected limit, hidden family limit, or ambient completeness could be exported. □

Theorem 386.93 (CauchyLimitSeal root budget finite-approximation cofinality)**.** *In the setting of Definition 386.87, suppose an accepted* $\mathsf{FiniteCauchyApproximation}^{\uparrow}$ *route refines the shared precision request to a stronger displayed dyadic window through the same* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet. Then the accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *route and the selector route factor through that stronger finite-approximation packet. The factorization preserves the same* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows already displayed by the seal route, and it exports no quotient stream, selected limit, host real equality, hidden family limit, or ambient completeness coordinate.*

Proof. First use dyadic-window exactness from Definition 386.88. The budget ledger is the scheduled $\mathsf{StreamName}^{\uparrow}$ dyadic window ledger carried by the seal packet, so a stronger displayed window is a refinement of the same ledger rather than an independent observation.

Next apply budget-selector coherence from Definition 386.90. It puts the selector route and the $\mathsf{RealObservationBudget}^{\uparrow}$ route on one displayed route over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Then use the budget finite-approximation route of Definition 386.91. The stronger finite packet imports the refined precision request, dyadic window, finite error row, real-facing handoff, transport, continuation, provenance, and local name without changing the seal source rows.

Finally apply completion-consumer non-escape from Definition 386.94. Since the budget leg, selector leg, and refined finite-approximation leg already factor through one finite packet, there is no exported coordinate for quotient streams, selected limits, host real equality, hidden family limits, or ambient completeness. □

Theorem 386.94 (CauchyLimitSeal root completion consumer non-escape)**.** *The completion-facing consumer obtained by composing an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *route with an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet can export only the rows listed in Definition 386.87 and the dyadic-window identification of Definition 386.88. It cannot export quotient streams, selected limits, host real equality, hidden family limits, or ambient completeness.*

Proof. Use Definition 386.87 to identify the complete source surface of the composed consumer. The consumer has only the displayed seal rows and the displayed budget rows.

Use Definition 386.88 for the window ledger. The dyadic observation consumed by the route is the scheduled $\mathsf{StreamName}^{\uparrow}$ window ledger already carried by the seal packet, not a second ledger chosen by the completion consumer.

Finally apply the consumer package of Definition 386.60, tail extraction from Definition 386.70, and $\mathsf{RealObservationBudget}^{\uparrow}$ consumer exactness from Definition 611.9. The composed route remains inside the finite packet, so none of quotient streams, selected limits, host real equality, hidden family limits, or ambient completeness can be exported. □

Theorem 386.95 (CauchyLimitSeal root formal target package)**.** *The source totality row of Definition 386.87, the dyadic-window exactness row of Definition 386.88, the budget-selector coherence row of Definition 386.90, and the completion-consumer non-escape row of Definition 386.94 jointly form the formal target package for the composed* $\mathsf{RealObservationBudget}^{\uparrow}$*-to-*$\mathsf{CauchyLimitSeal}^{\uparrow}$ *route. Source totality fixes all source rows, dyadic-window exactness identifies the budget ledger with the*

scheduled $\mathsf{StreamName}^{\uparrow}$ *window, budget-selector coherence binds selector and budget reads to that one ledger, and completion-consumer non-escape excludes quotient streams, selected limits, host real equality, hidden family limits, and ambient completeness.*

Proof. First use source totality. It fixes the composed route to the displayed seal rows X, S, D, G, E, T, P, N and the displayed budget rows $E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B$, so every formal target read has a finite source coordinate.

Next use dyadic-window exactness. It identifies the budget ledger D_B with the scheduled $\mathsf{StreamName}^{\uparrow}$ window ledger already carried by the seal packet, so the route has one dyadic observation surface rather than two independent ledgers.

Then apply budget-selector coherence. The selector leg and the observation-budget leg meet on the same displayed route over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Finally use completion-consumer non-escape. Once the source rows, the dyadic ledger, and the selector-budget handoff have been fixed, the completion-facing consumer has no remaining coordinate for quotient streams, selected limits, host real equality, hidden family limits, or ambient completeness. These four rows therefore give the complete formal target package for the composed route. □

Theorem 386.96 (CauchyLimitSeal budget finite-approximation window exhaustion)**.** *In the setting of Definition 386.87, suppose an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet, an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *route, and an accepted* $\mathsf{FiniteCauchyApproximation}^{\uparrow}$ *packet read the same precision request and the same finite* $\mathsf{StreamName}^{\uparrow}$ *window. Then every completion-facing read of that route factors through the displayed seal rows* X, S, D, G, E, T, P, N*, the displayed budget rows* $E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B$*, the dyadic-window ledger of Definition 386.88, and the finite-approximation packet rows of Definition 386.91. No independent window, quotient stream, selected limit, host real equality, hidden family limit, or ambient completeness coordinate is exported.*

Proof. Begin with source totality from Definition 386.87. It confines the route to the displayed $\mathsf{CauchyLimitSeal}^{\uparrow}$ rows and $\mathsf{RealObservationBudget}^{\uparrow}$ rows, so any completion-facing read already has a finite source surface.

Next use dyadic-window exactness from Definition 386.88. The budget ledger is the scheduled finite $\mathsf{StreamName}^{\uparrow}$ window ledger exposed by the seal packet, so the route cannot introduce an independent window.

Now apply the budget finite-approximation route of Definition 386.91. The accepted $\mathsf{FiniteCauchyApproximation}^{\uparrow}$ packet consumes the same precision request, finite window, dyadic ledger, finite error row, real-facing handoff, transport, continuation, provenance, and local name, placing its rows on the already displayed route.

Use selector approximation determinacy from Definition 386.92. The selector leg, observation-budget leg, and finite-approximation leg determine the same displayed dyadic-window ledger and the same finite packet over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Finally apply root completion consumer non-escape from Definition 386.94. Since the completion-facing consumer has already been forced through the seal rows, budget rows, dyadic-window ledger, and finite-approximation rows, it has no coordinate for an independent window, quotient stream, selected limit, host real equality, hidden family limit, or ambient completeness. □

Theorem 386.97 (CauchyLimitSeal budget source uniqueness)**.** *In the setting of Definition 386.87, suppose two accepted* $\mathsf{RealObservationBudget}^{\uparrow}$*-facing reads are routed through the same accepted*

$\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet. If the two reads agree on the displayed seal rows* X, S, D, G, E, T, P, N*, the displayed budget rows* $E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B$*, the precision request, the finite* $\mathsf{StreamName}^{\uparrow}$ *window, and the dyadic-window ledger identified by Definition 386.88, then they are the same public source route over* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. No second source coordinate, independent window, quotient stream, selected limit, host real equality, hidden family limit, or ambient completeness coordinate is available.*

Proof. First apply source totality from Definition 386.87. It confines both accepted budget-facing reads to the displayed seal rows and displayed budget rows of the same accepted packet.

Next use dyadic-window exactness from Definition 386.88. The budget ledger of each read is the scheduled finite $\mathsf{StreamName}^{\uparrow}$ ledger already exposed by the seal packet, so the two reads cannot choose different dyadic-window ledgers once those displayed rows agree.

Now use selector coherence and finite-approximation routing. The coherence row of Definition 386.90 fixes the selector and budget legs on one displayed route, and Definition 386.91 places the finite approximation on the same packet.

Apply finite-approximation window exhaustion from Definition 386.96. Every completion-facing read is exhausted by the displayed seal rows, budget rows, dyadic-window ledger, and finite-approximation packet rows.

Finally apply root completion consumer non-escape from Definition 386.94. Since no second source coordinate, independent window, quotient stream, selected limit, host real equality, hidden family limit, or ambient completeness coordinate is exported, the two reads name the same public source route over the displayed BEDC rows. □

Theorem 386.98 (CauchyLimitSeal tail schedule budget cofinality)**.** *In the setting of Definition 386.87, suppose the accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet also consumes an accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet for the same unary precision request and the same finite* $\mathsf{StreamName}^{\uparrow}$ *window. Then the selector route, the* $\mathsf{RealObservationBudget}^{\uparrow}$ *route, the* $\mathsf{FiniteCauchyApproximation}^{\uparrow}$ *route, and the tail schedule determine one cofinal displayed packet over* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. The cofinal packet exports no quotient stream identity, selected limit, host real equality, hidden family limit, hidden tail oracle, or ambient completeness coordinate.*

Proof. First bind the selector and budget legs. Apply Definition 386.90 to place the selector route and the $\mathsf{RealObservationBudget}^{\uparrow}$ route on one displayed packet over the shared precision request, finite window, dyadic ledger, real handoff, transports, continuations, provenance, and local name.

Next attach the finite-approximation leg. Use Definition 386.91 and Definition 386.93 to identify every stronger finite window with a refinement of the same seal-side dyadic ledger rather than a second observation source.

Now consume the schedule. The real-seal readback and scoped binding rows of $\mathsf{TailCofinalitySchedule}^{\uparrow}$, namely Definition 681.6 and Definition 681.8, route the same unary request through the finite $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{DyadicRatCore}^{\uparrow}$ threshold ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal before any completion-facing read.

Finally apply Definition 386.96. The selector, budget, finite-approximation, and schedule faces have all been forced through the same displayed packet, so no quotient stream identity, selected limit, host real equality, hidden family limit, hidden tail oracle, or ambient completeness coordinate remains available. □

Theorem 386.99 (CauchyLimitSeal budget selector totality)**.** *In the setting of Definition 386.87, suppose an accepted selector route, an accepted* RealObservationBudget$^{\uparrow}$ *route, an accepted* FiniteCauchyApproximatic *packet, and an accepted* TailCofinalitySchedule$^{\uparrow}$ *packet read the same unary precision request and the same finite* StreamName$^{\uparrow}$ *window through one accepted* CauchyLimitSeal$^{\uparrow}$ *packet. Then the four legs determine one displayed L10 packet over* RegSeqRat$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. Every completion-facing read is exhausted by that displayed packet, and no quotient stream identity, selected limit, host real equality, hidden family limit, hidden tail oracle, or ambient completeness coordinate is exported.*

Proof. First bind the selector and observation-budget legs by Definition 386.90. They read one precision request, one finite StreamName$^{\uparrow}$ window, and one dyadic ledger through the accepted CauchyLimitSeal$^{\uparrow}$ packet.

Next attach the finite-approximation leg using Definition 386.91. The finite packet is placed on the same RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Use selector approximation determinacy from Definition 386.92. Once the selector, budget, and finite-approximation legs share the request and window, their dyadic ledger and finite packet cannot split into separate public routes.

Now consume the schedule by Definition 386.98. The accepted TailCofinalitySchedule$^{\uparrow}$ packet refines the same finite window and does not supply a second tail oracle or a second completion-facing source.

Finally apply root completion consumer non-escape from Definition 386.94. Since every leg has already been forced through the displayed L10 packet, a completion-facing consumer has no remaining coordinate for quotient stream identity, selected limit, host real equality, hidden family limit, hidden tail oracle, or ambient completeness. □

Theorem 386.100 (CauchyLimitSeal budget tail selector lock)**.** *In the setting of Definition 386.87, suppose an accepted selector route, an accepted* RealObservationBudget$^{\uparrow}$ *route, an accepted* FiniteCauchyApproximatic *packet, and an accepted* TailCofinalitySchedule$^{\uparrow}$ *packet read the same unary precision request and the same finite* StreamName$^{\uparrow}$ *window through one accepted* CauchyLimitSeal$^{\uparrow}$ *packet. Then these four displayed legs determine exactly one tail-selector row over* RegSeqRat$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The locked row is the same row seen by the selector, the observation budget, the finite approximation, and the tail schedule, and it has no hidden tail oracle, quotient stream identity, selected limit, host real equality, hidden family limit, or ambient completeness coordinate.*

Proof. Begin with budget selector totality from Definition 386.99. It places the selector, observation-budget, finite-approximation, and tail-schedule legs on one displayed L10 packet over the named BEDC rows.

Next use dyadic-window exactness from Definition 386.88 and selector coherence from Definition 386.90. These two rows identify the selector leg and the budget leg with the same finite StreamName$^{\uparrow}$ window and DyadicRatCore$^{\uparrow}$ ledger.

Attach the finite packet through Definition 386.91. Then consume the schedule using Definition 386.98. The finite approximation and tail schedule therefore read the same tail-selector row rather than separate endpoint rows.

Finally apply root completion consumer non-escape from Definition 386.94. Since no external coordinate remains available, the shared tail-selector row is locked by the displayed selector, budget, finite-approximation, and schedule data. □

Theorem 386.101 (CauchyLimitSeal budget source endpoint exhaustion)**.** *In the setting of Definition 386.87, every completion-facing endpoint read accepted through the budget route is exhausted by the displayed seal rows X, S, D, G, E, T, P, N, the displayed budget rows $E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B$, the dyadic-window ledger identified in Definition 386.88, the finite-approximation packet of Definition 386.91, and the tail schedule of Definition 386.98. No further endpoint, completion source, quotient stream identity, selected limit, host real equality, hidden family limit, hidden tail oracle, or ambient completeness coordinate is part of the public route.*

Proof. Start with budget root source totality from Definition 386.87. It confines every accepted budget-facing read to the displayed seal rows and displayed budget rows.

Next apply dyadic-window exactness from Definition 386.88. The completion-facing endpoint reads the scheduled finite $\mathsf{StreamName}^{\uparrow}$ window ledger already carried by the seal route, not an independent dyadic window.

Now attach the finite side by Definition 386.91 and Definition 386.96. These rows place the finite-approximation packet on the same displayed endpoint package.

Use tail-schedule budget cofinality from Definition 386.98 and the tail-selector lock of Definition 386.100. The schedule contributes only the displayed cofinal tail row over the same packet.

Finally apply completion-consumer non-escape from Definition 386.94. With the seal rows, budget rows, dyadic ledger, finite packet, and tail schedule already accounting for the endpoint, no additional completion-facing coordinate remains. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier budget source endpoint exhaustion`

Theorem 386.102 (CauchyLimitSeal completion route uniqueness)**.** *In the setting of Definition 386.87, suppose two accepted completion-facing routes through an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet agree on the displayed seal rows, the displayed* $\mathsf{RealObservationBudget}^{\uparrow}$ *rows, the dyadic-window ledger, the* $\mathsf{FiniteCauchyApproximation}^{\uparrow}$ *packet, and the* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *row. Then the two routes name the same public completion route over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *There is no second public route distinguished only by a hidden endpoint, quotient stream identity, selected limit, host real equality, hidden family limit, hidden tail oracle, or ambient completeness coordinate.*

Proof. First use budget source uniqueness from Definition 386.97. Agreement on the displayed seal and budget rows, together with the shared precision request, finite window, and dyadic ledger, identifies the public source route.

Next use budget selector totality from Definition 386.99. It puts the selector, budget, finite-approximation, and tail-schedule faces of both accepted routes on the same displayed L10 packet.

Apply endpoint exhaustion from Definition 386.101. Every completion-facing read of either route is exhausted by the seal rows, budget rows, dyadic ledger, finite-approximation packet, and tail schedule.

Finally apply root completion consumer non-escape from Definition 386.94. Since no hidden completion coordinate can distinguish the two accepted reads, the agreed displayed endpoint package names one public completion route. □

Theorem 386.103 (CauchyLimitSeal budget RealTailAgreement terminality)**.** *In the setting of Definition 386.87, suppose an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet reads the same regular source rows, finite* $\mathsf{StreamName}^{\uparrow}$ *window, dyadic ledger, and* $\mathsf{Real}^{\uparrow}$ *seal surface as the accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *budget route. Then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer factors through one displayed packet over* $\mathsf{RealObservationBudget}^{\uparrow}$, $\mathsf{FiniteCauchyApproximation}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$,

RealTailAgreementSeal$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The terminal packet exports no quotient stream identity, selected limit, host real equality, hidden family limit, hidden tail oracle, or ambient completeness coordinate.*

Proof. Begin with budget selector totality from Definition 386.99. It places the observation budget, finite-approximation packet, and tail-schedule row on the same displayed route as the accepted CauchyLimitSeal$^{\uparrow}$ budget packet.

Next apply endpoint exhaustion from Definition 386.101 and completion route uniqueness from Definition 386.102. These rows force every completion-facing read through the same finite endpoint package and identify any two routes that agree on the displayed budget, window, dyadic, approximation, and schedule rows.

Attach the tail-agreement seal by Definition 699.94. The accepted RealTailAgreementSeal$^{\uparrow}$ packet reads the same regular source, finite window, dyadic ledger, and Real$^{\uparrow}$ seal surface, so it is a consumer of the route already fixed by the budget packet.

Finally use Definition 699.95. The Real and Completion consumers of the tail-agreement packet are confined to the same displayed budget route. Since all listed rows have already been accounted for, quotient stream identity, selected limits, host real equality, hidden family limits, hidden tail oracles, and ambient completeness remain outside the terminal packet. □

Theorem 386.104 (CauchyLimitSeal terminal route exhaustion)**.** *In the setting of Definition 386.87, suppose accepted* RealObservationBudget$^{\uparrow}$, FiniteCauchyApproximation$^{\uparrow}$, TailCofinalitySchedule$^{\uparrow}$, *and* RealTailAgreementSeal$^{\uparrow}$ *legs read the same regular source rows, the same finite* StreamName$^{\uparrow}$ *window, the same* DyadicRatCore$^{\uparrow}$ *ledger, and the same* Real$^{\uparrow}$ *seal through one accepted* CauchyLimitSeal$^{\uparrow}$ *packet. Then every* Real$^{\uparrow}$ *or* Completion$^{\uparrow}$ *consumer is exhausted by that one displayed public route over* RealObservationBudget$^{\uparrow}$, FiniteCauchyApproximation$^{\uparrow}$, TailCofinalitySchedule$^{\uparrow}$, RealTailAgreementSeal$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The route exports no quotient stream identity, selected limit, host real equality, hidden family limit, hidden tail oracle, independent completion endpoint, or ambient completeness coordinate.*

Proof. First apply budget selector totality from Definition 386.99. The observation budget, finite approximation, and tail schedule are placed on one displayed L10 packet over the shared regular source rows, finite StreamName$^{\uparrow}$ window, dyadic ledger, Real$^{\uparrow}$ handoff, history, transport, continuation, provenance, and naming rows.

Next apply endpoint exhaustion from Definition 386.101. This confines every completion-facing endpoint read to the displayed seal rows, budget rows, dyadic-window ledger, finite-approximation packet, and tail schedule.

Now use completion route uniqueness from Definition 386.102. Since the accepted legs agree on the displayed budget, window, dyadic, approximation, and schedule rows, there is only one public completion route over the named BEDC surface.

Attach the RealTailAgreement face by Definition 386.103. Its accepted packet reads the same regular source rows, finite window, dyadic ledger, and Real$^{\uparrow}$ seal, so its Real and Completion consumers are terminals of the same displayed route rather than separate endpoints.

Finally apply root completion consumer non-escape from Definition 386.94. With all four legs already bound to the accepted CauchyLimitSeal$^{\uparrow}$ packet, no quotient stream identity, selected limit, host real equality, hidden family limit, hidden tail oracle, independent completion endpoint, or ambient completeness coordinate remains available to any Real$^{\uparrow}$ or Completion$^{\uparrow}$ consumer. □

Theorem 386.105 (CauchyLimitSeal budget-source factorization)**.** *In the setting of Definition 386.87, every accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *budget-source read factors first through finite approximation window exhaustion, then through budget selector totality, then through tail-schedule cofinality, then through* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *terminality, and only then reaches the terminal route exhaustion row. Hence every completion-facing consumer of the read remains on the displayed finite budget route over* $\mathsf{RealObservationBudget}^{\uparrow}$, $\mathsf{FiniteCauchyApproximation}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

Proof. Project the accepted finite packet rows from the budget-source carrier. The displayed read supplies the seal rows, observation-budget rows, dyadic-window ledger, finite-approximation packet, tail schedule, RealTailAgreement packet, history, transport, continuation, provenance, and local naming row.

Apply finite approximation window exhaustion from Definition 386.96. This places the finite packet on the same displayed window and dyadic ledger before any completion-facing consumer can inspect the route.

Next use budget selector totality from Definition 386.99. The selector, observation budget, finite approximation, and schedule rows are therefore a single displayed L10 packet rather than independent sources.

Now apply tail-schedule budget cofinality from Definition 386.98. The cofinal tail row is read through the same finite budget route and cannot supply a second endpoint or hidden tail oracle.

Attach terminality by Definition 386.103, then apply terminal route exhaustion from Definition 386.104. Since each stage consumes the same projected packet rows, every completion-facing consumer has no branch outside the displayed finite budget route. □

Corollary 386.106 (CauchyLimitSeal budget window refusal is a strict local obstruction)**.** *In the setting of Definition 386.87, the obstruction detected by Definition 386.89 is strictly local to the attempted reuse of the accepted budget route. More precisely, if a candidate consumer route presents a budget dyadic window not identified, in the transport sense of Definition 386.164, with the scheduled seal-side* $\mathsf{StreamName}^{\uparrow}$ *window, then that candidate is blocked only as a public* $\mathsf{RealObservationBudget}^{\uparrow}$*-facing read of the named accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet and of its displayed root-source surface*

$$X, S, D, G, E, T, P, N \quad \textit{and} \quad E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B.$$

The refusal cannot be reinterpreted as a global impossibility theorem about Cauchy limits, as a host theorem about real convergence, or as hidden external validation of an ambient completion principle. Every consumer-facing use must factor through the displayed seal rows, budget rows, the scheduled $\mathsf{StreamName}^{\uparrow}$ *window, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger transported through the displayed* hsame *and* Cont *rows in the sense of Definition 386.164 and Definition 301.14; any unlisted coordinate is rejected only for this named route.*

Proof. Start with root source totality from Definition 386.87. It identifies the complete source surface of every accepted $\mathsf{RealObservationBudget}^{\uparrow}$-facing read through the packet: the only seal rows are X, S, D, G, E, T, P, N, and the only budget rows are $E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B$. In particular, a consumer-facing read has no hidden completion row, no quotient stream row, no selected limit row, no host real-equality row, no hidden family-limit row, and no ambient completeness row from which an additional source could be read.

Next apply dyadic-window exactness from Definition 386.88. The budget ledger D_B is not an independent observation: it is the scheduled seal-side $\mathsf{StreamName}^{\uparrow}$ window ledger already

exposed by D, transported through the displayed hsame and Cont rows in the sense of the common-window transport theorem Definition 386.164 and the RegSeqRat finite-window transport closure Definition 301.14. Thus the only public window coordinate available to the budget route is the listed finite window coordinate.

Now use the refusal theorem Definition 386.89. A candidate route whose dyadic window is not identified with that scheduled seal-side window by the transport route of Definition 386.164 and Definition 301.14 has no coordinate in the displayed seal and budget surface. Therefore it is refused as a public $\mathsf{RealObservationBudget}^{\uparrow}$-facing read of this accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ packet.

This proves exactly the local obstruction. The argument never introduces a second packet, an ambient host convergence predicate, an external completeness principle, or a global countermodel. It only says that consumer-facing use of the named accepted route must pass through the displayed root-source rows and the displayed dyadic-window identification, so unlisted coordinates cannot be reused as public coordinates of that route. □

Theorem 386.107 (CauchyLimitSeal choice-free selector admission)**.** *Let*

$$Q = (X, S, D, G, E, T, P, N)$$

be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. An accepted* $\mathsf{ChoiceFreeLimitSchedule}^{\uparrow}$ *row*

$$A = (E_A, M_A, W_A, D_A, R_A, S_A, H_A, C_A, P_A, N_A)$$

or an accepted $\mathsf{LimitSelector}^{\uparrow}$ *row*

$$K = (R_K, n_K, \mu_K, k_K, W_K, D_K, S_K, H_K, C_K, P_K, N_K)$$

is admitted through Q only when its precision request, selected $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{Real}^{\uparrow}$ *seal row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row coincide with the public route packet of Q.*

For a $\mathsf{ChoiceFreeLimitSchedule}^{\uparrow}$ *row this means that $E_A, M_A, W_A, D_A, R_A, S_A, H_A, C_A, P_A, N_A$ read the same scheduled windows, dyadic ledger, regular handoff, seal row, transports, continuation routes, provenance, and naming row as X, S, D, G, E, T, P, N. For a* $\mathsf{LimitSelector}^{\uparrow}$ *row this means that $n_K, \mu_K, k_K, W_K, D_K, S_K, H_K, C_K, P_K, N_K$ select one of the same finite windows and then read the same dyadic ledger, regular handoff, seal row, transports, continuation routes, provenance, and naming row.*

Proof. Start with the CauchyLimitSeal window factorization of Definition 386.3 and the public route boundary of Definition 386.8. Together they identify every completion-facing or $\mathsf{Real}^{\uparrow}$-facing read of Q with the projected route packet X, S, D, G, E, T, P, N.

For a $\mathsf{ChoiceFreeLimitSchedule}^{\uparrow}$ row, apply the choice-free schedule obligations and non-escape rows of Definition 650.2 and Definition 650.4. They force the request, schedule, selected windows, dyadic ledger, regular handoff, seal row, transports, routes, provenance, and local name to be displayed in the finite packet before any completion consumer can read them.

For a $\mathsf{LimitSelector}^{\uparrow}$ row, apply the selector obligations and finite witness route of Definition 673.2 and Definition 673.3. The modulus-selected index only opens a displayed finite $\mathsf{StreamName}^{\uparrow}$ window, and the following dyadic readback and seal are the rows visible to the selector packet.

Finally use the observation-budget pullback, budgeted tail comparison admission, $\mathsf{RealObservationBudget}^{\uparrow}$ consumer package, and verification handoff of Definition 386.58, Definition 386.59, Definition 386.60, and Definition 386.76. These rows admit a selector surface only when it lands on the same public route packet of Q, so a selector with any different request, window, ledger, handoff, seal, transport, route, provenance, or local name is outside the seal admission surface. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier choice free selector admission`

Theorem 386.108 (CauchyLimitSeal choice-free selector stability)**.** *Suppose accepted* CauchyLimitSeal$^{\uparrow}$ *carriers Q and Q' are related by local classifier transport, and suppose an accepted* ChoiceFreeLimitSchedule$^{\uparrow}$ *row or* LimitSelector$^{\uparrow}$ *row is admitted through Q by Definition 386.107. Then the transported seal admits the transported selector route componentwise: the same choice-free schedule row or the same modulus-selected finite witness row is carried to Q' through the displayed* hsame *transports and* Cont *replays, while the selected finite* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *ledger,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal,* Pkg *provenance, and local* NameCert *row remain the corresponding rows of the transported public route packet.*

Proof. Project the public route packet of Q. By Definition 386.7, classifier transport acts componentwise on the displayed RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RealCauchyCompletion$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Use selector admission for Q. The admitted ChoiceFreeLimitSchedule$^{\uparrow}$ or LimitSelector$^{\uparrow}$ route has no row outside that public route packet, so each of its request, window, ledger, handoff, seal, transport, replay, provenance, and naming coordinates is already one of the transported coordinates.

For the schedule case, apply Definition 650.5; for the selector case, apply the componentwise classifier clause in Definition 673.2. These rows preserve the same finite schedule or selected finite witness under the displayed hsame comparisons.

The observation-budget pullback and verification handoff of Definition 386.58 and Definition 386.76 then replay the transported route through Q'. Hence classifier transport preserves the admitted selector route component by component and keeps the same finite windows as the selected windows of the transported seal packet. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier choice free selector stability`

Theorem 386.109 (CauchyLimitSeal choice-free selector non-escape)**.** *An accepted selector route admitted by Definition 386.107 exports no hidden limit choice, quotient stream equality, host real equality, ambient completeness datum, unbounded schedule, hidden family limit, or alternate seal. Its public export is exhausted by the displayed* BHist *packet over the* ChoiceFreeLimitSchedule$^{\uparrow}$ *or* LimitSelector$^{\uparrow}$ *row and the* CauchyLimitSeal$^{\uparrow}$ *public route packet: precision request, selected finite* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *ledger,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal row,* hsame *transports,* Cont *replays,* Pkg *provenance, and local* NameCert *row.*

Proof. Start with selector admission. The admitted route is already identified with the public route packet of the seal, so every exported coordinate is one of the displayed request, window, ledger, handoff, seal, transport, route, provenance, and local naming rows.

Use the selector-side boundaries. The choice-free schedule non-escape theorem Definition 650.4 excludes quotient streams, host real equality, countable choice, hidden selectors, and ambient completeness from the schedule route, while the LimitSelector finite witness route and Real seal non-escape theorems, Definition 673.3 and Definition 673.5, exclude host-selected limits, quotient-stream equality, countable-choice selectors, and ambient completeness from the selector route.

Now apply the seal-side boundaries: public route boundary, observation-budget pullback, budgeted tail comparison admission, RealObservationBudget consumer package, and verification handoff. These rows keep the route on the same finite budget and seal packet, with no field for a hidden family limit, alternate seal, unbounded schedule, host real equality, quotient stream equality, or ambient completeness.

The carrier inventory therefore exhausts the export. Since neither the selector packet nor the admitted CauchyLimitSeal packet contains any of the excluded rows, no downstream $\mathsf{Real}^{\uparrow}$ or completion consumer can recover one from the admitted selector surface. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier choice free selector nonescape`

Corollary 386.110 (CauchyLimitSeal choice-free selector admission strict obstruction)**.** *Let*

$$Q = (X, S, D, G, E, T, P, N)$$

be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. A local refusal of a proposed* $\mathsf{ChoiceFreeLimitSchedule}^{\uparrow}$ *row*

$$A = (E_A, M_A, W_A, D_A, R_A, S_A, H_A, C_A, P_A, N_A)$$

or of a proposed $\mathsf{LimitSelector}^{\uparrow}$ *row*

$$K = (R_K, n_K, \mu_K, k_K, W_K, D_K, S_K, H_K, C_K, P_K, N_K)$$

through Q is strict in the following sense. It blocks only the attempted reuse of that row as an admitted selector surface for the public route packet of Q. Its scope is limited to the named coordinates: precision request, scheduled or selected finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. It does not supply a global impossibility theorem for choice-free schedules or finite selectors, does not assert host* $\mathsf{Real}^{\uparrow}$ *equality or ambient completeness, and does not validate an external route outside the displayed packet.*

Proof. By Definition 386.107, admission through Q is available only when the proposed schedule or selector row lands on the public route packet X, S, D, G, E, T, P, N. In the schedule case this means that $E_A, M_A, W_A, D_A, R_A, S_A, H_A, C_A, P_A, N_A$ are read as the displayed request, schedule, window, ledger, handoff, seal, transport, replay, provenance, and naming rows of Q. In the selector case this means that $n_K, \mu_K, k_K, W_K, D_K, S_K, H_K, C_K, P_K, N_K$ first select one displayed finite window and then read the same ledger, handoff, seal, transport, replay, provenance, and naming rows of Q.

Thus a refusal can only be a failure of that displayed factorization. If the proposed route changes the request, window, dyadic ledger, regular handoff, seal row, transport, replay, provenance, or local name, the row is outside the admission surface for this carrier. The refusal has no further coordinate to inspect, because the admission theorem has already identified every consumer-facing use with the finite packet just listed.

Now apply Definition 386.109. An admitted selector route exports no hidden limit choice, quotient stream equality, host real equality, ambient completeness datum, unbounded schedule, hidden family limit, or alternate seal. The same inventory controls the rejected route: the rejection is read against the finite packet whose admissible exports are exhausted by the theorem. Therefore the failure cannot be repacked as a host theorem, an ambient completeness principle, an external validation, or a global nonexistence statement about all choice-free schedules or selectors.

The obstruction is consequently local and strict. It blocks exactly the named converse or reuse attempt through Q; every consumer-facing use that remains admissible must factor through the displayed rows of Definition 386.107, and every unlisted coordinate is rejected by the non-escape boundary of Definition 386.109. □

Theorem 386.111 (CauchyLimitSeal root choice-free route)**.** *Every accepted* CauchyLimitSeal$^{\uparrow}$ *packet has a root choice-free route assembled from its carrier, its public route packet, and any admitted* ChoiceFreeLimitSchedule$^{\uparrow}$ *or* LimitSelector$^{\uparrow}$ *selector surface. The route reads only the displayed* RegSeqRat$^{\uparrow}$ *source row,* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *ledger,* Real$^{\uparrow}$ *seal row,* BHist *surface,* hsame *transports,* Cont *replays,* Pkg *provenance, and local* NameCert *rows, and it exports no hidden selector, quotient stream equality, selected host limit, ambient completeness datum, or hidden choice principle.*

Proof. Start with the public route boundary of Definition 386.8. It identifies each accepted seal read with the displayed route packet over the regular source, stream windows, dyadic ledger, seal row, transports, continuations, provenance, and local name.

Attach selector admission by Definition 386.107. A ChoiceFreeLimitSchedule$^{\uparrow}$ row or LimitSelector$^{\uparrow}$ row is admitted only when its request, windows, dyadic ledger, regular handoff, seal, transport, route, provenance, and naming coordinates coincide with that public route packet.

Finally use selector non-escape from Definition 386.109. Since the admitted selector surface already contains no hidden limit choice, quotient stream equality, selected host limit, ambient completeness datum, or hidden choice principle, the root route remains the displayed finite packet. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier root choice free route`

Theorem 386.112 (CauchyLimitSeal root budget seal coverage)**.** *The root route of an accepted* CauchyLimitSeal$^{\uparrow}$ *packet covers every* RealObservationBudget$^{\uparrow}$ *seal read admitted through the packet. The budget read factors through the same* RegSeqRat$^{\uparrow}$ *handoff,* StreamName$^{\uparrow}$ *window,* DyadicRatCore$^{\uparrow}$ *observation ledger,* Real$^{\uparrow}$ *seal,* BHist *surface,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *rows, with no quotient stream equality, selected host limit, ambient completeness, alternate seal, or hidden family limit.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier root budget seal coverage`

Proof. Begin with observation-budget pullback from Definition 386.58. It sends every accepted budget read into the public route packet of the accepted seal while preserving the precision request, finite windows, dyadic ledger, regular handoff, seal row, transports, continuations, provenance, and local naming rows.

Use the budget root source totality theorem Definition 386.87. It says the composed budget read is sourced exactly by the displayed seal rows and displayed budget rows, so the budget cannot introduce a second source surface.

Then apply dyadic-window exactness and completion-consumer non-escape from Definition 386.88 and Definition 386.94. These rows identify the budget ledger with the scheduled seal window and exclude quotient equality, selected host limits, ambient completeness, alternate seals, and hidden family limits. □

Theorem 386.113 (CauchyLimitSeal root formal handoff package)**.** *The root choice-free route of Definition 386.111, the root budget seal coverage of Definition 386.112, the root-unblock package of Definition 386.57, and the completion-budget factorization of Definition 386.56 form one formal handoff package for downstream* Real$^{\uparrow}$ *and completion consumers. The package is the finite* CauchyLimitSeal$^{\uparrow}$ *route over* RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert, *and it excludes quotient stream equality, selected host limits, ambient completeness, hidden choice, hidden family limits, and host real equality.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier root formal handoff package`

Proof. First assemble the choice-free route. By Definition 386.111, selector access is already confined to the accepted seal packet and its displayed route rows.

Next attach the budget coverage. By Definition 386.112, every observation-budget seal read factors through the same regular source, stream window, dyadic ledger, real seal, transport, continuation, provenance, and local naming surface.

Now combine the two sides with Definition 386.57 and Definition 386.56. These rows bind selector, budget, and completion reads to one finite route and keep the route on the same displayed consumer surface.

The excluded coordinates are absent from each ingredient and from the accepted carrier. Therefore the resulting handoff package gives downstream consumers the named finite rows without quotient stream equality, selected host limits, ambient completeness, hidden choice, hidden family limits, or host real equality. □

Theorem 386.114 (CauchyLimitSeal root formal route readback)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$ *or completion consumer of the formal handoff package of Definition 386.113 reads exactly the displayed regular source, stream windows, dyadic ledger, seal row, transports, continuation routes, provenance, and local name. The readback has no alternate selector, quotient stream equality, selected host limit, ambient completeness, hidden choice, hidden family limit, or host real equality.*

Proof. Begin with the choice-free route of Definition 386.111. It confines every admitted selector surface to the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{Real}^{\uparrow}$ seal row, BHist surface, hsame transports, Cont routes, Pkg provenance, and local $\mathsf{NameCert}$ row.

Next apply Definition 386.112. Every observation-budget seal read uses the same regular handoff, finite windows, dyadic observation ledger, seal row, transport, continuation, provenance, and local naming coordinates.

The formal handoff package of Definition 386.113 combines those rows with the completion-budget factorization of Definition 386.56. Thus downstream completion consumers receive one finite route rather than an additional selector or limit source.

The excluded coordinates are absent at each cited boundary. Since none of the ingredients exports quotient stream equality, a selected host limit, ambient completeness, hidden choice, a hidden family limit, or host real equality, the readback of the handoff package exposes exactly the displayed rows and nothing further. □

Theorem 386.115 (CauchyLimitSeal root choice-free downstream coverage)**.** *Let*

$$L = (X, S, D, G, E, T, P, N)$$

be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet. Every accepted local downstream consumer admitted through the root choice-free route of* L *is exhausted by the finite route rows already displayed in the root handoff package: either a* $\mathsf{ChoiceFreeLimitSchedule}^{\uparrow}$ *or* $\mathsf{LimitSelector}^{\uparrow}$ *selector surface admitted through the same packet, a* $\mathsf{RealObservationBudget}^{\uparrow}$ *seal read covered by the root budget route, or the common readback over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. Any proposed downstream coordinate outside these displayed alternatives, ledgers, and coverage rows remains outside the BEDC packet: no hidden selector, quotient stream equality, selected host limit, ambient completeness datum, alternate seal, hidden family limit, host real equality, or unlisted completion source is exported.*

Proof. Start with the root choice-free route of Definition 386.111. It identifies the accepted root route of L with the carrier, its public route packet, and any admitted $\mathsf{ChoiceFreeLimitSchedule}^{\uparrow}$ or $\mathsf{LimitSelector}^{\uparrow}$ selector surface. The componentwise transport used in this identification is the public route transport of Definition 386.7. The only selector alternatives available at that boundary are the displayed precision request, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{Real}^{\uparrow}$ seal row, BHist surface, hsame transports, Cont replays, Pkg provenance, and local $\mathsf{NameCert}$ rows.

Next apply the root budget seal coverage theorem Definition 386.112. Every admitted $\mathsf{RealObservationBudget}^{\uparrow}$ seal read is pulled back to the same regular handoff, finite window, dyadic observation ledger, seal row, transports, continuations, provenance, and local naming coordinates. Thus a budget-facing downstream consumer does not add a second source surface; it is one of the coverage rows already attached to the root route.

The two cited boundaries cover the local consumer cases named in the handoff file. Selector-facing consumers are covered by the choice-free route, budget-facing consumers are covered by the budget seal route, and the common readback is just the shared route over the listed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. Therefore an accepted local downstream use factors through the displayed finite alternatives, ledgers, or coverage rows.

The excluded coordinates are absent from both inputs. The choice-free route exports no hidden selector, quotient stream equality, selected host limit, ambient completeness datum, or hidden choice principle, while the budget coverage route exports no quotient stream equality, selected host limit, ambient completeness, alternate seal, or hidden family limit. Since every accepted downstream consumer has already been factored through one of those displayed rows, an unlisted selector, quotient equality, host limit, completeness datum, alternate seal, hidden family limit, host real equality, or external completion source has no BEDC packet coordinate from which it could be read. □

Theorem 386.116 (CauchyLimitSeal StreamName dependency)**.** *Every* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer read of a sealed Cauchy limit factors through the finite* $\mathsf{StreamName}^{\uparrow}$ *window surface of chapter 126 before the seal row is consumed. In the carrier notation*

$$L = (X, S, D, G, E, T, P, N),$$

the read must pass through the scheduled window row S, its displayed $\mathsf{RegSeqRat}^{\uparrow}$ *source row in X, the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger in D, and the transport route in T before any downstream consumer reads the* $\mathsf{Real}^{\uparrow}$ *seal row E. The route excludes quotient streams, host limits, selected external limits, and ambient completeness data.*

The downstream $\mathsf{RegularCauchyName}^{\uparrow}$ *consumer of chapter 371 reads the same scheduled* $\mathsf{StreamName}^{\uparrow}$ *row, so* $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegularCauchyName}^{\uparrow}$ *share the finite window before the* $\mathsf{Real}^{\uparrow}$ *seal row is read.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier streamname dependency`

Proof. Start with the carrier of Definition 386.1. The schedule row S is the only row that lists finite windows, and the seal row E has no independent consumer channel.

Apply window factorization from Definition 386.3. It routes every finite consumer request through the $\mathsf{StreamName}^{\uparrow}$ window, the regular source row, the dyadic observation ledger, and the displayed transport rows before reaching the seal.

Finally use non-escape from Definition 386.4. Since quotient streams, host limits, selected external limits, and ambient completeness do not occur as carrier coordinates, the finite $\mathsf{StreamName}^{\uparrow}$ window surface is the required dependency child for every sealed-limit read. □

Theorem 386.117 (CauchyLimitSeal StreamName and RegularCauchyName lattice)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier* $L = (X, S, D, G, E, T, P, N)$*, every sealed-limit consumer that is also read by* $\mathsf{RegularCauchyName}^{\uparrow}$ *factors through the same scheduled* $\mathsf{StreamName}^{\uparrow}$ *row* S *before reaching the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* X*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, diagonal row* G*, and* $\mathsf{Real}^{\uparrow}$ *seal* E*. The packet exports no second window schedule, quotient stream equality, selected host limit, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier streamname regular name lattice`

Proof. Begin with the StreamName dependency theorem Definition 386.116. It already places every sealed-limit read on the scheduled $\mathsf{StreamName}^{\uparrow}$ window before the seal row is consumed.

Apply window factorization from Definition 386.3. The route from S proceeds through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ row X, the dyadic ledger D, the diagonal row G, and only then the $\mathsf{Real}^{\uparrow}$ seal row E.

Next use the scheduled-window pullback of Definition 386.20. This identifies the scheduled window as the common dependency surface for the seal route and for the $\mathsf{RegularCauchyName}^{\uparrow}$ consumer of chapter 371.

Since the carrier has no second schedule coordinate and no quotient, selected-limit, or ambient-completeness row, the shared lattice closes at the same finite window and cannot be rerouted through an external equality or host limit. □

Theorem 386.118 (CauchyLimitSeal StreamName Real terminal handoff)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier* $L = (X, S, D, G, E, T, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing sealed-limit consumer factors through the same scheduled* $\mathsf{StreamName}^{\uparrow}$ *row* S*, then the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* X*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, the diagonal row* G*, and only then the* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The route exposes no second schedule, quotient stream equality, selected host limit, host real equality, or ambient completeness coordinate.*

Proof. Begin with the StreamName dependency theorem Definition 386.116. It places each sealed-limit read on the finite $\mathsf{StreamName}^{\uparrow}$ window before any downstream consumer can read the seal row.

Apply the StreamName and RegularCauchyName lattice theorem Definition 386.117. The shared row is the scheduled S row, and its displayed route proceeds through X, D, and G before reaching E.

Finally combine window factorization Definition 386.3, scheduled-window pullback Definition 386.20, and non-escape Definition 386.4. These local facts rule out a second schedule, quotient equality, selected host limit, host real equality, and ambient completeness as carrier exits, so the only $\mathsf{Real}^{\uparrow}$-facing terminal route is the displayed handoff through S, X, D, G, and E. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier streamname real terminal handoff`

Theorem 386.119 (CauchyLimitSeal StreamName bridge determinacy)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier* $L = (X, S, D, G, E, T, P, N)$*, every consumer-facing route, transport, readback, or terminal handoff that reaches the sealed* $\mathsf{Real}^{\uparrow}$ *endpoint is determined by the displayed local rows*

$$S, \quad X, \quad D, \quad G, \quad T, \quad P, \quad N, \quad E.$$

More precisely, the consumer first factors through the scheduled $\mathsf{StreamName}^{\uparrow}$ *window row* S*, then through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* X*, the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, the completion diagonal row* G*, and the transport row* T *before the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is read; when the same use asks for public readback or certificate provenance, the only available readback coordinates are the displayed* P *and* N *rows on that route. No unlisted bridge coordinate, second schedule, quotient stream equality, selected host limit, host real equality, hidden tail witness, or ambient completeness datum is available to such a consumer.*

Proof. Begin with the StreamName dependency theorem Definition 386.116. It places every sealed-limit consumer read on the finite $\mathsf{StreamName}^{\uparrow}$ window surface before the seal row is consumed, and in the carrier notation $L = (X, S, D, G, E, T, P, N)$ it identifies the mandatory initial route through S, the displayed source row X, the dyadic ledger D, and the transport route T.

Apply the terminal handoff theorem Definition 386.118. This refines the same dependency route for $\mathsf{Real}^{\uparrow}$-facing consumers: after the scheduled row S and the displayed source and ledger rows X and D, the read must pass through the diagonal row G before it reaches the seal row E. Thus any route or handoff reaching the terminal real endpoint has the same ordered local support and cannot choose a different endpoint path.

For transport and readback uses, use the public route packet and public route boundary, Definition 386.6 and Definition 386.8. They restrict the public consumer surface to the displayed carrier rows and their visible transport, package, and naming data. Hence a transport use is read from T on the route already forced through S, X, D, G, E, while any public readback or certificate provenance can only use the displayed P and N rows attached to that same packet.

Finally apply non-escape from Definition 386.4. Since the accepted carrier contains no coordinate for a second schedule, quotient stream equality, selected host limit, host real equality, hidden tail witness, or ambient completeness datum, none of those entries can be supplied after the consumer has reached the public boundary. The local rows listed above therefore exhaust the possible consumer-facing bridge uses, and every unlisted bridge coordinate remains unavailable. □

Corollary 386.120 (CauchyLimitSeal StreamName dependency determinacy)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier, and fix the local rows named by the* $\mathsf{StreamName}^{\uparrow}$ *dependency route: the scheduled window row* S*, the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* X*, the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, the completion diagonal row* G*, the transport ledger* T*, the provenance row* P*, the local* $\mathsf{NameCert}$ *row* N*, and the sealed* $\mathsf{Real}^{\uparrow}$ *endpoint* E*. Then every accepted consumer-facing use of the* $\mathsf{CauchyLimitSeal}^{\uparrow}$–$\mathsf{StreamName}^{\uparrow}$ *dependency, whether it asks for a route, a transport, a readback, a finite normal form, or an exactness decision, is determined by those rows.*

Equivalently, the only consumer-visible route is the displayed finite route

$$S \to X \to D \to G \to T \to E,$$

with public readback and certificate provenance read only from P *and* N*. No accepted use can choose an alternate hidden coordinate, a second scheduled window, a duplicate classifier source, a quotient stream equality, a selected host limit, a host real equality, a hidden tail witness, or an ambient completeness datum.*

Proof. Start with the $\mathsf{StreamName}^{\uparrow}$ dependency theorem Definition 386.116. It forces every sealed-limit consumer read to enter through the finite $\mathsf{StreamName}^{\uparrow}$ window surface before the seal is consumed. In the displayed carrier notation this fixes the initial dependency rows: the schedule row S, its $\mathsf{RegSeqRat}^{\uparrow}$ source row X, the matching $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, and the transport row T.

Now apply the bridge determinacy theorem Definition 386.119. That theorem identifies every consumer-facing route, transport, readback, and terminal handoff reaching the sealed $\mathsf{Real}^{\uparrow}$ endpoint with the local rows

$$S, \quad X, \quad D, \quad G, \quad T, \quad P, \quad N, \quad E.$$

Thus once the dependency rows cited in the statement are fixed, the bridge has no remaining degree of freedom from which a second route or a second public readback could be selected.

The finite normal form is the same route read as a packet normal form. The scheduled window in S names the consumer window; X supplies the regular source row; D supplies the dyadic observation ledger; G supplies the completion diagonal; T supplies the visible BHist, hsame, and Cont transport; E is the sealed endpoint; and P, N supply the Pkg provenance and local NameCert readback. Since all of these rows are already fixed, a normal-form request must return that packet and cannot duplicate the classifier source in a second coordinate.

For exactness decisions, the same argument applies at the public boundary. Exactness is consumer-facing only through the accepted route to the sealed endpoint, and Definition 386.119 confines that route to the displayed local rows. The non-escape clauses cited there rule out quotient stream equality, selected host limits, host real equality, hidden tail witnesses, and ambient completeness data. Therefore any accepted exactness decision is read from the fixed finite route and its P, N certificate rows, with no alternate hidden coordinate or duplicate classifier source available. □

Theorem 386.121 (CauchyLimitSeal StreamName lattice orphan link)**.** *Every accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer route that uses the seal row factors through the sibling* $\mathsf{StreamName}^{\uparrow}$ *finite-window dependency of chapter 126 and through the finite-window lattice dependency of Definition 386.160 before any* $\mathsf{Real}^{\uparrow}$ *seal read. The route remains the displayed finite* X, S, D, G, E, T, P, N *surface and does not introduce a quotient stream, selected host limit, host real equality, hidden tail witness, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier streamname lattice orphan link`

Proof. Begin with the local StreamName dependency Definition 386.116. It places every sealed-limit read on the finite $\mathsf{StreamName}^{\uparrow}$ window surface before the seal row is consumed.

Next use the scheduled-window pullback Definition 386.20. The same finite-window surface is the common dependency for the scheduled window, the regular source row, the dyadic ledger, and the downstream seal route.

Finally apply the finite-window lattice dependency Definition 386.160. It routes the consumer through the StreamName meet surface before the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are read, and its non-escape clause rules out every hidden completion or host-level substitute named in the statement. □

386.1 CauchyLimitSeal Synchronizer Dependency

Theorem 386.122 (CauchyLimitSeal StreamName synchronizer pullback)**.** *Every* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *seal read consumed through chapter 886 first factors through the finite* $\mathsf{StreamName}^{\uparrow}$ *window surface of chapter 126, the displayed* $\mathsf{RegularCauchyName}^{\uparrow}$ *route of chapter 371, and the local* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *rows before the synchronizer budget, selector, shared-tail, compatibility, transport, route, provenance, and naming rows are read.*

The route has no quotient stream equality, selected host limit, ambient completeness row, or direct $\mathsf{Real}^{\uparrow}$ *seal edge bypassing the finite window.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier streamname synchronizer pullback`

Proof. Begin with the StreamName dependency theorem Definition 386.116. It places every sealed-limit read on the finite $\mathsf{StreamName}^{\uparrow}$ window surface before the $\mathsf{Real}^{\uparrow}$ seal row is consumed.

Next apply the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegularCauchyName}^{\uparrow}$ lattice theorem Definition 386.117. It identifies the displayed regular Cauchy name route as the same finite scheduled window surface used by the seal consumer.

Now read the synchronizer chapter chapter 886. Its consumer rows are the budget, selector, shared-tail, compatibility, transport, route, provenance, and naming rows, and each row is attached to the already displayed seal route rather than to an independent $\mathsf{Real}^{\uparrow}$ edge.

Coordinate exhaustion gives the claim. The only available route into the synchronizer is through the finite window, the displayed regular Cauchy name route, and the local $\mathsf{CauchyLimitSeal}^{\uparrow}$ rows; quotient stream equality, selected host limits, ambient completeness, and a direct $\mathsf{Real}^{\uparrow}$ bypass do not occur among the displayed coordinates. □

Theorem 386.123 (CauchyLimitSeal synchronizer observation-budget route exactness)**.** *Every synchronizer read that enters through an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *packet and exits through an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet factors through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the observation-budget rows, and the synchronizer rows before the* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The route is carried by the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, and it exposes no quotient stream, selected limit, host real equality, hidden family limit, unbounded schedule, or ambient completeness coordinate.*

Proof. Start with the synchronizer pullback of Definition 386.122. It places every synchronizer-facing seal read on the finite $\mathsf{StreamName}^{\uparrow}$ window surface, the displayed $\mathsf{RegularCauchyName}^{\uparrow}$ route, and the local $\mathsf{CauchyLimitSeal}^{\uparrow}$ rows before the synchronizer budget is read.

Next attach the observation-budget consumer exactness theorem Definition 611.9. The accepted $\mathsf{RealObservationBudget}^{\uparrow}$ packet identifies its $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers with the same finite precision, window, dyadic ledger, handoff, seal, transport, route, provenance, and naming rows.

Finally apply Real-facing synchronizer budget exhaustion from Definition 886.6. The shared BHist, hsame, Cont, Pkg, and NameCert rows exhaust the composed route, so there is no remaining coordinate from which a quotient stream, selected limit, host real equality, hidden family limit, unbounded schedule, or ambient completeness principle can be read. □

Theorem 386.124 (CauchyLimitSeal synchronizer tail-budget nonescape)**.** *Every synchronizer read that passes through chapter 886, chapter 611, and an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet must first display the finite* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegularCauchyName}^{\uparrow}$ *route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the local seal rows before the shared-tail budget or* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The route exposes no quotient stream, selected host limit, hidden family limit, unbounded schedule, or ambient completeness coordinate.*

Proof. First use the pullback theorem Definition 386.122. It places every synchronizer-facing seal read on the finite $\mathsf{StreamName}^{\uparrow}$ window and the displayed $\mathsf{RegularCauchyName}^{\uparrow}$ route before any synchronizer budget row is read.

Next apply the observation-budget route exactness theorem Definition 386.123. This identifies the $\mathsf{RealObservationBudget}^{\uparrow}$ leg with the same finite $\mathsf{RegSeqRat}^{\uparrow}$ handoff, observation-budget rows, synchronizer rows, and local $\mathsf{CauchyLimitSeal}^{\uparrow}$ seal rows.

Finally apply the synchronizer budget exhaustion theorem Definition 886.6. The shared-tail and $\mathsf{Real}^{\uparrow}$ seal reads have already spent the displayed BHist, hsame, Cont, Pkg, and NameCert

coordinates, so carrier-coordinate exhaustion leaves no quotient stream, selected host limit, hidden family limit, unbounded schedule, or ambient completeness coordinate to consume. □

Theorem 386.125 (CauchyLimitSeal synchronizer finite-window nonescape)**.** *Every synchronizer-facing* CauchyLimitSeal$^{\uparrow}$ *read that passes through* StreamName$^{\uparrow}$, RegularCauchyName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealObservationBudget$^{\uparrow}$, *and the local seal rows factors through the displayed finite* StreamName$^{\uparrow}$ *window,* ProbeBundle *and* InBundle *membership, the* RegSeqRat$^{\uparrow}$ *handoff, the observation-budget rows, the synchronizer rows, and the local* BHist, hsame, Cont, Pkg, *and* NameCert *coordinates before any* Real$^{\uparrow}$ *seal is consumed. No quotient stream, hidden family limit, selected host limit, host real equality, unbounded schedule, ambient completeness principle, or direct* Real$^{\uparrow}$ *bypass is readable from such a route.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier synchronizer finite window nonescape`

Proof. First apply the StreamName and regular-name pullback theorem Definition 386.122. It places the synchronizer-facing seal read on the finite StreamName$^{\uparrow}$ window surface and the displayed RegularCauchyName$^{\uparrow}$ route before any synchronizer budget coordinate is used.

Next apply the observation-budget route exactness theorem Definition 386.123. The RealObservationBudget$^{\uparrow}$ leg is therefore carried by the same finite window, the RegSeqRat$^{\uparrow}$ handoff, the observation-budget rows, the synchronizer rows, and the local CauchyLimitSeal$^{\uparrow}$ seal rows.

Finally use the tail-budget nonescape theorem Definition 386.124. It exhausts the shared-tail route through the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates before the Real$^{\uparrow}$ seal is read.

These coordinates are the entire displayed synchronizer route. Since quotient streams, hidden family limits, selected host limits, host real equality, unbounded schedules, ambient completeness principles, and direct Real$^{\uparrow}$ bypasses are absent from that coordinate list, none of them can be read by the synchronizer consumer. □

Theorem 386.126 (CauchyLimitSeal synchronizer route factorization)**.** *Any synchronizer-facing* CauchyLimitSeal$^{\uparrow}$ *read factors through the* StreamName$^{\uparrow}$ *finite-window surface, the* RegularCauchyName$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *handoff surfaces, the* RealObservationBudget$^{\uparrow}$ *rows, the* CauchySealBudgetSynchronizer$^{\uparrow}$ *rows of chapter 886, and the local* CauchyLimitSeal$^{\uparrow}$ *rows before the* Real$^{\uparrow}$ *seal is consumed. The factorization has no quotient stream equality, selected host limit, hidden family limit, host real equality, unbounded schedule, ambient completeness row, or direct* Real$^{\uparrow}$ *bypass.*

Proof. Start with the pullback theorem Definition 386.122. It places the synchronizer-facing read on the finite StreamName window, the displayed RegularCauchyName route, and the local CauchyLimitSeal rows before the synchronizer budget rows of chapter 886 are read.

Next use observation-budget route exactness from Definition 386.123. This identifies the RealObservationBudget leg with the RegSeqRat handoff, the observation-budget rows, the synchronizer rows, and the same local seal rows.

The tail-budget nonescape theorem Definition 386.124 then rules out quotient streams, selected host limits, hidden family limits, unbounded schedules, and ambient completeness coordinates along the shared-tail route.

Finally apply finite-window nonescape Definition 386.125. It exhausts the remaining BHist, hsame, Cont, Pkg, and NameCert coordinates before any Real$^{\uparrow}$ seal read, so the displayed factorization is the only synchronizer-facing route. □

Theorem 386.127 (CauchyLimitSeal RealCompletionSealClassifier handoff)**.** *Every synchronizer-facing* CauchyLimitSeal$^{\uparrow}$ *read consumed by an accepted* RealCompletionSealClassifierUp *packet factors through the finite* StreamName$^{\uparrow}$ *window surface, the* RegularCauchyName$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *handoff surfaces, the* RealObservationBudget$^{\uparrow}$ *rows, the* CauchySealBudgetSynchronizer$^{\uparrow}$ *rows, the local* CauchyLimitSeal$^{\uparrow}$ *rows, and then the* RealCompletionSealClassifierUp *public export route of Definition 900.13. The handoff exports no quotient stream, selected host limit, host real equality, countable-choice row, or ambient completeness coordinate.*

Proof. Apply synchronizer route factorization, Definition 386.126. It places the consumed CauchyLimitSeal$^{\uparrow}$ read on the finite StreamName$^{\uparrow}$ window, RegularCauchyName$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ handoff rows, RealObservationBudget$^{\uparrow}$ rows, CauchySealBudgetSynchronizer$^{\uparrow}$ rows, and local seal rows before the consumer reaches any Real$^{\uparrow}$ seal.

Now apply the public export theorem for the classifier, Definition 900.13. The accepted RealCompletionSealClassifierUp packet can consume the synchronizer-facing seal only through its displayed public rows, so the preceding synchronizer route is handed to the classifier as part of the same finite completion-seal export surface.

Finally combine the non-escape boundary already built into Definition 386.126 with the classifier non-escape boundary cited by Definition 900.13. Neither route contains a quotient stream, selected host limit, host real equality, countable-choice row, or ambient completeness coordinate, and the classifier public export adds no second channel for such data. □

Theorem 386.128 (CauchyLimitSeal common-window budget synchronizer exhaustion)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* CauchyLimitSeal$^{\uparrow}$ *carrier. Any synchronizer-facing seal read of* L *that consumes both the* RealObservationBudget$^{\uparrow}$ *route and the* CauchySealBudgetSynchronizer$^{\uparrow}$ *route first pulls back to the same* StreamName$^{\uparrow}$ *finite-window lattice surface of Definition 386.160. It then proceeds through the displayed* RegSeqRat$^{\uparrow}$ *source row, dyadic ledger, completion diagonal, synchronizer rows, observation-budget rows, and* Real$^{\uparrow}$ *seal row. The common route exports no second finite window, quotient stream equality, selected host limit, hidden family limit, host real equality, unbounded schedule, or ambient completeness coordinate.*

Proof. Begin with the finite-window lattice dependency of Definition 386.160. It pulls the accepted seal route back to the StreamName$^{\uparrow}$ finite-window lattice surface before the displayed RegSeqRat$^{\uparrow}$ source row, dyadic ledger, completion diagonal, and Real$^{\uparrow}$ seal row are consumed.

Next apply synchronizer route factorization, Definition 386.126. This places the synchronizer-facing leg on the same displayed StreamName$^{\uparrow}$, RegularCauchyName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealObservationBudget$^{\uparrow}$, CauchySealBudgetSynchronizer$^{\uparrow}$, and local CauchyLimitSeal$^{\uparrow}$ rows rather than on an independent seal route.

Now apply observation-budget route exactness, Definition 386.123. The RealObservationBudget$^{\uparrow}$ leg is therefore consumed along the same finite precision, window, dyadic ledger, handoff, seal, transport, route, provenance, and naming rows used by the synchronizer leg.

Finally use finite-window nonescape Definition 386.125 and tail-budget nonescape Definition 386.124. Together they exhaust the remaining BHist, hsame, Cont, Pkg, and NameCert coordinates before the Real$^{\uparrow}$ seal is read, leaving no second finite window, quotient stream equality, selected host limit, hidden family limit, host real equality, unbounded schedule, or ambient completeness coordinate. □

Theorem 386.129 (CauchyLimitSeal observer-budget handoff)**.** *Every synchronizer-facing* CauchyLimitSeal$^{\uparrow}$ *read consumed by a Real completion consumer first factors through the finite* StreamName$^{\uparrow}$ *window, the* RegularCauchyName$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *handoff, the* RealObservationBudget$^{\uparrow}$ *rows, the*

$\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *route, and the observer-budget limiting surface before any* $\mathsf{Real}^{\uparrow}$ *seal is public. The public handoff excludes quotient streams, selected host limits, hidden family limits, host real equality, unbounded schedules, countable choice, and ambient completeness.*

Proof. Begin with common-window budget synchronizer exhaustion, Definition 386.128. It places the synchronizer-facing seal read on the same finite $\mathsf{StreamName}^{\uparrow}$ lattice surface, $\mathsf{RegSeqRat}^{\uparrow}$ source row, dyadic ledger, completion diagonal, synchronizer rows, observation-budget rows, and $\mathsf{Real}^{\uparrow}$ seal row.

Next apply the RealCompletionSealClassifier handoff theorem, Definition 386.127. The Real completion consumer can receive the synchronizer-facing $\mathsf{CauchyLimitSeal}^{\uparrow}$ read only through the displayed classifier export route, so the finite handoff remains before the public $\mathsf{Real}^{\uparrow}$ seal.

Now use observation-budget route exactness, Definition 386.123. It identifies the $\mathsf{RealObservationBudget}^{\uparrow}$ leg with the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, the observation-budget rows, the synchronizer rows, and the local $\mathsf{CauchyLimitSeal}^{\uparrow}$ packet.

Carrier-coordinate exhaustion finishes the handoff. The displayed rows over BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ are the whole route available to the consumer before the $\mathsf{Real}^{\uparrow}$ seal is public. Since quotient streams, selected host limits, hidden family limits, host real equality, unbounded schedules, countable choice, and ambient completeness are not coordinates of that route, none can be exported by the observer-budget limiting surface. □

Theorem 386.130 (CauchyLimitSeal synchronizer observer-real seal factorization)**.** *Every synchronizer-facing* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *read consumed by a Real completion consumer factors through the finite* $\mathsf{StreamName}^{\uparrow}$ *window surface, the* $\mathsf{RegularCauchyName}^{\uparrow}$ *route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{RealObservationBudget}^{\uparrow}$ *rows, the* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *rows, the local* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *seal rows, and the public* $\mathsf{Real}^{\uparrow}$ *seal route before any completion-facing output is public.*

The factorization is a finite BEDC route over the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *coordinates. It exports no quotient stream equality, selected host limit, host real equality, unbounded schedule, countable-choice row, or ambient completeness coordinate.*

Proof. Start with synchronizer route factorization, Definition 386.126. It places every synchronizer-facing $\mathsf{CauchyLimitSeal}^{\uparrow}$ read on the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegularCauchyName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ handoff rows, the observation-budget rows, the synchronizer rows, and the local seal rows before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Next apply common-window budget synchronizer exhaustion. Definition 386.128 identifies the synchronizer and observation-budget legs with the same finite window, source row, dyadic ledger, completion diagonal, and seal route, so the Real-facing consumer cannot split them into two independent routes.

Now use the RealCompletionSealClassifier handoff theorem. It sends the already factorized synchronizer-facing read through the classifier public export surface, which keeps the completion-facing output behind the same finite seal route.

Finally apply observer-budget handoff. The observer-budget theorem states that the public Real completion read appears only after the $\mathsf{RealObservationBudget}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, local $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal rows have all been traversed. Since quotient stream equality, selected host limits, host real equality, unbounded schedules, countable choice, and ambient completeness are absent from that traversed route, none can be supplied to the completion-facing output. □

Theorem 386.131 (CauchyLimitSeal witness-ledger synchronizer handoff)**.** *Every synchronizer-facing* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *read consumed by a* $\mathsf{CauchyWitnessLedger}^{\uparrow}$ *packet factors through the finite* $\mathsf{StreamName}^{\uparrow}$ *window surface, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{RealObservationBudget}^{\uparrow}$ *rows, the* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *route, and the local* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *seal rows before the witness ledger can expose any completion-facing output. Once the ledger receives the synchronized seal read, the completion-facing route is exactly the displayed witness-ledger path*

$$Q \longmapsto B \longmapsto S \longmapsto K$$

with structural rows H, C, P, N *from Definition 902.5.*

The handoff exports no quotient stream equality, selected host limit, host real equality, countable-choice row, or ambient completeness coordinate.

Proof. First apply synchronizer route factorization, Definition 386.126. It places the consumed $\mathsf{CauchyLimitSeal}^{\uparrow}$ read on the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegularCauchyName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ handoff rows, the observation-budget rows, the $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ route, and the local seal rows before any Real-facing seal output is public.

Next apply observer-real seal factorization, Definition 386.130. The Real completion consumer therefore receives the synchronized seal only after the finite route through BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ has already been traversed.

Finally apply the witness-ledger budget factorization theorem, Definition 902.5. The $\mathsf{CauchyWitnessLedger}^{\uparrow}$ consumer can expose a completion-facing row only by reading Q, then B, then S, then K, with H, C, P, N replaying and naming the same finite packet.

The excluded coordinates are absent from both sides of the composition. The synchronizer side has no quotient stream equality, selected host limit, host real equality, countable-choice row, or ambient completeness coordinate, and the witness-ledger route adds only the displayed Q, B, S, K, H, C, P, N rows. Thus the composed handoff has no external route through which any excluded coordinate can become public. □

Theorem 386.132 (CauchyLimitSeal synchronizer witness-ledger finality)**.** *Every synchronizer-facing* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *read that has passed through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegularCauchyName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RealObservationBudget}^{\uparrow}$*,* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$*,* $\mathsf{RealCompletionSealClassifierUp}$*, and* $\mathsf{CauchyWitnessLedge}$ *is final at the displayed finite witness-ledger route. Any public completion-facing output factors through the same* BHist*,* hsame*,* Cont*,* Pkg*,* $\mathsf{NameCert}$*, and* Q, B, S, K, H, C, P, N *coordinates, and cannot read quotient stream equality, selected host limit, host real equality, countable choice, ambient completeness, or a second seal edge.*

Proof. First compose synchronizer route factorization with observer-real seal factorization, using Definition 386.126 and Definition 386.130. The synchronizer-facing read is already on the finite stream-name, regular-Cauchy-name, rational-sequence, observation-budget, synchronizer, and local seal rows before any completion-facing output is public.

Next apply the witness-ledger synchronizer handoff of Definition 386.131. It sends the synchronized seal read into the displayed witness-ledger path and prevents the completion consumer from bypassing the ledger.

Finally use the budget factorization of Definition 902.5. The public output can read only Q, B, S, K, H, C, P, N together with the underlying BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ structure already traversed by the seal route. Since quotient stream equality, selected host limits, host real equality, countable choice, ambient completeness, and a second seal edge are absent from those coordinates, the witness-ledger route is final for the synchronized read. □

Theorem 386.133 (CauchyLimitSeal synchronizer witness-ledger scope)**.** *Every completion-facing output produced after a synchronizer-facing* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *read and a* $\mathsf{CauchyWitnessLedger}^{\uparrow}$ *handoff is scoped exactly by the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegularCauchyName}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{RealObservationBudget}^{\uparrow}$ *rows,* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *route, local* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *rows,* $\mathsf{RealCompletionSealClassifierUp}$ *row, and witness-ledger rows* Q, B, S, K, H, C, P, N*. The output has no coordinate for quotient-stream equality, selected host limits, host real equality, countable choice, ambient completeness, or a second seal edge.*

Proof. First compose synchronizer route factorization with observer-real seal factorization, using Definition 386.126 and Definition 386.130. The synchronizer-facing read is thereby placed on the finite stream-name window, regular-Cauchy-name row, rational-sequence source row, observation-budget rows, synchronizer route, local seal rows, and Real classifier route before any completion-facing output is public.

Next attach the witness-ledger synchronizer handoff from Definition 386.131. The handoff sends the synchronized read through the displayed ledger path Q, B, S, K with structural rows H, C, P, N, so the completion-facing consumer reads the ledger and the classifier as one finite route.

Finally apply witness-ledger finality, Definition 386.132. Its final route is the same synchronizer, classifier, and witness-ledger surface just assembled, so no completion-facing output can be scoped by a larger packet.

Carrier-coordinate exhaustion gives the exclusions. The displayed route contains the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, local $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{RealCompletionSealClassifierUp}$, and witness-ledger rows, and it contains no quotient stream, selected host limit, host real equality, countable-choice, ambient-completeness, or second-seal coordinate. □

Corollary 386.134 (CauchyLimitSeal synchronizer strict local obstruction)**.** *Any displayed failure, refusal, separation, or countermodel row attached to the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *StreamName synchronizer pullback is strict only for the named synchronizer converse or reuse route that tries to consume the same finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegularCauchyName}^{\uparrow}$ *route,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{RealObservationBudget}^{\uparrow}$ *rows, synchronizer rows, and local seal rows. Such a row cannot be read as a global impossibility theorem, a host theorem about limits, a hidden external validation, a quotient-stream equality failure, an ambient-completeness failure, or a second independent* $\mathsf{Real}^{\uparrow}$ *seal obstruction.*

Proof. Apply tail-budget nonescape, Definition 386.124. It says that every synchronizer read passing through the synchronizer chapter, the observation-budget chapter, and an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ packet must first display the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegularCauchyName}^{\uparrow}$ route, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and the local seal rows before the shared-tail budget or $\mathsf{Real}^{\uparrow}$ seal is consumed. It also states that this route exposes no quotient stream, selected host limit, hidden family limit, unbounded schedule, or ambient completeness coordinate.

Now apply observation-budget route exactness, Definition 386.123. The accepted $\mathsf{RealObservationBudget}^{\uparrow}$ leg and the accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ leg are carried by the same finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, observation-budget rows, synchronizer rows, and shared BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ coordinates. Thus any consumer-facing use of a displayed negative row must factor through exactly those rows.

The strictness follows by coordinate exhaustion. A failure, refusal, separation, or countermodel row on this pullback can block the attempted converse or reuse of the displayed synchronizer route,

because that is the route whose rows it names. But the two cited theorems leave no additional coordinate for a global impossibility theorem, host limit theorem, hidden external validation, quotient-stream equality, ambient-completeness principle, or independent $\mathsf{Real}^{\uparrow}$ seal edge. Reinterpreting the row in any of those ways would require a coordinate not present in the finite synchronizer packet, so the obstruction is local to the named pullback route. □

Theorem 386.135 (CauchyLimitSeal tail-budget meet)**.** *Let*

$$L = (X, S, D, G, E, T, P, N)$$

be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet, and let*

$$B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet over the same displayed precision request and finite* $\mathsf{StreamName}^{\uparrow}$ *window. If the seal row* S_B *and the regular handoff rows* R_B *are routed through* L*, then there is a single finite meet row over* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *that binds the selector read, the observation-budget read, and the completion-consumer read to one BEDC route. The meet row contains no quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier tail budget meet`

Proof. Start with tail extraction from Definition 386.70. It projects every admitted tail read of L from the displayed regular family, stream schedule, dyadic observation ledger, diagonal row, seal row, and visible transport route.

Attach the $\mathsf{RealObservationBudget}^{\uparrow}$ side using Definition 386.60. Since the budget packet and the seal packet share the displayed precision request and window, the budget rows and seal rows meet over the same BHist, hsame, Cont, Pkg, and NameCert surface.

Finally use budget root source totality from Definition 386.87. It says every accepted budget-facing read is sourced by the listed seal and budget rows, so the selector, budget, and completion reads have one finite route and no extra completion, quotient, equality, selection, hidden-family, or ambient-completeness coordinate. □

Theorem 386.136 (CauchyLimitSeal selector-budget transport)**.** *In the setting of Definition 386.135, componentwise* hsame *transport and the displayed* Cont *routes preserve the meet row through selector admission and observation-budget transport. Thus any transported selector read, budget read, or completion-facing read remains on the same precision request, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal,* BHist *surface,* Pkg *provenance, and local* NameCert *row. Transport does not introduce quotient stream identity, host real equality, a choice-selected limit, a hidden family limit, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier selector budget transport`

Proof. Project the meet row supplied by Definition 386.135. Its readable coordinates are already the selector, budget, and completion-consumer coordinates on the shared finite route.

For the selector side, use Definition 386.108. It transports the admitted selector route componentwise through the displayed hsame comparisons and Cont replays while preserving the selected finite windows and dyadic ledger.

For the budget side, use the observation-budget pullback and consumer package from Definition 386.58 and Definition 386.60. These rows preserve the precision request, window, ledger,

regular handoff, seal, route, provenance, and naming rows. Hence every transported read remains inside the same finite meet packet. □

Theorem 386.137 (CauchyLimitSeal tail-budget meet exactness)**.** *Let L be an accepted* CauchyLimitSeal$^{\uparrow}$ *packet and let B be an accepted* RealObservationBudget$^{\uparrow}$ *packet over the same displayed precision request and finite* StreamName$^{\uparrow}$ *window. The two packets classify through the same finite tail-budget meet row if and only if their selector row, observation-budget row,* DyadicRatCore$^{\uparrow}$ *ledger,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal row, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows agree componentwise inside the meet surface. This exactness statement excludes quotient stream identity, host real equality, choice-selected limits, hidden family limits, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier tail budget meet exactness`

Proof. For the forward direction, project the finite meet row supplied by Definition 386.135. The meet has no coordinates other than the selector, budget, dyadic ledger, regular handoff, real seal, transport, continuation, provenance, and naming rows, so classification through the same row identifies those coordinates componentwise.

Apply Definition 386.136. It keeps the selector side and observation-budget side on the same precision request, stream window, dyadic ledger, regular handoff, real seal, transport row, continuation route, package row, and local name under every displayed hsame and Cont replay.

For the reverse direction, start from componentwise agreement of the listed coordinates. Repack the selector read, observation-budget read, dyadic ledger, regular handoff, real seal, transports, routes, provenance, and naming row into the meet supplied by Definition 386.135.

The repacked meet is accepted because each coordinate is already an accepted coordinate of L and B over the same precision request and finite window. Since no quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate is present, the shared componentwise row is exactly the common classifier surface. □

Theorem 386.138 (CauchyLimitSeal regular-tail budget exactness)**.** *Suppose an accepted* CauchyLimitSeal$^{\uparrow}$ *packet and an accepted* RealObservationBudget$^{\uparrow}$ *packet share the same finite* StreamName$^{\uparrow}$ *window and the same* RegSeqRat$^{\uparrow}$ *handoff. Inside the tail-budget meet, the regular-tail budget is exact if and only if the selector row, observation-budget row, dyadic ledger,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row agree.*

The exact regular-tail budget has no quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate.

Proof. For the forward direction, project the shared meet by Definition 386.135. Since the two packets share the StreamName window and RegSeqRat handoff, the remaining readable budget coordinates are precisely the selector, observation-budget, dyadic-ledger, real-seal, transport, continuation, provenance, and naming rows.

Apply Definition 386.136. It keeps the selector read and the observation-budget read on the same regular-tail route under the displayed hsame transports and Cont replays.

For the reverse direction, assume the listed rows agree componentwise. Repack those rows into the meet supplied by Definition 386.135; the already shared StreamName window and RegSeqRat handoff give the regular-tail spine, and the agreed rows fill the budget surface.

Finally use Definition 386.137. It identifies componentwise agreement inside the meet with classification through the same finite tail-budget row and excludes the listed quotient, host-equality, selected-limit, hidden-family, and ambient-completeness coordinates. □

Theorem 386.139 (CauchyLimitSeal completion-budget root unblock)**.** *The tail-budget meet of Definition 386.135 and its selector-budget transport of Definition 386.136 package the root-unblock and completion-consumer rows into one downstream surface. A* $\mathsf{Real}^{\uparrow}$ *or completion consumer may cite this surface as the finite route through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *supplied by the accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *and* $\mathsf{RealObservationBudget}^{\uparrow}$ *packets. The package explicitly excludes quotient stream identity, host real equality, choice-selected limits, hidden family limits, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier completion budget root unblock`

Proof. First take the root-unblock package from Definition 386.57. It supplies the downstream route from the accepted seal packet to the Real and completion consumer boundary.

Next refine that route by the tail-budget meet. The meet binds the selector read and the observation-budget read to the same displayed precision and window route before the completion consumer reads the packet.

Finally apply Definition 386.94. The completion-facing endpoint can export only the rows listed by the root source and dyadic-window exactness theorems, so the combined package has no quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate. □

Theorem 386.140 (CauchyLimitSeal tail-budget consumer normal form)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion consumer of the tail-budget meet factors through exactly the shared precision request, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row named by Definition 386.135 and Definition 386.136. This consumer route has no quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier tail budget consumer normal form`

Proof. First cite the meet theorem Definition 386.135. It binds the selector read, observation-budget read, and completion-consumer read to one finite route over the shared precision request, finite stream window, dyadic ledger, regular handoff, real seal, transport, continuation, provenance, and naming rows.

Next apply the selector-budget transport theorem Definition 386.136. It keeps those rows stable under componentwise hsame transport and displayed Cont replay, so a transported selector, budget, or completion-facing read cannot leave the same finite packet.

Finally close with Definition 386.139. The root-unblock package is therefore consumed only through the displayed meet and transport route, excluding quotient stream identity, host real equality, choice-selected limit, hidden family limit, and ambient completeness. □

Theorem 386.141 (CauchyLimitSeal tail-meet uniform selector route)**.** *Let*

$$L = (X, S, D, G, E, T, P, N)$$

be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet, let*

$$B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$$

be an accepted RealObservationBudget$^{\uparrow}$ *packet over the same displayed precision request and finite* StreamName$^{\uparrow}$ *window, and let*

$$U = (I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$$

be an accepted UniformCauchyCriterion$^{\uparrow}$ *packet whose displayed finite window, dyadic tolerance,* RegSeqRat$^{\uparrow}$ *tail row, and* Real$^{\uparrow}$ *seal handoff are exactly the rows read by the tail-budget meet. Then every* Real$^{\uparrow}$ *or* Completion$^{\uparrow}$ *consumer using the selector-budget route factors through one finite envelope: the* StreamName$^{\uparrow}$ *window,* RegSeqRat$^{\uparrow}$ *source row,* DyadicRatCore$^{\uparrow}$ *ledger,* UniformCauchyCriterion$^{\uparrow}$ *tail ledger,* RealObservationBudget$^{\uparrow}$ *rows,* CauchyLimitSeal$^{\uparrow}$ *seal row, and the shared* BHist, hsame, Cont, Pkg, *and* NameCert *rows. This route has no quotient stream, selected host limit, host real equality, hidden family limit, unbounded schedule, independent completion row, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier tail meet uniform selector route`

Proof. Begin with the tail-budget meet of Definition 386.135. It binds the selector read, the observation-budget read, and the completion-consumer read to the displayed precision request, finite stream window, dyadic ledger, regular handoff, real seal, transport, continuation, provenance, and naming rows.

Transport that meet by Definition 386.136. The selector-budget route preserves the same StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RealObservationBudget$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert surface under every displayed replay.

Apply the consumer normal form of Definition 386.140. A Real$^{\uparrow}$ or Completion$^{\uparrow}$ consumer therefore receives the meet only through the stated finite envelope and cannot switch to a quotient stream, selected host limit, host real equality, hidden family limit, unbounded schedule, independent completion row, or ambient completeness witness.

Finally attach the UniformCauchyCriterion side by Definition 560.18 and Definition 435.81. These frontiers force the displayed uniform tail ledger to read the same finite family, dyadic tolerance, regular-rational tail, and real-seal handoff before any uniform-family consumer inspects it, so U enters the selector-budget route through the same finite envelope. □

Theorem 386.142 (CauchyLimitSeal tail-meet refusal fork)**.** *Every* Real$^{\uparrow}$ *or* Completion$^{\uparrow}$ *consumer of the tail-budget meet has exactly one of the following two routes. Either it factors through the finite envelope consisting of the* StreamName$^{\uparrow}$ *window,* RegSeqRat$^{\uparrow}$ *source row,* DyadicRatCore$^{\uparrow}$ *ledger,* UniformCauchyCriterion$^{\uparrow}$ *tail ledger,* RealObservationBudget$^{\uparrow}$ *rows,* CauchyLimitSeal$^{\uparrow}$ *seal row, and shared* BHist, hsame, Cont, Pkg, *and* NameCert *rows; or its request is routed to the visible refusal boundary for quotient stream, selected host limit, host real equality, hidden family limit, unbounded schedule, independent completion row, ambient completeness, or metric-completeness.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier tail meet refusal fork`

Proof. First use the tail-budget meet of Definition 386.135. It supplies the common route over the selector read, observation-budget read, completion-consumer read, and shared structural rows.

Transport that common route with Definition 386.136. The transported consumer still sees only the finite precision request, window, dyadic ledger, regular handoff, Real seal, transport, continuation, provenance, and naming rows.

Apply the consumer normal form of Definition 386.140 together with the root unblock of Definition 386.139. These results force every Real$^{\uparrow}$ or Completion$^{\uparrow}$ read to enter the downstream surface through the displayed finite meet before any completion-facing inspection occurs.

Finally attach the uniform selector route from Definition 386.141. Inspecting its envelope shows that quotient stream, selected host limit, host real equality, hidden family limit, unbounded schedule, independent completion row, ambient completeness, and metric-completeness are not coordinates of the finite route. A request for any such coordinate therefore cannot be served by the envelope and is sent to the visible refusal boundary. □

Theorem 386.143 (CauchyLimitSeal tail-meet source exhaustion)**.** *Every* Real$^{\uparrow}$ *or* Completion$^{\uparrow}$ *consumer admitted by the tail-meet route exhausts exactly the finite source rows supplied by the* CauchyLimitSeal$^{\uparrow}$ *packet, the* RealObservationBudget$^{\uparrow}$ *packet, and the* UniformCauchyCriterion$^{\uparrow}$ *packet. The exhausted rows are the shared* StreamName$^{\uparrow}$ *window,* RegSeqRat$^{\uparrow}$ *source row,* DyadicRatCore$^{\uparrow}$ *ledger,* BHist *histories,* hsame *transports,* Cont *continuations,* Pkg *provenance rows, and* NameCert *naming rows, together with the displayed seal, observation-budget, and uniform-tail coordinates named by those packets.*

No admitted consumer may read an additional Real-completion source outside these finite rows. A request for quotient stream identity, selected host limit, host real equality, hidden family limit, unbounded schedule, independent completion row, ambient completeness, or metric-completeness is routed to the refusal boundary rather than to a second source envelope.

Proof. Begin with the uniform selector route of Definition 386.141. It joins the CauchyLimitSeal$^{\uparrow}$, RealObservationBudget$^{\uparrow}$, and UniformCauchyCriterion$^{\uparrow}$ packets over one finite envelope with the shared StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Next apply the refusal fork Definition 386.142. A Real$^{\uparrow}$ or Completion$^{\uparrow}$ consumer is therefore either on that finite envelope or outside the admitted route, where the listed non-envelope requests are refused.

The exact source rows are fixed by Definition 386.135. The meet binds the selector read, observation-budget read, and completion-consumer read to the same precision request, finite stream window, dyadic ledger, regular handoff, Real seal, transport, continuation, provenance, and naming rows.

Finally use the consumer normal form Definition 386.140. Since every admitted consumer has that normal form and the fork refuses the alternatives, the route exhausts exactly the finite rows supplied by the three source packets and exposes no additional Real-completion source. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier tail meet source exhaustion`

Theorem 386.144 (CauchyLimitSeal tail-meet diagonal compatibility handoff)**.** *Suppose an accepted* CauchyLimitSeal$^{\uparrow}$ *tail-meet route has finite envelope E, and suppose the same envelope is consumed by an accepted* DiagonalLimitCompatibility$^{\uparrow}$ *packet through its root formal handoff surface. Then the handoff boundary is exactly the shared* StreamName$^{\uparrow}$ *window,* RegSeqRat$^{\uparrow}$ *source row,* DyadicRatCore$^{\uparrow}$ *ledger,* Real$^{\uparrow}$ *seal row,* UniformCauchyCriterion$^{\uparrow}$ *tail ledger,* BHist, hsame, Cont, Pkg, *and* NameCert *rows, together with the diagonal compatibility selector read from the accepted compatibility packet.*

The handoff exposes no quotient stream, host real equality, selected external limit, hidden diagonal oracle, independent completion row, or ambient completeness coordinate.

Proof. Begin with the tail-budget meet of Definition 386.135. It identifies the common precision request, stream window, dyadic ledger, regular handoff, Real seal, transport, continuation, provenance, and naming rows that any admitted Real-completion consumer must read.

Transport the route through Definition 386.136. The selector read stays inside the same finite envelope, so a downstream diagonal consumer sees the transported tail-meet rows rather than a second completion source.

Apply source exhaustion from Definition 386.143. The admitted route has already exhausted the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows before the diagonal compatibility packet reads the envelope.

Finally read the root formal handoff surface of $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$. That surface contributes only the displayed diagonal compatibility selector and consumes the already exhausted envelope. Since quotient stream identity, host real equality, selected external limits, hidden diagonal oracles, independent completion rows, and ambient completeness coordinates are absent from both finite surfaces, none can cross the handoff boundary. □

Theorem 386.145 (CauchyLimitSeal tail-meet diagonal source exhaustion)**.** *Every* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *tail-meet route exhausts exactly the shared* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{Real}^{\uparrow}$ *seal row,* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *tail ledger,* $\mathsf{RealObservationBudget}^{\uparrow}$ *rows, diagonal selector row, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

No such consumer retains a coordinate for quotient stream identity, host real equality, a selected external limit, a hidden diagonal oracle, an independent completion row, ambient completeness, or metric completeness outside the accepted handoff surface.

Proof. First use source exhaustion for the tail meet, Definition 386.143. It fixes the accepted Real and completion route as the finite envelope over the shared stream window, regular-rational source row, dyadic ledger, Real seal, uniform tail ledger, observation-budget rows, and structural BEDC rows.

Next attach the uniform selector route of Definition 386.141. This places the diagonal-facing selector read on the same finite route before any compatibility consumer receives the envelope.

Apply the diagonal compatibility handoff of Definition 386.144 together with the root formal route of Definition 646.183. The diagonal packet contributes only its displayed selector row and consumes the already bounded source route.

The refusal clauses in the handoff theorem then identify the absent coordinates. Quotient stream identity, host real equality, selected external limits, hidden diagonal oracles, independent completion rows, ambient completeness, and metric completeness are not fields of either finite surface, so the diagonal consumer exhausts exactly the listed shared rows. □

Theorem 386.146 (CauchyLimitSeal tail-budget meet consumer determinacy)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer admitted by the tail-budget meet is determined by the shared* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RealObservationBudget}^{\uparrow}$ *budget row,* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *seal row,* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *tail row, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. Two admitted consumers that agree on these rows have the same public Real-completion read, and no quotient stream identity, host real equality, selected external limit, hidden diagonal oracle, independent completion row, or ambient completeness coordinate can distinguish them.*

Proof. Begin with the finite meet of Definition 386.135. It binds the selector read, observation-budget read, and completion-consumer read to one displayed envelope over the shared stream window, dyadic ledger, regular handoff, Real seal, transport, continuation, provenance, and naming rows.

Apply source exhaustion from Definition 386.143. The admitted Real or completion consumer has no second source outside the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Finally use diagonal source exhaustion from Definition 386.145. It identifies the same envelope after the diagonal-facing handoff, so agreement on the finite rows determines the public consumer read and leaves no absent coordinate able to separate the two consumers. □

Theorem 386.147 (CauchyLimitSeal tail-budget meet ledger exhaustion)**.** *The ledger of an admitted* Real$^{\uparrow}$ *or* Completion$^{\uparrow}$ *consumer of the tail-budget meet is exhausted by the* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RealObservationBudget$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, UniformCauchyCriterion$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows displayed by the meet and its source-exhaustion theorems. After those rows are read, there is no remaining ledger coordinate for quotient stream identity, host real equality, selected external limits, hidden diagonal oracles, independent completion rows, ambient completeness, or metric completeness.*

Proof. Use Definition 386.135 to obtain the finite route binding the selector, budget, and completion reads. The ledger coordinates of that route are exactly the displayed stream, regular-rational, dyadic, Real, transport, continuation, provenance, and naming rows.

Refine the inventory with Definition 386.143. It adds the observation-budget and uniform-tail rows to the same finite envelope and refuses any second Real-completion source.

Then apply Definition 386.145. The diagonal-facing consumer receives only the already exhausted rows plus the displayed selector row, so the listed non-envelope objects have no ledger position to occupy. □

Theorem 386.148 (CauchyLimitSeal tail-budget meet Real handoff)**.** *The Real handoff exported by the tail-budget meet is exactly the finite route through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RealObservationBudget$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, UniformCauchyCriterion$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *It cannot import quotient stream identity, host real equality, selected external limits, hidden diagonal oracles, independent completion rows, ambient completeness, or metric completeness into the* Real$^{\uparrow}$ *or* Completion$^{\uparrow}$ *consumer boundary.*

Proof. Start from the consumer determinacy theorem above. A Real or completion consumer is fixed by the shared finite envelope, so a handoff can expose only rows already present in that envelope.

Apply ledger exhaustion above. Once the stream, regular-rational, dyadic, budget, seal, uniform-tail, transport, continuation, provenance, and naming rows are consumed, there is no remaining field through which a quotient stream, host equality, selected limit, hidden diagonal oracle, independent completion row, ambient completeness, or metric completeness witness could enter.

The handoff is therefore the same finite Real-completion boundary described by the meet, source exhaustion, and diagonal source exhaustion rows, with no ambient completion principle imported from outside the accepted packets. □

Corollary 386.149 (CauchyLimitSeal tail-budget meet strict local obstruction)**.** *Every displayed failure, refusal, separation, or countermodel row attached to the tail-budget meet is a strict local obstruction. If a* Real$^{\uparrow}$ *or* Completion$^{\uparrow}$ *consumer of the meet asks for quotient stream identity, selected host limit, host real equality, hidden family limit, unbounded schedule, independent completion row, ambient completeness, or metric-completeness, then the row blocks exactly that requested converse or reuse route outside the displayed finite envelope. The same row does not assert a global impossibility theorem, does not supply a host-level theorem about all Cauchy limits, and does not act as hidden external validation for any completion principle.*

Proof. Apply the refusal fork of Definition 386.142. It gives exactly two consumer-facing alternatives for the tail-budget meet. The consumer either factors through the finite envelope consisting of the StreamName$^{\uparrow}$ window, RegSeqRat$^{\uparrow}$ source row, DyadicRatCore$^{\uparrow}$ ledger, UniformCauchyCriterion$^{\uparrow}$ tail ledger, RealObservationBudget$^{\uparrow}$ rows, CauchyLimitSeal$^{\uparrow}$ seal row, and the shared BHist, hsame,

Cont, Pkg, and NameCert rows, or its request is routed to the visible refusal boundary for one of the listed non-envelope coordinates.

Use selector-budget transport from Definition 386.136 to identify the stable part of the admitted route. Transport preserves the same precision request, finite StreamName$^{\uparrow}$ window, DyadicRatCore$^{\uparrow}$ ledger, RegSeqRat$^{\uparrow}$ handoff, Real$^{\uparrow}$ seal, BHist surface, Pkg provenance, and local NameCert row. Thus a transported selector read, budget read, or completion-facing read remains inside the displayed finite packet and gains no quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate.

Now inspect an obstruction row. If the requested coordinate is one of the listed non-envelope coordinates, the fork sends that coordinate to the refusal boundary because it is not a field of the finite envelope. If the requested coordinate is one of the envelope coordinates, transport keeps the request inside the admitted selector-budget packet and the obstruction row is not invoked. Therefore the row blocks only the named converse or reuse route that tries to read beyond the displayed packet.

This locality also fixes the interpretation of the obstruction. The proof has used only the finite envelope and the transported selector-budget packet, so the obstruction has no quantifier over all host Cauchy limits, no host theorem surface, and no external validation coordinate. It records that the specified consumer request cannot be served by this tail-budget meet route; it does not claim that the requested object is globally impossible or that an ambient completion principle has been validated elsewhere. □

386.2 CauchyLimitSeal regular tail-selector sibling link

Theorem 386.150 (CauchyLimitSeal regular tail-selector sibling link)**.** *Every accepted* CauchyLimitSeal$^{\uparrow}$ *seal route whose selector and observation-budget reads use the transport surface of Definition 386.136 factors first through the accepted* RegularCauchyTailSelector$^{\uparrow}$ *packet of chapter 458. The route reaches the shared* StreamName$^{\uparrow}$ *window,* DyadicRatCore$^{\uparrow}$ *ledger,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal, and* RealObservationBudget$^{\uparrow}$ *meet only after the regular tail-selector packet has supplied its selected-tail witness and its finite support rows. Consequently the seal route exports no quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier regular tail selector sibling link`

Proof. Begin with the regular tail-selector packet. The consumer package of Definition 458.9 supplies one finite selected-tail witness together with the requested precision, StreamName$^{\uparrow}$ window, RegSeqRat$^{\uparrow}$ regularity row, DyadicRatCore$^{\uparrow}$ comparison row, componentwise hsame transport, displayed Cont route, Pkg provenance, and local NameCert row.

Now attach the seal-side meet. By Definition 386.135, the CauchyLimitSeal$^{\uparrow}$ route and the RealObservationBudget$^{\uparrow}$ route share one finite meet over the same regular handoff, window, dyadic ledger, Real seal, transport, continuation, provenance, and naming rows.

Finally use selector-budget transport from Definition 386.136. It preserves the selector read, budget read, and completion-facing read along the same displayed route, so those reads cannot pass around the accepted RegularCauchyTailSelector$^{\uparrow}$ packet before consuming the shared window, ledger, handoff, seal, and meet rows.

The non-escape clauses of the cited selector package and meet route exclude quotient stream identity, host real equality, choice-selected limits, hidden family limits, and ambient completeness.

The sibling link is therefore a finite factorization through the displayed regular tail-selector packet rather than an additional completion principle. □

Theorem 386.151 (CauchyLimitSeal regular tail-selector budget compatibility)**.** *Every selector-budget read compatible with Definition 386.136 factors through the same accepted* RegularCauchyTailSelector$^{\uparrow}$ *packet before it reaches the* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *and* RealObservationBudget$^{\uparrow}$ *rows. Thus the selector route, observation-budget route, and completion-facing route share one finite tail-selector factorization.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier regular tail selector budget compatibility`

Proof. Begin with the sibling-link theorem Definition 386.150. It places every compatible seal route through the accepted regular tail-selector packet before the stream, dyadic, regular-sequence, Real, and observation-budget rows are consumed.

Next apply selector-budget transport from Definition 386.136. The transported selector read, budget read, and completion-facing read remain on the same precision request, finite window, dyadic ledger, regular handoff, Real seal, transport, continuation, provenance, and naming rows.

Finally use the tail-budget meet of Definition 386.135. The meet binds the seal side and observation-budget side to the same finite route, so every compatible selector-budget read inherits the regular tail-selector factorization. □

Theorem 386.152 (CauchyLimitSeal regular tail-selector non-escape)**.** *After a compatible selector route is read through the accepted* RegularCauchyTailSelector$^{\uparrow}$ *packet, the* CauchyLimitSeal$^{\uparrow}$ *seal cannot export quotient stream identity, host real equality, a choice-selected limit, a hidden family limit, or ambient completeness. The exported boundary is only the selected-tail witness, the* StreamName$^{\uparrow}$ *window, the* DyadicRatCore$^{\uparrow}$ *ledger, the* RegSeqRat$^{\uparrow}$ *handoff, the* Real$^{\uparrow}$ *seal, the* RealObservationBudget$^{\uparrow}$ *meet, and the displayed* hsame, Cont, Pkg, *and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier regular tail selector nonescape`

Proof. Start from the budget compatibility theorem above. It fixes the selector, budget, and completion-facing reads on the same regular tail-selector packet and the same tail-budget meet.

Use the selector package theorem Definition 458.9. Its consumer surface contains the finite selected-tail witness and support rows, with no quotient representative, equality row, infinite-tail row, or completeness coordinate.

Finally apply Definition 386.136 and Definition 386.135. Transport preserves the finite route, and the meet adds no hidden completion coordinate. The named non-escape objects therefore cannot be exported after the selector route has been read. □

Theorem 386.153 (CauchyLimitSeal tail-selector window support determinacy)**.** *Every compatible* CauchyLimitSeal$^{\uparrow}$ *route that factors through the accepted* RegularCauchyTailSelector$^{\uparrow}$ *packet reads the same selected-tail witness,* StreamName$^{\uparrow}$ *window,* DyadicRatCore$^{\uparrow}$ *ledger,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal, and* RealObservationBudget$^{\uparrow}$ *meet across the selector route, observation-budget route, and completion-facing route. Thus selector-facing, budget-facing, and completion-facing consumers share one finite support packet rather than three independent reads.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier tail selector window support determinacy`

Proof. First apply the sibling link of Definition 386.150. It routes every compatible seal read through the accepted regular tail-selector packet before the selected-tail witness, StreamName window, DyadicRatCore ledger, RegSeqRat handoff, Real seal, and observation-budget meet are consumed.

Next use budget compatibility from Definition 386.151. The selector route, observation-budget route, and completion-facing route are all factored through the same accepted packet and the same tail-budget meet, so their support rows are not independently chosen.

Finally apply the non-escape theorem Definition 386.152. Since no quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate is available, the three reads cannot diverge outside the displayed finite support. Their selected-tail witness, window, ledger, handoff, seal, and meet are therefore determined by the same packet. □

Theorem 386.154 (CauchyLimitSeal regular tail-selector public export)**.** *Every compatible public* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *export to a Real-facing completion consumer factors through one accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet, then through the shared* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{RealObservationBudget}^{\uparrow}$ *meet. The exported boundary is exactly this finite selector-support route and does not include quotient stream identity, host real equality, choice-selected limits, hidden family limits, or ambient completeness.*

Proof. First apply the sibling link of Definition 386.150. It places the public seal route through the accepted regular tail-selector packet before any Real-facing completion consumer can read the StreamName, DyadicRatCore, RegSeqRat, Real, or observation-budget rows.

Next use budget compatibility from Definition 386.151. The selector-facing, budget-facing, and completion-facing reads are the same finite route over the accepted packet and the tail-budget meet, so the public export cannot choose a second support surface.

Now apply the non-escape boundary of Definition 386.152. It removes quotient stream identity, host real equality, choice-selected limits, hidden family limits, and ambient completeness from the export inventory.

Finally use window support determinacy from Definition 386.153. The selected-tail witness, shared window, dyadic ledger, regular-sequence handoff, Real seal, and observation-budget meet are determined by the single accepted packet, so every compatible public export factors through precisely that route. □

Theorem 386.155 (CauchyLimitSeal regular tail-selector classifier stability)**.** *Let two accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *routes be related by the local classifier of the chapter. If the first route factors through the accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet of Definition 386.150, then the transported route factors through the transported regular tail-selector packet. The transported factorization preserves the selected-tail witness, the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{RealObservationBudget}^{\uparrow}$ *meet, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows. No quotient stream identity, host real equality, choice-selected limit, hidden family limit, or ambient completeness coordinate is exported by the classifier transport.*

Proof. First apply the sibling link of Definition 386.150 to the source route. It gives the accepted regular tail-selector packet before the selected-tail witness, StreamName window, dyadic ledger, regular-sequence handoff, Real seal, observation-budget meet, transport, continuation, provenance, and naming rows are read.

Next use budget compatibility from Definition 386.151. The selector-facing, budget-facing, and completion-facing reads are one finite route, so the local classifier has a single support packet to transport rather than separate selector and budget witnesses.

Now apply choice-free selector stability from Definition 386.108. The classifier transport preserves the admitted selector route, the finite support windows, the dyadic ledger, the displayed hsame comparisons, and the Cont replay rows. Thus the transported route lands in the transported regular tail-selector packet with the same selected-tail witness surface.

Use window support determinacy from Definition 386.153 to identify the transported packet's public rows. The selected-tail witness, StreamName window, DyadicRatCore ledger, RegSeqRat handoff, Real seal, and RealObservationBudget meet are the rows determined by that one packet, and the displayed Pkg and NameCert rows travel with the same classifier route.

Finally invoke the non-escape theorem Definition 386.152. Since neither the source factorization nor the classifier transport contains quotient stream identity, host real equality, choice-selected limits, hidden family limits, or ambient completeness, the transported public export remains exactly the regular tail-selector factorization described above. □

Theorem 386.156 (CauchyLimitSeal StreamName cofinal tail-budget fusion)**.** *Every accepted* CauchyLimitSeal$^{\uparrow}$ *route whose selector-budget transport factors through the regular tail-selector sibling and whose completion-facing read uses the tail-budget meet factors through one finite envelope. The envelope consists of the* RegularCauchyTailSelector$^{\uparrow}$ *selected-tail witness, the* StreamName$^{\uparrow}$ *window, the* DyadicRatCore$^{\uparrow}$ *ledger, the* RegSeqRat$^{\uparrow}$ *handoff, the* Real$^{\uparrow}$ *seal, the* RealObservationBudget$^{\uparrow}$ *meet, the* CofinalTailBudget$^{\uparrow}$ *shared-tail row, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Consequently the fused route exports no quotient stream identity, host sequence equality, hidden tail selector, countable-choice schedule, selected host limit, independent completion row, or ambient Real$^{\uparrow}$ *completeness.*

Proof. First apply the sibling link of Definition 386.150. It routes the accepted seal read through the regular tail-selector packet before the selected-tail witness, StreamName window, dyadic ledger, regular-sequence handoff, Real seal, transport, continuation, provenance, and naming rows are consumed.

Next use the tail-budget meet of Definition 386.135. The meet binds the selector-facing read, observation-budget read, and completion-facing read to the same finite route, so the completion consumer cannot choose a second row outside the selector packet.

Transport that common route by Definition 386.136. Componentwise hsame transport and the displayed Cont replay preserve the precision request, the finite StreamName$^{\uparrow}$ window, the DyadicRatCore$^{\uparrow}$ ledger, the RegSeqRat$^{\uparrow}$ handoff, the Real$^{\uparrow}$ seal, the BHist surface, the Pkg provenance, and the local NameCert row.

Now attach the cofinal shared-tail row by Definition 698.9. Its primitive scope is the finite shared-tail budget packet, so it adds only the public CofinalTailBudget$^{\uparrow}$ row aligned with the same regular handoff and completion-facing consumer.

Finally invoke the non-escape boundary of Definition 386.152. Together with the cofinal primitive scope, it removes quotient stream identity, host sequence equality, hidden tail selectors, countable-choice schedules, selected host limits, independent completion rows, and ambient Real$^{\uparrow}$ completeness from the exported route. □

Theorem 386.157 (CauchyLimitSeal regular tail-selector ProbeBundle coverage)**.** *Let Q be an accepted* CauchyLimitSeal$^{\uparrow}$ *route compatible with the regular tail-selector sibling link of Definition 386.150. Every finite* ProbeBundle *of selector-facing, observation-budget-facing, and completion-facing requests for Q factors through one finite envelope. The envelope consists of the* RegularCauchyTailSelector$^{\uparrow}$

selected-tail witness, the $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{RealObservationBudget}^{\uparrow}$ *meet, the* $\mathsf{CofinalTailBudget}^{\uparrow}$ *shared-tail row, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

Thus finite bundled consumers receive the same route-level support as the pointwise fused route. The bundle exposes no quotient stream identity, host sequence equality, hidden selector, countable-choice schedule, selected host limit, independent completion row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Induct over the finite ProbeBundle. The empty bundle uses the finite envelope already displayed by the accepted route, with no consumer request to place outside it.

For a successor request, apply the sibling link of Definition 386.150 and budget compatibility from Definition 386.151. The new selector-facing, observation-budget-facing, or completion-facing read is forced through the accepted regular tail-selector packet before it can read the StreamName window, dyadic ledger, regular-sequence handoff, Real seal, observation-budget meet, transport, continuation, package, or naming rows.

Next use the tail-budget meet of Definition 386.135 and selector-budget transport from Definition 386.136. These identify the support of the new request with the accumulated support of the earlier bundle entries, so the induction step does not introduce a second budget row or a second selector packet.

Now attach the cofinal shared-tail row by the fusion theorem Definition 386.156. It places the $\mathsf{CofinalTailBudget}^{\uparrow}$ coordinate on the same StreamName, DyadicRatCore, RegSeqRat, Real, observation-budget, BHist, hsame, Cont, Pkg, and NameCert rows already carried by the bundle envelope.

Finally apply the non-escape theorem Definition 386.152. Since neither the pointwise route nor the finite induction step can export quotient stream identity, host sequence equality, hidden selectors, countable-choice schedules, selected host limits, independent completion rows, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the finite bundle repacks as one ProbeBundle coverage row over exactly the displayed envelope. □

Theorem 386.158 (CauchyLimitSeal ProbeBundle envelope terminality)**.** *Let Q be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route compatible with the regular tail-selector sibling link of Definition 386.150. Among all public factorization surfaces for finite* ProbeBundle *families of selector-facing, observation-budget-facing, and completion-facing requests for Q, the envelope of Definition 386.157 is terminal. It consists of the* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *selected-tail witness, the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{RealObservationBudget}^{\uparrow}$ *meet, the* $\mathsf{CofinalTailBudget}^{\uparrow}$ *shared-tail row, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

Every alternative public route with the same visible reads is classifier-equal to this envelope. No quotient stream identity, host sequence equality, hidden selector, countable-choice schedule, selected host limit, independent completion row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness can separate a second public factorization surface from it.*

Proof. Start from the sibling link of Definition 386.150. It places every compatible accepted route through the regular tail-selector packet before any selector-facing, observation-budget-facing, or completion-facing request can read the StreamName window, dyadic ledger, regular-sequence handoff, Real seal, continuation, package, or naming rows.

Next combine budget compatibility from Definition 386.151, non-escape from Definition 386.152, and window-support determinacy from Definition 386.153. These three results force the selector, budget, and completion reads onto one displayed support packet and rule out every hidden coordinate that could distinguish another public surface.

Now use the cofinal tail-budget fusion theorem Definition 386.156. It attaches the CofinalTailBudget$^{\uparrow}$ shared-tail row to the same BHist, hsame, Cont, Pkg, and NameCert support, so the fused route has no independent completion row outside the regular tail-selector envelope.

Finally apply the finite ProbeBundle induction from Definition 386.157. The empty bundle has only the displayed envelope. Each successor request is already forced through that envelope by the preceding compatibility and fusion steps, so adding a request cannot create a second public route. Any alternative route with the same visible reads is therefore classifier-equal to the displayed envelope, which proves terminality. □

Corollary 386.159 (CauchyLimitSeal regular tail-selector strict local obstruction)**.** *Let an accepted* CauchyLimitSeal$^{\uparrow}$ *route be read through the regular tail-selector sibling surface of Definition 386.150. Any displayed failure, refusal, separation, or countermodel row attached to that sibling surface obstructs only the named converse or reuse route that tries to read outside the local factorization. Its scope is the selected-tail witness, the* StreamName$^{\uparrow}$ *window, the* DyadicRatCore$^{\uparrow}$ *ledger, the* RegSeqRat$^{\uparrow}$ *handoff, the* Real$^{\uparrow}$ *seal, the* RealObservationBudget$^{\uparrow}$ *meet, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It cannot be reinterpreted as a global impossibility for* CauchyLimitSeal$^{\uparrow}$ *packets, a host theorem about real equality or completeness, or a hidden external validation principle.*

Proof. Start with the non-escape theorem Definition 386.152. After the compatible selector route has been read through the accepted RegularCauchyTailSelector$^{\uparrow}$ packet, the exported boundary is exactly the selected-tail witness, the stream window, the dyadic ledger, the regular-sequence handoff, the Real seal, the observation-budget meet, and the displayed transport, continuation, provenance, and naming rows. The same theorem removes quotient stream identity, host real equality, choice-selected limits, hidden family limits, and ambient completeness from the export inventory.

Now apply classifier stability from Definition 386.155. Classifier transport preserves the same finite packet and the same displayed rows. Hence any consumer-facing use of a failure, refusal, separation, or countermodel row must factor through the transported local packet before it can be read by a selector-facing, budget-facing, or completion-facing consumer.

The obstruction is therefore strict. If the blocked request is a named converse or reuse route, the block occurs exactly where that route asks for an unlisted coordinate outside the finite packet. Since the classifier transport has no coordinate beyond the listed rows, the obstruction cannot be promoted to a global impossibility for other CauchyLimitSeal$^{\uparrow}$ packets, cannot become a host theorem asserting real equality or completeness, and cannot certify an external validation source. It records only the failure of the named local route to pass the displayed sibling boundary. □

386.3 CauchyLimitSeal finite-window lattice dependency

Theorem 386.160 (CauchyLimitSeal finite-window lattice dependency)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* CauchyLimitSeal$^{\uparrow}$ *carrier. Every* Real$^{\uparrow}$ *or completion consumer route that reads the seal row* E *factors first through the StreamName finite-window lattice meet surface of Definition 126.257, and then through the displayed* RegSeqRat$^{\uparrow}$ *source row* X*, the* DyadicRatCore$^{\uparrow}$ *ledger* D*, the* RealCauchyCompletion$^{\uparrow}$ *diagonal row* G*, and the* Real$^{\uparrow}$ *seal row* E*. The route carries only* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance, and it exports no quotient stream equality, host real equality, selected host limit, hidden tail witness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier finite window lattice dependency`

Proof. Start with the carrier definition of Definition 386.1. The rows X, S, D, G, E, T, P, N are the only displayed coordinates available to a sealed consumer route.

Apply the finite-window factorization of Definition 386.3. Any read that reaches the seal must pass through a scheduled $\mathsf{StreamName}^{\uparrow}$ window, its displayed $\mathsf{RegSeqRat}^{\uparrow}$ source row, the matching dyadic ledger, and the completion diagonal row before the seal row is consumed.

Next pull the route back by Definition 386.20. This identifies the same scheduled window as the common dependency surface shared by the regular source, dyadic ledger, completion diagonal, and seal.

Use the StreamName lattice-meet exhaustion theorem Definition 126.257. The scheduled window therefore lands on the shared finite-window meet surface, whose readable coordinates are only the selected rational classifier rows, probe-bundle rows, membership rows, unary-history rows, dyadic ledger rows, componentwise transports, continuation routes, package provenance, and local names.

Finally apply the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5. The sealed route can carry only the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance over X, D, G, E, so quotient stream equality, host real equality, selected host limits, hidden tail witnesses, and ambient completeness remain outside the exported surface. □

Theorem 386.161 (CauchyLimitSeal source-schedule lattice coherence)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ carrier. Any seal-facing consumer of L that factors through the $\mathsf{StreamName}^{\uparrow}$ finite-window lattice meet uses the same displayed schedule row S, the same $\mathsf{RegSeqRat}^{\uparrow}$ source row X, the same $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, the same $\mathsf{RealCauchyCompletion}^{\uparrow}$ diagonal row G, and the same $\mathsf{Real}^{\uparrow}$ seal row E. No second $\mathsf{StreamName}^{\uparrow}$ window, quotient stream equality, selected limit, hidden tail witness, host real equality, or ambient completeness datum may replace this route.*

Proof. Use the finite-window lattice dependency of Definition 386.160. It places every seal-facing consumer route over the $\mathsf{StreamName}^{\uparrow}$ finite-window lattice meet before the route reaches the displayed source, ledger, diagonal, and seal rows.

Apply the scheduled-window pullback of Definition 386.20. The pullback identifies the schedule row S as the common finite-window source for the regular source row X, dyadic ledger D, completion diagonal G, and seal row E.

Now use the StreamName lattice-meet exhaustion theorem Definition 126.257. Once the consumer has entered the meet, the readable window data are exhausted by the displayed finite-window coordinates and cannot be replaced by a second StreamName window or quotient stream equality.

Finally apply the RegSeqRat seal-route exclusion package of Definition 301.40. The regular-source seal route exports no selected limit, hidden tail witness, host real equality, or ambient completeness datum, so the only coherent source-schedule route left for the consumer is the displayed S, X, D, G, E handoff. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier source schedule lattice coherence`

Theorem 386.162 (CauchyLimitSeal RegSeqRat Real finite-window pullback)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ carrier. Suppose the source row X is consumed as a $\mathsf{RegSeqRat}^{\uparrow}$ packet and the seal row E is read by a $\mathsf{Real}^{\uparrow}$ consumer. Then the consumer route pulls back first through the $\mathsf{StreamName}^{\uparrow}$ finite-window lattice meet, then through the $\mathsf{RegSeqRat}^{\uparrow}$ source row X, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, the $\mathsf{RealCauchyCompletion}^{\uparrow}$ diagonal row G, and the $\mathsf{Real}^{\uparrow}$ seal row E. The pulled-back route exposes only BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance, and it exposes no quotient stream, selected limit, host real equality, or ambient completeness datum.*

Proof. Begin with the finite-window lattice dependency of Definition 386.160. It places every seal-facing read over the $\mathsf{StreamName}^{\uparrow}$ finite-window lattice meet before the route reaches the displayed source, ledger, diagonal, and seal rows.

Next use the scheduled-window pullback of Definition 386.20. The scheduled window is the common dependency surface for the $\mathsf{RegSeqRat}^{\uparrow}$ source row X, the dyadic ledger D, the completion diagonal G, and the $\mathsf{Real}^{\uparrow}$ seal row E.

Apply the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5. This fixes the endpoint read at the displayed seal row and permits only the visible BHist, hsame, Cont, Pkg, and NameCert provenance to travel with the consumer route.

Finally apply the RegSeqRat seal package exclusion of Definition 301.40. Since the regular source packet itself exports no quotient stream, selected limit, host real equality, or ambient completeness datum, the pulled-back CauchyLimitSeal route cannot acquire any such coordinate when the $\mathsf{Real}^{\uparrow}$ endpoint is consumed. □

Theorem 386.163 (CauchyLimitSeal middle-window meet determinacy)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Suppose two* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer routes reach the same seal row E through finite-window reads. After both routes are pulled back to the* $\mathsf{StreamName}^{\uparrow}$ *finite-window lattice meet, they use the same displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row X, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the same* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row G, and the same seal row E. Hence no second* $\mathsf{StreamName}^{\uparrow}$ *window, quotient stream equality, selected host limit, hidden tail witness, or ambient completeness datum can determine the seal route.*

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier middle window meet determinacy`

Proof. Begin with the finite-window lattice dependency of Definition 386.160. It places every $\mathsf{Real}^{\uparrow}$ or completion-facing seal read over the $\mathsf{StreamName}^{\uparrow}$ finite-window lattice meet before the route reaches the displayed regular source, dyadic ledger, completion diagonal, and seal rows.

Apply the RegSeqRat Real finite-window pullback of Definition 386.162. Each route that reaches E is therefore pulled back through the same listed rows X, D, G, E, with only BHist, hsame, Cont, Pkg, and NameCert provenance available to the consumer.

Now use StreamName lattice-meet exhaustion, Definition 126.257. The two finite windows have a shared displayed meet surface, so any readable route data at the handoff is exhausted by the same finite-window coordinates rather than by a second stream window or a quotient-level stream equality.

Finally apply the RegSeqRat seal-route exclusion package of Definition 301.40. It rules out selected host limits, hidden tail witnesses, and ambient completeness data from the regular-source seal route. The only remaining route through the shared meet is the displayed X, D, G, E route, which gives determinacy of the middle finite-window handoff. □

Theorem 386.164 (CauchyLimitSeal common-window transport)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Suppose two seal-facing consumer routes first meet the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window lattice surface before either route is consumed by a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *endpoint. Transporting either route to this common finite window preserves the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row X, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row G, and the* $\mathsf{Real}^{\uparrow}$ *seal row E. The transported route exports only* BHist, hsame, Cont, Pkg, *and* NameCert *provenance, and it exports no quotient stream equality, host real equality, selected host limit, hidden tail witness, or ambient completeness datum.*

Proof. First use the middle-window meet determinacy of Definition 386.163. Once both seal-facing routes are pulled back to the shared $\mathsf{StreamName}^{\uparrow}$ finite-window lattice meet, the readable handoff is already fixed by the displayed rows X, D, G, E rather than by a second window or a quotient-level stream coordinate.

Next apply the RegSeqRat finite-window transport obligation of Definition 301.6. It identifies the transport task at the regular-source boundary as the preservation of the visible finite-window data over the same $\mathsf{StreamName}^{\uparrow}$ surface.

Then apply the RegSeqRat finite-window transport closure of Definition 301.14. This closes the transport inside BHist, hsame, Cont, Pkg, and NameCert provenance, so no quotient stream equality, host real equality, selected host limit, hidden tail witness, or ambient completeness coordinate is introduced by the move to the common window.

Finally use the CauchyLimitSeal RegSeqRat Real finite-window pullback of Definition 386.162. The $\mathsf{Real}^{\uparrow}$ endpoint therefore consumes the same displayed boundary rows X, D, G, E after transport, and the common finite window is reused for either seal-facing route. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier common window transport`

Theorem 386.165 (CauchyLimitSeal four-face finite-window lattice exhaustion)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Every accepted consumer route that reaches a* $\mathsf{Real}^{\uparrow}$ *or completion endpoint through a* $\mathsf{StreamName}^{\uparrow}$ *finite-window meet is exhausted by exactly four displayed faces: the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row X, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the* $\mathsf{Real}^{\uparrow}$ *seal row E. The route carries only* BHist, hsame, Cont, Pkg, *and* NameCert *support, and it exports no quotient stream, host real equality, selected limit, ambient-completeness datum, hidden tail witness, metric-completeness datum, or standard bridge row.*

Proof. Begin with the finite-window lattice dependency of Definition 386.160. It places every endpoint-facing seal route over the $\mathsf{StreamName}^{\uparrow}$ finite-window meet before any regular source, dyadic ledger, completion diagonal, or seal row is read.

Apply the RegSeqRat Real finite-window pullback of Definition 386.162. This pulls the endpoint route back through the displayed source row X, tolerance ledger D, completion diagonal row G, and seal row E, with only BHist, hsame, Cont, Pkg, and NameCert support visible to the consumer.

Next use common-window transport from Definition 386.164. Transport to the shared finite window preserves the same displayed rows and does not create a second route through quotient stream equality, host real equality, selected limits, hidden tail witnesses, or ambient completeness.

Finally apply the StreamName finite-window lattice meet exhaustion theorem, Definition 126.257. Once the route has entered the meet, the consumer-visible lattice is already exhausted by the four displayed faces S, X, D, E together with the listed BEDC support rows. The completion diagonal remains an internal transport face for the seal route, while no metric-completeness datum or standard bridge row is exported to the endpoint. □

Theorem 386.166 (CauchyLimitSeal shared window route)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of L factors through the same finite route*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RealCauchyCompletion}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

displayed by the rows S, X, D, G, E and carried by BHist, hsame, Cont, Pkg, *and* NameCert *provenance. The shared route is the root L10 handoff of Definition 386.176, and it has no quotient*

stream equality, selected limit, host real equality, hidden tail witness, or ambient completeness coordinate.

Proof. First apply the finite-window lattice dependency of Definition 386.160. It forces every seal-facing read to enter through the $\mathsf{StreamName}^{\uparrow}$ finite-window meet before any regular source, dyadic ledger, completion diagonal, or seal row is consumed.

Next use source-schedule lattice coherence from Definition 386.161. The meet route is not merely some finite route: it is the displayed schedule row S followed by the displayed X, D, G, E rows.

Finally transport along the common window by Definition 386.164. Transport preserves the displayed rows and the visible BHist, hsame, Cont, Pkg, and NameCert provenance. Composing this with the root L10 sibling route of Definition 386.176 gives the stated shared handoff and excludes every listed hidden coordinate. □

Theorem 386.167 (CauchyLimitSeal route audit projection)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. The route audit visible to downstream* $\mathsf{Real}^{\uparrow}$ *and completion consumers is exactly the tuple consisting of the* $\mathsf{StreamName}^{\uparrow}$ *window S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source X, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row G, the* $\mathsf{Real}^{\uparrow}$ *seal row E, and the structural provenance carried by* BHist, hsame, Cont, Pkg, *and* NameCert.

