Proof. Use selector parity exactness to split any consumer read into the even branch and the odd branch. The even branch selects the A, S_A side and the first ledger component, while the odd branch selects the B, S_B side and the second ledger component.

Apply classifier transport and combined modulus exactness on each branch. These rows determine the selected source row and the matching modulus component before any public seal read occurs.

Schedule-window coverage rules out a third schedule and forces both parity branches through the two displayed StreamName$^{\uparrow}$ windows. The bridge readback scope keeps the same hsame, Cont, Pkg, and NameCert rows attached to the selected read.

Finally apply real-seal non-escape and the public Real seal export. Both branches terminate at the same interleaved seal row E, so the branch distinction is internal to the finite-window route and does not create a second public Real$^{\uparrow}$ seal surface. □

Theorem 414.17 (Regular Cauchy interleaving finite-tail budget route)**.** *Every finite-tail diagonal consumer of the interleaved* Real$^{\uparrow}$ *seal of an accepted packet* $I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$

factors through the two displayed StreamName$^{\uparrow}$ *schedules* S_A, S_B*, the matching* RegSeqRat$^{\uparrow}$ *source rows* A, B*, the combined modulus ledger* M*, the downstream* FiniteTailDiagonalSeal$^{\uparrow}$ *witness surface, and the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. No finite-tail budget read bypasses this route through quotient equality, selected host limits, ambient completeness, or an unlisted schedule.*

Proof. Begin with the finite-tail consumer boundary. It already places any diagonal-limit or finite-tail consumer downstream of a selected schedule, a matching regular source row, the combined modulus ledger, and the local naming row.

Use selector parity exactness and schedule-window coverage to identify the only two possible schedule windows. The selected window is S_A for an even read and S_B for an odd read, with no further schedule coordinate in the packet.

Combined modulus exactness supplies the budget component attached to that selected window. Carrier admission supplies the finite BHist packet, and the scoped kernel route keeps the selected read attached to the displayed hsame, Cont, Pkg, and NameCert rows.

The sibling chapters chapter 126, chapter 371, and chapter 559 provide the schedule, regular-source, and finite-tail witness surfaces named by the boundary. Therefore every finite-tail budget read factors through the displayed route and has no bypass through the excluded public objects. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket finite tail budget route`

Theorem 414.18 (Regular Cauchy interleaving public bridge readiness)**.** *The obligation closure package, scoped kernel route, public real seal export, bridge readback scope, finite-tail consumer boundary, window-seal symmetry, and finite-tail budget route assemble the public bridge surface for* RegularCauchyInterleaving$^{\uparrow}$*. A bridge-facing consumer of an accepted packet can read the two* RegSeqRat$^{\uparrow}$ *source names, the two* StreamName$^{\uparrow}$ *schedules, selector parity, the combined modulus ledger, source and interleaved* Real$^{\uparrow}$ *seal rows,* BHist *support,* hsame *transports,* Cont *routes,* Pkg *provenance, local* NameCert *row, and the downstream finite-tail witness route; it cannot read quotient real equality, selected host limits, ambient completeness, or a third schedule.*

Proof. The obligation closure package gives the carrier, classifier, combined modulus, schedule coverage, and seal-boundary rows. The scoped kernel route binds these rows to the displayed RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, Real$^{\uparrow}$, Rat$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert coordinates.

The public Real seal export exposes the seal row visible to outside consumers, and the bridge readback scope describes exactly which packet rows a bridge-facing readback can inspect. The finite-tail consumer boundary then places diagonal consumers downstream of the same selected schedule and budget route.

Window-seal symmetry shows that the even and odd branches preserve one public seal surface rather than two branch-specific exports. The finite-tail budget route supplies the budget and witness path needed by downstream finite-tail consumers.

Combining these rows yields the public bridge surface for RegularCauchyInterleaving$^{\uparrow}$. Since every component in the assembled surface is one of the displayed packet rows or one of the named sibling surfaces, the route has no coordinate for quotient equality of reals, selected host limits, ambient completeness, or any schedule beyond S_A and S_B. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket public bridge readiness`

Theorem 414.19 (Regular Cauchy interleaving RegSeqRat Real consumer factorization)**.** *Let*

$$I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *packet. Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, *or terminal* $\mathsf{Real}^{\uparrow}$ *consumer of the interleaved seal factors through the selected parity branch, then through the selected* $\mathsf{StreamName}^{\uparrow}$ *schedule, the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the corresponding component of* M*, and finally through* E, H, C, P, N*. The factorization exports no quotient stream, selected host limit, host real equality, ambient completeness principle, or third schedule.*

Proof. Use selector parity exactness to split the consumer read. The even branch is routed through A and S_A, while the odd branch is routed through B and S_B.

Apply combined modulus exactness on the selected branch. The even route reads the first component of M, the odd route reads the second component of M, and the selected ledger component is fixed before any $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, or terminal $\mathsf{Real}^{\uparrow}$ consumer can inspect the interleaved seal.

Schedule-window coverage rules out an unscheduled route. Thus the selected $\mathsf{StreamName}^{\uparrow}$ window and the matching $\mathsf{RegSeqRat}^{\uparrow}$ source row are the only finite-name entry points for the consumer.

Finally apply real-seal non-escape and the public Real seal export. These rows keep the consumer downstream of the interleaved seal E, the displayed hsame transports H, the Cont routes C, package provenance P, and the local naming row N, while leaving quotient streams, selected host limits, host real equality, ambient completeness, and any third schedule outside the exported route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket regseqrat real consumer factorization`

Theorem 414.20 (Regular Cauchy interleaving even–odd subsequence seal)**.** *Let*

$$I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *packet whose even reads use the source and schedule rows* A, S_A *and whose odd reads use* B, S_B*. An even-subsequence consumer recovers the* A*-side* $\mathsf{Real}^{\uparrow}$ *seal route, and an odd-subsequence consumer recovers the* B*-side* $\mathsf{Real}^{\uparrow}$ *seal route. Both recoveries pass through the same selector parity row, combined modulus row, schedule-window coverage row, and Real seal non-escape row, so neither consumer exports quotient stream equality, host real equality, an ambient completeness principle, or a third schedule.*

Proof. Selector parity exactness separates the two subsequence requests. Apply Definition 414.5: even reads are routed through A, S_A, while odd reads are routed through B, S_B.

Combined modulus exactness then fixes the matching ledger component for the selected side. Use Definition 414.9 so the even consumer reads the first component of M and the odd consumer reads the second component.

Schedule-window coverage rules out bypass routes. By Definition 414.10, every subsequence read must remain inside the displayed S_A or S_B window and cannot switch to a third schedule.

Finally apply Definition 414.8. The selected subsequence seal remains downstream of the selected source row, selected schedule, selected modulus component, displayed hsame transport, displayed Cont route, package provenance, and local naming row. Thus the two parity consumers recover their side-specific Real seal routes and nothing outside the displayed packet. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket even odd subsequence seal`

Theorem 414.21 (Regular Cauchy interleaving completion selector nonescape)**.** *Let*

$$I = (A, B, S_A, S_B, \sigma, M, E_A, E_B, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *packet. Every completion-facing consumer of* I *must read the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows* A, B*, the parity selector* σ*, the two* $\mathsf{StreamName}^{\uparrow}$ *schedules* S_A, S_B*, the merged window schedule governed by* M*, the dyadic tail modulus selected from* M*, and the visible* $\mathsf{Real}^{\uparrow}$ *seal route through* E_A, E_B, E, H, C, P, N *before it can consume any completion selector. The packet exports no quotient stream, hidden selected limit, host real equality, ambient completeness principle, or third schedule.*

Proof. Start with the classifier route. The selector parity exactness theorem separates every read into the even branch through A, S_A and the odd branch through B, S_B.

Apply combined modulus exactness and the finite-tail budget route. These rows place the merged window schedule and the selected dyadic tail budget inside M before any diagonal or completion-facing consumer can inspect the interleaved seal.

Use schedule-window coverage and the even–odd subsequence seal. The schedules S_A, S_B are the only windows available, and each subsequence recovery remains downstream of the selected source row, selected schedule, selected modulus component, and Real seal non-escape route.

Finally read H, C, P, N. These rows transport, replay, source, and name the same finite packet, but they add no selector coordinate. Therefore every completion selector remains inside the displayed interleaving route and cannot escape to quotient streams, hidden selected limits, host equality, ambient completeness, or a third schedule. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingUp.RegularCauchyInterleavingPacket completion selector nonescape`

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleaving}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ regular names, their $\mathsf{StreamName}^{\uparrow}$ schedules, an alternating unary selector, a combined modulus ledger, source $\mathsf{Real}^{\uparrow}$ readbacks, an interleaved $\mathsf{Real}^{\uparrow}$ seal row, displayed hsame and Cont rows, package provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyInterleaving}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 414.13 gives the public $\mathsf{Real}^{\uparrow}$ seal export, and Definition 414.18 records the checked public bridge readiness target over the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyInterleaving}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close quotient equality of reals, selected host limits, ambient completeness, diagonal-completion uniqueness, or bridge checking.

Upgrade path: The remaining work is Lean-side formal bridge verification for the displayed public bridge surface.

Chapter 415

A Concrete Naming Certificate for $\mathsf{CauchyRate}^{\uparrow}$

The $\mathsf{CauchyRate}^{\uparrow}$ interface names the effective-rate certificate consumed between regular Cauchy data and real-completion readers. In the constructive-analysis reading of Bishop and Bridges, *Constructive Analysis*, a usable real name supplies an explicit precision request, a modulus schedule, a tolerance row, and a regular rational source before any completion-facing consumer may read a real seal. The packet below records exactly that finite route through $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{RealCauchyCompletion}^{\uparrow}$.

The same packet is the effective-rate dependency edge from chapter 126 and chapter 301 into the completion-facing chapter 38 seal boundary: a precision request selects a modulus schedule, the schedule opens a finite $\mathsf{StreamName}^{\uparrow}$ window, the window licenses the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the resulting regular row is admitted through the $\mathsf{Real}^{\uparrow}$ seal gate.

The rate-facing carrier is also the consumer surface of chapter 292. Its tolerance and readback route consumes the dyadic tail-bound ledger of chapter 379 and the regular-rational source of chapter 301 before the packet reaches the $\mathsf{RealCauchyCompletion}^{\uparrow}$ boundary.

Definition 415.1 (CauchyRate BHist source)**.** *A* $\mathsf{CauchyRate}^{\uparrow}$ *source packet is a finite* BHist *row*

$$K = (p, \mu, \tau, F, Q, E, H, C, P, N)$$

with the following visible coordinates:

1. *p is a unary precision row naming the requested effective rate;*
2. *μ is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row that assigns the finite inspection window for p;*
3. *τ is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *tolerance row used to justify the scheduled tail comparison;*
4. *F is the* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *source row whose inspected family entries are read through the schedule μ;*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row obtained from the same scheduled family window and tolerance row;*
6. *E is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer row reached only through Q, F, τ, and μ;*
7. *H records the componentwise* hsame *transports for precision, schedule, tolerance, family source, regular-sequence source, and completion-consumer rows;*

8. *C records the displayed* Cont *routes from the consumer request to the schedule, tolerance, source, regular readback, and completion boundary;*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRate}^{\uparrow}}$ *row.*

The displayed transports and routes are the rows

$$\mathsf{hsame}(p,p'),\quad \mathsf{hsame}(\mu,\mu'),\quad \mathsf{hsame}(\tau,\tau'),\quad \mathsf{hsame}(F,F'),\quad \mathsf{hsame}(Q,Q'),\quad \mathsf{hsame}(E,E'),$$
$$\mathsf{Cont}(p,\mu),\quad \mathsf{Cont}(\mu,\tau),\quad \mathsf{Cont}((\mu,\tau),F),\quad \mathsf{Cont}((F,\tau),Q),\quad \mathsf{Cont}((Q,F,\tau,\mu),E).$$

The classifier compares accepted packets only by these displayed rows, their Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CauchyRate}^{\uparrow}}$ *row.*

Theorem 415.2 (CauchyRate NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyRate}^{\uparrow}}$ *surface for the packet of Definition 415.1 consists of five finite obligations:*

1. *carrier exposure: the precision, schedule, tolerance, regular-family source, regular rational readback, completion consumer, transport, route, package, and local certificate rows are all visible coordinates of K;*
2. *classifier exactness: accepted packets are compared only by componentwise* hsame *transport and displayed* Cont *reads of those coordinates;*
3. *regular-family handoff: the row Q is read from the scheduled* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *source F using the tolerance row τ and no separate stream;*
4. *completion-consumer boundary: the row E is reachable only after the* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows have been displayed;*
5. *ledger exhaustion: every rate-facing dependency is named by P and N, with no row for real completeness, quotient stream equality, selected limits, or host real equality.*

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier namecert obligations`

Proof. Project the packet K of Definition 415.1. Its carrier coordinates list precisely the rows used by the certificate, so carrier exposure is immediate from the finite BHist shape.

Classifier exactness follows by replaying the stored transports and continuation routes. The classifier has no coordinate outside p,μ,τ,F,Q,E,H,C,P,N, hence a transported accepted packet is compared only through those rows.

The regular-family handoff is the projection to Q. The route $\mathsf{Cont}((F,\tau),Q)$ keeps the scheduled family window and the dyadic tail bound together, so the readback cannot be replaced by an unrecorded rational stream.

The completion-consumer boundary is the projection to E. Since the only displayed route into E is $\mathsf{Cont}((Q,F,\tau,\mu),E)$, the consumer sees the modulus schedule, tolerance, family source, and regular rational readback before it sees a completion-facing row.

Finally, P and N account for the package provenance and the local naming surface. They add no coordinate for RealUp completeness, quotient stream equality, selected limits, or host real equality, so the ledger is exhausted by the displayed finite packet. □

Theorem 415.3 (CauchyRate regular-family handoff)**.** *For every accepted* $\mathsf{CauchyRate}^{\uparrow}$ *packet*

$$K=(p,\mu,\tau,F,Q,E,H,C,P,N),$$

the $\mathsf{RegSeqRat}^{\uparrow}$ *source row* Q *is obtained from the same* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row* μ*, the same* $\mathsf{DyadicTailBound}^{\uparrow}$ *tolerance row* τ*, and the same* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *source row* F*. Any consumer of* Q *through the displayed* Cont *routes must retain those three rows as the rate certificate for the inspected finite window.*

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier regular family handoff`

Proof. Read the schedule, tolerance, family, and regular-sequence coordinates from K. The row μ selects the finite inspection window, the row τ supplies the displayed tail budget, and the row F supplies the regular Cauchy family entries inspected on that window.

The continuation route $\mathsf{Cont}((F,\tau),Q)$ repacks exactly those rows as the $\mathsf{RegSeqRat}^{\uparrow}$ source row. Because τ and F are stored in the same packet as μ, the handoff cannot drop the rate schedule or substitute a separate tolerance ledger.

Any consumer of Q must use the displayed routes in C and the provenance rows P and N. These rows certify the same finite packet and do not introduce quotient stream equality, selected limits, host sequence equality, or a real-completeness principle. □

Theorem 415.4 (CauchyRate real-completion consumer boundary)**.** *For an accepted* $\mathsf{CauchyRate}^{\uparrow}$ *packet*

$$K = (p,\mu,\tau,F,Q,E,H,C,P,N),$$

every read of the $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer row* E *factors through the scheduled modulus row* μ*, the dyadic tail-bound row* τ*, the regular-family source row* F*, and the regular rational readback row* Q*. The boundary exports an effective completion-facing consumer route, not RealUp completeness, quotient stream equality, a selected limit, or host real equality.*

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier real completion consumer boundary`

Proof. Project the completion row from the source packet. The only route displayed for E is $\mathsf{Cont}((Q,F,\tau,\mu),E)$, so the consumer boundary is downstream of the schedule, tolerance, family source, and regular rational readback.

The handoff theorem Definition 415.3 identifies Q as the regular rational row obtained from F with the same μ and τ. Thus reading E necessarily preserves the effective-rate data that produced the readback.

The packet contains no coordinate for a quotient of streams, a selected limiting object, a host real equality test, or an ambient completeness witness. The completion-facing row is therefore a consumer boundary over the displayed effective certificate only. □

Theorem 415.5 (CauchyRate ledger exactness)**.** *Let* $K = (p,\mu,\tau,F,Q,E,H,C,P,N)$ *be an accepted* $\mathsf{CauchyRate}^{\uparrow}$ *source packet. The ledger named by* P *and* N *is exact over the rows* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{DyadicTailBound}^{\uparrow}$*,* $\mathsf{RegularCauchyFamily}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*: every accepted rate read is accounted for by one of those displayed coordinates, and no hidden carrier may be used as an additional premise.*

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier ledger exactness`

Proof. Start from the finite carrier of Definition 415.1. The rows p,μ,τ,F,Q,E,H,C,P,N are the full list of data available to the local classifier.

The obligation theorem Definition 415.2 identifies the carrier, classifier, handoff, boundary, and ledger rows. The handoff theorem Definition 415.3 accounts for reads of Q, and Definition 415.4 accounts for reads of E.

It remains only to inspect provenance. The row P names the dependency package and N names the local certificate, both over the displayed finite packet. Since no other coordinate is present, no hidden carrier can serve as an additional premise for the effective-rate read. □

Theorem 415.6 (CauchyRate transport stability)**.** *Let $K = (p, \mu, \tau, F, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyRate}^{\uparrow}$ *packet. Any componentwise* hsame *transport recorded in H, together with the displayed* Cont *routes recorded in C, preserves the* $\mathsf{NameCert}_{\mathsf{CauchyRate}^{\uparrow}}$ *classifier on the transported precision, schedule, tolerance, regular-family source, regular rational readback, completion consumer, package, and local certificate rows.*

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier transport stability`

Proof. Project the classifier from Definition 415.1. It compares only the precision, schedule, tolerance, family, readback, consumer, transport, route, package, and local naming coordinates.

Transport each visible coordinate by the corresponding hsame row in H. Then replay the routes in C: first from the precision request to the schedule, then to the tolerance, then to the family source, then to the regular readback, and finally to the completion consumer boundary.

The ledger exactness theorem Definition 415.5 rules out any additional premise during this transport. Hence the transported packet is accepted by the same classifier surface and still withholds RealUp completeness, quotient stream equality, selected limits, and host real equality. □

Theorem 415.7 (CauchyRate scheduled window totality)**.** *For every accepted* $\mathsf{CauchyRate}^{\uparrow}$ *packet*

$$K = (p, \mu, \tau, F, Q, E, H, C, P, N),$$

each precision request admitted by the packet is answered first by the displayed $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row μ. The consumer route must expose the finite window selected by μ before it may read the* $\mathsf{DyadicTailBound}^{\uparrow}$ *tolerance row τ, the* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *source row F, or the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q.*

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier scheduled window totality`

Proof. Project the carrier of Definition 415.1. The precision row p and the schedule row μ are stored as visible coordinates, and the route inventory contains $\mathsf{Cont}(p, \mu)$ as the first consumer step.

The downstream rows are reached only along the displayed continuation chain. The tolerance row is exposed by $\mathsf{Cont}(\mu, \tau)$, the regular-family source by $\mathsf{Cont}((\mu, \tau), F)$, and the regular rational readback by $\mathsf{Cont}((F, \tau), Q)$.

Apply Definition 415.12 to identify this chain as the only effective-rate consumer route, and apply Definition 415.6 to keep the same route under componentwise hsame transport. Hence every accepted precision request receives its scheduled finite window before any of the later rows can be read. □

Theorem 415.8 (CauchyRate finite-tail induction)**.** *Let $K = (p, \mu, \tau, F, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyRate}^{\uparrow}$ *packet. Finite induction over the displayed unary precision row and the scheduled window preserves the route*

$$p \longmapsto \mu \longmapsto \tau \longmapsto F \longmapsto Q \longmapsto E$$

for every admitted tail request. At each finite stage the consumer reads the same $\mathsf{CauchyModulus}^{\uparrow}$ *schedule, the same* $\mathsf{DyadicTailBound}^{\uparrow}$ *tolerance row, the same* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *source, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the same completion-facing row stored in K; it never replaces them by quotient streams, selected limits, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The base request is the displayed precision row p in Definition 415.1. By Definition 415.7, the request first reaches the schedule row μ and exposes its finite window before any downstream row is visible.

For the induction step, enlarge only the displayed finite tail request admitted by the same schedule. The carrier still supplies the rows $p, \mu, \tau, F, Q, E, H, C, P, N$, and the continuation entries keep the new finite request on the route through μ and τ before the family row F is read.

Apply Definition 415.3. The readback row Q is obtained from the scheduled family and the dyadic tail-bound row already present in the packet, so the step cannot introduce a new rational stream or selected limiting object.

Finally use Definition 415.5. The ledger rows P and N exhaust the dependency surface for every finite tail stage, and the route into E remains the displayed completion-facing continuation. Thus finite induction preserves the route and refuses quotient streams, selected limits, host real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 415.9 (CauchyRate tolerance readback exactness)**.** *For every accepted* $\mathsf{CauchyRate}^{\uparrow}$ *packet* $K = (p, \mu, \tau, F, Q, E, H, C, P, N)$*, the displayed tolerance row* τ *and the displayed regular-family row* F *determine the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *through the packet route* $\mathsf{Cont}((F, \tau), Q)$*. No hidden rational stream, quotient representative, host sequence equality, or selected limiting object participates in the readback.*

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier tolerance readback exactness`

Proof. The readback coordinate Q is part of the finite packet in Definition 415.1. Its incoming displayed route is exactly $\mathsf{Cont}((F, \tau), Q)$.

Apply Definition 415.3. It states that Q is obtained from the same $\mathsf{CauchyModulus}^{\uparrow}$ schedule, the same $\mathsf{DyadicTailBound}^{\uparrow}$ tolerance row, and the same $\mathsf{RegularCauchyFamily}^{\uparrow}$ source row carried by the packet.

Finally apply Definition 415.5. The package and local naming rows exhaust the available dependency surface, so there is no extra coordinate from which a hidden rational stream or host-level equality could determine Q. □

Theorem 415.10 (CauchyRate scoped consumer exhaustion)**.** *The scoped consumer surface of an accepted* $\mathsf{CauchyRate}^{\uparrow}$ *packet is exhausted by its displayed carrier rows, regular-family handoff, completion-consumer boundary, ledger exactness, and transport stability over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. Every consumer-facing read of* Q *or* E *is therefore a read of the same finite packet, not a use of an ambient completion principle or an unrecorded stream equality.*

Proof. Start with the carrier definition. The packet exposes only $p, \mu, \tau, F, Q, E, H, C, P, N$, so the consumer surface has no raw coordinate outside the displayed BHist row.

Use Definition 415.3 and Definition 415.4 for the two downstream reads. The first places Q behind the scheduled family and tolerance rows, while the second places E behind Q, F, τ, μ.

The ledger and transport steps close the surface. By Definition 415.5, P and N account for every accepted dependency over Pkg and NameCert; by Definition 415.6, the same classifier is preserved under the stored hsame and Cont rows. Thus the scoped consumer has exhausted exactly the displayed finite packet. □

Theorem 415.11 (CauchyRate BHist source scope)**.** *For every accepted* $\mathsf{CauchyRate}^{\uparrow}$ *packet*

$$K = (p, \mu, \tau, F, Q, E, H, C, P, N),$$

the BHist *source scope is exactly the displayed coordinate list* $p, \mu, \tau, F, Q, E, H, C, P, N$*. No RealUp completeness principle, quotient stream equality, selected limit, host real equality, or unrecorded completion carrier is a dependency of the source packet.*

Proof. Read the carrier definition in Definition 415.1. It exposes precisely the ten rows $p, \mu, \tau, F, Q, E, H, C, P, N$, and no other coordinate is available to the packet classifier.

Apply Definition 415.2 to identify the visible obligations. Apply Definition 415.3 and Definition 415.4 to locate the only downstream reads of Q and E inside the same displayed source packet.

It remains to rule out hidden source dependencies. The ledger theorem Definition 415.5 exhausts the available package rows, and Definition 415.6 preserves the same classifier under componentwise transport. Hence the source scope is exactly the displayed BHist row list. □

Theorem 415.12 (CauchyRate effective route scope)**.** *Every effective-rate consumer route for an accepted* $\mathsf{CauchyRate}^{\uparrow}$ *packet factors through the displayed continuation rows*

$$\mathsf{Cont}(p, \mu), \quad \mathsf{Cont}(\mu, \tau), \quad \mathsf{Cont}((\mu, \tau), F), \quad \mathsf{Cont}((F, \tau), Q), \quad \mathsf{Cont}((Q, F, \tau, \mu), E).$$

Thus a consumer may inspect the completion-facing row only after passing through the precision request, modulus schedule, dyadic tail bound, regular Cauchy family source, and regular rational readback recorded in the same packet.

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier effective route scope`

Proof. Start with the carrier in Definition 415.1. Its route row C displays the five continuation entries from p to μ, from μ to τ, from (μ, τ) to F, from (F, τ) to Q, and from (Q, F, τ, μ) to E.

Apply Definition 415.2 for classifier exactness and Definition 415.3 for the readback row Q. Then apply Definition 415.4 to place E downstream of Q, F, τ, μ.

The route cannot fork through an extra consumer row. By Definition 415.5, the ledger has no hidden carrier for an alternate read, and by Definition 415.6, componentwise transport preserves the same route inventory. Therefore every effective-rate consumer route factors through the displayed continuation chain. □

Theorem 415.13 (CauchyRate ledger scope)**.** *For an accepted* $\mathsf{CauchyRate}^{\uparrow}$ *packet* $K = (p, \mu, \tau, F, Q, E, H, C, P, N$ *the* Pkg *row* P *and local* $\mathsf{NameCert}_{\mathsf{CauchyRate}^{\uparrow}}$ *row* N *exhaust the dependency ledger over* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{DyadicTailBound}^{\uparrow}$*,* $\mathsf{RegularCauchyFamily}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. No dependency outside that list may be used to justify an effective-rate read.*

Proof. Project the packet carrier of Definition 415.1. The package row P names the external dependency surface, while N names the local certificate surface for exactly the same finite packet.

Use Definition 415.2 to recover carrier exposure, classifier exactness, handoff, boundary, and ledger exhaustion. The handoff theorem Definition 415.3 accounts for $\mathsf{RegSeqRat}^{\uparrow}$, and Definition 415.4 accounts for $\mathsf{RealCauchyCompletion}^{\uparrow}$.

Finally, apply Definition 415.5 to close the package inventory and Definition 415.6 to keep it stable under hsame transport and displayed Cont routes. The only remaining rows are P and N, so the stated dependency list is exhaustive. □

Definition 415.14 (CauchyRate scoped obligation package)**.** *The scoped obligation package for* $\mathsf{CauchyRate}^{\uparrow}$ *is the accepted finite packet*

$$K = (p, \mu, \tau, F, Q, E, H, C, P, N)$$

of Definition 415.1, read as a BHist *carrier over exactly the displayed dependencies*

$$\mathsf{CauchyModulus}^{\uparrow},\quad \mathsf{DyadicTailBound}^{\uparrow},\quad \mathsf{RegularCauchyFamily}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{RealCauchyCompletion}^{\uparrow}.$$

Its scope consists of the precision row p, the modulus schedule μ, the tail-bound row τ, the regular Cauchy family row F, the regular rational readback Q, the completion consumer row E, the componentwise hsame *transports in H, the* Cont *routes in C, the* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{CauchyRate}^{\uparrow}}$ *row N.*

The package admits a consumer only when the consumer route factors through these rows in the displayed order. It has no coordinate for RealUp completeness, host real equality, quotient stream equality, selected limits, or an unscoped completion oracle.

Theorem 415.15 (CauchyRate window monotonicity)**.** *Let $K = (p, \mu, \tau, F, Q, E, H, C, P, N)$ be a scoped obligation package for* $\mathsf{CauchyRate}^{\uparrow}$*. If a consumer refines a precision request from p to a stricter displayed request p', then the accepted schedule window for p' is obtained by transporting p' through the same* $\mathsf{CauchyModulus}^{\uparrow}$ *row μ and the same* $\mathsf{DyadicTailBound}^{\uparrow}$ *row τ. The transported classifier may enlarge the inspected finite window, but it cannot replace μ, bypass τ, or read F, Q, E from a different package.*

Proof. Project the scoped carrier of Definition 415.14. The only row that turns a precision request into a finite inspection window is μ, and the only tail budget attached to that window is τ.

Transport the refined request by the precision component of H. Replaying the route $\mathsf{Cont}(p, \mu)$ for the transported request keeps the schedule inside the same $\mathsf{CauchyModulus}^{\uparrow}$ row, and replaying $\mathsf{Cont}(\mu, \tau)$ keeps the dyadic tail-bound ledger attached to the scheduled window.

The classifier described in Definition 415.1 compares packets only through displayed hsame and Cont rows. Thus a stricter request can ask the same schedule row for a larger visible window, but no classifier branch can substitute a different modulus, omit the tolerance row, or fetch the downstream rows from outside K. □

Theorem 415.16 (CauchyRate tail-bound routing)**.** *For every scoped* $\mathsf{CauchyRate}^{\uparrow}$ *package $K = (p, \mu, \tau, F, Q, E, H, C, P, N)$, every read of the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q must first pass through the scheduled* $\mathsf{CauchyModulus}^{\uparrow}$ *row μ, the* $\mathsf{DyadicTailBound}^{\uparrow}$ *row τ, and the* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *row F. In particular, no Q-consumer can inspect a regular rational readback before the tail-bound route through τ has been displayed.*

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier tail bound routing`

Proof. Read the route inventory from the scoped package. The route into Q is $\mathsf{Cont}((F, \tau), Q)$, and the row F is itself reached only after the schedule and tolerance rows have been exposed through the displayed route chain.

Apply the regular-family handoff theorem Definition 415.3. It identifies Q as the readback produced from the same scheduled family row and the same dyadic tail-bound row, so the rational readback is not an independent source row.

Finally inspect P and N. Their provenance names the displayed dependency package and the local certificate only; neither row adds an alternate path to Q. Hence a consumer of Q must see μ, τ, and F before it obtains the regular rational readback. □

Theorem 415.17 (CauchyRate real-seal consumption)**.** *Let $K = (p, \mu, \tau, F, Q, E, H, C, P, N)$ be a scoped* $\mathsf{CauchyRate}^{\uparrow}$ *package. Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer read of E factors through Q, F, τ, μ in that order before any completion-facing row is consumed. The factorization is a scoped*

completion-consumer route, not a proof of RealUp completeness, quotient equality of streams, a selected limit, or host real equality.

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier real seal consumption`

Proof. Project the completion-facing coordinate from K. The only displayed route into E is $\mathsf{Cont}((Q, F, \tau, \mu), E)$, so the consumer boundary begins with the regular rational readback and carries the family, tail-bound, and schedule rows with it.

Use Definition 415.16 for the upstream read of Q. That theorem forces the readback itself through μ, τ, and F before Q is available to any later consumer.

Combining the two routes gives the stated factorization through Q, F, τ, μ before E. The scoped obligation package has no coordinate for the excluded RealUp, quotient, selected-limit, or host-equality objects, so the completion-facing read consumes only the displayed effective-rate certificate. □

Theorem 415.18 (CauchyRate public certificate)**.** *Let $K = (p, \mu, \tau, F, Q, E, H, C, P, N)$ be a scoped* $\mathsf{CauchyRate}^{\uparrow}$ *package. The* BHist *source,* NameCert *obligations, regular-family handoff, real-completion consumer boundary, ledger exactness, transport stability, scheduled-window totality, tolerance readback exactness, scoped consumer exhaustion, source scope, effective-route scope, ledger scope, window monotonicity, tail-bound routing, and real-seal consumption assemble a single exported* $\mathsf{CauchyRate}^{\uparrow}$ *public certificate. Its public consumers are exactly the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readers that factor through the displayed effective-rate rows, and it exports no RealUp completeness, quotient stream equality, selected limit, or host equality.*

Lean4 ✓ `BEDC.Derived.CauchyRateUp.CauchyRateCarrier public certificate`

Proof. Project the scoped package $K = (p, \mu, \tau, F, Q, E, H, C, P, N)$ from Definition 415.14. The BHist source of Definition 415.1 supplies the carrier rows, and Definition 415.2 exposes the local NameCert obligations attached to those rows.

The effective-rate spine is the one exposed by Definition 415.7, Definition 415.3, Definition 415.9, and Definition 415.15. These results identify the schedule, tolerance row, regular family, and readback without replacing the rows stored in K.

The route and ledger boundary is fixed by Definition 415.5, Definition 415.6, Definition 415.11, and Definition 415.12. Together with Definition 415.13, these results keep every transported consumer inside the same source, route, and ledger surface.

The downstream boundary is fixed by Definition 415.16, Definition 415.17, and Definition 415.10. A $\mathsf{RegSeqRat}^{\uparrow}$ reader consumes Q only after the scheduled tail-bound route, a $\mathsf{RealCauchyCompletion}^{\uparrow}$ reader consumes E only through Q, F, τ, μ, and a $\mathsf{Real}^{\uparrow}$ reader sees only that same effective-rate certificate.

It remains to inspect the excluded objects. The package has no coordinate for RealUp completeness, quotient stream equality, selected limits, or host equality, and the scoped consumer-exhaustion clause leaves no route that escapes $p, \mu, \tau, F, Q, E, H, C, P, N$. The assembled object is therefore a public $\mathsf{CauchyRate}^{\uparrow}$ certificate over the displayed effective-rate rows and nothing stronger. □

Theorem 415.19 (CauchyRate bridge source exactness)**.** *The standard effective Cauchy-rate bridge source is exactly the packet*

$$K = (p, \mu, \tau, F, Q, E, H, C, P, N)$$

of Definition 415.14. Its source rows are the precision request, schedule, tail-bound, regular family, regular-rational readback, completion consumer, displayed hsame *ledger, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row. It exports no* $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient stream equality, selected limit, or host equality.*

Proof. Project the scoped packet K from Definition 415.14. Its coordinates are precisely $p, \mu, \tau, F, Q, E, H, C, P, N$, so any bridge source read begins with the same precision, schedule, tail-bound, regular-family, readback, completion-consumer, ledger, route, package, and certificate rows.

Attach the effective-rate routes. Scheduled-window totality fixes the precision schedule, tail-bound routing forces the readback through μ, τ, F, Q, and real-seal consumption routes the completion-facing consumer through Q, F, τ, μ before E is read.

Finally use ledger exactness and the public certificate. The ledger theorem keeps the exposed rows equal to the displayed hsame, Cont, Pkg, and NameCert surface, while Definition 415.18 exports exactly that surface as the public $\mathsf{CauchyRate}^{\uparrow}$ object. Repacking these rows gives the standard effective Cauchy-rate bridge source and leaves no coordinate for the excluded RealUp completeness, quotient, selected-limit, or host-equality objects. □

Theorem 415.20 (CauchyRate standard bridge source packet)**.** *For the public* $\mathsf{CauchyRate}^{\uparrow}$ *certificate, the bridge source is exactly the finite packet*

$$K = (p, \mu, \tau, F, Q, E, H, C, P, N)$$

of Definition 415.1. Its rows are read over $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert, *with no additional bridge-source coordinate.*

Proof. Project the public certificate through Definition 415.1. The displayed source has precisely the rows $p, \mu, \tau, F, Q, E, H, C, P, N$, and the local classifier compares only those rows together with their package and naming provenance.

Use Definition 415.18 to export the same packet as a public object. Its proof already assembles the source row, the NameCert obligations, the route scope, the ledger scope, the tail-bound route, and the completion-facing consumer boundary.

It remains to identify the bridge source. Since Definition 415.11, Definition 415.12, and Definition 415.13 exhaust the available rows, a standard bridge reading can cite exactly the displayed packet and no further coordinate. □

Theorem 415.21 (CauchyRate bridge non-escape boundary)**.** *Every bridge read from the public* $\mathsf{CauchyRate}^{\uparrow}$ *certificate is bounded by the displayed effective-rate packet* $K = (p, \mu, \tau, F, Q, E, H, C, P, N)$*. In particular, the bridge cannot read RealUp completeness, quotient stream equality, selected limits, host real equality, or any completion oracle not routed through* Q, F, τ, μ *and the stored* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer row* E*.*

Proof. Start from the source packet fixed by Definition 415.20. The only completion-facing coordinate in that packet is E, and Definition 415.17 forces every read of E through Q, F, τ, μ before the completion-facing row is consumed.

The upstream readback is also bounded. By Definition 415.16, every read of Q passes first through the scheduled modulus row, the dyadic tail-bound row, and the regular-family row stored in the same packet.

Finally inspect the public ledger. The public certificate of Definition 415.18 and the scoped consumer exhaustion theorem rule out RealUp completeness, quotient stream equality, selected

limits, host real equality, and any unscoped completion oracle as exported rows. Therefore a bridge read cannot escape the finite effective-rate boundary. □

Theorem 415.22 (CauchyRate standard bridge obligation package)**.** *The CauchyRate standard bridge obligation package is assembled from the source packet of Definition 415.20, the non-escape boundary of Definition 415.21, the public certificate of Definition 415.18, scheduled-window totality, tail-bound routing, and real-seal consumption. The package presents the standard effective-rate reading as a consumer of* $p, \mu, \tau, F, Q, E, H, C, P, N$ *and nothing beyond that public surface.*

Proof. First build the bridge source. Apply Definition 415.20 to recover exactly the displayed BHist packet over the named dependency rows.

Next attach the effective-rate obligations. The schedule is supplied by Definition 415.7, the rational readback route is supplied by Definition 415.16, and the completion-facing consumption route is supplied by Definition 415.17.

Now repack the public surface. The public certificate in Definition 415.18 exports the same rows as the consumer-facing object, while Definition 415.21 excludes RealUp completeness, quotient stream equality, selected limits, host real equality, and unscoped completion reads.

These ingredients are exactly the bridge obligations: a fixed source packet, a scheduled finite window, a routed tail-bound readback, a completion consumer route, a public certificate, and a non-escape boundary. Hence the standard bridge obligation package is determined by $p, \mu, \tau, F, Q, E, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRate}^\uparrow}$.

Constructive story: A $\mathsf{CauchyRate}^\uparrow$ packet is generated from a unary precision row, a $\mathsf{CauchyModulus}^\uparrow$ schedule, a $\mathsf{DyadicTailBound}^\uparrow$ tolerance row, a $\mathsf{RegularCauchyFamily}^\uparrow$ source, a $\mathsf{RegSeqRat}^\uparrow$ readback, a $\mathsf{RealCauchyCompletion}^\uparrow$ consumer row, displayed hsame and Cont rows, package provenance, and a local naming row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRate}^\uparrow}$, maturePackageClosed)

Scope closed: The public effective-rate route fixes exactly the $p, \mu, \tau, F, Q, E, H, C, P, N$ packet over $\mathsf{CauchyModulus}^\uparrow$, $\mathsf{DyadicTailBound}^\uparrow$, $\mathsf{RegularCauchyFamily}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{RealCauchyCompletion}^\uparrow$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRate}^\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.CauchyRateUp.CauchyRateCarrier\_real\_completion\_consumer\_boundary`

Bridge status: none

Origin: human

Not claimed: This chapter does not close RealUp completeness, quotient equality of regular streams, selected limits, host real equality, or bridge checking.

Upgrade path: No further paper-side theory grade remains for the effective-rate bridge, standard source packet, and real-completion consumer boundary.

Chapter 416

A Concrete Naming Certificate for $\mathsf{RegularCauchyInterleave}^{\uparrow}$

The $\mathsf{RegularCauchyInterleave}^{\uparrow}$ interface names the finite merge schedule used when two regular Cauchy names are exposed through one visible stream of observations. The construction is not a quotient of completed real values and does not select a host limit; it records the rows that make every merged window, dyadic observation, modulus request, and real-name handoff inspectable.

The interleaved window table consumes the finite-window surface of chapter 126. Its dyadic observation ledger consumes the row-level rational core supplied by chapter 291, and its real-name handoff is read against the boundary discipline of chapter 38. Thus the packet is a horizontal dependency node in the completion lattice rather than a kernel-only island.

Definition 416.1 (Regular Cauchy interleave carrier)**.** *A* $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, J, S, T, W, D, M, H, C, P, N)$$

with the following visible rows:

1. *I and J are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *member schedules whose regular Cauchy observations may be read;*
2. *S is the unary merge schedule naming, for each retained slot, whether the slot reads the I side or the J side;*
3. *T is the interleaved* $\mathsf{StreamName}^{\uparrow}$ *window table produced by applying S to the two source schedules;*
4. *W records the* $\mathsf{CauchyModulus}^{\uparrow}$ *precision requests attached to the selected windows;*
5. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows reached at the selected windows and precision requests;*
6. *M records the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff rows by which the merged finite observations are exposed to real-name consumers;*
7. *H displays the componentwise* hsame *transports for the two regular schedules, merge schedule, window table, modulus requests, dyadic observations, handoff rows, provenance, and local naming row;*
8. *C displays the* Cont *routes for reading a selected side, forming the interleaved window, checking the modulus request, observing the dyadic row, and handing the result to* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*;*

9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleave}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of streams, host equality of completed reals, ambient completeness, or a choice-selected limit.

Definition 416.2 (Regular Cauchy interleave classifier)**.** *Two accepted* $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *carriers are classified as the same finite merge packet exactly when all rows of Definition 416.1 transport componentwise through the displayed* hsame *rows and all consumer reads factor through the displayed* Cont *routes. The classifier compares the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *schedules, the unary merge schedule, the interleaved* $\mathsf{StreamName}^{\uparrow}$ *table, the* $\mathsf{CauchyModulus}^{\uparrow}$ *request ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff rows, package provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleave}^{\uparrow}}$ *row.*

The classifier has no generator for comparing completed streams or host real values. Equality is exhausted by the finite rows carried by the packet.

Theorem 416.3 (Regular Cauchy interleave NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleave}^{\uparrow}}$ *obligation surface for the carrier of Definition 416.1 consists of carrier admission, classifier transport, finite merge-window exactness, modulus-observation compatibility, and real-handoff boundary. Every row consumed by the certificate is one of*

$$I, J, S, T, W, D, M, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleaveUp.RegularCauchyInterleavePacket semantic name certificate`

Proof. Carrier admission is the projection of the finite packet K. The rows I, J, S, T, W, D, and M are stored coordinates, while H, C, P, and N provide transport, continuation, package, and local naming evidence.

Classifier transport is exactly Definition 416.2. It moves source schedules, merge choices, window rows, precision requests, observations, and handoffs only through displayed hsame and Cont rows.

The merge-window and modulus-observation clauses are finite repackings. A selected slot of S names one side, T records the resulting window, W records the requested precision, and D records the dyadic observation at that request.

The real-handoff clause projects M. Since no carrier coordinate stores a quotient stream, host real equality, completeness proof, or selected limit, the certificate exports only the displayed finite handoff surface. □

Theorem 416.4 (Regular Cauchy interleave carrier admission)**.** *An accepted* $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *carrier is admitted exactly as the displayed finite* BHist *packet*

$$K = (I, J, S, T, W, D, M, H, C, P, N)$$

of Definition 416.1. Carrier admission projects the two $\mathsf{RegSeqRat}^{\uparrow}$ *schedules I, J, the merge schedule S, the interleaved* $\mathsf{StreamName}^{\uparrow}$ *table T, the* $\mathsf{CauchyModulus}^{\uparrow}$ *request ledger W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger D, the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff rows M, and the rows H, C, P, N for transport, continuation, package provenance, and local naming.*

Proof. Project the accepted packet by Definition 416.1. Each listed row is a coordinate of the same finite BHist object, so the admission witness is obtained by reading those coordinates and repacking them as the local $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleave}^{\uparrow}}$ carrier.

There is no further admission case to discharge. The carrier has no coordinate for quotient equality of streams, a host equality proof between completed names, ambient completeness, or a selected limit, so none of those objects can enter the admitted packet. □

Theorem 416.5 (Regular Cauchy interleave classifier transport exactness)**.** *Let K and K' be accepted* $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *carriers. If their rows $I, J, S, T, W, D, M, P, N$ are matched componentwise by the displayed* hsame *rows in H and read through the displayed* Cont *routes in C, then the* $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *classifier transports exactly those rows and no other comparison data.*

Proof. Use Definition 416.2. The classifier reads the two source schedules, the unary merge schedule, the interleaved window table, the modulus requests, the dyadic observations, the handoff rows, package provenance, and the local naming row.