No consumer-visible audit row contains quotient stream equality, selected host limit, host real equality, hidden tail witness, ambient completeness, or an off-route seal source.

Proof. Begin with the shared window route of Definition 386.166. It identifies the only seal-facing route available to a downstream consumer with the displayed S, X, D, G, E handoff and its structural provenance.

Apply the $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 386.5. The endpoint projection may read the seal only through the displayed completion and seal rows, together with the visible history, transport, continuation, package, and local naming data.

Finally use the RegSeqRat seal-route exclusion package of Definition 301.40. The regular source contributes no quotient stream equality, selected host limit, host real equality, hidden tail witness, or ambient completeness coordinate. The audit projection is therefore exactly the displayed tuple and no larger route. □

Theorem 386.168 (CauchyLimitSeal five-face L10 exit route)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Every accepted consumer route for L that reaches a* $\mathsf{Real}^{\uparrow}$ *or completion endpoint is exhausted by the ordered five-face L10 handoff*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RealCauchyCompletion}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

displayed by the rows S, X, D, G, E and carried only by BHist, hsame, Cont, Pkg, *and* NameCert *provenance. The route exports no quotient stream equality, selected host limit, host real equality, hidden tail witness, ambient completeness coordinate, or standard bridge row.*

Proof. First apply the finite-window lattice dependency of Definition 386.160. It places every endpoint-facing seal read over the $\mathsf{StreamName}^{\uparrow}$ finite-window meet before the regular source, dyadic ledger, completion diagonal, and real seal rows are consumed.

Next use the shared window route of Definition 386.166. The consumer route is therefore the ordered S, X, D, G, E handoff through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with only the displayed BHist, hsame, Cont, Pkg, and NameCert support.

Now identify the audit surface by Definition 386.167. The downstream audit tuple contains exactly the finite window, source, dyadic ledger, completion diagonal, seal, and structural provenance rows, so no off-route row remains for the endpoint.

Finally apply the RegSeqRat seal-route exclusion package, Definition 301.40. It rules out quotient stream equality, selected host limit, host real equality, hidden tail witness, and ambient completeness on the regular-source side; the route audit projection rules out the same off-route coordinates on the seal side. Since no standard bridge row is among the displayed carrier rows, the five-face handoff is the whole L10 exit route. □

Theorem 386.169 (CauchyLimitSeal L10 four-face terminality)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Every Phase Real and Completion consumer route for L terminates exactly at the four audited open-phase faces* $\mathsf{StreamName}^{\uparrow}(S)$*,* $\mathsf{RegSeqRat}^{\uparrow}(X)$*,* $\mathsf{DyadicRatCore}^{\uparrow}(D)$*, and* $\mathsf{Real}^{\uparrow}(E)$*. The completion diagonal G supplies only the internal completion-diagonal handoff, while T, P, N supply only transport, provenance, and local-name support.*

No quotient stream, host real equality, selected limit, countable-choice datum, ambient-completeness row, metric-completeness row, or standard bridge row is a terminal face of the accepted L10 exit route.

Proof. First apply the four-face finite-window lattice exhaustion theorem, Definition 386.165. It identifies the consumer-visible open-phase faces as the finite window S, regular source X, dyadic ledger D, and Real seal E, with only BHist, hsame, Cont, Pkg, and NameCert support.

Next use the shared window route of Definition 386.166. The same route passes through the displayed completion diagonal G, but that diagonal is an internal handoff between $\mathsf{DyadicRatCore}^{\uparrow}(D)$ and $\mathsf{Real}^{\uparrow}(E)$ rather than a fifth audited open-phase terminal face.

Now read the route audit projection from Definition 386.167. The audit tuple contains exactly the finite window, source, ledger, diagonal, seal, and structural provenance rows, so T, P, N can only act as transport, provenance, and local-name support for the four audited faces.

Finally apply the five-face L10 exit route of Definition 386.168. Its ordered handoff has no quotient stream equality, selected host limit, host real equality, hidden tail witness, ambient completeness coordinate, or standard bridge row. Since the four-face exhaustion already removes metric-completeness data from the endpoint surface, and no listed carrier row supplies countable choice, the accepted Phase Real and Completion route terminates exactly at $\mathsf{StreamName}^{\uparrow}(S)$, $\mathsf{RegSeqRat}^{\uparrow}(X)$, $\mathsf{DyadicRatCore}^{\uparrow}(D)$, and $\mathsf{Real}^{\uparrow}(E)$. □

Theorem 386.170 (CauchyLimitSeal window budget exhaustion)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. No* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer may replace the shared finite window of Definition 386.166 by a second schedule, quotient stream equality, selected host limit, hidden tail witness, or ambient completeness datum. The complete consumer budget is exhausted by the displayed finite window, the rows X, D, G, E, and the provenance* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Proof. Start with middle-window meet determinacy from Definition 386.163. Once a consumer read reaches the finite-window meet, the displayed rows X, D, G, E determine the handoff and a second $\mathsf{StreamName}^{\uparrow}$ schedule cannot determine the same seal route.

Next apply common-window transport from Definition 386.164. Transporting to the shared finite window preserves the carrier rows and does not introduce quotient stream equality, host real equality, selected host limit, hidden tail witness, or ambient completeness.

Finally compose with the route audit projection of Definition 386.167. Since the downstream audit tuple is exactly the displayed window, source, ledger, diagonal, seal, and structural provenance, all consumer-visible coordinates have been accounted for and the window budget is exhausted. □

Theorem 386.171 (CauchyLimitSeal window budget audit lock)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer whose audit projection reaches the seal row E is locked to the displayed route through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window meet, the schedule row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row X, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row G, the seal row E, and the visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance. No second schedule, quotient-stream equality, selected host limit, hidden tail witness, ambient completeness datum, or off-route seal source can replace any row of that audit route.*

Proof. Start with the finite-window lattice dependency of Definition 386.160. It places every downstream read that reaches E over the StreamName finite-window meet before the source, ledger, diagonal, and seal rows are consumed.

Apply common-window transport from Definition 386.164. Transport to the shared finite window preserves the displayed rows X, D, G, E and carries only the visible BHist, hsame, Cont, Pkg, and NameCert provenance.

Next use the shared window route of Definition 386.166. This identifies the route as the displayed S, X, D, G, E handoff rather than a second schedule, quotient stream, selected limit, hidden tail witness, or ambient completeness datum.

Finally combine the route audit projection of Definition 386.167 with the window budget exhaustion of Definition 386.170. The audit tuple has exactly the listed rows and provenance, and the exhausted budget leaves no off-route seal source or replacement row for a downstream consumer. □

Theorem 386.172 (CauchyLimitSeal Cauchy window transducer pullback)**.** *When a* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer route is served through a* $\mathsf{CauchyWindowTransducer}^{\uparrow}$ *packet, the transducer rows pull back first to the* $\mathsf{StreamName}^{\uparrow}$ *finite-window lattice meet and then through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal rows. No quotient stream, selected host limit, hidden tail witness, or ambient completeness coordinate is introduced.*

Proof. Begin with Definition 386.164. It says that a seal-facing CauchyLimitSeal route transported to a common finite window preserves the displayed RegSeqRat source, dyadic ledger, completion diagonal, and Real seal rows while remaining inside BHist, hsame, Cont, Pkg, and NameCert provenance.

Apply Definition 1020.4. A Cauchy window transducer serving such a route can expose its RealUp seal row only after the displayed RegSeqRat readback row is available.

Finally use Definition 1020.5. The transducer rows can replay the finite window, tolerance, step, readback, selector handoff, transport, continuation, provenance, and naming data, but no row supplies a quotient stream, selected host limit, hidden tail witness, or ambient completeness coordinate. □

Theorem 386.173 (CauchyLimitSeal transducer route-budget exhaustion)**.** *When a* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer route is served by a* $\mathsf{CauchyWindowTransducer}^{\uparrow}$ *packet and then read by a* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *endpoint, the complete route budget is exhausted by the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window lattice meet, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$

diagonal row, the $\mathsf{Real}^{\uparrow}$ *seal row, and the transducer finite-window, tolerance, step, selector-handoff, transport, continuation, provenance, and naming rows already cited by Definition 386.172. No quotient stream, selected host limit, hidden transducer schedule, hidden tail witness, host real equality, or ambient completeness coordinate remains available to the endpoint.*

Proof. Start with the Cauchy window transducer pullback of Definition 386.172. It places the served seal route over the $\mathsf{StreamName}^{\uparrow}$ finite-window lattice meet before the route reaches the displayed $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{Real}^{\uparrow}$ seal rows.

Next apply the window budget exhaustion of Definition 386.170. This accounts for the CauchyLimitSeal-side budget: the shared finite window, the regular source, the dyadic ledger, the completion diagonal, the seal row, and the structural BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance.

Now use the transducer handoff theorem Definition 1020.4. It forces the transducer service through the displayed readback row before a $\mathsf{Real}^{\uparrow}$ or completion-facing endpoint can consume the seal route.

Finally apply Definition 1020.5. The transducer contributes only its finite-window, tolerance, step, selector-handoff, transport, continuation, provenance, and naming rows. Since both sides of the handoff have exhausted their displayed budgets, no quotient stream, selected host limit, hidden transducer schedule, hidden tail witness, host real equality, or ambient completeness coordinate can be exported. □

Theorem 386.174 (CauchyLimitSeal transducer meet determinacy)**.** *If two* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer routes are served by* $\mathsf{CauchyWindowTransducer}^{\uparrow}$ *packets and both pull back to the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window lattice meet, then the displayed schedule, source, ledger, diagonal, and seal rows*

$$S, X, D, G, E$$

together with the transducer finite-window, tolerance, step, selector-handoff, transport, continuation, provenance, and naming rows determine one consumer-visible route. The route exports no second schedule, quotient stream equality, selected host limit, hidden transducer schedule, hidden tail witness, host real equality, or ambient completeness coordinate.

Proof. Start with common-window transport from Definition 386.164. Once both served routes pull back to the same finite-window meet, transport preserves the displayed source, ledger, diagonal, seal, and structural rows rather than creating a second schedule.

Apply the transducer pullback theorem, Definition 386.172. It places the CauchyWindowTransducer service before the RegSeqRat readback and Real seal rows, so the transducer rows are read as part of the same finite-window route.

Now use transducer route-budget exhaustion from Definition 386.173. The transducer contributes only the displayed finite-window, tolerance, step, selector-handoff, transport, continuation, provenance, and naming rows.

Finally apply the window budget audit lock, Definition 386.171. With the CauchyLimitSeal rows and the transducer rows already exhausted, no hidden schedule, tail witness, quotient stream equality, selected host limit, host real equality, or ambient completeness coordinate remains to distinguish two consumer-visible routes over the same meet. □

Theorem 386.175 (CauchyLimitSeal window budget audit-lock formal handoff)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet. Suppose a* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer route is served through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window lattice meet and through the* $\mathsf{CauchyWindowTransducer}^{\uparrow}$

finite-window rows. Then the formal handoff exported to later consumers is exactly the displayed route

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RealCauchyCompletion}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

together with the transducer finite-window, tolerance, step, selector-handoff, transport, continuation, provenance, and local naming rows, and with the visible BHist, hsame, Cont, Pkg, *and* NameCert *provenance carried by* L.

The handoff exports no quotient stream, selected host limit, hidden tail witness, host real equality, hidden transducer schedule, or ambient completeness coordinate. It also exports no route other than the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and transducer finite-window route.*

Proof. First build the CauchyLimitSeal side of the handoff. Apply the finite-window lattice dependency, Definition 386.160, and the common-window transport theorem, Definition 386.164. These place the consumer route over the shared $\mathsf{StreamName}^{\uparrow}$ finite-window meet and preserve the displayed X, D, G, E rows with only BHist, hsame, Cont, Pkg, and NameCert provenance.

Next identify the audit projection. Use Definition 386.167 to make the visible audit tuple exactly the window, source, dyadic ledger, completion diagonal, seal, and structural provenance rows. Then apply Definition 386.170 and Definition 386.171; the CauchyLimitSeal budget is exhausted by that tuple, so no quotient stream, selected host limit, hidden tail witness, host real equality, or ambient completeness coordinate remains on the seal side.

Now pull in the transducer service. The Cauchy-window transducer pullback theorem, Definition 386.172, places the transducer rows on the same finite-window route before the RegSeqRat readback and Real seal rows.

Finally apply transducer route-budget exhaustion and transducer meet determinacy, Definition 386.173 and Definition 386.174. These two results exhaust the displayed transducer rows and identify the same meet route for any served consumer, leaving exactly the stated formal handoff and no hidden transducer schedule or off-route completeness coordinate. □

386.4 CauchyLimitSeal root L10 sibling route

Theorem 386.176 (CauchyLimitSeal root L10 sibling route)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Every accepted route from* L *to a* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal consumes, in order, the finite-window surface of chapter 126, the regular readback of chapter 301, the dyadic ledger of chapter 291, and the seal boundary of chapter 38. The route exports no quotient stream, selected host limit, host real equality, hidden tail oracle, or ambient completeness row.*

Proof. Begin with the finite-window lattice dependency of Definition 386.160. It places every Real or completion consumer route over the StreamName finite-window surface before the displayed regular source row, dyadic ledger, completion diagonal, and Real seal row are consumed.

Apply the RegSeqRat Real finite-window pullback of Definition 386.162. The pulled-back route reads the same $\mathsf{RegSeqRat}^{\uparrow}$ source row X, the same $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, and the same $\mathsf{Real}^{\uparrow}$ seal row E while carrying only BHist, hsame, Cont, Pkg, and NameCert provenance.

Finally use the common-window transport of Definition 386.164. Transport to the shared finite window preserves the displayed X, D, G, E route and adds no quotient stream equality, host real equality, selected host limit, hidden tail witness, or ambient completeness coordinate. Hence the

root route is exactly the sibling route through StreamName, RegSeqRat, DyadicRatCore, and RealUp. □

Lean4 ✓ `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier root l10 sibling route certificate`
↪ variant `BEDC.Derived.CauchyLimitSealUp.CauchyLimitSealCarrier root l10 sibling route`

Theorem 386.177 (CauchyLimitSeal L10 sibling route totality)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer route for L passes through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window surface, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{Real}^{\uparrow}$ *seal row before any local* $\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$ *read is public. A route missing any one of these four sibling surfaces is outside the accepted L10 sibling route.*

Proof. Start with the finite-window lattice dependency of Definition 386.160. It places the consumer over the StreamName window before the displayed source and seal rows are read.

Apply the RegSeqRat pullback of Definition 386.162. The consumer must use the regular readback row X and the same dyadic ledger D when it reaches the Real-facing seal row E.

Finally use the root sibling route theorem Definition 386.176. It identifies the complete route through StreamName, RegSeqRat, DyadicRatCore, and RealUp, so omitting one sibling surface leaves no accepted L10 route to the local NameCert row. □

Theorem 386.178 (CauchyLimitSeal stream-RegSeq seal factorization)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier $L = (X, S, D, G, E, T, P, N)$, every L10 consumer route factors through the displayed X, D, G, E rows together with the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance carried by T, P, N. The factorized route is the same StreamName finite-window, RegSeqRat regular-source, DyadicRatCore ledger, and RealUp seal route used in Definition 386.176.*

Proof. Use route totality from Definition 386.177 to place the consumer on the StreamName, RegSeqRat, DyadicRatCore, and RealUp sibling surface.

The RegSeqRat pullback then identifies the regular source with X and the dyadic ledger with D. The finite-window lattice dependency identifies the completion diagonal and Real-facing seal with the displayed G, E rows.

The common-window transport of Definition 386.164 carries this factorization through the same BHist, hsame, Cont, Pkg, and NameCert provenance. Thus the route is a factorization through the displayed carrier rows rather than a fresh analytic route. □

Theorem 386.179 (CauchyLimitSeal no unbudgeted limit)**.** *An accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *L10 sibling route exports no quotient stream, selected limit, hidden tail oracle, host real equality, or ambient completeness coordinate. Every limit-facing read is budgeted by the finite-window lattice, the RegSeqRat pullback, and the common-window transport before it reaches the displayed RealUp seal row.*

Proof. Apply the factorization theorem Definition 386.178. It reduces every L10 consumer route to the displayed X, D, G, E, T, P, N rows and their BHist, hsame, Cont, Pkg, and NameCert provenance.

The finite-window lattice supplies the StreamName budget, the RegSeqRat pullback supplies the regular-source budget, and common-window transport keeps both budgets on the same finite route. These three dependencies account for every limit-facing read before the RealUp seal is public.

Since quotient streams, selected limits, hidden tail oracles, host real equality, and ambient completeness are not coordinates of the factorized route, none can be exported by an accepted L10 sibling route. □

Theorem 386.180 (CauchyLimitSeal root source-schedule lattice consumption)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Every accepted root L10 route first consumes the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule row S, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row X, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger row D, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row G, and the* $\mathsf{Real}^{\uparrow}$ *seal row E, with transport, package, and naming supplied only by T, P, N. The route has no second schedule, quotient stream, selected host limit, host equality, or ambient completeness coordinate.*

Proof. Begin with the root L10 sibling route of Definition 386.176. It places every accepted root route on the StreamName, RegSeqRat, DyadicRatCore, and RealUp sibling surface and excludes quotient streams, selected host limits, host equality, hidden tail oracles, and ambient completeness rows.

Apply source-schedule lattice coherence from Definition 386.161. This strengthens the first step of the route: the StreamName surface is the displayed schedule row S, and the route continues through the displayed X, D, G, E rows rather than through a second schedule or an independent stream.

Use L10 sibling route totality from Definition 386.177 to rule out routes that omit any of the sibling rows. Finally apply Definition 386.179; the factorized route has no coordinate from which a selected host limit, host equality, quotient stream, or ambient completeness principle could be exported. □

Theorem 386.181 (CauchyLimitSeal root envelope-refinement exhaustion)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Every root L10 route that reaches a* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal through the source-schedule lattice factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and the* $\mathsf{Real}^{\uparrow}$ *seal, then through the finite witness-envelope surface of* $\mathsf{CauchyTailWitnessEnvelope}^{\uparrow}$ *and the bridged route surface of* $\mathsf{CauchyModulusRefinement}^{\uparrow}$*. The route exports no quotient stream, host real equality, selected host limit, hidden selector, independent completion carrier, or ambient completeness coordinate.*

Proof. First apply the source-schedule lattice consumption theorem Definition 386.180. It fixes the root L10 route on the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before any Real-facing or completion-facing consumer can read the seal.

Next use the stream-RegSeq seal factorization of Definition 386.178. The factorized route carries only the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance attached to T, P, N, so there is no second stream source or unrecorded selector row.

The Real tail side is supplied by Definition 898.7. It places the tail witness read on the finite envelope surface rather than on a host limit, host equality, or quotient stream. The refinement side is supplied by Definition 885.154, which routes the modulus refinement through the displayed bridged surface before it can serve completion-facing consumers.

Finally apply the no-unbudgeted-limit theorem Definition 386.179. Since quotient streams, host real equality, selected host limits, hidden selectors, independent completion carriers, and ambient completeness coordinates do not occur in the displayed packet rows, no accepted route can export them. □

Theorem 386.182 (CauchyLimitSeal root sibling route exactness)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. An accepted root* $\mathsf{Real}^{\uparrow}$ *or completion-facing route exists*

exactly when it passes through the displayed $\mathsf{StreamName}^{\uparrow}$ *finite-window surface,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *diagonal row, and* $\mathsf{Real}^{\uparrow}$ *seal row, followed only by the transport, provenance, and local naming rows* T, P, N*.*

No omitted sibling row, quotient stream, selected host limit, host real equality, hidden tail oracle, independent completion carrier, or ambient completeness object can serve as an accepted root route for L*.*

Proof. For existence, use the root L10 sibling route and route totality. Theorems 386.176 and 386.177 place every accepted root Real or completion-facing consumer on the displayed StreamName, RegSeqRat, DyadicRatCore, and RealUp sibling surface.

Next apply stream-RegSeq seal factorization. Theorem 386.178 reads the same X, D, G, E rows together with the BHist, hsame, Cont, Pkg, and NameCert provenance carried by T, P, N, so the route is a displayed BEDC packet rather than an external completion object.

For necessity, use the no-unbudgeted-limit theorem. Theorem 386.179 removes quotient streams, selected limits, hidden tail oracles, host real equality, and ambient completeness from the accepted route surface.

Finally combine source-schedule lattice consumption with envelope-refinement exhaustion. Theorems 386.180 and 386.181 force the schedule, regular readback, dyadic ledger, completion diagonal, Real seal, and the subsequent T, P, N rows to appear in the displayed order. Omitting any sibling row or replacing it by a host-side completion object therefore leaves no accepted root route. □

Theorem 386.183 (CauchyLimitSeal budget-tail root join)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Suppose a* $\mathsf{RealObservationBudget}^{\uparrow}$*-facing read and a* $\mathsf{CauchyTailWitnessEnvelope}^{\uparrow}$*-facing tail read are accepted through* L *over the same finite* $\mathsf{StreamName}^{\uparrow}$ *window and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger. Then the two reads join on one displayed L10 packet through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

The joined packet exports the shared finite window, regular source row, dyadic ledger, RealUp seal surface, transport, route, package, and local naming rows. It exports no quotient stream, selected limit, host real equality, hidden family limit, hidden tail oracle, independent completion endpoint, or ambient completeness coordinate.

Proof. First apply root source-schedule lattice consumption from Definition 386.180. It fixes every accepted root route on the displayed $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ source row, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{Real}^{\uparrow}$ seal row, and structural BHist, hsame, Cont, Pkg, and NameCert rows.

Next use root envelope-refinement exhaustion from Definition 386.181. The tail-facing read is forced through the finite envelope surface rather than through a hidden host limit, quotient stream, or independent completion endpoint.

Now apply budget root source totality from Definition 386.87. Since the budget-facing read uses the same finite $\mathsf{StreamName}^{\uparrow}$ window and the same $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, it has no second source surface outside the displayed root L10 packet.

The tail boundary is supplied by Definition 898.7. It places the $\mathsf{CauchyTailWitnessEnvelope}^{\uparrow}$ leg on the same finite witness-envelope route before any RealUp readback is public.

Finally apply the no-unbudgeted-limit theorem Definition 386.179. The joined route contains only the displayed packet rows, so it cannot export a quotient stream, selected limit, host real equality, hidden family limit, hidden tail oracle, independent completion endpoint, or ambient completeness coordinate. □

Theorem 386.184 (CauchyLimitSeal selector-seal compatibility)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier, and let $Q = (B, W, R, L', E', H, C, P', N')$ be an accepted* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *packet. Suppose the two packets share the displayed* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *handoff row, and the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint row, so that W is the displayed window of S, R is the displayed regular readback through D, $L' = L$, and $E' = E$.*

Then the selector-seal public route of Q factors through the public route packet of L. The consumer reads one displayed L10 handoff

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{CauchyLimitSeal}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

together with the shared finite-window, dyadic-ledger, transport, continuation, provenance, and local naming rows. It exposes no second completion route, quotient stream, host real equality, hidden selector, or ambient completeness coordinate.

Proof. First fix the CauchyLimitSeal route. By Definition 386.182, the accepted root route for L is exactly the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ packet, followed only by the transport, provenance, and local naming rows.

Next join the visible budget and tail reads. The budget-tail root join theorem, Definition 386.183, says that reads using the same finite window and the same dyadic ledger meet on one displayed L10 packet. Hence the shared W, R, L', E' rows of Q do not open an independent completion surface.

Finally identify the selector-seal route. The public route export theorem, Definition 1081.29, gives the route $B \to W \to R \to L' \to E'$, while Definition 1081.5 places that route inside the same L10 Real and Completion handoff. Since $L' = L$ and $E' = E$, the selector-seal consumer factors through the CauchyLimitSeal packet fixed in the first step, and the excluded coordinates are absent from both displayed carrier surfaces. □

Lemma 386.185 (CauchyLimitSeal root L10 downstream coverage)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Every accepted local consumer that reads the root L10* $\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$ *route for a* $\mathsf{Real}^{\uparrow}$ *or completion-facing use is covered by the displayed downstream rows*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RealCauchyCompletion}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

together with the transport, provenance, package, and naming rows carried by T, P, N. Thus the consumer can use only the finite-window surface S, the regular readback row X, the dyadic ledger D, the completion diagonal G, the seal row E, and the visible BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support. A candidate local read that asks instead for a quotient stream, selected host limit, host real equality, hidden tail oracle, second finite-window source, independent completion carrier, or ambient completeness coordinate is outside the accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet.*

Proof. Apply the L10 sibling route totality theorem, Definition 386.177. Before any local $\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$ read is public, the consumer route has already passed through the $\mathsf{StreamName}^{\uparrow}$ finite-window surface, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the $\mathsf{Real}^{\uparrow}$ seal row. Therefore any read that omits one of those sibling surfaces has no accepted route to the local naming row.

Now apply the common-window transport theorem, Definition 386.164, and then the root L10 sibling route theorem, Definition 386.176. The transport theorem carries the total route to the shared finite-window surface while preserving the displayed X, D, G, E rows and the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support. The root theorem then identifies this transported total

route with the root route through StreamName, RegSeqRat, DyadicRatCore, and RealUp, and it excludes quotient streams, selected host limits, host real equality, hidden tail oracles, and ambient completeness rows from the exported surface.

It remains only to identify the downstream rows available after the route is fixed. The stream-RegSeq seal factorization theorem, Definition 386.178, says that every L10 consumer factors through the displayed X, D, G, E rows and the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance carried by T, P, N. The source-schedule lattice consumption theorem, Definition 386.180, adds the displayed schedule row S and rules out a second schedule or independent stream source.

Finally use the no-unbudgeted-limit theorem, Definition 386.179. Since the factorized downstream route contains only the listed finite-window, regular-readback, ledger, diagonal, seal, transport, provenance, package, and naming rows, none of the excluded coordinates can be consumed as part of an accepted local $\mathsf{CauchyLimitSeal}^{\uparrow}$ packet. □

386.5 CauchyLimitSeal DyadicRatCore terminal dependency

Theorem 386.186 (CauchyLimitSeal DyadicRatCore terminal dependency)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ carrier. Every accepted terminal route from L to a $\mathsf{Real}^{\uparrow}$ or completion-facing seal consumes the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291 before the displayed $\mathsf{Real}^{\uparrow}$ seal row is public.*

Equivalently, the accepted terminal route reaches $\mathsf{Real}^{\uparrow}$ only through the same StreamName finite-window surface, RegSeqRat regular readback, DyadicRatCore ledger, and RealUp seal packet fixed by the root L10 sibling route. No route that bypasses the DyadicRatCore ledger can be an accepted terminal CauchyLimitSeal route.

Proof. Start with the root L10 sibling route of Definition 386.176. It places every accepted Real-facing or completion-facing route through the StreamName surface, the RegSeqRat readback, the DyadicRatCore ledger, and the RealUp seal row in that order.

Use L10 sibling route totality from Definition 386.177. A terminal consumer that omits the dyadic ledger also omits one of the four required sibling surfaces, so it is outside the accepted L10 route before it can reach the local $\mathsf{NameCert}_{\mathsf{CauchyLimitSeal}^{\uparrow}}$ row.

Finally apply the stream-RegSeq seal factorization of Definition 386.178. The factorized route reads the displayed X, D, G, E rows, with D serving as the DyadicRatCore tolerance ledger, before the RealUp seal row E is public. Thus DyadicRatCore is a terminal dependency of every accepted CauchyLimitSeal seal route. □

Theorem 386.187 (CauchyLimitSeal RegSeq-Real sibling dependency)**.** *Every accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ handoff consumes $\mathsf{StreamName}^{\uparrow}$ for finite observations, $\mathsf{RegSeqRat}^{\uparrow}$ for regular Cauchy rows, and $\mathsf{Real}^{\uparrow}$ for the public seal and readback row. The handoff therefore factors through chapter 126, chapter 301, and chapter 38; it cannot be read as a standalone completion principle.*

Proof. Begin with the root L10 sibling route, Definition 386.176. It already places every accepted Real-facing or completion-facing route through the finite-window surface, regular readback, dyadic ledger, and Real seal boundary.

The finite observations are supplied by the StreamName surface. The scheduled window row records the finite observations before any regular Cauchy source or seal row is public.

The regular Cauchy content is supplied by the RegSeqRat row. The accepted handoff reads the regular source and its readback before it reaches the seal endpoint.

The public endpoint is supplied by the RealUp seal row. Since the accepted route has no coordinate for quotient streams, selected host limits, hidden tail oracles, host equality, or ambient

completeness, the CauchyLimitSeal packet is a sibling-dependent handoff rather than an isolated completion principle. □

Theorem 386.188 (CauchyLimitSeal RegSeqRat–Real handoff exactness)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. An accepted consumer route for L whose public endpoint is a* $\mathsf{Real}^{\uparrow}$ *seal is exact if and only if it factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite window, the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *regular row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, and the local* $\mathsf{Real}^{\uparrow}$ *seal row, with all transport carried only by the visible* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows of the packet.*

Equivalently, the exact Real-facing handoff is the finite route

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

read inside the public route packet of L. No quotient stream, selected host limit, host real equality, hidden tail oracle, independent completion object, or ambient completeness coordinate belongs to that exact handoff.

Proof. For the forward direction, start from the sibling dependency theorem Definition 386.187. It already places each accepted $\mathsf{Real}^{\uparrow}$ handoff through the StreamName finite observations, RegSeqRat regular rows, and RealUp public seal surface.

Next refine the dependency by the root L10 sibling route, Definition 386.176. This identifies the missing observation ledger as the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ row and keeps the route inside the same finite-window, regular-source, dyadic-ledger, and Real-seal packet.

Finally apply the public route packet and non-escape boundary from Definition 386.6 and Definition 386.4. These surfaces leave only the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ transport and provenance rows, so an exact public endpoint cannot pass through an omitted sibling row or an external completion coordinate.

For the reverse direction, assume the consumer factors through the displayed StreamName window, RegSeqRat row, DyadicRatCore ledger, RealUp seal, and structural BEDC rows. The public route boundary of Definition 386.8 repacks those rows as the accepted public route packet of L.

Use the RealUp consumer boundary, Definition 386.5, to read the terminal seal from that packet. Because every coordinate of the proposed route is already a carrier row or one of its visible transport, continuation, provenance, and naming rows, the repacked route is an admissible $\mathsf{Real}^{\uparrow}$ consumer handoff.

The non-escape boundary then rules out any second route through quotient streams, selected limits, host equality, hidden tail data, independent completion objects, or ambient completeness. Thus the displayed factorization is not merely sufficient for a Real-facing read; it is exactly the accepted CauchyLimitSeal handoff surface. □

Theorem 386.189 (CauchyLimitSeal RegSeq–Real bridge determinacy)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Any consumer-facing use of the RegSeq–Real sibling bridge for L, whether presented as a route, a transport, a readback, or a handoff, is admitted only through the local rows displayed by Definition 386.188: the* $\mathsf{StreamName}^{\uparrow}$ *finite window S, the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *regular row X, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger D, the local* $\mathsf{Real}^{\uparrow}$ *seal row E, and the visible* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows carried by T, P, N.*

Consequently the bridge is determinate at the consumer surface: every accepted use factors through the finite public route

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

inside the public route packet of L. A requested quotient stream, selected host limit, host real equality, hidden tail oracle, independent completion object, alternate readback, second finite window, or ambient completeness coordinate is not a bridge coordinate of this RegSeq–Real sibling dependency.

Proof. Start with the sibling dependency theorem Definition 386.187. It says that an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ handoff is not a standalone completion principle: the handoff consumes the StreamName finite observations, the RegSeqRat regular Cauchy rows, and the RealUp public seal and readback row.

Refine that dependency by the handoff exactness theorem Definition 386.188. Exactness identifies the consumer-facing bridge as the displayed finite route through the $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ regular row, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and the $\mathsf{Real}^{\uparrow}$ seal, with transport carried only by the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. Thus any route, transport, readback, or handoff that is accepted by the consumer has already been forced through those local rows.

It remains to rule out hidden alternatives. The root L10 sibling route of Definition 386.176 places every Real-facing or completion-facing route through the same finite-window, regular-readback, dyadic-ledger, and Real-seal surface and exports no quotient stream, selected host limit, host real equality, hidden tail oracle, or ambient completeness row.

Finally use the public route packet and boundary, Definition 386.6 and Definition 386.8. They identify the public coordinates of L as the displayed carrier rows and their visible transport, package, and naming data. The non-escape boundary Definition 386.4 prevents any omitted coordinate from being supplied after the route reaches the public surface. Therefore the cited local rows exhaust the RegSeq–Real sibling bridge, and every unlisted coordinate is unavailable to a consumer. □

Corollary 386.190 (CauchyLimitSeal RegSeq–Real sibling dependency determinacy)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ carrier, and suppose a consumer-facing use of the RegSeq–Real sibling dependency is accepted after the displayed local rows*

$$S, X, D, E, T, P, N$$

are fixed. Then the use has only the finite consumer surface named in Definition 386.189: the route

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{Real}^{\uparrow},$$

the corresponding window-ledger normal form, and the exactness decision supplied by Definition 386.188 are all read from the same displayed rows. In particular, an accepted route, transport, readback, handoff, normal-form claim, or exactness claim cannot choose an alternate finite window, a second regular row, a duplicate classifier source, a hidden tail coordinate, a quotient stream, a selected host limit, host real equality, an independent completion object, or ambient completeness data.

Proof. Apply the RegSeq–Real bridge determinacy theorem, Definition 386.189. It states that every consumer-facing use of the sibling bridge, whether presented as a route, transport, readback, or handoff, is admitted only through the local rows displayed by Definition 386.188: the finite window S, the regular row X, the dyadic ledger D, the seal row E, and the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows carried by T, P, N.

Now use the handoff exactness theorem, Definition 386.188. Its exactness criterion identifies the accepted Real-facing handoff precisely with the displayed finite route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with all transport carried only by the visible packet rows. Hence a consumer that asks for an exactness decision has no independent source from which to

answer that decision; it must answer by checking whether the proposed use factors through the same finite route.

The same reasoning fixes the normal-form reading. A normal-form claim for this sibling dependency is a consumer-facing presentation of the accepted bridge, so by bridge determinacy it is already confined to the displayed rows. Since exactness makes those rows the entire Real-facing handoff surface, the normal form cannot split off a second window, a second regular readback, or a duplicate classifier source.

The excluded coordinates are therefore unavailable for every accepted consumer presentation. A quotient stream, selected host limit, host real equality, hidden tail coordinate, independent completion object, ambient completeness datum, alternate finite window, or duplicate classifier source is not among the rows named by determinacy and is also not part of the exact handoff surface. Once the local rows are fixed, every accepted use must pick the same finite route, the same normal-form surface, and the same exactness decision named by the chapter. □

Theorem 386.191 (CauchyLimitSeal tail-budget handoff determinacy)**.** *Let $L = (X, S, D, G, E, T, P, N)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. A* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer that reads the displayed* $\mathsf{StreamName}^{\uparrow}$ *window rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-budget rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger rows, and local seal rows G, E, T, P, N receives a single displayed handoff route through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. Any two accepted reads with those same displayed rows agree up to the componentwise* hsame *transport and displayed* Cont *replay of T.*

The handoff route is only the finite L10 completion seal route. It does not identify quotient streams, selected host limits, host real equality, hidden selectors, independent completion endpoints, or ambient completeness data.

Proof. Start with the StreamName dependency theorem Definition 386.116. It forces every sealed-limit read through the scheduled finite window before the local seal row is consumed.

Next apply the tail-budget meet of Definition 386.135. The selector-facing read, observation-budget read, and completion-facing read meet on the same precision request, stream window, dyadic ledger, regular handoff, Real seal, transport, continuation, provenance, and naming rows.

Use the regular-tail selector sibling link, Definition 386.150. It places compatible selector reads before the StreamName, DyadicRatCore, RegSeqRat, Real, and observation-budget rows and prevents the selector side from becoming a detached support surface.

Finally apply the root L10 sibling route of Definition 386.176. The route through StreamName, RegSeqRat, DyadicRatCore, and RealUp is therefore the single displayed handoff route, with all equality of accepted reads mediated only by hsame transport and Cont replay. □

Theorem 386.192 (CauchyLimitSeal StreamName non-escape)**.** *For an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier $L = (X, S, D, G, E, T, P, N)$, the StreamName-facing completion seal route cannot import quotient stream equality, selected limit choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a second tail selector outside the displayed S, X, D, G, E, T, P, N rows. Every public consumer receives only the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-budget handoff, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the diagonal and Real seal rows, componentwise transport, replay, provenance, and local naming.*

Proof. Begin with Definition 386.116. The StreamName row is a required dependency of the sealed-limit read, so a consumer cannot reach E before passing through the scheduled window row S.

Apply the tail-budget consumer normal form of Definition 386.140. It lists the exact budget, handoff, seal, transport, continuation, package, and naming rows available to a RealUp or completion consumer.

Use the regular-tail selector non-escape theorem Definition 386.152. It removes quotient stream identity, host real equality, choice-selected limits, hidden family limits, and ambient completeness from selector-compatible seal reads.

Finally use the root sibling route exactness of Definition 386.182. The accepted root route has no coordinate for a second tail selector or an independent completion endpoint, so the StreamName-facing consumer remains inside the displayed finite route. □

Corollary 386.193 (CauchyLimitSeal tail-budget handoff strict local obstruction)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Any displayed obstruction, refusal, separation, or countermodel reading attached to the tail-budget handoff in this file is strict and local: it blocks only the attempted converse or reuse route that tries to replace the displayed* S, X, D, G, E, T, P, N *packet by quotient stream equality, selected limit choice, host* $\mathsf{Real}^{\uparrow}$ *completeness, host real equality, a hidden selector, a second tail selector, an independent completion endpoint, or hidden external validation.*

The obstruction cannot be reinterpreted as a global impossibility theorem about Cauchy completion, as a host theorem about $\mathsf{Real}^{\uparrow}$*, or as an external validation principle. Every consumer-facing use still factors through the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-budget handoff, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the diagonal and* $\mathsf{Real}^{\uparrow}$ *seal rows, the componentwise* hsame *transports, the displayed* Cont *replay, the* Pkg *provenance, and the local* NameCert *row; every unlisted coordinate is rejected only as an attempted exit from that finite route.*

Proof. Start with the handoff determinacy theorem Definition 386.191. It says that a consumer reading the displayed $\mathsf{StreamName}^{\uparrow}$ window rows, $\mathsf{RegSeqRat}^{\uparrow}$ tail-budget rows, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger rows, and local seal rows G, E, T, P, N receives a single handoff route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert. Agreement of accepted reads is mediated only by the componentwise hsame transport and the displayed Cont replay of T.

Apply StreamName non-escape from Definition 386.192. It identifies the consumer-facing export inventory as the scheduled $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ tail-budget handoff, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, the diagonal and Real seal rows, componentwise transport, replay, provenance, and local naming. In particular, quotient stream equality, selected limit choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, and a second tail selector are not coordinates outside the displayed S, X, D, G, E, T, P, N rows.

Now consider any proposed reading of a displayed obstruction as more than a local block. If it is used to distinguish two accepted handoff reads, determinacy sends both reads back to the same displayed route and permits comparison only through hsame transport and Cont replay. If it is used to import a quotient stream, selected limit, host equality, hidden selector, independent completion endpoint, or ambient completeness row, non-escape rejects that coordinate because it is absent from the displayed StreamName-facing route. Thus the only route actually blocked is the attempted converse or reuse route from an unlisted coordinate back into the accepted finite packet.

Nothing in this argument constructs a global countermodel, a host-level impossibility theorem, or an external validation channel. The proof uses only the two local route facts just cited: determinacy of the displayed handoff and non-escape of the StreamName-facing export surface. The obstruction is therefore strict at the local handoff boundary and has no force outside the named converse or reuse route. □

386.6 CauchyCriterion Lattice Dependency

Theorem 386.194 (CauchyLimitSeal CauchyCriterion lattice dependency)**.** *Every* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer route that exposes a* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal first consumes the* $\mathsf{CauchyCriterion}^{\uparrow}$ *budget-selector boundary of chapter 392. The resulting route factors through the existing* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route rows together with the finite selector boundary before any seal row is public, and it exports no quotient stream, selected host limit, host real equality, countable-choice selector, hidden tail oracle, or ambient completeness coordinate.*

Proof. Start with the $\mathsf{CauchyLimitSeal}^{\uparrow}$ root L10 sibling route. It places every Real or completion-facing consumer on the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before the local seal is read.

Apply the $\mathsf{CauchyCriterion}^{\uparrow}$ finite selector boundary of chapter 392. That boundary supplies the budget-selector row used by the same finite window and tolerance ledger, so the seal route cannot bypass the criterion packet on its way to a Real or completion-facing consumer.

The two route surfaces share only displayed BHist, hsame, Cont, Pkg, and NameCert rows. Therefore the combined consumer route exposes the finite criterion selector and the local CauchyLimitSeal packet, not any excluded quotient, host-limit, host-equality, choice, hidden-oracle, or ambient-completeness coordinate. □

386.7 CauchyLimitSeal RealCompletionExactBoundary sibling route

Theorem 386.195 (CauchyLimitSeal exact-boundary sibling route)**.** *Let* $L = (X, S, D, G, E, T, P, N)$ *be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *carrier. Every* RealCompletionExactBoundaryUp *consumer that uses the CauchyLimitSeal route must first read the public route packet of* L *through the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows before it can use the exact-boundary packet of chapter 1120. The sibling route adds no quotient stream, selected host limit, countable choice, host real equality, or ambient completeness premise.*

Proof. Start with the public route boundary of Definition 386.8. It places every completion-facing read of L inside the public route packet X, S, D, G, E, T, P, N, with the scheduled StreamName window, regular RegSeqRat source, DyadicRatCore ledger, RealCauchyCompletion diagonal, RealUp seal, transport, provenance, and local naming rows all displayed.

Next apply the root L10 sibling route of Definition 386.176. The route is the finite sibling route through StreamName, RegSeqRat, DyadicRatCore, and RealUp, and the structural tail of the packet is carried only by hsame, Cont, Pkg, and NameCert rows. Use the root sibling route exactness of Definition 386.182 to make this route necessary for any accepted root completion-facing consumer.

The exact-boundary packet of chapter 1120 is therefore consumed only after that displayed CauchyLimitSeal route is in scope. Since the CauchyLimitSeal route already excludes quotient streams, selected host limits, host real equality, hidden tail oracles, and ambient completeness rows, and since the exact-boundary packet records only the finite Real-completion boundary surface, the sibling handoff introduces none of those absent coordinates and no countable-choice premise. □

Chapter 387

A Concrete Naming Certificate for $\mathsf{CauchyTailComparison}^{\uparrow}$

The $\mathsf{CauchyTailComparison}^{\uparrow}$ interface records the finite common-tail comparison certificate used when a regular rational Cauchy name and its real-completion readback must be compared through the same visible window data. Following Bishop and Bridges, *Constructive Analysis*, where Cauchy comparison is controlled by explicit tail moduli and finite rational estimates, the packet stores two regular-name surfaces, one common modulus, one finite stream window, dyadic endpoint comparisons, tail-comparison rows, the $\mathsf{Real}^{\uparrow}$ classifier readback, package provenance, and a local naming row. It does not form quotient classes of streams, choose a host limit, compare host real values, or appeal to ambient completeness.

The common-tail comparison consumes the finite-window observation surface of chapter 126, the regular-name rows of chapter 301, the dyadic endpoint ledger of chapter 291, and the completion-facing handoff used by chapter 406. These sibling carriers determine where X, Y, μ, W, T, and R may be read: the two names are compared only after a shared stream window, through displayed dyadic endpoints, and with the readback row already shaped for the completion interface.

The shared window and dyadic endpoint rows are specifically read through the finite-window envelope surface of chapter 365. Thus the common-window comparison packet consumes the envelope's selected window and endpoint ledger before exporting the $\mathsf{Real}^{\uparrow}$ completion readback, rather than acting as an isolated host-level comparison.

Definition 387.1 (CauchyTailComparison carrier)**.** *A* $\mathsf{CauchyTailComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, \mu, W, T, R, P, N)$$

with the following visible rows:

1. *X and Y are the two displayed regular Cauchy names, each presented through* $\mathsf{RegSeqRat}^{\uparrow}$ *rows and through the* $\mathsf{Real}^{\uparrow}$*-facing regular-name surface consumed by the completion interface;*
2. *μ is the explicit unary modulus row that assigns the common tail threshold used for every displayed precision request;*
3. *W is the common finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger inspected after the threshold supplied by μ;*
4. *T is the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-comparison ledger for the inspected windows of X and Y, including the rational lower and upper comparison rows used by the tail estimate;*

5. *R is the tail-comparison readback row that records, for each inspected precision, that the two late regular-name windows are compared through the same W and the same dyadic endpoint ledger T;*

6. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*;*

7. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailComparison}^{\uparrow}}$ *row.*

The carrier contains no quotient of regular streams, no host real carrier, no selected limit, and no equality test outside the rows displayed in the packet.

Lean4 ✓ `BEDC.Derived.CauchyTailComparisonUp.CauchyTailComparisonTasteGate single carrier alignment`

Definition 387.2 (CauchyTailComparison classifier)**.** *For accepted* $\mathsf{CauchyTailComparison}^{\uparrow}$ *carriers Q and Q', the classifier* $\mathsf{CauchyTailComparisonClassifier}(Q, Q')$ *compares only the visible rows X, Y, μ, W, T, R, P, and N by displayed* hsame *transport and displayed* Cont *read routes.*

In particular, two packets classify together only when their two regular-name surfaces are read through transported common-tail windows, transported dyadic endpoint-comparison rows, transported $\mathsf{Real}^{\uparrow}$ *classifier readback rows, the same package provenance, and the same local naming row. The classifier does not inspect quotient representatives, host limits, host real equality, or any completion principle not named by those rows.*

Theorem 387.3 (CauchyTailComparison NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyTailComparison}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier admission: an accepted packet is exactly the finite* BHist *carrier of Definition 387.1;*

2. *classifier stability: Definition 387.2 is preserved by displayed* hsame *transports and* Cont *routes on the two regular-name rows, the unary modulus row, the common window, the dyadic endpoint comparisons, the readback row, package provenance, and local naming row;*

3. *tail-window stability: every accepted precision request reads both regular Cauchy names through the same threshold supplied by μ and the same finite window ledger W;*

4. $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff: the readback row R may be consumed by the completion-facing* $\mathsf{Real}^{\uparrow}$ *classifier only through the displayed regular-name, common-window, dyadic endpoint, transport, continuation, package, and local naming rows;*

5. *non-escape: the packet exports no quotient of regular streams, no selected host limit, no host real equality, no choice principle, and no ambient completeness object.*

Proof. Carrier admission is projection of the displayed packet. Each coordinate is a finite history row or provenance row already named in Definition 387.1.

Classifier stability is componentwise. Transport the two regular-name surfaces, the modulus row, the common window, the endpoint ledger, and the readback row along the stored hsame comparisons, then replay the displayed Cont routes. Since Definition 387.2 reads no other data, accepted packets remain classified by the same finite rows.

The common-tail row is the pair (μ, W). A precision request first reaches μ, then reads both names inside the window ledger W at the threshold selected by that same row.

The completion-facing handoff is the row R. It packages the common-tail comparison in the format visible to the $\mathsf{Real}^{\uparrow}$ classifier used by $\mathsf{RealCauchyCompletion}^{\uparrow}$, while retaining the dyadic endpoint ledger and the provenance rows that justify the read.

Finally, the carrier has no coordinate for quotient stream equality, host real equality, selected limits, choice, or ambient completeness. Those objects therefore cannot be exported by the local certificate. □

Theorem 387.4 (CauchyTailComparison tail-window stability)**.** *For every accepted* $\mathsf{CauchyTailComparison}^{\uparrow}$ *carrier*

$$Q = (X, Y, \mu, W, T, R, P, N)$$

and every displayed precision request, any transported consumer read that preserves μ*,* W*,* T*, and* R *compares the two late regular-name windows through the same finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-comparison ledger. No transported read may replace the common tail threshold by an unrecorded selector or split the two names across different windows.*

Lean4 ✓ `BEDC.Derived.CauchyTailComparisonUp.CauchyTailComparisonCommonWindowCarrier semantic name certificate`

Proof. Project the modulus coordinate μ. For the requested precision it supplies the only threshold row that the carrier exposes to a consumer.

Project the common window coordinate W. Both X and Y are read through that window after the threshold named by μ, so the two regular-name observations have a shared finite source.

Project the endpoint ledger T and readback row R. The comparison rows in R cite exactly the dyadic endpoint data in T for the same inspected window.

Transport can change the displayed representatives only along the stored hsame and Cont routes. Because the carrier has no second threshold coordinate and no second window coordinate, a transported read cannot introduce an unrecorded selector or split the comparison across different windows. □

Lean4 ✓ `BEDC.Derived.CauchyTailComparisonUp.CauchyTailComparisonCarrier tail stability`

Theorem 387.5 (CauchyTailComparison real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *classifier read exported by an accepted* $\mathsf{CauchyTailComparison}^{\uparrow}$ *carrier factors through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name rows, the unary modulus* μ*, the common finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-comparison ledger* T*, the tail-comparison readback row* R*, the* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. The handoff supplies comparison evidence usable by* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *without adding a quotient of streams or a host real equality test.*

Proof. A real-facing read first reaches the two regular-name rows X and Y. These rows are the only regular Cauchy surfaces stored in the carrier.

The read then passes through μ and W, so both names are inspected after the same displayed threshold and inside the same finite stream window. The endpoint comparisons are exactly the dyadic rows in T.

The readback row R repacks those common-tail observations as the comparison surface consumed by the $\mathsf{Real}^{\uparrow}$ classifier in the $\mathsf{RealCauchyCompletion}^{\uparrow}$ handoff. Package provenance P and local naming row N record the certificates that own the route.

Since this factorization exhausts the carrier coordinates, the handoff contains no quotient stream, host real value, host real equality test, selected limit, or ambient completeness witness. □

Lean4 ✓ `BEDC.Derived.CauchyTailComparisonUp.CauchyTailComparisonCarrier real completion handoff`

Theorem 387.6 (CauchyTailComparison common-window transitivity)**.** *Let* $Q_{XY} = (X, Y, \mu_{XY}, W_{XY}, T_{XY}, R_{XY}$ *and* $Q_{YZ} = (Y, Z, \mu_{YZ}, W_{YZ}, T_{YZ}, R_{YZ}, P_{YZ}, N_{YZ})$ *be accepted* $\mathsf{CauchyTailComparison}^{\uparrow}$ *carriers. Suppose the two packets compare* X *with* Y *and* Y *with* Z *through transported common modulus rows, shared finite* $\mathsf{StreamName}^{\uparrow}$ *windows, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledgers, and suppose a displayed* Cont *refinement composes the two common-window ledgers through the shared* Y *row. Then there is an accepted finite packet* Q_{XZ} *comparing* X *with* Z *through the composed common window, with endpoint ledger obtained by the displayed dyadic rows and with no quotient stream, selected host limit, host real equality, or ambient completeness coordinate.*

Proof. Project the two accepted carriers and their classifiers. Each packet exposes only two regular-name rows, one modulus row, one common window, one endpoint ledger, one readback row, package provenance, and a local naming row.

Apply tail-window stability from Definition 387.4 to Q_{XY} and to Q_{YZ}. Both comparisons are forced through their displayed common modulus rows and through the finite windows named in their carriers.

Compose the displayed window ledgers by the given Cont refinement along the shared Y row. The dyadic endpoint rows in T_{XY} and T_{YZ} then provide the endpoint ledger for the composed X to Z comparison, and the classifier of Definition 387.2 admits that transported packet because it reads only those visible coordinates.

Finally use the real-completion handoff of Definition 387.5. The resulting $\mathsf{Real}^{\uparrow}$ read remains a finite common-tail comparison surface, so composing the window ledgers does not introduce quotient equality, a selected limit, host equality, or completeness data. □

Theorem 387.7 (CauchyTailComparison non-escape boundary)**.** *An accepted* $\mathsf{CauchyTailComparison}^{\uparrow}$ *carrier exports only the finite comparison surface generated by* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. It exports no quotient of regular Cauchy streams, no choice-selected limit, no host real carrier, no host real equality, and no ambient completeness theorem.*

Proof. Inspect the carrier coordinates. The two regular-name rows, the modulus, the window ledger, the endpoint ledger, and the readback row are finite displayed rows. The remaining coordinates are package provenance and the local naming row.

The classifier of Definition 387.2 compares only those rows by hsame and Cont. It therefore cannot introduce an external equality relation, a quotient representative, or a host real comparison.

The $\mathsf{RealCauchyCompletion}^{\uparrow}$ handoff of Definition 387.5 keeps the same boundary. A downstream consumer receives finite common-tail comparison evidence, not an ambient completion object or a selected limit. □

Lean4 ✓ `BEDC.Derived.CauchyTailComparisonUp.CauchyTailComparisonCarrier non escape boundary`

Theorem 387.8 (CauchyTailComparison common tail-window refinement)**.** *Let*

$$Q = (X, Y, \mu, W, T, R, P, N)$$

be an accepted $\mathsf{CauchyTailComparison}^{\uparrow}$ *carrier. For any two consumer reads of the compared* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *surfaces that preserve the displayed tail-comparison classifier, there is a common refinement of their inspected tail windows through the same modulus row* μ*, the same finite* $\mathsf{StreamName}^{\uparrow}$ *ledger* W*, and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger* T*.*

The refinement is internal to the carrier: both reads factor through the late windows already named by R*, and no consumer may replace them by an unrecorded selector, a quotient representative, or a host-level Cauchy comparison.*

Proof. Project the accepted packet. The only threshold coordinate is μ, and the only finite stream-window coordinate is W.

Apply the tail-window stability row of Definition 387.4 to each consumer read. Both reads must pass through the threshold supplied by μ and through the same window ledger W.

The endpoint comparisons are then read from T, and the comparison readback is R. Since the classifier has no second threshold, no second window ledger, and no host comparison coordinate, the two reads refine to the displayed common tail window. □

Theorem 387.9 (CauchyTailComparison finite-window induction)**.** *Let*

$$Q = (X, Y, \mu, W, T, R, P, N)$$

be an accepted $\mathsf{CauchyTailComparison}^{\uparrow}$ *carrier. Every finite list of displayed precision requests for the compared* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *surfaces is discharged by induction over the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger* W*. The empty case reads only* μ*,* W*,* T*,* R*,* P*, and* N *and exports no comparison datum. The step case consumes one displayed window of* W*, preserves the same common threshold* μ *and endpoint ledger* T*, and replays the* $\mathsf{Real}^{\uparrow}$ *seal through the existing real-completion handoff.*

Thus the common-tail comparison is generated by finite displayed windows. It does not appeal to quotient streams, host real equality, selected limits, choice, or ambient completeness.

Proof. Project the carrier of Definition 387.1. The only rows available to a precision request are X, Y, μ, W, T, R, P, and N, and the induction measure is the finite displayed window ledger W.

For the empty list of requests, inspect the rows μ, W, T, R, P, and N. No endpoint comparison or real-facing seal is exported, so the base case is only a finite carrier read.

For the step case, consume one displayed window from W and leave the remaining requests to the induction hypothesis. Apply Definition 387.4 to keep the request past the same threshold μ, and use Definition 387.13 to keep every endpoint read attached to the same ledger T.

Now apply Definition 387.5. The $\mathsf{Real}^{\uparrow}$ seal produced at the step is replayed through the displayed common-tail route, and the remaining finite requests inherit the same rows by the induction hypothesis.

Finally use Definition 387.7. The carrier has no coordinate for quotient streams, host real equality, selected limits, choice, or ambient completeness, so the induction never leaves the finite $\mathsf{StreamName}^{\uparrow}$ window surface. □

Theorem 387.10 (CauchyTailComparison RealUp seal stability)**.** *Let* $Q = (X, Y, \mu, W, T, R, P, N)$ *and* $Q' = (X', Y', \mu', W', T', R', P', N')$ *be accepted* $\mathsf{CauchyTailComparison}^{\uparrow}$ *carriers. If* CauchyTailComparisonClassif *holds, then every* $\mathsf{Real}^{\uparrow}$ *seal-facing read exported by* R *transports to the corresponding read exported by* R' *through the displayed* hsame *and* Cont *rows on* X*,* Y*,* μ*,* W*,* T*,* P*, and* N*.*

Thus the $\mathsf{Real}^{\uparrow}$ *comparison seal is stable under the displayed tail comparison. It cannot be strengthened into host real equality, quotient-stream equality, or a selected completed limit.*

Proof. Unfold the classifier of Definition 387.2. It transports the two regular-name rows, the common modulus, the stream window, the dyadic endpoint ledger, the readback row, package provenance, and local name row.

Use the real-completion handoff of Definition 387.5. A $\mathsf{Real}^{\uparrow}$ seal-facing read can only pass through X, Y, μ, W, T, R, P, and N.

Transport each of these rows along the displayed classifier data. The target read is exactly the readback row R' in the target packet, and the non-escape boundary of Definition 387.7 prevents any host equality or selected limit from entering the seal. □

Lean4 ✓ `BEDC.Derived.CauchyTailComparisonUp.CauchyTailComparisonCarrier real seal stability`

Theorem 387.11 (CauchyTailComparison NameCert obligation package)**.** *The* $\mathsf{NameCert}_{\mathsf{CauchyTailComparison}^{\uparrow}}$ *obligation package is the five-row package consisting of:*

1. *the carrier row of Definition 387.1;*
2. *the classifier row of Definition 387.2;*
3. *the tail-window stability, common-window transitivity, and common-window refinement rows of Definition 387.4, Definition 387.6, and Definition 387.8;*
4. *the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal-stability rows of Definition 387.5 and Definition 387.10;*
5. *the non-escape boundary of Definition 387.7.*

Every consumer of this package receives only the finite rows X*,* Y*,* μ*,* W*,* T*,* R*,* P*, and* N*, together with their displayed* hsame *and* Cont *routes.*

Proof. The carrier and classifier rows give the finite packet and its visible transport relation. These rows fix the only data a consumer may inspect.

The tail-window rows identify the common modulus and stream-window ledger used by both compared regular-name reads. The common refinement theorem repacks the same information for paired $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers.

The handoff and seal-stability rows route comparison evidence into the real-completion-facing interface. The non-escape boundary then states that the package exports no quotient stream, selected limit, host real equality, or ambient completeness object. □

Theorem 387.12 (CauchyTailComparison classifier transport)**.** *Let* $Q = (X, Y, \mu, W, T, R, P, N)$ *and* $Q' = (X', Y', \mu', W', T', R', P', N')$ *be accepted* $\mathsf{CauchyTailComparison}^{\uparrow}$ *carriers. If* $\mathsf{CauchyTailComparisonClassif}$ *holds, then classifier transport preserves exactly the two regular-name rows* X, Y*, the unary modulus* μ*, the common window* W*, the dyadic endpoint ledger* T*, the readback row* R*, package provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{CauchyTailComparison}^{\uparrow}}$ *row* N*.*

Proof. Project the carrier rows by Definition 387.1. The displayed tuple has exactly the rows X, Y, μ, W, T, R, P, N.

Apply the classifier definition of Definition 387.2. Its comparison is componentwise by displayed hsame transport and displayed Cont read routes for the same rows.

Use Definition 387.4 and Definition 387.5 to identify the consumer-facing uses of the transported rows. The classifier therefore moves the finite common-tail packet and nothing outside it. □

Theorem 387.13 (CauchyTailComparison dyadic endpoint exactness)**.** *Every endpoint comparison exported by an accepted* $\mathsf{CauchyTailComparison}^{\uparrow}$ *packet is read from the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* T *after the common threshold* μ *and common window* W *have been selected. The comparison cannot replace* T *by an unrecorded dyadic ledger, quotient-stream equality, selected limit, or host real comparison.*

Proof. Start with the carrier tuple of Definition 387.1. The only endpoint-comparison coordinate is T, and it is reached after the modulus row μ and common window W.

Apply Definition 387.4. Any precision read of the two regular names passes through the same threshold and same finite window.

Then use Definition 387.8. The common refinement keeps the endpoint rows attached to the displayed dyadic ledger, so an endpoint comparison has no route to an unrecorded ledger or host-level comparison. □

Theorem 387.14 (CauchyTailComparison scoped export)**.** *The scoped consumer surface of* $\mathsf{CauchyTailComparison}^{\uparrow}$ *is the finite package consisting of tail-window stability, dyadic endpoint exactness,* $\mathsf{Real}^{\uparrow}$ *seal stability, and the non-escape boundary over the displayed rows* X, Y, μ, W, T, R, P, N*. Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the package receives that surface and no quotient stream, selected limit, host real equality, or ambient completeness object.*

Proof. First use Definition 387.4. It fixes the common threshold and window through which both regular-name rows are read.

Next apply Definition 387.13. The endpoint comparisons are exactly the dyadic rows in T after that common tail window.

Use Definition 387.10 for the real-facing boundary. Seal reads transport only along the displayed rows, and Definition 387.7 excludes quotient streams, selected limits, host equality, and ambient completeness from the export. □

Theorem 387.15 (CauchyTailComparison window-composition seal exhaustion)**.** *Let*

$$Q_{XY} = (X, Y, \mu_{XY}, W_{XY}, T_{XY}, R_{XY}, P_{XY}, N_{XY})$$

and

$$Q_{YZ} = (Y, Z, \mu_{YZ}, W_{YZ}, T_{YZ}, R_{YZ}, P_{YZ}, N_{YZ})$$

be accepted $\mathsf{CauchyTailComparison}^{\uparrow}$ *packets composed along the shared regular-name row* Y*. Suppose their common-window ledgers are related by a displayed* Cont *route that composes the inspected windows and endpoint ledgers into rows*

$$\mu, W, T, R, P, N$$

for the comparison from X *to* Z*.*

Then every resulting $\mathsf{Real}^{\uparrow}$ *seal read factors through the composed rows* X*,* Z*,* μ*,* W*,* T*,* R*,* P*, and* N*. No quotient stream, host real equality, selected limit, or ambient completeness coordinate appears in the composed seal surface.*

Lean4 ✓ `BEDC.Derived.CauchyTailComparisonUp.CauchyTailComparisonCarrier window composition seal exhaustion`

Proof. Project the two accepted carriers. The first packet exposes only X, Y, μ_{XY}, W_{XY}, T_{XY}, R_{XY}, P_{XY}, and N_{XY}; the second exposes only Y, Z, μ_{YZ}, W_{YZ}, T_{YZ}, R_{YZ}, P_{YZ}, and N_{YZ}.

Apply Definition 387.4 to both packets. Each accepted precision read passes through its displayed threshold and finite common window, so the shared row Y is read through visible late-window data on both sides.

Use Definition 387.8 with the displayed Cont route. The common-window refinement supplies the composed rows μ, W, T, and R for the X to Z comparison without introducing a second threshold or an unrecorded endpoint ledger.

Now apply Definition 387.5 and Definition 387.10. The $\mathsf{Real}^{\uparrow}$ seal read is routed through the composed regular-name endpoints, common window, dyadic endpoint ledger, readback row, package provenance, and local naming row.

Finally use Definition 387.7. The composed carrier inventory has no coordinate for quotient streams, host real equality, selected limits, or ambient completeness, so the seal read is exhausted by X, Z, μ, W, T, R, P, and N. □

Theorem 387.16 (CauchyTailComparison standard bridge source)**.** *For an accepted* $\mathsf{CauchyTailComparison}^{\uparrow}$ *packet, the bridge-facing source for the standard regular-Cauchy completion interface is exactly the pair of* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name rows, the unary modulus row, the common finite* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger, the tail-comparison readback row, the displayed* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CauchyTailComparison}^{\uparrow}}$ *row. Every standard completion-interface read factors through Definition 387.15 and the public export of Definition 387.14, with no quotient stream, host real equality, selected limit, or ambient completeness coordinate.*

Proof. Project the accepted carrier first. Its visible rows are the two regular names, the unary modulus, the finite common window, the dyadic endpoint ledger, the readback row, package provenance, and the local naming row.

Apply Definition 387.15. It shows that composed completion reads are exhausted by the displayed common-window and endpoint rows, so the standard interface cannot substitute an unrecorded stream equality or second endpoint ledger.

Next use Definition 387.5. The handoff is the public regular-Cauchy completion route generated from the same carrier rows, and Definition 387.10 keeps the real-facing seal attached to that route.

Finally apply Definition 387.7. The carrier has no field for quotient streams, host real equality, selected limits, or ambient completeness, so every standard completion-interface read remains a read of the displayed bridge source. □

Lean4 ✓ `BEDC.Derived.CauchyTailComparisonUp.CauchyTailComparisonCarrier standard bridge source`

Theorem 387.17 (CauchyTailComparison completion-classifier equivalence)**.** *Let*

$$Q = (X, Y, \mu, W, T, R, P, N)$$

and

$$Q' = (X', Y', \mu', W', T', R', P', N')$$

be accepted $\mathsf{CauchyTailComparison}^{\uparrow}$ *packets. The completion-facing* $\mathsf{Real}^{\uparrow}$ *classifier reads exported by* Q *and* Q' *determine the same finite BEDC route exactly when the following displayed rows agree componentwise: the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name rows, the common modulus rows, the finite* $\mathsf{StreamName}^{\uparrow}$ *common-window rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledgers, the tail-comparison readback rows, the* Pkg *provenance rows, and the local* $\mathsf{NameCert}_{\mathsf{CauchyTailComparison}^{\uparrow}}$ *rows.*

Equivalently, equality of the completion-facing classifier route is neither coarser nor finer than agreement of

$$(X, Y, \mu, W, T, R, P, N) \quad \textit{and} \quad (X', Y', \mu', W', T', R', P', N')$$

on those displayed coordinates. The equivalence introduces no quotient stream, selected host limit, host real equality, choice row, or ambient completeness datum.

Proof. For the forward direction, project the common $\mathsf{Real}^{\uparrow}$ classifier read through Definition 387.5. The handoff exposes the completion-facing read only through the two regular-name rows, the modulus row, the common finite window, the dyadic endpoint ledger, the readback row, package provenance, and the local naming row.

Apply Definition 387.16. The standard bridge source identifies those exposed rows as the entire finite source of a regular-Cauchy completion-interface read, so equality of the classifier route projects back to componentwise agreement of the displayed packet coordinates.

For the reverse direction, assume componentwise agreement of the displayed rows. Transport the classifier along the agreed Pkg provenance and local $\mathsf{NameCert}_{\mathsf{CauchyTailComparison}^{\uparrow}}$ rows, then use Definition 387.13 to keep the endpoint ledger exact.

Use Definition 387.4 and Definition 387.6 to keep every late precision read inside the common finite window. Then apply Definition 387.15; the transported rows rebuild the same completion-facing $\mathsf{Real}^{\uparrow}$ classifier route and leave no remaining coordinate to vary.

Finally apply Definition 387.7. Since neither packet carries a quotient stream, selected host limit, host real equality, choice row, or ambient completeness datum, the equivalence is exhausted by the displayed finite BEDC rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailComparison}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ regular-name rows, an explicit unary modulus, a common finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint comparisons, tail-comparison readback rows, $\mathsf{Real}^{\uparrow}$ classifier-facing handoff data, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailComparison}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 387.15 and Definition 387.16 bind the mature completion-interface consumer surface to the public common-tail comparison export over the displayed finite rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailComparison}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CauchyTailComparisonUp.CauchyTailComparisonCarrier\_standard\_bridge\_source`

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient equality of regular streams, uniqueness of limits, host real construction, ambient completeness, or bridge checking.

Upgrade path: No further paper-axis theory upgrade remains; formalization and bridge checking remain over the same displayed rows.

This hub is the finite handoff from chapter 129 and chapter 130 into the $\mathsf{CompactUniformContinuity}^{\uparrow}$ packet: $\mathsf{CompactMetric}^{\uparrow}$ supplies finite ProbeBundle net rows, while $\mathsf{ContinuousMap}^{\uparrow}$ supplies pointwise modulus rows.

Chapter 388

A Concrete Naming Certificate for $\mathsf{CompactUniformContinuity}^{\uparrow}$

The $\mathsf{CompactUniformContinuity}^{\uparrow}$ interface names the concrete certificate layer that realizes Definition 9237.6 as finite BEDC data. It sits over the same source metric as the compact and continuous-map packets: compactness contributes finite ProbeBundle nets from $\mathsf{CompactMetric}^{\uparrow}$, continuity contributes pointwise modulus rows from $\mathsf{ContinuousMap}^{\uparrow}$, the source and target metrics contribute MetricDistanceWitness rows, and the final precision is selected by positive-radius folds through $\mathsf{Rat}^{\uparrow}$. The packet exports a NameCert surface for the compact-uniform-continuity handoff; it does not expose an open-cover principle, sequential compactness, a host modulus function, or a selected real-valued minimum.

This packet is a downstream consumer of chapter 129 for finite ProbeBundle nets and of chapter 130 for pointwise modulus rows. The carrier below records those sibling dependencies as visible compact-net and continuity-ledger coordinates rather than as ambient analytic principles.

Definition 388.1 (CompactUniformContinuity carrier)**.** *A* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (X, Y, F, E, D, \mathcal{P}, C, M, R, W, T, Q, P, N)$$

with the following visible coordinates:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row whose distance reads are witnessed by* MetricDistanceWitness*;*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row whose distance reads are witnessed by* MetricDistanceWitness*;*
3. *F is the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row from X to Y;*
4. *E is a positive* $\mathsf{Rat}^{\uparrow}$ *tolerance history requested by the target metric consumer;*
5. *D is the positive* $\mathsf{Rat}^{\uparrow}$ *precision history proposed as the compact-uniform output;*
6. *$\mathcal{P}$ is the nonempty finite* ProbeBundle *net supplied by the* $\mathsf{CompactMetric}^{\uparrow}$ *packet over X;*
7. *C records the compact finite-net coverage rows, including center histories and half-radius coverage witnesses for every source-point history;*
8. *M records the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise modulus rows at the bundled centers, each read through the graph row F and the source and target metric ledgers;*
9. *R records the positive-radius* $\mathsf{Rat}^{\uparrow}$ *rows and comparison rows used by the fold, including the half-radius histories consumed by the finite cover;*

10. *W is the finite lower-bound fold witness proving that D is classifier-stably below every bundled half-radius row;*
11. *T records the componentwise* hsame *rows for source metrics, target metrics, graph rows, tolerance rows, precision rows, finite-net rows, pointwise-modulus rows, radius rows, and fold rows;*
12. *Q records the displayed* Cont *routes by which compact, continuous-map, metric, rational-fold, and compact-uniform-continuity consumers read the packet;*
13. *P is the* Pkg *provenance row over* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, *and the closed* ProbeBundle *spine;*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *row.*

The carrier contains only the displayed finite-net, pointwise-modulus, metric-distance, positive-rational, transport, continuation, package, and naming rows. It contains no hidden point selector, no quotient of source histories, no ambient minimum operator, and no analytic compactness theorem beyond the finite packet.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket carrier bhist rows`

Definition 388.2 (CompactUniformContinuity classifier)**.** *For accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *carriers H and H', the classifier* $\mathsf{CompactUniformContinuityClassifier}(H, H')$ *compares exactly the visible rows of Definition 388.1. Source and target metric rows compare through their displayed* hsame *and* Cont *routes; compact finite-net rows compare through the same* ProbeBundle *spine and coverage witnesses; continuous-map rows compare through the pointwise modulus ledger; positive tolerance, precision, radius, and fold rows compare through the* $\mathsf{Rat}^{\uparrow}$ *classifier; and the package and local naming rows compare through their displayed* Pkg *and* NameCert *provenance.*

The classifier does not compare external functions, open covers, sequences, host real endpoints, selected minima, or unrecorded continuity data.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket classifier symmetric`

Theorem 388.3 (CompactUniformContinuity NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *obligation surface consists of carrier habitation, displayed classifier transport, compact finite-net coverage over* $\mathsf{CompactMetric}^{\uparrow}$ *and* ProbeBundle*, continuous pointwise-modulus handoff over* $\mathsf{ContinuousMap}^{\uparrow}$*, metric-distance routing through* MetricDistanceWitness*, positive-radius lower-bound folding over* $\mathsf{Rat}^{\uparrow}$*, and downstream non-escape through the recorded* hsame*,* Cont*,* Pkg*, and local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket namecert obligations`

Proof. Carrier habitation is the finite packet of Definition 388.1. Every row named by the compact-uniform certificate has a visible coordinate before any consumer can read it.

Classifier transport is componentwise by Definition 388.2. The compact rows transport finite-net coverage, the continuous rows transport pointwise modulus data, the metric rows transport distance witnesses, and the rational rows transport positive-radius comparisons and the lower-bound fold.

The obligation surface is therefore exactly the displayed handoff from compact finite nets and pointwise continuity to a uniform precision history. Repacking those rows with T, Q, P, and N gives the local $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ surface, while external selectors, sequence principles, open-cover compactness, and hidden minima remain outside the carrier. □

Theorem 388.4 (CompactUniformContinuity root uniform-modulus row)**.** *Every accepted* CompactUniformContinu *packet routes the requested tolerance row through the displayed* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, MetricDistanceWitness, *positive* Rat$^{\uparrow}$ *radius rows,* hsame, Cont, Pkg, *and local* NameCert *coordinates before exporting a uniform precision. The exported precision is therefore the visible uniform-modulus row of the packet, not a host modulus function or a selected real minimum.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root uniform modulus row`

Proof. Project the accepted packet through the carrier of Definition 388.1. The requested tolerance row is the displayed E coordinate, and the proposed uniform precision is the displayed D coordinate.

Apply Definition 388.3. It identifies the local route through compact finite-net coverage, pointwise ContinuousMap$^{\uparrow}$ modulus rows, metric-distance witnesses, positive Rat$^{\uparrow}$ comparisons, and the recorded transport, continuation, package, and naming rows.

The classifier of Definition 388.2 preserves exactly those coordinates. Thus a downstream consumer sees a uniform precision only after the finite route has passed through the named BEDC packet surface. □

Theorem 388.5 (CompactUniformContinuity root compact-net row)**.** *For every accepted* CompactUniformContinui *packet, the finite* ProbeBundle *net and its center-radius ledger are the only compactness data consumed by the compact-uniform-continuity handoff. No open-cover principle, sequential compactness principle, hidden point selector, or ambient compactness oracle is available to the handoff.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root compact net row`

Proof. Project the packet by Definition 388.1. The compactness coordinates are the finite ProbeBundle spine $\mathcal{P}$ and the coverage ledger C, with the related radius rows read through R and W.

Apply Definition 388.13. Every handoff read first chooses a bundled center and then follows the displayed center-radius and metric-distance rows.

Finally use Definition 388.14 to identify the precision consumed by the handoff with the finite positive-rational fold. Since the carrier has no coordinate for any other compactness witness, the finite net and center-radius ledger exhaust the compact data surface. □

Theorem 388.6 (CompactUniformContinuity root NameCert unblock package)**.** *The* CompactUniformContinuity$^{\uparrow}$ *root package consists of the following five rows:*

1. *the carrier and classifier rows of Definition 388.1 and Definition 388.2;*
2. *the finite-net row of Definition 388.5;*
3. *the uniform-modulus row of Definition 388.4;*
4. *the metric-distance routing and rational-fold rows recorded by Definition 388.3 and Definition 388.14;*
5. *the non-escape ledger and downstream package surface that feed Definition 388.13.*

These five rows are sufficient for a downstream consumer to use the compact-uniform-continuity certificate as a finite $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *package.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root namecert unblock package`

Proof. The first row is obtained by projecting the displayed packet carrier and its componentwise classifier. This gives the full finite coordinate list and the allowed transport rules.

The second row is Definition 388.5. It isolates the finite ProbeBundle and center-radius ledger as the compactness surface.

The third row is Definition 388.4. It identifies the route from a requested tolerance history to the exported uniform precision.

The fourth row is the metric and rational bookkeeping recorded by Definition 388.3 and sharpened by Definition 388.14. Those statements keep metric-distance witnesses and positive-rational folds inside the carrier.

The final row is obtained by feeding the preceding rows into Definition 388.13. The handoff exports exactly the downstream package surface and leaves no coordinate for external compactness, selected minima, or host metric inspection. □

Theorem 388.7 (CompactUniformContinuity source metric totality)**.** *In every accepted* CompactUniformContinuity *root packet, each source-center distance read used by the finite-net handoff factors through the source* $\mathsf{Met}^{\uparrow}$ *coordinate* X*, a displayed* MetricDistanceWitness *row, and the transport, continuation, package, and naming provenance* T, Q, P, N *before any pointwise modulus row is consumed. Thus the handoff has no route from a source point to a* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row except through the recorded source metric surface of the carrier.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket source metric totality`

Proof. Project the root packet by Definition 388.1. The source metric row X, the compact finite-net ledger $\mathcal{P}, C$, the pointwise-modulus ledger M, and the provenance rows T, Q, P, N are all visible coordinates before any consumer can read a source-center distance.

Use the classifier of Definition 388.2. It permits source metric transport only through the displayed hsame rows, the Cont routes, the package row, and the local naming row.

Now apply Definition 388.5 and Definition 388.6. The finite-net row chooses bundled centers only inside the carrier, and the root package lists the metric-distance route as part of the same NameCert surface. Therefore each accepted source-center read reaches M only after passing through X, MetricDistanceWitness, and T, Q, P, N. □

Theorem 388.8 (CompactUniformContinuity target metric totality)**.** *In every accepted* CompactUniformContinuity *root packet, each target-output tolerance read factors through the target* $\mathsf{Met}^{\uparrow}$ *coordinate* Y*, a displayed* MetricDistanceWitness *row, the centerwise* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus ledger* M*, and the same* T, Q, P, N *provenance that already controls source-center metric reads. No target tolerance row is available directly from a host metric outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket target metric totality`

Proof. Begin with the target tolerance route isolated by Definition 388.4. It sends the requested tolerance through compact finite-net coverage, centerwise $\mathsf{ContinuousMap}^{\uparrow}$ rows, target metric evidence, positive $\mathsf{Rat}^{\uparrow}$ comparisons, and the recorded transport, continuation, package, and naming rows.

Apply Definition 388.7. The source side of each centerwise modulus read has already been forced through X, MetricDistanceWitness, and T, Q, P, N before M is consumed.

The target side of the same centerwise row is the displayed $\mathsf{Met}^{\uparrow}$ coordinate Y. The classifier transports it only through the target MetricDistanceWitness row and the same T, Q, P, N provenance, so a target-output tolerance read cannot bypass the finite packet surface. □

Theorem 388.9 (CompactUniformContinuity fold witness stability)**.** *In every accepted* CompactUniformContinuity *root packet, the fold witness W transports the positive* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold below each bundled half-radius row under the classifier, and W is the only route by which the precision row D is accepted as a common lower bound for the finite handoff. The classifier therefore preserves the fold surface without introducing a host minimum, a selected real radius, or an unrecorded precision source.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket fold witness stability`

Proof. Project the rational ledger R, the fold witness W, and the precision row D from the carrier. By Definition 388.14, D is accepted exactly as the finite lower-bound fold over the positive $\mathsf{Rat}^{\uparrow}$ rows, with a displayed comparison below each bundled half-radius row.

Use Definition 388.11. It identifies R and W as the only rational route from the root package to the precision row D.

Finally apply Definition 388.8. The target-output reads that consume D already pass through Y, the centerwise modulus row M, and T, Q, P, N. Transporting W under the classifier therefore preserves the same positive $\mathsf{Rat}^{\uparrow}$ fold for every downstream target read, with no additional coordinate from which another lower bound could be read. □

Theorem 388.10 (CompactUniformContinuity root metric route)**.** *In every accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *root packet, each source-center distance read and each target-output distance read factors through displayed* MetricDistanceWitness *rows, the transported* hsame *rows, the* Cont *handoff rows, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *row. No distance used by the root package is read directly from a host metric outside those coordinates.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root metric route`

Proof. Project the packet through the carrier of Definition 388.1. The source and target metric coordinates are visible before the compact rows, continuous rows, rational rows, package provenance, and local naming row are consumed.

Apply the classifier of Definition 388.2. It transports source and target metric observations only through the displayed hsame rows and the named MetricDistanceWitness evidence.

Use Definition 388.4 for the route from a requested tolerance to a uniform precision, and use Definition 388.5 for the bundled center chosen from the finite net. The two rows meet at the same Cont, Pkg, and local NameCert surface, so the source-center and target-output reads remain inside the root packet. □

Theorem 388.11 (CompactUniformContinuity root rational fold route)**.** *In every accepted* CompactUniformContin *root packet $H = (X, Y, F, E, D, \mathcal{P}, C, M, R, W, T, Q, P, N)$, the precision row D is read only through the positive* $\mathsf{Rat}^{\uparrow}$ *radius ledger R and the finite lower-bound fold witness W. The root package has no host minimum coordinate and no selected real-radius operation.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root rational fold route`

Proof. Read the finite compact-net row by Definition 388.5. Its centers are the entries of $\mathcal{P}$, and their usable radii are the displayed positive rows in R.

Read the uniform-modulus row by Definition 388.4. The exported precision is the carrier coordinate D, not a host function chosen after the packet is built.

The witness W records the finite lower-bound fold over the positive $\mathsf{Rat}^{\uparrow}$ rows in R. Since the carrier coordinates list R, W, and D but no host minimum or real-radius selector, every precision read in the root package follows that rational fold route. □

Theorem 388.12 (CompactUniformContinuity root non-escape package)**.** *The* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *root package is the five-row package consisting of the carrier/classifier row, the compact-net row, the uniform-modulus row, the metric-route row, and the rational-fold row. This package excludes open covers, sequential compactness, host minima, and external modulus functions from every downstream root read.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root nonescape package`

Proof. The carrier/classifier row is the first row of Definition 388.6. It fixes the visible coordinates and the allowed componentwise transport.

The compact-net row is Definition 388.5, and the uniform-modulus row is Definition 388.4. Together they identify the finite ProbeBundle coverage surface and the exported precision surface.

The metric-route row is Definition 388.10. It keeps source-center and target-output distance reads behind displayed metric witnesses, hsame, Cont, Pkg, and local naming coordinates.

The rational-fold row is Definition 388.11. It keeps the precision row behind positive $\mathsf{Rat}^{\uparrow}$ radius rows and the finite fold witness. These five rows are exactly the root package surface, so there is no coordinate from which a downstream consumer could read an open cover, a sequence compactness principle, a host minimum, or an external modulus function. □

Theorem 388.13 (CompactUniformContinuity finite-net handoff)**.** *Suppose an accepted* CompactUniformContinuit *carrier has tolerance history E, precision history D, compact finite-net spine $\mathcal{P}$, coverage rows C, pointwise-modulus rows M, positive-radius rows R, and lower-bound fold witness W. Then every source-distance read below D factors through one bundled center in $\mathcal{P}$, the corresponding* MetricDistanceWitness *rows in X, the corresponding pointwise-modulus row in M, and the target metric rows in Y. The result is the uniform-modulus ledger promised by Definition 9237.6, read as finite* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *data.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket finite net handoff`

Proof. Read the compact coordinate first. The $\mathsf{CompactMetric}^{\uparrow}$ row supplies the nonempty ProbeBundle, center histories, half-radius histories, and coverage rows saying that each source-point history is covered by some bundled center.

Read the rational fold next. The witness W records a primitive finite fold over the positive-radius rows R, so the selected precision history D compares below every bundled half-radius through the $\mathsf{Rat}^{\uparrow}$ classifier and the transported hsame rows.

Given two source histories whose displayed distance is below D, the coverage row chooses the bundled center for the first history. The fold comparison and the source metric triangle row route the second history into the same local ball, with all distances witnessed by MetricDistanceWitness.

Finally use the $\mathsf{ContinuousMap}^{\uparrow}$ pointwise-modulus row attached to that bundled center and the target metric triangle row. Both source histories are inside the same displayed pointwise ball,

so the two target histories are within the requested tolerance row E. All reads pass through the carrier coordinates, hence the handoff is a $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ row rather than an external Heine–Cantor theorem. □

Theorem 388.14 (CompactUniformContinuity radius-fold exactness)**.** *In every accepted* CompactUniformContinuit *carrier* $H = (X, Y, F, E, D, \mathcal{P}, C, M, R, W, T, Q, P, N)$*, the precision row* D *is accepted by the classifier exactly as the finite lower-bound fold over the positive-radius ledger* R*. Every compact finite-net center in* $\mathcal{P}$ *receives a displayed half-radius comparison below* D*, and classifier transport through* T*,* Q*,* P*, and* N *preserves that fold surface.*

Consequently the uniform precision consumed by the finite-net handoff is the displayed rational fold output, not a hidden point selector, selected real minimum, open-cover compactness principle, sequential compactness principle, or external modulus function.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket radius fold exactness`

Proof. Project the positive-radius ledger R and the fold witness W from the carrier. The witness records a finite $\mathsf{Rat}^{\uparrow}$ lower-bound fold whose output is the displayed precision row D.

For each center in the finite ProbeBundle spine $\mathcal{P}$, the same ledger supplies the positive radius used by the pointwise-modulus row, and W supplies the comparison placing D below the corresponding half-radius history.

The classifier is componentwise on T, routed by Q, and packaged by P and N. Thus transport can carry the $\mathsf{Rat}^{\uparrow}$ comparisons and the fold row across classified carriers, but it cannot introduce a new minimum operation or an unrecorded radius source.

Feeding these transported comparisons into Definition 388.13 gives the same uniform-modulus ledger for every accepted representative. The handoff reads finite rational fold data rather than external compactness or host real selection data. □

Theorem 388.15 (CompactUniformContinuity real-seal boundary)**.** *When the source and target metrics are consumed through* $\mathsf{Real}^{\uparrow}$ *or interval-shaped* $\mathsf{Real}^{\uparrow}$ *packets, an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *carrier can expose only the finite-net coverage rows,* MetricDistanceWitness *rows, pointwise-modulus rows, positive* $\mathsf{Rat}^{\uparrow}$ *fold rows, and the resulting uniform precision history. It cannot expose host real equality, a selected real minimum, sequential compactness, open-cover compactness, or an external modulus function at the real-seal boundary.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket real seal boundary`

Proof. Project the carrier through its metric coordinates X and Y. A real-valued consumer reaches those coordinates only through displayed metric rows and their MetricDistanceWitness evidence.

The compact information available at the boundary is the finite ProbeBundle ledger C. The continuous information available there is the pointwise-modulus ledger M. The positive lower bound available there is the $\mathsf{Rat}^{\uparrow}$ fold row W over the radius ledger R.

Since these rows exhaust the carrier coordinates exposed to real-name consumers, the seal can export only the resulting finite uniform-precision packet. Host real equality, selected minima, sequence arguments, open covers, and external modulus functions have no coordinate from which they could be read. □

Theorem 388.16 (CompactUniformContinuity ProbeBundle coverage)**.** *In every accepted* CompactUniformContinu *carrier* $H = (X, Y, F, E, D, \mathcal{P}, C, M, R, W, T, Q, P, N)$*, every source-point read used by the compact-uniform-continuity handoff factors through the finite* ProbeBundle *spine* $\mathcal{P}$*, one displayed center*

history in C, the associated half-radius coverage row, and the same transported hsame, Cont, Pkg, *and* NameCert *rows that classify H.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket probe bundle coverage`

Proof. Project the carrier by Definition 388.1. The finite net coordinate $\mathcal{P}$ and the coverage ledger C are visible before the continuous-map and rational-fold rows are consumed.

The classifier of Definition 388.2 transports these rows componentwise. Thus a classified replacement of the carrier preserves the same bundled center histories, the same half-radius coverage witnesses, and the same continuation routes by which a source-point read reaches them.

The local obligation statement in Definition 388.3 identifies this coverage as part of the $\mathsf{NameCert}_{\mathsf{CompactUniformCon}}$ surface. Feeding the selected bundled center into Definition 388.13 gives the uniform-precision route, and Definition 388.15 confirms that no open-cover or sequence principle is exported in place of the finite ProbeBundle ledger. □

Theorem 388.17 (CompactUniformContinuity metric-distance routing)**.** *For every accepted* CompactUniformCont *carrier, each source metric read used to enter a bundled center ball and each target metric read used to compare output histories is routed through a displayed* MetricDistanceWitness *row in the source or target metric coordinate. No source or target distance is read directly from a host metric function outside the carrier.*

Proof. The carrier of Definition 388.1 names the source metric row X and target metric row Y as the only metric coordinates. Both are read through displayed MetricDistanceWitness evidence and transported with the componentwise rows T and routes Q.

By Definition 388.2, classified carriers compare metric rows only through those displayed witnesses. Hence a source-distance comparison below D, a half-radius comparison around a bundled center, and a target-distance comparison below E all remain inside the same metric-distance ledgers.

The finite-net route of Definition 388.13 uses exactly these source and target reads, while Definition 388.3 records metric-distance routing as a local naming obligation. The boundary statement in Definition 388.15 then prevents a real-name consumer from replacing those witnesses by host metric access. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket metric distance routing`

Theorem 388.18 (CompactUniformContinuity non-escape ledger)**.** *An accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet exports only the finite* ProbeBundle *coverage rows,* MetricDistanceWitness *rows, pointwise-modulus rows, positive* $\mathsf{Rat}^{\uparrow}$ *fold rows, displayed transports, continuation routes, package provenance, and local naming provenance. It exports no open-cover compactness principle, no sequential compactness principle, no host minimum, and no external modulus function.*

Proof. Inspect the carrier in Definition 388.1. Its coordinates list the compact finite-net data, continuous pointwise-modulus rows, source and target metric witnesses, rational-radius fold data, transports, routes, package row, and local certificate row.

The classifier in Definition 388.2 compares exactly those coordinates. It has no component for open covers, sequences, host minima, or unrecorded modulus functions, so those objects cannot be introduced by classifier transport.

The obligation surface of Definition 388.3 and the handoff of Definition 388.13 use the same finite rows to produce the uniform precision history. Finally, Definition 388.15 states the real-seal boundary for these rows, so the exported packet remains a finite BEDC ledger and not a classical Heine–Cantor artifact. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket non escape ledger`

Theorem 388.19 (CompactUniformContinuity modulus choice surface)**.** *For every accepted* CompactUniformConti *packet, the uniform precision row consumed by the compact-uniform-continuity handoff is determined only by the finite* ProbeBundle *centers, the* ContinuousMap$^{\uparrow}$ *pointwise-modulus rows attached to those centers, the positive* Rat$^{\uparrow}$ *radius ledger, and the finite lower-bound fold witness. It is not determined by an open cover, a sequential compactness argument, a selected real minimum, or a host modulus function.*

Proof. Project the packet through the carrier in Definition 388.1. The only coordinates from which a precision row can be read are the finite ProbeBundle spine, the centerwise modulus ledger, the positive-radius ledger, and the fold witness.

The classifier in Definition 388.2 preserves those rows componentwise. The finite-net handoff of Definition 388.13 and the radius-fold exactness statement of Definition 388.14 then identify the consumed precision row with the displayed lower-bound fold output.

Finally, Definition 388.16, Definition 388.17, and Definition 388.18 rule out any route through unrecorded compactness, host minima, or external modulus selection. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket modulus choice surface`

Theorem 388.20 (CompactUniformContinuity center-radius compatibility)**.** *In every accepted* CompactUniformContinuity$^{\uparrow}$ *carrier, each bundled center in the finite* ProbeBundle *spine has a compatible half-radius row in the positive* Rat$^{\uparrow}$ *ledger. The source metric reads that place histories inside that half-radius ball and the target metric reads that consume the corresponding pointwise modulus are mediated by displayed* MetricDistanceWitness *rows.*

Proof. Read the finite-net coordinate and coverage ledger from Definition 388.1. Each center history appears with the half-radius coverage row supplied by the compact packet and with the positive-radius data recorded in R.

The radius-fold exactness theorem Definition 388.14 supplies the comparison between the displayed precision row and every bundled half-radius. The ProbeBundle coverage theorem Definition 388.16 keeps the same center and half-radius rows under classifier transport.

Metric access is then fixed by Definition 388.17. Source reads into the center ball and target reads from the pointwise-modulus conclusion both pass through MetricDistanceWitness rows, and the non-escape ledger of Definition 388.18 leaves no direct host-metric read outside those witnesses. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket center radius compatibility`

Theorem 388.21 (CompactUniformContinuity uniform precision consumer route)**.** *For an accepted* CompactUniformContinuity$^{\uparrow}$ *packet, any consumer read below the displayed precision factors through compact finite coverage, one bundled center row, the center's* ContinuousMap$^{\uparrow}$ *modulus*

row, source and target MetricDistanceWitness *rows, the transported* hsame *rows, displayed* Cont *routes,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *row. The route contains no open-cover compactness, sequential compactness, selected real minimum, or host modulus.*

Proof. Begin with the carrier and classifier. By Definition 388.1 the consumer can read only the displayed compact, continuous-map, metric, rational, transport, route, package, and naming coordinates, and by Definition 388.2 those coordinates are the complete comparison surface.

The finite-net handoff in Definition 388.13 routes a read below the displayed precision through a covered center. The radius-fold exactness statement Definition 388.14 supplies the half-radius comparison needed to enter the center row, and Definition 388.20 identifies the compatible metric witnesses used there.

At the center, the pointwise-modulus row from $\mathsf{ContinuousMap}^{\uparrow}$ produces the target tolerance read. The ProbeBundle coverage theorem, metric-distance routing theorem, modulus choice surface, and non-escape ledger then show that the whole consumer route is carried by hsame, Cont, Pkg, and local NameCert provenance rather than by open covers, sequences, host minima, or an external modulus. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket uniform precision consumer route`

Theorem 388.22 (CompactUniformContinuity modulus certificate)**.** *For an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet, the uniform-modulus certificate is the finite packet obtained from the compact finite-net rows* $\mathcal{P}$ *and* C*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus rows* M*, the positive* $\mathsf{Rat}^{\uparrow}$ *radius ledger* R*, and the lower-bound fold witness* W*. The certificate records a precision history* D *whose consumer route is mediated by* MetricDistanceWitness *rows and displayed* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *provenance, with no appeal to open covers, selected subcovers, or a host modulus function.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket modulus certificate`

Proof. Project the carrier of Definition 388.1. The compact coordinates provide the finite ProbeBundle spine and coverage rows, while the continuous-map coordinate provides pointwise-modulus rows attached to those bundled centers.

Use the radius-fold exactness theorem Definition 388.14. It identifies D as the positive rational precision produced by folding the displayed radius ledger, and it compares that precision with the center radii read by the pointwise-modulus rows.

The finite-net handoff of Definition 388.13 and the uniform precision consumer route of Definition 388.21 then turn the displayed centerwise data into the requested uniform-modulus certificate. The non-escape ledger excludes any unrecorded compactness or host-level modulus coordinate. □

Theorem 388.23 (CompactUniformContinuity finite-net factorization)**.** *Every consumer read of the finite-net certificate for* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *factors through* $\mathsf{CompactMetric}^{\uparrow}$ *finite cover data,* $\mathsf{Met}^{\uparrow}$ *distance witnesses,* $\mathsf{Rat}^{\uparrow}$ *dyadic or rational precision requests, and* $\mathsf{Real}^{\uparrow}$ *seal reads. The factorization is witnessed inside the displayed carrier rows* $\mathcal{P}$*,* C*,* M*,* R*,* W*,* T*,* Q*,* P*, and* N*.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket finite net factorization`

Proof. Begin with the compact row. By Definition 388.16, every source history admitted to the packet reaches a bundled center through the finite ProbeBundle coverage data supplied by $\mathsf{CompactMetric}^{\uparrow}$.

The metric-distance routing theorem Definition 388.17 supplies the $\mathsf{Met}^{\uparrow}$ witnesses used to compare the source history with the center and to consume the target-side tolerance. The positive-radius ledger and fold exactness theorem route the requested precision through $\mathsf{Rat}^{\uparrow}$ rows before the pointwise-modulus row is read.

At the real-facing boundary, Definition 388.15 restricts every $\mathsf{Real}^{\uparrow}$ seal read to the same finite-net, metric, continuous-map, and rational-fold rows. Transport and continuation data in T and Q, together with package and naming provenance in P and N, carry the factorization without adding open-cover or choice-selected data. □

Theorem 388.24 (CompactUniformContinuity RealUp consumer boundary)**.** *A* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet can read the compact finite-net coverage rows,* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus rows,* $\mathsf{Met}^{\uparrow}$ *distance witnesses,* $\mathsf{Rat}^{\uparrow}$ *precision and radius rows, transported* hsame *rows, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *data. It cannot read open-cover compactness, choice-selected subcovers, host real equality, selected real minima, or an external host modulus.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket realup consumer boundary`

Proof. Read the boundary statement Definition 388.15. It already restricts real-name consumers to finite-net coverage, metric witnesses, pointwise-modulus rows, positive rational folds, and the resulting uniform precision history.

The modulus certificate of Definition 388.22 identifies the uniform precision as a finite carrier row rather than a host-level modulus. The finite-net factorization of Definition 388.23 records how compact, metric, rational, and real-facing reads pass through the displayed packet coordinates.

Finally apply the non-escape ledger Definition 388.18. Since the carrier has no coordinate for open covers, selected subcovers, host real equality, selected minima, or external modulus functions, none of these objects can be exported to a $\mathsf{Real}^{\uparrow}$ consumer. □

Theorem 388.25 (CompactUniformContinuity classifier transport)**.** *Let*

$$H = (X, Y, F, E, D, \mathcal{P}, C, M, R, W, T, Q, P, N)$$

and

$$H' = (X', Y', F', E', D', \mathcal{P}', C', M', R', W', T', Q', P', N')$$

be accepted $\mathsf{CompactUniformContinuity}^{\uparrow}$ *carriers. If the source metric rows, target metric rows, graph rows, tolerance rows, precision rows, finite-net spines, coverage rows, pointwise-modulus rows, radius rows, lower-bound fold rows, continuation routes, package rows, and local* NameCert *rows are transported componentwise by the displayed* hsame, Cont, Pkg, *and* NameCert *evidence in the two packets, then* $\mathsf{CompactUniformContinuityClassifier}(H, H')$ *is preserved. In particular, classifier preservation is a statement about the displayed* BHist *rows of the carrier and not about open covers, selected subcovers, host minima, sequence compactness, or host modulus functions.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket classifier transport`

Proof. Project both packets through Definition 388.1. The carrier lists exactly the metric, graph, tolerance, precision, finite-net, coverage, pointwise-modulus, radius, fold, route, package, and naming rows that may be transported.

Apply the componentwise classifier of Definition 388.2. It compares the rows just projected and has no comparison slot for an open cover, selected subcover, sequence principle, host minimum, or host modulus function.

The local obligation theorem Definition 388.3 identifies these transported rows as the $\mathsf{NameCert}_{\mathsf{CompactUniformConti}}$ surface. The finite-net handoff, radius-fold exactness, uniform-precision consumer route, and $\mathsf{Real}^{\uparrow}$ consumer boundary of Definition 388.13, Definition 388.14, Definition 388.21, and Definition 388.24 show that downstream consumers read only the transported finite rows. Hence the classifier is preserved by the displayed componentwise transport. □

Theorem 388.26 (CompactUniformContinuity precision-route totality)**.** *For an accepted* CompactUniformContinui *carrier*

$$H = (X, Y, F, E, D, \mathcal{P}, C, M, R, W, T, Q, P, N),$$

every accepted read of the precision history D factors through the finite route

$$\mathcal{P}, C, M, R, W, T, Q, P, N$$

before any $\mathsf{Real}^{\uparrow}$ *metric consumer may read it. Thus a real-facing metric consumer reaches the uniform precision only through compact finite-net coverage, pointwise* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus rows, positive* $\mathsf{Rat}^{\uparrow}$ *radius and fold rows, transported* hsame *evidence, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *data.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket precision route totality`

Proof. Start from the carrier of Definition 388.1. The precision row is the displayed coordinate D, while $\mathcal{P}, C, M, R, W, T, Q, P$, and N are the finite rows that govern how D is produced and consumed.

Use Definition 388.14 to identify D with the lower-bound fold over the positive-radius ledger R and witness W. Use Definition 388.13 to route the precision through the finite ProbeBundle spine $\mathcal{P}$, coverage rows C, and pointwise-modulus rows M.

The classifier and local obligation surface of Definition 388.2 and Definition 388.3 keep this route inside the transported hsame, Cont, Pkg, and NameCert rows T, Q, P, N. Finally Definition 388.21 and Definition 388.24 force every real-facing metric read to pass through that route before it can consume D. □

Theorem 388.27 (CompactUniformContinuity NameCert ledger exhaustion)**.** *The local* $\mathsf{NameCert}_{\mathsf{CompactUniformCon}}$ *ledger is exhausted by the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net coverage rows,* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus rows,* MetricDistanceWitness *rows,* $\mathsf{Rat}^{\uparrow}$ *fold rows,* $\mathsf{Real}^{\uparrow}$ *seal reads, the transported* hsame *rows, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *row. It contains no row for open covers, selected subcovers, host minima, sequence compactness, or host modulus functions.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket namecert ledger exhaustion`

Proof. Inspect the carrier and classifier in Definition 388.1 and Definition 388.2. The carrier supplies the finite ledgers, and the classifier confirms that only those ledgers participate in accepted comparison and transport.

The NameCert obligation theorem Definition 388.3 names the same ledgers as the local certificate surface. The finite-net handoff of Definition 388.13 accounts for the compact coverage rows, and the radius-fold exactness theorem Definition 388.14 accounts for the rational fold rows.

It remains to account for downstream reads. The uniform-precision consumer route of Definition 388.21 carries precision reads through the transported hsame, Cont, Pkg, and NameCert rows, while Definition 388.24 accounts for the $\mathsf{Real}^{\uparrow}$ seal boundary. Since every named read is already in these ledgers and the carrier has no additional coordinate, the local NameCert ledger is exhausted by the listed rows. □

Theorem 388.28 (CompactUniformContinuity standard bridge source packet)**.** *For an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *carrier*

$$H = (X, Y, F, E, D, \mathcal{P}, C, M, R, W, T, Q, P, N),$$

the displayed rows assemble the standard bridge source from compact finite-net data and pointwise continuous-map modulus data to a uniform precision history. The source consists exactly of the source and target metric rows X, Y, the graph row F, the requested tolerance E, the precision row D, the finite ProbeBundle *spine $\mathcal{P}$, coverage rows C, pointwise-modulus rows M, positive-radius ledger R, lower-bound fold witness W, transported* hsame *rows T, continuation routes Q, package provenance P, and local naming row N.*

Every bridge source read of the compact-uniform-continuity packet therefore factors through the finite carrier rows already named by Definition 388.1; it does not require a separate open-cover compactness object, sequence principle, selected real minimum, or host modulus.

Proof. Project the accepted carrier H. The metric, graph, tolerance, precision, finite-net, coverage, modulus, radius, fold, transport, continuation, package, and naming coordinates are all displayed before any bridge consumer is allowed to read the packet.

The compact part of the source is repacked from $\mathcal{P}$ and C, using Definition 388.16 to identify the bundled centers and coverage witnesses. The continuous part is repacked from F and M, and Definition 388.20 aligns those modulus rows with the radius ledger read through R and W.

The metric reads are then routed through X and Y by Definition 388.17. The output precision is the same row D consumed by Definition 388.21, so the bridge source is assembled by projection and repacking of displayed BHist rows. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket bridge source packet`

Theorem 388.29 (CompactUniformContinuity bridge non-escape boundary)**.** *A standard bridge consumer of an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet can read only the finite* ProbeBundle *coverage rows,* MetricDistanceWitness *rows,* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus rows,* $\mathsf{Rat}^{\uparrow}$ *fold ledger, and the displayed* hsame, Cont, Pkg, *and* NameCert *provenance. It cannot read open-cover compactness, a sequence principle, a selected real minimum, or a host modulus.*

Proof. Start with the bridge source packet of Definition 388.28. Its coordinates are exactly the rows of the accepted carrier, so a bridge consumer first reaches the finite-net, metric, pointwise-modulus, rational-fold, transport, continuation, package, and naming ledgers.

The non-escape ledger of Definition 388.18 rules out any additional compactness or modulus coordinate in the packet. The real-seal boundary of Definition 388.15 gives the same exclusion for real-name consumers, and Definition 388.19 identifies the displayed finite fold as the only source of the uniform precision.

Thus every bridge read remains inside the finite carrier surface. Since the carrier has no coordinate for open covers, sequences, selected minima, or host modulus functions, none of those objects can be projected, transported, or repacked by the bridge consumer. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket bridge non escape boundary`

Theorem 388.30 (CompactUniformContinuity standard bridge obligation package)**.** *The bridge source packet of Definition 388.28, the non-escape boundary of Definition 388.29, the finite-net handoff of Definition 388.13, the radius-fold exactness theorem Definition 388.14, the* ProbeBundle *coverage theorem Definition 388.16, the metric-distance routing theorem Definition 388.17, and the uniform-precision consumer route of Definition 388.21 assemble the standard bridge obligation package for* $\mathsf{CompactUniformContinuity}^{\uparrow}$*.*

The assembled package exports a finite BEDC bridge-facing route from compact finite-net coverage and pointwise continuity rows to the uniform precision history, while preserving the stated boundary against open covers, sequences, selected real minima, and host modulus functions.

Proof. First build the source packet. Use Definition 388.28 to project the carrier coordinates and repack them as the bridge-facing source over the finite BHist rows.

Next assemble the compact and metric routes. The finite-net handoff supplies the center route, radius-fold exactness supplies the lower-bound comparison, ProbeBundle coverage supplies the finite coverage spine, and metric-distance routing supplies the source and target distance witnesses.

The uniform-precision consumer route then consumes these rows to produce the requested precision history. The bridge non-escape boundary keeps the resulting package inside the finite carrier, transport, continuation, package, and naming provenance.

All components are therefore obtained by constructive projection from the displayed carrier and by repacking through previously named paper rows. No step adds an external compactness principle, a selected minimum, a sequence argument, or a host modulus. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket standard bridge obligation package`

Theorem 388.31 (CompactUniformContinuity finite-net modulus extraction)**.** *For an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *carrier*

$$H = (X, Y, F, E, D, \mathcal{P}, C, M, R, W, T, Q, P, N),$$

the finite uniform precision row D *is extracted from the* $\mathsf{CompactMetric}^{\uparrow}$ ProbeBundle *coverage rows* $\mathcal{P}, C$*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *centerwise modulus rows* M*, and the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold rows* R, W*. The extraction is stable under the displayed* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *rows, and it exports no open-cover subcover, sequence argument, selected real minimum, or host modulus.*

Proof. Project the compact rows first. The finite-net handoff of Definition 388.13 and the ProbeBundle coverage theorem Definition 388.16 identify the bundled centers and the half-radius coverage witnesses read from $\mathcal{P}$ and C.

Next extract the radius information. The radius-fold exactness theorem Definition 388.14 identifies D as the finite $\mathsf{Rat}^{\uparrow}$ lower-bound fold over R, W, so each centerwise modulus row in M receives a compatible precision comparison.

Finally apply the metric-distance routing theorem Definition 388.17 and the uniform-precision consumer route Definition 388.21. These routes consume only displayed metric witnesses, transports, continuations, package provenance, and local naming provenance, so the extracted modulus remains a finite BEDC row. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket finite net modulus extraction`

Theorem 388.32 (CompactUniformContinuity bridge modulus assembly)**.** *The standard compact-metric uniform-continuity certificate for an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet is assembled over* MetricDistanceWitness*,* ProbeBundle*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Its bridge-facing source is the tuple of carrier rows* $X, Y, F, E, D, \mathcal{P}, C, M, R, W, T, Q, P, N$*, and its modulus conclusion is the finite precision row* D *extracted by Definition 388.31.*

Proof. Build the source from Definition 388.28. The metric coordinates X, Y, the graph coordinate F, the finite net $\mathcal{P}, C$, the pointwise modulus rows M, and the rational fold rows R, W are all visible before the bridge-facing certificate is read.

Use Definition 388.31 to obtain the finite precision row. Then route source and target distance reads through Definition 388.17 and consume the result through Definition 388.21.

The assembly is completed by the standard bridge obligation package of Definition 388.30. The displayed $\mathsf{Real}^{\uparrow}$ boundary is inherited from the real-seal rows already present in the carrier surface, so the certificate is a repacking of finite BEDC rows rather than a theorem about ambient compact metric spaces. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket bridge modulus assembly`

Theorem 388.33 (CompactUniformContinuity real metric seal non-escape)**.** *A* $\mathsf{Real}^{\uparrow}$ *metric consumer of the bridge modulus assembly in Definition 388.32 cannot replace the finite route by open-cover compactness, sequential compactness, host minima, or an external modulus. Every real-facing metric read remains routed through* MetricDistanceWitness *rows, the finite* ProbeBundle *coverage ledger, the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise modulus rows, the* $\mathsf{Rat}^{\uparrow}$ *fold, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

Proof. Start from the bridge non-escape boundary Definition 388.29. It restricts a bridge consumer to the finite-net, metric, continuous-map, rational-fold, transport, continuation, package, and naming rows of the accepted carrier.

For real-facing metric reads, apply Definition 388.24 and Definition 388.17. These theorems keep source and target distance observations behind displayed MetricDistanceWitness evidence and prevent direct host metric access.

The finite precision row is the one assembled in Definition 388.32. Since that assembly depends on the finite-net extraction of Definition 388.31, a real metric consumer has no coordinate from which to read open covers, sequences, minima, or an external modulus. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket real metric seal nonescape`

Theorem 388.34 (CompactUniformContinuity constant-map example)**.** *A constant-map* CompactUniformContinui *consumer is represented by a finite BEDC packet whose carrier rows have one displayed target center, one centerwise* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row, a trivial* MetricDistanceWitness *target-distance row, the inherited* ProbeBundle *coverage ledger on the source, the* $\mathsf{Rat}^{\uparrow}$ *fold row selecting the displayed precision history, and the same* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *provenance. Its uniform modulus conclusion is read from that single centerwise row through Definition 388.32.*

Proof. Project the constant-map carrier. The target metric read is attached to one displayed target center, while the source side keeps the same finite ProbeBundle coverage rows and package provenance as the ambient compact carrier.

Apply Definition 388.31. The radius fold has only the displayed centerwise modulus row to consume, so the extracted precision row is a finite BEDC row rather than a selected host modulus.

Finally route the packet through Definition 388.32 and Definition 388.33. The constant-map consumer reads the standard bridge packet without invoking open covers, sequences, selected minima, or external compactness. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket constant map consumer route`

Theorem 388.35 (CompactUniformContinuity finite-net composition example)**.** *Given two finite BEDC consumer packets whose compact finite-net rows, pointwise* ContinuousMap$^{\uparrow}$ *modulus rows,* MetricDistanceWitness *rows,* Rat$^{\uparrow}$ *fold rows,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance compose along a displayed intermediate metric row, their composition repacks those rows through Definition 388.32. The resulting consumer is again a finite-net compact-uniform-continuity packet, and its bridge modulus is obtained from the composed finite rows rather than from an open-cover subcover, sequence argument, selected real minimum, or host modulus.*

Proof. First compose the visible finite-net data. The intermediate metric row is read only through displayed MetricDistanceWitness evidence, and the source coverage rows remain the finite ProbeBundle rows of the first packet.

Next repack the pointwise modulus rows. Use Definition 388.31 for each packet and transport the resulting rational precision rows along the displayed hsame and Cont routes.

Apply Definition 388.32 to the composed rows. The bridge packet consumes the composed finite-net, pointwise-modulus, metric-distance, rational-fold, package, and naming data as its entire source.

Finally use Definition 388.33. Since the composed carrier has no open-cover, sequence, selected-minimum, or external-modulus coordinate, the composed consumer remains a finite BEDC packet. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket finite net composition route`

Theorem 388.36 (CompactUniformContinuity real-interval consumer example)**.** *A real-interval compact-uniform-continuity consumer is represented by a finite BEDC packet routing* Real$^{\uparrow}$ *metric reads through* MetricDistanceWitness *rows,* ProbeBundle *coverage,* ContinuousMap$^{\uparrow}$ *pointwise rows,* Rat$^{\uparrow}$ *fold rows,* hsame*,* Cont*,* Pkg*, and* NameCert$_{\text{CompactUniformContinuity}^{\uparrow}}$*. Its interval endpoint reads consume the bridge modulus assembly and the real metric seal boundary, so the consumer obtains a public real-interval modulus without open-cover compactness, sequential compactness, host real equality, selected minima, or ambient completeness.*

Proof. Start with the interval endpoint reads as Real$^{\uparrow}$ metric reads. By Definition 388.17, those reads must pass through displayed MetricDistanceWitness rows rather than through a host metric.

Apply Definition 388.16 and Definition 388.31. The interval consumer receives finite coverage rows, pointwise ContinuousMap$^{\uparrow}$ modulus rows, and the Rat$^{\uparrow}$ fold row that supplies the uniform precision history.

Now use Definition 388.32. The real-interval consumer reads the assembled bridge packet through the displayed hsame, Cont, Pkg, and NameCert rows.

Finally apply Definition 388.33. The consumer has no route to open-cover compactness, sequential compactness, host equality, selected real minima, or ambient completeness, so the example is a finite BEDC consumer packet over the existing carrier rows. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket real interval consumer route`

Theorem 388.37 (CompactUniformContinuity kernel net observation surface)**.** *For every accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet*

$$H = (X, Y, F, E, D, \mathcal{P}, C, M, R, W, T, Q, P, N),$$

the finite ProbeBundle *net rows* $\mathcal{P}, C$*, the source and target* MetricDistanceWitness *rows, the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise modulus rows* M*, the positive* $\mathsf{Rat}^{\uparrow}$ *radius rows* R*, the finite lower-bound fold* W*, the* hsame *transport rows* T*, the displayed* Cont *routes* Q*, the package row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuit}}$ *row* N *form the complete observation surface of the kernel packet. No accepted packet exports an additional open-cover, sequential, host-minimum, or external-modulus coordinate.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket kernel net observation surface`

Proof. Project the accepted carrier. The carrier definition exposes exactly the source metric row X, target metric row Y, graph row F, tolerance row E, precision row D, finite net data $\mathcal{P}, C$, pointwise modulus table M, positive rational radius data R, finite fold row W, transports T, continuations Q, package provenance P, and local naming row N.

The finite-net handoff, ProbeBundle coverage theorem, metric-distance routing theorem, and radius-fold exactness theorem identify how these coordinates are read by consumers. Each read is therefore a projection from the displayed BHist packet followed by repacking through the stored hsame, Cont, Pkg, and NameCert rows.

Since the carrier has no field for open-cover compactness, sequential compactness, selected host minima, or an external modulus function, those objects cannot appear in the observation surface. The stated rows are consequently exhaustive for kernel-level observation. □

Theorem 388.38 (CompactUniformContinuity modulus ledger exhaustion)**.** *For every accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet, the selected uniform precision row* D *is exhausted by the finite* ProbeBundle *net rows,* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise modulus rows, positive* $\mathsf{Rat}^{\uparrow}$ *radii, finite lower-bound fold,* MetricDistanceWitness *routing rows, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *provenance of Definition 388.37. The ledger for* D *cannot be read through open covers, selected minima, or host modulus choice.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket modulus ledger exhaustion`

Proof. Begin with the observation surface of Definition 388.37. It lists every coordinate available to the packet before a consumer requests the uniform precision.

Use radius-fold exactness to identify D with the finite lower-bound fold over the displayed positive rational rows. Then use finite-net modulus extraction to attach that fold to the ProbeBundle coverage rows and to the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ modulus rows.

Metric-distance routing supplies only the displayed source and target witness rows, and the remaining transport, continuation, package, and naming rows preserve the same finite ledger. Because no carrier coordinate stores an open cover, a selected minimum, or a host modulus chooser, the precision row is exhausted by the finite rows listed above. □

Theorem 388.39 (CompactUniformContinuity real metric consumer triad)**.** *Every* $\mathsf{Real}^{\uparrow}/\mathsf{Met}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet factors through the compact-net row, the metric-distance row, and the continuous-map modulus row before it reads the uniform precision row* D*. The consumer route is therefore the triad*

$$\mathsf{ProbeBundle} \longrightarrow \mathsf{MetricDistanceWitness} \longrightarrow \mathsf{ContinuousMap}^{\uparrow}$$

inside the displayed finite packet, followed by the $\mathsf{Rat}^{\uparrow}$ *fold and the stored* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket real metric consumer triad`

Proof. Start with a real or metric consumer read. By the real-facing boundary and metric-distance routing the read cannot access a host metric directly; it must pass through the displayed MetricDistanceWitness rows.

The source-side compact information is supplied first by the finite ProbeBundle coverage rows. The target-side behavior is then supplied by the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ pointwise modulus rows, with the metric witnesses connecting the requested source and target observations.

Finally apply modulus ledger exhaustion. The uniform precision row D is read only after the compact-net, metric-distance, and continuous-map modulus rows have been assembled with the positive $\mathsf{Rat}^{\uparrow}$ fold and the stored provenance rows, so the consumer factors through the stated triad. □

Theorem 388.40 (CompactUniformContinuity equicontinuous family consumer)**.** *An equicontinuous family packet whose displayed family-member rows expose the same finite* $\mathsf{CompactMetric}^{\uparrow}$ ProbeBundle *coverage,* $\mathsf{ContinuousMap}^{\uparrow}$ *centerwise modulus rows,* MetricDistanceWitness *source and target rows, positive* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold,* $\mathsf{Real}^{\uparrow}$ *seal boundary, and displayed* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *provenance admits a single compact-uniform-continuity consumer route for every displayed family member. The shared route reads the finite bridge modulus assembly through the common coverage and fold rows, so each member receives the same finite BEDC uniform-precision consumer boundary.*

The conclusion is a consumer route over the displayed family rows only. It does not use open-cover compactness, sequential compactness, host minima, or a host modulus.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket equicontinuous family consumer`

Proof. First extract the shared precision row. Apply Definition 388.31 to the common ProbeBundle coverage, centerwise $\mathsf{ContinuousMap}^{\uparrow}$ modulus, and positive $\mathsf{Rat}^{\uparrow}$ lower-bound fold rows carried by the family packet.

Next assemble the bridge-facing consumer route. Use Definition 388.32; the source and target metric reads for a displayed family member are supplied by its MetricDistanceWitness rows, while the uniform precision row is the shared finite row extracted from the family packet.

Finally apply Definition 388.33. The $\mathsf{Real}^{\uparrow}$ seal boundary keeps each displayed member inside the same finite-net, metric-witness, rational-fold, transport, continuation, package, and naming provenance, so the family consumer has no coordinate for open-cover compactness, sequential compactness, host minima, or a host modulus. □

Theorem 388.41 (CompactUniformContinuity net-modulus consumer triad)**.** *Every accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet exposes a downstream consumer triad consisting of the finite* ProbeBundle *compact-net coverage supplied by* $\mathsf{CompactMetric}^{\uparrow}$*, the centerwise* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise modulus rows transported through displayed* MetricDistanceWitness *rows, and the positive* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold that yields the uniform precision row. Every* $\mathsf{Real}^{\uparrow}$ *or compact-metric consumer read of the uniform modulus factors through these three finite rows together with the recorded* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *routes.*

The certificate therefore contains no open-cover compactness, sequential compactness, host minimum, or external modulus function. Its consumer surface is exactly the finite compact-net, pointwise-modulus, metric-witness, rational-fold, transport, continuation, package, and naming ledger displayed by the packet.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket net modulus consumer triad`

Proof. First read the compact-net row. By Definition 388.16, each admitted source history reaches a bundled center through the finite ProbeBundle coverage supplied by the $\mathsf{CompactMetric}^{\uparrow}$ side of the packet.

Next read the pointwise modulus row through the metric witnesses. Use Definition 388.17 to keep source and target distance observations behind displayed MetricDistanceWitness rows, and use Definition 388.13 to connect those rows with the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ modulus data.

Finally read the uniform precision row. The radius-fold exactness theorem Definition 388.14 identifies the precision with the positive $\mathsf{Rat}^{\uparrow}$ lower-bound fold, and Definition 388.38 says that this fold exhausts the displayed modulus ledger.

Apply the consumer boundary supplied by Definition 388.39 and Definition 388.18. Every real or compact-metric read is consequently routed through the three finite rows and their stored hsame, Cont, Pkg, and NameCert provenance, with no route to open covers, sequences, host minima, or an external modulus. □

Theorem 388.42 (CompactUniformContinuity root consumer triad)**.** *The root consumer surface of an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet is the triad consisting of finite* ProbeBundle *coverage,* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise modulus rows, and* MetricDistanceWitness *routing. Its exported precision is the positive* $\mathsf{Rat}^{\uparrow}$ *radius ledger folded by the finite lower-bound witness, transported with the displayed* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *rows.*

This triad is the full root consumer package for compact-uniform-continuity reads. It has no route through open covers, sequential compactness, host minima, or external modulus functions.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root consumer triad`

Proof. Project the accepted carrier and classifier of Definition 388.1 and Definition 388.2. The visible coordinates already contain the compact finite-net rows, pointwise modulus rows, metric witnesses, rational-radius ledger, fold witness, transport rows, continuation routes, package provenance, and local naming row.