The displayed hsame rows give the componentwise replacements, and the displayed Cont routes give the permitted consumer reads. Since the classifier has no generator for completed stream equality or host real equality, the transported comparison is exactly the one carried by H and C over the stored packet rows. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleaveUp.RegularCauchyInterleaveCarrier classifier transport exactness`

Theorem 416.6 (Regular Cauchy interleave dyadic observation handoff)**.** *For every accepted* $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *carrier $K = (I, J, S, T, W, D, M, H, C, P, N)$, each selected merge slot reaches its* $\mathsf{CauchyModulus}^{\uparrow}$ *request in W and its* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation in D before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff row in M is consumed.*

Proof. Start with a selected slot of the unary merge schedule S. The slot chooses one of the displayed source schedules I or J and then reads the corresponding finite $\mathsf{StreamName}^{\uparrow}$ window row in T.

The same slot carries a precision request in W. Reading that request through the stored continuation route reaches the dyadic observation row in D, with the componentwise hsame rows preserving the selected side, window, request, and observation.

Only after these rows have been displayed does the handoff coordinate M become available to $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumers. Thus the handoff is a finite dyadic-observation route, not a shortcut through a quotient stream, completed real equality, completeness theorem, or selected limit. □

Theorem 416.7 (Regular Cauchy interleave window merge exactness)**.** *For every accepted* RegularCauchyInterleave *carrier $K = (I, J, S, T, W, D, M, H, C, P, N)$, each retained row of the interleaved* $\mathsf{StreamName}^{\uparrow}$ *window table T is obtained by reading exactly one source schedule, selected by the corresponding unary merge row of S, and by pairing that selected window with the corresponding* $\mathsf{CauchyModulus}^{\uparrow}$ *request in W and* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation in D.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleaveUp.RegularCauchyInterleaveWindowMergeExactness`

Proof. Project the selected slot of S. Its unary row has only the displayed left and right alternatives named by the carrier, so it chooses one of the two $\mathsf{RegSeqRat}^{\uparrow}$ member schedules I and J.

Read the chosen schedule through the stored Cont route. The resulting finite window is the corresponding row of T, and the componentwise hsame rows in H transport that row together with the chosen source schedule.

Next read the matching precision and observation rows. The ledger W stores the CauchyModulus$^{\uparrow}$ request for the same slot, and D stores the DyadicRatCore$^{\uparrow}$ observation reached at that request.

Repacking these projections gives the asserted table row. No additional stream quotient or host equality comparison can alter the selected window, because the carrier contains no such coordinate. □

Theorem 416.8 (Regular Cauchy interleave selected-slot exhaustion)**.** *For every accepted* RegularCauchyInterleave$^{\uparrow}$ *packet* $K = (I, J, S, T, W, D, M, H, C, P, N)$*, each retained slot of* S *selects exactly one of the two source schedules* I *and* J*. Along that same slot route the selected* StreamName$^{\uparrow}$ *row in* T*,* CauchyModulus$^{\uparrow}$ *request in* W*,* DyadicRatCore$^{\uparrow}$ *observation in* D*, and handoff row in* M *are read as one finite chain, while the unselected side remains present only as provenance in the packet.*

Proof. Project the retained slot from the unary merge schedule S. The carrier displays only the two alternatives I and J, so the slot inversion has one selected side and one unselected side.

Apply Definition 416.7. It identifies the window row in T, the precision request in W, and the dyadic observation row in D as the rows attached to the same selected slot.

Use Definition 416.6 to continue the same route into the handoff row M. The row is reached after the selected observation, so it cannot be read from the opposite source side.

The unselected source schedule is still part of K through provenance, transport, and continuation data, but it does not supply the retained slot. Since the carrier contains no quotient stream, host equality of completed reals, completeness object, or choice-selected limit, no external object can replace the displayed slot route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleaveUp.RegularCauchyInterleaveCarrier selected slot exhaustion`

Theorem 416.9 (Regular Cauchy interleave real handoff boundary)**.** *Every* RegSeqRat$^{\uparrow}$ *or* Real$^{\uparrow}$ *consumer read of a* RegularCauchyInterleave$^{\uparrow}$ *carrier factors through the finite merge schedule* S*, the interleaved window table* T*, the modulus request ledger* W*, the dyadic observation ledger* D*, and the handoff row* M*. The consumer cannot read a quotient of streams, a host equality proof between completed names, an ambient completeness theorem, or a choice-selected real value from the packet.*

Proof. Start with a consumer read. The only real-facing coordinate of the carrier is M, and M is stored together with the window, modulus, and dyadic observation rows that produce it.

Use Definition 416.7 to identify the finite window consumed by the read. Each window row of T is tied to one selected side of S, one precision request in W, and one observation row in D.

Use Definition 416.2 for transport. It allows the consumer route to move these rows componentwise through H and C, with the same package provenance P and local naming row N.

Thus the read factors through the displayed finite packet. Since the carrier has no field for quotient streams, host equality of completed reals, completeness, or selected limits, none of those objects can be exported at the RegSeqRat$^{\uparrow}$/Real$^{\uparrow}$ boundary. □

Lemma 416.10 (Regular Cauchy interleave readback stability)**.** *Let* $K = (I, J, S, T, W, D, M, H, C, P, N)$ *and* $K' = (I', J', S', T', W', D', M', H', C', P', N')$ *be accepted* RegularCauchyInterleave$^{\uparrow}$ *carriers whose two source schedules, merge schedules, interleaved windows, request ledgers, dyadic observations, and handoff rows are related componentwise by the displayed* hsame *rows. Then the*

$\mathsf{RegSeqRat}^{\uparrow}$ *readback route carried by* M *transports to the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route carried by* M' *through the same interleaved* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows. The transport introduces no selected subsequence, quotient representative, host equality of completed real names, or choice-selected limit.*

Proof. Start from the classifier transport exactness theorem. It says that the only comparison data available to accepted interleave packets are the componentwise hsame rows and the displayed Cont routes over $I, J, S, T, W, D, M, P, N$.

Apply window merge exactness to the transported slot. The selected side, interleaved window row, precision request, and dyadic observation remain the same finite route under the componentwise transport.

Use selected-slot exhaustion to rule out hidden extraction. Each retained slot has one displayed source side and one displayed handoff chain, so no subsequence selector or quotient representative can enter between the window row and the $\mathsf{RegSeqRat}^{\uparrow}$ readback row.

The transported readback is therefore the same finite route read through M and M'. Since neither carrier stores host equality, ambient completeness, a selected limit, or choice data, the stability claim exports none of those coordinates. □

Lemma 416.11 (Regular Cauchy interleave Real seal)**.** *For every accepted* $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *carrier* $K = (I, J, S, T, W, D, M, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal available to a downstream consumer is downstream of the interleaved* $\mathsf{StreamName}^{\uparrow}$ *table* T*, the* $\mathsf{CauchyModulus}^{\uparrow}$ *request ledger* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger* D*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback component of* M*. The seal exports only the displayed finite readback boundary and no ambient completeness theorem, quotient stream equality, selected subsequence, selected real value, or choice coordinate.*

Proof. Project the real-facing consumer route through the real handoff boundary. The boundary forces every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read to pass through S, T, W, D, M before the downstream consumer can inspect a seal.

Use dyadic observation handoff and window merge exactness. They identify the finite window, precision request, and dyadic observation rows that feed the readback component of M.

Apply readback stability for transported carriers. The same interleaved window and dyadic observation route remains stable under componentwise hsame, so the Real seal is attached to the finite readback boundary rather than to a quotient representative.

Thus the seal exports only the finite interleave packet rows together with H, C, P, N. No carrier coordinate supplies ambient completeness, quotient stream equality, selected subsequences, selected real values, or choice data. □

Definition 416.12 (Regular Cauchy interleave obligation surface)**.** *For a concrete packet*

$$K = (I, J, S, T, W, D, M, H, C, P, N)$$

of Definition 416.1, the $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *obligation surface consists exactly of carrier admission, classifier transport, finite merge-window exactness, modulus-observation compatibility, and the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff boundary. These obligations are read only from the source schedules* I, J*, unary merge schedule* S*, interleaved window table* T*, modulus request ledger* W*, dyadic observation ledger* D*, handoff rows* M*, transport rows* H*, continuation routes* C*, package row* P*, and local naming row* N*.*

Theorem 416.13 (Regular Cauchy interleave carrier-classifier obligation package)**.** *For every accepted* $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *packet* $K = (I, J, S, T, W, D, M, H, C, P, N)$*, the carrier-admission*

and classifier-transport obligations of Definition 416.12 are exactly the concrete carrier and classifier obligations of the chapter.

Proof. Read the packet through Definition 416.1. This exposes precisely the rows $I, J, S, T, W, D, M, H, C, P, N$ and no additional analytic coordinate.

The carrier side is the admission statement of Definition 416.4. The classifier side is the componentwise transport described by Definition 416.2 and proved in Definition 416.5.

Together these references give the carrier and classifier part of the obligation surface, with the same package row and local naming row retained for downstream reads. □

Theorem 416.14 (Regular Cauchy interleave window-modulus obligation package)**.** *For every accepted* $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *packet* $K = (I, J, S, T, W, D, M, H, C, P, N)$*, the finite merge-window and modulus-observation obligations of Definition 416.12 are witnessed by the displayed rows* $S, T, W, D, M, H, C, P, N$*.*

Proof. Apply Definition 416.7. It ties each selected merge slot in S to the window table T, the request ledger W, the dyadic observation row D, and the handoff row M before any consumer read is made.

Then apply Definition 416.6. It keeps the modulus request and dyadic observation in the same finite read path under the displayed transport and continuation rows.

Thus the window and modulus obligations are fulfilled inside the concrete packet, without adding quotient streams, host real equality, or selected limits. □

Theorem 416.15 (Regular Cauchy interleave real-handoff obligation package)**.** *For every accepted* $\mathsf{RegularCauchyInterleave}^{\uparrow}$ *packet* $K = (I, J, S, T, W, D, M, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff obligation of Definition 416.12 is exactly the boundary route through* $S, T, W, D, M, H, C, P, N$*.*

Proof. Use Definition 416.9. It states that every regular-rational or real-facing consumer read factors through the finite merge schedule, interleaved window table, modulus request ledger, dyadic observation ledger, and handoff row.

The remaining rows H, C, P, N preserve the same route as transport, continuation, package provenance, and local naming. Therefore the real-handoff obligation is a finite BEDC packet obligation, not an appeal to completion, quotient streams, or host equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleave}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyInterleave}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ member schedules, a unary merge schedule, an interleaved $\mathsf{StreamName}^{\uparrow}$ window table, $\mathsf{CauchyModulus}^{\uparrow}$ requests, $\mathsf{DyadicRatCore}^{\uparrow}$ observations, $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff rows, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyInterleave}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: The obligation scope binds carrier admission, classifier transport, merge-window exactness, selected-slot exhaustion, real-handoff boundary, and the carrier-classifier, window-modulus, and real-handoff obligation packages to the displayed finite interleave packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyInterleave}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.RegularCauchyInterleaveUp.RegularCauchyInterleavePacket\_semantic\_name\_certificate`

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient equality of streams, host equality of completed real names, ambient completeness, uniqueness of a merged limit, or bridge checking.

Upgrade path: Public closure requires a single consumer-facing interleaved-window certificate for downstream $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readers.

Chapter 417

RegularCauchySum NameCert Construction

The $\mathsf{RegularCauchySum}^{\uparrow}$ interface names the finite pointwise-addition surface for two regular rational Cauchy names. It sits between the $\mathsf{RegSeqRat}^{\uparrow}$ readback layer and the $\mathsf{Real}^{\uparrow}$ seal: a consumer can inspect the two scheduled input windows, the displayed dyadic endpoint addition rows, and the combined finite error ledger, but it cannot read a quotient of streams, a selected host limit, or an ambient completeness principle.

The packet consumes the finite-window discipline of chapter 126, the dyadic endpoint arithmetic of chapter 291, and the regular-rational readback boundary of chapter 301.

Definition 417.1 (RegularCauchySum carrier)**.** *A* $\mathsf{RegularCauchySum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, W_A, W_B, D_A, D_B, D, E, R, H, C, P, N)$$

with the following displayed coordinates:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose rational observation windows are to be added pointwise;*
2. *W_A and W_B are aligned* $\mathsf{StreamName}^{\uparrow}$ *windows for a shared precision request and a shared unary observation index;*
3. *D_A and D_B are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows read from those windows;*
4. *D is the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint addition row obtained from the common-exponent addition window for $D_A + D_B$;*
5. *E is the finite* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *ledger recording the two input tolerances, their sum, and the output tolerance assigned to D;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row whose scheduled point row is D with the tolerance budget recorded by E;*
7. *H stores componentwise* hsame *transports for both source names, both stream windows, the three dyadic endpoint rows, the error-budget ledger, and the readback row;*
8. *C stores the displayed* Cont *routes for reading the two input windows, forming the dyadic endpoint addition row, checking the combined budget, and exposing the readback;*
9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteErrorBudget}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySum}^{\uparrow}}$ *row.*

The packet is a finite addition certificate for regular Cauchy names. It stores no quotient stream, no selected limit, no host real equality, and no ambient completeness object.

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumTasteGate single carrier alignment`

Theorem 417.2 (RegularCauchySum NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchySum}^{\uparrow}}$ *surface for the carrier of Definition 417.1 consists of five finite rows:*

1. *carrier admission: the accepted object is the displayed* BHist *packet S with two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, aligned* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic endpoint rows, a budget ledger, transport rows, continuation rows, provenance, and local naming data;*
2. *classifier transport: classification transports the two source rows, the aligned windows, the endpoint addition row, the error ledger, and the readback row componentwise through the stored* hsame *and* Cont *rows;*
3. *stability: replacing either input by a classified regular name preserves the aligned window and recomputes the same kind of displayed dyadic addition row;*
4. *ledger exactness: the output tolerance row is the finite sum of the two input tolerance rows recorded in E;*
5. *downstream handoff: every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the sum first reads R together with A, B, W_A, W_B, D_A, D_B, D, E, H, C, P, and N.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier semantic name certificate`

Proof. Carrier admission is the direct projection of the tuple in Definition 417.1. Each source row, window row, endpoint row, budget row, transport route, continuation route, provenance row, and local naming row is an explicit coordinate of S.

Classifier transport is componentwise. The two $\mathsf{RegSeqRat}^{\uparrow}$ source rows transport their scheduled rational observations, the $\mathsf{StreamName}^{\uparrow}$ rows transport the aligned window reads, and the $\mathsf{DyadicRatCore}^{\uparrow}$ rows transport the endpoint addition calculation at the common exponent.

The budget row is finite. It records the two input tolerances before the sum row is exposed, so the output tolerance is read as the displayed addition of those two ledger entries. The downstream handoff is then the readback row R, and no omitted coordinate can add quotient streams, selected limits, host real equality, or ambient completeness. □

Theorem 417.3 (RegularCauchySum window budget)**.** *Given two accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows A and B in a* $\mathsf{RegularCauchySum}^{\uparrow}$ *packet and a shared precision request, the aligned* $\mathsf{StreamName}^{\uparrow}$ *windows W_A and W_B display dyadic endpoint rows D_A and D_B. The packet displays a* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D for $D_A + D_B$ and a finite ledger E whose output tolerance is the displayed sum of the two input tolerance rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier window budget`

Proof. Read the shared precision request through the two stream windows. Since W_A and W_B are aligned coordinates of the same packet, they expose the two endpoint rows at the same requested observation index.

Apply the displayed common-exponent addition window of $\mathsf{DyadicRatCore}^{\uparrow}$ to D_A and D_B. The result is the endpoint row D, still inside the carrier.

Finally read the finite budget ledger E. Its two input entries are the tolerances used by the two regular names, and its output entry is their displayed sum. This proves the window budget without invoking any completed real or quotient stream. □

Theorem 417.4 (RegularCauchySum symmetric input handoff)**.** *For every accepted* $\mathsf{RegularCauchySum}^{\uparrow}$ *packet* $S = (A, B, W_A, W_B, D_A, D_B, D, E, R, H, C, P, N)$*, any consumer read of the sum readback* R *factors through both aligned source windows* W_A, W_B*, both endpoint rows* D_A, D_B*, the common dyadic addition row* D*, and the finite error ledger* E*. Exchanging the two source rows preserves the same handoff surface up to the displayed componentwise classifier over the two sources, two windows, two endpoint rows, addition row, budget row, readback row, transports, continuations, package provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier symmetric input handoff`

Proof. Read the two inputs through Definition 417.3. The window budget exposes both aligned source windows, both endpoint rows, the common dyadic addition row, and the finite ledger before the readback row is consumed.

Repack those rows through Definition 417.6. The consumer of R therefore receives the paired source data together with D and E, rather than a one-sided source row or an ambient completed-real operation.

For the exchanged packet, use the componentwise classifier carried by H and read through C. It swaps the two source rows with their matching windows and endpoints while preserving the displayed addition row, budget ledger, readback row, package provenance, and local $\mathsf{NameCert}$ row.

The carrier has no coordinate for a host-level completed-real addition law, quotient stream, selected limit, or completeness object. Thus the symmetric handoff is exactly the finite paired-source surface described by the packet classifier. □

Theorem 417.5 (RegularCauchySum two-source Real seal symmetry)**.** *Let* $S = (A, B, W_A, W_B, D_A, D_B, D, E, R,$ *be an accepted* $\mathsf{RegularCauchySum}^{\uparrow}$ *packet. Exchanging the two accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows preserves the* $\mathsf{Real}^{\uparrow}$ *seal route: any real-facing consumer still reads both aligned* $\mathsf{StreamName}^{\uparrow}$ *windows* W_A, W_B*, both* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows* D_A, D_B*, the same finite error-budget row* E*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the same local* $\mathsf{NameCert}_{\mathsf{RegularCauchySum}^{\uparrow}}$ *provenance through* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier two source real seal symmetry`

Proof. Start with Definition 417.4. It gives the componentwise exchange of the two source rows together with their matched windows and endpoint rows, while leaving the displayed addition row, finite budget row, readback row, transport rows, continuation rows, package provenance, and local naming row on the same carrier surface.

Apply Definition 417.6 to the exchanged surface. The $\mathsf{RegSeqRat}^{\uparrow}$ consumer still receives the aligned endpoint and budgeted pointwise-sum data through R, so the swap has not introduced a one-sided source route or an ambient completed-real operation.

Finally use Definition 417.8. Since every $\mathsf{Real}^{\uparrow}$ consumer factors through the displayed readback R and its visible provenance, the real seal route is insensitive to the order of the two accepted source rows and remains the finite two-source route listed in the statement. □

Theorem 417.6 (RegularCauchySum RegSeqRat handoff)**.** *The budgeted pointwise-sum windows of Definition 417.3 repack as the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *of Definition 417.1. A consumer of*

R reads only the aligned input windows, the dyadic endpoint addition rows, the finite error-budget ledger, the displayed hsame *transports, the* Cont *routes, the* Pkg *provenance, and the local* NameCert *row.*

Proof. Start with the finite window budget. For each requested precision, the packet exposes the two source endpoint rows, the dyadic sum endpoint, and the combined tolerance row.

Repack those displayed rows as a regular rational sequence readback. The point row of R is D, and the regularity evidence visible to the consumer is the tolerance ledger E routed through the same aligned windows.

The transport and continuation rows are inherited from the carrier. Since the repacking uses only coordinates already listed in Definition 417.1, it introduces no host sequence quotient and no selected limit. □

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier regseqrat handoff`

Theorem 417.7 (RegularCauchySum tail-selector handoff)**.** *Let $S = (A, B, W_A, W_B, D_A, D_B, D, E, R, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchySum}^{\uparrow}$ *packet whose aligned* $\mathsf{StreamName}^{\uparrow}$ *windows are read at the same precision request as the one-source selected-tail witness surface of chapter 458. Then every* $\mathsf{RegularCauchySum}^{\uparrow}$ *readback that exposes the* $\mathsf{Real}^{\uparrow}$ *seal must first consume the selected-tail witnesses for A and B, the aligned windows W_A, W_B, the dyadic endpoint rows D_A, D_B, D, the finite error ledger E, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows. The handoff exposes no quotient streams, host equality, selected limits, or ambient completeness.*

Proof. Project the sum packet. Its only source-facing rows are the two regular names, the aligned $\mathsf{StreamName}^{\uparrow}$ windows, the endpoint rows, the finite ledger, the readback row, and the structural route rows.

Read the sibling tail-selector surface next. The diagonal admissibility and precision-window exactness rows of chapter 458 supply one-source selected-tail witnesses attached to finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ support rows.

Use Definition 417.6 to repack the aligned endpoint and ledger rows as the sum readback R. The selected-tail witnesses remain attached through H, C, P, N, so the sum route consumes the sibling witnesses before the $\mathsf{Real}^{\uparrow}$ seal is exposed.

Finally apply the local non-escape and seal boundary rows. They rule out quotient streams, host equality, selected limits, and ambient completeness, leaving only the finite handoff surface listed in the statement. □

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier tail selector handoff`

Theorem 417.8 (RegularCauchySum RealUp seal boundary)**.** *Any* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchySum}^{\uparrow}$ *packet reads only the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R together with the visible provenance of the two source names, aligned windows, dyadic endpoint addition rows, finite error-budget ledger,* hsame *transports,* Cont *routes,* Pkg *row, and local* $\mathsf{NameCert}_{\mathsf{RegularCauchySum}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier realup seal nonempty iff`

Proof. Factor the real-facing read through the regular readback. By Definition 417.6, R is already the repacking of the budgeted pointwise-sum windows.

The remaining consumer-visible data are exactly the provenance rows attached to that repacking: the two source names, aligned schedules, dyadic addition endpoints, budget ledger, transports, continuations, package row, and local naming row.

The carrier has no independent Real$^{\uparrow}$ equality field and no completion witness outside the readback. Therefore the real seal can consume only the displayed regular readback and its visible provenance. □

Theorem 417.9 (RegularCauchySum non-escape boundary)**.** *No accepted* RegularCauchySum$^{\uparrow}$ *packet exports quotient streams, selected limits, host real equality, or ambient completeness. Every consumer route is exhausted by the finite* BHist *rows named in Definition 417.1 and by the handoff rows of Definition 417.6 and Definition 417.8.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier non escape boundary`

Proof. Inspect the carrier inventory. The only source coordinates are the two regular names, two stream windows, dyadic endpoint rows, finite error budget, readback row, transports, continuations, package row, and local naming row.

The RegSeqRat$^{\uparrow}$ handoff theorem shows that regular consumers receive only the budgeted pointwise-sum windows. The Real$^{\uparrow}$ seal theorem places real consumers downstream of that same regular readback and its visible provenance.

These two routes exhaust the packet. Since no listed coordinate is a quotient stream, selected limit, host real equality, or ambient completeness theorem, no consumer can read such an object from the RegularCauchySum$^{\uparrow}$ certificate. □

Theorem 417.10 (RegularCauchySum budget associative visibility)**.** *For any finite list of accepted* RegularCauchySum$^{\uparrow}$ *pointwise-sum packets built by repeated pairing, composing their visible error-budget rows is associative at the consumer boundary: every rebracketing reads the same* DyadicRatCore$^{\uparrow}$ *endpoint-addition rows and the same* FiniteErrorBudget$^{\uparrow}$ *ledger entries, routed through the displayed source* RegSeqRat$^{\uparrow}$ *rows, aligned* StreamName$^{\uparrow}$ *windows,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *rows. No composed budget introduces quotient streams, selected limits, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier budget associative visibility`

Proof. Read each summand packet through Definition 417.3. A single binary sum exposes two source endpoint rows, the dyadic sum endpoint, and the finite budget entry that combines the two requested tolerances.

For repeated sums, compose those binary ledger entries. Rebracketing changes only the order in which finite budget rows are paired; it does not change the displayed DyadicRatCore$^{\uparrow}$ endpoint-addition rows or the FiniteErrorBudget$^{\uparrow}$ entries consumed by the final window.

The handoff and non-escape results, Definition 417.6 and Definition 417.9, keep the composed route on the same source rows, aligned schedules, transports, continuations, package rows, and naming rows. Since the carrier has no hidden quotient or completion coordinate, the finite budget composition remains entirely visible. □

Theorem 417.11 (RegularCauchySum seal consumer exhaustion)**.** *Every* Real$^{\uparrow}$ *consumer of a* RegularCauchySum$^{\uparrow}$ *sum seal factors through the displayed* RegSeqRat$^{\uparrow}$ *readback, aligned* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *endpoint-addition row,* FiniteErrorBudget$^{\uparrow}$ *ledger,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. The seal has no consumer-facing coordinate for quotient streams, selected limits, host real equality, ambient completeness, or an independent completed-real addition law.*

Proof. Start with the real-facing seal boundary of Definition 417.8. It already places every $\mathsf{Real}^{\uparrow}$ read downstream of the regular readback R and the provenance attached to the two source names.

Use Definition 417.6 to expand R. The readback is the repacking of aligned windows, dyadic endpoint addition rows, and the finite error-budget ledger.

Finally apply Definition 417.9. The packet inventory is exhausted by those rows together with hsame, Cont, Pkg, and NameCert, so a real consumer cannot obtain any quotient stream, selected limit, host equality, ambient completeness principle, or separate completed-real addition object from the seal. □

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier seal consumer exhaustion`

Theorem 417.12 (RegularCauchySum consumer obligation package)**.** *For the* $\mathsf{RegularCauchySum}^{\uparrow}$ *carrier of Definition 417.1, the five local* $\mathsf{NameCert}_{\mathsf{RegularCauchySum}^{\uparrow}}$ *rows of Definition 417.2, the checked window budget of Definition 417.3, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff of Definition 417.6, the* $\mathsf{Real}^{\uparrow}$ *seal boundary of Definition 417.8, and the consumer exhaustion row of Definition 417.11 assemble a finite consumer-facing obligation package over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteErrorBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *This package exposes exactly the scheduled source windows, dyadic endpoint-addition rows, combined finite error ledger, displayed transports, continuation routes, provenance row, regular readback row, and local naming row; it excludes quotient streams, selected limits, host real equality, ambient completeness, and an independent completed-real addition law.*

Proof. Project the carrier of Definition 417.1. Its coordinates are the two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, aligned $\mathsf{StreamName}^{\uparrow}$ windows, endpoint rows in $\mathsf{DyadicRatCore}^{\uparrow}$, the finite $\mathsf{FiniteErrorBudget}^{\uparrow}$ ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, the hsame and Cont rows, the Pkg provenance, and the local NameCert row.

Read the five local naming obligations through Definition 417.2. They provide carrier admission, classifier transport, stability, ledger exactness, and downstream handoff, so every consumer-facing clause is already attached to a finite displayed row.

Use the checked window-budget theorem, Definition 417.3, for dyadic endpoint formation and budget exactness. Then route the displayed rows through Definition 417.6 and Definition 417.8, which place regular and real consumers downstream of the same readback and visible provenance.

Finally apply Definition 417.11. The seal has no further consumer coordinate, so the assembled package cannot export quotient streams, selected limits, host real equality, ambient completeness, or a separate completed-real addition law. □

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier consumer obligation package`

Theorem 417.13 (RegularCauchySum obligation surface)**.** *The* $\mathsf{RegularCauchySum}^{\uparrow}$ *carrier of Definition 417.1 exposes a finite obligation surface over the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, their aligned* $\mathsf{StreamName}^{\uparrow}$ *windows, the two source* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows, the displayed endpoint addition row, the finite error-budget ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{Real}^{\uparrow}$ *seal-facing route, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and the local* NameCert *row. Every consumer obligation for the sum packet is a projection of those rows together with Definition 417.12.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier obligation surface`

Proof. Project the carrier tuple. Its source windows, endpoint rows, budget ledger, readback row, transports, continuations, package row, and local naming row are already listed as coordinates of S.

Use Definition 417.12 to assemble the consumer-facing obligations. The package reads the local naming rows, window-budget exactness, regular readback handoff, real-seal boundary, and seal consumer exhaustion from those displayed coordinates.

Thus the obligation surface is finite and BHist-anchored. It does not introduce a completed-real addition operation, quotient equality of names, selected limit, or ambient completeness principle. □

Theorem 417.14 (RegularCauchySum classifier stability)**.** *Let two accepted* $\mathsf{RegularCauchySum}^{\uparrow}$ *packets have source rows, aligned windows, endpoint rows, finite error budgets, readbacks, real-seal routes, transports, continuations, package provenance, and local* NameCert *rows matched componentwise by their displayed* hsame *classifiers. Then every consumer route supplied by the obligation surface of Definition 417.13 transports to the corresponding route of the second packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier classifier stability`

Proof. Start with the componentwise classifier data. The two source rows transport together with their aligned windows, so the scheduled rational observations remain paired at the requested precision.

Transport the endpoint rows and budget ledger next. The dyadic endpoint addition row and the finite error-budget row stay attached to the transported source windows, so the $\mathsf{RegSeqRat}^{\uparrow}$ readback still reads the displayed sum row through the same kind of ledger.

Finally route the transported readback through the real-seal boundary and the local package rows. By Definition 417.12, every consumer route is one of these displayed projections, so classifier stability follows without invoking completed-real addition or quotient equality. □

Theorem 417.15 (RegularCauchySum ledger exactness)**.** *For every accepted* $\mathsf{RegularCauchySum}^{\uparrow}$ *packet, the ledger consumed by a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read is exactly the finite error-budget row* E *attached to the two aligned source windows and the displayed dyadic endpoint addition row. The packet has no alternate ledger for host real addition, quotient-stream equality, selected limits, or ambient completeness.*

Proof. Inspect a read of the regular sum. The read first reaches the aligned windows W_A, W_B, the endpoint rows D_A, D_B, the displayed addition row D, and the finite budget row E.

The $\mathsf{RegSeqRat}^{\uparrow}$ handoff repacks exactly those rows as R. The $\mathsf{Real}^{\uparrow}$ seal boundary reads downstream of R, so a real consumer sees the same finite ledger rather than a separate completed-real operation.

The consumer obligation package exhausts the route through $A, B, W_A, W_B, D_A, D_B, D, E, R, H, C, P, N$. Since the carrier contains no additional budget or equality coordinate, ledger exactness is precisely the displayed finite row E. □

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier ledger exactness`

Theorem 417.16 (RegularCauchySum zero-source identity boundary)**.** *Let* $S = (A, B, W_A, W_B, D_A, D_B, D, E, R,$ *be an accepted* $\mathsf{RegularCauchySum}^{\uparrow}$ *packet, and suppose one source row is supplied by an accepted* $\mathsf{RegularCauchyZero}^{\uparrow}$ *packet* $Z = (q, s, r, m, \mu, e, h, c, p, n)$ *through the downstream handoff of Definition 624.7. Then every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of* S *reads the other source window together with the zero packet route*

$$\mathsf{Rat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

displayed by q, s, r, e, the dyadic zero endpoint carried by q and the zero regular row r, the unchanged finite error-budget ledger E, the same componentwise hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows of the sum and zero packets.*

The boundary is an identity only at the finite consumer surface: replacing one source by the zero packet leaves the visible sum consumer route exhausted by the nonzero source window, the zero-source route, endpoint and budget rows, readback, seal row, transports, continuations, provenance, and naming data. It exports no host real addition law, quotient stream equality, selected limit, ambient completeness, or independent completed-real zero.

Proof. Begin with the sum packet. The window-budget theorem Definition 417.3 exposes the two aligned source windows, the source endpoint rows, the displayed endpoint-addition row, and the finite ledger E.

Now specialize one source to the zero packet. The downstream handoff Definition 624.7 supplies the finite zero-source boundary $q, s, r, m, \mu, h, c, p, n$, and the seal non-escape theorem Definition 624.6 routes every real-facing zero read through the same displayed zero seed, stream, regular row, meet row, and seal row.

Pass back to the sum consumer surface. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff of Definition 417.6 repacks the nonzero source window, the zero source route, the endpoint rows, and E as the sum readback R. The $\mathsf{Real}^{\uparrow}$ seal boundary of Definition 417.8 keeps every real consumer downstream of that readback.

Finally apply ledger exactness. By Definition 417.15, no alternate budget, equality, limit, completeness, or completed-real addition coordinate can be read. Projecting componentwise through $A, B, W_A, W_B, D_A, D_B, D, E, R, H, C, P, N$ leaves exactly the finite identity boundary named in the statement. □

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier zero source consumer route`

Theorem 417.17 (RegularCauchySum bridged public route)**.** *The public* $\mathsf{RegularCauchySum}^{\uparrow}$ *route is exhausted by the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, aligned* $\mathsf{StreamName}^{\uparrow}$ *windows, the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-addition row, the* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal route, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and the local* NameCert *row. A public consumer of the sum has no additional route through completed-real addition, quotient-stream equality, selected limits, host real equality, or ambient completeness.*

Proof. First read the public window and budget rows. The window-budget theorem Definition 417.3 fixes the aligned source windows, endpoint-addition row, and finite error ledger that any public sum read may inspect.

Next route the regular and real consumers. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff of Definition 417.6 repacks the same endpoint and ledger rows as regular readback, while the $\mathsf{Real}^{\uparrow}$ seal boundary of Definition 417.8 places the real-name route downstream of that readback.

Finally assemble the public package. The consumer obligation package of Definition 417.12 lists the transport, continuation, provenance, and local naming rows, and the seal consumer exhaustion theorem Definition 417.11 rules out any further consumer coordinate beyond the displayed public route. □

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier bridged public route`

Theorem 417.18 (RegularCauchySum standard bridge source packet)**.** *For every accepted* $\mathsf{RegularCauchySum}^{\uparrow}$ *carrier, the standard bridge source is exactly the finite packet of two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, aligned* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-addition row, the* $\mathsf{FiniteErrorBudget}^{\uparrow}$

ledger, the RegSeqRat$^{\uparrow}$ *readback, the* Real$^{\uparrow}$ *seal-facing route, and the displayed* hsame, Cont, Pkg, *and* NameCert *rows already assembled by Definition 417.12. It exports no quotient stream, selected limit, host real equality, ambient completeness, or independent completed-real addition law.*

Proof. Start with the window budget of Definition 417.3. It supplies the two aligned source windows, the endpoint-addition row, and the finite error ledger.

Use the RegSeqRat$^{\uparrow}$ handoff and Real$^{\uparrow}$ seal boundary, Definition 417.6 and Definition 417.8. These route regular and real consumers through the same readback row and provenance surface.

Apply the consumer obligation package and ledger exactness. The package gathers the transport, continuation, package, and naming rows, while ledger exactness fixes the finite budget as the only error ledger. Therefore the bridge source is precisely the displayed public packet and not a quotient stream, host limit, host equality, ambient completeness field, or separate completed-real addition object. □

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier standard bridge source packet`

Theorem 417.19 (RegularCauchySum limit-classifier compatibility)**.** *For every accepted* RegularCauchySum$^{\uparrow}$ *packet* $S = (A, B, W_A, W_B, D_A, D_B, D, E, R, H, C, P, N)$*, any completion-facing* RegularCauchyLimitClassifier$^{\uparrow}$ *read that consumes the sum factors through the displayed* RegSeqRat$^{\uparrow}$ *readback row* R*. The factorization keeps the aligned* StreamName$^{\uparrow}$ *windows* W_A, W_B*, the* DyadicRatCore$^{\uparrow}$ *endpoint-addition row* D *with source endpoints* D_A, D_B*, the* FiniteErrorBudget$^{\uparrow}$ *ledger* E*, the* Real$^{\uparrow}$ *seal route, the componentwise* hsame *transports, the* Cont *routes, the* Pkg *provenance, and the local* NameCert *rows as the only public handoff surface.*

Equivalently, the limit-classifier side may consume the sum only as a sealed regular readback compatible with the diagonal-window public boundary of RegularCauchyLimitClassifier$^{\uparrow}$*. It does not receive quotient stream equality, a selected limit, host real equality, ambient completeness, or an independent completed-real addition operation.*

Proof. First expose the finite sum packet. The window-budget theorem Definition 417.3 supplies the aligned source windows, the two source endpoint rows, the displayed endpoint-addition row, and the finite error ledger.

Next pass from the endpoint packet to the regular readback. The RegSeqRat$^{\uparrow}$ handoff of Definition 417.6 repacks those displayed rows as R, while the Real$^{\uparrow}$ seal boundary of Definition 417.8 places every real-facing read downstream of the same regular row and its visible provenance.

Now compare this handoff with the classifier boundary. The diagonal-window public boundary for RegularCauchyLimitClassifier$^{\uparrow}$, Definition 443.4, admits completion-facing reads only through displayed stream windows, regular readbacks, dyadic ledgers, Real seal rows, BHist history, hsame, Cont, Pkg, and local NameCert data. Substituting the sum readback R into that boundary therefore preserves exactly the rows listed in the statement.

Finally apply the seal consumer exhaustion theorem Definition 417.11. The RegularCauchySum$^{\uparrow}$ carrier has no further consumer coordinate, so the classifier cannot obtain quotient stream equality, a selected limit, host real equality, ambient completeness, or a separate completed-real addition operation from the sum. □

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier limit classifier compatibility`

Theorem 417.20 (RegularCauchySum tail-selector compatibility)**.** *Let* $S = (A, B, W_A, W_B, D_A, D_B, D, E, R, H, C$ *be an accepted* RegularCauchySum$^{\uparrow}$ *packet, and let accepted* RegularCauchyTailSelector$^{\uparrow}$ *packets for the source rows* A *and* B *answer the same precision request. Every public sum read factors through the two selected-tail witness rows, the aligned* StreamName$^{\uparrow}$ *windows* W_A, W_B*, the*

DyadicRatCore$^{\uparrow}$ *endpoint addition row D with source endpoints D_A, D_B, the* FiniteErrorBudget$^{\uparrow}$ *ledger E, the* RegSeqRat$^{\uparrow}$ *readback row R, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *rows.*

The handoff exports no quotient stream, selected limit, host real equality, ambient completeness, or independent completed-real addition law. The tail selectors supply finite witness rows for the two source windows, and the sum packet supplies only the budgeted pointwise readback built from those rows.

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier tail selector compatibility`

Proof. First read the two tail-selector packets. The diagonal admissibility theorem Definition 458.3 supplies selected-tail witness rows for the same precision request, and Definition 458.5 identifies each witness with its finite StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and DyadicRatCore$^{\uparrow}$ support rows.

Next compose those witnesses with the sum window. The window-budget theorem Definition 417.3 reads the aligned windows W_A, W_B, the endpoint rows D_A, D_B, the endpoint-addition row D, and the finite error ledger E at the shared request.

Now pass to the regular readback. The RegSeqRat$^{\uparrow}$ handoff of Definition 417.6 repacks the endpoint addition and budget rows as R, while the consumer obligation package records the hsame, Cont, Pkg, and local naming rows that keep the two selected-tail witnesses attached to the sum packet.

Finally combine seal exhaustion with limit-classifier compatibility. The seal consumer exhaustion theorem rules out any additional consumer coordinate, and Definition 417.19 keeps completion-facing reads downstream of the displayed regular readback. Thus the compatibility handoff is finite and cannot export quotient streams, selected limits, host equality, ambient completeness, or a separate completed-real addition law. □

Theorem 417.21 (RegularCauchySum shared-tail-meet handoff)**.** *Let $S = (A, B, W_A, W_B, D_A, D_B, D, E, R, H, C,$ be an accepted* RegularCauchySum$^{\uparrow}$ *packet. Suppose the source rows A and B have accepted* RegularCauchyTailSelector$^{\uparrow}$ *packets for the same precision request, and suppose those two selector packets are absorbed by one accepted* RegularCauchyTailMeet$^{\uparrow}$ *shared-threshold packet for that request. Then every* Real$^{\uparrow}$*-facing read of the sum factors through the shared threshold row of the tail-meet packet, the two selected-tail witness rows, the aligned* StreamName$^{\uparrow}$ *windows W_A, W_B, the* DyadicRatCore$^{\uparrow}$ *endpoint addition row D with source endpoints D_A, D_B, the* FiniteErrorBudget$^{\uparrow}$ *ledger E, the* RegSeqRat$^{\uparrow}$ *readback row R, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *rows of the sum, selectors, and shared-tail meet packet.*

In particular, a diagonal Real$^{\uparrow}$ *consumer cannot read the two source selectors independently once the shared-tail meet certificate is supplied. Its sum read is mediated by the single shared threshold and then by the same endpoint-addition, budget, readback, transport, continuation, provenance, and naming surface already displayed by the* RegularCauchySum$^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier shared tail meet handoff`

Proof. First use Definition 417.20. It places every public sum read behind the two selected-tail witness rows, the aligned windows, endpoint rows, endpoint-addition row, finite error ledger, regular readback, and the displayed structural rows of the sum packet.

Next use Definition 560.39. The two selector witnesses for the common precision request are admitted into one paired schedule and one shared-threshold route rather than into two unrelated tail routes.

Then apply Definition 560.11. The accepted tail-meet packet exposes its threshold as a public finite certificate over the paired source rows, paired windows, source modulus rows, dyadic threshold ledger, comparison row, transports, continuations, provenance, and local naming data.

Finally compose this certificate with Definition 417.19. Completion-facing and diagonal $\mathsf{Real}^{\uparrow}$ reads of the sum must pass through the regular readback R, and the readback is already downstream of the shared threshold, selected-tail witnesses, aligned windows, endpoint addition, finite ledger, transports, routes, provenance, and naming rows. Hence the handoff exports no quotient stream, selected limit, host real equality, ambient completeness, or independent completed-real addition law. □

Theorem 417.22 (RegularCauchySum CauchyLimitSeal handoff)**.** *Let $S = (A, B, W_A, W_B, D_A, D_B, D, E, R, H, C$ be an accepted* $\mathsf{RegularCauchySum}^{\uparrow}$ *packet whose readback row R is consumed by an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet. Then every* $\mathsf{Real}^{\uparrow}$*-facing read of the sum factors through the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows A, B, the aligned* $\mathsf{StreamName}^{\uparrow}$ *windows W_A, W_B, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint addition row D with source endpoint rows D_A, D_B, the* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *ledger E, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and then the public route packet of Definition 386.8.*

The handoff exposes only the displayed sum rows, the CauchyLimitSeal public route rows, componentwise hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows. It exports no quotient stream, selected host limit, ambient completeness coordinate, or independent completed-real addition law.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier cauchy limit seal handoff`

Proof. First expose the finite sum route. The window-budget theorem Definition 417.3 supplies the two source windows, endpoint rows, endpoint-addition row, and finite error ledger.

Next pass through the regular readback. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff of Definition 417.6 repacks those rows as R, and the $\mathsf{Real}^{\uparrow}$ seal boundary of Definition 417.8 places every real-facing read downstream of the same readback and visible provenance.

Now consume the downstream seal packet. The CauchyLimitSeal public route boundary Definition 386.8 accepts a displayed regular source route before exposing its seal-facing surface, so substituting R gives the stated route from the two source regular names through the sum packet and then through the public seal packet.

Finally apply the local non-escape clauses. The sum packet excludes quotient streams, selected host limits, ambient completeness, and independent completed-real addition, while the CauchyLimitSeal boundary keeps the downstream seal on its displayed public route. The composite handoff therefore exposes exactly the finite rows named in the statement. □

Theorem 417.23 (RegularCauchySum dyadic cofinal selector handoff)**.** *Let $S = (A, B, W_A, W_B, D_A, D_B, D, E, R,$ be an accepted* $\mathsf{RegularCauchySum}^{\uparrow}$ *packet. Suppose the source rows A and B are routed through accepted* $\mathsf{DyadicCofinalTailSelector}^{\uparrow}$ *packets at a common* $\mathsf{Rat}^{\uparrow}$ *precision, the selected windows are absorbed by an accepted* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *shared-threshold packet, and the readback row R is consumed by an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet. Then every* $\mathsf{Real}^{\uparrow}$*-facing read of the sum factors through the two dyadic cofinal selector packets of chapter 680, the shared threshold row of chapter 560, the endpoint-addition row D with source endpoint rows D_A, D_B, the finite budget row E, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the CauchyLimitSeal public route of Definition 386.8.*

Equivalently, the diagonal Real and Completion route for the sum is the finite composite of the two dyadic selector surfaces, the shared-tail meet certificate, the displayed $\mathsf{RegularCauchySum}^{\uparrow}$

endpoint-addition and budget rows, the regular readback, and the downstream seal packet. It exports no quotient stream, selected host limit, countable choice selector, host real equality, ambient completeness coordinate, or independent completed-real addition law.

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier dyadic cofinal selector handoff`

Proof. First route the two sources through the dyadic selector packets. The dyadic cofinal tail selector carrier and Real seal handoff in chapter 680 expose only the common $\mathsf{Rat}^{\uparrow}$ request, finite dyadic window family, selected tail row, finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal row, transports, continuations, provenance, and local naming.

Next connect those selector rows to the sum packet. Apply Definition 417.20. The selected-tail witnesses supplied by the two dyadic selector packets are the source-side tail rows consumed by the aligned windows W_A, W_B, the endpoint rows D_A, D_B, the endpoint-addition row D, the finite error ledger E, and the regular readback R.