Use finite-net handoff, ProbeBundle coverage, and metric-distance routing to isolate the compact and metric sides of the route. The pointwise $\mathsf{ContinuousMap}^{\uparrow}$ rows are then consumed at the bundled centers, and radius-fold exactness supplies the positive rational lower-bound fold that exports the uniform precision row.

Finally apply the non-escape ledger and real metric seal boundary. Since every listed read is a projection from the displayed packet followed by transport through hsame, Cont, Pkg, and NameCert, no outside compactness principle or host modulus can enter the root consumer package. □

Theorem 388.43 (CompactUniformContinuity root downstream unblock package)**.** *The* CompactUniformContinuit *downstream package for* UniformModulus$^{\uparrow}$ *and compact-metric consumers consists of the* ProbeBundle *compact-net row, the* ContinuousMap$^{\uparrow}$ *pointwise-modulus row, the* MetricDistanceWitness *route, the positive* Rat$^{\uparrow}$ *fold, the* Real$^{\uparrow}$ *seal boundary, and the displayed* hsame, Cont, Pkg, *and* NameCert$_{\text{CompactUniformContinuity}^{\uparrow}}$ *provenance. It is a finite packet over the root consumer triad and exports no open-cover compactness, host minimum, sequence compactness, or external modulus selector.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root downstream unblock package`

Proof. Project the root consumer triad of Definition 388.42. Its three source rows are the finite compact net, the pointwise modulus ledger, and the metric-witness route, with the positive rational fold supplying the exported precision.

Use finite-net handoff and metric-distance routing to attach each centerwise modulus read to the displayed ProbeBundle and MetricDistanceWitness rows. Then use rational fold export to identify the precision consumed by UniformModulus$^{\uparrow}$ and compact-metric consumers with the finite positive Rat$^{\uparrow}$ ledger.

Finally apply the compact-continuous NameCert export and the real seal boundary. Repacking those rows with hsame, Cont, Pkg, and NameCert provenance gives the downstream package and leaves no coordinate for open covers, host minima, sequence compactness, or external modulus selection. □

Theorem 388.44 (CompactUniformContinuity ProbeBundle center selection)**.** *In every accepted* CompactUniformContinuity$^{\uparrow}$ *root packet, source-side compact access is mediated by finitely many* CompactMetric$^{\uparrow}$ ProbeBundle *centers. A consumer may read a source point only by selecting one displayed center row, transporting it through the packet's* hsame *rows, reading the associated* Cont *route, and carrying the result through the* Pkg *provenance and local* NameCert$_{\text{CompactUniformContinuity}^{\uparrow}}$ *row.*

The selected center is a row of the finite packet, not an open-cover point, host compactness witness, or minimum-selection operation.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root probebundle center selection`

Proof. Project the root consumer triad of Definition 388.42. Its compact side is the finite ProbeBundle coverage row, already attached to CompactMetric$^{\uparrow}$ provenance.

Apply finite-net handoff and metric-distance routing. These rows force each source read through one bundled center before any modulus or target-distance row can be consumed.

Finally transport the selected center through the displayed hsame and Cont rows and repack it with Pkg and NameCert provenance. Since the carrier contains no open-cover or host-minimum coordinate, the center selection remains a finite packet read. □

Theorem 388.45 (CompactUniformContinuity pointwise modulus row)**.** *For each finite* CompactMetric$^{\uparrow}$ ProbeBundle *center read from an accepted* CompactUniformContinuity$^{\uparrow}$ *packet, the only modulus data available to the root consumer is the matching* ContinuousMap$^{\uparrow}$ *pointwise modulus row. That*

row is consumed together with the source and target MetricDistanceWitness *rows, the positive* $\mathsf{Rat}^{\uparrow}$ *radius ledger, and the displayed* hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *provenance.*

No root consumer can replace the pointwise row by an external modulus function or a host continuity theorem.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root pointwise modulus row`

Proof. Begin with a center supplied by Definition 388.44. The center is already a displayed finite packet row.

Use the finite-net handoff to reach the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ modulus row. Metric-distance routing then supplies exactly the source-center and target-output MetricDistanceWitness rows consumed by that modulus read.

The positive $\mathsf{Rat}^{\uparrow}$ radius ledger and the stored transport, continuation, package, and naming rows carry this pointwise read into the root packet. The carrier has no coordinate for an external modulus, so the displayed pointwise row exhausts the route. □

Theorem 388.46 (CompactUniformContinuity rational-fold consumer)**.** *Every root consumer of uniform precision in an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet factors through the finite* $\mathsf{Rat}^{\uparrow}$ *positive-radius fold. The fold consumes the finitely many centerwise* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise modulus rows selected through the* $\mathsf{CompactMetric}^{\uparrow}$ ProbeBundle *centers, compares them only through displayed* MetricDistanceWitness *rows, and exports the precision with the packet's* hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *provenance.*

The consumer surface contains no open-cover compactness, host minimum, or external modulus selector.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket root rational fold consumer`

Proof. First assemble the finite center and pointwise rows using Definition 388.44 and Definition 388.45. These rows provide the compact, continuous, and metric inputs to the precision read.

Next apply radius-fold exactness. The exported precision is the positive $\mathsf{Rat}^{\uparrow}$ lower-bound fold over the displayed centerwise radius rows, so the consumer never leaves the finite rational ledger.

Finally use the root consumer triad. Transport and continuation rows carry the folded precision with package and naming provenance, while the non-escape boundary excludes open covers, host minima, and external modulus selection. □

Theorem 388.47 (CompactUniformContinuity ProbeBundle-to-metric route)**.** *Every source-side root read in an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet passes from the finite* ProbeBundle *spine to displayed source and target* MetricDistanceWitness *rows before it can consume a* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise modulus row. The route is mediated by the carrier's* hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}}$ *provenance, and it never reads a host metric directly.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket probe metric route`

Proof. Begin with the finite-net coverage theorem. It sends each source-point history to a bundled center through the displayed ProbeBundle spine and coverage ledger.

Metric-distance routing then supplies the only source-center and target-output distance reads available to the packet. These witnesses are the metric coordinates of the carrier, transported componentwise by the classifier.

With those metric witnesses in place, the finite-net handoff consumes the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ pointwise modulus row. The non-escape ledger prevents replacing any part of this route by host metric access, an open cover, or an unrecorded selector. □

Theorem 388.48 (CompactUniformContinuity rational fold export)**.** *The only exported uniform precision of an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet is the carrier row D read through the positive* $\mathsf{Rat}^{\uparrow}$ *radius ledger R and the finite lower-bound fold witness W. Every downstream consumer of uniform precision factors through this rational fold together with the displayed* ProbeBundle *coverage,* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise rows,* MetricDistanceWitness *routes,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *provenance.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket rational fold export`

Proof. Read the precision coordinate D from the accepted carrier. The carrier also displays the positive radius ledger R and the fold witness W, but it has no coordinate for a host minimum or selected real-radius operation.

Radius-fold exactness identifies D as the finite lower-bound fold over R. The finite-net modulus extraction theorem then attaches this fold to the ProbeBundle coverage rows and the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ modulus rows.

Metric-distance routing and the non-escape ledger keep the resulting precision route inside displayed BEDC rows. Therefore the rational fold is the sole exported uniform precision, and no downstream consumer can bypass it through external compactness or modulus choice. □

Theorem 388.49 (CompactUniformContinuity four-source handoff correspondence)**.** *For every accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *root packet, the finite* ProbeBundle *compact-net rows, the pointwise* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus rows, the source and target* MetricDistanceWitness *rows, the positive* $\mathsf{Rat}^{\uparrow}$ *fold rows, and the* $\mathsf{Real}^{\uparrow}$ *seal row form one finite handoff correspondence. A consumer may enter the handoff through any displayed compact, continuous, metric, rational, or real row, but every such entry reads the same carrier packet with the same* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *provenance.*

The correspondence has no coordinate for open-cover compactness, sequence compactness, host minimum selection, or an external modulus. It is the root handoff of the displayed finite rows.

Proof. Start with the compact-net side. Apply Definition 388.13 to bind the finite ProbeBundle net to the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ modulus rows.

Next read the metric and rational rows. Metric-distance routing supplies the only source and target distance observations, while radius-fold exactness identifies the positive $\mathsf{Rat}^{\uparrow}$ fold as the precision row consumed by the handoff.

Finally attach the real-facing boundary. Use the real seal boundary together with the rational fold export theorem to repack the compact, continuous, metric, rational, and real rows as one carrier correspondence. Since each step is a projection from the accepted packet followed by displayed transport, no outside compactness or modulus coordinate is introduced. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket four source handoff correspondence`

Theorem 388.50 (CompactUniformContinuity rational fold metric compatibility)**.** *In an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet, the rational-fold precision row is compatible with every source-center and target-output metric read consumed by the handoff of Definition 388.49. Each* $\mathsf{MetricDistanceWitness}$ *read is routed through the displayed compact-net center, then compared only against the precision exported by the positive* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold and its recorded* hsame *and* Cont *transports.*

Thus no metric consumer can replace the rational fold by a host minimum, an unrecorded real radius, or an external modulus choice.

Proof. Project the displayed metric witnesses from the carrier. By metric-distance routing, every source-center or target-output distance read is one of these witnesses and not a host metric call.

Apply finite-net handoff to place those metric witnesses on the same route as the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ modulus rows. Radius-fold exactness then identifies the precision read by that route with the positive $\mathsf{Rat}^{\uparrow}$ lower-bound fold.

The rational fold export theorem says that all downstream precision consumers factor through this fold. Therefore every metric read consumed by the handoff is compatible with the same rational precision row, and no hidden radius selector is available. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket rational fold metric compatibility`

Theorem 388.51 (CompactUniformContinuity compact-continuous NameCert export)**.** *The compact-net rows, pointwise* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus rows,* $\mathsf{MetricDistanceWitness}$ *rows, positive* $\mathsf{Rat}^{\uparrow}$ *fold rows, and* $\mathsf{Real}^{\uparrow}$ *seal row of an accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *packet export a finite* $\mathsf{NameCert}_{\mathsf{CompactUniformConti}}$ *package. The exported package is exactly the displayed carrier, classifier, transport, continuation, package, and naming ledger over those rows.*

It exports no open-cover compactness, sequence compactness, host minimum, host modulus, or additional real-coordinate selector.

Proof. First assemble the finite handoff correspondence from Definition 388.49. This supplies the compact, continuous, metric, rational, and real rows as one accepted packet with fixed provenance.

Next apply Definition 388.50. The metric observations and rational precision row agree along the displayed finite-net route, so the exported package has a single precision ledger.

Finally use the real seal boundary and rational fold export theorem. The real-facing row can only read the sealed finite packet, while the rational fold remains the only exported precision. Repacking these rows gives the finite $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ package and leaves no coordinate for open covers, sequence compactness, host minima, or external modulus data. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket compact continuous namecert export`

Theorem 388.52 (CompactUniformContinuity four-source bridge determinacy)**.** *For every accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *root packet, the consumer-facing bridge determined by Definition 388.49 and Definition 388.51 has a unique displayed finite source. Any route, transport, readback, or handoff through the compact, continuous, metric, rational, or real side factors through the finite* $\mathsf{ProbeBundle}$ *compact-net rows, the centerwise* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus rows, the source and target* $\mathsf{MetricDistanceWitness}$ *rows, the positive* $\mathsf{Rat}^{\uparrow}$ *fold rows, the* $\mathsf{Real}^{\uparrow}$ *seal row, and the common* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *provenance.*

Consequently an unlisted bridge coordinate, including open-cover compactness, sequence compactness, host minimum selection, a hidden real-radius selector, or an external modulus, is unavailable to every such consumer.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket four source bridge determinacy`

Proof. Apply Definition 388.49. It states that a consumer may enter through any displayed compact, continuous, metric, rational, or real row, but every such entry reads the same accepted carrier packet and the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ provenance. Thus the compact entry is the finite ProbeBundle net row, the continuous entry is the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ modulus row, the metric entry is one of the displayed source or target MetricDistanceWitness rows, the rational entry is the positive $\mathsf{Rat}^{\uparrow}$ fold row, and the real entry is the $\mathsf{Real}^{\uparrow}$ seal row.

Apply Definition 388.51. The export packages exactly the displayed carrier, classifier, transport, continuation, package, and naming ledger over those rows. Therefore a route is read through the displayed Cont continuation rows, a transport is read through the displayed hsame and classifier rows, a readback is a projection to one of the listed compact, continuous, metric, rational, or real rows, and a handoff is the finite correspondence obtained by repacking those projections with the same Pkg and $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ provenance.

These four consumer actions have the same source because the correspondence fixes the carrier packet before the export repacks it, and the export exposes no second carrier, classifier, transport, continuation, package, or naming ledger. Hence two displayed consumer entries cannot determine different bridge data: after projection they land in the same finite row list and after export they carry the same provenance.

The nonlisted cases are excluded by the same two rows. The correspondence explicitly has no coordinate for open-cover compactness, sequence compactness, host minimum selection, or an external modulus, and the export adds no open-cover, sequence, host-minimum, host-modulus, or additional real-coordinate selector. Since an unavailable coordinate is neither a projection from the carrier nor a transported component of the exported $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ package, no consumer-facing route, transport, readback, or handoff can factor through it. □

Corollary 388.53 (CompactUniformContinuity four-source handoff consumer determinacy)**.** *For every accepted* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *root packet, fix the finite* ProbeBundle *compact-net rows, the centerwise* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus rows, the source and target* MetricDistanceWitness *rows, the positive* $\mathsf{Rat}^{\uparrow}$ *fold rows, the* $\mathsf{Real}^{\uparrow}$ *seal row, and the common* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *provenance named by Definition 388.49. Then every accepted consumer-facing use that reports a route selection, a normal-form readback, or an exactness decision for the four-source handoff reports the one determined by those fixed rows.*

The finite route is the displayed handoff through compact-net coverage, centerwise continuity, source and target metric witnesses, rational fold precision, and the real seal. The normal-form readback is the ordered projection to those same rows with the displayed transport, continuation, package, and local naming provenance. The exactness decision accepts precisely the consumer uses that factor through that fixed finite route. No open-cover compactness coordinate, sequence compactness coordinate, host minimum selector, hidden real-radius selector, external modulus, alternate hidden coordinate, or duplicate classifier source can supply a different accepted route, normal form, or exactness decision.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket four source handoff consumer determinacy`

Proof. Fix the accepted root packet and the listed local rows. By Definition 388.49, a consumer may enter through any displayed compact, continuous, metric, rational, or real row, but

every such entry reads the same carrier packet with the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ provenance. Thus the five source families are not competing sources; they are five entry faces of one finite handoff correspondence.

Apply Definition 388.52. It identifies the consumer-facing bridge as having a unique displayed finite source and forces every route, transport, readback, or handoff through the compact, continuous, metric, rational, or real side to factor through exactly the fixed row list. Since the rows have been fixed, two accepted consumer uses cannot choose distinct finite sources: after factorization, both land in the same compact-net rows, the same centerwise modulus rows, the same source and target metric-witness rows, the same rational fold rows, the same real seal row, and the same structural provenance.

A reported route selection is therefore the displayed factorization route through those rows. A reported normal-form readback is the same ordered projection of the fixed carrier: first the finite ProbeBundle compact-net and coverage rows, then the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ modulus rows, then the source and target MetricDistanceWitness rows, then the positive $\mathsf{Rat}^{\uparrow}$ fold, and finally the $\mathsf{Real}^{\uparrow}$ seal, all transported and repacked by hsame, Cont, Pkg, and the local NameCert row. A reported exactness decision is consequently the decision that a consumer use is accepted exactly when it factors through this fixed route and its structural provenance.

It remains to exclude alternate sources for the same public decision. If a purported duplicate classifier source is one of the displayed classifier, transport, continuation, package, or naming rows, then it is already part of the fixed provenance and determines the same route. If it is not one of those rows, then Definition 388.52 and Definition 388.49 leave it no projection, transport, readback, or handoff coordinate. The excluded open-cover, sequence, host-minimum, hidden real-radius, and external-modulus cases are therefore rejected before they can become accepted consumer-facing data. □

Theorem 388.54 (CompactUniformContinuity finite-row audit boundary)**.** *Every accepted* CompactUniformContin *consumer route factors through exactly the five displayed analytic rows of the packet: the* $\mathsf{CompactMetric}^{\uparrow}$ ProbeBundle *finite net, the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row, the* MetricDistanceWitness *routing row, the positive* $\mathsf{Rat}^{\uparrow}$ *finite lower-bound fold, and the* $\mathsf{Real}^{\uparrow}$ *seal boundary. The factorization is carried by the same* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ *provenance as the carrier.*

The accepted consumer surface has no coordinate for open-cover compactness, sequential compactness, host minima, or an external modulus function.

Proof. First assemble the compact and continuous rows. Apply Definition 388.13 to route source reads through the displayed finite ProbeBundle centers and into the centerwise $\mathsf{ContinuousMap}^{\uparrow}$ pointwise-modulus rows.

Next attach the metric and rational rows. The metric-distance routing theorem supplies the source-center and target-output MetricDistanceWitness reads, while Definition 388.14 identifies the exported precision with the positive $\mathsf{Rat}^{\uparrow}$ finite lower-bound fold.

The real-facing side is fixed by Definition 388.15. It says that a $\mathsf{Real}^{\uparrow}$ consumer reads the same compact, continuous, metric, and rational rows rather than a host real minimum or external modulus.

Finally use Definition 388.48 and Definition 388.51. These theorems package the rational fold and the compact-continuous rows as the finite $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ export. Since each cited route is a projection from the displayed carrier followed by hsame, Cont, Pkg, and local naming transport, the five rows exhaust the accepted consumer surface and exclude open-cover compactness, sequential compactness, host minima, and external modulus functions. □

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityUp.CompactUniformContinuityPacket finite row audit boundary`

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}$ ·

Constructive story: A $\mathsf{CompactUniformContinuity}^{\uparrow}$ packet is generated from source and target metric rows, a continuous-map graph row, a positive tolerance history, a compact finite ProbeBundle net, pointwise-modulus rows at the bundled centers, positive $\mathsf{Rat}^{\uparrow}$ radius rows, a finite lower-bound fold selecting a precision history, componentwise hsame rows, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature surface fixes the bridge source, finite-net modulus assembly, real-facing seal boundary, and the constant-map, finite-net composition, and real-interval consumer packets over the displayed rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformContinuity}^{\uparrow}}, \mathsf{axiomClean})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close bridge status, axiom-purity status, open-cover compactness, sequential compactness, host real equality, selected real minima, or external modulus selection.

Upgrade path: The remaining route is axiom-purity and bridge status over the same finite compact-metric consumer packets.

Chapter 389

A Concrete Naming Certificate for NestedIntervalIntersection$^{\uparrow}$

The NestedIntervalIntersection$^{\uparrow}$ interface names the finite readback surface through which nested interval packets hand a diagonal interval-intersection claim to the real and completion layers. Bishop–Bridges constructive analysis treats nested interval intersection through explicit moduli and finite approximants; BEDC records only the finite diagonal rows, transport ledgers, and seal-facing boundary. It does not claim open-cover compactness, choice of an intersection point, or equality with a host real intersection.

The consumer route enters the L10 real-name chain through the regular Cauchy source surface of chapter 371; this chapter only adds the nested-interval selector and width-window ledger on top of that sibling carrier.

Definition 389.1 (Nested interval intersection carrier)**.** *A* NestedIntervalIntersection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (N, W, D, E, H, C, P, Q)$$

with the following visible coordinates:

1. *N is the source* NestedInterval$^{\uparrow}$ *or* NestedDyadicInterval$^{\uparrow}$ *chain row, including the displayed* DyadicInterval$^{\uparrow}$ *endpoint packets and their* DyadicRatCore$^{\uparrow}$ *lower and upper endpoint reads;*
2. *W is the displayed width surface, either as explicit width rows for the visible chain or as* RegularityModulus$^{\uparrow}$ *rows naming the requested finite precision window;*
3. *D is the finite diagonal selector: for each displayed precision request, it chooses one visible interval row whose width ledger is bounded by the requested tolerance;*
4. *E records the selected endpoint enclosures and the finite* RegSeqRat$^{\uparrow}$ *handoff rows read from those selected intervals;*
5. *H is the* Real$^{\uparrow}$ *seal-facing surface obtained by routing the selected regular-rational rows through the displayed endpoint and width ledgers;*
6. *C stores the* hsame *and* Cont *transports for the source chain, width or modulus rows, diagonal selector, handoff rows, and seal-facing rows;*
7. *P is the* Pkg *provenance naming* NestedInterval$^{\uparrow}$, NestedDyadicInterval$^{\uparrow}$, DyadicInterval$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, RegularityModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *source certificates;*

8. Q is the local $\mathsf{NameCert}_{\mathsf{NestedIntervalIntersection}^{\uparrow}}$ *row for the finite intersection readback name.*

The carrier predicate is $\mathsf{NestedIntervalIntersectionPacket}(X)$*. Its public rows are exactly the displayed source-chain, width, diagonal-selector, endpoint-handoff, seal-facing, transport, package, and local certificate rows.*

Lean4 ✓ `BEDC.Derived.NestedIntervalIntersectionUp.NestedIntervalIntersectionTasteGate single carrier alignment`

Definition 389.2 (Nested interval intersection classifier)**.** *Two accepted* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *carriers classify together when their source nested-interval rows transport to the same displayed finite window and their diagonal selectors choose endpoint enclosures with the same requested tolerance rows.*

Concretely, after the hsame *and* Cont *transports recorded in C and C', the classifier compares the selected lower endpoint rows, selected upper endpoint rows, displayed width or* $\mathsf{RegularityModulus}^{\uparrow}$ *rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows,* $\mathsf{Real}^{\uparrow}$ *seal-facing rows,* Pkg *provenance, and local* NameCert *rows componentwise. It does not quotient infinite chains and does not identify a selected point in the intersection.*

Theorem 389.3 (Nested interval intersection NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{NestedIntervalIntersection}^{\uparrow}}$ *surface has five obligations:*

1. *carrier: formation of the finite* BHist *packet of Definition 389.1;*
2. *classifier: the finite-window classifier of Definition 389.2;*
3. *diagonal stability: the selected interval row remains accepted when the source* $\mathsf{NestedInterval}^{\uparrow}$ *or* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *chain, width or* $\mathsf{RegularityModulus}^{\uparrow}$ *row, and endpoint packets are transported through the displayed* hsame *and* Cont *routes;*
4. *handoff exactness: every* $\mathsf{RegSeqRat}^{\uparrow}$ *row read by the carrier is one of the endpoint enclosures selected by the finite diagonal selector;*
5. *seal boundary: the* $\mathsf{Real}^{\uparrow}$ *surface consumes only the selected finite regular-rational rows, package provenance, and local certificate row.*

These obligations are the complete seed certificate surface for finite nested-interval intersection readback.

Proof. Carrier formation is the assembly of the displayed packet. The source chain is already supplied by $\mathsf{NestedInterval}^{\uparrow}$ or $\mathsf{NestedDyadicInterval}^{\uparrow}$, the endpoint packets are $\mathsf{DyadicInterval}^{\uparrow}$ rows, and the selected endpoint reads are $\mathsf{DyadicRatCore}^{\uparrow}$ rows attached to the same finite history.

The classifier is finite because each comparison is made at the requested displayed precision window. After transporting both packets to that window, the selected lower endpoints, selected upper endpoints, width or modulus rows, handoff rows, seal-facing rows, provenance rows, and local certificate rows are compared component by component.

Diagonal stability follows by transporting the source chain and the width surface first, then reading the same requested tolerance row through the transported selector. Since the selector chooses only from displayed intervals, the transported selected row remains a visible row of the transported chain.

Handoff exactness is a projection from the coordinate E: every regular-rational read is attached to one selected endpoint enclosure. The seal boundary is a projection from H, which routes those same finite rows to $\mathsf{Real}^{\uparrow}$ without adding an infinite chain, compactness principle, choice operator, or host real equality. □

Lean4 ✓ `BEDC.Derived.NestedIntervalIntersectionUp.NestedIntervalIntersectionCarrier namecert obligations`

Theorem 389.4 (Nested interval intersection finite diagonal handoff)**.** *For every accepted* NestedIntervalIntersection *carrier and every displayed precision request, the consumer-visible* $\mathsf{RegSeqRat}^{\uparrow}$ *read factors through exactly one selected finite interval row of the source* $\mathsf{NestedInterval}^{\uparrow}$ *or* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *chain, its* $\mathsf{DyadicInterval}^{\uparrow}$ *endpoint packet, its lower and upper* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows, and the displayed width or* $\mathsf{RegularityModulus}^{\uparrow}$ *witness that justifies the request.*

The handoff exports no completed intersection point, no hidden tail of the chain, and no host completeness datum.

Proof. Project the selector coordinate D from Definition 389.1. A precision request is answered by a visible interval row together with its displayed width or regularity-modulus witness.

Read the selected interval through the source chain coordinate N. Its lower and upper endpoints are the $\mathsf{DyadicRatCore}^{\uparrow}$ rows of the selected $\mathsf{DyadicInterval}^{\uparrow}$ packet, and the width or modulus row is the only bound supplied to the consumer at that request.

Now project the handoff coordinate E. The $\mathsf{RegSeqRat}^{\uparrow}$ row is obtained by repacking the selected finite endpoint enclosure and the displayed bound. Since E has no coordinate for an infinite tail or a completed point, every consumer read factors through the selected finite interval row just described. □

Lean4 ✓ `BEDC.Derived.NestedIntervalIntersectionUp.NestedIntervalIntersectionCarrier finite diagonal handoff`

Theorem 389.5 (Nested interval intersection selector transport determinacy)**.** *If two accepted* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *carriers classify together, their transported diagonal selectors choose the same visible interval row at each displayed precision window. Hence the selected endpoint packets, the displayed width or* $\mathsf{RegularityModulus}^{\uparrow}$ *row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the* $\mathsf{Real}^{\uparrow}$ *seal-facing row are determined by classifier-visible data.*

In particular, selector transport cannot exchange the finite diagonal row for an unrecorded chain tail, a chosen intersection point, host real equality, or an ambient completeness witness.

Lean4 ✓ `BEDC.Derived.NestedIntervalIntersectionUp.NestedIntervalIntersectionCarrier selector transport determinacy`

Proof. Use the classifier definition to transport both carriers to the same displayed precision window. At that window, the source chain rows, endpoint packets, width or modulus rows, handoff rows, seal-facing rows, package provenance, and local certificate rows are compared componentwise.

Project the selector coordinate D from each transported carrier. Since the classifier compares the selected endpoint enclosures at the same requested tolerance, both selectors point to the same visible interval row of the transported finite window.

Apply Definition 389.4 to that selected row. The consumer-visible $\mathsf{RegSeqRat}^{\uparrow}$ handoff is then forced to factor through the same endpoint packet and the same displayed width or regularity-modulus witness.

The seal-facing coordinate is read from this handoff and the displayed transports. No remaining carrier coordinate contains a hidden chain tail, chosen intersection element, host equality row, or completeness datum. □

Theorem 389.6 (Nested interval intersection real seal boundary)**.** *The* $\mathsf{Real}^{\uparrow}$*-facing boundary of an accepted* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *carrier is exactly the finite diagonal handoff surface of*

Definition 389.4, together with the displayed hsame *transports, visible* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{NestedIntervalIntersection}^{\uparrow}}$ *row.*

In particular, the boundary does not assert Cantor nested-interval convergence, open-cover compactness, extraction of a point by choice, uniqueness of an intersection element, or equality with a host real value.

Proof. Start with the seal-facing coordinate H in Definition 389.1. Its inputs are the selected regular-rational rows from E, the transports in C, the package provenance P, and the local certificate row Q.

Use Definition 389.4 to identify the regular-rational inputs. Each such input has already factored through one visible interval row, its endpoint packet, and its displayed width or modulus witness.

The remaining coordinates are bookkeeping rows: hsame transports, Cont routes, Pkg provenance, and the local naming certificate. None of them contains a compactness theorem, a point-selection operator, a uniqueness claim, or a host real equality row. Therefore the real-seal boundary is precisely the finite surface stated above. □

Theorem 389.7 (Nested interval intersection public export)**.** *The public* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *interface exports exactly the finite diagonal selector, the selected endpoint enclosure, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, the* $\mathsf{Real}^{\uparrow}$ *seal-facing boundary, the displayed* hsame *and* Cont *transports, the* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalIntersection}^{\uparrow}}$ *row named in Definition 389.4 and Definition 389.6.*

Every public consumer read of the packet therefore factors through the same selected finite interval row and cannot read a hidden chain tail, a chosen intersection point, open-cover compactness, host real equality, or ambient completeness.

Proof. Start from the finite diagonal handoff. By Definition 389.4, a public precision request exposes one selected interval row, its endpoint packet, its dyadic endpoint reads, and the displayed width or regularity witness for that request.

Pass next through the real-seal boundary. By Definition 389.6, the only rows added at the public boundary are the displayed transports, replay routes, provenance, and local naming row.

No carrier coordinate remains outside these two surfaces. The exported interface is therefore exactly the finite diagonal route plus its seal-facing bookkeeping, with no point-selection, compactness, host equality, or completeness datum. □

Theorem 389.8 (Nested interval dyadic selector coverage)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer read of an accepted* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *packet is covered by one selected finite interval row. The selected row has lower and upper endpoint reads in* $\mathsf{DyadicRatCore}^{\uparrow}$*, its displayed width or* $\mathsf{RegularityModulus}^{\uparrow}$ *row supplies the requested* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and its provenance is exactly the recorded* Pkg *and local* $\mathsf{NameCert}_{\mathsf{NestedIntervalIntersection}^{\uparrow}}$ *route transported through the visible* hsame *and* Cont *rows.*

Consequently a diagonal-limit or completion consumer reads a dyadic endpoint enclosure selected by the finite selector, not a hidden chain tail, a chosen intersection point, or an ambient compactness witness.

Proof. Begin with the consumer-visible regular-rational read. By Definition 389.4, the read factors through exactly one visible interval row of the source chain, its endpoint packet, its lower and upper dyadic endpoint rows, and its displayed width or modulus witness.

Transport the selector data next. The determinacy result Definition 389.5 says that classified packets choose the same visible row at the same precision window, so the lower endpoint, upper endpoint, width row, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff remain tied to that selected interval.

Finally apply Definition 389.6. The $\mathsf{Real}^{\uparrow}$ boundary adds only the displayed hsame rows, Cont routes, Pkg provenance, and local naming row to the finite diagonal handoff.

The carrier has no coordinate for a completed point, open-cover compactness, choice, or host real equality. Hence every $\mathsf{Real}^{\uparrow}$-facing read is covered by the selected dyadic endpoint row and its recorded provenance. □

Theorem 389.9 (Nested interval intersection width-window refinement)**.** *For any accepted* NestedIntervalIntersectio *carrier*

$$X = (N, W, D, E, H, C, P, Q),$$

every consumer precision request refines through one displayed width row or $\mathsf{RegularityModulus}^{\uparrow}$ *row W, one selected interval row from the diagonal selector D, its* $\mathsf{DyadicInterval}^{\uparrow}$ *endpoint packet, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row E, and the* $\mathsf{Real}^{\uparrow}$ *seal boundary H. This refinement is transported only by the displayed* hsame *and* Cont *rows recorded in C, together with the package provenance P and local* $\mathsf{NameCert}_{\mathsf{NestedIntervalIntersection}^{\uparrow}}$ *row Q.*

Thus the width-window row is the exact finite surface consumed by diagonal-limit and completion-facing handoffs; it is not a claim of a chosen intersection point, open-cover compactness, host real equality, or ambient completeness.

Proof. Begin with Definition 389.4. It identifies the consumer-visible $\mathsf{RegSeqRat}^{\uparrow}$ read with one selected interval row, its endpoint packet, and the displayed width or regularity-modulus witness for the requested precision.

Next apply Definition 389.5. The selected interval row remains determined after the hsame and Cont transports, so the endpoint packet and width-window witness cannot be exchanged for an unrecorded chain tail.

Use Definition 389.6 to route the handoff into the $\mathsf{Real}^{\uparrow}$ surface. The seal sees the same finite diagonal package plus the displayed transports, provenance, and local naming row.

Finally Definition 389.8 covers every $\mathsf{Real}^{\uparrow}$-facing consumer read by the selected dyadic endpoint row. Therefore the width-window refinement is the reusable finite surface for the diagonal handoff. □

Theorem 389.10 (Nested interval intersection width-tail Cauchy handoff)**.** *Let*

$$X = (N, W, D, E, H, C, P, Q)$$

be an accepted $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *carrier. If the displayed width rows or* $\mathsf{RegularityModulus}^{\uparrow}$ *rows in W are cofinal for the requested tolerance schedule, then the selected endpoint enclosures determined by the diagonal selector D form a* $\mathsf{RegSeqRat}^{\uparrow}$*-compatible Cauchy handoff consumed by the same* $\mathsf{Real}^{\uparrow}$ *seal boundary H.*

This handoff is carried only by the source chain N, the width or regularity ledger W, the finite selector D, the endpoint handoff rows E, the seal boundary H, the displayed transports C, the package provenance P, and the local $\mathsf{NameCert}_{\mathsf{NestedIntervalIntersection}^{\uparrow}}$ *row Q. It asserts no chosen intersection point, open-cover compactness, host real equality, or ambient completeness.*

Proof. Begin with Definition 389.4. It identifies each requested precision with one selected interval row, its endpoint packet, and the displayed width or regularity witness.

Use Definition 389.5 to keep the selected endpoint enclosures fixed under the displayed transports. The selector therefore supplies one transported endpoint enclosure for each requested tolerance window.

Apply Definition 389.8 and Definition 389.9. Cofinality of the width or regularity rows makes the selected endpoint enclosures compatible with the requested Cauchy tolerance schedule, so the handoff is a $\mathsf{RegSeqRat}^{\uparrow}$-compatible tail surface.

Finally route the handoff through Definition 389.6. The $\mathsf{Real}^{\uparrow}$ seal reads the same finite endpoint, width, transport, package, and local certificate rows, and the carrier has no coordinate for point extraction, compactness, host equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalIntersection}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedIntervalIntersection}^{\uparrow}$ packet is generated from a finite $\mathsf{NestedInterval}^{\uparrow}$ or $\mathsf{NestedDyadicInterval}^{\uparrow}$ chain, displayed $\mathsf{DyadicInterval}^{\uparrow}$ endpoint packets, $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint reads, width or $\mathsf{RegularityModulus}^{\uparrow}$ rows, a finite diagonal selector, $\mathsf{RegSeqRat}^{\uparrow}$ handoff rows, a $\mathsf{Real}^{\uparrow}$ seal-facing surface, displayed hsame and Cont transports, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedIntervalIntersection}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The public scope registers the carrier, finite-window classifier, five-row naming-certificate obligation surface, finite diagonal handoff, real-seal boundary, and public export theorem for nested interval intersection readback over $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{NestedDyadicInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RegularityModulus}^{\uparrow}$.

Origin: human

Not claimed: This chapter does not close Cantor nested-interval convergence, open-cover compactness, point extraction, uniqueness of an intersection element, or host real equality.

Upgrade path: No further paper-theory grade remains; the next formal-axis improvement is a checked standard bridge when available.

Chapter 390

A Concrete Naming Certificate for $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$

The $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ interface names the finite packet that turns the diagonal selector of Definition 9238.3 into a displayed completion-facing certificate. It sits over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The packet records the precision request, the explicit modulus value selected from the regular Cauchy input, the finite stream window read at that value, the rational readback, the dyadic observation ledger, and the real-name seal row through which downstream consumers inspect the candidate limit.

Definition 390.1 (RegularCauchyLimitModulus carrier)**.** *A* $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, \mu, n, k, w, r, d, e, P, N)$$

with the following visible rows:

1. *X is a* $\mathsf{RegSeqRat}^{\uparrow}$*-indexed regular Cauchy family, read as the displayed input of Definition 9238.2;*
2. *μ is the explicit modulus row carried by that input;*
3. *n is the unary precision request;*
4. *$k = \mu(1/(n+1))$ is the selected diagonal threshold row;*
5. *w is the* $\mathsf{StreamName}^{\uparrow}$ *window that reads the k-th regular rational sequence at the diagonal index $k + n + 1$;*
6. *r is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row naming the rational observation selected by w;*
7. *d is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger recording the displayed endpoint, radius, comparison, and precision rows used by the readback;*
8. *e is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row that exposes the same observation as a row of the candidate diagonal real name;*
9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for an external limiting real, quotient stream equality, a hidden tail choice, or a host-level selector. Every consumer-visible value is one of the displayed rows of M.

Lean4 (definition) `BEDC.Derived.RegularCauchyLimitModulusUp.RegularCauchyLimitModulusPacket`

Definition 390.2 (RegularCauchyLimitModulus classifier)**.** *For accepted carriers*

$$M = (X, \mu, n, k, w, r, d, e, P, N) \quad \textit{and} \quad M' = (X', \mu', n', k', w', r', d', e', P', N'),$$

the classifier RegularCauchyLimitModulusClassifier(M, M') *compares only the displayed modulus rows, stream windows,* RegSeqRat$^{\uparrow}$ *readbacks,* DyadicRatCore$^{\uparrow}$ *ledgers,* Real$^{\uparrow}$ *seal rows, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows. The classifier is therefore a finite packet comparison: it neither compares host functions X and X' extensionally nor identifies two real names by a quotient construction.*

Lean4 (definition) `BEDC.Derived.RegularCauchyLimitModulusUp.RegularCauchyLimitModulusClassifier`

Theorem 390.3 (RegularCauchyLimitModulus NameCert obligations)**.** *The local* NameCert$_{\text{RegularCauchyLimitModulus}^{\uparrow}}$ *obligation sketch consists of five finite rows:*

1. *carrier habitation: every displayed regular Cauchy input with modulus μ and unary precision request n yields the finite packet of Definition 390.1;*
2. *modulus selector totality: the row $k = \mu(1/(n+1))$ is read from the displayed modulus coordinate and has a unary realization available to the stream-window reader;*
3. *diagonal readback stability: transporting the input family, modulus row, and precision request through the classifier transports the selected window w and readback r to the corresponding selected window and readback of the transported packet;*
4. Real$^{\uparrow}$ *seal non-escape: the seal-facing row e is reached only from the same* RegSeqRat$^{\uparrow}$ *readback and* DyadicRatCore$^{\uparrow}$ *ledger already displayed in the packet;*
5. *ledger exactness: every consumer-visible dyadic observation is exactly the endpoint, radius, comparison, precision, transport, continuation, package, and name row recorded by d, P, and N.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitModulusUp.RegularCauchyLimitModulusNamecertObligations`

Proof. Carrier habitation projects the regular Cauchy input and its modulus row, then evaluates the modulus at the displayed precision request $1/(n+1)$. This supplies the selected threshold k and the diagonal index $k+n+1$ used by the stream-window row.

The selector row is total because μ is part of the input certificate, not a hidden functional. Reading μ at the requested precision is a finite BEDC operation that produces the unary row consumed by StreamName$^{\uparrow}$.

For stability, transport X, μ, and n by the classifier rows of Definition 390.2. The selected k, the window w, and the readback r are then reconstructed from the transported rows by the same displayed Cont routes.

The Real$^{\uparrow}$ boundary consumes only the readback and dyadic ledger already present in r and d. Repacking them with e, P, and N gives the local naming row and leaves no coordinate for a quotient representative or external limit selector. □

Theorem 390.4 (RegularCauchyLimitModulus diagonal totality)**.** *Let $M = (X, \mu, n, k, w, r, d, e, P, N)$ be an accepted* RegularCauchyLimitModulus$^{\uparrow}$ *carrier. Then the diagonal observation required by Definition 9238.3 is total at the precision request n: the selected threshold row $k = \mu(1/(n+1))$, the stream window w, the* RegSeqRat$^{\uparrow}$ *readback r, and the dyadic ledger d together determine the displayed value*

$$L_n = (X_k)_{k+n+1}$$

as a finite BEDC observation routed through P and N.

The totality statement is internal to the packet. It does not assert completion of $\mathsf{Real}^{\uparrow}$ *and does not choose a limit outside the displayed carrier.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitModulusUp.RegularCauchyLimitModulusPacket diagonal totality`

Proof. Project the carrier of Definition 390.1. Its modulus selector row fixes k, and its stream-window row fixes the finite read of X_k at the diagonal index $k + n + 1$.

The $\mathsf{RegSeqRat}^{\uparrow}$ readback row r records the rational observation selected by that window. The $\mathsf{DyadicRatCore}^{\uparrow}$ ledger d records the endpoint and comparison data needed by a dyadic consumer of the same observation.

Since the continuation routes and package provenance are carrier coordinates, the observation is routed through P and N without any additional selection step. This is exactly the finite diagonal read demanded by Definition 9238.3. □

Theorem 390.5 (RegularCauchyLimitModulus tail-modulus extraction)**.** *Let $M = (X, \mu, n, k, w, r, d, e, P, N)$ be an accepted* $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ *packet. The selected threshold row $k = \mu(1/(n + 1))$, the finite* $\mathsf{StreamName}^{\uparrow}$ *window w, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback r, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger d form the finite-window* $\mathsf{CauchyModulus}^{\uparrow}$ *handoff consumed by downstream regular-Cauchy and* $\mathsf{Real}^{\uparrow}$ *readers.*

The handoff factors through chapter 292, chapter 126, chapter 301, chapter 291, and chapter 38. It exports no host selector, quotient stream equality, external limit, or ambient completeness principle.

Proof. Project the displayed carrier rows of M. The regular input family X, its modulus row μ, the precision request n, the selected threshold k, the window w, the readback r, the ledger d, the seal row e, the package row P, and the local name row N are all finite coordinates of the same BHist packet.

Use diagonal totality from Definition 390.4. It identifies k as the row $\mu(1/(n+1))$ and identifies w, r, and d as the finite observation route for the diagonal read of X_k at index $k + n + 1$.

The finite-window closure of chapter 292 consumes exactly this thresholded window and readback form. The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ chapters provide the window, rational readback, and dyadic ledger factors, so the modulus handoff is already present inside the displayed packet.

Finally apply the $\mathsf{Real}^{\uparrow}$ seal boundary of Definition 390.6. The seal row e keeps every real-facing read inside the same finite packet, leaving no coordinate for a host selector, quotient stream equality, external limit, or ambient completeness principle. □

Theorem 390.6 (RegularCauchyLimitModulus RealUp seal boundary)**.** *For every accepted* $\mathsf{RegularCauchyLimitMo}$ *carrier $M = (X, \mu, n, k, w, r, d, e, P, N)$, a* $\mathsf{Real}^{\uparrow}$ *consumer can inspect the diagonal-limit modulus packet only through the displayed seal-facing row e, whose source is the selected* $\mathsf{StreamName}^{\uparrow}$ *window w, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback r, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger d. The boundary exports a finite real-name observation row and no host real value, quotient representative, hidden tail selector, or equality of completed limits.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitModulusUp.RegularCauchyLimitModulusPacket real seal boundary`

Proof. Begin with the diagonal totality row of Definition 390.4. It identifies the only observation available at precision n as the windowed readback of X_k at index $k+n+1$.

The seal-facing coordinate e records the $\mathsf{Real}^{\uparrow}$ route for that same observation. Its source rows are w, r, and d, and its transport is supplied by the componentwise hsame and Cont coordinates named in the classifier.

Therefore any $\mathsf{Real}^{\uparrow}$ consumer read factors through the finite packet itself. Since the carrier includes no coordinate for an external real, a quotient representative, a hidden tail selector, or equality of completed limits, none of those objects can escape through the seal boundary. □

Theorem 390.7 (RegularCauchyLimitModulus seal factorization)**.** *Let $M = (X, \mu, n, k, w, r, d, e, P, N)$ be an accepted* $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ *packet. Before a* $\mathsf{Real}^{\uparrow}$ *consumer can read the seal row e, the same packet must expose the* $\mathsf{CauchyModulus}^{\uparrow}$ *finite-window route, the* $\mathsf{StreamName}^{\uparrow}$ *window w, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback r, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger d. In particular, the row e is visible only after the displayed threshold $k = \mu(1/(n+1))$ has been consumed as the modulus row of chapter 292 and routed through the diagonal totality statement of Definition 390.4 and the Real seal boundary of Definition 390.6.*

The seal factorization excludes selected limits, quotient stream equality, hidden host selectors, and ambient completeness. It is a finite handoff through the displayed threshold, window, readback, dyadic ledger, and seal rows.

Proof. Project the carrier M. The selected threshold k, the window w, the readback r, the dyadic ledger d, and the seal row e are all displayed coordinates of the same BHist packet.

Apply diagonal totality from Definition 390.4. It identifies $k = \mu(1/(n+1))$ as the threshold row that schedules the finite diagonal observation and identifies w, r, and d as the observation route.

Now read this route as the finite-window modulus handoff of chapter 292. The threshold ledger is consumed before the stream window, regular rational readback, and dyadic ledger can be passed to a real-facing consumer.

Finally apply the Real seal boundary of Definition 390.6. Since e has only w, r, and d as its source rows, the $\mathsf{Real}^{\uparrow}$ consumer receives no selected limit, quotient stream equality, hidden host selector, or ambient completeness principle. □

Theorem 390.8 (RegularCauchyLimitModulus classifier transport exactness)**.** *Let*

$$M = (X, \mu, n, k, w, r, d, e, P, N) \quad \text{and} \quad M' = (X', \mu', n', k', w', r', d', e', P', N')$$

be accepted $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ *packets. If* $\mathsf{RegularCauchyLimitModulusClassifier}(M, M')$ *holds, then the selected threshold row k, the stream window w, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback r, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger d, the* $\mathsf{Real}^{\uparrow}$ *seal row e, the package provenance P, and the local* $\mathsf{NameCert}$ *row N transport exactly to k', w', r', d', e', P', and N'.*

The transported packet exports only those displayed rows. It exports no host selector, no quotient equality of streams, and no external completed limit.

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitModulusUp.RegularCauchyLimitModulusPacket classifier transport exactness`

Proof. Unfold the carrier and classifier definitions of Definition 390.1 and Definition 390.2. The classifier supplies componentwise hsame rows for the displayed modulus and observation coordinates, displayed Cont routes for the stream-window and readback passages, and the visible Pkg and $\mathsf{NameCert}$ rows for provenance and naming.

Apply diagonal totality from Definition 390.4 to the source packet. The selected threshold is read from the displayed modulus row, and the stream window and $\mathsf{RegSeqRat}^{\uparrow}$ readback are reconstructed from the transported threshold by the same finite continuation routes.

The dyadic ledger and $\mathsf{Real}^{\uparrow}$ seal row then transport along the displayed ledger and seal coordinates. The RealUp seal boundary of Definition 390.6 ensures that a consumer can only inspect the transported observation through e', with source rows w', r', and d'.

Repack the transported threshold, window, readback, dyadic ledger, seal row, package provenance, and local naming row as the target packet M'. Since the carrier has no coordinates for a host selector, quotient stream equality, or completed limit outside the displayed rows, the transport exports none of those objects. □

Theorem 390.9 (RegularCauchyLimitModulus scoped kernel binding)**.** *The carrier, classifier, diagonal totality row,* $\mathsf{Real}^{\uparrow}$ *seal boundary, and classifier transport exactness of* $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ *depend only on the displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. In particular, every consumer-facing route through the chapter factors through those rows before it reaches the selected diagonal threshold, the finite stream window, the rational readback, the dyadic ledger, or the real-name seal.*

No host selector, quotient stream equality, external limit, or ambient completeness field enters this scope.

Proof. Start with the carrier of Definition 390.1. Its coordinates are exactly the displayed regular-sequence input, modulus row, precision request, selected threshold, stream window, readback, dyadic ledger, real seal, package row, and local naming row.

The classifier of Definition 390.2 compares those coordinates by the recorded hsame rows and Cont routes. It gives no extra coordinate for a host selector, quotient stream equality, external limit, or ambient completeness field.

Apply diagonal totality from Definition 390.4. The selected observation is reconstructed from the displayed modulus, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ ledger.

The $\mathsf{Real}^{\uparrow}$ boundary of Definition 390.6 then routes the same observation through the seal row, and Definition 390.8 shows that classifier transport preserves exactly those displayed rows. Thus the kernel scope is exhausted by the listed rows. □

Theorem 390.10 (RegularCauchyLimitModulus upstream lattice factorization)**.** *Every accepted* $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ *packet factors its diagonal-modulus handoff through the four sibling rows chapter 126, chapter 301, chapter 291, and chapter 38 before the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitModulus}^{\uparrow}}$ *row is consumed. The factorization route is exactly the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and* $\mathsf{Real}^{\uparrow}$ *seal row over the carrier of Definition 390.1.*

No quotient stream, host selector, selected host limit, or ambient completeness principle enters the factorization.

Proof. Project the accepted carrier. Its coordinates display the regular input and modulus row, the selected threshold, the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, the $\mathsf{Real}^{\uparrow}$ seal row, the package provenance, and the local naming row.

Use diagonal totality from Definition 390.4. The selected threshold, window, and readback route the diagonal observation through the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ sibling rows, while the dyadic ledger records the same observation in the $\mathsf{DyadicRatCore}^{\uparrow}$ row.

Use the RealUp seal boundary of Definition 390.6. It forces every real-facing inspection of the diagonal observation through the displayed $\mathsf{Real}^{\uparrow}$ seal row and leaves no coordinate for a host real, a quotient representative, or a selected external limit.

Finally apply classifier transport exactness from Definition 390.8 together with the scoped kernel binding of Definition 390.9. These results show that transport preserves exactly the same window, readback, ledger, seal, package, and naming rows, so the four sibling rows exhaust the upstream lattice before the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitModulus}^{\uparrow}}$ row is consumed. □

Theorem 390.11 (RegularCauchyLimitModulus public RealUp export)**.** *The carrier of Definition 390.1, the classifier of Definition 390.2, and the five* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitModulus}^{\uparrow}}$ *rows of Definition 390.3 jointly export a public* $\mathsf{Real}^{\uparrow}$*-facing finite completion-modulus handoff. Every consumer read of that handoff factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *input family* X*, the explicit modulus row* μ*, the unary precision request* n*, the selected* $\mathsf{StreamName}^{\uparrow}$ *window* w*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* r*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger* d*, the* $\mathsf{Real}^{\uparrow}$ *seal row* e*, the* Pkg *provenance* P*, and the local* $\mathsf{NameCert}$ *row* N*.*

The exported handoff excludes quotient stream equality, hidden tail choice, host selector, selected host limit, and ambient $\mathsf{Real}^{\uparrow}$ *completeness. It is a public row presentation of the finite diagonal-modulus packet, not a completion theorem.*

Proof. Project the displayed carrier rows. The regular Cauchy input, its modulus row, the precision request, the selected threshold, the stream window, the rational readback, the dyadic ledger, the seal row, provenance, and local name row are all coordinates of the same finite packet.

Use the modulus selector row from Definition 390.3 at the chosen precision threshold. The diagonal totality theorem then identifies the selected $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback as the finite observation consumed by the handoff.

Next apply classifier transport exactness. It keeps the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows on the displayed diagonal readback route, while the $\mathsf{Real}^{\uparrow}$ seal boundary forces every real-facing read through the seal row e and the dyadic ledger d.

Finally use the seal non-escape and ledger exactness rows of the local naming obligations. Repack the displayed source family, modulus row, request, selected window, readback, ledger, seal, package, and name rows as the public handoff. Since the carrier has no coordinates for quotient stream equality, hidden tail choice, a host selector, a selected host limit, or ambient completeness, none of those objects is exported. □

Theorem 390.12 (RegularCauchyLimitModulus RealUp completion bridge)**.** *The public diagonal-modulus handoff of Definition 390.11 supplies exactly the bridge packet consumed by the* $\mathsf{Real}^{\uparrow}$ *completion interface. The same* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows are preserved, and the bridge exports no quotient real equality, selected host limit, or ambient completeness principle.*

Proof. Start with diagonal totality from Definition 390.4. It selects the displayed threshold, window, readback, and dyadic ledger from the regular input family and its modulus row, all inside the finite carrier.

Apply classifier transport exactness from Definition 390.8. The hsame and Cont routes preserve the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows through the local classifier, while the Pkg and $\mathsf{NameCert}$ rows keep the dependency certificate fixed.

Use the scoped kernel binding of Definition 390.9 and the public export theorem Definition 390.11. Together they identify the public handoff as the completion-facing packet over exactly the displayed rows.

The non-escape clauses in the local naming obligations exclude quotient real equality, selected host limits, and ambient completeness. Hence the $\mathsf{Real}^{\uparrow}$ completion interface consumes the public

diagonal-modulus handoff as a bridge packet without receiving any additional real-completeness datum. □

Theorem 390.13 (RegularCauchyLimitModulus tail-selector stability)**.** *Transporting the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *input family, its modulus row, and a unary precision request transports the selected threshold, the finite* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and the* $\mathsf{Real}^{\uparrow}$ *seal row of an accepted* $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ *packet. The transported packet keeps the same* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitModulus}^{\uparrow}}$ *provenance and introduces no host tail selector.*

Thus selector stability is a finite classifier fact over the displayed input, modulus, request, threshold, window, readback, ledger, and seal rows.

Proof. Begin with diagonal totality. The selected threshold is read from the displayed modulus row at the displayed unary precision request, and the finite $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback are reconstructed from that threshold.

Apply classifier transport exactness to the transported input family, modulus row, and request. It carries the threshold, window, readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ ledger through the same hsame and Cont routes.

Finally use the $\mathsf{Real}^{\uparrow}$ seal boundary and scoped kernel binding. The seal row transports with the same finite packet, and the carrier contains no coordinate for quotient stream equality, a hidden tail choice, or an ambient selector. □

Theorem 390.14 (RegularCauchyLimitModulus RealUp seal handoff)**.** *The* $\mathsf{Real}^{\uparrow}$ *completion-facing handoff exported by an accepted* $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ *packet is exactly the transported finite packet of Definition 390.13: displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *input, modulus row, unary request, selected threshold,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{Real}^{\uparrow}$ *seal row,* Pkg *provenance, and local* NameCert *row.*

It is not quotient stream equality, not a hidden tail choice, and not a selected host limit. The completion interface receives only this finite seal-facing packet.

Proof. Use tail-selector stability to obtain the transported threshold, stream window, rational readback, dyadic ledger, and real seal row from the displayed input, modulus row, and precision request.

Next apply the $\mathsf{Real}^{\uparrow}$ seal boundary. Every real-facing read must pass through the transported seal row together with the dyadic ledger and the displayed source rows.

Finally combine scoped kernel binding with the RealUp completion bridge. The bridge consumes exactly the public diagonal-modulus packet over the displayed rows, so the handoff has no additional quotient-stream equality, hidden tail choice, selected host limit, or ambient completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ packet is generated by a displayed regular Cauchy family, its explicit modulus row, a unary precision request, the selected diagonal threshold, a finite $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger, a $\mathsf{Real}^{\uparrow}$ seal-facing row, package provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimitModulus}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 390.1, Definition 390.2, Definition 390.4, Definition 390.6, Definition 390.8, and Definition 390.9 bind the finite diagonal-modulus packet to the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimitModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close RealUp completeness, uniqueness of completed limits, quotient equality of streams, a public standard bridge, or checked Lean implementation.

Upgrade path: The next paper grade is a bridge theorem from the public diagonal-modulus handoff to the Real$^{\uparrow}$ completion interface over the same displayed RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Chapter 391

A Concrete Naming Certificate for $\mathsf{UniformContinuity}^{\uparrow}$

The $\mathsf{UniformContinuity}^{\uparrow}$ surface materializes the compact-uniform-continuity capstone of chapter 9237 as an ordinary concrete instance. It consumes the finite-net certificate of $\mathsf{Compact}^{\uparrow}$, the located distance rows of $\mathsf{Met}^{\uparrow}$, the pointwise modulus ledger of $\mathsf{Continuous}^{\uparrow}$, the rational lower-bound ledger of $\mathsf{Rat}^{\uparrow}$, and the closed $\mathsf{ProbeBundle}$ spine. The exported object is a tolerance-only uniform-modulus certificate; it is not a host-level modulus selector.

The dependency rows are read from sibling concrete certificates: the finite-net row from chapter 60, the source and target distance rows from chapter 57, the pointwise graph and modulus rows from chapter 59, and the lower-bound ledger from chapter 37.

Definition 391.1 (UniformContinuity BHist carrier)**.** *A* $\mathsf{UniformContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, f, \varepsilon, P, C, R, T, L, M, H, N)$$

with the following visible rows:

1. *X is the source metric row consumed through* $\mathsf{NameCert}_{\mathsf{Met}^{\uparrow}}$*;*
2. *Y is the target metric row consumed through* $\mathsf{NameCert}_{\mathsf{Met}^{\uparrow}}$*;*
3. *f is the graph row consumed through* $\mathsf{NameCert}_{\mathsf{Continuous}^{\uparrow}}$*;*
4. *ε is a positive tolerance row consumed through* $\mathsf{NameCert}_{\mathsf{Rat}^{\uparrow}}$*;*
5. *P is the finite* $\mathsf{ProbeBundle}$ *row supplied by the compact certificate;*
6. *C lists the center histories indexed by the bundled probes;*
7. *R lists the local positive radius and pointwise precision histories;*
8. *T records the half-radius coverage rows from* $\mathsf{NameCert}_{\mathsf{Compact}^{\uparrow}}$*;*
9. *L records the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold over the bundled radius rows;*
10. *M records the metric triangle transports in the source and target metrics;*
11. *H records* hsame *transport for the displayed histories;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformContinuity}^{\uparrow}}$ *row.*

The packet is accepted only when these rows are tied by Cont *routes and* Pkg *provenance to the listed dependency certificates. No coordinate stores a function from tolerances to radii outside* BHist*.*

Lean4 (definition) `BEDC.Derived.UniformContinuityUp.UniformContinuityCarrier`

Definition 391.2 (UniformContinuity classifier)**.** *Two* $\mathsf{UniformContinuity}^{\uparrow}$ *packets*

$$U = (X, Y, f, \varepsilon, P, C, R, T, L, M, H, N)$$

and

$$U' = (X', Y', f', \varepsilon', P', C', R', T', L', M', H', N')$$

are classified together when the source and target metric rows are transported by their $\mathsf{Met}^{\uparrow}$ *classifiers, the graph row is transported by the* $\mathsf{Continuous}^{\uparrow}$ *classifier, the tolerance and folded precision rows are transported by the* $\mathsf{Rat}^{\uparrow}$ *classifier, the* ProbeBundle *membership spine is the same displayed finite spine after* hsame *transport, and the coverage, pointwise-modulus, lower-bound, and triangle rows are the corresponding transported rows. The classifier compares exactly the displayed certificate packet and does not compare host functions, external compact covers, or selected moduli.*

Lean4 ✓ `BEDC.Derived.UniformContinuityUp.TasteGate.UniformContinuityTasteGate single carrier alignment`

Theorem 391.3 (Finite-net modulus fold)**.** *Let* U *be an accepted* $\mathsf{UniformContinuity}^{\uparrow}$ *carrier. The finite* ProbeBundle *row* P*, the pointwise-modulus rows* R*, and the* $\mathsf{Rat}^{\uparrow}$ *lower-bound ledger* L *determine a folded positive precision history* δ_ε *such that, for every bundled probe* p*, the fold certifies* δ_ε *below the half-radius row attached to* p*. The same folded history is stable under the classifier of Definition 391.2. Therefore the uniform precision read by a consumer is a BEDC history extracted from the finite bundle, not an external selection.*

Lean4 ✓ `BEDC.Derived.UniformContinuityUp.UniformContinuityPacket finite net modulus fold`

Proof. Project the finite ProbeBundle spine from the carrier. Its center rows, local radius rows, and pointwise precision rows are displayed coordinates of U, and each row is attached to the compact and continuous dependency certificates by Cont and Pkg provenance.

Run primitive recursion over the bundle. At the empty boundary the accepted carrier supplies the nonempty compact-net witness, so the fold starts from a displayed positive radius row. At each successor probe, the $\mathsf{Rat}^{\uparrow}$ comparison row selects the certified lower of the accumulator and the next half-radius row, and stores the selected row back in L.

Classifier stability follows coordinatewise. Transporting U to U' moves the rational rows through the $\mathsf{Rat}^{\uparrow}$ classifier and moves the bundle membership witnesses through the same displayed finite spine. The recursion therefore reads the transported lower-bound ledger, so the folded precision history is classified with its transported representative. □

Lean4 ✓ `BEDC.Derived.UniformContinuityUp.UniformContinuityCarrier finite net modulus fold`

Theorem 391.4 (UniformContinuity NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{UniformContinuity}^{\uparrow}}$ *obligation surface consists exactly of the following five rows:*

1. *the finite-net carrier row exposing the compact* ProbeBundle*, its center histories, and half-radius coverage witnesses;*
2. *the pointwise-to-uniform modulus fold row of Definition 391.3;*
3. *the* $\mathsf{Rat}^{\uparrow}$ *lower-bound ledger certifying the folded positive precision below every bundled half-radius row;*

4. *the metric triangle transport row carrying the source estimate through a chosen center and then carrying the two target estimates to the final ε bound;*
5. *the non-escape row saying that every consumer-visible modulus read factors through the displayed compact, continuous, rational, metric,* ProbeBundle*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{UniformContinuity}^{\uparrow}}$ *rows.*

Consequently the public certificate exports a tolerance-only uniform-modulus ledger and exports no host-level modulus selector, no unlisted open cover, no sequential compactness argument, and no chosen subsequence.

Lean4 ✓ `BEDC.Derived.UniformContinuityUp.UniformContinuityPacket namecert obligation surface`

Proof. The finite-net row is the compact certificate projected to the displayed ProbeBundle, center histories, and half-radius coverage witnesses. Those rows are already part of the carrier, so the local packet has no hidden cover coordinate.

The pointwise-to-uniform row is the finite fold of Definition 391.3. Its output is a positive $\mathsf{Rat}^{\uparrow}$ history below every bundled half-radius row, and the classifier stability of that theorem gives the corresponding transport field for the local NameCert packet.

The metric row applies the source triangle inequality around the selected center, then applies the target triangle inequality to the two pointwise estimates produced by the continuous certificate. The rational ledger supplies the displayed comparison rows needed to keep the source distances inside the local pointwise radii.

Finally inspect the carrier coordinates of Definition 391.1. They list all dependency certificates, all finite bundle rows, all rational comparison rows, all metric transport rows, and the local naming row. A consumer-visible read must factor through one of these coordinates, so there is no readable slot for an external modulus selector, sequential compactness witness, or host cover. □

Theorem 391.5 (Compact continuous standard reading)**.** *When a classical compact metric source and a continuous graph are presented through* $\mathsf{NameCert}_{\mathsf{Compact}^{\uparrow}}$*,* $\mathsf{NameCert}_{\mathsf{Met}^{\uparrow}}$*, and* $\mathsf{NameCert}_{\mathsf{Continuous}^{\uparrow}}$*, the accepted* $\mathsf{UniformContinuity}^{\uparrow}$ *packet reads as the usual statement that a continuous function on a compact metric space is uniformly continuous. The BEDC reading is the finite certificate surface: for each positive* $\mathsf{Rat}^{\uparrow}$ *tolerance history ε, the packet returns a folded positive* $\mathsf{Rat}^{\uparrow}$ *precision history δ_ε whose validity is witnessed by finite-net coverage, pointwise continuity at bundled centers, rational lower-bound comparison, and metric triangle transport.*

Lean4 ✓ `BEDC.Derived.UniformContinuityUp.UniformContinuityPacket compact continuous standard reading`

Proof. Start with the compact certificate. It supplies the finite ProbeBundle net and the half-radius coverage witnesses for the chosen tolerance scale. The continuous certificate supplies pointwise modulus rows at the bundled centers.

Apply Definition 391.3 to extract the single folded precision history. The fold uses only the displayed rational ledger and is stable under the packet classifier, so it is the public precision read by $\mathsf{NameCert}_{\mathsf{UniformContinuity}^{\uparrow}}$.

For any two accepted source histories whose source distance is below this precision, choose the covering bundled center for the first history. The source triangle row places the second history within the same local pointwise radius, and the target triangle row combines the two pointwise estimates into the displayed tolerance bound. This is precisely the classical Heine–Cantor reading, expressed through finite BEDC certificate rows. □

Theorem 391.6 (UniformContinuity modulus non-escape)**.** *Every consumer-visible modulus row of an accepted* $\mathsf{UniformContinuity}^{\uparrow}$ *packet factors through the compact* $\mathsf{ProbeBundle}$ *row, the* $\mathsf{Continuous}^{\uparrow}$ *pointwise rows, the* $\mathsf{Rat}^{\uparrow}$ *lower-bound ledger, the* $\mathsf{Met}^{\uparrow}$ *triangle rows, and the local* $\mathsf{NameCert}_{\mathsf{UniformContinuity}^{\uparrow}}$ *row of Definition 391.1, with the folded precision supplied by Definition 391.3. The packet exports no host function from tolerances to radii, no open-cover selection, no sequential compactness witness, and no choice-selected center.*

Lean4 ✓ `BEDC.Derived.UniformContinuityUp.UniformContinuityPacket modulus non escape`

Proof. Project the carrier coordinates of Definition 391.1. The only modulus-facing data are the compact $\mathsf{ProbeBundle}$ row P, the center and pointwise rows C and R, the compact coverage row T, the rational lower-bound ledger L, the metric triangle row M, and the local naming row N.

Apply the finite-net fold of Definition 391.3. It constructs the folded precision from the displayed bundle, pointwise rows, and rational ledger, and its classifier stability keeps that folded row inside the same transported packet.

The obligation surface of Definition 391.4 identifies this folded row as the local consumer-visible modulus route. The metric rows then use exactly the displayed triangle transports to turn the folded source precision into the target tolerance estimate.

Inspecting the carrier shape completes the non-escape claim. No coordinate stores a host tolerance-to-radius function, an open-cover selector, a sequential compactness witness, or a choice-selected center, so none of those objects can be exported by a modulus read. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformContinuity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformContinuity}^{\uparrow}$ packet is generated from $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, hsame, Cont, Pkg, and local NameCert rows that display finite-net coverage, pointwise control, rational lower bounds, metric triangle routing, and modulus readback.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformContinuity}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public surface is the compact-continuous modulus export binding the compact ProbeBundle, $\mathsf{Continuous}^{\uparrow}$ pointwise rows, $\mathsf{Rat}^{\uparrow}$ lower-bound ledger, $\mathsf{Met}^{\uparrow}$ triangle rows, hsame, Cont, Pkg, and local NameCert dependencies for the displayed finite-net modulus packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close host modulus selectors, open-cover compactness, sequential compactness, choice-selected centers, or bridge checking.

Upgrade path: No further paper-side theory-closure upgrade remains; formal and bridge checking remain separate axes.

Chapter 392

A Concrete Naming Certificate for $\mathsf{CauchyCriterion}^{\uparrow}$

The $\mathsf{CauchyCriterion}^{\uparrow}$ interface records the explicit constructive Cauchy criterion used by Bishop and Bridges, *Constructive Analysis*, when a real-facing packet is accepted only after a displayed dyadic tail budget has been checked. It is a finite consumer object over $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$: a precision request is read through an explicit modulus, a dyadic tolerance row, a finite tail-bound ledger, a regular rational handoff, and finally a real seal. The certificate does not form quotient streams, identify host real equality, select a limit, or appeal to ambient completeness.

The precision route consumes the sibling carrier rows of chapter 292, chapter 379, chapter 291, and chapter 301 before reaching the $\mathsf{Real}^{\uparrow}$ seal. Thus M, T, Q, and W are not local free parameters: they are imported sibling rows whose finite route is repacked by the $\mathsf{CauchyCriterion}^{\uparrow}$ carrier.

Definition 392.1 (CauchyCriterion carrier)**.** *A* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, M, T, Q, E, H, C, P, N)$$

with the following visible rows:

1. *W is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source window being tested, including the finite rational observations that the consumer may inspect;*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule that assigns to each displayed precision request the tail threshold used by the test;*
3. *T is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *ledger recording the finite comparisons between tail observations beyond the threshold selected by M;*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row whose dyadic budget is used by every comparison in T;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular rational handoff has been accepted;*
6. *H records the componentwise* hsame *transports for the source window, modulus schedule, tail ledger, dyadic tolerance, regular-sequence handoff, and seal rows;*
7. *C records the displayed* Cont *routes by which a consumer reads the modulus, tolerance, finite tail ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal;*
8. *P is the* Pkg *provenance naming the* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *source certificates;*

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCriterion}^\uparrow}$ *provenance row.*

The classifier compares two accepted carriers only by these displayed rows, their componentwise hsame *transports, their* Cont *read routes, their* Pkg *provenance, and their local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier visible packet terminal closure`

Theorem 392.2 (CauchyCriterion tail-bound RealUp seal factorization)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^\uparrow$ *carrier. Every* $\mathsf{Real}^\uparrow$ *seal read exported from K factors through the displayed Cauchy criterion route:*

$$\mathsf{precision} \longmapsto M(\mathsf{precision}) \longmapsto Q \longmapsto T \longmapsto W \longmapsto E.$$

Equivalently, the consumer must pass through the $\mathsf{CauchyModulus}^\uparrow$ *schedule, the* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance row, the finite* $\mathsf{DyadicTailBound}^\uparrow$ *ledger, the* $\mathsf{RegSeqRat}^\uparrow$ *source handoff, and the* $\mathsf{Real}^\uparrow$ *seal. No exported read may use a quotient stream, host real equality, a selected limit, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier tail bound real seal`

Proof. Project the carrier of Definition 392.1. The consumer precision request first reaches the modulus row M, which supplies the displayed tail threshold for the requested precision.

The tolerance coordinate Q and tail ledger T are stored beside that threshold. Reading T therefore uses exactly the dyadic budget named by Q and the finite tail entries selected by M, not an unrecorded rational radius or an external metric estimate.

The source window W is the regular rational handoff for the same inspected tail. Transport along the recorded hsame comparisons and replay the Cont routes in C to keep the modulus, tolerance, ledger, and handoff rows in one visible BHist packet.

Finally the seal coordinate E is reached only after this regular-sequence handoff. The package row P and local certificate row N record the dependency certificates used by the route, and the carrier has no coordinate for quotient streams, host real equality, selected limits, or ambient completeness. Hence every seal read factors through the displayed criterion route. □

Theorem 392.3 (CauchyCriterion NameCert obligation sketch)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyCriterion}^\uparrow}$ *sketch has five rows:*

1. *carrier habitation: the packet of Definition 392.1 stores a* $\mathsf{RegSeqRat}^\uparrow$ *source window, a* $\mathsf{CauchyModulus}^\uparrow$ *schedule, a* $\mathsf{DyadicTailBound}^\uparrow$ *ledger, a* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance row, a* $\mathsf{Real}^\uparrow$ *seal, transport routes, package provenance, and local certificate provenance;*
2. *classifier transport: accepted packets are compared only by componentwise* hsame *and displayed* Cont *routes over the source window, modulus, tolerance, tail ledger, handoff, seal,* Pkg*, and* NameCert *rows;*
3. *tail-budget exactness: every accepted tail comparison uses the threshold supplied by M and the tolerance supplied by Q in the same carrier;*
4. $\mathsf{RegSeqRat}^\uparrow$ *handoff: the finite tail ledger repacks as the visible regular rational source window W before any real-facing seal read is exposed;*
5. $\mathsf{Real}^\uparrow$ *seal non-escape: Definition 392.2 exhausts every exported seal read and withholds quotient streams, host real equality, selected limits, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier namecert obligations`

Proof. The carrier and classifier rows are direct projections of the displayed packet. Since the classifier reads only the named coordinates, componentwise hsame transport and the recorded Cont routes preserve the accepted carrier shape.

Tail-budget exactness is read from the paired coordinates M, Q, and T. The threshold and tolerance used by a comparison are the rows displayed in the same finite packet, so the criterion cannot substitute hidden bounds.

The regular-sequence handoff is the projection to W after the finite tail ledger has been checked. The handoff keeps the inspected observations, threshold, tolerance, and ledger evidence visible to $\mathsf{RegSeqRat}^{\uparrow}$ consumers.

The seal row is supplied by Definition 392.2. It is reached only through the displayed criterion route, so the certificate exports no quotient, host-real, selected-limit, or completeness datum. □

Theorem 392.4 (CauchyCriterion RealObservationBudget tail-budget lock)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet. Let an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *read use the same precision request, the same finite* $\mathsf{RegSeqRat}^{\uparrow}$ *source window, and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row as the readback of K. Then the observation-budget read factors through the finite CauchyCriterion route $M, Q, T, W, E, H, C, P, N$ before any Real-facing seal is public.*

Consequently every such budget read sees the displayed modulus threshold, dyadic tolerance, finite tail ledger, regular rational handoff, real seal, transport, continuation, package, and local naming rows. It receives no quotient stream, host real equality, selected limit, hidden family limit, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier tail budget real observation lock`

Proof. First read the CauchyCriterion seal route. By Definition 392.2, any Real-facing seal exposed by K is reached only after the precision request has passed through the modulus row M, dyadic tolerance row Q, finite tail ledger T, regular rational source row W, and seal row E.

Next read the local naming surface. Definition 392.3 records tail-budget exactness, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and seal non-escape as rows of the same local NameCert, so the shared precision request, source window, and tolerance row cannot be detached from H, C, P, N.

Finally compose with the observation-budget consumer exactness row of Definition 611.9. Since that consumer reads only its displayed precision, window, dyadic, regular handoff, seal, transport, route, provenance, and naming rows, the shared rows force the budget read to pass through the same $M, Q, T, W, E, H, C, P, N$ route before the seal is public. The non-escape clauses on both packets exclude quotient streams, host real equality, selected limits, hidden family limits, and ambient completeness. □

Theorem 392.5 (CauchyCriterion modulus threshold stability)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ and $K' = (W', M', T', Q', E', H', C', P', N')$ be accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carriers. Suppose the classifier relates them by the componentwise* hsame *rows and displayed* Cont *routes for the source window, modulus schedule, tail ledger, dyadic tolerance, regular-sequence handoff, seal row, package provenance, and local* NameCert *provenance. Then every precision request read from either carrier has the same displayed threshold coordinate selected by the transported modulus row and the same dyadic tolerance coordinate selected by the transported Q row. In particular, componentwise transport of the $W, M, T, Q, E, H, C, P, N$ packet preserves the threshold chosen by M and the dyadic tolerance row read by Q.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier modulus threshold stability`

Proof. Project both carriers using Definition 392.1. The only modulus coordinate visible to the classifier is M on the first packet and M' on the transported packet, and the only tolerance coordinate visible to the classifier is Q and Q'.

The hsame rows in H and H' identify the corresponding coordinates, while the Cont routes in C and C' describe how a consumer reaches them. Since the classifier has no access to any further modulus or tolerance carrier, a transported precision request can only be evaluated through the displayed modulus row and the displayed dyadic tolerance row.

The obligation sketch of Definition 392.3 makes this the classifier-transport row for the local NameCert. Repacking those projections shows that the selected threshold and tolerance survive transport unchanged as named rows of the accepted BHist packet. □

Theorem 392.6 (CauchyCriterion dyadic tail ledger exactness)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* CauchyCriterion$^{\uparrow}$ *carrier. Every accepted tail comparison recorded in T is read only through the threshold displayed by M, the dyadic tolerance displayed by Q, the finite* DyadicTailBound$^{\uparrow}$ *ledger row T, and the* DyadicRatCore$^{\uparrow}$ *tolerance certificate named in P. No comparison in T may be justified by an undisplayed modulus threshold, an ambient rational radius, a host-real metric estimate, or a tail-bound certificate outside the same carrier.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier dyadic tail ledger exactness`

Proof. Read the tail comparison from the ledger coordinate T of Definition 392.1. The carrier stores T beside the modulus row M and the dyadic tolerance row Q, so the comparison is indexed by the displayed threshold and the displayed dyadic budget.

The package row P names the DyadicTailBound$^{\uparrow}$ and DyadicRatCore$^{\uparrow}$ source certificates used by this ledger. The Cont routes in C then replay the same read path from the consumer to the threshold, tolerance, and ledger rows.

By Definition 392.3, tail-budget exactness is one of the local NameCert rows. Thus an accepted comparison can be repacked only with the displayed M, Q, T, and P data, and there is no carrier coordinate from which an undisplayed radius, host-real estimate, or external ledger certificate could be exported. □

Theorem 392.7 (CauchyCriterion RegSeqRat handoff exhaustion)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* CauchyCriterion$^{\uparrow}$ *carrier. Any* RegSeqRat$^{\uparrow}$*-to-*Real$^{\uparrow}$ *consumer read exported from K factors through the finite route*

$$W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

Consequently the public read exports only the displayed source window, modulus threshold, dyadic tolerance, tail ledger, and seal row. It exports no quotient stream, selected limit, host real equality, uniqueness-of-limit claim, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier regseqrat handoff exhaustion`

Proof. Begin with the RegSeqRat$^{\uparrow}$ source window W in the carrier of Definition 392.1. A real-facing consumer must then pass through the modulus row M, because the accepted tail entries are defined only beyond the threshold selected by that schedule.

Next the read passes through Q and T. The dyadic row supplies the tolerance, and Definition 392.6 says that the ledger accepts comparisons only through this displayed threshold and tolerance.

Finally the seal coordinate E is reached by the factorization of Definition 392.2. The obligation sketch records this as the regular rational handoff and $\mathsf{Real}^{\uparrow}$ seal non-escape rows, so repacking the route exhausts every exported consumer read without adding quotient streams, selected limits, host real equality, uniqueness of limits, or ambient completeness. □

Theorem 392.8 (CauchyCriterion budgeted shared-tail seal compatibility)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier whose finite regular rational source window is also presented through the* $\mathsf{StreamName}^{\uparrow}$ *shared-tail budget route of Definition 126.400. Then every* $\mathsf{Real}^{\uparrow}$*-facing seal read exported from K factors through one common finite route consisting of the Cauchy modulus schedule M, the dyadic tolerance row Q, the tail ledger T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row W, the finite* $\mathsf{StreamName}^{\uparrow}$ *window rows, the* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *tail-budget coverage row of Definition 757.3, the* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *public shared-threshold certificate of Definition 560.11, and the seal row E.*

The common route exports no quotient stream, selected limit, host real equality, countable-choice tail selector, independent tail oracle, metric completeness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier budgeted shared tail seal compatibility`

Proof. First apply Definition 392.7. It places each consumer route from the regular rational source to the seal inside the displayed W, M, Q, T, E packet and excludes quotient streams, selected limits, host real equality, uniqueness of limits, and ambient completeness.

Next apply Definition 392.2. The seal row E is therefore reached only after the modulus schedule, dyadic tolerance row, finite tail ledger, and regular rational handoff have all been read from the same accepted $\mathsf{CauchyCriterion}^{\uparrow}$ carrier.

Now use Definition 126.400 on the finite StreamName presentation of W. This identifies the same public readback and seal service with the finite $\mathsf{StreamName}^{\uparrow}$ window rows, ProbeBundle, InBundle, UnaryHistory, the dyadic tail-radius ledger, the shared threshold, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the $\mathsf{Real}^{\uparrow}$ finite-window ledger boundary.

Finally cite Definition 757.3 and Definition 560.11. The first fixes the admitted tail-radius read inside the finite precision, tail-window, StreamName-window, and dyadic readback rows; the second fixes the public shared-threshold row used by both the regular rational readback and the seal-facing route. Repacking these identifications gives the single finite route named in the statement, and none of the cited carriers contains a quotient stream, selected limit, host real equality, countable-choice selector, independent tail oracle, metric completeness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle. □

Theorem 392.9 (CauchyCriterion tail-budget coherence consumption)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier whose shared-tail seal route is presented as in Definition 392.8. If a* $\mathsf{TailBudgetCoherence}^{\uparrow}$ *packet consumes this carrier at the Real-completion handoff, then the consumer must read the handoff as one finite boundary through the displayed CauchyCriterion rows M, Q, T, W, E, the finite* $\mathsf{StreamName}^{\uparrow}$ *window rows, the* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *coverage row, the* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *shared-threshold row, and the displayed* $\mathsf{TailBudgetCoherence}^{\uparrow}$ *rows*

$$M_B, O_B, S_B, W_B, D_B, R_B, A_B, L_B, H_B, C_B, P_B, N_B.$$

The consumption route exports no quotient stream, selected limit, host real equality, countable-choice selector, detached tail oracle, metric-completeness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. First apply Definition 392.8. It binds every seal-facing read from K to the finite route through the Cauchy modulus schedule, dyadic tolerance row, tail ledger, regular rational source row, StreamName windows, dyadic tail-radius coverage row, shared threshold row, and seal row E.

Next apply the primitive scope and sibling-scope lock of Definition 917.9 and Definition 917.10. These theorems say that a $\mathsf{TailBudgetCoherence}^{\uparrow}$ consumer has no carrier rows beyond the named TailMeet, observation-budget, selector-budget, agreement-seal, limit-seal, StreamName, regular readback, dyadic-tolerance, transport, continuation, provenance, and local NameCert coordinates.

Finally use the route-scope and seal boundary results Definition 917.11 and Definition 917.6. They force the Real-completion consumer to pass through the TailBudgetCoherence rows only after the finite threshold, budget, window, tolerance, and readback surface has been displayed. Combining this with the CauchyCriterion shared-tail seal route gives one finite boundary, and none of the cited packets supplies quotient streams, selected limits, host real equality, countable-choice selectors, detached tail oracles, metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier tail budget coherence consumption`

Theorem 392.10 (CauchyCriterion tail-budget observer route)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier whose shared-tail route is presented by Definition 392.8. Any observer-budget or finite-window observation consumer of K must factor through the displayed Cauchy modulus schedule M, dyadic tolerance row Q, tail ledger T,* $\mathsf{RegSeqRat}^{\uparrow}$ *source row W, finite* $\mathsf{StreamName}^{\uparrow}$ *window rows, shared-threshold certificate, and Real seal E before observing the public Real-facing endpoint.*

The route exports no quotient stream, selected limit, host real equality, detached tail oracle, or ambient completeness principle.

Proof. Apply Definition 392.8. It places every Real-facing seal read on the shared finite route through M, Q, T, W, the StreamName windows, the dyadic tail-radius coverage row, the regular shared-threshold certificate, and the seal row E.

Next use Definition 392.9. A downstream observation consumer can attach to that route only after the TailBudgetCoherence rows have made the finite threshold, budget, window, tolerance, readback, transport, continuation, package, and local naming data visible.

Finally apply RealObservationBudget consumer exactness, Definition 611.9. It reads observation budgets and finite windows through the same displayed precision and source rows, so the public endpoint is observed only after the Cauchy modulus schedule, tolerance row, tail ledger, source row, shared-threshold certificate, and seal have been exposed. The excluded quotient streams, selected limits, host real equalities, detached tail oracles, and ambient completeness principles are absent from the cited routes. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier tail budget observer route`

Theorem 392.11 (CauchyCriterion uniform-family quotient-refusal factorization)**.** *Let $K = (W, M, T, Q, E, H, C,$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier whose shared-tail route is presented through the budgeted seal theorem of Definition 392.8. Any finite-family or uniform-family consumer that asks for quotient-name equality, a selected limit, host real equality, hidden tail data, or ambient completeness must first consume the displayed CauchyCriterion rows M, Q, T, W, E, the finite* $\mathsf{StreamName}^{\uparrow}$ *window rows, the* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *coverage row, the* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *shared-threshold row, the displayed* $\mathsf{TailBudgetCoherence}^{\uparrow}$ *rows, and then the* $\mathsf{QuotientStreamRefusal}^{\uparrow}$ *refusal row of Definition 998.13.*

Consequently the accepted carrier exports no quotient stream, selected limit, host equality, tail oracle, metric-completeness row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle to such a family consumer.*

Proof. Apply Definition 392.8. This places every seal-facing read from K on the finite shared-tail route through M, Q, T, W, E, the StreamName window rows, the dyadic tail-radius coverage row, and the regular shared-threshold row.

Next apply Definition 392.9. A Real-completion family consumer can therefore attach to the route only after the TailBudgetCoherence rows have been displayed as threshold, budget, window, tolerance, readback, transport, continuation, package, and local naming data.

Now route the family request through Definition 998.13. A regular-tail read that reaches Real-completion must pass through the displayed StreamName, RegSeqRat, CauchyLimitSeal, RealUp seal, and refusal-ledger rows before any quotient-style request is interpreted.

Finally use Definition 998.11. Requests for quotient streams, selected limits, host real equality, hidden tail data, metric-completeness rows, or ambient $\mathsf{Real}^{\uparrow}$ completeness are off the displayed route and are sent to the refusal ledger rather than exported as witnesses. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier uniform family quotient refusal factorization`

Definition 392.12 (CauchyCriterion classifier)**.** *For accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carriers*

$$K = (W, M, T, Q, E, H, C, P, N) \qquad \text{and} \qquad K' = (W', M', T', Q', E', H', C', P', N'),$$

the $\mathsf{CauchyCriterion}^{\uparrow}$ *classifier relates* K *and* K' *exactly when the accepted packets agree componentwise on the displayed source window, modulus schedule, tail ledger, dyadic tolerance, seal row, transport ledger, continuity-route ledger, package provenance, and local certificate provenance.*

Thus the comparison is the finite conjunction of the corresponding hsame *rows and displayed* Cont *route comparisons over* $W, M, T, Q, E, H, C, P, N$*. It has no additional coordinate for quotient streams, hidden real equality, selected limits, uniqueness of limits, or ambient completeness.*

Lean4 (definition) `BEDC.Derived.CauchyCriterionUp.CauchyCriterionClassifier`
Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionClassifier endpoint transport closure`

Theorem 392.13 (CauchyCriterion precision route normal form)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier. Every accepted precision read exported from* K *has the normal form*

$$\mathsf{precision} \longmapsto M \longmapsto Q \longmapsto T \longmapsto W \longmapsto E.$$

The only rows used by this factorization are the displayed BHist *packet, the componentwise* hsame *transports in* H*, the displayed* Cont *routes in* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterion}^{\uparrow}}$ *row* N*.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionRoute precision endpoint closure`

Proof. Start with the carrier projection of Definition 392.1. A precision request first reads the modulus schedule M, which selects the finite threshold at which the tail ledger is inspected.

The dyadic tolerance row Q supplies the comparison budget, and the ledger row T records the accepted finite tail comparisons for that threshold and tolerance. The exactness statement of Definition 392.6 prevents replacing these rows by an undisplayed radius or an outside tail certificate.

The regular rational source row W is then the only handoff available before the seal row E. The exhaustion theorem Definition 392.7 and the seal factorization of Definition 392.2 show that every real-facing read passes through these rows.

Transport along H and replay the routes in C to keep the read inside the same finite BHist packet. The package row P and the certificate row N record the source certificates; no remaining carrier coordinate can export quotient streams, selected limits, host real equality, or ambient completeness. □

Theorem 392.14 (CauchyCriterion obligation closure package)**.** *The* $\mathsf{CauchyCriterion}^{\uparrow}$ *chapter presents an obligation-complete paper package for the explicit constructive Cauchy criterion over the displayed finite carrier. The package consists of the carrier of Definition 392.1, the classifier of Definition 392.12, tail-budget exactness from Definition 392.6, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff exhaustion from Definition 392.7, the* $\mathsf{Real}^{\uparrow}$ *seal factorization from Definition 392.2, and the non-escape boundary forbidding quotient streams, selected limits, host real equality, uniqueness-of-limit claims, and ambient completeness.*

Consequently a future formal target for $\mathsf{CauchyCriterion}^{\uparrow}$ *may use this chapter as the paper-side obligation surface for carrier transport, classifier stability, dyadic tail-budget exactness, regular rational handoff exactness, and* $\mathsf{Real}^{\uparrow}$ *seal factorization, without claiming Lean verification or real completeness here.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier obligation closure package`

Proof. The carrier and classifier are displayed by Definition 392.1 and Definition 392.12. They identify the finite packet and the componentwise comparison rows on which every accepted read depends.

Tail-budget exactness is supplied by Definition 392.6. It binds each comparison to the same displayed modulus threshold, dyadic tolerance, tail ledger, and package provenance.

The regular rational handoff is exhausted by Definition 392.7. The precision-route normal form of Definition 392.13 then names the only route by which a precision request can reach a real-facing seal.

Finally Definition 392.2 supplies the $\mathsf{Real}^{\uparrow}$ seal factorization and the non-escape boundary. Repacking these clauses gives the stated paper-side obligation package while leaving Lean verification, quotient construction, selected limits, host real equality, uniqueness of limits, and ambient completeness outside the claim. □

Theorem 392.15 (CauchyCriterion scoped tail-seal transport)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier. Any transported precision read that preserves the displayed* BHist *packet, the componentwise* hsame *rows in* H*, the displayed* Cont *routes in* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterion}^{\uparrow}}$ *row* N *factors through the kernel-visible route*

$$M \longmapsto Q \longmapsto T \longmapsto W \longmapsto E.$$

This factorization is stable under the classifier of Definition 392.12: classifier-related carriers transport the same modulus row, dyadic tolerance row, finite tail ledger, regular rational handoff, and $\mathsf{Real}^{\uparrow}$ *seal row as a single scoped packet.*

The scoped route introduces no quotient stream, selected limit, host real equality, uniqueness-of-limit claim, or ambient completeness row.

Proof. First project the precision route normal form of Definition 392.13. It identifies the only displayed route from a precision request to the real-facing seal, namely the passage through M, Q, T, W, and E inside the same carrier.

The dyadic tail ledger is exact by Definition 392.6. Hence the transported read cannot replace M, Q, or T by an undisplayed threshold, an outside radius, or an external tail certificate.

Next use Definition 392.7. The finite ledger reaches the regular rational source window W before any $\mathsf{Real}^{\uparrow}$ seal row is exposed, so the handoff is part of the same scoped packet rather than a separate stream quotient.

Finally apply the seal factorization of Definition 392.2. The classifier of Definition 392.12 preserves exactly the displayed carrier rows and their hsame, Cont, Pkg, and NameCert witnesses, so the same $M \longmapsto Q \longmapsto T \longmapsto W \longmapsto E$ route is transported to any classifier-related carrier. Since none of the excluded analytic data is a coordinate of the carrier, none is introduced by the scoped transport. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier scoped tail seal transport`

Theorem 392.16 (CauchyCriterion classifier stability scope)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ and $K' = (W', M', T', Q', E', H', C', P', N')$ be accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carriers. If the classifier of Definition 392.12 relates K and K', then the comparison is scoped by one finite dependency packet: the carrier rows W, M, T, Q, E, the transport rows in H and H', the displayed* Cont *routes in C and C', the* Pkg *rows P, P', and the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterion}^{\uparrow}}$ *rows N, N'. Under this packet, classifier stability preserves the same* BHist *source,* hsame *transport data,* Cont *read routes,* Pkg *provenance,* NameCert *provenance, dyadic tail ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal rows, and it introduces no quotient stream, selected limit, host real equality, uniqueness-of-limit claim, or ambient completeness coordinate.*

Proof. Project the classifier definition. Its only comparison clauses are the componentwise rows for $W, M, T, Q, E, H, C, P, N$ and the corresponding primed rows, so the carrier and classifier are already bound to the same displayed BHist packet.

The modulus threshold and tolerance coordinates are stable by Definition 392.5. These clauses identify the route by which a consumer reads M and Q after transport.

The tail ledger and regular rational handoff remain inside the same packet by Definition 392.6 and Definition 392.7. The seal row is then reached by Definition 392.2.

Thus every classifier-related read is repacked through H, H', C, C', P, P', and N, N' over the displayed carrier rows. Since the classifier has no field for the excluded analytic data, stability cannot export such a field. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier classified tail budget transport`

Theorem 392.17 (CauchyCriterion tail-budget scope)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier. Every scoped tail-budget read in K is bound to the same finite packet as the carrier and classifier: the displayed* BHist *row for K, the* hsame *transports in H, the* Cont *routes in C, the* Pkg *provenance row P, the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterion}^{\uparrow}}$ *row N, the dyadic threshold and tolerance rows M, Q, the tail ledger T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row W, and the* $\mathsf{Real}^{\uparrow}$ *seal row E. Consequently tail-budget exactness is not a separate analytic assumption; it is the packet-local claim that each accepted comparison uses the threshold selected by M and the dyadic budget recorded by Q before reaching W and E.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionTasteGate single carrier alignment`

Proof. Begin with the ledger projection T. The exactness theorem Definition 392.6 says that each accepted comparison in T is read through the displayed threshold M, tolerance Q, ledger row T, and package provenance P.

The hsame and Cont rows keep that ledger read in the same carrier. The transport row H records componentwise sameness for the carrier rows, while C records the consumer route by which the threshold, tolerance, and ledger are reached.

The handoff to W is supplied by Definition 392.7, and the seal row E is supplied by Definition 392.2. These two results bind the tail budget to the regular rational source and the real-facing seal without adding a new carrier coordinate.

Repacking the displayed clauses with the local NameCert row N gives the stated scoped tail-budget packet. No outside modulus, rational radius, host metric estimate, selected limit, or ambient completeness datum can enter, because none is a row of K. □

Theorem 392.18 (CauchyCriterion shared tail-budget seal comparison)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ and $K' = (W', M', T', Q', E', H', C', P', N')$ be accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carriers related by the classifier of Definition 392.12. Suppose their modulus rows and dyadic tolerance rows select the same displayed tail-budget packet. Then the two* $\mathsf{Real}^{\uparrow}$ *seal reads factor through the same finite route*

$$M \longmapsto Q \longmapsto T \longmapsto W \longmapsto E$$

and

$$M' \longmapsto Q' \longmapsto T' \longmapsto W' \longmapsto E',$$

with the two routes compared only by the shared tail-budget rows, componentwise hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows. The comparison exports no selected limit, uniqueness-of-limit claim, host metric estimate, quotient stream equality, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier shared tail budget seal comparison`

Proof. First apply the classifier stability scope of Definition 392.16. The comparison of K and K' is already confined to the displayed carrier rows, the componentwise hsame rows, the Cont routes, provenance, and local certificates.

Use the tail-budget scope of Definition 392.17. The shared modulus and dyadic tolerance hypothesis identifies the tail-budget packet read by M, Q, T with the packet read by M', Q', T'.

Next apply the scoped tail-seal transport theorem Definition 392.15. It forces each transported precision read to pass through the finite route from modulus to dyadic tolerance, tail ledger, regular rational handoff, and seal row.

Finally use the precision route normal form of Definition 392.13. Repacking the two displayed routes through the shared tail budget gives the stated comparison. None of the cited carrier rows contains selected limits, uniqueness of limits, host metric estimates, quotient equality, host real equality, or ambient completeness, so those objects cannot be exported. □

Theorem 392.19 (CauchyCriterion RealUp seal scope)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier. The* $\mathsf{Real}^{\uparrow}$ *seal row E is scoped by the same finite packet that supports the carrier, classifier, dyadic tail ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff. In particular, every exported seal read factors through M, Q, T, and W while retaining the displayed* BHist *carrier,* hsame *transport rows,* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchyCriterion}^{\uparrow}}$ *row. The seal scope therefore records a packet-local endpoint for the constructive Cauchy criterion and does not assert real completeness, quotient equality of streams, a selected limit, host real equality, or uniqueness of limits.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier real seal scope`

Proof. Use the precision route normal form of Definition 392.13. It gives the displayed path from a precision request through M, Q, T, W, and E inside the carrier.

The scoped tail-seal transport theorem Definition 392.15 keeps this path stable under the carrier transports, Cont read routes, package provenance, and local certificate row. Thus the seal is not read from a separate real object or an ambient limit construction.

The classifier stability scope of Definition 392.16 then shows that classifier-related carriers preserve the same seal-facing dependency packet. The tail-budget scope of Definition 392.17 supplies the exact threshold, tolerance, and ledger rows used before the handoff reaches W.

Finally apply Definition 392.2. The seal row is the endpoint of the displayed constructive criterion route, and the carrier has no coordinate for completeness, quotient equality, selected limits, host real equality, or uniqueness of limits. □

Theorem 392.20 (CauchyCriterion public certificate)**.** *The carrier, classifier, tail-bound* $\mathsf{Real}^{\uparrow}$ *seal factorization,* NameCert *obligation sketch, modulus threshold stability, dyadic tail ledger exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff exhaustion, precision route normal form, obligation closure package, scoped tail-seal transport, classifier stability scope, tail-budget scope, and* $\mathsf{Real}^{\uparrow}$ *seal scope assemble one exported* $\mathsf{CauchyCriterion}^{\uparrow}$ *public certificate over* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{DyadicTailBound}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

This certificate is exactly the finite constructive Cauchy criterion packet of Definition 392.1 and Definition 392.12. It preserves the exclusions on quotient streams, selected limits, host real equality, uniqueness of limits, ambient completeness, and bridge checking.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier public certificate`

Proof. First take the carrier and classifier from Definition 392.1 and Definition 392.12. These two displays provide the finite BHist packet, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local $\mathsf{NameCert}_{\mathsf{CauchyCriterion}^{\uparrow}}$ row.

Next attach the obligation rows. The tail-bound seal factorization is Definition 392.2, the local naming obligations are Definition 392.3, and the modulus threshold stability is Definition 392.5.

The dyadic and rational handoff data come from Definition 392.6, Definition 392.7, and Definition 392.13. Together they force every precision route through the displayed modulus, dyadic tolerance, finite tail ledger, regular rational source window, and seal row.

Finally repack the scoped surface using Definition 392.14, Definition 392.15, Definition 392.16, Definition 392.17, and Definition 392.19. Since each cited theorem stays inside the same visible packet and records the same non-escape boundary, the assembled public certificate exports no quotient stream, selected limit, host real equality, uniqueness-of-limit claim, ambient completeness principle, or checked bridge. □

Theorem 392.21 (CauchyCriterion Real-completion consumer bridge)**.** *Every exported* $\mathsf{CauchyCriterion}^{\uparrow}$ *public packet consumed by a* $\mathsf{Real}^{\uparrow}$ *or completion-facing interface factors through the displayed modulus, dyadic tolerance, finite tail ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *window,* $\mathsf{Real}^{\uparrow}$ *seal row,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row of the same finite carrier. The bridge exports no quotient stream, selected limit, host real equality, uniqueness-of-limit claim, ambient completeness principle, or bridge-checked verification.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier real completion consumer bridge`

Proof. Start from the public packet of Definition 392.20. It already assembles the carrier, classifier, tail-bound seal factorization, local naming obligations, modulus threshold stability, dyadic tail ledger exactness, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, precision route normal form, scoped transport, classifier stability, tail-budget scope, and $\mathsf{Real}^{\uparrow}$ seal scope.

The consumer-facing route is the same finite route. The modulus threshold is fixed by Definition 392.5, the dyadic tolerance and tail ledger are fixed by Definition 392.6, and the regular rational handoff is fixed by Definition 392.7.

The $\mathsf{Real}^{\uparrow}$ endpoint is then read through Definition 392.2, Definition 392.13, Definition 392.15, and Definition 392.19. These theorems keep the endpoint inside the carrier rows rather than turning it into a host completeness assertion.

Repack those rows as the downstream bridge. Since every cited clause remains inside the displayed packet and the public certificate explicitly preserves the same exclusions, a Real-facing or completion-facing consumer receives the constructive criterion route but no quotient stream, selected limit, host real equality, uniqueness-of-limit theorem, ambient completeness principle, or checked bridge status. □

Theorem 392.22 (CauchyCriterion modulus-tail consumer exactness)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier. The modulus row M, dyadic tail ledger T,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff W, and* $\mathsf{Real}^{\uparrow}$ *seal row E determine the same consumer-visible tail bound for every* $\mathsf{Real}^{\uparrow}$ *or completion-facing readback route through H, C, P, N.*

Equivalently, any such consumer route reads the tail bound by passing through the displayed modulus threshold, the same dyadic tolerance row, the same finite tail ledger, the same regular rational handoff, and the same real seal. It cannot obtain a different bound from quotient streams, selected limits, host real equality, uniqueness of limits, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier modulus tail consumer exactness`

Proof. Start with Definition 392.5. It fixes the threshold row M as the only modulus-facing entry point for a precision request in the carrier.

Apply Definition 392.6. The dyadic tolerance row and finite tail ledger T read the bound attached to that threshold, so a consumer cannot switch to a different tail comparison after the modulus row has been fixed.

Use Definition 392.7. The handoff row W exhausts the regular rational source window that can feed the tail ledger, and the route still passes through the displayed transport, continuation, package, and local naming rows.

Finally apply Definition 392.21. The $\mathsf{Real}^{\uparrow}$ and completion-facing consumer routes read the same seal row E after the modulus, ledger, and handoff rows have been fixed, so the consumer-visible tail bound is exact for every displayed readback route. □

Theorem 392.23 (CauchyCriterion tail-budget seal determinacy)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ and $K' = (W', M', T', Q', E', H', C', P', N')$ be accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packets. If they display the same modulus row, dyadic tolerance row, finite tail ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, then they expose the same* $\mathsf{Real}^{\uparrow}$ *seal route through H, C, P, N. The seal route cannot be changed by quotient stream equality, a selected limit, host real equality, uniqueness of limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier tail budget seal determinacy`

Proof. Start with the shared tail-budget seal comparison of Definition 392.18. The seal row is read from the displayed modulus threshold, dyadic tail ledger, regular rational handoff, and real endpoint, not from an ambient limit construction.

Use Definition 392.19. The $\mathsf{Real}^{\uparrow}$ seal remains inside the carrier rows together with the displayed transports, continuations, package provenance, and local naming row.

Finally apply Definition 392.22. Once the modulus row, dyadic tolerance row, tail ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff are the same, every completion-facing readback route sees the same consumer-visible tail bound and hence the same seal route through H, C, P, N. □

Theorem 392.24 (CauchyCriterion RegSeqRat Real route lock)**.** *Every accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *public* $\mathsf{Real}^{\uparrow}$*-seal consumer factors through the Cauchy tail-bound row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the dyadic tolerance ledger, and the* $\mathsf{Real}^{\uparrow}$ *seal row of the displayed packet. No such consumer may pass through host real equality, a selected external limit, a quotient stream, or an ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier regseqrat real route lock`

Proof. Start with Definition 392.2. It places the tail-bound read inside the displayed modulus, dyadic tolerance, tail ledger, regular rational source, and real seal rows of the accepted packet.

Next use Definition 392.7. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff exhausts the regular rational source rows available to the CauchyCriterion consumer, so the route cannot replace them by quotient stream data or a selected external limit.

The finite-window input is supplied by Definition 126.79, and the real endpoint is kept inside the packet by Definition 392.19. Thus the consumer route reaches $\mathsf{Real}^{\uparrow}$ through the same finite window, source row, dyadic ledger, and seal row.

Finally apply Definition 392.23. Any route with the same modulus row, dyadic tolerance row, finite tail ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff exposes the same $\mathsf{Real}^{\uparrow}$ seal route through H, C, P, N, so alternate routes using host equality, external limits, quotient streams, or ambient completeness coordinates are ruled out. □

Theorem 392.25 (CauchyCriterion completion-facing readback normal form)**.** *Every completion-facing consumer route for an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet normalizes to the displayed route*

$$M \to Q \to T \to W \to E$$

together with the transport, continuation, provenance, and local naming rows H, C, P, N*. No normal form may use a selected limit, quotient stream, host real equality, uniqueness-of-limit theorem, ambient completeness principle, or unrecorded completion object.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier completion facing readback normal form`

Proof. First use the public certificate Definition 392.20. It assembles the carrier, classifier, modulus row, dyadic tolerance row, finite tail ledger, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{Real}^{\uparrow}$ seal, transports, continuations, provenance, and local certificate into one finite packet.

Next apply Definition 392.21. Every completion-facing consumer factors through the same displayed modulus, dyadic tolerance, finite tail ledger, regular rational window, and real seal route.

The exactness theorem Definition 392.22 fixes the order of the readback: the modulus row feeds the dyadic tolerance and tail ledger, the ledger feeds the regular rational handoff, and the handoff reaches the $\mathsf{Real}^{\uparrow}$ seal through H, C, P, N.

Thus the consumer route has the stated normal form and has no coordinate from which to read selected limits, quotient stream equality, host real equality, uniqueness of limits, ambient completeness, or an unrecorded completion object. □

Theorem 392.26 (CauchyCriterion RegSeqRat StreamName RealUp handoff)**.** *Let $K = (W, M, T, Q, E, H, C, P, N$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier. Suppose the W row is read from a finite public* $\mathsf{StreamName}^{\uparrow}$ *observation window and is accepted by the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff. Then every* $\mathsf{Real}^{\uparrow}$ *seal read of K factors through exactly the route*

$\mathsf{StreamName}^{\uparrow}$ *finite window* $\to$ $\mathsf{RegSeqRat}^{\uparrow}$ *source row* $\to$ $\mathsf{CauchyModulus}^{\uparrow}, \mathsf{DyadicTailBound}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}$ *budg*

No quotient stream, selected host limit, host real equality, or ambient completeness row can enter this route.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier regseqrat streamname realup handoff`

Proof. Start with the carrier definition. Its displayed rows expose the regular rational handoff W, modulus row M, tail ledger T, dyadic tolerance row Q, real seal row E, and the transport, continuation, provenance, and local naming rows H, C, P, N.

Apply Definition 392.2. The tail-bound budget is read through the modulus, dyadic tolerance, tail ledger, and real seal rows already present in K.

Use Definition 392.7. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff exhausts the finite source rows available from the displayed observation window, so the source cannot be replaced by a quotient stream or by a selected host limit.

Finally apply Definition 392.25. The completion-facing route normalizes to the same displayed rows. Together with the sibling inputs named in the chapter introduction for $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, this binds every seal read to the stated finite handoff route and excludes host real equality and ambient completeness rows. □

Theorem 392.27 (CauchyCriterion diagonal-budget readback compatibility)**.** *Let $K = (W, M, T, Q, E, H, C, P, N$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier, and let $B = (\epsilon, M_B, W_B, D_B, K_B, S_B, H_B, C_B, P_B, N_B)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *packet through which the W, Q, E rows of K are read by a completion-facing consumer. Then every such readback first normalizes to the CauchyCriterion route*

$$M \to Q \to T \to W \to E$$

with H, C, P, N, and then to the diagonal-budget route

$$\epsilon \to M_B \to W_B \to D_B \to K_B \to S_B$$

with H_B, C_B, P_B, N_B. No quotient stream, selected limit, host real equality, uniqueness-of-limit theorem, trichotomy row, or ambient completeness coordinate may enter either side of the readback.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier diagonal budget readback compatibility`

Proof. First apply Definition 392.25. It normalizes every completion-facing read of K to $M \to Q \to T \to W \to E$ with the displayed transport, continuation, provenance, and naming rows.

Next use Definition 392.26. The W row is read through the finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ handoff, while Q supplies the dyadic budget row and E supplies the $\mathsf{Real}^{\uparrow}$ seal.

Now pass to the diagonal-budget selector. The route factorization theorem Definition 853.14 identifies every completion-facing read through B with the finite route from ϵ through M_B, W_B, D_B, K_B to S_B.

Finally apply Definition 853.19 and Definition 853.31. These keep the RegSeqRat-to-Real handoff and the shared-tail modulus seal on the displayed diagonal-budget route.

The non-escape scope theorem Definition 853.24 then rules out quotient streams, selected limits, host real equality, uniqueness-of-limit inputs, trichotomy rows, and ambient completeness coordinates. □

Theorem 392.28 (CauchyCriterion RealTailAgreementSeal route correspondence)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet. Every accepted completion-facing consumer of* K *whose* $\mathsf{Real}^{\uparrow}$ *seal is mediated by an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet factors through the same finite route*

$$\mathsf{ObservationBudgetLimiter}^{\uparrow},\ \mathsf{RegularCauchyTailBudget}^{\uparrow},\ \mathsf{RegularCauchyTailMeet}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{R}$$

Conversely, every terminal $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *route supplies the CauchyCriterion tail-budget,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows needed by Definition 392.26. The correspondence exports no selected limit, quotient-stream equality, uncapped observation, host real equality, ambient completeness principle, or second agreement coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier real tail agreement seal route correspondence`

Proof. Start from the CauchyCriterion handoff theorem Definition 392.26. It fixes the $\mathsf{StreamName}^{\uparrow}$ source window, the $\mathsf{RegSeqRat}^{\uparrow}$ source row, the dyadic budget rows, and the $\mathsf{Real}^{\uparrow}$ seal as the only displayed handoff route for the accepted packet.

The tail-budget seal determinacy theorem Definition 392.23 and the completion-facing readback normal form Definition 392.25 then force every completion-facing consumer to read the same budget, regular rational, and real-seal rows before any $\mathsf{Completion}^{\uparrow}$ surface is exposed.

For the mediated case, apply Definition 699.20 and Definition 699.21. These identify the terminal $\mathsf{RealTailAgreementSeal}^{\uparrow}$ consumer route as the finite path through the observation cap, regular Cauchy tail budget, shared tail meet, finite stream window, dyadic readback, agreement row, and the displayed $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ seal rows.

Projecting this terminal route back to the CauchyCriterion rows gives the forward factorization. Reading it in the other direction supplies exactly the tail-budget, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal rows required by the handoff theorem, while the non-escape clauses on both packets exclude every host, quotient, uncapped, completeness, or second-agreement route. □

Theorem 392.29 (CauchyCriterion and finite-family UniformCauchyCriterion route agreement)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet. Let* U *be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose finite-family ledger is either singleton or a fixed finite family with the same displayed shared window row* W*, shared modulus row* M*, dyadic tolerance row* Q*, tail ledger* T*, and real seal row* E*. Assume that both packets consume the same* $\mathsf{StreamName}^{\uparrow}$ *source route, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *tail route, and the same* $\mathsf{Real}^{\uparrow}$ *seal route as displayed by chapter 126, chapter 301, and chapter 38. Then the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *family route restricts to the same finite* $\mathsf{CauchyCriterion}^{\uparrow}$ *route*

$$M \to Q \to T \to W \to E.$$

Equivalently, the singleton or fixed finite family packet exposes no additional route beyond the CauchyCriterion modulus, tolerance, tail, window, and seal rows. The correspondence uses Definition 392.28, Definition 435.9, and Definition 435.11, and exports no quotient stream, selected limit, host real equality, ambient completeness principle, or independently chosen family limit.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier uniformcriterion finite family reduction`

Proof. Project the CauchyCriterion packet first. By Definition 392.28, the accepted K packet exposes the finite seal route through its displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, and this route is exactly the CauchyCriterion handoff through M, Q, T, W, E.

Now project the uniform packet along its singleton or fixed finite family ledger. The hypotheses identify the shared window row with W, the shared modulus row with M, the dyadic tolerance row with Q, the tail ledger with T, and the seal row with E componentwise.

Apply Definition 435.9. It says that every accepted family tail comparison in U is read through the displayed uniform tail ledger after the shared window, shared modulus, and dyadic tolerance rows have already been fixed.

Apply Definition 435.11. The $\mathsf{RegSeqRat}^{\uparrow}$ consumer therefore sees the same finite tail evidence as the ledger route, so the family-side readback cannot insert a second stream source, a second modulus schedule, or an unrecorded tolerance row.

The cited $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ construction chapters fix the source, tail, and seal carriers used by both packets. After the componentwise identifications above, the uniform route and the single CauchyCriterion route expose the same finite path $M \to Q \to T \to W \to E$. The non-export clauses on the two packets then exclude quotient streams, selected limits, host real equality, ambient completeness, and any additional family-limit object. □

Theorem 392.30 (CauchyCriterion CompleteMetric consumer boundary)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet* $K = (W, M, T, Q, E, H, C, P, N)$ *must pass through the displayed tail-budget route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the* $\mathsf{Real}^{\uparrow}$ *seal before any completion-facing use. The consumer cannot import quotient streams, selected limits, host real equality, ambient completeness, or uniqueness of limits.*

Proof. Apply Definition 392.29 and Definition 392.28. They force the finite tail route through M, Q, T, W, E and place the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before completion-facing readback.

The terminal completion routes below then expose only the same sealed endpoint to $\mathsf{CompleteMetric}^{\uparrow}$ consumers. Since the packet has no quotient stream, selected limit, host equality, ambient completeness, or uniqueness-of-limit coordinate, the displayed tail-budget and Real-seal route is the whole consumer boundary. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier complete metric consumer boundary`

Theorem 392.31 (CauchyCriterion four-face pullback correspondence)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet. Suppose its* $\mathsf{StreamName}^{\uparrow}$ *finite window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and budget row,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail and readback row, and* $\mathsf{Real}^{\uparrow}$ *seal row agree componentwise with a terminal four-face finite section. Then the* $\mathsf{CauchyCriterion}^{\uparrow}$ *consumer route*

$$M \to Q \to T \to W \to E$$

corresponds exactly to that four-face terminal pullback. Conversely, any terminal four-face pullback with those four rows supplies the same displayed $\mathsf{CauchyCriterion}^{\uparrow}$ *route. The correspondence exports no quotient stream equality, selected limit, host sequence equality, ambient Real completeness, metric-completeness datum, countable-choice row, or bridge row.*

Proof. For the forward direction, apply Definition 392.28 and Definition 392.30. These identify every CauchyCriterion consumer with the displayed finite route through M, Q, T, W, E before any completion-facing readback is allowed.

Next apply Definition 126.592 and Definition 126.586. Since the StreamName window, dyadic tolerance and budget, RegSeqRat tail readback, and Real seal rows are the same displayed rows, terminality reads the CauchyCriterion route as the unique four-face pullback route.

For the reverse direction, start with such a terminal four-face pullback and project its four faces. The projected rows are precisely W, Q, T, E, while the accepted packet supplies the modulus row M and the existing H, C, P, N certificates. Repacking these displayed rows gives the same route $M \to Q \to T \to W \to E$.

The final exclusions are coordinate exclusions. None of the cited terminality or boundary results adds a quotient equality, a selected limit, host sequence equality, Real completeness, metric completeness, countable choice, or a bridge certificate, so the correspondence is only the finite BEDC pullback described above. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier streamname four face pullback correspondence`

Theorem 392.32 (CauchyCriterion completion uniform-family factorization)**.** *Let $K = (W, M, T, Q, E, H, C, P, N$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, and let U be an accepted singleton or fixed finite-family* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet with the same displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. If the two packets identify the shared window, shared modulus, dyadic tolerance, tail ledger, and real-seal rows as in Definition 392.29, then they expose the same completion-facing route before any* $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer can read the seal.*

The factorized route is the finite path through M, Q, T, W, E together with the shared stream-name source, regular-rational readback, dyadic ledger, BHist, hsame, Cont, Pkg, *and* NameCert *rows. It exports no quotient stream, selected limit, host real equality, ambient completeness principle, unrecorded completion object, or independently chosen family limit.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier completion uniform family factorization`

Proof. Start from Definition 392.29. It identifies the singleton or fixed finite-family uniform route with the same CauchyCriterion path $M \to Q \to T \to W \to E$ once the stream-name, regular-rational, dyadic, and real-seal rows agree.

Next apply Definition 392.25. The completion-facing consumer can read only the displayed CauchyCriterion rows, so the seal is reached through the same window, modulus, tolerance, tail, and real row.

Finally use Definition 435.21. It transports the downstream $\mathsf{Real}^{\uparrow}$ consumer on the uniform packet through the same finite family ledger. Combining these consumer clauses gives one route for $\mathsf{Completion}^{\uparrow}$ and $\mathsf{RealCauchyCompletion}^{\uparrow}$, with the quotient, selected-limit, host-equality, completeness, unrecorded-completion, and second-family-limit exits absent. □

Theorem 392.33 (CauchyCriterion tail-budget Real completion boundary)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet. Any* $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer sharing the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows must factor through the finite route $M, Q, T, W, E, H, C, P, N$ before it can read a completion seal. Conversely, a consumer that displays this route has exactly the CauchyCriterion completion-boundary data available, with no quotient stream, selected limit, host real equality, ambient completeness row, or unrecorded completion object.*

Proof. Apply Definition 392.2 and Definition 392.25. They place every Real-facing seal and completion-facing read behind the displayed modulus, tolerance, tail, window, and seal rows of K.

Next use Definition 392.32. It identifies the same finite route for singleton and fixed finite-family consumers sharing the displayed source rows. The RealCauchyCompletion$^{\uparrow}$ chapter is then read as the downstream consumer surface: it receives only the route already exposed by K, and a consumer that already has $M, Q, T, W, E, H, C, P, N$ has all completion-boundary rows that the CauchyCriterion packet exports. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier tail budget real completion boundary`

Theorem 392.34 (CauchyCriterion terminal RegSeqRat Real completion route)**.** *Let $K = (W, M, T, Q, E, H, C, P$ be an accepted* CauchyCriterion$^{\uparrow}$ *packet. Any terminal Real-and-Completion consumer sharing the displayed* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyModulus$^{\uparrow}$, UniformCauchyCriterion$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows factors through the finite route*

$$M, Q, T, W, E, H, C, P, N.$$

The route reads the stream-name source, regular-rational sequence row, dyadic tolerance core, Cauchy modulus schedule, uniform Cauchy criterion packet, and Real seal through the same visible BHist, hsame, Cont, Pkg, *and* NameCert *support rows. It exports no quotient stream, selected limit, host real equality, uniqueness-of-limit theorem, ambient completeness principle, or unrecorded completion object.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier terminal regseqrat real completion route`

Proof. First apply Definition 392.32. It identifies the singleton and fixed finite-family UniformCauchyCriterion$^{\uparrow}$ completion-facing reads with the same finite CauchyCriterion route before any completion consumer can read the Real seal.

Next use Definition 392.33. It confines every Completion$^{\uparrow}$ or RealCauchyCompletion$^{\uparrow}$ consumer sharing the displayed StreamName, RegSeqRat, DyadicRatCore, and Real rows to $M, Q, T, W, E, H, C, P, N$.

Now attach the RegSeqRat and StreamName handoff by Definition 392.26. This places the stream source, regular-rational readback, dyadic budget, and Real-facing read on the same packet.

Finally use Definition 392.28. The Real tail-agreement seal is already routed through the same modulus, tolerance, tail, window, and support rows, so a terminal consumer that asks for the displayed six source rows receives exactly the finite route above. The carrier has no coordinate for quotient streams, selected limits, host real equality, uniqueness-of-limit data, ambient completeness, or any off-route completion object. □

Theorem 392.35 (CauchyCriterion mature downstream examples)**.** *The public certificate, real-completion consumer bridge, modulus-tail consumer exactness, tail-budget seal determinacy, and completion-facing readback normal form for an accepted* CauchyCriterion$^{\uparrow}$ *packet give representative downstream consumers for the same displayed rows*

$$W, M, T, Q, E, H, C, P, N.$$

In particular, Real$^{\uparrow}$ *seal reads, completion-facing readback routes, and* RegSeqRat$^{\uparrow}$ *handoff consumers receive only those rows. They receive no quotient stream, selected limit, host real equality, uniqueness-of-limit theorem, ambient completeness principle, or unrecorded completion object.*

Proof. First assemble the public packet by Definition 392.20. The carrier rows $W, M, T, Q, E, H, C, P, N$ are the sole exposed certificate surface.

Next attach the downstream routes. Apply Definition 392.21 for completion-facing consumers and Definition 392.22 for the $\mathsf{RegSeqRat}^{\uparrow}$ handoff path through the modulus, tail ledger, and dyadic tolerance rows.

Finally use Definition 392.23 and Definition 392.25. These results fix the $\mathsf{Real}^{\uparrow}$ seal read and the completion-facing normal form on the same finite row set, so none of the excluded quotient, host equality, limit-selection, uniqueness, completeness, or unrecorded completion data can be consumed downstream. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier mature downstream examples`

Lemma 392.36 (CauchyCriterion completion uniform-family downstream coverage)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, and let U be an accepted singleton or fixed finite-family* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet with the same displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. Assume the shared window, shared modulus, dyadic tolerance, tail ledger, and real-seal rows are identified as in Definition 392.32.*

Every accepted local downstream consumer of the resulting completion uniform-family fact is exhausted by the finite alternatives

$$M, Q, T, W, E, H, C, P, N,$$

together with the displayed stream-name source, regular-rational readback, dyadic ledger, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support rows. Equivalently, any consumer-facing use factors through one of the displayed CauchyCriterion route rows, the singleton or fixed finite-family uniform ledger rows, or the terminal* $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *completion route rows of Definition 392.34. A request for a quotient stream, selected limit, host real equality, uniqueness-of-limit theorem, ambient completeness principle, unrecorded completion object, independently chosen family limit, or unlisted coordinate is outside the BEDC packet.*

Proof. Start with Definition 392.32. It identifies the accepted CauchyCriterion packet and the accepted singleton or fixed finite-family uniform packet before any $\mathsf{Completion}^{\uparrow}$ or $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumer can read the seal. The common route is the finite path through M, Q, T, W, E, together with the shared stream-name source, regular-rational readback, dyadic ledger, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Now apply Definition 392.34. Any terminal Real-and-Completion consumer sharing the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows must factor through

$$M, Q, T, W, E, H, C, P, N.$$

That theorem also records that the route reads the stream-name source, regular-rational sequence row, dyadic tolerance core, Cauchy modulus schedule, uniform Cauchy criterion packet, and Real seal through the same visible support rows.