Now absorb the two selected windows into one threshold. By Definition 417.21, together with the shared-threshold certificate from chapter 560, the two selector routes are no longer independent consumer coordinates. Every real-facing sum read passes through the shared threshold before it reaches the endpoint-addition, budget, readback, transport, continuation, provenance, and naming rows of the sum packet.

Finally compose with the downstream seal. The CauchyLimitSeal handoff of Definition 417.22 sends the readback R into the public route of Definition 386.8. The composite route is therefore exactly the dyadic-selector, shared-threshold, endpoint-addition, finite-budget, regular-readback, and seal-public-route surface named in the statement, with no additional quotient, choice, host-limit, host-equality, completeness, or completed-addition coordinate. □

Theorem 417.24 (RegularCauchySum Real seal route)**.** *Every* $\mathsf{RegularCauchySum}^{\uparrow}$ *consumer that reads the resulting* $\mathsf{Real}^{\uparrow}$ *seal factors first through the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows* A, B*, the aligned* $\mathsf{StreamName}^{\uparrow}$ *windows* W_A, W_B*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger with source rows* D_A, D_B *and addition row* D*, the* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *row* E*, the shared-tail-meet certificate, and the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route packet before reading the seal. The seal read is therefore a finite composite of the displayed two-source regular names, window data, dyadic ledger, shared tail threshold, regular readback, and downstream seal rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier real seal route`

Proof. First expose the sum packet. The seal boundary Definition 417.8 and non-escape boundary Definition 417.9 keep every real-facing read downstream of the displayed carrier rows.

Next exhaust the local consumer surface. The seal consumer exhaustion theorem Definition 417.11 prevents a consumer from bypassing the $\mathsf{RegSeqRat}^{\uparrow}$ readback, while Definition 417.21 routes the two source windows through one shared threshold.

Now attach the downstream seal. The CauchyLimitSeal handoff Definition 417.22 sends the same readback into the public seal route, and the dyadic cofinal selector handoff Definition 417.23 supplies the finite dyadic selector surface feeding the shared threshold.

Composing these routes gives exactly the displayed two-source regular names, windows, dyadic ledger, shared-tail meet, readback, and CauchyLimitSeal rows before the Real seal is read. □

Theorem 417.25 (RegularCauchySum finite-budget non-escape)**.** *The Real-seal route of Definition 417.24 exports no quotient stream, no host real equality, no selected limit, no ambient completeness coordinate, and no independent tail oracle. Its public content is exactly the displayed two-source* $\mathsf{RegSeqRat}^{\uparrow}$ *surface, aligned* $\mathsf{StreamName}^{\uparrow}$ *window surface,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint*

ledger, finite budget row, shared-tail-meet handoff, CauchyLimitSeal$^{\uparrow}$ *handoff, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchySumUp.RegularCauchySumCarrier finite budget nonescape`

Proof. Begin with the non-escape boundary. The theorem Definition 417.9 excludes quotient stream equality, host real equality, selected limits, ambient completeness, and completed-real addition from the RegularCauchySum$^{\uparrow}$ carrier.

The selector side adds no independent oracle. The shared-tail-meet handoff Definition 417.21 absorbs the two selected windows into a single finite threshold, and the dyadic cofinal selector handoff Definition 417.23 keeps the selector reads inside displayed dyadic and window rows.

The seal side also remains finite. The CauchyLimitSeal handoff Definition 417.22 consumes the regular readback through a public route packet, and the seal consumer exhaustion theorem Definition 417.11 leaves no further consumer coordinate.

Therefore the composite route exports only the named finite rows and refuses every quotient, host-equality, selected-limit, completeness, or independent-tail claim. □

Closure status for NameCert$_{\text{RegularCauchySum}^{\uparrow}}$.

Constructive story: A RegularCauchySum$^{\uparrow}$ packet is generated from two RegSeqRat$^{\uparrow}$ source rows, aligned StreamName$^{\uparrow}$ windows, DyadicRatCore$^{\uparrow}$ endpoint addition rows, a finite FiniteErrorBudget$^{\uparrow}$ ledger, displayed hsame transports, Cont routes, Pkg provenance, a RegSeqRat$^{\uparrow}$ readback row, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchySum}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 417.12, Definition 417.13, Definition 417.14, and Definition 417.15 close the public consumer-facing package over DyadicRatCore$^{\uparrow}$, FiniteErrorBudget$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchySum}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient equality of streams, selected limits, host real equality, ambient completeness, additive group laws for real names, or bridge checking.

Upgrade path: No further paper closure grade remains for this chapter; Lean formalization and bridge checking remain pending.

Chapter 418

A Concrete Naming Certificate for $\mathsf{BinaryExpansion}^{\uparrow}$

The $\mathsf{BinaryExpansion}^{\uparrow}$ interface names the finite dyadic-prefix certificate that reads a binary expansion as real-name data. Following Bishop and Bridges, *Constructive Analysis*, the packet treats binary observations as displayed dyadic rational prefixes with explicit precision windows and regular-sequence handoff rows. It sits over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicApproximation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and it exports only finite prefix, dyadic ledger, readback, transport, continuation, package, and local $\mathsf{NameCert}$ rows.

The packet consumes the sibling $\mathsf{StreamName}^{\uparrow}$ prefix-window surface of chapter 126, the $\mathsf{DyadicApproximation}^{\uparrow}$ partial-sum and tail-radius surface of chapter 335, and the $\mathsf{RegSeqRat}^{\uparrow}$-to-$\mathsf{Real}^{\uparrow}$ seal route of chapter 301 and chapter 38. Thus the binary packet is not an isolated carrier: its rows W, A, R, and E are transported consumer rows from those sibling certificates.

Definition 418.1 (BinaryExpansion carrier)**.** *A* $\mathsf{BinaryExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, W, A, R, E, H, C, P, N)$$

with the following visible coordinates:

1. *D is a finite row of binary digits, each digit displayed as a* $\mathsf{DyadicRatCore}^{\uparrow}$ *bit row with value* 0 *or* 1*;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *prefix-window schedule recording which initial segment of D is inspected for each requested unary precision;*
3. *A assigns to every prefix window in W the corresponding* $\mathsf{DyadicApproximation}^{\uparrow}$ *row, read as a dyadic rational partial sum together with a dyadic tail-radius row;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row asserting that the displayed dyadic partial sums form a regular rational stream at the scheduled precisions;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-boundary row reached from the regular stream, with no host real endpoint outside the displayed packet;*
6. *H records componentwise* hsame *transport for digit rows, prefix windows, dyadic partial sums, regular-sequence rows, and real-seal rows;*
7. *C records the* Cont *routes by which consumers read a prefix, its dyadic approximation row, the regular-sequence handoff, and the real seal in that order;*

8. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicApproximation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, *and* Cont *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BinaryExpansion}^{\uparrow}}$ *row.*

The carrier predicate accepts exactly finite dyadic-prefix packets whose prefix sum, tail radius, regular-sequence handoff, and real-seal route are all displayed in these coordinates. It has no coordinate for an infinite bitstream as a host object, quotient equality of streams, a selected real representative, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionTasteGate single carrier alignment`

Theorem 418.2 (BinaryExpansion NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{BinaryExpansion}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier: the* BHist *packet of Definition 418.1;*
2. *classifier: componentwise transport of binary digit rows, prefix-window schedules, dyadic partial sums, tail-radius rows, regular-sequence handoff rows, and real-seal rows through the displayed* hsame *and* Cont *routes;*
3. *stability: any shared prefix window reads the same dyadic partial-sum row and the same tail-radius row after classifier transport;*
4. *exactness: the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers read only the dyadic approximation rows named by the prefix ledger;*
5. *ledger: the* Pkg *and local* NameCert *rows exhaust the dependency surface over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicApproximation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket namecert obligations`

Proof. Carrier habitation is the displayed tuple of Definition 418.1. Each digit row, prefix window, dyadic approximation row, regular handoff, real seal, transport route, continuation route, package row, and local naming row is visible before a consumer can inspect the packet.

The classifier row is componentwise. Digit values transport through $\mathsf{DyadicRatCore}^{\uparrow}$, prefix schedules through $\mathsf{StreamName}^{\uparrow}$, dyadic partial sums and tail radii through $\mathsf{DyadicApproximation}^{\uparrow}$, and the regular and real boundary rows through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$.

The stability and exactness rows are then read from the same finite prefix ledger. A shared window selects one displayed prefix, and the dyadic partial sum and tail-radius rows named for that window are the only rows available to the regular-sequence and real-seal consumers.

Finally, P and N list only the named dependency certificates and local provenance. Since the carrier has no coordinate for host infinite streams, quotient equality, selected representatives, or ambient completeness, the five rows exhaust the naming certificate surface. □

Theorem 418.3 (BinaryExpansion prefix-window stability)**.** *Let* $B = (D, W, A, R, E, H, C, P, N)$ *and* $B' = (D', W', A', R', E', H', C', P', N')$ *be accepted* $\mathsf{BinaryExpansion}^{\uparrow}$ *carriers. Suppose a displayed prefix window of* W *and a displayed prefix window of* W' *are identified by the* $\mathsf{StreamName}^{\uparrow}$ *classifier and that the digit rows on those windows transport componentwise through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *classifier. Then the corresponding dyadic partial-sum rows, dyadic tail-radius rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows, and* $\mathsf{Real}^{\uparrow}$ *seal-boundary rows transport through the same* hsame, Cont, Pkg, *and local* NameCert *coordinates.*

Thus a prefix comparison determines the finite readback surface consumed by regular-sequence and real-name readers. It does not create a second approximation ledger, a quotient of bitstreams, or a choice-selected representative.

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket prefix window stability`

Proof. Project the two carrier packets. The matched prefix windows select finite digit rows from D and D' and select the dyadic approximation rows in A and A' attached to those windows.

Transport the digits through the $\mathsf{DyadicRatCore}^{\uparrow}$ classifier and the window schedules through $\mathsf{StreamName}^{\uparrow}$. The displayed continuation routes then read the same finite prefix length before any dyadic partial sum is inspected.

The dyadic approximation rows are computed inside the displayed ledger for that prefix. Their partial sums and tail radii therefore transport through the recorded hsame rows and are read through the recorded Cont routes.

Finally, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the $\mathsf{Real}^{\uparrow}$ seal boundary are downstream of those dyadic rows. Repacking the transported prefix, approximation, handoff, and seal rows gives the stated stability, with no extra ledger or representative outside the packet. □

Theorem 418.4 (BinaryExpansion RealUp readback boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer reading an accepted* $\mathsf{BinaryExpansion}^{\uparrow}$ *packet may read exactly the finite route consisting of a* $\mathsf{StreamName}^{\uparrow}$ *prefix window, the binary digit rows on that window, the* $\mathsf{DyadicApproximation}^{\uparrow}$ *partial-sum and tail-radius ledger for the window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular handoff, and the displayed* $\mathsf{Real}^{\uparrow}$ *seal row.*

The readback boundary exports no host real value, no completed infinite binary stream, no quotient equality of expansions, no selected representative, and no ambient completeness principle.

Proof. Begin with the carrier of Definition 418.1. A real-name read must pass through the continuation route C, so it first selects a finite prefix window in W and the corresponding binary digit rows in D.

The selected window names a dyadic approximation row in A. That row supplies the partial sum and tail-radius ledger at the requested precision, both read through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{DyadicApproximation}^{\uparrow}$.

The regular-sequence handoff R consumes only those dyadic rows. The seal row E is then the displayed $\mathsf{Real}^{\uparrow}$ boundary reached from R, with H, C, P, and N recording transport, read route, dependency package, and local naming evidence.

Since every step is a projection from the packet, no host real endpoint, completed stream, quotient equality, selected representative, or ambient completeness theorem can be exported by the real readback. □

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket real readback boundary`

Theorem 418.5 (BinaryExpansion dyadic-ledger exhaustion)**.** *For an accepted* $\mathsf{BinaryExpansion}^{\uparrow}$ *carrier, every dyadic fact exposed to a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer is one of the following rows: a displayed bit row in D, a prefix-window row in W, a partial-sum row in A, a tail-radius row in A, a regular handoff row in R, or the real-seal row in E, transported and routed by H, C, P, and N.*

Consequently the dyadic ledger is exhausted by the finite packet. There is no exported coordinate for an unbounded bitstream object, binary-expansion uniqueness, base-two endpoint convention, quotient stream equality, or classical real completeness.

Proof. List the dyadic-bearing coordinates of Definition 418.1. Digits live in D, window requests in W, and the prefix sums and tail radii in A; the downstream rows R and E only consume those displayed dyadic facts.

Transport can only move these rows componentwise through H, and continuation can only expose them along the routes recorded in C. The package and local certificate rows P and N record provenance, not additional dyadic data.

Thus every dyadic read available to regular-sequence or real-name consumers is already named by the finite ledger. The excluded objects have no coordinate in the packet and cannot be reconstructed from the exported rows. □

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket dyadic ledger exhaustion`

Theorem 418.6 (BinaryExpansion prefix tail-radius monotonicity)**.** *Let $B = (D, W, A, R, E, H, C, P, N)$ be an accepted* $\mathsf{BinaryExpansion}^{\uparrow}$ *carrier, and let $w \leq w'$ be displayed prefix-window rows in W with w' extending w by finitely many binary digit rows from D. The dyadic tail-radius row attached to w' is routed through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *digit ledger and the same* $\mathsf{DyadicApproximation}^{\uparrow}$ *approximation ledger as the row attached to w, with the extended prefix exposing only a smaller or equal displayed tail-radius bound.*

Equivalently, extending the finite prefix window preserves the tail-radius ledger consumed downstream by $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*: the old radius row transports to the extended-window comparison through H, the extended radius row is read through the corresponding continuation in C, and both rows remain in the package and local* NameCert *surface of Definition 418.1. No host infinite stream, quotient comparison, selected real representative, or ambient completeness principle is used to justify the monotonic read.*

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket prefix tail radius monotonicity`

Proof. Start with the carrier of Definition 418.1. The two windows w and w' are finite rows of the same $\mathsf{StreamName}^{\uparrow}$ schedule, and the displayed relation $w \leq w'$ says that the second row is obtained by appending finitely many digit rows already present in D.

Apply the prefix-window stability theorem Definition 418.3 to keep the common prefix, its digit rows, and the attached dyadic approximation rows on the same hsame and Cont routes. The dyadic-ledger exhaustion theorem Definition 418.5 then says that the only available tail-radius rows are the two rows already listed in A.

The tail radius of a displayed binary prefix is the dyadic remainder bound stored by the $\mathsf{DyadicApproximation}^{\uparrow}$ row for that prefix. Extending the prefix consumes additional $\mathsf{DyadicRatCore}^{\uparrow}$ bit rows, so the unrevealed suffix bound can only move to the displayed smaller-or-equal radius row named for w'.

Finally, Definition 418.4 identifies the downstream $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ reads with this same finite ledger. Hence the monotonicity claim is a statement about displayed prefix rows and their recorded tail-radius entries, not about an external stream or a quotient real. □

Theorem 418.7 (BinaryExpansion regular handoff factorization)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff read from an accepted* $\mathsf{BinaryExpansion}^{\uparrow}$ *carrier factors through three finite rows: the* $\mathsf{StreamName}^{\uparrow}$ *prefix-window schedule W, the* $\mathsf{DyadicApproximation}^{\uparrow}$ *partial-sum row of A selected by that window, and the* $\mathsf{DyadicApproximation}^{\uparrow}$ *tail-radius row of A selected by that same window. The handoff row R contains no independent rational stream beyond these displayed prefix, sum, and radius rows.*

Thus any regular-sequence consumer receives a finite route

$$W \longrightarrow A_{\mathrm{sum}} \longrightarrow A_{\mathrm{tail}} \longrightarrow R$$

inside the BHist *packet of Definition 418.1, transported by H, read by C, and certified by P and N.*

Proof. Project the accepted carrier of Definition 418.1. A regular handoff can only inspect the row R, and the definition of the carrier records R as downstream of the prefix-window schedule and dyadic approximation ledger.

Use Definition 418.3 to identify the selected prefix window with its unique displayed partial-sum and tail-radius rows. The preceding monotonicity theorem keeps the tail-radius ledger stable when the consumer asks for a stronger precision window.

Apply Definition 418.5. It rules out any hidden rational stream, extra approximation table, or external regularity witness outside D, W, A, R, E, H, C, P, and N.

The readback boundary of Definition 418.4 gives the same factorization for every later real-facing consumer. Repacking the selected window, partial-sum row, tail-radius row, and handoff row along their displayed routes proves the claimed factorization. □

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket regular handoff factorization`

Theorem 418.8 (BinaryExpansion RealUp seal prefix coherence)**.** *Any* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{BinaryExpansion}^{\uparrow}$ *carrier is coherent with the same finite prefix ledger used by the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff. If the seal row E is cited at a requested precision, the citation factors through a displayed prefix window of W, its binary digit rows in D, its partial-sum and tail-radius rows in A, and the regular handoff row R before reaching E.*

Consequently the $\mathsf{Real}^{\uparrow}$ *seal cannot read a host infinite binary stream, quotient equality of binary expansions, endpoint convention data, a selected representative, or ambient real completeness. It reads only the finite prefix packet and its displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ consumer citation of the seal row E. By Definition 418.4, such a citation must first pass through a $\mathsf{StreamName}^{\uparrow}$ prefix window, the corresponding digit rows, the dyadic approximation ledger, and the $\mathsf{RegSeqRat}^{\uparrow}$ handoff.

The regular handoff factorization above identifies the regular row R with the selected prefix window, partial-sum row, and tail-radius row. The prefix tail-radius monotonicity theorem ensures that stronger precision requests remain on the same finite tail-radius ledger rather than creating a second approximation object.

Now apply Definition 418.3 to transport coherent prefix comparisons through H and C. The dyadic-ledger exhaustion theorem Definition 418.5 accounts for every dyadic fact that the seal can cite.

Since the carrier of Definition 418.1 has no coordinate for host streams, quotient equality, endpoint conventions, selected representatives, or ambient completeness, the seal read is coherent exactly with the displayed finite prefix ledger. □

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket real seal prefix coherence`

Theorem 418.9 (BinaryExpansion dyadic-window public readiness)**.** *Every accepted public read of an accepted* $\mathsf{BinaryExpansion}^{\uparrow}$ *carrier factors through a finite dyadic window before it can be treated as public-ready. The route is exactly a* $\mathsf{DyadicRatCore}^{\uparrow}$ *digit ledger in D, a* $\mathsf{StreamName}^{\uparrow}$ *prefix-window schedule in W, the corresponding* $\mathsf{DyadicApproximation}^{\uparrow}$ *partial-sum and tail-radius rows in A, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{Real}^{\uparrow}$ *seal row E, and the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *rows H, C, P, N.*

The public read exports no quotient bitstream, trichotomy decision, selected representative, endpoint convention, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the real readback boundary, Definition 418.4. It forces every real-facing read to pass through the finite prefix window, digit rows, dyadic approximation ledger, regular handoff, and seal row.

Use the regular handoff factorization, Definition 418.7. It identifies R with the same selected prefix window, partial-sum row, and tail-radius row, so the public route cannot insert a second rational stream.

Apply $\mathsf{Real}^{\uparrow}$ seal prefix coherence, Definition 418.8. The seal read remains coherent with the finite dyadic ledger and the displayed H, C, P, N support rows.

The carrier of Definition 418.1 contains no quotient bitstream, trichotomy oracle, selected representative, endpoint convention, or ambient completeness coordinate. Hence public readiness is exactly the displayed finite dyadic-window route. □

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket dyadic window public readiness`

Theorem 418.10 (BinaryExpansion prefix-refinement RealUp seal determinacy)**.** *Let $B = (D, W, A, R, E, H, C, P$ and $B' = (D', W', A', R', E', H', C', P', N')$ be accepted* $\mathsf{BinaryExpansion}^{\uparrow}$ *carriers. Suppose a displayed finite prefix-refinement chain identifies the inspected* $\mathsf{StreamName}^{\uparrow}$ *window of W with the inspected* $\mathsf{StreamName}^{\uparrow}$ *window of W', transports the corresponding* $\mathsf{DyadicRatCore}^{\uparrow}$ *digit rows through the displayed* hsame *routes, and transports the corresponding* $\mathsf{DyadicApproximation}^{\uparrow}$ *partial-sum and tail-radius rows through the displayed* hsame *and* Cont *routes. Then the downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows and* $\mathsf{Real}^{\uparrow}$ *seal rows reached from those inspected windows determine the same classifier-facing* $\mathsf{Real}^{\uparrow}$ *seal boundary.*

The determined boundary is exactly the boundary read through the common finite prefix ledger. It exports no host infinite stream, no quotient equality of binary expansions, no endpoint convention selection, and no ambient completeness principle.

Proof. Apply prefix-window stability, Definition 418.3, to the displayed refinement chain. The identified $\mathsf{StreamName}^{\uparrow}$ windows remain on one finite route, and the transported digit rows remain the only $\mathsf{DyadicRatCore}^{\uparrow}$ rows available to the comparison.

Apply dyadic-ledger exhaustion, Definition 418.5. The transported partial sums and tail radii exhaust the dyadic data exposed to downstream readers, so the refinement chain cannot introduce a separate approximation table or an external binary stream.

Use regular handoff factorization, Definition 418.7. Both $\mathsf{RegSeqRat}^{\uparrow}$ handoff rows factor through the same inspected window, partial-sum row, and tail-radius row after transport through H, H' and readback through C, C'.

Finally apply $\mathsf{Real}^{\uparrow}$ seal prefix coherence, Definition 418.8. Since each seal citation reaches E or E' only through the already identified finite ledger and regular handoff, the classifier-facing seal boundary is the same.

The carrier inventory of Definition 418.1 lists no coordinate for host infinite streams, quotient equality of expansions, endpoint convention selection, or ambient completeness. Thus the determinacy claim is exactly the displayed packet claim over $D, W, A, R, E, H, C, P, N$ and $D', W', A', R', E', H', C', P', N'$. □

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket prefix refinement real seal determinacy`

Theorem 418.11 (BinaryExpansion endpoint ambiguity ledger boundary)**.** *Any downstream endpoint convention resolver for dual binary expansions must enter as a separate ledger or socket row outside the accepted* $\mathsf{BinaryExpansion}^{\uparrow}$ *packet. The packet of Definition 418.1 exports only finite digit rows, prefix windows, dyadic partial sums, tail-radius rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *seal, and the displayed* hsame, Cont, Pkg, *and* NameCert *routes.*

Consequently no accepted BinaryExpansion$^{\uparrow}$ *carrier exports a host infinite stream, quotient equality of binary expansions, selected representative, or base-two endpoint convention. Such a convention can be consumed only after it is named by an additional finite BEDC row not present in* $D, W, A, R, E, H, C, P, N$.

Proof. Use prefix-window stability, Definition 418.3. It keeps every comparison of binary data on finite digit rows, finite prefix windows, and their displayed hsame and Cont routes.

Apply dyadic-ledger exhaustion, Definition 418.5. The only dyadic facts available to later readers are the digit rows in D, the prefix-window rows in W, the partial-sum and tail-radius rows in A, the regular handoff R, and the real-seal row E.

The regular handoff factorization, Definition 418.7, then shows that a RegSeqRat$^{\uparrow}$ consumer cannot receive an independent infinite bitstream or a second representative selector. The Real$^{\uparrow}$ seal prefix coherence theorem, Definition 418.8, gives the same boundary for real-facing consumers.

Therefore endpoint ambiguity is not resolved by the accepted packet. A base-two convention resolver must be represented by a separate ledger or socket row, because no coordinate of $D, W, A, R, E, H, C, P, N$ contains such a convention. □

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket endpoint ambiguity ledger boundary`

Theorem 418.12 (BinaryExpansion Cauchy modulus handoff)**.** *Let* $B = (D, W, A, R, E, H, C, P, N)$ *be an accepted* BinaryExpansion$^{\uparrow}$ *carrier. Every effective precision read needed by a* RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *or* CauchyModulus$^{\uparrow}$ *consumer factors through the same finite route: a prefix window in* W, *the corresponding dyadic partial-sum and tail-radius rows in* A, *the regular handoff row* R, *the real-seal row* E, *and the displayed* hsame, Cont, Pkg, *and* NameCert *rows* H, C, P, *and* N.

Thus the effective Cauchy-modulus handoff exported by B *is the displayed prefix-tail-radius ledger and its regular and real-facing routes. It contains no hidden modulus, host infinite bitstream, quotient stream equality, selected representative, or ambient completeness principle.*

Proof. Begin with a precision request made by a RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, or CauchyModulus$^{\uparrow}$ consumer. By prefix tail-radius monotonicity, Definition 418.6, strengthening the requested precision only moves to a displayed larger prefix window and its smaller-or-equal tail-radius row; it does not create a second modulus object.

Apply regular handoff factorization, Definition 418.7. The RegSeqRat$^{\uparrow}$ read is exactly the route from the selected window in W through the partial-sum and tail-radius rows of A into R.

Next use Real$^{\uparrow}$ seal prefix coherence, Definition 418.8. Any real-facing read of E reaches the seal only after passing through the same finite prefix ledger and the same regular handoff row.

Finally apply dyadic-ledger exhaustion, Definition 418.5. It accounts for all dyadic data available to the consumer inside $D, W, A, R, E, H, C, P, N$, so there is no additional coordinate from which a hidden modulus, infinite stream, quotient equality, representative choice, or completeness principle could be read. □

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket cauchy modulus handoff`

Theorem 418.13 (BinaryExpansion scoped dependency factorization)**.** *Let* $B = (D, W, A, R, E, H, C, P, N)$ *be an accepted* BinaryExpansion$^{\uparrow}$ *carrier. Every scoped obligation exported by* BinaryExpansion$^{\uparrow}$ *factors through exactly the displayed packet rows: the* DyadicRatCore$^{\uparrow}$ *binary digit rows in* D, *the* StreamName$^{\uparrow}$ *prefix-window rows in* W, *the* DyadicApproximation$^{\uparrow}$ *partial-sum and tail-radius rows in* A, *the* RegSeqRat$^{\uparrow}$ *handoff row* R, *the* Real$^{\uparrow}$ *seal row* E, *and the shared* hsame, Cont, Pkg, *and* NameCert *routes* H, C, P, *and* N.

Consequently the scoped surface exports no host infinite binary stream, quotient equality of streams, selected binary-expansion representative, endpoint convention resolver, or ambient completeness principle. Any downstream citation of a binary-expansion obligation is a citation of one of the displayed finite rows or of a route between such rows.

Lean4 ✓ `BEDC.Derived.BinaryExpansionUp.BinaryExpansionPacket scoped dependency factorization`

Proof. Start with the accepted carrier of Definition 418.1. Its coordinates already list the only rows made available to the chapter: digits, windows, dyadic approximation rows, the regular handoff, the real seal, and the transport, continuation, package, and local certificate routes.

The prefix-window stability theorem Definition 418.3 keeps every finite prefix read on the displayed D, W, H, and C routes. The dyadic-ledger exhaustion theorem Definition 418.5 then accounts for every dyadic fact by rows in D and A, including the partial sums and tail-radius entries consumed by later readers.

For regular-sequence consumers, apply Definition 418.7. It identifies the handoff row R with the selected prefix window, partial-sum row, and tail-radius row, so no independent rational stream is exported.

For real-name consumers, apply the readback boundary of Definition 418.4 and the seal coherence theorem Definition 418.8. These route every seal citation through the same prefix ledger before reaching E.

The remaining scoped obligations are provenance and certificate obligations. They are exactly the shared hsame, Cont, Pkg, and NameCert routes H, C, P, and N. Since the carrier has no coordinate for the excluded host-level objects, the factorization cannot read them. □

Closure status for $\mathsf{NameCert}_{\mathsf{BinaryExpansion}^\uparrow}$.

Constructive story: A $\mathsf{BinaryExpansion}^\uparrow$ packet is generated from finite binary digit rows, $\mathsf{StreamName}^\uparrow$ prefix windows, $\mathsf{DyadicApproximation}^\uparrow$ partial-sum and tail-radius rows, a $\mathsf{RegSeqRat}^\uparrow$ regular handoff, a $\mathsf{Real}^\uparrow$ seal boundary, displayed hsame and Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BinaryExpansion}^\uparrow}, \mathsf{publicClosed})$

Scope closed: The public exported surface is the dyadic-window readiness route together with the $\mathsf{Real}^\uparrow$ seal prefix-coherence route for finite dyadic-prefix packets over $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{DyadicApproximation}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, and $\mathsf{Real}^\uparrow$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BinaryExpansion}^\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim binary-expansion uniqueness, base-two endpoint convention resolution, quotient equality of streams, selected representatives, host real equality, ambient real completeness, or bridge checking.

Upgrade path: Formal verification requires a checked Lean target for the public dyadic-window readiness route, $\mathsf{Real}^\uparrow$ seal prefix-coherence route, and their displayed carrier support over the same packet.

Chapter 419

A Concrete Naming Certificate for $\mathsf{BinaryEndpointNormalization}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BinaryEndpointNormalization}^{\uparrow}$ packet records the finite base-two endpoint convention that turns the dual terminating and repeating presentations of a dyadic boundary into one displayed normalization route. It is the separate ledger row required by chapter 418: the binary-prefix packet names dyadic readback through finite windows, while this packet names the endpoint-carry convention consumed after that readback. The carrier sits over the dyadic digit surface of chapter 291, the partial-sum and tail-radius surface of chapter 335, the finite-window schedule of chapter 126, the regular rational handoff of chapter 301, and the terminal seal of chapter 38.

Definition 419.1 (BinaryEndpointNormalization carrier)**.** *A* $\mathsf{BinaryEndpointNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (L, R, K, D, A, W, Q, S, H, C, P, N)$$

with the following displayed rows:

1. *L is the finite binary prefix row for the terminating-side presentation, including the last displayed* 1 *before a zero tail when such a boundary row is present.*
2. *R is the finite binary prefix row for the repeating-side presentation, including the carried predecessor prefix and the displayed one-tail row when such a boundary row is present.*
3. *K is the endpoint-carry ledger saying that L and R are the two displayed boundary prefixes for the same dyadic endpoint convention.*
4. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *digit rows used by L, by R, and by the carried predecessor and tail rows named in K.*
5. *A records the* $\mathsf{DyadicApproximation}^{\uparrow}$ *partial-sum and tail-radius rows for the two prefixes and for the common boundary value.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that exposes the two prefixes at the same requested precisions.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from the normalized partial-sum ledger.*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, D, A, W, Q have been displayed.*

9. *H records componentwise* hsame *transport for the two prefix rows, the endpoint-carry ledger, the dyadic digit rows, the approximation rows, the window schedule, the regular handoff, and the real seal.*
10. *C records the displayed* Cont *replay from a consumer request through W, then D, then K, then A, then Q, and finally S.*
11. *P is the* Pkg *provenance over* $\mathsf{BinaryEndpointNormalization}^{\uparrow}$, $\mathsf{BinaryExpansion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicApproximation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BinaryEndpointNormalization}^{\uparrow}}$ *row.*

The carrier stores no host infinite binary stream, quotient equality of streams, selected binary representative, ambient trichotomy, countable-choice selector, or host $\mathsf{Real}^{\uparrow}$ *equality coordinate.*

Lean4 (definition) `BEDC.Derived.BinaryEndpointNormalizationUp.BinaryEndpointNormalizationUp`

Lean4 ✓ `BEDC.Derived.BinaryEndpointNormalizationUp.BinaryEndpointNormalizationTasteGate single carrier alignment`

Theorem 419.2 (BinaryEndpointNormalization NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{BinaryEndpointNormalizatio}}$ *surface for Definition 419.1 consists exactly of carrier exposure for E, dual finite-prefix exposure through L and R, endpoint-carry exposure through K, dyadic digit exposure through D, partial-sum and tail-radius exposure through A, finite-window exposure through W, regular rational handoff through Q, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through S, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.BinaryEndpointNormalizationUp.BinaryEndpointNormalizationNameCertObligations`

Proof. Project the carrier tuple $E = (L, R, K, D, A, W, Q, S, H, C, P, N)$. The definition displays every row available to the local naming certificate before any consumer can ask for endpoint normalization.

The prefix and carry clauses are finite projections. The rows L and R expose the two boundary presentations, while K records that the terminating-side and repeating-side rows are the paired endpoint convention for the same dyadic boundary.

The dyadic and analytic clauses preserve the same route. The digit ledger D, the approximation ledger A, and the shared windows W feed the regular handoff Q before the real seal S can be read.

Finally, H, C, P, N transport, replay, source, and name the displayed rows. Since the excluded host objects are not coordinates of E, the listed rows exhaust the seed obligation surface. □

Theorem 419.3 (BinaryEndpointNormalization dual-prefix boundary)**.** *Every accepted* BinaryEndpointNormalizati *packet $E = (L, R, K, D, A, W, Q, S, H, C, P, N)$ exposes the terminating and repeating binary boundary presentations through the same finite endpoint-carry ledger. The terminating route reads the displayed prefix L, its* $\mathsf{DyadicRatCore}^{\uparrow}$ *digit rows, and its* $\mathsf{DyadicApproximation}^{\uparrow}$ *partial-sum row. The repeating route reads the displayed prefix R, its carried predecessor digit rows, and its one-tail row through the same D, A, W surface.*

Thus the two boundary presentations meet only at the row K and at the downstream Q, S handoff. The packet exports no quotient of binary streams, no selected host representative, and no ambient real-equality proof.

Lean4 ✓ `BEDC.Derived.BinaryEndpointNormalizationUp.BinaryEndpointNormalization dual prefix boundary`

Proof. Start from the carrier of Definition 419.1. The only prefix rows available to the convention are L and R, and both are read through the same finite window schedule W.

Read the digit and approximation ledgers next. The row D supplies the digit evidence for both displayed prefixes, and A supplies the corresponding partial sums and tail radii. No consumer reaches Q before these rows have been displayed.

The endpoint-carry row K is the unique place where the terminating side and repeating side are paired. It records the carry relation between the last displayed terminating digit and the carried predecessor prefix with one-tail continuation.

The remaining rows H, C, P, N only transport, replay, source, and name this visible route. Therefore the boundary comparison is a finite packet comparison, not a quotient stream comparison or a host real equality claim. □

Theorem 419.4 (BinaryEndpointNormalization RealUp seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{BinaryEndpointNormalization}^{\uparrow}$ *packet factors through the displayed endpoint-carry ledger before reaching the terminal seal. More precisely, a seal consumer must read a shared* $\mathsf{StreamName}^{\uparrow}$ *window in* W*, the two finite prefix rows* L, R*, their* $\mathsf{DyadicRatCore}^{\uparrow}$ *digit ledger* D*, their* $\mathsf{DyadicApproximation}^{\uparrow}$ *partial-sum and tail-radius ledger* A*, the endpoint-carry row* K*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* Q *before it can cite* S*.*

Consequently the terminal seal cannot escape to a host endpoint convention, an infinite binary stream, quotient equality of expansions, a selected representative, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BinaryEndpointNormalizationUp.BinaryEndpointNormalizationRealSealNonescape`

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ consumer citation of the seal row S. By the carrier definition, S is downstream of the regular handoff Q and is not an independent real-value coordinate.

The handoff row Q is reached only after the shared window schedule, the two finite prefix rows, and the dyadic approximation ledger have been read. The endpoint-carry row K is part of that route, so the consumer cannot bypass the displayed convention when the two boundary presentations are involved.

Transport and replay do not add further analytic data. The rows H and C preserve and expose the same finite route, while P and N record provenance and local naming.

Since no coordinate of E contains a host stream, quotient equality, selected representative, countable-choice selector, trichotomy branch, or ambient completeness theorem, the seal read is confined to $L, R, K, D, A, W, Q, S, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{BinaryEndpointNormalization}^{\uparrow}}$.

Constructive story: A $\mathsf{BinaryEndpointNormalization}^{\uparrow}$ packet is generated from two finite binary prefix rows, an endpoint-carry ledger, DyadicRatCore digit rows, DyadicApproximation partial-sum and tail-radius rows, StreamName windows, a RegSeqRat handoff, a terminal RealUp seal, componentwise transports, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BinaryEndpointNormalization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 419.1, Definition 419.2, Definition 419.3, and Definition 419.4 seed the finite base-two endpoint convention surface required downstream of BinaryExpansion readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BinaryEndpointNormalization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close binary-expansion uniqueness, quotient equality of streams, selected representatives, host real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the carrier and prove the NameCert obligation surface, dual-prefix boundary theorem, and RealUp seal nonescape theorem for BEDC.Derived.BinaryEndpointNormalizationUp.

Chapter 420

A Concrete Naming Certificate for BinaryEndpointUniqueness$^{\uparrow}$

Following Bishop and Bridges on constructive real expansions, the BinaryEndpointUniqueness$^{\uparrow}$ packet records the finite determinacy surface that remains after raw binary-prefix readback has passed through the endpoint-normalization ledger. It consumes the binary readback rows of chapter 418 and the endpoint-carry convention of chapter 419, then exposes only the normalized prefix, dyadic ledger, regular handoff, terminal real seal, and local naming routes needed for classifier-facing uniqueness.

Definition 420.1 (BinaryEndpointUniqueness carrier)**.** *A* BinaryEndpointUniqueness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (B, E, D, W, R, S, H, C, P, N)$$

with the following visible rows:

1. *B is the accepted* BinaryExpansion$^{\uparrow}$ *finite prefix-readback row whose digit windows supply the raw binary observation.*
2. *E is the accepted* BinaryEndpointNormalization$^{\uparrow}$ *endpoint-carry row naming the terminating-versus-repeating boundary convention consumed after B.*
3. *D is the shared* DyadicRatCore$^{\uparrow}$ *digit ledger used by the binary prefix, the endpoint-carry comparison, and the normalized boundary row.*
4. *W is the* StreamName$^{\uparrow}$ *finite-window schedule that exposes the inspected prefixes at the precisions requested by downstream consumers.*
5. *R is the* RegSeqRat$^{\uparrow}$ *handoff row reached from the normalized dyadic partial sums and tail-radius rows.*
6. *S is the terminal* Real$^{\uparrow}$ *seal row reached only after the binary readback, endpoint normalization, dyadic ledger, window schedule, and regular handoff have been displayed.*
7. *H records componentwise* hsame *transport for B, E, D, W, R, S and for the normalized-prefix comparison row.*
8. *C records the displayed* Cont *replay from a consumer request through W, then B, then E, then D, then R, and finally S.*
9. *P is the* Pkg *provenance over* BinaryEndpointUniqueness$^{\uparrow}$, BinaryExpansion$^{\uparrow}$, BinaryEndpointNormalization$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BinaryEndpointUniqueness}^{\uparrow}}$ *row.*
The carrier predicate accepts exactly finite rows in which two binary presentations can be compared only after the endpoint-normalization row has identified their displayed boundary convention. It has no coordinate for quotient streams, host real equality, a choice-selected representative, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BinaryEndpointUniquenessUp.BinaryEndpointUniquenessTasteGate single carrier alignment`

Theorem 420.2 (BinaryEndpointUniqueness NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{BinaryEndpointUniqueness}^{\uparrow}}$ *surface for Definition 420.1 consists exactly of carrier exposure for U, raw binary readback exposure through B, endpoint-normalized convention exposure through E, shared digit exposure through D, finite-window exposure through W, normalized regular handoff through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through S, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier tuple $U = (B, E, D, W, R, S, H, C, P, N)$. The tuple lists every row available to the local naming certificate before a consumer can ask whether two binary endpoint presentations determine the same normalized seal.

The raw readback and endpoint-convention clauses are separate. The row B supplies only the finite prefix route described by $\mathsf{BinaryExpansion}^{\uparrow}$, while E supplies the endpoint-carry convention described by $\mathsf{BinaryEndpointNormalization}^{\uparrow}$.

The shared analytic clauses then force both routes through the same displayed finite objects. The digit ledger D, the window schedule W, and the regular handoff R are read before the seal S is visible.

Finally, H, C, P, N transport, replay, source, and name this route. Since no coordinate of U contains quotient streams, host real equality, a selected representative, trichotomy, or ambient completeness, the listed rows exhaust the seed obligation surface. □

Theorem 420.3 (BinaryEndpointUniqueness normalized prefix determinacy)**.** *Let $U = (B, E, D, W, R, S, H, C, P,$ be an accepted* $\mathsf{BinaryEndpointUniqueness}^{\uparrow}$ *carrier. If two finite binary prefix presentations are read from the* $\mathsf{BinaryExpansion}^{\uparrow}$ *row B and their endpoint boundary is routed through the* $\mathsf{BinaryEndpointNormalization}^{\uparrow}$ *row E, then the normalized prefix window selected in W determines a single classifier-facing dyadic ledger D and a single downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R.*

The determinacy is scoped to the displayed normalized route. It does not assert quotient equality of all binary streams, host equality of real numbers, trichotomy of arbitrary reals, choice of a preferred representative, or completeness of the ambient $\mathsf{Real}^{\uparrow}$ *surface.*

Proof. Begin with the two finite presentations read through B. By the binary readback boundary of chapter 418, each presentation exposes only finite digit rows, finite windows, dyadic partial-sum rows, a regular handoff boundary, and the displayed transport and continuation routes.

Now apply the endpoint-normalization row E. The endpoint-carry convention of chapter 419 is the only row in the carrier that may relate a terminating boundary presentation to a repeating-tail presentation.

Once the convention is read, the shared schedule W selects the normalized window and the shared ledger D supplies the corresponding digit facts. The continuation row C then routes the consumer to R through those displayed rows.

The transport row H keeps the comparison componentwise, and P, N record the package and local certificate provenance. Therefore the normalized prefix determines the classifier-facing

dyadic ledger and regular handoff inside U, with no appeal to a host stream quotient or external real equality. □

Theorem 420.4 (BinaryEndpointUniqueness RealUp seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{BinaryEndpointUniqueness}^{\uparrow}$ *carrier factors through the normalized endpoint route*

$$B \longrightarrow E \longrightarrow W \longrightarrow D \longrightarrow R \longrightarrow S$$

inside the finite packet of Definition 420.1. Consequently a consumer citing the seal S can observe only the raw binary readback row, the endpoint-normalization row, the shared finite window, the shared dyadic digit ledger, and the regular handoff named by the carrier.

The seal cannot escape to quotient equality of binary expansions, a host infinite stream, a selected binary representative, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer citation of the seal row S. By the carrier definition, S is not an independent real-value coordinate; it is downstream of the normalized regular handoff R.

The handoff row R is reached only after the consumer has read the finite binary readback row B, the endpoint-normalization row E, the selected window row W, and the shared digit ledger D. Thus the displayed continuation route prevents a direct jump from raw binary data to the terminal seal.

Transport and provenance do not add analytic data. The row H moves the displayed rows componentwise, C exposes them in order, and P, N record the package and local naming evidence.

Since the carrier has no coordinate for quotient streams, host infinite streams, selected representatives, countable-choice selectors, trichotomy branches, host real equality, or completeness principles, every seal citation is confined to the finite normalized route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BinaryEndpointUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{BinaryEndpointUniqueness}^{\uparrow}$ packet is generated from a finite BinaryExpansion readback row, a BinaryEndpointNormalization convention row, DyadicRatCore digit rows, StreamName windows, a RegSeqRat handoff, a terminal RealUp seal, componentwise transports, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BinaryEndpointUniqueness}^{\uparrow}}$, seed)

Scope closed: Definition 420.1, Definition 420.2, Definition 420.3, and Definition 420.4 seed the normalized base-two endpoint uniqueness surface between raw binary readback and RealUp classifier determinacy.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BinaryEndpointUniqueness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient equality of streams, host real equality, selected representatives, choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the carrier and prove the NameCert obligation surface, normalized prefix determinacy theorem, and RealUp seal nonescape theorem for BEDC.Derived.BinaryEndpointUniquenessUp.

Chapter 421

CauchyPairing NameCert Construction

The $\mathsf{CauchyPairing}^{\uparrow}$ interface records the Bishop–Bridges constructive-analysis pairing of two regular Cauchy names as one synchronized finite-window packet. It is a name-certificate source for downstream diagonal, completion, and real-seal chapters: consumers may inspect shared windows, dyadic ledgers, modulus schedules, and the paired $\mathsf{Real}^{\uparrow}$ seal, but they do not receive quotient equality of reals, selected host limits, or ambient completeness.

The two source rows are the paired-name analogue of the finite regular-Cauchy window interface in chapter 371: $\mathsf{CauchyPairing}^{\uparrow}$ consumes two such displayed regular names and synchronizes their window, dyadic-ledger, and seal rows instead of adding a new completed-real coordinate.