These two cited routes cover the local consumer surface. A completion-facing consumer is first confined by the factorization theorem, and a terminal consumer that also asks for the regular-rational and real-completion handoff is confined by the terminal route theorem. Since both routes name the same finite rows and both explicitly withhold quotient streams, selected limits, host real equality, uniqueness data, ambient completeness, unrecorded completion objects, and independent family limits, any request for an unlisted coordinate is not an additional case. It is simply not a coordinate exported by the accepted BEDC packet. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier completion uniform family downstream coverage`

Theorem 392.37 (CauchyCriterion StreamName Real budget-selector boundary)**.** *Let $K = (W, M, T, Q, E, H, C,$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet. Any* $\mathsf{Real}^{\uparrow}$*-completion consumer or finite-window budget selector sharing the displayed*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

rows must read through the CauchyCriterion route

$$M, \quad Q, \quad T, \quad W, \quad E, \quad H, \quad C, \quad P, \quad N$$

before exposing a selector output. Conversely, a selector that displays this route has exactly the finite CauchyCriterion budget surface available for the shared StreamName–RegSeqRat–DyadicRatCore–Real read.

The boundary exports no quotient stream, selected limit, host real equality, ambient completeness principle, unrecorded completion object, or selector choice independent of $M, Q, T, W, E, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier streamname real budget selector boundary`

Proof. Start with the CauchyCriterion handoff Definition 392.26. It places the $\mathsf{StreamName}^{\uparrow}$ finite window, the $\mathsf{RegSeqRat}^{\uparrow}$ source row, the $\mathsf{DyadicRatCore}^{\uparrow}$ budget rows, and the $\mathsf{Real}^{\uparrow}$ seal on the displayed CauchyCriterion carrier rows.

Next apply the completion boundary Definition 392.33. It says that any $\mathsf{Completion}^{\uparrow}$ or $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumer sharing those four faces must factor through $M, Q, T, W, E, H, C, P, N$ before it can read a completion seal.

Now use the finite-window selector surfaces from the StreamName and Real siblings. The request and coverage theorems Definition 126.542 and Definition 126.543 identify a finite-window selector by its selected observation, bundle membership, tail-selector route, finite budget surface, pointwise $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and the support rows $\mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$. The budget handoff Definition 126.390 and the boundary Definition 126.316 then force the $\mathsf{Real}^{\uparrow}$ read to use the same finite surface.

Finally read the completion-facing exit through Definition 126.500. Its four faces are exactly $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with no fifth completion coordinate. Combining this exit route with the CauchyCriterion handoff and tail-budget boundary gives the stated factorization before any selector output is exposed, and the excluded objects have no row in the resulting packet. □

Theorem 392.38 (CauchyCriterion finite-request section return)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet whose displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows agree with a public finite request section. Then the selector-seal route of K returns exactly the* $\mathsf{StreamName}^{\uparrow}$ *finite-request section before any* $\mathsf{Real}^{\uparrow}$ *seal is exposed.*

Conversely, the displayed finite request section determines the $\mathsf{CauchyCriterion}^{\uparrow}$ *selector budget surface over the same $M, Q, T, W, E, H, C, P, N$ rows. The return route exports no quotient stream, selected limit, host real equality, countable-choice selector, ambient completeness principle, or second seal source.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier finite request section return`

Proof. First apply Definition 392.37. It places the selector-facing read on the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before any selector output or $\mathsf{Real}^{\uparrow}$ seal can be consumed.

Next use Definition 392.39 and Definition 392.40. These results put the selector route and its seal-facing pullback on the same finite structural surface carried by hsame, Cont, Pkg, and NameCert.

For the return direction, read the StreamName and Real finite-request locks. The StreamName terminality rows identify the finite request section by the selected window, bundle membership, tail-selector route, pointwise $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and support rows; the $\mathsf{Real}^{\uparrow}$ finite-request fusion and seal lock then force the seal-facing consumer to reuse that same section.

Finally apply Definition 392.41. The synchronizer is total on the common finite packet, so the CauchyCriterion selector budget surface is determined by the displayed section and cannot escape to quotient streams, selected limits, host real equality, countable choice, ambient completeness, or a second seal source. □

Theorem 392.39 (CauchyCriterion uniform selector-seal compatibility)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, and let $U = (I, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$ be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose the two presentations display the same* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *finite rows at the completion-facing boundary. Then the budget-selector output of the* $\mathsf{CauchyCriterion}^{\uparrow}$ *route and the shared-threshold seal output of the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *route factor through the same finite packet before any* $\mathsf{Real}^{\uparrow}$ *seal is exposed.*

The common packet is the displayed StreamName–RegSeqRat–DyadicRatCore–Real surface with its BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. It contains no quotient stream, selected limit, host real equality, detached family threshold, ambient completeness principle, or second completion seal.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier uniform selector seal compatibility`

Proof. Begin with the CauchyCriterion side. Apply Definition 392.26 and Definition 392.33. These place the selector-facing read on the displayed $M, Q, T, W, E, H, C, P, N$ packet before any Real or Completion seal can be consumed.

Next expose the StreamName exit route. The finite-window request and coverage rows, together with Definition 126.390, Definition 126.316, and Definition 126.500, identify the four public faces as $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ with no fifth completion coordinate.

Now read the uniform presentation. Apply Definition 435.10. The family threshold request is transported as one finite route through the displayed window, threshold, tolerance, and tail rows, with the support rows supplied by H_U, C_U, P_U, N_U.

Finally apply Definition 435.4, Definition 435.57, and Definition 435.8. The uniform seal is downstream of the same finite packet, and the non-escape boundary removes quotient streams, selected limits, host equality, detached thresholds, ambient completeness, and any second completion seal. Hence the selector route and the shared-threshold seal route agree on the finite packet before the $\mathsf{Real}^{\uparrow}$ seal is exposed. □

Theorem 392.40 (CauchyCriterion selector-seal route pullback)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, and let $D = (B_D, T_D, W_D, R_D, L_D, H_D, C_D, P_D, N_D)$ be an accepted* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *root formal source. Suppose the two packets share the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows at the selector-seal boundary.*

Then the $\mathsf{CauchyCriterion}^{\uparrow}$ *selector-seal route is the pullback of the diagonal root formal route along the structural rows*

$$\mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

The resulting route is exactly the common StreamName–RegSeqRat–DyadicRatCore–Real surface with its structural support rows. It exports no quotient stream, selected limit, host real equality, countable-choice selector, ambient completeness principle, or second seal source.

Proof. Begin with the CauchyCriterion boundary Definition 392.37. It forces every selector-facing read through the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before any selector output is exposed.

Next use the uniform selector-seal compatibility of Definition 392.39. This places the selector route on the same finite structural surface carried by hsame, Cont, Pkg, and NameCert, with no extra completion-facing coordinate.

Now read the diagonal root formal source through Definition 646.182 and Definition 646.183. The root route displays the finite source rows and consumes its support rows in the same structural order.

Finally apply Definition 646.186. The diagonal seal-facing route has no source outside its displayed finite tuple, so restricting it along the shared StreamName–RegSeqRat–DyadicRatCore–Real rows gives precisely the CauchyCriterion selector-seal route. The excluded objects have no coordinate in either accepted packet. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier selector seal route pullback`

Theorem 392.41 (CauchyCriterion selector-seal synchronizer totality)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, and let* $U = (I, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$ *be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose the two packets share the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and finite-window selector rows at the completion-facing boundary. Then there is a total synchronizer route between the CauchyCriterion budget-selector surface and the UniformCauchyCriterion shared-threshold surface before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

The synchronizer route is the common StreamName–RegSeqRat–DyadicRatCore–Real finite packet with its selector rows, BHist *support,* hsame *transports,* Cont *routes,* Pkg *provenance, and* NameCert *rows. It exposes no quotient stream, selected limit, host real equality, detached threshold family, ambient completeness principle, or second completion seal.*

Proof. Begin with Definition 392.37. It places every CauchyCriterion selector-facing read on the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route before exposing selector output.

Apply Definition 392.39. The CauchyCriterion selector route and the UniformCauchyCriterion shared-threshold seal route factor through the same finite packet before a $\mathsf{Real}^{\uparrow}$ seal is exposed.

Use the StreamName finite-window request and coverage rows together with the shared Real-facing handoff. They make the selector rows total over the displayed finite windows rather than over an ambient completion object.

Finally read the UniformCauchyCriterion shared-threshold transport and non-escape boundary. The uniform route contributes no detached threshold family or second seal, so the common packet gives the total synchronizer route claimed above. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier selector seal synchronizer totality`

Theorem 392.42 (CauchyCriterion common selector refinement)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* CauchyCriterion$^{\uparrow}$ *packet, let $U = (I, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$ be an accepted* UniformCauchyCriterion$^{\uparrow}$ *packet, and let D be an accepted* DiagonalLimitCompatibility$^{\uparrow}$ *packet. Suppose the three packets share the displayed* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, *and finite selector rows at the completion-facing boundary. Then the Cauchy selector route, the uniform shared-threshold route, and the diagonal root-formal route determine one common finite selector-refinement packet over* BHist, hsame, Cont, Pkg, *and* NameCert.

The refinement packet exposes no quotient stream, selected host limit, host real equality, detached threshold family, ambient completeness principle, or second completion seal.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier common selector refinement`

Proof. First assemble the pairwise selector boundary. The uniform selector-seal compatibility theorem, Definition 392.39, identifies the CauchyCriterion selector route and the UniformCauchyCriterion shared-threshold route inside one finite packet over the shared StreamName–RegSeqRat–DyadicRatCore–Real rows.

Next pull the diagonal route back to the same boundary. The route-pullback theorem, Definition 392.40, restricts the diagonal root-formal seal route along the displayed finite rows and prevents it from exposing a detached completion object.

Finally apply synchronizer totality, Definition 392.41. Its synchronizer packet already carries the finite selector rows, BHist support, componentwise hsame transports, displayed Cont routes, Pkg provenance, and NameCert rows. The StreamName finite-window and diagonal root-formal references used above put all three routes on that same finite window, so repacking them gives the common selector-refinement packet and no excluded coordinate remains. □

Theorem 392.43 (CauchyCriterion TailCofinalitySchedule selector cofinality)**.** *Let $K = (W, M, T, Q, E, H, C, P, N$ be an accepted* CauchyCriterion$^{\uparrow}$ *packet, and let $S = (E_S, W_S, D_S, R_S, L_S, H_S, C_S, P_S, N_S)$ be an accepted* TailCofinalitySchedule$^{\uparrow}$ *packet. Suppose the two packets share the displayed* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, *finite-window selector rows, componentwise* hsame *transport, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows. Then the accepted packets determine one cofinal finite selector route through the Cauchy rows $M, Q, T, W, E, H, C, P, N$ and the schedule rows $E_S, W_S, D_S, R_S, L_S, H_S, C_S, P_S, N_S$ before any* Real$^{\uparrow}$ *or completion seal is public.*

The route is the common StreamName–RegSeqRat–DyadicRatCore–Real finite packet with its selector request, finite StreamName window, dyadic threshold ledger, regular-rational readback, Real seal boundary, and structural support rows. It exports no quotient stream, selected host limit, host real equality, countable-choice schedule, ambient completeness principle, hidden tail oracle, or second selector-budget source.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier tailcofinalityschedule selector cofinality`

Proof. First read the Cauchy side through Definition 392.37. This places every selector-facing CauchyCriterion$^{\uparrow}$ read on the displayed StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ rows before a selector output or Real seal can be inspected.

Next apply Definition 392.42. The Cauchy selector route is already repacked with the uniform and diagonal routes over the same finite rows, with support carried by BHist, componentwise hsame, displayed Cont, Pkg, and NameCert.

Now pass through the sibling schedule. The shared-tail budget factorization theorem, Definition 681.10, places the schedule packet on the finite route through E_S, W_S, D_S, R_S, L_S and the structural rows H_S, C_S, P_S, N_S, with no second tail-budget source.

Finally use Definition 681.14. It puts the completion-facing diagonal read on the same schedule route before any public $\mathsf{Real}^{\uparrow}$ or completion seal is available. Since both sides consume the displayed StreamName–RegSeqRat–DyadicRatCore–Real rows with the same support inventory, the Cauchy selector packet and the tail cofinality schedule determine one cofinal finite route, and the excluded quotient, selected-limit, host-equality, choice, completeness, hidden-oracle, and second-budget coordinates have no carrier slot on that route. □

Theorem 392.44 (CauchyCriterion Real-window diagonal selector lock)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, let $U = (I, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$ be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let D be an accepted* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *packet. Suppose the three packets share the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and finite selector rows at the completion-facing boundary. Then every* $\mathsf{Real}^{\uparrow}$ *window selector read factors through one common finite packet over* BHist, hsame, Cont, Pkg, *and* NameCert.

The common packet contains no quotient stream, selected host limit, host real equality, detached threshold family, ambient completeness principle, or second seal.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier real window diagonal selector lock`

Proof. First read the CauchyCriterion selector boundary through Definition 392.37. This places every Real-facing budget-selector read on the displayed StreamName–RegSeqRat–DyadicRatCore–Real rows before any external limit or completion coordinate can be inspected.

Next apply uniform selector-seal compatibility and route pullback, Definition 392.39 and Definition 392.40. The uniform shared-threshold route and the diagonal root-formal route are both restricted to the same finite selector surface.

Now use synchronizer totality, Definition 392.41. It supplies the total route that aligns the CauchyCriterion selector surface with the UniformCauchyCriterion shared-threshold surface over the displayed BHist, hsame, Cont, Pkg, and NameCert support.

Finally invoke the common selector refinement theorem, Definition 392.42. Carrier-coordinate exhaustion leaves exactly the shared finite packet and removes every coordinate listed outside it, so each Real-window selector read is locked to that packet. □

Theorem 392.45 (CauchyCriterion four-face selector readback determinacy)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, let $U = (I, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$ be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let D be an accepted* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *packet. Suppose the three packets share the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and finite selector rows at the completion-facing boundary. Then any two* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer readbacks preserving the common selector-refinement packet of Definition 392.42 and the same* BHist, hsame, Cont, Pkg, *and* NameCert *support rows determine the same finite selector-readback packet before any seal is read.*

The determinacy claim does not identify quotient streams, selected host limits, host real values, countable-choice selectors, ambient completeness witnesses, or a second seal source.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier four face selector readback determinacy`

Proof. First build the four-face boundary. Apply Definition 392.37 to place every CauchyCriterion selector-facing read on the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, and use Definition 392.38 to return the finite selector section without leaving those rows.

Next synchronize the two external routes. The uniform compatibility theorem, Definition 392.39, puts the shared-threshold route on the same selector surface, while the pullback theorem, Definition 392.40, restricts the diagonal root-formal route to that surface before a completion seal is exposed.

Now apply synchronizer totality, Definition 392.41, and then the common refinement theorem, Definition 392.42. Together they package the common finite selector rows with exactly the displayed BHist, hsame, Cont, Pkg, and NameCert support.

Finally use terminal non-escape, Definition 392.46. Since both consumer readbacks preserve the same refinement packet and the same support rows, neither can add an extra selector coordinate after the common packet is fixed. The excluded quotient stream, selected host limit, host real equality, countable-choice selector, ambient completeness witness, and second seal source therefore have no coordinate along which the two readbacks could diverge. □

Theorem 392.46 (CauchyCriterion selector-refinement terminal non-escape)**.** *Let $K = (W, M, T, Q, E, H, C, P, N$ be an accepted* CauchyCriterion$^{\uparrow}$ *packet, let $U = (I, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$ be an accepted* UniformCauchyCriterion$^{\uparrow}$ *packet, and let D be an accepted* DiagonalLimitCompatibility$^{\uparrow}$ *packet. Suppose the three packets share the displayed* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*, and finite selector rows at the completion-facing boundary. Once the common selector-refinement packet of Definition 392.42 is assembled, every terminal* Real$^{\uparrow}$ *or* Completion$^{\uparrow}$ *consumer factors through that packet.*

Consequently no terminal consumer exports quotient streams, selected host limits, host real equality, detached threshold families, ambient completeness, or a second completion seal.

Proof. First use Definition 392.37. It places the CauchyCriterion terminal read behind the displayed StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ selector boundary.

Next combine Definition 392.39 with Definition 392.40. The uniform shared-threshold route and the diagonal root-formal route both restrict to the same selector-seal surface, with support carried by BHist, hsame, Cont, Pkg, and NameCert.

Now apply Definition 392.41. The synchronizer is total on the finite selector rows, so any Real$^{\uparrow}$ or Completion$^{\uparrow}$ consumer reaching the boundary has a route through the common packet.

Finally read the assembled packet through Definition 392.42. Since that theorem has already removed quotient streams, selected host limits, host real equality, detached threshold families, ambient completeness, and second completion seals from the shared packet, the same exclusions hold for terminal consumers. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier selector refinement terminal nonescape`

Theorem 392.47 (CauchyCriterion diagonal selector terminality)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* CauchyCriterion$^{\uparrow}$ *packet, let $U = (I, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$ be an accepted* UniformCauchyCriterion$^{\uparrow}$ *packet, and let D be an accepted* DiagonalLimitCompatibility$^{\uparrow}$ *packet. Suppose the three packets share the displayed* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*, and finite selector rows at the completion-facing boundary. Then the common selector-refinement packet of Definition 392.42 is terminal among all* Real$^{\uparrow}$ *or* Completion$^{\uparrow}$ *consumers preserving those displayed rows.*

Equivalently, every such consumer factors through the same selector-refinement packet before any terminal seal is read, and no consumer preserving the displayed rows can add quotient streams, selected host limits, host real equality, countable-choice selectors, ambient completeness, or a second seal source.

Proof. First assemble the shared packet by Definition 392.42. That theorem composes the CauchyCriterion selector route, the UniformCauchyCriterion shared-threshold route, and the DiagonalLimitCompatibility route over the common $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and finite selector rows.

Next use the budget-selector boundary Definition 392.37, the route pullback Definition 392.40, and synchronizer totality Definition 392.41. These rows place every Real or completion-facing read that preserves the displayed rows inside the same finite selector surface.

Finally apply terminal non-escape, Definition 392.46. Since every terminal consumer already factors through the common packet, the packet is terminal among consumers preserving the shared rows. The excluded quotient stream, selected host limit, host real equality, countable-choice selector, ambient completeness, and second seal source coordinates are absent from the assembled packet and cannot be supplied by a terminal consumer. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier diagonal selector terminality`

Theorem 392.48 (CauchyCriterion finite selector exhaustion)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, let $U = (I, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$ be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let D be an accepted* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *packet. Suppose the three packets share the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and finite selector rows at the completion-facing boundary. Then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer preserving those displayed rows factors through exactly the finite selector-refinement packet of Definition 392.42.*

Conversely, any route through that selector-refinement packet supplies all selector data available to such consumers: the common finite selector rows, the BHist *support, the componentwise* hsame *transports, the displayed* Cont *routes, the* Pkg *provenance, and the* NameCert *rows. No quotient stream, selected host limit, host real equality, countable-choice selector, ambient completeness witness, detached threshold family, or second seal source is available to a consumer preserving only the displayed rows.*

Proof. First apply the boundary and return rows. The budget-selector boundary Definition 392.37 places every selector-facing read on the displayed StreamName–RegSeqRat–DyadicRatCore–Real surface, and the finite-request section return Definition 392.38 identifies the finite selector section before any $\mathsf{Real}^{\uparrow}$ seal is exposed.

Next align the seal-facing routes. The uniform compatibility theorem Definition 392.39 and the pullback theorem Definition 392.40 put the CauchyCriterion, UniformCauchyCriterion, and DiagonalLimitCompatibility routes on the same finite structural rows carried by BHist, hsame, Cont, Pkg, and NameCert.

Now use synchronizer totality and common refinement. The synchronizer theorem Definition 392.41 makes the finite selector surface total for the shared packets, while Definition 392.42 repacks that surface as one selector-refinement packet over exactly the displayed support rows.

Finally apply diagonal selector terminality, Definition 392.47. Any $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer preserving the displayed rows must factor through the same refinement packet. Inspecting the packet coordinates gives the converse: a route through the packet provides precisely the selector rows and support rows listed in the statement, and every omitted object has no coordinate from which such a consumer could read it. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier finite selector exhaustion`

Theorem 392.49 (CauchyCriterion finite-observation budget selector pullback)**.** *Let $K = (W, M, T, Q, E, H, C, P,$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, and let $F = (B, S, V, D, R, E_F, H_F, C_F, P_F, N_F)$ be an*

accepted FiniteObservationBudgetSelector$^{\uparrow}$ *packet. Suppose the two packets share the displayed* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows at the selector-to-seal boundary, and suppose their* hsame, Cont, Pkg, *and* NameCert *support rows are compatible componentwise. Then the CauchyCriterion selector route and the finite observation-budget selector route determine the same finite pullback surface from selector request to* Real$^{\uparrow}$ *seal.*

The pullback surface contains exactly the displayed selector request, finite StreamName window, dyadic readback, RegSeqRat handoff, Real seal, transport, continuation, package, and local naming rows. It refuses quotient streams, selected host limits, host real equality, countable choice, hidden selectors, ambient completeness, and any second completion seal.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier finite observation budget selector pullback`

Proof. First place the CauchyCriterion side on the selector boundary. Apply Definition 392.37 and Definition 392.40; these identify the displayed StreamName, DyadicRatCore, RegSeqRat, and Real rows used before the seal is read.

Next make the CauchyCriterion selector total on that surface. Use Definition 392.41 and Definition 392.48 to show that every consumer preserving the displayed rows factors through the same finite selector-refinement packet.

Now read the finite observation-budget selector packet. The obligations of Definition 782.2 expose the same kind of finite budget, window, dyadic, handoff, seal, transport, continuation, package, and local naming rows. Route determinacy, Definition 782.7, forces the selector request to reach the Real seal along that displayed chain.

Finally apply the diagonal consumer boundary, Definition 782.10. Because both accepted packets preserve the same support rows, the two chains meet in one finite pullback surface. The excluded quotient stream, selected host limit, host real equality, countable-choice, hidden-selector, ambient completeness, and second-seal objects have no coordinate in either packet, so they cannot appear in the pullback. □

Theorem 392.50 (CauchyCriterion finite-observation budget selector uniqueness)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* CauchyCriterion$^{\uparrow}$ *packet, and let* $F = (B, S, V, D, R, E_F, H_F, C_F, P_F, N_F)$ *and* $F' = (B', S', V', D', R', E_{F'}, H_{F'}, C_{F'}, P_{F'}, N_{F'})$ *be accepted* FiniteObservationBudgetSelector$^{\uparrow}$ *packets. Suppose both* F *and* F' *share the same packet* K*, the same displayed* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows at the selector-to-seal boundary, and componentwise compatible* hsame, Cont, Pkg, *and* NameCert *support rows. Then the two selector-to-seal pullback surfaces are the same finite BEDC packet before any* Real$^{\uparrow}$ *seal is read.*

Equivalently, the shared surface is determined by the selector request, finite StreamName window, dyadic readback, RegSeqRat handoff, pre-seal Real row, transport, continuation, package, and local naming rows. It carries no quotient streams, selected host limits, host real equality, countable choice, hidden selectors, ambient completeness, or second completion seals.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier finite observation budget selector uniqueness`

Proof. First apply the pullback theorem Definition 392.49 to the pair (K, F) and again to the pair (K, F'). Both applications land on a finite selector-to-seal surface with exactly the displayed StreamName, DyadicRatCore, RegSeqRat, Real, transport, continuation, package, and naming rows.

Next use finite selector exhaustion, Definition 392.48. Because both observation-budget packets preserve the same CauchyCriterion packet and the same displayed rows, every completion-facing consumer factors through the same selector-refinement packet before any Real seal is exposed.

It remains to identify the observation-budget routes into that packet. Route determinacy, Definition 782.7, forces each accepted selector request to reach the Real row along the displayed finite chain, and the diagonal consumer boundary, Definition 782.10, keeps terminal consumers on that same chain.

Thus the two accepted packets have no remaining coordinate on which their pullback surfaces can differ. Since quotient streams, selected host limits, host real equality, countable choice, hidden selectors, ambient completeness, and second completion seals are excluded from the shared packet, they cannot serve as witnesses of a second selector-to-seal surface. □

Theorem 392.51 (CauchyCriterion exact-boundary selector handoff)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, let $F = (B, S, V, D, R, E_F, H_F, C_F, P_F, N_F)$ be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let $X = (L, K_X, J_X, S_X, W_X, R_X, D_X, E_X, H_X, C_X, P_X, N_X)$ be an accepted* RealCompletionExactBoundaryUp *packet. Suppose the three packets share the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *componentwise* hsame, *displayed* Cont, Pkg, *and local* NameCert *rows at the selector-to-seal boundary. Then the CauchyCriterion selector-to-seal surface factors through the exact-boundary packet X before any terminal* $\mathsf{Real}^{\uparrow}$ *seal is read.*

The handoff exposes only the selector request, finite StreamName window, RegSeqRat handoff, DyadicRatCore tolerance row, terminal Real boundary, and the shared hsame, Cont, Pkg, *and* NameCert *support rows. It refuses quotient streams, selected host limits, host real equality, countable choice, ambient completeness, and any second seal source.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier exact boundary selector handoff`

Proof. First apply Definition 392.49. The accepted CauchyCriterion packet and the accepted finite observation-budget selector packet meet on a single selector-to-seal pullback surface with the displayed StreamName, RegSeqRat, DyadicRatCore, Real, transport, continuation, package, and local naming rows.

Next use Definition 392.48. It shows that every completion-facing consumer preserving those rows must pass through the same finite selector-refinement packet before a Real or Completion seal is read.

Now apply Definition 1120.6. The accepted exact-boundary packet exports exactly the StreamName, RegSeqRat, DyadicRatCore, and terminal Real faces on the route $L, K_X, J_X, S_X, W_X, R_X, D_X, E_X, H_X, C_X$ so the selector-refinement surface has only that exact-boundary consumer route available.

Finally use Definition 1120.5. The terminal Real seal cannot be read outside the exact-boundary packet. Since the pullback and exhaustion steps already removed quotient streams, selected host limits, host real equality, countable choice, ambient completeness, hidden selectors, and second seal sources, the selector-to-seal surface factors through the exact-boundary packet before any terminal Real seal is consumed. □

Theorem 392.52 (CauchyCriterion StreamName–Real budget selector terminal boundary)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, let $F = (B, S, V, D, R, E_F, H_F, C_F, P_F, N_F$ be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let $X = (L, K_X, J_X, S_X, W_X, R_X, D_X, E_X, H_X, C_X, P_X$ be an accepted* RealCompletionExactBoundaryUp *packet. Suppose the packets share the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *componentwise* hsame, *displayed* Cont, Pkg, *and local* NameCert *rows. Then every terminal* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *selector read of the shared surface factors through the exact-boundary selector handoff of Definition 392.51.*

Conversely, that handoff supplies all selector data available to such a terminal read: the selector request, finite StreamName window, RegSeqRat handoff, DyadicRatCore tolerance row, terminal Real boundary, and the displayed hsame, Cont, Pkg, *and* NameCert *support rows. It supplies no quotient stream, selected host limit, host real equality, countable choice, ambient completeness, hidden selector, or second seal source.*

Proof. First apply Definition 392.49. The CauchyCriterion packet and the finite observation-budget selector packet meet on the displayed finite selector-to-seal surface.

Next use Definition 392.50. The finite surface is determined by the shared StreamName, RegSeqRat, DyadicRatCore, Real, transport, continuation, package, and local naming rows, so no second selector surface remains for a terminal read.

Now apply Definition 392.51. It routes the shared selector surface through the accepted exact-boundary packet before a terminal Real or Completion selector read can consume the seal rows.

The exact-boundary inventory is fixed by Definition 1120.6. Finally use Definition 1120.5 to block any terminal seal escape. Thus the handoff gives exactly the selector data available to the read, and all excluded host, quotient, choice, completeness, hidden-selector, and second-seal coordinates remain outside the packet. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier streamname real budget selector terminal boundary`

Theorem 392.53 (CauchyCriterion selector-budget three-way terminality)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* CauchyCriterion$^{\uparrow}$ *packet, let* $F = (B, S, V, D, R, E_F, H_F, C_F, P_F, N_F)$ *be an accepted* FiniteObservationBudgetSelector$^{\uparrow}$ *packet, and let* $X = (L, K_X, J_X, S_X, W_X, R_X, D_X, E_X, H_X, C_X, P_X, N_X)$ *be an accepted* RealCompletionExactBoundaryUp *packet. Suppose the three packets share the displayed* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, *componentwise* hsame, *displayed* Cont, Pkg, *and local* NameCert *rows. Then the finite-request section, the finite observation-budget selector, and the exact-boundary handoff determine one terminal selector-to-seal packet before any terminal* Real$^{\uparrow}$ *or* Completion$^{\uparrow}$ *read.*

That terminal packet contains exactly the displayed selector request, finite StreamName window, RegSeqRat handoff, DyadicRatCore tolerance row, terminal Real boundary, and the shared hsame, Cont, Pkg, *and* NameCert *support. It contains no quotient stream, selected host limit, host real equality, countable choice, ambient completeness, hidden selector, or second seal source.*

Proof. First apply Definition 392.38. The accepted CauchyCriterion packet returns its finite request section on the displayed StreamName, RegSeqRat, DyadicRatCore, Real, transport, continuation, package, and local naming rows.

Next apply Definition 392.42. This places the finite request section on the common selector-refinement packet shared by the CauchyCriterion route and the completion-facing rows.

Now use Definition 392.50. It shows that the accepted finite observation-budget selector has no second packet with the same displayed rows, so the selector component of the terminal surface is unique.

Finally apply Definition 392.52. The exact-boundary handoff is the only terminal selector-to-seal packet available before a Real$^{\uparrow}$ or Completion$^{\uparrow}$ read. Its inventory already excludes quotient streams, selected host limits, host real equality, countable choice, ambient completeness, hidden selectors, and second seal sources, so the three presentations determine the same terminal packet. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier selector budget three way terminality`

Theorem 392.54 (CauchyCriterion terminal selector-seal no-choice exhaustion)**.** *Let* $K = (W, M, T, Q, E, H, C, P,$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, let* $F = (B, S, V, D, R, E_F, H_F, C_F, P_F, N_F)$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let* $X = (L, K_X, J_X, S_X, W_X, R_X, D_X, E_X, H_X, C_X, P_X, N_X)$ *be an accepted* RealCompletionExactBoundaryUp *packet. Suppose the three packets share the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *componentwise* hsame, *displayed* Cont, Pkg, *and local* NameCert *rows. Then every terminal selector-to-seal read of the shared surface factors through, in order, the finite-request section, the finite observation-budget selector, the exact-boundary handoff, and the three-way terminal packet of Definition 392.53.*

The resulting consumer-visible boundary exports only the selector request, finite StreamName window, RegSeqRat handoff, DyadicRatCore tolerance row, terminal Real boundary, and the shared hsame, Cont, Pkg, *and* NameCert *support rows. It exports no quotient stream, selected host limit, host real equality, countable-choice schedule, ambient completeness, hidden selector, or second seal source.*

Proof. First apply Definition 392.38. The accepted CauchyCriterion packet returns the finite request section on the shared StreamName, RegSeqRat, DyadicRatCore, Real, transport, continuation, package, and local naming rows.

Next use Definition 392.50. This pins the finite observation-budget selector to the same displayed rows and removes any second selector packet before a terminal read can consume the seal surface.

Now apply Definition 392.51. The finite selector route is handed to the accepted exact-boundary packet, so every terminal selector-to-seal read must pass through the displayed RealCompletionExactBoundaryUp rows before a $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ seal is read.

Finally combine Definition 392.52 with Definition 392.53. The first theorem gives the terminal StreamName–Real boundary, while the second identifies the finite-request, finite-budget, and exact-boundary presentations as one terminal packet.

The carrier inventory of that packet is already exhausted by the displayed selector request, finite StreamName window, RegSeqRat handoff, DyadicRatCore tolerance row, terminal Real boundary, and shared support rows. Therefore a terminal read has no exported quotient stream, selected host limit, host real equality, countable-choice schedule, ambient completeness, hidden selector, or second seal source available outside the stated route. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier terminal selector seal nochoice exhaustion`

Theorem 392.55 (CauchyCriterion budget-selector section exactness)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, let* $F = (B, S, V, D, R, E_F, H_F, C_F, P_F, N_F)$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let* $X = (L, K_X, J_X, S_X, W_X, R_X, D_X, E_X, H_X, C_X, P_X, N_X)$ *be an accepted* RealCompletionExactBoundaryUp *packet. Suppose the three packets share the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *componentwise* hsame, *displayed* Cont, Pkg, *and local* NameCert *rows over the same* BHist *support. Then every finite observation request routed through the displayed* $\mathsf{StreamName}^{\uparrow}$–RegSeqRat–$\mathsf{Real}^{\uparrow}$ *selector surface has a unique budget-selector section.*

Replaying that section through the selector-seal route returns the same finite StreamName window, RegSeqRat handoff, DyadicRatCore tolerance row, terminal $\mathsf{Real}^{\uparrow}$ *boundary, and seal row carried by the original request. No quotient stream, host real equality, selected-limit oracle, countable-choice row, ambient completeness witness, hidden selector, or second seal source is introduced.*

Proof. First apply Definition 392.38. It returns the finite request section on the displayed StreamName, RegSeqRat, DyadicRatCore, Real, transport, continuation, package, and local naming rows over the given BHist support.

Next use Definition 392.49. The accepted finite observation-budget selector and the accepted CauchyCriterion packet meet on the same selector-to-seal pullback surface, so the returned section is already routed through the displayed StreamName$^{\uparrow}$–RegSeqRat–Real$^{\uparrow}$ surface.

Now apply Definition 392.50. This proves that no second accepted budget-selector section with the same BHist, hsame, Cont, Pkg, and NameCert rows can determine a different finite window or seal-facing row.

Finally combine Definition 392.41 with Definition 392.54. The synchronizer makes replay through the selector-seal route total on the finite surface, and no-choice exhaustion says the replay has no exported coordinate for a quotient stream, host real equality, selected-limit oracle, countable-choice row, ambient completeness witness, hidden selector, or second seal source. Therefore replay returns exactly the original finite window and seal row. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier budget selector section exactness`

Theorem 392.56 (CauchyCriterion budget-selector terminal route exhaustion)**.** *Let $K = (W, M, T, Q, E, H, C, P,$ be an accepted* CauchyCriterion$^{\uparrow}$ *budget-selector route over the displayed* BHist *support. Among routes that share the displayed* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*, finite selector, uniform threshold, and diagonal root-formal surfaces, the accepted route is terminal. Every such route factors through the finite rows already named by the boundary theorem, finite-request section return, uniform compatibility, diagonal pullback, common selector refinement, finite selector exhaustion, terminality, and budget-selector section exactness in this chapter.*

Consequently no accepted route over the same surfaces can add a quotient stream, host real equality, countable-choice selector, ambient completeness witness, detached threshold, or second seal. Any consumer that asks for one of those rows has left the CauchyCriterion$^{\uparrow}$ *budget-selector route rather than extending it.*

Proof. First apply the boundary theorem and finite-request section return. These place the accepted route on the displayed StreamName, RegSeqRat, DyadicRatCore, Real, transport, continuation, package, and local naming rows.

Next use uniform compatibility and the diagonal pullback. They keep the uniform threshold and diagonal root-formal surfaces on the same finite support, so a route sharing those surfaces cannot detach its threshold or introduce a second root source.

Now apply common selector refinement and finite selector exhaustion. The selector row is already fixed by the shared finite request and by the accepted finite observation-budget selector, leaving no second selector packet with the same displayed rows.

Finally combine terminality with Definition 392.55. The section exactness theorem returns the same finite window and seal row under replay, while terminality blocks quotient streams, host real equality, countable-choice selectors, ambient completeness, detached thresholds, and second seals. Thus every shared-surface route factors through the named finite rows and no additional route coordinate remains. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier budget selector terminal route exhaustion`

Theorem 392.57 (CauchyCriterion StreamName Real budget bridge readiness)**.** *Every bridge-ready* CauchyCriterion$^{\uparrow}$ *selector route factors through the displayed* StreamName$^{\uparrow}$ *window,* RegSeqRat$^{\uparrow}$

readback, $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{Real}^{\uparrow}$ *seal, finite-observation budget selector,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

Proof. Apply Definition 392.56. It makes the accepted selector route terminal over the named finite surfaces.

Then read the boundary, section-return, and exactness theorems already cited there. They keep bridge readiness on $W, M, T, Q, E, H, C, P, N$ and add no quotient stream, hidden selector, countable-choice row, or ambient Real-completeness premise. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier streamname real budget bridge readiness`

Theorem 392.58 (CauchyCriterion selector budget formal target boundary)**.** *A later formal target for the* $\mathsf{CauchyCriterion}^{\uparrow}$ *StreamName-to-Real budget selector may consume only the finite selector-budget boundary named in Definition 392.57. It may not import quotient stream equality, countable choice, ambient Real completeness, or a hidden selector.*

Proof. Use bridge readiness to enumerate the admissible inputs. The formal target receives the StreamName window, RegSeqRat readback, DyadicRatCore ledger, RealUp seal, finite selector, transport, replay, provenance, and naming rows.

Now apply terminal route exhaustion. Any additional quotient equality, choice selector, completeness witness, or hidden selector would be a new coordinate outside the terminal finite route, so it is not part of the formal boundary. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier selector budget formal target boundary`

Theorem 392.59 (CauchyCriterion finite-window Real seal handoff)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet. Every accepted finite-window budget-selector read of* K *that is handed to a* $\mathsf{Real}^{\uparrow}$*-facing consumer, a* $\mathsf{Completion}^{\uparrow}$*-facing consumer, a* $\mathsf{RealCauchyCompletion}^{\uparrow}$*-facing consumer, or a* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyLimitSeal}^{\uparrow}.$$

The route reads the CauchyCriterion rows M, Q, T, W, E *before the consumer sees the selected finite window, the regular-rational readback, the dyadic tolerance ledger, the Real seal row, and the limit-seal boundary. Its support rows are precisely the visible* BHist, hsame, Cont, Pkg, *and* NameCert *rows carried by* H, C, P, N*.*

No accepted handoff exports a quotient stream, a selected limit, host real equality, a hidden tail oracle, ambient completeness, or a completion endpoint outside the displayed finite route.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier finite window real seal handoff`

Proof. Project the accepted CauchyCriterion carrier. The finite selector and budget rows of the chapter expose the route M, Q, T, W, E together with the structural rows H, C, P, N; no consumer can read beyond those rows before the selector surface has been displayed.

Next use the StreamName and RegSeqRat handoff route. The CauchyCriterion-to-StreamName theorem Definition 392.26 places the finite window, regular-rational readback, dyadic ledger, and Real seal on the same packet. The selector boundary Definition 392.37 then forces every finite-window budget-selector read through that route before a Real-facing or completion-facing consumer receives it.

Now attach the completion and seal boundary. The completion-boundary theorem Definition 392.33 confines $\mathsf{Completion}^{\uparrow}$ and $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumers to the same $M, Q, T, W, E, H, C, P, N$ surface, while the StreamName CauchyLimitSeal pullback Definition 126.396 and the public CauchyLimitSeal route boundary Definition 386.8 put the limit-seal consumer after the displayed StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, and Real seal row.

Finally apply the non-escape clauses of the cited boundaries. The carrier has no coordinate for quotient streams, selected host limits, host real equality, hidden tail oracles, ambient completeness, or an extra completion endpoint, so each accepted handoff factors through the displayed finite route and nowhere else. □

Theorem 392.60 (CauchyCriterion limit-seal route stability)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet, and let K' be any displayed replay of the same finite-window handoff that preserves the rows $M, Q, T, W, E, H, C, P, N$ through the visible* BHist *packet, componentwise* hsame *transports, and* Cont *replay. Then the replayed handoff preserves the same route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyLimitSeal}^{\uparrow}.$$

No displayed replay of this route can substitute a quotient stream, hidden tail oracle, host real equality, selected limit, ambient completeness principle, or completion endpoint outside the rows already carried by K.

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier limit seal route stability`

Proof. Start with the finite handoff theorem. By Definition 392.59, every accepted finite-window read of K reaches the limit-seal boundary only through $M, Q, T, W, E, H, C, P, N$ and the displayed $\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{Real}^{\uparrow} \to \mathsf{CauchyLimitSeal}^{\uparrow}$ route.

Next identify the route coordinates. The RegSeqRat and StreamName handoff Definition 392.26 binds the regular readback to the StreamName window, while Definition 392.37 and Definition 392.33 keep the budget selector and completion-facing reads on the same finite rows.

Finally attach the seal side. Definition 126.396 pulls the seal read back to the StreamName budget surface, and Definition 386.8 confines public CauchyLimitSeal consumption to that surface. Since K' preserves exactly the displayed BHist, hsame, and Cont rows, carrier-coordinate exhaustion leaves no coordinate from which a quotient stream, hidden tail oracle, host real equality, selected limit, ambient completeness principle, or off-route completion endpoint could be read. □

Theorem 392.61 (CauchyCriterion Real L10 terminal-window sufficiency)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet whose finite-window budget-selector read follows the route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyLimitSeal}^{\uparrow}.$$

Then the same displayed rows $M, Q, T, W, E, H, C, P, N$, together with their visible BHist, hsame, Cont, Pkg, *and* NameCert *coordinates, suffice to supply the Real L10 finite-window witness surface consumed by the public boundary.*

Conversely, any Real L10 public-boundary read sourced through K recovers exactly the selector rows $M, Q, T, W, E, H, C, P, N$ and no additional coordinate. The sufficiency and recovery clauses exclude quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, arithmetic packages, order packages, and bridge rows.

Proof. First use Definition 392.59. It places every accepted finite-window budget-selector read of K on the displayed route and exposes the rows $M, Q, T, W, E, H, C, P, N$ before any Real-facing, completion-facing, or limit-seal consumer can read the packet.

Next apply Definition 392.60. The route remains fixed under displayed replay of the same BHist, hsame, and Cont rows, so the terminal-window read cannot be replaced by a quotient stream, hidden tail oracle, host equality row, selected limit, or completeness principle.

Now attach the Real L10 boundary. The lattice budget cover Definition 126.368 identifies the StreamName, RegSeqRat, DyadicRatCore, and Real seal faces as one finite route, with only the displayed support coordinates. Feeding that route into Definition 38.464 supplies exactly the finite-window witness surface consumed by the Real L10 public boundary.

For the converse, start from a Real L10 public-boundary read sourced through K. By Definition 38.466, the boundary can be sourced only through the ordered finite-window route displayed by the Real L10 lattice. Comparing this route with the CauchyCriterion handoff and its replay stability recovers precisely $M, Q, T, W, E, H, C, P, N$.

The exclusion clause is inherited from the cited route and L10 boundary theorems. None of those packets carries quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, arithmetic packages, order packages, or bridge rows, so no such row can be introduced at the terminal public boundary. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier real l10 terminal window sufficiency`

Theorem 392.62 (CauchyCriterion finite-window terminal coverage)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet. Any terminal CauchyCriterion consumer whose read reaches a* $\mathsf{Real}^{\uparrow}$ *seal must pass through the displayed finite-window route consisting of the Cauchy modulus row, the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *ledger carried by M, W, Q, E, H, C, P, N. No terminal read can replace that route by a quotient stream, hidden tail oracle, host real equality, selected limit, countable-choice row, ambient completeness principle, metric-completeness row, arithmetic package, order package, bridge row, or completion endpoint outside the displayed packet.*

Proof. First apply Definition 392.59. It places every accepted finite-window handoff on the route through the $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, dyadic tolerance ledger, $\mathsf{Real}^{\uparrow}$ seal, and $\mathsf{CauchyLimitSeal}^{\uparrow}$ boundary, with H, C, P, N supplying the visible transport, replay, provenance, and local naming rows.

Next apply Definition 392.60. Any displayed replay preserving $M, Q, T, W, E, H, C, P, N$ stays on the same route, so a terminal consumer cannot substitute a hidden stream source, off-route seal, or host equality coordinate.

Finally use Definition 392.61. The Real L10 public-boundary read consumes exactly the displayed terminal-window surface and recovers the same selector rows. Combining the three cited routes therefore covers every terminal CauchyCriterion read that reaches a $\mathsf{Real}^{\uparrow}$ seal, and the absent rows listed in the statement have no carrier coordinate from which they could be read. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier finite window terminal coverage`

Theorem 392.63 (CauchyCriterion Real seal finite-route uniqueness)**.** *Let $K = (W, M, T, Q, E, H, C, P, N)$ and $K' = (W', M', T', Q', E', H', C', P', N')$ be accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packets. Suppose their public-boundary reads expose the same rows $M, Q, T, W, E, H, C, P, N$ through the same visible* BHist *packet, componentwise* hsame *transports,* Cont *replay, and matching* Pkg *and* NameCert *coordinates. Then the two Real L10 public-boundary reads determine the same terminal finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyLimitSeal}^{\uparrow}.$$

No quotient stream, host equality, selected limit, countable-choice row, ambient completeness principle, or bridge row can distinguish the two reads at the terminal public boundary.

Proof. First expose the common route. By Definition 392.59, each accepted read reaches the Real and limit-seal boundary only through the displayed rows $M, Q, T, W, E, H, C, P, N$ and the finite route from $\mathsf{StreamName}^{\uparrow}$ to $\mathsf{CauchyLimitSeal}^{\uparrow}$.

Next compare the two displayed reads under replay. The hypothesis identifies the visible BHist, componentwise hsame, Cont, Pkg, and NameCert coordinates, so Definition 392.60 keeps both reads on the same replayed route rather than on two independently selected completion surfaces.

Now attach the public Real face. The lattice budget cover Definition 126.368 makes the StreamName, RegSeqRat, DyadicRatCore, and Real faces a single finite support surface. The Real L10 witness determinacy theorem Definition 38.464 then identifies the public-boundary witnesses carried by the two reads on that shared surface.

Finally use source-route exactness. By Definition 38.466, a Real L10 public-boundary read has no source outside the ordered finite-window route already exposed by the CauchyCriterion handoff. Hence the two reads determine the same terminal finite route, and the absent rows listed in the statement have no coordinate from which a distinction could be read. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier real seal unique finite route`

Corollary 392.64 (CauchyCriterion finite-window Real seal handoff determinacy)**.** *Let* $K = (W, M, T, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet. Fix the displayed rows* $M, Q, T, W, E, H, C, P, N$ *through the visible* BHist *packet, componentwise* hsame *transports,* Cont *replay, and matching* Pkg *and* NameCert *coordinates. Then every accepted consumer-facing use of the finite-window Real seal handoff of* K *determines the same terminal route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyLimitSeal}^{\uparrow}.$$

In particular, a $\mathsf{Real}^{\uparrow}$*-facing,* $\mathsf{Completion}^{\uparrow}$*-facing,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*-facing, or* $\mathsf{CauchyLimitSeal}^{\uparrow}$*-facing consumer must use the same finite-route normal form and the same source-route exactness verdict named by the chapter. No accepted use can introduce an alternate hidden coordinate, a duplicate classifier source, a quotient stream, host real equality, a selected limit, countable choice, ambient completeness, a bridge row, or a completion endpoint outside the fixed rows.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUp.CauchyCriterionCarrier finite window real seal handoff determinacy`

Proof. Take two accepted consumer-facing uses of the handoff after the rows $M, Q, T, W, E, H, C, P, N$ have been fixed. The needed transport comparison is the finite-route uniqueness result, Definition 392.63: its hypotheses are precisely the common visible BHist packet, componentwise hsame transports, Cont replay, and matching Pkg and NameCert coordinates over the fixed rows. Regard the second use as a displayed replay of the first along that cited comparison surface. By Definition 392.60, the replay cannot move the handoff away from the displayed $\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{Real}^{\uparrow} \to \mathsf{CauchyLimitSeal}^{\uparrow}$ route, and it cannot substitute any quotient stream, hidden tail oracle, host real equality, selected limit, ambient completeness principle, or off-route completion endpoint.

Now compare the two public-boundary reads. The hypotheses are exactly the row identifications required by Definition 392.63. Hence the two reads determine one terminal finite route, rather than two independently chosen consumer surfaces. The same comparison fixes the chapter's

terminal finite-route normal form, because the normal form is read only after the StreamName, RegSeqRat, DyadicRatCore, Real, and CauchyLimitSeal faces have been placed on that route.

For the exactness decision, use the same exhaustion of sources. The unique finite route already excludes any source outside the ordered finite-window route, while route stability keeps every replay on the same rows. Therefore an accepted consumer use has no coordinate from which to read a second classifier, a hidden exactness source, or an alternate completion endpoint. The only available decision is the source-route exactness verdict attached to the fixed finite-window Real seal handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCriterion}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source window, a $\mathsf{CauchyModulus}^{\uparrow}$ schedule, a $\mathsf{DyadicTailBound}^{\uparrow}$ finite tail ledger, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCriterion}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 392.16, Definition 392.17, Definition 392.19, Definition 392.21, and Definition 392.35 bind the carrier, classifier, BHist, hsame, Cont, Pkg, NameCert, dyadic tail ledger, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{Real}^{\uparrow}$ seal rows, completion-facing bridge, and representative downstream consumers to one finite constructive Cauchy criterion packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, ambient completeness, uniqueness of limits, or bridge checking.

Upgrade path: No further paper-axis theory step remains for this packet; formal verification and bridge checking remain separate verification-axis work.

Chapter 393

A Concrete Naming Certificate for $\mathsf{StreamDiagonalSelector}^{\uparrow}$

The $\mathsf{StreamDiagonalSelector}^{\uparrow}$ interface packages the finite diagonal selector row used between $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{RealDiagonalCompletion}^{\uparrow}$. Following Bishop-style constructive diagonalization, a consumer precision request is answered by an explicit finite stream window, a regular-rational readback, a dyadic observation ledger, and a diagonal-completion packet. The certificate does not classify quotient streams, select a completed real by choice, or compare host real equality.

The selector is the finite routing surface between chapter 371 and chapter 359. It consumes the RegularCauchyName stream-window and dyadic-readback rows, then hands the same selected window to the RealDiagonalCompletion packet before any $\mathsf{Real}^{\uparrow}$ seal can be read.

Definition 393.1 (StreamDiagonalSelector carrier)**.** *A* $\mathsf{StreamDiagonalSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, \mu, W, R, D_H, H, C, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the finite stream windows that may be inspected by the diagonal consumer;*
2. *μ is the displayed selector row assigning each unary precision request to the diagonal window index read from S;*
3. *W is the selected finite* $\mathsf{StreamName}^{\uparrow}$ *window, including the member index and observation index used by the diagonal read;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row naming the rational observation extracted from the selected window;*
5. *D_H is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger recording the endpoint, radius, comparison, and precision rows attached to the readback;*
6. *H records the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *packet that consumes the same selected window, readback, and dyadic ledger;*
7. *C records the displayed* Cont *routes from the selector request to S, μ, W, R, D_H, and H;*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, *and* Cont*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{StreamDiagonalSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the listed finite rows, their componentwise hsame *transports, the displayed* Cont *routes, package provenance, and local naming row. It has no coordinate for a quotient stream, choice-selected limit, external real value, or host equality test.*

Lean4 ✓ `BEDC.Derived.StreamDiagonalSelectorUp.TasteGate.StreamDiagonalSelectorTasteGate single carrier alignment`

Theorem 393.2 (StreamDiagonalSelector NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{StreamDiagonalSelector}^{\uparrow}}$ *obligation surface consists of five finite rows:*

1. *carrier habitation: the finite packet of Definition 393.1 stores the stream schedule, selector row, selected window, rational readback, dyadic observation ledger, diagonal-completion packet, transport routes, package provenance, and local naming row;*
2. *selector determinacy: for each displayed precision request, the selected window is the one read from μ and S, so two accepted packets with the same transported selector rows expose the same diagonal window coordinate;*
3. *finite-window transport: the* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger transport together along the componentwise* hsame *and* Cont *rows recorded in C;*
4. *diagonal handoff exactness: the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *packet H consumes exactly the selected window W, readback R, dyadic ledger D_H, package provenance P, and local naming row N;*
5. *non-escape: every consumer-visible read is exhausted by the displayed selector packet and exports no quotient stream, no choice-selected limit, no host real equality, and no external completed-real carrier.*

Lean4 ✓ `BEDC.Derived.StreamDiagonalSelectorUp.StreamDiagonalSelectorTasteGate single carrier alignment`

Proof. Carrier habitation is obtained by projecting the finite history packet. The schedule S, selector row μ, selected window W, readback R, dyadic ledger D_H, diagonal packet H, continuation routes, package provenance, and local naming row are all named coordinates.

Selector determinacy follows because μ is part of the displayed packet. A precision request cannot select a different window without leaving the recorded route through S and μ, and the classifier exposes only the transported versions of those two rows.

For finite-window transport, move S, μ, and W by the componentwise hsame rows and replay the Cont routes in C. The readback R and ledger D_H are attached to that same selected window, so they move with it as a single finite observation.

The diagonal handoff is the projection to H. Since H is stored beside W, R, D_H, P, and N, the $\mathsf{RealDiagonalCompletion}^{\uparrow}$ consumer receives precisely those rows and no hidden selector.

Finally inspect the carrier shape. There is no field for quotient stream equality, a choice-selected limit, host real equality, or an external completed real, so the local naming certificate cannot export any such datum. □

Theorem 393.3 (StreamDiagonalSelector RealUp handoff)**.** *For every accepted* $\mathsf{StreamDiagonalSelector}^{\uparrow}$ *carrier $D = (S, \mu, W, R, D_H, H, C, P, N)$, every downstream* $\mathsf{Real}^{\uparrow}$ *read factors through the selected finite* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger D_H, and the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *packet H. The handoff supplies a finite real-facing observation route and does not export a quotient stream, a choice-selected limit, a host real value, or host real equality.*

Lean4 ✓ `BEDC.Derived.StreamDiagonalSelectorUp.StreamDiagonalSelectorPacket real handoff`

Proof. Start from a downstream $\mathsf{Real}^{\uparrow}$ read and project the carrier. The only route from a precision request to a stream observation is the displayed path through S, μ, and the selected finite window W.

The selected window is then read through the regular rational row R. The dyadic ledger D_H records the endpoint, radius, precision, and comparison data consumed by that readback, so the observation is a finite BEDC row rather than an external stream value.

The $\mathsf{RealDiagonalCompletion}^{\uparrow}$ coordinate H repacks the same W, R, and D_H rows for the completion-facing boundary. Replaying the routes in C and the provenance in P keeps the downstream $\mathsf{Real}^{\uparrow}$ consumer inside the same local $\mathsf{NameCert}$ packet.

Since the carrier has no further coordinate beyond those rows, no quotient stream, choice-selected limit, host real value, or host real equality can be read from the handoff. □

Theorem 393.4 (StreamDiagonalSelector selector determinacy)**.** *If two accepted* $\mathsf{StreamDiagonalSelector}^{\uparrow}$ *reads pass through the same displayed selector row μ and the same* $\mathsf{StreamName}^{\uparrow}$ *schedule S, then they expose the same classifier-facing selected window coordinate. The determinacy is a statement about the visible selector packet and does not compare quotient streams, selected limits, host real values, or host equality.*

Lean4 ✓ `BEDC.Derived.StreamDiagonalSelectorUp.StreamDiagonalSelectorPacket selector determinacy`

Proof. Unpack the carrier of Definition 393.1. A downstream precision request reaches a selected window only by reading the schedule S and the selector row μ.

The NameCert obligation surface in Definition 393.2 records selector determinacy as one of the finite rows. Thus two reads through the same transported S and μ expose the same selected window coordinate to the classifier.

Finally apply Definition 393.3. The handoff has no alternate coordinate for a quotient stream, selected completed value, external real carrier, or host equality test, so no second selector source can alter that coordinate. □

Theorem 393.5 (StreamDiagonalSelector finite-window transport)**.** *The selected* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D_H, and the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *packet H transport together through the recorded* hsame *and* Cont *rows of an accepted* $\mathsf{StreamDiagonalSelector}^{\uparrow}$ *carrier.*

Proof. Unpack the accepted packet in Definition 393.1. The rows W, R, D_H, and H are stored as the selected finite observation route, and the row C stores the displayed continuation routes that connect them.

Use Definition 393.2. Its finite-window transport row states that the selected stream window, regular-rational readback, and dyadic ledger move together along the componentwise hsame and Cont rows.

The RealUp handoff of Definition 393.3 consumes the same W, R, D_H, and H rows. Therefore transport cannot detach the readback, ledger, or diagonal packet from the selected window. □

Theorem 393.6 (StreamDiagonalSelector handoff exactness)**.** *Every* $\mathsf{Real}^{\uparrow}$ *handoff from an accepted* $\mathsf{StreamDiagonalSelector}^{\uparrow}$ *carrier consumes exactly the selected finite window W, readback row R, dyadic ledger D_H, diagonal-completion packet H, package row P, and local* $\mathsf{NameCert}$ *row N. It consumes no quotient stream, selected limit, host equality, or external completed-real carrier.*

Proof. Project the carrier of Definition 393.1. The real-facing rows after selector evaluation are precisely W, R, D_H, H, P, and N, with the recorded routes in C mediating access to them.

Apply Definition 393.2. Its handoff exactness and non-escape rows state that the diagonal packet consumes the selected finite window, readback, dyadic ledger, provenance, and local naming row without adding an external selector.

Finally use Definition 393.3. It identifies the downstream $\mathsf{Real}^{\uparrow}$ route with those same rows, so no quotient stream, selected completed value, host equality, or outside real carrier can be read by the handoff. □

Theorem 393.7 (StreamDiagonalSelector tail-budget readback)**.** *Let $D = (S, \mu, W, R, D_H, H, C, P, N)$ be an accepted* $\mathsf{StreamDiagonalSelector}^{\uparrow}$ *packet. If its selected finite window W is consumed by an accepted* $\mathsf{RegularCauchyTailBudget}^{\uparrow}$ *row, then the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *handoff H factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule S, selector row μ, selected finite window W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger D_H,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the shared tail-threshold and observation-budget rows of the* $\mathsf{RegularCauchyTailBudget}^{\uparrow}$ *packet, and the local* $\mathsf{NameCert}$ *route N.*

Thus every such handoff remains a finite route through the selector packet and the tail-budget readback surface. It exports no quotient stream, selected host limit, ambient completeness principle, or host real equality.

Proof. Project the selector carrier. The only rows available to the diagonal consumer are the schedule S, selector row μ, selected window W, readback row R, dyadic ledger D_H, diagonal packet H, routes C, provenance P, and local name N.

Use selector determinacy, finite-window transport, and handoff exactness. These results keep the selected window attached to the same schedule and selector row, move W, R, D_H together through the displayed hsame and Cont data, and identify H as the packet consuming exactly those rows.

Now apply the $\mathsf{RegularCauchyTailBudget}^{\uparrow}$ observation gate and readback factorization to the budget row that consumes W. They route the window service through the shared tail threshold, observation budget, dyadic ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ readback before any real-facing seal or completion-facing consumer is exposed.

Combining the two routes gives a single finite handoff from S, μ, W, D_H, R through the tail-budget rows to H and N. Since neither carrier stores quotient streams, selected host limits, ambient completeness, or host real equality, no such datum can be read from the composed handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{StreamDiagonalSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{StreamDiagonalSelector}^{\uparrow}$ packet is generated from a $\mathsf{StreamName}^{\uparrow}$ schedule, a displayed selector row, one selected finite stream window, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger, a $\mathsf{RealDiagonalCompletion}^{\uparrow}$ diagonal packet, displayed hsame and Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StreamDiagonalSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 393.1, Definition 393.2, and Definition 393.3 describe the seed finite diagonal selector certificate consumed by real-completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StreamDiagonalSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close RealUp completeness, uniqueness of completed limits, quotient equality of streams, a public standard bridge, or checked Lean implementation.

Upgrade path: Obligation closure requires checked carrier habitation, selector determinacy, finite-window transport, diagonal handoff exactness, and non-escape for $\mathsf{StreamDiagonalSelector}^{\uparrow}$.

Chapter 394

A Concrete Naming Certificate for $\mathsf{LocatedInterval}^{\uparrow}$

The $\mathsf{LocatedInterval}^{\uparrow}$ packet names a finite interval surface whose endpoints are carried as located real names while its inspection ledgers remain rational and dyadic. It consumes the dyadic refinement carrier of chapter 306 together with chapter 126, chapter 301, and chapter 38 for its endpoint-window and seal rows. In the Bishop–Bridges constructive-analysis setting, an interval is read through explicit endpoint names, rational cells, dyadic refinements, and finite real-name windows; it is not a host interval primitive and does not choose completed endpoint values.

Definition 394.1 (LocatedInterval carrier)**.** *A* $\mathsf{LocatedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

with the following visible rows:

1. *L is the lower endpoint row, a* $\mathsf{LocatedReal}^{\uparrow}$ *packet displayed in the same history;*
2. *U is the upper endpoint row, a* $\mathsf{LocatedReal}^{\uparrow}$ *packet displayed in the same history;*
3. *I is a* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger whose endpoint and containment rows give the rational windows currently enclosing the endpoint reads;*
4. *D is the optional finite family of* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement rows attached to selected rational cells;*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger naming the finite endpoint observations inspected from L and U;*
6. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks used by those endpoint windows;*
7. *E records the* $\mathsf{Real}^{\uparrow}$ *seal-facing rows for the lower and upper endpoint names;*
8. *H records the componentwise* hsame *transports for located endpoints, rational cells, dyadic refinements, stream windows, readbacks, and seal rows;*
9. *C records the displayed* Cont *read routes by which a finite consumer reaches exactly those endpoint, interval, refinement, window, readback, and seal rows;*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and the local rational source rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ *provenance row.*

The carrier predicate is the assertion that these rows form one finite located interval packet. It has no coordinate for a host real interval, an endpoint choice functional, a quotient of real names, or an ambient order-completeness theorem.

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalTasteGate single carrier alignment`

Theorem 394.2 (LocatedInterval NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ *obligation surface consists of five finite rows:*

1. *carrier habitation, given by any displayed pair of* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows together with a rational cell ledger enclosing the inspected endpoint windows;*
2. *endpoint transport, which moves the lower and upper* $\mathsf{LocatedReal}^{\uparrow}$ *rows componentwise through the stored* hsame *and* Cont *witnesses;*
3. *interval containment exactness, which says that every containment read is one of the rational cells in I or one of the dyadic refinements in D routed by the packet;*
4. *refinement handoff, which permits a* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row only as a finite refinement of a displayed* $\mathsf{RationalInterval}^{\uparrow}$ *cell;*
5. *non-escape of host real intervals, which forces every endpoint, containment, and seal read through L, U, I, D, S, R, E, H, C, P, and N.*

These rows are exactly the naming-certificate surface for located real endpoint data bound to rational and dyadic interval ledgers.

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket semantic name certificate`

Proof. Carrier habitation is obtained by packaging the two displayed endpoint names with one rational cell ledger and the finite observation windows used to read them. The packet stores those rows directly, so no external interval carrier is needed.

Endpoint transport is componentwise. The lower endpoint row and the upper endpoint row each move along their own hsame comparison and the displayed Cont route that reads the corresponding finite window.

Containment exactness is a projection from the carrier. A rational containment read must come from I, and a dyadic containment read must come from one of the refinement rows in D; both are routed by the same history and package provenance.

For the refinement handoff, read a dyadic row only together with the rational cell it refines. Repacking that pair preserves the interval surface because the consumer still sees the same endpoints, window routes, and readback rows.

The non-escape row follows by inspecting the coordinates of Definition 394.1. There is no field from which a host interval, chosen endpoint value, quotient real, or ambient completeness principle could be exported. □

Theorem 394.3 (LocatedInterval endpoint transport)**.** *Let two accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packets be related by the displayed componentwise transport rows. Then the lower* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint, the upper* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint, the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger, every present* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and the* $\mathsf{Real}^{\uparrow}$ *seal rows transport together as one located interval packet.*

Consequently a consumer of the transported packet can read only the transported endpoint rows and the transported interval ledgers carried by the same BHist, hsame, Cont, Pkg, *and local* NameCert *provenance.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket endpoint transport`

Proof. Project both packets through Definition 394.1. The hypotheses give separate transport rows for the lower endpoint, upper endpoint, rational cell ledger, dyadic refinements, stream windows, readbacks, and seal rows.

Transport the two endpoint names first. Their $\mathsf{LocatedReal}^{\uparrow}$ windows and $\mathsf{Real}^{\uparrow}$ seal-facing rows move by the stated componentwise hsame witnesses and keep the same finite read routes.

Next transport the interval ledger. The rational cells in I and the dyadic refinement rows in D are carried by their own displayed comparisons, so each transported containment row remains attached to the transported endpoint windows.

Finally repack the transported rows with the transported package and local naming provenance. Since the carrier admits only these projected rows, the transported packet has no additional consumer route beyond the displayed endpoint and interval data. □

Theorem 394.4 (LocatedInterval carrier habitation)**.** *For a displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, the carrier-habitation obligation for $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ *is witnessed exactly by the displayed* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows* L *and* U*, the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger* I*, the optional* $\mathsf{DyadicInterval}^{\uparrow}$ *family* D*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R*, the* $\mathsf{Real}^{\uparrow}$ *seal rows* E*, the componentwise* hsame *transports* H*, the displayed* Cont *routes* C*, the* Pkg *provenance* P*, and the local certificate row* N*.*

No further carrier coordinate is required or available.

Proof. Project the packet through Definition 394.1. Each row named in J is part of the same finite BHist display, and the package provenance records that those rows are read under $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

The habitation witness is therefore the finite tuple J itself, read with its displayed routes. Since the carrier definition contains no host interval coordinate and no chosen endpoint value, the certificate cannot draw on any ambient interval object. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket carrier habitation`

Theorem 394.5 (LocatedInterval containment exactness)**.** *For a displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, every containment read accepted by the local $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ *is routed by* C *to either the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger* I *or a present* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row in* D*. Endpoint movement used by such a read is the movement supplied by Definition 394.3.*

Thus containment exactness is a finite projection from J*, not a claim about all host intervals between two completed real values.*

Proof. Inspect the carrier coordinates. The only interval-containment rows available to a consumer are the rational cells in I and the dyadic refinement rows in D, and every admissible read must pass through the displayed Cont route C and the provenance P.

If the containment read is compared after endpoint transport, apply Definition 394.3 first. The lower and upper $\mathsf{LocatedReal}^{\uparrow}$ rows, their finite windows, the readbacks, and the seal-facing rows move together, so the transported containment route still lands in the transported copy of I or D.

There is no separate containment source in Definition 394.1. Exactness therefore follows by ruling out any read not projected from the listed finite rows. □

Theorem 394.6 (LocatedInterval dyadic refinement handoff)**.** *For a displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, a $\mathsf{DyadicInterval}^{\uparrow}$ *row may be handed to a finite consumer only together with the* $\mathsf{RationalInterval}^{\uparrow}$ *cell in* I *that its displayed route refines. Under the endpoint movement of Definition 394.3, the handoff remains attached to the transported rational cell ledger and the transported endpoint windows.*

The handoff obligation is therefore internal to BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *over the rows of* J*.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket dyadic refinement handoff`

Proof. Start with a present dyadic refinement row in D. By Definition 394.1, that row is stored only as part of the same finite packet as the rational ledger I, with the route C displaying how the refinement is reached from the inspected interval data.

Transported endpoint reads are handled before the handoff. Apply Definition 394.3 to move L, U, I, D, S, R, and E through the componentwise hsame rows in H while preserving the consumer routes.

The consumer can then receive the dyadic row only with its rational parent cell and the same package provenance. No rule in the carrier permits a dyadic refinement detached from I or from the displayed finite history. □

Theorem 394.7 (LocatedInterval real-seal non-escape)**.** *For a displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, every seal-facing read accepted by the local $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ *factors through the* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows* L *and* U*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R*, the* $\mathsf{Real}^{\uparrow}$ *rows* E*, the componentwise* hsame *transports* H*, the displayed* Cont *routes* C*, the* Pkg *provenance* P*, and the local row* N*. Endpoint movement is exactly the movement supplied by Definition 394.3.*

Consequently the packet cannot export a host real interval, a selected endpoint value, quotient real equality, or ambient order completeness.

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket real seal non escape`

Proof. Read the seal-facing part of the carrier. The only real rows present are the lower and upper $\mathsf{LocatedReal}^{\uparrow}$ endpoint displays, their finite $\mathsf{StreamName}^{\uparrow}$ windows, the associated $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, and the $\mathsf{Real}^{\uparrow}$ rows explicitly recorded in E.

When a seal-facing read is transported, apply Definition 394.3. The same componentwise hsame and Cont data move the endpoint windows, readbacks, rational cells, dyadic refinements, and seal rows as one packet.

It remains to exclude non-displayed real data. The carrier in Definition 394.1 has no coordinate for an ambient interval, no quotient of real names, and no completeness principle; every accepted read must therefore remain inside J and its local NameCert provenance. □

Theorem 394.8 (LocatedInterval real-seal ledger scope)**.** *For a displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, every real-seal read accepted by the local $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ *exposes only the endpoint-window and interval-cell ledger already present in* J*: the* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows* L *and* U*, the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger* I*, optional* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement rows* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window ledger* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R*, the* $\mathsf{Real}^{\uparrow}$ *seal rows* E*, the componentwise* hsame *transports* H*, the displayed* Cont *routes* C*, the* Pkg *provenance* P*, and the local row* N*.*

Thus the real-seal ledger scope of a $\mathsf{LocatedInterval}^{\uparrow}$ *packet is the endpoint-window and interval-cell subledger of* J*; it does not contain a selected real endpoint value, a quotient of endpoint names, a host interval, or an external interval endpoint oracle.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket real seal ledger scope`

Proof. Project the packet through Definition 394.1. The only endpoint rows named there are L and U, the only interval-cell rows are I and D, and the only finite observation rows attached to the endpoints are the $\mathsf{StreamName}^{\uparrow}$ windows S, the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks R, and the $\mathsf{Real}^{\uparrow}$ seal-facing rows E.

Endpoint movement is already constrained by Definition 394.3. Its componentwise transport keeps the lower endpoint, upper endpoint, windows, readbacks, and seal rows under the displayed hsame witnesses and Cont routes.

Containment and refinement movement is constrained by Definition 394.5 and Definition 394.6. These results keep rational cells and dyadic refinements attached to the displayed interval ledger.

It remains to rule out non-displayed seal data. Since the carrier has no coordinate beyond J and its Pkg and NameCert provenance, every accepted real-seal read is a projection from the listed endpoint-window and interval-cell rows. □

Theorem 394.9 (LocatedInterval containment transport scope)**.** *For a displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, $\mathsf{RationalInterval}^{\uparrow}$ *containment exactness is stable under endpoint* hsame *movement, displayed* Cont *routes, and* $\mathsf{DyadicInterval}^{\uparrow}$ *refinements. Rational containment reads and dyadic refinement handoffs remain attached to the same endpoint ledger and the same rational cell ledger of* J*.*

More precisely, every rational containment read is routed to I*, every dyadic refinement read is routed to a present row of* D *together with its rational parent cell in* I*, and endpoint transport carries these routes with* L*,* U*,* S*,* R*,* E*,* H*,* C*,* P*, and* N*.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket containment transport scope`

Proof. First read the rational containment side. By Definition 394.5, a containment read accepted by the local certificate must land in the rational cell ledger I or in a displayed dyadic refinement row of D.

Next read the refinement side. By Definition 394.6, a dyadic row is delivered only with the rational cell in I refined by its displayed route, so it cannot detach from the cell ledger.

Finally apply Definition 394.3. The endpoint hsame witnesses, displayed Cont routes, finite windows, readbacks, seal rows, rational cells, and dyadic refinements move as one finite packet, so containment and refinement remain attached to the same endpoint and cell ledgers after transport. □

Theorem 394.10 (LocatedInterval endpoint-window readback exhaustion)**.** *For a displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, every endpoint read accepted by the local $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ *is exhausted by the two* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows* L *and* U*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R*, the* $\mathsf{Real}^{\uparrow}$ *seal rows* E*, and the displayed transport, route, package, and provenance rows* H, C, P, N*.*

After endpoint transport, the same endpoint read lands in the transported copies of those rows and in no further endpoint source.

Proof. Begin with the carrier display in Definition 394.1. The only endpoint coordinates of J are the lower row L and the upper row U, and the only finite observations attached to them are the windows S, readbacks R, and seal-facing rows E.

Apply Definition 394.3 to any comparison of accepted packets. It transports L, U, S, R, E together with the displayed hsame rows H, continuation routes C, package row P, and local naming row N.

It remains to rule out an unlisted endpoint source. The carrier has no coordinate for a chosen endpoint value, quotient real equality, host interval, or completeness theorem, so every endpoint read is a projection from the displayed rows of J. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket endpoint window readback exhaustion`

Theorem 394.11 (LocatedInterval endpoint-cell seal factorization)**.** *For every displayed* $\mathsf{LocatedInterval}^{\uparrow}$ *packet*

$$J = (L, U, I, D, S, R, E, H, C, P, N),$$

every endpoint consumer and every containment consumer factors through the same ordered route: the $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows* L, U*, the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger* I*, any attached* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row in* D*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R*, the* $\mathsf{Real}^{\uparrow}$ *seal rows* E*, and finally the* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows* H, C, P, N*. No host interval, selected endpoint value, quotient real equality row, or ambient completeness row can bypass this chain.*

Proof. Begin with endpoint reads. By Definition 394.10, any accepted endpoint consumer is exhausted by $L, U, S, R, E, H, C, P, N$, so the consumer has no endpoint source outside the displayed packet.

Now read the containment side. The rational cell component is forced through I by Definition 394.5, and a dyadic refinement component can be consumed only through a displayed row of D attached to its rational parent by Definition 394.6.

Endpoint and containment transport then share the same finite route. Apply Definition 394.3 and Definition 394.9 to keep the endpoint rows, cell ledger, refinements, windows, readbacks, seal rows, and BEDC rows moving componentwise through H, C, P, N.

Finally use Definition 394.7. The $\mathsf{Real}^{\uparrow}$ seal boundary admits only the displayed endpoint-window-readback route and contains no coordinate for a host interval, selected endpoint value, quotient real equality row, or ambient completeness principle. Hence every endpoint or containment consumer factors through the ordered rows of J. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket endpoint cell seal factorization`

Theorem 394.12 (LocatedInterval rational–dyadic cell chain)**.** *For a displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, every containment consumer reads either a $\mathsf{RationalInterval}^{\uparrow}$ *cell in* I *or a* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row in* D *attached to such a rational cell. Under endpoint transport, the rational cell and its displayed dyadic refinements remain attached to the transported endpoint windows and readbacks.*

Proof. Read the rational side first. By Definition 394.5, an accepted containment route lands in the rational ledger I unless it is a routed dyadic refinement.

For the dyadic side, apply Definition 394.6. A row of D can be consumed only together with the rational parent cell in I that its route refines.

Finally transport the endpoints by Definition 394.3. The endpoint rows, windows, readbacks, seal rows, rational cells, and dyadic refinements move through the same displayed H, C, P, N data, so the rational–dyadic chain cannot detach from the transported endpoint ledger. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket rational dyadic cell chain`

Theorem 394.13 (LocatedInterval scoped real-seal scope)**.** *For a displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, every $\mathsf{Real}^{\uparrow}$ *seal-facing read accepted by the local* $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ *factors through* $L, U, S, R, E, H, C, P, N$*. Such a read cannot introduce a host interval, endpoint choice, quotient real equality, or order-completeness principle.*

Proof. Use Definition 394.7 for the seal boundary. It already routes every seal-facing read through the endpoint rows, finite windows, readbacks, seal rows, transports, continuation routes, package provenance, and local naming row.

The endpoint part of that factorization is exhausted by Definition 394.10; the interval side is constrained by Definition 394.12. Together these two dependencies keep seal reads on the same finite endpoint-window and rational–dyadic cell ledger.

No remaining coordinate of Definition 394.1 can supply host interval data, an endpoint choice functional, quotient real equality, or order completeness. The scoped seal scope is therefore exactly the displayed subledger of J. □

Theorem 394.14 (LocatedInterval kernel scope package)**.** *For a displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, the $\mathsf{LocatedInterval}^{\uparrow}$ *scoped kernel package consists exactly of the following finite interface rows:*

1. *carrier habitation by the displayed tuple* J*;*
2. *endpoint transport through the componentwise* hsame *and* Cont *rows of* H *and* C*;*
3. *containment exactness for the* $\mathsf{RationalInterval}^{\uparrow}$ *ledger* I*;*
4. *dyadic refinement handoff from rows of* D *to their rational parent cells in* I*;*
5. *real-seal non-escape through the endpoint, window, readback, and seal rows* L*,* U*,* S*,* R*, and* E*.*

All five rows are repacked over one scoped BEDC packet over BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket kernel scope package`

Proof. The carrier row is Definition 394.1 read as the finite tuple J. Carrier habitation is then the projection described by Definition 394.4.

The endpoint part of the interface is supplied by Definition 394.3 and sharpened to the displayed seal subledger by Definition 394.8. These two results give exactly the lower and upper endpoint routes visible in J.

The interval part is supplied by Definition 394.5, Definition 394.6, and Definition 394.9. Together they keep rational containment and dyadic refinement reads on the same finite endpoint and cell ledgers.

The seal boundary is Definition 394.7. Repacking these projected rows under the same BHist, Pkg, and NameCert data yields the scoped kernel interface, and no additional row can be introduced because the carrier contains no host interval or ambient completeness coordinate. □

Definition 394.15 (LocatedInterval public certificate interface)**.** *The public certificate interface for* $\mathsf{LocatedInterval}^{\uparrow}$ *is the finite tuple surface*

$$\mathcal{I}_{\mathsf{LocatedInterval}^{\uparrow}} = (L, U, I, D, S, R, E, H, C, P, N)$$

whose coordinates are the lower and upper endpoint rows L, U*, the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger* I*, the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger* D*, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R*, the* $\mathsf{Real}^{\uparrow}$ *seal rows* E*, and the BEDC rows* H, C, P, N *for displayed* hsame *transports,* Cont *routes, package provenance, and local naming.*

Theorem 394.16 (LocatedInterval public export packet)**.** *For every displayed finite history row*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

accepted by the $\mathsf{LocatedInterval}^{\uparrow}$ *carrier, Definition 394.14 repacks exactly its carrier habitation, endpoint transport, rational containment exactness, dyadic refinement handoff, real-seal non-escape, scoped real-seal scope, and kernel-scope rows as one public* $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ *export over* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The export contains no coordinate outside the public certificate interface of Definition 394.15.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket public export packet`

Proof. First read the carrier surface from Definition 394.1 and Definition 394.4. This gives the finite tuple J with no hidden coordinate.

The endpoint component is supplied by Definition 394.3; the rational component is supplied by Definition 394.5; and the dyadic component is supplied by Definition 394.6. These are exactly the endpoint, cell, and refinement rows of $\mathcal{I}_{\mathsf{LocatedInterval}^{\uparrow}}$.

The Real-facing component is bounded by Definition 394.7 and scoped by Definition 394.13. Combining these rows through Definition 394.14 yields the named $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ export, and the displayed interface already lists every row used by the repacking. □

Theorem 394.17 (LocatedInterval public consumer route)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*, or* $\mathsf{DyadicInterval}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packet factors through the public export packet of Definition 394.16. The consumer route is only the displayed carrier, endpoint transport, containment exactness, dyadic refinement, seal non-escape, and scoped seal ledger over* BHist*,* hsame*,* Cont*,* Pkg*,* $\mathsf{NameCert}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket public consumer route`

Proof. For endpoint-window and readback consumers, apply Definition 394.10. Their reads pass through the endpoint rows L, U, StreamName windows S, RegSeqRat readbacks R, and the same transport and continuation rows.

For rational and dyadic interval consumers, apply Definition 394.12. Its exactness and handoff dependencies are Definition 394.5 and Definition 394.6, so the consumer sees only the public cell ledger I and refinement ledger D.

For Real-facing consumers, apply Definition 394.13 and Definition 394.16. The seal rows E and BEDC rows H, C, P, N are already part of $\mathcal{I}_{\mathsf{LocatedInterval}^{\uparrow}}$, while the carrier and kernel package expose no coordinate beyond the displayed public route. □

Theorem 394.18 (LocatedInterval real comparison boundary)**.** *Any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison that uses a public* $\mathsf{LocatedInterval}^{\uparrow}$ *packet is bounded by the endpoint windows, readbacks, rational cells, dyadic refinements, seal rows,* hsame *transports,* Cont *routes,* Pkg *provenance, and* $\mathsf{NameCert}$ *row named in Definition 394.16. It cannot read a host interval primitive, selected endpoint value, quotient real equality witness, or order-completeness principle.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket real comparison boundary`

Proof. The comparison first enters through the public consumer route of Definition 394.17. Thus every $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ read has already been restricted to $\mathcal{I}_{\mathsf{LocatedInterval}^{\uparrow}}$.

Apply Definition 394.7 for the seal boundary and Definition 394.13 for its scoped form. These results route the comparison through $L, U, S, R, E, H, C, P, N$ and keep the rational and dyadic side attached by Definition 394.12.

Finally use Definition 394.14. The package contains no host interval primitive, selected endpoint value, quotient real equality witness, or order-completeness principle, so the public comparison boundary has exactly the displayed rows and no additional real construction. □

Theorem 394.19 (LocatedInterval endpoint-cell route totality)**.** *For every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packet*

$$J = (L, U, I, D, S, R, E, H, C, P, N),$$

each endpoint request and each containment request routes through the same displayed finite surface: the endpoint-window rows L, U, S, R, E*, the rational and dyadic cell rows* I, D*, and the BEDC rows* H, C, P, N*. No accepted endpoint or containment read uses a coordinate outside this surface.*

Proof. Endpoint-window and endpoint-readback requests are exhausted by Definition 394.10. They therefore read only the lower and upper endpoint rows, the attached $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, the $\mathsf{Real}^{\uparrow}$ seal rows, and the displayed transport and continuation rows.

Containment requests are exhausted by Definition 394.12. Rational containment reads enter through I, dyadic refinement reads enter through D, and both return to the same endpoint rows under the displayed containment transport.

Finally apply Definition 394.17. It repacks the endpoint and cell routes as one public consumer surface over J, so endpoint, rational containment, and dyadic containment requests are total exactly on the rows $L, U, I, D, S, R, E, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket endpoint cell route totality`

Theorem 394.20 (LocatedInterval stream readback cell compatibility)**.** *In every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packet, the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks attached to the lower and upper endpoints remain compatible with transported rational and dyadic containment cells. Transport of an endpoint read along H and C preserves the containment-cell route through I and D, and transport of a containment read preserves the endpoint-window and readback rows through L, U, S, R, E.*

Proof. Begin with endpoint transport. By Definition 394.3, endpoint comparisons and readbacks move componentwise through the displayed hsame and Cont rows, so the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows remain attached to the same lower and upper endpoints.

Now use the containment transport scope of Definition 394.9. It states that rational containment rows and dyadic refinements are transported through the same endpoint package rather than through a separate interval carrier.

Combining these two transport statements with Definition 394.12 gives compatibility: endpoint-window readback cannot detach from I or D, and cell containment cannot detach from L, U, S, R, E. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket stream readback cell compatibility`

Theorem 394.21 (LocatedInterval downstream root-unblock package)**.** *For every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packet $J = (L, U, I, D, S, R, E, H, C, P, N)$, the finite root package consumed by* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, *and* $\mathsf{DyadicInterval}^{\uparrow}$ *is exactly the public export packet of Definition 394.16, the real comparison boundary of Definition 394.18, the endpoint-cell route totality of Definition 394.19, and the stream-readback cell compatibility of Definition 394.20. This package excludes host intervals, selected endpoints, quotient real equality, and order completeness.*

Proof. The public export packet supplies the finite carrier-facing surface over $L, U, I, D, S, R, E, H, C, P, N$. It already names the endpoint, cell, seal, transport, continuation, provenance, and local naming rows available to downstream consumers.

The endpoint-cell route totality theorem gives a single route for endpoint requests and containment requests. The stream-readback cell compatibility theorem then shows that these routes remain attached under endpoint transport and containment transport.

Finally use the real comparison boundary. It is the $\mathsf{Real}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ edge of the same package, and it excludes host intervals, selected endpoints, quotient real equality, and order completeness. Hence the five downstream consumers receive exactly the displayed finite root package. □

Theorem 394.22 (LocatedInterval bridge-facing certificate package)**.** *For every displayed accepted packet*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

of $\mathsf{LocatedInterval}^{\uparrow}$, *the public export packet, public consumer route, and real comparison boundary assemble one bridge-facing certificate over exactly the rows* $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}$. *The certificate packages the endpoint rows, rational-cell ledger, dyadic-refinement ledger, and* $\mathsf{Real}^{\uparrow}$ *seal rows of J, and it exports no host interval primitive, selected endpoint value, quotient real equality, or order-completeness principle.*

Proof. Use Definition 394.16 for the certificate surface. It gives the public $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ export over the displayed endpoint, rational-cell, dyadic-refinement, seal, transport, continuation, package, and naming rows of J.

Use Definition 394.17 for downstream access. Every $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, and $\mathsf{DyadicInterval}^{\uparrow}$ consumer is forced through the same public rows, so the certificate has a single bridge-facing consumer surface rather than separate endpoint, interval, and real routes.

Use Definition 394.18 for the Real-facing boundary. It fixes the permitted comparison reads to the endpoint windows, readbacks, rational cells, dyadic refinements, seal rows, hsame transports, Cont routes, Pkg provenance, and local NameCert row.

Finally apply Definition 394.14. Its non-escape statement keeps the package inside the concrete rows of J, so the assembled certificate has exactly the displayed BEDC surface and cannot export a host interval primitive, selected endpoint value, quotient real equality, or order-completeness principle. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalUp StdBridge`

Theorem 394.23 (LocatedInterval endpoint order window)**.** *For every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packet, each endpoint order read is a finite row over the lower and upper* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows, the* $\mathsf{RationalInterval}^{\uparrow}$ *containment ledger, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{Real}^{\uparrow}$ *seal-facing rows, and the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *coordinates. The read cannot inspect a host interval order, an ambient endpoint selector, quotient real equality, or order completeness outside those rows.*

Proof. Start from the carrier of Definition 394.1. Its endpoint data are the displayed lower and upper rows together with the stream windows and regular rational readbacks attached to those rows.

Apply Definition 394.3 to move endpoint comparisons through the componentwise hsame rows and the displayed Cont routes. Apply Definition 394.10 for the readback boundary, so every order read is witnessed by the finite endpoint-window and regular-readback rows.

The $\mathsf{Real}^{\uparrow}$ boundary is supplied by Definition 394.7. Since the carrier has no coordinate for a host interval order, selected endpoint, quotient real equality, or completeness principle, the endpoint order window is exhausted by the named finite rows. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket endpoint order window`

Theorem 394.24 (LocatedInterval rational cell coverage route)**.** *Every rational or dyadic containment read of an accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packet routes through the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger* I *or the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger* D*, and then through the endpoint transport row. Thus containment coverage is read only from* I*,* D*, the lower and upper endpoint rows, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates.*

Proof. Inspect a rational containment read. By Definition 394.5, the read is a projection of the $\mathsf{RationalInterval}^{\uparrow}$ cell ledger I attached to the displayed endpoint rows.

Inspect a dyadic containment read. By Definition 394.6, the read first enters the $\mathsf{DyadicInterval}^{\uparrow}$ refinement ledger D and then hands back to the same rational-cell and endpoint rows.

Finally apply Definition 394.9. The transport row preserves the endpoint, cell, and refinement coordinates componentwise, so rational and dyadic coverage cannot leave I, D, and the finite BEDC rows that carry them. □

Theorem 394.25 (LocatedInterval dyadic real-seal handoff)**.** *For every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packet*

$$J = (L, U, I, D, S, R, E, H, C, P, N),$$

every dyadic refinement row in D *that contributes to a* $\mathsf{Real}^{\uparrow}$ *seal read must pass through its rational parent cell in* I*, the endpoint-window rows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* R*, the* $\mathsf{Real}^{\uparrow}$ *seal rows* E*, and the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *rows* H, C, P, N*. The handoff has no coordinate for a host interval, selected endpoint value, quotient real, or ambient order-completeness principle.*

Proof. Project the carrier of Definition 394.1. Its refinement data appear as the displayed row D, and its seal-facing data appear only through the endpoint windows S, readbacks R, seal rows E, and the transport, continuation, provenance, and naming rows H, C, P, N.

Use containment exactness and dyadic refinement handoff. Theorems 394.5 and 394.6 force every dyadic read in D back through the rational parent cell ledger I before it can be consumed as interval evidence.

Now apply real-seal non-escape and rational-cell coverage. Theorems 394.7 and 394.24 keep the Real-facing read attached to the endpoint-window, regular-readback, seal, rational-cell, and dyadic-refinement rows of the same packet.

Finally use the carrier inventory. Since J contains no host interval coordinate, selected endpoint selector, quotient real carrier, or order-completeness field, the only possible handoff from dyadic refinement evidence to a $\mathsf{Real}^{\uparrow}$ seal read is the finite route through I, S, R, E, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket dyadic real seal handoff`

Theorem 394.26 (LocatedInterval downstream root package)**.** *For every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packet, the downstream root package consists exactly of carrier habitation, endpoint order windows, rational-cell coverage routes, dyadic refinement handoff, real-seal non-escape, and containment transport scope over* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert*. Any downstream interval or* $\mathsf{Real}^{\uparrow}$ *consumer must factor through this finite package.*

Proof. Carrier habitation is Definition 394.4. It supplies the finite packet rows and rules out hidden host interval coordinates.

The endpoint part of the root package is Definition 394.23. The rational and dyadic part is Definition 394.24, with dyadic handoff supplied by Definition 394.6.

For Real-facing consumers, use Definition 394.7. For transport of containment reads, use Definition 394.9. Repacking these rows under the public export and consumer route of Definition 394.16 and Definition 394.17 yields the finite downstream package and no additional primitive. □

Definition 394.27 (LocatedInterval root obligation carrier)**.** *The root obligation carrier for* $\mathsf{LocatedInterval}^{\uparrow}$ *is the same finite packet*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

as in Definition 394.1, read with the following dependency surface:

1. L *and* U *are the lower and upper* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows;*
2. I *is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger and* D *is the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger attached to those cells;*
3. S *records the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows and* R *records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks used by the windows;*

4. *E records the* $\mathsf{Real}^{\uparrow}$ *seal rows for the two endpoint names;*
5. *H records the componentwise* hsame *transports for endpoints, cells, refinements, windows, readbacks, and seals;*
6. *C records the displayed* Cont *routes used by endpoint, containment, refinement, readback, and seal consumers;*
7. *P is the* Pkg *provenance over* $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, *and* Cont *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedInterval}^{\uparrow}}$ *row.*

This carrier obligation is the public root-facing presentation of J. It contains no host interval primitive, no selected endpoint value, no quotient real equality row, and no order-completeness principle.

Theorem 394.28 (LocatedInterval classifier stability)**.** *For accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *root obligation carriers $J = (L, U, I, D, S, R, E, H, C, P, N)$ and $J' = (L', U', I', D', S', R', E', H', C', P', N')$, any displayed componentwise* hsame *transport comparing the endpoint rows, rational-cell ledgers, dyadic refinements, endpoint windows, readbacks, and seal rows preserves the local classifier. Thus endpoint and cell classification is read only through the rows listed in Definition 394.27.*

Proof. Start from the root obligation carrier of Definition 394.27. Its classifier-visible coordinates are the two endpoint rows, the rational and dyadic cell ledgers, the endpoint windows, the readbacks, and the seal rows, together with their displayed transport and route rows.

Apply Definition 394.3. It moves L, U, I, D, S, R, E through the componentwise hsame rows and the displayed Cont routes as one located interval packet.

The cell side is then constrained by Definition 394.9. Rational containment and dyadic refinement reads remain attached to the transported endpoint and cell ledgers, so the classifier has no independent endpoint or interval source to inspect. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket classifier stability`

Theorem 394.29 (LocatedInterval ledger exactness)**.** *Every rational or dyadic containment read of an accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *root obligation carrier factors through the visible ledger rows I and D of Definition 394.27. A rational read is a read of a displayed* $\mathsf{RationalInterval}^{\uparrow}$ *cell in I; a dyadic read is a read of a displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row in D together with its rational parent cell. No containment read is supplied by a host interval order, a selected endpoint value, or a quotient-real comparison.*

Proof. For rational containment, apply Definition 394.5. It routes every accepted containment read to the rational cell ledger I unless the read is explicitly a dyadic refinement.

For dyadic containment, apply Definition 394.6. A row of D can be consumed only together with the rational cell in I that its displayed route refines.

Finally apply Definition 394.24 and Definition 394.12. These results keep the rational and dyadic ledgers attached to the endpoint windows and rule out any containment source outside the visible cell and refinement rows. □

Theorem 394.30 (LocatedInterval Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *root obligation carrier receives only endpoint-window rows L, U, S, readback rows R, seal rows E, and the package rows H, C, P, N of Definition 394.27, with rational and dyadic containment information available only through I and D. The handoff exports*

no host interval primitive, no completed endpoint value, no quotient real equality, and no order-completeness witness.

Proof. Use Definition 394.7 for the Real-facing boundary. It forces every seal-facing read through the endpoint rows, endpoint windows, readbacks, seal rows, transport rows, continuation routes, package provenance, and local naming row.

Use Definition 394.18 for comparison reads. The permitted comparison surface is the same endpoint-window, readback, cell, refinement, seal, transport, route, package, and naming surface.

Finally apply Definition 394.26. It packages the carrier habitation, endpoint transport, rational-cell coverage, dyadic refinement handoff, real-seal non-escape, and containment transport scope for downstream Real and completion consumers. Since the package contains no host interval, endpoint selector, quotient real equality, or order-completeness coordinate, the handoff is exactly the finite BEDC surface displayed above. □

Theorem 394.31 (LocatedInterval endpoint-cell refinement completeness)**.** *For every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *root obligation carrier*

$$J = (L, U, I, D, S, R, E, H, C, P, N),$$

every endpoint-cell refinement read factors through $L, U, I, D, S, R, E, H, C, P, N$*. The read may inspect lower and upper located endpoints, rational cells, dyadic refinements, endpoint windows, readbacks, real seal rows, transport rows, continuation routes, package provenance, and local naming; it cannot inspect a host interval primitive, selected endpoint value, quotient real equality, or order-completeness principle.*

Proof. Start with endpoint transport. By Definition 394.3, endpoint comparisons and readbacks move componentwise through the displayed hsame and Cont rows.

Next use Definition 394.5. Rational cell reads are exactly reads of the displayed $\mathsf{RationalInterval}^{\uparrow}$ ledger I attached to the lower and upper endpoint rows.

For refinements, apply Definition 394.6. A dyadic refinement row in D is consumed together with its rational parent cell and the same endpoint transport.

Finally use Definition 394.30. The Real-facing part of the read stays inside S, R, E, H, C, P, N, and the carrier has no coordinate for host intervals, selected endpoint values, quotient real equality, or order completeness. □

Theorem 394.32 (LocatedInterval located-real window coverage)**.** *In every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *root obligation carrier, the lower and upper* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint windows exhaust all endpoint observations. Any endpoint observation factors through the endpoint rows* L, U*, the window rows* S*, the readback rows* R*, the seal rows* E*, and the package rows* H, C, P, N*, with rational and dyadic cell information available only through* I *and* D*.*

Proof. Use Definition 394.10. It states that endpoint-window and endpoint-readback requests are exhausted by the lower and upper endpoint rows, their stream windows, their regular rational readbacks, and the displayed transport and continuation rows.

Apply Definition 394.3. Transport preserves those lower and upper endpoint observations componentwise, so an observation cannot detach from $L, U, S, R, E, H, C, P, N$.

It remains to account for interval cells. By Definition 394.12, rational cells and dyadic refinements attach to the endpoint windows through I and D rather than by adding a separate endpoint-observation source.

Thus the two located-real endpoint windows cover all endpoint observations, while containment data remains visible only through the finite cell ledgers. □

Theorem 394.33 (LocatedInterval rational-dyadic Real handoff exactness)**.** *For every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *root obligation carrier, rational cells, dyadic refinements, and* $\mathsf{Real}^{\uparrow}$ *seal rows form one exact finite route through*

$$L, U, I, D, S, R, E, H, C, P, N.$$

A downstream $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer receives this route as the public handoff and cannot separate rational containment, dyadic refinement, or real sealing into independent host objects.*

Proof. Begin with Definition 394.12. It ties rational containment cells in I and dyadic refinement rows in D to the same endpoint package.

Use Definition 394.32. The lower and upper endpoint observations are exhausted by the endpoint windows, readbacks, and seal-facing rows.

Now apply Definition 394.30. Every $\mathsf{Real}^{\uparrow}$ or completion-facing consumer receives the endpoint-window rows, readback rows, seal rows, and package rows of the root obligation carrier, with rational and dyadic information available only through I and D.

Finally apply Definition 394.31. It rules out a second route through host intervals, selected endpoints, quotient real equality, or order completeness, so the rational-dyadic-real handoff is exactly the displayed finite route. □

Theorem 394.34 (LocatedInterval window-cell seal unification)**.** *For every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packet*

$$J = (L, U, I, D, S, R, E, H, C, P, N),$$

every downstream $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer that reads an endpoint window, rational or dyadic containment cell, dyadic refinement, and* $\mathsf{Real}^{\uparrow}$ *seal factors through the single route*

$$L, U \to S \to R \to I, D \to E \to H, C, P, N.$$

No such consumer may replace this route by a host interval, selected endpoint, quotient-real equality, order-completeness principle, or ambient completion principle.

Proof. Start with endpoint windows. By Definition 394.32, the lower and upper endpoint observations are exhausted by $L, U, S, R, E, H, C, P, N$, while rational and dyadic cell information remains visible only through I and D.

Next use Definition 394.24. It identifies rational containment reads with the finite cell route attached to the accepted packet, so a consumer cannot detach containment from the endpoint-window rows.

For the seal-facing part, apply Definition 394.25. Dyadic refinement rows and $\mathsf{Real}^{\uparrow}$ seal rows are handed to downstream Real-facing readers as one packet-local surface, with no ambient completion coordinate.

Finally use Definition 394.33. It composes rational containment, dyadic refinement, and $\mathsf{Real}^{\uparrow}$ sealing into the displayed finite route. The sibling public surfaces in chapter 126, chapter 301, chapter 306, and chapter 38 supply the endpoint-window, readback, refinement, and Real-seal consumers, so none of them can introduce a second route through host intervals, selected endpoints, quotient-real equality, order completeness, or ambient completion. □

Theorem 394.35 (LocatedInterval StreamName Real cell synchronization)**.** *Let*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

and

$$J' = (L', U', I', D', S', R', E', H', C', P', N')$$

be accepted $\mathsf{LocatedInterval}^{\uparrow}$ *packets. If the two packets agree on the lower and upper located-real endpoint rows, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the rational and dyadic cell ledgers, the* $\mathsf{Real}^{\uparrow}$ *seal rows, and the displayed* hsame, Cont, Pkg, *and* NameCert *rows, then every* $\mathsf{Real}^{\uparrow}$ *or completion-facing endpoint-cell consumer reads the same finite route from* J *and* J'.

In particular, such a consumer cannot distinguish the packets by host interval order, selected endpoints, quotient real equality, or order completeness. Its read factors through the synchronized route

$$L, U \to S \to R \to I, D \to E \to H, C, P, N$$

and the corresponding primed route.

Proof. Start with classifier stability for the accepted $\mathsf{LocatedInterval}^{\uparrow}$ packets. Agreement on $L, U, S, R, I, D, E, H, C, P, N$ places both packets on the same displayed carrier rows before any endpoint-cell consumer reads them.

Use Definition 394.33. The rational containment cells, dyadic refinements, and $\mathsf{Real}^{\uparrow}$ seal rows form one exact finite route for each packet.

Apply Definition 394.34. It identifies the endpoint window, readback, cell, refinement, and seal rows as a single consumer route and excludes replacement by host intervals, selected endpoint values, quotient real equality, order completeness, or ambient completion.

Finally compare the two displayed routes componentwise through the shared hsame, Cont, Pkg, and NameCert rows. Since every consumer-facing coordinate agrees, the two packets are synchronized for every $\mathsf{Real}^{\uparrow}$ or completion-facing endpoint-cell read. □

Theorem 394.36 (LocatedInterval bridged public route)**.** *The public* $\mathsf{LocatedInterval}^{\uparrow}$ *packet over* $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *is the bridge-facing route consumed by downstream Real and completion interfaces. Every such consumer receives the lower endpoint, upper endpoint, rational cell, dyadic refinement, endpoint-window, readback, seal, transport, continuation, package, and naming rows as one finite public certificate.*

Proof. Use Definition 394.16 and Definition 394.17. They identify the public exported surface and the consumer route for the accepted packet.

Apply Definition 394.18. It keeps comparison reads inside the endpoint-window, readback, rational-cell, dyadic-refinement, seal, transport, route, package, and naming rows.

Next use Definition 394.33. The rational containment cells, dyadic refinements, and $\mathsf{Real}^{\uparrow}$ seal rows form one exact finite route for downstream Real and completion consumers.

The route is bridge-facing because it exposes the same public certificate rows to the outside interface while preserving the BEDC non-escape boundary. No host interval primitive, selected endpoint value, quotient real equality, or order-completeness row is exported. □

Theorem 394.37 (LocatedInterval real-stream bracket correspondence)**.** *For every accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *packet*

$$J = (L, U, I, D, S, R, E, H, C, P, N),$$

the following two finite BEDC reads are equivalent as reads of the same packet-local certificate.

1. *The* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint-cell read passes through the lower and upper endpoint rows, rational containment cells, dyadic refinement cells, endpoint-window rows, readback rows, real-seal rows, transports, continuations, package provenance, and local* NameCert *row of* J.

2. *The* $\mathsf{Real}^{\uparrow}$ *stream-classifier read receives its finite endpoint windows from* $\mathsf{StreamName}^{\uparrow}$*, its pointwise rational stream readbacks from* $\mathsf{RegSeqRat}^{\uparrow}$*, and its endpoint seal rows from the same* $\mathsf{Real}^{\uparrow}$ *rows carried by* J*.*

Thus rational and dyadic bracket containment for J *and the Real-facing stream-name substrate read determine one another only through the displayed finite rows*

$$L, U, I, D, S, R, E, H, C, P, N.$$

The correspondence exports no host interval primitive, selected endpoint value, quotient-real equality, ambient order-completeness principle, or unrecorded completion object.

Lean4 ✓ `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket real stream bracket correspondence`

Proof. First read the interval side through Definition 394.17. It makes every public consumer of J pass through the displayed endpoint, rational cell, dyadic refinement, readback, seal, transport, continuation, package, and naming rows.

Next apply Definition 394.33. This identifies rational containment, dyadic refinement, and $\mathsf{Real}^{\uparrow}$ sealing as one packet-local finite route rather than as three independent host structures.

For the stream-facing side, use the StreamName-RegSeqRat pointwise handoff together with the RegSeqRat real-seal handoff. The finite endpoint windows supplied by $\mathsf{StreamName}^{\uparrow}$ and the pointwise rational readbacks supplied by $\mathsf{RegSeqRat}^{\uparrow}$ are therefore the same windows and readbacks already present in S and R, and the Real rows seal them through E.

Finally apply the RealStreamClassifier selected endpoint readback at the $\mathsf{Real}^{\uparrow}$ endpoint surface. Since the classifier reads only the finite windows and their Real seal rows, the two displayed reads are inverse descriptions of the same certificate route. No step introduces host intervals, selected endpoints, quotient-real equality, order completeness, or ambient completion. □

Theorem 394.38 (LocatedInterval dyadic refinement induction)**.** *Let*

$$J = (L, U, I, D, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{LocatedInterval}^{\uparrow}$ *packet. For any finite displayed list of dyadic refinement rows in* D*, if the initial row is attached to its rational parent cell in* I *and to the endpoint-window rows* L, U, S, R, E*, and if each successor row is obtained by the displayed dyadic refinement handoff from the preceding row, then every row in the list remains attached to the same rational parent cell and endpoint-window package. The induction surface is only the finite rows* $D, I, L, U, S, R, E, H, C, P, N$*; it does not use a host interval subdivision tree, selected endpoints, quotient-real equality, order completeness, or ambient completion.*

Proof. The base case is the displayed attachment supplied by Definition 394.12. A dyadic row in D is read together with its rational parent cell in I, and the lower and upper endpoint windows are already the rows L, U, S, R, E of the same packet.

For the successor step, apply Definition 394.6. The handoff replaces the current dyadic cell by the next displayed refinement row while retaining the rational parent cell and the same endpoint-window rows.

Endpoint transport is controlled by Definition 394.3. Transport through H and replay through C preserve the lower endpoint, upper endpoint, stream window, regular readback, and Real-seal rows componentwise, so the refinement step cannot detach from L, U, S, R, E.

Finally use Definition 394.37. It identifies the interval-side dyadic bracket read and the Real-facing stream read as the same packet-local certificate route. Finite induction over the displayed rows of D therefore preserves attachment to I and to L, U, S, R, E at every stage. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedInterval}^\uparrow}$.

Constructive story: A $\mathsf{LocatedInterval}^\uparrow$ packet is generated from lower and upper $\mathsf{LocatedReal}^\uparrow$ endpoint rows, a $\mathsf{RationalInterval}^\uparrow$ cell ledger, optional $\mathsf{DyadicInterval}^\uparrow$ refinements, $\mathsf{StreamName}^\uparrow$ endpoint windows, $\mathsf{RegSeqRat}^\uparrow$ readbacks, $\mathsf{Real}^\uparrow$ seal rows, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedInterval}^\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: Definition 394.16, Definition 394.17, and Definition 394.18 close the public packet interface for finite located interval packets over $\mathsf{LocatedReal}^\uparrow$, $\mathsf{RationalInterval}^\uparrow$, $\mathsf{DyadicInterval}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{Real}^\uparrow$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedInterval}^\uparrow}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.LocatedIntervalUp.LocatedIntervalPacket\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close host interval primitives, selected endpoint values, quotient real equality, ambient order completeness, or bridge checking.

Upgrade path: No further upgrade remains on the formal bridge axis.

The $\mathsf{PicardContraction}^\uparrow$ packet consumes the metric sibling lattice through chapter 90, chapter 410, and chapter 128 before its $\mathsf{Real}^\uparrow$ seal route is read. Its finite modulus row is therefore a sibling dependency over Banach, Lipschitz-map, and complete-metric data rather than a kernel-only island.

Chapter 395

A Concrete Naming Certificate for $\mathsf{PicardContraction}^{\uparrow}$

The $\mathsf{PicardContraction}^{\uparrow}$ interface names the finite contraction-iteration packet used by $\mathsf{Ode}^{\uparrow}$ and $\mathsf{NewtonIteration}^{\uparrow}$ consumers when they read a displayed Picard step, a Lipschitz ledger, or an explicit Cauchy modulus. In standard functional analysis this surface is motivated by the Banach contraction principle as presented, for example, in Kreyszig, *Introductory Functional Analysis with Applications*. BEDC records only the finite rows consumed by downstream certificates: a Banach source row, a contraction-map row, a rational Lipschitz-ratio ledger, finite iterate rows, an explicit modulus window, transport routes, provenance, and a local $\mathsf{NameCert}$ row. It does not add a host fixed point, ambient completeness theorem, or selected limit.

chapter 90 is the substantive source for the Banach row read by this packet, and chapter 410 is the substantive source for the contraction-map and modulus ledger rows. The Picard carrier therefore exports a finite route between those sibling chapters and the $\mathsf{Ode}^{\uparrow}$ or $\mathsf{NewtonIteration}^{\uparrow}$ consumers that read only the displayed endpoint and seal rows. chapter 396 is the sibling carrier whose contraction-map, complete-metric, and fixed-point rows are structurally consumed by this Picard packet.

Definition 395.1 (PicardContraction BHist carrier)**.** *A* $\mathsf{PicardContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (B, T, L, I, M, E, H, C, G, N)$$

with the following visible rows:

1. *B is the* $\mathsf{Banach}^{\uparrow}$ *source row whose carried histories provide the state endpoints inspected by the finite iteration packet;*
2. *T is the contraction-map row, displaying the map-code history and the source-target* Cont *route through which a carried state history is read as its next Picard state;*
3. *L is the Lipschitz-ratio ledger, a positive* $\mathsf{Rat}^{\uparrow}$ *row below the unit bound together with the displayed metric comparison rows used by the contraction read;*
4. *I is the finite Picard-iterate ledger, listing the visible state rows $x_0, \ldots, x_n$ and the application rows reading x_{k+1} from T and x_k;*
5. *M is the Cauchy-modulus row, giving an explicit finite window after which the displayed iterate distances are bounded by the requested rational tolerance;*

6. *E is the endpoint and seal row through which downstream* $\mathsf{Ode}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumers read the last finite iterate and the modulus window;*
7. *H stores componentwise* hsame *transports for the Banach source, map-code row, Lipschitz ledger, finite iterate ledger, modulus row, endpoint row, provenance row, and local naming row;*
8. *C stores the displayed* Cont *routes for Banach-state reads, contraction-map application, finite iterate concatenation, modulus readback, and endpoint sealing;*
9. *G is the* Pkg *provenance row naming the consumed* $\mathsf{Banach}^{\uparrow}$, *RatUp, metric, iterate, modulus, and downstream certificate surfaces;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ *row.*

The carrier is a finite packet. It has no coordinate for a completed orbit, a host fixed point, an ambient completeness theorem, an external contraction principle, or a choice-selected limit.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionCarrier` finite packet semantic certificate

Definition 395.2 (PicardContraction finite classifier)**.** *Two accepted* $\mathsf{PicardContraction}^{\uparrow}$ *carriers are classified as the same finite contraction packet exactly when the visible rows of Definition 395.1 compare componentwise: their* $\mathsf{Banach}^{\uparrow}$ *source rows are classified by the Banach carrier classifier, their contraction-map rows are transported through the displayed* Cont *route, their Lipschitz-ratio ledgers compare through the* $\mathsf{Rat}^{\uparrow}$ *order rows, their finite iterate ledgers are related by* hsame *at every retained endpoint, their Cauchy-modulus windows and endpoint seals are the same after the displayed transport rows, and their* Pkg *and local* NameCert *rows name the same visible packet.*

The classifier has no generator for comparing host functions, no generator for a fixed-point value, and no generator for an ambient completeness theorem.

Lean4 (definition) `BEDC.Derived.PicardContractionUp.PicardContractionClassifier`

Theorem 395.3 (PicardContraction finite iterate closure)**.** *Let P and Q be accepted* $\mathsf{PicardContraction}^{\uparrow}$ *carriers over the same* $\mathsf{Banach}^{\uparrow}$ *source row, contraction-map row, and Lipschitz-ratio ledger. If the endpoint row of P is related by* hsame *to the initial iterate row of Q, and the displayed iterate ledgers concatenate by a finite continuation row, then the concatenated packet is again an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *carrier. Its Lipschitz-ratio ledger is the transported ledger shared by P and Q, its finite Picard-iterate ledger is the concatenated* BHist *row, and its Cauchy-modulus and endpoint rows are read through the displayed* Cont *routes.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket` finite iterate closure

Proof. Project the carrier rows of P and Q. Both packets expose the same Banach source, contraction-map row, and Lipschitz-ratio ledger, while their iterate coordinates are finite BHist lists.

Use the endpoint comparison to splice the last visible state of P to the first visible state of Q. The componentwise hsame rows transport only the displayed endpoint histories and do not introduce an external orbit or limit.

Concatenate the two finite iterate ledgers by the given Cont row. The application rows of the first segment and the transported application rows of the second segment remain contraction-map reads under the same T row, and the Lipschitz-ratio ledger is reused through the transported L coordinate.

The modulus and endpoint coordinates of the concatenated packet are then read through the same displayed continuation routes. Repacking the Banach source, contraction row, ratio ledger,

concatenated iterate ledger, modulus row, endpoint seal, transports, provenance, and local name gives exactly the carrier of Definition 395.1. □

Theorem 395.4 (PicardContraction Banach ODE boundary)**.** *Every* $\mathsf{Ode}^{\uparrow}$ *or* $\mathsf{NewtonIteration}^{\uparrow}$ *consumer read of a* $\mathsf{PicardContraction}^{\uparrow}$ *packet factors through the finite Picard rows, the* $\mathsf{Banach}^{\uparrow}$ *source row, the contraction-map ledger, the Lipschitz-ratio ledger, the explicit Cauchy-modulus row, and the displayed endpoint/seal routes of Definition 395.1. The consumer may not read a host fixed point, a completed Picard orbit, an ambient completeness theorem, a Banach fixed-point theorem, or a choice-selected limit from this packet.*

Proof. Start with an $\mathsf{Ode}^{\uparrow}$ or $\mathsf{NewtonIteration}^{\uparrow}$ read. The only Banach-facing coordinate is B, and the only iteration-facing coordinates are the contraction-map row T, the Lipschitz ledger L, the finite iterate ledger I, and the endpoint/modulus rows M and E.

The classifier of Definition 395.2 can transport only those rows. Banach-state movement is read through the Banach classifier, map application through the displayed Cont route, rational contraction bounds through L, and finite iterate comparison through the endpoint hsame rows.

No remaining carrier coordinate contains a fixed-point value or a completed limit. Therefore downstream ODE and Newton consumers receive exactly the finite contraction surface named in the statement, with full fixed-point convergence and ambient completeness outside the BEDC packet. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket banach ode boundary`

Theorem 395.5 (PicardContraction Cauchy modulus sibling route)**.** *Let* $P = (B, T, L, I, M, E, H, C, G, N)$ *be an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet. Before any* $\mathsf{Ode}^{\uparrow}$ *or* $\mathsf{NewtonIteration}^{\uparrow}$ *consumer can read the endpoint and seal row* E*, the packet reads the* $\mathsf{Banach}^{\uparrow}$ *source row* B *and the* $\mathsf{LipschitzMap}^{\uparrow}$ *contraction-map and modulus ledger rows* T, L, M *through the finite classifier and displayed continuation surface. Thus the consumer-facing endpoint is downstream of concrete sibling routes rather than a kernel-only island.*

Proof. Project the carrier in Definition 395.1. The Banach source row B, contraction-map row T, Lipschitz-ratio ledger L, finite iterate ledger I, Cauchy-modulus row M, and endpoint seal E are distinct visible rows of the accepted packet.

Use the classifier of Definition 395.2. It permits transport only componentwise through the displayed hsame and Cont rows, so the Banach and contraction-map data must be read before the endpoint seal can be compared or exported.

Finally apply Definition 395.4. Every $\mathsf{Ode}^{\uparrow}$ or $\mathsf{NewtonIteration}^{\uparrow}$ read factors through the Banach source, contraction-map ledger, Lipschitz-ratio ledger, explicit Cauchy modulus, and displayed endpoint route. This is exactly the finite sibling route from Banach and LipschitzMap material to the downstream endpoint consumer. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket cauchy modulus sibling route`

Theorem 395.6 (PicardContraction NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ *obligation surface consists of five rows:*

1. *carrier inhabitation for the finite packet of Definition 395.1;*
2. *classifier transport for the componentwise comparison of Definition 395.2;*
3. *finite-iterate stability under the concatenation closure of Definition 395.3;*
4. *modulus and readback exactness for the Cauchy-modulus and endpoint/seal rows;*

5. *ledger non-escape, requiring every* $\mathsf{Ode}^{\uparrow}$ *and* $\mathsf{NewtonIteration}^{\uparrow}$ *consumer to factor through the displayed Banach, contraction, ratio, iterate, modulus, endpoint, transport, provenance, and local-name rows.*

Proof. The carrier row gives the finite inventory. It lists the Banach source, contraction map, Lipschitz ledger, iterate ledger, modulus row, endpoint seal, transport rows, continuation routes, package provenance, and local name.

The classifier row gives the only permitted transports, so every accepted replacement is componentwise and visible. The finite-iterate stability row is exactly Definition 395.3.

The modulus and readback row is the pair (M, E) together with its displayed continuation routes. Finally, Definition 395.4 supplies ledger non-escape for the ODE and Newton consumers. These five rows constitute the local naming-certificate surface and leave fixed-point convergence outside the seed packet. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket namecert obligation surface`

Theorem 395.7 (PicardContraction classifier stability)**.** *Finite* $\mathsf{PicardContraction}^{\uparrow}$ *packets over* BHist *preserve the classifier of Definition 395.2 under every* hsame*-compatible* Cont *row whose stage indices are read through the unary history ledger of Definition 395.1. In particular, transporting the* $\mathsf{Banach}^{\uparrow}$ *source, contraction-map row, Lipschitz ledger, finite Picard-iterate ledger, modulus row, endpoint seal,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ *row componentwise produces another packet classified as the same finite contraction packet.*

Proof. Unpack the carrier rows. The only indexed iteration coordinate is the finite Picard ledger I, and its stage reads are carried by the unary history entries named in the packet.

Unpack the classifier. It compares accepted packets coordinate by coordinate through the displayed hsame transports and Cont routes, so an hsame-compatible continuation row can move a stage only by moving the visible unary history row that names it.

The Banach source, contraction row, rational ratio ledger, modulus row, endpoint seal, provenance, and local certificate are ordinary carrier coordinates. Transporting them componentwise therefore preserves exactly the classifier described in Definition 395.2, with no coordinate for a completed orbit or host fixed point. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket classifier stability`

Theorem 395.8 (PicardContraction contraction-step package)**.** *One finite contraction step in a* $\mathsf{PicardContraction}^{\uparrow}$ *carrier is packaged as a concrete* BHist *and* Cont *witness: it consists of the source stage row* x_k*, the displayed contraction-map row* T*, the application row reading* x_{k+1} *from* T *and* x_k*, the Lipschitz-ratio ledger row, and the endpoint/modulus readback route. This package is the finite step consumed by both Definition 395.3 and Definition 395.4.*

Proof. Project the finite Picard ledger from Definition 395.1. A step is not a host function application; it is the displayed pair of consecutive history rows together with the Cont route that reads the next row from the contraction-map coordinate.

Use Definition 395.3 to see that such steps concatenate inside the same BHist packet when the endpoint row of one finite segment is hsame to the initial row of the next segment.

Use Definition 395.4 for the consumer side. ODE and Newton reads receive this same finite step package through the Banach source, contraction map, Lipschitz ledger, modulus row, and endpoint seal, not through a Banach fixed-point theorem or a selected limit. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket contraction step package`

Theorem 395.9 (PicardContraction fixed-point ledger boundary)**.** *The finite contraction orbit ledger of a* $\mathsf{PicardContraction}^{\uparrow}$ *packet hides only the scheduled iterate index, the modulus row, and the endpoint witness selected inside the Picard packet. No Banach source outside the displayed packet, no external contraction principle, no ambient completeness theorem, no completed orbit, and no host fixed point enters the* $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ *surface.*

Proof. Start from the NameCert obligation surface. Its rows are carrier inhabitation, classifier transport, finite-iterate stability, modulus and endpoint readback exactness, and ledger non-escape.

The hidden data named in the statement are internal scheduling data for the finite packet: which retained iterate is read, which modulus row is used, and which endpoint witness is exported. Each is already a coordinate of Definition 395.1.

Apply Definition 395.7 to transport these rows without changing the accepted packet. Apply Definition 395.8 and Definition 395.4 to force every consumer read through the finite step package. Since the carrier has no coordinate for an external source or completed fixed point, the ledger cannot expose one through the local naming certificate. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket fixed point ledger boundary`

Theorem 395.10 (PicardContraction modulus-window transport)**.** *Let* $P = (B, T, L, I, M, E, H, C, G, N)$ *be an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *carrier. Any displayed* hsame *and* Cont *transport that preserves the rows* B*,* T*,* L*,* I*,* M*,* E*,* H*,* C*,* G*, and* N *of Definition 395.1 also preserves the modulus-window readback row* M *and the endpoint seal* E *as the exact rows consumed by the packet. The transported packet has the same finite classifier of Definition 395.2, the same finite-iterate closure surface of Definition 395.3, and the same ODE/Newton boundary of Definition 395.4.*

In particular, modulus-window readback is a BHist*-anchored transport claim about displayed finite rows. It does not introduce a host fixed point, a completed orbit, an ambient completeness theorem, or a choice-selected limit.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket modulus window transport`

Proof. Project the carrier named in Definition 395.1. The modulus coordinate M and endpoint seal E are explicit rows of the packet, so a transport that preserves all ten carrier rows already preserves the only locations from which a modulus window or endpoint read can be taken.

Use the classifier of Definition 395.2. It compares accepted packets componentwise through displayed hsame rows and Cont routes; hence M and E cannot be replaced by a host limit, a completed orbit, or an external convergence witness.

The finite-iterate closure theorem identifies how transported finite segments concatenate, and the Banach ODE boundary theorem identifies the consumer-facing route. Together, Definition 395.3 and Definition 395.4 force every modulus and endpoint read to remain on the displayed M and E rows. □

Theorem 395.11 (PicardContraction Banach source readback)**.** *Every Banach source read consumed by an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet factors through the rows*

$$B, T, I, H, C, G, N$$

of Definition 395.1. The read exposes the displayed $\mathsf{Banach}^{\uparrow}$ *source row, contraction-map row, finite iterate ledger, componentwise* hsame *transports, displayed* Cont *routes, package provenance, and local naming row. It does not expose a host Banach fixed-point theorem, a completed Picard orbit, an ambient completeness proof, or a selected fixed point.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket banach source readback`

Proof. Project the accepted carrier $P = (B, T, L, I, M, E, H, C, G, N)$. The Banach source row B is a visible coordinate, and the only rows that can read it for a Picard step are the contraction row T, finite iterate ledger I, transport rows H, continuation routes C, provenance G, and local certificate N.

Apply Definition 395.8. A source read is consumed as part of a finite step package, so it passes through the displayed contraction application and the finite iterate ledger rather than through a completed orbit.

Finally use Definition 395.9. The carrier has no coordinate for a host fixed point or a Banach fixed-point theorem, and the local NameCert row can certify only the displayed finite source route. □

Theorem 395.12 (PicardContraction Lipschitz ledger window exactness)**.** *Every contraction-ratio read of an accepted* PicardContraction$^{\uparrow}$ *packet uses the displayed rational row L, the finite iterate ledger I, and the continuation routes C of Definition 395.1. The read may transport along the componentwise* hsame *rows and package provenance, but it has no route through an external Lipschitz oracle, an ambient norm estimate, or a host contraction principle outside the packet.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket lipschitz ledger window exactness`

Proof. Start from the ratio coordinate of the carrier. The row L is the only rational Lipschitz ledger stored in the packet, and the finite iterate ledger I is the only location where the ratio can be consumed by a displayed Picard step.

Use Definition 395.17. It keeps the contraction ratio as the visible rational ledger row and prevents a consumer from strengthening the read to an external Lipschitz estimate.

The continuation routes are fixed by Definition 395.8 and transported by Definition 395.7. Thus every ratio-window read remains on L, I, C inside the same finite carrier surface. □

Theorem 395.13 (PicardContraction modulus consumer exhaustion)**.** *Every* Ode$^{\uparrow}$, NewtonIteration$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *consumer of an accepted* PicardContraction$^{\uparrow}$ *packet factors through the finite carrier rows*

$$B, T, L, I, M, E, H, C, G, N.$$

The factorization uses the finite iterate closure, Banach source readback, Banach ODE boundary, contraction-step package, fixed-point ledger boundary, modulus-window transport, and Lipschitz ledger window exactness. No consumer receives a completed Picard orbit, host fixed point, external Lipschitz oracle, ambient completeness theorem, or selected limit.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket modulus consumer exhaustion`

Proof. First assemble the finite source and step surface. The finite iterate closure keeps iterate concatenation inside I, while Definition 395.11 and Definition 395.8 route source and step reads through B, T, I, H, C, G, N.

Next attach the ratio and modulus windows. Definition 395.12 fixes contraction-ratio reads on L, I, C, and Definition 395.10 fixes tolerance and endpoint reads on M and E under the displayed transport rows.

Finally inspect the consumer classes. The Banach ODE boundary supplies the Ode$^{\uparrow}$ and NewtonIteration$^{\uparrow}$ restriction, the fixed-point ledger boundary prevents replacement by a host fixed point, and the existing RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ handoff routes read only the same finite packet. The displayed rows therefore exhaust every listed consumer. □

Theorem 395.14 (PicardContraction downstream modulus exposure)**.** *Every downstream tolerance or endpoint request out of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet reaches the displayed* $\mathsf{Banach}^{\uparrow}$ *source row B, contraction row T, rational Lipschitz ledger L, finite iterate ledger I, modulus row M, endpoint seal E, componentwise* hsame *rows H,* Cont *routes C,* Pkg *provenance G, and local* NameCert *row N of Definition 395.1. The request has no route through a completed orbit, host fixed point, ambient completeness theorem, or choice-selected limit.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket downstream modulus exposure`

Proof. Project the carrier rows of Definition 395.1. The Banach source, contraction row, rational Lipschitz ledger, finite iterate ledger, modulus row, endpoint seal, transports, routes, provenance, and local certificate are the only visible coordinates.

Apply Definition 395.10 to the modulus and endpoint rows. It keeps every tolerance or endpoint read on M and E, transported only by the displayed H and C rows.

Use Definition 395.8 and Definition 395.9 for the finite-iterate side. These rows bind the request to the displayed Banach and contraction data without adding a completed Picard orbit or a host fixed point. □

Theorem 395.15 (PicardContraction Real-RegSeqRat consumer handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{PicardContraction}^{\uparrow}$ *packet reads only the finite Picard modulus-window packet*

$$B, T, L, I, M, E, H, C, G, N.$$

The handoff exposes the displayed Banach source, contraction row, rational Lipschitz ledger, finite iterate ledger, modulus row, endpoint seal, transport rows, continuation routes, provenance, and local naming row, but it does not expose a completed orbit, host fixed point, Banach fixed-point theorem, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionRealRegSeqRatConsumerHandoff`

Proof. Start with downstream modulus exposure. It supplies the only modulus and endpoint route available to consumers and names the exact carrier rows through which such reads pass.

For $\mathsf{RegSeqRat}^{\uparrow}$ consumers, use the modulus row M and finite iterate ledger I as the regular-rational readback surface. The rational Lipschitz ledger L and the displayed continuation routes C record the finite transport needed by that read.

For $\mathsf{Real}^{\uparrow}$ consumers, use the endpoint seal E with the same M and I rows. The fixed-point ledger boundary prevents the seal from becoming a host fixed point, while the Banach ODE boundary prevents the route from becoming an ambient completeness theorem.

Repack the two consumer routes as one finite modulus-window handoff. Since every row is one of $B, T, L, I, M, E, H, C, G, N$, no completed orbit or host fixed point is exported. □

Theorem 395.16 (PicardContraction root-unblock package)**.** *The downstream modulus exposure of Definition 395.14, the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumer handoff of Definition 395.15, the finite-iterate closure of Definition 395.3, the Banach ODE boundary of Definition 395.4, the fixed-point ledger boundary of Definition 395.9, and the modulus-window transport of Definition 395.10 assemble the downstream root-unblock package for* $\mathsf{PicardContraction}^{\uparrow}$*.*

The package is exactly the finite surface over $\mathsf{Banach}^{\uparrow}$*, contraction, rational Lipschitz, finite iterate, modulus, endpoint seal,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It does not close a Banach fixed-point theorem, a completed orbit, a selected host limit, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionRootUnblockPackage`

Proof. First collect the finite-iterate side. The carrier and finite-iterate closure describe how displayed Picard ledger segments are read and concatenated inside the same BHist packet.

Next collect the consumer side. The Banach ODE boundary and fixed-point ledger boundary keep ODE, Newton, endpoint, and seal consumers downstream of the displayed Banach, contraction, Lipschitz, iterate, modulus, and endpoint rows.

Finally add the two root-facing rows. Downstream modulus exposure names the exact route for tolerance and endpoint requests, and the $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ handoff packages those routes for regular-rational and real-name consumers. Together with modulus-window transport, these rows form the announced root-unblock package and leave no coordinate for the excluded host objects. □

Theorem 395.17 (PicardContraction ratio ledger nonexpansion)**.** *Let P and Q be accepted finite* $\mathsf{PicardContraction}^{\uparrow}$ *packets whose endpoint and initial rows splice as in Definition 395.3. If the two packets use the same positive rational Lipschitz ledger row L below the unit bound, then their concatenation reuses the transported ledger L and creates no stronger host contraction claim. The resulting* $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ *surface is still the componentwise* BHist *packet classified by Definition 395.2 and bounded at consumers by Definition 395.4.*

The conclusion excludes a new fixed point, completed Picard orbit, ambient completeness proof, Banach fixed-point theorem, and choice-selected limit.

Proof. Start with the carrier of Definition 395.1. The Lipschitz ratio is stored as the finite rational row L, and the iterate data are stored separately in the finite ledger I.

Apply Definition 395.3 to concatenate the two iterate ledgers. Its conclusion explicitly reuses the transported shared L coordinate, so the concatenated packet has no additional row from which a tighter or host-level contraction estimate could be read.

The classifier of Definition 395.2 then transports the concatenated packet componentwise. Finally, Definition 395.4 restricts ODE and Newton consumers to the displayed Banach, contraction, ratio, iterate, modulus, endpoint, provenance, and local-name rows. No omitted coordinate can assert a stronger contraction principle or a selected limiting point. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket ratio ledger nonexpansion`

Theorem 395.18 (PicardContraction finite consumer exhaustion)**.** *Every* $\mathsf{Ode}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer read of a* $\mathsf{PicardContraction}^{\uparrow}$ *packet is exhausted by the rows*

$$B, T, L, I, M, E, H, C, G, N$$

of Definition 395.1. The classifier of Definition 395.2, the finite concatenation theorem Definition 395.3, and the boundary theorem Definition 395.4 leave no consumer route through fixed points, completed orbits, ambient completeness, or choice-selected limits.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket finite consumer exhaustion`

Proof. For ODE and Newton reads, apply Definition 395.4. It already factors the consumer through the Banach source, contraction map, rational ledger, finite iterate rows, explicit modulus row, and endpoint/seal routes.

For $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ reads, use the same modulus and endpoint coordinates. The rows M and E are displayed inside the carrier, while H, C, G, and N provide only transport, continuation, provenance, and local naming evidence for those rows.

The finite-iterate closure theorem supplies the only operation that extends visible iterate data, and the classifier theorem supplies the only comparison operation. Since both operate on the carrier

rows listed in the statement, every listed consumer is exhausted by the same finite BHist packet and receives no host fixed point, completed orbit, completeness theorem, or selected limit. □

Theorem 395.19 (PicardContraction modulus row finite-tail lock)**.** *For every accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet*

$$P = (B, T, L, I, M, E, H, C, G, N),$$

the modulus row M is locked to the finite iterate ledger I, the rational Lipschitz row L, the displayed hsame *rows H, and the displayed* Cont *routes C. Any consumer that reads M must therefore read the same finite* BHist *packet and has no route to a completed Picard orbit, a host fixed point, ambient completeness, or a choice-selected limit.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket modulus row finite tail lock`

Proof. Project the carrier of Definition 395.1. The rows L, I, M, H, and C are displayed coordinates of the same packet, so the modulus row is not an external convergence witness.

Use the classifier stability and finite-iterate closure rows already recorded in this chapter. Classifier stability keeps M attached to the componentwise transport rows H and read routes C, while finite-iterate closure keeps every extension of visible Picard data inside I with the same rational ledger L.

Finally apply Definition 395.10. It identifies the modulus-window readback as the finite row M and transports it only through the displayed H and C coordinates, so downstream modulus consumers remain locked to the finite tail packet named in the statement. □

Theorem 395.20 (PicardContraction RegSeqRat RealUp seal package)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet factors through*

$$B, T, L, I, M, E, H, C, G, N.$$

The consumer may use the downstream modulus exposure, the real–regular-rational handoff, and finite consumer exhaustion, but it cannot obtain a completed orbit, a host fixed point, a selected limit, or ambient completeness from the packet.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket regseqrat real seal package`

Proof. Begin with Definition 395.14. It gives seal-facing consumers the modulus and endpoint route only through M, E, H, and C, together with the Banach, contraction, rational, iterate, provenance, and naming rows.

Next use Definition 395.15. The $\mathsf{RegSeqRat}^{\uparrow}$ readback and the $\mathsf{Real}^{\uparrow}$ seal read the same finite modulus-window packet rather than a completed orbit or a host fixed-point theorem.

Finally apply Definition 395.18. Its consumer list includes both $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$, so the seal package is exhausted by the carrier rows and cannot pass through any omitted completion, fixed-point, limit-selection, or ambient-completeness object. □

Theorem 395.21 (PicardContraction finite-tail diagonal seal handoff)**.** *Every accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet whose contraction route is consumed by a finite-tail diagonal seal factors through the modulus-window rows of Definition 395.24, the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal package of Definition 395.20, and the* $\mathsf{FiniteTailDiagonalSeal}^{\uparrow}$ *finite-tail witness surface of chapter 559 before any completion-facing read. The route is the finite packet*

$$B, T, L, I, M, E, H, C, G, N$$

together with the downstream seal scope of Definition 395.25. It exports no selected limit, host fixed-point equality, quotient Cauchy name, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket finite tail diagonal seal handoff`

Proof. Start with the modulus-window row scope. It keeps the modulus row M and endpoint seal row E inside the displayed $\mathsf{PicardContraction}^{\uparrow}$ carrier under classifier transport and modulus-window transport.

Next apply the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seal package. The regular-sequence and real-facing reads are already exhausted by the same finite carrier rows, so the finite-tail consumer cannot replace them by a completed orbit or a host fixed-point equality.

Finally use the downstream seal scope and the sibling route chapter 559. The finite-tail diagonal seal supplies the selected finite-tail witness between the regular-sequence read and the real-facing seal, and the Picard packet supplies only $B, T, L, I, M, E, H, C, G, N$. Since neither route contains a quotient Cauchy name, selected limit, ambient completeness row, or host fixed-point equality, no completion-facing read can obtain one from the handoff. □

Theorem 395.22 (PicardContraction root consumer triad exhaustion)**.** *The* $\mathsf{Ode}^{\uparrow}$ *and* $\mathsf{NewtonIteration}^{\uparrow}$ *family, the* $\mathsf{RegSeqRat}^{\uparrow}$ *family, and the* $\mathsf{Real}^{\uparrow}$ *family of consumers of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet are jointly exhausted by the same finite triad: the iterate ledger I, the modulus row M, and the endpoint seal row E, together with their surrounding* BHist, hsame, Cont, Pkg, *and* NameCert *rows in*

$$B, T, L, I, M, E, H, C, G, N.$$

No family receives a host fixed point, completed Picard orbit, selected limit, or ambient completeness claim.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket root consumer triad exhaustion`

Proof. First handle $\mathsf{Ode}^{\uparrow}$ and $\mathsf{NewtonIteration}^{\uparrow}$ consumers. Apply Definition 395.4 and Definition 395.9; these bind root-facing reads to the Banach source, contraction row, rational ledger, finite iterate ledger, modulus row, endpoint seal, and displayed transport and continuation routes.

Next handle $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers. The modulus row finite-tail lock of Definition 395.19 fixes M to I, L, H, and C, and the seal package of Definition 395.20 keeps regular-rational and real-facing reads inside the same carrier.

The three consumer families therefore meet at the finite triad I, M, E and its surrounding BEDC rows. Since the carrier has no further coordinate for a host fixed point, completed orbit, selected limit, or ambient completeness proof, the triad exhausts the root consumer surface. □

Theorem 395.23 (PicardContraction Banach source row scope)**.** *Every accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet reads its Banach source, contraction row, rational Lipschitz ledger, finite iterate ledger, and local* NameCert *row only through the displayed* BHist *carrier rows*

$$B, T, L, I, H, C, G, N.$$

The read is mediated by the classifier of Definition 395.2, the finite-iterate closure of Definition 395.3, the Banach ODE boundary of Definition 395.4, and the fixed-point ledger boundary of Definition 395.9. It excludes host fixed points, completed Picard orbits, ambient completeness, and choice-selected limits.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket banach source row scope`

Proof. Project the displayed carrier of Definition 395.1. The rows B, T, L, I, H, C, G, N contain the source, contraction, rational ledger, finite iterate ledger, transports, continuations, package provenance, and local certificate data named in the statement.

Use the classifier of Definition 395.2 to keep comparisons componentwise on those rows. The finite-iterate closure theorem then accounts for every extension of visible iterate data without adding a completed orbit.

The modulus-window transport theorem identifies the M and E rows as the only modulus and endpoint channels adjacent to this Banach source read. The Banach ODE boundary, fixed-point ledger boundary, and finite consumer exhaustion theorem then restrict consumer reads to the same finite packet. Since none of the displayed rows is a host fixed point, an ambient completeness proof, or a selected limiting object, the Banach source row scope is exhausted by the carrier rows. □

Theorem 395.24 (PicardContraction modulus window row scope)**.** *For every accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet, the modulus row M and endpoint seal row E are preserved under both the classifier route of Definition 395.2 and the transport route of Definition 395.10. The preserved rows remain part of the finite packet*

$$B, T, L, I, M, E, H, C, G, N$$

and do not become a completed orbit, an ambient completeness claim, a host fixed point, or a choice-selected limit.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket modulus window row scope`

Proof. Read M and E from the carrier of Definition 395.1. They are explicit finite rows of the packet, not derived host objects.

Apply the classifier route of Definition 395.2. Because classifier comparison is componentwise, the modulus and endpoint rows are transported only through the displayed hsame and Cont coordinates.

Apply Definition 395.10 to the same rows. The finite-iterate closure and fixed-point ledger boundary keep the endpoint seal downstream of visible iterate data, while the Banach ODE boundary prevents a consumer from replacing M or E by a host convergence theorem.

Finally, Definition 395.18 exhausts downstream reads by the displayed carrier rows. Thus preserving M and E under classifier and transport routes preserves exactly finite packet evidence. □

Theorem 395.25 (PicardContraction downstream seal scope)**.** *Every* $\mathsf{Ode}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumer route out of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet factors through the rows named by Definition 395.18. Thus downstream seal reads are finite* BHist *reads of*

$$B, T, L, I, M, E, H, C, G, N$$

and never a route through host fixed points, completed orbits, ambient completeness, or choice-selected limits.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket downstream seal scope`

Proof. Begin with the carrier of Definition 395.1 and the finite consumer exhaustion theorem. Together they list exactly the rows available to the four downstream consumer families named in the statement.

For $\mathsf{Ode}^{\uparrow}$ and $\mathsf{NewtonIteration}^{\uparrow}$, the Banach ODE boundary supplies the consumer-facing restriction. For $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$, the modulus-window transport and fixed-point ledger boundary keep the read on the displayed modulus and endpoint rows.

Finally, the classifier and finite-iterate closure theorems show that transport and finite concatenation do not add new carrier coordinates. The downstream seal scope is therefore the finite row scope of Definition 395.18, with no completed orbit, host fixed point, ambient completeness proof, or selected limit. □

Theorem 395.26 (PicardContraction metric complete Lipschitz consumer route)**.** *Let $P = (B, T, L, I, M, E, H, C,$ be an accepted $\mathsf{PicardContraction}^{\uparrow}$ packet. Every $\mathsf{Ode}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer of P reads the $\mathsf{Banach}^{\uparrow}$ source row through chapter 90, the $\mathsf{CompleteMetric}^{\uparrow}$ boundary through chapter 128, the contraction and Lipschitz rows through chapter 410, and the Cauchy-modulus row M before the endpoint seal E.*

Thus the consumer route is the finite dependency route

$$B, T, L, I, M, E, H, C, G, N$$

with the Banach, complete-metric, Lipschitz, and Cauchy-modulus rows visible before the endpoint seal. It does not export a host fixed point, completed orbit, ambient completeness theorem, selected limit, quotient stream equality, or external real-equality witness.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket metric complete lipschitz consumer route`

Proof. Project the packet P. The carrier rows are the Banach source B, contraction-map row T, rational Lipschitz ledger L, finite iterate ledger I, Cauchy-modulus row M, endpoint seal E, componentwise transport H, displayed continuation C, provenance G, and local naming row N.

Use the existing finite route theorems. The finite-iterate theorem Definition 395.3 keeps iteration inside the displayed Banach and contraction rows, Definition 395.4 routes ODE and Newton consumers through the Banach source and Lipschitz ledgers, and Definition 395.5 places the Cauchy-modulus row before the endpoint seal.

Now read the sibling boundaries. The Banach source is the packet row cited through chapter 90; the complete-metric boundary is the finite convergence boundary of chapter 128; and the contraction and modulus ledgers are the LipschitzMap rows of chapter 410.

It remains to inspect the excluded coordinates. None of $B, T, L, I, M, E, H, C, G, N$ is a host fixed point, completed orbit, ambient completeness theorem, selected limit, quotient stream equality, or external real-equality witness. Hence every listed downstream consumer receives only the displayed metric, complete, Lipschitz, and modulus route before the endpoint seal. □

Theorem 395.27 (PicardContraction Cauchy modulus handoff)**.** *For every accepted $\mathsf{PicardContraction}^{\uparrow}$ packet*

$$P = (B, T, L, I, M, E, H, C, G, N),$$

the row M is the only Cauchy-modulus evidence exported by the packet. Any Cauchy consumer may transport M through the displayed hsame rows H and read it through the displayed Cont routes C, but it cannot replace M by an external convergence proof, a completed Picard orbit, an ambient completeness theorem, or a choice-selected limiting point.

Proof. First isolate the modulus row. Apply Definition 395.10: the carrier exposes M as the exact modulus-window readback row, transported only through the displayed H and C coordinates.

Then apply Definition 395.18. Cauchy-facing reads are among the finite packet reads exhausted by $B, T, L, I, M, E, H, C, G, N$, so no consumer can obtain a second modulus source outside the packet.

The excluded objects are not carrier coordinates. Hence the exported Cauchy evidence is precisely the displayed row M with its finite transport and continuation witnesses. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket cauchy modulus handoff`

Theorem 395.28 (PicardContraction regular sequence consumer route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet factors through the finite rows*

$$B, T, L, I, M, E, H, C, G, N.$$

The read may use the Banach source row B, contraction-map row T, rational Lipschitz ledger L, finite iterate ledger I, modulus row M, endpoint and seal row E, transports H, continuations C, package provenance G, and local naming row N; it cannot read a completed orbit or a host-level regular sequence built outside the packet.

Proof. Start from Definition 395.27. It gives the regular-sequence consumer its only modulus evidence, namely the displayed row M.

Next use Definition 395.3 for the visible iterate data and Definition 395.17 for the rational Lipschitz ledger. These theorems keep the construction on B, T, L, I and do not create a stronger host contraction claim.

Finally apply Definition 395.18. Its consumer list includes $\mathsf{RegSeqRat}^{\uparrow}$, so the regular-sequence route is exhausted by $B, T, L, I, M, E, H, C, G, N$ and cannot pass through an omitted completed orbit. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket regseqrat consumer route`

Theorem 395.29 (PicardContraction real seal noncompletion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet receives only the displayed endpoint and seal row E, together with the finite route through*

$$B, T, L, I, M, H, C, G, N.$$

The packet does not export a fixed point, a Banach fixed-point theorem, ambient completeness, a completed Picard orbit, or a selected limit as part of the real-facing seal.

Proof. Use Definition 395.27 to bind the Cauchy evidence to M and Definition 395.28 to bind the regular-sequence route to the displayed finite rows.

Now read the real-facing boundary through Definition 395.4. The theorem permits consumers to cite the packet rows and the endpoint/seal coordinate, but it does not provide a host fixed point or a completed orbit.

Finally apply Definition 395.18. Since $\mathsf{Real}^{\uparrow}$ reads are exhausted by the carrier, the seal remains a finite endpoint row rather than a completion theorem or selected limiting object. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket real seal noncompletion`

Theorem 395.30 (PicardContraction public carrier surface)**.** *For every accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet*

$$P = (B, T, L, I, M, E, H, C, G, N),$$

the public carrier surface consists exactly of the $\mathsf{Banach}^{\uparrow}$ *source row B, contraction-map row T, rational Lipschitz ledger L, finite iterate ledger I, Cauchy-modulus row M, endpoint and* $\mathsf{Real}^{\uparrow}$ *seal*

row E, componentwise hsame *transports H, displayed* Cont *routes C,* Pkg *provenance G, and local* NameCert *row N. This surface is public over* Banach$^{\uparrow}$, Rat$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert, *and it contains no fixed point, ambient completeness proof, completed orbit, or choice-selected limit.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket public carrier surface`

Proof. Start with the carrier of Definition 395.1. Its coordinates are precisely $B, T, L, I, M, E, H, C, G, N$, with no additional host fixed-point coordinate.

Use the classifier of Definition 395.2 and the classifier stability theorem. They compare and transport accepted packets componentwise, so the public surface remains the displayed finite carrier rather than a host theorem about contractions.

Finally apply Definition 395.18. It exhausts downstream ODE, Newton, regular-rational, and real-name reads by the same carrier rows, preserving the exclusions in the statement. □

Theorem 395.31 (PicardContraction public iterate ledger)**.** *The only public iteration evidence exported by an accepted* PicardContraction$^{\uparrow}$ *packet is the finite iterate ledger I together with the rational ratio ledger L and the displayed transport and continuation rows that read them. Downstream* NewtonIteration$^{\uparrow}$ *and* Ode$^{\uparrow}$ *consumers may use this finite evidence, but they receive no completed Picard orbit, host fixed point, ambient completeness theorem, or selected limiting point.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket public iterate ledger`

Proof. First isolate the finite iteration rows through Definition 395.3. Concatenating visible iterate data stays inside the displayed ledger I and the surrounding carrier rows.

Next use Definition 395.17. The rational Lipschitz evidence remains the finite row L and cannot be replaced by a stronger host contraction estimate.

Finally apply Definition 395.4 and Definition 395.9. They are the consumer-facing restrictions for Ode$^{\uparrow}$ and NewtonIteration$^{\uparrow}$, and they rule out every omitted completion or fixed-point object. □

Theorem 395.32 (PicardContraction public seal export)**.** *For every accepted* PicardContraction$^{\uparrow}$ *packet, the public* Real$^{\uparrow}$ *seal export factors through the modulus row M, the endpoint and seal row E, and the finite route*

$$B, T, L, I, H, C, G, N.$$

The export is a finite BEDC carrier read over the public carrier surface of Definition 395.30; it does not claim a fixed point, ambient completeness, completed orbit, or choice-selected limit.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket public seal export`

Proof. Begin with Definition 395.27. It identifies M as the only Cauchy-modulus evidence available to seal-facing consumers.

Then use Definition 395.28. The regular-sequence route reads the same finite carrier rows and supplies no completed orbit outside the packet.

Finally apply Definition 395.29 together with Definition 395.30. The seal is therefore the displayed endpoint row read through the finite route, with the fixed-point and completeness exclusions still in force. □

Theorem 395.33 (PicardContraction CompleteMetric handoff)**.** *For every accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet*

$$P = (B, T, L, I, M, E, H, C, G, N),$$

every $\mathsf{CompleteMetric}^{\uparrow}$*-facing read of* P *factors through the finite rows*

$$B, T, L, I, M, E, H, C, G, N.$$

The row M *is the explicit Cauchy modulus exposed to the downstream metric consumer, and the row* E *is the endpoint and seal row available to real-facing consumers. The handoff exports no host fixed point, ambient completeness theorem, completed orbit, quotient stream, or selected limit.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket complete metric handoff`

Proof. First read the public carrier surface through Definition 395.30. It exposes exactly the rows $B, T, L, I, M, E, H, C, G, N$ and excludes the fixed-point and completion objects named in the statement.

Next isolate the metric evidence. By Definition 395.27, the only Cauchy-modulus evidence exported by the packet is the displayed row M.

The regular-sequence side is already finite. Apply Definition 395.28; any regular-rational read is exhausted by the same carrier rows and cannot pass through a completed orbit outside the packet.

Finally use Definition 395.32. The real-facing endpoint and seal data factor through M, E, and the displayed finite route, so a $\mathsf{CompleteMetric}^{\uparrow}$ consumer receives the explicit modulus handoff without importing host completeness, quotient-stream data, or a selected limiting point. □

Theorem 395.34 (PicardContraction CauchyRate source extraction)**.** *For every accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet*

$$P = (B, T, L, I, M, E, H, C, G, N),$$

the finite iterate ledger I*, rational Lipschitz row* L*, Cauchy-modulus row* M*, endpoint seal* E*, displayed* hsame *transports* H*, displayed* Cont *routes* C*,* Pkg *provenance* G*, and local* NameCert *row* N *determine the* $\mathsf{CauchyRate}^{\uparrow}$*-facing source packet read from* P*. The extracted packet is a finite read of the same* BHist *carrier and contains no completed Picard orbit, ambient completeness proof, Banach fixed-point object, quotient stream equality, or selected limit.*

Proof. Project the public carrier surface of Definition 395.30. The rows named in the statement are visible coordinates of the finite packet, and the theorem excludes every host-level completion object from that surface.

Next isolate the effective-rate data. Apply Definition 395.31 to bind the visible iteration evidence to I and L, and use Definition 395.27 to bind the tolerance schedule to M. The endpoint and real-facing seal are then the displayed row E rather than a selected limit.

Finally use the transport and provenance rows H, C, G, N to package the read as a $\mathsf{CauchyRate}^{\uparrow}$ source. Since each row is already part of P, the extracted source is determined by the finite carrier and cannot introduce an additional completion or fixed-point premise. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket cauchyrate source extraction`

Theorem 395.35 (PicardContraction CauchyRate real seal compatibility)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal export from an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet factors through the* $\mathsf{CauchyRate}^{\uparrow}$*-facing source packet of Definition 395.34. In particular, a real-facing consumer must read the finite packet rows*

$$L, I, M, E, H, C, G, N$$

before it reads the seal, and it has no route that bypasses the finite rate packet by invoking ambient completeness, a completed orbit, a host fixed point, or a selected real representative.

Proof. Start with Definition 395.32. It factors the $\mathsf{Real}^{\uparrow}$ seal through the modulus row M, endpoint row E, and the finite carrier route surrounding B, T, L, I, H, C, G, N.

Now replace the rate-facing part of that route by the source extraction theorem. The rows L, I, M, E, H, C, G, N are exactly the finite rate, endpoint, transport, continuation, package, and naming rows used by the $\mathsf{CauchyRate}^{\uparrow}$ source packet.

It remains to rule out escape around the extracted source. Apply Definition 395.29; the real-facing boundary exports only the finite endpoint and seal row. Therefore seal compatibility factors through the extracted CauchyRate source and not through any omitted completion object. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket cauchyrate real seal compatibility`

Theorem 395.36 (PicardContraction finite-rate seal triangle)**.** *For every accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet*

$$P = (B, T, L, I, M, E, H, C, G, N),$$

the $\mathsf{CauchyRate}^{\uparrow}$ *source extraction,* $\mathsf{Real}^{\uparrow}$ *seal compatibility, and public seal export form a single finite triangle over the rows* L, I, M, E, H, C, G, N*. A downstream consumer may move from the Picard packet to the CauchyRate source, from that source to the Real seal, and back to the public seal export only through the displayed finite carrier rows; it cannot insert ambient completeness, a completed Picard orbit, a host fixed point, quotient stream equality, or a selected real representative at any side of the triangle.*

Proof. First read the source side through Definition 395.34. It identifies the finite rate-facing packet with the visible iterate, ratio, modulus, endpoint, transport, route, provenance, and local naming rows.

Next read the seal side through Definition 395.35. The real-facing path must pass through those same finite rate rows before the seal is read.

Finally close the public side with Definition 395.32. The public seal export factors through M, E, and the same finite carrier route, so the three sides share the displayed rows and exclude the omitted completion objects. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket finite rate seal triangle`

Theorem 395.37 (PicardContraction Newton ODE shared modulus route)**.** *Every* $\mathsf{NewtonIteration}^{\uparrow}$ *or* $\mathsf{Ode}^{\uparrow}$ *consumer of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet uses the same finite modulus row* M*, rational ratio ledger* L*, and finite iterate ledger* I*. The two consumer families may read these rows through the displayed* hsame *transports* H*,* Cont *routes* C*,* Pkg *provenance* G*, and local naming row* N*, but neither consumer receives a second modulus source, a completed orbit, a host fixed point, an ambient completeness proof, or a selected limiting state.*

Proof. Start with the public iterate ledger. By Definition 395.31, the only iteration evidence exported to Newton and ODE consumers is the finite ledger I together with L and the displayed transport and route rows.

Attach the Cauchy evidence using Definition 395.27. This theorem identifies M as the only modulus evidence available from the packet.

Now apply Definition 395.43 and Definition 395.48. They exhaust both consumer families by the same finite packet rows, so Newton and ODE reads share L, I, M rather than branching to omitted completion or fixed-point data. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket newton ode shared modulus route`

Theorem 395.38 (PicardContraction RegSeqRat Real rate non-escape)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet that reads rate information factors through the finite rows*

$$L, I, M, E, H, C, G, N.$$

The consumer may use the rational ratio ledger, finite iterate ledger, Cauchy modulus row, endpoint and seal row, transport rows, continuation routes, provenance, and local naming row, but it cannot bypass the finite rate packet through ambient completeness, a completed orbit, a host fixed point, quotient stream equality, selected limits, or extra real representatives.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket regseqrat real rate nonescape`

Proof. For regular-rational reads, use Definition 395.28. The route binds the consumer to the finite carrier rows and excludes a completed orbit built outside the packet.

For real-facing reads, use Definition 395.29. The seal boundary supplies only the endpoint and finite route, not a host fixed point or a selected limit.

Finally apply Definition 395.36. It forces both consumer families to pass through the extracted CauchyRate source and the public seal route, so no quotient stream equality, ambient completeness row, or extra real representative can be inserted around the finite rate packet. □

Theorem 395.39 (PicardContraction CauchyRate root-unblock package)**.** *The public* $\mathsf{PicardContraction}^{\uparrow}$ *surface assembles a* $\mathsf{CauchyRate}^{\uparrow}$*-facing root-unblock package for downstream* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Ode}^{\uparrow}$*, and* $\mathsf{NewtonIteration}^{\uparrow}$ *consumers. The package consists of the carrier surface of Definition 395.30, the iteration ledger of Definition 395.31, the seal export of Definition 395.32, the source extraction of Definition 395.34, and the real-seal compatibility of Definition 395.35. Its conclusion is a finite rate/modulus bridge only; it is not a Banach fixed-point theorem, an ambient completeness theorem, a completed-orbit construction, or a selected-limit principle.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket cauchyrate root unblock package`

Proof. First assemble the public surface. The carrier theorem gives the visible rows $B, T, L, I, M, E, H, C, G, N$, and the public iterate ledger identifies the only iteration evidence available to root-facing consumers.

Next attach the seal route. The public seal export sends real-facing reads through M, E, and the finite carrier route, while the source extraction theorem repackages the rate-facing rows as the $\mathsf{CauchyRate}^{\uparrow}$ source packet.

Finally use real-seal compatibility to bind the downstream real path to that finite source. The cited theorems already exclude fixed points, completed orbits, ambient completeness, and selected limits, so the assembled package is exactly the finite rate/modulus bridge claimed in the statement. □

Theorem 395.40 (PicardContraction finite-modulus obligation triad)**.** *For every accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet*

$$P = (B, T, L, I, M, E, H, C, G, N),$$

the Banach source row B, the rational Lipschitz-ratio ledger L, and the Cauchy-modulus window M jointly form the finite $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ *obligation surface for downstream modulus reads. The triad is read together with the contraction row T, finite iterate ledger I, endpoint seal E,*

componentwise hsame *transports H, displayed* Cont *routes C,* Pkg *provenance G, and local naming row N, and it contains no Banach fixed point, completed orbit, ambient completeness theorem, or selected limit.*

Proof. Unpack Definition 395.1. The rows B, L, and M are visible coordinates of the same finite packet, while T, I, E, H, C, G, and N record how those rows are consumed and transported.

Use Definition 395.11 for the source row and Definition 395.12 for the ratio ledger. These rows keep Banach and Lipschitz evidence inside the displayed carrier rather than in an external contraction principle.

Finally apply Definition 395.27 and Definition 395.19. They identify M as the only modulus evidence and lock it to I, L, H, and C. The three displayed rows therefore form the finite modulus obligation surface named in the statement. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket finite modulus obligation triad`

Theorem 395.41 (PicardContraction ratio-window carrier transport)**.** *Let*

$$P = (B, T, L, I, M, E, H, C, G, N)$$

and

$$P' = (B', T', L', I', M', E', H', C', G', N')$$

be accepted PicardContraction$^{\uparrow}$ *packets related by the finite classifier. Every* hsame*-compatible transport through the displayed* Cont *routes preserves the rational ratio ledger and the Cauchy-modulus window: L' and M' are read as the transported images of L and M inside the same carrier surface, not as external Lipschitz or convergence witnesses.*

Proof. Start with the classifier of Definition 395.2. It compares the accepted packets coordinate by coordinate through the displayed hsame and Cont rows, so the ratio and modulus coordinates are transported as packet rows.

Apply Definition 395.7 and Definition 395.10. The first theorem keeps the carrier comparison on the finite Banach, map, ratio, iterate, modulus, endpoint, provenance, and naming rows; the second identifies M and E as exact transported readback rows.

It remains to bind the ratio ledger. Use Definition 395.17 and Definition 395.12. They keep the rational ledger on L with its finite iterate and continuation context. Thus transport preserves both the ratio ledger and the modulus window without adding any host-level contraction or completion object. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket ratio window carrier transport`

Theorem 395.42 (PicardContraction Lean ratio-ledger nonexpansion sync)**.** *Let*

$$P = (B, T, L, I, M, E, H, C, G, N)$$

be an accepted PicardContraction$^{\uparrow}$ *packet whose finite iterate ledgers concatenate and whose Lipschitz row is the displayed positive rational ratio row below the unit bound. The concatenated packet reuses the transported ratio ledger L as its finite nonexpanding ledger row. It exports no stronger host contraction, no Banach fixed-point theorem, no completed orbit, no ambient completeness proof, and no selected limit.*

Proof. Apply Definition 395.17. The concatenated iterate ledger is read through the same positive rational row below the unit bound, so the concatenated packet cannot enlarge the ratio evidence beyond the displayed finite ledger.

Next use Definition 395.41. It keeps the ratio ledger and the Cauchy-modulus window inside the accepted carrier rows rather than turning them into an external host contraction or convergence witness.

Finally combine Definition 395.40 and Definition 395.46. They consume the same finite rows $B, T, L, I, M, E, H, C, G, N$: B for the source boundary, T for the contraction row, L for the rational ratio ledger, I for finite iterates, M for the modulus window, E for the endpoint seal, H and C for transport and displayed routes, G for Pkg provenance, and N for the local naming row. Since the public boundary has no coordinate for a stronger contraction principle, fixed point, completed orbit, ambient completeness proof, or selected limit, the concatenated packet exports only the transported finite ledger. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket lean ratio ledger nonexpansion sync`

Theorem 395.43 (PicardContraction Banach ODE consumer non-escape)**.** *Every* $\mathsf{Ode}^{\uparrow}$ *or* $\mathsf{NewtonIteration}^{\uparrow}$ *consumer of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet can read only the finite Banach row B, contraction row T, rational ratio ledger L, finite iterate ledger I, Cauchy-modulus row M, endpoint seal E,* Pkg *provenance G, local* NameCert *row N, and the surrounding* BHist, hsame, *and* Cont *evidence. No ODE or Newton consumer receives a Banach fixed-point object, completed Picard orbit, ambient completeness proof, or selected limiting state from this packet.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket banach ode consumer nonescape`

Proof. Read the packet through Definition 395.1. The consumer-visible coordinates are exactly $B, T, L, I, M, E, H, C, G, N$.

For the ODE and Newton side, apply Definition 395.4. It already factors these consumer reads through the Banach source, contraction row, rational ledger, finite iterate rows, explicit modulus row, and endpoint/seal routes.

Now attach the modulus obligation and transport rows. The triad theorem Definition 395.40 binds B, L, and M as one finite obligation surface, while Definition 395.41 preserves that surface under displayed classifier transport. Finally Definition 395.18 exhausts every listed consumer by the same finite carrier rows, proving non-escape. □

Theorem 395.44 (PicardContraction public NameCert export)**.** *Every public* $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ *read used by* $\mathsf{Ode}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{CauchyRate}^{\uparrow}$ *consumers factors through the displayed rows*

$$B, T, L, I, M, E, H, C, G, N$$

of the accepted $\mathsf{PicardContraction}^{\uparrow}$ *packet. The exported public surface assembles the carrier, classifier, finite-iterate closure, Banach and ODE boundary, modulus-window transport,* $\mathsf{CauchyRate}^{\uparrow}$ *extraction, real-seal compatibility,* Pkg *provenance, and local naming row into* $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$. *No fixed point, completed orbit, ambient completeness object, quotient stream equality, or selected limit is exported from this public naming surface.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket public namecert export`

Proof. Project the carrier of Definition 395.1. Its public coordinates are the ten displayed rows $B, T, L, I, M, E, H, C, G, N$.

Apply Definition 395.30, Definition 395.7, and Definition 395.3. These give the public row inventory, classifier transport, and finite iteration scope while keeping host fixed points, completed Picard orbits, ambient completeness proofs, quotient stream equalities, and selected limits outside the export surface.

For rate and modulus reads, use Definition 395.39. It routes the $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers through the same carrier, iterate-ledger, seal, source-extraction, and real-seal rows.

For root-facing ODE and Newton reads, apply Definition 395.43. The remaining consumer families are then exhausted by Definition 395.22. Hence every public $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ read has the stated source and no omitted completion, fixed-point, stream-equality, or limit-selection object can escape through the certificate. □

Theorem 395.45 (PicardContraction public Banach CauchyRate factorization)**.** *Every public* $\mathsf{Banach}^{\uparrow}$ *or* $\mathsf{CauchyRate}^{\uparrow}$ *consumer of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet factors through the finite rows*

$$B, T, L, I, M, E, H, C, G, N.$$

The factorization reads the Banach source, contraction row, rational ratio ledger, finite iterate ledger, modulus window, endpoint seal, transports, routes, provenance, and local NameCert *row, and it exports no host fixed-point or completed-orbit object.*

Proof. Begin with the public export theorem Definition 395.44. It identifies the complete public certificate surface with the displayed packet rows.

For Banach-facing reads, apply Definition 395.30 and Definition 395.40. These bind B, T, L, and M to the same finite carrier and obligation triad.

For rate-facing reads, use Definition 395.39. The package factors through the same carrier, iterate, modulus, seal, transport, provenance, and naming rows, so every public Banach or CauchyRate consumer is exhausted by $B, T, L, I, M, E, H, C, G, N$. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket public banach cauchyrate factorization`

Theorem 395.46 (PicardContraction public real consumer boundary)**.** *Public* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, *and* $\mathsf{NewtonIteration}^{\uparrow}$ *consumers of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet receive only the finite packet rows*

$$B, T, L, I, M, E, H, C, G, N.$$

They receive no fixed point, completed Picard orbit, ambient completeness proof, selected limit, quotient stream equality, or extra real representative from the public $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ *export.*

Proof. First use Definition 395.44. It packages the public certificate as the displayed finite rows and states the missing completion and limit objects are not exported.

For real and regular-rational consumers, apply Definition 395.39. It routes the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ reads through the finite rate and seal rows.

For ODE and Newton consumers, apply Definition 395.43. The same finite rows exhaust the consumer surface, so no downstream real-facing or dynamical consumer receives data outside the packet. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket public real consumer boundary`

Theorem 395.47 (PicardContraction public Banach source modulus seal)**.** *For every accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet*

$$P = (B, T, L, I, M, E, H, C, G, N),$$

the public packet exports exactly the $\mathsf{Banach}^{\uparrow}$ *source row* B*, contraction row* T*, Lipschitz ratio ledger* L*, finite iterate ledger* I*, Cauchy-modulus row* M*, endpoint seal* E*, and the displayed* BHist*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *provenance rows* H, C, G, N*. This export is a finite source/modulus/seal surface and contains no host fixed point, completed orbit, ambient completeness proof, external contraction principle, or selected limit.*

Proof. Project the carrier of Definition 395.1. Its visible rows are precisely $B, T, L, I, M, E, H, C, G, N$, so the public export starts from the finite packet rather than from a host contraction theorem.

Use Definition 395.2, Definition 395.3, and Definition 395.41. These rows keep the source, contraction, ratio, and iterate data inside the finite classifier and its displayed transport surface.

For the modulus and seal side, apply Definition 395.34 and Definition 395.35. Together with Definition 395.30, they identify M and E as the public Cauchy-rate and real-seal rows. The exported packet is therefore exactly the stated finite source/modulus/seal surface. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket public banach source modulus seal`

Theorem 395.48 (PicardContraction public ODE Newton export)**.** *Every* $\mathsf{Ode}^{\uparrow}$ *or* $\mathsf{NewtonIteration}^{\uparrow}$ *consumer route out of an accepted* $\mathsf{PicardContraction}^{\uparrow}$ *packet factors through the public packet of Definition 395.47. Such a consumer can read the displayed rows* $B, T, L, I, M, E, H, C, G, N$*, but it cannot read a completed Picard orbit, host fixed point, ambient completeness proof, selected limit, or external Banach fixed-point object.*

Proof. Start with Definition 395.4. It already routes ODE and Newton reads through the Banach source, contraction row, rational ledger, finite iterate rows, explicit modulus row, and endpoint/seal routes.

Apply Definition 395.43. This exhausts the same consumer families by the finite packet rows and excludes completed orbits, host fixed points, ambient completeness proofs, and selected limits.

Finally use Definition 395.47 to name the public packet through which these rows are exported. The ODE and Newton routes therefore factor through that public surface and no omitted completion object is readable. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket public ode newton export`

Theorem 395.49 (PicardContraction public NameCert package)**.** *The public* $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ *export is the package assembled from the source/modulus/seal surface of Definition 395.47, the ODE and Newton route boundary of Definition 395.48, and the local obligation surface of Definition 395.6. It exports exactly the displayed finite rows* $B, T, L, I, M, E, H, C, G, N$ *for* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{CauchyRate}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Ode}^{\uparrow}$*, and* $\mathsf{NewtonIteration}^{\uparrow}$ *readers.*

Proof. The local obligation surface supplies the carrier, classifier, finite-iterate, modulus-readback, and ledger non-escape rows of the naming certificate.

The public source/modulus/seal theorem identifies the rows exported to Banach, Cauchy-rate, regular-rational, and real-facing consumers. The public ODE/Newton theorem identifies the same finite packet as the only route for dynamical consumers.

Repack these rows under the local $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ entry. Since each component is already one of $B, T, L, I, M, E, H, C, G, N$, the assembled public package introduces no fixed point, completed orbit, ambient completeness proof, external contraction principle, or selected limit. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket public namecert package`

Theorem 395.50 (PicardContraction bridged source-window package)**.** *The checked public export, Banach and ODE consumer non-escape, ratio-ledger non-expansion, and root source-window checked handoff form the bridge packet from the concrete* PicardContraction$^{\uparrow}$ *carrier to the public interface. Concretely, every public read of an accepted packet factors through the displayed rows*

$$B, T, L, I, M, E, H, C, G, N$$

and the source-window handoff target `BEDC.Derived.PicardContractionUp.PicardContractionPacket_root_s` *records the checked root-side handoff for that same finite packet surface.*

Proof. Start with the public NameCert package. Definition 395.49 assembles the source/modulus/seal export, ODE and Newton route boundary, and local obligation surface as the public package over $B, T, L, I, M, E, H, C, G, N$.

Next use consumer non-escape and ratio control. Definition 395.43 keeps ODE and Newton reads inside the same finite carrier, while Definition 395.17 prevents the rational Lipschitz row from expanding into a stronger host contraction claim.

Finally attach the checked source-window handoff. The Lean target named in the statement is the source-window handoff for the root-side surface, so the paper bridge is the displayed public package together with the checked handoff, not an ambient Banach fixed-point theorem or a completed-orbit construction. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket bridged source window package`

Closure status for NameCert$_{\text{PicardContraction}^{\uparrow}}$.

Constructive story: A PicardContraction$^{\uparrow}$ packet is generated from a Banach$^{\uparrow}$ source row, a displayed contraction-map row, a positive rational Lipschitz-ratio ledger below the unit bound, a finite Picard-iterate ledger, an explicit Cauchy-modulus row, endpoint and seal rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PicardContraction}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 395.1, Definition 395.2, Definition 395.3, Definition 395.4, Definition 395.6, Definition 395.7, Definition 395.8, Definition 395.9, Definition 395.10, Definition 395.17, Definition 395.18, Definition 395.44, Definition 395.34, Definition 395.35, Definition 395.36, Definition 395.37, Definition 395.38, Definition 395.39, Definition 395.45, Definition 395.46, Definition 395.47, Definition 395.48, Definition 395.49, and Definition 395.50 describe the mature consumer scope: the finite packet, classifier, finite-iterate closure, consumer boundary, NameCert surface, classifier stability, contraction-step package, fixed-point ledger boundary, modulus-window transport, ratio-ledger nonexpansion, finite consumer exhaustion, public certificate export, CauchyRate source extraction, CauchyRate Real seal compatibility, finite-rate seal triangle, Newton ODE shared modulus route, RegSeqRat Real rate non-escape, CauchyRate root-unblock package, Banach and CauchyRate factorization, real-facing consumer boundary, Banach source/modulus/seal export, ODE/Newton public export, public NameCert package, and source-window bridge packet.

Formal verification: FormalStatus(NameCert$_{\text{PicardContraction}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close full Banach fixed-point convergence, uniqueness of a host fixed point, ambient completeness, a choice-selected limit, or bridge checking.

Upgrade path: The theory axis is mature; the next obligation is formal-axis Lean verification for the displayed finite packet, CauchyRate, RegSeqRat, Real, ODE, and Newton consumer rows.

Definition 395.51 (PicardContraction root source-window packet)**.** *A* PicardContraction$^{\uparrow}$ *root source-window packet is a finite extension*

$$R = (B, T, L, I, M, E, H, C, G, N, U)$$

of the carrier rows of Definition 395.1. The rows $B, T, L, I, M, E, H, C, G, N$ *are the displayed* Banach$^{\uparrow}$ *source row, contraction-map row, rational Lipschitz ledger, finite Picard-iterate ledger,*

Cauchy-modulus window, endpoint and seal row, componentwise hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ *row. The extra row U is a finite downstream consumer request row naming which of the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, *or* $\mathsf{CauchyRate}^{\uparrow}$ *routes is being read from the same packet.*

The row U is not an additional analytic object. It is a request index over the public carrier surface of Definition 395.30 and the public naming export of Definition 395.44. Thus the packet has no coordinate for a Banach fixed point, completed Picard orbit, ambient completeness theorem, quotient stream equality, or selected limit.

The sibling source surfaces are already the displayed NameCert boundaries: the Banach source surface in chapter 90, the Cauchy-rate consumer boundary in chapter 415, and the regular-rational naming boundary in chapter 371. Thus U only selects among downstream consumer families whose rows are present on those finite surfaces; it does not add analytic data beyond the packet rows $B, T, L, I, M, E, H, C, G, N$.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionRootSourceWindowPacket request row certificate`

Theorem 395.52 (PicardContraction root source-window admission)**.** *Every packet $R = (B, T, L, I, M, E, H, C, G$ satisfying Definition 395.51 is admitted by the root* $\mathsf{PicardContraction}^{\uparrow}$ *consumer surface as a finite* BHist *source-window. Its analytic rows are exactly the carrier rows of Definition 395.1, its public read surface is the one described by Definition 395.30, and its consumer request row U may only choose among the displayed downstream routes named by Definition 395.44.*

Proof. Project the first ten coordinates of R. They are precisely the $B, T, L, I, M, E, H, C, G, N$ rows of Definition 395.1, so carrier admission is the ordinary finite BHist admission for the Picard packet.

Read the same rows through Definition 395.30. The public surface lists the Banach source, contraction row, Lipschitz ledger, finite iterate ledger, modulus row, endpoint seal, hsame transports, Cont routes, Pkg provenance, and local NameCert row.

Finally inspect U. By definition it only records which downstream consumer route is requested, and Definition 395.44 already restricts those routes to the displayed public rows. Hence admission adds no completed orbit, fixed point, ambient completeness witness, quotient stream equality, or selected limit. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionRootSourceWindowPacket admission`

Theorem 395.53 (PicardContraction root modulus consumer lock)**.** *For every admitted root source-window packet $R = (B, T, L, I, M, E, H, C, G, N, U)$, any* $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *read of the modulus or seal is locked to the displayed rows*

$$L, I, M, E, H, C, G, N.$$

The lock is the finite source extraction of Definition 395.34 together with the public carrier and public NameCert *rows of Definition 395.30 and Definition 395.44.*

Proof. Begin with the admitted packet of Definition 395.52. Its modulus row M, endpoint seal E, transports H, continuations C, package row G, and naming row N are visible carrier coordinates, not hidden completion data.

Apply Definition 395.34. It identifies the $\mathsf{CauchyRate}^{\uparrow}$-facing source as a finite read of L, I, M, E, H, C, G, N from the same BHist packet.

For $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers, use Definition 395.44. The public $\mathsf{NameCert}_{\mathsf{PicardContraction}^{\uparrow}}$ export routes those reads through the same displayed finite rows. Therefore the consumer request row U can select only that finite modulus-and-seal route and cannot replace it by a Banach fixed-point theorem, completed orbit, ambient completeness proof, quotient stream equality, or selected limit. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionRootSourceWindowPacket modulus consumer lock`

Theorem 395.54 (PicardContraction root downstream handoff exhaustion)**.** *Every downstream handoff out of an admitted root source-window packet* $R = (B, T, L, I, M, E, H, C, G, N, U)$ *is exhausted by the rows*

$$B, T, L, I, M, E, H, C, G, N, U.$$

For $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Ode}^{\uparrow}$*,* $\mathsf{NewtonIteration}^{\uparrow}$*, and* $\mathsf{CauchyRate}^{\uparrow}$ *consumers, the handoff is a projection of the displayed* BHist *carrier, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, local* NameCert *row, and the request row* U*. No consumer route invokes a Banach fixed point, completed Picard orbit, ambient completeness theorem, external contraction principle, quotient stream equality, or selected limit.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionRootSourceWindowPacket downstream handoff exhaustion`

Proof. First project the carrier coordinates. By Definition 395.51, the rows before U are exactly the rows of Definition 395.1; the extra row merely names the requested downstream route.

For rate, regular-rational, and real-facing consumers, apply Definition 395.53. It binds the modulus and seal handoff to L, I, M, E, H, C, G, N inside the same packet.

For ODE and Newton consumers, read the public surface through Definition 395.30 and then through Definition 395.44. These theorems route the Banach source, contraction row, ratio ledger, iterate ledger, modulus row, endpoint seal, transport rows, continuation rows, provenance, and local name through the finite public packet.

The request row U has no data beyond the selected consumer family. Since each family has already been routed through the displayed carrier and naming rows, the handoff is exhausted by $B, T, L, I, M, E, H, C, G, N, U$. □

Theorem 395.55 (PicardContraction source-window formal target)**.** *For a root source-window packet*

$$R = (B, T, L, I, M, E, H, C, G, N, U),$$

the displayed rows $B, T, L, I, M, E, H, C, G, N, U$ *constitute the exact paper-side formal target for the future Lean encoding of the* $\mathsf{PicardContraction}^{\uparrow}$ *source window. The target consists of carrier admission, modulus consumer lock, downstream handoff exhaustion, and the exclusion of fixed-point data, completion data, quotient stream equality, and selected-limit data.*

Thus the intended formal surface is the finite packet admitted by Definition 395.52, constrained by Definition 395.53, and exhausted by Definition 395.54.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket source window formal target`

Proof. The admission theorem first fixes the carrier. It identifies the first ten rows with the displayed $\mathsf{PicardContraction}^{\uparrow}$ carrier and reads U only as a downstream consumer request row.

The modulus-lock theorem then fixes the analytic handoff. Any $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ read of the modulus or seal is forced through L, I, M, E, H, C, G, N inside the same finite packet.

The downstream-exhaustion theorem closes the consumer side. It covers the named $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, and $\mathsf{CauchyRate}^{\uparrow}$ routes and shows that each route is a projection of $B, T, L, I, M, E, H, C, G, N, U$.

Combining these three statements gives the formal target surface. Since each cited theorem explicitly excludes fixed points, completed Picard orbits, ambient completion, quotient stream equality, and selected limits, the future Lean target has no additional row to encode. □

Theorem 395.56 (PicardContraction root source-window obligation package)**.** *For a root source-window packet*

$$R = (B, T, L, I, M, E, H, C, G, N, U),$$

the consumer-facing root obligation package is exactly the conjunction of root source-window admission, root modulus consumer lock, downstream handoff exhaustion, and the source-window formal target. Equivalently, an accepted package is obtained by composing Definition 395.52, Definition 395.53, Definition 395.54, and Definition 395.55; it contains no Banach fixed-point existence theorem, completed Picard orbit, quotient stream equality, or selected limit.

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionRootSourceWindowPacket obligation package`

Proof. Use root source-window admission first. It fixes the finite carrier rows $B, T, L, I, M, E, H, C, G, N$ and reads U only as a downstream request row.

Next use the root modulus consumer lock. It forces every $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ read of the modulus or seal through L, I, M, E, H, C, G, N inside the same packet.

Then use downstream handoff exhaustion. It shows that the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, and $\mathsf{CauchyRate}^{\uparrow}$ consumer routes are projections of the displayed rows $B, T, L, I, M, E, H, C, G, N, U$.

Finally use the source-window formal target. That theorem identifies the exact paper-side formal surface as admission, modulus lock, downstream exhaustion, and the exclusions of fixed-point data, completion data, quotient stream equality, and selected-limit data.

Combining the four statements gives the advertised package. Since each component already leaves Banach fixed-point existence, completed Picard orbit, quotient stream equality, and selected limits outside the packet, the conjunction has no additional analytic coordinate. □

Theorem 395.57 (PicardContraction root source-window checked handoff)**.** *For a root source-window packet*

$$R = (B, T, L, I, M, E, H, C, G, N, U),$$

the same finite rows certified by the checked public export targets `PicardContractionPacket_public_namecert_ea` `PicardContractionPacket_banach_ode_consumer_nonescape`*, and* `PicardContractionPacket_ratio_ledger_` *consume the paper-side source window. The request row U may select only one of the displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Ode}^{\uparrow}$*,* $\mathsf{NewtonIteration}^{\uparrow}$*, or* $\mathsf{CauchyRate}^{\uparrow}$ *consumer families, and each selected family reads the packet through $B, T, L, I, M, E, H, C, G, N$ rather than through a Banach fixed point, completed orbit, quotient stream equality, or selected limit.*

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionPacket root source window checked handoff`

Proof. First use the public naming export. It exposes the Banach source, contraction row, ratio ledger, finite iterate ledger, modulus row, endpoint row, transport row, route row, provenance row, and local naming row as the checked public NameCert surface.

Next use the Banach-to-ODE non-escape row. It routes ODE-facing consumer reads through the same finite carrier coordinates and blocks any replacement of the source window by a fixed-point theorem, completed orbit, or ambient completion principle.

Finally use the ratio-ledger non-expansion row. It keeps rate-facing and ratio-facing consumers inside the displayed Lipschitz and iterate ledger coordinates. Since U only names which of the five consumer families is requested, composing the three checked rows gives the advertised handoff without adding any new analytic coordinate. □

Theorem 395.58 (PicardContraction root source-window determinacy)**.** *For a root source-window packet*

$$R = (B, T, L, I, M, E, H, C, G, N, U),$$

the request row U determines only the downstream consumer family and never changes the source-window rows $B, T, L, I, M, E, H, C, G, N$. If two reads have the same $B, T, L, I, M, E, H, C, G, N$ rows and the same request family, then they have the same finite handoff surface for $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, *or* $\mathsf{CauchyRate}^{\uparrow}$.

Proof. Use root source-window admission from Definition 395.52. It fixes the carrier rows $B, T, L, I, M, E, H, C, G,$ and reads U only as a downstream request row.

For $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ requests, apply the modulus consumer lock of Definition 395.53. The rate, rational-readback, and real-facing handoffs are forced through the displayed Lipschitz row, iterate ledger, modulus row, endpoint seal, transport, replay, provenance, and local name.

For $\mathsf{Ode}^{\uparrow}$ and $\mathsf{NewtonIteration}^{\uparrow}$ requests, apply downstream handoff exhaustion from Definition 395.54. The two consumer families are projections of the same finite packet and do not introduce a second source window.

Finally cite the checked handoff of Definition 395.57. It excludes replacement of the finite handoff by fixed-point data, completed-orbit data, quotient stream equality, completion data, or selected-limit data.

Thus two reads that agree on the source-window rows and the request family have no remaining coordinate on which their finite handoff surfaces can diverge. □

Lean4 ✓ `BEDC.Derived.PicardContractionUp.PicardContractionRootSourceWindowPacket determinacy`

Chapter 396

A Concrete Naming Certificate for $\mathsf{BanachFixedPoint}^{\uparrow}$

The $\mathsf{BanachFixedPoint}^{\uparrow}$ interface names the finite BEDC contraction packet that carries a Banach fixed-point construction as displayed data. Its human reference is Banach's contraction principle, but the certificate records only the rows consumed by BEDC: a Banach carrier row, a complete-metric distance row, a contraction-map row, a rational Lipschitz ledger below the unit bound, a finite Picard ledger, an explicit Cauchy modulus, a regular-rational convergence handoff, a seal-facing real-name endpoint row, transport and continuation rows, package provenance, and a local $\mathsf{NameCert}$ row.

Its dependency list is $\mathsf{Banach}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The finite Picard ledger row I is consumed through the $\mathsf{PicardContraction}^{\uparrow}$ carrier of chapter 395, so the fixed-point packet exposes its actual contraction-iteration sibling before any completion handoff is read. The Picard iteration ledger is the concrete contraction-iteration sibling, and the fixed-point packet reaches completion only after consuming chapter 395 together with chapter 128 and the metric carrier.

Definition 396.1 (BanachFixedPoint carrier)**.** *A* $\mathsf{BanachFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, d, T, \lambda, I, M, R, E, H, C, P, N)$$

with the following visible coordinates:

1. *B is the* $\mathsf{Banach}^{\uparrow}$ *carrier row whose state histories provide the domain inspected by the fixed-point packet;*
2. *d is the* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{Met}^{\uparrow}$ *distance row used to read finite iterate distances and the carried completeness surface;*
3. *T is the contraction-map row displaying the map-code history and the continuation route from a carried state row to the next Picard state;*
4. *λ is a rational Lipschitz ledger with a displayed positivity row and a displayed unit-bound row;*
5. *I is the finite Picard-iterate ledger, recording $x_0, \ldots, x_n$ together with the application rows for $x_{k+1} = T(x_k)$;*
6. *M is the explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *row built from the iterate ledger and the Lipschitz-ratio row;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *convergence handoff, exposing the regular rational name and the carried completion route used by consumers;*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing endpoint row attached to the handoff;*
9. *H stores componentwise* hsame *transports for the Banach, distance, contraction, ratio, iterate, modulus, handoff, endpoint, package, and naming rows;*
10. *C stores the displayed* Cont *routes for metric reads, contraction application, finite Picard concatenation, modulus readback, completion handoff, and endpoint sealing;*
11. *P is the* Pkg *provenance row naming the* $\mathsf{Banach}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *dependencies;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachFixedPoint}^{\uparrow}}$ *row.*

The carrier has no coordinate for host real equality, a choice-selected limit, a global nonlinear-analysis theorem, or ambient completeness outside the carried $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Theorem 396.2 (BanachFixedPoint NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{BanachFixedPoint}^{\uparrow}}$ *obligation surface consists of carrier habitation, componentwise classifier transport, finite Picard-iterate stability, explicit Cauchy-modulus construction from the rational contraction ledger,* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *convergence handoff,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, endpoint determinacy, package dependency stability, and local naming for the finite carrier of Definition 396.1.*

Proof. Project the packet F. Carrier habitation is exactly the displayed tuple of Banach, metric, contraction, ratio, iterate, modulus, handoff, endpoint, transport, continuation, package, and naming rows.

Classifier transport is componentwise. The hsame rows move the displayed histories, while the Cont rows preserve the metric read, contraction application, Picard concatenation, modulus readback, handoff, and endpoint seal.

The Picard, modulus, handoff, uniqueness-boundary, and export obligations are the visible theorem rows of this chapter. Repacking those rows gives the local naming-certificate surface without adding a hidden fixed point or an ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.BanachFixedPointUp.BanachFixedPointPacket namecert obligations`

Theorem 396.3 (BanachFixedPoint iteration ledger)**.** *Every accepted* $\mathsf{BanachFixedPoint}^{\uparrow}$ *carrier exposes a finite* $\mathsf{PicardContraction}^{\uparrow}$ *ledger I over the carried* $\mathsf{Banach}^{\uparrow}$ *row B, distance row d, contraction row T, and rational Lipschitz ledger λ. For each displayed adjacent pair x_k, x_{k+1} in I, the application row reads x_{k+1} from T and x_k, and the distance comparison is read through d and λ.*

Lean4 ✓ `BEDC.Derived.BanachFixedPointUp.BanachFixedPointPacket iteration ledger`

Proof. Read the I coordinate of Definition 396.1. It is a finite Picard ledger, so every adjacent pair in the ledger is a visible BHist row rather than a completed orbit.

The contraction-map coordinate T supplies the application route for each step. The distance row d supplies the metric read, and the rational ledger λ supplies the displayed Lipschitz comparison below the unit bound.

Thus the finite iteration surface is exactly the $\mathsf{PicardContraction}^{\uparrow}$ surface carried inside F. No infinite sequence object or host fixed-point value is read from the packet. □

Theorem 396.4 (BanachFixedPoint Cauchy handoff)**.** *For an accepted* $\mathsf{BanachFixedPoint}^{\uparrow}$ *carrier, the finite Picard ledger I and the rational Lipschitz ledger λ determine the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *row M. The convergence handoff R routes this modulus through* $\mathsf{RegSeqRat}^{\uparrow}$ *and the carried* $\mathsf{CompleteMetric}^{\uparrow}$ *row d, and the endpoint seal E exposes only the resulting* $\mathsf{Real}^{\uparrow}$*-facing name boundary.*

Lean4 ✓ `BEDC.Derived.BanachFixedPointUp.BanachFixedPointPacket cauchy handoff`

Proof. Start with the finite iteration ledger supplied by Definition 396.3. The rational ledger λ is stored with a displayed unit-bound row, so repeated contraction estimates produce a finite threshold for each requested rational tolerance.

That threshold is the visible $\mathsf{CauchyModulus}^{\uparrow}$ coordinate M. It is constructed from displayed iterate distances and the rational ratio ledger, not from a host convergence theorem.

The handoff row R then records the regular rational name and the carried complete-metric route. The endpoint row E is seal-facing: it is consumable by $\mathsf{Real}^{\uparrow}$ readers only after the modulus and handoff rows have been displayed. □

Theorem 396.5 (BanachFixedPoint uniqueness boundary)**.** *If two accepted* $\mathsf{BanachFixedPoint}^{\uparrow}$ *carriers have the same displayed* $\mathsf{Banach}^{\uparrow}$ *row, distance row, contraction row, rational Lipschitz ledger, Cauchy-modulus row, and convergence handoff up to the recorded classifier transports, then their* $\mathsf{Real}^{\uparrow}$ *seal-facing endpoint rows are classifier-determinate. This uniqueness boundary is endpoint determinacy inside the BEDC classifier; it is not a claim of host real equality.*

Lean4 ✓ `BEDC.Derived.BanachFixedPointUp.BanachFixedPointPacket uniqueness boundary`

Proof. Compare the two packets componentwise through their H and C rows. The shared Banach, distance, contraction, ratio, iterate, modulus, and handoff data force the same route to the seal-facing endpoint row.

The usual Banach uniqueness argument is used only as a finite classifier pattern: the contraction ratio below the unit bound collapses two displayed endpoint routes to the same certificate boundary. The conclusion is therefore a statement about the $\mathsf{Real}^{\uparrow}$ seal row after BEDC transport.

Because the carrier never stores a host real object, the theorem cannot export host equality. It records only determinacy of the endpoint row seen by the local classifier. □

Theorem 396.6 (BanachFixedPoint public export)**.** *Every public consumer of a* $\mathsf{BanachFixedPoint}^{\uparrow}$ *certificate must factor through the carrier rows*

$$B,\ d,\ T,\ \lambda,\ I,\ M,\ R,\ E,\ H,\ C,\ P,\ N.$$

The exported surface provides a finite Picard ledger, an explicit Cauchy modulus, a $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *convergence handoff, and a* $\mathsf{Real}^{\uparrow}$ *seal-facing endpoint row. It does not export host fixed-point equality, choice-selected limits, global nonlinear analysis, or completeness beyond the carried distance row.*

Lean4 ✓ `BEDC.Derived.BanachFixedPointUp.BanachFixedPointPacket public export`

Proof. Take any public read of the certificate. The carrier definition lists all accessible rows, so the read must pass through the displayed Banach, metric, contraction, ratio, Picard, modulus, handoff, endpoint, transport, continuation, package, and naming coordinates.

Definition 396.3 identifies the finite Picard surface. Definition 396.4 identifies the modulus and convergence handoff. Definition 396.5 identifies the endpoint determinacy available to the classifier.

These rows repack as the public $\mathsf{BanachFixedPoint}^{\uparrow}$ surface. Since no other coordinate is present, the exported certificate cannot be used to read host fixed-point equality, an externally selected limit, global nonlinear-analysis structure, or ambient completeness beyond d. □

Theorem 396.7 (BanachFixedPoint scoped transport route)**.** *Every consumer route through the* $\mathsf{BanachFixedPoint}^{\uparrow}$ *carrier factors through the displayed* BHist *packet rows*

$$B,\ d,\ T,\ \lambda,\ I,\ M,\ R,\ E,\ H,\ C,\ P,\ N.$$

The row H supplies the componentwise hsame *routes for the Banach, distance, contraction, ratio, iterate, modulus, handoff, endpoint, provenance, and naming coordinates. The row C replays the corresponding* Cont *routes for metric reads, contraction application, finite Picard concatenation, modulus readback, completion handoff, and endpoint sealing. The row P records package provenance, and N supplies the local* $\mathsf{NameCert}_{\mathsf{BanachFixedPoint}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.BanachFixedPointUp.BanachFixedPointPacket scoped transport route`

Proof. Project the carrier of Definition 396.1. Its listed coordinates are precisely the rows displayed in the statement, so any consumer route starts by reading one of those coordinates.

The finite Picard surface is identified by Definition 396.3. The modulus and completion-facing handoff are identified by Definition 396.4. The endpoint boundary is identified by Definition 396.5.

Finally, Definition 396.6 says that public access has no route outside the displayed packet. Thus the only available scoped route is through the BHist rows, with H carrying hsame, C carrying Cont, P carrying Pkg provenance, and N carrying the local naming certificate. □

Theorem 396.8 (BanachFixedPoint completion handoff scope)**.** *The handoff from finite Picard data to the seal-facing endpoint of an accepted* $\mathsf{BanachFixedPoint}^{\uparrow}$ *carrier passes, in order, through the rational Lipschitz ledger λ, the* $\mathsf{CauchyModulus}^{\uparrow}$ *row M, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, the carried* $\mathsf{CompleteMetric}^{\uparrow}$ *distance row d, and only then the* $\mathsf{Real}^{\uparrow}$ *endpoint row E. This scoped handoff does not expose host fixed-point equality, a choice-selected limit, or ambient completeness beyond the carried row d.*

Proof. Begin with the finite Picard ledger from Definition 396.3. Its adjacent application rows are read through T, while all distance comparisons are read through d and the rational Lipschitz ledger λ.

Next apply Definition 396.4. The ratio ledger and finite Picard rows determine the explicit modulus M, and the handoff row R routes that modulus through the regular rational name and the carried complete-metric surface.

The endpoint row E is reached only after this handoff route is present. By Definition 396.6, there is no exported coordinate for host fixed-point equality, selected limits, or an ambient completeness theorem, so the completion handoff remains confined to the displayed BEDC rows. □

Theorem 396.9 (BanachFixedPoint endpoint fixedness)**.** *Let*

$$F = (B, d, T, \lambda, I, M, R, E, H, C, P, N)$$

be an accepted $\mathsf{BanachFixedPoint}^{\uparrow}$ *carrier. The endpoint row E is classifier-fixed under the carried contraction row T: reading T at the endpoint route supplied by the completion handoff R, and then sealing the result through the displayed rows R, E, H, C, P, N, returns the same* $\mathsf{Real}^{\uparrow}$ *seal-facing endpoint classifier as E. This is a fixed-point statement internal to the BEDC classifier; it does not assert host fixed-point equality or select a limit outside the displayed packet.*

Proof. Start from the finite contraction surface. By Definition 396.3, every application row in the Picard ledger is read through the same carried contraction row T, with distance comparisons read only through d and λ.

Use Definition 396.4 to pass from the finite ledger to the displayed modulus M and the handoff row R. The route to E is therefore already a route through the contraction ledger, the modulus, and the carried complete-metric surface rather than through an ambient convergence object.

Now compare the endpoint route with the route obtained by one more displayed read of T at that endpoint. The uniqueness boundary of Definition 396.5 identifies these two seal-facing routes inside the classifier, because they share the same B, d, T, λ, M, R data and the recorded componentwise transports.

Finally apply Definition 396.8. The sealing operation can pass only through R, E, H, C, P, N, so the comparison returns the same $\mathsf{Real}^{\uparrow}$ endpoint classifier and cannot be upgraded into host equality, a choice-selected limit, or an external completeness assertion. □

Theorem 396.10 (BanachFixedPoint contractive-orbit handoff)**.** *Every* $\mathsf{BanachFixedPoint}^{\uparrow}$ *endpoint read that consumes a* $\mathsf{ContractiveCauchyOrbit}^{\uparrow}$ *packet must factor through the contraction row* T*, the finite Picard ledger* I*, the residual Cauchy-modulus extraction, the carried* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*, and the* $\mathsf{Real}^{\uparrow}$ *endpoint seal* E *before endpoint fixedness is read. The route is therefore a consumer of the finite orbit packet of chapter 3506, but it exports only the displayed* $\mathsf{BanachFixedPoint}^{\uparrow}$ *rows of Definition 396.1.*

Proof. Start with the carrier

$$F = (B, d, T, \lambda, I, M, R, E, H, C, P, N).$$

The carrier definition makes T, I, M, R, d, and E visible rows, while the $\mathsf{ContractiveCauchyOrbit}^{\uparrow}$ chapter supplies the finite orbit-to-modulus packet that a completion consumer may read before the endpoint boundary.

Apply Definition 396.4. The Picard ledger and rational contraction row determine the displayed modulus row M, so the orbit consumer enters the Banach fixed-point route through the same residual Cauchy-modulus extraction rather than through a selected orbit limit.

Next the handoff runs through R and the carried complete-metric row d. Only after that route is displayed can the $\mathsf{Real}^{\uparrow}$ endpoint seal E be read.

Finally apply Definition 396.9. Endpoint fixedness is therefore read after the contraction, Picard, modulus, completion, regular-rational, and real-seal rows have all been consumed, with no access to host fixed-point equality or a selected endpoint outside the packet. □

Theorem 396.11 (BanachFixedPoint Picard modulus consumption)**.** *The threshold row of a* $\mathsf{PicardFixedPointModulus}^{\uparrow}$ *packet consumed by an accepted* $\mathsf{BanachFixedPoint}^{\uparrow}$ *carrier is consumed exactly as the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M *of*

$$F = (B, d, T, \lambda, I, M, R, E, H, C, P, N).$$

Thus the Banach endpoint route cannot replace that finite modulus row by selected limits, host fixed-point equality, quotient maps, or ambient $\mathsf{Real}^{\uparrow}$ *completeness. It may only continue through the displayed handoff rows* R, d, E, H, C, P, N*.*

Proof. Read the $\mathsf{PicardFixedPointModulus}^{\uparrow}$ chapter as the source of the finite threshold packet. Its threshold row is a displayed Picard-tail modulus, not an endpoint selector and not a completed orbit equality.

Project the carrier of Definition 396.1. The only modulus coordinate available to the Banach fixed-point certificate is M, and every later endpoint read must still pass through R, the carried complete-metric row d, and the seal-facing endpoint row E.

Apply Definition 396.4. This identifies M as the Cauchy-modulus row determined by the finite Picard ledger and rational contraction row, matching the threshold consumption supplied by chapter 3442.

Finally apply Definition 396.9. Since endpoint fixedness is sealed only after M, R, d, E, H, C, P, N are displayed, no consumer can replace the threshold row by selected limits, host fixed-point equality, quotient maps, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 396.12 (BanachFixedPoint contraction Cauchy route)**.** *Every accepted* $\mathsf{BanachFixedPoint}^{\uparrow}$ *packet reads its fixed-point route in the following order. It first reads contraction data through the displayed* $\mathsf{ContractionMapping}^{\uparrow}$ *and* $\mathsf{PicardContraction}^{\uparrow}$ *rows carried by* T *and* I*. It then reads the explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*, the carried* $\mathsf{CompleteMetric}^{\uparrow}$ *row* d*, and only then the* $\mathsf{Real}^{\uparrow}$ *endpoint seal* E*. The route exports no host fixed-point equality, selected limit, quotient-map equality, or ambient completeness outside the carried* $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Proof. Start with the finite iteration surface. By Definition 396.3, every adjacent Picard step is read through the carried contraction row T, the finite ledger I, the metric row d, and the rational Lipschitz ledger λ. This is the displayed $\mathsf{ContractionMapping}^{\uparrow}$ and $\mathsf{PicardContraction}^{\uparrow}$ part of the packet, not a host orbit.

Next use Definition 396.4. The finite contraction ledger and the rational unit-bound row determine the explicit modulus M, and the handoff row R routes that modulus through the regular-rational name and the carried complete-metric surface.

Finally apply Definition 396.9. The endpoint fixedness comparison is sealed only after the route has reached R and E, so the result is an internal classifier statement about the $\mathsf{Real}^{\uparrow}$ endpoint boundary.

The refusal clauses are inherited from Definition 396.6 and Definition 396.8. Since the carrier contains no coordinate for host fixed-point equality, selected limits, quotient-map equality, or ambient completeness outside d, a consumer cannot extract any of those readings from the contraction-to-Cauchy route. □

Theorem 396.13 (BanachFixedPoint bridge packet scope)**.** *Any standard bridge for* $\mathsf{BanachFixedPoint}^{\uparrow}$ *must factor through the displayed packet rows*

$$B,\ d,\ T,\ \lambda,\ I,\ M,\ R,\ E,\ H,\ C,\ P,\ N,$$

the public export surface of Definition 396.6, and the completion handoff scope of Definition 396.8. Such a bridge may transport the finite Picard ledger, the explicit Cauchy modulus, the regular-rational completion handoff, and the seal-facing endpoint classifier, but it may not read host fixed-point equality, choice-selected limits, global nonlinear analysis, or ambient completeness outside the carried $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Proof. Begin with the carrier projection from Definition 396.1. The displayed rows are the only accessible coordinates of an accepted packet.

Apply Definition 396.3 to identify the finite Picard route. Apply Definition 396.4 to route that ledger through the explicit modulus M, the regular-rational handoff R, and the carried complete-metric row d.

Next apply Definition 396.6 and Definition 396.7. Every public consumer and every transported route must pass through the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Finally apply Definition 396.8 and Definition 396.9. The endpoint comparison is therefore sealed inside R, E, H, C, P, N, so a standard bridge has no coordinate from which to extract host fixed-point equality, a choice-selected limit, or ambient completeness beyond the carried row d. □

Theorem 396.14 (BanachFixedPoint standard bridge)**.** *The displayed packet rows*

$$B,\ d,\ T,\ \lambda,\ I,\ M,\ R,\ E,\ H,\ C,\ P,\ N$$

provide the paper standard bridge from the $\mathsf{BanachFixedPoint}^{\uparrow}$ *certificate to the ordinary contraction-principle reading. The bridge preserves exactly the finite Picard ledger, explicit rational contraction modulus, completion handoff, seal-facing endpoint classifier, componentwise transport, replay, provenance, and local naming rows. It preserves no host fixed-point equality, choice-selected limit, quotient-map equality, global nonlinear-analysis structure, or ambient completeness beyond the carried* $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Proof. Begin with the carrier projection from Definition 396.1. The rows $B, d, T, \lambda, I, M, R, E, H, C, P, N$ are the whole readable packet surface.

Apply Definition 396.13. Any standard bridge must factor through these rows, the public export surface, and the completion handoff scope.

The ordinary contraction-principle reading is therefore obtained only by reading the finite Picard ledger I, the rational contraction row λ, the explicit modulus M, the completion handoff R, and the endpoint classifier E. The structural rows H, C, P, N transport, replay, source, and name the same data.

The exclusions follow from the same packet scope. Since the bridge has no coordinate for host fixed-point equality, choice-selected limits, quotient-map equality, global nonlinear-analysis structure, or ambient completeness beyond d, none of those readings is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachFixedPoint}^{\uparrow}$ packet is generated from a $\mathsf{Banach}^{\uparrow}$ carrier row, a $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$ distance row, a contraction-map row, a rational Lipschitz ledger below the unit bound, a finite $\mathsf{PicardContraction}^{\uparrow}$ ledger, an explicit $\mathsf{CauchyModulus}^{\uparrow}$ row, a $\mathsf{RegSeqRat}^{\uparrow}$ convergence handoff, a $\mathsf{Real}^{\uparrow}$ seal-facing endpoint row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BanachFixedPoint}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 396.7 binds every consumer route to the displayed BHist, hsame, Cont, Pkg, and NameCert rows, while Definition 396.14 supplies the paper standard bridge to the ordinary contraction-principle reading.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BanachFixedPoint}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.BanachFixedPointUp.BanachFixedPointPacket\_public\_export`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close host fixed-point equality, choice-selected limits, global nonlinear analysis, ambient completeness beyond the carried $\mathsf{CompleteMetric}^{\uparrow}$ row, or bridge checking.

Upgrade path: No further theory-axis upgrade is pending for the displayed BanachFixedPoint packet.

Chapter 397

A Concrete Naming Certificate for CompletionUniversalProperty$^{\uparrow}$

The CompletionUniversalProperty$^{\uparrow}$ interface records the finite universal-property surface for the constructive real-completion phase. Following Bishop and Bridges, *Constructive Analysis*, where completion is handled through explicit Cauchy data and extension control rather than by selecting host limits, the packet names the data needed to extend uniformly continuous maps out of the regular rational completion envelope. It is a certificate over CauchyCompletionMonad$^{\uparrow}$, RealDiagonalCompletion$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, ContinuousMap$^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows.

The universal-property packet consumes the unit-and-bind schedule of chapter 378, the diagonal finite-window route of chapter 359, the regular rational source of chapter 301, the real seal of chapter 38, and the dense-map row of chapter 130. These sibling rows supply the source, diagonal, dense, seal, and map coordinates M, D, R, A, F of Definition 397.1; the local chapter packages extension and uniqueness ledgers over that displayed route.

The extension ledger is the downstream consumer of the Cauchy-name and completion-envelope surfaces: chapter 406 supplies the finite common-window presentation, and chapter 378 supplies the completion-envelope source. This is a substantive dependency row for the extension and uniqueness ledgers, not background prose.

Definition 397.1 (CompletionUniversalProperty carrier)**.** *A* CompletionUniversalProperty$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, D, R, A, F, E, L, P, N)$$

with the following visible rows:

1. *M is the* CauchyCompletionMonad$^{\uparrow}$ *completion-envelope row that supplies the completion-facing source packet;*
2. *D is the* RealDiagonalCompletion$^{\uparrow}$ *diagonal packet that reads regular rational Cauchy data through finite diagonal windows;*
3. *R is the* RegSeqRat$^{\uparrow}$ *regular rational input row whose stream windows provide the dense source observations;*
4. *A is the* Real$^{\uparrow}$ *real-name seal row through which the completed source is inspected;*
5. *F is the* ContinuousMap$^{\uparrow}$ *row on the dense regular rational surface, including its displayed modulus and graph-read ledger;*

6. *E is the extension-existence ledger, a finite* Cont *route from F, R, D, and A to a completion-facing* $\mathsf{ContinuousMap}^{\uparrow}$ *read;*
7. *L is the uniqueness ledger, a displayed* hsame *comparison between two extension rows whenever they agree on the same R, D, A, F, and E coordinates;*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{ContinuousMap}^{\uparrow}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionUniversalProperty}^{\uparrow}}$ *row.*

The carrier contains no quotient of regular streams, no selected host limit, no host-level complete metric space, and no equality principle outside the displayed hsame *and* Cont *ledgers.*

Lean4 ✓ `BEDC.Derived.CompletionUniversalPropertyUp.CompletionUniversalPropertyTasteGate single carrier alignment`

Theorem 397.2 (CompletionUniversalProperty extension obligations)**.** *Let $U = (M, D, R, A, F, E, L, P, N)$ be an accepted* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *carrier. Every extension read exported by U factors through the completion-envelope row M, the diagonal-completion row D, the regular rational source row R, the* $\mathsf{Real}^{\uparrow}$ *seal A, the dense* $\mathsf{ContinuousMap}^{\uparrow}$ *row F, and the finite continuation ledger E.*

Consequently the extension obligation is finite: for each displayed precision request, the consumer reads a diagonal packet from D, a regular rational observation from R, a real-name seal from A, and a modulus-controlled graph row from F, then repacks them through E as a completion-facing continuous-map row. No quotient representative, host limit, or ambient completeness theorem is introduced by the extension read.

Lean4 ✓ `BEDC.Derived.CompletionUniversalPropertyUp.CompletionUniversalPropertyPacket extension obligations`

Proof. Project the accepted carrier. The completion source is the row M, and the only diagonal access to its real-name observations is the displayed row D.

The dense map data are exactly the $\mathsf{RegSeqRat}^{\uparrow}$ row R and the $\mathsf{ContinuousMap}^{\uparrow}$ row F. For a requested precision, F supplies the graph-read and modulus ledger on the dense surface, while D and A supply the completion-facing observation route.

The extension row E is the only coordinate that repacks those observations as a completion-facing continuous map. Since the carrier has no coordinate for a quotient of streams, a selected host limit, or a host complete space, the exported extension remains a finite BEDC packet. □

Theorem 397.3 (CompletionUniversalProperty uniqueness ledger)**.** *Let $U = (M, D, R, A, F, E, L, P, N)$ and $U' = (M, D, R, A, F, E', L', P, N')$ be accepted* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *carriers with the same completion envelope, diagonal row, dense regular rational row, real seal, dense continuous-map row, and package provenance. If the extension ledgers E and E' agree on every displayed finite diagonal packet read from D and every displayed regular rational source read from R, then the two exported extension rows are compared by the displayed* hsame *ledger L and L'.*

The uniqueness claim is therefore a ledger statement over visible rows. It identifies extensions only by the carried hsame *comparison generated from their finite dense-source and diagonal reads, not by function extensionality over a host completion.*

Lean4 ✓ `BEDC.Derived.CompletionUniversalPropertyUp.CompletionUniversalPropertyPacket uniqueness ledger`

Proof. Read the common coordinates M, D, R, A, F, and P from the two packets. These rows fix the completion envelope, the dense-source observations, and the continuous-map data available to both extension ledgers.

The hypothesis says that E and E' agree on the displayed finite reads supplied by D and R. Transport those reads through the shared Cont routes in F and through the common real-name seal A.

The uniqueness coordinate is precisely the displayed hsame ledger. Applying L and L' to the transported extension rows yields the required comparison, with no appeal to host function equality or an external completion object. □

Theorem 397.4 (CompletionUniversalProperty NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CompletionUniversalProperty}}$ *surface consists of five finite rows:*

1. *carrier: an accepted object is exactly the finite* BHist *packet of Definition 397.1;*
2. *classifier: two accepted packets classify together only by componentwise* hsame *transport of M, D, R, A, F, E, L, P, and N, and by the displayed* Cont *routes carried by the dense and extension map rows;*
3. *extension existence over finite diagonal packets: Definition 397.2 supplies the extension row from the displayed* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *reads;*
4. *uniqueness by displayed ledger: Definition 397.3 compares any two extension rows only through the carried* hsame *uniqueness ledger;*
5. *non-escape: every consumer read remains inside* $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CompletionUniversalPropertyUp.CompletionUniversalPropertyPacket namecert obligations`

Proof. Carrier admission and classification are projections from Definition 397.1. The classifier has no fields beyond the displayed packet coordinates, their hsame transports, and the Cont ledgers attached to the dense and extension map rows.

Extension existence is the obligation of Definition 397.2. It constructs the public extension read from finite diagonal-completion packets and regular rational observations.

Uniqueness is the ledger obligation of Definition 397.3. The comparison is carried by the displayed hsame row, so it does not require equality of host functions.

The non-escape row follows by inspecting the carrier. There is no coordinate for quotient streams, choice-selected limits, host completeness, or host real equality; every exported object is one of the listed BEDC rows or a finite route between them. □

Theorem 397.5 (CompletionUniversalProperty extension-uniqueness scope)**.** *Let* $U = (M, D, R, A, F, E, L, P, N)$ *be an accepted* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *carrier over* $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The packet combines extension existence and uniqueness ledger stability into one* NameCert*-consumable* BHist *row: the extension ledger E reads the dense* $\mathsf{ContinuousMap}^{\uparrow}$ *row through the completion envelope, diagonal row, regular rational source, and real seal, while the uniqueness ledger L compares any two such extension rows by displayed* hsame *transport over the same provenance.*

Consequently the completion universal-property surface exports a single finite packet for extension existence, uniqueness, and non-escape. It does not export quotient streams, selected host limits, host complete spaces, or function extensionality outside the displayed hsame *and* Cont *rows.*

Proof. First construct the extension component. Apply Definition 397.2: every extension read factors through M, D, R, A, F, and the finite continuation ledger E.

Next bind uniqueness to the same displayed rows. Apply Definition 397.3: two extension rows agreeing on the finite diagonal and regular rational reads are compared by the carried hsame uniqueness ledger.

Finally repack the two components as a local naming-certificate surface. Apply Definition 397.4, which lists carrier admission, classifier transport, extension existence, uniqueness by displayed ledger, and non-escape over exactly the rows of U.

The resulting packet is therefore a single BHist scope for the completion universal property. Since every row is displayed in the carrier, the construction has no route to quotient streams, selected host limits, host complete spaces, or host-level function equality. □

Theorem 397.6 (CompletionUniversalProperty classifier transport)**.** *Let*

$$U = (M, D, R, A, F, E, L, P, N)$$

and

$$U' = (M', D', R', A', F', E', L', P', N')$$

be accepted $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *carriers. Suppose the classifier records componentwise comparisons*

$$\mathsf{hsame}(M, M'), \quad \mathsf{hsame}(D, D'), \quad \mathsf{hsame}(R, R'), \quad \mathsf{hsame}(A, A'), \quad \mathsf{hsame}(F, F'),$$
$$\mathsf{hsame}(E, E'), \quad \mathsf{hsame}(L, L'), \quad \mathsf{hsame}(P, P'), \quad \mathsf{hsame}(N, N')$$

and the displayed Cont *routes on the completion envelope, diagonal packet, regular rational source, real seal, dense map, extension ledger, uniqueness ledger, package provenance, and local naming rows. Then accepted transport preserves the carrier of Definition 397.1 and preserves the* $\mathsf{NameCert}_{\mathsf{CompletionUniversalProperty}^{\uparrow}}$ *classifier. No transported row leaves the nine displayed coordinates.*

Proof. Project both accepted packets through Definition 397.1. The carrier boundary is exactly the ordered tuple of nine rows, and each row named in the transport hypothesis is one of those coordinates.

The componentwise hsame comparisons preserve the displayed row identities. The recorded Cont routes only say where the same rows are read inside the finite packet, so they do not add a new completion object, quotient stream, or host equality principle.

Therefore the classifier after transport is the same local classifier with primed coordinates. Since every transported component is still one of M', D', R', A', F', E', L', P', and N', the carrier and classifier are preserved on the accepted $\mathsf{CompletionUniversalProperty}^{\uparrow}$ surface. □

Lean4 ✓ `BEDC.Derived.CompletionUniversalPropertyUp.CompletionUniversalPropertyPacket classifier transport`

Theorem 397.7 (CompletionUniversalProperty dense-source factorization)**.** *Let* $U = (M, D, R, A, F, E, L, P, N)$ *be an accepted* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *carrier. Every exported extension read factors through the completion envelope* M*, the finite diagonal packet* D*, the dense regular-rational source* R*, the* $\mathsf{Real}^{\uparrow}$ *seal* A*, the dense* $\mathsf{ContinuousMap}^{\uparrow}$ *row* F*, and the extension ledger* E*. In this factorization,* R *is the dense regular-rational source and* D *is the finite diagonal packet through which completion-facing reads are admitted.*

Proof. Apply Definition 397.2. It already identifies the six coordinates through which every extension read passes: M, D, R, A, F, and E.

It remains only to name the roles of the two source coordinates. By Definition 397.1, R is the regular rational input row whose finite stream windows provide dense source observations, while D is the $\mathsf{RealDiagonalCompletion}^{\uparrow}$ row reading regular rational Cauchy data through finite diagonal windows.

Composing these coordinate projections with the extension obligation gives the stated factorization. No other carrier row can serve as a dense source or diagonal admission route, because the exported extension is repacked only by the finite continuation ledger E. □

Theorem 397.8 (CompletionUniversalProperty dense-source exhaustion)**.** *Let*

$$U = (M, D, R, A, F, E, L, P, N)$$

be an accepted $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *carrier, and let*

$$C = (S, W, R_0, T, E_0, Q, H, C_0, P_0, N_0)$$

be an accepted $\mathsf{CompletionDensity}^{\uparrow}$ *packet whose source rows display the same regular-rational source and terminal* $\mathsf{Real}^{\uparrow}$ *seal as the* R, A *coordinates of* U*. Every extension read exported by* U *that uses the dense source must first pass through the* $\mathsf{CompletionDensity}^{\uparrow}$ *route*

$$S, W, R_0, T, E_0, Q, H, C_0, P_0, N_0,$$

including the $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ *row* Q*, before it reaches the diagonal packet* D*, the* $\mathsf{Real}^{\uparrow}$ *seal* A*, the dense map row* F*, and the extension ledger* E *of* U*.*

Thus the universal-property dense source is exhausted by the same finite density route that exposes source names, finite windows, regular rational readbacks, dyadic tolerances, completion embedding, regular Cauchy dense embedding, transport, replay, provenance, and local naming. No extension read may substitute a detached dense subset, quotient completion, selected host limit, countable-choice schedule, host real equality, or ambient completeness principle for that route.

Proof. First bind the dense source to the density packet. By Definition 1560.3, every regular Cauchy density read of the source image factors through $S, W, R_0, T, E_0, Q, H, C_0, P_0, N_0$; by Definition 1560.4, every Real-facing completion read using that dense image consumes the same route before the terminal real-name seal is reached.

Next identify the Real boundary inside the dense-image row. Apply Definition 1453.3 to the row Q: its exported $\mathsf{Real}^{\uparrow}$ read must pass through the displayed regular source, stream schedule, and dyadic tolerance ledger before any Real seal is available.

Finally compose this density route with the universal-property packet. The extension obligation of Definition 397.2 routes every exported extension through M, D, R, A, F, E, while Definition 397.7 identifies R as the dense regular-rational source and D as the diagonal admission packet.

Since the accepted density packet displays the same regular-rational source and terminal Real seal as R, A, the dense-source portion of any extension read must already have passed through $S, W, R_0, T, E_0, Q, H, C_0, P_0, N_0$. The carrier rows of U then carry that exhausted source into D, A, F, E. Neither packet contains a coordinate for a detached dense subset, quotient completion, selected host limit, countable choice, host real equality, or ambient completeness, so none can be exported by the composed route. □

Theorem 397.9 (CompletionUniversalProperty extension non-escape)**.** *For any accepted* CompletionUniversalProp *carrier, the extension-plus-uniqueness packet exposes no quotient stream, selected host limit, host complete metric space, or function extensionality outside the displayed* hsame *and* Cont *rows. Its visible data are exactly the completion envelope, diagonal packet, dense source, real seal, dense continuous-map row, extension ledger, uniqueness ledger, package provenance, and local naming row.*

Proof. The extension side is controlled by Definition 397.2. Each exported extension read is routed through M, D, R, A, F, and E, all of which are displayed coordinates of the accepted carrier.

The uniqueness side is controlled by Definition 397.3. Two extension rows are compared only by the carried hsame ledger over the same finite dense-source and diagonal reads.

Finally, Definition 397.4 lists the local certificate rows and its non-escape boundary. Since that list contains no quotient stream, host-selected limit, host complete metric space, or function-extensionality row, the extension-plus-uniqueness packet cannot export any of them outside the displayed hsame and Cont routes. □

Theorem 397.10 (CompletionUniversalProperty downstream consumer use)**.** *Any downstream completion consumer that uses the extension-plus-uniqueness interface of an accepted* CompletionUniversalProperty$^{\uparrow}$ *carrier factors through the same packet*

$$U = (M, D, R, A, F, E, L, P, N).$$

Its extension reads consume the completion envelope M, diagonal packet D, regular rational source R, real seal A, dense continuous-map row F, and extension ledger E; its uniqueness reads consume the displayed ledger L over the same coordinates; its classifier transport and dense-source reads are those of Definition 397.6 and Definition 397.7; and its boundary is the non-escape surface of Definition 397.9.

Proof. Start with the consumer's extension request. By Definition 397.2, the request factors through M, D, R, A, F, and E, so the consumer sees the same finite extension packet.

For uniqueness, apply Definition 397.3. Any comparison of two extension rows is read through the displayed hsame ledger L over the same completion envelope, diagonal packet, dense source, real seal, dense map, and provenance rows.

The classifier and dense-source uses are fixed by Definition 397.6 and Definition 397.7. They admit no alternate carrier because transport and dense reads remain inside the listed coordinates.

Finally, Definition 397.9 supplies the consumer boundary. The downstream consumer therefore uses the single finite packet U and no quotient stream, selected host limit, host complete metric space, or function-extensionality row. □

Closure status for NameCert$_{\text{CompletionUniversalProperty}^{\uparrow}}$.

Constructive story: A CompletionUniversalProperty$^{\uparrow}$ packet is generated by a completion-envelope row, a diagonal-completion row, a regular rational source row, a real-name seal, a dense continuous-map row, a finite extension ledger, a uniqueness hsame ledger, package provenance, and a local naming row.

Theory closure: TheoryGate(NameCert$_{\text{CompletionUniversalProperty}^{\uparrow}}$, maturePackageClosed)

Upgrade path: No theory-axis upgrade remains; bridge checking is a formal-axis matter.

Chapter 398

A Concrete Naming Certificate for $\mathsf{BoundedVariation}^{\uparrow}$

The $\mathsf{BoundedVariation}^{\uparrow}$ interface names the finite partition-variation packet used by real-analysis consumers of $\mathsf{Real}^{\uparrow}$ data. It follows the Jordan bounded-variation surface treated in Rudin, *Principles of Mathematical Analysis*, and Folland, *Real Analysis*, but expresses every read as a finite partition ledger over regular rational names, dyadic observations, endpoint transports, and package provenance. The packet does not introduce a completed function space, a supremum over all partitions, a variation measure, or a host real-valued function quotient.

Its dependency list is $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and interval-partition rows supplied by $\mathsf{RationalInterval}^{\uparrow}$ or $\mathsf{NestedInterval}^{\uparrow}$ when such endpoints are available.

The finite partition-variation ledger consumes the real-name seal of chapter 38, the regular rational stream surface of chapter 301, and the dyadic observation rows of chapter 291.

Definition 398.1 (BoundedVariation carrier)**.** *A* $\mathsf{BoundedVariation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, \Pi, X, D, V, R, H, C, P, N)$$

with the following visible coordinates:

1. *I is the rational or nested interval row on which the variation packet is read;*
2. *Π is a finite ordered interval-partition ledger with displayed endpoint rows and common-refinement rows;*
3. *X records the* $\mathsf{Real}^{\uparrow}$ *endpoint values or their* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name representatives at the partition points;*
4. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows used to compare endpoint differences on each partition edge;*
5. *V is the finite dyadic variation-sum ledger attached to the displayed partition;*
6. *R records common-refinement comparison rows for transported partitions and endpoint reads;*
7. *H, C, P, and N are respectively the visible* hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{BoundedVariation}^{\uparrow}}$ *provenance rows.*

The classifier compares accepted packets only through common refinements of Π, transported endpoint values, dyadic variation-sum ledgers, endpoint-difference comparisons, and the displayed provenance rows.

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationTasteGate single carrier alignment`

Theorem 398.2 (BoundedVariation NameCert obligations)**.** *Every accepted* BoundedVariation$^{\uparrow}$ *packet with carrier Definition 398.1 carries the following naming-certificate obligations:*

1. *carrier habitation by a constant* Real$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *endpoint row, with zero dyadic variation sum on every displayed finite partition;*
2. *classifier comparison by common refinement of the finite partition ledgers and componentwise endpoint transport;*
3. *dyadic variation-sum exactness for each displayed partition edge, read through* DyadicRatCore$^{\uparrow}$ *observations and* RegSeqRat$^{\uparrow}$ *endpoint comparisons;*
4. *carrier transport under displayed* hsame *and* Cont *routes for interval rows, partitions, endpoint names, dyadic observations, variation sums, and refinement rows;*
5. *boundary exclusion of completed function spaces, variation measures, host supremum principles, quotient functions, and hidden partitions.*

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationCarrier namecert obligations`

Proof. For habitation, take a constant real-name or regular-rational endpoint row. Every edge of a displayed finite partition has equal endpoint reads, so the dyadic edge differences and their finite sum are the zero variation ledger.

Classifier comparison is by common refinement. Refine two displayed partition ledgers to a shared finite ledger, transport the endpoint rows componentwise, and compare the dyadic edge observations along that shared list.

Variation-sum exactness is read edge by edge from the carrier. The DyadicRatCore$^{\uparrow}$ observations give the displayed endpoint-difference rows, and the finite sum row V records exactly those edge rows and no unlisted partition.

Transport uses the stored hsame and Cont coordinates. Moving the interval, partition, endpoint, dyadic, sum, and refinement rows along those routes repacks the same finite packet with the same local NameCert provenance.

The boundary exclusion follows because the carrier has no coordinate for a completed function space, variation measure, host supremum over all partitions, quotient of functions, or hidden partition family. □

Theorem 398.3 (BoundedVariation variation-ledger exactness)**.** *For every accepted* BoundedVariation$^{\uparrow}$ *packet and every displayed finite partition row* Π*, the public variation read factors through the interval row, the ordered endpoint ledger, the* Real$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *endpoint names, the* DyadicRatCore$^{\uparrow}$ *edge-difference observations, and the finite dyadic variation-sum row* V*. A common-refinement read transports the same edge data and repacks the same finite sum ledger.*

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationCarrier variation ledger exactness`

Proof. Start from the displayed partition row Π. Its ordered endpoint ledger gives the only edges whose variation contribution may be read by the packet.

For each edge, read the two endpoint names through X and the dyadic comparison row through D. The regular-name and real-seal data are therefore consumed before the finite variation sum is formed.

The row V stores the finite sum of exactly those displayed edge observations. When a common refinement is supplied by R, the endpoint transports and dyadic edge rows are repacked along the refinement ledger, so the public read remains a finite partition-sum read. □

Theorem 398.4 (BoundedVariation common-refinement classifier exactness)**.** *Let B and B' be accepted* BoundedVariation$^{\uparrow}$ *packets with carrier coordinates as in Definition 398.1. The local* BoundedVariation$^{\uparrow}$ *classifier identifies B and B' if and only if there is a displayed common finite refinement whose interval row, transported endpoint* Real$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *names,* DyadicRatCore$^{\uparrow}$ *edge observations, finite variation-sum ledger, and* Pkg *and* NameCert *provenance rows compare componentwise by the visible* hsame *and* Cont *routes stored in the two packets.*

Proof. Unfold the carrier of Definition 398.1. The classifier has no hidden coordinate beyond the interval row, finite partition ledger, endpoint names, dyadic edge observations, variation-sum ledger, common-refinement rows, and displayed hsame, Cont, Pkg, and NameCert provenance.

For the forward direction, project the classifier witness to its common-refinement rows. Apply Definition 398.3 to both packets on that refinement. Both public variation reads therefore factor through the same displayed endpoint ledger, dyadic edge observations, and finite variation-sum row, with the endpoint and provenance coordinates transported by the recorded hsame and Cont routes.

For the reverse direction, start from the displayed common finite refinement and its componentwise comparisons. Repack the transported interval, endpoint, edge-observation, variation-sum, Pkg, and NameCert rows into the local classifier data. Since the exactness theorem accounts for every public variation read through that finite ledger, no further comparison data are required. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationCarrier common refinement classifier exactness`

Theorem 398.5 (BoundedVariation carrier transport)**.** *Let B and B' be accepted* BoundedVariation$^{\uparrow}$ *packets. If their interval rows, finite partition ledgers, endpoint-name rows, dyadic observation rows, variation-sum ledgers, and common-refinement rows are transported componentwise by displayed* hsame *routes and read through the corresponding* Cont *routes, then the local classifier identifies the same bounded-variation packet on every common finite refinement.*

Proof. Unfold the classifier of Definition 398.1. It compares only the interval row, partition ledger, endpoint names, dyadic observations, finite variation sums, refinement rows, and provenance.

Move each of those coordinates along the displayed hsame routes. The Cont routes preserve the read order from an interval request to a partition, then to endpoint names, edge observations, and the finite sum row.

Apply Definition 398.3 on the common refinement. The transported endpoint and dyadic rows repack the same finite variation ledger, leaving no extra classifier coordinate on which the packets could differ. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationCarrier transport`

Theorem 398.6 (BoundedVariation no-escape boundary)**.** *The* BoundedVariation$^{\uparrow}$ *public boundary exports only finite interval-partition rows, transported endpoint names, dyadic edge-difference observations, common-refinement ledgers, finite variation sums, and visible* hsame, Cont, Pkg, *and* NameCert *provenance. It exports no completed function-space carrier, variation measure, supremum over all partitions, quotient of real-valued functions, or hidden partition family.*

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationCarrier public rows zero head absurd`

Proof. Inspect the carrier coordinates of Definition 398.1. The only analysis-facing data are the displayed interval row, the finite partition ledger, endpoint names, dyadic observations, the finite sum row, and common-refinement rows.

The exactness theorem Definition 398.3 shows that every public variation read factors through those rows. The transport theorem Definition 398.5 shows that moving the packet preserves the same finite ledger.

No coordinate names a completed function space, variation measure, host supremum over all partitions, quotient function, or hidden partition family. Hence none of those objects is exported by the public boundary. □

Theorem 398.7 (BoundedVariation partition scope binding)**.** *The carrier, NameCert obligation surface, and variation-ledger exactness rows of Definition 398.1, Definition 398.2, and Definition 398.3 bind the finite partition-variation packet to* DyadicRatCore$^{\uparrow}$, NestedInterval$^{\uparrow}$, RationalInterval$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

The bound is a finite partition-sum scope: every variation read passes through the displayed interval row, partition ledger, endpoint rows, dyadic edge observations, finite variation sum, and local provenance before it can be consumed by a bounded-variation classifier.

Proof. Start with the carrier in Definition 398.1. It names the interval row, finite partition ledger, endpoint rows, dyadic observations, finite variation sum, common-refinement rows, and provenance rows.

Apply Definition 398.2. The local certificate records habitation, classifier comparison, variation-sum exactness, carrier transport, and boundary exclusion for those same coordinates.

Finally use Definition 398.3. Each public variation read factors through a displayed finite partition and its dyadic edge ledger, so the partition-sum scope is exactly the listed dependency stack. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationCarrier partition scope binding`

Theorem 398.8 (BoundedVariation refinement ledger scope)**.** *The common-refinement classifier exactness row of Definition 398.4, together with the variation-ledger exactness row of Definition 398.3, gives the scoped refinement ledger for* BoundedVariation$^{\uparrow}$. *Accepted packets compare only by a displayed common finite refinement whose interval, endpoint, dyadic observation, finite sum,* BHist, hsame, Cont, Pkg, *and* NameCert *rows are visible over* DyadicRatCore$^{\uparrow}$, NestedInterval$^{\uparrow}$, RationalInterval$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* StreamName$^{\uparrow}$.

No classifier comparison in this scope uses a hidden partition family, host supremum, variation measure, quotient function, or completed function-space carrier.

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationPartitionLedger refinement ledger scope`

Proof. Project the classifier through Definition 398.4. The comparison data are a displayed common finite refinement with componentwise endpoint, dyadic, finite-sum, package, and naming rows.

Use Definition 398.3 on that refinement. Both public variation reads are finite sums over the displayed edge observations and transported endpoint rows.

Thus the refinement ledger is already the classifier scope. Since the carrier has no hidden partition family or host supremum coordinate, no additional comparison object can enter. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationPartitionLedger refinement scope semantic name certificate`

Theorem 398.9 (BoundedVariation finite Jordan-split scope)**.** *For an accepted* $\mathsf{BoundedVariation}^{\uparrow}$ *packet, a displayed finite partition may be split into positive-edge and negative-edge dyadic variation ledgers using only the listed endpoint rows. The split reads the* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint names, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-difference observations, the finite partition ledger, and the visible* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{BoundedVariation}^{\uparrow}}$ *provenance.*

This is only a finite displayed partition split. It does not assert Jordan decomposition, a variation measure, a host supremum over all partitions, or a completed function-space object.

Proof. Project the finite partition ledger and endpoint rows from the carrier. Each edge already carries two endpoint reads and a displayed dyadic difference observation.

Split the finite list of edge observations by the sign recorded in the $\mathsf{DyadicRatCore}^{\uparrow}$ row. The positive-edge and negative-edge ledgers are therefore subledgers of the displayed partition, transported by the same hsame and Cont routes as the original variation sum.

Repack the two ledgers with the existing package and naming provenance. Since the construction uses only the displayed finite partition, it does not create a Jordan decomposition or a measure-valued object. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationPartitionLedger jordan finite split scope`

Theorem 398.10 (BoundedVariation Jordan consumer exhaustion)**.** *Every Jordan-facing consumer of an accepted* $\mathsf{BoundedVariation}^{\uparrow}$ *packet must read finite partition rows, endpoint* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *names,* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations, finite variation sums, common-refinement rows, and visible* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{BoundedVariation}^{\uparrow}}$ *provenance before any Jordan split is exported.*

The exported split is exhausted by the displayed finite partition ledgers. It contains no variation measure, host supremum over all partitions, completed function space, quotient real-valued function, hidden partition family, selected decomposition, or ambient Jordan theorem.

Proof. Start with the finite Jordan-split scope of Definition 398.9. Any positive-edge or negative-edge ledger is built from the displayed finite partition, its endpoint names, and its dyadic edge observations.

Use refinement additivity, Definition 398.11. When a Jordan-facing consumer compares two displayed packets, the common-refinement rows force every block sum to remain inside the same finite dyadic variation ledger.

Now apply the no-escape boundary, Definition 398.6. The public boundary exports only finite partition rows, transported endpoints, dyadic edge observations, common refinements, finite sums, and visible provenance.

Therefore the consumer has exhausted the available Jordan-facing data once it has read those rows. No carrier coordinate remains from which to export a variation measure, host supremum, completed function space, quotient function, hidden partition family, selected decomposition, or ambient Jordan theorem. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationPartitionLedger jordan consumer exhaustion`

Theorem 398.11 (BoundedVariation refinement additivity scope)**.** *For two accepted* $\mathsf{BoundedVariation}^{\uparrow}$ *packets compared on a displayed common finite refinement, the variation read is additive over the refinement blocks in the finite dyadic ledger. Each block sum uses only* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations, the common-refinement row, and the visible* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{BoundedVariation}^{\uparrow}}$ *provenance.*

The additivity claim is restricted to the displayed common refinement and exports no supremum principle, variation measure, hidden partition family, quotient function, or completed function space.

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationPartitionLedger refinement additivity scope`

Proof. Start with the refinement ledger scope. It supplies one displayed common finite refinement whose endpoint and dyadic edge rows are visible to both packets.

Use variation-ledger exactness on each block of that common refinement. The finite dyadic sum for a block is obtained by summing exactly the edge observations in that block, with endpoint transports carried by the displayed hsame and Cont rows.

Concatenate the finite block sums inside the same common-refinement ledger. The package and naming rows remain unchanged, and the statement never ranges over all partitions or any completed function object. □

Theorem 398.12 (BoundedVariation regular Cauchy filter handoff)**.** *Let L be an accepted* $\mathsf{BoundedVariation}^{\uparrow}$ *partition ledger whose endpoint reads are transported along a directed* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *tail basis. Then every variation read exposed from L factors through the finite interval row, the ordered endpoint ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations, the displayed common-refinement row, and the directed* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *meet before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

The handoff exports only the displayed finite-variation ledger together with the regular Cauchy filter tail route. It exports no host supremum over partitions, variation measure, quotient function, selected limit, hidden cofinal tail, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationPartitionLedger regular cauchy filter handoff`

Proof. Project the ledger through Definition 398.16. The interval row, ordered endpoint list, dyadic edge observations, finite sum row, and common-refinement row are the only coordinates available to a variation consumer.

Use Definition 398.3 and Definition 398.11. They force each displayed variation read to be assembled from the same finite edge observations and then repacked along the displayed common-refinement ledger.

Now apply the $\mathsf{RegularCauchyFilter}^{\uparrow}$ basis factorization of Definition 1445.5. The transported endpoint reads pass through the directed tail windows and their meet row before the regular-rational readback or Real seal can be consumed.

Finally use Definition 398.6. Since the variation side has only finite interval, endpoint, dyadic, sum, refinement, transport, replay, package, and naming rows, and the filter side contributes only the displayed directed meet, no absent analytic or quotient coordinate can enter the handoff. □

Theorem 398.13 (BoundedVariation partition-concatenation ledger)**.** *Let L_0 and L_1 be displayed* $\mathsf{BoundedVariation}^{\uparrow}$ *partition ledgers in the sense of Definition 398.16. Suppose the final endpoint row of L_0 and the initial endpoint row of L_1 are related by a displayed transported endpoint row over the same* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *name, with matching* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{BoundedVariation}^{\uparrow}}$ *provenance. Then the concatenated ordered partition row is again a displayed* $\mathsf{BoundedVariation}^{\uparrow}$ *partition ledger, and its finite dyadic variation-sum row is the concatenation of the visible edge-observation sums of L_0 and L_1.*

This ledger composition is restricted to the displayed finite partitions and their transported shared endpoint. It does not assert Jordan decomposition, variation measures, host suprema, quotient function equality, completed function spaces, or any hidden partition family.

Proof. Project L_0 and L_1 through Definition 398.16. Each ledger exposes an interval row, an ordered finite partition, adjacent-edge rows, endpoint-name rows, dyadic edge observations, a finite variation sum, refinement rows, transport, continuation, package provenance, and local naming data.

Use the transported shared endpoint to identify the terminal endpoint row of L_0 with the initial endpoint row of L_1 inside the displayed hsame and Cont surface. This supplies the only splice row needed to concatenate the two ordered partition ledgers without adding an unrecorded endpoint.

Apply Definition 398.11 to read the two edge lists as finite dyadic blocks, and apply Definition 398.15 to keep the shared endpoint and the adjacent edge observations on the displayed dependency stack. The concatenated variation row is therefore the finite concatenation of the two visible edge-observation sums.

Finally use Definition 398.6. The construction has used only displayed partition, endpoint, dyadic, transport, continuation, package, and naming rows, so the resulting ledger cannot export a host supremum, variation measure, quotient function, completed function-space carrier, or hidden partition family. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationPartitionLedger concatenation ledger`

Theorem 398.14 (BoundedVariation finite-variation-ledger consumer)**.** *Every accepted* BoundedVariation$^{\uparrow}$ *partition read factors through the* FiniteVariationLedger$^{\uparrow}$ *carrier rows before a bounded-variation consumer reads the variation value. The required route exposes the interval row, displayed finite partition, endpoint* Real$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *names,* DyadicRatCore$^{\uparrow}$ *edge observations, finite variation sum, common-refinement row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Thus the bounded-variation packet consumes the reusable finite ledger of Definition 6254.1. It exports no host supremum over all partitions, variation measure, quotient function equality, completed function-space carrier, hidden partition family, or ambient Real$^{\uparrow}$ *completeness coordinate.*

Proof. Project the accepted packet through Definition 398.1 and the partition ledger through Definition 398.16. The visible rows are exactly the interval, displayed finite partition, endpoint names, dyadic edge observations, finite variation sum, common-refinement data, transport, replay, provenance, and local naming rows.

Apply Definition 398.3. It forces every public variation read to be assembled from the displayed endpoint ledger and the finite dyadic edge-observation sum.

Apply Definition 398.11 and Definition 398.13. Refinement and concatenation keep the same finite rows and only repack them along displayed common-refinement or splice coordinates.

Finally repack those rows as the FiniteVariationLedger$^{\uparrow}$ consumer route of Definition 6254.1. Since the source packet and the reusable ledger both lack host suprema, variation measures, quotient functions, completed function spaces, hidden partitions, and ambient completeness coordinates, no additional object can enter the bounded-variation read. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationPartitionLedger finite variation ledger consumer`

Theorem 398.15 (BoundedVariation endpoint transport scope)**.** *The carrier transport and no-escape boundary rows of Definition 398.5 and Definition 398.6 give the endpoint transport scope*

for BoundedVariation$^{\uparrow}$. *Endpoint reads may move only along displayed* hsame *and* Cont *routes for the interval row, finite partition ledger,* Real$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *endpoint names,* StreamName$^{\uparrow}$ *read schedule,* DyadicRatCore$^{\uparrow}$ *observations, finite variation ledger,* BHist, Pkg, *and* NameCert *provenance.*

The endpoint transport scope exports no completed function space, variation measure, host supremum over all partitions, quotient real-valued function, or hidden partition row.

Proof. Apply Definition 398.5. It moves interval rows, finite partition ledgers, endpoint-name rows, dyadic observation rows, variation-sum ledgers, and common-refinement rows componentwise through displayed transport and continuation routes.

Then use Definition 398.6. The public boundary exports only the finite partition rows, transported endpoints, dyadic edge observations, common refinements, finite sums, and visible provenance.

The two rows together give the endpoint transport scope. Every endpoint read remains attached to the displayed dependency stack, and no absent host object is exported. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationPartitionLedger endpoint transport scope`

Definition 398.16 (BoundedVariation partition ledger)**.** *A* BoundedVariation$^{\uparrow}$ *partition ledger is a finite* BHist *packet*

$$L = (I, \Pi, E, X, D, V, R, H, C, P, N)$$

whose rows refine the carrier of Definition 398.1 for a single displayed interval read:

1. *I is the displayed rational or nested interval row;*
2. *Π is a finite ordered partition of I with endpoint order and edge rows;*
3. *E is the finite edge ledger induced by adjacent endpoints of Π;*
4. *X records the endpoint* Real$^{\uparrow}$ *rows or their* RegSeqRat$^{\uparrow}$ *regular-name representatives;*
5. *D records the* DyadicRatCore$^{\uparrow}$ *edge observations used to compare adjacent endpoint values;*
6. *V is the finite dyadic variation sum over exactly the edge observations in D;*
7. *R records refinement rows comparing Π with displayed finer partitions and their transported edge ledgers;*
8. *H records the componentwise* hsame *transports for interval, partition, endpoint, edge-observation, finite-sum, refinement, package, and naming rows;*
9. *C records the displayed* Cont *routes from an interval request to endpoints, dyadic edge reads, finite variation sums, refinement comparison, and consumer exposure;*
10. *P and N are the* Pkg *provenance and local* NameCert$_{\text{BoundedVariation}^{\uparrow}}$ *rows.*

The ledger has no coordinate for a host supremum over all partitions, a completed function space, a variation measure, a quotient of real-valued functions, or a hidden partition family.

Theorem 398.17 (BoundedVariation partition refinement monotonicity)**.** *Let $L = (I, \Pi, E, X, D, V, R, H, C, P, N)$ be a* BoundedVariation$^{\uparrow}$ *partition ledger in the sense of Definition 398.16. If Π' is a displayed finite refinement of Π whose endpoint, edge-observation, and finite-sum rows are recorded in R, then the variation read on Π' is obtained by repacking the same finite edge-observation ledger through H and C. The refinement comparison therefore cannot introduce a host supremum over all partitions or any unrecorded variation object.*

Proof. Project the ledger L. The only partition rows available to a consumer are the displayed partition Π and the displayed refinement rows stored in R.

Read the refinement edge by edge. Each refined edge obtains its endpoint names from X and its dyadic observation from D after the transports recorded in H and the continuation routes recorded in C.

The finite sum row for the refinement is therefore a repacking of visible edge observations. Since the packet has no row ranging over all partitions and no measure-valued coordinate, the refinement read is monotone only inside the displayed finite ledger surface. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationPartitionLedger refinement monotonicity`

Theorem 398.18 (BoundedVariation Cauchy consumer boundary)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{BoundedVariation}^{\uparrow}$ *packet may read bounded variation only through finite partition ledgers of Definition 398.16. Such a consumer receives endpoint regular-name or real-name rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations, displayed refinement rows,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *data; it receives no host supremum, variation measure, completed function-space carrier, quotient function, or hidden partition family.*

Proof. Start from a consumer request. The carrier of Definition 398.1 and the ledger of Definition 398.16 expose only interval, partition, endpoint, dyadic observation, finite-sum, refinement, transport, route, provenance, and naming rows.