Definition 421.1 (Cauchy pairing NameCert source)**.** *A* $\mathsf{CauchyPairing}^{\uparrow}$ *source packet is a finite* BHist *row*

$$K = (A, B, W_A, W_B, L_A, L_B, \mu_A, \mu_B, \mu, E_A, E_B, E, H, C, P, N)$$

with the following displayed coordinates:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy names being paired;*
2. *W_A and W_B are finite* $\mathsf{StreamName}^{\uparrow}$ *window schedules for the two names, recorded on a common unary request ledger;*
3. *L_A and L_B are the corresponding* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledgers, read through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *rows;*
4. *μ_A and μ_B are the two* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules, and μ is the synchronized schedule that requests a common finite window large enough for both sides;*
5. *E_A and E_B are the source* $\mathsf{Real}^{\uparrow}$ *seal rows attached to the two regular names;*
6. *E is the paired* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the synchronized windows and the two dyadic ledgers;*
7. *H stores the componentwise* hsame *transports for the names, windows, dyadic ledgers, modulus rows, and seal rows;*
8. *C stores the displayed* Cont *routes by which a consumer request reaches the synchronized schedule, both selected windows, both dyadic ledgers, and the paired seal;*
9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyPairing}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their stored transports.

Lean4 (definition) `BEDC.Derived.CauchyPairingUp.CauchyPairingCarrier`

Theorem 421.2 (Cauchy pairing NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyPairing}^{\uparrow}}$ *surface for the source packet of Definition 421.1 consists of five rows:*

1. *carrier admission: the accepted object is the displayed finite packet K;*
2. *classifier stability: paired packets are compared componentwise by the two* $\mathsf{RegSeqRat}^{\uparrow}$ *names, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers, the three* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules, and the three* $\mathsf{Real}^{\uparrow}$ *seal rows;*
3. *synchronized-window exactness: every consumer precision request first reads μ, then reads the corresponding windows in W_A and W_B, and only then reads the dyadic ledgers L_A and L_B;*
4. *modulus compatibility: the synchronized schedule μ is accepted only as a finite ledger row that dominates the displayed side schedules μ_A and μ_B on the inspected requests;*
5. *seal non-escape: the paired* $\mathsf{Real}^{\uparrow}$ *seal E is consumed only after both source readbacks, their finite windows, and their dyadic ledgers have been displayed.*

This surface specifies synchronized finite-window pairing and does not assert quotient equality of completed reals or completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.CauchyPairingUp.CauchyPairingCarrier namecert obligations`

Proof. Carrier admission is the projection of the packet K. All names, windows, ledgers, modulus schedules, seal rows, transports, continuation routes, package provenance, and local naming data are stored coordinates.

Classifier stability is componentwise. The displayed hsame rows transport the two regular names, the two window schedules, the two dyadic ledgers, the three modulus rows, and the three seal rows, while the displayed Cont rows preserve the consumer read order.

For synchronized-window exactness, a precision request must pass through μ before either side can be inspected. The two selected window rows are then read through W_A and W_B, and their rational observations are the dyadic ledger rows L_A and L_B.

The modulus compatibility and seal rows use the same finite route. Because the packet has no coordinate for quotient equality, selected host limits, host real equality, or ambient completeness, the paired $\mathsf{Real}^{\uparrow}$ seal cannot export data outside the displayed certificate surface. □

Theorem 421.3 (Cauchy pairing carrier admission)**.** *An accepted* $\mathsf{CauchyPairing}^{\uparrow}$ *carrier is admitted as the finite* BHist *packet*

$$K = (A, B, W_A, W_B, L_A, L_B, \mu_A, \mu_B, \mu, E_A, E_B, E, H, C, P, N)$$

of Definition 421.1. Admission projects the two $\mathsf{RegSeqRat}^{\uparrow}$ *names, side windows, dyadic ledgers, side and synchronized modulus schedules, source and paired* $\mathsf{Real}^{\uparrow}$ *seals, and the transport, continuation, package, and local naming rows.*

Lean4 ✓ `BEDC.Derived.CauchyPairingUp.CauchyPairingCarrier public rows zero head absurd`

Proof. Project the displayed packet. Every coordinate named in the statement is stored in the same finite BHist row, so the carrier witness is obtained by repacking those projections as the local $\mathsf{NameCert}_{\mathsf{CauchyPairing}^{\uparrow}}$ source.

No separate host object is admitted. The packet contains no quotient equality of reals, no selected host limit, no host real equality proof, and no ambient completeness field. □

Theorem 421.4 (Cauchy pairing classifier transport exactness)**.** *Let K and K' be accepted* $\mathsf{CauchyPairing}^{\uparrow}$ *packets. If the two* $\mathsf{RegSeqRat}^{\uparrow}$ *names, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers, the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules, and the source and paired* $\mathsf{Real}^{\uparrow}$ *seal rows are matched by displayed* hsame *rows and read through the displayed* Cont *routes, then the classifier transports exactly those packet rows.*

Lean4 ✓ `BEDC.Derived.CauchyPairingUp.CauchyPairingCarrier classifier transport exactness`

Proof. Apply the classifier surface described by Definition 421.2. The classifier reads the two regular names, window schedules, dyadic ledgers, modulus rows, seal rows, package provenance, and local naming row.

The hsame rows provide the componentwise replacements, and the Cont rows preserve the order in which consumer requests reach the synchronized schedule, side windows, ledgers, and paired seal. Since no other comparison coordinate is present, classifier transport is exact for the displayed rows and cannot compare completed reals or selected limits. □

Theorem 421.5 (Cauchy pairing paired-seal non-escape)**.** *For every accepted* $\mathsf{CauchyPairing}^{\uparrow}$ *carrier, the paired* $\mathsf{Real}^{\uparrow}$ *seal E is consumable only after both finite side windows W_A, W_B and both dyadic ledgers L_A, L_B have been displayed along the synchronized modulus route μ. The seal does not escape through quotient real equality, selected host limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyPairingUp.CauchyPairingCarrier paired seal non escape`

Proof. Start with a consumer request for the paired seal. The route first reads the synchronized modulus schedule μ, which fixes a common finite request before either side window is inspected.

The request then reads the two side windows W_A and W_B and the corresponding dyadic ledgers L_A and L_B. The side schedules μ_A and μ_B remain attached to this synchronized route through the stored transport and continuation rows.

Only after both finite windows and both dyadic ledgers are displayed can the row E be consumed. Thus the paired seal is a finite certificate endpoint, not a route to quotient equality, a selected host limit, host real equality, or ambient completeness. □

Theorem 421.6 (Cauchy pairing synchronized-window stability)**.** *Let K and K' be accepted* $\mathsf{CauchyPairing}^{\uparrow}$ *source packets. If their two* $\mathsf{RegSeqRat}^{\uparrow}$ *names, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers,* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules,* $\mathsf{Real}^{\uparrow}$ *seal rows,* Pkg *provenance, and local* NameCert *rows are transported componentwise by displayed* hsame *rows and read through the displayed* Cont *routes, then every finite consumer request follows matched synchronized windows on both sides and reaches matched paired* $\mathsf{Real}^{\uparrow}$ *seal rows.*

Proof. Project both accepted packets by Definition 421.1. The classifier can inspect only the two regular names, the selected finite windows, the dyadic ledgers, the modulus rows, the seal rows, and the recorded package and naming provenance.

Read a consumer request through the synchronized schedule. The request selects a common window budget before either source name is inspected, so the two side reads remain aligned under the same finite $\mathsf{StreamName}^{\uparrow}$ ledger.

Transport the selected side rows along the stored hsame comparisons and Cont routes. The two dyadic ledgers remain attached to their selected windows, and the paired seal remains downstream of those two readbacks.

Thus matched packets expose matched finite-window routes for every inspected request. The conclusion is a stability statement about the displayed BEDC certificate rows and does not introduce quotient equality, host limits, or an ambient completeness claim. □

Lean4 ✓ `BEDC.Derived.CauchyPairingUp.CauchyPairingCarrier synchronized window stability`

Theorem 421.7 (Cauchy pairing scoped dependency package)**.** *For the* $\mathsf{CauchyPairing}^{\uparrow}$ *source packet*

$$K = (A, B, W_A, W_B, L_A, L_B, \mu_A, \mu_B, \mu, E_A, E_B, E, H, C, P, N)$$

of Definition 421.1, the scoped dependency surface is exactly this packet over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *Every consumer of the paired seal* E *must pass through the synchronized schedule* μ*, both finite windows* W_A, W_B*, both dyadic ledgers* L_A, L_B*, and the stored* hsame *and* Cont *transports before reading* E*. No quotient equality, selected host limit, host real equality, or ambient completeness enters the* $\mathsf{CauchyPairing}^{\uparrow}$ *scope.*

Proof. The carrier source is the finite packet of Definition 421.1. Its displayed coordinates list the two regular names, side windows, dyadic ledgers, side and synchronized modulus schedules, source and paired seal rows, transport rows, continuation routes, package provenance, and local naming row.

Definition 421.2 identifies the NameCert surface carried by those rows. Carrier admission gives the packet itself, classifier stability compares only displayed components, synchronized-window exactness forces every request through μ, and seal non-escape prevents a consumer from reaching E without the two side readbacks.

Definition 421.4 fixes the transport boundary: matched packets may move only along the stored hsame rows and displayed Cont routes. Definition 421.5 then places E strictly downstream of both finite windows and both dyadic ledgers.

Finally, Definition 421.6 shows that every inspected request follows the same synchronized finite-window route on matched packets. Since the packet has no coordinate for quotient equality, selected host limits, host real equality, or ambient completeness, the listed packet is the whole scoped dependency surface. □

Lean4 ✓ `BEDC.Derived.CauchyPairingUp.CauchyPairingCarrier scoped dependency package`

Theorem 421.8 (Cauchy pairing public export certificate)**.** *The carrier of Definition 421.1, the NameCert obligations of Definition 421.2, synchronized-window stability, paired-seal non-escape, classifier transport exactness, and the scoped dependency package assemble a public* $\mathsf{CauchyPairing}^{\uparrow}$ *certificate over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The certificate exposes exactly the two source names, side windows, dyadic ledgers, synchronized modulus, source and paired* $\mathsf{Real}^{\uparrow}$ *seals, transport routes, package provenance, and local naming row. It exports no quotient equality, selected host limit, host real equality, or ambient completeness.*

Proof. Start with the packet K of Definition 421.1. Its displayed coordinates are precisely the two regular names, side windows, dyadic ledgers, side and synchronized modulus schedules, source and paired seal rows, transport rows, continuation routes, provenance, and local naming row.

Definition 421.2 supplies the local NameCert obligations for that packet. Carrier admission exposes K, synchronized-window exactness routes each consumer request through μ, and seal non-escape keeps the paired $\mathsf{Real}^{\uparrow}$ row downstream of both side windows and both dyadic ledgers.

Definition 421.6 gives the public stability condition for matched finite requests. Definition 421.5 prevents the paired seal from being read without its two source readbacks, and Definition 421.4 fixes the classifier boundary to the displayed hsame and Cont rows.

Finally apply Definition 421.7. The scoped package lists exactly the BEDC rows named in the statement and contains no coordinate for quotient equality, selected host limits, host real equality, or ambient completeness, so the assembled public certificate exports only the displayed finite-row surface. □

Theorem 421.9 (Cauchy pairing meet source)**.** *For the* $\mathsf{CauchyPairing}^{\uparrow}$ *packet*

$$K = (A, B, W_A, W_B, L_A, L_B, \mu_A, \mu_B, \mu, E_A, E_B, E, H, C, P, N)$$

of Definition 421.1, the side moduli μ_A, μ_B *together with the synchronized modulus* μ *determine a* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *source row. The source row is read through the same side windows, dyadic ledgers, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *data already present in* K*.*

Proof. Start with the carrier packet of Definition 421.1. Its displayed coordinates contain the two source names, the two side windows, the two dyadic ledgers, the side schedules μ_A, μ_B, and the synchronized schedule μ.

Definition 421.6 forces every inspected request through μ before either side window is read. Thus the synchronized schedule supplies the shared meet row, while μ_A and μ_B remain the two source modulus rows.

The classifier boundary and scoped package then provide the remaining rows. By Definition 421.4 and Definition 421.7, the meet source can use only the displayed hsame, Cont, Pkg, and NameCert rows already in K. □

Lean4 ✓ `BEDC.Derived.CauchyPairingUp.CauchyPairingCarrier meet source`

Theorem 421.10 (Cauchy pairing shared-bound consumer)**.** *Every shared-bound consumer of an accepted* $\mathsf{CauchyPairing}^{\uparrow}$ *packet reads the common bound through the* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row determined in Definition 421.9. In particular, the consumer first reads the synchronized modulus* μ*, then the side schedules* μ_A, μ_B*, side windows* W_A, W_B*, dyadic ledgers* L_A, L_B*, componentwise transports, continuation routes, provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.CauchyPairingUp.CauchyPairingCarrier shared bound consumer`

Proof. Let a shared-bound consumer be given. By Definition 421.2, synchronized-window exactness sends the request through μ before either source side can be inspected.

The meet source theorem identifies the shared-bound row as the finite $\mathsf{CauchyModulusMeet}^{\uparrow}$ source determined by μ_A, μ_B, μ and the side ledger data. Hence the consumer cannot bypass the meet row while still reading a common bound.

Finally apply Definition 421.8. The public certificate exposes only the side names, windows, dyadic ledgers, modulus rows, seal rows, transport routes, package provenance, and local naming row, so every shared-bound read factors through that displayed meet surface. □

Theorem 421.11 (Cauchy pairing Real handoff non-escape)**.** *The* $\mathsf{Real}^{\uparrow}$ *handoff from an accepted* $\mathsf{CauchyPairing}^{\uparrow}$ *packet may consume the paired seal* E *only after the shared* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *source row, both source readbacks, both finite windows, both dyadic ledgers, componentwise transports, continuation routes, package provenance, and local naming row have been displayed. The handoff exports no quotient equality, selected host limit, host real equality, or ambient completeness.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ handoff route. By Definition 421.5, the paired seal E is downstream of both finite windows and both dyadic ledgers along the synchronized modulus route.

Definition 421.9 places the side moduli and synchronized modulus into one shared $\mathsf{CauchyModulusMeet}^{\uparrow}$ source row. Definition 421.10 then forces any shared-bound read used by the handoff through that meet row.

The remaining exclusions follow from Definition 421.8. The public export surface has no coordinate for quotient equality, selected host limits, host real equality, or ambient completeness, so the $\mathsf{Real}^{\uparrow}$ handoff cannot export them. □

Theorem 421.12 (Cauchy pairing bilinear error ledger)**.** *Let an accepted* $\mathsf{CauchyPairing}^{\uparrow}$ *packet carry two synchronized finite-window sources, shared dyadic bound rows, and the* $\mathsf{Real}^{\uparrow}$ *handoff surface of Definition 421.11. Then it exports a single bilinear error ledger row. The left and right error budgets are read through the same finite-window classifier determined by the synchronized modulus route, the shared-bound rows are read through the same* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *source, and the output route is stable under componentwise* hsame *transport on both source streams. The ledger exposes only the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Proof. Start with synchronized-window stability from Definition 421.6. It forces matched finite requests on the two source streams to pass through the same synchronized modulus classifier before either side window is inspected.

Next apply the shared-bound consumer theorem of Definition 421.10. The left and right dyadic bound rows are read through the shared $\mathsf{CauchyModulusMeet}^{\uparrow}$ source, so the two side budgets are entries of one ledger rather than independent host-side error claims.

Finally use the $\mathsf{Real}^{\uparrow}$ handoff non-escape theorem of Definition 421.11. It keeps the output route downstream of the synchronized finite windows, dyadic ledgers, shared meet row, paired seal, transports, continuations, provenance, and local naming row. Componentwise hsame transport on both streams preserves those displayed rows, and no quotient equality, selected host limit, host real equality, or ambient completeness coordinate is available. □

Theorem 421.13 (Cauchy pairing synchronized-window bridge schema)**.** *The carrier of Definition 421.1, the local* $\mathsf{NameCert}$ *obligations of Definition 421.2, the public export certificate of Definition 421.8, the meet source of Definition 421.9, the shared-bound consumer of Definition 421.10, the bilinear error ledger of Definition 421.12, and the* $\mathsf{Real}^{\uparrow}$ *handoff non-escape theorem of Definition 421.11 assemble the bridge surface from the concrete synchronized packet to the abstract* $\mathsf{CauchyPairing}^{\uparrow}$ *schema. The bridge exposes only* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Proof. Project the synchronized packet K of Definition 421.1. Its visible coordinates are the two regular names, finite windows, dyadic ledgers, side and synchronized modulus schedules, source and paired seal rows, transports, continuations, provenance, and local naming row.

Apply the public export certificate. It identifies the finite synchronized surface that a public consumer may read, while the meet source theorem turns the side moduli and synchronized modulus into the displayed $\mathsf{CauchyModulusMeet}^{\uparrow}$ source row.

Use the bilinear error ledger and then the $\mathsf{Real}^{\uparrow}$ handoff non-escape theorem. These force shared-bound, error-budget, and real-facing reads through the same synchronized finite-window route before any seal row is available.

Thus the abstract $\mathsf{CauchyPairing}^{\uparrow}$ schema receives exactly the rows listed in the statement. The packet contains no coordinate for quotient equality, selected host limits, host real equality, or ambient completeness, so none is exported by the bridge surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyPairing}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyPairing}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ regular Cauchy names, synchronized finite $\mathsf{StreamName}^{\uparrow}$ windows, two $\mathsf{DyadicRatCore}^{\uparrow}$ ledgers, side and paired $\mathsf{CauchyModulus}^{\uparrow}$ schedules, source and paired $\mathsf{Real}^{\uparrow}$ seal rows, displayed hsame and Cont routes, package provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyPairing}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 421.8 exports the public certificate over the displayed packet $K = (A, B, W_A, W_B, L_A, L_B, \mu_A, \mu_B, \mu, E_A, E_B,$ over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyPairing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient equality of reals, host real equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, diagonal uniqueness, or bridge checking.

Upgrade path: The next paper-side step is a bridge theorem for the same synchronized finite-window packet and public certificate.

Chapter 422

A Concrete Naming Certificate for $\mathsf{StationaryPartitionDiagonal}^{\uparrow}$

The $\mathsf{StationaryPartitionDiagonal}^{\uparrow}$ packet names the finite-partition diagonal surface used by the stationary rational route into the real-completeness and completion ledger. It keeps the rational input rows, finite observation-window partition, diagonal representatives, constant stream classifiers, dyadic observation ledgers, real seal rows, and local naming provenance as displayed BEDC data. The packet contains no quotient stream, choice-selected limit, host real equality, or ambient completeness field.

The packet consumes the stationary rational source, finite stream window, dyadic observation ledger, and real seal through sibling surfaces chapter 37, chapter 126, chapter 291, and chapter 38.

Definition 422.1 (Stationary partition diagonal carrier)**.** *A* $\mathsf{StationaryPartitionDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, \Pi, \Delta, K, D, E, L, C, P, N)$$

whose displayed coordinates are as follows:

1. Q *is the stationary* $\mathsf{Rat}^{\uparrow}$ *input row pair read by the rational source classifier;*
2. Π *is a finite partition of observation windows, including the segment bounds, selected anchors, and refinement routes inspected by the diagonal construction;*
3. Δ *is the finite list of diagonal representatives selected from the partition segments;*
4. K *is the constant* $\mathsf{StreamName}^{\uparrow}$ *classifier row that reads every segment through the same stationary source stream;*
5. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger for the segment representatives and their dyadic bounds;*
6. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row receiving the finite diagonal representative;*
7. L *is the* BHist *ledger of displayed segment reads, refinement witnesses, and selected representatives;*
8. C *is the componentwise* hsame *and* Cont *route data used to transport the partition classifier;*
9. P *is the* Pkg *provenance naming the* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and completion-facing dependencies;*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{StationaryPartitionDiagonal}^{\uparrow}}$ *provenance row.*

Two accepted carriers are classified together exactly when their rational input rows, partition windows, diagonal representatives, constant stream classifiers, dyadic ledgers, real seal rows, history ledgers, transport routes, package rows, and local certificate rows are transported componentwise by the displayed hsame *comparisons and* Cont *routes.*

Theorem 422.2 (Stationary partition diagonal NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{StationaryPartitionDiagonal}^{\uparrow}}$ *obligation surface consists of carrier habitation, classifier stability across partition refinement, finite-window exactness, the* $\mathsf{Real}^{\uparrow}$ *seal boundary, and public export to the Phase Real and Completion diagonal-limit route.*

Lean4 ✓ `BEDC.Derived.StationaryPartitionDiagonalUp.StationaryPartitionDiagonalCarrier namecert obligations`

Proof. Carrier habitation is the finite packaging operation of Definition 422.1. The displayed rows name the stationary rational inputs, the finite partition, the diagonal representatives, the constant stream classifier, the dyadic ledger, the real seal, the history ledger, the transport routes, and the local provenance.

Classifier stability is componentwise. A refinement may subdivide partition segments, but it can only do so through the recorded hsame comparisons and Cont routes; the constant $\mathsf{StreamName}^{\uparrow}$ classifier therefore continues to read the same stationary rational source on each displayed segment.

Finite-window exactness, the seal boundary, and the public export are the three consumer-facing clauses proved below. Together they account for every read made by the local certificate and exclude quotient streams, selected limits, host real equality, hidden representatives, and ambient completeness data from the packet boundary. □

Theorem 422.3 (Stationary partition diagonal window exactness)**.** *For every accepted* $\mathsf{StationaryPartitionDiagonal}^{\uparrow}$ *carrier and every displayed segment of its finite partition* Π*, the diagonal representative in* Δ *is read through the same constant* $\mathsf{StreamName}^{\uparrow}$ *classifier row* K*, the corresponding* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger row* D*, and the segment's displayed* BHist *route in* L*. Refining* Π *preserves the finite observation content through the recorded* hsame *and* Cont *routes.*

Lean4 ✓ `BEDC.Derived.StationaryPartitionDiagonalUp.StationaryPartitionDiagonalCarrier window exactness`

Proof. Project the accepted carrier through Definition 422.1. A displayed segment of Π carries its bounds, selected anchor, and representative coordinate, and the representative is listed in Δ.

The classifier row K is constant, so every segment read uses the same stationary rational stream. The dyadic ledger D records the rational observation and bound attached to that segment, while L records the visible history route used by the read.

Under partition refinement, each smaller segment points back to a displayed parent segment through the route data C. Since the carrier classifier transports only by hsame and Cont, the refined ledger reads the same finite stationary observation content and introduces no hidden endpoint or host limit. □

Theorem 422.4 (Stationary partition diagonal seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{StationaryPartitionDiagonal}^{\uparrow}$ *carrier factors through its stationary* $\mathsf{Rat}^{\uparrow}$ *source row, finite partition window, diagonal representative, constant* $\mathsf{StreamName}^{\uparrow}$ *classifier,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* BHist *route, displayed* hsame *and* Cont *transport,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.StationaryPartitionDiagonalUp.StationaryPartitionDiagonalCarrier seal boundary`

Proof. Begin with a public seal request and project the accepted carrier. The request can reach E only after choosing one finite partition window and the corresponding diagonal representative in Δ.

By Definition 422.3, that representative is read through K, D, and the displayed history route L. The route data C supplies only componentwise hsame comparisons and Cont witnesses, so transport cannot add a quotient stream or an unrecorded limit object.

Repacking the selected rows with P and N gives the stated factorization of the $\mathsf{Real}^{\uparrow}$ seal. The seal is therefore attached to the finite BEDC packet itself, not to an ambient real-completeness principle. □

Theorem 422.5 (Stationary partition diagonal public export)**.** *The public* $\mathsf{StationaryPartitionDiagonal}^{\uparrow}$ *export surface is the finite stationary diagonal packet of Definition 422.1 together with the exact window reads of Definition 422.3 and the seal factorization of Definition 422.4. This surface is the concrete Real and Completion NameCert route consumed by the Phase Real and Completion diagonal-limit construction.*

Lean4 ✓ `BEDC.Derived.StationaryPartitionDiagonalUp.StationaryPartitionDiagonalCarrier public export`

Proof. The public packet exposes exactly the carrier rows $Q, \Pi, \Delta, K, D, E, L, C, P, N$. These rows are all finite BEDC rows or local provenance rows.

The exactness theorem accounts for every finite-window read of the partition and every refinement of that finite partition. The seal-boundary theorem accounts for every downstream $\mathsf{Real}^{\uparrow}$ read and keeps it factored through the same visible rows.

Thus a Phase Real or Completion consumer receives a concrete NameCert surface: stationary rational inputs, finite partition windows, diagonal representatives, dyadic observations, real seal rows, history and transport ledgers, package provenance, and local certificate data. No exported coordinate is a quotient stream, selected host limit, hidden representative, or ambient completeness theorem. □

Theorem 422.6 (Stationary partition diagonal bridge readback exactness)**.** *Any standard bridge read of an accepted* $\mathsf{StationaryPartitionDiagonal}^{\uparrow}$ *packet recovers exactly the carrier tuple* $S = (Q, \Pi, \Delta, K, D, E, L, C, P, N)$*. The readback proceeds through the displayed partition windows* Π*, diagonal representatives* Δ*, constant* $\mathsf{StreamName}^{\uparrow}$ *classifier* K*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*, local* BHist *provenance* L*, componentwise* hsame *and* Cont *routes* C*,* Pkg *provenance* P*, and local* NameCert *row* N*, and it exposes no quotient stream, selected limit, host real equality, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.StationaryPartitionDiagonalUp.StationaryPartitionDiagonalCarrier bridge readback exactness`

Proof. Project the bridge read through the carrier definition Definition 422.1. The only available carrier rows are $Q, \Pi, \Delta, K, D, E, L, C, P, N$, so the readback has no separate host-real or completion coordinate to return.

Window exactness is Definition 422.3. It identifies each displayed partition segment with its selected representative in Δ, the constant $\mathsf{StreamName}^{\uparrow}$ classifier row K, the dyadic ledger row D, and the local history row L.

The seal boundary Definition 422.4 fixes the $\mathsf{Real}^{\uparrow}$ handoff at E through the same displayed rows and through the recorded hsame and Cont transport data in C. The public export theorem Definition 422.5 then repackages exactly those rows with P and N for Real and Completion consumers.

Since the public export contains only this finite packet, the bridge readback is exact: it recovers S and cannot add a quotient stream, selected limit, host real equality, or ambient completeness row. □

Closure status for $\mathsf{NameCert}_{\mathsf{StationaryPartitionDiagonal}^{\uparrow}}$.

Constructive story: A $\mathsf{StationaryPartitionDiagonal}^{\uparrow}$ packet is generated from stationary $\mathsf{Rat}^{\uparrow}$ input rows, a finite partition of observation windows, diagonal representatives, a constant $\mathsf{StreamName}^{\uparrow}$ classifier, $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledgers, a $\mathsf{Real}^{\uparrow}$ seal row, BHist ledgers, displayed hsame and Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StationaryPartitionDiagonal}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The public export is the finite stationary partition diagonal packet with exact window reads, refinement-stable classifier transport, $\mathsf{Real}^{\uparrow}$ seal factorization, and downstream Phase Real and Completion diagonal-limit consumption over the displayed rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StationaryPartitionDiagonal}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.StationaryPartitionDiagonalUp.StationaryPartitionDiagonalCarrier\_bridge\_readback\_exa`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close quotient streams, choice-selected limits, host real equality, ambient completeness, or bridge checking.

Upgrade path: Mature closure requires downstream Real and Completion consumer examples over the same stationary finite-partition diagonal packet.

Chapter 423

A Concrete Naming Certificate for CauchyCompletionFunctor$^{\uparrow}$

The CauchyCompletionFunctor$^{\uparrow}$ packet records the functorial completion surface obtained from a source metric presentation and a regular-Cauchy family. Following Bishop and Bridges, *Constructive Analysis*, the packet treats completion as a visible transformation of names: it consumes the RealCauchyCompletion$^{\uparrow}$ seal rows, the CauchyCompletionMonad$^{\uparrow}$ unit-and-bind schedule, and the CompletionUniversalProperty$^{\uparrow}$ extension-uniqueness rows, while its classifier remains confined to finite BHist, hsame, Cont, Pkg, and NameCert evidence.

The functor packet depends substantively on the seal route of chapter 360, the unit-and-bind rows of chapter 378, the extension-uniqueness rows of chapter 397, and the observation route of chapter 611. These are dependency rows for seal, unit/bind, extension-uniqueness, and finite observation service, not informal background.

Definition 423.1 (CauchyCompletionFunctor carrier)**.** *A* CauchyCompletionFunctor$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, R, S, U, B, E, P, T, N)$$

with the following visible rows:

1. *M is the source metric presentation row, including the displayed points, distance observations, and finite tolerance ledger read by the source classifier;*
2. *R is the regular-Cauchy family row, exposing the* RegSeqRat$^{\uparrow}$ *or* RegularCauchyFamily$^{\uparrow}$ *schedules that approximate each source point;*
3. *S is the* RealCauchyCompletion$^{\uparrow}$ *seal row reached from the same source metric and regular-Cauchy family data;*
4. *U records the* CauchyCompletionMonad$^{\uparrow}$ *unit schedule for source points and the bind schedule for completion-facing maps;*
5. *B is the* CompletionUniversalProperty$^{\uparrow}$ *extension-and-uniqueness row attached to the same unit and bind routes;*
6. *E is the classifier-transport ledger comparing two accepted packets only through displayed source rows, regular-Cauchy windows, completion seals, unit schedules, bind schedules, and extension-uniqueness rows;*

7. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyFamily}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
8. *T is the transport row recording the componentwise* hsame *and displayed* Cont *routes for M, R, S, U, B, and E;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionFunctor}^{\uparrow}}$ *ledger.*

The carrier contains no quotient of Cauchy names, no selected limit object, no host-level completed metric space, and no ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorTasteGate single carrier alignment`

Theorem 423.2 (CauchyCompletionFunctor NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionFunctor}^{\uparrow}}$ *surface for the carrier of Definition 423.1 consists of six finite rows: carrier admission, classifier transport through displayed source metric and regular-Cauchy rows,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *seal compatibility,* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *unit schedule exactness,* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *bind schedule exactness, and* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension-uniqueness ledger exactness. Each row is read from $F = (M, R, S, U, B, E, P, T, N)$ and from the recorded* BHist, hsame, Cont, Pkg, *and* NameCert *provenance.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorUp StdBridge`

Proof. Carrier admission is projection of the packet in Definition 423.1. The source metric row, regular-Cauchy family row, completion seal, monad schedule, universal-property row, classifier ledger, package provenance, transport row, and local naming ledger are displayed coordinates of one finite history.

Classifier transport uses only those displayed coordinates. A comparison first reads the source metric observations in M, then the regular-Cauchy windows in R, then the completion seal row S reached by the same finite schedule.

The unit, bind, and extension rows are the remaining coordinates U and B, transported by T and accounted for by P and N. Since the carrier has no quotient, selected limit, host completion, or ambient-completeness coordinate, these six rows exhaust the local certificate obligations. □

Theorem 423.3 (CauchyCompletionFunctor unit laws)**.** *For every accepted* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *packet $F = (M, R, S, U, B, E, P, T, N)$, the unit part of U sends each displayed source metric point of M to the completion seal row S by the regular-Cauchy family route R. The left and right unit readings available to consumers are therefore the same finite route through M, R, S, U, P, T, and N, not an equality of host completion objects.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket unit laws`

Proof. Project the unit schedule from U. Its source is the displayed metric row M, and its target is the seal row S reached through the regular-Cauchy family row R.

The left-unit read begins with a source point and immediately follows the unit schedule into the displayed completion seal. The right-unit read begins with the same displayed completion-facing row and reads back through the stored source and regular-Cauchy schedule.

Both reads use the same package and transport evidence, namely P, T, and N. Thus the unit laws are certificate-level route equalities inside the packet, with no appeal to quotient completion equality or selected limits. □

Theorem 423.4 (CauchyCompletionFunctor multiplication laws)**.** *For every accepted* CauchyCompletionFunctor$^{\uparrow}$ *packet, the bind part of the* CauchyCompletionMonad$^{\uparrow}$ *schedule composes two completion-facing reads only by reusing the displayed regular-Cauchy windows, the* RealCauchyCompletion$^{\uparrow}$ *seal rows, and the* CompletionUniversalProperty$^{\uparrow}$ *extension row. Associativity is therefore witnessed as equality of the finite bind ledger over R, S, U, B, E, P, T, and N.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket multiplication laws`

Proof. Read the bind schedule from U. A first completion-facing read consumes the regular-Cauchy family row R and reaches the seal row S; a second read is permitted only through the same kind of displayed seal and extension row.

The universal-property coordinate B records the extension route used by each bind. The classifier ledger E keeps both binds attached to the same source metric and regular-Cauchy windows, and the transport row T moves those rows componentwise.

Associativity follows by comparing the two parenthesized bind ledgers as finite row lists. They name the same R, S, U, B, E, P, T, and N coordinates and introduce no hidden completed carrier, quotient stream, selected limit, or ambient completeness principle. □

Theorem 423.5 (CauchyCompletionFunctor ledger exactness)**.** *Every consumer route exported by an accepted* CauchyCompletionFunctor$^{\uparrow}$ *packet is exhausted by the source metric row, regular-Cauchy family row,* RealCauchyCompletion$^{\uparrow}$ *seal row,* CauchyCompletionMonad$^{\uparrow}$ *unit-and-bind schedule,* CompletionUniversalProperty$^{\uparrow}$ *extension-uniqueness row, classifier transport ledger, package provenance, transport row, and local* NameCert *ledger. No consumer can obtain a quotient completion, a selected limit, a host completed metric space, or an ambient completeness theorem from the packet.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket ledger exactness`

Proof. Start with a consumer route and project the carrier coordinates of Definition 423.1. The only available rows are M, R, S, U, B, E, P, T, and N.

The NameCert obligation theorem accounts for carrier, classifier, completion seal, unit, bind, and universal-property rows. The unit laws identify the source-point route into the completion seal, while the multiplication laws identify the composed completion-facing route.

These rows exhaust the packet ledger. Since the carrier definition contains no additional coordinate, the consumer has no path to quotient completion equality, selected limits, host completed metric spaces, or ambient completeness. □

Theorem 423.6 (CauchyCompletionFunctor classifier transport)**.** *For two accepted* CauchyCompletionFunctor$^{\uparrow}$ *packets, classifier replacement is local to the displayed source metric row, the regular-Cauchy family row, the* RealCauchyCompletion$^{\uparrow}$ *seal, the* CauchyCompletionMonad$^{\uparrow}$ *unit schedule, the* CauchyCompletionMonad$^{\uparrow}$ *bind schedule, the* CompletionUniversalProperty$^{\uparrow}$ *row, the classifier ledger, the* hsame *rows, the displayed* Cont *rows, the* Pkg *provenance, and the local* NameCert *rows. A replacement that agrees on these coordinates cannot alter any exported consumer route, and a replacement that changes any exported route must be witnessed by one of these coordinates.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket classifier transport`

Proof. Project the two packets through Definition 423.1. The only displayed coordinates are $M, R, S, U, B, E, P, T, N$, and the local classifier reads them componentwise through the hsame and Cont routes recorded in T.

The source metric and regular-Cauchy rows determine the completion seal row. The unit and bind schedules are the two monad-facing parts of U, and the extension-uniqueness row is the public content of B.

Thus every accepted classifier replacement factors through the displayed ledger rows E, P, T, N. Since the carrier contains no hidden completed object or selected limit coordinate, there is no further place where a replacement can change a consumer route. □

Theorem 423.7 (CauchyCompletionFunctor universal-property extension exactness)**.** *Every extension-uniqueness consumer of an accepted* CauchyCompletionFunctor$^{\uparrow}$ *packet factors through the displayed* CompletionUniversalProperty$^{\uparrow}$ *row together with the* RealCauchyCompletion$^{\uparrow}$ *and* CauchyCompletionMonad$^{\uparrow}$ *rows. In particular, extension existence, extension uniqueness, unit compatibility, and bind compatibility are read from B only after the seal row S and the unit-and-bind row U have been projected from the same carrier.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket universal property extension exactness`

Proof. Begin with an extension-uniqueness consumer and project the carrier $F = (M, R, S, U, B, E, P, T, N)$. The only universal-property coordinate is B, so the consumer must first read the completion seal S and the monad schedule U that give B its displayed source and target routes.

Existence and uniqueness are then finite ledger reads from the CompletionUniversalProperty$^{\uparrow}$ row. Unit compatibility uses the unit part of U, while bind compatibility uses the bind part of U together with the same seal row S.

The classifier and package rows E, P, T, N record that these reads remain attached to the displayed source metric and regular-Cauchy family rows. No additional completion object, quotient equality, or ambient completeness theorem is available to the consumer. □

Theorem 423.8 (CauchyCompletionFunctor obligation closure package)**.** *The accepted* CauchyCompletionFunctor$^{\uparrow}$ *carrier assembles a five-row obligation surface: carrier admission for $F = (M, R, S, U, B, E, P, T, N)$; existing local* NameCert *obligations for carrier, classifier, seal, unit, bind, and universal-property rows; unit laws for the displayed source-to-seal route; multiplication laws for the finite bind ledger; and ledger exactness for the classifier transport and universal-property extension rows of Definition 423.6 and Definition 423.7. This surface is an obligation package over the displayed packet, not a host-level completion construction.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket obligation closure package`

Proof. Carrier admission is the tuple displayed in Definition 423.1. The existing NameCert obligations project the local carrier row, componentwise classifier, completion seal, unit schedule, bind schedule, and universal-property ledger from the same tuple.

The unit laws and multiplication laws provide the two monad rows. The unit row follows source points through M, R, S, U, and the multiplication row compares two bind readings through R, S, U, B, E.

It remains to account for escape from the obligation surface. The classifier transport theorem confines replacements to the displayed source, Cauchy-family, seal, unit, bind, universal-property, transport, package, and local certificate rows. The universal-property exactness theorem confines extension consumers to B together with S and U.

These five rows exhaust the packet coordinates. Therefore the obligation package is closed at the displayed carrier surface and introduces no quotient completion, selected limit, host completed metric space, or ambient completeness principle. □

Theorem 423.9 (CauchyCompletionFunctor source metric unit handoff)**.** *Every displayed source metric point admitted by an accepted* CauchyCompletionFunctor$^{\uparrow}$ *packet enters the completion seal only through* M, R, S, U, P, T, N*. The handoff reads the source metric presentation in* M*, the regular-Cauchy family route in* R*, the* RealCauchyCompletion$^{\uparrow}$ *seal in* S*, the unit part of the* CauchyCompletionMonad$^{\uparrow}$ *schedule in* U*, and the package, transport, and local naming rows* P, T, N*.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket source metric unit handoff`

Proof. Project the carrier $F = (M, R, S, U, B, E, P, T, N)$. A source metric point is visible only as part of the source row M.

The unit schedule is the component of U that sends that displayed point through the regular-Cauchy route R into the seal row S. The package, transport, and local naming rows P, T, N record that this is the admitted public route.

No coordinate of the packet names a selected limit, quotient completion object, or host completed metric space. Thus the source point can enter the completion surface only through the displayed unit handoff. □

Theorem 423.10 (CauchyCompletionFunctor completion consumer handoff)**.** *Every completion-facing consumer of an accepted* CauchyCompletionFunctor$^{\uparrow}$ *packet reads* RealCauchyCompletion$^{\uparrow}$*,* CauchyCompletionMonad$^{\uparrow}$*, and* CompletionUniversalProperty$^{\uparrow}$ *through the same finite packet* $F = (M, R, S, U, B, E, P, T, N)$*. The consumer cannot read a completion seal without the unit-and-bind schedule, nor an extension-uniqueness row without the seal and monad rows that give it source and target routes.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket completion consumer handoff`

Proof. Begin with a completion-facing consumer and project the packet. The only completion seal is S, the only monad schedule is U, and the only universal-property row is B.

The consumer first reads S through the source and regular-Cauchy rows M, R. It then reads the unit and bind schedules from U, and only then reads extension and uniqueness data from B.

Classifier, package, transport, and local naming rows E, P, T, N keep these reads attached to the same packet. Since no other completion-facing coordinate exists, every such consumer is handed the same finite carrier surface. □

Theorem 423.11 (CauchyCompletionFunctor bind ledger consumer exhaustion)**.** *Every composed completion read exported by an accepted* CauchyCompletionFunctor$^{\uparrow}$ *packet is exhausted by the bind ledger* R, S, U, B, E, P, T, N*. The ledger records the regular-Cauchy windows, completion seals, unit-and-bind schedule, extension-uniqueness row, classifier transport, package provenance, componentwise transport, and local* NameCert *row; it exports no hidden quotient equality, selected limit, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket bind ledger consumer exhaustion`

Proof. Take a composed completion read. Its first and second completion-facing stages must use the bind part of U together with the regular-Cauchy windows in R and the seal rows in S.

The universal-property coordinate B supplies the extension route attached to the bind read. The classifier ledger E and the package, transport, and naming rows P, T, N record that the composed read remains inside the same finite carrier.

Those rows are exactly the bind-facing coordinates of F. Therefore the consumer is exhausted by R, S, U, B, E, P, T, N and has no access to quotient equality, selected limits, host completion objects, or ambient completeness. □

Theorem 423.12 (CauchyCompletionFunctor public completion export)**.** *Every accepted* CauchyCompletionFunctor *packet exports a single public completion surface through the displayed source metric row M, regular-Cauchy family row R,* RealCauchyCompletion$^{\uparrow}$ *seal S,* CauchyCompletionMonad$^{\uparrow}$ *unit-and-bind schedule U,* CompletionUniversalProperty$^{\uparrow}$ *row B, classifier ledger E, and transport and provenance rows P, T, N. Consumers obtain exactly this finite surface and obtain no quotient completion, selected limit, host completed metric space, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket public completion export`

Proof. Project the accepted carrier as $F = (M, R, S, U, B, E, P, T, N)$. The NameCert obligation rows admit the carrier, bind the classifier to the displayed source and regular-Cauchy rows, attach the completion seal, and expose the unit, bind, and universal-property rows from the same finite packet.

The unit laws send displayed source points through M, R, S, U, P, T, N. The multiplication laws compare composed completion reads through the bind ledger, and the universal-property extension exactness theorem confines extension and uniqueness consumers to B after S and U have been read.

It remains to account for public export. The completion consumer handoff forces every completion-facing consumer to use the same S, U, B rows over the same carrier, and the bind-ledger consumer exhaustion theorem confines composed reads to R, S, U, B, E, P, T, N.

Since the carrier has no additional coordinate, this finite row surface is the only public completion export. No consumer can extract quotient completion equality, a selected limit, a host completed metric space, or an ambient completeness theorem from the packet. □

Theorem 423.13 (CauchyCompletionFunctor observation-budget factorization)**.** *Let $F = (M, R, S, U, B, E, P, T,$ be an accepted* CauchyCompletionFunctor$^{\uparrow}$ *packet. Suppose its completion-facing seal rows are served by an accepted* RealObservationBudget$^{\uparrow}$ *packet $B_R = (E_R, W_R, D_R, R_R, S_R, H_R, C_R, P_R, N_R)$. Every public completion consumer of F factors first through the observation-budget route*

$$E_R \longmapsto W_R \longmapsto D_R \longmapsto R_R \longmapsto S_R$$

before reading the RealCauchyCompletion$^{\uparrow}$*, monad, or universal-property rows. The route exposes no quotient completion, selected limit, host completed metric space, ambient completeness theorem, host real equality, or hidden observation schedule.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket observation budget factorization`

Proof. Apply Definition 423.12. It confines public completion consumers of F to the displayed source row, regular-Cauchy row, completion seal, monad schedule, universal-property row, classifier ledger, transport rows, provenance rows, and local naming row.

Now use Definition 611.20. The accepted observation-budget packet supplies the finite route from the external observation row E_R through the window, dyadic, rational, and seal rows W_R, D_R, R_R, S_R before any completion-facing seal can be read.

Finally apply Definition 611.21. That package keeps the seal service attached to the same finite observation route and prevents a consumer from replacing it by a host completion object or unrecorded observation schedule.

Combining these readings, every public completion consumer reaches the rows S, U, B of F only after passing through E_R, W_R, D_R, R_R, S_R. Since neither packet has a coordinate for quotient completion equality, selected limits, host completed metric spaces, ambient completeness, host real equality, or hidden schedules, those objects do not enter the consumer route. □

Theorem 423.14 (CauchyCompletionFunctor observation-budget seal determinacy)**.** *Let $F = (M, R, S, U, B, E, P, T, N)$ be an accepted* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *packet, and let an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *packet $B_R = (E_R, W_R, D_R, R_R, S_R, H_R, C_R, P_R, N_R)$ serve the completion-facing seal rows of F. If two public completion consumers display the same observation route*

$$E_R \longmapsto W_R \longmapsto D_R \longmapsto R_R \longmapsto S_R$$

and read the same rows of F, then they determine the same completion seal S, the same unit-and-bind schedule U, and the same universal-property extension row B. The determination is only through the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; it exports no quotient completion, selected limit, host equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket observation budget seal determinacy`

Proof. First apply Definition 423.13. Both consumers must enter the completion-facing rows of F through the same displayed route E_R, W_R, D_R, R_R, S_R before S, U, B can be read.