If the consumer is a $\mathsf{RegSeqRat}^{\uparrow}$ consumer, it reads endpoint data through the regular-name rows in X before any dyadic edge observation is formed. If the consumer is a $\mathsf{Real}^{\uparrow}$ consumer, it reads the same endpoint positions through the displayed real-name rows and then through the dyadic observation rows.

Apply the refinement monotonicity row Definition 398.17. Refinement access remains finite and displayed, so the consumer boundary is exhausted by partition ledgers and dyadic observations rather than by any absent host supremum or completed function object. □

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationCarrier cauchy consumer boundary`

Theorem 398.19 (BoundedVariation real dependency scope)**.** *Every endpoint-variation read consumed from a* $\mathsf{BoundedVariation}^{\uparrow}$ *packet reads* $\mathsf{Real}^{\uparrow}$ *endpoint rows through chapter 38,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name rows through chapter 301,* $\mathsf{StreamName}^{\uparrow}$ *read windows through chapter 126, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations through chapter 291. The* $\mathsf{BoundedVariation}^{\uparrow}$ *packet only packages those sibling rows into a finite interval-partition ledger with visible transport, continuation, package, and naming provenance.*

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationCarrier real dependency scope`

Proof. Start from the carrier of Definition 398.1. Its endpoint coordinate X stores only $\mathsf{Real}^{\uparrow}$ endpoint values or $\mathsf{RegSeqRat}^{\uparrow}$ regular-name representatives, while D stores the $\mathsf{DyadicRatCore}^{\uparrow}$ observations attached to partition edges.

Use the partition ledger of Definition 398.16. A consumer reaches endpoints by first selecting a displayed finite partition and then reading the endpoint rows, stream windows, dyadic edge rows, and finite variation-sum row through the recorded routes.

Finally apply Definition 398.18. Every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer is exhausted by those ledger rows, so the dependency scope is exactly the cited RealUp, RegSeqRatUp, StreamNameUp, and DyadicRatCoreUp sibling surface together with the local $\mathsf{BoundedVariation}^{\uparrow}$ provenance. □

Theorem 398.20 (BoundedVariation public NameCert export)**.** *Every public* $\mathsf{BoundedVariation}^{\uparrow}$ *consumer receives exactly the finite interval-partition rows of Definition 398.16, the endpoint rows of Definition 398.1, the dyadic variation rows, the common-refinement rows of Definition 398.4, the displayed* hsame *rows, the* Cont *replay rows, the* Pkg *provenance rows, and the local* NameCert *rows described by the carrier and obligation theorems.*

Lean4 ✓ `BEDC.Derived.BoundedVariationUp.BoundedVariationCarrier public namecert export`

Proof. Read the carrier through Definition 398.1. Its interval, endpoint, dyadic variation, refinement, transport, route, provenance, and naming coordinates are the only coordinates available to a $\mathsf{BoundedVariation}^{\uparrow}$ packet.

Next read the partition ledger through Definition 398.16. It adds only finite ordered partition rows, edge rows, endpoint rows, dyadic observations, variation sums, and common-refinement rows.

Apply Definition 398.2, Definition 398.7, and Definition 398.19. These results keep every public consumer on the same finite carrier, partition, endpoint, dyadic, refinement, hsame, Cont, Pkg, and NameCert surface, and no row outside that surface is present for export. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedVariation}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedVariation}^{\uparrow}$ packet is generated from an interval row, a finite ordered partition ledger, $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ endpoint names, $\mathsf{DyadicRatCore}^{\uparrow}$ edge observations, a finite dyadic variation-sum row, common-refinement rows, displayed transport, continuation, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundedVariation}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 398.7, Definition 398.8, Definition 398.15, Definition 398.19, and Definition 398.20 bind finite partition variation, common-refinement comparison, endpoint transport, dyadic variation-sum ledger, sibling dependency scope, no-escape boundary, and the public finite-partition export as the paper-side bridge surface to the displayed $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert scope.

Bridge status: none

Origin: human

Not claimed: This chapter does not close completed function spaces, variation measures, host suprema over all partitions, quotient real-valued functions, hidden partition families, Jordan decomposition, Lean verification, or bridge checking.

Upgrade path: The paper-side mature package is recorded; the verification axis still requires Lean checking and bridge checking for the same public finite-variation consumer surface.

Chapter 399

A Concrete Naming Certificate for $\mathsf{WeierstrassMTest}^{\uparrow}$

The $\mathsf{WeierstrassMTest}^{\uparrow}$ interface names the finite majorant packet behind the Weierstrass M-test as used in Bishop–Bridges constructive analysis: uniform convergence is read from displayed majorant rows and finite tail ledgers. The chapter packages finite majorant rows for uniformly bounded series. It does not assert open-cover compactness, host completeness, quotient equality of function series, or an unrecorded infinite summation object.

The uniform-tail budget is consumed through chapter 435, the regular-sequence handoff through chapter 301, and the real-facing seal through chapter 38. Thus the carrier below records the L10 handoff lattice already used by its majorant, tail, regularity, and real-seal rows rather than treating the M-test packet as a kernel-only island.

Definition 399.1 (Weierstrass M-test carrier)**.** *A* $\mathsf{WeierstrassMTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (F, M, B, T, R, E, H, C, P, N)$$

with the following visible rows:

1. *F is a displayed family of* $\mathsf{FastConvergentSeries}^{\uparrow}$ *summand windows, indexed only by the finite inspection rows named by the packet;*
2. *M is the majorant* $\mathsf{FastConvergentSeries}^{\uparrow}$ *packet whose tail rows supply the common comparison budget;*
3. *B is the finite domination ledger, recording each inspected summand-window bound against the corresponding majorant row;*
4. *T is the uniform tail ledger obtained by combining the domination ledger B with the fast tail schedule of M;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that reads the uniform tail ledger as regular rational convergence data;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached through R and through no separate real-facing coordinate;*
7. *H records the componentwise* hsame *transports for source windows, majorant rows, domination ledgers, tail ledgers, handoff rows, and seal rows;*
8. *C records the displayed* Cont *routes by which consumers read the source family, the majorant packet, the domination ledger, the uniform tail ledger, the regular handoff, and the real seal;*

9. *P is the* Pkg *provenance over* $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and the finite rational comparison rows used by the ledger;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{WeierstrassMTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows and their recorded hsame, Cont, Pkg, *and local* NameCert *provenance.*

Lean4 (definition) `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier`

Theorem 399.2 (Weierstrass M-test NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{WeierstrassMTest}^{\uparrow}}$ *surface consists of carrier admission, finite majorant domination, uniform tail exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal factorization for the carrier of Definition 399.1. A consumer may project the displayed source windows, the majorant* $\mathsf{FastConvergentSeries}^{\uparrow}$ *packet, the domination ledger, the uniform tail ledger, the regular handoff, the real seal, and the transport, continuation, package, and naming rows, but obtains no open-cover compactness, host completeness, quotient of function series, or selected limiting sum.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier namecert obligations`

Proof. Carrier admission is the projection of the finite packet W. The displayed family F, majorant packet M, domination ledger B, tail ledger T, handoff row R, and seal row E are all stored coordinates.

The majorant obligation projects B. Each inspected source summand window is paired with the corresponding comparison row of M, so the certificate exposes a finite domination record instead of an ambient boundedness theorem.

Uniform tail exactness projects T and composes it with the $\mathsf{FastConvergentSeries}^{\uparrow}$ tail surface of M and the $\mathsf{DyadicTailBound}^{\uparrow}$ budget rows. Repacking T gives the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R, and the $\mathsf{Real}^{\uparrow}$ seal E then reads only through that handoff.

The rows H, C, P, and N certify componentwise transport, consumer reads, dependency provenance, and local naming for the same packet. Since no coordinate names compact open covers, host completeness, quotient series, or a selected limiting sum, none can be exported by the certificate. □

Theorem 399.3 (Weierstrass M-test majorant tail exactness)**.** *For every accepted carrier*

$$W = (F, M, B, T, R, E, H, C, P, N),$$

the uniform tail ledger T is obtained by composing the finite domination ledger B with the tail schedule of the majorant $\mathsf{FastConvergentSeries}^{\uparrow}$ *packet M. Every displayed source-family tail comparison consumed from T therefore factors through the same majorant packet, the same finite domination rows, and the same* $\mathsf{DyadicTailBound}^{\uparrow}$ *budget surface.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier majorant tail transport`

Proof. Project M and B from the carrier. The packet M supplies the fast-convergent majorant tail schedule, while B records the inspected domination comparisons between the summand windows in F and the majorant rows.

For a requested uniform precision, read the threshold supplied by M and apply the domination rows in B only over the finite inspected windows. The resulting comparison is recorded as the corresponding row of T.

The DyadicTailBound$^{\uparrow}$ budget rows certify that the tolerance used by the comparison is the displayed one. Thus a consumer of T cannot replace the majorant packet, domination ledger, or tail budget by unrecorded boundedness data. □

Theorem 399.4 (Weierstrass M-test RegSeqRat handoff)**.** *For every accepted* WeierstrassMTest$^{\uparrow}$ *carrier, the* RegSeqRat$^{\uparrow}$ *row R is obtained by repacking the displayed uniform tail ledger T together with the majorant packet M and the domination ledger B. A* RegSeqRat$^{\uparrow}$ *consumer can read the resulting uniformly convergent name only through those rows and through the stored* hsame*,* Cont*,* Pkg*, and local* NameCert *provenance.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier regseqrat handoff`

Proof. Read the carrier coordinates M, B, T, and R. The row T is already the finite tail ledger produced from the majorant and domination rows by Definition 399.3.

Repack that ledger as regular rational sequence evidence. The handoff retains the majorant schedule and domination rows because they are stored in the same BHist packet and reached by the displayed continuation routes.

The transport, package, and local naming rows certify the same finite dependency surface. Hence R is a visible RegSeqRat$^{\uparrow}$ handoff and not a quotient of function series, a chosen sum, or a completeness argument. □

Theorem 399.5 (Weierstrass M-test real-seal factorization)**.** *For every accepted* WeierstrassMTest$^{\uparrow}$ *carrier*

$$W = (F, M, B, T, R, E, H, C, P, N),$$

the Real$^{\uparrow}$ *seal row E factors through the* RegSeqRat$^{\uparrow}$ *handoff R, which is determined by the majorant packet M, the domination ledger B, and the uniform tail ledger T. The rows H, C, P, and N certify transport, continuation readback, package provenance, and local naming, but they do not supply open-cover compactness, ambient completeness, quotient equality of function series, or a selected limiting sum.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier real seal factorization`

Proof. Project the seal row E and the handoff row R from the carrier. By definition, E has no real-facing route except the regular rational readback R.

Use Definition 399.4 to identify R with the repacking of M, B, and T. Then use Definition 399.3 to bind T to the finite majorant comparison surface and the displayed tail budget.

The remaining rows are transport, continuation, package, and local naming witnesses for those displayed coordinates. Since the carrier has no coordinate for open covers, host completeness, quotient series, or selected sums, the real seal factors only through the finite majorant certificate. □

Theorem 399.6 (Weierstrass M-test uniform tail budget scope)**.** *Let $W = (F, M, B, T, R, E, H, C, P, N)$ be an accepted* WeierstrassMTest$^{\uparrow}$ *carrier whose displayed summand windows in F are dominated by the majorant packet M through the finite ledger B. Then the packet carries a single* BHist *uniform-tail budget T whose* RegSeqRat$^{\uparrow}$ *handoff row R and* Real$^{\uparrow}$ *seal row E are transported by the stored* hsame *rows and read by the stored* Cont *routes along the same package provenance P.*

Equivalently, a consumer of the WeierstrassMTest$^{\uparrow}$ *seal must pass through the majorant domination ledger, the uniform-tail budget, and the regular-sequence handoff before reaching E. No consumer obtains a separate host summation, quotient series, open-cover compactness, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier uniform tail budget scope`

Proof. First build the uniform-tail budget. Apply Definition 399.3: the ledger T is produced from the displayed domination rows B and the tail schedule of the majorant packet M.

Next route the budget to regular Cauchy data. Apply Definition 399.4 to repack T, together with M and B, as the $\mathsf{RegSeqRat}^{\uparrow}$ handoff row R.

Finally route the regular handoff to the real-facing seal. Apply Definition 399.5: the seal row E factors through R and keeps the same H, C, P, and N provenance.

The composed route is a single displayed BHist budget scope. Since each step uses only the carried rows of W, no unrecorded summation object, quotient series, compactness principle, or completeness principle is introduced. □

Theorem 399.7 (Weierstrass M-test tail majorant ledger)**.** *For every accepted* $\mathsf{WeierstrassMTest}^{\uparrow}$ *carrier*

$$W = (F, M, B, T, R, E, H, C, P, N),$$

each tail comparison recorded in the uniform tail ledger T is pinned to the displayed majorant packet M and the finite domination ledger B. The carrier has no alternate route for deriving tail bounds from open-cover compactness, ambient completeness, a quotient series object, or a selected sum.

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier tail majorant ledger`

Proof. Project M, B, and T from the carrier. These are the only rows that name the majorant schedule, domination evidence, and uniform tail budget.

Apply Definition 399.3. It identifies every tail read in T with the majorant packet M and the domination ledger B.

The remaining rows H, C, P, N only transport, read, package, and locally name those displayed coordinates. Since the carrier has no coordinate for compactness, completeness, quotient series, or selected sums, no such object can supply a competing tail comparison. □

Theorem 399.8 (Weierstrass M-test uniform Cauchy handoff)**.** *The* $\mathsf{RegSeqRat}^{\uparrow}$ *row R of an accepted* $\mathsf{WeierstrassMTest}^{\uparrow}$ *carrier is exactly the uniform Cauchy handoff produced by the rows*

$$M, B, T, H, C, P, N.$$

It records the majorant packet, domination ledger, uniform tail budget, transport witnesses, continuation reads, package provenance, and local naming row, and it does not add a separate summation object or host completeness proof.

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier uniform cauchy handoff`

Proof. Begin with the ledger boundary. Apply Definition 399.7 to bind the tail budget T to M and B.

Next apply Definition 399.4. The handoff repacks the majorant-ledger and tail-budget data as the $\mathsf{RegSeqRat}^{\uparrow}$ row R.

Finally use the displayed H, C, P, N rows for transport, continuation readback, package provenance, and local naming. These rows certify the same uniform Cauchy surface and do not create a completed sum or a host completeness argument. □

Theorem 399.9 (Weierstrass M-test real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read of an accepted* $\mathsf{WeierstrassMTest}^{\uparrow}$ *carrier factors through the uniform Cauchy handoff row* R *determined by*

$$M, B, T, H, C, P, N.$$

The seal row E *therefore exposes only the finite majorant-ledger surface and not a quotient series, selected sum, open-cover compactness proof, ambient completeness proof, or host-level uniform convergence theorem.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier real seal boundary`

Proof. First apply Definition 399.8. This identifies R as the regular rational handoff produced by the majorant, domination, and tail rows together with their transport and naming evidence.

Then apply Definition 399.5. The real-facing seal E factors through R, so every seal read must pass through the same finite handoff.

The excluded objects are absent from the carrier and from the handoff route. Thus the real seal remains a boundary over the displayed majorant-ledger surface. □

Definition 399.10 (Weierstrass M-test obligation surface)**.** *For an accepted* $\mathsf{WeierstrassMTest}^{\uparrow}$ *carrier*

$$W = (F, M, B, T, R, E, H, C, P, N),$$

the obligation surface consists of carrier admission, finite majorant domination, uniform tail exactness, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal factorization. It is read from the displayed summand windows* F*, majorant packet* M*, domination ledger* B*, uniform tail ledger* T*, regular handoff* R*, real seal* E*, and provenance rows* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestObligationSurface namecert rows`

Theorem 399.11 (Weierstrass M-test majorant domination package)**.** *For every accepted* $\mathsf{WeierstrassMTest}^{\uparrow}$ *carrier* $W = (F, M, B, T, R, E, H, C, P, N)$*, the carrier-admission and finite majorant-domination obligations of Definition 399.10 are witnessed by the local NameCert surface and the tail-majorant ledger.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier majorant domination package`

Proof. Apply Definition 399.2. It exposes the accepted carrier rows and the local naming obligations over $F, M, B, T, R, E, H, C, P, N$.

Apply Definition 399.7. It binds the displayed summand windows to the majorant packet through the finite domination ledger B.

Thus the majorant-domination package remains a finite BEDC packet over the listed rows. □

Theorem 399.12 (Weierstrass M-test majorant tail domination surface)**.** *For every accepted* $\mathsf{WeierstrassMTest}^{\uparrow}$ *carrier* $W = (F, M, B, T, R, E, H, C, P, N)$*, the local majorant-domination package and the tail-majorant ledger share the same displayed domination row* B*, tail row* T*, regular handoff* R*, and package provenance* P, N*.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier majorant tail domination surface`

Proof. Apply Definition 399.11 to expose the local naming surface and the read of the finite majorant-domination row.

Apply Definition 399.7 to expose the uniform tail read and its hsame alignment with the regular handoff row.

The combined surface is still the same finite carrier route through $F, M, B, T, R, E, H, C, P, N$ and adds no ambient convergence principle. □

Theorem 399.13 (Weierstrass M-test uniform-tail obligation package)**.** *For every accepted* WeierstrassMTest$^{\uparrow}$ *carrier* $W = (F, M, B, T, R, E, H, C, P, N)$*, the uniform tail and regular-rational handoff obligations of Definition 399.10 are witnessed by* M, B, T, R, H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.TasteGate.WeierstrassMTestTasteGate single carrier alignment`

Proof. Use Definition 399.3. The majorant tail request is the finite source of the uniform tail budget.

Use Definition 399.6. It keeps the uniform budget inside the displayed tail ledger T and the provenance rows.

Finally use Definition 399.8. The regular-rational handoff row R is therefore read from the same finite majorant and tail rows. □

Theorem 399.14 (Weierstrass M-test real-seal obligation package)**.** *For every accepted* WeierstrassMTest$^{\uparrow}$ *carrier* $W = (F, M, B, T, R, E, H, C, P, N)$*, the* Real$^{\uparrow}$ *seal-factorization obligation of Definition 399.10 is the displayed route through* R, E, H, C, P, N *after the finite majorant and uniform-tail ledgers* M, B, T *have been read.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier real seal obligation package`

Proof. Apply Definition 399.4. It identifies R as the regular-rational row built from the domination and uniform-tail data.

Apply Definition 399.5 and Definition 399.9. These show that every real-facing seal read factors through R and the same finite majorant-ledger route.

The carrier has no coordinate for open-cover compactness, host completeness, quotient series, or a selected limiting sum, so the obligation remains inside the displayed packet. □

Theorem 399.15 (Weierstrass M-test obligation closure package)**.** *Every accepted* WeierstrassMTest$^{\uparrow}$ *carrier*

$$W = (F, M, B, T, R, E, H, C, P, N)$$

admits the five obligation rows of Definition 399.10. The package is read over FastConvergentSeries$^{\uparrow}$*,* DyadicTailBound$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, and it exports carrier admission, finite majorant domination, uniform tail exactness,* RegSeqRat$^{\uparrow}$ *handoff, and* Real$^{\uparrow}$ *seal factorization without open-cover compactness, host completeness, quotient series, or a selected limiting sum.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier obligation closure package`

Proof. Project the accepted carrier W and read the displayed rows $F, M, B, T, R, E, H, C, P, N$. The definition of the obligation surface asks only for the five rows named in Definition 399.10.

Apply Definition 399.11. This supplies carrier admission and finite majorant domination from the local naming surface and the tail-majorant ledger.

Apply Definition 399.13. This supplies the uniform tail row and the regular-rational handoff through M, B, T, R, H, C, P, N.

Apply Definition 399.14. This supplies the real-seal factorization through R, E, H, C, P, N after the finite majorant and uniform-tail ledgers have been read.

The carrier non-escape inventory is exactly the listed packet surface. Since no coordinate names open-cover compactness, host completeness, quotient series, or a selected limiting sum, the combined package closes precisely the displayed obligation rows and no stronger host theorem. □

Theorem 399.16 (Weierstrass M-test scoped dependency package)**.** *For every accepted* $\mathsf{WeierstrassMTest}^{\uparrow}$ *carrier*

$$W = (F, M, B, T, R, E, H, C, P, N),$$

the finite series packet, dyadic tail bound, fast convergent series row, $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transports,* Cont *consumer routes,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{WeierstrassMTest}^{\uparrow}}$ *row exhaust the scoped proof surface. Every domination, uniform tail, regular-sequence handoff, and real-seal read factors through those displayed rows.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier scoped dependency package`

Proof. Project the carrier and the obligation package from Definition 399.15. The rows $F, M, B, T, R, E, H, C, P, N$ supply the finite summand packet, majorant packet, dyadic tail ledger, uniform-tail route, regular rational handoff, real seal, transport rows, consumer routes, package provenance, and local naming row.

Route the estimates through the existing tail machinery. The dyadic tail bound is read through Definition 399.13, while the fast convergent series and majorant rows are read through Definition 399.11.

Route convergence reads through Definition 399.4, Definition 399.14, and Definition 399.9. These results keep the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ outputs attached to the same finite package, with no host infinite sum, ambient completeness principle, quotient series, or selected limiting sum in scope. □

Theorem 399.17 (Weierstrass M-test public convergence export)**.** *For every accepted* $\mathsf{WeierstrassMTest}^{\uparrow}$ *carrier*

$$W = (F, M, B, T, R, E, H, C, P, N),$$

the finite series packet F*, majorant packet* M*, dyadic tail ledger* T*, uniform-tail route,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*,* $\mathsf{Real}^{\uparrow}$ *seal* E*,* hsame *rows* H*,* Cont *routes* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N *form the public M-test consumer surface. The surface exports convergence through the displayed majorant domination, uniform-tail obligation package, regular-rational handoff, and real-seal boundary, and it exports no open-cover compactness, host completeness, quotient equality of function series, or selected limiting sum.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier public convergence export`

Proof. First compose the scoped dependency package with the obligation closure package. This reads the accepted carrier as one finite packet and exposes exactly the source series, majorant, domination ledger, tail ledger, regular handoff, real seal, transport, continuation, package, and naming rows.

Next apply majorant domination and the uniform-tail obligation package. These rows turn the finite domination ledger and dyadic tail budget into the uniform-tail route consumed by the $\mathsf{RegSeqRat}^{\uparrow}$ handoff.

Finally apply the RegSeqRat handoff, the real-seal obligation package, and the real-seal boundary. They factor every real-facing convergence read through R and E, so the public consumer surface remains the displayed BHist packet and never uses compactness, host completeness, quotient series, or a selected sum. □

Theorem 399.18 (Weierstrass M-test bridge majorant seal)**.** *For every accepted* WeierstrassMTest$^{\uparrow}$ *carrier* $W = (F, M, B, T, R, E, H, C, P, N)$*, an accepted majorant-tail package consumed by a* Real$^{\uparrow}$ *convergence consumer must pass through the* RegSeqRat$^{\uparrow}$ *handoff* R*, the uniform-tail obligation package, the real-seal obligation package, and the* CauchyLimitSeal$^{\uparrow}$ *boundary before it exports the public convergence row of Definition 399.17. The bridge exposes only the displayed rows* $F, M, B, T, R, E, H, C, P, N$ *and no selected sum, quotient series, open-cover compactness, or host completeness.*

Lean4 ✓ `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier bridge majorant seal`

Proof. Begin with majorant-tail exactness. Definition 399.3 reads the accepted majorant packet and domination ledger as the source of the tail budget, and Definition 399.13 packages that budget as the uniform-tail row consumed by the carrier.

Next pass through the regular and real-facing rows. Definition 399.4 repacks the uniform-tail data as the RegSeqRat$^{\uparrow}$ handoff R, and Definition 399.14 factors the Real$^{\uparrow}$ seal read through R, E, H, C, P, N.

Finally compare the exported surface with the seal route. Definition 399.17 exposes the public convergence row from the same finite packet, while Definition 399.19 identifies the compatible CauchyLimitSeal$^{\uparrow}$ boundary. Hence the public export is reached only after the majorant-tail, uniform-tail, regular-handoff, real-seal, and CauchyLimitSeal rows have been read. □

Theorem 399.19 (Weierstrass M-test CauchyLimitSeal route)**.** *For every accepted* WeierstrassMTest$^{\uparrow}$ *carrier* $W = (F, M, B, T, R, E, H, C, P, N)$*, the uniform tail ledger* T*,* RegSeqRat$^{\uparrow}$ *handoff* R*, and* Real$^{\uparrow}$ *seal* E *determine a* CauchyLimitSeal$^{\uparrow}$*-compatible finite route through the displayed* FastConvergentSeries$^{\uparrow}$ *majorant,* DyadicTailBound$^{\uparrow}$ *budget,* RegSeqRat$^{\uparrow}$ *row,* Real$^{\uparrow}$ *seal,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The route exports no quotient series, selected sum, host completeness, or open-cover compactness.*

The Cauchy-limit boundary is the finite seal route of chapter 386, consumed after the majorant-tail, uniform-tail, regular-handoff, and Real-seal rows have been displayed.

Proof. First read the uniform tail budget. By Definition 399.6, the tail ledger T is tied to the displayed majorant and dyadic budget rows, so every tail estimate remains inside the finite M-test packet.

Next pass to the regular rational handoff. The RegSeqRat handoff theorem Definition 399.4 routes the same tail data through R, and the real-seal factorization of Definition 399.5 then sends the real-facing read through E with the packet's BHist, hsame, Cont, Pkg, and NameCert rows.

Finally compare this route with the CauchyLimitSeal window and consumer boundaries, Definition 386.3 and Definition 386.5. Both boundaries require a displayed regular source route before the real seal is consumed, which is exactly the route supplied by T, R, and E. The non-escape clauses in the M-test public export keep quotient series, selected sums, host completeness, and compactness outside the packet. □

Theorem 399.20 (Weierstrass M-test finite-majorant exhaustion)**.** *For every accepted* WeierstrassMTest$^{\uparrow}$ *carrier*

$$W = (F, M, B, T, R, E, H, C, P, N),$$

every public M-test seal factors through the displayed majorant packet M, the finite domination ledger B, the uniform tail budget T, the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R, and the* $\mathsf{Real}^{\uparrow}$ *seal E. Equivalently, the public seal is exhausted by the L10 route*

$$M, B \longrightarrow T \longrightarrow R \longrightarrow E$$

with H, C, P, N transporting, replaying, packaging, and naming the route.

No open-cover compactness, quotient series object, host summation operation, ambient completeness principle, selected limiting sum, or alternate real seal is available to the public consumer.

Proof. First bind the majorant surface. Apply Definition 399.3 and Definition 399.7: every tail comparison read from T is produced from the displayed majorant packet M and the finite domination ledger B.

Next pass through the regular handoff. Apply Definition 399.13 and Definition 399.4. These results identify R as the regular rational readback obtained from the same majorant packet, domination ledger, and uniform tail budget.

Finally seal the route at the real boundary. Apply Definition 399.5, Definition 399.9, and Definition 399.19. The seal row E is therefore reached only after the majorant, domination, tail, and regular handoff rows have been read.

The transport rows H, continuation rows C, package provenance P, and local naming row N replay the same displayed route. Since the carrier has no coordinate for open covers, quotient series, host summation, ambient completeness, selected sums, or alternate real seals, the public M-test seal is exhausted by the finite majorant packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{WeierstrassMTest}^{\uparrow}}$.

Constructive story: A $\mathsf{WeierstrassMTest}^{\uparrow}$ packet is generated from displayed $\mathsf{FastConvergentSeries}^{\uparrow}$ summand windows, a majorant $\mathsf{FastConvergentSeries}^{\uparrow}$ packet, a finite domination ledger, a uniform tail ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeierstrassMTest}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature surface binds the majorant, uniform-tail, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{Real}^{\uparrow}$ seal, hsame, Cont, Pkg, local NameCert rows, and public convergence export to one displayed BHist package.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeierstrassMTest}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.WeierstrassMTestUp.WeierstrassMTestCarrier\_public\_convergence\_export`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host completeness, quotient equality of function series, selected limiting sums, or bridge checking.

Upgrade path: Bridge checking requires an explicit standard-bridge theorem for the same $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert route.

Chapter 400

A Concrete Naming Certificate for $\mathsf{FanTheorem}^{\uparrow}$

The $\mathsf{FanTheorem}^{\uparrow}$ interface names the finite-spread packet used when later compactness and uniform-continuity consumers read a constructive finite fan argument. In Bishop constructive analysis and in the Troelstra–van Dalen treatment of finite spreads and bars, the finite fan theorem is a boundedness principle for decidable bars on finitely branching binary spreads. BEDC records only the visible finite packet: binary branch rows, branch-prefix $\mathsf{List}^{\uparrow}$ and tree rows, a decidable finite bar classifier, unary depth bounds, componentwise hsame transports, Cont traversal routes, Pkg provenance, and a local $\mathsf{NameCert}$ row.

The packet is not Brouwer bar induction, not open-cover compactness, not a choice principle, and not a $\mathsf{Real}^{\uparrow}$ completeness theorem. It is a concrete finite naming surface that downstream certificates can consume without importing an ambient compact space.

The finite fan packet is a sibling input for chapter 388. $\mathsf{CompactUniformContinuity}^{\uparrow}$ consumes $\mathsf{FanTheorem}^{\uparrow}$ only as a finite branch-depth and prefix-window certificate, never as open-cover compactness or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 400.1 (FanTheorem binary spread carrier)**.** *A* $\mathsf{FanTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, B, D, W, H, C, P, N)$$

with the following visible rows:

1. *T is the finite binary spread row, displayed as a prefix-closed tree of* $\mathsf{Bool}^{\uparrow}$ *branch histories and branch-prefix* $\mathsf{List}^{\uparrow}$ *rows;*
2. *B is the decidable finite bar row, assigning to each displayed prefix a visible* $\mathsf{Bool}^{\uparrow}$ *classifier saying whether that prefix is barred;*
3. *D is the unary depth-bound ledger, a finite* $\mathsf{Nat}^{\uparrow}$ *row recording the candidate depth through which every branch-prefix read is inspected;*
4. *W is the finite witness window, listing the branch-prefix rows of length at most the displayed depth and the bar decisions actually read from B;*
5. *H stores componentwise* hsame *transports for the tree row, prefix rows, bar decisions, depth ledger, witness window, provenance row, and local naming row;*
6. *C stores the displayed* Cont *traversal routes for root reads, left and right branch extension, prefix restriction, depth comparison, and bar-decision readback;*

7. *P is the* Pkg *provenance naming the consumed* $\mathsf{Bool}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, BHist, hsame, *and* Cont *rows;*

8. *N is the local* $\mathsf{NameCert}_{\mathsf{FanTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite binary sequence, a host compact space, an open cover, a choice-selected branch, Brouwer bar induction, or real completeness.

Lean4 ✓ `BEDC.Derived.FanTheoremUp.FanTheoremTasteGate single carrier alignment`

Definition 400.2 (FanTheorem bar classifier)**.** *Two accepted* $\mathsf{FanTheorem}^{\uparrow}$ *carriers are classified as the same finite fan packet exactly when their displayed rows compare componentwise. Their binary spread rows agree by transported* $\mathsf{Tree}^{\uparrow}$ *and* $\mathsf{List}^{\uparrow}$ *prefix classifiers, their bar decisions agree by the displayed* $\mathsf{Bool}^{\uparrow}$ *rows, their depth ledgers agree by the unary* $\mathsf{Nat}^{\uparrow}$ *rows, their finite witness windows agree prefix by prefix, and their* Pkg *provenance and local* NameCert *rows name the same packet.*

The classifier has no generator for comparing infinite branches, no generator for an open-cover index, no generator for a choice function, and no generator for a $\mathsf{Real}^{\uparrow}$ *completion object.*

Lean4 (definition) `BEDC.Derived.FanTheoremUp.FanTheoremPacket bar classifier`
Lean4 (definition) `BEDC.Derived.FanTheoremUp.FanTheoremBarClassifier`

Theorem 400.3 (FanTheorem NameCert obligations)**.** *The finite packet of Definition 400.1 satisfies the local* $\mathsf{NameCert}_{\mathsf{FanTheorem}^{\uparrow}}$ *obligation surface for a decidable finite bar on a binary spread. Carrier habitation is witnessed by the empty prefix tree with its displayed depth row, classifier stability is the componentwise classifier of Definition 400.2, and ledger exactness says that every accepted read factors through the displayed prefix tree, bar decision row, unary depth ledger, finite witness window,* hsame *transports,* Cont *traversal routes,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.FanTheoremUp.FanTheoremPacket namecert obligations`

Proof. For habitation, take the root prefix as the finite binary spread and use the displayed unary depth row for the witness window. The bar classifier row is decidable because it is a finite $\mathsf{Bool}^{\uparrow}$ ledger over the retained prefixes.

For stability, compare two accepted packets by the rows named in Definition 400.2. Tree transport moves prefix rows only through the displayed $\mathsf{Tree}^{\uparrow}$ and $\mathsf{List}^{\uparrow}$ classifiers, bar decisions move only through $\mathsf{Bool}^{\uparrow}$, and depth rows move only through $\mathsf{Nat}^{\uparrow}$.

For exactness, inspect any consumer read of the packet. The read must project one of the coordinates T, B, D, W, H, C, P, or N, and each coordinate is part of the finite carrier. Repacking these projections gives the stated local $\mathsf{NameCert}_{\mathsf{FanTheorem}^{\uparrow}}$ surface without adding infinite branches, open covers, choice functions, bar induction, or real-completeness data. □

Theorem 400.4 (FanTheorem finite bar handoff)**.** *Every downstream compactness or uniform-continuity consumer that reads an accepted* $\mathsf{FanTheorem}^{\uparrow}$ *packet receives only the finite bar handoff: a prefix-closed binary spread row, a decidable finite bar classifier, a unary depth bound, the finite branch-prefix window through that depth, componentwise* hsame *transports, displayed* Cont *traversal routes,* Pkg *provenance, and the local* NameCert *row.*

The handoff supplies a bounded finite inspection surface for binary fan arguments. It does not supply Brouwer bar induction, open-cover compactness, a choice-selected branch, a host Cantor-space object, or a $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.FanTheoremUp.FanTheoremPacket finite bar handoff`

Proof. Project the accepted carrier of Definition 400.1. The only branch data available to the consumer are the finite tree row T and the finite prefix window W.

Read the bar information through B and the depth information through D. Decidability is the stored $\mathsf{Bool}^{\uparrow}$ row at each retained prefix, while boundedness is the stored unary $\mathsf{Nat}^{\uparrow}$ row; neither read mentions an infinite branch or an open cover.

The traversal routes are exactly the continuations in C, transported by the componentwise hsame rows in H. Repacking those rows with P and N gives the finite bar handoff, and coordinate exhaustion excludes Brouwer bar induction, choice, host Cantor space, and $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 400.5 (FanTheorem real completion boundary)**.** *When a* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*, or* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *consumer cites a* $\mathsf{FanTheorem}^{\uparrow}$ *packet, the citation can use only the finite fan rows of Definition 400.4. In particular, the citation may bound a finite branch-prefix inspection, but it cannot assert real completeness, quotient equality of real names, selection of a real limit, open-cover compactness, sequential compactness, or Brouwer bar induction.*

Lean4 ✓ `BEDC.Derived.FanTheoremUp.FanTheoremPacket real completion boundary`

Proof. Start with the consumer citation and factor it through the local $\mathsf{NameCert}_{\mathsf{FanTheorem}^{\uparrow}}$ surface of Definition 400.3. The cited packet exposes only the finite carrier rows and their displayed transport routes.

Apply the finite bar handoff of Definition 400.4. It identifies the available data as a binary spread row, decidable bar row, unary depth row, finite prefix window, transports, continuations, provenance, and local naming row.

None of these coordinates is a $\mathsf{Real}^{\uparrow}$ completion object, quotient classifier for real names, selected real limit, open-cover compactness witness, sequential compactness principle, or Brouwer bar-induction rule. The real-facing consumer therefore receives only a finite inspection bound and cannot read any stronger compactness or completeness principle from the packet. □

Theorem 400.6 (FanTheorem bar uniform modulus handoff)**.** *A* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *or finite compactness consumer citing an accepted* $\mathsf{FanTheorem}^{\uparrow}$ *packet can extract only a unary finite branch depth, the displayed finite witness window, and the pointwise modulus rows routed through the recorded* Cont *and* Pkg *provenance. The resulting uniform bound is a finite BEDC packet over the branch-prefix rows and their modulus ledgers, not an open-cover compactness theorem, a selected branch, choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FanTheoremUp.FanTheoremPacket bar uniform modulus`

Proof. Read the accepted fan packet through Definition 400.4. The consumer receives the prefix-closed binary spread row, decidable bar row, unary depth ledger, finite witness window, componentwise transports, continuation routes, provenance, and local naming row.

The pointwise modulus rows consumed by a compact-uniform-continuity argument are therefore attached only to the retained branch-prefix window. The unary depth row bounds the branch inspection, and the displayed Cont routes record how each pointwise row is reached from the finite spread data.

Apply Definition 400.5 to the same citation. It prevents the consumer from replacing the finite inspection bound by $\mathsf{Real}^{\uparrow}$ completeness, an open-cover compactness principle, sequential compactness, Brouwer bar induction, or a choice-selected branch.

Repacking the depth, witness window, pointwise modulus rows, Cont routes, Pkg provenance, and local $\mathsf{NameCert}$ row gives the uniform-modulus handoff. Since all coordinates are finite carrier rows, the handoff remains a BEDC packet. □

Theorem 400.7 (FanTheorem public uniform bar export)**.** *The carrier, classifier, NameCert obligations, finite-bar handoff, real-completion boundary, and uniform-modulus handoff assemble a single public* $\mathsf{FanTheorem}^{\uparrow}$ *export packet consumable by* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *and constructive compact-metric fan arguments. The public row exposes only the binary-spread carrier, bar classifier, finite subcover witness window, real-completion boundary, and uniform-modulus ledger; it does not add open-cover compactness or choice-selected bars.*

Lean4 ✓ `BEDC.Derived.FanTheoremUp.FanTheoremPacket public uniform bar export`

Proof. First use Definition 400.1 and Definition 400.2. They identify the binary-spread carrier and the componentwise bar classifier that every exported packet must expose.

Next apply Definition 400.3 and Definition 400.4. These results bind the local naming obligations and supply the finite subcover witness window available to downstream compactness consumers.

Finally apply Definition 400.5 and Definition 400.6. The public packet therefore exports the finite bar rows and uniform-modulus ledger while retaining the stated boundary against open-cover compactness, choice-selected bars, Brouwer bar induction, and $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 400.8 (FanTheorem compact uniform continuity obligation surface)**.** *The public uniform bar export of Definition 400.7 supplies exactly the rows a* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *consumer may read over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, *and* $\mathsf{UniformModulus}^{\uparrow}$*: finite binary-spread rows, decidable-bar rows, unary-depth rows, finite witness-window rows, the* $\mathsf{UniformModulus}^{\uparrow}$ *ledger, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite coverage surface, the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus surface,* BHist *histories, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FanTheorem}^{\uparrow}}$ *row.*

It supplies no open-cover compactness row, no choice-selected bar, no sequential compactness row, and no $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.FanTheoremUp.FanTheoremPacket compact uniform continuity obligation surface`

Proof. Start with the finite bar handoff of Definition 400.4. It contributes the finite binary-spread rows, decidable-bar classifier, unary-depth bound, finite witness window, transport rows, continuation routes, package provenance, and local naming row.

Use the bar uniform modulus handoff of Definition 400.6. That result is the route by which a compact-uniform-continuity consumer may read the finite witness window as a $\mathsf{UniformModulus}^{\uparrow}$-facing ledger over the relevant pointwise rows.

Now combine the public uniform bar export of Definition 400.7 with the compact-facing rows named there. The export is therefore readable by $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{ContinuousMap}^{\uparrow}$ consumers only through finite coverage, pointwise-modulus, and uniform-modulus coordinates.

Finally apply the real completion boundary of Definition 400.5. It removes any coordinate for open-cover compactness, choice-selected bars, sequential compactness, or $\mathsf{Real}^{\uparrow}$ completeness, so the listed rows are exactly the public obligation surface. □

Theorem 400.9 (FanTheorem standard finite-fan bridge)**.** *The public uniform bar export of Definition 400.7 interprets as the standard finite binary fan packet over finite spread rows, decidable bar rows, a unary depth bound, a finite witness window, the* $\mathsf{UniformModulus}^{\uparrow}$ *ledger, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite coverage surface, the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus surface,* BHist *histories, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FanTheorem}^{\uparrow}}$ *row.*

This interpretation refuses Brouwer bar induction, open-cover compactness, choice-selected bars, sequential compactness, and $\mathsf{Real}^{\uparrow}$ *completeness. Those principles are not bridge data for the finite fan packet.*

Lean4 ✓ `BEDC.Derived.FanTheoremUp.FanTheoremPacket standard finite fan bridge`

Proof. First apply the finite bar handoff of Definition 400.4. It supplies the finite binary spread row, decidable finite bar classifier, unary depth ledger, finite witness window, componentwise transports, traversal routes, provenance, and local naming row.

Next apply the real completion boundary of Definition 400.5. This step removes any reading of the packet as $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, sequential compactness, choice-selected bar selection, or Brouwer bar induction.

Use the bar uniform modulus handoff of Definition 400.6. The finite witness window can be read as a $\mathsf{UniformModulus}^{\uparrow}$-facing ledger over pointwise modulus rows, with no additional compactness principle beyond the displayed finite rows.

Finally combine the public uniform bar export of Definition 400.7 with the compact uniform continuity obligation surface of Definition 400.8. The resulting bridge packet has exactly the finite spread, decidable bar, depth, witness-window, uniform-modulus, compact-coverage, pointwise-modulus, BHist, hsame, Cont, Pkg, and NameCert coordinates stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{FanTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FanTheorem}^{\uparrow}$ packet is generated from a finite binary spread over BHist, a decidable finite bar predicate, a unary depth-bound ledger, branch-prefix $\mathsf{List}^{\uparrow}$ and tree rows, componentwise hsame transports, displayed Cont traversal routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FanTheorem}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 400.1, Definition 400.2, Definition 400.3, Definition 400.4, Definition 400.5, Definition 400.6, and Definition 400.7 bind the binary spread carrier, bar classifier, finite bar handoff, real completion boundary, bar uniform modulus handoff, and public uniform bar export over the displayed BHist, hsame, Cont, Pkg, and NameCert dependencies.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FanTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not claim Brouwer bar induction, open-cover compactness, choice, host Cantor-space compactness, sequential compactness, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: The chapter is at the top of the paper closure axis; Lean verification and bridge checking remain separate verification-axis work.

Chapter 401

A Concrete Naming Certificate for $\mathsf{FibonacciCube}^{\uparrow}$

The $\mathsf{FibonacciCube}^{\uparrow}$ interface is a BEDC-native finite certificate surface. It packages the finite-path independent-set reading of Fibonacci cubes as visible BHist rows rather than importing an external graph library or theorem.

The carrier consumes the path-graph row from chapter 118, the word row from chapter 36, and the unary length row from chapter 28.

Definition 401.1 (FibonacciCube carrier)**.** *A* $\mathsf{FibonacciCube}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (n, G, W, I, Z, D, P, N)$$

with the following displayed coordinates:

1. *n is a unary* $\mathsf{Nat}^{\uparrow}$ *length row;*
2. *G is the path-graph source row with vertices indexed by the visible initial segment of length n and edges only between successor indices;*
3. *W is a* $\mathsf{List}^{\uparrow}$ *word row over* $\mathsf{Bool}^{\uparrow}$ *whose support has no adjacent* 1 *entries;*
4. *I is the path-independent-set row listing exactly the positions where W carries* 1*;*
5. *Z is the Zeckendorf and* $\mathsf{GoldenMeanShift}^{\uparrow}$ *provenance row recording the same no-adjacent-*1 *classifier as a finite shift word;*
6. *D records dependency rows for* $\mathsf{Graph}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*, and* $\mathsf{Nat}^{\uparrow}$ *together with the visible* hsame *comparisons and* Cont *routes between path vertices, list positions, word support, and independent-set membership;*
7. *P is the* Pkg *provenance row naming the* $\mathsf{Graph}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{ZeckendorfNormal}^{\uparrow}$*, and* $\mathsf{GoldenMeanShift}^{\uparrow}$ *sources;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FibonacciCube}^{\uparrow}}$ *row.*

The local classifier compares carriers componentwise by the length row, path-graph row, no-adjacent word row, independent-set row, provenance row, dependency rows, package row, and local certificate row.

Lean4 ✓ `BEDC.Derived.FibonacciCubeUp.FibonacciCubeTasteGate single carrier alignment`

Theorem 401.2 (FibonacciCube carrier habitation)**.** *For each displayed unary length row n, the empty support word on the path graph of length n supplies an accepted* $\mathsf{FibonacciCube}^{\uparrow}$ *carrier. Its path-independent-set row is empty, its no-adjacent-*1 *word row is the all-*0 *word, and its provenance is witnessed by the* $\mathsf{Graph}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{ZeckendorfNormal}^{\uparrow}$, *and* $\mathsf{GoldenMeanShift}^{\uparrow}$ *dependency rows.*

Lean4 ✓ `BEDC.Derived.FibonacciCubeUp.FibonacciCubeCarrier habitation`

Proof. Build the path-graph source row from the unary length row and choose the all-0 list word. The support row is empty, so no edge of the path graph can have both endpoints in the support.

The empty support is also the independent-set row. The Zeckendorf and golden-mean-shift provenance rows read the same all-0 finite word, and the componentwise hsame and Cont routes are the identity routes on the displayed rows. □

Theorem 401.3 (FibonacciCube word and path-independent-set correspondence)**.** *For an accepted* $\mathsf{FibonacciCube}^{\uparrow}$ *carrier, the no-adjacent-*1 *word row W and the path-independent-set row I determine each other on the visible path graph: a position belongs to I exactly when the corresponding entry of W is* 1*, and path independence is exactly the absence of adjacent* 1 *entries along successor edges.*

Lean4 ✓ `BEDC.Derived.FibonacciCubeUp.FibonacciCubePacket word path support correspondence`

Proof. Read I from W by taking the displayed support row. Since W has no adjacent 1 entries, no successor edge of the path graph has both endpoints in the support.

Conversely, read W from I by marking precisely the listed positions with 1 and all other visible positions with 0. Path independence of I forbids a successor pair from both being marked, so the reconstructed word satisfies the no-adjacent-1 classifier.

The two readings use only the stored vertex-position hsame comparisons and the finite Cont routes between list entries and graph vertices, so they remain inside the carrier. □

Theorem 401.4 (FibonacciCube finite path coverage)**.** *Every classifier read of an accepted* $\mathsf{FibonacciCube}^{\uparrow}$ *carrier is covered by the finite path graph of the displayed unary length row. There is no vertex outside the initial segment, no edge outside successor adjacency, and no membership query outside the listed* $\mathsf{List}^{\uparrow}$ *word and path-independent-set rows.*

Proof. The carrier records the length row and path-graph source row as coordinates. Hence every vertex read is mediated by the visible initial segment, and every edge read is mediated by the successor-edge row.

The word row and independent-set row are indexed by the same displayed positions. The dependency coordinate records the hsame comparisons and Cont routes that identify list positions with path vertices, so a classifier query cannot name an external vertex, edge, or membership source. □

Theorem 401.5 (FibonacciCube classifier transport)**.** *Displayed* hsame *transport preserving the length row, path-graph row, word row, independent-set row, Zeckendorf and* $\mathsf{GoldenMeanShift}^{\uparrow}$ *provenance row, dependency rows, package row, and local certificate row preserves the* $\mathsf{FibonacciCube}^{\uparrow}$ *carrier predicate and its local classifier.*

Proof. The classifier is componentwise by Definition 401.1. Transport of the length and path-graph rows preserves the visible initial segment and successor-edge relation.

Transport of the word, support, and independent-set rows preserves the no-adjacent-1 and path-independent-set readings because the relevant entries and successor-edge checks are exactly

the transported rows. The provenance, package, and local certificate rows then repack the same finite surface with no additional classifier data. □

Theorem 401.6 (FibonacciCube ledger non-escape)**.** *An accepted* $\mathsf{FibonacciCube}^{\uparrow}$ *carrier exports no ambient graph theory, no infinite binary shift, no external Fibonacci-counting theorem, and no external object. Its public ledger consists only of the finite path-graph row, no-adjacent word row, path-independent-set row, Zeckendorf and* $\mathsf{GoldenMeanShift}^{\uparrow}$ *provenance row, dependency rows for* $\mathsf{Graph}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*, and* $\mathsf{Nat}^{\uparrow}$*,* hsame *transports,* Cont *routes,* Pkg *provenance, and the local* NameCert *row.*

Proof. Inspect the carrier coordinates. Each exported field is a finite history row or a route between finite history rows.

The path-independent-set correspondence is recorded as a BEDC classifier relation between the word support and the path graph, not as an imported theorem about an external graph type. The counting interpretation is therefore only provenance for the concrete certificate surface.

Since no coordinate contains an ambient graph carrier, an infinite shift object, or an external artifact, a downstream consumer can cite only the listed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{FibonacciCube}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FibonacciCube}^{\uparrow}$ packet is generated from a unary $\mathsf{Nat}^{\uparrow}$ length row, a finite $\mathsf{Graph}^{\uparrow}$ path row, a no-adjacent-1 $\mathsf{List}^{\uparrow}$ word row, a path-independent-set support row, Zeckendorf and $\mathsf{GoldenMeanShift}^{\uparrow}$ provenance, componentwise hsame transport, Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FibonacciCube}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The obligation surface names carrier habitation, support correspondence, finite path coverage, classifier transport, and ledger non-escape for the concrete finite-path word/support packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FibonacciCube}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.FibonacciCubeUp.FibonacciCubePacket\_word\_path\_support\_correspondence`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close Fibonacci-cube enumeration, outside candidate records, imported theorem-source records, external formalization objects, graph-isomorphism completeness, or full Lean coverage of every obligation row.

Upgrade path: No further paper-side theory-axis upgrade remains for this finite path word/support packet; bridge verification remains a separate formal-axis task over the same $\mathsf{Graph}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{ZeckendorfNormal}^{\uparrow}$, $\mathsf{GoldenMeanShift}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Chapter 402

A Concrete Naming Certificate for $\mathsf{HausdorffCompletion}^{\uparrow}$

The $\mathsf{HausdorffCompletion}^{\uparrow}$ interface records the separated completion seal used when completion data must remain visible as named finite rows rather than becoming quotient-by-class data. Following Bourbaki, *General Topology*, and Bishop and Bridges, *Constructive Analysis*, the packet treats separatedness as displayed seal evidence over Cauchy and uniform data. It depends on $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows.

The separated-completion packet consumes the regular-sequence source of chapter 301, the uniform entourage route of chapter 339, and the diagonal handoff of chapter 378 before exposing its local Hausdorff seal.

Definition 402.1 (HausdorffCompletion carrier)**.** *A* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (S, U, A, M, L, C, P, N)$$

with the following visible rows:

1. *S is a* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source row;*
2. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage route controlling the compared source windows;*
3. *A is the* $\mathsf{Real}^{\uparrow}$ *seal-facing separated classifier row;*
4. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *diagonal handoff row;*
5. *L records the displayed* hsame *transports for source, entourage, separated-seal, and completion-handoff rows;*
6. *C records the displayed* Cont *routes through the source, entourage, separated classifier, and handoff ledgers;*
7. *P is the* Pkg *provenance over the visible dependency certificates;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *row.*

The carrier contains no quotient class of Cauchy filters, no host completion object, no selected representative, and no ambient completeness principle.

Theorem 402.2 (HausdorffCompletion NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier habitation by a displayed* CauchyFilter$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *source, a* UniformSpace$^{\uparrow}$ *entourage route, a separated* Real$^{\uparrow}$ *classifier row, and a* CauchyCompletionMonad$^{\uparrow}$ *handoff;*
2. *separated classifier stability under the stored* hsame *transports and displayed* Cont *routes;*
3. *Cauchy-filter handoff from the source row through the entourage route into the completion handoff row;*
4. *completion-seal non-escape, stating that the* Real$^{\uparrow}$ *read is reached only through the separated classifier and the finite handoff ledger;*
5. *ledger exactness for the* Pkg *provenance and local* NameCert *row.*

These rows name separated completion data without turning the packet into a quotient of Cauchy classes or an ambient complete space.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionPacket namecert obligations`

Proof. Carrier habitation is projection of Definition 402.1. The source, entourage, separated classifier, handoff, transport, continuation, package, and naming rows are finite coordinates of the same BHist packet.

Classifier stability is componentwise. Move the source row, entourage route, separated seal row, and completion handoff along the stored hsame transports, then replay the displayed Cont routes for the same coordinates.

The Cauchy-filter handoff uses S, U, and M. A consumer first reads the Cauchy or regular rational source, then the entourage route controlling the displayed windows, and only then the completion handoff row.

The non-escape and exactness rows follow from the absence of any quotient-class, host-completion, selected-representative, or ambient-completeness coordinate. The package and local naming rows are therefore the complete provenance surface for the separated seal. □

Theorem 402.3 (HausdorffCompletion separated seal boundary)**.** *Every* Real$^{\uparrow}$ *seal-facing read exported by an accepted* HausdorffCompletion$^{\uparrow}$ *carrier factors through the* CauchyFilter$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *source row, the* UniformSpace$^{\uparrow}$ *entourage route, the separated classifier row, the* CauchyCompletionMonad$^{\uparrow}$ *diagonal handoff, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *provenance rows. Thus separated completion is exported as finite seal data, not as quotient-by-class data, host completion equality, selected representatives, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier separated seal boundary`

Proof. Start with an accepted carrier $H = (S, U, A, M, L, C, P, N)$. The only source coordinate is S, and the only uniform-control coordinate is the entourage route U.

Use the NameCert obligations of Definition 402.2. They force the separated classifier and completion handoff to remain attached to the same source, entourage, transport, continuation, package, and naming rows.

The Real$^{\uparrow}$ read reaches the separated classifier row A and the completion handoff row M only through that finite route. Since the carrier has no quotient, host completion, selected representative, or ambient completeness coordinate, the listed rows exhaust the public seal boundary. □

Theorem 402.4 (HausdorffCompletion uniform RegSeqRat seal coherence)**.** *Let*

$$H = (S, U, A, M, L, C, P, N)$$

be an accepted HausdorffCompletion$^{\uparrow}$ *carrier whose source row S is a* RegSeqRat$^{\uparrow}$ *source. Then the uniform entourage route U, the separated* Real$^{\uparrow}$ *seal row A, the* CauchyCompletionMonad$^{\uparrow}$ *handoff row M, and the displayed support rows L, C, P, N cohere as one finite separated ledger over the source S.*

Every consumer of this ledger reaches the separated Real seal only through the displayed route

$$S, \quad U, \quad A, \quad M, \quad L, \quad C, \quad P, \quad N.$$

There is no direct RegSeqRat-to-Real completion edge through quotient classes, selected representatives, host completion equality, uniqueness-of-limit data, or ambient completeness.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier uniform regseqrat seal coherence`

Proof. Project the carrier through Definition 402.1. The source, uniform entourage, separated seal, handoff, transport, continuation, package, and local naming rows are the only displayed coordinates.

Use Definition 402.2. Its Cauchy-filter handoff and ledger rows attach the RegSeqRat$^{\uparrow}$ source to the entourage route, the completion handoff, and the separated seal through the same L, C, P, N support.

Apply Definition 402.3 and Definition 402.5. The seal-facing read and any classified replacement remain on the displayed route through S, U, A, M, L, C, P, N.

Finally use Definition 402.6. Since the ledger exports no quotient class, selected representative, host completion equality, uniqueness-of-limit datum, or ambient-completeness coordinate, the RegSeqRat source has no direct completion edge outside the finite separated ledger. □

Theorem 402.5 (HausdorffCompletion classifier transport)**.** *Let*

$$H = (S, U, A, M, L, C, P, N)$$

be an accepted HausdorffCompletion$^{\uparrow}$ *carrier. Any classified replacement transports the source row S, the uniform entourage route U, the separated* Real$^{\uparrow}$ *classifier row A, the completion handoff M, the displayed* hsame *rows L, the* Cont *routes C, the* Pkg *provenance P, and the local* NameCert *row N componentwise. The transported packet is accepted only through those displayed rows, and the classifier cannot compare quotient classes, selected representatives, host completion equality, or ambient completeness evidence.*

Proof. Project the carrier of Definition 402.1. The source, entourage, separated seal, handoff, transport, continuation, package, and naming rows are the full list of displayed coordinates.

Use the stability row in Definition 402.2. It moves the separated classifier and completion handoff along the stored hsame transports and then replays the displayed Cont routes for the same coordinates.

The separated seal boundary of Definition 402.3 keeps the transported read attached to the source, entourage, handoff, package, and naming rows. Since the carrier has no quotient, representative, host completion, or ambient completeness coordinate, the classifier transport has no additional comparison source. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier classifier transport`

Theorem 402.6 (HausdorffCompletion ledger exactness)**.** *For every accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier, the* Pkg *provenance row and the local* NameCert *row exhaust the public separated-completion surface. They record exactly the source row, uniform entourage route, separated* $\mathsf{Real}^{\uparrow}$ *classifier row, completion handoff, displayed* hsame *transports, and* Cont *routes. They cannot export quotient Cauchy classes, selected representatives, host completion equality, uniqueness of limits, or ambient completeness.*

Proof. Read the package and local certificate coordinates P and N from Definition 402.1. They name the visible dependency rows and the local separated-completion certificate surface.

Apply Definition 402.2. Its exactness row states that the package and naming data are the complete provenance surface for the separated seal.

Finally use Definition 402.3. Every exported $\mathsf{Real}^{\uparrow}$ seal-facing read factors through the same finite route, so no quotient class, selected representative, host completion equality, uniqueness-of-limit datum, or ambient completeness principle can be exported by the ledger. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier ledger exactness`

Theorem 402.7 (HausdorffCompletion uniform-entourage Cauchy handoff)**.** *Every separated-completion consumer read of an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier routes through the* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, then through the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage route, and only then through the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff row. The displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *rows record this order, so the consumer has no direct source-to-completion edge through quotient classes, selected representatives, host completion equality, uniqueness of limits, or ambient completeness.*

Proof. Project the carrier coordinates of Definition 402.1. The source row S, entourage route U, completion handoff row M, transport row L, continuation row C, package row P, and naming row N are displayed coordinates of the same finite packet.

Use the Cauchy-filter handoff clause of Definition 402.2. It places any source read through the entourage route before the completion handoff can be consumed.

Finally apply Definition 402.6. The package and local certificate expose exactly those rows and no quotient-completion, representative-selection, host-equality, limit-uniqueness, or ambient-completeness coordinate, so the listed handoff order exhausts the consumer route. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier uniform entourage cauchy handoff`

Theorem 402.8 (HausdorffCompletion real-seal ledger scope)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal-facing read exported by an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier is exhausted by the separated classifier row together with the displayed* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *provenance. The read cannot cite a quotient class of Cauchy filters, a selected representative, host completion equality, uniqueness of limits, or ambient completeness outside that finite ledger.*

Proof. Start with the separated classifier coordinate A in the carrier

$$H = (S, U, A, M, L, C, P, N).$$

The definition places the real-facing seal at A and supplies L, C, P, and N as the only transport, continuation, package, and naming coordinates around it.

Apply the completion-seal non-escape and ledger-exactness rows from Definition 402.2. They force the real-facing read to remain attached to the separated classifier and to the displayed provenance rows.

Use Definition 402.3 to exclude any unlisted route. Since the carrier has no quotient class, selected representative, host equality, limit-uniqueness, or ambient-completeness coordinate, the separated classifier ledger is the complete scope of every $\mathsf{Real}^{\uparrow}$ seal-facing read. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier real seal ledger scope`

Theorem 402.9 (HausdorffCompletion obligation unblock package)**.** *The carrier of Definition 402.1, classifier transport of Definition 402.5, uniform-entourage Cauchy handoff of Definition 402.7, real-seal ledger scope of Definition 402.8, and ledger exactness of Definition 402.6 assemble the five-row* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *obligation surface. The assembled package names exactly carrier habitation, classifier stability, Cauchy handoff, completion-seal non-escape, and ledger exactness over the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. First read carrier habitation from Definition 402.1. It supplies the source, entourage, separated classifier, completion handoff, transport, continuation, package, and local naming rows.

Classifier stability is supplied by Definition 402.5. The theorem keeps replacements componentwise over the displayed source, entourage, separated classifier, completion handoff, transport, continuation, package, and naming rows.

The handoff row is Definition 402.7. The seal row is Definition 402.8. These two results place consumer reads through the Cauchy source, uniform entourage, completion handoff, separated classifier, and displayed provenance routes.

Finally apply Definition 402.6. It identifies the package and local certificate as the complete provenance surface, so the five NameCert rows have no remaining slot for quotient completion, host equality, selected representatives, uniqueness of limits, or ambient completeness. □

Theorem 402.10 (HausdorffCompletion Cauchy-entourage handoff exactness)**.** *Let*

$$H = (S, U, A, M, L, C, P, N)$$

be an accepted $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier. Every accepted carrier handoff from a* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source into the completion row factors through the source row S, the entourage route U, the completion handoff row M, the displayed* hsame *transports L, the displayed* Cont *routes C, the package provenance P, and the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *row N. The handoff has no direct edge from a Cauchy source to a quotient class, host completion object, selected representative, uniqueness-of-limit datum, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier cauchy entourage handoff exactness`

Proof. Project the carrier coordinates from Definition 402.1. The only source coordinate is S, the only uniform control coordinate is U, and the only completion-facing handoff coordinate is M.

Apply the Cauchy-filter handoff row of Definition 402.2. It sends any source read through the displayed entourage route before the completion handoff row is consumed.

Use Definition 402.3 to keep the handoff attached to the separated classifier route, and use Definition 402.6 to bind the route to L, C, P, N. Since the carrier contains no quotient, representative, host completion, limit-uniqueness, or ambient-completeness coordinate, no other handoff can be exported. □

Theorem 402.11 (HausdorffCompletion separated ledger transport scope)**.** *For an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier*

$$H = (S, U, A, M, L, C, P, N),$$

any classified replacement preserves the separated $\mathsf{Real}^{\uparrow}$ *classifier row and the completion handoff only by transporting the displayed source, entourage, classifier, handoff,* Pkg*, and* NameCert *rows along the stored* hsame *ledger* L *and replaying the displayed* Cont *routes* C*. The transport does not compare quotient Cauchy classes, selected representatives, host completion equality, uniqueness of limits, or ambient completeness evidence.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier separated ledger transport scope`

Proof. Read the displayed rows from Definition 402.1. The separated classifier and the completion handoff are coordinates of the same finite packet, so a classified replacement must move them with the surrounding source and entourage rows.

Apply Definition 402.5. It states that replacement is componentwise over S, U, A, M, L, C, P, N and that acceptance is recovered only through the displayed transport and continuation rows.

The separated seal boundary of Definition 402.3 and ledger exactness of Definition 402.6 rule out the unlisted comparison sources. Thus the separated classifier and completion handoff are preserved precisely on the displayed L and C transport scope. □

Theorem 402.12 (HausdorffCompletion separated source identity criterion)**.** *Let*

$$H = (S, U, A, M, L, C, P, N) \quad \textit{and} \quad H' = (S', U', A', M', L', C', P', N')$$

be accepted $\mathsf{HausdorffCompletion}^{\uparrow}$ *packets. The two packets expose the same separated completion identity only when their* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows agree, their* $\mathsf{UniformSpace}^{\uparrow}$ *entourage routes agree, their* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff rows agree, their* $\mathsf{Real}^{\uparrow}$ *separated classifier rows agree, and their provenance rows* L, C, P, N *agree componentwise with* L', C', P', N'*. No quotient Cauchy class, selected representative, host completion equality, uniqueness-of-limit datum, or ambient completeness witness can substitute for these displayed agreements.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier separated source identity criterion`

Proof. Begin with classifier transport, Definition 402.5. It identifies accepted replacement as componentwise transport over the displayed source, entourage, classifier, handoff, transport, continuation, package, and local naming rows.

Use the uniform-entourage Cauchy handoff and Cauchy-entourage handoff exactness, Definition 402.7 and Definition 402.10. These force the completion-facing identity read to pass through the source row, the entourage route, and the completion handoff row before the separated classifier is exported.

Finally apply the separated seal boundary and ledger exactness, Definition 402.3 and Definition 402.6. They bind the exposed identity to L, C, P, N and exclude hidden comparison routes, so sameness of the separated completion identity is exactly sameness of the displayed source, entourage, handoff, classifier, and provenance rows. □

Theorem 402.13 (HausdorffCompletion separated package exhaustion)**.** *For every accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier, the* Pkg *row and the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *provenance exhaust the separated completion surface. They expose only the source row, entourage route, separated classifier row,*

completion handoff, displayed hsame *transports, and displayed* Cont *routes, and they export no quotient Cauchy class, selected representative, host equality, uniqueness-of-limit datum, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier separated package exhaustion`

Proof. Begin with the package and local naming coordinates P and N in Definition 402.1. They are provenance rows for the displayed source, entourage, classifier, handoff, transport, and continuation data.

Apply the exactness row of Definition 402.2. It identifies P and N as the complete provenance surface for the separated seal.

Finally use Definition 402.6, together with the classifier transport theorem Definition 402.5. The exported separated completion packet is exhausted by the displayed rows, so quotient classes, representatives, host equality, limit uniqueness, and ambient completeness never appear as package output. □

Theorem 402.14 (HausdorffCompletion separated reflection)**.** *Let*

$$H = (S, U, A, M, L, C, P, N)$$

be an accepted $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier. Every separated reflection consumer reads only the displayed Cauchy or regular-rational source S, the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage route U, the completion handoff M, the* $\mathsf{Real}^{\uparrow}$ *separated classifier row A, the* hsame *transports L, the* Cont *routes C, the* Pkg *provenance P, and the local* NameCert *row N. The reflection cannot import quotient completion classes, host completion equality, selected representatives, ambient completeness, or uniqueness outside the displayed classifier ledger.*

Proof. Project the finite carrier of Definition 402.1. It lists exactly the source, entourage, separated classifier, handoff, transport, continuation, package, and local naming rows.

Use classifier transport and the separated seal boundary. These force the reflected separated row to move along L and C while staying attached to the same source, entourage, handoff, and classifier coordinates.

Finally apply separated package exhaustion and ledger exactness. Since P and N exhaust the exported package, the reflected consumer has no further coordinate through which quotient completions, host equality, selected representatives, ambient completeness, or outside uniqueness could enter. □

Theorem 402.15 (HausdorffCompletion Cauchy source route scope)**.** *Let*

$$H = (S, U, A, M, L, C, P, N)$$

be an accepted $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier. Every separated-completion consumer route from a* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source is scoped by the displayed path from S through the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row U, then through the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff M, and then into the separated* $\mathsf{Real}^{\uparrow}$ *classifier row A, with L, C, P, N carrying transport, continuation, provenance, and local naming.*

Proof. Read the route from the carrier. The only source coordinate is S, the only uniform-control coordinate is U, and the only completion-facing handoff coordinate is M.

Apply the Cauchy-entourage handoff exactness theorem and the Cauchy-filter seal route. They place every source read on the route through S, U, and M before a separated classifier can be consumed.

Use separated ledger transport scope and separated package exhaustion to attach the route to L, C, P, N. The carrier and ledger exactness theorems leave no alternate source route through quotient Cauchy classes, host equality, selected representatives, ambient completeness, or an independent limit-uniqueness principle. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier cauchy source route scope`

Theorem 402.16 (HausdorffCompletion Real seal nonquotient boundary)**.** *Let*

$$H = (S, U, A, M, L, C, P, N)$$

be an accepted HausdorffCompletion$^{\uparrow}$ *carrier. Every* Real$^{\uparrow}$ *seal-facing read is the separated classifier row A reached through the displayed Cauchy or regular-rational source S,* UniformSpace$^{\uparrow}$ *entourage route U,* CauchyCompletionMonad$^{\uparrow}$ *handoff M,* hsame *transports L,* Cont *routes C,* Pkg *provenance P, and local* NameCert *row N. It is not a quotient-completion equality, host real equality, selected representative, or ambient completeness claim.*

Proof. Start from the separated seal boundary. It identifies the real-facing endpoint with the displayed classifier row A inside the finite carrier.

Apply classifier transport, Cauchy-entourage handoff exactness, and separated ledger transport scope. Together they bind the path into A to the displayed source, entourage, completion handoff, transport, and continuation rows.

Finally use separated package exhaustion and ledger exactness. The package and local certificate rows exhaust the exported Real seal surface, so no quotient-completion equality, host real equality, selected representative, or ambient-completeness coordinate can be read by separated reflection consumers. □

Theorem 402.17 (HausdorffCompletion separated reflection)**.** *Let*

$$H = (S, U, A, M, L, C, P, N)$$

be an accepted HausdorffCompletion$^{\uparrow}$ *carrier. If a separated classifier row is reflected through the displayed* hsame *transports L, the displayed* Cont *routes C, the package row P, and the local* NameCert *row N, then the reflected read preserves exactly the finite packet coordinates S, U, A, M, L, C, P, and N. The reflection has no quotient class, host completion equality, selected representative, uniqueness-of-limit datum, or ambient completeness coordinate from which to obtain additional separated-completion data.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier separated reflection`

Proof. Project the carrier of Definition 402.1. The packet exposes only the source row, entourage route, separated classifier row, completion handoff, displayed transport rows, continuation routes, package provenance, and local naming row.

Apply the stability and exactness rows of Definition 402.2. The separated classifier may move through hsame and Cont only along the stored rows, while P and N keep the provenance attached to those same coordinates.

Use the separated seal boundary of Definition 402.3 and the classifier transport theorem Definition 402.5. They identify the reflected classifier with the same finite route through S, U, A, M, L, C, P, and N.

Finally apply ledger exactness from Definition 402.6. Since the ledger exports no quotient, representative, host-completion, limit-uniqueness, or ambient-completeness coordinate, the reflected separated row preserves the packet and nothing beyond it. □

Theorem 402.18 (HausdorffCompletion Cauchy-filter seal route)**.** *For every accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier, any source read from the* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *coordinate reaches the* $\mathsf{Real}^{\uparrow}$ *separated seal only through the displayed* $\mathsf{UniformSpace}^{\uparrow}$ *entourage route and the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff. No direct source-to-seal edge, quotient-completion edge, host-completion edge, selected-representative edge, or ambient-completeness edge is part of the packet.*

Proof. Begin with the carrier coordinates of Definition 402.1. The source coordinate is S, the uniform-control coordinate is U, and the completion handoff coordinate is M.

Apply the Cauchy-filter handoff and completion-seal non-escape rows from Definition 402.2. A source read must pass through the displayed entourage route before it reaches the handoff ledger, and the separated $\mathsf{Real}^{\uparrow}$ read is attached to that handoff.

The separated seal boundary in Definition 402.3 keeps the seal-facing read inside the same finite route. The classifier transport theorem Definition 402.5 shows that moving the classifier cannot introduce a different source-to-seal path.

Ledger exactness from Definition 402.6 removes the remaining escape cases. The package and local certificate record the displayed route through S, U, and M, and they export no quotient, host-completion, representative, or ambient-completeness edge. □

Theorem 402.19 (HausdorffCompletion uniform consumer package)**.** *Any downstream* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier receives exactly the carrier coordinates listed in Definition 402.1: the source row, uniform entourage route, separated classifier row, completion handoff, displayed* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. The consumer receives no quotient class, host completion object, selected representative, uniqueness-of-limit witness, or ambient completeness principle.*

Proof. Read the public consumer interface from the carrier definition. Its coordinates are the eight rows S, U, A, M, L, C, P, and N, and the definition explicitly excludes quotient classes, host completion objects, selected representatives, and ambient completeness principles.

Use the NameCert obligations of Definition 402.2. They bind carrier habitation, classifier stability, source handoff, seal non-escape, and ledger exactness to those eight rows.

The separated boundary and classifier transport theorems, Definition 402.3 and Definition 402.5, show that $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers can read the packet only along the displayed entourage, handoff, classifier, transport, continuation, package, and naming routes.

Finally apply Definition 402.6. The package and local certificate exhaust the exported surface, so every downstream consumer receives exactly the carrier coordinates and no outside completion data. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier uniform consumer package`

Theorem 402.20 (HausdorffCompletion entourage-filter coherence)**.** *For every accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier*

$$H = (S, U, A, M, L, C, P, N),$$

each accepted carrier handoff reads the source row S, then the displayed $\mathsf{UniformSpace}^{\uparrow}$ *entourage route U, then the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff row M before any separated* $\mathsf{Real}^{\uparrow}$ *seal is consumed. No separated seal can be read directly from S, from a quotient Cauchy class, from a host completion equality, from a selected representative, or from an ambient completeness coordinate.*

Proof. Project the carrier of Definition 402.1. The only source-facing route begins at S, the only uniform-control route is U, and the only completion handoff route is M.

Apply the Cauchy-filter handoff and seal non-escape rows of Definition 402.2. These rows force a source read to pass through the displayed entourage route before the completion handoff can be presented to a separated consumer.

Use Definition 402.5 to check that changing the separated classifier moves only along the displayed L and C rows. Then apply Definition 402.6. The ledger has no quotient, representative, host-equality, uniqueness-of-limit, or ambient-completeness coordinate, so the handoff route is exactly S through U through M before the seal is consumed. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier entourage filter coherence`

Theorem 402.21 (HausdorffCompletion separated transport certificate)**.** *For every accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier, any classified replacement of the separated row preserves the separated classifier coordinate A and the completion handoff coordinate M only through the displayed* hsame *transport rows L and the displayed* Cont *continuation rows C. The certificate does not preserve A or M by quotient equality, selected representatives, host completion equality, uniqueness of limits, or ambient completeness.*

Proof. Start from the finite carrier in Definition 402.1. The separated classifier row A and handoff row M occur in the packet together with the displayed transport row L and continuation row C.

The NameCert obligation surface in Definition 402.2 binds classifier stability and completion handoff to those displayed rows. It gives no separate preservation principle outside the packet.

Apply Definition 402.5. Classified replacement transports the relevant separated and handoff reads componentwise along L and routes their public consumption through C.

Finally use Definition 402.6. Since the ledger exports only the displayed carrier rows and package provenance, there is no hidden quotient, representative, host-completion, limit-uniqueness, or ambient-completeness source from which a stronger preservation claim could be read. □

Theorem 402.22 (HausdorffCompletion consumer handoff exhaustion)**.** *Every downstream* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier receives exactly the rows*

$$S, U, A, M, L, C, P, N$$

from the displayed packet. The handoff exports no quotient completion class, selected representative, host equality, uniqueness-of-limit witness, ambient-completeness principle, or unlisted completion datum.

Proof. Read the consumer packet from Definition 402.1. Its public rows are precisely the source row, entourage route, separated classifier row, completion handoff, displayed transport, displayed continuation, package provenance, and local naming row.

Apply Definition 402.2. The obligation rows attach carrier habitation, classifier stability, source handoff, separated non-escape, and ledger exactness to the same displayed packet.

Use Definition 402.5 for the separated replacement route and Definition 402.6 for the exported ledger. Together they show that the three downstream consumers can consume exactly S, U, A, M, L, C, P, and N, with no further completion-side coordinate. □

Theorem 402.23 (HausdorffCompletion Cauchy-filter NameCert obligations)**.** *Every accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *Cauchy-filter or regular-rational source read must pass through the source row* S*, the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage route* U*, the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff row* M*, and the displayed* Pkg *and* $\mathsf{NameCert}$ *provenance rows before it is consumed as a separated completion datum. The obligation surface provides no alternate read through quotient Cauchy classes, host completion equality, selected representatives, uniqueness of limits, or ambient completeness.*

Proof. Start from the carrier packet of Definition 402.1. Its source-facing coordinate is S, its uniform-control route is U, its completion handoff is M, and its public provenance is carried by P and N.

Apply the Cauchy-filter handoff and ledger rows of Definition 402.2. They attach every source read to the same finite route and bind the route to the displayed package and local certificate.

Use the separated seal boundary of Definition 402.3 to keep the separated endpoint inside the same packet. The consumer package of Definition 402.19 then shows that downstream reads receive only the listed rows, so the excluded host and quotient data have no obligation field. □

Theorem 402.24 (HausdorffCompletion separated limit uniqueness boundary)**.** *Whenever separated limit uniqueness is consumed from an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *packet, the consumed uniqueness is only the finite separated* $\mathsf{Real}^{\uparrow}$ *classifier row* A *transported by the displayed* hsame *rows* L *and* Cont *rows* C*. It is not host equality, quotient equality, a representative choice, an ambient completeness assertion, or an unrestricted uniqueness-of-limit principle.*

Proof. Read the separated component from Definition 402.1. The only separated classifier coordinate is A, and the only transport and continuation coordinates available to move it are L and C.

The NameCert obligations of Definition 402.2 bind classifier stability and ledger exactness to those displayed rows. The separated seal boundary of Definition 402.3 prevents a consumer from replacing that finite classifier route with host completion equality or an outside representative.

Finally apply the uniform consumer package of Definition 402.19. Since every downstream consumer receives the same finite packet S, U, A, M, L, C, P, N, any uniqueness read available to it is the transported separated classifier row, not an additional completion principle. □

Theorem 402.25 (HausdorffCompletion Real and RegSeqRat consumer package)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *packet receives exactly the rows*

$$S, U, A, M, L, C, P, N$$

from the displayed carrier. The consumer package exports no quotient completion class, host completion object, selected representative, host equality, uniqueness-of-limit witness, or ambient completeness row.

Proof. Project the finite packet of Definition 402.1. Its complete public surface is the source row, uniform route, separated classifier, completion handoff, displayed transport, displayed continuation, package provenance, and local certificate.

Use Definition 402.2 to attach carrier habitation, classifier stability, handoff, non-escape, and ledger exactness to those rows. The separated seal boundary of Definition 402.3 keeps the real-facing endpoint inside the same packet.

Apply the uniform consumer package of Definition 402.19. It exhausts the downstream $\mathsf{Real}^{\uparrow}$ and regular-rational consumption route by S, U, A, M, L, C, P, N, leaving no coordinate for any excluded host or quotient completion datum. □

Theorem 402.26 (HausdorffCompletion scoped kernel interface)**.** *The separated reflection, Cauchy-filter seal route, uniform consumer package, classifier transport, and ledger exactness rows of an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier are scoped exactly by the displayed* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. Within that scope the carrier exposes only the finite packet*

$$H = (S, U, A, M, L, C, P, N)$$

and its named route data; it does not invoke a host quotient completion, host completion equality, a choice-selected representative, uniqueness of limits, or an ambient completeness principle.

Proof. Start from the carrier definition and the five NameCert obligation rows. They place every accepted packet in a finite BHist carrier with the displayed source, uniform, separated-seal, handoff, transport, continuation, package, and naming coordinates.

Apply the Cauchy-entourage handoff exactness theorem, then the separated ledger transport and separated package exhaustion theorems. These results bind the handoff, transport, and provenance rows to the displayed $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, hsame, Cont, Pkg, and $\mathsf{NameCert}$ dependencies.

Next use separated reflection, the Cauchy-filter seal route, classifier transport, and the uniform consumer package theorem. They show that every separated read and every downstream consumer route remains inside the same finite packet coordinates.

Finally apply ledger exactness. Since the ledger exports no quotient class, host completion object, choice-selected representative, limit-uniqueness witness, or ambient-completeness row, the displayed kernel rows are the exact scoped interface. □

Theorem 402.27 (HausdorffCompletion public certificate)**.** *For every accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier*

$$H = (S, U, A, M, L, C, P, N),$$

the carrier row, classifier transport row, Cauchy-filter seal route, separated package exhaustion row, and scoped kernel interface assemble the public $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *export over* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *The export exposes exactly the displayed source, entourage, separated classifier, completion handoff, transport, continuation, package, and local naming rows, and it exports no quotient completion object, host completion equality, selected representative, uniqueness-of-limit witness, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier public certificate`

Proof. The carrier definition supplies the finite packet $H = (S, U, A, M, L, C, P, N)$ and identifies the source, uniform entourage, separated classifier, completion handoff, displayed transport, continuation, package, and naming rows.

The NameCert obligations give the five public clauses: carrier habitation, classifier stability, Cauchy-filter handoff, completion-seal non-escape, and ledger exactness. The classifier transport theorem then moves the separated classifier and completion handoff only along the displayed hsame and Cont rows.

The Cauchy-filter seal route and separated package exhaustion theorems identify the consumer-facing route from S through U and M into the separated $\mathsf{Real}^{\uparrow}$ seal, with P and N as the exhaustive provenance rows. The uniform consumer package records the same route for downstream $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers.

Finally apply the scoped kernel interface. It binds all listed rows to the displayed $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert dependencies, so the public certificate has no remaining coordinate from which quotient completion, host equality, selected representatives, limit uniqueness, or ambient completeness could be exported. □

Theorem 402.28 (HausdorffCompletion separated reflector route)**.** *Every separated reflector read of an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage route, the* $\mathsf{Real}^{\uparrow}$ *separated seal row, the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff row, the componentwise classifier transport, the displayed* hsame *and* Cont *continuation rows, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *row. The reflector has no independent route through quotient Cauchy classes, host completion equality, selected representatives, uniqueness of limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier separated reflector route`

Proof. Begin with the accepted carrier coordinates. The carrier theorem provides the source row, entourage route, separated seal, handoff, transport ledger, continuation ledger, package provenance, and local NameCert row as the complete displayed packet.

Use the NameCert obligations to keep the separated read attached to carrier habitation, classifier stability, Cauchy-filter handoff, seal non-escape, and ledger exactness. The classifier transport theorem supplies the componentwise movement of the reflector through the stored hsame transports and displayed Cont routes.

Next apply the Cauchy-filter seal route. It forces every source read to pass through the entourage route and completion handoff before it reaches the separated $\mathsf{Real}^{\uparrow}$ seal.

The separated package exhaustion and uniform consumer package theorems place the reflector output under the package and local NameCert rows. The scoped kernel interface then rules out any unlisted quotient, representative, host-completion, limit-uniqueness, or ambient-completeness route. □

Theorem 402.29 (HausdorffCompletion Cauchy-filter uniqueness boundary)**.** *Inside an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier, Cauchy-filter uniqueness is only classifier-separated uniqueness in the displayed ledger: two source reads are identified for public separated-completion use only when the* $\mathsf{Real}^{\uparrow}$ *separated classifier, the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage route, the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff, the stored* hsame *transports, the displayed* Cont *routes, the* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *row certify the same finite route. This boundary does not assert quotient completion equality, selected representatives, host completion equality, ambient completeness, or uniqueness of limits outside the displayed classifier ledger.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier cauchy filter uniqueness boundary`

Proof. Read the uniqueness claim inside the carrier $H = (S, U, A, M, L, C, P, N)$. The only public source data are the $\mathsf{CauchyFilter}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ row S and the displayed entourage route U leading to the handoff row M.

The NameCert obligations and classifier transport theorem determine how the separated classifier row A can be transported and consumed. They permit comparison only through the stored hsame transports, displayed Cont routes, package row P, and local naming row N.

Use the Cauchy-filter seal route to bind source reads to the same route through S, U, and M. Use separated package exhaustion and the uniform consumer package to keep the public output inside P and N.

Finally apply the scoped kernel interface. Since the carrier contains no quotient completion object, selected representative, host completion equality, ambient completeness principle, or independent uniqueness-of-limit coordinate, the only uniqueness available to the public package is the classifier-separated uniqueness certified by the displayed ledger. □

Theorem 402.30 (HausdorffCompletion public route composition)**.** *For every accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier*

$$H = (S, U, A, M, L, C, P, N),$$

the public separated read composes exactly through the source row S, the $\mathsf{UniformSpace}^{\uparrow}$ *entourage route U, the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff M, the separated* $\mathsf{Real}^{\uparrow}$ *classifier A, and the provenance packet L, C, P, N. No public read has an additional coordinate through quotient Cauchy classes, selected representatives, host completion equality, limit uniqueness outside A, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier public route composition`

Proof. Project the accepted carrier. The carrier theorem and NameCert obligations expose S, U, A, M, L, C, P, and N as the finite displayed rows, with carrier habitation, classifier stability, handoff, non-escape, and ledger exactness attached to those rows.

Next use classifier transport and the Cauchy-filter seal route. They force any separated read to move from S through U and M before it reaches the classifier row A, and they allow transport only along the displayed ledger rows L and C.

Finally apply the uniform consumer package and the scoped kernel interface. These rows place the public read under the package provenance P and local certificate N, and the Cauchy-filter uniqueness boundary keeps every identification inside the displayed separated classifier ledger. □

Theorem 402.31 (HausdorffCompletion downstream exactness package)**.** *The downstream* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers of an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier receive only the displayed packet*

$$(S, U, A, M, L, C, P, N)$$

through the public route composition of Definition 402.30. Their consumer surface contains the source row, entourage route, separated classifier, completion handoff, transport ledger, continuation ledger, package provenance, and local naming row, and it contains no quotient completion object, selected representative, host completion equality, ambient completeness datum, or independent limit-uniqueness witness.

Proof. Start with the uniform consumer package. It already names the $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumption route and records the consumer-facing coordinates S, U, A, M, L, C, P, and N.

Use the public route composition theorem to identify that consumer route with the exact separated read route through S, U, M, and A. The classifier transport row accounts for L and C, while separated package exhaustion accounts for P and N.

The scoped kernel interface and Cauchy-filter uniqueness boundary then remove every possible unlisted source of downstream data. Thus the consumers receive precisely the displayed packet and no host quotient, representative, equality, completeness, or external uniqueness component. □

Theorem 402.32 (HausdorffCompletion public separated certificate)**.** *The public route composition of Definition 402.30, the downstream exactness package of Definition 402.31, and the scoped kernel interface of Definition 402.26 assemble the public separated-completion certificate for* $\mathsf{HausdorffCompletion}^{\uparrow}$*. The certificate is exactly the finite* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *packet over* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{UniformSpace}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, with no claim of quotient completion, selected representatives, uniqueness of limits outside the classifier ledger, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier public separated certificate`

Proof. First assemble the route row. The public route composition fixes the only separated read path through S, U, M, A, and the provenance rows L, C, P, N.

Next assemble the consumer row. The downstream exactness package shows that $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers receive that same displayed packet and no extra host-side completion data.

Finally attach the scoped kernel interface. It binds the route and consumer rows to the carrier, classifier transport, uniform consumer package, and Cauchy-filter uniqueness rows, so the resulting public separated-completion certificate is exactly the displayed finite $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ surface. □

Definition 402.33 (HausdorffCompletion standard separated reading)**.** *The standard separated-completion reading of an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *packet is the finite BEDC route*

$$(S, U, A, M, L, C, P, N)$$

read as follows: S *is the* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* U *is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage-control row,* A *is the separated* $\mathsf{Real}^{\uparrow}$ *classifier row,* M *is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff row,* L *is the displayed* BHist/hsame *transport ledger,* C *is the displayed* Cont *continuation ledger,* P *is the package-provenance row, and* N *is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *row. The reading contains exactly these rows and treats separated completion as classifier-separated export along this finite route.*

Theorem 402.34 (HausdorffCompletion BEDC-to-standard separated bridge)**.** *Every accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *packet exports the standard separated-completion reading of Definition 402.33. The exported object is exactly the finite route*

$$(S, U, A, M, L, C, P, N)$$

with Cauchy or regular-rational source data, uniform entourage control, separated $\mathsf{Real}^{\uparrow}$ *classifier, completion-monad handoff, transport ledger, continuation ledger, package provenance, and local naming row. It exports no quotient Cauchy class, selected representative, host equality, ambient completeness principle, or independent host completion object.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionUp StdBridge`

Proof. Start with an accepted carrier $H = (S, U, A, M, L, C, P, N)$. The public separated certificate identifies these eight rows as the complete public $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ packet.

The public route composition orders the source row, entourage route, completion handoff, separated classifier, and provenance rows exactly as the standard separated reading requires. The downstream exactness package shows that every consumer receives the same rows and no additional completion data.

Finally use the Cauchy-filter uniqueness boundary and the scoped kernel interface. They rule out quotient classes, selected representatives, host equality, ambient completeness, and any host completion object outside the displayed classifier ledger. Thus the BEDC packet exports precisely the standard separated-completion reading. □

Theorem 402.35 (HausdorffCompletion standard-to-BEDC separated bridge)**.** *Any standard separated-completion reading with displayed rows*

$$(S, U, A, M, L, C, P, N)$$

where S is a $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, U is a* $\mathsf{UniformSpace}^{\uparrow}$ *entourage-control row, A is a separated* $\mathsf{Real}^{\uparrow}$ *classifier row, M is a* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff row, L is a* $\mathsf{BHist/hsame}$ *transport ledger, C is a* Cont *continuation ledger, P is package provenance, and N is a local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *row repacks as the public* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated-completion certificate of Definition 402.32. The repacked certificate has no further quotient, representative, host-equality, or ambient-completeness coordinate.*

Proof. Read the standard separated-completion input as the eight displayed rows. The definition fixes the same row order and the same consumer interpretation as the public route composition.

Use the downstream exactness package to route the $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers through those rows. The transport and continuation ledgers provide the visible hsame and Cont data, while P and N provide package provenance and local naming.

Attach the scoped kernel interface and the public separated certificate. Since the standard reading has no additional quotient, representative, host-equality, or ambient-completeness field, the repacked object is exactly the existing public $\mathsf{HausdorffCompletion}^{\uparrow}$ certificate. □

Theorem 402.36 (HausdorffCompletion standard bridge source packet)**.** *For every accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier*

$$H = (S, U, A, M, L, C, P, N),$$

the bridge-facing source packet is exactly the displayed separated-completion row family: the $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source row S, the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row U, the separated* $\mathsf{Real}^{\uparrow}$ *classifier row A, the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *handoff row M, the transport and continuation rows L, C, the package provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *row N. This packet is the only bridge source offered by the public separated certificate.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier standard bridge source packet`

Proof. Start with the carrier inventory of Definition 402.1. It displays S, U, A, M, L, C, P, N as the complete finite tuple and assigns each coordinate to the corresponding source, entourage, separated classifier, handoff, transport, continuation, package, and local naming role.

Apply the public certificate of Definition 402.27. It shows that the public read of the carrier is already exhausted by the same row family, with no additional completion object or representative row.

Finally use the public separated certificate of Definition 402.32. The separated-completion reading consumed by a bridge is therefore the public packet itself, not a host-side completion carrier supplied outside H. □

Theorem 402.37 (HausdorffCompletion bridge non-escape boundary)**.** *Every standard separated-completion bridge read of the source packet in Definition 402.36 factors through the rows S, U, A, M, L, C, P, N. It cannot read quotient Cauchy classes, host completion equality, selected representatives, uniqueness outside the separated classifier ledger, or ambient completeness.*

Proof. The bridge source packet is the finite row family S, U, A, M, L, C, P, N. The carrier definition supplies no coordinate for quotient classes, selected representatives, host equality, uniqueness outside A, or an ambient completeness principle.

The public separated certificate identifies the separated read with the route through S, U, M, and A, transported only by L and C and repackaged only by P and N.

Use the downstream exactness package of Definition 402.31. It states that downstream $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers receive exactly the displayed packet. Thus the bridge has no further row from which hidden host completion data could enter. □

Theorem 402.38 (HausdorffCompletion standard bridge obligation package)**.** *The bridge obligation surface for $\mathsf{HausdorffCompletion}^{\uparrow}$ is the finite package consisting of Definition 402.36 and Definition 402.37, grounded in the public separated certificate of Definition 402.32. Its source field, classifier field, exactness field, ledger field, stability field, and non-escape field are all read from S, U, A, M, L, C, P, N.*

Proof. The source and classifier fields are S, U, A, M as exposed by the carrier and public separated certificate. The exactness and stability fields are the displayed transport and continuation rows L, C together with the separated classifier ledger.

The ledger field is the package provenance and local naming pair P, N. The downstream exactness package shows that those rows exhaust every consumer-facing use of the separated-completion packet.

The non-escape field is supplied by Definition 402.37. Combining these rows gives the bridge obligation surface without importing host completion structure into the BEDC carrier. □

Theorem 402.39 (HausdorffCompletion mature consumer examples)**.** *The $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMon}$ $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers of a $\mathsf{HausdorffCompletion}^{\uparrow}$ carrier all read the same separated-completion bridge packet*

$$S, U, A, M, L, C, P, N.$$

The example routes are the uniform entourage consumer through U, the regular-rational diagonal consumer through S and M, and the real-seal separated classifier consumer through A, all transported and packaged by L, C, P, N. These examples reuse the same finite rows and introduce no quotient completion, host equality, selected representative, uniqueness outside the separated classifier, or ambient completeness.

Proof. Begin with the public separated certificate and the standard bridge source packet. They identify S, U, A, M, L, C, P, N as the public separated-completion route and as the bridge-facing source packet.

Apply the bridge non-escape boundary and the standard bridge obligation package. These keep the uniform entourage read, the regular-rational diagonal read, and the real-seal separated classifier read inside the same finite row family.

Finally use the uniform consumer package already recorded by the chapter. Since $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers all project from the same packet, the examples add no quotient completion, host equality, selected representative, uniqueness outside A, or ambient completeness coordinate. □

Theorem 402.40 (HausdorffCompletion separated-limit induction)**.** *Let $H = (S, U, A, M, L, C, P, N)$ be an accepted* $\mathsf{HausdorffCompletion}^{\uparrow}$ *carrier whose Cauchy-filter route and separated comparison row are both exposed to a public consumer. For every finite refinement chain of displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *windows read from S, induction along the chain preserves the same regular-rational readback through S, the same* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row U, the same separated ledger A, the same* $\mathsf{Real}^{\uparrow}$ *seal-facing read, the same* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *transport through M, the same replay rows C, the same provenance row P, and the same local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$ *row N. Hence two terminal limit reads exported by that chain can differ only through a displayed failure of the separated comparison row; no quotient completion class, selected representative, host completion equality, or ambient completeness coordinate is available as an alternate source of difference.*

Proof. Use the Cauchy-filter uniqueness boundary of Definition 402.29. It confines every source comparison to the displayed route through S, U, M, the separated classifier A, the transport rows L, the replay rows C, the provenance row P, and the local naming row N.

For the induction base, a terminal read with no refinement is exactly the public separated packet of Definition 402.32. The uniform consumer package of Definition 402.19 gives the same row family to the $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers.

For the refinement step, replace one displayed Cauchy-filter or regular-rational window by its next displayed refinement. The Cauchy-filter boundary keeps the source read on the same entourage and completion-handoff route, while the separated limit uniqueness boundary of Definition 402.24 permits comparison only through the transported separated classifier row.

Thus every finite refinement preserves the same readback, entourage, separated ledger, seal-facing read, transport, replay, provenance, and local NameCert rows. If the two terminal reads disagree, the disagreement must be visible as failure of the separated comparison row; the public packet contains no other coordinate that could witness such a difference. □

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HausdorffCompletion}^{\uparrow}$ packet is generated from a Cauchy-filter or regular rational source, a uniform entourage route, a separated real-seal classifier, a completion-monad handoff, displayed transport and continuation rows, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 402.27, Definition 402.28, Definition 402.29, and Definition 402.26 bind the public separated-completion packet over the displayed $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows, with no host quotient completion or choice-selected representative.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HausdorffCompletion}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.HausdorffCompletionUp.HausdorffCompletionCarrier\_public\_separated\_certificate`

Bridge status: bridgeChecked

Not claimed: This chapter does not close quotient completion construction, host completion equality, selected representatives, ambient completeness, uniqueness of limits, or bridge checking.

Upgrade path: No further upgrade – chapter at top of formal axis.

Chapter 403

A Concrete Naming Certificate for CompletionReflection$^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the completion reflection boundary is read here inside the BEDC mathlib-free substrate: completion data are admitted only as finite named rows, and reflection across the real seal is expressed by displayed transports rather than by host quotient objects. The CompletionReflection$^{\uparrow}$ packet ties together the construction surface of RealCauchyCompletion$^{\uparrow}$, the extension surface of CompletionUniversalProperty$^{\uparrow}$, and the separated boundary of HausdorffCompletion$^{\uparrow}$.

The reflection packet consumes the completion construction of chapter 360, the universal-property extension row from chapter 397, the separated boundary row from chapter 402, the regular-rational source row from chapter 301, and the real seal row from chapter 38. These sibling rows are the source of C, U, H, Q, A in the carrier tuple, and the CompletionReflection$^{\uparrow}$ packet only repackages their finite routes through hsame, Cont, Pkg, and NameCert.

Theorem 403.1 (CompletionReflection metric-existence route)**.** *Before a* CompletionReflection$^{\uparrow}$ *carrier exposes the* HausdorffCompletion$^{\uparrow}$ *separated boundary or the* RealCauchyCompletion$^{\uparrow}$ *construction handoff, it reads the metric-completion existence route of chapter 5721. The consumed route supplies only the displayed source metric, Cauchy schedule, dense embedding, finite windows, regular readback, dyadic tolerance ledger, completion seal, transport, replay, provenance, and local naming rows; it does not add a selected quotient completion or host completeness theorem to the reflection packet.*

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket metric existence route`

Proof. Project the dependency paragraph and the carrier rows of Definition 403.3. The construction row C and separated boundary row H are the only completion-facing rows that a reflection consumer can inspect before transport and provenance are read.

The metric-completion existence chapter supplies the finite route that justifies reading those completion-facing rows as displayed BEDC data. Since that route is itself a finite NameCert packet, its contribution is provenance for C and H, not a new carrier coordinate.

Thus the handoff to HausdorffCompletion$^{\uparrow}$ or RealCauchyCompletion$^{\uparrow}$ remains inside the local tuple $C, U, H, D, Q, A, S, T, K, P, N$ and cannot expose a quotient completion, selected host limit, or ambient completeness theorem. □

Theorem 403.2 (CompletionReflection StreamName-RegSeqRat-Real factorization)**.** *Every accepted* $\mathsf{CompletionReflection}^{\uparrow}$ *read factors through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window surface, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{Real}^{\uparrow}$ *seal row, and the local reflection rows*

$$C, U, H, Q, A$$

before any completion-facing consumer can use the reflected object. The factorization is the finite route supplied by chapter 301, chapter 38, chapter 360, chapter 397, and chapter 402.

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket stream regseq real factor`

Proof. Project the dependency paragraph and the carrier rows. The completion construction row C, universal-property row U, Hausdorff boundary row H, regular-rational source row Q, and Real seal row A are exactly the local reflection rows available before transport and provenance are read.

Use the RegSeqRat and Real sibling rows to identify the finite source route. The StreamName finite-window surface feeds the regular rational readback, and the regular readback is the finite row through which the Real seal is consumed.

Now compose the completion-construction, universal-property, and Hausdorff-completion sibling rows. They allow the reflected object to be used only after the same finite C, U, H, Q, A route has been transported, replayed, cited, and named.

Thus a completion-facing consumer receives a reflected finite route, not a quotient stream, selected host limit, host real equality principle, or ambient completeness theorem. □

Definition 403.3 (CompletionReflection carrier)**.** *A* $\mathsf{CompletionReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (C, U, H, D, Q, A, S, T, K, P, N)$$

with the following visible rows:

1. C *is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *completion-construction row;*
2. U *is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension row attached to the same completion-facing source;*
3. H *is the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated completion boundary row;*
4. D *is the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *diagonal real-seal row;*
5. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row inspected by the diagonal and completion packets;*
6. A *is the* $\mathsf{Real}^{\uparrow}$ *seal row through which the completed object is consumed;*
7. S *records the componentwise* hsame *transports for construction, extension, separatedness, diagonal, regular-sequence, and real-seal rows;*
8. T *records the displayed* Cont *routes through the same rows;*
9. K *is the* Pkg *provenance over* $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*;*
10. P *records the local reflection packet provenance over* BHist, hsame, Cont, *and* Pkg *rows;*
11. N *is the local* $\mathsf{NameCert}_{\mathsf{CompletionReflection}^{\uparrow}}$ *row.*

The carrier contains no quotient stream, no selected host limit, no host equality of completed reals, and no ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.TasteGate.CompletionReflectionTasteGate single carrier alignment`

Definition 403.4 (CompletionReflection classifier)**.** *For accepted* $\mathsf{CompletionReflection}^{\uparrow}$ *carriers* R *and* R'*, the classifier* $\mathsf{CompletionReflectionClassifier}(R, R')$ *compares exactly the displayed rows of Definition 403.3. The construction row compares through* $\mathsf{RealCauchyCompletion}^{\uparrow}$*, the extension row through* $\mathsf{CompletionUniversalProperty}^{\uparrow}$*, the separated boundary through* $\mathsf{HausdorffCompletion}^{\uparrow}$*, the diagonal row through* $\mathsf{RealDiagonalCompletion}^{\uparrow}$*, the regular rational source through* $\mathsf{RegSeqRat}^{\uparrow}$*, and the seal row through* $\mathsf{Real}^{\uparrow}$*.*

The classifier has no component for a quotient of regular streams, a selected host limit, host real equality, or an external complete-space object. Transport is therefore confined to the displayed hsame*,* Cont*,* Pkg*, and local* NameCert *rows.*

Lean4 (definition) `BEDC.Derived.CompletionReflectionUp.CompletionReflectionClassifier`

Theorem 403.5 (CompletionReflection NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CompletionReflection}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier admission by the finite packet of Definition 403.3;*
2. *classifier transport by the visible comparison surface of Definition 403.4;*
3. *diagonal real-seal reflection from* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *into the* $\mathsf{Real}^{\uparrow}$ *seal row;*
4. *universal-property extension reflection from* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *back into the same completion and seal provenance;*
5. *non-escape from quotient streams, selected host limits, host equality, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket namecert obligations`

Proof. Carrier admission is projection of the finite packet. Each row required by the reflection boundary appears as a coordinate before any consumer can read it.

Classifier transport is componentwise. Use the displayed hsame rows to compare construction, extension, separatedness, diagonal, regular-sequence, and real-seal data, then replay the Cont routes attached to those same coordinates.

The diagonal reflection row reads D, Q, and A together. It states that the real-seal observation is reached through regular rational diagonal data and not through a host real representative.

The extension reflection row reads U against the same construction and seal provenance. Since the extension ledger is carried by U and routed through T, the reflected extension cannot introduce a separate completion object.

Finally the provenance rows K, P, and N account for package and local naming data. Because the carrier has no quotient-stream, selected-limit, host-equality, or ambient-completeness coordinate, no such object can be exported. □

Theorem 403.6 (CompletionReflection real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer read of an accepted* $\mathsf{CompletionReflection}^{\uparrow}$ *packet factors through the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *construction row, the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *diagonal row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated boundary row, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *provenance. The read exposes no quotient stream, selected host limit, host real equality, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket real seal boundary`

Proof. Project an accepted carrier $R = (C, U, H, D, Q, A, S, T, K, P, N)$. The only real-facing coordinate is A, and it is paired in the packet with the completion construction row C, diagonal row D, regular source row Q, and separated boundary row H.

Use the classifier of Definition 403.4 to move between accepted representatives. It preserves exactly those rows by displayed transport and continuation, so any real-seal read remains attached to the same finite provenance.

Apply the non-escape row of Definition 403.5. There is no coordinate from which a quotient stream, host limit, host equality, or ambient completeness theorem could be read, so the real-seal boundary is the displayed finite route. □

Theorem 403.7 (CompletionReflection extension reflects)**.** *Let $R = (C, U, H, D, Q, A, S, T, K, P, N)$ be an accepted* $\mathsf{CompletionReflection}^{\uparrow}$ *carrier. Any completion-facing extension read exported by U reflects back to the same construction row C, diagonal row D, regular rational source Q, real-seal row A, separated boundary row H, and provenance rows S, T, K, P, N. No reflected extension can switch to a quotient stream, selected host limit, host equality principle, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket extension reflects`

Proof. Read the extension coordinate U inside the carrier. Its source and target provenance are not external: the same packet records the completion construction row C, diagonal row D, regular source row Q, and real-seal row A.

The separated boundary row H fixes the Hausdorff-facing route. Transport along S and T keeps the extension ledger attached to that route, while the package rows K and P record the dependency surface consumed by the local certificate.

The obligation surface in Definition 403.5 then repacks the extension read as a $\mathsf{NameCert}_{\mathsf{CompletionReflection}^{\uparrow}}$ row. Since every exported coordinate is visible in the carrier, the reflected extension has no path to unrecorded quotient, limit, equality, or completeness data. □

Theorem 403.8 (CompletionReflection carrier scope)**.** *The scoped carrier of* $\mathsf{CompletionReflection}^{\uparrow}$ *is exactly the finite packet*

$$(C, U, H, D, Q, A, S, T, K, P, N)$$

over $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *No scoped carrier coordinate names a quotient stream, selected host limit, host real equality, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket carrier scope`

Proof. Project the accepted carrier through Definition 403.3. The definition lists the six construction-facing rows C, U, H, D, Q, A and then the five structural rows S, T, K, P, N.

The same definition also states the exclusions. Since every carrier read is a projection from this finite tuple, any object outside these coordinates has no scoped carrier slot from which it can be read. □

Theorem 403.9 (CompletionReflection classifier scope)**.** *The* $\mathsf{CompletionReflection}^{\uparrow}$ *classifier transports the scoped rows componentwise along the same $C, U, H, D, Q, A, S, T, K, P, N$ surface. It can compare construction, extension, separated-boundary, diagonal, regular-source, real-seal, transport, continuation, package, packet-provenance, and local naming rows, but it cannot add quotient streams, selected host limits, host real equality, or ambient completeness data.*

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket classifier scope`

Proof. Apply Definition 403.4. Its comparison clauses are exactly the rows already displayed in the carrier definition, with hsame and Cont supplying componentwise transport for the visible packet.

Because the classifier is defined only on accepted carriers and has no extra field, transport preserves the listed rows without creating a new coordinate. The excluded quotient, limit, equality, and completeness objects therefore remain outside the classifier scope. □

Theorem 403.10 (CompletionReflection consumer scope)**.** *Every consumer read exported by* $\mathsf{CompletionReflection}^{\uparrow}$ *factors through the displayed real-seal and extension rows: the real-facing read passes through* A *over* $C, D, Q, H, S, T, K, P, N$*, and the extension-facing read passes through* U *over the same construction, diagonal, regular-source, real-seal, separated-boundary, transport, continuation, package, and local naming rows.*

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket consumer scope`

Proof. For real-facing consumers, apply Definition 403.6. It routes every $\mathsf{Real}^{\uparrow}$ read through the displayed construction, diagonal, regular-source, separated-boundary, transport, continuation, package, and naming coordinates.

For extension-facing consumers, apply Definition 403.7. The extension coordinate U reflects back to the same rows and cannot switch to an unrecorded completion object.

Combining the two routes exhausts the consumer surface: a consumer can read only the displayed real-seal row or the displayed extension row, each with the same finite provenance boundary. □

Theorem 403.11 (CompletionReflection public export)**.** *Any public consumer of* $\mathsf{NameCert}_{\mathsf{CompletionReflection}^{\uparrow}}$ *may read exactly the completion construction row* C*, universal-property extension row* U*, Hausdorff separated boundary row* H*, diagonal regular-sequence reflection row* D*, regular rational source row* Q*,* $\mathsf{Real}^{\uparrow}$ *seal row* A*, displayed* hsame *and* Cont *transports* S, T*,* Pkg *provenance* K, P*, and the local* NameCert *row* N *from the carrier*

$$(C, U, H, D, Q, A, S, T, K, P, N).$$

The public export has no coordinate for quotient completion objects, selected host limits, host equality of completed reals, or ambient completeness.

Proof. First apply Definition 403.8. It identifies the public carrier surface with the finite tuple $C, U, H, D, Q, A, S, T, K, P, N$ and excludes quotient streams, selected host limits, host real equality, and ambient completeness from the carrier coordinates.

Next apply Definition 403.9. Public movement between accepted packets is componentwise along the same construction, extension, separated-boundary, diagonal, regular-source, real-seal, transport, continuation, package, packet-provenance, and local naming rows.

Finally apply Definition 403.10. Every public consumer read factors through the real-seal row or the extension row over the same finite provenance surface, so the exported $\mathsf{NameCert}_{\mathsf{CompletionReflection}^{\uparrow}}$ interface is exactly the displayed tuple and nothing outside it. □

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket public export`

Theorem 403.12 (CompletionReflection universal real-seal factorization)**.** *Let $R = (C, U, H, D, Q, A, S, T, K, P, N$ be an accepted* $\mathsf{CompletionReflection}^{\uparrow}$ *carrier. Every universal-property extension route exported by U factors through the displayed* $\mathsf{Real}^{\uparrow}$ *seal row A before any completion-facing consumer can read it. The factorization uses the completion construction row C, diagonal row D, regular rational source row Q, Hausdorff boundary row H, componentwise* hsame *rows S, displayed* Cont *routes T, package provenance K, P, and local* NameCert *row N.*

No universal-property consumer can bypass the real-seal row by reading a quotient completion object, selected host limit, host equality of completed reals, or ambient completeness theorem.

Proof. Begin with Definition 403.6. It identifies the $\mathsf{Real}^{\uparrow}$ seal row A as the real-facing boundary through which completion data become consumable.

Apply Definition 403.7. Any extension route supplied by U reflects back to the same construction row, diagonal row, regular source, real-seal row, separated boundary, and provenance surface.

Use Definition 403.10 to align the two reads. It states that real-facing and extension-facing consumers share the same finite rows, so the extension route cannot be consumed before the real-seal boundary is present.

Finally apply Definition 403.11. The public packet exposes exactly $C, U, H, D, Q, A, S, T, K, P, N$ and no quotient, selected limit, host equality, or ambient completeness coordinate, so the universal route factors through the displayed seal for every completion-facing consumer. □

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket universal real seal factorization`

Theorem 403.13 (CompletionReflection real-seal extension coherence)**.** *Let $R = (C, U, H, D, Q, A, S, T, K, P, N)$ be an accepted* $\mathsf{CompletionReflection}^{\uparrow}$ *packet. The public real-seal read through A and the universal-property extension read through U are coherent exactly when both reads factor through the same displayed rows*

$$C, D, Q, A, H, S, T, K, P, N.$$

Neither read may replace those rows with a quotient stream, selected host limit, host equality, or ambient completeness datum.

Proof. For the real-facing direction, apply Definition 403.6. Every $\mathsf{Real}^{\uparrow}$ read is routed through the displayed construction, diagonal, regular-source, separated-boundary, transport, continuation, package, and naming rows before it reaches the seal row A.

For the extension-facing direction, apply Definition 403.7. The route exported by U reflects back to $C, D, Q, A, H, S, T, K, P, N$, so the extension read cannot introduce a second completion surface.

Now align the two readings by Definition 403.10. Its consumer boundary says that the real-facing read and the extension-facing read use the same finite packet surface, with A and U as the two visible public entries.

Finally apply Definition 403.11. Since the public export exposes only $C, U, H, D, Q, A, S, T, K, P, N$ and excludes quotient streams, selected host limits, host equality, and ambient completeness, coherence is exactly shared factorization through the displayed rows. □

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket real seal extension coherence`

Theorem 403.14 (CompletionReflection regular-source tail reflection)**.** *Let $R = (C, U, H, D, Q, A, S, T, K, P, N)$ be an accepted* $\mathsf{CompletionReflection}^{\uparrow}$ *packet whose reflected completion read starts from a regular rational tail window. Then every such read factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{RealCauchyCompletion}^{\uparrow} \longrightarrow \mathsf{CompletionUniversalProperty}^{\uparrow} \longrightarrow \mathsf{Hausdo}$$

before it reaches the local $\mathsf{NameCert}_{\mathsf{CompletionReflection}^{\uparrow}}$ *row N. The factorization uses the carrier rows C, D, Q, A, H, the classifier transport rows S, the displayed* Cont *routes T, package provenance K, P, and the local naming row N.*

No reflected regular-source tail read may replace this route by quotient streams, selected host limits, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket regular source tail reflection`

Proof. Start with the accepted carrier. By Definition 403.8, the only regular-source data visible to the packet are the diagonal reflection row D, the regular rational source row Q, the real-seal row A, the Hausdorff boundary row H, and the completion construction row C.

Apply Definition 403.5. The local NameCert obligations read Q through the same finite packet surface and route it through the completion construction, universal extension, Hausdorff separated boundary, diagonal reflection, real seal, transport, continuation, provenance, and naming rows.

Next use Definition 403.9. Componentwise hsame transport preserves the regular-source, real-seal, completion-construction, universal-property, and Hausdorff-boundary rows, so the reflected tail read cannot branch into an unlisted completion surface.

Finally apply Definition 403.11. The exported packet exposes only $C, U, H, D, Q, A, S, T, K, P, N$, which realizes the displayed $\mathsf{StreamName}^{\uparrow}$ to $\mathsf{HausdorffCompletion}^{\uparrow}$ route before the local $\mathsf{NameCert}_{\mathsf{CompletionReflection}^{\uparrow}}$ row. Since quotient streams, selected host limits, host real equality, and ambient completeness are absent from that export, no regular-source tail reflection may read them. □

Theorem 403.15 (CompletionReflection standard bridge boundary)**.** *Let $R = (C, U, H, D, Q, A, S, T, K, P, N)$ be an accepted* $\mathsf{CompletionReflection}^{\uparrow}$ *packet. If the carrier row, classifier row, local* $\mathsf{NameCert}$ *obligations, real-seal boundary, extension-reflection row, consumer scope, provenance-route scope, and public export of R are displayed, then R induces a standard bridge boundary read only through the finite rows already named by this chapter:* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the real-seal row, classifier row,* hsame, Cont, Pkg, *and the local* $\mathsf{NameCert}$ *row.*

The bridge boundary exports no quotient completion, no host equality of completed reals, no selected host limit, and no ambient completeness claim.

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket standard bridge boundary`

Proof. First read the accepted packet through its displayed local obligations. Apply Definition 403.5 to bind the completion construction, universal extension, separated boundary, diagonal reflection, regular rational source, real-seal, transport, continuation, package, provenance, and naming rows.

Next route the real-facing and extension-facing reads. Apply Definition 403.6 for the $\mathsf{Real}^{\uparrow}$ seal row and Definition 403.7 for the universal-extension row; both routes return to the same displayed construction, regular-source, real-seal, classifier, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ surface.

Now restrict the consumers and provenance routes. Apply Definition 403.10 and Definition 403.9 to ensure that every admitted read uses only the rows already visible in the chapter.

Finally apply Definition 403.11. The public export exposes exactly the finite completion-reflection tuple and excludes quotient completion objects, host equality, selected host limits, and ambient completeness. This is precisely the standard bridge boundary over the displayed rows, with no additional completion-side coordinate. □

Theorem 403.16 (CompletionReflection real-completion functor handoff)**.** *Let $R = (C, U, H, D, Q, A, S, T, K, P, N$ be an accepted* CompletionReflection$^{\uparrow}$ *packet whose regular-source row Q and real-seal row A are consumed by an accepted* RealCompletionFunctor$^{\uparrow}$ *packet. Then every completion-facing read handed from R to* CauchyCompletionFunctor$^{\uparrow}$ *factors through the displayed L10 route*

DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, hsame, Cont, Pkg, NameCert.

In particular, the handoff uses only the reflection rows $C, U, H, D, Q, A, S, T, K, P, N$, the four-face functor rows of RealCompletionFunctor$^{\uparrow}$*, and the unit-and-bind surface of* CauchyCompletionFunctor$^{\uparrow}$*. It exports no quotient completion object, selected limit, host real equality, ambient completeness theorem, or hidden completion coordinate.*

Lean4 ✓ `BEDC.Derived.CompletionReflectionUp.CompletionReflectionPacket real completion functor handoff`

Proof. Begin with the accepted reflection packet. By Definition 403.15, any standard bridge boundary read from R is already confined to the displayed regular-source, real-seal, classifier, hsame, Cont, Pkg, and local NameCert rows.

Read the consuming RealCompletionFunctor$^{\uparrow}$ packet next. Its terminal-seal non-escape theorem, Definition 2073.3, forces the same completion-facing request through DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ before the completion-functor and universal-property rows are inspected.

Now attach the CauchyCompletionFunctor$^{\uparrow}$ unit-and-bind surface. The unit laws of Definition 423.3 and the multiplication laws of Definition 423.4 read only the displayed source, regular-Cauchy, completion-seal, unit, bind, universal-property, transport, provenance, and local naming rows.

Composing these three routes gives the asserted handoff. Each step preserves the same displayed hsame, Cont, Pkg, and NameCert provenance, so there is no point at which a quotient completion object, selected limit, host real equality, ambient completeness theorem, or hidden completion coordinate can enter. □

Closure status for NameCert$_{\text{CompletionReflection}^{\uparrow}}$**.**

Constructive story: A CompletionReflection$^{\uparrow}$ packet is generated from completion construction, universal-property extension, Hausdorff separated boundary, diagonal regular-sequence reflection, real-seal, transport, continuation, package, and local naming rows.

Theory closure: TheoryGate(NameCert$_{\text{CompletionReflection}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 403.8, Definition 403.9, Definition 403.10, Definition 403.11, and Definition 403.16 bind the finite carrier, componentwise classifier transport, public export, real-seal universal factorization route, and consumer read-back boundary over RealCauchyCompletion$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, HausdorffCompletion$^{\uparrow}$, RealDiagonalCompletion$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{CompletionReflection}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient completion construction, selected host limits, host equality of completed reals, ambient completeness, or bridge checking.

Upgrade path: No further paper-side theory closure remains; bridge verification remains a separate verification-axis obligation.

Chapter 404

A Concrete Naming Certificate for $\mathsf{LocatedCut}^{\uparrow}$

The $\mathsf{LocatedCut}^{\uparrow}$ interface records the constructive real described by located lower and upper rational information while keeping the completion-facing readback visible as finite rows. Following Bishop and Bridges, *Constructive Analysis*, locatedness is represented as explicit interval evidence at each unary precision, not as a quotient of cuts or a selected supremum. The packet depends on $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, dyadic interval ledgers, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

The StreamName window row is read through chapter 126, the regular-rational handoff row follows the finite schedule boundary of chapter 301, and the seal row is the consumer-facing RealUp route of chapter 38.

Definition 404.1 (LocatedCut carrier)**.** *A* $\mathsf{LocatedCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D^-, D^+, W, R, S, H, C, P, N)$$

with the following visible rows:

1. D^- *is the lower dyadic interval ledger, recording finite witnesses that a dyadic rational lies below the presented cut;*
2. D^+ *is the upper dyadic interval ledger, recording finite witnesses that a dyadic rational lies above the presented cut;*
3. W *is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing, for each unary precision visible in the packet, the finite lower and upper ledger entries exposed to consumers;*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row extracted from the displayed located windows;*
5. S *is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row reached through the regular rational handoff;*
6. H *records the componentwise* hsame *transports for lower ledger, upper ledger, stream-window, regular-sequence, and real-seal rows;*
7. C *records the displayed* Cont *routes through the same rows;*
8. P *is the* Pkg *provenance over the displayed dyadic, stream, regular-sequence, and real-seal dependencies;*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *row.*

The carrier contains no quotient cut, no host real equality, no selected supremum, and no use of Classical.choice.

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutTasteGate single carrier alignment`

Theorem 404.2 (LocatedCut NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{LocatedCut}^\uparrow}$ *surface consists of six finite rows:*

1. *carrier habitation by lower and upper dyadic ledgers,* $\mathsf{StreamName}^\uparrow$ *windows, a* $\mathsf{RegSeqRat}^\uparrow$ *handoff, a* $\mathsf{Real}^\uparrow$ *seal row, displayed transports, continuations, package provenance, and local naming;*
2. *lower-ledger and upper-ledger stability under the stored* hsame *transports;*
3. *locatedness evidence at each unary precision, witnessed by a finite pair of dyadic bounds in the corresponding* $\mathsf{StreamName}^\uparrow$ *window row;*
4. *compatibility of those windows with the* $\mathsf{RegSeqRat}^\uparrow$ *handoff row;*
5. *factorization of the* $\mathsf{Real}^\uparrow$ *seal through the handoff row and displayed provenance;*
6. *exactness of the* Pkg *and local* NameCert *rows for the listed dependencies.*

These rows certify a located constructive real without quotient cuts, host real equality, selected suprema, or Classical.choice.

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier namecert obligations`

Proof. Carrier habitation is projection of Definition 404.1. The lower ledger, upper ledger, stream-window, regular-sequence, real-seal, transport, continuation, package, and local naming rows are finite coordinates of the same BHist packet.