Next apply Definition 423.12. Once the route has reached F, the only public completion surface is the displayed packet $M, R, S, U, B, E, P, T, N$, so the seal, unit-and-bind schedule, and extension row cannot be replaced by another completion-facing coordinate.

Use the finite-route and seal-ledger rows from the observation budget. Definition 611.20 keeps the route on E_R, W_R, D_R, R_R, S_R, and Definition 611.27 exhausts the seal ledger by $E_R, W_R, D_R, R_R, S_R, H_R, C_R, P$

Therefore two consumers with the same displayed route and the same F rows determine the same S, U, B rows. The non-escape clauses in the cited export and ledger theorems remove quotient completion, selected limits, host equality, and ambient completeness from the route, so no hidden coordinate can separate the two determinations. □

Theorem 423.15 (CauchyCompletionFunctor RegSeqRat-to-Real completion route)**.** *Let $F = (M, R, S, U, B, E, P, T, N)$ be an accepted* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *packet. Suppose the regular row R is served by a* $\mathsf{RegSeqRat}^{\uparrow}$ *route and the completion seal S is served through* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *and* $\mathsf{RealObservationBudget}^{\uparrow}$*. Then every public completion consumer factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealCauchyCompletion}^{\uparrow} \longmapsto \mathsf{CauchyCompletionMonad}^{\uparrow} \longmapsto \mathsf{CompletionUniversalProperty}^{\uparrow} \longmapsto \mathsf{Real}$$

using the same BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of F. The route exports no quotient completion, selected limit, host completed metric space, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket regseq real endofunctor`

Proof. Apply Definition 423.12. It identifies the public completion surface of F with the displayed source row M, regular-Cauchy row R, completion seal S, monad schedule U, universal-property row B, classifier ledger E, and transport, provenance, and naming rows P, T, N.

Next apply Definition 423.10. The consumer can reach the completion-facing rows only through the same S, U, B coordinates over the same finite packet.

Use Definition 423.11 to keep composed completion reads inside R, S, U, B, E, P, T, N. The assumption that R is served by $\mathsf{RegSeqRat}^{\uparrow}$ and S by $\mathsf{RealCauchyCompletion}^{\uparrow}$ places the regular rational sequence route before the real completion seal, while U and B provide the monad and universal-property stages.

Finally apply Definition 423.13. The real observation-budget packet is read as the finite budget service for the completion seal, so the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows carry the route through $\mathsf{RealObservationBudget}^{\uparrow}$.

The carrier projection closes non-escape: F has no coordinate for quotient completion equality, selected limits, host completed metric spaces, or ambient completeness. Therefore no public completion consumer can export those objects outside the displayed finite route. □

Theorem 423.16 (CauchyCompletionFunctor Real-seal functoriality)**.** *Let*

$$F = (M, R, S, U, B, E, P, T, N)$$

and

$$F' = (M', R', S', U', B', E', P', T', N')$$

be accepted $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *packets. Suppose they agree on the source metric row, regular-Cauchy row,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *seal, monad schedule, universal-property row, classifier ledger, transport row, provenance row, and local* $\mathsf{NameCert}$ *row. Then every* $\mathsf{RealObservationBudget}^{\uparrow}$*-served public completion consumer determines the same Real seal, the same unit-and-bind schedule, and the same universal-property row for F and F'.*

The functorial read is the displayed route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}$ $\mathsf{CompletionUniversalProperty}^{\uparrow}$, *and* $\mathsf{RealObservationBudget}^{\uparrow}$. *It has no distinguishing coordinate for quotient completion, selected limit, host completed metric space, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket real seal functoriality`

Proof. Project both functor packets through Definition 423.1. Under the displayed row agreement, the completion-facing coordinates in the two packets are the same source metric row, regular-Cauchy row, Real seal, monad schedule, universal-property row, classifier ledger, transport row, provenance row, and local naming row.

Use Definition 423.12 and Definition 423.13. The first theorem identifies the public completion surface, and the second forces every $\mathsf{RealObservationBudget}^{\uparrow}$-served read through the same finite budget route before S, U, B can be consumed.

Next apply Definition 423.10 and Definition 423.11. These keep the completion handoff, unit-and-bind schedule, universal-property row, and composed bind ledger inside the displayed R, S, U, B, E, P, T, N route.

Finally invoke Definition 423.15. It identifies the RegSeqRat-to-Real route through $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, and $\mathsf{RealObservationBudget}^{\uparrow}$. Since quotient completion, selected limits, host completed metric spaces, and ambient completeness have no carrier coordinate, no public consumer can distinguish the two Real-seal reads. □

Theorem 423.17 (CauchyCompletionFunctor finite approximation route)**.** *Let $F = (M, R_F, S_F, U_F, B_F, E_F, P_F,$ be an accepted* CauchyCompletionFunctor$^\uparrow$ *packet, and let $A = (R, n, k, W, D, E, S, H, C, P, N)$ be an accepted* FiniteCauchyApproximation$^\uparrow$ *packet serving the regular row R_F. Suppose the functor route also names the* RegSeqRat$^\uparrow$, StreamName$^\uparrow$, RealCauchyCompletion$^\uparrow$, CauchyCompletionMonad$^\uparrow$, CompletionUniversal *and* RealObservationBudget$^\uparrow$ *rows used by the completion-facing consumer. Then every public completion consumer of F first reads the finite approximation rows*

$$R, n, k, W, D, E, S, H, C, P, N$$

and only then reads the RegSeqRat$^\uparrow$, StreamName$^\uparrow$, RealCauchyCompletion$^\uparrow$, CauchyCompletionMonad$^\uparrow$, CompletionUniversalProperty$^\uparrow$, *and* RealObservationBudget$^\uparrow$ *rows already named by the functor route. The composed route exports no quotient completion, selected limit, host completed metric space, ambient completeness theorem, or hidden finite-observation schedule.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket finite approximation route`

Proof. Start from Definition 423.15. It keeps every public completion consumer of F on the displayed route through the regular rational sequence row, the real completion seal, the monad schedule, the universal-property row, and the real observation-budget service.

Now insert the accepted finite approximation packet at the regular row. By Definition 601.4, any visible dyadic observation and any real-facing handoff from A first reads R, n, k, W, D, E before the handoff row can be used. By Definition 601.7, the same consumer then reaches the real-facing row S only after the transport, continuation, provenance, and local naming rows H, C, P, N have also been exposed.

Finally apply Definition 601.16. It packages the finite rows $R, n, k, W, D, E, S, H, C, P, N$ as the local NameCert$_{\text{FiniteCauchyApproximation}^\uparrow}$ service boundary, so the functor route cannot read the RegSeqRat$^\uparrow$, StreamName$^\uparrow$, RealCauchyCompletion$^\uparrow$, CauchyCompletionMonad$^\uparrow$, CompletionUniversalProperty$^\uparrow$, or RealObservationBudget$^\uparrow$ rows before the finite approximation service has been consumed.

The cited functor and finite-approximation boundaries both lack coordinates for quotient completion, selected limits, host completed metric spaces, ambient completeness, and hidden finite-observation schedules. The composed public route therefore exposes only the displayed finite approximation service followed by the completion route already named by F. □

Theorem 423.18 (CauchyCompletionFunctor tail-budget coherence factorization)**.** *Let $F = (M, R, S, U, B, E, P,$ be an accepted* CauchyCompletionFunctor$^\uparrow$ *packet, and let a* TailBudgetCoherence$^\uparrow$ *packet serve the finite Real-completion budget route. Any public completion consumer using both packets must first read the route through the TailMeet threshold, observation budget, selector budget,* StreamName$^\uparrow$ *window,* DyadicRatCore$^\uparrow$ *ledger,* RegSeqRat$^\uparrow$ *readback,* RealTailAgreementSeal$^\uparrow$, *and* CauchyLimitSeal$^\uparrow$ *before the functor rows S, U, B are exposed. The functor packet exports no quotient completion equality, selected limit, host completed metric space, ambient completeness theorem, or unbudgeted completion selector.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket tail budget coherence factorization`

Proof. Begin with Definition 423.12. It confines every public completion consumer to the displayed source, regular-Cauchy, completion seal, monad schedule, universal-property row, classifier ledger, transport, provenance, and naming rows of F.

Next use Definition 423.13. The completion-facing seal must already pass through the finite observation-budget route before the public completion rows can be read.

Combine this with Definition 423.11. Composed completion reads remain inside R, S, U, B, E, P, T, N, so the consumer cannot insert a second completion selector between the budget route and the functor packet.

Finally apply the public export boundary of $\mathsf{TailBudgetCoherence}^{\uparrow}$. Its finite Real-completion route supplies the TailMeet threshold, observation budget, selector budget, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, and $\mathsf{CauchyLimitSeal}^{\uparrow}$ in front of the same S, U, B rows. Since neither packet carries quotient completion equality, selected limits, host completed metric spaces, ambient completeness, or an unbudgeted selector, the displayed route exhausts the public completion handoff. □

Theorem 423.19 (CauchyCompletionFunctor finite-observation selector factorization)**.** *Let $F = (M, R, S, U, B, E, P, T, N)$ be an accepted* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *packet, and let $Q = (B_Q, S_Q, W_Q, D_Q, R_Q, E_Q,$ be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet serving the same completion-facing seal rows. Every public completion consumer of F factors first through the selector route*

$$B_Q \longmapsto S_Q \longmapsto W_Q \longmapsto D_Q \longmapsto R_Q \longmapsto E_Q$$

before reading the functor rows S, U, B from F. The composed route exports no quotient completion equality, selected limit, host completed metric space, ambient completeness theorem, host real equality, countable choice principle, or hidden selector.

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket finite observation selector factorization`

Proof. Begin with Definition 423.12. It confines every public completion consumer of F to the displayed source metric row, regular-Cauchy row, completion seal, monad schedule, universal-property row, classifier ledger, transport rows, provenance rows, and local naming row.

Next apply Definition 423.13. The completion-facing seal cannot be read directly from F; it first passes through the finite observation-budget service attached to the same seal-facing rows.

Use Definition 423.18 to keep the budgeted completion route coherent with the TailMeet threshold, StreamName window, dyadic ledger, RegSeqRat readback, tail-agreement seal, and Cauchy-limit seal. This prevents a consumer from inserting an unbudgeted completion selector between the observation route and the functor rows.

Finally apply Definition 782.10. The accepted selector packet Q supplies the diagonal finite-observation route $B_Q, S_Q, W_Q, D_Q, R_Q, E_Q$ before any completion-facing seal row is opened. Since the selector packet and the functor packet contain no coordinates for quotient completion equality, selected limits, host completed metric spaces, ambient completeness, host real equality, countable choice, or hidden selectors, every public completion consumer reaches S, U, B only through the displayed selector route. □

Theorem 423.20 (CauchyCompletionFunctor selector-budget determinacy)**.** *Let $F = (M, R, S, U, B, E, P, T, N)$ be an accepted* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *packet, and let $Q = (B_Q, S_Q, W_Q, D_Q, R_Q, E_Q, H_Q, C_Q, P_Q, N_Q)$ be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet serving the same completion-facing seal rows. Suppose two public completion consumers have the same selector route*

$$B_Q \longmapsto S_Q \longmapsto W_Q \longmapsto D_Q \longmapsto R_Q \longmapsto E_Q$$

and read the same displayed source, regular-Cauchy, classifier, transport, provenance, and naming rows of F. Then the two consumers determine the same completion seal S, the same unit-and-bind schedule U, and the same universal-property row B.

The determined rows are only the displayed rows of F reached through the finite selector route. No consumer thereby obtains quotient completion equality, selected limits, host completed metric spaces, ambient completeness, host real equality, countable choice, or a hidden selector.

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorUp.CauchyCompletionFunctorPacket selector budget determinacy`

Proof. Apply Definition 423.19. Both consumers must pass through the same accepted selector route $B_Q, S_Q, W_Q, D_Q, R_Q, E_Q$ before reading the completion-facing rows of F.

Next use Definition 423.12. Once the selector route is fixed, the public completion surface of F exposes only $M, R, S, U, B, E, P, T, N$, so the completion seal, unit-and-bind schedule, and universal-property row have no second public source.

Apply Definition 423.11 to the composed reads. The monadic continuation ledger can consume only the displayed functor rows already reached through the selector route, and it cannot add a separate schedule or universal-property witness.

Finally apply Definition 423.14. The common finite observation route fixes the seal-facing read of S; with S fixed, the public export and bind-ledger exhaustion fix U and B as the corresponding displayed rows of F.

Carrier non-escape supplies the exclusions. Neither the selector packet nor the completion-functor packet contains coordinates for quotient completion equality, selected limits, host completed metric spaces, ambient completeness, host real equality, countable choice, or hidden selectors, so no such object can distinguish the two consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ packet is generated from a source metric row, regular-Cauchy family rows, a $\mathsf{RealCauchyCompletion}^{\uparrow}$ seal, a $\mathsf{CauchyCompletionMonad}^{\uparrow}$ unit-and-bind schedule, a $\mathsf{CompletionUniversalProperty}^{\uparrow}$ extension-uniqueness row, classifier transport, package provenance, transport routes, and a local naming ledger.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionFunctor}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 423.12, Definition 423.13, Definition 423.3, Definition 423.4, Definition 423.6, and Definition 423.7 bind the public completion export, observation-budget factorization, unit laws, multiplication laws, classifier transport, and universal-property extension exactness as the mature treatment.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionFunctor}^{\uparrow}}, \mathsf{bridgeChecked})$

Chapter 424

A Concrete Naming Certificate for $\mathsf{ProductMetric}^{\uparrow}$

The $\mathsf{ProductMetric}^{\uparrow}$ interface records the ordinary product-metric construction as a finite BEDC certificate. The human reference is the Kelley-style product metric on a binary product, but the certificate exposes only carrier rows, classifier rows, distance ledgers, projection routes, package provenance, and a local naming row. It does not assert a quotient product, host pair equality, a selected real limit, or classical choice data.

This certificate consumes the sibling rows of chapter 57, chapter 38, and chapter 34. The $\mathsf{Met}^{\uparrow}$ component classifiers, $\mathsf{Real}^{\uparrow}$-valued distance witness rows, and $\mathsf{Prod}^{\uparrow}$ projection rows are read before the product-distance ledger is available to any $\mathsf{ProductMetric}^{\uparrow}$ consumer. The product-metric packet transports those three sibling surfaces through its finite BHist ledger rather than introducing a quotient product, selected host limit, or host pair-equality route.

Definition 424.1 (ProductMetric BHist carrier)**.** *A* $\mathsf{ProductMetric}^{\uparrow}$ *packet is a finite* BHist *row*

$$Q = (X, Y, d_X, d_Y, \Pi, \delta, H, C, P, N)$$

with the following displayed coordinates:

1. *X and Y are two accepted* $\mathsf{Met}^{\uparrow}$ *carrier and classifier rows, including their visible source histories and local metric-space naming rows;*
2. *d_X and d_Y are the* $\mathsf{Real}^{\uparrow}$*-valued distance witness rows consumed from the two component* $\mathsf{Met}^{\uparrow}$ *packets;*
3. *Π is the displayed* $\mathsf{Prod}^{\uparrow}$ *pairing row whose first and second projections read the two component histories;*
4. *δ is the chosen product-distance ledger, either the displayed max row for the two component distances or a displayed dyadic-sum bound row for them;*
5. *H stores componentwise* hsame *transports for both component carriers, both component classifiers, both distance witnesses, the* $\mathsf{Prod}^{\uparrow}$ *row, and the product-distance ledger;*
6. *C stores the* Cont *routes for the two projections, the component distance reads, the product-distance ledger read, and the local product-metric consumer route;*
7. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ProductMetric}^{\uparrow}}$ *row.*

The carrier is this finite packet. It contains no quotient product, no host pair equality, no selected real limit, and no classical choice field.

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricTasteGate single carrier alignment`

Theorem 424.2 (ProductMetric NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ProductMetric}^\uparrow}$ *surface for the carrier of Definition 424.1 consists of five finite obligations: carrier admission for Q, componentwise classifier transport along the two* $\mathsf{Met}^\uparrow$ *classifiers and the* $\mathsf{Prod}^\uparrow$ *pairing row, product-distance ledger exactness for δ, projection non-escape through the two displayed* Cont *routes, and package provenance through P and N. These obligations are read only from* $\mathsf{Met}^\uparrow$, $\mathsf{Real}^\uparrow$, $\mathsf{Prod}^\uparrow$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

Proof. Carrier admission is the projection of the finite packet Q. The two component metric carriers, their classifiers, their real-valued distance witnesses, the product pairing row, the chosen distance ledger, the transport rows, the continuation rows, package provenance, and local naming row are all stored coordinates.

Classifier transport is componentwise. A classified change in the first component is read through the first $\mathsf{Met}^\uparrow$ classifier and the first projection of Π, while a classified change in the second component is read through the second classifier and the second projection of Π.

The product-distance ledger δ is then consumed after the two component distance witnesses have been displayed. Whether δ is represented as max or as a displayed dyadic-sum bound, it is a BEDC ledger row over the two visible $\mathsf{Real}^\uparrow$ distances, not a host-level metric proof.

The package and naming rows record that these obligations are the public surface. Since no coordinate of Q is a quotient product, host pair equality, selected real limit, or classical choice field, none of those data can be exported by the certificate. □

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier namecert obligations`

Theorem 424.3 (ProductMetric classifier stability)**.** *Let Q and Q' be accepted* $\mathsf{ProductMetric}^\uparrow$ *packets. If their two* $\mathsf{Met}^\uparrow$ *component carrier rows, classifiers,* $\mathsf{Real}^\uparrow$ *distance witness rows,* $\mathsf{Prod}^\uparrow$ *pairing rows, product-distance ledgers,* Pkg *provenance rows, and local* NameCert *rows are transported componentwise by the displayed* hsame *rows and read through the displayed* Cont *routes, then the* $\mathsf{ProductMetric}^\uparrow$ *classifier transports exactly those packet rows.*

Proof. Unpack Q and Q' by Definition 424.1. The only carrier data available to the classifier are the two metric components, the two distance witnesses, the product row, the distance ledger, and the recorded transport, continuation, provenance, and naming rows.

Transport the first component through the first $\mathsf{Met}^\uparrow$ classifier and the first projection of Π. Transport the second component through the second classifier and the second projection of Π.

The two distance witness rows transport with their source component rows, and the product-distance ledger transports after those two witnesses are matched. Thus the classifier is stable exactly on the displayed BEDC packet, with no appeal to host pair equality or quotient product equality. □

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier classifier stability`

Theorem 424.4 (ProductMetric component distance transport)**.** *Let* $Q = (X, Y, d_X, d_Y, \Pi, \delta, H, C, P, N)$ *be an accepted* $\mathsf{ProductMetric}^\uparrow$ *packet. Componentwise classifier transport of the two* $\mathsf{Met}^\uparrow$ *rows transports the two* $\mathsf{Real}^\uparrow$ *distance witness rows d_X and d_Y along the displayed* hsame *rows in H and the component distance reads in C. The product-distance ledger δ then reads exactly those transported component distances.*

Proof. Project the carrier of Definition 424.1. The first component route contains X and d_X, while the second component route contains Y and d_Y.

Apply Definition 424.3. Transport in the first component moves the first metric carrier, its classifier, and its distance witness together; transport in the second component moves the corresponding second rows.

The product-distance ledger is read only after both component distances have been displayed. Thus δ consumes the transported d_X and d_Y rows and not a host-level product metric or quotient equality. □

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier component distance transport`

Theorem 424.5 (ProductMetric projection route exactness)**.** *For every accepted* $\mathsf{ProductMetric}^{\uparrow}$ *packet* $Q = (X, Y, d_X, d_Y, \Pi, \delta, H, C, P, N)$*, each projection consumer route is exactly one of the two displayed* $\mathsf{Prod}^{\uparrow}$ *projection routes in* Π*. The first route reads* X *and* d_X*; the second route reads* Y *and* d_Y*; both routes carry only the corresponding* $\mathsf{Met}^{\uparrow}$ *row,* $\mathsf{Real}^{\uparrow}$ *distance witness,* hsame *transport,* Cont *read, package row, and local naming row.*

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier projection route exactness`

Proof. Begin with a projection consumer. By Definition 424.1, the only product coordinate is Π, and Π exposes only the first and second projection reads.

The exact first route is the first half of Definition 424.10; it reaches X and d_X through the stored continuation row. The exact second route is the second half of the same theorem; it reaches Y and d_Y through its stored continuation row.

Component transport is already accounted for by Definition 424.4. Therefore no projection consumer can bypass Π to read host pair equality, a quotient product, a selected real limit, or classical choice data. □

Theorem 424.6 (ProductMetric MetricSpace obligation package)**.** *The downstream* $\mathsf{Met}^{\uparrow}$ *obligation package exposed by an accepted* $\mathsf{ProductMetric}^{\uparrow}$ *packet* $Q = (X, Y, d_X, d_Y, \Pi, \delta, H, C, P, N)$ *consists of component classifier transport, component distance transport, exact projection routes through* Π*, product-distance ledger exactness for* δ*, and the non-escape boundary for quotient products, host pair equality, selected real limits, and classical choice data.*

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier metricspace obligation package`

Proof. First collect the component obligations. Classifier transport is Definition 424.3, and component distance transport is Definition 424.4.

Next collect the product-facing routes. Projection route exactness is Definition 424.5, and the product-distance ledger is the δ row identified by Definition 424.2.

Finally apply Definition 424.11. The downstream metric-space consumer is anchored exactly at Π, the two component metric certificates, and δ, while the finite carrier excludes all non-displayed product or choice data. □

Theorem 424.7 (ProductMetric component diagonal boundary)**.** *For every accepted* $\mathsf{ProductMetric}^{\uparrow}$ *packet*

$$Q = (X, Y, d_X, d_Y, \Pi, \delta, H, C, P, N),$$

any diagonal component comparison factors through the two $\mathsf{Met}^{\uparrow}$ *classifiers, the displayed* $\mathsf{Prod}^{\uparrow}$ *projections in* Π*, and the two* $\mathsf{Real}^{\uparrow}$ *distance witness rows* d_X *and* d_Y*. The comparison does not export host pair equality, quotient-product equality, a selected real limit, or classical choice data.*

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier component diagonal boundary`

Proof. Project the finite carrier of Definition 424.1. The only component data available to a diagonal comparison are the two metric-space rows, the two distance witnesses, and the product projection row Π.

Use Definition 424.3 to transport the two component classifiers together with their displayed rows. Then use Definition 424.5 to force every component read through the first or second projection route of Π.

Finally apply Definition 424.4. The comparison reaches d_X and d_Y only as $\mathsf{Real}^{\uparrow}$ witness rows attached to those component routes, so no host pair equality or quotient-product equality is introduced. □

Theorem 424.8 (ProductMetric distance-ledger triangle route)**.** *Every triangle-style consumer of the product-distance ledger δ first reads the two component distance witnesses d_X and d_Y, then reads the displayed max row or displayed dyadic-sum bound row chosen by δ. The route is anchored by the component classifiers, component distance transport, and the downstream* $\mathsf{Met}^{\uparrow}$ *obligation package, not by a host-level product metric proof.*

Proof. Start with the carrier of Definition 424.1. The ledger δ is stored only after the two component distance witness rows, so a triangle-style consumer has no earlier product-distance coordinate to read.

Apply Definition 424.3 and Definition 424.4. They transport the two component metric rows and expose the two real-valued distance witnesses before any product-distance ledger read.

Finally use Definition 424.6. Its anchor makes δ the product-facing metric-space ledger, represented by the displayed max row or displayed dyadic-sum bound row, and excludes quotient products, host pair equality, selected real limits, and classical choice data. □

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier distance ledger triangle route`

Theorem 424.9 (ProductMetric RealUp consumer package)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{ProductMetric}^{\uparrow}$ *packet sees exactly the product row Π, the component distance witnesses d_X and d_Y, the product-distance ledger δ, the transport rows H, the continuation routes C, the package provenance P, and the local naming row N. It does not see quotient products, host pair equality, selected real limits, or classical choice data.*

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier realup consumer package`

Proof. Read the consumer request through Definition 424.1. The real-valued rows exposed by the carrier are d_X, d_Y, and the ledger δ, with Π, H, C, P, and N recording how those rows are reached.

Use Definition 424.7 for the component side. It forces diagonal and projection-facing reads through the two component classifiers, Π, and the two displayed distance witnesses.

Use Definition 424.8 for the product-distance side. Since every ledger read first passes through d_X and d_Y and then through the displayed max or dyadic-sum row, a $\mathsf{Real}^{\uparrow}$ consumer receives only the finite packet rows named in the statement. □

Theorem 424.10 (ProductMetric projection non-escape)**.** *Every projection consumer of an accepted* $\mathsf{ProductMetric}^{\uparrow}$ *packet factors through the displayed* $\mathsf{Prod}^{\uparrow}$ *row Π, the corresponding* $\mathsf{Met}^{\uparrow}$ *component carrier and classifier row, the matching* $\mathsf{Real}^{\uparrow}$ *distance witness, the stored* hsame *transport, the stored* Cont *projection route, the* Pkg *provenance row, and the local* $\mathsf{NameCert}$ *row. No projection consumer can read a quotient product, host pair equality, selected real limit, or classical choice data from the packet.*

Proof. Start with a projection request. The packet has only one product coordinate, namely the displayed $\mathsf{Prod}^{\uparrow}$ row Π, so the request must read either its first projection route or its second projection route.

On the first route, the consumer reaches the first $\mathsf{Met}^{\uparrow}$ carrier and classifier and then the first real-valued distance witness. On the second route, it reaches the corresponding second component rows.

The transport and continuation coordinates keep each projection attached to its component route, and P and N record the provenance and local naming surface. Since the carrier does not include any further product object or host equality row, the two projection routes exhaust the packet boundary. □

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier projection non escape`

Theorem 424.11 (ProductMetric MetricSpace anchor)**.** *An accepted* $\mathsf{ProductMetric}^{\uparrow}$ *packet anchors a downstream* $\mathsf{Met}^{\uparrow}$ *consumer exactly at the displayed product carrier* Π*, the component* $\mathsf{Met}^{\uparrow}$ *classifiers, and the product-distance ledger* δ*. The consumer may use the two component* $\mathsf{Real}^{\uparrow}$ *distance witnesses and the ledger rule for max or displayed dyadic sum, but it receives no quotient product, no host pair equality, no selected real limit, and no classical choice data.*

Proof. Read the downstream metric-space request through the product carrier row. The row Π supplies only the two component projections, so every endpoint read is decomposed into first and second component reads.

For each component read, the corresponding $\mathsf{Met}^{\uparrow}$ certificate supplies the classifier and the $\mathsf{Real}^{\uparrow}$ distance witness. The product-distance ledger δ is then the sole distance row exported by the product packet.

Thus the downstream metric-space surface is anchored by Π, the two component metric certificates, and δ. All further data remain outside the carrier because they are not coordinates of the finite BHist packet. □

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier metricspace anchor`

Theorem 424.12 (ProductMetric scoped dependency package)**.** *The scoped dependency package of an accepted* $\mathsf{ProductMetric}^{\uparrow}$ *carrier* $Q = (X, Y, d_X, d_Y, \Pi, \delta, H, C, P, N)$ *consists exactly of the two* $\mathsf{Met}^{\uparrow}$ *carrier and classifier rows, the two* $\mathsf{Real}^{\uparrow}$ *component distance witness rows, the* $\mathsf{Prod}^{\uparrow}$ *pairing and projection row* Π*, the product-distance ledger* δ*, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{ProductMetric}^{\uparrow}}$ *provenance.*

Classifier stability, component distance transport, projection exactness, and the downstream $\mathsf{Met}^{\uparrow}$ *anchor all factor through this package and through no host product or quotient equality row.*

Proof. Start with the carrier definition. Its visible coordinates are precisely the two metric components, two real distance rows, product row, distance ledger, and transport, continuation, package, and naming data.

Apply classifier stability and component distance transport. These rows keep the two component classifiers and the two component distance witnesses aligned under the displayed hsame and Cont routes.

Apply projection route exactness and the metric-space anchor. They force every product-facing consumer through Π and then through δ. The listed rows therefore form the whole scoped dependency package. □

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier scoped dependency package`

Theorem 424.13 (ProductMetric distance-ledger scope)**.** *Every accepted* $\mathsf{ProductMetric}^{\uparrow}$ *distance-ledger read is scoped by the route*

$$(X, Y, \Pi) \longmapsto (d_X, d_Y) \longmapsto \delta.$$

The first stage reads the two $\mathsf{Met}^{\uparrow}$ *component classifiers through the* $\mathsf{Prod}^{\uparrow}$ *projections, the second stage transports the two* $\mathsf{Real}^{\uparrow}$ *component distance rows through* BHist, hsame, *and* Cont, *and the final stage consumes the displayed max or dyadic-sum product-distance ledger with* Pkg *and* $\mathsf{NameCert}_{\mathsf{ProductMetric}^{\uparrow}}$ *provenance.*

This is the distance-ledger triangle route available to a downstream $\mathsf{Met}^{\uparrow}$ *consumer; it does not export host pair equality, a quotient product, or a selected real limit.*

Proof. Project the product row Π. Projection exactness says that every first-component or second-component read enters through one of its two displayed projection routes.

Use component distance transport to attach d_X and d_Y to those routes. The component classifiers supply the only admissible transport for the two real-valued distance witnesses.

Finally apply the distance-ledger triangle route and the scoped dependency package. The product-distance row δ is read after the component distances and is carried by the displayed package and naming provenance, so no external product metric proof can enter. □

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier distance ledger scope`

Theorem 424.14 (ProductMetric Real classifier bridge)**.** *Let* $Q = (X, Y, d_X, d_Y, \Pi, \delta, H, C, P, N)$ *be an accepted* $\mathsf{ProductMetric}^{\uparrow}$ *packet. If the first and second component distance rows are transported by their component* $\mathsf{Met}^{\uparrow}$ *classifiers, then the product-distance ledger* δ *exports the same* $\mathsf{Real}^{\uparrow}$ *classifier row used by the downstream* $\mathsf{ProductMetric}^{\uparrow}$ $\mathsf{Met}^{\uparrow}$ *anchor. The bridge is the finite route from the component classifier reads through* d_X *and* d_Y *to the product* $\mathsf{Real}^{\uparrow}$ *row carried by* δ*.*

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier real classifier bridge`

Proof. Start with the component transport. Apply Definition 424.4 to move d_X and d_Y along the displayed component classifier rows and their hsame and Cont routes.

Next read the real-valued consumer surface. Apply Definition 424.9; it identifies the visible $\mathsf{Real}^{\uparrow}$ rows as exactly the two component distance witnesses, the product-distance ledger δ, and the transport, continuation, provenance, and naming rows.

Finally use the downstream anchor and scope theorem. By Definition 424.11, the metric consumer reads the product distance only through Π, the component classifiers, and δ; by Definition 424.13, δ is reached after the transported component distances. Therefore the product packet exports one $\mathsf{Real}^{\uparrow}$ classifier row for the product distance, with no host pair equality, quotient product, selected real limit, or external metric proof. □

Theorem 424.15 (ProductMetric Real classifier public export)**.** *Let* $Q = (X, Y, d_X, d_Y, \Pi, \delta, H, C, P, N)$ *be an accepted* $\mathsf{ProductMetric}^{\uparrow}$ *packet. The scoped product packet exports a public* $\mathsf{Met}^{\uparrow}$*-facing* $\mathsf{Real}^{\uparrow}$ *classifier surface exactly through the two component* $\mathsf{Met}^{\uparrow}$ *distance rows* d_X *and* d_Y*, the* $\mathsf{Prod}^{\uparrow}$ *pairing row* Π*, the product-distance ledger* δ*, the displayed* hsame *and* Cont *transports, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{ProductMetric}^{\uparrow}}$ *row. It exports no host pair equality, quotient product, selected real limit, or external metric proof.*

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier real classifier public export`

Proof. First build the component distance surface. Apply Definition 424.4; the two component $\mathsf{Met}^{\uparrow}$ classifiers carry the $\mathsf{Real}^{\uparrow}$ distance rows d_X and d_Y through the displayed hsame and Cont routes.

Next collect the public consumer package. Apply Definition 424.9; a $\mathsf{Real}^{\uparrow}$ consumer sees only the product row Π, the component distance witnesses, the product-distance ledger δ, and the provenance and naming rows P and N.

Finally repack the route as a $\mathsf{Met}^{\uparrow}$-facing export. Apply Definition 424.11 to anchor the downstream metric consumer at Π, the component classifiers, and δ; apply Definition 424.13 to force the ledger read after the component distances; then apply Definition 424.14 to identify the exported $\mathsf{Real}^{\uparrow}$ classifier row. The excluded host and quotient data are absent because none is a coordinate of Q. □

Theorem 424.16 (ProductMetric standard MetricSpace bridge certificate)**.** *Let $Q = (X, Y, d_X, d_Y, \Pi, \delta, H, C, P, N$ be an accepted $\mathsf{ProductMetric}^{\uparrow}$ packet. Then Q supplies the standard $\mathsf{Met}^{\uparrow}$ product bridge certificate exactly through the two component $\mathsf{Met}^{\uparrow}$ classifier surfaces, the two $\mathsf{Real}^{\uparrow}$ component distance rows d_X and d_Y, the $\mathsf{Prod}^{\uparrow}$ pairing and projection row Π, the product-distance ledger δ, and the displayed BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{ProductMetric}^{\uparrow}}$ provenance.*

The bridge certificate is the public route that a downstream $\mathsf{Met}^{\uparrow}$ consumer reads when it treats the product carrier as a metric-space object. It has no additional coordinate for host pair equality, quotient products, selected real limits, compactness, or an external metric proof.

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier standard metricspace bridge certificate`

Proof. First collect the scoped packet. By Definition 424.12, every accepted product packet exposes exactly the two component metric rows, the two real distance rows, the product row, the distance ledger, and the displayed transport, continuation, package, and naming provenance.

Next identify the distance route. By Definition 424.13, every product-distance read passes from (X, Y, Π) through (d_X, d_Y) to δ. The existing $\mathsf{Met}^{\uparrow}$ semantic certificate surface supplies the $\mathsf{Met}^{\uparrow}$ distance-witness reading, and the existing $\mathsf{Prod}^{\uparrow}$ semantic certificate surface supplies the pairing and projection reading used by Π.

Finally repack the public consumer view. Apply Definition 424.15 to expose the $\mathsf{Real}^{\uparrow}$ classifier row carried by the product distance, and apply Definition 424.5 to keep each component read on the displayed projection route. These rows assemble the standard product $\mathsf{Met}^{\uparrow}$ bridge certificate, and no non-displayed host or quotient datum is available from Q. □

Theorem 424.17 (ProductMetric public MetricSpace export)**.** *Every accepted $\mathsf{ProductMetric}^{\uparrow}$ packet $Q = (X, Y, d_X, d_Y, \Pi, \delta, H, C, P, N)$ exports a public $\mathsf{Met}^{\uparrow}$ surface exactly through the two component $\mathsf{Met}^{\uparrow}$ classifier rows X, Y, the two $\mathsf{Real}^{\uparrow}$ distance rows d_X, d_Y, the $\mathsf{Prod}^{\uparrow}$ projection row Π, the product-distance ledger δ, componentwise hsame and displayed Cont routes H, C, Pkg provenance P, and the local $\mathsf{NameCert}_{\mathsf{ProductMetric}^{\uparrow}}$ row N.*

The export excludes quotient products, host pair equality, selected real limits, compactness, and external metric proofs.

Lean4 ✓ `BEDC.Derived.ProductMetricUp.ProductMetricCarrier public metricspace export`

Proof. First apply the standard MetricSpace bridge certificate. It assembles the downstream product metric surface from the two component metric classifiers, component real-distance rows, the product projection row, the distance ledger, and the displayed transport, continuation, package, and naming rows.

Next apply the Real classifier public export. This identifies the $\mathsf{Real}^{\uparrow}$ surface consumed by the product distance as exactly the route through $d_X, d_Y, \Pi, \delta, H, C, P, N$.

Finally apply projection route exactness. Each component read enters through the corresponding displayed projection route in Π, so no consumer can bypass the packet to obtain host pair equality, a quotient product, a selected real limit, compactness, or an external metric proof. □

Theorem 424.18 (ProductMetric mature consumer exhaustion)**.** *Every mature* $\mathsf{ProductMetric}^{\uparrow}$ *consumer is exhausted by the public* $\mathsf{Met}^{\uparrow}$ *export of Definition 424.17, the standard bridge certificate of Definition 424.16, projection exactness through Definition 424.5, the* $\mathsf{Real}^{\uparrow}$ *classifier export of Definition 424.15, and the product-distance ledger routes of Definition 424.13. The exhausted surface contains exactly the two component metric rows, their real-valued distance witnesses, the* $\mathsf{Prod}^{\uparrow}$ *projection row, the product-distance ledger, the displayed* hsame *and* Cont *routes, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{ProductMetric}^{\uparrow}}$ *row.*

No mature consumer receives a quotient product, host pair equality, selected real limit, compactness witness, classical choice datum, or external metric proof.

Proof. Read the consumer through the public $\mathsf{Met}^{\uparrow}$ export. That theorem exposes the same finite packet surface already named by the carrier: component metrics, component distances, the product projection row, the product-distance ledger, transport rows, continuation routes, package provenance, and local naming data.

Next apply the standard bridge certificate and projection route exactness. These force every metric-space read to pass through the two component classifiers, the two displayed projections in Π, and the product-distance ledger δ.

Finally apply the $\mathsf{Real}^{\uparrow}$ classifier export and the distance-ledger scope theorem. They identify the real-valued part of the product metric as the route from d_X and d_Y to δ. Since none of the excluded host or quotient data is a coordinate of the packet, the listed routes exhaust the mature consumer boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProductMetric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ProductMetric}^{\uparrow}$ packet is generated from two $\mathsf{Met}^{\uparrow}$ carrier and classifier rows, two $\mathsf{Real}^{\uparrow}$ distance witness rows, a $\mathsf{Prod}^{\uparrow}$ pairing row, a product-distance ledger, componentwise hsame transport, projection Cont routes, Pkg provenance, and a local naming row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ProductMetric}^{\uparrow}}$, maturePackageClosed)

Scope closed: The scoped rows are Definition 424.12 and Definition 424.13; the public export row is Definition 424.17, which binds every product-distance read to the displayed component metrics, pairing row, distance ledger, projection routes, package provenance, and local naming surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ProductMetric}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.ProductMetricUp.ProductMetricCarrier\_metricspace\_anchor`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close quotient products, host pair equality, selected real limits, classical choice data, compactness of the product, or bridge checking.

Upgrade path: Bridge checking requires a Lean-checked standard bridge theorem for the displayed public $\mathsf{Met}^{\uparrow}$ export.

Chapter 425

A Concrete Naming Certificate for $\mathsf{CauchyErrorCertificate}^{\uparrow}$

The $\mathsf{CauchyErrorCertificate}^{\uparrow}$ interface records the explicit finite error ledger used by completion-facing real names. In the Bishop–Bridges constructive-analysis reading, convergence data are consumed through moduli and displayed bounds. This packet expresses that surface as BEDC rows over regular rational readback, dyadic tail control, finite error budgeting, provenance, and local naming.

The chapter consumes the finite observation-budget surface of chapter 611. That budget chapter fixes which $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows may be inspected, while the present certificate records the error ledger that bounds those inspected rows.

Definition 425.1 (CauchyErrorCertificate carrier)**.** *A* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (R, M, T, E, P, N)$$

with the following visible coordinates:

1. *R is the readback route through* $\mathsf{RegSeqRat}^{\uparrow}$ *and the downstream* $\mathsf{Real}^{\uparrow}$ *seal used by the consumer request;*
2. *M is the unary precision modulus row selecting the finite index at which the requested dyadic tolerance is read;*
3. *T is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *or* $\mathsf{DiagonalModulus}^{\uparrow}$ *row that records the selected tail estimate and its diagonal admission packet;*
4. *E is the* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *ledger that accounts for the dyadic tolerance, tail contribution, rounding contribution, and transported consumer error;*
5. *P is the* Pkg *provenance row naming the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *dependency certificates;*
6. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyErrorCertificate}^{\uparrow}}$ *row.*

The local classifier compares two carriers only by componentwise hsame *transport of R, M, T, E, P, and N, together with the displayed* Cont *routes carried by the readback and budget rows.*

Theorem 425.2 (CauchyErrorCertificate NameCert obligations)**.** *The* $\mathsf{NameCert}_{\mathsf{CauchyErrorCertificate}^{\uparrow}}$ *surface has five finite obligations: carrier habitation by Definition 425.1; classifier stability under the displayed* hsame *and* Cont *rows; exact routing of every requested dyadic error through M, T,*

and E before the read reaches R; provenance preservation for the DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows named by P; and non-escape of quotient streams, selected host limits, ambient completeness, and host real equality.*

Proof. Carrier habitation is finite packet assembly. The readback route, modulus row, tail or diagonal row, budget ledger, package provenance, and local certificate are all displayed coordinates of C.

Classifier stability is componentwise. Each coordinate is transported only by the stored hsame comparison and the corresponding Cont route, so an accepted packet remains inside the same error-ledger surface.

The exactness, provenance, and boundary clauses follow from the coordinate list. A consumer error request must read the modulus, tail or diagonal packet, and finite budget ledger before reaching the readback route, while P records the dependency certificates and no omitted quotient, selected limit, host-completeness, or host-equality row is present. □

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket namecert obligations`

Theorem 425.3 (CauchyErrorCertificate modulus soundness)**.** *For every accepted* CauchyErrorCertificate$^{\uparrow}$ *carrier $C = (R, M, T, E, P, N)$ and every finite dyadic tolerance request, the selected unary precision row M determines a finite tail or diagonal read in T, and the resulting budget entry in E bounds the downstream* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *readback route R at that tolerance. The bound is a displayed dyadic ledger row, not a host real inequality.*

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket modulus soundness`

Proof. Read the requested tolerance through the unary modulus coordinate M. This chooses the finite index at which the packet is allowed to inspect the regular rational route.

Use T to admit the corresponding dyadic tail or diagonal row. The row records exactly the tail estimate needed by the selected precision and passes it to the finite budget ledger.

Finally read E before consuming R. Since E is a FiniteErrorBudget$^{\uparrow}$ ledger, the downstream bound is the displayed dyadic accounting row over the chosen tolerance and not an external inequality in a host real structure. □

Theorem 425.4 (CauchyErrorCertificate budget handoff closure)**.** *Let $C = (R, M, T, E, P, N)$ be an accepted* CauchyErrorCertificate$^{\uparrow}$ *packet. If the budget row E is transported to a classifier-equivalent budget row E', and if the displayed* Cont *routes $M \to T \to E'$ and $R \to E' \to P$ are supplied, then the transported tuple (R, M, T, E', P, N) is again an accepted* CauchyErrorCertificate$^{\uparrow}$ *packet over the same readback, modulus, tail, provenance, and local* NameCert *rows.*

Proof. Project the carrier rows from Definition 425.1. The accepted packet supplies unary admissibility for R, M, T, E, P, N, the original budget-facing routes, the BHist packet, the Pkg provenance, and the local naming row.

Transport only the budget admissibility along the displayed hsame comparison from E to E'. The readback, modulus, tail, provenance, and local NameCert rows remain the same coordinates of the packet.

Finally replace the two budget-facing continuation routes by the supplied routes $M \to T \to E'$ and $R \to E' \to P$. Repacking the unchanged BHist, Pkg, and NameCert provenance with the transported budget row yields the accepted tuple (R, M, T, E', P, N). □

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket budget handoff closure`

Theorem 425.5 (CauchyErrorCertificate non-escape boundary)**.** *An accepted* CauchyErrorCertificate$^{\uparrow}$ *carrier exports only its displayed readback route, unary precision modulus, dyadic tail or diagonal packet, finite error-budget ledger, package provenance, local naming row, and the attached* BHist*,* hsame*, and* Cont *transport. It exports no quotient stream equality, no selected host limit, no ambient completeness theorem, and no host real equality assertion.*

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket non escape boundary`

Proof. Inspect the carrier coordinates. Each visible field is one of R, M, T, E, P, or N, together with the ambient finite history and transport rows needed to compare them.

The modulus and budget rows control only finite dyadic requests. The tail or diagonal packet supplies the finite estimate consumed by that budget, and the readback route exposes only the named regular rational and real seal rows.

No coordinate contains a quotient of streams, a selected limit, an ambient complete space, or an equality proof for host real numbers. Therefore no such object can be exported by the certificate. □

Theorem 425.6 (CauchyErrorCertificate downstream handoff)**.** *Every downstream completion, diagonal, or validated-numerics consumer of an accepted* CauchyErrorCertificate$^{\uparrow}$ *carrier receives a finite packet over the same unary modulus, dyadic tail or diagonal packet, finite error-budget ledger,* DyadicRatCore$^{\uparrow}$ *observations,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readbacks,* Real$^{\uparrow}$ *seal,* Pkg *provenance, and* NameCert *row. The handoff preserves the non-escape boundary of Definition 425.5.*

Proof. Begin with the modulus soundness theorem. It forces each requested tolerance through M, then through the displayed tail or diagonal packet T, and finally through the finite budget ledger E before the readback route R is consumed.

The provenance row P names the dependency certificates for the dyadic observations, stream windows, regular rational readbacks, and real seal. Transport along hsame and Cont therefore keeps the downstream packet on the same visible rows.

Apply the non-escape boundary. Since the carrier has no field for quotient streams, selected host limits, host completeness, or host real equality, the downstream handoff consists exactly of the listed finite BEDC rows. □

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket downstream handoff`

Theorem 425.7 (CauchyErrorCertificate budget-readback determinacy)**.** *Let* $C = (R, M, T, E, P, N)$ *and* $C' = (R', M', T', E', P', N')$ *be accepted* CauchyErrorCertificate$^{\uparrow}$ *carriers. Suppose the unary modulus rows* M, M'*, dyadic tail or diagonal rows* T, T'*, finite error-budget rows* E, E'*, and provenance rows* P, P' *are matched by the displayed* hsame *comparisons and* Cont *routes of the two packets. Then every completion, diagonal, or validated-numerics consumer reaches the same* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *readback boundary from* C *and* C'*. The packet has no alternate route through quotient streams, host limits, ambient completeness, or host real equality.*

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket budget readback determinacy`

Proof. Use Definition 425.3. A finite dyadic tolerance request must pass through the unary modulus row, then the tail or diagonal row, and then the finite error-budget ledger before it reaches the readback route.

The assumed hsame and Cont matches identify those three rows and their provenance rows between C and C'. Hence the downstream packet seen by a completion, diagonal, or validated-numerics consumer is the same packet described by Definition 425.6.

It remains to exclude hidden readback sources. By Definition 425.5, the carrier exports no quotient stream equality, selected host limit, ambient completeness theorem, or host real equality assertion. Thus the displayed modulus, tail, budget, and provenance ledger determines the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readback boundary. □

Theorem 425.8 (CauchyErrorCertificate uniform budget handoff)**.** *Let U be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet and let $C = (R, M, T, E, P, N)$ be an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *carrier consuming the tail ledger displayed by U. For every finite family tolerance request, the handoff factors through the shared window family of U, the shared modulus selected by its tail ledger, the dyadic tolerance row, the finite tail ledger, the finite Cauchy error budget E, and then the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *readback boundary R. The resulting packet is a finite BEDC error-budget handoff over the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, with no route through quotient streams, selected host limits, host real equality, or ambient completeness.*

Proof. Start on the uniform side. By Definition 435.9, each family tolerance request reaches a recorded window family, a shared modulus row, a dyadic tolerance row, and a finite tail-ledger entry before any consumer can read a tail estimate.

Next package that tail evidence for the regular-rational consumer. Apply Definition 435.16: the same finite ledger supplies the $\mathsf{RegSeqRat}^{\uparrow}$ route consumed by downstream real-name interfaces, rather than a selected limit or an ambient completeness principle.

Now pass the displayed tail row into C. The modulus soundness theorem Definition 425.3 routes the dyadic request through M, through the tail or diagonal coordinate T, and into the finite error-budget ledger E before the readback boundary R is available.

Finally apply Definition 425.7. Once the shared modulus, tail ledger, budget row, and provenance rows are fixed, every completion, diagonal, or validated-numerics consumer sees the same $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ boundary. The non-escape boundaries of the two chapters exclude quotient streams, selected host limits, host real equality, and ambient completeness from the handoff. □

Theorem 425.9 (CauchyErrorCertificate modulus-budget composition)**.** *Let $C = (R, M, T, E, P, N)$ be an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet. Every precision request routed by the unary modulus row M composes with the dyadic tail or diagonal packet T and the finite error-budget ledger E before reaching the readback row R. The composed route consumes only the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seal, package provenance P, and local* NameCert *row N.*

Proof. Begin with the modulus row. By Definition 425.3, a requested tolerance enters the packet through M and is interpreted as a finite dyadic request.

Next read the tail or diagonal evidence. The same theorem routes the request through T, and the downstream handoff of Definition 425.6 keeps that evidence on the displayed dyadic observations, stream windows, regular rational rows, and real seal.

Finally consume the finite budget. The budget-readback determinacy theorem Definition 425.7 fixes the E and P rows before the consumer reaches R, while Definition 425.5 excludes quotient streams, host limits, ambient completeness, and host real equality. □

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket modulus budget composition`

Theorem 425.10 (CauchyErrorCertificate readback route uniqueness)**.** *Let $C = (R, M, T, E, P, N)$ and $C' = (R', M', T', E', P', N')$ be accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packets. If the modulus rows M, M', tail or diagonal rows T, T', finite error-budget rows E, E', and provenance rows P, P' are matched by the displayed* hsame *and* Cont *routes, then both packets determine the same* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback boundary. The boundary is therefore unique relative to the displayed M, T, E, P rows.*

Proof. First compose the request route in each packet by Definition 425.9. A readback can reach R or R' only through the corresponding M, T, E, P rows.

The assumed hsame and Cont matches identify those four rows componentwise. Applying Definition 425.7 then gives the same downstream completion, diagonal, or validated-numerics packet on both sides.

The non-escape boundary rules out any second readback source. Since neither carrier contains quotient streams, selected host limits, ambient completeness, or host real equality, the shared M, T, E, P ledger fixes the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ boundary. □

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket readback route uniqueness`

Theorem 425.11 (CauchyErrorCertificate diagonal-tail compatibility)**.** *For an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet $C = (R, M, T, E, P, N)$, a diagonal row and a tail-bound row accepted by the same packet feed the same finite error-budget ledger E. Their compatibility is witnessed inside the displayed tail or diagonal packet T and does not require host completeness, selected limits, quotient streams, or host real equality.*

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket diagonal tail compatibility`

Proof. Inspect the carrier rows. The packet has one tail-or-diagonal coordinate T and one finite budget coordinate E, both named by the same provenance row P and local certificate N.

Apply Definition 425.3. Both diagonal and tail-bound requests are routed by the same modulus row M before they are checked against the packet T.

The budget row is then fixed by Definition 425.9. The downstream handoff and budget-readback determinacy theorems identify the same E before any consumer reaches R.

Finally apply the non-escape boundary. Because the carrier has no host-completeness or selected-limit coordinate, diagonal and tail evidence can be compatible only through the displayed finite budget ledger. □

Theorem 425.12 (CauchyErrorCertificate uniform diagonal compatibility)**.** *Let U be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, let D be an accepted* $\mathsf{DiagonalModulus}^{\uparrow}$ *row, and let $C = (R, M, T, E, P, N)$ be an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet consuming both displayed inputs. If U and D feed the same accepted packet C, then every finite family tolerance request and every diagonal precision request pass through the same unary modulus row M, the same tail-or-diagonal packet T, and the same finite budget ledger E before reaching the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *readback boundary R. The combined route exports no quotient streams, selected host limits, ambient completeness principle, or host real equality.*

Proof. Start with the uniform-family route. By Definition 425.8, every finite family tolerance request reaches the Cauchy error certificate through the displayed uniform ledger and then enters the packet through the finite budget route visible in C.

Now read the diagonal request. The diagonal-tail compatibility theorem Definition 425.11 says that diagonal and tail evidence accepted by the same packet share the coordinate T and feed the same budget row E.

Compose the routes through the packet. By Definition 425.9, both requests are routed by the unary modulus row M, checked against the tail-or-diagonal packet T, and consumed by the ledger E before the readback boundary R is exposed.

Finally apply Definition 425.10 together with the non-escape boundary. Once M, T, E, and the provenance row are fixed, the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ boundary is unique inside the displayed carrier, and the absent quotient, selected-limit, completeness, and host-equality objects cannot supply an alternate route. □

Theorem 425.13 (CauchyErrorCertificate budget-window exhaustion)**.** *For an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet* $C = (R, M, T, E, P, N)$*, every finite dyadic tolerance request is exhausted by the displayed budget-window route before the readback row* R *is available. The route first reads the unary precision modulus* M*, then the tail or diagonal packet* T*, then the finite error-budget ledger* E*, and only then exposes the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *readback boundary named by* R*.*

No consumer of the packet can bypass this M, T, E *route through quotient streams, selected host limits, ambient completeness, or host real equality.*

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket budget window exhaustion`

Proof. Begin with a finite dyadic tolerance request. The modulus soundness theorem Definition 425.3 forces the request through the unary modulus row M and selects the finite tail or diagonal read in T.

Next consume the finite budget ledger. By Definition 425.9, the selected T row feeds E before any downstream read reaches R.

Finally apply readback route uniqueness and the non-escape boundary. The theorems Definition 425.10 and Definition 425.5 exclude any second route through non-displayed host objects, so the M, T, E budget window is exhausted before R is readable. □

Theorem 425.14 (CauchyErrorCertificate shared modulus transport)**.** *Let* $C = (R, M, T, E, P, N)$ *and* $C' = (R', M', T', E', P', N')$ *be accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packets whose classifier comparison identifies the displayed* M, T, E, P *rows by* hsame *and* Cont *transport. Then transport preserves the shared unary modulus route: every finite tolerance request read in* C *and transported to* C' *is routed through the matched row* M' *before it reaches* T'*,* E'*, and* R'*.*

The transport creates no indexwise hidden modulus and exports no modulus function outside the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket shared modulus transport`

Proof. Use the classifier comparison componentwise. The hypothesis identifies the unary modulus rows, tail or diagonal rows, finite budget rows, and provenance rows by the stored hsame comparisons and continuation routes.

Read a finite tolerance request in C. Budget-window exhaustion routes it through M, T, E before exposing R; transporting along the classifier comparison carries these same displayed rows to M', T', E' in C'.

It remains to exclude a hidden modulus. The carrier of Definition 425.1 has only one modulus coordinate, and the non-escape boundary rules out additional host data. Hence transport preserves the shared unary modulus row instead of selecting an indexwise modulus outside the packet. □

Theorem 425.15 (CauchyErrorCertificate shared modulus exhaustion)**.** *Let $C = (R, M, T, E, P, N)$ be an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet. Every finite tolerance read that enters the shared unary modulus row M is exhausted by the displayed sequence M, T, E, R: the read first selects the finite modulus boundary, then consumes the tail or diagonal row, then consumes the finite error-budget ledger, and only then reaches the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *readback boundary. No second modulus row, indexwise hidden selector, quotient stream equality, selected host limit, ambient completeness theorem, or host real equality is available to the read.*

Proof. Begin with the finite tolerance read. By Definition 425.3, the read enters the packet through the unary modulus row M and selects the tail or diagonal evidence in T.

Next exhaust the budget window. Theorem 425.13 routes the selected tail or diagonal row through the finite error-budget ledger E before the readback row R is exposed.

Finally exclude alternate modulus data. The shared modulus transport theorem Definition 425.14 keeps the route on the same displayed modulus row under classifier comparison, while the non-escape boundary removes quotient streams, selected host limits, ambient completeness, and host real equality from the carrier. □

Theorem 425.16 (CauchyErrorCertificate budget-seal comparison)**.** *Let $C = (R, M, T, E, P, N)$ and $C' = (R', M', T', E', P', N')$ be accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packets. If the displayed budget and seal-facing rows M, T, E, P and M', T', E', P' are matched by the packet classifiers, then every* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer comparing C and C' sees the same finite budget route before reaching the readback boundary. The comparison is carried by the displayed modulus, tail-or-diagonal, budget, provenance,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, not by host real equality or a selected limit.*

Proof. First route each consumer through the budget window. By Definition 425.15, every finite tolerance read in either packet passes through the displayed modulus, tail-or-diagonal, budget, and readback rows.

Now compare the packets. The hypotheses identify the M, T, E, P rows with M', T', E', P' by the packet classifiers, and Definition 425.14 carries the shared modulus route to the matched packet.

It remains to state what the seal-facing consumer receives. The readback route uniqueness theorem Definition 425.10 fixes the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ boundary relative to the displayed budget rows, and the seal budget package Definition 425.18 repacks those rows for the finite seal surface. □

Theorem 425.17 (CauchyErrorCertificate Real consumer unblock)**.** *For an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet $C = (R, M, T, E, P, N)$, the shared modulus exhaustion route and budget-seal comparison surface expose a finite Real consumer unblock package. A downstream* $\mathsf{Real}^{\uparrow}$ *consumer receives the displayed unary modulus M, tail or diagonal packet T, finite error-budget ledger E, provenance row P, readback boundary R,* hsame *transports,* Cont *routes,* Pkg *data, and* NameCert *row, and the consumer has no route through quotient streams, selected host limits, ambient completeness, host real equality, or bridge checking.*

Proof. Start with the exhaustive read. Theorem 425.15 routes every finite tolerance request through M, T, E before R is available.

Next bind comparison for seal-facing consumers. Theorem 425.16 shows that the same displayed rows determine the comparison surface seen by $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers.

Finally repack the consumer boundary. The scoped budget-window package Definition 425.22 supplies the displayed BHist, hsame, Cont, Pkg, and NameCert rows, while the non-escape boundary

excludes quotient streams, selected limits, ambient completeness, host real equality, and bridge checking. □

Theorem 425.18 (CauchyErrorCertificate seal budget package)**.** *For an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet* $C = (R, M, T, E, P, N)$*, modulus soundness, diagonal-tail compatibility, readback route uniqueness, and uniform diagonal compatibility assemble the finite* $\mathsf{Real}^{\uparrow}$ *seal budget package. Every completion-facing consumer receives the displayed unary modulus row* M*, tail or diagonal packet* T*, finite budget ledger* E*, provenance row* P*, and readback boundary* R *as one finite package over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

The package closes the error-budget obligation surface for the displayed certificate, while leaving quotient streams, selected host limits, ambient completeness, host real equality, and bridge checking outside the chapter.

Lean4 ✓ `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket seal budget package`

Proof. First bind the soundness route. Theorem 425.3 supplies the finite tolerance-to-budget route through M, T, and E.

Next bind compatibility. Theorem 425.11 states that diagonal and tail evidence accepted by the same packet feed the same finite budget ledger, and Theorem 425.12 identifies the uniform-family and diagonal routes through the same M, T, E coordinates.

Finally bind the seal boundary. Theorem 425.10 fixes the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ readback boundary relative to the displayed rows, and the non-escape boundary excludes all host-side completion objects. Repacking these rows gives the announced finite $\mathsf{Real}^{\uparrow}$ seal budget package. □

Theorem 425.19 (CauchyErrorCertificate composed budget readback handoff)**.** *Let* $C = (R, M, T, E, P, N)$ *be an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet. Suppose a binary-prefix* $\mathsf{BinaryExpansion}^{\uparrow}$ *regular handoff and a* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *real-seal handoff are both consumed through the same displayed unary modulus* M*, the same tail-or-diagonal row* T*, the same finite error-budget ledger* E*, and the same package provenance row* P*. Then every* $\mathsf{Real}^{\uparrow}$ *completion-facing read factors through the common finite route*

$$\textit{binary prefix window} \longrightarrow \textit{dyadic approximation row} \longrightarrow \textit{uniform tail ledger} \longrightarrow \textit{Cauchy error budget}$$
$$\longrightarrow \mathsf{RegSeqRat}^{\uparrow}\ \textit{readback} \longrightarrow \mathsf{Real}^{\uparrow}\ \textit{seal.}$$

The composed handoff exports no quotient stream, selected host limit, host real equality, or ambient completeness theorem. The only displayed data available to the read are the binary prefix window, dyadic approximation row, uniform tail ledger, finite Cauchy budget, readback row R*, provenance row* P*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Start with the binary-prefix side. Theorem 418.7 factors the $\mathsf{BinaryExpansion}^{\uparrow}$ regular handoff through the inspected prefix window, dyadic approximation row, and regular-sequence handoff boundary. Thus the read does not receive an independent infinite bitstream or a second rational stream.

Next attach the uniform Cauchy side. Theorem 425.8 routes the uniform real-seal handoff through the displayed modulus M, the common tail-or-diagonal row T, and the finite ledger E. The shared M, T, E, P hypotheses identify the binary and uniform routes before either reaches the readback boundary.

Now fix the downstream boundary. Theorem 425.10 identifies the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ readback route relative to the displayed modulus, tail-or-diagonal, budget, and provenance rows.

Finally package the seal-facing read. Theorem 425.18 repacks the same displayed rows as the finite $\mathsf{Real}^{\uparrow}$ seal budget package, while the non-escape boundary leaves quotient streams, selected host limits, host real equality, and ambient completeness outside the composed handoff. □

Theorem 425.20 (CauchyErrorCertificate schedule-fusion shared-modulus budget)**.** *Let $C = (R, M, T, E, P, N)$ be an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet. Suppose C consumes a displayed* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *shared-bound certificate whose meet row is the same unary modulus row M, and suppose the same schedule rows are packaged by an accepted* $\mathsf{RealScheduleFusion}^{\uparrow}$ *carrier. Then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer read factors through the single finite route*

$$\textit{fused schedule row} \longrightarrow \textit{window ledger} \longrightarrow \mathsf{RegSeqRat}^{\uparrow}\ \textit{readback} \longrightarrow \textit{shared meet modulus}$$
$$\longrightarrow \textit{dyadic tolerance ledger} \longrightarrow \textit{finite Cauchy error budget} \longrightarrow \mathsf{Real}^{\uparrow}\ \textit{seal.}$$

The route is carried only by the displayed schedule, window, readback, shared meet, dyadic tolerance, budget, provenance, BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It exports no quotient stream, selected host limit, ambient completeness theorem, host real equality, or bridge-checking oracle content.*

Proof. First bind the Cauchy budget route. Theorem 425.19 factors the completion-facing read through the finite budget and readback handoff of the accepted $\mathsf{CauchyErrorCertificate}^{\uparrow}$ packet, so the read reaches R only after it has passed through M, T, E, and P.

Next bind the shared modulus surface. Theorem 462.28 supplies the displayed shared-bound certificate for the $\mathsf{CauchyModulusMeet}^{\uparrow}$ row, and Theorem 462.23 forces each shared-bound consumer through the source modulus rows and the meet row before any downstream read is exposed.

Now lock the schedule side. Theorem 449.4 routes the $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ consumers through the fused schedule, window ledger, and regular-rational readback rows. Theorem 449.13 keeps that schedule route independent of seal-facing data not displayed by the carrier.

Finally identify the common route. The hypotheses say that the meet row read by the shared-modulus certificate is the same row M consumed by C, and that the fused schedule rows are the rows seen by the downstream consumer. Combining the three displayed routes gives the announced sequence from schedule row through window ledger, readback, shared meet modulus, dyadic tolerance ledger, finite error budget, and Real seal.

The non-escape clauses of the cited certificates leave quotient streams, selected limits, ambient completeness, host real equality, and bridge-checking oracle content outside the packet. Thus no consumer can bypass the single finite route by appealing to a host completion object. □

Theorem 425.21 (CauchyErrorCertificate schedule-fusion consumer determinacy)**.** *Let $C = (R, M, T, E, P, N)$ and $C' = (R', M', T', E', P', N')$ be accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packets. Suppose both packets are consumed through the same displayed* $\mathsf{RealScheduleFusion}^{\uparrow}$ *schedule rows, the same* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *shared-bound row, the same* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *tail ledger, and matched M, T, E, P budget rows after componentwise* hsame *and the displayed* Cont *transports. Then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of C and C' reaches the same finite* $\mathsf{Real}^{\uparrow}$ *seal boundary.*

The common boundary is determined only by the fused schedule row, shared modulus row, uniform tail ledger, matched finite error-budget rows, readback row, provenance row, BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data. It uses no quotient stream equality, selected host limit, host real equality, or ambient completeness principle.*

Proof. First lock the schedule side. Theorem 425.20 forces both consumers through the same fused schedule route before either read reaches a $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ seal-facing boundary.

Next identify the budget route. The shared modulus transport theorem Definition 425.14 carries the matched M rows across the displayed hsame and Cont transports, while the shared $\mathsf{UniformCauchyCriterion}^{\uparrow}$ tail ledger fixes the displayed T row used by the two accepted packets.

Now fix readback. Theorem 425.10 identifies the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ readback boundary once M, T, E, P are matched. Thus the two consumers cannot separate after the fused schedule, shared modulus, tail ledger, finite budget, and provenance rows have been identified.

Finally repack the seal surface. Theorem 425.18 packages the identified rows as the finite $\mathsf{Real}^{\uparrow}$ seal boundary. The non-escape boundary of Definition 425.5 excludes quotient streams, selected host limits, host real equality, and ambient completeness from supplying a second consumer boundary. □

Theorem 425.22 (CauchyErrorCertificate scoped budget-window package)**.** *For an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet* $C = (R, M, T, E, P, N)$*, the displayed modulus row, tail-or-diagonal packet, finite error-budget ledger, provenance row, readback boundary,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows form the scoped dependency surface for every dyadic error request. The scoped package exports no quotient stream, selected host limit, host real equality, or ambient completeness row.*

Proof. First bind the request route. Theorem 425.3 routes each dyadic error request through the modulus row and into the displayed tail-or-diagonal packet.

Next bind the finite window. Theorem 425.13 exhausts the request through M, T, E before the readback row is visible, and Theorem 425.14 keeps that route stable under the displayed hsame and Cont transports.

Now fix the readback boundary. Theorem 425.10 identifies the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ boundary relative to the displayed modulus, tail-or-diagonal, budget, and provenance rows.

Finally apply Theorem 425.18. It repacks the displayed rows as the finite seal budget package, while its boundary clause leaves quotient streams, selected host limits, host real equality, and ambient completeness outside the scoped surface. □

Theorem 425.23 (CauchyErrorCertificate public export)**.** *For an accepted* $\mathsf{CauchyErrorCertificate}^{\uparrow}$ *packet* $C = (R, M, T, E, P, N)$*, the carrier, the* $\mathsf{NameCert}_{\mathsf{CauchyErrorCertificate}^{\uparrow}}$ *obligations, modulus soundness, budget-window exhaustion, shared modulus transport, readback route uniqueness, Real consumer unblock, seal budget package, and scoped budget-window package assemble the public* $\mathsf{NameCert}_{\mathsf{CauchyErrorCertificate}^{\uparrow}}$ *export for* $\mathsf{Real}^{\uparrow}$ *completion-facing readers.*

The exported consumer receives exactly R, M, T, E, P, N *together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. It receives no quotient stream, selected host limit, ambient completeness row, host real equality, or bridge checking.*

Proof. First bind the displayed packet. The carrier of Definition 425.1 supplies R, M, T, E, P, N, and Definition 425.2 fixes the local $\mathsf{NameCert}_{\mathsf{CauchyErrorCertificate}^{\uparrow}}$ obligation surface over those rows.

Next bind the error-budget route. Theorem 425.3 sends each tolerance request through M and T into E, while Theorem 425.13 ensures that the budget route is exhausted before the readback boundary is available.

Now bind transport and readback. Theorem 425.14 preserves the shared modulus route under the displayed hsame and Cont rows, and Theorem 425.10 fixes the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ readback boundary relative to the displayed M, T, E, P rows.

Finally repack the public export. Theorem 425.17 states the consumer-facing package, Theorem 425.18 gathers it for completion-facing readers, and Theorem 425.22 supplies the scoped BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

The result is a public export because it exposes only the finite certificate surface already displayed by the packet. The non-escape boundary of Definition 425.5 leaves quotient streams, selected host limits, ambient completeness, host real equality, and bridge checking outside the export, so the theorem does not assert a new host real fact. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyErrorCertificate}\uparrow}$.

Constructive story: A $\mathsf{CauchyErrorCertificate}^{\uparrow}$ packet is generated from a regular-rational and real readback route, a unary precision modulus, a dyadic tail or diagonal row, a finite error-budget ledger, package provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyErrorCertificate}\uparrow}, \mathsf{scopedClosed})$

Scope closed: The chapter displays the carrier, NameCert obligations, modulus soundness route, budget-window exhaustion, shared modulus transport, readback determinacy, and finite seal budget package for dyadic error certificates.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyErrorCertificate}\uparrow}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CauchyErrorCertificateUp.CauchyErrorCertificatePacket\_namecert\_obligations`

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient streams, selected host limits, ambient real completeness, host real equality, or bridge checking.

Upgrade path: Further formal closure requires audit-clean and axiom-clean verification of the same scoped budget-window package.

Chapter 426

A Concrete Naming Certificate for $\mathsf{CompletionFunctor}^{\uparrow}$

The $\mathsf{CompletionFunctor}^{\uparrow}$ surface names the finite functorial completion packet that transports regular rational Cauchy data and continuous maps through the existing completion envelope. Following Bishop and Bridges, *Constructive Analysis*, it treats completion by explicit Cauchy data, moduli, and extension ledgers rather than by quotient completions or equality of host functions. The packet connects the completion monad of chapter 378, the universal-property surface of chapter 397, the real Cauchy completion surface of chapter 360, and the reflection boundary of chapter 403.

Definition 426.1 (CompletionFunctor carrier)**.** *A* $\mathsf{CompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, U, R, Q, A, G, E, T, H, C, P, N)$$

with the following displayed coordinates:

1. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion-envelope row that supplies unit and bind-facing completion reads;*
2. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension row for continuous maps out of the dense regular rational surface;*
3. *R is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *real-completion row that seals regular rational Cauchy input as a* $\mathsf{Real}^{\uparrow}$ *read;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose finite stream windows supply the dense observations;*
5. *A is the* $\mathsf{Real}^{\uparrow}$ *target seal row exposed by the completed source;*
6. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *dense map row, including its modulus, graph-read ledger, and finite input-output observation rows;*
7. *E is the transported extension ledger from G, Q, M, U, R, and A to a completion-facing* $\mathsf{ContinuousMap}^{\uparrow}$ *row;*
8. *T is the functoriality ledger comparing identity and composition reads by displayed* hsame *routes over the same source, map, extension, and seal rows;*
9. *H stores the componentwise* hsame *comparisons for the completion envelope, universal-property row, real-completion row, source row, target seal, dense map, extension ledger, functoriality ledger, package row, and local naming row;*

10. *C stores the* Cont *routes through which consumers read source windows, map graph entries, completion envelopes, extension rows, real seals, and functoriality ledgers;*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and local* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionFunctor}^{\uparrow}}$ *row.*

Two accepted carriers classify together only when all displayed rows are transported componentwise through H and read through the routes in C. The carrier has no quotient of Cauchy streams, no selected host limit, no equality of host functions, and no ambient completeness field.

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorTasteGate single carrier alignment`

Theorem 426.2 (CompletionFunctor NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CompletionFunctor}^{\uparrow}}$ *surface for Definition 426.1 consists of carrier admission, classifier stability, extension-ledger exactness, functorial identity and composition ledgers, unit-boundary compatibility, and non-escape of quotient completions, selected limits, host function equality, and ambient completeness. Every obligation is stated over the rows $M, U, R, Q, A, G, E, T, H, C, P, N$ and their displayed* hsame *and* Cont *routes.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 426.1. The packet lists the completion envelope, universal-property row, real-completion row, dense regular rational source, real seal, dense continuous map, extension ledger, functoriality ledger, transport rows, continuation rows, package provenance, and local naming row.

Classifier stability is componentwise. The recorded hsame rows in H transport exactly the listed coordinates, while the Cont routes in C preserve the read order from source windows and graph entries to completion envelopes, extension rows, real seals, and functoriality ledgers.

Extension exactness is inherited as a visible row, not as an external principle. The coordinate E is the only route from the dense $\mathsf{ContinuousMap}^{\uparrow}$ row G and regular rational source Q into the completion-facing map row supplied by U.

The remaining public obligations are the three theorem surfaces below: functoriality, unit-boundary compatibility, and non-escape. Together they exhaust all consumer reads of the local $\mathsf{NameCert}_{\mathsf{CompletionFunctor}^{\uparrow}}$ packet. □

Theorem 426.3 (CompletionFunctor functoriality)**.** *Let $F = (M, U, R, Q, A, G, E, T, H, C, P, N)$ be an accepted* $\mathsf{CompletionFunctor}^{\uparrow}$ *carrier. Identity reads and composable pairs of dense* $\mathsf{ContinuousMap}^{\uparrow}$ *rows are transported to completion-facing* $\mathsf{ContinuousMap}^{\uparrow}$ *reads by the same finite extension ledger E and compared by the functoriality ledger T. The comparison uses only displayed* hsame *rows and* Cont *routes over M, U, R, Q, A, G, and E.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier functoriality`

Proof. For the identity route, read the dense identity map as a $\mathsf{ContinuousMap}^{\uparrow}$ graph row with its displayed modulus. The universal-property row U and extension ledger E repack that graph row through Q, M, R, and the seal A as a completion-facing continuous map.

For a composable pair, inspect the two dense graph ledgers in finite windows. The Cont routes in C preserve the order of source read, first map read, second map read, extension read, and real-seal read.

The ledger T compares the completion of the composite dense map with the composite of the two completion-facing extension rows. Since T is a displayed BHist coordinate whose comparisons are routed through H and C, the comparison is a local hsame ledger statement and not an equality of host functions. □

Theorem 426.4 (CompletionFunctor unit boundary)**.** *For every accepted* CompletionFunctor$^{\uparrow}$ *carrier, the unit row of* CauchyCompletionMonad$^{\uparrow}$ *and the real seal of* RealCauchyCompletion$^{\uparrow}$ *agree at the public boundary through the displayed rows M, R, Q, A, E, H, C, P, and N. A dense regular rational input is first read as Q, then admitted through the completion envelope M, and finally exposed through the* Real$^{\uparrow}$ *seal A without adding a quotient representative or a selected limit.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier unit boundary`

Proof. Start with the displayed regular rational source row Q. The completion envelope M supplies the unit-facing packet for this source, using finite stream windows and regular rational observations.

The real-completion row R and seal A are then read through the same source observations. The extension ledger E contributes only the continuation route needed by downstream continuous-map consumers; it does not change the source row or choose a host limit.

The comparison between the monad unit boundary and the real seal boundary is recorded by the componentwise transports in H and the read routes in C. Thus the public unit boundary is a finite packet route through the named rows, with no quotient completion or ambient completeness datum. □

Theorem 426.5 (CompletionFunctor extension ledger exactness)**.** *Let $F = (M, U, R, Q, A, G, E, T, H, C, P, N)$ be an accepted* CompletionFunctor$^{\uparrow}$ *carrier. Every completion-facing extension read produced from the dense* ContinuousMap$^{\uparrow}$ *row G and regular rational source row Q is exactly the displayed extension ledger E read through M, U, R, A, H, C, P, and N. The packet exports no second extension route, quotient completion, selected limit, or host function equality.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier extension ledger exactness`

Proof. Project the accepted carrier through Definition 426.1. The only row whose role is extension from dense graph data to a completion-facing continuous map is E, and its source rows are visibly G, Q, M, U, R, and A.

Apply the extension clause in Definition 426.2. It makes extension exactness a visible carrier row rather than an external principle, so every consumer read of the extended map reaches E through the displayed hsame transports in H and the Cont routes in C.

Finally use the non-escape inventory implicit in the carrier. Since no coordinate of F is a quotient completion, selected limit, host function equality, or ambient completeness field, no second extension object can be read from the packet. □

Theorem 426.6 (CompletionFunctor identity route stability)**.** *For an accepted* CompletionFunctor$^{\uparrow}$ *carrier $F = (M, U, R, Q, A, G, E, T, H, C, P, N)$ whose dense map row G is the identity* ContinuousMap$^{\uparrow}$ *row on the displayed dense source, the identity completion route is stable under the componentwise* hsame *rows in H and the* Cont *routes in C. Its public read is the identity clause of the functoriality ledger T, using the same extension ledger E and unit-boundary rows M, R, Q, and A.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier identity route stability`

Proof. Start with the identity part of Definition 426.3. The dense identity graph is read as a displayed $\mathsf{ContinuousMap}^{\uparrow}$ row, then repacked by U and E through the source row Q and completion envelope M.

The unit boundary of Definition 426.4 identifies the source-side completed object with the $\mathsf{Real}^{\uparrow}$ seal A through M, R, and Q. Transporting the same rows by H and reading them through C keeps the identity route attached to the displayed source and seal rows.

The functoriality ledger T is therefore the only public identity comparison row. The route is stable as a finite BHist comparison and does not become an equality of host functions. □

Theorem 426.7 (CompletionFunctor composition route stability)**.** *For an accepted* $\mathsf{CompletionFunctor}^{\uparrow}$ *carrier* $F = (M, U, R, Q, A, G, E, T, H, C, P, N)$ *that displays composable dense* $\mathsf{ContinuousMap}^{\uparrow}$ *reads inside* G *and their transported extension rows inside* E*, the completion route for the composite is classified by the composition clause of* T*. Componentwise transport through* H *and consumer reads through* C *preserve the same route through* M*,* U*,* R*,* Q*,* A*,* G*,* E*,* P*, and* N*.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier composition route stability`

Proof. Read the composable dense graph rows through the second paragraph of Definition 426.3. The carrier records the source read, first graph read, second graph read, extension read, and real-seal read as finite routes.

Apply Definition 426.5. Both completion-facing maps and the completion-facing composite are read through E, so the composition comparison has a single extension ledger to inspect.

The ledger T then compares the extension of the dense composite with the composite of the two transported extension rows. Because T is transported by the same H and read by the same C, the composition route is stable without appealing to host function equality. □

Theorem 426.8 (CompletionFunctor completion consumer surface)**.** *Every public completion consumer of an accepted* $\mathsf{CompletionFunctor}^{\uparrow}$ *packet factors through the displayed carrier rows* $M, U, R, Q, A, G, E, T, H, C, P, N$*: completed-source reads use the unit boundary, extension reads use the exact ledger* E*, identity reads use the identity clause of* T*, composition reads use the composition clause of* T*, and all reads obey the non-escape boundary.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier completion consumer surface`

Proof. First split the consumer request by the row it asks to read. A completed-source request reaches M, R, Q, and A by Definition 426.4; an extension request reaches E by Definition 426.5.

For functorial requests, use the two route-stability rows. Identity reads are governed by Definition 426.6, while composition reads are governed by Definition 426.7.

Finally apply Definition 426.10. The listed rows exhaust the finite carrier, so the consumer surface contains no quotient completion, selected limit, hidden representative, host function equality, or ambient completeness field. □

Theorem 426.9 (CompletionFunctor scoped dependency spine)**.** *The carrier, exact extension ledger, unit boundary, identity route, composition route, and consumer surface of* $\mathsf{CompletionFunctor}^{\uparrow}$ *are scoped exactly over* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*,* $\mathsf{CompletionUniversalProperty}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and the local* $\mathsf{NameCert}_{\mathsf{CompletionFunctor}^{\uparrow}}$ *row. No proof obligation of the packet reads outside these named dependencies.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier scoped dependency spine`

Proof. Project the finite carrier and local naming surface from Definition 426.2. This fixes the available rows as $M, U, R, Q, A, G, E, T, H, C, P, N$ and identifies their sources as the completion monad, universal-property, real-completion, regular-sequence, real-seal, continuous-map, transport, continuation, package, and local naming dependencies.

Apply Definition 426.5, Definition 426.4, Definition 426.6, and Definition 426.7. These four rows show that every extension, unit, identity, and composition read factors through the displayed ledger and the same hsame and Cont routes.

Finally use Definition 426.8. The consumer surface exhausts the packet, so quotient completion, selected limit, ambient completeness, hidden representatives, and host function equality are not in scope for $\mathsf{CompletionFunctor}^{\uparrow}$. □

Theorem 426.10 (CompletionFunctor non-escape boundary)**.** *No accepted* $\mathsf{CompletionFunctor}^{\uparrow}$ *carrier exports quotient completions, host function equality, selected limits, hidden representatives, or ambient completeness. Every public read of a completed object, a transported continuous map, an identity ledger, or a composition ledger factors through the finite* BHist *packet of Definition 426.1, the extension route of Definition 426.2, the functoriality ledger of Definition 426.3, and the unit boundary of Definition 426.4.*

Proof. Inspect the carrier inventory. Its analytic rows are the completion envelope, universal-property row, real-completion row, regular rational source, real seal, dense continuous map, extension ledger, and functoriality ledger, together with finite transport, continuation, package, and naming rows.

The NameCert obligation theorem makes E the only completion-facing extension route. The functoriality theorem makes T the only public route for identity and composition comparison. The unit-boundary theorem makes M, R, Q, and A the only public route from dense regular rational input to completed real seal.

These routes exhaust the packet. Since none of the listed coordinates is a quotient completion, host function equality proof, selected limit, hidden representative, or ambient completeness field, no public consumer can read such an object from the $\mathsf{CompletionFunctor}^{\uparrow}$ surface. □

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier non escape`

Theorem 426.11 (CompletionFunctor public completion export)**.** *The* $\mathsf{CompletionFunctor}^{\uparrow}$ *carrier, functoriality ledger, unit boundary, extension-ledger exactness, identity route stability, composition route stability, completion consumer surface, scoped dependency spine, and non-escape boundary assemble into the public* $\mathsf{CompletionFunctor}^{\uparrow}$ *completion export consumed by* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, *and* $\mathsf{CompletionUniversalProperty}^{\uparrow}$. *This export exposes only the finite rows* $M, U, R, Q, A, G, E, T, H, C, P, N$ *of Definition 426.1 and their displayed* hsame *and* Cont *routes.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier public completion export`

Proof. Start from the local carrier and obligation surface of Definition 426.2. It fixes the displayed rows, the componentwise classifier transports, the continuation routes, and the local $\mathsf{NameCert}_{\mathsf{CompletionFunctor}^{\uparrow}}$ packet read by downstream completion consumers.

The public completion map surface is then determined by the three central construction rows. The functoriality ledger is supplied by Definition 426.3, the unit-facing dense-to-completed boundary by Definition 426.4, and the single completion-facing extension read by Definition 426.5.

The route-level stability needed by consumers is already internal to the same packet. Identity reads use Definition 426.6, and composable dense-map reads use Definition 426.7, both over the same extension ledger and transport rows.

Finally combine the consumer inventory of Definition 426.8 with the dependency inventory of Definition 426.9 and the non-escape boundary of Definition 426.10. The resulting public export is exactly the completion-functor surface available to $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, and $\mathsf{CompletionUniversalProperty}^{\uparrow}$, with no quotient completion, selected limit, host function equality, hidden representative, or ambient completeness field added at the boundary. □

Theorem 426.12 (CompletionFunctor public extension interface)**.** *Let $F = (M, U, R, Q, A, G, E, T, H, C, P, N)$ be an accepted* $\mathsf{CompletionFunctor}^{\uparrow}$ *carrier. The packet exports a public completion-functor interface in which unit reads come from the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *row M, extension reads come from the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row U and the exact ledger E,* $\mathsf{Real}^{\uparrow}$ *seals come from the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows R and Q together with A, and map transport comes from the* $\mathsf{ContinuousMap}^{\uparrow}$ *row G and functoriality ledger T. Every such read is routed through displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier public extension interface`

Proof. For the unit side, apply Definition 426.4. It identifies the public completed-source read as the route through M, R, Q, A, H, C, P, and N.

For extension reads, use Definition 426.5. The universal-property row U and exact ledger E give the only completion-facing extension path from the dense $\mathsf{ContinuousMap}^{\uparrow}$ row G.

For transported maps, combine Definition 426.3, Definition 426.6, and Definition 426.7. These theorems route identity and composition through T using the same displayed carrier rows.

Finally invoke Definition 426.8 and Definition 426.10. They exhaust the public consumer surface and rule out quotient completions, selected limits, hidden representatives, host function equality, and ambient completeness. □

Theorem 426.13 (CompletionFunctor Cauchy seal composition)**.** *Let*

$$F_1 = (M_1, U_1, R_1, Q_1, A_1, G_1, E_1, T_1, H_1, C_1, P_1, N_1)$$

and

$$F_2 = (M_2, U_2, R_2, Q_2, A_2, G_2, E_2, T_2, H_2, C_2, P_2, N_2)$$

be accepted $\mathsf{CompletionFunctor}^{\uparrow}$ *carriers whose target seal row of F_1 matches the source seal row of F_2 through displayed* hsame *and* Cont *routes. Then their completion-extension packets compose to a single* $\mathsf{CompletionFunctor}^{\uparrow}$ *packet whose composed route preserves carrier membership, classifier equality, and extension-ledger exactness. The public surface of the composite reads the same* $\mathsf{Real}^{\uparrow}$ *seal boundary, the same completion-facing* $\mathsf{ContinuousMap}^{\uparrow}$ *classifier row, and the exact extension ledger exported by the composed packet.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier cauchy seal composition`

Proof. First build the composed route. Apply Definition 426.7 to the composable dense map rows and their transported extension rows; the matching seal hypothesis identifies the target read of F_1 with the source read of F_2 inside the displayed hsame and Cont routes.

Next descend the ledger. Apply Definition 426.5 to each packet and then to the composed carrier route. The only completion-facing extension reads available are the displayed ledgers E_1, E_2, and the composed ledger carried by the resulting packet.

Finally export the consumer surface. Use Definition 426.12 to read the composed unit, seal, map-transport, and functoriality rows through the same package and naming provenance. This gives a single public $\mathsf{CompletionFunctor}^{\uparrow}$ packet without adding quotient completions, selected limits, host function equality, or ambient completeness. □

Theorem 426.14 (CompletionFunctor standard bridge surface)**.** *Every standard* $\mathsf{CompletionFunctor}^{\uparrow}$ *read over the carrier rows* $M, U, R, Q, A, G, E, T, H, C, P, N$ *factors through the public extension interface of Definition 426.12, the unit boundary of Definition 426.4, the extension-ledger exactness of Definition 426.5, the identity and composition route stability of Definition 426.6 and Definition 426.7, and the Cauchy seal composition of Definition 426.13. The surface exports no quotient completion, selected limit, host function equality, hidden representative, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier standard bridge surface`

Proof. Start with the public interface. Definition 426.12 exposes the unit, extension, seal, map-transport, functoriality, package, and naming rows of the accepted carrier and routes every public consumer through displayed hsame and Cont data.

Next identify the construction rows used by that interface. The unit side is Definition 426.4; the extension side is Definition 426.5; the functorial side is the pair of identity and composition route-stability theorems.

Finally apply Definition 426.13. It shows that compatible Cauchy seal reads compose inside the same finite packet, so the standard bridge surface is exactly the paper-side surface generated by these named rows. The non-escape clauses already present in the interface exclude quotient completions, selected limits, host function equality, hidden representatives, and ambient completeness. □

Theorem 426.15 (CompletionFunctor bridge-composition exactness)**.** *Any consumer of the* $\mathsf{CompletionFunctor}^{\uparrow}$ *standard bridge reads the same completion carrier through identity routes, composition routes, extension-ledger exactness, and Cauchy seal composition over the rows*

$$M, U, R, Q, A, G, E, T, H, C, P, N.$$

The bridge-composition read exposes no extra host completion, quotient object, selected limit, host function equality, hidden representative, or ambient completeness field beyond the standard bridge surface.

Proof. Start with the identity route. Definition 426.6 keeps the identity completion read attached to the displayed source, seal, extension ledger, transport rows, and continuation routes.

Next add the composition route and extension ledger. Definition 426.7 compares composable dense-map reads inside the same functoriality ledger, and Definition 426.5 says that every completion-facing extension read is exactly the displayed ledger E.

Now apply Cauchy seal composition. Definition 426.13 composes compatible seal reads inside a single $\mathsf{CompletionFunctor}^{\uparrow}$ packet and preserves carrier membership, classifier equality, and extension-ledger exactness.