Ledger stability is componentwise. Move the lower and upper dyadic rows along the stored hsame transports, then replay the displayed Cont routes for the same window entries. Since each unary precision appears only through a finite window row, locatedness is a displayed witness rather than an ambient order-completeness claim.

The compatibility and seal rows use the same finite path. The $\mathsf{RegSeqRat}^\uparrow$ handoff reads only the located dyadic windows, and the $\mathsf{Real}^\uparrow$ seal reads only that handoff together with the package and local naming rows.

The exclusions follow from the carrier shape. No coordinate stores a quotient cut, host real equality proof, selected supremum, or classical choice term, so the listed finite rows exhaust the certificate surface. □

Theorem 404.3 (LocatedCut regular Cauchy handoff)**.** *Every accepted* $\mathsf{LocatedCut}^\uparrow$ *packet exports a* $\mathsf{RegSeqRat}^\uparrow$ *handoff whose* n*th visible approximation is selected from the finite lower and upper dyadic ledgers displayed in the* $\mathsf{StreamName}^\uparrow$ *row for unary precision* n*. The handoff is transported only by the stored* hsame *rows and displayed* Cont *routes, and it introduces no quotient cut, host real equality, selected supremum, or* Classical.choice.

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier regular cauchy handoff`

Proof. Fix an accepted carrier $L = (D^-, D^+, W, R, S, H, C, P, N)$. For a visible unary precision n, the window row W supplies the finite lower and upper dyadic ledger entries associated with n.

The handoff row R is one of the carrier coordinates. Its readback is constrained by the NameCert obligations of Definition 404.2, so it may inspect only the displayed ledger entries in W and the stored transport and continuation rows.

Transport is therefore internal to the packet. Moving along H and replaying C changes the presented row names but not the finite dependency route from located windows to R.

Because neither the carrier nor the obligations contain a quotient-cut coordinate, a host real equality test, a supremum selector, or a classical choice row, the resulting regular Cauchy handoff is constructive and finite-row based. □

Theorem 404.4 (LocatedCut dyadic interval exhaustion)**.** *For every accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet and every unary precision row visible in its* $\mathsf{StreamName}^{\uparrow}$ *window ledger, the lower and upper dyadic interval rows supply a finite located interval whose width is bounded by that precision row and whose endpoints remain attached to the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance. No appeal is made to a quotient of cuts, host real equality, selected supremum, or* Classical.choice*.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier dyadic interval exhaustion`

Proof. Read the visible unary precision row from W. By the locatedness clause in Definition 404.2, the same window carries a finite lower dyadic witness from D^- and a finite upper dyadic witness from D^+.

The interval bound is a displayed row of the packet, not a completeness theorem. Its width claim is checked against the unary precision row inside the finite window ledger, and the endpoint names remain tied to the same package and local naming coordinates.

Stability follows by replaying the stored hsame transports and Cont routes for the lower endpoint, upper endpoint, precision row, and window row. The transported interval is still read from the same finite packet.

Thus the visible precision rows are exhausted by displayed dyadic interval evidence. The construction never forms a cut quotient, never compares host real equalities, never selects a supremum, and never invokes classical choice. □

Theorem 404.5 (LocatedCut Real seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal-facing read exported by an accepted* $\mathsf{LocatedCut}^{\uparrow}$ *carrier factors through the lower and upper dyadic ledgers, the* $\mathsf{StreamName}^{\uparrow}$ *located window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *provenance rows. The exported seal cannot bypass those rows by using quotient cuts, host real equality, selected suprema, or* Classical.choice*.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier real seal nonescape`

Proof. Start with an accepted carrier $L = (D^-, D^+, W, R, S, H, C, P, N)$. The only real-facing coordinate is S, and the only handoff coordinate feeding it is R.

Apply Definition 404.3. The handoff R is reached through the located dyadic windows in W, with lower and upper evidence read from D^- and D^+.

Apply Definition 404.4. Each visible precision row is exhausted by finite interval evidence carrying the same transport, continuation, package, and local naming provenance.

The $\mathsf{Real}^{\uparrow}$ seal therefore has no escape route outside the displayed chain

$$(D^-, D^+) \longrightarrow W \longrightarrow R \longrightarrow S.$$

Since the carrier has no quotient, host equality, supremum selector, or classical choice coordinate, the listed rows give the complete seal boundary. □

Theorem 404.6 (LocatedCut classifier transport)**.** *Let $L = (D^-, D^+, W, R, S, H, C, P, N)$ and $L' = (D'^-, D'^+, W', R', S', H', C', P', N')$ be accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packets. Classifier transport is componentwise over the lower ledger, upper ledger, stream-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, displayed* hsame *rows, displayed* Cont *routes, package provenance, and local* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *row. It transports no quotient cut, host real equality, selected supremum, or ambient order-completeness datum.*

Proof. Project the carrier tuple of Definition 404.1. Its visible coordinates are exactly the two dyadic ledgers, window row, handoff row, seal row, transport rows, continuation rows, provenance, and local naming row.

Apply the finite-row clauses of Definition 404.2. The lower and upper ledgers move along the stored hsame transports, while the displayed Cont routes replay the same window, handoff, and seal reads.

The non-escape part is immediate from the carrier shape. None of the transported coordinates stores a quotient cut, host real equality proof, supremum selector, or order-completeness object. □

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier classifier transport`

Theorem 404.7 (LocatedCut located-window exactness)**.** *For every accepted packet $L = (D^-, D^+, W, R, S, H, C, P$ and every visible unary precision row, the stream-window row W reads a finite lower dyadic entry from D^- and a finite upper dyadic entry from D^+. The corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff is computed from that same displayed window and not from a quotient cut or selected supremum.*

Proof. Use the locatedness row of Definition 404.2. For each visible precision it requires a finite lower witness and a finite upper witness in the same $\mathsf{StreamName}^{\uparrow}$ window row.

Apply Definition 404.4. The dyadic endpoints and the precision row remain attached to the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance.

Finally apply Definition 404.3. The handoff row R reads the located window supplied by W, so the visible precision is answered by finite dyadic data rather than by an ambient cut object. □

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier located window exactness`

Theorem 404.8 (LocatedCut seal-boundary exactness)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet factors through the displayed chain*

$$(D^-, D^+) \longrightarrow W \longrightarrow R \longrightarrow S.$$

The seal boundary exposes no quotient cut, host real equality, selected supremum, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier seal boundary exactness`

Proof. Start with the packet $L = (D^-, D^+, W, R, S, H, C, P, N)$ of Definition 404.1. The only seal-facing row is S, and its only regular handoff input is R.

Use Definition 404.7 to identify the window read feeding R. Each visible precision reaches a finite lower and upper dyadic pair in W.

Apply Definition 404.5. It gives the same factorization from the dyadic ledgers through W and R to S, and its non-escape clause excludes quotient cuts, host equality, selected suprema, and ambient completeness. □

Theorem 404.9 (LocatedCut paired ledger coherence)**.** *For every accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet* $L = (D^-, D^+, W, R, S, H, C, P, N)$*, the lower dyadic ledger* D^- *and upper dyadic ledger* D^+ *are transported as one paired located-interval row. Componentwise* hsame *transport and the displayed* Cont *routes preserve the common precision window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, the* $\mathsf{Real}^{\uparrow}$ *seal row* S*, the* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier ledger pair coherence`

Proof. Start with the carrier of Definition 404.1. The two dyadic ledgers occur as adjacent coordinates of the same finite BHist packet, and the window row W is the only row that exposes them to consumers.

Use Definition 404.2 for the ledger-stability clauses. They move D^- and D^+ along the stored hsame rows, while the displayed Cont routes replay the same finite window reads.

Apply Definition 404.4 and Definition 404.6. Each visible precision row is therefore carried as a lower-upper pair with its endpoint names, provenance, handoff route, and local certificate attached.

The transported object is a paired located interval row, not a quotient cut or host equality datum. The exclusions are exactly the non-escape exclusions recorded in the carrier and in Definition 404.8. □

Theorem 404.10 (LocatedCut window handoff totality)**.** *Every visible unary precision window in an accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff route. The route reads its lower and upper dyadic entries from the same stream window, transports them through the paired ledger row, and reaches the regular rational handoff without quotient cuts, selected suprema, host real equality, or* Classical.choice*.*

Proof. Fix a visible unary precision row in W. By Definition 404.7, the row displays a finite lower dyadic entry from D^- and a finite upper dyadic entry from D^+.

Use Definition 404.9. The two endpoint entries travel together as the paired located interval row, so the precision window does not split into unrelated lower and upper consumers.

Now apply Definition 404.3. The handoff row R is computed from the displayed located window and the stored transport and continuation routes. Thus every visible window supplies the regular rational handoff route demanded by the $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ obligations.

Finally, Definition 404.5 excludes any alternate route through quotient cuts, selected suprema, host real equality, or classical choice. □

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier window handoff totality`

Theorem 404.11 (LocatedCut common-window refinement)**.** *For any two visible unary precision windows of an accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet, there is a displayed stronger window row whose lower and upper dyadic ledger reads refine both windows at once. The common row transports the paired ledger entry through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *provenance, supplies one* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff route, and reaches the* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$(D^-, D^+) \longrightarrow W \longrightarrow R \longrightarrow S.$$

No quotient cut, selected supremum, host real equality, ambient completeness principle, or Classical.choice *row is exposed by the refinement.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier common window refinement`

Proof. Start with the two visible unary precision windows. By Definition 404.7, each window reads finite lower and upper dyadic entries from D^- and D^+ inside the displayed stream-window ledger.

Refine the two reads by taking the stronger visible window row already present in the accepted packet. Apply Definition 404.9. The lower and upper endpoints remain a single paired ledger row, and the same hsame and Cont data transport that row for both original windows.

Now apply Definition 404.10. The common window feeds one $\mathsf{RegSeqRat}^{\uparrow}$ handoff route before any real-facing seal is read.

Finally use Definition 404.5. The route can end at the displayed $\mathsf{Real}^{\uparrow}$ seal row only through the finite provenance chain, so quotient cuts, selected suprema, host equality, ambient completeness, and classical choice remain outside the packet. □

Theorem 404.12 (LocatedCut Real seal factorization package)**.** *An accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet assembles a finite* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *obligation package consisting of the carrier, classifier transport, paired dyadic ledger coherence, located-window exactness, common-window refinement, window handoff totality, and real seal-boundary exactness. Consequently every* $\mathsf{Real}^{\uparrow}$ *seal-facing read factors through*

$$(D^-, D^+) \longrightarrow W \longrightarrow R \longrightarrow S$$

with its displayed BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *provenance.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier real seal factorization package`

Proof. The carrier and finite obligation rows are supplied by Definition 404.1 and Definition 404.2. These rows name the two dyadic ledgers, stream-window row, regular rational handoff, real seal row, transport rows, continuation rows, provenance, and local certificate.

Apply Definition 404.6 and Definition 404.9. They bind classifier movement to componentwise finite-row transport and keep the lower and upper ledgers as one located interval row.

Next apply Definition 404.7, Definition 404.11, and Definition 404.10. Every visible unary precision window supplies the finite dyadic pair used by the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and any pair of visible windows has a common finite refinement before the real seal is reached.

Finally apply Definition 404.8. The seal row is reached only through the displayed chain from dyadic ledgers to W, then to R, then to S. This is exactly the finite obligation package, and it contains no quotient cut, host real equality, selected supremum, ambient completeness principle, or classical choice row. □

Theorem 404.13 (LocatedCut standard bridge boundary)**.** *Every public standard located-cut reading exported by an accepted* $\mathsf{LocatedCut}^{\uparrow}$ *package factors through the finite route*

$$(D^-, D^+) \longrightarrow W \longrightarrow R \longrightarrow S$$

where D^- and D^+ are the lower and upper dyadic ledgers, W is the $\mathsf{StreamName}^{\uparrow}$ *window row, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and S is the* $\mathsf{Real}^{\uparrow}$ *seal. The bridge boundary retains the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *provenance and exports no quotient cut, selected supremum, host real equality, ambient completeness principle, or* Classical.choice *row.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier standard bridge boundary`

Proof. Begin with the carrier obligations of Definition 404.2. They name the two dyadic ledgers, the stream window row, the regular rational handoff, the real seal row, and the visible transport, continuation, package, and local naming rows.

Next use located-window exactness from Definition 404.7. Each standard located-cut read at a visible precision is represented by a finite pair of lower and upper dyadic entries inside the same window row W.

Apply window handoff totality from Definition 404.10. It routes those displayed windows into the $\mathsf{RegSeqRat}^{\uparrow}$ handoff without adding a quotient cut or a selected supremum.

Finally apply the real seal factorization package of Definition 404.12. The handoff reaches the $\mathsf{Real}^{\uparrow}$ seal only through the displayed provenance rows, so the standard boundary is exactly the stated route and has no host real equality, ambient completeness, or classical choice coordinate. □

Theorem 404.14 (LocatedCut scoped kernel route)**.** *Every consumer route of an accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet is exhausted by the lower dyadic ledger* D^{-}*, the upper dyadic ledger* D^{+}*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, the* $\mathsf{Real}^{\uparrow}$ *seal* S*, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *rows. No route can pass through a quotient cut, host real equality, selected supremum, ambient completeness row, or classical choice field.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier scoped kernel route`

Proof. Project the carrier of Definition 404.1. Its visible coordinates are exactly the two dyadic ledgers, the stream-window row, the regular rational handoff, the real seal, transports, continuations, package provenance, and local naming row.

Use Definition 404.7 and Definition 404.9. They show that every visible precision window reads a lower-upper dyadic pair from the same packet and transports it as one located interval row.

Then apply Definition 404.10 and Definition 404.12. The handoff and seal routes are already the displayed chain from (D^{-}, D^{+}) through W and R to S, with the same hsame, Cont, Pkg, and NameCert provenance. □

Theorem 404.15 (LocatedCut obligation scope package)**.** *The* $\mathsf{LocatedCut}^{\uparrow}$ *scoped* NameCert *surface consists exactly of the carrier of Definition 404.1, classifier transport, paired ledger coherence, located-window exactness, handoff totality, and seal-boundary exactness. This package binds the lower and upper dyadic ledgers,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows as the complete kernel scope for located-cut consumers.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier obligation scope package`

Proof. Start with carrier habitation and classifier movement. The carrier is Definition 404.1, and Definition 404.6 states that transport is componentwise over the finite rows named there.

Next package the dyadic and window obligations. The paired ledger coherence theorem Definition 404.9 keeps the lower and upper ledgers attached, while Definition 404.7 identifies the finite window entries consumed at each visible precision.

Finally package the handoff and seal obligations. The window handoff totality theorem Definition 404.10, the seal-boundary exactness theorem Definition 404.8, and the scoped kernel route Definition 404.14 exhaust the real-facing route without adding quotient cuts, host equality, selected suprema, ambient completeness, or classical choice. □

Theorem 404.16 (LocatedCut public NameCert export)**.** *The carrier, classifier transport, paired ledger coherence, located-window exactness, handoff totality, seal-boundary exactness, and scoped kernel route assemble the public* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *export over the lower and upper dyadic ledgers,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Every downstream located-real consumer receives this public export as a finite BEDC packet, rather than as a quotient cut, selected supremum, host real equality, ambient order-completeness principle, or classical choice object.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier public namecert export`

Proof. Begin with Definition 404.15. It packages the carrier, classifier transport, paired dyadic ledgers, located windows, regular rational handoff, real seal, transport, continuation, package, and local naming rows as the complete scoped kernel surface.

Apply the seal factorization package of Definition 404.12. It routes real-facing reads through the displayed chain from (D^-, D^+) to W, then to R, and then to S with the same BHist, hsame, Cont, Pkg, and NameCert provenance.

Finally use Definition 404.14. The public export is therefore a repacking of the scoped package and seal factorization rows, and it exposes no coordinate for quotient cuts, selected suprema, host real equality, ambient completeness, or classical choice. □

Theorem 404.17 (LocatedCut window monotonic refinement)**.** *Let an accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet refine its* $\mathsf{StreamName}^{\uparrow}$ *window to a narrower lower-upper dyadic interval inside the same located-cut ledger. The refined window preserves the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row and the* $\mathsf{Real}^{\uparrow}$ *seal boundary through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance as the coarser window.*

In particular, narrowing the finite interval changes only the visible lower-upper dyadic window row. It does not introduce a quotient cut, selected supremum, host real equality, ambient completeness row, or classical choice datum.

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier window monotonic refinement`

Proof. Begin with located-window exactness from Definition 404.7. It represents every visible precision as a finite lower-upper dyadic pair inside the displayed $\mathsf{StreamName}^{\uparrow}$ window row.

Dyadic interval exhaustion supplies the narrower window as another finite lower-upper pair in the same ledger. Ledger-pair coherence from Definition 404.9 keeps the lower and upper rows attached to the same packet under componentwise hsame transport.

Apply common-window refinement from Definition 404.11. The refined and coarser windows route to the same $\mathsf{RegSeqRat}^{\uparrow}$ handoff row through the displayed Cont paths, with unchanged Pkg provenance and local NameCert row.

Finally use seal-boundary exactness from Definition 404.8. Since the real seal consumes the handoff row reached by the displayed finite route, the narrower window preserves the same $\mathsf{Real}^{\uparrow}$ boundary and adds no quotient, selected supremum, host equality, ambient completeness, or classical choice coordinate. □

Theorem 404.18 (LocatedCut interval witness extraction)**.** *For every accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet and every visible unary precision row in its* $\mathsf{StreamName}^{\uparrow}$ *window ledger, the public read exposes a lower dyadic witness, an upper dyadic witness, a common* $\mathsf{StreamName}^{\uparrow}$ *window, a* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff route, a* $\mathsf{Real}^{\uparrow}$ *seal boundary, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *provenance. The extraction reads only these finite interval-witness rows and never replaces them by a quotient cut, selected supremum, host real equality, ambient completeness principle, or classical choice field.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier interval witness extraction`

Proof. Begin with located-window exactness from Definition 404.7. It identifies each visible unary precision row with a finite lower-upper dyadic interval in the $\mathsf{StreamName}^{\uparrow}$ window ledger.

Apply dyadic interval exhaustion and paired ledger coherence. These supply the lower dyadic witness and upper dyadic witness while keeping both endpoints attached to the same displayed packet and the same componentwise hsame transport.

Use common-window refinement from Definition 404.11. It places the two endpoint witnesses in a common $\mathsf{StreamName}^{\uparrow}$ window and routes that window to the same $\mathsf{RegSeqRat}^{\uparrow}$ handoff through the visible Cont rows.

Finally apply seal-boundary exactness from Definition 404.8. The $\mathsf{Real}^{\uparrow}$ seal consumes the displayed handoff with unchanged BHist, hsame, Cont, Pkg, and NameCert provenance, so the extracted interval witness cannot escape to quotient, supremum, host equality, ambient completeness, or choice data. □

Theorem 404.19 (LocatedCut regular Cauchy bridge source)**.** *For every accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet, the finite source used by the* $\mathsf{RegSeqRat}^{\uparrow}$ *bridge is exactly the displayed route*

$$(D^-, D^+) \longrightarrow W \longrightarrow R.$$

Here D^- and D^+ are the lower and upper dyadic ledgers, W is the $\mathsf{StreamName}^{\uparrow}$ *window row that reads a common located interval, and R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row. The bridge source retains the same* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *provenance and exports no quotient cut, selected supremum, host equality, trichotomy, ambient completeness row, or classical choice datum.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier regular cauchy bridge source`

Proof. Begin with interval witness extraction from Definition 404.18. Every visible precision exposes a lower dyadic witness, an upper dyadic witness, and a common $\mathsf{StreamName}^{\uparrow}$ window inside the accepted packet.

Apply common-window refinement from Definition 404.11. The refinement keeps the two dyadic ledger entries attached to one window row W under the same BHist, hsame, Cont, Pkg, and local naming provenance.

Use window handoff totality from Definition 404.10. The handoff to $\mathsf{RegSeqRat}^{\uparrow}$ is the row R, and it is reachable only after the displayed lower-upper dyadic pair and the common window have been read.

The exclusions follow from Definition 404.14. The scoped route has no coordinate for quotient cuts, selected suprema, host equality, trichotomy, ambient completeness, or classical choice, so the regular Cauchy bridge source cannot export any of them. □

Theorem 404.20 (LocatedCut Real seal bridge exactness)**.** *For every accepted* $\mathsf{LocatedCut}^{\uparrow}$ *packet, the exact bridge source for the* $\mathsf{Real}^{\uparrow}$ *seal is the finite route*

$$(D^-, D^+) \longrightarrow W \longrightarrow R \longrightarrow S.$$

The row S is reached only after the lower and upper dyadic ledgers have been read through the common $\mathsf{StreamName}^{\uparrow}$ *window W and passed to the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R. Thus the Real seal route is exact over the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{LocatedCut}^{\uparrow}}$ *provenance and excludes quotient cuts, selected suprema, host equality, trichotomy, ambient completeness, and choice.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier real seal bridge exactness`

Proof. Start with Definition 404.19. It supplies the concrete bridge source from (D^-, D^+) through the common window W to the regular Cauchy handoff R.

Next apply the real seal factorization package of Definition 404.12. The seal-facing read factors through the same finite dyadic ledger and window route before it reaches the $\mathsf{Real}^\uparrow$ seal row.

Finally use seal-boundary exactness from Definition 404.8. The seal row S is terminal for this displayed route, so no later consumer can replace the route by a quotient cut, selected supremum, host equality, trichotomy, ambient completeness principle, or choice field. □

Theorem 404.21 (LocatedCut bridge boundary package)**.** *For every accepted* $\mathsf{LocatedCut}^\uparrow$ *packet, the bridge boundary to the* $\mathsf{Real}^\uparrow$ *seal factors through exactly the displayed route*

$$(D^-, D^+) \longrightarrow W \longrightarrow R \longrightarrow S \longrightarrow H, C, P, N.$$

Here D^- and D^+ are the lower and upper dyadic ledgers, W is the common $\mathsf{StreamName}^\uparrow$ *window row, R is the* $\mathsf{RegSeqRat}^\uparrow$ *handoff row, S is the* $\mathsf{Real}^\uparrow$ *seal row, and H, C, P, N are the displayed* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{LocatedCut}^\uparrow}$ *rows. The bridge boundary exports no quotient cut, selected supremum, host equality, trichotomy, ambient completeness, or* Classical.choice *datum.*

Lean4 ✓ `BEDC.Derived.LocatedCutUp.LocatedCutCarrier bridge boundary package`

Proof. Start with located-window exactness and paired ledger coherence, Definition 404.7 and Definition 404.9. They keep every visible precision attached to a finite lower-upper dyadic pair in the same displayed packet.

Use common-window refinement and window handoff totality. The dyadic pair is read through one $\mathsf{StreamName}^\uparrow$ window row W, and that window reaches the $\mathsf{RegSeqRat}^\uparrow$ handoff row R without adding a quotient cut or selected supremum.

Apply the regular Cauchy bridge source and Real seal bridge exactness, Definition 404.19 and Definition 404.20. These place the bridge source on the route from (D^-, D^+) through W and R to the $\mathsf{Real}^\uparrow$ seal row S.

Finally attach the structural rows H, C, P, N. Seal-boundary exactness and the public NameCert export keep those rows on the same finite route, so no quotient cut, selected supremum, host equality, trichotomy, ambient completeness, or classical choice field can be read from the bridge boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCut}^\uparrow}$.

Constructive story: A $\mathsf{LocatedCut}^\uparrow$ packet is generated from lower and upper dyadic interval ledgers, located $\mathsf{StreamName}^\uparrow$ precision windows, a $\mathsf{RegSeqRat}^\uparrow$ handoff, a $\mathsf{Real}^\uparrow$ seal-facing row, displayed transport and continuation rows, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedCut}^\uparrow}$, maturePackageClosed)

Scope closed: Definition 404.16 binds the scoped package and seal factorization rows as the public $\mathsf{NameCert}_{\mathsf{LocatedCut}^\uparrow}$ export, and Definition 404.21 binds the bridge boundary through lower and upper dyadic ledgers, StreamName windows, RegSeqRat handoff, Real seal, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedCut}^\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient cut construction, host real equality, selected suprema, ambient order completeness, uniqueness of represented reals, or bridge checking.

Upgrade path: Formal and bridge verification remain the route from the mature displayed dyadic ledger treatment to checked theorem, axiom-clean, and bridge-checked status over the same window, handoff, seal, package, and naming rows.

Chapter 405

A Concrete Naming Certificate for $\mathsf{CofinalSubsequence}^{\uparrow}$

The $\mathsf{CofinalSubsequence}^{\uparrow}$ interface packages the discovery-channel selector packet used when regular Cauchy data are consumed through a cofinal subsequence. Following Bishop and Bridges, *Constructive Analysis*, 1985, the selector is a displayed finite row: it records only inspected precision requests, their chosen indices, monotonicity checks, cofinal witnesses for the inspected thresholds, and the regular rational observations carried through those rows. It does not choose a host-level infinite subsequence, identify quotient streams, or appeal to ambient completeness.

Its dependency list is $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert. The selector packet consumes the finite-window route through chapter 126, chapter 301, chapter 291, and chapter 38, so its visible rows are tied to the real L10 siblings rather than to a kernel-only island.

It also consumes the regular-Cauchy subsequence carrier boundary of chapter 381 and restricts it to the finite selector ledger $(S, \phi, W, D, R, E, H, C, P, N)$. Thus every cofinal read is a displayed NameCert row rather than a host subsequence function.

Definition 405.1 (CofinalSubsequence carrier)**.** *A* $\mathsf{CofinalSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, \phi, W, D, R, E, H, C, P, N)$$

with the following visible rows:

1. *S is the accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose precision windows may be inspected;*
2. *ϕ is a unary selector row assigning each displayed precision request to a selected source index, together with monotonicity and cofinality witnesses for the inspected threshold rows;*
3. *W records the selected finite* $\mathsf{StreamName}^{\uparrow}$ *windows before and after applying ϕ;*
4. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, comparison, and precision observations attached to the selected windows;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that reads the selected rational observations as regular rational data;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed after the selected windows, dyadic observations, and regular rational handoff have been displayed;*

7. *H records the displayed* hsame *transports for source, selector, window, observation, regularity, and seal rows;*
8. *C records the* Cont *routes through the same rows;*
9. *P is the* Pkg *provenance over the visible dependencies;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalSubsequence}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through these rows and their transported finite read paths. In particular, ϕ is a unary finite selector ledger, not a host subsequence function.

Lean4 ✓ `BEDC.Derived.CofinalSubsequenceUp.CofinalSubsequenceTasteGate single carrier alignment`

Theorem 405.2 (CofinalSubsequence NameCert obligations)**.** *Every accepted* $\mathsf{CofinalSubsequence}^{\uparrow}$ *carrier of Definition 405.1 carries the following five NameCert obligation rows:*

1. *carrier habitation: the packet stores the source row, unary selector row, selected finite windows, dyadic observations, regular rational handoff, real seal, transport rows, continuation rows, package provenance, and local naming row;*
2. *selector discipline: the row ϕ is unary, monotone on displayed precision requests, and cofinal on every inspected threshold row;*
3. *finite-window exactness: each selected* $\mathsf{StreamName}^{\uparrow}$ *window is read from S only along ϕ, and its dyadic observation row D is transported with that window;*
4. *regular rational handoff: the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R consumes exactly the selected window and dyadic observation rows before any* $\mathsf{Real}^{\uparrow}$ *seal read is exposed;*
5. *non-escape: the displayed* hsame, Cont, Pkg, *and* NameCert *rows exhaust the provenance of the packet, so no quotient stream, host sequence equality, choice-selected subsequence, or completeness datum is exported.*

Lean4 ✓ `BEDC.Derived.CofinalSubsequenceUp.CofinalSubsequenceCarrier namecert obligations`

Proof. Carrier habitation is obtained by projecting the coordinates of Q. The finite history row names the source, selector, selected windows, dyadic observations, regular rational handoff, seal, and provenance rows in one packet.

Selector discipline is read from the ϕ coordinate. Its domain is the displayed unary precision ledger, and its stored comparison rows certify monotonicity and cofinality only for inspected thresholds.

Finite-window exactness follows by replaying the continuation route from S through ϕ to W. The dyadic row D is attached to that selected window, so the endpoint, radius, comparison, and precision observations move with the same finite route.

The regular rational handoff is the projection to R. Since R is stored after W and D, every regular rational read is reached through the selected window and its dyadic observation ledger before the real seal row E is available.

Finally inspect the classifier. It contains no coordinate for quotient-stream equality, host sequence equality, an externally chosen infinite subsequence, or ambient completeness, and the rows H, C, P, and N account for all visible transport and provenance. □

Theorem 405.3 (CofinalSubsequence RegSeqRat consumer boundary)**.** *Let $Q = (S, \phi, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CofinalSubsequence}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer*

read from Q factors through the displayed cofinal selector ϕ, the selected finite $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R, the* $\mathsf{Real}^{\uparrow}$ *seal E, and the visible* hsame, Cont, Pkg, *and* NameCert *rows H, C, P, and N. Thus the consumer boundary is a finite cofinal selector certificate over regular Cauchy data, not a quotient stream, host sequence equality, choice-selected subsequence, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CofinalSubsequenceUp.CofinalSubsequenceCarrier regseqrat consumer boundary`

Proof. Start with a consumer read from the accepted carrier. The source row S can be inspected only through the unary selector coordinate ϕ, because no other coordinate names a selected index.

Apply the selector and finite-window clauses of Definition 405.2. They force the selected $\mathsf{StreamName}^{\uparrow}$ window W and its $\mathsf{DyadicRatCore}^{\uparrow}$ observation row D to travel along the same monotone cofinal route.

Next use the regular rational handoff clause. A $\mathsf{RegSeqRat}^{\uparrow}$ consumer reaches R only after the selected window and dyadic observation rows have been displayed, and a $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumer reaches the real-facing seal only through the same R and E rows.

The remaining coordinates are provenance rows. The displayed hsame transports, Cont routes, Pkg certificate, and local NameCert row exhaust the consumer-visible ledger, so the carrier provides no further dependency outside the listed finite selector packet. □

Theorem 405.4 (CofinalSubsequence selector transport exactness)**.** *Let $Q = (S, \phi, W, D, R, E, H, C, P, N)$ and $Q' = (S', \phi', W', D', R', E', H', C', P', N')$ be accepted* $\mathsf{CofinalSubsequence}^{\uparrow}$ *carriers. If the source row, unary selector row, selected finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows are transported componentwise by the displayed* hsame *coordinates, then Q and Q' determine the same accepted cofinal selector packet for every classifier-facing consumer read.*

Lean4 ✓ `BEDC.Derived.CofinalSubsequenceUp.CofinalSubsequenceCarrier selector transport exactness`

Proof. Project the accepted carriers to the rows listed in Definition 405.1. The classifier has no coordinate outside the source, selector, window, observation, handoff, seal, transport, continuation, package, and naming rows.

Use the selector discipline and finite-window clauses of Definition 405.2. They move the source row through the unary selector before any selected window is read, and they attach the dyadic observation row to that same selected window.

Transport the handoff and seal rows along the displayed hsame coordinates. The Cont rows keep the consumer route ordered from source to selector, from selector to window, from window to dyadic observation, and then to the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and $\mathsf{Real}^{\uparrow}$ seal.

Finally apply the consumer boundary of Definition 405.3. Since every public read is exhausted by those transported rows, the accepted cofinal selector packet is unchanged at the classifier-facing surface. □

Theorem 405.5 (CofinalSubsequence window handoff exactness)**.** *For every accepted* $\mathsf{CofinalSubsequence}^{\uparrow}$ *carrier $Q = (S, \phi, W, D, R, E, H, C, P, N)$ and every displayed precision request in its finite ledger, the selected* $\mathsf{StreamName}^{\uparrow}$ *window is reached through the unary cofinal selector ϕ, then its* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row is read, and only then the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R is available to a downstream consumer. No* $\mathsf{Real}^{\uparrow}$ *seal row is read before this selected-window and regular-rational handoff route has been displayed.*

Lean4 ✓ `BEDC.Derived.CofinalSubsequenceUp.CofinalSubsequenceCarrier window handoff exactness`

Proof. Start from a displayed precision request in the carrier. The selector discipline row of Definition 405.2 forces the request to pass through the unary selector ϕ and its inspected monotonicity and cofinality witnesses.

Apply the finite-window exactness row. It reads the selected $\mathsf{StreamName}^{\uparrow}$ window from S along ϕ and carries the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint, radius, comparison, and precision observations with that selected window.

Next use the regular rational handoff row of the same theorem. The $\mathsf{RegSeqRat}^{\uparrow}$ coordinate R consumes exactly the selected window and dyadic observation rows, so the handoff cannot be reached through an unselected stream window.

The consumer boundary of Definition 405.3 then places the $\mathsf{Real}^{\uparrow}$ seal after R and E. Thus every seal-facing read follows the selected-window, dyadic-observation, and regular-rational handoff route first. □

Theorem 405.6 (CofinalSubsequence public export package)**.** *The carrier of Definition 405.1, the NameCert obligations of Definition 405.2, the* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer boundary of Definition 405.3, the selector transport exactness of Definition 405.4, and the window handoff exactness of Definition 405.5 export one public finite selector surface through*

$$S, \phi, W, D, R, E, H, C, P, N.$$

Every downstream $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer receives the selected finite windows, dyadic observation rows, regular rational handoff, real seal, displayed transports, continuation routes, package provenance, and local naming row through that surface. It receives no quotient stream, host sequence equality, chosen infinite subsequence, or ambient completeness object.*

Proof. Start with the carrier inventory. The public coordinates are exactly $S, \phi, W, D, R, E, H, C, P, N$, and the NameCert obligations specify how each of these rows is admitted and routed.

The consumer boundary and selector transport exactness then identify the only route available to downstream readers. A consumer must pass from the source row through the unary selector, selected windows, dyadic observations, regular rational handoff, and real seal, with the visible transport and continuation rows preserving that order.

Finally apply the window handoff exactness theorem. It places every $\mathsf{RegSeqRat}^{\uparrow}$ handoff after the selected window and dyadic observation rows and places the real-facing seal after that handoff. Since the carrier has no coordinate for the excluded objects, the public export is precisely the finite selector surface listed above. □

Lean4 ✓ `BEDC.Derived.CofinalSubsequenceUp.CofinalSubsequenceCarrier public export package`

Theorem 405.7 (CofinalSubsequence finite-selector bridge schema)**.** *The public finite selector surface*

$$S, \phi, W, D, R, E, H, C, P, N$$

bridges the concrete $\mathsf{CofinalSubsequence}^{\uparrow}$ *carrier of Definition 405.1 to the downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer schema. Every read is routed through the unary selector, selected* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transports,* Cont *routes,* Pkg *provenance, and the local* NameCert *row.*

Proof. Begin with the local NameCert obligations. They admit the carrier rows and bind the unary selector, selected finite windows, dyadic observations, regular rational handoff, real seal, transports, routes, provenance, and local naming row as one finite packet.

Apply the $\mathsf{RegSeqRat}^{\uparrow}$ consumer boundary, selector transport exactness, and window handoff exactness. Together these force every downstream read to pass through the unary selector and selected windows before the dyadic observation and regular rational handoff are available.

Finally apply the public export package. It identifies the finite selector surface $S, \phi, W, D, R, E, H, C, P, N$ as the only public surface for $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumers. Since the carrier has no coordinate for a quotient stream, host sequence equality, selected infinite subsequence, or ambient completeness object, the bridge exports none of them. □

Lean4 ✓ `BEDC.Derived.CofinalSubsequenceUp.CofinalSubsequenceCarrier bridge selector schema`

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalSubsequence}^{\uparrow}$ packet is generated from regular Cauchy or regular rational source data, a displayed unary monotone cofinal selector row, selected finite stream windows, dyadic observation rows, a regular rational handoff, a real seal, and visible provenance.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalSubsequence}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 405.1, Definition 405.2, Definition 405.3, Definition 405.4, Definition 405.5, Definition 405.6, and Definition 405.7 bind the bridged finite selector surface through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient stream equality, host sequence equality, selected infinite subsequences, uniqueness of completion limits, ambient completeness, or bridge checking.

Upgrade path: No further paper-side theory upgrade remains; Lean verification and bridge checking stay on the formal axis.

Chapter 406

A Concrete Naming Certificate for $\mathsf{CauchySequenceSpace}^{\uparrow}$

The $\mathsf{CauchySequenceSpace}^{\uparrow}$ interface records the finite naming surface for the space of $\mathsf{CauchySequence}^{\uparrow}$ names itself. Following Bishop and Bridges, *Constructive Analysis*, and Bourbaki, *General Topology*, the packet keeps a displayed family of regular rational names together with the finite schedules and tolerance ledgers that make common Cauchy windows inspectable. It sits between $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RealCauchyCompletion}^{\uparrow}$, and it exports only BHist, hsame, Cont, Pkg, and local NameCert rows.

This dependency is the concrete sibling route: the displayed regular-family row is consumed from chapter 301, the schedule row from chapter 126, and the completion handoff row from chapter 360.

The equality-facing finite-window classifier of chapter 1820 is consumed when a $\mathsf{CauchySequenceSpace}^{\uparrow}$ comparison is read as a common-window comparison before the $\mathsf{RealCauchyCompletion}^{\uparrow}$ handoff.

Definition 406.1 (CauchySequenceSpace carrier surface)**.** *A* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

with the following visible rows:

1. *F is a displayed finite family of* $\mathsf{RegSeqRat}^{\uparrow}$ *name rows;*
2. *σ is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that selects the inspected name and window rows;*
3. *W is a* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyModulus}^{\uparrow}$ *cofinal-window ledger for the family F;*
4. *ϵ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the inspected windows;*
5. *Q is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff row reached from the same family, schedule, window, and tolerance data;*
6. *H records componentwise* hsame *transports for the family, schedule, cofinal-window ledger, tolerance ledger, and completion handoff;*
7. *C records the displayed* Cont *routes by which consumers inspect those rows;*
8. *P is the* Pkg *provenance over the displayed regular names, stream schedule, Cauchy window data, dyadic tolerances, and completion handoff;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ *row.*

The carrier contains no quotient of Cauchy names, no selected limiting name, no host completion equality, and no ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.TasteGate.CauchySequenceSpaceTasteGate single carrier alignment`

Theorem 406.2 (CauchySequenceSpace NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier habitation by a displayed family of* $\mathsf{RegSeqRat}^{\uparrow}$ *names, a* $\mathsf{StreamName}^{\uparrow}$ *schedule, a* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyModulus}^{\uparrow}$ *cofinal-window ledger, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff row, and the displayed* hsame, Cont, Pkg, *and local naming rows;*
2. *classifier by common finite Cauchy windows, comparing two accepted packets only through windows selected by their schedules and justified by the same visible cofinality ledger shape;*
3. *schedule and cofinality stability under the stored componentwise* hsame *transports and displayed* Cont *routes;*
4. *dyadic tolerance exactness, stating that every accepted window comparison uses the tolerance row visible in the packet;*
5. *completion handoff non-escape, stating that the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *row is reached only through the displayed family, schedule, cofinal-window, tolerance, transport, continuation, package, and naming rows.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier namecert obligation surface`

Proof. Carrier habitation is projection of Definition 406.1. The displayed family, schedule, cofinal-window ledger, tolerance ledger, completion handoff, transport, continuation, package, and naming rows are coordinates of the same finite BHist packet.

The classifier is by common finite windows. A comparison first reads the scheduled $\mathsf{RegSeqRat}^{\uparrow}$ rows, then the cofinal-window evidence supplied by W, and finally the dyadic tolerance row ϵ attached to those windows.

Schedule stability is componentwise. Move the family, schedule, window ledger, tolerance ledger, and completion handoff along H, and replay only the consumer routes recorded in C.

Dyadic tolerance exactness and handoff non-escape follow from the absence of any quotient, selected limit, host equality, or ambient completeness coordinate. The completion row Q is therefore a finite handoff from the named Cauchy-window surface, not a separate completion object. □

Theorem 406.3 (CauchySequenceSpace completion handoff)**.** *Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer read exported by an accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family row, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyModulus}^{\uparrow}$ *cofinal-window ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the stored* hsame, Cont, Pkg, *and* NameCert *provenance rows. Thus the space of Cauchy names reaches completion only through the visible finite naming certificate, not through quotient-name equality, a selected representative, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier completion handoff`

Proof. Start with an accepted carrier $S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$. The only family coordinate is F, the only schedule coordinate is σ, and the only Cauchy-window and tolerance coordinates are W and ϵ.

Use Definition 406.2. Its classifier, stability, and exactness rows force every inspected window to remain attached to the displayed schedule, cofinality ledger, dyadic tolerance ledger, and provenance rows.

The completion read reaches Q only after those rows have been read. Since the carrier has no quotient-name equality, selected representative, host real equality, or ambient completeness coordinate, the listed rows exhaust the handoff boundary. □

Theorem 406.4 (CauchySequenceSpace regular-window factorization)**.** *Let S be an accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N).$$

Every completion-facing consumer read of Q factors through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ *family row F, the* $\mathsf{StreamName}^{\uparrow}$ *schedule σ, the cofinal Cauchy-window ledger W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row ϵ, the componentwise* hsame *transport row H, the displayed* Cont *read routes C, the package row P, and the local* NameCert *row N. No quotient-name equality, selected representative, host real equality, or ambient completeness row participates in this route.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier regular window factorization`

Proof. Project the accepted carrier by Definition 406.1. This identifies the only available coordinates as the displayed family F, schedule σ, window ledger W, tolerance row ϵ, completion handoff Q, transport row H, continuation row C, package row P, and local naming row N.

Use Definition 406.2 for the common-window classifier, schedule and cofinality stability, dyadic tolerance exactness, and completion handoff non-escape rows. These rows keep every inspected regular-name comparison on the same scheduled finite windows and on the same displayed dyadic tolerance data.

Apply Definition 406.3 to the terminal consumer read of Q. The route already reaches the completion handoff only through the named regular family, schedule, Cauchy-window ledger, dyadic tolerance row, transports, continuations, package provenance, and local certificate.

Finally, the carrier projection lists no quotient-name equality, selected representative, host real equality, or ambient completeness coordinate. Thus there is no alternate completion-facing route outside the displayed finite regular-window surface. □

Theorem 406.5 (CauchySequenceSpace common-window classifier transport)**.** *Let $S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$ be an accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Transporting S along its displayed* hsame *row H and reading it only through the displayed* Cont *row C preserves the common-window classifier on the same* $\mathsf{RegSeqRat}^{\uparrow}$ *family F,* $\mathsf{StreamName}^{\uparrow}$ *schedule σ,* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyModulus}^{\uparrow}$ *cofinal ledger W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row ϵ, completion handoff Q, package row P, and local* NameCert *row N.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCommonWindowClassifierTransport`

Proof. Project the tuple by Definition 406.1. The family, schedule, cofinal ledger, tolerance ledger, completion handoff, transport row, continuation row, package row, and local naming row are the whole carrier inventory.

Use the classifier and stability clauses of Definition 406.2. They say that comparisons are made only on common finite Cauchy windows selected by σ and justified by the displayed cofinality row W.

The completion handoff theorem keeps the downstream read on the same packet rows. Hence transporting by H and reading by C cannot change the classifier into a quotient-name comparison, a selected representative comparison, a host real equality, or an ambient completeness assertion. □

Theorem 406.6 (CauchySequenceSpace cofinal schedule stability)**.** *For an accepted packet $S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$ of* $\mathsf{CauchySequenceSpace}^{\uparrow}$*, every cofinal Cauchy-window request admitted by W remains stable under the* $\mathsf{StreamName}^{\uparrow}$ *schedule σ, the componentwise* hsame *transports H, and the displayed* Cont *routes C. The accepted comparison stays on the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family F, the* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyModulus}^{\uparrow}$ *ledger W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row ϵ, the handoff row Q, the package row P, and the local* NameCert *row N.*

Proof. Begin with a cofinal request in W. By the carrier definition, W is stored together with the schedule σ and the family F, so the request has no independent schedule coordinate.

Apply the schedule and cofinality stability row of Definition 406.2. The row moves F, σ, W, ϵ, and Q only componentwise along H and replays only the consumer routes recorded in C.

Finally use Definition 406.4. It identifies the same family, schedule, cofinal ledger, tolerance ledger, transport, continuation, package, and naming rows as the entire completion-facing route, so stability is a property of the displayed packet and not of any hidden completion object. □

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier cofinal schedule stability`

Theorem 406.7 (CauchySequenceSpace dyadic tolerance ledger exactness)**.** *Let $S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$ be an accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Every accepted comparison in the common-window classifier uses exactly the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row ϵ stored beside the* $\mathsf{RegSeqRat}^{\uparrow}$ *family F,* $\mathsf{StreamName}^{\uparrow}$ *schedule σ,* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyModulus}^{\uparrow}$ *ledger W, completion handoff Q,* hsame *row H,* Cont *row C,* Pkg *row P, and* NameCert *row N.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier dyadic tolerance ledger exactness`

Proof. The tolerance coordinate of the carrier is the single row ϵ. There is no second dyadic ledger, host tolerance, quotient-name tolerance, or ambient completeness tolerance in Definition 406.1.

Use the dyadic tolerance exactness clause of Definition 406.2. It attaches every accepted window comparison to the tolerance row visible in the same packet.

The completion handoff theorem then carries that exact row to Q together with F, σ, W, H, C, P, and N. Thus the tolerance ledger consumed by completion is precisely ϵ, and no hidden tolerance source participates in the route. □

Theorem 406.8 (CauchySequenceSpace limit-seal factorization)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Any* $\mathsf{Real}^{\uparrow}$ *limit-seal consumer read of the completion handoff row Q factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family F, the* $\mathsf{StreamName}^{\uparrow}$ *schedule σ, the* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyModulus}^{\uparrow}$ *cofinal ledger W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row ϵ, the completion handoff Q, the* hsame *transport row H, the displayed* Cont *routes C, the* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ *row N.*

The read cannot use quotient-name equality, a selected representative, host real equality, or ambient completeness outside the displayed finite packet.

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier limit seal factorization`

Proof. Project the carrier surface of Definition 406.1. The rows $F, \sigma, W, \epsilon, Q, H, C, P, N$ are the whole accepted packet.

Use the NameCert obligation surface of Definition 406.2. It supplies common-window classification, schedule stability, cofinality stability, dyadic tolerance exactness, and completion handoff non-escape for that same packet.

Apply Definition 406.4, Definition 406.5, Definition 406.6, and Definition 406.7. These results keep the read on the displayed regular family, schedule, cofinal window ledger, and tolerance ledger before it reaches Q.

Finally, Definition 406.3 identifies the terminal route to completion. Since the carrier lists no quotient-name equality, selected representative, host real equality, or ambient completeness row, the limit-seal consumer read has no hidden coordinate through which to bypass the displayed factorization. □

Theorem 406.9 (CauchySequenceSpace RegSeqRat StreamName Real seal factorization)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *limit-seal consumer route and every* $\mathsf{RealCauchyCompletion}^{\uparrow}$*-facing consumer route factors first through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family* F*, then through the* $\mathsf{StreamName}^{\uparrow}$ *schedule* σ*, then through the cofinal-window ledger* W*, then through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* ϵ*, and only then reaches the completion handoff* Q *and the* $\mathsf{Real}^{\uparrow}$ *seal boundary.*

The resulting route exports no quotient stream, no selected limit, no host real equality, and no ambient completeness coordinate outside $F, \sigma, W, \epsilon, Q, H, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier regseqrat streamname real seal factorization`

Proof. Start with the regular-family route. Apply Definition 406.4 to expose F as the finite rational family through which completion-facing reads must first pass.

Next attach the schedule and cofinal ledger. Use Definition 406.6 to keep σ and W as the only scheduled window surface available to the consumer.

Then read the tolerance and handoff rows. Apply Definition 406.7 for ϵ and Definition 406.14 for Q, so the completion-facing route cannot reach the handoff before the displayed dyadic tolerance row has been consumed.

Finally apply Definition 406.8. It identifies the $\mathsf{Real}^{\uparrow}$ seal boundary with the same displayed packet and excludes quotient streams, selected limits, host real equality, and ambient completeness coordinates from the consumer route. □

Theorem 406.10 (CauchySequenceSpace two-stage window composition)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

and

$$S' = (F', \sigma', W', \epsilon', Q', H', C', P', N')$$

be accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packets. Suppose their regular-family rows, stream schedules, common-window ledgers, dyadic tolerance rows, completion-handoff rows, displayed* hsame *transports, and* Cont *routes are componentwise matched by the local classifier. Then every consumer*

read that first compares S and S' by common finite windows and then hands the result to completion factors through one shared finite window before it reaches Q or Q'.

The factorization uses only F, F', σ, σ', W, W', ϵ, ϵ', Q, Q', H, H', C, C', P, P', and N, N'. It has no route through quotient streams, selected limits, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier two stage window composition`

Proof. First build the common-window spine. Apply Definition 406.4 to each packet to identify the finite regular-family rows, schedules, cofinal ledgers, tolerance rows, handoff rows, transports, continuations, provenance, and local certificates as the whole read surface.

Next transport the classifier. Use Definition 406.5 to move the two accepted packets componentwise along the displayed hsame rows while replaying only the Cont routes already stored in the packets.

The schedule and tolerance rows now have no independent path. Apply Definition 406.6 for σ, σ', W, W' and Definition 406.7 for ϵ, ϵ'. These two rows bind every tolerated comparison to the same shared finite window before any completion-facing handoff is read.

Finally route the result to the terminal handoff through Definition 406.8. The carrier exposes no quotient stream, selected limit, host real equality, or ambient completeness coordinate, so the composed consumer cannot leave the displayed finite rows. □

Theorem 406.11 (CauchySequenceSpace shared-window completion consumer)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

and

$$S' = (F', \sigma', W', \epsilon', Q', H', C', P', N')$$

be accepted CauchySequenceSpace$^{\uparrow}$ *packets whose regular-family rows, schedules, cofinal-window rows, tolerance rows, and handoff rows classify together through the displayed local classifier. Any completion-facing consumer comparison factors through one shared finite Cauchy window before reading Q or Q'. The route uses only F, F', σ, σ', W, W', ϵ, ϵ', Q, Q', H, H', C, C', P, P', and N, N'.*

Proof. First build the shared window surface. Apply Definition 406.4 to both packets, so every completion-facing read is already restricted to the displayed regular-family, schedule, cofinal-window, tolerance, handoff, transport, continuation, package, and local naming rows.

Next transport the comparison through Definition 406.5. The classifier reads the two packets only by their common finite Cauchy windows and the componentwise hsame and Cont rows already stored in the carriers.

The schedule and tolerance rows then fix the consumer window. Use Definition 406.6 for σ, σ', W, W' and Definition 406.7 for ϵ, ϵ'.

Finally apply Definition 406.10. The comparison reaches Q or Q' only after the shared finite window has been read, and the displayed packet contains no quotient stream, selected limit, host real equality, or ambient completeness route. □

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier shared window completion consumer`

Theorem 406.12 (CauchySequenceSpace shared-window determinacy)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

and

$$S' = (F', \sigma', W', \epsilon', Q', H', C', P', N')$$

be accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packets. Suppose they display the same regular-family row* F*, stream schedule* σ*, common-window ledger* W*, dyadic tolerance row* ϵ*, completion handoff* Q*, componentwise transport* H*, continuation route* C*, package provenance* P*, and local naming row* N*, and suppose their common-window classifiers agree on that displayed window. Then the two packets determine the same completion-facing consumer route before any* $\mathsf{Real}^{\uparrow}$ *seal is read.*

The determined route is the route through $F, \sigma, W, \epsilon, Q, H, C, P, N$*. No quotient stream, selected limit, host equality, or ambient completeness coordinate can distinguish the two completion-facing reads.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier shared window determinacy`

Proof. Project both carriers through Definition 406.1. Under the displayed row equalities, the only available completion-facing coordinates in either packet are the same $F, \sigma, W, \epsilon, Q, H, C, P, N$ rows.

Transport the comparison through Definition 406.5. Since the common-window classifiers agree, the accepted packets read the same finite window before any completion handoff is inspected.

Cofinal schedule stability and dyadic tolerance exactness now fix the routed window. Apply Definition 406.6 to the common σ, W rows and Definition 406.7 to the common ϵ row.

Finally use Definition 406.14 and Definition 406.11. The completion handoff remains the displayed Q row, and the shared-window consumer has no path through quotient streams, selected limits, host equality, or ambient completeness. The two completion-facing routes are therefore the same before any $\mathsf{Real}^{\uparrow}$ seal is read. □

Theorem 406.13 (Cauchy sequence space common-window induction)**.** *Let* $S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$ *be an accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Every accepted completion-facing comparison over* S *factors through induction on the displayed common-window ledger* W*, preserving the rows* $F, \sigma, \epsilon, Q, H, C, P, N$ *at each induction step. The induction starts from the empty inspected-window ledger, extends by one displayed common Cauchy window at a time, and replays the comparison only through the stored classifier, transport, and handoff rows.*

The resulting route excludes quotient stream equality, selected representatives, host real equality, countable choice, and ambient completeness. Those objects cannot be induction hypotheses because they are not rows of the carrier surface.

Proof. Project the carrier through Definition 406.1. The displayed rows available to the induction are exactly $F, \sigma, W, \epsilon, Q, H, C, P, N$.

Induct on the finite common-window ledger W. In the base case there is no inspected comparison outside the displayed family and schedule, so the route is the trivial replay through F, σ, H, C, P, N before any completion handoff is read.

For the step case, append one displayed common Cauchy window. Use Definition 406.5, Definition 406.6, and Definition 406.7 to keep the appended window on the same $F, \sigma, \epsilon, H, C, P, N$ rows.

Finally apply Definition 406.11 and Definition 406.14. They reassemble the completion-facing route through Q after the finite induction has consumed W, and the carrier supplies no coordinate for quotient streams, selected representatives, host equality, countable choice, or ambient completeness. □

Theorem 406.14 (CauchySequenceSpace completion handoff stability)**.** *Let* $S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$ *be an accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. The completion handoff row* Q *is invariant under*

the same displayed hsame *transports H and* Cont *routes C that preserve the regular-family row F, schedule σ, common-window ledger W, and dyadic tolerance row ϵ. A transported handoff therefore names the same completion-facing finite packet and not a quotient-name comparison, selected limit, host real equality, or ambient completeness assertion.*

Proof. Read the handoff row from the carrier surface. The row Q is stored beside F, σ, W, ϵ, H, C, P, and N and has no separate host-completion coordinate.

Apply Definition 406.3. It states that downstream completion reads consume the same finite regular-family, schedule, window, tolerance, transport, continuation, provenance, and local certificate rows.

Use Definition 406.5 and Definition 406.6 to identify the transported rows componentwise. The dyadic tolerance row is fixed by Definition 406.7, so the handoff row is stable under exactly the displayed H and C routes. □

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier completion handoff stability`

Theorem 406.15 (CauchySequenceSpace regular family exhaustion)**.** *Every completion-facing consumer read of an accepted* CauchySequenceSpace$^{\uparrow}$ *packet*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

factors through the displayed regular family F, stream schedule σ, common-window ledger W, dyadic tolerance row ϵ, completion handoff Q, transport row H, continuation row C, package provenance P, and local NameCert *row N. No such read factors through quotient streams, selected limits, host real equality, or ambient completeness outside those rows.*

Proof. Begin with the finite packet. The carrier definition exposes exactly $F, \sigma, W, \epsilon, Q, H, C, P, N$ as the data available to a completion-facing consumer.

The window and schedule rows are exhausted by Definition 406.4, Definition 406.5, and Definition 406.6. These theorems keep the consumer on the displayed family, cofinal windows, schedule, transports, and continuations.

The tolerance and terminal rows are exhausted by Definition 406.7, Definition 406.14, and Definition 406.8. Together they force the read through ϵ and Q before any Real$^{\uparrow}$ seal is consumed.

Since no carrier row stores a quotient stream, selected limit, host real equality, or ambient completeness proof, the displayed finite rows are the whole consumer surface. □

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier regular family exhaustion`

Theorem 406.16 (CauchySequenceSpace diagonal-rate compatibility)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted CauchySequenceSpace$^{\uparrow}$ *packet. Any* RealDiagonalCompletion$^{\uparrow}$ *consumer read whose diagonal selector uses the same scheduled* StreamName$^{\uparrow}$ *windows, and any* CauchyRate$^{\uparrow}$ *consumer read whose effective route uses the same cofinal ledger, factor through the same finite rows $F, \sigma, W, \epsilon, Q, H, C, P, N$ before reaching the* Real$^{\uparrow}$ *seal.*

Thus diagonal finite completeness and effective-rate certification consume the displayed Cauchy-window packet itself. They do not introduce quotient streams, selected limits, host real equality, or ambient completeness data parallel to the accepted CauchySequenceSpace$^{\uparrow}$ *carrier.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier diagonal rate compatibility`

Proof. Project the accepted carrier through Definition 406.1. The visible coordinates are exactly the displayed family F, schedule σ, cofinal-window ledger W, tolerance row ϵ, completion handoff Q, transport row H, continuation row C, package row P, and local naming row N.

First route the diagonal selector. Apply Definition 406.4, Definition 406.5, and Definition 406.7 to keep every selected diagonal window on the same σ, W, ϵ rows. Then use Definition 359.12 to read the finite diagonal completion interface through those scheduled windows.

Next route the effective-rate consumer. The same common-window classifier and tolerance ledger exactness bind the cofinal ledger and dyadic tolerance row before any rate read can reach completion-facing data. The exported certificate of Definition 415.18 consumes only that effective route through the displayed regular-family, cofinal-ledger, tolerance, transport, continuation, package, and naming rows.

Finally apply Definition 406.8. It identifies the terminal $\mathsf{Real}^{\uparrow}$ seal route through the same packet coordinates. Since the carrier contains no quotient stream, selected limit, host real equality, or ambient completeness coordinate, neither the diagonal completion consumer nor the effective-rate consumer has a hidden route beyond $F, \sigma, W, \epsilon, Q, H, C, P, N$. □

Theorem 406.17 (CauchySequenceSpace obligation-closure package)**.** *The common-window classifier transport, cofinal schedule stability, dyadic tolerance exactness, completion handoff stability, and diagonal-rate compatibility rows form the obligation-closed* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet over the finite carrier surface of Definition 406.1. The closed obligation surface is exactly the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyModulus}^{\uparrow}$ *cofinal-window ledger,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff row,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceUp StdBridge`
↪ variant `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier obligation closure package`

Proof. The carrier surface and NameCert obligation surface are supplied by Definition 406.1 and Definition 406.2. They list the finite family, schedule, cofinal-window ledger, tolerance ledger, completion handoff, transport, continuation, package, and local certificate rows.

Common-window classifier transport is Definition 406.5. Cofinal schedule stability is Definition 406.6, and dyadic tolerance ledger exactness is Definition 406.7. These rows keep every accepted comparison on the same finite Cauchy-window packet.

Completion handoff stability is Definition 406.14. Diagonal-rate compatibility is Definition 406.16. Together they show that completion, diagonal, and effective-rate consumers all remain inside the same displayed packet, so the paper-side obligation surface is closed at the stated grade. □

Theorem 406.18 (CauchySequenceSpace kernel scope packet)**.** *The carrier surface, NameCert obligation surface, common-window classifier transport, cofinal schedule stability, dyadic tolerance exactness, completion handoff stability, regular family exhaustion, and diagonal-rate compatibility assemble into a single kernel-scoped* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet over* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Every completion-facing, diagonal-completion, effective-rate, or real-seal consumer must read through the displayed regular-family rows, stream schedule, common-window ledger, dyadic tolerance row, completion handoff, componentwise transports, continuation routes, package provenance, and local naming row. The packet excludes quotient completion, selected representatives, host real equality, and ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier kernel scope packet`

Proof. Begin with Definition 406.1 and Definition 406.2. They list the displayed family, schedule, cofinal-window ledger, tolerance ledger, completion handoff, transport, continuation, package, and local certificate rows, and they bind the classifier and stability obligations to those rows.

Next apply Definition 406.5, Definition 406.6, and Definition 406.7. These rows keep every accepted comparison on the same scheduled finite windows and the same displayed dyadic tolerance ledger.

Then use Definition 406.14 and Definition 406.15. The terminal completion-facing route and every regular-family consumer are exhausted by the same finite packet coordinates.

Finally apply Definition 406.16 and Definition 406.17. Diagonal finite-completion and effective-rate readers consume the same kernel-scoped surface, so quotient completion, selected representatives, host real equality, and ambient completeness have no row through which to enter. □

Theorem 406.19 (CauchySequenceSpace UniformCauchyCriterion consumption)**.** *Let $S = (F, \sigma, W, \epsilon, Q, H, C, P,$ be an accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Suppose its common-window ledger W is presented by an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose shared threshold and real-seal handoff read the same regular family, stream schedule, Cauchy-modulus row, dyadic tolerance row, and completion handoff. Then every completion-facing read of S factors through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *family F,* $\mathsf{StreamName}^{\uparrow}$ *schedule σ,* $\mathsf{CauchyModulus}^{\uparrow}$ *row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ϵ, and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff Q.*

The consumer route has no row for quotient streams, selected limits, host equality, or ambient completeness. The $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *presentation supplies only the shared-threshold ledger and real-seal handoff already consumed by the displayed* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier uniformcriterion consumption`

Proof. Project the accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ carrier by Definition 406.1. The only completion-facing coordinates are the regular family F, schedule σ, common-window ledger W, dyadic tolerance row ϵ, handoff Q, transports, continuations, provenance, and local naming row.

Use Definition 406.5, Definition 406.6, and Definition 406.7. These rows keep the common-window classifier, schedule, cofinal Cauchy-modulus evidence, and dyadic tolerance on the displayed packet before completion-facing data can be read.

Now read the accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ presentation through Definition 435.10 and Definition 435.57. The shared threshold and real-seal handoff are consumer routes over the same finite family, schedule, modulus, tolerance, and seal rows; they do not introduce an independent completion object.

Finally apply Definition 406.14 and Definition 406.18. The completion handoff stays on $F, \sigma, W, \epsilon, Q, H, C, P, N$, so the uniform-criterion ledger is consumed as a presentation of the same route rather than as quotient completion, a selected limit, host equality, or ambient completeness. □

Theorem 406.20 (CauchySequenceSpace modulus-family factorization)**.** *Let $S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$ be an accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Any completion-facing consumer of S that uses a* $\mathsf{CauchyModulus}^{\uparrow}$ *row or a* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row must first factor through the displayed regular family F, the schedule σ, the modulus or cofinal-window ledger W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row ϵ, and the completion handoff Q before any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *seal is read.*

The factorization route is

$$F, \sigma, W, \epsilon \longmapsto Q \longmapsto H, C, P, N.$$

It has no coordinate for quotient streams, selected limits, host equality, detached modulus selectors, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier modulus family factorization`

Proof. Project the accepted carrier through Definition 406.1. The displayed packet stores exactly the family F, schedule σ, common-window or modulus ledger W, dyadic tolerance row ϵ, completion handoff Q, transports, continuations, provenance, and local name.

Apply Definition 406.19 when the consumer presents W through a $\mathsf{UniformCauchyCriterion}^{\uparrow}$ row. The shared-threshold and real-seal reads still use the same regular family, schedule, modulus evidence, dyadic tolerance, and completion handoff already present in S.

For a direct $\mathsf{CauchyModulus}^{\uparrow}$ read, use Definition 406.6 and Definition 406.7. These theorems keep the modulus request on the displayed schedule, window ledger, and dyadic tolerance before Q can be consumed.

Finally use Definition 406.14 and Definition 406.18. The public completion handoff stays on $F, \sigma, W, \epsilon, Q, H, C, P, N$, so quotient streams, selected limits, host equality, detached modulus selectors, and ambient completeness have no route through the carrier. □

Theorem 406.21 (CauchySequenceSpace RealObservationBudget factorization)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Suppose a* $\mathsf{RealObservationBudget}^{\uparrow}$ *presentation records the same precision request, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks and radii,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows, and* $\mathsf{Real}^{\uparrow}$ *seal rows as the completion-facing request for S. Then that observation-budget presentation factors through the displayed CauchySequenceSpace rows before any completion-facing read of Q.*

The factorized route uses only the regular-family row F, schedule σ, common-window ledger W, dyadic tolerance row ϵ, completion handoff Q, componentwise transports H, continuation routes C, provenance row P, and local naming row N. It cannot use quotient streams, host equality, hidden limit selection, unbounded schedules, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier real observation budget factorization`

Proof. Project the accepted carrier through Definition 406.1. The visible packet rows are exactly the regular rational family, stream schedule, common-window ledger, dyadic tolerance row, completion handoff, transports, continuations, provenance, and local name.

First bind the observation windows to the same CauchySequenceSpace route. Common-window classifier transport, cofinal schedule stability, and dyadic tolerance ledger exactness identify the precision-indexed windows, stream reads, dyadic readbacks, and displayed radii with W, σ, and ϵ.

Next route the source and seal consumers. Completion handoff stability keeps the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the $\mathsf{Real}^{\uparrow}$ seal boundary on the same Q row, and the kernel scope packet prevents any completion-facing read from leaving $F, \sigma, W, \epsilon, Q, H, C, P, N$.

Finally read the $\mathsf{RealObservationBudget}^{\uparrow}$ carrier through Definition 611.1, Definition 611.3, Definition 611.4, Definition 611.5, and Definition 611.6. Those rows present the same finite observation route and exclude quotient streams, host equality, hidden limit selection, unbounded schedules, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier public observation budget factorization`

Theorem 406.22 (CauchySequenceSpace scoped completion route inventory)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Every completion-facing consumer read, and every* $\mathsf{Real}^{\uparrow}$ *limit-seal read of the completion handoff, is scoped by the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family row* F*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* σ*, the* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyModulus}^{\uparrow}$ *window ledger* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* ϵ*, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff* Q*, the componentwise* hsame *transports* H*, the displayed* Cont *routes* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ *row* N*.*

Consequently the completion-facing route inventory of S *is a scoped BEDC route over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. It exports no quotient-name equality, selected representative, host real equality, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier scoped completion route inventory`

Proof. Start from the carrier surface in Definition 406.1 and the NameCert obligation surface in Definition 406.2. These two rows name the accepted tuple and bind its family, schedule, window ledger, tolerance row, completion handoff, transports, continuations, provenance, and local certificate to the same finite BHist packet.

Next isolate the completion-facing route. Apply Definition 406.3 and Definition 406.4. The terminal handoff to $\mathsf{RealCauchyCompletion}^{\uparrow}$ can only be read after the displayed regular family, scheduled finite windows, Cauchy ledger, dyadic tolerance, transport, continuation, package, and naming rows have been consumed.

Now bind the RealUp seal boundary. Use Definition 406.8 to route every limit-seal read through $F, \sigma, W, \epsilon, Q, H, C, P, N$, and use Definition 406.15 to show that no other regular-family consumer row remains outside the displayed packet.

The route inventory is therefore a scoped BEDC route over the primitive rows BHist, hsame, Cont, Pkg, and NameCert. Since the carrier surface supplies no quotient-name equality, selected representative, host real equality, or ambient completeness coordinate, none of those objects is exported by the completion-facing or limit-seal route. □

Theorem 406.23 (CauchySequenceSpace public completion export)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. The public completion export of* S *is the single BEDC surface consisting of the finite carrier rows* $F, \sigma, W, \epsilon, Q, H, C, P, N$*, the* $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ *obligation rows, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff row, common-window classifier transport, dyadic tolerance exactness, completion handoff stability, regular-family exhaustion, and the scoped route inventory of Definition 406.22.*

Every completion-facing consumer of S *must factor through that public export before reading a completion handoff or a* $\mathsf{Real}^{\uparrow}$ *seal. The export is public only as a BEDC route over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*; it does not assert quotient completion, equality of Cauchy-name classes, uniqueness of limits, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier public completion export`

Proof. Start with Definition 406.1 and Definition 406.2. These identify the visible tuple $F, \sigma, W, \epsilon, Q, H, C, P, N$ and bind its local naming, transport, continuation, and package rows to the same finite packet.

Next add the completion-facing rows. Apply Definition 406.3, Definition 406.5, and Definition 406.7 to keep the handoff, classifier, windows, and dyadic tolerance on the displayed coordinates.

Then use Definition 406.14 and Definition 406.15. They show that completion reads and regular-family consumers remain inside the same finite route.

Finally package those rows by Definition 406.22. The cited inventory is already a BEDC route over BHist, hsame, Cont, Pkg, and NameCert, so the public export has exactly the stated surface and no stronger completion object. □

Theorem 406.24 (CauchySequenceSpace RealObservationBudget public consumer)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Suppose a* $\mathsf{RealObservationBudget}^{\uparrow}$ *presentation uses the same finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks and radii,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows, and* $\mathsf{Real}^{\uparrow}$ *seal factors as the completion-facing request for* S*. Then that observation presentation factors through the public completion export of Definition 406.23.*

In particular, the observation consumer reads $F, \sigma, W, \epsilon, Q, H, C, P, N$ *and the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ *rows before it can present a real observation. It cannot bypass the public export by selecting a quotient name, a representative limit, a host real equality proof, an ambient completeness principle, or an unbounded schedule.*

Proof. First project the $\mathsf{RealObservationBudget}^{\uparrow}$ presentation through Definition 611.1. The relevant observation rows are the finite request, window, dyadic readback, handoff, seal, transport, and naming data.

Use Definition 611.3, Definition 611.4, and Definition 611.5 to align those rows with the same finite windows, regular-rational handoffs, dyadic readbacks, and $\mathsf{Real}^{\uparrow}$ seal factors named by S.

Now apply Definition 406.21. It already routes such an observation-budget presentation through $F, \sigma, W, \epsilon, Q, H, C, P, N$ before the completion handoff is read.

Finally compose with Definition 406.23 and Definition 611.6. The first theorem supplies the public export for the routed packet, and the second excludes quotient names, selected representatives, host equality, ambient completeness, and unbounded schedules from the observation route. □

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier public real observation consumer`

Theorem 406.25 (CauchySequenceSpace public nonescape)**.** *For every accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet* $S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$*, the public completion export of Definition 406.23 exposes no quotient-name equality, no selected representative, no host real equality, no ambient completeness principle, and no hidden limit selector. Its observable routes are exhausted by the displayed finite carrier, obligation, completion handoff, classifier transport, tolerance, stability, family-exhaustion, and scoped-inventory rows.*

Proof. The public export is defined by Definition 406.23 as a package of previously displayed BEDC rows. Each row is a carrier, naming, transport, continuation, package, tolerance, handoff, stability, exhaustion, or scoped-route row over the tuple $F, \sigma, W, \epsilon, Q, H, C, P, N$.

Apply Definition 406.18 and Definition 406.22. These two results state that completion-facing and limit-seal consumers are scoped by the displayed BEDC packet and that quotient completion, selected representatives, host real equality, and ambient completeness have no exported coordinate.

It remains to exclude a hidden limit selector. The only limit-seal route available to the export is the factorization of Definition 406.8, which routes through $F, \sigma, W, \epsilon, Q, H, C, P, N$. Since that route is already included in the scoped inventory and supplies no selector coordinate, the public export cannot expose one. □

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier public nonescape`

Theorem 406.26 (CauchySequenceSpace tail-window factorization)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Every tail-window completion-facing read of* S *factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family* F*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* σ*, the cofinal Cauchy-window ledger* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* ϵ*, the completion handoff* Q*, the transport row* H*, the continuation row* C*, the package row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ *row* N*. The route reaches completion and any* $\mathsf{Real}^{\uparrow}$ *seal only through those finite BEDC rows, not through quotient-name equality, selected representatives, host real equality, ambient completeness, or a hidden limit selector.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier tail window factorization`

Proof. Begin with the public completion surface. The public completion export theorem Definition 406.23 packages the visible tuple $F, \sigma, W, \epsilon, Q, H, C, P, N$ together with the completion handoff and scoped route inventory, while public nonescape Definition 406.25 excludes quotient, representative, host equality, completeness, and selector coordinates.

Next isolate the finite tail window. Regular-window factorization Definition 406.4 routes the completion-facing read through the displayed regular family, schedule, cofinal ledger, tolerance row, transport, continuation, package, and naming rows. Cofinal schedule stability Definition 406.6 keeps every cofinal request attached to the same schedule and ledger.

Finally read the tolerance and terminal handoff. Dyadic tolerance ledger exactness Definition 406.7 fixes the tolerance row before the completion handoff is consumed, and the public export supplies the handoff, transport, continuation, package, and NameCert rows. Thus every tail-window completion-facing read factors through the displayed finite route. □

Theorem 406.27 (CauchySequenceSpace quotient refusal route)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Any accepted consumer that asks for quotient-name equality, a selected representative, host real equality, or ambient completeness must route through chapter 998 after it has read the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family* F*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* σ*, the cofinal-window ledger* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* ϵ*, and the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff* Q*.*

Thus the quotient-facing request is not a projection from $\mathsf{CauchySequenceSpace}^{\uparrow}$ *itself. It is a refusal route over the same finite Cauchy-window packet, with no additional quotient stream, selected limit, host equality, or completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier quotient refusal route`

Proof. First read the completion handoff of Definition 406.3. It forces every completion-facing consumer to pass through the displayed family, schedule, window, tolerance, transport, continuation, package, and local naming rows before the handoff row Q is consumed.

Next use public non-escape and the tail-window factorization. By Definition 406.25 and Definition 406.26, quotient-name equality, selected representatives, host real equality, ambient completeness, and hidden limit selectors are absent from the $\mathsf{CauchySequenceSpace}^{\uparrow}$ carrier and from its public completion export.

Finally apply the $\mathsf{QuotientStreamRefusal}^{\uparrow}$ route of Definition 998.3. That sibling chapter is exactly the Real-completion refusal packet for requests that leave the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route. Therefore a quotient-facing consumer may proceed only as a refusal-route consumer after the CauchySequenceSpace rows have been read. □

Theorem 406.28 (CauchySequenceSpace RealLimitUniquenessSeal public consumer)**.** *Let*

$$S_0 = (F_0, \sigma_0, W_0, \epsilon_0, Q_0, H_0, C_0, P_0, N_0)$$

and

$$S_1 = (F_1, \sigma_1, W_1, \epsilon_1, Q_1, H_1, C_1, P_1, N_1)$$

be accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packets. Suppose their public completion exports supply two* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff rows and that the comparison route displays the same* $\mathsf{RegSeqRat}^{\uparrow}$ *family row, the same finite* $\mathsf{StreamName}^{\uparrow}$ *window row, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and the same terminal* $\mathsf{Real}^{\uparrow}$ *classifier row for both exported seals. Then any* $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$ *consumer comparing those two exported seals factors through exactly the two public completion exports, the shared comparison-window-tolerance route, and the two local* $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ *rows.*

The consumer cannot read a selected limit, quotient stream equality, host real equality, detached selector choice, or ambient completeness theorem from the two $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packets. Its only uniqueness-facing surface is the finite two-seal packet routed through* $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceRealLimitUniquenessSealPublicConsumer`

Proof. First expose the two public completion endpoints. Apply Definition 406.23 separately to S_0 and S_1. The two applications provide the two $\mathsf{RealCauchyCompletion}^{\uparrow}$ handoff rows together with their displayed family, stream-window, dyadic tolerance, transport, continuation, package, and local NameCert rows.

Next restrict the comparison route to the shared finite data. Use Definition 406.25 to remove quotient-name equality, selected representatives, host equality, ambient completeness, and hidden limit selectors from both public exports. Then apply Definition 406.26 to keep each endpoint on the displayed $\mathsf{RegSeqRat}^{\uparrow}$ family, finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and terminal handoff route.

Finally read the uniqueness consumer through the sibling comparison packet. The obligation surface of Definition 1039.2 supplies exactly the two seal rows, shared regular-rational comparison row, finite window row, dyadic ledger, terminal $\mathsf{Real}^{\uparrow}$ classifier row, uniqueness handoff, transport, continuation, provenance, and local name. The nonescape theorem Definition 1039.3 prevents any replacement by a selected limit, quotient stream equality, host Real equality, detached selector, or ambient completeness theorem. Hence the consumer factors only through the two public exports, the shared comparison-window-tolerance route, and the local NameCert rows. □

Theorem 406.29 (CauchySequenceSpace finite-section pullback correspondence)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet. Suppose that the public completion export of* S *is read through an accepted finite request section of* $\mathsf{StreamName}^{\uparrow}$*, and that a* $\mathsf{Real}^{\uparrow}$ *seal consumer reads the same finite windows, dyadic tolerance rows, regular-rational handoff rows, terminal seal row, displayed* BHist *entry, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ *row. Then the exported completion handoff and the* $\mathsf{Real}^{\uparrow}$ *seal consumer are exactly the same four-face route named by the StreamName finite-section pullback exactness theorem:*

$$\mathsf{StreamName}^{\uparrow}, \qquad \mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

Equivalently, every such CauchySequenceSpace completion read pulls back to the StreamName finite section with the displayed window face, dyadic face, regular-rational face, and Real seal face, and then returns to the same public completion export. The correspondence exports no quotient stream, no selected representative, no host real equality, no countable-choice row, no ambient completeness principle, and no route-level aggregate closure or verification status.

Proof. First expose the public completion side. Apply Definition 406.23 to S to obtain the displayed tuple $F, \sigma, W, \epsilon, Q, H, C, P, N$, the $\mathsf{RealCauchyCompletion}^{\uparrow}$ handoff row, and the local $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ obligation rows.

Next restrict the read to finite StreamName data. Use Definition 406.26 to present the family, schedule, tolerance, and handoff rows as the same finite $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route that the accepted request section consumes.

Now invoke the StreamName pullback surface. Theorem 126.586 identifies the four visible faces of the request section, and Definition 126.589 keeps the Real seal, regular-rational handoff, dyadic tolerance row, and finite StreamName window locked to the same BHist, hsame, Cont, Pkg, and NameCert data.

Finally apply Definition 406.25 and Definition 38.494. The first result excludes quotient streams, selected representatives, host real equality, countable-choice routes, and ambient completeness from the CauchySequenceSpace export. The second keeps the closure and verification coordinates objectwise on the four faces rather than converting them into a route-level aggregate status. □

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier finite section pullback correspondence`

Theorem 406.30 (CauchySequenceSpace exact-boundary terminal pullback)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet, and let*

$$B = (L_B, K_B, J_B, S_B, W_B, R_B, D_B, E_B, H_B, C_B, P_B, N_B)$$

be an accepted $\mathsf{RealCompletionExactBoundaryUp}$ *packet. Suppose the public completion export of* S *and the terminal consumer route of* B *are displayed over the same finite* $\mathsf{StreamName}^{\uparrow}$ *window, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the same terminal* $\mathsf{Real}^{\uparrow}$ *seal, the same* BHist *entry, the same componentwise* hsame *transports, the same* Cont *routes,*

the same Pkg *provenance, and the same local NameCert rows. Then the CauchySequenceSpace public completion read and the RealCompletionExactBoundary terminal consumer are one four-face terminal pullback route:*

$$\mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

This identification reads the finite Cauchy-name export through the exact-boundary terminal consumer and returns to the same public completion surface. It exports no quotient stream, no selected representative, no host real equality, no countable-choice row, no ambient completeness row, no metric-completeness row, and no bridge row.

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier real completion exact boundary terminal pullback`

Proof. First expose the CauchySequenceSpace public completion surface. Apply Definition 406.23 to S to obtain the displayed family, schedule, cofinal-window, dyadic tolerance, completion handoff, transport, continuation, provenance, and local naming rows. Then apply Definition 406.29 to identify that public read with the finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route over the shared BHist, hsame, Cont, Pkg, and NameCert data.

Next read the RealCompletionExactBoundary side. Theorem 1120.6 says that the accepted boundary exports exactly the four terminal faces W_B, R_B, D_B, E_B after the governing rows L_B, K_B, J_B, S_B. Theorem 1120.13 places every completion-facing and terminal $\mathsf{Real}^{\uparrow}$ consumer on the same finite route through $L_B, K_B, J_B, S_B, W_B, R_B, D_B, E_B, H_B, C_B, P_B, N_B$.

Finally compare the two exclusions. The CauchySequenceSpace public nonescape theorem Definition 406.25 removes quotient streams, selected representatives, host real equality, countable-choice routes, and ambient completeness from the public export. The exact-boundary no-completeness theorem Definition 1120.14 removes quotient streams, host equality, selected limits, metric-completeness rows, bridge rows, and ambient-completeness coordinates from the terminal consumer. Since the hypotheses identify the displayed window, readback, tolerance, Real seal, history, transport, continuation, package, and local NameCert rows, no additional coordinate remains on either side; both consumers are the same four-face terminal pullback route. □

Theorem 406.31 (CauchySequenceSpace terminal pullback exactness)**.** *Let*

$$S = (F, \sigma, W, \epsilon, Q, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet, and let an accepted L10 Phase Real and Completion read of S display a finite* $\mathsf{StreamName}^{\uparrow}$ *section, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, a terminal* $\mathsf{Real}^{\uparrow}$ *seal, a* BHist *entry, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$ *row. This read is the L10 terminal exit route completely determined by the Phase Real and Completion terminal data if and only if the following two projections hold over those same rows:*

1. *its* $\mathsf{StreamName}^{\uparrow}$ *finite-section projection satisfies the pullback exactness criterion of Definition 126.586;*
2. *its* RealCompletionExactBoundaryUp *projection satisfies the terminal pullback of Definition 406.30.*

Thus the terminal exit route has no coordinate beyond the shared $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. In particular it exports no quotient stream, no selected representative, no host real equality, no countable-choice row, no ambient completeness row, no metric-completeness row, no bridge row, and no route-level aggregate closure or verification status.*

Lean4 ✓ `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier terminal pullback exactness`

Proof. For the forward direction, assume the accepted read is already the L10 terminal exit route determined by the Phase Real and Completion terminal data. Apply Definition 406.29 to expose the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ four-face route carried by the public completion export. Then use Definition 126.586 to identify the finite-section projection over the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

The same terminal read also supplies the exact-boundary endpoint. Apply Definition 406.30 to read the RealCompletionExactBoundaryUp projection through the same finite window, readback row, tolerance row, terminal Real seal, history, transport, continuation, package, and local NameCert data.

For the reverse direction, suppose the two displayed projections satisfy those exactness criteria over the same rows. The finite-section correspondence first pins the CauchySequenceSpace public completion read to the StreamName four-face route, while the StreamName theorem makes that route terminal among finite request sections. The exact-boundary terminal pullback then identifies the RealCompletionExactBoundary consumer with the same four faces and support rows.

Finally apply Definition 38.494. Since the StreamName projection and the exact-boundary projection share the same objectwise $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows, the L10 exit is determined by those two projections. The nonescape clauses in the cited CauchySequenceSpace, StreamName, and exact-boundary theorems exclude quotient streams, selected representatives, host real equality, countable choice, ambient completeness, metric-completeness rows, bridge rows, and any route-level aggregate closure or verification status. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceSpace}^{\uparrow}$ packet is generated from a displayed family of regular rational names, a stream schedule, finite Cauchy-window evidence, dyadic tolerance data, a completion handoff, componentwise transport, displayed continuation routes, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 406.23, Definition 406.25, and Definition 406.26 supply the mature paper surface: a public finite Cauchy-name route with the sibling $\mathsf{RegSeqRat}^{\uparrow}$ family, $\mathsf{StreamName}^{\uparrow}$ schedule, and $\mathsf{RealCauchyCompletion}^{\uparrow}$ handoff displayed in the chapter.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySequenceSpace}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.CauchySequenceSpaceUp.CauchySequenceSpaceCarrier\_public\_completion\_export`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close quotient completion construction, equality of Cauchy-name classes, uniqueness of limits, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: No further upgrade – chapter at top of the formal bridge axis.

Chapter 407

A Concrete Naming Certificate for $\mathsf{SqueezeReal}^{\uparrow}$

The $\mathsf{SqueezeReal}^{\uparrow}$ interface names the finite dyadic sandwich packet used when a constructive squeeze argument is consumed by $\mathsf{Real}^{\uparrow}$ and completion-facing certificates. The mathematical squeeze theorem is usually stated as a convergence principle for a middle sequence bounded between two convergent endpoints; BEDC records only the visible finite certificate: lower and upper $\mathsf{RegularCauchyName}^{\uparrow}$ rows, a middle $\mathsf{RegularCauchyName}^{\uparrow}$ row, a shared $\mathsf{DyadicTailBound}^{\uparrow}$ tolerance row, sandwich ledgers, a $\mathsf{Real}^{\uparrow}$ seal row, package provenance, and a local $\mathsf{NameCert}$ row.

The packet is not a quotient of streams, not an ambient equality of host reals, and not a choice-selected limit. It is a finite ledger surface over $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Definition 407.1 (SqueezeReal finite sandwich carrier)**.** *A* $\mathsf{SqueezeReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (l, x, u, \epsilon, L, U, S, E, P, N)$$

with the following visible rows:

1. *l is the lower* $\mathsf{RegularCauchyName}^{\uparrow}$ *row, read through its* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$ *observation surface;*
2. *x is the middle* $\mathsf{RegularCauchyName}^{\uparrow}$ *row whose real-facing seal is to be exposed only through the sandwich packet;*
3. *u is the upper* $\mathsf{RegularCauchyName}^{\uparrow}$ *row, read through the same kind of regular rational observation surface as l;*
4. *ϵ is the shared* $\mathsf{DyadicTailBound}^{\uparrow}$ *tolerance row consumed by all three regular names;*
5. *L is the lower sandwich ledger certifying the displayed finite comparisons $l \leq x$ at every requested dyadic window;*
6. *U is the upper sandwich ledger certifying the displayed finite comparisons $x \leq u$ and the width bound $u - l \leq \epsilon$ at the same requested dyadic windows;*
7. *S is the shared* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the lower and upper ledgers have consumed the shared tolerance row;*
8. *E stores componentwise* hsame *transports for the three regular-name rows, the tolerance row, both sandwich ledgers, the seal row, provenance, and the local naming row;*

9. *P is the* Pkg *provenance naming the consumed* $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, *and* Cont *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed host real, quotient stream equality, a selected limiting value, or an external completeness theorem.

Lean4 ✓ `BEDC.Derived.SqueezeRealUp.SqueezeRealTasteGate single carrier alignment`

Definition 407.2 (SqueezeReal packet classifier)**.** *Two accepted* $\mathsf{SqueezeReal}^{\uparrow}$ *carriers are classified as the same finite sandwich packet exactly when their displayed rows compare componentwise. The lower, middle, and upper* $\mathsf{RegularCauchyName}^{\uparrow}$ *rows agree through their scheduled* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *observations, the shared* $\mathsf{DyadicTailBound}^{\uparrow}$ *rows agree as the same tolerance request, the lower and upper sandwich ledgers transport through the displayed* hsame *rows, and the* $\mathsf{Real}^{\uparrow}$ *seal,* Pkg *provenance, and local* NameCert *rows name the same packet.*

The classifier has no generator for quotienting regular names, identifying host reals, selecting a limit, or replacing the two sandwich ledgers by a single ambient order proof.

Theorem 407.3 (SqueezeReal NameCert obligations)**.** *The carrier of Definition 407.1 satisfies the local* $\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}$ *obligation surface. Its five obligation rows are:*

1. *carrier habitation by any displayed triple of regular dyadic rows whose lower and upper ledgers use the same tolerance request;*
2. *classifier transport by the componentwise classifier of Definition 407.2;*
3. *lower and upper sandwich ledger stability under the displayed* hsame *and* Cont *routes;*
4. *dyadic tail exhaustion, saying that every precision read factors through the shared* $\mathsf{DyadicTailBound}^{\uparrow}$ *row before any seal read;*
5. $\mathsf{Real}^{\uparrow}$ *seal boundary, saying that the public real-facing read exposes only the middle regular name after both sandwich ledgers have been consumed.*

Proof. For habitation, take the displayed regular-name rows l, x, and u together with a single tolerance row ϵ. The packet is accepted only when L and U name the finite comparisons over that same tolerance request, so the carrier is a concrete BHist tuple.

For classifier transport, use Definition 407.2. Each regular-name row is transported through its scheduled rational observations, the tolerance row is transported as a shared request, and both sandwich ledgers are repacked with the transported provenance.

For ledger stability and tail exhaustion, inspect any consumer read. A lower or upper comparison read must project L or U, and both ledgers cite ϵ before exposing a dyadic endpoint comparison. Thus the two bounding rows cannot be separated from the shared dyadic tail request.

For the seal boundary, project S only after the previous rows have been read. Since no coordinate of Q is a quotient stream, host real equality, selected limit, or completeness datum, the local $\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}$ surface is exactly the displayed finite sandwich packet. □

Theorem 407.4 (SqueezeReal sandwich exactness)**.** *Every accepted* $\mathsf{SqueezeReal}^{\uparrow}$ *packet consumes the same* $\mathsf{DyadicTailBound}^{\uparrow}$ *tolerance row and both bounding ledgers before exposing the* $\mathsf{Real}^{\uparrow}$ *seal. Concretely, a read of S must factor through the rows ϵ, L, and U, where L certifies the lower comparisons $l \leq x$ and U certifies both the upper comparisons $x \leq u$ and the finite width bounds $u - l \leq \epsilon$ for the scheduled dyadic windows.*

Consequently a $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer receives a finite sandwich certificate for the middle regular name, not a host-real equality proof and not a selected limiting object.*

Lean4 ✓ `BEDC.Derived.SqueezeRealUp.SqueezeRealCarrier sandwich exactness`

Proof. Start with an accepted packet $Q = (l, x, u, \epsilon, L, U, S, E, P, N)$. By Definition 407.1, the only tolerance coordinate in the carrier is ϵ, and both ledgers are declared over the same requested dyadic windows.

Read the lower ledger L. It supplies exactly the finite comparisons from the lower regular row to the middle regular row at the scheduled windows; no seal row is projected by this read.

Read the upper ledger U. It supplies the finite comparisons from the middle regular row to the upper regular row and the displayed width bounds against the same tolerance row ϵ.

Only after these two reads may the consumer project S. Coordinate exhaustion shows that the exposed seal is the shared $\mathsf{Real}^{\uparrow}$ row named by the packet, and the consumer has not acquired quotient stream equality, host real equality, a selected limit, or a separate completeness principle. □

Theorem 407.5 (SqueezeReal RealUp boundary)**.** *When a* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or completion consumer cites an accepted* $\mathsf{SqueezeReal}^{\uparrow}$ *packet, the citation can use only the lower regular-name row, middle regular-name row, upper regular-name row, shared dyadic tolerance row, lower sandwich ledger, upper sandwich-and-width ledger, displayed transports, package provenance, and local naming row of Definition 407.1. The citation cannot infer a quotient of presentations, a host real equality, a selected limit, an ambient order-completeness theorem, or a standard bridge row.*

Lean4 ✓ `BEDC.Derived.SqueezeRealUp.SqueezeRealCarrier realup boundary`

Proof. Factor the consumer citation through the local $\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}$ surface of Definition 407.3. The visible packet supplies three regular-name rows, one shared tolerance row, two sandwich ledgers, transports, continuations, provenance, and the local naming row.

Apply the exactness statement of Definition 407.4. Any real-facing read must consume the tolerance row and both bounding ledgers before the seal row is visible.

None of the displayed coordinates is a quotient stream, host real equality, selected limiting value, order-completeness theorem, or standard bridge. The real-facing boundary is therefore the finite dyadic sandwich surface and nothing stronger. □

Theorem 407.6 (SqueezeReal transport stability)**.** *Let* $Q = (l, x, u, \epsilon, L, U, S, E, P, N)$ *be an accepted* $\mathsf{SqueezeReal}^{\uparrow}$ *packet. Componentwise* hsame *transport of the lower, middle, and upper* $\mathsf{RegularCauchyName}^{\uparrow}$ *rows, the shared* $\mathsf{DyadicTailBound}^{\uparrow}$ *row, both sandwich ledgers, the* $\mathsf{Real}^{\uparrow}$ *seal row, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}$ *row preserves the carrier of Definition 407.1 and the classifier of Definition 407.2. The transported packet is still classified only by the displayed regular-name observations, the single tolerance request, the two transported ledgers, the seal row, provenance, and local naming data.*

Lean4 ✓ `BEDC.Derived.SqueezeRealUp.SqueezeRealCarrier transport stability`

Proof. Project the carrier coordinates from Definition 407.1. Each transported row named in the statement is already a visible coordinate of Q, and the transport ledger E records the componentwise hsame routes for exactly those coordinates.

The carrier is preserved by repacking the transported lower, middle, and upper regular-name rows with the transported tolerance row, the transported lower and upper ledgers, the transported seal, provenance, and local naming row. No additional coordinate is available in the displayed BHist packet.

The classifier is preserved by Definition 407.2. Classification compares the same rows componentwise after transport: scheduled regular-name observations, the shared tolerance request, both sandwich ledgers, the $\mathsf{Real}^{\uparrow}$ seal, the Pkg row, and the local $\mathsf{NameCert}$ row. □

Theorem 407.7 (SqueezeReal dyadic tail exhaustion)**.** *Every precision read of the real-facing seal in an accepted* $\mathsf{SqueezeReal}^{\uparrow}$ *packet factors first through the shared* $\mathsf{DyadicTailBound}^{\uparrow}$ *tolerance row and then through both sandwich ledgers before any* $\mathsf{Real}^{\uparrow}$ *seal read. Thus a consumer can reach* S *only by the finite route* ϵ, L, U, S *inside the displayed* BHist *packet.*

Proof. Begin with a precision request addressed to the real-facing row. The carrier of Definition 407.1 stores only one dyadic tolerance coordinate, namely ϵ, so every such request has a unique tolerance row to consume.

Next read the sandwich ledgers. The lower ledger L records the finite lower comparisons against the middle regular name, and the upper ledger U records the finite upper comparisons and width bounds against the same tolerance request. These two ledger reads account for the sandwich data available to the request.

Only after those rows have been consumed can the seal coordinate S be projected. This is exactly the route isolated in Definition 407.4, so the precision read has no remaining access to quotient regular names, host equality, selected limits, or ambient completeness. □

Theorem 407.8 (SqueezeReal shared tail ledger determinacy)**.** *Let* $Q = (l, x, u, \epsilon, L, U, S, E, P, N)$ *be an accepted* $\mathsf{SqueezeReal}^{\uparrow}$ *packet. If two precision reads use the same lower, middle, and upper* $\mathsf{RegularCauchyName}^{\uparrow}$ *rows* l*,* x*, and* u*, and the same shared* $\mathsf{DyadicTailBound}^{\uparrow}$ *tolerance row* ϵ*, then their lower ledger, upper ledger, width-bound surface, and* $\mathsf{Real}^{\uparrow}$ *seal-facing route agree at the classifier-facing packet level. The agreement is only the finite packet agreement of Definition 407.2; it does not identify host real values, quotient regular names, selected limits, or an ambient completeness proof.*

Lean4 ✓ `BEDC.Derived.SqueezeRealUp.SqueezeRealCarrier shared tail ledger determinacy`

Proof. Project the accepted carrier of Definition 407.1. The rows l, x, u, and ϵ are the only inputs from which a precision read can obtain the three regular-name surfaces and the shared dyadic tail request.

Apply the sandwich exactness and dyadic-tail exhaustion rows, Definition 407.4 and Definition 407.7. They force each read to consume the same tolerance row before reading L, U, the width-bound data inside U, and then the seal-facing route S.

If a read is carried through displayed transport before comparison, use Definition 407.6. The transported packet preserves the lower, middle, upper, tolerance, ledger, seal, package, and local naming rows that the classifier can inspect.

The classifier of Definition 407.2 now compares the same visible rows componentwise. By the real-facing boundary of Definition 407.5, there is no additional coordinate from which the two reads could obtain a different host equality, quotient representative, selected limit, or order-completeness route. □

Theorem 407.9 (SqueezeReal completion consumer package)**.** *The carrier and classifier of Definition 407.1 and Definition 407.2, together with the* $\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}$ *obligations of Definition 407.3, sandwich exactness of Definition 407.4, real-facing boundary of Definition 407.5, transport stability of Definition 407.6, dyadic-tail exhaustion of Definition 407.7, and shared tail ledger determinacy of Definition 407.8, form the finite completion-facing packet consumed by* $\mathsf{RegSeqRat}^{\uparrow}$*,*

$\mathsf{Real}^{\uparrow}$*, and completion certificates. The packet excludes quotient regular names, host equality, selected limits, and ambient order completeness.*

Proof. Assemble the carrier and classifier rows first. They identify the finite BHist tuple and the componentwise equality route over the three regular-name rows, the shared tolerance request, both ledgers, the seal, provenance, and local naming data.

Add the naming-certificate obligations and sandwich exactness. These rows show that carrier habitation, classifier transport, ledger stability, tail exhaustion, and seal boundary are all witnessed inside the displayed packet, and that the seal can be read only through ϵ, L, and U.

Finally add transport stability, dyadic-tail exhaustion, and shared tail ledger determinacy. The resulting package is stable under the displayed hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows and supplies exactly the finite consumer surface needed by $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and completion certificates. Since all rows have been exhausted, no quotient regular name, host equality, selected limit, or ambient order-completeness coordinate is present. □

Theorem 407.10 (SqueezeReal scoped dependency packet)**.** *For an accepted* $\mathsf{SqueezeReal}^{\uparrow}$ *packet* $Q = (l, x, u, \epsilon, L, U, S, E, P, N)$*, the carrier row, classifier row, sandwich exactness row, transport-stability row, and dyadic-tail exhaustion row factor through exactly the displayed dependencies*

$$\mathsf{DyadicTailBound}^{\uparrow},\quad \mathsf{RegularCauchyName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The packet has no further dependency coordinate for quotient regular-name equality, host real equality, selected limits, or ambient order completeness.

Proof. Read the carrier and classifier of Definition 407.1 and Definition 407.2. They expose only the three regular-name rows, the shared dyadic tail row, both sandwich ledgers, the real seal, transport data, continuation routes, package provenance, and local naming row.

The naming obligations of Definition 407.3 identify those same rows as the local $\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}$ surface. Sandwich exactness in Definition 407.4 and dyadic-tail exhaustion in Definition 407.7 consume the shared tolerance row before any ledger or seal read is exported.

Transport stability in Definition 407.6 preserves precisely the displayed hsame, Cont, Pkg, and $\mathsf{NameCert}$ coordinates. The completion consumer package of Definition 407.9 then repacks the rows for $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ without adding a coordinate outside the listed dependencies. □

Theorem 407.11 (SqueezeReal shared-tail real-seal factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{SqueezeReal}^{\uparrow}$ *packet factors through the shared* $\mathsf{DyadicTailBound}^{\uparrow}$ *row together with both sandwich ledgers. In particular, the lower and upper ledger reads are forced to consume the same tail request before the seal row* S *can be read by a* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or completion-facing consumer.*

Proof. Start from the real-facing boundary of Definition 407.5. It states that a seal-facing consumer can see only the regular-name rows, the shared tolerance row, both ledger rows, the displayed transport and continuation data, provenance, and the local naming row.

Apply sandwich exactness from Definition 407.4. The lower and upper ledger reads are tied to the same middle regular-name row and to the same width-bound route, so neither side can supply an independent seal coordinate.

Use dyadic-tail exhaustion from Definition 407.7 and shared tail ledger determinacy from Definition 407.8. These rows force every precision read to pass through ϵ before reading L, U, and S, and transport stability preserves that factorization under the displayed classifier route. □

Theorem 407.12 (SqueezeReal completion handoff scope)**.** *The scoped completion-facing handoff for* $\mathsf{SqueezeReal}^{\uparrow}$ *is exactly the packet assembled from the scoped dependency packet of Definition 407.10, the shared-tail seal factorization of Definition 407.11, and the completion consumer package of Definition 407.9. It exports the finite dyadic sandwich handoff to* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and completion certificates, while excluding quotient regular names, host real equality, selected limits, and ambient order completeness.*

Proof. First assemble the dependency surface. The carrier, classifier, local naming obligations, transport stability, and dyadic-tail exhaustion rows give the finite BHist packet over $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Next attach the seal factorization. The shared tolerance row and both sandwich ledgers determine every $\mathsf{Real}^{\uparrow}$ seal read, so the completion-facing consumer cannot replace the finite ledger by a host equality or a selected limit.

Finally use Definition 407.9. It repacks the dependency and seal rows as the completion-facing handoff, and the boundary rows already rule out every coordinate not displayed in the accepted $\mathsf{SqueezeReal}^{\uparrow}$ carrier. □

Theorem 407.13 (SqueezeReal scoped tail ledger package)**.** *The carrier and classifier of Definition 407.1 and Definition 407.2, the sandwich exactness of Definition 407.4, the dyadic-tail exhaustion of Definition 407.7, the shared-tail determinacy of Definition 407.8, the completion consumer package of Definition 407.9, the scoped dependency packet of Definition 407.10, the shared-tail real-seal factorization of Definition 407.11, and the completion handoff of Definition 407.12 assemble one scoped finite ledger over*

$$\mathsf{DyadicTailBound}^{\uparrow},\quad \mathsf{RegularCauchyName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

Every $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or completion-facing read of the packet is exhausted by this ledger and cannot introduce quotient regular-name equality, host real equality, selected limits, or ambient order completeness.*

Proof. First collect the local packet rows. The carrier and classifier identify the finite sandwich tuple, and sandwich exactness forces every seal-facing read through the shared tolerance row and the two displayed ledgers.

Next bind the tail ledger. Dyadic-tail exhaustion and shared-tail determinacy show that all precision reads use the same $\mathsf{DyadicTailBound}^{\uparrow}$ request before consuming L, U, and S.

Finally assemble the completion-facing scope. The completion consumer package, scoped dependency packet, shared-tail real-seal factorization, and completion handoff repack the same rows over BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. Since those rows are the entire displayed packet, no unlisted completion or host-real coordinate remains. □

Theorem 407.14 (SqueezeReal public interval seal export)**.** *An accepted* $\mathsf{SqueezeReal}^{\uparrow}$ *packet whose lower, middle, and upper rows satisfy the* $\mathsf{RegularCauchyName}^{\uparrow}$ *carrier clauses, whose tolerance is the shared* $\mathsf{DyadicTailBound}^{\uparrow}$ *row, and whose sandwich exactness,* $\mathsf{Real}^{\uparrow}$ *boundary, transport stability, and scoped tail ledger package are displayed, exports a public* $\mathsf{Real}^{\uparrow}$ *interval-seal certificate for the middle row. The certificate is the finite package over the lower and upper ledgers, the middle regular name, the shared tail request,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}$*; it does not assert host real equality, select a limit, or appeal to ambient order completeness.*

Proof. Start from the three $\mathsf{RegularCauchyName}^{\uparrow}$ rows and the shared $\mathsf{DyadicTailBound}^{\uparrow}$ request. Sandwich exactness ties the middle row to the lower and upper ledgers, while dyadic-tail exhaustion makes the shared request the common precision source for both sides.

Apply the $\mathsf{Real}^{\uparrow}$ boundary and transport stability rows. They keep the interval read on the displayed sandwich ledgers, componentwise hsame transports, continuation routes, package provenance, and local naming row.

Before exposing the public interval seal, read the finite sandwich carrier through chapter 394: its endpoint-cell refinement and interval-containment route supply the located interval ledger consumed by the lower and upper rows.

The shared-tail real-seal factorization then places the middle seal after the shared tolerance and both ledger reads. Repack this route with the scoped tail ledger package to obtain the public interval-seal certificate for the middle row, with no host real equality or selected limit available as an additional coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}$.

Constructive story: A $\mathsf{SqueezeReal}^{\uparrow}$ packet is generated from lower, middle, and upper $\mathsf{RegularCauchyName}^{\uparrow}$ rows, a shared $\mathsf{DyadicTailBound}^{\uparrow}$ tolerance row, two finite sandwich ledgers, componentwise hsame transports, displayed Cont routes, Pkg provenance, a $\mathsf{Real}^{\uparrow}$ seal row, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 407.1, Definition 407.2, Definition 407.3, Definition 407.4, Definition 407.5, Definition 407.6, Definition 407.7, Definition 407.8, Definition 407.9, Definition 407.10, Definition 407.11, Definition 407.12, Definition 407.13, and Definition 407.14 bind the finite shared-tail ledger and export the public interval-seal certificate route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SqueezeReal}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.SqueezeRealUp.SqueezeRealCarrier\_sandwich\_exactness`

Bridge status: none

Origin: human

Not claimed: This chapter does not claim quotient equality of regular names, host real equality, a selected limit, ambient order completeness, or a standard bridge.

Upgrade path: Bridge closure requires a standard-facing route for the public interval-seal certificate.

Chapter 408

A Concrete Naming Certificate for $\mathsf{FoldDefectStokes}^{\uparrow}$

The $\mathsf{FoldDefectStokes}^{\uparrow}$ interface is a BEDC-native finite certificate surface.

The $\mathsf{FoldDefectStokes}^{\uparrow}$ interface names a finite fold-defect ledger whose boundary row accounts for the visible difference between a fold input and its projected fold output. It consumes the fold-source, visible fiber-ledger, and moment-index rows of the $\mathsf{FoldMomentKernel}^{\uparrow}$ carrier in chapter 384, and repackages their endpoint mismatch as its boundary-defect row B and interior ledger L. It is a BHist packet, not an import of external algebra, a chain complex, a topological Stokes theorem, or an ambient quotient calculus. The packet is meant to sit between finite fold consumers such as $\mathsf{GoldenMeanShift}^{\uparrow}$, $\mathsf{ZeckendorfNormal}^{\uparrow}$, $\mathsf{AxisAdd}^{\uparrow}$, and $\mathsf{FoldMomentKernel}^{\uparrow}$ while exporting only displayed rows, routes, provenance, and local $\mathsf{NameCert}$ evidence.

Definition 408.1 (FoldDefectStokes carrier)**.** *A* $\mathsf{FoldDefectStokes}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, O, B, L, H, C, P, N)$$

with the following visible rows:

1. *I is the fold-input row naming the displayed finite source segment and its local fold order;*
2. *O is the projected fold-output row read from I through the displayed fold projection;*
3. *B is the boundary-defect row recording the visible mismatch left at the endpoints of the projection;*
4. *L is the interior ledger whose entries pair each internal fold step with the local defect contribution that cancels inside the segment;*
5. *H records componentwise* hsame *transports for the input, output, boundary-defect, and interior-ledger rows;*
6. *C records the* Cont *routes by which a consumer reads I, then O, then the boundary row B, and finally the interior ledger L;*
7. *P is the* Pkg *provenance naming the finite BEDC packets that own the fold source, projection rule, boundary read, and ledger read;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FoldDefectStokes}^{\uparrow}}$ *row.*

The carrier contains no infinite cochain object, no ambient differential operator, no quotient by invisible cancellations, no host summation law, and no external object.

Theorem 408.2 (FoldDefectStokes NameCert obligations)**.** *Every accepted* $\mathsf{FoldDefectStokes}^{\uparrow}$ *packet with carrier Definition 408.1 carries five local naming-certificate obligations:*

1. *carrier habitation by the empty fold input, empty projected output, empty boundary-defect row, and empty interior ledger;*
2. *classifier laws inherited componentwise from* hsame *on the displayed rows I, O, B, L, H, C, P, and N;*
3. *projection stability under the displayed* Cont *route from fold input I to projected output O;*
4. *boundary-ledger exactness: every internal defect contribution listed in L is paired with a displayed cancellation route, and the unpaired residue is exactly the boundary row B;*
5. *non-escape: every public read of the packet factors through I, O, B, L, H, C, P, and N before it can be consumed by another concrete instance.*

Lean4 ✓ `BEDC.Derived.FoldDefectStokesUp.FoldDefectStokesPacket namecert obligation surface`

Proof. For habitation, use the empty BHist row for I, O, B, and L. The identity hsame rows, trivial Cont routes, empty provenance, and local certificate row repack this as the empty fold-defect carrier.

The classifier laws are componentwise. Reflexivity, symmetry, and transitivity never inspect hidden fold semantics; they compare only the displayed input, output, boundary, ledger, transport, continuation, provenance, and certificate rows.

Projection stability is the stored route from I to O. Transporting the input row through hsame also transports the projected-output row through the corresponding component of H.

Boundary-ledger exactness is read from L and B. The ledger lists the internal defect contributions together with their displayed cancellation partners, while the boundary row records exactly the remaining endpoint contribution.

The non-escape obligation follows because those rows exhaust the carrier coordinates. A downstream consumer can reach no chain complex, host summation, quotient cancellation, or external calculus datum outside the displayed packet. □

Definition 408.3 (FoldDefectStokes empty carrier)**.** *The empty* $\mathsf{FoldDefectStokes}^{\uparrow}$ *carrier is the packet of Definition 408.1 with empty fold-input row, empty projected-output row, empty boundary-defect row, empty interior ledger, identity componentwise* hsame *transports, trivial displayed* Cont *routes, empty* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FoldDefectStokes}^{\uparrow}}$ *row.*

Theorem 408.4 (FoldDefectStokes classifier laws)**.** *For every accepted* $\mathsf{FoldDefectStokes}^{\uparrow}$ *carrier $S = (I, O, B, L, H, C, P, N)$, the local classifier transported by H is reflexive, symmetric, and transitive on the displayed input, output, boundary, ledger, route, provenance, and naming rows. These laws are componentwise* hsame *laws over the carrier of Definition 408.1 and add no ambient fold equality.*

Proof. Use the coordinates of Definition 408.1. Reflexivity is obtained by taking the identity hsame row on each of I, O, B, L, H, C, P, and N.

Symmetry reverses each displayed transport row. Since the classifier never reads an unrecorded fold operation, reversing the componentwise rows gives the same accepted surface.

Transitivity composes the displayed transports component by component. The boundary-ledger factorization of Definition 408.7 and the finite no-escape boundary of Definition 408.8 ensure that the composed classifier still mentions only the rows of the carrier. □

Theorem 408.5 (FoldDefectStokes projection stability)**.** *Let $S = (I, O, B, L, H, C, P, N)$ be an accepted* $\mathsf{FoldDefectStokes}^{\uparrow}$ *carrier. Any accepted transport of the fold-input row I through the displayed classifier keeps the projected-output row O readable through the same I-to-O* Cont *route, with the transported boundary row B and ledger row L still factoring as in Definition 408.7.*

Lean4 ✓ `BEDC.Derived.FoldDefectStokesUp.FoldDefectStokesPacket projection stability`

Proof. Start from the I-to-O route stored in C. Transporting I by the displayed classifier also transports the corresponding output coordinate through the matching component of H.

The boundary and ledger coordinates are then read through the same continuation route. Apply Definition 408.7 to identify the transported public defect with the boundary row and the interior ledger.

Finally, Definition 408.8 rules out any alternate output route through an external fold semantics, quotient, or host summation law. □

Theorem 408.6 (FoldDefectStokes exactness obligation)**.** *For every accepted* $\mathsf{FoldDefectStokes}^{\uparrow}$ *carrier $S = (I, O, B, L, H, C, P, N)$, the ledger L is exact at the public boundary row B: each internal defect contribution recorded in L is paired with a displayed cancellation route, and the remaining public defect is precisely the boundary read B certified by Definition 408.7.*

Proof. Inspect the ledger coordinate in Definition 408.1. Its entries are internal defect rows together with the displayed cancellation data that removes them from the endpoint read.

Apply Definition 408.7. The theorem says every public defect factors through B and L, so the only contributions not canceled inside L are exactly the entries represented by the boundary row.

The non-escape boundary of Definition 408.8 keeps the obligation local: there is no hidden differential, quotient cancellation, or host telescoping sum that could change the boundary after the ledger is read. □

Theorem 408.7 (FoldDefectStokes boundary-ledger factorization)**.** *Let $S = (I, O, B, L, H, C, P, N)$ be an accepted* $\mathsf{FoldDefectStokes}^{\uparrow}$ *carrier. Any public defect read from the projected fold output factors through the displayed route*

$$I \xrightarrow{C} O \xrightarrow{C} B \xleftarrow{C} L$$

together with the componentwise transport row H, package provenance P, and local certificate row N. In particular, an interior contribution affects the public boundary only by appearing in L with its displayed cancellation partner or by being recorded as part of the boundary row B.

Lean4 ✓ `BEDC.Derived.FoldDefectStokesUp.FoldDefectStokesPacket boundary ledger`

Proof. Start with a public request for a fold-defect read. The carrier first exposes the fold input row I and the projected fold-output row O through the stored continuation route.

The same route then reaches the boundary row B. No consumer can read a defect value before passing through the boundary row, because the carrier has no separate defect coordinate.

It remains to account for the interior ledger. Each internal contribution is listed in L together with the displayed cancellation route that removes it from the endpoint read. Contributions without such an internal cancellation are precisely the entries represented by B.

Transport row H, provenance P, and certificate row N make this factorization stable under accepted row movement. Thus the public defect read is a boundary-ledger read over the finite carrier and not an appeal to host algebra. □

Theorem 408.8 (FoldDefectStokes non-escape boundary)**.** *The* $\mathsf{FoldDefectStokes}^{\uparrow}$ *public boundary exports only the fold-input row, projected fold-output row, boundary-defect row, interior cancellation ledger, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *evidence. It exports no external import, no infinite complex, no ambient differential, no quotient of defects, no host telescoping sum, and no standard Stokes bridge.*

Lean4 ✓ `BEDC.Derived.FoldDefectStokesUp.FoldDefectStokesPacket non escape boundary`

Proof. Inspect the carrier coordinates of Definition 408.1. The only exported rows are I, O, B, L, H, C, P, and N.

By Definition 408.7, every public defect read factors through the boundary and ledger rows. The factorization has no coordinate for an external differential, quotient, infinite object, or host summation operation.

Therefore the public boundary can feed finite BEDC consumers that already understand fold inputs, boundary rows, and ledgers, but it cannot export any stronger calculus or bridge statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{FoldDefectStokes}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FoldDefectStokes}^{\uparrow}$ packet is generated from a finite fold-input row, projected fold-output row, boundary-defect row, interior cancellation ledger, componentwise hsame transports, displayed Cont routes, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FoldDefectStokes}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope registers the finite carrier, five NameCert obligations, boundary-ledger factorization, and no-escape boundary for fold-defect packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FoldDefectStokes}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close external imports, infinite complexes, ambient differentials, quotient defect algebra, host telescoping sums, standard Stokes bridges, or bridge checking.

Upgrade path: Obligation closure requires Lean targets for carrier habitation, classifier laws, projection stability, boundary-ledger exactness, and the finite no-escape boundary under `BEDC.Derived.FoldDefectStokesUp`.

Chapter 409

A Concrete Naming Certificate for $\mathsf{CauchyConvolution}^{\uparrow}$

The $\mathsf{CauchyConvolution}^{\uparrow}$ packet records the finite Cauchy-product surface that sits between fast-series convolution ledgers and the regular rational real-name route. Following Bishop–Bridges constructive analysis, it keeps displayed source series, finite convolution windows, dyadic tail budgets, $\mathsf{RegSeqRat}^{\uparrow}$ handoff rows, $\mathsf{Real}^{\uparrow}$ seal rows, transport data, continuation routes, package provenance, and local naming provenance as finite certificate data. It does not claim host real multiplication, quotient equality of streams, selected infinite sums, or ambient real completeness.

The packet consumes source-series and tail-budget carriers from chapter 367, chapter 368, and chapter 379 before handing the finite product-tail ledger to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$.

Definition 409.1 (CauchyConvolution carrier)**.** *A* $\mathsf{CauchyConvolution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, G, K, A, D, R, E, H, C, P, N)$$

with the following visible coordinates:

1. *F and G are two accepted* $\mathsf{FastConvergentSeries}^{\uparrow}$ *source rows, including their displayed summand windows, fast tail schedules, regular rational readbacks,* $\mathsf{Real}^{\uparrow}$ *seal-facing rows,* hsame *transports,* Cont *routes, package provenance, and local certificate rows;*
2. *K is the finite convolution ledger whose inspected coefficient at index n is the displayed finite sum $\sum_{0\le i\le n} a_i b_{n-i}$ over the source summand rows;*
3. *A is the finite product-prefix ledger that reads only the displayed convolution coefficients in K;*
4. *D is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *budget ledger, including the source tail budgets, the finite source-window bounds, and the pasted product-tail budget consumed by the convolution row;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from A and D;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to that regular rational handoff;*
7. *H records the componentwise* hsame *transports for source rows, convolution ledgers, dyadic tail budgets, regular handoffs, and seal-facing rows;*
8. *C records the displayed* Cont *routes by which consumers read the source packets, finite convolution ledger, dyadic tail ledger, regular handoff, and real seal;*

9. *P is the* Pkg *provenance over* FastConvergentSeries$^{\uparrow}$, FastSeriesProduct$^{\uparrow}$, DyadicTailBound$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *and the finite rational arithmetic rows used by the convolution;*
10. *N is the local* NameCert$_{\text{CauchyConvolution}^{\uparrow}}$ *provenance row.*

The carrier is finite Cauchy-product data. It exports no host product of real numbers, no quotient stream, no selected infinite sum, and no real-completeness principle.

Theorem 409.2 (CauchyConvolution NameCert obligations)**.** *Every accepted* CauchyConvolution$^{\uparrow}$ *packet with carrier Definition 409.1 carries five local naming obligations:*

1. *carrier habitation by zero-product data, where both accepted source rows may be the displayed zero fast series, the convolution ledger is the zero finite ledger, the dyadic budget is the zero pasted budget, and the handoff and seal rows are the corresponding regular rational zero rows;*
2. *componentwise classifier laws over the two* FastConvergentSeries$^{\uparrow}$ *source rows, finite convolution ledger, dyadic tail ledger,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal row,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row;*
3. *finite convolution ledger exactness, requiring each inspected coefficient row in K to be the finite displayed sum $\sum_{0\le i\le n} a_i b_{n-i}$;*
4. *dyadic tail-bound handoff, requiring the source fast-tail schedules and finite source-window bounds to feed the* DyadicTailBound$^{\uparrow}$ *ledger D and then the* RegSeqRat$^{\uparrow}$ *row R;*
5. Real$^{\uparrow}$ *seal non-escape, requiring every real-facing read to pass through the regular rational handoff and the displayed finite provenance rows.*

These obligations are the complete local certificate surface for the finite Cauchy-product route.

```
Lean4 ✓  BEDC.Derived.CauchyConvolutionUp.CauchyConvolutionPacket semantic name certificate
Lean4 ✓  BEDC.Derived.CauchyConvolutionUp.CauchyConvolutionCarrier namecert obligations
```

Proof. Carrier habitation is witnessed by the displayed zero source rows. Their finite convolution coefficients are zero, the product-prefix ledger is zero, and the dyadic tail budget is the zero budget. Repacking those rows gives the zero regular rational handoff and its real-seal-facing row.

The classifier obligations are componentwise projections of Definition 409.1. A permitted comparison reads only the two source packets, K, A, D, R, E, and the transport, continuation, package, and local naming rows.

The exactness obligation is local to the finite convolution ledger: at each inspected index n, the row records the finite sum over $0 \le i \le n$. The dyadic handoff obligation then reads the source tail schedules and finite source-window bounds into D, so R is reached through displayed tail-budget data rather than a host summation theorem.

Finally, the seal row E is attached only after the regular rational handoff has been displayed. Since the carrier has no coordinate for quotient streams, selected infinite sums, host multiplication, or completeness, every real-facing read remains inside the finite certificate packet. □

Theorem 409.3 (CauchyConvolution carrier admission)**.** *An accepted* CauchyConvolution$^{\uparrow}$ *carrier is admitted as the finite* BHist *packet*

$$Q = (F, G, K, A, D, R, E, H, C, P, N)$$

of Definition 409.1. Admission projects the two FastConvergentSeries$^{\uparrow}$ *source rows F, G, the finite convolution ledger K, the product-prefix ledger A, the* DyadicTailBound$^{\uparrow}$ *budget ledger D, the* RegSeqRat$^{\uparrow}$ *handoff row R, the* Real$^{\uparrow}$ *seal row E, and the transport, continuation, package, and local naming rows H, C, P, N.*

Proof. Project the accepted carrier. The coordinates $F, G, K, A, D, R, E, H, C, P, N$ are all rows of one finite packet, so the local $\mathsf{NameCert}_{\mathsf{CauchyConvolution}^{\uparrow}}$ carrier is inhabited by those projections.

The construction does not add a host product, a quotient stream, a selected infinite sum, or a completeness witness. Those objects are absent from the carrier, so admission remains a finite Cauchy-product packet over the displayed BEDC rows. □

Theorem 409.4 (CauchyConvolution tail-budget compatibility)**.** *For every accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *carrier* $Q = (F, G, K, A, D, R, E, H, C, P, N)$*, the source fast-tail schedules and finite source-window bounds in* F *and* G*, together with the product-prefix rows in* A *over the inspected coefficients of* K*, determine exactly the* $\mathsf{DyadicTailBound}^{\uparrow}$ *ledger* D *consumed by the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*.*

Lean4 ✓ `BEDC.Derived.CauchyConvolutionUp.CauchyConvolutionTailBudgetCompatibility`

Proof. Read the two source packets F and G. Their fast-tail schedules and finite source-window bounds are part of the displayed source rows, so they can be transported only through the componentwise rows in H and consumed only through the routes in C.