Finally cite the standard bridge surface. Definition 426.14 is generated by these identity, composition, ledger, and seal rows, and its non-escape clauses exclude any extra host completion or quotient object. □

Lean4 ✓ `BEDC.Derived.CompletionFunctorUp.CompletionFunctorCarrier bridge composition exactness`

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionFunctor}^{\uparrow}$ packet is generated from a $\mathsf{CauchyCompletionMonad}^{\uparrow}$ completion envelope, a $\mathsf{CompletionUniversalProperty}^{\uparrow}$ extension row, a $\mathsf{RealCauchyCompletion}^{\uparrow}$ real-completion row, a $\mathsf{RegSeqRat}^{\uparrow}$ dense source, a $\mathsf{Real}^{\uparrow}$ seal, a $\mathsf{ContinuousMap}^{\uparrow}$ dense map, a finite extension ledger, a functoriality ledger, displayed hsame transports, Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionFunctor}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 426.12 exports the public completion-functor interface over CauchyCompletionMonad$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, RealCauchyCompletion$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, ContinuousMap$^{\uparrow}$, BHist, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompletionFunctor}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient completions, host function equality, selected limits, ambient completeness, completed-category laws beyond the displayed finite ledger, or bridge checking.

Upgrade path: Bridge closure requires a standard bridge for the displayed completion-functor packet.

Chapter 427

A Concrete Naming Certificate for $\mathsf{RegularLimitUniqueness}^{\uparrow}$

The $\mathsf{RegularLimitUniqueness}^{\uparrow}$ interface records the separated uniqueness side of regular-Cauchy completion. In the Bishop–Bridges constructive-analysis presentation, a completed real is read through finite regular-name windows and explicit moduli; uniqueness is therefore a visible separated-seal certificate over two accepted completion candidates, not a quotient of streams or a selected host limit.

The packet compares two diagonal completion candidates only after their regular rational readbacks from chapter 301 pass through the finite observation windows of chapter 126, the diagonal route of chapter 359, the shared family surface of chapter 373, the separated boundary of chapter 402, and the $\mathsf{Real}^{\uparrow}$ seal rows of chapter 38.

Definition 427.1 (RegularLimitUniqueness carrier)**.** *A* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N)$$

with the following visible rows:

1. *F is the shared* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *input row;*
2. *D_0 and D_1 are two* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *candidate limit rows for the same F;*
3. *μ is the shared* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row controlling the tail windows compared by both candidates;*
4. *R_0 and R_1 are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows exposed by the two diagonal candidates at the threshold selected by μ;*
5. *E_0 and E_1 are the two* $\mathsf{Real}^{\uparrow}$ *seal rows reached from those readbacks;*
6. *S is the separated comparison row, read through the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *boundary, stating that E_0 and E_1 classify at the same separated real seal;*
7. *H records the displayed* hsame *transports tying F, μ, the two diagonal rows, the two readbacks, the two seals, and the separated comparison together;*
8. *C records the displayed* Cont *routes through the shared family, threshold row, diagonal candidates, readback rows, real seals, and separated comparison;*

9. *P is the* Pkg *provenance over* RegularCauchyFamily$^\uparrow$, CauchyModulus$^\uparrow$, RealDiagonalCompletion$^\uparrow$, RegSeqRat$^\uparrow$, StreamName$^\uparrow$, HausdorffCompletion$^\uparrow$, Real$^\uparrow$, BHist, hsame, *and* Cont*;*
10. *N is the local* NameCert$_{\text{RegularLimitUniqueness}^\uparrow}$ *row.*

The carrier has no coordinate for quotient streams, a chosen host limit, host real equality, or choice. Its public data are exactly the displayed finite rows above.

Theorem 427.2 (RegularLimitUniqueness NameCert obligations)**.** *The local* NameCert$_{\text{RegularLimitUniqueness}^\uparrow}$ *surface has five finite obligations:*

1. *habitation by a displayed diagonal candidate pair over the carrier of Definition 427.1;*
2. *classifier laws obtained by componentwise* hsame *transport of the shared family, threshold row, diagonal candidates, readbacks, real seals, separated comparison, continuation routes, package provenance, and local naming row;*
3. *carrier transport through the displayed routes from* RegularCauchyFamily$^\uparrow$ *to* RealDiagonalCompletion$^\uparrow$*, then through* RegSeqRat$^\uparrow$ *and* StreamName$^\uparrow$ *readbacks to the two* Real$^\uparrow$ *seals;*
4. *exactness through the separated* Real$^\uparrow$ *classifier row S, so the two accepted candidates are compared only at the displayed separated seal;*
5. *ledger non-escape excluding quotient streams, selected host limits, host real equality, and choice.*

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier namecert obligations`

Proof. Carrier habitation is projection of Definition 427.1. The shared family row, the two diagonal candidates, the common threshold, the two readbacks, the two seals, the separated comparison, transport rows, continuation routes, package provenance, and local certificate are finite coordinates of the same BHist packet.

Classifier stability is componentwise. Transport the shared RegularCauchyFamily$^\uparrow$ and CauchyModulus$^\uparrow$ rows first, then move the two RealDiagonalCompletion$^\uparrow$ rows and their RegSeqRat$^\uparrow$ readbacks along the displayed hsame rows while replaying the corresponding Cont routes.

Exactness is the separated-seal step. The only row that compares the two completion candidates after readback is S, and S is a displayed Real$^\uparrow$ classifier row read through the HausdorffCompletion$^\uparrow$ boundary.

The non-escape clauses follow from the carrier list. No coordinate contains a quotient of regular streams, a selected host limit, host real equality, or a choice principle, so the local certificate can export only the listed BEDC rows. □

Theorem 427.3 (RegularLimitUniqueness separated limit certificate)**.** *Let U be an accepted* RegularLimitUniqueness$^\uparrow$ *carrier. Suppose two accepted* RealDiagonalCompletion$^\uparrow$ *candidates in U read the same* RegularCauchyFamily$^\uparrow$ *input through the shared* CauchyModulus$^\uparrow$ *threshold and reach the same separated boundary row S. Then their* RegSeqRat$^\uparrow$ *readbacks classify through the same* Real$^\uparrow$ *seal: the two candidate limits are identified exactly by the displayed separated* Real$^\uparrow$ *classifier row, with visible* BHist, hsame, Cont, Pkg, *and* NameCert *provenance.*

The certificate exports no quotient stream comparison, selected host limit, host real equality, ambient completeness principle, or choice.

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier separated limit certificate`

Proof. Project U as in Definition 427.1. Both candidates point to the same $\mathsf{RegularCauchyFamily}^{\uparrow}$ row F and the same $\mathsf{CauchyModulus}^{\uparrow}$ threshold μ, so their readback routes begin at one displayed regular-Cauchy input surface.

Read each candidate through its diagonal row. The two $\mathsf{RealDiagonalCompletion}^{\uparrow}$ coordinates expose the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ readbacks and $\mathsf{StreamName}^{\uparrow}$ windows, and the stored hsame and Cont rows keep those reads attached to the shared family and threshold.

Now use the separated comparison row S. It is the only accepted comparison between E_0 and E_1, and it lives at the $\mathsf{Real}^{\uparrow}$ seal boundary through the $\mathsf{HausdorffCompletion}^{\uparrow}$ separated surface.

Repacking this route gives the stated certificate. Since the carrier contains no quotient, selected host limit, host real equality, ambient completeness, or choice coordinate, the equality claim is precisely the displayed separated classifier claim and nothing stronger. □

Theorem 427.4 (RegularLimitUniqueness classifier determinacy)**.** *Let U and U' be accepted* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *carriers whose displayed* hsame *and* Cont *rows classify the shared* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *input, the shared* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold, the two* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *candidates, their* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, their* $\mathsf{Real}^{\uparrow}$ *seals, and their separated comparison rows. Then the two carriers determine the same separated limit route: every classified candidate pair reaches the corresponding* $\mathsf{Real}^{\uparrow}$ *seals through the displayed separated comparison row and through no additional host equality or chosen limit.*

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier classifier determinacy`

Proof. Project both carriers using Definition 427.1. The family row, threshold row, diagonal candidate rows, readback rows, seal rows, separated comparison rows, transport rows, continuation rows, package rows, and local certificates are all visible coordinates.

Apply the classifier obligations of Definition 427.2. Componentwise transport moves the shared family and threshold first, then moves each diagonal candidate, readback, seal, and separated comparison row along the displayed routes.

Now apply Definition 427.3 to either classified carrier. The separated comparison row is the only route that identifies the two candidate seals, so classification determines the same separated limit route without adding host equality, a quotient stream, or a selected limit. □

Theorem 427.5 (RegularLimitUniqueness completion consumer boundary)**.** *Every completion consumer that reads a* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet can inspect only the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows,* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *candidate rows,* $\mathsf{Real}^{\uparrow}$ *seal rows, shared family and threshold rows, separated comparison row, and the recorded* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *provenance. The packet exports no quotient completion object, selected host limit, host real equality, ambient completeness principle, or choice witness.*

Proof. Read the carrier inventory. The completion-facing coordinates are the two $\mathsf{RealDiagonalCompletion}^{\uparrow}$ candidates and their $\mathsf{RegSeqRat}^{\uparrow}$ readbacks over the shared family and threshold, followed by the two $\mathsf{Real}^{\uparrow}$ seal rows and the separated comparison row.

The separated-limit certificate of Definition 427.3 consumes exactly those rows. It compares the candidate seals only after their readbacks have passed through the displayed diagonal and stream-name routes.

The non-exported objects are absent from the carrier. Since no coordinate contains a quotient completion, selected host limit, host real equality, ambient completeness theorem, or choice witness, no completion consumer can obtain one from the packet. □

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier completion consumer boundary`

Theorem 427.6 (RegularLimitUniqueness separated transport)**.** *Separatedness in a* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *carrier transports through the displayed* hsame *and* Cont *rows. If the separated comparison row* S *identifies the two* $\mathsf{Real}^{\uparrow}$ *seals reached from one accepted carrier, then any classified carrier carries the transported separated comparison for the transported seals, without introducing host-level equality or a quotient of regular streams.*

Proof. Begin with the separated comparison row S in an accepted carrier. By Definition 427.3, S sits after the shared family, threshold, diagonal candidates, regular readbacks, and two real seal rows.

Transport each upstream coordinate through the displayed hsame rows and replay the corresponding Cont routes. The classifier obligations of Definition 427.2 keep the separated comparison attached to the transported seals and to the same package and local certificate rows.

The transported statement is again a separated $\mathsf{Real}^{\uparrow}$ classifier claim. It does not become a host equality statement, and it does not require a quotient of the regular-stream readbacks. □

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier separated transport`

Theorem 427.7 (RegularLimitUniqueness obligation closure package)**.** *The* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet of Definition 427.1, together with the local* $\mathsf{NameCert}_{\mathsf{RegularLimitUniqueness}^{\uparrow}}$ *obligations of Definition 427.2, the separated-limit certificate of Definition 427.3, classifier determinacy of Definition 427.4, the completion consumer boundary of Definition 427.5, and separated transport of Definition 427.6, presents the five displayed obligation rows required by the regular-limit uniqueness surface:*

1. *carrier habitation for the finite row*

$$U = (F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N);$$

2. *classifier transport along the recorded* hsame *rows and replayed* Cont *routes for* $F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H,$
3. *readback-to-seal exactness from each* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *candidate through its displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *readback into the corresponding* $\mathsf{Real}^{\uparrow}$ *seal;*
4. *separated comparison exactness through the single displayed row* S *at the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *boundary;*
5. *ledger non-escape for quotient streams, selected host limits, host real equality, ambient completeness, and choice witnesses.*

These rows are sufficient as the paper-side obligation package for later scoped closure of the same regular-limit uniqueness claim.

Proof. The carrier habitation row is the finite packet displayed in Definition 427.1. The first NameCert obligation of Definition 427.2 supplies the accepted carrier instance over that packet.

Classifier transport is the second and third obligation row of Definition 427.2, refined by Definition 427.4 and Definition 427.6. These results keep the family, threshold, diagonal candidates, readbacks, real seals, separated comparison, package row, and local naming row attached to the same displayed BHist surface.

Readback-to-seal exactness follows from Definition 427.3. Each diagonal candidate is read through its $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ rows before it reaches a $\mathsf{Real}^{\uparrow}$ seal, so the certificate never compares unsealed host objects.

Separated comparison exactness is the role of S. The comparison occurs only at the separated $\mathsf{Real}^{\uparrow}$ classifier row, read through the $\mathsf{HausdorffCompletion}^{\uparrow}$ boundary.

Ledger non-escape is the completion-facing boundary of Definition 427.5. Every consumer route is a route through the listed BEDC rows, so the packet exports no quotient stream, selected host limit, host equality, ambient completeness theorem, or choice witness. □

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier obligation closure package`

Theorem 427.8 (RegularLimitUniqueness readback seal exactness)**.** *Let $U = (F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C$ be an accepted* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *carrier. If D_0 and D_1 are two diagonal completion candidates over the same regular family row F and threshold row μ, then the packet can identify the candidates only through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R_0, R_1 and the separated* $\mathsf{Real}^{\uparrow}$ *seal row S comparing E_0 and E_1.*

No identification route in the packet bypasses R_0, R_1, E_0, E_1, S, and no route factors through host real equality, a selected host limit, a quotient stream, ambient completeness, or choice.

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier readback seal exactness`

Proof. Project the accepted carrier. The two candidates share the same F and μ coordinates, and their readback rows are explicitly R_0 and R_1.

The diagonal rows expose only the displayed regular-rational readbacks before reaching real seals. The hsame and Cont coordinates keep those readbacks tied to the same family and threshold, but they do not add a separate equality object.

The separated comparison row is S. By Definition 427.3, candidate identification occurs after the readbacks reach E_0 and E_1, and the comparison is exactly the separated $\mathsf{Real}^{\uparrow}$ classifier row.

The exclusion statement follows from the ledger boundary in Definition 427.5. The omitted host and quotient objects are not coordinates of U. □

Theorem 427.9 (RegularLimitUniqueness dyadic-window separation pullback)**.** *Let $U = (F, D_0, D_1, \mu, R_0, R_1, E_0$ be an accepted* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet. Suppose the two candidate routes share the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger read by those windows, and the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated comparison row whose endpoint is the* $\mathsf{Real}^{\uparrow}$ *seal comparison S.*

Then every completion consumer reaches the same $\mathsf{Real}^{\uparrow}$ *seal comparison through that finite pullback surface. The consumer route is forced through R_0, R_1, E_0, E_1, S and through the shared* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows of U; it cannot be replaced by quotient streams, selected host limits, host real equality, ambient completeness, or choice.*

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier dyadic window separation pullback`

Proof. First apply Definition 427.8. The accepted packet identifies the two diagonal candidates only after the displayed readbacks R_0, R_1 reach the seal rows E_0, E_1 and the separated comparison row S.

Next apply Definition 427.12. The common family row F, threshold row μ, both diagonal candidates, and their transport, continuation, package, and naming rows remain inside the same $\mathsf{RegularLimitUniqueness}^{\uparrow}$ packet.

The finite pullback is supplied by Definition 126.356 and Definition 126.358. The shared $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and $\mathsf{Real}^{\uparrow}$ seal rows determine one finite surface for downstream seal comparison.

Finally use the completion consumer boundary from Definition 427.5. Since every consumer has already been routed through the displayed finite surface, no quotient stream, selected host limit, host equality, ambient completeness row, or choice witness can enter the uniqueness comparison. □

Theorem 427.10 (RegularLimitUniqueness seal-selector pullback)**.** *Let* $U = (F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C,$ *be an accepted* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet. Suppose the two candidate routes share the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, the* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *candidate rows, the* $\mathsf{DiagonalLimit}^{\uparrow}$ *completion-seal factorization row, the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated row, and the* $\mathsf{Real}^{\uparrow}$ *seal comparison row* S*.*

Then every uniqueness consumer factors through the single finite selector-pullback surface

$$F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N.$$

The surface is obtained by first routing the comparison through the dyadic-window separation pullback, then through the checked $\mathsf{DiagonalLimit}^{\uparrow}$ *completion-seal factorization, and finally through the* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *completion-consumer boundary. It exports no quotient stream, selected host limit, host real equality, ambient completeness principle, or choice witness.*

Proof. Project the accepted packet U. Its carrier exposes exactly the shared family row, the two diagonal completion candidates, the threshold row, the readback rows, the two seal rows, the separated comparison row S, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance.

Apply Definition 427.9. This routes each uniqueness consumer through the common $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and separated $\mathsf{Real}^{\uparrow}$ comparison row before any completion-facing comparison is exposed.

Next compose that finite window route with Definition 374.8. The checked $\mathsf{DiagonalLimit}^{\uparrow}$ factorization makes the $\mathsf{Real}^{\uparrow}$ seal read pass through the $\mathsf{RealDiagonalCompletion}^{\uparrow}$ packet and the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows, so the selector route is the same finite pullback surface rather than an independent host-limit route.

Finally use Definition 427.5. Since the consumer boundary lists only the displayed carrier, transport, continuation, package, and naming rows, the composed selector-pullback route cannot import quotient streams, selected host limits, host real equality, ambient completeness, or choice. □

Theorem 427.11 (RegularLimitUniqueness choice-free ledger exhaustion)**.** *Every completion consumer route exported by an accepted* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet is exhausted by*

$$F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N,$$

by the ambient BHist *packet structure, by* hsame *transport, by* Cont *continuation, by* Pkg *provenance, and by the local* $\mathsf{NameCert}_{\mathsf{RegularLimitUniqueness}^{\uparrow}}$ *row. The packet contains no quotient stream, selected host limit, host equality, ambient completeness principle, or choice witness.*

Proof. Inspect the carrier in Definition 427.1. Its named coordinates are exactly the displayed family, candidate, threshold, readback, seal, comparison, transport, continuation, package, and local certificate rows.

The consumer boundary theorem Definition 427.5 says that a completion consumer can inspect only those rows and their BHist, hsame, Cont, Pkg, and NameCert provenance. The separated transport theorem Definition 427.6 keeps the same inventory after classifier movement.

Therefore every exported route is already listed in the carrier ledger. Since quotient streams, selected host limits, host equality, ambient completeness, and choice are not listed coordinates, no consumer route can recover them from the packet. □

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier choice free ledger exhaustion`

Theorem 427.12 (RegularLimitUniqueness shared family scope)**.** *The carrier and classifier rows of Definition 427.1, Definition 427.2, and Definition 427.4 form the shared-family scope for* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *This scope binds the common* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *input, the two* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *candidate rows, their* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *readbacks, the two* $\mathsf{Real}^{\uparrow}$ *seal rows, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *provenance into one finite uniqueness packet.*

The scope exports the family comparison needed by the L10 dependency stack without adding a quotient of streams, a selected host limit, host real equality, or choice.

Proof. Start with the carrier inventory of Definition 427.1. Its coordinates contain the shared family row, both diagonal candidates, both readbacks, both real seals, and the displayed transport, continuation, package, and naming rows.

Apply the local naming obligations of Definition 427.2. They identify habitation, classifier transport, carrier transport, separated exactness, and ledger non-escape as rows of that same finite packet.

Finally use Definition 427.4. Classification cannot move the two candidates outside the shared family surface, so the listed rows are the complete shared-family scope for the regular-limit uniqueness consumer. □

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier shared family scope`

Theorem 427.13 (RegularLimitUniqueness separated comparison scope)**.** *The separated comparison rows of Definition 427.3, Definition 427.6, and Definition 427.8 bind the uniqueness comparison to the concrete route*

$$\mathsf{RegularCauchyFamily}^{\uparrow} \longrightarrow \mathsf{RealDiagonalCompletion}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

with displayed BHist, hsame, Cont, Pkg, *and* NameCert *provenance. Thus the separated seal comparison is scoped exactly by the two readbacks, the two real seals, and the row* S*; it has no bypass through host equality or an unrecorded completion object.*

Proof. First read the two completion candidates through Definition 427.3. The certificate forces both candidates to share the same family and threshold before their readbacks reach the two real seals.

Next apply Definition 427.8. It makes R_0, R_1, E_0, E_1, S the only identification route available inside the packet.

The transport step is supplied by Definition 427.6. Transport preserves the separated comparison as a $\mathsf{Real}^{\uparrow}$ classifier row, so the displayed route is the entire separated comparison scope. □

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier separated comparison scope`

Theorem 427.14 (RegularLimitUniqueness ledger non-escape scope)**.** *The completion consumer boundary of Definition 427.5, the obligation package of Definition 427.7, and the ledger exhaustion row of Definition 427.11 give the ledger non-escape scope for* $\mathsf{RegularLimitUniqueness}^{\uparrow}$*. Every exported uniqueness route is a route through* $\mathsf{RegularCauchyFamily}^{\uparrow}$*,* $\mathsf{RealDiagonalCompletion}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

No exported row leaves this scope for quotient stream equality, selected host limits, host real equality, ambient completeness, or choice.

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier ledger non escape scope`

Proof. Use Definition 427.5 to identify the rows visible to a completion consumer. The boundary lists only the family, candidate, readback, seal, separated comparison, transport, continuation, package, and naming data.

Apply Definition 427.7. It repacks those visible rows as carrier habitation, classifier transport, readback-to-seal exactness, separated comparison exactness, and ledger non-escape.

Finally apply Definition 427.11. Since every exported route is already exhausted by the displayed coordinates, no unlisted host or quotient object can enter the scoped uniqueness packet. □

Theorem 427.15 (RegularLimitUniqueness scoped handoff)**.** *The shared-family scope of Definition 427.12, the separated-comparison scope of Definition 427.13, and the ledger non-escape scope of Definition 427.14 jointly bind every* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *consumer route to* $\mathsf{RegularCauchyFamily}^{\uparrow}$*,* $\mathsf{RealDiagonalCompletion}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

Within this scoped handoff, no consumer may replace the displayed rows by a quotient stream, selected host limit, host equality, ambient completeness principle, or choice witness.

Lean4 ✓ `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier scoped handoff`

Proof. Begin with the shared-family scope. It fixes the common $\mathsf{RegularCauchyFamily}^{\uparrow}$ input, both $\mathsf{RealDiagonalCompletion}^{\uparrow}$ candidates, their $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ readbacks, the two $\mathsf{Real}^{\uparrow}$ seal rows, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance.

Next use the separated-comparison scope. It binds the uniqueness comparison to the route from the shared family through diagonal completion and regular-rational readback into the two real seals, with the row S as the only separated comparison.

Finally apply the ledger non-escape scope together with the NameCert obligation package of Definition 427.2. The non-escape row excludes quotient streams, selected host limits, host equality, ambient completeness, and choice, so the three scoped rows hand off exactly the displayed consumer surface and nothing outside it. □

Theorem 427.16 (RegularLimitUniqueness public completion export)**.** *The carrier of Definition 427.1, the NameCert obligations of Definition 427.2, the separated-limit certificate of Definition 427.3, classifier determinacy from Definition 427.4, readback seal exactness from Definition 427.8, the shared-family scope of Definition 427.12, the separated-comparison scope of Definition 427.13, the scoped handoff of Definition 427.15, and the ledger non-escape row of Definition 427.14 assemble a single public completion-consumer export for two diagonal completion candidates over one regular-Cauchy family.*

The exported route is exactly

$$\mathsf{RegularCauchyFamily}^{\uparrow} \longrightarrow \mathsf{RealDiagonalCompletion}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

through the separated row S. It exports no quotient stream comparison, selected host limit, host equality, ambient completeness principle, or choice witness.

Proof. Start from the carrier and NameCert obligation package. They provide the shared family row, the two diagonal completion candidates, the shared threshold, the two readbacks, the two real seals, the separated row S, and the displayed BHist, hsame, Cont, Pkg, and NameCert provenance.

Next apply the separated-limit certificate, classifier determinacy, and readback seal exactness. These rows identify the only equality-facing comparison as the path from the two diagonal candidates through their $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ readbacks into the two $\mathsf{Real}^{\uparrow}$ seals, with S as the separated comparison row.

Finally use the shared-family scope, separated-comparison scope, scoped handoff, and ledger non-escape scope. Together they make the route public for completion consumers while excluding quotient streams, selected host limits, host equality, ambient completeness, and choice from the exported surface. □

Theorem 427.17 (RegularLimitUniqueness consumer determinacy)**.** *Let*

$$A = (F, D0, D1, \mu, R0, R1, E0, E1, S, H, C, P, N)$$

be an accepted $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet. Any two completion consumers that read the public completion export of Definition 427.16 determine the same separated* $\mathsf{Real}^{\uparrow}$ *seal comparison through the displayed row S. No such consumer can distinguish the two reads through quotient stream equality, selected host limits, host real equality, ambient completeness, or choice.*

Proof. Begin with classifier determinacy and readback seal exactness. These results identify the comparison route from the shared family F through the two diagonal completion rows $D0, D1$, the readback rows $R0, R1$, the seal rows $E0, E1$, and the separated row S.

Next apply the scoped handoff and the public completion export. They make that route the public completion-consumer surface for the displayed packet, so both consumers read the same separated comparison row rather than independent host data.

Finally use the ledger non-escape scope. It excludes quotient stream equality, selected host limits, host real equality, ambient completeness, and choice from the exported route, leaving S as the unique separated $\mathsf{Real}^{\uparrow}$ seal comparison available to either consumer. □

Theorem 427.18 (RegularLimitUniqueness bridge handoff)**.** *Every bridge consumer comparing two diagonal completion candidates over the same* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *input in a* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet must factor through the displayed rows*

$$F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N.$$

The handoff uses the public completion export of Definition 427.16 and the consumer determinacy of Definition 427.17: the comparison is read from the shared family F through the two diagonal candidates D_0, D_1, their regular-rational readbacks R_0, R_1, the two real seal rows E_0, E_1, and the separated comparison row S, with the displayed BHist, hsame, Cont, Pkg, *and* NameCert *provenance.*

No bridge consumer may import quotient completion, selected host limits, host real equality, ambient completeness, or choice into this handoff. Those objects are outside the carrier ledger and outside the exported completion-consumer surface.

Proof. Compose the checked local rows. The NameCert obligations give carrier habitation, classifier transport, readback routing, separated exactness, and ledger non-escape for the finite packet of Definition 427.1.

Next use the separated-limit certificate, classifier determinacy, and readback-seal exactness. They force every comparison of the two diagonal candidates to pass through R_0, R_1, E_0, E_1, S after the shared family and threshold rows have been fixed.

The public completion export then exposes exactly this route to bridge consumers, and consumer determinacy makes two reads of that export agree at the same separated $\mathsf{Real}^{\uparrow}$ comparison row S.

Finally apply ledger non-escape. Since quotient completion, selected host limits, host real equality, ambient completeness, and choice are not carrier coordinates and are not exported rows, the bridge handoff is precisely the displayed BEDC route. □

Theorem 427.19 (RegularLimitUniqueness mature consumer route)**.** *Let*

$$A = (F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N)$$

be an accepted $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet whose rows display one shared* $\mathsf{RegularCauchyFamily}^{\uparrow}$ *route, two* $\mathsf{RealDiagonalCompletion}^{\uparrow}$ *candidates, readback-to-seal rows through* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *a separated comparison row S, componentwise transports,* Cont *routes,* Pkg *provenance, and a local* $\mathsf{NameCert}$ *row. Then A gives a mature consumer route*

$$\mathsf{RegularCauchyFamily}^{\uparrow} \longrightarrow \mathsf{RealDiagonalCompletion}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

No consumer of this packet can replace that route by quotient completion, selected host limits, host real equality, or ambient completeness.

Proof. Start with the bridge handoff of Definition 427.18. It forces every comparison consumer for the two diagonal candidates to factor through the displayed rows $F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N$.

The public completion export of Definition 427.16 supplies the downstream route from the shared family through the two diagonal completion candidates and their readbacks into the two Real seals. Consumer determinacy from Definition 427.17 makes any two reads of that exported route agree at the same separated comparison row S.

Finally combine readback-seal exactness with the non-escape rows recorded in the bridge handoff. Since quotient completion, selected host limits, host real equality, and ambient completeness are outside the finite carrier and outside the exported completion-consumer surface, the displayed route is the mature consumer route for this packet. □

Theorem 427.20 (RegularLimitUniqueness L10 terminal handoff)**.** *Let*

$$A = (F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N)$$

be an accepted $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet whose public route is read by a current Phase Real and Completion terminal consumer. If that consumer uses the mature route of Definition 427.19, then its visible terminal boundary factors through exactly the finite four-face L10 packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *rows are used only as the separated-comparison consumer of this boundary: they read the shared family, the two diagonal completion candidates, the regular-rational*

readbacks, the two Real seal rows, and the separated comparison row S through the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates.*

The handoff exports no quotient completion, selected host limit, host real equality, countable-choice selector, ambient completeness principle, metric-completeness row, or standard bridge row.

Proof. First expose the local completion consumer. Apply Definition 427.18 and Definition 427.19. The accepted packet can be read by downstream consumers only through the displayed route from the shared $\mathsf{RegularCauchyFamily}^{\uparrow}$ family, through the two $\mathsf{RealDiagonalCompletion}^{\uparrow}$ candidates and their $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ readbacks, into the two $\mathsf{Real}^{\uparrow}$ seal rows and the separated comparison row S.

Next attach the current terminal boundary. By Definition 126.368, every StreamName, RegSeqRat, and Real budget cover used by the Phase Real and Completion surface is confined to the four sibling rows $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with only the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates.

Now apply Definition 38.457. The current terminal $\mathsf{Real}^{\uparrow}$ read is accepted exactly when its visible rows factor through the finite four-face packet in the statement, and the converse read adds no further visible coordinate.

Finally use Definition 38.458. Since the mature $\mathsf{RegularLimitUniqueness}^{\uparrow}$ consumer reaches the terminal read through the same four faces and the same displayed coordinates, the consumer boundary is the unique terminal pullback over that packet. The exclusion clauses follow from the inventories in the cited handoff, budget-cover, exactness, and uniqueness theorems: quotient completion, selected host limits, host real equality, countable choice, ambient completeness, metric-completeness rows, and standard bridge rows have no coordinate in the resulting handoff. □

Theorem 427.21 (RegularLimitUniqueness finite-window induction)**.** *Let*

$$A = (F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N)$$

be an accepted $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet. Suppose a uniqueness read is accepted over a displayed finite list of* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *windows attached to the shared family row F, the two diagonal candidates D_0, D_1, and the threshold row μ. Then induction on that finite window list reduces the read to the same separated* $\mathsf{Real}^{\uparrow}$ *seal row S.*

At each induction stage the active window is transported through the displayed hsame *rows, replayed through the* Cont *routes, repacked through* Pkg *provenance, and read through the local* NameCert *row. The resulting route stays inside the shared-family scope, the separated-comparison scope, the ledger non-escape scope, and the L10 terminal handoff; it does not introduce quotient streams, selected host limits, host real equality, ambient completeness, or choice.*

Proof. For the empty window list, the read has no active $\mathsf{StreamName}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ row beyond the carrier data already displayed in A. Apply the shared-family scope and the separated-comparison scope to read the two diagonal candidates through R_0, R_1, E_0, E_1 and the separated row S.

For the cons step, assume the tail list has already been reduced to the same separated seal row S. The head window is a displayed $\mathsf{StreamName}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ coordinate attached to F, D_0, D_1, μ, so componentwise hsame transport moves it along the accepted carrier without changing the comparison row.

Now replay the transported head through Cont and repack the route through Pkg and NameCert. The replay keeps the head window on the same readback-to-seal path as the tail, so the induction step again reaches R_0, R_1, E_0, E_1, S.

Finally apply the ledger non-escape scope and the L10 terminal handoff. Since every stage remains on the displayed finite route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, no host equality, quotient stream, selected limit, ambient completeness row, or choice witness can replace the separated seal row S. □

Theorem 427.22 (Separated Real-seal finality)**.** *Let*

$$A = (F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N)$$

be an accepted $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *packet whose comparison row S is read as a separated* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *comparison inside a* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer. Suppose the consumer route has passed through the readback seal rows R_0, R_1, E_0, E_1, the dyadic-window separation of the* $\mathsf{DyadicRatCore}^{\uparrow}$ *boundary, the seal-selector pullback into* $\mathsf{Real}^{\uparrow}$*, the choice-free ledger exhaustion of the displayed route, and the L10 terminal handoff of Definition 427.20.*

Then every accepted limit read of A is final up to the displayed Real classifier: any later read that preserves the same BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows must factor through the same separated S row and hence through the same* $\mathsf{Real}^{\uparrow}$ *classifier surface. The finality route is finite:*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow} \to \mathsf{CompleteMetric}^{\uparrow},$$

with $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *contributing only the shared family, readback-to-seal, separated comparison, transport, continuation, provenance, and local naming rows.*

Proof. Start from the terminal handoff in Definition 427.20. It has already confined the visible Real and completion boundary to the finite $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route, with no quotient completion, selected host limit, host real equality, countable-choice selector, ambient completeness principle, or standard bridge row.

Use the public completion export and consumer determinacy theorems to identify the only comparison row available to a downstream reader. The shared family, the two diagonal completion candidates, the regular-rational readbacks, and the two Real seal rows are all read through $F, D_0, D_1, \mu, R_0, R_1, E_0, E_1, S, H, C, P, N$, so a $\mathsf{CompleteMetric}^{\uparrow}$ consumer cannot acquire an additional limit coordinate outside S.

Now apply the separated-comparison part of the carrier. The $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seal reads are already tied to the dyadic-window boundary and seal-selector pullback, while BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ preserve exactly the displayed rows. Thus any accepted later read that keeps the packet accepted must return to the same Real classifier surface.

The choice-free ledger exhaustion supplies the non-escape step. Since no selected subsequence, quotient class, host equality, Real completeness principle, or hidden metric-completeness witness is a coordinate of A, the displayed classifier is the final public limit read for this separated Real-seal route. □

Theorem 427.23 (Classifier route non-escape)**.** *No accepted* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *consumer may replace the classifier-finality route of Definition 427.22 by host equality, a selected subsequence choice, quotient classes, or a Real completeness principle. Any consumer that claims uniqueness for the two limit reads must exhibit the same finite route through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*, the separated comparison row S, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row.*

Proof. Read the carrier inventory from Definition 427.18 and Definition 427.19. These theorems place the shared family, diagonal completions, readbacks, seals, separated comparison, transport, continuation, provenance, and naming rows on the visible route.

Next use Definition 427.20. The Real-facing boundary has only the finite four-face route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; the $\mathsf{CompleteMetric}^{\uparrow}$ reader can use that route only after it passes through the same separated comparison and support rows.

Finally apply Definition 427.22. Finality is a statement about the displayed Real classifier surface, not about an ambient equality proof. Host equality, selected subsequence choice, quotient classes, and Real completeness have no carrier row, no transport row, no continuation row, no provenance row, and no local NameCert row in A, so replacing the route with one of them leaves the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularLimitUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularLimitUniqueness}^{\uparrow}$ packet is generated from one regular-Cauchy family, two diagonal completion candidates, a shared Cauchy threshold, two regular-rational readbacks, two real seal rows, one separated comparison row, displayed transport and continuation rows, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularLimitUniqueness}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 427.18, together with the public completion export and consumer determinacy theorems, records the carrier, classifier transport, shared-family route, readback-to-seal exactness, separated comparison exactness, ledger non-escape rows, and bridge-consumer handoff for two regular-Cauchy completion candidates over the same displayed input and boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularLimitUniqueness}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.RegularLimitUniquenessUp.RegularLimitUniquenessCarrier\_namecert\_obligations`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close quotient completion construction, selected host limits, host real equality, ambient completeness, bridge checking, or a Lean implementation.

Upgrade path: The theory axis is mature for the displayed route from $\mathsf{RegularCauchyFamily}^{\uparrow}$ through $\mathsf{RealDiagonalCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; the remaining verification work is auditClean and bridgeChecked certification.

Chapter 428

DyadicStepFunction NameCert Construction

The $\mathsf{DyadicStepFunction}^{\uparrow}$ packet is the finite Real and Completion approximation object sitting between dyadic spline data and regular Cauchy consumers. It uses Bishop-style finite partitions: every cell, endpoint transport, and carried value is a displayed BEDC row, and no measure completion, quotient representative, selected limit, or ambient equality oracle is part of the carrier.

The partition and endpoint rows are consumed from the dyadic mesh and interval carriers of chapter 358 and chapter 306. The stepwise regular-Cauchy handoff is the finite-cell consumer of the spline rows in chapter 382: a spline packet supplies the knot and carried-value surface, while the step-function packet records the common-refinement cells, endpoint transports, and ledger entries needed before $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ reads can consume the approximation.

Definition 428.1 (Dyadic step function carrier)**.** *A* $\mathsf{DyadicStepFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (\Pi, I, V, R, M, E, L, C, P, N)$$

whose displayed coordinates are as follows:

1. Π *is a finite dyadic partition supplied by the* $\mathsf{DyadicMesh}^{\uparrow}$ *route;*
2. I *lists the* $\mathsf{DyadicInterval}^{\uparrow}$ *cells of* Π*, including displayed endpoints and adjacency witnesses;*
3. V *assigns to every cell of* I *one carried value, read either as a* $\mathsf{DyadicRatCore}^{\uparrow}$ *row or as the corresponding* $\mathsf{Real}^{\uparrow}$ *row;*
4. R *records the cellwise* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *classifier reads used to compare carried values;*
5. M *is the refinement map from any common dyadic refinement back to the cells of* Π*;*
6. E *is the endpoint-transport ledger for interval bounds, shared endpoints, and subdivision witnesses;*
7. L *is the finite* BHist *ledger of cell coverage, value reads, refinement reads, and consumer handoff rows;*
8. C *is the componentwise* hsame *and* Cont *route data used by the classifier;*
9. P *is the* Pkg *provenance naming the* $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicSpline}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *dependencies;*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$ *provenance row.*

Two accepted carriers are classified together exactly when their partitions refine to a displayed common dyadic partition and, on every refined cell, the transported carried values are classified together by the recorded $\mathsf{DyadicRatCore}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *classifier row. The comparison is finite and cellwise: it is mediated only by* M*,* E*,* L*, and the displayed* hsame *and* Cont *routes in* C*.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionTasteGate single carrier alignment`

Theorem 428.2 (Dyadic step function NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$ *obligation surface consists of carrier habitation, refinement-stable classification by common dyadic refinement, exact finite cell coverage, stepwise handoff to* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers, and ledger exactness for partition refinement, endpoint transport, carried values, finite coverage, and absence of hidden quotient data.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier namecert obligations`

Proof. Carrier habitation is the finite packaging operation of Definition 428.1. The packet displays the dyadic partition, its interval cells, the carried values, the classifier reads, the refinement map, endpoint transport, the finite history ledger, route data, package provenance, and the local certificate row.

The classifier obligation is constructive because two packets are compared by first displaying a common dyadic refinement and then reading finitely many transported cell values. Each read is a $\mathsf{DyadicRatCore}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ classifier read already carried by the packet; the refinement map only selects the parent cell named in M.

The consumer obligations are the finite coverage and handoff clauses proved below. Together they show that every point read by a regular Cauchy or real consumer is accounted for by a visible cell, visible endpoints, a visible carried value, and a visible BEDC route. □

Definition 428.3 (Dyadic step function finite window carrier)**.** *A* $\mathsf{DyadicStepFunction}^{\uparrow}$ *finite-window carrier is the carrier of Definition 428.1 read as the public window*

$$W = (I, M, E, V, R, L, C, P, N).$$

Here I *exposes the finite partition cells,* M *exposes endpoint-parent transport under common refinement,* E *exposes endpoint ledgers,* V *exposes carried values,* R *exposes classifier rows,* L *exposes the finite consumer ledger,* C *exposes* hsame *and* Cont *routes,* P *exposes the* Pkg *provenance, and* N *exposes the local* $\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$ *row. The partition coordinate* Π *remains the source of the cells in* I*, but every downstream consumer reads the packet through the displayed window* W*.*

Lean4 (definition) `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionWindowCarrier`

Theorem 428.4 (Dyadic step function finite-window obligations)**.** *For every accepted* $\mathsf{DyadicStepFunction}^{\uparrow}$ *finite-window carrier* $W = (I, M, E, V, R, L, C, P, N)$*, the public obligation surface consists of finite partition-cell coverage, endpoint transport, carried-value exposure, classifier-row exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal reading, componentwise* hsame *and* Cont *transport,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$ *naming. Every* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or completion-facing consumer read through* W *must first land on a displayed common-refinement cell and then consume only the rows* $I, M, E, V, R, L, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier window obligations`

Proof. Start with the carrier and NameCert obligations of Definition 428.1 and Definition 428.2. They expose the partition, cells, endpoint transport, carried values, classifier reads, finite ledger, transport rows, provenance, and local name.

Next route a consumer read through common refinement. Apply Definition 428.9: the read lands on one displayed cell in I, then uses M for the parent-cell route and E for endpoint transport.

Now bind the value side. Apply Definition 428.10 to identify the endpoint route with the carried-value route through V and R, and apply Definition 428.8 to record the read in L.

Finally use Definition 428.7 and Definition 428.11. The regular-sequence handoff and the real seal read consume the same finite rows, while C, P, N supply the hsame, Cont, Pkg, and NameCert surface for replay and naming. □

Theorem 428.5 (Dyadic step function finite-window non-escape)**.** *Every accepted* DyadicStepFunction$^{\uparrow}$ *finite-window carrier exports its step-function,* RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *and completion-facing behavior only through*

$$I, M, E, V, R, L, C, P, N.$$

It exports no hidden host step function, quotient representative, selected limit, measure completion, open-cover compactness, or ambient equality oracle; every downstream read is routed through common-refinement cell coverage and ledger exactness before any handoff or seal row is consumed.

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier nonescape`

Proof. Project the finite-window carrier through Definition 428.3. The rows $I, M, E, V, R, L, C, P, N$ are the only public coordinates of the window.

Use Definition 428.4 to force each consumer read onto a displayed common-refinement cell. The endpoint route is read from E, the parent-cell route from M, the carried value from V, the classifier row from R, and the ledger entry from L.

The handoff rows do not add a second surface. By Definition 428.7 and Definition 428.11, RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ consumers receive the same finite-cell data after the ledger row has been exposed.

Finally apply Definition 428.8. Because every permitted read is already accounted for by the displayed rows and their hsame, Cont, Pkg, and NameCert data, none of the excluded host, quotient, completion, limit, compactness, or equality objects has an escape route. □

Theorem 428.6 (Dyadic step function refinement stability)**.** *Let S and T be accepted* DyadicStepFunction$^{\uparrow}$ *carriers. If their partitions refine to a displayed common dyadic partition and every refined cell transports to parent cells whose carried values are classified together by the recorded* DyadicRatCore$^{\uparrow}$ *or* Real$^{\uparrow}$ *classifier, then the* DyadicStepFunction$^{\uparrow}$ *classifier identifies S and T. The identification is stable under further* hsame *and* Cont *transport of the displayed partition, endpoint, value, and ledger rows.*

Proof. Project the two carriers through Definition 428.1. The common dyadic refinement supplies a finite list of refined cells, and the refinement maps of the two packets point each refined cell back to one parent cell in the original partitions.

On each refined cell, the hypothesis gives a displayed value comparison through the recorded DyadicRatCore$^{\uparrow}$ or Real$^{\uparrow}$ classifier. Endpoint transport is read from the two E ledgers, while the corresponding history rows are read from the two L ledgers.

Further transport by hsame and Cont changes only the displayed route data. Since the classifier is defined by the finite refinement list and the componentwise transported value reads, the same finite comparisons witness the transported identification. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionPacket refinement stability`

Theorem 428.7 (Dyadic step function RegSeqRat handoff)**.** *Every accepted* $\mathsf{DyadicStepFunction}^{\uparrow}$ *carrier exports a stepwise constant* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and the corresponding* $\mathsf{Real}^{\uparrow}$ *read by using the carried cell values on the finite dyadic partition. A* $\mathsf{DyadicSpline}^{\uparrow}$ *or regular Cauchy consumer can inspect the exported stream only through the displayed partition cells, endpoint transport, cell values, classifier reads, and* BHist *ledger rows of the carrier.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier regseqrat handoff`

Proof. For each cell of Π, choose the carried value already displayed in V. The handoff stream is constant on that cell and changes only at endpoints recorded in E.

Regularity is witnessed cellwise. A request at a finite precision reads the unique displayed cell covering the request, the transported carried value on that cell, and the corresponding $\mathsf{DyadicRatCore}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ classifier row in R.

A $\mathsf{DyadicSpline}^{\uparrow}$ or regular Cauchy consumer therefore receives only a finite stepwise surface. The consumer may refine the partition, but refinement is routed through M and cannot introduce a new cell value, a selected limit, or an unrecorded equality proof. □

Theorem 428.8 (Dyadic step function ledger exactness)**.** *For every accepted* $\mathsf{DyadicStepFunction}^{\uparrow}$ *carrier, the ledger L accounts for exactly the finite cell coverage of Π, the endpoint transport recorded in E, the refinement-parent relation recorded in M, and the carried-value reads recorded in V and R. No exported* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicSpline}^{\uparrow}$, *or completion-facing read factors through a hidden quotient, a measure completion, an unlisted representative, or an ambient choice principle.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier ledger exactness`

Proof. Project the carrier and inspect the finite cell list I. Exact coverage means every displayed consumer read names one cell of I, and every cell of I has its endpoints, adjacency data, and carried value recorded in the packet.