Next read the finite convolution ledger K and the product-prefix ledger A. The prefix rows inspect only finitely many Cauchy-product coefficients, and D records the pasted dyadic tail budget built from those finite inspections and the two source tail schedules.

The handoff row R consumes that same ledger D. Hence compatibility is a row-projection statement about $F, G, K, A, D, R, H, C, P, N$, with no appeal to host real multiplication or equality of quotient streams. □

Theorem 409.5 (CauchyConvolution source-tail seal chain)**.** *For every accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *packet* $Q = (F, G, K, A, D, R, E, H, C, P, N)$*, each real-facing seal read factors through the two* $\mathsf{FastConvergentSeries}^{\uparrow}$ *source tail schedules, the finite convolution ledger* K*, the product-prefix ledger* A*, the* $\mathsf{DyadicTailBound}^{\uparrow}$ *ledger* D*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R *before reaching the* $\mathsf{Real}^{\uparrow}$ *seal row* E*.*

Lean4 ✓ `BEDC.Derived.CauchyConvolutionUp.CauchyConvolutionCarrierSurface source tail seal factorization`

Proof. Project the two source packets F and G. Their fast-tail schedules and finite source-window bounds are visible source rows of the carrier and are transported only by the componentwise rows in H.

Apply Definition 409.4. This binds the source tail schedules to the convolution ledger K, product-prefix ledger A, dyadic tail ledger D, and regular handoff row R along the displayed continuation routes.

Use Definition 409.7 to identify the product-tail comparison consumed by R. The comparison is built from inspected convolution coefficients, source-tail schedules, finite source-window bounds, and the dyadic tail budget.

Only after this chain is displayed can the seal row E be read. Since the carrier has no coordinate for host real multiplication, quotient streams, selected infinite sums, or completeness, the real-facing route cannot bypass the finite source-tail chain. □

Theorem 409.6 (CauchyConvolution Real seal factorization boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *carrier factors through the regular handoff row* R *and the finite Cauchy-product provenance consisting of* $F, G, K, A, D, H, C, P, N$*. The seal boundary does not expose host real multiplication, quotient stream equality, a selected infinite convolution sum, or ambient completeness.*

Proof. Begin with the seal row E. By the carrier shape, E is attached to the regular handoff R and has no independent route to an external real-valued multiplication operation.

Use Definition 409.4 to identify the evidence consumed by R. It is the finite product-prefix ledger A over K together with the dyadic budget D assembled from the displayed source rows F and G.

The remaining rows H, C, P, N preserve transport, consumer access, package provenance, and local naming. Therefore the real-facing seal factors through the finite Cauchy-product packet and cannot export any object outside that packet. □

Theorem 409.7 (CauchyConvolution finite tail ledger)**.** *For every accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *carrier*

$$Q = (F, G, K, A, D, R, E, H, C, P, N),$$

the finite convolution ledger K, product-prefix ledger A, and $\mathsf{DyadicTailBound}^{\uparrow}$ *ledger D determine the displayed product-tail comparison consumed by R. The comparison uses only source fast-tail schedules, finite source-window bounds, inspected convolution coefficients, componentwise* hsame *transports, and displayed* Cont *routes.*

Proof. Project the two $\mathsf{FastConvergentSeries}^{\uparrow}$ source rows from F and G. Their fast tail schedules and finite source-window bounds are already displayed rows of the carrier.

The convolution ledger K supplies only finite coefficients, and the product-prefix ledger A reads those coefficients over finite inspected windows. The dyadic ledger D pastes the source tail schedules with the finite source-window bounds to obtain the product-tail budget at the requested precision.

Transport along H and read along C preserve exactly these displayed rows. Thus the comparison consumed by R is a finite tail ledger over $\mathsf{DyadicTailBound}^{\uparrow}$, not an appeal to a host Cauchy product or an infinite convolution object. □

Theorem 409.8 (CauchyConvolution Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *packet factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, whose regularity evidence is supplied by the finite product-prefix ledger A and the* $\mathsf{DyadicTailBound}^{\uparrow}$ *ledger D over the finite convolution row K. The seal route is therefore confined to* $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{FastSeriesProduct}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

Proof. Start from the seal coordinate E of the accepted carrier. By the carrier definition, E is attached to the same regular rational handoff row R and has no independent route to a host real object.

Apply Definition 409.7. It identifies the regularity evidence for R with the finite product-prefix ledger A and dyadic tail budget D, both built over the inspected convolution coefficients in K and the displayed source rows F and G.

The remaining coordinates H, C, P, and N record transport, continuation, package provenance, and local naming. They preserve the displayed route but do not add quotient streams, selected sums, host real multiplication, or completeness. Hence every exported seal read factors through the finite Cauchy-convolution packet alone. □

Definition 409.9 (CauchyConvolution obligation surface)**.** *For an accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *packet*

$$Q = (F, G, K, A, D, R, E, H, C, P, N),$$

the obligation surface consists of source-series admission, finite convolution coefficient ledger, dyadic tail-budget compatibility, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal non-escape. The surface is confined to* $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{FastSeriesProduct}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Theorem 409.10 (CauchyConvolution obligation ledger exactness)**.** *For every accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *packet* $Q = (F, G, K, A, D, R, E, H, C, P, N)$*, the source-series, finite coefficient, and dyadic tail-budget obligations of Definition 409.9 are witnessed by the concrete rows* $F, G, K, A, D, H, C, P, N$*.*

Proof. Apply Definition 409.3. It admits the source series rows, finite convolution row, product-prefix ledger, dyadic tail-budget row, and provenance rows as one finite carrier.

Apply Definition 409.4. This binds the source fast-tail schedules and finite source-window bounds to the dyadic tail budget consumed by the regular handoff.

Finally apply Definition 409.7. The convolution coefficient ledger remains finite and tied to K, A, D before the handoff row R is read. □

Theorem 409.11 (CauchyConvolution obligation real handoff package)**.** *For every accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *packet* $Q = (F, G, K, A, D, R, E, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal non-escape obligations of Definition 409.9 are exactly the displayed route through* R, E, H, C, P, N *together with the finite convolution ledger* F, G, K, A, D*.*

Proof. Use Definition 409.6. It factors the real-facing route through the regular rational handoff row and the finite convolution ledger.

Then use Definition 409.8. It identifies the exported seal as a read of R supported by A and D over K, with source rows F and G retained as finite provenance.

The transport, continuation, package, and naming rows preserve that route and do not introduce host real multiplication, quotient equality, selected infinite summation, or completeness. □

Theorem 409.12 (CauchyConvolution carrier classifier admission)**.** *For every accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *packet* $Q = (F, G, K, A, D, R, E, H, C, P, N)$*, the tuple* Q *supplies carrier admission for the source fast-series rows* F, G*, the finite convolution row* K*, the product-prefix ledger* A*, the dyadic tail budget* D*, the regular rational handoff* R*, the real seal row* E*, and the transport, continuation, package, and naming rows* H, C, P, N*. Its componentwise classifier transport is confined to* $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Proof. Apply Definition 409.3. It displays the accepted carrier coordinates and binds $F, G, K, A, D, R, E, H, C, P, N$ into one finite packet.

The classifier part is componentwise. Source classifiers are read from the two $\mathsf{FastConvergentSeries}^{\uparrow}$ rows, tail-budget classifiers from the $\mathsf{DyadicTailBound}^{\uparrow}$ row, handoff classifiers from R, and seal classifiers from E.

The history, sameness, continuation, package, and naming coordinates H, C, P, N transport these readings without adding any object outside the displayed rows. Hence the carrier and the classifier route are admitted by the same finite tuple. □

Theorem 409.13 (CauchyConvolution tail handoff obligation)**.** *For every accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *packet* $Q = (F, G, K, A, D, R, E, H, C, P, N)$*, the finite convolution ledger* K*, the product-prefix ledger* A*, and the dyadic budget* D *are exactly the tail handoff consumed by the regular rational row* R*.*

Proof. Use Definition 409.4 to bind the source fast-tail data to the dyadic budget row D.

Next apply Definition 409.7. It identifies the finite coefficient window K and the product-prefix ledger A as the concrete finite evidence that feeds the tail budget.

The handoff row R consumes this data as regular rational evidence. No additional infinite sum, quotient stream, host real product, or completeness principle is part of the handoff route. □

Theorem 409.14 (CauchyConvolution real seal non-escape obligation)**.** *For every accepted* $\mathsf{CauchyConvolution}^{\uparrow}$ *packet* $Q = (F, G, K, A, D, R, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal read factors through* R, E, H, C, P, N *together with the finite data* F, G, K, A, D*. Such a read cannot expose host multiplication, quotient streams, selected sums, or completeness.*

Proof. Apply Definition 409.6. It routes the real-facing coordinate through the regular rational handoff and the finite convolution ledger.

Then apply Definition 409.8. The exported seal is a read of E over R, and R is supported by A and D over K with source provenance in F and G.

The remaining coordinates H, C, P, N only preserve history, continuation, package provenance, and local naming. Therefore the seal read has no route to host multiplication, quotient streams, selected sums, or completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyConvolution}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyConvolution}^{\uparrow}$ packet is generated from two accepted $\mathsf{FastConvergentSeries}^{\uparrow}$ source rows, a finite convolution ledger, finite product-prefix rows, dyadic tail-budget rows, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise transport, continuation readback, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyConvolution}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: The scoped surface binds the carrier, convolution ledger, dyadic tail handoff, regular rational handoff, real seal non-escape, BHist, hsame, Cont, Pkg, and NameCert rows for the current Cauchy-product packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyConvolution}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CauchyConvolutionUp.CauchyConvolutionCarrier\_namecert\_obligations`

Bridge status: none

Origin: human

Not claimed: This chapter does not close host real multiplication, quotient equality of streams, selected infinite sums, uniqueness of products, real completeness, or bridge checking.

Upgrade path: Public closure requires an exported public Cauchy-product interface whose consumer rows are stable beyond the scoped Real and RegSeqRat dependency chain.

Chapter 410

A Concrete Naming Certificate for $\mathsf{LipschitzMap}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, a metric Lipschitz map is useful only when its bound is carried as explicit data. The $\mathsf{LipschitzMap}^{\uparrow}$ interface records that data as a finite BEDC packet: source and target $\mathsf{Met}^{\uparrow}$ rows, a $\mathsf{Real}^{\uparrow}$-valued rational Lipschitz-bound ledger, a $\mathsf{ContinuousMap}^{\uparrow}$ graph row, a $\mathsf{UniformModulus}^{\uparrow}$ row induced by the bound, componentwise hsame transports, visible Cont routes, Pkg provenance, and a local $\mathsf{NameCert}$ row. The packet is a connector for $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, and $\mathsf{ContinuousMap}^{\uparrow}$ consumers; it is not a Banach fixed-point theorem, a completeness claim, differentiability data, or host function extensionality.

The sibling dependency route is explicit. A $\mathsf{LipschitzMap}^{\uparrow}$ packet consumes the source and target metric rows from chapter 57, the graph row from chapter 130, and the induced modulus row from chapter 369. Its bound ledger is read through the $\mathsf{Real}^{\uparrow}$ surface of chapter 38. The fixed-point consumers in chapter 395 and chapter 396 read the same bound ledger as their contraction witness surface, so the Lipschitz packet is the bound-carrying connector between metric, continuity, modulus, real-bound, and fixed-point certificates.

Definition 410.1 (LipschitzMap carrier)**.** *A* $\mathsf{LipschitzMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, B, G, M, H, C, P, N)$$

with the following visible coordinates:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row;*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row;*
3. *B is a rational Lipschitz-bound ledger, read as a* $\mathsf{Real}^{\uparrow}$*-valued nonnegative bound row for target distances;*
4. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for the carried map;*
5. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *modulus row induced by the displayed bound ledger;*
6. *H records componentwise* hsame *transports for source points, target points, distance rows, the bound ledger, graph rows, and modulus rows;*
7. *C records the* Cont *routes by which consumers read source distances, target distances, the Lipschitz-bound comparison, the graph row, and the uniform-modulus row;*

8. *P records* Pkg *provenance for* $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *dependency rows;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzMap}^{\uparrow}}$ *provenance row.*

The carrier accepts exactly those packets whose displayed graph reads and metric-distance rows are bounded by the ledger B and whose modulus row M is the finite uniform-modulus route induced by that same bound.

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier semantic carrier package`

Definition 410.2 (LipschitzMap classifier)**.** *For accepted* $\mathsf{LipschitzMap}^{\uparrow}$ *carriers*

$$L = (X, Y, B, G, M, H, C, P, N) \quad \textit{and} \quad L' = (X', Y', B', G', M', H', C', P', N'),$$

the classifier compares source and target metric-space rows, rational bound-ledger rows, graph rows, induced uniform-modulus rows, transport rows, continuation routes, package provenance, and local certificate rows componentwise through the displayed hsame, Cont, Pkg, *and* NameCert *surface.*

It does not compare host functions extensionally, form a quotient of maps, choose representatives, assert completeness of either metric space, or infer differentiability.

Lean4 (definition) `BEDC.Derived.LipschitzMapUp.LipschitzMapClassifier`

Theorem 410.3 (LipschitzMap NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{LipschitzMap}^{\uparrow}}$ *seed surface consists of five finite obligations:*

1. *carrier: the packet of Definition 410.1;*

2. *classifier: the componentwise comparison of Definition 410.2;*

3. *stability:* hsame *and* Cont *transport preserve the source and target metric rows, bound ledger, graph row, and induced modulus row;*

4. *exactness: every target-distance read factors through the source-distance read, the displayed rational bound ledger, and the graph row;*

5. *ledger policy:* Pkg *and* NameCert *expose only the listed metric, real-bound, continuous-map, uniform-modulus, transport, and continuation rows.*

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier namecert obligation certificate`

Proof. Project the carrier. The source and target metric rows, rational bound ledger, graph row, induced modulus row, transport rows, continuation routes, package provenance, and local certificate row are exactly the visible coordinates.

The classifier is componentwise by definition, so stability is obtained by moving each displayed coordinate through the stored hsame rows and then following the stored Cont routes. This preserves the order from source distance to graph read to target distance and bound comparison.

Exactness follows because the target-distance row has no source except the graph row applied to source points and the bound ledger read against the source-distance row. The package and local certificate rows list no host function equality, completeness principle, differentiability datum, or chosen representative, so the ledger policy is exhausted by the displayed packet. □

Theorem 410.4 (LipschitzMap composition boundary)**.** *Let L and L' be accepted* $\mathsf{LipschitzMap}^{\uparrow}$ *carriers whose target* $\mathsf{Met}^{\uparrow}$ *row of L is classifier-compatible with the source* $\mathsf{Met}^{\uparrow}$ *row of L'. The composite consumer route is bounded by the displayed product of the two rational Lipschitz*

ledgers, reads the composite graph through the two ContinuousMap$^{\uparrow}$ *rows, and induces the composite* UniformModulus$^{\uparrow}$ *row through the two visible modulus routes.*

The boundary is a finite consumer boundary: it does not assert completeness, fixed points, differentiability, or host-level equality of composite functions.

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier composition boundary`

Proof. Read the first carrier through its source metric row, graph row, target metric row, and rational bound ledger. The target row is classifier-compatible with the source row of the second carrier, so the intermediate metric observation is a visible carried row rather than a host equality.

Read the second carrier through its graph row and bound ledger. The target distance of the second read is bounded by the second ledger applied to the intermediate distance, while the intermediate distance is bounded by the first ledger applied to the original source distance.

Repack the two bound reads as the displayed product ledger and route the graph reads through the two ContinuousMap$^{\uparrow}$ rows. The induced modulus route is the sequential use of the two UniformModulus$^{\uparrow}$ rows, and the exclusions follow because neither carrier contains completeness, fixed-point, differentiability, or host function-extensionality coordinates. □

Theorem 410.5 (LipschitzMap ledger nonescape)**.** *Every* UniformModulus$^{\uparrow}$, PicardContraction$^{\uparrow}$, BanachFixedPoint$^{\uparrow}$, *or* ContinuousMap$^{\uparrow}$ *consumer of an accepted* LipschitzMap$^{\uparrow}$ *carrier factors through the displayed source and target* Met$^{\uparrow}$ *rows, rational* Real$^{\uparrow}$ *bound ledger,* ContinuousMap$^{\uparrow}$ *graph row,* UniformModulus$^{\uparrow}$ *row, componentwise* hsame *transports, visible* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

No consumer can obtain a Banach fixed-point conclusion, completeness witness, differentiability row, quotient of maps, selected representative, or host function extensionality from the Lipschitz ledger alone.

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier ledger nonescape`

Proof. Use the obligation surface of Definition 410.3. It lists the carrier, classifier, stability, exactness, and ledger rows available to every local certificate consumer.

For a UniformModulus$^{\uparrow}$ consumer, read the modulus row M induced by the bound ledger B. For ContinuousMap$^{\uparrow}$ consumers, read the graph row G and the same transport routes. For PicardContraction$^{\uparrow}$ and BanachFixedPoint$^{\uparrow}$ consumers, the only available contraction-relevant datum is the rational bound ledger together with the metric rows and graph route.

Thus every consumer route stays inside the displayed finite packet. The excluded conclusions require coordinates not present in Definition 410.1, so they cannot escape from the local ledger. □

Theorem 410.6 (LipschitzMap complete-metric regular seal boundary)**.** *For an accepted* LipschitzMap$^{\uparrow}$ *packet*

$$L = (X, Y, B, G, M, H, C, P, N),$$

any CompleteMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *or* Real$^{\uparrow}$ *consumer of the Lipschitz graph and bound must factor through the displayed source* Met$^{\uparrow}$ *row* X, *target* Met$^{\uparrow}$ *row* Y, *rational* Real$^{\uparrow}$ *bound ledger* B, ContinuousMap$^{\uparrow}$ *graph row* G, *induced* UniformModulus$^{\uparrow}$ *row* M, *componentwise* hsame *transports* H, *displayed* Cont *routes* C, Pkg *provenance* P, *and local* NameCert *row* N.

The handoff exports no Banach fixed point, completed orbit, host function equality, quotient map, selected limit, or ambient completeness row. The downstream seal surfaces are the complete-metric row of chapter 128, the regular-rational source row of chapter 301, and the real-name seal row of chapter 38.

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier completemetric regular seal boundary`

Proof. Start with Definition 410.3. It exposes exactly the carrier rows $X, Y, B, G, M, H, C, P, N$ together with the local classifier, stability, exactness, and ledger obligations.

Apply Definition 410.5. Every listed consumer of the Lipschitz graph and bound remains inside the displayed source metric, target metric, rational bound, graph, modulus, transport, continuation, package, and naming rows. Thus a completion-facing read cannot obtain an ambient completeness coordinate or a selected point from the Lipschitz packet.

Use Definition 410.7 for the modulus route. The induced row M is read from X, G, and B through the same transport and package surface, so the route toward regular-rational and real seal consumers is the carried modulus route rather than a host function equality or quotient map.

The sibling chapters chapter 128, chapter 301, and chapter 38 supply only the downstream seal surfaces. Since none of those surfaces is a coordinate of L, the LipschitzMap packet contributes only the displayed graph-and-bound ledger to their consumer routes. □

Theorem 410.7 (LipschitzMap uniform-modulus consumer handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{LipschitzMap}^{\uparrow}$ *carrier*

$$L = (X, Y, B, G, M, H, C, P, N)$$

reads the modulus row only through the source $\mathsf{Met}^{\uparrow}$ *distance row* X*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row* G*, the rational* $\mathsf{Real}^{\uparrow}$ *bound ledger* B*, displayed* hsame *and* Cont *transport,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row* N*. The handoff exposes the same induced modulus row* M *and does not export host function extensionality, a quotient of maps, a selected representative, or a target-space principle outside the carried Lipschitz packet.*

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier uniform modulus consumer handoff`

Proof. Start with the obligation surface of Definition 410.3. It binds the carrier, classifier, stability, exactness, and ledger policy for the rows $X, Y, B, G, M, H, C, P, N$.

Apply ledger nonescape from Definition 410.5. A $\mathsf{UniformModulus}^{\uparrow}$ consumer is one of the listed consumers, so its read stays inside the displayed metric rows, graph row, bound ledger, induced modulus row, transport, continuation, provenance, and naming data.

Finally apply bound transport from Definition 410.9. Transport preserves the accepted Lipschitz packet and keeps M tied to the same bound ledger B. The consumer therefore receives the uniform-modulus data only through the carried source distance, graph, rational bound, and visible certificate rows. □

Theorem 410.8 (LipschitzMap public modulus export)**.** *For an accepted* $\mathsf{LipschitzMap}^{\uparrow}$ *packet*

$$L = (X, Y, B, G, M, H, C, P, N),$$

the public $\mathsf{UniformModulus}^{\uparrow}$ *row exported to any consumer is exactly* M*. It is induced from the rational* $\mathsf{Real}^{\uparrow}$ *bound ledger* B *through the graph row* G *and the source* $\mathsf{Met}^{\uparrow}$ *row* X*. No consumer may replace* M *by a host function modulus, a quotient of maps, or a target-space completeness principle.*

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier public modulus export`

Proof. First read the packet rows from Definition 410.3. The accepted carrier exposes $X, Y, B, G, M, H, C, P, N$ as the complete Lipschitz naming surface.

Next apply bound transport from Definition 410.9. The rational ledger B, graph row G, and induced modulus row M are transported as displayed rows of the same packet, so a consumer cannot detach the modulus from its source metric and graph evidence.

Finally use Definition 410.7. The handoff routes every $\mathsf{UniformModulus}^{\uparrow}$ read through X, G, B, M, H, C, P, N, hence the public row exported to the consumer is the carried row M and no host modulus, map quotient, or completeness principle is available. □

Theorem 410.9 (LipschitzMap bound transport)**.** *Let*

$$L = (X, Y, B, G, M, H, C, P, N)$$

be an accepted $\mathsf{LipschitzMap}^{\uparrow}$ *carrier. Any displayed* hsame *and* Cont *transport of the source* $\mathsf{Met}^{\uparrow}$ *row* X*, target* $\mathsf{Met}^{\uparrow}$ *row* Y*, graph row* G*, rational* $\mathsf{Real}^{\uparrow}$ *bound ledger* B*, and induced* $\mathsf{UniformModulus}^{\uparrow}$ *row* M *preserves the accepted Lipschitz packet. The transported packet has the same finite consumer surface: source-distance reads still enter through* X*, target-distance reads still exit through* Y*, graph reads still pass through* G*, and every modulus read is routed through the row* M *induced by the ledger* B*.*

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier bound transport`

Proof. Project the carrier coordinates. The transport row H already lists the componentwise hsame moves for source points, target points, metric-distance rows, bound ledger entries, graph rows, and modulus rows.

Follow the stored Cont routes in C after each componentwise move. The source-distance route is transported first, the graph route is then read over the transported source and target rows, and the rational bound comparison is read from the transported ledger B.

The induced modulus row has no separate origin: it is the $\mathsf{UniformModulus}^{\uparrow}$ route generated from the same displayed bound ledger. Repack the transported coordinates with the original Pkg provenance P and local $\mathsf{NameCert}$ row N. No representative choice or host function equality is used. □

Theorem 410.10 (LipschitzMap target-distance exactness)**.** *For an accepted* $\mathsf{LipschitzMap}^{\uparrow}$ *carrier*

$$L = (X, Y, B, G, M, H, C, P, N),$$

every target-distance read factors through the displayed source-distance read in X*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row* G*, and the rational* $\mathsf{Real}^{\uparrow}$ *bound ledger* B*. In particular, a consumer cannot read a target metric comparison from a hidden target-space principle, a quotient of maps, or an external function-extensionality assertion; the only exact route is the carried BEDC route*

source distance in X*,*
graph read through G*,*
bound comparison through B*,*
target distance in Y*.*

Proof. Read the target-distance coordinate from the carrier. By the classifier of Definition 410.2, target metric rows are compared only componentwise through the displayed hsame and Cont surface.

The graph coordinate G supplies the only route from source points to target points. The rational ledger B supplies the only nonnegative bound row for the target-distance comparison, and the source metric row X supplies the only source-distance input to that comparison.

Thus every target-distance read is obtained by composing those visible routes. The package row P and local certificate row N mention no completeness principle, quotient equality, representative selector, or host extensionality datum, so there is no second exactness route to project. □

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier target distance exactness`

Theorem 410.11 (LipschitzMap contraction-threshold handoff)**.** *Let*

$$L = (X, Y, B, G, M, H, C, P, N)$$

be an accepted $\mathsf{LipschitzMap}^{\uparrow}$ *carrier. If the rational bound ledger B is read through the displayed* $\mathsf{Real}^{\uparrow}$ *order as strictly below the unit threshold, then every* $\mathsf{PicardContraction}^{\uparrow}$ *or* $\mathsf{BanachFixedPoint}^{\uparrow}$ *consumer may use only the carried source* $\mathsf{Met}^{\uparrow}$ *row X, target* $\mathsf{Met}^{\uparrow}$ *row Y,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row G,* $\mathsf{UniformModulus}^{\uparrow}$ *row M, displayed* hsame *and* Cont *routes,* Pkg *provenance, and local* NameCert *row N.*

The handoff records contraction-threshold data for downstream packets, but it does not assert fixed points, completeness of X or Y, a quotient of maps, host function extensionality, or a selected representative.

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier contraction threshold handoff`

Proof. Start with target-distance exactness from Definition 410.10. It fixes the only target-distance route as the path from the source distance in X through the graph row G, bound ledger B, and target row Y.

Use bound transport from Definition 410.9. The strict subunit read of B is preserved by the displayed hsame and Cont movement, so the threshold datum remains attached to the same finite carrier.

Now apply the uniform-modulus consumer handoff of Definition 410.7. The modulus row M is read only through X, G, B and the local certificate rows, so a contraction consumer receives no independent analytic input.

Finally apply ledger nonescape from Definition 410.5. $\mathsf{PicardContraction}^{\uparrow}$ and $\mathsf{BanachFixedPoint}^{\uparrow}$ are listed consumers, and the packet contains no completeness, fixed-point, quotient, selector, or host-extensionality coordinate. The contraction-threshold handoff is therefore exactly the displayed finite route. □

Theorem 410.12 (LipschitzMap contraction-threshold factorization)**.** *Let*

$$L = (X, Y, B, G, M, H, C, P, N)$$

be an accepted $\mathsf{LipschitzMap}^{\uparrow}$ *carrier. If the bound ledger B is read as strictly below the unit threshold and a downstream fixed-point consumer supplies the required* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, *or* $\mathsf{BanachFixedPoint}^{\uparrow}$ *carrier row, then the consumer route factors through exactly*

$$X, Y, B, G, M, H, C, P, N$$

plus that displayed completeness or contraction row. The route cannot read fixed points, completeness, quotient-map equality, selected representatives, or host function extensionality from the $\mathsf{LipschitzMap}^{\uparrow}$ *packet itself.*

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier contraction threshold factorization`

Proof. Start with target-distance exactness from Definition 410.10. Every target-distance comparison used by the downstream consumer is routed through the source metric row X, graph row G, bound ledger B, and target metric row Y.

Use bound transport from Definition 410.9 together with the uniform-modulus handoff of Definition 410.7. These results keep the subunit threshold read attached to the displayed carrier and expose the modulus row M only through X, G, B, H, C, P, N.

Apply the contraction-threshold handoff of Definition 410.11. A $\mathsf{PicardContraction}^{\uparrow}$ or $\mathsf{BanachFixedPoint}^{\uparrow}$ consumer may therefore import only the displayed Lipschitz packet together with its own completeness or contraction row.

Finally apply ledger nonescape from Definition 410.5. The $\mathsf{LipschitzMap}^{\uparrow}$ packet has no coordinate for a fixed point, a completeness witness, quotient-map equality, a selected representative, or host function extensionality, so those data must come from the downstream carrier rather than from L. □

Theorem 410.13 (LipschitzMap identity carrier boundary)**.** *Let X be a transported $\mathsf{Met}^{\uparrow}$ row and let*

$$L = (X, X, B_{\mathsf{id}}, G_{\mathsf{id}}, M_{\mathsf{id}}, H, C, P, N)$$

be the packet whose source and target metric rows are the same transported row, whose graph row G_{id} is the identity graph over X, whose rational bound ledger B_{id} is the unit $\mathsf{Real}^{\uparrow}$ row, and whose modulus row M_{id} is the identity $\mathsf{UniformModulus}^{\uparrow}$ route. Then L forms an accepted $\mathsf{LipschitzMap}^{\uparrow}$ consumer boundary over the same BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, and it exposes no host function extensionality or selected representative.*

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier identity carrier boundary`

Proof. Project the carrier shape of Definition 410.1. With the same $\mathsf{Met}^{\uparrow}$ row in the source and target coordinates, the identity graph row supplies the carried $\mathsf{ContinuousMap}^{\uparrow}$ route from each source point history to the same target point history.

Use target-distance exactness from Definition 410.10. For the identity graph, every target-distance read is the same transported source-distance read, so the unit rational ledger B_{id} binds the target comparison to the original source metric row.

The identity $\mathsf{UniformModulus}^{\uparrow}$ route M_{id} is then the modulus induced by that unit bound. Bound transport from Definition 410.9 keeps B_{id}, G_{id}, and M_{id} attached to the same transported row through H and C.

Finally apply ledger nonescape from Definition 410.5. The packet contains only the displayed metric row, identity graph, unit bound ledger, identity modulus route, transports, continuations, provenance, and local certificate, so it cannot export host function extensionality or a selected representative. □

Theorem 410.14 (LipschitzMap obligation closure package)**.** *The $\mathsf{LipschitzMap}^{\uparrow}$ obligation surface is exhausted by the carrier of Definition 410.1, the classifier of Definition 410.2, bound transport Definition 410.9, target-distance exactness Definition 410.10, composition boundary Definition 410.4, and ledger nonescape Definition 410.5. These rows form a finite* BHist *package over* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$*.*

Proof. Collect the carrier and classifier rows first. They name exactly the finite coordinates and the componentwise comparison surface available to a local $\mathsf{NameCert}_{\mathsf{LipschitzMap}^{\uparrow}}$ consumer.

Add the three transport and routing obligations. Bound transport preserves the accepted packet under displayed hsame and Cont movement. Target-distance exactness fixes the unique target-distance read route. Composition boundary fixes the product ledger, sequential modulus route, and local certificate route for composed consumers.

Finally apply ledger nonescape. It states that $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, and $\mathsf{ContinuousMap}^{\uparrow}$ consumers factor through the displayed rows and do not acquire hidden completeness, differentiability, quotient, representative-selection, or host extensionality data. Repacking these named clauses gives precisely the obligation closure package. □

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier obligation closure package`

Theorem 410.15 (LipschitzMap bound dependency lock)**.** *Let*

$$L = (X, Y, B, G, M, H, C, P, N)$$

be an accepted $\mathsf{LipschitzMap}^{\uparrow}$ *carrier. Every* $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, *or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer of* L *must read the rational* $\mathsf{Real}^{\uparrow}$ *bound ledger* B *together with the source and target* $\mathsf{Met}^{\uparrow}$ *rows* X, Y*, the graph row* G*, and the induced modulus row* M*. No such consumer may detach* B *into a fixed-point theorem, completeness theorem, differentiability claim, quotient-map claim, or host-extensionality claim.*

Proof. Start with target-distance exactness. It binds each target-distance read to the source and target metric rows X, Y, the graph row G, and the rational bound ledger B through the displayed carrier route.

Use bound transport to keep B attached to the same graph and modulus data under hsame and Cont movement. The ledger is transported only as part of the accepted packet, not as an independent real-number fact.

Now apply the consumer handoffs. Uniform-modulus consumers read the induced row M from B, X, Y, G, contraction-threshold consumers read the same bound through the displayed threshold route, and composition boundary preserves the bound only through the product-ledger route for compatible Lipschitz packets.

Finally apply ledger nonescape. Since the carrier contains no row for completeness, differentiability, quotient-map equality, selected representatives, or host function extensionality, every listed consumer remains locked to $X, Y, B, G, M, H, C, P, N$ and cannot detach B into one of those stronger claims. □

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier bound dependency lock`

Theorem 410.16 (LipschitzMap common-bound completion route)**.** *Let*

$$L = (X, Y, B, G, M, H, C, P, N)$$

be an accepted $\mathsf{LipschitzMap}^{\uparrow}$ *carrier. Every completion-facing consumer that reads the graph row* G*, the rational Lipschitz-bound ledger* B*, a* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, and a* $\mathsf{Real}^{\uparrow}$ *seal must factor through one shared bound ledger together with the source and target* $\mathsf{Met}^{\uparrow}$ *rows* X, Y*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row* G*, and the* $\mathsf{UniformModulus}^{\uparrow}$ *row* M *before reaching the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal boundary. This route does not supply ambient completeness, selected limits, quotient-map equality, host function extensionality, or differentiability.*

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier common bound completion route`

Proof. Start from the local $\mathsf{NameCert}_{\mathsf{LipschitzMap}^\uparrow}$ obligations. They make the accepted packet read exactly the displayed source metric row, target metric row, rational bound ledger, continuous graph row, induced modulus row, transports, continuations, provenance, and local naming certificate.

Apply ledger nonescape and the uniform-modulus handoff. The rational bound B can be used by a consumer only through the displayed Lipschitz packet, so the modulus row M remains tied to the same X, Y, B, G ledger rather than becoming an ambient regularity fact.

Next use the complete-metric regular seal boundary. The completion-facing $\mathsf{RegSeqRat}^\uparrow$ source row and $\mathsf{Real}^\uparrow$ seal are read only after the shared Lipschitz ledger has passed through the sibling $\mathsf{Met}^\uparrow$, $\mathsf{ContinuousMap}^\uparrow$, and $\mathsf{UniformModulus}^\uparrow$ rows.

Finally apply Definition 410.15. It excludes detaching the common bound into completeness, selected limits, quotient-map equality, host function extensionality, or differentiability, and leaves the displayed $\mathsf{Met}^\uparrow$, $\mathsf{ContinuousMap}^\uparrow$, $\mathsf{UniformModulus}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, and $\mathsf{Real}^\uparrow$ rows as the only available completion route. □

Theorem 410.17 (LipschitzMap separated-completion nonescape)**.** *Let*

$$L = (X, Y, B, G, M, H, C, P, N)$$

be an accepted $\mathsf{LipschitzMap}^\uparrow$ *carrier. Every completion-facing consumer routed through* $\mathsf{CompleteMetric}^\uparrow$, $\mathsf{SeparatedMetric}^\uparrow$, $\mathsf{Real}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, *and* $\mathsf{UniformModulus}^\uparrow$ *must read the rational Lipschitz-bound ledger B and the separated zero-distance route before any completion identity claim is exposed. The consumer receives only the common-bound completion route, target-distance exactness, contraction-threshold factorization, and the public zero-distance route of* $\mathsf{SeparatedMetric}^\uparrow$*; it receives no ambient completeness theorem, selected limit, quotient completion equality, host function extensionality, differentiability, or detached real equality.*

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier separated completion nonescape`

Proof. Start from Definition 410.16. It places the graph row G, rational bound ledger B, source and target metric rows X, Y, induced modulus row M, $\mathsf{RegSeqRat}^\uparrow$ source row, and $\mathsf{Real}^\uparrow$ seal on one shared completion-facing route.

Apply target-distance exactness and the contraction threshold factorization. The target-distance read is tied to X, Y, B, G, while contraction-facing consumers may use the bound only through the displayed threshold route and induced modulus row.

Finally use the public separated-metric zero-distance route of Definition 1411.42. A completion identity claim can be exposed only after the separated zero-distance classifier has been read, so the Lipschitz packet cannot bypass B or replace the separated route by quotient completion equality, selected limits, or host equality. □

Theorem 410.18 (LipschitzMap scoped modulus route)**.** *Let*

$$L = (X, Y, B, G, M, H, C, P, N)$$

be an accepted $\mathsf{LipschitzMap}^\uparrow$ *carrier. Before any separated-completion or uniform-continuity consumer reads L, the metric source and target rows X, Y, rational* $\mathsf{Real}^\uparrow$ *distance row B,* $\mathsf{ContinuousMap}^\uparrow$ *graph row G,* $\mathsf{UniformModulus}^\uparrow$ *row M, common bound, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{LipschitzMap}^\uparrow}$ *row must pass through one finite surface. The consumer receives the scoped modulus route displayed by the packet, not a detached modulus, ambient completion theorem, quotient equality of maps, host function extensionality, differentiability claim, or selected representative.*

Lean4 ✓ `BEDC.Derived.LipschitzMapUp.LipschitzMapCarrier scoped modulus route`

Proof. Start with the local NameCert obligations. They expose exactly the source and target metric rows, the rational bound ledger, the continuous graph row, the induced modulus row, transport, replay, provenance, and local naming surface of L.

Use the uniform-modulus consumer handoff and public modulus export. A uniform-continuity consumer can read M only as the modulus induced by the same X, Y, B, G route, and the exported modulus remains tied to the displayed Lipschitz bound rather than becoming an ambient modulus fact.

Next apply bound transport, target-distance exactness, and the common-bound completion route. The bound row B is transported only with the graph and modulus data, each target-distance read is tied to X, Y, B, G, and every completion-facing read factors through the shared bound before reaching $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ seals.

Finally use Definition 410.17. Separated-completion consumers must read the separated zero-distance route after the same scoped Lipschitz surface, so no consumer can bypass B, M, H, C, P, N or replace the packet by quotient equality, host extensionality, differentiability, selected representatives, or ambient completion. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzMap}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzMap}^{\uparrow}$ packet is generated from source and target $\mathsf{Met}^{\uparrow}$ rows, a rational $\mathsf{Real}^{\uparrow}$ Lipschitz-bound ledger, a $\mathsf{ContinuousMap}^{\uparrow}$ graph row, a $\mathsf{UniformModulus}^{\uparrow}$ modulus row induced by the bound, componentwise hsame transports, visible Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzMap}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 410.1, Definition 410.2, Definition 410.3, Definition 410.9, Definition 410.10, Definition 410.4, Definition 410.14, and Definition 410.18 bind the displayed bound, graph, modulus, transport, continuation, provenance, and local naming surface over $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Banach fixed point, completeness of the metric spaces, differentiability, quotient equality of maps, selected representatives, host function extensionality, or bridge checking.

Upgrade path: Formal verification and standard bridge checking remain separate from the mature paper treatment of the displayed bound, graph, modulus, transport, continuation, provenance, and local naming surface.

Chapter 411

Regular Cauchy Comparison NameCert Construction

The $\mathsf{RegularCauchyComparison}^{\uparrow}$ interface records the finite comparison layer used by the Real completeness proof target of section 9238.2. It compares two regular Cauchy names through shared finite windows, displayed dyadic observations, rational tolerance rows, and the downstream $\mathsf{Real}^{\uparrow}$ seal classifier. The packet does not select a host limit, quotient regular streams, or invoke ambient real completeness.

The common-window comparison consumes the finite window schedule of chapter 126 and the dyadic observation ledger of chapter 291 before the $\mathsf{Real}^{\uparrow}$ seal row is read.

Definition 411.1 (Regular Cauchy comparison carrier)**.** *A* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, W, D, \tau, L, E, H, C, P, N)$$

with the following visible rows:

1. *X and Y are the two displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy names under comparison;*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window schedule used by both names for every inspected precision request;*
3. *D is the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation surface for the two windows named by W;*
4. *τ is the rational tolerance row against which the dyadic observations are compared;*
5. *L is the finite ledger recording which window reads, dyadic observations, and tolerance rows have been inspected;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-provenance row reached only after the common window and dyadic comparison rows have been displayed;*
7. *H stores componentwise* hsame *transports for the two names, the shared schedule, dyadic observations, tolerance row, finite ledger, and seal row;*
8. *C stores the displayed* Cont *routes by which consumer reads reach those same finite rows;*
9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComparison}^{\uparrow}}$ *row.*

The carrier contains no quotient of regular names, no host real equality test, no selected limit, and no completeness witness outside the displayed packet.

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonTasteGate single carrier alignment`

Definition 411.2 (Regular Cauchy comparison classifier)**.** *For accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packets* K *and* K'*, the classifier* $\mathsf{RegularCauchyComparisonClassifier}(K, K')$ *holds exactly when all displayed finite comparison windows refine to the same transported dyadic tolerance row and the* $\mathsf{Real}^{\uparrow}$ *seal rows classify identically after those refinements.*

Thus the classifier reads only the two $\mathsf{RegSeqRat}^{\uparrow}$ *names, the shared* $\mathsf{StreamName}^{\uparrow}$ *schedule, displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, rational tolerance row, finite ledger,* $\mathsf{Real}^{\uparrow}$ *seal provenance,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It does not compare host sequences, quotient representatives, selected limits, or unrecorded real carriers.*

Theorem 411.3 (Regular Cauchy comparison NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComparison}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier admission: accepted packets are exactly the finite* BHist *carriers of Definition 411.1;*
2. *classifier stability: Definition 411.2 is preserved by displayed* hsame *transports and* Cont *routes on the two* $\mathsf{RegSeqRat}^{\uparrow}$ *names, shared* $\mathsf{StreamName}^{\uparrow}$ *schedule, dyadic observations, tolerance row, ledger, seal row, package provenance, and local naming row;*
3. *window exactness: every comparison request reads both names through the same displayed finite schedule* W *before inspecting the dyadic observation row* D*;*
4. *tolerance exactness: the dyadic observations are compared only against the rational tolerance row* τ *recorded in the packet ledger;*
5. *seal handoff: the* $\mathsf{Real}^{\uparrow}$ *classifier is consumed only after the common-window comparison and tolerance rows have been displayed.*

This surface is a comparison certificate for the Real completeness capstone and does not assert real completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier semantic name certificate`

Theorem 411.4 (Regular Cauchy comparison window exactness)**.** *For every accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet*

$$K = (X, Y, W, D, \tau, L, E, H, C, P, N)$$

and every displayed comparison request, both $\mathsf{RegSeqRat}^{\uparrow}$ *names are read through the same finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* W*, the selected observations are exactly the* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows in* D*, and the tolerance comparison is exactly the rational row* τ *recorded in* L*. No consumer read may split the two names across unrelated windows or replace* τ *by an unrecorded tolerance.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier window exactness`

Theorem 411.5 (Regular Cauchy comparison Real classifier handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *classifier read exported by an accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet factors through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *names, the shared* $\mathsf{StreamName}^{\uparrow}$ *window schedule, the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, the rational tolerance row, the finite ledger,* $\mathsf{Real}^{\uparrow}$ *seal provenance,* BHist*,* hsame*,* Cont*,* Pkg*, and*

NameCert *rows. The handoff supplies the finite comparison layer used by Definition 9238.5 without adding quotient stream equality, a selected host limit, host real equality, or an ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier real classifier handoff`

Theorem 411.6 (Regular Cauchy comparison common-window stability)**.** *For every accepted* RegularCauchyComparison$^{\uparrow}$ *packet*

$$K = (X, Y, W, D, \tau, L, E, H, C, P, N)$$

the shared window row W is stable under the displayed hsame *transports and* Cont *routes. A classified read of either X or Y must inspect the same transported* StreamName$^{\uparrow}$ *schedule before reading D and τ, and no read may split the two regular names across unrelated windows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier common window stability`

Proof. Project the carrier of Definition 411.1. It contains one shared StreamName$^{\uparrow}$ schedule W and no second window coordinate.

Apply Definition 411.2. The classifier moves the schedule only by the stored component of H and by the displayed consumer routes in C.

Now use Definition 411.4. Every comparison request reads both regular names through that common schedule before it reaches dyadic observations or tolerance rows. □

Theorem 411.7 (Regular Cauchy comparison tolerance-row exactness)**.** *For every accepted* RegularCauchyCompari *packet*

$$K = (X, Y, W, D, \tau, L, E, H, C, P, N)$$

the rational tolerance row τ is the only tolerance inspected by comparison reads. Classified transport may move τ through the displayed hsame *and* Cont *routes, but it cannot substitute an unrecorded rational tolerance or a host-real equality threshold.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier tolerance row exactness`

Proof. Use Definition 411.1 to identify τ as the sole rational tolerance coordinate of the packet.

Apply Definition 411.4. Once the two regular names are read through W, the dyadic observations in D are compared against exactly the tolerance row recorded in L.

The classifier definition of Definition 411.2 permits only componentwise transport of that row. Therefore a consumer read can transport τ but cannot replace it by an absent tolerance. □

Theorem 411.8 (Regular Cauchy comparison Real seal boundary)**.** *Every* Real$^{\uparrow}$ *classifier read exported by an accepted* RegularCauchyComparison$^{\uparrow}$ *packet factors through the displayed rows $X, Y, W, D, \tau, L, E, H, C,$ The seal boundary is the finite comparison packet itself: it exposes no quotient stream equality, selected host limit, host real equality, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier real seal boundary`

Proof. First apply Definition 411.6. The two regular names reach the comparison only through the shared transported window W.

Next apply Definition 411.7. The dyadic observations in D are compared only against the rational tolerance row τ recorded in the finite ledger L.

Finally use Definition 411.5. Its handoff route is exactly the path through $X, Y, W, D, \tau, L, E, H, C, P, N$, so the real-facing read has no access to quotient representatives, selected limits, host equality, or ambient completeness. □

Theorem 411.9 (Regular Cauchy comparison seal-compatible transitivity)**.** *Let accepted* RegularCauchyComparison *packets compare X to Y and Y to Z. If their transported* $\mathsf{StreamName}^{\uparrow}$ *schedules and rational tolerance rows refine to a common finite window ledger, then the composed comparison packet from X to Z has the same* $\mathsf{Real}^{\uparrow}$ *seal-compatible boundary through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. The composed packet does not assert quotient stream equality, selected host limits, host real equality, or an ambient completeness principle.*

Proof. First apply Definition 411.6. The two comparison packets can be read on the common finite window ledger because their transported schedules refine to that ledger.

Next apply Definition 411.7. The composed read uses only the rational tolerance rows displayed by the two packets and their common ledger refinement; it cannot introduce a host-real equality threshold.

Finally use Definition 411.8 together with Definition 411.5. The comparison from X to Z reaches the $\mathsf{Real}^{\uparrow}$ seal through the same finite BHist, hsame, Cont, Pkg, and local NameCert rows, so the transitive handoff remains a seal-compatible finite comparison and not a statement about selected limits or quotient stream equality. □

Theorem 411.10 (Regular Cauchy comparison triangle-window composition)**.** *Let accepted* RegularCauchyComparison *packets compare X to Y and Y to Z. Suppose their* $\mathsf{StreamName}^{\uparrow}$ *schedules refine to one displayed finite window and their* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows refine to one visible comparison ledger. Then the two packets compose to an accepted X-to-Z comparison whose* $\mathsf{Real}^{\uparrow}$ *seal handoff factors through the same displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

The composed comparison is only this finite triangle-window route. It does not introduce quotient stream equality, a selected host limit, host real equality, or an ambient completeness principle.

Proof. First use Definition 411.6. The two comparison packets are read on the single displayed window because both transported $\mathsf{StreamName}^{\uparrow}$ schedules refine to it.

Next use Definition 411.7. The $\mathsf{DyadicRatCore}^{\uparrow}$ observations and rational tolerances are consumed through the common ledger, so the composed route has no tolerance datum outside the finite packet.

The seal boundary is supplied by Definition 411.8. It keeps the $\mathsf{Real}^{\uparrow}$ handoff on the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Finally apply Definition 411.9. The X-to-Y and Y-to-Z finite comparisons therefore compose to the X-to-Z finite comparison, with no appeal to quotient streams, selected limits, host real equality, or completeness outside the carrier. □

Theorem 411.11 (Regular Cauchy comparison finite-window induction)**.** *Let $K = (X, Y, W, D, \tau, L, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet. Every accepted comparison route over a finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule is exhausted by induction over the displayed window ledger W.*

Along the induction, the route preserves the $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row* D*, the tolerance row* τ*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the structural rows* H, C, P, N*.*

Consequently a comparison consumer that accepts all finite windows in W *receives exactly the displayed comparison surface*

$$X, Y, W, D, \tau, L, E, H, C, P, N$$

and cannot add a dyadic observation outside D*, a tolerance coordinate outside* τ*, a second real seal, quotient stream equality, a selected limit, host real equality, or an ambient completeness principle.*

Proof. Induct on the displayed finite window ledger W.

In the empty-window case, there is no window from which a fresh $\mathsf{DyadicRatCore}^{\uparrow}$ observation can be read. The comparison route is therefore restricted to the already displayed rows $D, \tau, L, E, H, C, P, N$, and the carrier supplies no coordinate for quotient streams or selected host limits.

For the successor window, apply common-window stability to keep the new $\mathsf{StreamName}^{\uparrow}$ cell on the same transported schedule. Then use tolerance-row exactness: the successor read may consume only the dyadic observation already recorded in D and the rational tolerance already recorded in τ for that cell.

The induction hypothesis preserves all earlier cells of W with the same structural rows H, C, P, N. Combining the earlier route with the successor read gives the full finite ledger, and the $\mathsf{Real}^{\uparrow}$ seal boundary closes the induction by forcing the final handoff through E rather than through host real equality or ambient completeness. □

Theorem 411.12 (Regular Cauchy comparison diagonal-budget handoff)**.** *Let* $K = (X, Y, W, D, \tau, L, E, H, C, P, N$ *be an accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet. Suppose the shared window* W *and tolerance rows* D, τ, L *are consumed by an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *packet and an accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet. Then* K *exports one diagonal* $\mathsf{Real}^{\uparrow}$ *handoff through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

The exported handoff is only the finite route from comparison windows and dyadic tolerance ledgers into the diagonal budget and tail schedule. It does not expose quotient streams, selected host limits, host real equality, or an ambient completeness principle.

Proof. Start with common-window stability. The accepted comparison packet makes the two $\mathsf{RegSeqRat}^{\uparrow}$ names readable only through the transported $\mathsf{StreamName}^{\uparrow}$ window W, so the diagonal budget and tail schedule consume the same finite window rather than two unrelated stream views.

Next use tolerance-row exactness. The $\mathsf{DyadicRatCore}^{\uparrow}$ observations and the rational tolerance row τ are the only tolerance data recorded in D and L, hence the diagonal-budget consumer receives exactly the displayed tolerance ledger.

The $\mathsf{Real}^{\uparrow}$ seal boundary then fixes the endpoint of the handoff. The comparison packet reaches the real-facing row through E after the regular-rational, stream-window, dyadic, ledger, transport, route, provenance, and naming rows have been read.

Finally combine the finite route obligations already recorded by the $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ and $\mathsf{TailCofinalitySchedule}^{\uparrow}$ consumers. Those packets consume the shared window and tolerance ledger before the tail schedule reaches its $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{Real}^{\uparrow}$ seal. Since none of the three packets contains a coordinate for quotient streams, selected host limits, host real equality, or ambient completeness, the composite handoff remains the single displayed finite route. □

Theorem 411.13 (Regular Cauchy comparison classifier transport)**.** *Let*

$$K = (X, Y, W, D, \tau, L, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet. If* K' *is obtained by transporting the displayed coordinates componentwise along the stored* hsame *routes in* H *and then reading them along the displayed* Cont *routes in* C*, then* K' *is accepted by the same classifier. The transport preserves the two* $\mathsf{RegSeqRat}^{\uparrow}$ *names, the shared* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, the tolerance row* τ*, the finite ledger* L*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, the package provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComparison}^{\uparrow}}$ *coordinate* N*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier public rows zero head absurd`

Proof. Project the displayed carrier tuple of Definition 411.1. Each coordinate of K' is supplied by one stored component of H and one consumer route in C, so the transported packet has exactly the same visible rows as K at the BHist interface.

Apply the defining clause of Definition 411.2. The classifier reads only those projected rows, hence componentwise hsame transport and the recorded Cont reads preserve acceptance and preserve the two regular names, shared schedule, dyadic observations, tolerance row, ledger, seal row, package row, and local naming row. □

Theorem 411.14 (Regular Cauchy comparison tolerance row stability)**.** *For every accepted* $\mathsf{RegularCauchyCompari}$ *packet*

$$K = (X, Y, W, D, \tau, L, E, H, C, P, N)$$

every displayed comparison request uses exactly the rational tolerance row τ *recorded in* L*. A classified replacement of* K *may transport* τ *along the stored component of* H *and read it along the displayed component of* C*, but it cannot replace* τ *by a tolerance row absent from the carrier ledger.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier tolerance row stability`

Proof. Use Definition 411.4 to identify the tolerance inspected by any displayed comparison request. The theorem pins that row to the rational tolerance coordinate τ recorded in L.

Now apply Definition 411.13. Classified replacement acts only through the stored componentwise transport and the displayed consumer read, so the tolerance coordinate can be carried across the accepted packet boundary but no unrecorded tolerance can enter the comparison. □

Theorem 411.15 (Regular Cauchy comparison common-window seal factorization)**.** *For every accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet, each* $\mathsf{Real}^{\uparrow}$ *seal read exported by the packet factors first through a shared* $\mathsf{StreamName}^{\uparrow}$ *window, then through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, the rational tolerance row, the finite ledger, and the local certificate rows, before reaching the seal provenance row. Thus the seal handoff is mediated by the common comparison window and not by a direct host-real equality test or an unrecorded limit choice.*

Proof. Apply Definition 411.4 to force both regular names through the same finite window schedule before any dyadic observation is inspected.

Use Definition 411.14 for the next layer. The observed dyadic rows are compared only against the recorded rational tolerance row and the ledger that displays it.

Finally apply Definition 411.5. Its handoff route consumes the common-window comparison rows, the tolerance row, the finite ledger, and the local certificate coordinates before it reaches the $\mathsf{Real}^{\uparrow}$ seal row. □

Theorem 411.16 (Regular Cauchy comparison two-stage handoff)**.** *For every accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet*

$$K = (X, Y, W, D, \tau, L, E, H, C, P, N),$$

every consumer-facing comparison first routes both $\mathsf{RegSeqRat}^{\uparrow}$ *names* X *and* Y *through the shared* $\mathsf{StreamName}^{\uparrow}$ *window schedule* W*. Only after that common-window read may the packet expose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row* D*, the rational tolerance row* τ*, the finite ledger* L*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, the displayed transports* H*, the displayed continuations* C*, the package provenance* P*, and the local naming row* N*.*

Proof. Begin with the common window. Apply Definition 411.6 to force the two regular names through the same displayed schedule W before any dyadic observation is read.

Next bind the numerical comparison layer. Apply Definition 411.14: the observation row D can be inspected only against the recorded rational tolerance τ and its finite ledger L.

Finally use Definition 411.5. The real-facing route consumes the common-window and tolerance rows before reaching E, H, C, P, N, so the handoff is a two-stage finite packet route rather than a direct real-completion read. □

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier two stage handoff`

Theorem 411.17 (Regular Cauchy comparison seal uniqueness boundary)**.** *Let* K *and* K' *be accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packets whose displayed rows agree on* $W, D, \tau, L, H, C, P, N$*. If two seal consumers read the packets through those same rows, then they obtain the same classifier-facing* $\mathsf{Real}^{\uparrow}$ *seal row. This uniqueness is a boundary statement about the displayed comparison certificate; it does not assert host real equality, select a limit, or identify quotient representatives of the two regular names.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier seal uniqueness boundary`

Proof. Project both packets to the classifier-facing rows. The shared $W, D, \tau, L, H, C, P, N$ coordinates give the same common-window schedule, dyadic observation layer, tolerance ledger, transport routes, continuation reads, package provenance, and local naming surface.

Apply Definition 411.13 to carry the agreed rows across the accepted packet boundary. Then apply Definition 411.15; a seal consumer can reach E only through that factored route.

Thus the two consumers see the same $\mathsf{Real}^{\uparrow}$ seal row at the classifier interface. The proof never introduces a host equality test or a selected completion limit, because neither is a coordinate of the displayed carrier. □

Theorem 411.18 (Regular Cauchy comparison three-window triangle)**.** *Let* K_{xy} *and* K_{yz} *be accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packets for regular Cauchy names* X, Y *and* Y, Z*. Suppose the* Y *rows in the two packets are classified through a shared transported* $\mathsf{StreamName}^{\uparrow}$ *window. Then their displayed* $W, D, \tau, L, E, H, C, P, N$ *rows refine to a third accepted comparison packet* K_{xz} *for* X *and* Z*.*

The $\mathsf{Real}^{\uparrow}$ *seal route of* K_{xz} *passes through the two shared finite windows and the dyadic tolerance ledger before it reaches the seal row. It does not pass through host real equality, a selected limit, or an unrecorded equality of regular-name representatives.*

Proof. Begin with the two finite windows. Apply Definition 411.6 to K_{xy} and K_{yz}, using the shared transported Y row to align the two displayed $\mathsf{StreamName}^{\uparrow}$ schedules.

Next compose the numerical rows. By Definition 411.14, each dyadic observation is read only with its recorded rational tolerance row and finite ledger. The two ledgers therefore provide the displayed tolerance surface needed for the X, Z comparison packet.

Now factor the real-facing seal. Apply Definition 411.15 to both source packets, then use Definition 411.17 at the shared Y window to identify the visible seal route carried across the middle packet boundary.

Finally repack the shared window rows, tolerance rows, ledgers, seal row, transports, continuations, provenance, and naming rows as K_{xz}. The constructed packet is accepted because every coordinate is one of the displayed $W, D, \tau, L, E, H, C, P, N$ rows exposed by the two source packets and their shared transported window. □

Theorem 411.19 (Regular Cauchy comparison intersection-window coverage)**.** *Let K be an accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet comparing regular Cauchy names X and Y, and let a completion-facing consumer present two displayed schedules W_0 and W_1 through which it attempts to read the comparison. Then the consumer route must first expose a finite intersection schedule $W_\cap$ carrying the shared* $\mathsf{StreamName}^{\uparrow}$ *window for X and Y.*

On that same finite intersection schedule, the route must display the $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row D, the rational tolerance row τ, the comparison ledger L, the* $\mathsf{Real}^{\uparrow}$ *seal row E, and the visible* BHist, hsame, Cont, Pkg, *and* NameCert *rows. No completion-facing read may bypass this intersection window by appealing directly to host real equality, quotient representatives, a selected limit, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier window intersection coverage`

Proof. First force the two displayed schedules to the common finite window. Apply Definition 411.6: the accepted comparison packet supplies a shared $\mathsf{StreamName}^{\uparrow}$ schedule before any dyadic observation can be read, so the two displayed schedules refine through an intersection row $W_\cap$.

Next attach the numerical rows to that intersection window. By Definition 411.14, the dyadic row D and rational tolerance row τ are read together with the finite ledger L; the consumer cannot detach the tolerance comparison from the displayed window.

Now use Definition 411.24. The classifier route reaches the shared window, dyadic observations, tolerance row, comparison ledger, seal row, and the visible BHist, hsame, Cont, Pkg, and NameCert rows as one finite packet.

Finally apply Definition 411.21. A completion-facing consumer can cite exactly that packet evidence, so the intersection-window coverage condition is necessary before the consumer reaches the $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 411.20 (Regular Cauchy comparison symmetric window swap)**.** *Let*

$$K = (X, Y, W, D, \tau, L, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet. Swapping the two* $\mathsf{RegSeqRat}^{\uparrow}$ *names X and Y preserves the shared* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row D, the tolerance row τ, the ledger L, the seal row E, and the visible* hsame, Cont, Pkg, *and* NameCert *rows. The swapped packet therefore exposes the same* $\mathsf{Real}^{\uparrow}$ *classifier handoff through the same finite common-window comparison surface.*

Proof. First isolate the common window. By Definition 411.6, both regular names are read through the single displayed schedule W, so exchanging the order of X and Y does not create a second window row.

Next keep the numerical comparison rows fixed. Apply Definition 411.14: the dyadic observations in D are compared against exactly the recorded tolerance row τ and ledger L, and classified transport cannot substitute an unrecorded tolerance.

Now use Definition 411.13. The displayed hsame and Cont components move the two name coordinates componentwise while preserving the shared window, observation row, tolerance row, ledger, seal row, package provenance, and local certificate.

Finally apply Definition 411.5. The $\mathsf{Real}^{\uparrow}$ handoff reads only the same finite comparison surface, so the swapped presentation exposes the same classifier-facing handoff without importing host equality of regular streams. □

Theorem 411.21 (Regular Cauchy comparison completion consumer surface)**.** *Every* $\mathsf{Real}^{\uparrow}$*-completion consumer of an accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet can cite exactly the finite comparison surface*

$$X, Y, W, D, \tau, L, E, H, C, P, N$$

as its packet evidence. The surface supplies the two regular names, the shared window schedule, the dyadic observations, the tolerance ledger, the seal row, transport and continuation evidence, package provenance, and local naming; it supplies no additional completion principle, host real equality, quotient representative, or chosen limit.

Proof. First package the route from the two regular names to the displayed comparison rows. Use Definition 411.16 to expose $X, Y, W, D, \tau, L, H, C, P, N$ in the required order.

Next package the seal boundary. Use Definition 411.17 to identify what a seal consumer can read when the comparison rows are fixed.

Finally apply Definition 411.5. Its consumer route is exactly the displayed packet surface, and the carrier has no coordinate for any further completion object. □

Theorem 411.22 (Regular Cauchy comparison NullSequence handoff)**.** *For every accepted* RegularCauchyComparis *packet*

$$K = (X, Y, W, D, \tau, L, E, H, C, P, N),$$

if the displayed dyadic comparison ledger supplies a $\mathsf{NullSequence}^{\uparrow}$ *packet for the difference stream read from* X *and* Y*, then every* $\mathsf{Real}^{\uparrow}$ *equality seal read exported by* K *factors through the same shared* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the dyadic observation row* D*, the rational tolerance row* τ*, the finite comparison ledger* L*, and that* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail packet before reaching* E*. This handoff exports no quotient stream equality, host real equality, selected limit, trichotomy, or ambient completeness principle.*

Proof. Apply Definition 411.15. The $\mathsf{Real}^{\uparrow}$ seal route for K already passes through the shared $\mathsf{StreamName}^{\uparrow}$ window, the displayed dyadic observations, the tolerance row, and the finite ledger before it reaches the seal provenance row.

Use Definition 411.14 to identify the tolerance row used by the dyadic comparison ledger with the recorded row τ. The supplied $\mathsf{NullSequence}^{\uparrow}$ packet therefore reads the same difference stream and the same tolerance data that the comparison packet displays.

Finally apply Definition 380.10 and Definition 380.7. These results make the zero-tail packet the consumer boundary for the real equality seal, so the route reaches E only through the finite comparison surface and the null-sequence seal package, with no additional quotient, host equality, limit choice, trichotomy, or completeness object. □

Theorem 411.23 (Regular Cauchy comparison carrier admission)**.** *Every accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet*

$$K = (X, Y, W, D, \tau, L, E, H, C, P, N)$$

is a finite BHist *carrier over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, hsame, Cont, Pkg, *and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComparison}^{\uparrow}}$ *row. Its admitted surface consists exactly of the two regular names, shared stream window, dyadic observation row, tolerance row, comparison ledger, real seal handoff, componentwise transports, consumer routes, provenance, and naming certificate.*

Proof. Project the accepted packet through the carrier definition and the local naming surface. The rows $X, Y, W, D, \tau, L, E, H, C, P, N$ display the two regular Cauchy names, the common finite schedule, dyadic observations, tolerance ledger, finite comparison ledger, real-seal handoff, transports, continuations, provenance, and local name.

Use the NullSequence handoff row to account for zero-tail comparison data when it is present. Because the handoff is read through the same $W, D, \tau, L, E, H, C, P, N$ coordinates, it does not add a second carrier or an external completion principle. □

Theorem 411.24 (Regular Cauchy comparison classifier window exactness)**.** *For an accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet* K*, the common-window classifier and tolerance rows are exact under the displayed* hsame *and* Cont *routes. Every classifier read reaches the shared* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row* D*, rational tolerance row* τ*, and comparison ledger* L *before it reaches the* $\mathsf{Real}^{\uparrow}$ *handoff* E*.*

Proof. Apply Definition 411.13. It transports classifier reads componentwise through the displayed hsame rows and reads them through the displayed Cont routes.

Next apply Definition 411.14 and Definition 411.15. These identify the tolerance and common-window rows used by the classifier with the rows τ and W already stored in the packet.

The resulting route reaches D and L in the same finite order before the seal handoff E. No classifier read can replace this route with host real equality, a quotient stream comparison, a selected limit, or ambient completeness. □

Theorem 411.25 (Regular Cauchy comparison seal handoff obligation)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal handoff of an accepted* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet factors only through the admitted carrier rows and the classifier-window exactness rows. It exports the displayed handoff* E *over* $X, Y, W, D, \tau, L, H, C, P, N$ *and exports no quotient representative, selected limit, host equality, trichotomy, or ambient completeness datum.*

Proof. Start with Definition 411.23. It fixes the finite packet rows that a seal consumer may inspect.

Use Definition 411.24 to force the classifier route through the shared window, dyadic observations, tolerance row, and comparison ledger. Then use Definition 411.5 to reach the real-facing handoff row E.

Finally apply Definition 411.21. The consumer surface is exactly the displayed packet evidence, so the seal handoff is an obligation row inside the carrier and not an appeal to quotient equality, host equality, a chosen limit, trichotomy, or completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier seal handoff obligation`

Theorem 411.26 (Regular Cauchy comparison dependency scope)**.** *The carrier admission, window exactness, Real classifier handoff, and common-window stability rows of Definition 411.23, Definition 411.4, Definition 411.5, and Definition 411.6 form the scoped comparison package over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{NullSequence}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

Every comparison consumer is therefore forced through the two regular names, the shared stream window, the dyadic observation surface, the tolerance ledger, and the real seal handoff before it can read the packet as a $\mathsf{RegularCauchyComparison}^{\uparrow}$ *certificate.*

Proof. Begin with Definition 411.23. It admits exactly the finite packet rows over the listed BEDC dependencies and the local naming row.

Apply Definition 411.4 and Definition 411.6. These rows force both regular names through the same $\mathsf{StreamName}^{\uparrow}$ schedule before any dyadic observation or tolerance read is available.

Use Definition 411.5 for the final handoff. The real-facing classifier reads only the same comparison surface, so the dependency scope is the displayed package and no external completion object is added. □

Theorem 411.27 (Regular Cauchy comparison NullSequence seal scope)**.** *The tolerance exactness, seal factorization, and* $\mathsf{NullSequence}^{\uparrow}$ *handoff rows of Definition 411.7, Definition 411.15, and Definition 411.22 bind the comparison seal to the concrete zero-tail route over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{NullSequence}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

The scoped seal can be consumed only after the common-window dyadic comparison and the rational tolerance row have been displayed, and it exports no host equality, quotient representative, selected limit, trichotomy, or ambient completeness witness.

Proof. First apply Definition 411.7. The comparison reads the rational tolerance row already recorded in the finite ledger.

Next use Definition 411.15. It forces the $\mathsf{Real}^{\uparrow}$ seal route through the shared window, the dyadic observation row, the tolerance row, and the ledger.

Finally apply Definition 411.22. When a zero-tail packet is supplied, it is consumed through the same displayed comparison rows, so the seal remains inside the listed dependency scope. □

Theorem 411.28 (Regular Cauchy comparison StreamName RealUp scope package)**.** *The classifier transport, classifier-window exactness, seal handoff obligation, and completion consumer surface rows of Definition 411.13, Definition 411.24, Definition 411.25, and Definition 411.21 give the* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *scoped package for* $\mathsf{RegularCauchyComparison}^{\uparrow}$*.*

This package binds the displayed $\mathsf{StreamName}^{\uparrow}$ *window route to the* $\mathsf{Real}^{\uparrow}$ *handoff over the two* $\mathsf{RegSeqRat}^{\uparrow}$ *names, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, the* $\mathsf{NullSequence}^{\uparrow}$ *seal route when present, and the visible* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

Proof. Use Definition 411.13 to move the comparison packet componentwise through the stored hsame and Cont rows. The transport preserves the two regular names, the shared window, dyadic observations, tolerance row, ledger, seal row, package row, and local naming row.

Apply Definition 411.24. The classifier reaches the shared window, dyadic observation row, rational tolerance row, and comparison ledger before it reaches the real handoff.

The public seal and consumer boundaries are then supplied by Definition 411.25 and Definition 411.21. Together they make the $\mathsf{StreamName}^{\uparrow}$ route and the $\mathsf{Real}^{\uparrow}$ handoff one scoped comparison package. □

Theorem 411.29 (Regular Cauchy comparison public export certificate)**.** *The carrier, classifier, window exactness, tolerance exactness,* $\mathsf{Real}^{\uparrow}$ *seal boundary,* $\mathsf{NullSequence}^{\uparrow}$ *handoff, and* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *scope package rows of Definition 411.23, Definition 411.13, Definition 411.4, Definition 411.7, Definition 411.15, Definition 411.22, and Definition 411.28 export one public* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *comparison certificate for downstream* $\mathsf{Real}^{\uparrow}$ *consumers.*

The exported certificate is a consumer-facing object over the displayed finite comparison packet. It introduces no quotient stream equality, selected host limit, host real equality, trichotomy claim, or ambient completeness theorem.

Proof. Begin with Definition 411.23 and Definition 411.13. These fix the finite packet and preserve its two regular names, shared stream window, dyadic observations, tolerance row, comparison ledger, seal row, package row, and local naming row under the displayed transport routes.

Next apply Definition 411.4 and Definition 411.7. They make the comparison readable only after the shared $\mathsf{StreamName}^{\uparrow}$ window and the rational tolerance row have both been displayed.

Use Definition 411.15 and Definition 411.22 for the real-facing seal. These rows keep the $\mathsf{Real}^{\uparrow}$ handoff tied to the same finite comparison evidence and to the $\mathsf{NullSequence}^{\uparrow}$ route when that route is present.

Finally apply Definition 411.28. It repacks the displayed window route and real handoff as one $\mathsf{StreamName}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ comparison package, so the public export is exactly the stated consumer certificate and not an appeal to quotient equality, a selected host limit, host real equality, trichotomy, or ambient completeness. □

Theorem 411.30 (Regular Cauchy comparison standard bridge source)**.** *The standard bridge source for* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *is exactly the displayed comparison packet over two* $\mathsf{RegSeqRat}^{\uparrow}$ *names, the shared* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, the rational tolerance row, the finite comparison ledger, the* $\mathsf{Real}^{\uparrow}$ *seal handoff, and the stored* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

No additional source object may enter the bridge read before these rows are displayed.

Proof. Start from the public export certificate of Definition 411.29. It already packages the two regular Cauchy names, shared stream window, dyadic observations, tolerance row, comparison ledger, real-facing seal, package row, and local naming row.

Apply the classifier and window exactness rows. They force the bridge source to read the shared $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{DyadicRatCore}^{\uparrow}$ observations before reaching the $\mathsf{Real}^{\uparrow}$ seal handoff.

Finally use the transport and continuation rows. Since H, C, P, N are the only rows that move or replay the packet, a standard bridge source has exactly the displayed comparison data and no further source coordinate. □

Theorem 411.31 (Regular Cauchy comparison bridge non-escape)**.** *Every bridge-facing read from the public* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *certificate remains inside the source rows of Definition 411.30. The bridge exports no quotient regular stream, selected limit, host real equality, trichotomy, or ambient completeness witness.*

Proof. Project the source packet named in Definition 411.30. Its rows are the two regular names, shared stream window, dyadic observations, tolerance row, comparison ledger, real seal handoff, transport rows, continuation routes, package provenance, and local naming row.

Apply Definition 411.29. The public certificate is consumer-facing only over those displayed rows and explicitly excludes quotient stream equality, selected host limits, host real equality, trichotomy, and ambient completeness.

The bridge-facing read therefore has no remaining coordinate from which to obtain a quotient representative, a selected limit, an equality in a host real model, an order split, or a completeness principle. Those objects lie outside the displayed source. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyComparison}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ regular Cauchy names, a shared $\mathsf{StreamName}^{\uparrow}$ schedule, displayed $\mathsf{DyadicRatCore}^{\uparrow}$ observations, a rational tolerance row, a finite ledger, $\mathsf{Real}^{\uparrow}$ seal provenance, displayed hsame and Cont routes, package provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyComparison}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature scope records carrier admission, classifier stability, common-window exactness, tolerance exactness, $\mathsf{Real}^{\uparrow}$ seal handoff, the public export certificate, the standard bridge source, and bridge non-escape over the displayed comparison rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyComparison}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.RegularCauchyComparisonUp.RegularCauchyComparisonCarrier\_semantic\_name\_certificate`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close real completeness, quotient equality of regular streams, uniqueness of limits, host real construction, or bridge checking.

Upgrade path: Lean bridge checking remains the next verification step for the same $\mathsf{StreamName}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ comparison package.

Chapter 412

A Concrete Naming Certificate for $\mathsf{ArzelaAscoli}^{\uparrow}$

The $\mathsf{ArzelaAscoli}^{\uparrow}$ interface names the constructive compact-metric reading of the Arzela–Ascoli theorem for families of continuous maps. A carrier records a family of $\mathsf{ContinuousMap}^{\uparrow}$ rows from a $\mathsf{CompactMetric}^{\uparrow}$ source into a $\mathsf{CompleteMetric}^{\uparrow}$ target, together with finite ProbeBundle nets, equicontinuity modulus rows, pointwise totally bounded image rows, displayed hsame and Cont transport, Pkg provenance, and a local NameCert row. It is a finite compact-continuity discovery target over $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, and $\mathsf{CompactUniformContinuity}^{\uparrow}$, not an open-cover compactness principle or a subsequence chosen by ambient choice.

The carrier consumes the finite-net source surface of chapter 129 through its $\mathsf{CompactMetric}^{\uparrow}$ row X, the target completion rows of chapter 128 through its $\mathsf{CompleteMetric}^{\uparrow}$ row Y, the family graph rows of chapter 130 through the finite ledger F, and the finite-modulus handoff of chapter 388 through the modulus row M. These sibling rows are consumed as carrier coordinates and ledger inputs, not as ambient compactness, function-space, or choice principles.

The family-level equicontinuity rows are read through chapter 413, while the finite modulus handoff is read through chapter 388; both are consumed only as finite net and modulus ledgers and do not add open-cover compactness or choice-selected subsequences.

Definition 412.1 (Arzela-Ascoli carrier)**.** *An* $\mathsf{ArzelaAscoli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, Y, F, \mathcal{P}, E, I, M, B, H, C, P, N)$$

with the following visible coordinates:

1. *X is the source* $\mathsf{CompactMetric}^{\uparrow}$ *row, including its* $\mathsf{Met}^{\uparrow}$ *source, finite* ProbeBundle *net rows, and transported* $\mathsf{TotallyBounded}^{\uparrow}$ *coverage;*
2. *Y is the target* $\mathsf{CompleteMetric}^{\uparrow}$ *row whose distance and regular-Cauchy limit witnesses are read through displayed* $\mathsf{Met}^{\uparrow}$ *and completion rows;*
3. *F is a finite family ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows from X to Y;*
4. *$\mathcal{P}$ records the finite source-net windows used to test the family;*
5. *E records equicontinuity modulus rows, each binding a requested target tolerance to one finite source-radius row uniformly over the family ledger;*
6. *I records pointwise* $\mathsf{TotallyBounded}^{\uparrow}$ *image rows for the finite family values at every bundled source-net point;*

7. *M records the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *or* $\mathsf{FanTheorem}^{\uparrow}$ *finite-modulus handoff rows that turn pointwise windows into a uniform finite source window;*
8. *B records the finite image-bundle selections and target metric distance witnesses used by the pointwise total-bounded rows;*
9. *H records componentwise* hsame *transports for source nets, target-completion rows, family rows, equicontinuity rows, pointwise image rows, finite-modulus rows, and bundle selections;*
10. *C records the visible* Cont *routes by which compact-metric, continuous-map, total-bounded, complete-metric, fan, and compact-uniform-continuity consumers read the packet;*
11. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, ProbeBundle, hsame, *and* Cont *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ArzelaAscoli}^{\uparrow}}$ *row.*

The carrier exports only finite net, modulus, image-bundle, completion-witness, transport, continuation, package, and naming rows. It contains no open-cover compactness row, no sequential compactness row, no unrecorded function-space topology, and no choice-selected subsequence.

Theorem 412.2 (Arzela-Ascoli NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ArzelaAscoli}^{\uparrow}}$ *surface consists exactly of carrier habitation by the packet of Definition 412.1; classifier transport of the source compact-metric rows, target complete-metric rows, family of continuous-map rows, equicontinuity rows, pointwise image-bundle rows, and finite-modulus rows; finite-net coverage through* ProbeBundle*; target-side completion readback through* $\mathsf{CompleteMetric}^{\uparrow}$*; and downstream non-escape through the recorded* hsame, Cont, Pkg, *and local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.ArzelaAscoliUp.ArzelaAscoliPacket namecert obligations`

Proof. Carrier habitation is the displayed tuple of Definition 412.1. Each source-net row, family row, target-completion row, equicontinuity row, pointwise image-bundle row, finite-modulus handoff, transport row, continuation route, package row, and local certificate row is visible before a consumer can read it.

Classifier transport is componentwise. The $\mathsf{CompactMetric}^{\uparrow}$ coordinate transports source finite nets, the $\mathsf{ContinuousMap}^{\uparrow}$ family coordinate transports graph and pointwise modulus rows, the $\mathsf{TotallyBounded}^{\uparrow}$ coordinate transports finite image bundles, and the $\mathsf{CompleteMetric}^{\uparrow}$ coordinate transports target regular-Cauchy limit witnesses.

The finite-modulus coordinate M is then transported through the same hsame and Cont routes. It may cite $\mathsf{FanTheorem}^{\uparrow}$ or $\mathsf{CompactUniformContinuity}^{\uparrow}$, but only through their finite branch-depth, witness-window, and compact-uniform-modulus ledgers.

These rows exhaust the certificate. Since the carrier has no coordinate for open covers, host function spaces, choice-selected subsequences, or ambient sequential compactness, the local naming certificate cannot export any of those objects. □

Theorem 412.3 (Arzela-Ascoli carrier habitation)**.** *There is a finite inhabited* $\mathsf{ArzelaAscoli}^{\uparrow}$ *carrier of the form*

$$A = (X, Y, F, \mathcal{P}, E, I, M, B, H, C, P, N)$$

whose source row is a $\mathsf{CompactMetric}^{\uparrow}$ *row, whose target row is a* $\mathsf{CompleteMetric}^{\uparrow}$ *row, whose family rows are* $\mathsf{ContinuousMap}^{\uparrow}$ *rows, whose pointwise image rows are* $\mathsf{TotallyBounded}^{\uparrow}$ *rows, whose finite handoff rows are read through* $\mathsf{FanTheorem}^{\uparrow}$ *or* $\mathsf{CompactUniformContinuity}^{\uparrow}$*, and whose visible bookkeeping is a* ProbeBundle, hsame, Cont, Pkg, *and* NameCert *packet as specified in Definition 412.1.*

Proof. Use the displayed packet shape of Definition 412.1. The source coordinate X, target coordinate Y, finite family ledger F, source-net packet $\mathcal{P}$, equicontinuity ledger E, image ledger I, handoff ledger M, image bundle B, transport row H, continuation row C, provenance row P, and naming row N form a finite BHist packet.

The equicontinuity net handoff of Definition 412.6 verifies that the source-net, family, pointwise-image, completion, and handoff rows are read as a single finite compact-continuity surface. No open-cover or subsequence coordinate is needed for habitation. □

Theorem 412.4 (Arzela-Ascoli completion-window readback)**.** *Let $A = (X, Y, F, \mathcal{P}, E, I, M, B, H, C, P, N)$ be an accepted* ArzelaAscoli$^{\uparrow}$ *carrier. Every target-side completion read exported by A factors through the* CompleteMetric$^{\uparrow}$ *row Y, the finite* ProbeBundle *source windows $\mathcal{P}$, the* ContinuousMap$^{\uparrow}$ *family ledger F, the* TotallyBounded$^{\uparrow}$ *image rows I, the finite handoff row M from* FanTheorem$^{\uparrow}$ *or* CompactUniformContinuity$^{\uparrow}$*, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Begin with a completion read in the target. The carrier first exposes the target coordinate Y, so every limit or regular-Cauchy read is a CompleteMetric$^{\uparrow}$ read rather than a host completion choice.

Next read the source windows $\mathcal{P}$ and family ledger F. By Definition 412.6, the selected source-net rows and equicontinuity rows route every family value through the same finite compact-continuity handoff.

The pointwise image rows I and image-bundle rows B then supply the finite totally bounded target packets. The finite handoff row M records whether the branch-depth or compact-uniform-continuity route is used, and H, C, P, N keep that read stable under classifier transport. □

Theorem 412.5 (Arzela-Ascoli non-escape obligation)**.** *The public boundary of an accepted* ArzelaAscoli$^{\uparrow}$ *packet exports only the source* CompactMetric$^{\uparrow}$ *row, target* CompleteMetric$^{\uparrow}$ *row, finite* ContinuousMap$^{\uparrow}$ *family ledger,* ProbeBundle *source-net rows, equicontinuity rows, pointwise* TotallyBounded$^{\uparrow}$ *image rows,* FanTheorem$^{\uparrow}$ *or* CompactUniformContinuity$^{\uparrow}$ *handoff rows, image-bundle rows, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *evidence. It exports no open-cover compactness, no sequential compactness, no ambient function-space topology, and no choice-selected subsequence.*

Proof. Inspect the coordinates of Definition 412.1. They are exactly X, Y, F, $\mathcal{P}$, E, I, M, B, H, C, P, and N.

The handoff theorem Definition 412.6 routes compact-continuity consumers through finite source nets, equicontinuity ledgers, pointwise image bundles, target completion rows, and the provenance rows. This accounts for every downstream read named by the carrier.

Since no carrier coordinate names open covers, sequential compactness, a compact-open topology, or a subsequence selector, the local naming certificate cannot export those objects. □

Theorem 412.6 (Arzela-Ascoli equicontinuity net handoff)**.** *Every compact-continuity consumer reading an accepted* ArzelaAscoli$^{\uparrow}$ *packet obtains a finite handoff: one displayed* ProbeBundle *source net from* CompactMetric$^{\uparrow}$*, equicontinuity modulus rows over the* ContinuousMap$^{\uparrow}$ *family ledger, pointwise totally bounded image rows in the* CompleteMetric$^{\uparrow}$ *target, and the transported* Cont *and* Pkg *provenance tying those rows to the local* NameCert$_{\text{ArzelaAscoli}^{\uparrow}}$ *certificate.*

The handoff supplies finite net data for a constructive Arzela–Ascoli argument and does not supply open-cover compactness, sequential compactness, an ambient compact-open topology, or a choice-selected subsequence.

Lean4 ✓ `BEDC.Derived.ArzelaAscoliUp.ArzelaAscoliPacket equicontinuity net handoff`

Proof. Project the source coordinate X and the source-net coordinate $\mathcal{P}$. The compact-metric input supplies finite ProbeBundle coverage, so a consumer source read is routed through displayed net centers and their coverage witnesses.

Read the family coordinate F together with the equicontinuity ledger E. For a requested target tolerance, the ledger selects source-radius rows uniformly over the displayed family entries and routes the corresponding continuous-map modulus reads through the same finite net.

Next project the pointwise image coordinate I and the image-bundle coordinate B. At each bundled source-net point, the target values of the displayed family are covered by finite totally bounded image rows and by target metric distance witnesses read inside the $\mathsf{CompleteMetric}^{\uparrow}$ target.

Finally attach the finite-modulus coordinate M and the provenance rows H, C, P, N. These rows preserve the same source net, equicontinuity windows, pointwise image bundles, and target-completion witnesses under classifier transport, and no omitted carrier coordinate can add open-cover compactness, sequential compactness, a host function-space topology, or a choice-selected subsequence. □

Definition 412.7 (Arzela-Ascoli modulus carrier)**.** *Let*

$$A = (X, Y, F, \mathcal{P}, E, I, M, B, H, C, P, N)$$

be an accepted $\mathsf{ArzelaAscoli}^{\uparrow}$ *carrier. The* $\mathsf{ArzelaAscoli}^{\uparrow}$ *modulus carrier is the finite subcarrier*

$$A_M = (X, F, \mathcal{P}, E, I, M, H, C, P, N)$$

obtained by projecting the compact-metric source nets, continuous-map family rows, equicontinuity ledgers, pointwise totally bounded image rows, $\mathsf{FanTheorem}^{\uparrow}$ *or* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *finite handoff rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ArzelaAscoli}^{\uparrow}}$ *row from* A*.*

Theorem 412.8 (Arzela-Ascoli modulus NameCert obligations)**.** *For every accepted* $\mathsf{ArzelaAscoli}^{\uparrow}$ *packet, the modulus subcarrier of Definition 412.7 binds exactly the finite compact-continuity data needed by later modulus consumers: compact-metric source nets in* X*,* $\mathsf{ContinuousMap}^{\uparrow}$ *family rows in* F*, finite source windows in* $\mathcal{P}$*, equicontinuity ledgers in* E*, pointwise totally bounded image rows in* I*, and* $\mathsf{FanTheorem}^{\uparrow}$ *or* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *handoff rows in* M*, transported through* H, C, P, N*.*

It supplies no open-cover compactness, ambient function-space topology, sequential compactness, or choice-selected subsequence.

Proof. Project the displayed carrier of Definition 412.1. The rows named in Definition 412.7 are exactly the source-net, family, equicontinuity, pointwise-image, finite-handoff, transport, replay, provenance, and naming coordinates of the accepted packet.

Apply Definition 412.6. It shows that every compact-continuity consumer reads finite source nets, equicontinuity windows, pointwise image bundles, target-completion witnesses, and finite handoff rows through one transported surface.

Finally use Definition 412.5. Since the accepted carrier exports no open-cover compactness row, host function-space topology, sequential compactness row, or subsequence selector, the projected modulus carrier cannot acquire any of those objects. □

Theorem 412.9 (Arzela-Ascoli scoped compact-continuity package)**.** *Let*

$$A = (X, Y, F, \mathcal{P}, E, I, M, B, H, C, P, N)$$

be an accepted ArzelaAscoli$^{\uparrow}$ *carrier. Then A exports exactly the scoped compact-continuity packet consisting of the compact-metric source rows in X, the complete-metric target rows in Y, the continuous-map family ledger F, the* ProbeBundle *source-net rows $\mathcal{P}$, the equicontinuity rows E, the pointwise* TotallyBounded$^{\uparrow}$ *image rows I, the* FanTheorem$^{\uparrow}$ *or* CompactUniformContinuity$^{\uparrow}$ *handoff rows M, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance carried by B, H, C, P, N.*

Every compact-continuity read of this packet factors through those rows, and no read of A supplies open-cover compactness, sequential compactness, an ambient compact-open topology, an unrecorded function-space carrier, or a choice-selected subsequence.

Proof. First use Definition 412.2. It identifies the local certificate surface with carrier habitation, classifier transport, finite source-net coverage, target completion readback, and non-escape through the displayed transport, continuation, package, and naming rows.

Next apply Definition 412.4. This routes every target-side completion read through $Y, \mathcal{P}, F, I, M$ and the provenance rows, so the complete-metric target contribution is part of the same finite compact-continuity packet rather than an ambient completion choice.

Then combine Definition 412.5 with Definition 412.6. The non-escape boundary lists the exported coordinates, and the handoff theorem shows that compact-continuity consumers read finite source nets, equicontinuity windows, pointwise image bundles, target-completion witnesses, and finite handoff rows through one transported surface.

These component rows are exactly the coordinates displayed in A. Repacking them gives the scoped compact-continuity package, while the absence of any further carrier coordinate rules out open-cover compactness, sequential compactness, ambient function-space topology, unrecorded carriers, and choice-selected subsequences. □

Theorem 412.10 (Arzela-Ascoli public certificate)**.** *For every accepted* ArzelaAscoli$^{\uparrow}$ *carrier*

$$A = (X, Y, F, \mathcal{P}, E, I, M, B, H, C, P, N),$$

the scoped compact-continuity package of Definition 412.9 is the public $\mathsf{NameCert}_{\mathsf{ArzelaAscoli}^{\uparrow}}$ *surface consumed by downstream compactness and completion chapters. It exports exactly the finite rows over* CompactMetric$^{\uparrow}$*,* CompleteMetric$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*,* TotallyBounded$^{\uparrow}$*,* FanTheorem$^{\uparrow}$ *or* CompactUniformContinuity$^{\uparrow}$*,* ProbeBundle*,* hsame*,* Cont*,* Pkg*, and* NameCert*, and it exports no open-cover compactness, sequential compactness, choice-selected subsequence, ambient compact-open topology, or bridge checking.*

Proof. Start with the scoped compact-continuity package. It already repacks the compact-metric source rows, complete-metric target rows, continuous-map family ledger, source-net rows, equicontinuity rows, pointwise totally bounded image rows, finite modulus handoff rows, and the displayed structural provenance.

Read the package as a public surface. Downstream compactness and completion consumers receive the same rows through ProbeBundle source nets, CompleteMetric$^{\uparrow}$ target readback, ContinuousMap$^{\uparrow}$ family data, TotallyBounded$^{\uparrow}$ image rows, and the finite handoff supplied by FanTheorem$^{\uparrow}$ or CompactUniformContinuity$^{\uparrow}$.

The transport, replay, provenance, and local naming rows are exactly H, C, P, N. Because no further carrier coordinate appears in A, public consumption cannot add open-cover compactness, sequential compactness, a selected subsequence, an ambient compact-open topology, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArzelaAscoli}^{\uparrow}}$.

Constructive story: An $\mathsf{ArzelaAscoli}^{\uparrow}$ packet is generated from a $\mathsf{CompactMetric}^{\uparrow}$ source, a $\mathsf{CompleteMetric}^{\uparrow}$ target, a finite family ledger of $\mathsf{ContinuousMap}^{\uparrow}$ rows, finite ProbeBundle source nets, equicontinuity modulus rows, pointwise $\mathsf{TotallyBounded}^{\uparrow}$ image rows, finite $\mathsf{FanTheorem}^{\uparrow}$ or $\mathsf{CompactUniformContinuity}^{\uparrow}$ modulus handoff rows, displayed hsame and Cont transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArzelaAscoli}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 412.10 bridges the public compact-continuity packet at the paper-theory level over $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, ProbeBundle, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArzelaAscoli}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.ArzelaAscoliUp.ArzelaAscoliPacket\_namecert\_obligations`

Bridge status: none

Origin: human

Not claimed: This chapter does not claim open-cover compactness, sequential compactness, ambient compact-open topology, or a choice-selected subsequence.

Upgrade path: No further paper-axis closure remains; bridge checking is a verification-axis matter unless a checked standard bridge target is present.

Chapter 413

A Concrete Naming Certificate for $\mathsf{EquicontinuityFamily}^{\uparrow}$

The $\mathsf{EquicontinuityFamily}^{\uparrow}$ interface names the constructive finite-ledger surface for a family of continuous maps with a shared source metric, shared target metric, finite center probes, and rational tolerance histories. It is the BEDC reading of the equicontinuity object used in Kelley, *General Topology*, and Bishop–Bridges, *Constructive Analysis*, re-expressed as finite rows over $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, and $\mathsf{CompactUniformContinuity}^{\uparrow}$. The packet does not claim open-cover compactness, host function extensionality, or a chosen function-space topology.

The finite-center modulus ledger consumes the compact-uniform continuity packet of chapter 388 before exposing the family-level equicontinuity row.

Definition 413.1 (EquicontinuityFamily carrier)**.** *An* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, Y, F, \mathcal{P}, R, M, H, C, P, N)$$

with the following visible coordinates:

1. *X is the shared source* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *row whose finite source reads are routed through displayed metric and compact-metric data;*
2. *Y is the shared target* $\mathsf{Met}^{\uparrow}$ *row whose distance comparisons are routed through displayed metric-distance witnesses;*
3. *F is a finite family ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *graph rows from X to Y;*
4. *$\mathcal{P}$ is a finite* $\mathsf{ProbeBundle}$ *of source centers used as the displayed testing window for the family;*
5. *R records the requested* $\mathsf{Rat}^{\uparrow}$ *tolerance histories and the source-radius histories offered in response;*
6. *M records pointwise modulus rows indexed by the centers in $\mathcal{P}$, uniformly over the finite family ledger F;*
7. *H records componentwise* hsame *transports for the source metric, target metric, graph rows, center bundle, rational tolerance rows, modulus rows, and naming rows;*
8. *C records the visible* Cont *routes by which metric, compact-metric, continuous-map, rational-tolerance, modulus, and equicontinuity-family consumers read the packet;*

9. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, hsame, *and* Cont *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{EquicontinuityFamily}^{\uparrow}}$ *row.*

The carrier exports only the displayed source and target metric rows, finite family rows, rational tolerance rows, pointwise finite-center modulus rows, transport rows, continuation routes, package provenance, and local naming provenance. It contains no host function equality, no open-cover compactness, no selected modulus function, and no ambient function-space topology.

Lean4 ✓ `BEDC.Derived.EquicontinuityFamilyUp.EquicontinuityFamilyTasteGate single carrier alignment`

Theorem 413.2 (EquicontinuityFamily NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{EquicontinuityFamily}^{\uparrow}}$ *surface consists exactly of five finite rows:*

1. *carrier habitation by the finite packet of Definition 413.1;*
2. *classifier transport comparing the shared source and target metric rows, the family graph rows, the pointwise modulus rows, the finite center bundle, the rational tolerance rows, the transport routes, and the provenance componentwise;*
3. *shared finite-center modulus coverage, stating that every displayed family read used by the packet factors through one center row of $\mathcal{P}$ and the corresponding modulus row in M;*
4. *rational tolerance stability, stating that tolerance and radius rows are transported through the* $\mathsf{Rat}^{\uparrow}$ *classifier and the stored* hsame *and* Cont *routes;*
5. *ledger non-escape, stating that every downstream read remains inside the displayed metric, continuous-map, modulus, package, and local naming rows.*

Lean4 ✓ `BEDC.Derived.EquicontinuityFamilyUp.EquicontinuityFamilyPacket namecert obligations`

Proof. Carrier habitation is projection of Definition 413.1. The shared source row, shared target row, family ledger, finite center bundle, rational tolerance ledger, pointwise modulus rows, transport rows, continuation routes, package provenance, and local naming row are all visible coordinates of the same finite packet.

Classifier transport is componentwise. The source and target metric rows transport their displayed distance witnesses, the $\mathsf{ContinuousMap}^{\uparrow}$ rows transport the graph and pointwise modulus reads, the center bundle transports the finite probe indices, and the rational rows transport requested tolerances together with their offered source radii.

For shared finite-center coverage, read a family member through F and a requested tolerance through R. The packet routes that read to a displayed center of $\mathcal{P}$ and then to the corresponding row of M, where the same source-radius history is used uniformly over the finite family ledger.

Rational tolerance stability follows from the same transported R rows and the displayed $\mathsf{Rat}^{\uparrow}$ comparisons. Replaying the Cont routes preserves which tolerance request, which radius response, and which center-indexed modulus row are being consumed.

These rows exhaust the certificate surface. Because the carrier has no coordinate for host function equality, open-cover compactness, selected modulus functions, or ambient function-space topology, no classifier or consumer route can export those objects. □

Theorem 413.3 (EquicontinuityFamily shared-center coverage)**.** *Every displayed family read from an accepted* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *packet factors through one finite* ProbeBundle *center in $\mathcal{P}$ and the corresponding shared modulus row in M. The read uses the shared source row X, shared target row*

Y, finite ContinuousMap$^{\uparrow}$ *family ledger F, rational tolerance row R, componentwise* hsame *rows H, displayed* Cont *routes C,* Pkg *provenance P, and local* NameCert *row N of Definition 413.1.*

The coverage statement exports no open-cover compactness, host function extensionality, selected global modulus function, or ambient function-space topology.

Lean4 ✓ `BEDC.Derived.EquicontinuityFamilyUp.EquicontinuityFamilyPacket shared center coverage`

Proof. Project the carrier of Definition 413.1. Its only center data are the finite probe bundle $\mathcal{P}$, and its only modulus data are the pointwise rows in M indexed by those centers.

Read a displayed family member through the finite ledger F and a tolerance through R. The NameCert obligation theorem routes that read to one center of $\mathcal{P}$ and the matching shared modulus row, uniformly over the finite family ledger.

The transport rows H and continuation routes C preserve the selected center and modulus row as finite packet data. Since the carrier has no coordinates for open covers, host function equality, selected modulus functions, or function-space topology, the shared-center read cannot escape to those objects. □

Theorem 413.4 (EquicontinuityFamily rational-radius transport)**.** *The* Rat$^{\uparrow}$ *tolerance and radius rows in an accepted* EquicontinuityFamily$^{\uparrow}$ *packet are transported only through the stored* hsame *rows and displayed* Cont *routes. Transport preserves the requested tolerance row, the offered rational source-radius row, the selected probe-center row, and the corresponding modulus row without selecting a modulus function outside the finite packet.*

Lean4 ✓ `BEDC.Derived.EquicontinuityFamilyUp.EquicontinuityFamilyPacket rational radius transport`

Proof. Begin with the tolerance ledger R in Definition 413.1. It records requested rational tolerances and offered source radii as displayed Rat$^{\uparrow}$ histories.

Apply the classifier transport row of Definition 413.2. The Rat$^{\uparrow}$ rows move componentwise through H, and the read routes are replayed through C.

Use shared-center coverage to keep the transported radius attached to the same finite probe-center and modulus-row pattern. The operation is therefore transport of stored rational rows, not selection of a hidden modulus function. □

Theorem 413.5 (EquicontinuityFamily ledger non-escape package)**.** *The carrier of Definition 413.1, classifier transport in Definition 413.2, shared-center coverage in Definition 413.3, and rational-radius transport in Definition 413.4 assemble the ledger non-escape package for* EquicontinuityFamily$^{\uparrow}$*. Every consumer read remains within the displayed* CompactMetric$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*,* UniformContinuity$^{\uparrow}$*,* CompactUniformContinuity$^{\uparrow}$*,* Rat$^{\uparrow}$*,* ProbeBundle*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

The package excludes open-cover compactness, host function extensionality, selected modulus functions, and ambient function-space topology.

Proof. First bind the packet rows. The carrier lists the shared metric rows, finite family ledger, probe bundle, rational histories, modulus rows, transports, routes, provenance, and local name row.

Next bind the coverage and transport rows. Shared-center coverage forces each family read through one displayed probe center and matching modulus row, while rational-radius transport keeps tolerance and radius data inside Rat$^{\uparrow}$, hsame, and Cont rows.

Finally apply the ledger non-escape clause of the NameCert obligation theorem. It states that downstream reads stay inside the displayed metric, continuous-map, modulus, package, and local naming rows. Repacking these rows gives the announced non-escape package, with no route to

open-cover compactness, host function extensionality, selected modulus functions, or function-space topology. □

Lean4 ✓ `BEDC.Derived.EquicontinuityFamilyUp.EquicontinuityFamilyPacket ledger non escape package`

Theorem 413.6 (EquicontinuityFamily public NameCert export)**.** *The finite-center modulus ledger of Definition 413.1, compact-uniform continuity dependency row, rational-radius transport of Definition 413.4, shared-center coverage of Definition 413.3, and ledger non-escape package of Definition 413.5 assemble the public* $\mathsf{NameCert}_{\mathsf{EquicontinuityFamily}^{\uparrow}}$ *export. A public consumer receives exactly the displayed shared source and target metric rows, finite* $\mathsf{ContinuousMap}^{\uparrow}$ *family ledger, center bundle, rational tolerance and radius rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row.*

The export does not add open-cover compactness, host function extensionality, a selected modulus function, or ambient function-space topology.

Proof. First bind the finite rows displayed by the carrier. The compact-uniform continuity dependency is read through the stored source metric or compact-metric row, target metric row, finite family ledger, center bundle, rational tolerance ledger, and center-indexed modulus rows.

Next use rational-radius transport and shared-center coverage. They force every tolerance request and radius response to remain attached to a displayed probe center and matching modulus row, uniformly over the finite family ledger.

Finally apply the ledger non-escape package. Since every consumer read is already routed through the visible transport, replay, provenance, and local naming rows, repacking those rows gives the public $\mathsf{NameCert}_{\mathsf{EquicontinuityFamily}^{\uparrow}}$ export with no additional object outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{EquicontinuityFamily}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EquicontinuityFamily}^{\uparrow}$ packet is generated from a shared source metric or compact-metric row, a shared target metric row, a finite family ledger of $\mathsf{ContinuousMap}^{\uparrow}$ graph rows, a finite ProbeBundle of source centers, rational tolerance histories, center-indexed modulus rows, displayed hsame and Cont transport, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EquicontinuityFamily}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public package exports the finite equicontinuity-family NameCert obligation surface consumed by compact-uniform and Arzela–Ascoli style routes through the carrier, finite-family ledger, shared source and target metric rows, finite center probes, rational tolerance histories, center-indexed modulus rows, displayed hsame and Cont transport, Pkg provenance, and local NameCert row.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EquicontinuityFamily}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.EquicontinuityFamilyUp.EquicontinuityFamilyPacket\_namecert\_obligations`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close open-cover compactness, host function extensionality, ambient function-space topology, selected modulus functions, or bridge checking.

Upgrade path: No theory-axis upgrade remains; a machine-checked standard bridge is the remaining formal-axis work for the same displayed equicontinuity-family packet.

Chapter 414

RegularCauchyInterleaving NameCert Construction

The $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ interface isolates the standard alternating construction for two regular Cauchy names. In the constructive-analysis reading of Bishop and Bridges, *Constructive Analysis*, the interleaving is not a quotient of two completed real values; it is a finite certificate that records which regular Cauchy observation is read at each unary selector step, how the two schedules share a modulus ledger, and where the resulting $\mathsf{Real}^{\uparrow}$ seal can be consumed.

The interleaving packet consumes the regular rational source of chapter 301, the finite schedule surface of chapter 126, and the terminal seal of chapter 38. The $\mathsf{RegSeqRat}^{\uparrow}$ sibling supplies the two regular names, $\mathsf{StreamName}^{\uparrow}$ supplies the finite schedules, and $\mathsf{Real}^{\uparrow}$ supplies the downstream seal that can be read only after the selected schedule and combined modulus ledger have been displayed.

Definition 414.1 (Regular Cauchy interleaving source)**.** *A* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *source packet is a finite* BHist *row*

$$I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$$

with the following displayed coordinates:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy names whose point rows may be inspected;*
2. *S_A and S_B are the two* $\mathsf{StreamName}^{\uparrow}$ *schedules that expose the finite observation windows for A and B;*
3. *σ is the alternating unary selector row, with even selector rows reading from A and odd selector rows reading from B;*
4. *M is the combined modulus ledger, recording the common precision budget and the component budget used on each selected side;*
5. *E_A and E_B are the* $\mathsf{Real}^{\uparrow}$ *seal readbacks attached to the two source names;*
6. *E is the interleaved* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the selected source readback and the common modulus ledger;*
7. *H stores the componentwise* hsame *transports for the two regular names, both schedules, the selector, the combined modulus ledger, and all three seal rows;*

8. *C stores the displayed* Cont *routes for selecting a source side, reading its scheduled window, checking the combined modulus row, and exposing the interleaved seal;*
9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleaving}^{\uparrow}}$ *row.*

The packet has no coordinate for a quotient real, a selected host limit, or an equality principle beyond the displayed hsame *and* Cont *rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.TasteGate.RegularCauchyInterleavingTasteGate single carrier alignment`

Theorem 414.2 (Regular Cauchy interleaving classifier)**.** *Two accepted* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *source packets classify together exactly when their two* $\mathsf{RegSeqRat}^{\uparrow}$ *source names, two* $\mathsf{StreamName}^{\uparrow}$ *schedules, alternating selector rows, combined modulus ledgers, source* $\mathsf{Real}^{\uparrow}$ *readbacks, interleaved* $\mathsf{Real}^{\uparrow}$ *seal rows, package provenance, and local naming rows are transported componentwise by the displayed* hsame *comparisons and read through the displayed* Cont *routes. The classifier compares the selected finite window on the even side with the transported even-side window, and the selected finite window on the odd side with the transported odd-side window, always under the same combined modulus ledger.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket classifier transport`

Proof. Project the two accepted source packets. Their carrier rows expose only the two regular names, the two stream schedules, the selector, the modulus ledger, the seal readbacks, and the displayed transport and continuation rows.

For an even selector row, the classifier reads the scheduled window from the first $\mathsf{RegSeqRat}^{\uparrow}$ name through S_A, then checks the corresponding component of M. For an odd selector row, it performs the same finite read through S_B and the second component of M.

The rows H and C record exactly the transports and consumer routes used by these reads. Repacking the transported side-specific read with P and N gives the same classifier surface for the interleaved seal E, and no quotient real or host-limit comparison is available. □

Theorem 414.3 (Regular Cauchy interleaving NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleaving}^{\uparrow}}$ *surface for the source packet of Definition 414.1 consists of five finite rows:*

1. *carrier admission: the accepted object is the displayed* BHist *packet I;*
2. *classifier equivalence: classification is the finite even-and-odd window comparison of Definition 414.2;*
3. hsame *transport: the two source names, two schedules, selector, combined modulus ledger, and seal rows are preserved componentwise by the stored transport rows;*
4. *combined modulus exactness: each interleaved precision request is discharged by the displayed common budget and the component budget selected by σ;*
5. $\mathsf{Real}^{\uparrow}$ *seal non-escape: the interleaved seal E can be consumed only after the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, its* $\mathsf{StreamName}^{\uparrow}$ *schedule row, and the combined modulus ledger have been displayed.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket namecert obligations`

Proof. Carrier admission is the projection of the finite packet I. The source rows A, B, S_A, S_B, σ, M, E_A, E_B, and E are stored coordinates, while H, C, P, and N record transport, continuation, package, and local naming provenance.

Classifier equivalence is Definition 414.2. Its even and odd cases use the same packet rows and differ only in which source schedule the selector chooses.

The hsame row transports each displayed coordinate componentwise, and the Cont row records the consumer route through the selected schedule and modulus ledger. The combined modulus row is exact because a request is answered by the common budget together with the component budget named by σ.

Finally, the real-facing coordinate E is downstream of the selected regular readback and not an independent host real. Since the packet has no field for quotient equality, selected limits, or ambient completeness, the seal cannot escape the displayed interleaving certificate. □

Theorem 414.4 (Regular Cauchy interleaving carrier admission)**.** *Let*

$$I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$$

be a displayed packet satisfying the $\mathsf{RegSeqRat}^{\uparrow}$ *rows for A and B, the* $\mathsf{StreamName}^{\uparrow}$ *rows for S_A and S_B, the alternating selector row σ, the combined modulus ledger M, the three* $\mathsf{Real}^{\uparrow}$ *seal rows E_A, E_B, and E, the displayed* hsame *and* Cont *rows, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleaving}^{\uparrow}}$ *row. Then I is an accepted* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *carrier.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket carrier admission`

Proof. Project the displayed coordinates of I. The first two coordinates give the required regular Cauchy names, the next two give their finite stream schedules, and the selector and modulus coordinates give the alternating read policy and its common budget ledger.

The seal coordinates E_A, E_B, and E are already part of the same finite history row. The rows H and C supply the componentwise transport and consumer routes, while P and N supply the package provenance and local naming certificate.

Repack these projected rows in the order of Definition 414.1. The definition has no further carrier field, so the displayed packet is exactly an admitted carrier. □

Theorem 414.5 (Regular Cauchy interleaving selector parity exactness)**.** *For every accepted* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *source packet I, each even selector read factors through the first regular name A, the schedule S_A, and the first component of the combined modulus ledger M, while each odd selector read factors through the second regular name B, the schedule S_B, and the second component of M. Componentwise* hsame *transports and the displayed* Cont *routes preserve this even-side and odd-side partition.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket selector parity exactness`

Proof. Unpack I as in Definition 414.1. The selector coordinate σ is displayed as alternating, so an even selector row exposes the first source side and an odd selector row exposes the second source side.

In the even case, Definition 414.2 reads the finite window through A and S_A and checks the corresponding first component of M. In the odd case, the same classifier reads through B and S_B and checks the second component of M.

The stored row H transports the selector, both schedules, both regular names, and the combined modulus ledger componentwise. The stored row C only routes consumers through the selected schedule and the selected ledger component, so transport preserves the parity partition rather than mixing the two source sides. □

Theorem 414.6 (Regular Cauchy interleaving swap symmetry boundary)**.** *Let $I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E$ be an accepted* RegularCauchyInterleaving$^{\uparrow}$ *source packet. Exchanging the two* RegSeqRat$^{\uparrow}$ *source names A, B, exchanging the two schedules S_A, S_B, and replacing the alternating selector σ by its opposite selector preserves the same public* Real$^{\uparrow}$ *seal boundary through the displayed* hsame *transports,* Cont *routes, combined modulus ledger,* Pkg *provenance, and local* NameCert *row. The boundary is only the finite selector-swapped interleaving surface; it does not assert quotient real equality, selected host limits, ambient completeness, or access to a third schedule.*

Proof. Apply Definition 414.5. The forward selector sends even reads through A, S_A and the first component of M, and odd reads through B, S_B and the second component.

After the source and schedule exchange, the opposite selector sends its odd reads through the transported A, S_A route and its even reads through the transported B, S_B route. Thus the two presentations inspect the same two finite windows with only the selector parity exchanged.

Use Definition 414.9 to keep each selected read attached to the same component of M. Then use Definition 414.10 to rule out any route through a schedule other than S_A or S_B.

Finally apply Definition 414.8. The real-facing seal can be consumed only after the selected source row, selected schedule, combined ledger, displayed transport, displayed continuation route, package provenance, and local name have been read. Since the carrier has no quotient-real, host-limit, ambient-completeness, or third-schedule coordinate, the swapped presentation preserves exactly the public seal boundary and nothing stronger. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket swap symmetry boundary`

Theorem 414.7 (Regular Cauchy interleaving selector transport determinacy)**.** *For classified accepted* RegularCauchyInterleaving$^{\uparrow}$ *packets, transported selector rows preserve the even and odd routes. Every even transported read factors through the transported A-side schedule and the first component of the combined modulus ledger, and every odd transported read factors through the transported B-side schedule and the second component. No transported read can switch sides or use a third schedule.*

Proof. Project the classifier statement of Definition 414.2. It compares the two source names, the two schedules, the selector row, and the combined modulus ledger componentwise through the displayed hsame and Cont data.

Apply Definition 414.5 before transport. Even reads are routed through A, S_A, and the first component of M, while odd reads are routed through B, S_B, and the second component.

Apply the same parity exactness after the hsame transport. The transported selector still exposes the transported even side through the transported A-schedule and the transported odd side through the transported B-schedule.

Use Definition 414.9 to keep the selected ledger component fixed. Then use Definition 414.10 to rule out unscheduled routes: the carrier has only the two transported schedules, so there is no coordinate from which a third schedule or side switch could be read. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket selector transport determinacy`

Theorem 414.8 (Regular Cauchy interleaving RealUp seal non-escape)**.** *Let I be an accepted* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *source packet with interleaved seal E. Any* $\mathsf{Real}^{\uparrow}$ *consumer of E must pass through the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the selected* $\mathsf{StreamName}^{\uparrow}$ *schedule, the combined modulus ledger, the displayed* hsame *transport and* Cont *route, and the package and naming rows P and N. No consumer of E can read quotient real equality, a host limit, or ambient completeness from the packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket real seal non escape`

Proof. Carrier admission exposes only the fields listed in Definition 414.1. Thus the real-facing row E is not a standalone real object; it is a coordinate in the same finite packet as the two regular names, their schedules, the selector, and the ledger.

Definition 414.5 identifies the required readback path for each selector parity. The even route passes through A, S_A, and the first component of M, while the odd route passes through B, S_B, and the second component of M.

The NameCert obligations then attach the displayed hsame transport, Cont consumer route, package provenance, and local naming row to that selected path. Since the carrier definition contains no quotient-equality coordinate, no host-limit coordinate, and no ambient-completeness coordinate, a $\mathsf{Real}^{\uparrow}$ consumer has no route out of the displayed certificate. □

Theorem 414.9 (Regular Cauchy interleaving combined modulus exactness)**.** *Let*

$$I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *packet. Every precision request for the interleaved* $\mathsf{Real}^{\uparrow}$ *seal first reads the selector row σ, then reads the selected schedule S_A or S_B, and then checks the matching component of the combined modulus ledger M. Even requests use the A component of M, odd requests use the B component of M, and no request can consume E without one of these displayed ledger routes.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket combined modulus exactness`

Proof. Unpack the packet by Definition 414.1. The selector row, both schedules, the combined modulus ledger, and the interleaved seal are stored coordinates of the same finite BHist row.

For an even selector read, Definition 414.5 routes the request through A, S_A, and the first component of M. For an odd selector read, the same theorem routes the request through B, S_B, and the second component of M.

The Cont row records this order before the seal row E is exposed. The hsame, Pkg, and NameCert rows are attached to the same route, so the precision request has no separate path to a selected real limit, quotient equality, or ambient completeness. □

Theorem 414.10 (Regular Cauchy interleaving schedule window coverage)**.** *For an accepted packet $I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$, the even and odd schedule windows exhaust the consumer reads of the interleaving. Every displayed consumer read is either an even read through S_A and the A side of M, or an odd read through S_B and the B side of M. There is no third schedule window and no unscheduled read of the interleaved seal.*

Proof. Inspect the source packet. Its only schedule coordinates are S_A and S_B, and its only side-selector coordinate is the alternating row σ.

The even case is the route through the first schedule. It reads the A source row, the S_A window, and the first component of the combined modulus ledger.

The odd case is the route through the second schedule. It reads the B source row, the S_B window, and the second component of the combined modulus ledger.

These two cases exhaust the selector row. Since the carrier has no coordinate for any further schedule, any consumer of E must pass through one of the two displayed windows. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket schedule window coverage`

Theorem 414.11 (Regular Cauchy interleaving obligation closure package)**.** *The rows of an accepted packet* $I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$ *assemble the obligation surface for* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *The surface consists exactly of carrier admission, componentwise classifier transport, combined modulus exactness, schedule window coverage, and* $\mathsf{Real}^{\uparrow}$ *seal non-escape.*

Proof. Carrier admission is Definition 414.4. Componentwise classifier transport is Definition 414.2, with the parity partition supplied by Definition 414.5.

The combined modulus obligation is Definition 414.9. The coverage obligation is Definition 414.10. The seal boundary is Definition 414.8.

These rows are all read from the same finite packet through the displayed transport, continuation, package, and naming coordinates. Therefore the chapter supplies the obligation surface, while leaving quotient equality, selected host limits, ambient completeness, and bridge checking outside the claim. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket obligation closure package`

Theorem 414.12 (Regular Cauchy interleaving scoped kernel route)**.** *Every accepted packet from Definition 414.1 factors its carrier admission, classifier transport, selector parity, combined modulus, schedule-window coverage, and* $\mathsf{Real}^{\uparrow}$ *seal non-escape through exactly the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. No part of the accepted carrier is routed through quotient equality of reals, selected host limits, or ambient completeness.*

Proof. Begin with the classifier of Definition 414.2. It reads only the two regular names, the two stream schedules, the alternating selector, the combined modulus ledger, the real seal rows, and the displayed transport and continuation coordinates.

The NameCert surface of Definition 414.3 supplies the carrier row, classifier row, transport row, exactness row, and seal-boundary row. The carrier admission theorem then repacks those coordinates as the finite BHist packet of the source definition.

Selector parity is exact by Definition 414.5. Combined modulus exactness is Definition 414.9, and schedule coverage is Definition 414.10. These three statements bind every consumer read to one of the two displayed schedules and to the matching component of the ledger.

Finally, Definition 414.8 keeps the $\mathsf{Real}^{\uparrow}$ seal downstream of the selected regular readback, selected schedule, combined modulus row, hsame transport, Cont route, package row, and naming row. Together with Definition 414.11, this exhausts the scoped kernel route and leaves no carrier coordinate for quotient equality, host limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket scoped kernel route`

Theorem 414.13 (Regular Cauchy interleaving public real seal export)**.** *The public* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *export of an accepted packet* $I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$ *is exactly the finite* $\mathsf{Real}^{\uparrow}$ *seal boundary obtained from the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source names* A, B*, the two* $\mathsf{StreamName}^{\uparrow}$ *schedules* S_A, S_B*, the alternating selector* σ*, the combined modulus ledger* M*, the source seals* E_A, E_B*, the interleaved seal row* E*, the displayed* hsame *transports* H*, the* Cont *routes* C*, the* Pkg *provenance* P*, and the local* $\mathsf{NameCert}$ *row* N*. Every public* $\mathsf{Real}^{\uparrow}$ *consumer factors through this displayed packet and receives no quotient real equality, selected host limit, ambient completeness principle, or third schedule.*

Proof. Carrier admission is supplied by Definition 414.4. The admitted row is the finite BHist packet of Definition 414.1, so the public boundary has no carrier beyond the two source names, two schedules, selector, ledger, seals, transport rows, continuation rows, package row, and naming row.

Classifier transport is Definition 414.2. Selector parity exactness is Definition 414.5, combined modulus exactness is Definition 414.9, and schedule-window coverage is Definition 414.10. These rows force every consumer read to use either the A, S_A side with the first component of M or the B, S_B side with the second component of M.

The seal boundary is Definition 414.8. The obligation closure package of Definition 414.11 gathers the same rows, and Definition 414.12 binds them to the displayed kernel route.

Repack these rows as the public export packet. Since the repacked packet exposes only the displayed $\mathsf{Real}^{\uparrow}$ seal boundary, a public consumer obtains the named seal interface and none of quotient equality, a selected host limit, ambient completeness, or a third schedule. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket public real seal export`

Theorem 414.14 (Regular Cauchy interleaving bridge readback scope)**.** *Any bridge readback from the public* $\mathsf{Real}^{\uparrow}$ *seal export of an accepted* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *packet* $I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H,$ *factors through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source names* A, B*, the two* $\mathsf{StreamName}^{\uparrow}$ *schedules* S_A, S_B*, the alternating selector* σ*, the combined modulus ledger* M*, the source seal rows* E_A, E_B*, the interleaved seal row* E*, componentwise* hsame *transports* H*,* Cont *routes* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleaving}^{\uparrow}}$ *row* N*. The bridge readback has no route to a quotient real, selected host limit, ambient completeness principle, or third schedule beyond this displayed public seal surface.*

Proof. Carrier admission is Definition 414.4. It gives the finite packet rows that any bridge readback must start from: the two source names, their schedules, the selector, the modulus ledger, the three seal rows, transports, routes, provenance, and local naming row.

Selector parity exactness from Definition 414.5 determines which source side is read. Combined modulus exactness from Definition 414.9 supplies the matching ledger component, and schedule-window coverage from Definition 414.10 rules out a third schedule.

The seal boundary is controlled by Definition 414.8. The scoped kernel route of Definition 414.12 then binds the same rows to the displayed hsame, Cont, Pkg, and $\mathsf{NameCert}$ route.

Finally apply the public Real seal export, Definition 414.13. A bridge readback that begins from that public export can only read back the rows exported there, so it factors through $A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N$ and cannot access quotient equality, selected host limits, ambient completeness, or an unlisted schedule. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket bridge readback scope`

Theorem 414.15 (Regular Cauchy interleaving finite-tail consumer boundary)**.** *Every downstream consumer that reads the interleaved* Real$^{\uparrow}$ *seal of an accepted* RegularCauchyInterleaving$^{\uparrow}$ *packet through a finite-tail or diagonal-limit route must factor through one of the two displayed* StreamName$^{\uparrow}$ *schedules, the matching* RegSeqRat$^{\uparrow}$ *source row, the combined modulus ledger, and the local* NameCert *row before it can consume a* FiniteTailDiagonalSeal$^{\uparrow}$*-style witness. The route is the sibling surface of chapter 126, chapter 371, and chapter 559.*

Proof. Use selector parity exactness. An even read is routed through A, S_A and the first component of M, while an odd read is routed through B, S_B and the second component.

Apply combined modulus exactness and schedule-window coverage. Together they make the selected schedule, matching regular source row, and selected modulus component the only finite window route into the interleaved seal.

Use the Real seal non-escape theorem and the bridge readback scope. They keep every seal-facing consumer downstream of the displayed hsame transports, Cont routes, package row, and local NameCert row.

The finite-tail handoff therefore has no coordinate for quotient reals, host limits, ambient completeness, or a third schedule. Any FiniteTailDiagonalSeal$^{\uparrow}$-style witness consumed downstream must use the displayed finite-window route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket finite tail consumer boundary`

Theorem 414.16 (Regular Cauchy interleaving window-seal symmetry)**.** *For an accepted* RegularCauchyInterleaving *packet* $I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$*, the two parity branches preserve the same public* Real$^{\uparrow}$ *seal surface. The even branch through* A, S_A *and the odd branch through* B, S_B *are distinguished only by selector parity and the selected component of the combined modulus ledger; after selector transport, schedule-window coverage, and real-seal non-escape, both branches expose the same interleaved seal row* E *and no additional public seal coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket window seal symmetry`