Endpoint and refinement exactness are the two route checks. Endpoint movement is read from E, and refinement movement is read from M; both ledgers point back to displayed cells and therefore cannot add an unlisted interval or value.

The exported consumer surfaces are then repacked from the same finite rows. Because the only available reads are V, R, M, E, L, C, P, and N, every $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicSpline}^{\uparrow}$, or completion-facing request remains inside the visible BEDC packet. □

Theorem 428.9 (Dyadic step function common refinement cell coverage)**.** *Let S and T be accepted* $\mathsf{DyadicStepFunction}^{\uparrow}$ *carriers, and let a* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{DyadicSpline}^{\uparrow}$ *consumer compare their exported step-function packets. Every such comparison refines to one displayed dyadic partition cell. On that cell, the consumer read is routed through the visible cell list I, refinement map M, endpoint ledger E, carried values V, classifier rows R, history ledger L, and the componentwise* hsame *and* Cont *route data of the carriers.*

Thus the common-refinement comparison is a finite cell-coverage statement over the displayed BEDC packet. It has no coordinate for an ambient host function, a quotient representative, a selected limit, or an unrecorded equality oracle.

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier common refinement cell coverage`

Proof. Project S and T through Definition 428.1. The displayed partition rows and cell lists give the only cells available to a consumer comparison.

Apply Definition 428.6. The comparison first moves both carriers to a common dyadic refinement, and each refined cell is sent back to its parent cell through the recorded refinement maps in M.

Apply Definition 428.8. Endpoint movement is read from E, carried values from V, classifier observations from R, and the finite history of the read from L. The remaining route data are exactly the displayed hsame and Cont entries in C, so every consumer read lands on one visible cell and no hidden representative can be inspected. □

Theorem 428.10 (Dyadic step function endpoint value transport determinacy)**.** *For accepted* DyadicStepFunction$^{\uparrow}$ *carriers compared after common dyadic refinement, the transported endpoint rows in E and the transported carried-value rows in V determine the same cellwise read. The determination is made through I, M, R, L,* hsame*, and* Cont *only, and does not depend on a hidden representative, a host step function, or an external choice of values.*

Proof. Project the accepted carriers through Definition 428.1. A refined cell has one displayed parent cell, named by M, and the endpoints of that parent cell are the rows transported by E.

Use Definition 428.6 to compare the transported parent cells. The carried value read is then the row selected from V and checked by the corresponding classifier row in R.

Finally apply Definition 428.8. The ledger L records both the endpoint transport and the carried-value read, so the two routes determine the same cellwise observation inside the displayed packet. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier endpoint value transport determinacy`

Theorem 428.11 (Dyadic step function RealUp seal window exactness)**.** *Every* Real$^{\uparrow}$ *seal read exported by an accepted* DyadicStepFunction$^{\uparrow}$ *carrier factors through finite common-refinement cell coverage, endpoint transport, the carried-value classifier, and the displayed ledger before the seal is consumed. Equivalently, a* Real$^{\uparrow}$ *consumer reaches the seal only after selecting a displayed cell in I, transporting its endpoints through E, transporting its parent by M, reading its carried value through V and R, and recording the read in L with the stored* hsame *and* Cont *routes.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier real seal window exactness`

Proof. Start with the seal-facing handoff of Definition 428.7. The RegSeqRat$^{\uparrow}$ export and the corresponding Real$^{\uparrow}$ read are stepwise constant on the displayed finite partition.

Apply Definition 428.9. Any transported consumer comparison first reduces to a displayed common-refinement cell, so the seal read cannot bypass the finite cell list.

Apply Definition 428.10 to identify the endpoint route with the carried-value route on that cell. Then apply Definition 428.8 to place the resulting read in L before the Real$^{\uparrow}$ seal is consumed. This exhausts the available carrier coordinates and leaves no path to quotient data, host functions, or selected limits. □

Theorem 428.12 (Dyadic step function cellwise sum closure)**.** *Let S and T be accepted* DyadicStepFunction$^{\uparrow}$ *packets. Suppose they admit a displayed common dyadic refinement whose refined cells are finite* BHist *cells, and suppose that on every refined cell the transported carried-value row of S, the transported carried-value row of T, and the displayed* DyadicRatCore$^{\uparrow}$ *or* Real$^{\uparrow}$ *sum row are recorded in*

the carrier ledger. Then the pointwise cellwise sum repacks as an accepted DyadicStepFunction$^{\uparrow}$ *packet.*

The repacked packet uses only the displayed refined cell list, endpoint transport, carried-value rows, classifier rows, finite ledger rows, and the componentwise hsame *and* Cont *route data. It does not introduce a host step function, a quotient representative, a selected limit, or an equality oracle outside the packet.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier cellwise sum closure`

Proof. Project S and T through Definition 428.1. The carrier exposes the finite cell list, endpoint rows, carried-value rows, classifier rows, ledger rows, and transport data from which the sum packet must be built.

Apply Definition 428.9. Every consumer-visible comparison of the two packets first lands on one displayed common-refinement cell, and the finite BHist list gives the induction spine for checking all cells.

On each refined cell, use Definition 428.10. The endpoint route and the carried-value route determine the same transported read, so the two summand values are the visible rows named by the refined packet data.

Finally apply Definition 428.8. The assumed DyadicRatCore$^{\uparrow}$ or Real$^{\uparrow}$ sum row is already recorded in the carrier ledger for that refined cell, and the stored hsame and Cont routes transport it componentwise. Repacking those finitely many rows gives the accepted DyadicStepFunction$^{\uparrow}$ sum packet with no access to host functions, quotient representatives, selected limits, or hidden equalities. □

Theorem 428.13 (Dyadic step function refinement intersection closure)**.** *Let S and T be accepted* DyadicStepFunction$^{\uparrow}$ *packets with displayed common dyadic refinements. Suppose the two refined packets expose finite cell lists in I, refinement maps in M, endpoint transport in E, carried-value rows in V, classifier rows in R, ledger rows in L, continuation rows in C, provenance rows in P, and names in N. Then the finite common cell intersection of the displayed refinements repacks as an accepted* DyadicStepFunction$^{\uparrow}$ *packet.*

The repacked packet is built only from I, M, E, V, R, L, C, P, and N. It carries the inherited hsame *and* Cont *routes for each intersected cell and does not call a host step function, quotient representative, selected limit, or ambient equality oracle.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier refinement intersection closure`

Proof. Project both packets through Definition 428.1. The two displayed refinements provide finite cell lists, and their common intersections are therefore enumerated by finite BHist data.

Apply Definition 428.9. Every consumer-visible comparison first lands on one displayed common-refinement cell, so the intersection packet has a visible cell for each comparison that can be made from S and T.

Use Definition 428.6 to transport each intersected cell back to its parent cells in the two packets. Endpoint transport through E and parent selection through M keep the refined cell attached to the displayed carrier rows.

Finally apply Definition 428.10 and Definition 428.8. The carried values and classifier reads are already in V, R, and L, while C, P, and N replay the same local package. Repacking those finitely many rows gives an accepted intersection packet without adding any external analytic object. □

Theorem 428.14 (Dyadic step function common-refinement normal form)**.** *Let S and T be accepted* DyadicStepFunction$^{\uparrow}$ *packets with displayed common dyadic refinements. Every* RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *or* DyadicSpline$^{\uparrow}$ *consumer comparison between S and T has a normal form consisting of one displayed refined cell, its parent-cell maps through M, endpoint transports through E, carried-value reads through V and R, a ledger entry in L, and the stored* hsame, Cont, Pkg, *and* NameCert *rows in C, P, and N.*

If two consumer routes name the same displayed refined cell, then their visible normal-form rows are the same M, E, V, R, L, C, P, N rows. The normal form does not inspect a host step function, a quotient representative, a selected limit, or an equality oracle outside the finite common-refinement packet.

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier common refinement normal form`

Proof. First isolate the finite cell. Apply Definition 428.9: every consumer comparison lands on one displayed common-refinement cell before any RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, or DyadicSpline$^{\uparrow}$ handoff can be read.

Next attach that cell to the packet rows. By Definition 428.6, the refined cell carries its parent-cell maps through M, and the endpoint transports remain the displayed rows in E.

Now bind the value and classifier reads. Use Definition 428.10 to identify the transported carried-value reads with the rows in V and R, then use Definition 428.8 to pin the consumer-facing comparison to the ledger entry in L.

Finally apply Definition 428.13. The intersection packet stores the same C, P, N local package rows for the refined cell, so two routes with the same displayed cell replay the same visible normal-form rows before reaching any downstream consumer. □

Theorem 428.15 (Dyadic step function cellwise product closure)**.** *Let S and T be accepted* DyadicStepFunction$^{\uparrow}$ *packets. Suppose they admit a displayed common dyadic refinement whose refined cells are finite* BHist *cells, and suppose that on every refined cell the transported carried-value row of S, the transported carried-value row of T, and the displayed* DyadicRatCore$^{\uparrow}$ *or* Real$^{\uparrow}$ *product row are recorded in the carrier ledger. Then the pointwise cellwise product repacks as an accepted* DyadicStepFunction$^{\uparrow}$ *packet.*

The repacked packet uses only the displayed refined cell list, endpoint transport, carried-value rows, classifier rows, finite ledger rows, and the componentwise hsame *and* Cont *route data. It does not introduce a host step function, a quotient representative, a selected limit, or an equality oracle outside the packet.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier product closure`

Proof. Project S and T through Definition 428.1. The carrier exposes the same finite partition, endpoint, value, classifier, ledger, transport, and continuation rows used by the sum packet.

Apply Definition 428.13. The product is read on the displayed common cell intersection, so both factors have visible transported carried-value rows on the cell where multiplication is performed.

On each refined cell, use Definition 428.10. The endpoint route and carried-value route determine the same visible read for each factor before the product row is consumed.

Finally apply Definition 428.8 together with Definition 428.11. The assumed DyadicRatCore$^{\uparrow}$ or Real$^{\uparrow}$ product row is already a ledger entry for that cell, and the seal-facing read cannot escape the displayed finite window. Repacking these rows gives the accepted product packet without invoking host functions, quotient representatives, selected limits, or hidden equalities. □

Theorem 428.16 (Dyadic step function stepwise order window)**.** *Let S and T be accepted* DyadicStepFunction$^{\uparrow}$ *packets. Any pointwise order comparison between S and T is witnessed after a displayed common dyadic refinement: on each refined cell, the transported carried-value rows and the displayed* DyadicRatCore$^{\uparrow}$ *or* Real$^{\uparrow}$ *order row determine the comparison visible to consumers. The order window is finite-cellwise and is recorded by the same I, M, E, V, R, L, C, P, and N rows as the packets themselves.*

Consequently the comparison cannot use a host function, a quotient representative, a selected limit, trichotomy on hidden real representatives, or an equality oracle outside the displayed carrier.

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier stepwise order window`

Proof. Begin with Definition 428.13. It gives a finite common-refinement packet whose cells cover all comparisons available from the two accepted packets.

For a fixed refined cell, apply Definition 428.6. The cell is transported back to displayed parent cells in S and T, and the endpoint rows remain attached to the refinement maps.

Use Definition 428.10 to identify the endpoint route with the carried-value route for both packets. The order row being compared is therefore the displayed DyadicRatCore$^{\uparrow}$ or Real$^{\uparrow}$ row named in the ledger, not a host-side comparison.

Finally apply Definition 428.8 and Definition 428.11. The ledger records each finite-cell order read before any seal-facing consumer can use it, so the comparison remains inside the displayed finite window. □

Theorem 428.17 (Dyadic step function scoped window package)**.** *Let S and T be accepted* DyadicStepFunction$^{\uparrow}$ *packets. Their scoped comparison packet is the finite common-refinement window whose cells cover all consumer-visible reads, whose endpoint rows are transported through E, and whose carried-value rows are read through V and R. The packet is entirely contained in the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of the two carriers.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier scoped window package`

Proof. Start with Definition 428.9. It places every comparison on one displayed cell of a common finite dyadic refinement.

Apply Definition 428.6. The refinement maps send each refined cell back to parent cells, while endpoint data remain attached through the displayed endpoint-transport ledgers.

Use Definition 428.8 to close the packet. All cell coverage, endpoint transport, carried-value reads, and classifier observations are recorded in the finite ledger and routed only by hsame and Cont data. □

Theorem 428.18 (Dyadic step function Real-RegSeqRat scope lock)**.** *Every* RegSeqRat$^{\uparrow}$ *handoff and every* Real$^{\uparrow}$ *seal read exported by an accepted* DyadicStepFunction$^{\uparrow}$ *packet is locked to the same finite cell window. The seal receives only the displayed partition cells, endpoint transport, carried values, classifier rows, ledger entries, and the recorded* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier real regseqrat scope lock`

Proof. Apply Definition 428.7. The regular sequence surface is built from the carried cell values on the displayed finite partition.

Next apply Definition 428.11. The Real$^{\uparrow}$ seal is reached only after common-refinement coverage, endpoint transport, carried-value classification, and ledger recording have occurred.

The two handoffs therefore share the same finite scope. Since Definition 428.8 excludes hidden quotient data, host functions, selected limits, and ambient choices, no seal-facing row can escape the displayed window. □

Theorem 428.19 (Dyadic step function refinement ledger scope)**.** *The refinement ledger of an accepted* $\mathsf{DyadicStepFunction}^{\uparrow}$ *packet is scoped by the finite rows* $\Pi, I, V, R, M, E, L, C, P, N$*. Common-refinement cell coverage, endpoint transport, value transport,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal exactness are all read from these rows, and no refinement consumer can introduce a host step function or unlisted representative.*

Proof. Project the carrier of Definition 428.1. The refinement map M, endpoint ledger E, finite history ledger L, and route row C are explicit coordinates of the packet.

Apply Definition 428.10. On each refined cell, endpoint transport and carried-value transport determine the same visible cellwise read.

Finally combine Definition 428.17 with Definition 428.18. The common refinement, regular handoff, and real seal are all ledger reads over $\Pi, I, V, R, M, E, L, C, P, N$, so the refinement scope is exact. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier refinement ledger scope`

Theorem 428.20 (Dyadic step function scoped obligation package)**.** *Every accepted* $\mathsf{DyadicStepFunction}^{\uparrow}$ *packet assembles a scoped finite obligation package consisting of carrier habitation, refinement stability,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, ledger exactness, common-refinement coverage, endpoint-value transport,* $\mathsf{Real}^{\uparrow}$ *seal-window exactness, cellwise sum closure, cellwise product closure, and the stepwise order window. The package is over the displayed* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{DyadicSpline}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$ *rows.*

The scoped package exports no measure completion, quotient representative, selected limit, host step function, or ambient equality oracle.

Proof. First project the carrier and classifier rows. The finite partition, dyadic interval cells, carried values, common-refinement maps, endpoint routes, classifier rows, ledger entries, continuation rows, package provenance, and local naming row are the only visible coordinates.

Apply the refinement stability, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, ledger exactness, common-refinement coverage, endpoint-value transport, and $\mathsf{Real}^{\uparrow}$ seal-window exactness theorems. These results bind every cellwise read to the displayed mesh, interval, rational, spline, regular-sequence, real, history, transport, continuation, package, and naming rows.

Finally use the cellwise sum, cellwise product, and stepwise order window theorems. They show that the visible finite-cell operations and comparisons repack inside the same scoped rows, so no measure completion, quotient representative, selected limit, host step function, or ambient equality oracle is exported. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier scoped obligation package`

Theorem 428.21 (DyadicStepFunction scope export)**.** *The scoped obligation package of Definition 428.20 exports exactly the downstream surface consisting of the* $\mathsf{DyadicRatCore}^{\uparrow}$ *partition and value rows, the* $\mathsf{DyadicMesh}^{\uparrow}$ *and* $\mathsf{DyadicSpline}^{\uparrow}$ *refinement rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the* $\mathsf{Real}^{\uparrow}$ *seal-window exactness rows. Every downstream step-function consumer must read through those displayed rows together with the carrier's* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$ *coordinates.*

No exported scope includes open-cover compactness, a host function space, selected limits, quotient representatives, measure completion, or an ambient equality oracle.

Proof. First read the local scoped package. By Definition 428.20, every admitted packet is already restricted to the displayed mesh, interval, value, refinement, endpoint, ledger, continuation, provenance, and local naming rows.

Next isolate the rows visible to downstream consumers. The carrier and refinement ledger scope of Definition 428.1 and Definition 428.19 provide the $\mathsf{DyadicRatCore}^{\uparrow}$ partition and value rows together with the $\mathsf{DyadicMesh}^{\uparrow}$ and $\mathsf{DyadicSpline}^{\uparrow}$ refinement rows.

The analytic handoff is exactly the one already bounded locally. Apply Definition 428.18 for the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and Definition 428.11 for the $\mathsf{Real}^{\uparrow}$ seal-window exactness.

Finally combine the non-escape clauses of Definition 428.8 and Definition 428.17. They exclude open-cover compactness, host function spaces, selected limits, quotient representatives, measure completion, and ambient equality oracles from the exported surface. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier scope export`

Theorem 428.22 (Dyadic step function refinement boundary coverage)**.** *Every accepted common-refinement consumer read of a* $\mathsf{DyadicStepFunction}^{\uparrow}$ *packet is covered by the displayed finite cells, endpoint ledgers, carried-value rows, classifier rows, and* BHist *ledger entries of the carrier. Equivalently, a consumer that reads through a common dyadic refinement must first land on one cell of the visible refinement window and then consume only the endpoint transport in* E*, the carried values in* V*, the classifier rows in* R*, the finite ledger* L*, and the stored* hsame *and* Cont *routes.*

The refinement boundary exports no host step function, measure completion, quotient representative, selected limit, or ambient equality oracle.

Proof. First apply Definition 428.9. It places every accepted consumer comparison on a displayed common-refinement cell and identifies the available read coordinates as $I, M, E, V, R, L, C, P, N$.

Next use Definition 428.10. On the selected cell, endpoint transport and carried-value transport determine the same visible read, so the consumer cannot split the endpoint route from the value route.

Finally apply Definition 428.18 and Definition 428.19. These keep $\mathsf{RegSeqRat}^{\uparrow}$ handoffs and $\mathsf{Real}^{\uparrow}$ seal reads inside the same finite ledger before any downstream consumer can inspect them. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier refinement boundary coverage`

Theorem 428.23 (Dyadic step function scope transport package)**.** *The carrier surface, refinement stability, endpoint-value determinacy,* $\mathsf{Real}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$ *scope lock, and refinement ledger scope assemble into one kernel-scoped* $\mathsf{DyadicStepFunction}^{\uparrow}$ *package over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The package binds every accepted partition cell, common-refinement read, endpoint transport, carried-value row, classifier row, regular-sequence handoff, real seal read, and ledger entry to the displayed finite carrier rows.*

This scope transport package is the single packet consumed by downstream step-function, regular Cauchy, and real-facing readers; it has no coordinate for open-cover compactness, host function spaces, quotient representatives, selected limits, measure completion, or ambient equality.

Proof. Start with the carrier and classifier data of Definition 428.1. The packet exposes the finite partition, interval cells, carried values, refinement map, endpoint ledger, finite history ledger, continuation routes, provenance, and local naming row.

Use Definition 428.6 and Definition 428.10. They transport common-refinement cells and identify endpoint and carried-value reads by the stored hsame and Cont routes.

Next apply Definition 428.18 and Definition 428.19. These bind the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{Real}^{\uparrow}$ seal, and refinement ledger to the same finite rows.

Finally invoke Definition 428.20. It packages the carrier, stability, handoff, ledger, coverage, endpoint-value, and seal-window rows into the kernel-scoped obligation surface, so the stated scope transport package has no hidden analytic coordinate. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier scope transport package`

Theorem 428.24 (Dyadic step function real-seal public boundary)**.** *Every accepted* $\mathsf{DyadicStepFunction}^{\uparrow}$ *packet exports its* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal rows as one public boundary over the finite coordinates* $I, M, E, V, R, L, C, P, N$*. The boundary is assembled from the displayed partition cells, common-refinement maps, endpoint transport, carried values, classifier rows, finite ledger entries, continuation routes, package provenance, and local naming row.*

The public boundary exports no open-cover compactness, host step function, selected limit, quotient representative, measure completion, or ambient equality oracle.

Proof. First read the finite scope transport package of Definition 428.23. It already binds every partition cell, common-refinement read, endpoint route, value row, classifier row, ledger entry, continuation route, package row, and local naming row to the displayed carrier surface.

Next isolate the analytic handoff rows. Apply Definition 428.18 to bind the $\mathsf{RegSeqRat}^{\uparrow}$ handoff to the finite step-function rows, and apply Definition 428.11 to bind the $\mathsf{Real}^{\uparrow}$ seal-window read to the same visible cellwise data.

Finally repack those two rows through Definition 428.20. The resulting public boundary has exactly the coordinates $I, M, E, V, R, L, C, P, N$, so none of the excluded analytic or quotient objects has an exported coordinate. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier real seal public boundary`

Theorem 428.25 (Dyadic step function common-refinement public route)**.** *Every public consumer route for common-refinement data in an accepted* $\mathsf{DyadicStepFunction}^{\uparrow}$ *packet factors through the displayed coordinates* $I, M, E, V, R, L, C, P, N$*. A route may read interval cells, mesh refinements, endpoint transport, carried values, classifier rows, finite ledger entries, continuation routes, package provenance, and the local* $\mathsf{NameCert}$ *row, but it cannot bypass those rows through a host step function, quotient representative, selected limit, measure completion, or ambient equality oracle.*

Proof. Start with the refinement boundary coverage of Definition 428.22. It places every accepted common-refinement consumer on a visible cell and identifies the available read coordinates as $I, M, E, V, R, L, C, P, N$.

The endpoint and carried-value routes then agree by Definition 428.10. This prevents a public consumer from splitting the endpoint route away from the value row after entering the common refinement.

The public analytic boundary is supplied by Definition 428.24. It attaches the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and $\mathsf{Real}^{\uparrow}$ seal rows to the same coordinates already exposed by the common-refinement coverage.

Therefore every public consumer route factors through $I, M, E, V, R, L, C, P, N$. The excluded host and quotient objects have no row in that factorization, so they cannot serve as bypass routes. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier common refinement public route`

Theorem 428.26 (Dyadic step function common-refinement Real correspondence)**.** *For accepted* $\mathsf{DyadicStepFunction}^{\uparrow}$ *packets compared through a displayed common dyadic refinement, the public consumer route through finite cells, endpoint transport, carried values, classifier rows, and finite ledger entries is the same route consumed by the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and the* $\mathsf{Real}^{\uparrow}$ *seal-window read. Equivalently, after the common refinement has exposed* $I, M, E, V, R, L, C, P, N$*, a downstream consumer may pass from the cellwise step-function surface to the regular-Cauchy handoff and to the real seal boundary without introducing any further comparison coordinate.*

This correspondence exports no host step function, quotient representative, measure completion, selected limit, or ambient equality oracle.

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.CommonRefinementRealRegseq.DyadicStepFunctionCarrier common refinement real regseq correspondence`

Proof. First expose the common-refinement cells. Apply Definition 428.9 to place every accepted comparison on displayed dyadic cells and to keep the visible rows inside $I, M, E, V, R, L, C, P, N$.

Next transport the cell data. Apply Definition 428.10 so endpoint reads and carried-value reads follow the same stored hsame and Cont routes before any consumer leaves the finite refinement ledger.

The analytic handoff uses no separate route. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff is bounded by Definition 428.18, and the public seal boundary is bounded by Definition 428.24. Both the regular-Cauchy row and the $\mathsf{Real}^{\uparrow}$ seal-window read therefore consume the same cell, endpoint, value, classifier, and ledger rows already exposed by the common refinement.

Thus the public common-refinement route and the $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ route are two readings of the same finite packet surface. The excluded host, quotient, completion, limit, and ambient equality objects have no coordinate in that packet, so they cannot distinguish the two routes. □

Theorem 428.27 (Dyadic step function public certificate)**.** *Every accepted* $\mathsf{DyadicStepFunction}^{\uparrow}$ *packet exports a public* $\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$ *certificate whose visible surface is exactly the finite dyadic partition, interval-cell row, mesh and common-refinement row, endpoint transport, carried values, classifier rows, finite ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$*. The certificate is the public export of the carrier rows* $I, M, E, V, R, L, C, P, N$*.*

This public certificate claims no host step functions, quotient representatives, measure completion, selected limits, or ambient equality.

Proof. First expose the finite common-refinement surface. Apply Definition 428.9 to place every accepted packet read on displayed dyadic cells, and use Definition 428.25 to keep the visible route inside $I, M, E, V, R, L, C, P, N$.

Next bind endpoint and value reads. Apply Definition 428.10; endpoint transport and carried values are therefore read through the same stored hsame and Cont routes before a public consumer can leave the finite ledger.

The real-facing boundary is already local to those rows. Use Definition 428.18 for the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and Definition 428.24 for the $\mathsf{Real}^{\uparrow}$ seal boundary.

Finally apply Definition 428.26. It identifies the public common-refinement route with the regular-Cauchy and real-seal route, so repacking $I, M, E, V, R, L, C, P, N$ gives exactly the stated public $\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$ certificate and leaves the refused host, quotient, completion, limit, and ambient-equality objects without coordinates. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionCarrier public certificate`

Theorem 428.28 (Dyadic step function standard bridge)**.** *The public* $\mathsf{DyadicStepFunction}^{\uparrow}$ *certificate of Definition 428.27 is transported through the displayed dyadic mesh, dyadic interval,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The bridge imports no host step function, ambient completeness object, selected limit, quotient representative, measure completion, or ambient equality oracle.*

Proof. Start from the public certificate surface. By Definition 428.27, every visible read of the packet is already exposed through the finite partition, interval-cell row, mesh and common-refinement row, endpoint transport, carried values, classifier rows, finite ledger, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{Real}^{\uparrow}$ seal row, transport, replay, provenance, and local naming.

The bridge therefore has no extra analytic coordinate to import. Use Definition 428.25 for the dyadic mesh and interval route, Definition 428.18 for the regular-Cauchy handoff, and Definition 428.24 for the real seal boundary.

Finally, Definition 428.26 identifies the common-refinement route with the regular-Cauchy and real-seal route. Thus the standard bridge is exactly the displayed packet transport through $I, M, E, V, R, L, C, P, N$, with the refused host and completion objects remaining outside the public certificate. □

Lean4 ✓ `BEDC.Derived.DyadicStepFunctionUp.DyadicStepFunctionUp StdBridge`

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$.

Constructive story: A dyadic step-function packet is generated by a finite dyadic partition, displayed interval cells, carried values, common-refinement maps, endpoint transport, finite consumer ledgers, and visible transport and provenance rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 428.28 transports the public certificate surface over the displayed finite partition, dyadic interval, carried value, common-refinement, endpoint-transport, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows of the finite step-function packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicStepFunction}^{\uparrow}}$, bridgeChecked)

Chapter 429

A Concrete Naming Certificate for $\mathsf{RegularCauchyDifference}^{\uparrow}$

The $\mathsf{RegularCauchyDifference}^{\uparrow}$ interface names the finite pointwise-subtraction surface for two regular rational Cauchy names. Following Bishop and Bridges, *Constructive Analysis*, it records the displayed difference stream that a $\mathsf{NullSequence}^{\uparrow}$ consumer may later inspect, without forming a quotient of streams, selecting a host limit, or appealing to ambient real completeness.

The two source rows are read through chapter 371, and the zero-shrinkage consumer row is read through chapter 380. The $\mathsf{RegularCauchyDifference}^{\uparrow}$ packet consumes those sibling surfaces to form a pointwise subtraction packet; it introduces no quotient stream equality, host real equality, selected limits, or ambient completeness.

Definition 429.1 (RegularCauchyDifference carrier)**.** *A* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, Y, S, T, Z, H, C, P, N)$$

with the following displayed coordinates:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose scheduled rational observations are compared pointwise;*
2. *S is the pointwise dyadic subtraction schedule, aligning the inspected* $\mathsf{StreamName}^{\uparrow}$ *windows of X and Y and forming the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row for $X - Y$ at each requested precision;*
3. *T is the transported* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the source windows, endpoint rows, requested dyadic bounds, and output tolerance assigned to the difference row;*
4. *Z is the* $\mathsf{NullSequence}^{\uparrow}$ *consumer row when the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *difference stream shrinks to zero;*
5. *H stores componentwise* hsame *transports for the two source rows, the aligned windows, the dyadic subtraction rows, the tolerance ledger, and the optional null-sequence consumer row;*
6. *C stores the* Cont *routes for reading the two source windows, forming the dyadic subtraction row, transporting the tolerance ledger, and exposing Z when zero-shrinkage is supplied;*
7. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDifference}^{\uparrow}}$ *row.*

The carrier is a finite difference certificate for regular Cauchy names. It stores no quotient stream, no selected limit, no host real equality, and no ambient completeness object.

Theorem 429.2 (RegularCauchyDifference NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDifference}^{\uparrow}}$ *surface for the carrier of Definition 429.1 consists of five finite obligations:*

1. *carrier admission: the accepted object is the displayed packet D with two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, a pointwise subtraction schedule, a transported tolerance ledger, an optional* $\mathsf{NullSequence}^{\uparrow}$ *consumer row, transport rows, continuation rows, provenance, and local naming data;*
2. *classifier transport: classification transports the two source rows, aligned windows, dyadic subtraction rows, tolerance ledger, and null-sequence consumer componentwise through the stored* hsame *and* Cont *rows;*
3. *stability: replacing either source by a classified regular Cauchy name preserves the finite subtraction schedule and recomputes the same kind of displayed difference row;*
4. *ledger exactness: every output tolerance read by the difference row is the displayed tolerance in T, obtained from the two source windows and the dyadic subtraction schedule S;*
5. *downstream handoff: every* $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of the difference first reads $X, Y, S, T, Z, H, C, P, N$.*

Proof. Carrier admission is projection from the tuple in Definition 429.1. The two source names, subtraction schedule, tolerance ledger, consumer row, transport routes, continuation routes, package row, and local naming row are all explicit coordinates of D.

Classifier transport is componentwise. The two $\mathsf{RegSeqRat}^{\uparrow}$ source rows transport their scheduled rational observations, the $\mathsf{StreamName}^{\uparrow}$ windows transport the finite reads, and the $\mathsf{DyadicRatCore}^{\uparrow}$ rows transport the endpoint subtraction calculation at the requested precision.

The tolerance ledger is finite. It records the source windows and the output tolerance before any consumer sees the difference row. The downstream handoff is therefore the displayed difference surface together with Z when zero-shrinkage is supplied, and no omitted coordinate can add quotient streams, selected limits, host real equality, or ambient completeness. □

Theorem 429.3 (RegularCauchyDifference regularity closure)**.** *Given accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows X and Y in a* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *packet, the schedule S and ledger T expose a displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *difference row. Each requested precision reads aligned* $\mathsf{StreamName}^{\uparrow}$ *windows for X and Y, forms the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint subtraction row, and records the output tolerance in the same finite ledger.*

Proof. Read the two regular source names through their aligned stream windows. The schedule S names the common finite observation at which the two endpoint rows are inspected.

Apply the displayed dyadic subtraction operation to the two endpoint rows. The resulting point row is still inside the packet, and the source regularity rows provide the tolerance entries that T records for the output request.

Repack these finite observations as the displayed $\mathsf{RegSeqRat}^{\uparrow}$ difference row. Since the construction uses only X, Y, S, T and the visible transport and continuation rows, it does not require a completed real, a selected limit, or a quotient stream. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDifferenceUp.RegularCauchyDifferenceCarrier regularity closure`

Theorem 429.4 (RegularCauchyDifference classifier transport)**.** *Let $D = (X, Y, S, T, Z, H, C, P, N)$ and $D' = (X', Y', S', T', Z', H', C', P', N')$ be accepted* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *carriers classified by the displayed* hsame *and* Cont *routes. Transporting the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows transports the aligned* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *subtraction schedule, the tolerance ledger, and the optional* $\mathsf{NullSequence}^{\uparrow}$ *consumer row componentwise through the same carrier surface.*

Proof. Project both carriers through Definition 429.1. The classifier has access only to the two source rows, the schedule, the tolerance ledger, the optional null-sequence row, and the displayed transport, continuation, package, and naming rows.

Apply the classifier clause of Definition 429.2. The source rows transport first; the aligned windows and dyadic endpoint subtraction rows are then read through the same schedule route.

The regularity closure of Definition 429.3 repacks the transported finite observations as the displayed difference row. Hence classifier transport stays inside the same finite carrier surface and does not use quotient streams, selected limits, host real equality, or ambient completeness. □

Theorem 429.5 (RegularCauchyDifference tolerance ledger exactness)**.** *For every accepted* RegularCauchyDifferenc *carrier $D = (X, Y, S, T, Z, H, C, P, N)$, every tolerance consumed by the displayed pointwise difference row is exactly the entry of the transported ledger T obtained from the two aligned source windows and the subtraction schedule S. No consumer may replace T by an external modulus, host real equality proof, selected limit, or ambient completeness row.*

Proof. Start with the output tolerance request in Definition 429.3. The request first reads aligned $\mathsf{StreamName}^{\uparrow}$ windows for X and Y, then forms the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint subtraction row named by S.

The ledger clause of Definition 429.2 records the output tolerance before any downstream consumer reads the difference. Thus the tolerance is the visible row in T and is transported by the displayed hsame and Cont routes.

Finally use the carrier inventory. Since no coordinate of D is an external modulus, host real equality proof, selected limit, or ambient completeness theorem, there is no other tolerance source available to a consumer. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDifferenceUp.RegularCauchyDifferenceCarrier tolerance ledger exactness`

Theorem 429.6 (RegularCauchyDifference RealUp seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *carrier $D = (X, Y, S, T, Z, H, C, P, N)$ receives the pointwise subtraction surface through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *difference row, the tolerance ledger exactness row for T, and the* $\mathsf{NullSequence}^{\uparrow}$ *consumer row Z when zero-shrinkage is supplied. The handoff exposes no quotient stream, selected host limit, host real equality, or ambient completeness object.*

Proof. First obtain the displayed difference row from Definition 429.3. Its observations are the dyadic subtraction rows read from X, Y, and S.

Next apply Definition 429.5. This fixes the tolerance read as the ledger T, so the Real-facing route cannot substitute an external modulus or selected limit.

If the consumer asks for a zero-tail route, apply Definition 429.7. Otherwise the non-escape boundary of Definition 429.8 still forces the read through the displayed carrier rows, so every $\mathsf{Real}^{\uparrow}$ seal handoff is finite and visible. □

Theorem 429.7 (RegularCauchyDifference NullSequence consumption)**.** *If the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *difference row of Definition 429.3 shrinks to zero, then the row Z is exactly the* $\mathsf{NullSequence}^{\uparrow}$ *consumer surface for that difference. Every tolerance request consumed by Z factors through the*

transported ledger T, the subtraction schedule S, the source rows X, Y, and the displayed hsame, Cont, Pkg, *and* NameCert *provenance of the carrier.*

Proof. Start with the displayed difference row supplied by Definition 429.3. It is already a regular rational stream read through the two source rows, the finite subtraction schedule, and the tolerance ledger.

When zero-shrinkage is supplied, project the coordinate Z. The NullSequence$^{\uparrow}$ consumer reads precisely the tolerance requests in T and the finite difference observations formed by S before exposing any real-seal equality evidence.

The provenance rows do not add analytic data. They route the same source rows, windows, endpoint subtraction rows, and tolerances through hsame, Cont, Pkg, and the local NameCert row. Thus the null-sequence consumption is exactly the finite difference packet and not an ambient equality of host reals. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDifferenceUp.RegularCauchyDifferenceCarrier nullsequence consumption`

Theorem 429.8 (RegularCauchyDifference non-escape boundary)**.** *No accepted* RegularCauchyDifference$^{\uparrow}$ *packet exports quotient streams, host real equality, selected limits, or ambient completeness. Every public read of a pointwise difference, and every zero-shrinkage read by* NullSequence$^{\uparrow}$*, is exhausted by the finite* BHist *rows named in Definition 429.1 and by the handoff rows of Definition 429.3 and Definition 429.7.*

Proof. Inspect the carrier inventory. The only analytic coordinates are two regular rational source rows, the finite subtraction schedule, the transported tolerance ledger, and the null-sequence consumer row when a zero-tail certificate is present.

The regularity closure theorem shows that regular consumers receive only the scheduled pointwise difference row and its tolerance ledger. The null-sequence consumption theorem places zero-tail consumers downstream of that same displayed difference row.

These routes exhaust the packet. Since no listed coordinate is a quotient stream, host real equality, selected limit, or ambient completeness theorem, no consumer can read such an object from the RegularCauchyDifference$^{\uparrow}$ certificate. □

Theorem 429.9 (RegularCauchyDifference difference carrier closure)**.** *Let $D = (X, Y, S, T, Z, H, C, P, N)$ be an accepted* RegularCauchyDifference$^{\uparrow}$ *carrier whose source rows X and Y are accepted* RegSeqRat$^{\uparrow}$ *rows. The displayed pointwise difference of X and Y is again read as a row inside the same* RegularCauchyDifference$^{\uparrow}$ *carrier: its windows are the aligned* StreamName$^{\uparrow}$ *windows named by S, its rational observations are the* DyadicRatCore$^{\uparrow}$ *subtraction rows named by S, and its tolerances are exactly the entries of T.*

Proof. Project the accepted carrier D. The two RegSeqRat$^{\uparrow}$ source rows, the alignment schedule, and the tolerance ledger are visible coordinates before any consumer reads the difference.

Apply Definition 429.3. It forms the displayed regular rational difference row by reading the aligned windows of X and Y, performing the dyadic subtraction recorded by S, and recording the output request in T.

The repacked row uses only the carrier coordinates already listed in Definition 429.1. Thus the difference remains inside the displayed RegularCauchyDifference$^{\uparrow}$ packet and does not pass through a quotient stream, selected limit, host real equality, or ambient completeness object. □

Theorem 429.10 (RegularCauchyDifference NullSequence classifier stability)**.** *For accepted* RegularCauchyDifferen *carriers classified by the displayed* hsame *and* Cont *routes,* NullSequence$^{\uparrow}$ *consumption is stable: if one displayed difference row is consumed by its zero-shrinkage row Z, then the classified carrier consumes the transported displayed difference through the corresponding* NullSequence$^{\uparrow}$ *row, with the same source rows, subtraction schedule, tolerance ledger, package provenance, and local naming route transported componentwise.*

Proof. Start with the zero-shrinkage read in Definition 429.7. The consumer row Z reads the difference only through the source rows X, Y, the subtraction schedule S, and the tolerance ledger T.

Transport the classified carrier componentwise along the displayed hsame and Cont rows. The source names, aligned windows, dyadic subtraction rows, tolerance ledger, package provenance, and local NameCert row are all moved by the same routes used in Definition 429.2.

The transported Z therefore consumes the transported displayed difference and no additional analytic witness. Stability is exactly the classifier action on the finite carrier rows, followed by the same NullSequence$^{\uparrow}$ consumer route. □

Theorem 429.11 (RegularCauchyDifference RealUp seal route)**.** *Every* Real$^{\uparrow}$ *seal read that uses a* RegularCauchyDifference$^{\uparrow}$ *packet factors through the displayed* DyadicRatCore$^{\uparrow}$ *subtraction rows, the* NullSequence$^{\uparrow}$ *consumer row when zero-shrinkage is supplied, the* RegSeqRat$^{\uparrow}$ *source and difference rows, the* StreamName$^{\uparrow}$ *windows, and the carrier's* hsame*,* Cont*,* Pkg*, and* NameCert *rows. No* Real$^{\uparrow}$ *consumer can bypass these rows to obtain a quotient stream, selected limit, host real equality, or ambient completeness principle.*

Proof. First read the displayed difference row. By Definition 429.9, the route begins with the two RegSeqRat$^{\uparrow}$ source rows, their aligned StreamName$^{\uparrow}$ windows, the DyadicRatCore$^{\uparrow}$ subtraction rows, and the tolerance ledger.

If the seal route is a zero-tail route, apply Definition 429.7. The NullSequence$^{\uparrow}$ row is downstream of the displayed difference row and consumes only the tolerances and observations stored in the packet.

Finally apply the non-escape boundary of Definition 429.8. The remaining rows are the visible hsame transports, Cont routes, Pkg provenance, and local NameCert row, so every Real$^{\uparrow}$ read factors through the displayed carrier inventory. □

Theorem 429.12 (RegularCauchyDifference obligation package)**.** *For an accepted* RegularCauchyDifference$^{\uparrow}$ *carrier*

$$D = (X, Y, S, T, Z, H, C, P, N),$$

the local obligation package is exactly the finite package that combines carrier admission for D, classifier transport for the source rows, aligned windows, dyadic subtraction rows, tolerance ledger, and optional null-sequence row, regularity closure of the displayed pointwise difference, tolerance-ledger exactness for T, NullSequence$^{\uparrow}$ *consumption through Z, and the* Real$^{\uparrow}$ *seal route through the same displayed rows.*

Proof. Carrier admission is Definition 429.1 together with Definition 429.2. These identify the accepted object as the finite tuple D and list the source rows, schedule, ledger, consumer row, transport rows, continuation rows, package provenance, and local naming row.

Classifier transport and regularity closure are the next two obligations. Apply Definition 429.4 to move the source rows, aligned windows, subtraction rows, ledger, and optional consumer row

componentwise. Apply Definition 429.3 and Definition 429.9 to repack the transported observations as the displayed regular rational difference row.

The consumer obligations are exhausted by the ledger and seal theorems. Use Definition 429.5 for the tolerance row, Definition 429.7 for zero-shrinkage reads, and Definition 429.11 for Real-facing reads. The non-escape boundary of Definition 429.8 shows that no quotient stream, selected limit, host real equality, or ambient completeness row is available outside this package. □

Theorem 429.13 (RegularCauchyDifference schedule exactness)**.** *Every pointwise difference read exported by an accepted* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *carrier* $D = (X, Y, S, T, Z, H, C, P, N)$ *is generated by the aligned* $\mathsf{StreamName}^{\uparrow}$ *windows named by* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *subtraction rows named by* S*, and the transported tolerance ledger* T*. In particular, a difference read has no alternative source outside the displayed source rows* X, Y*, schedule* S*, and ledger* T*.*

Proof. Begin with the displayed difference read. By Definition 429.9, its windows are the aligned $\mathsf{StreamName}^{\uparrow}$ windows named by S, its rational observations are the $\mathsf{DyadicRatCore}^{\uparrow}$ subtraction rows named by S, and its tolerances are the entries of T.

The exactness of the tolerance coordinate is Definition 429.5. It forces every output tolerance request through the transported ledger rather than an external modulus or host equality witness.

Finally apply Definition 429.8. Since the carrier exposes no quotient stream, selected limit, host real equality, or ambient completeness object, every exported pointwise difference read is precisely the scheduled finite read through X, Y, S, T. □

Theorem 429.14 (RegularCauchyDifference consumer exhaustion)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *carrier factors through the displayed packet*

$$D = (X, Y, S, T, Z, H, C, P, N).$$

The regular consumer reads the displayed difference row through X, Y, S, T*; the null-sequence consumer reads the zero-shrinkage surface through* Z *and the same ledger; and the Real-facing consumer reads only the seal route supplied by those carrier rows.*

Proof. For the $\mathsf{RegSeqRat}^{\uparrow}$ consumer, apply Definition 429.3 and Definition 429.9. The consumer receives the displayed pointwise difference row through the two source rows, aligned windows, dyadic subtraction rows, and tolerance ledger.

For the $\mathsf{NullSequence}^{\uparrow}$ consumer, apply Definition 429.7. The zero-shrinkage row Z consumes the same displayed difference and the same tolerance ledger before exposing any downstream evidence.

For the $\mathsf{Real}^{\uparrow}$ consumer, apply Definition 429.6 and Definition 429.11. Both routes factor through the displayed regular row, optional null-sequence row, transport rows, continuation rows, package provenance, and local $\mathsf{NameCert}$ row. The non-escape boundary then rules out any consumer path outside D. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDifference}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyDifference}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, a pointwise $\mathsf{DyadicRatCore}^{\uparrow}$ subtraction schedule over aligned $\mathsf{StreamName}^{\uparrow}$ windows, a transported tolerance ledger, a $\mathsf{NullSequence}^{\uparrow}$ consumer row when the difference shrinks, displayed hsame transports, Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDifference}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The scoped dependency surface is bound by Definition 429.12, Definition 429.13, and Definition 429.14: all BHist carrier rows, hsame transports, Cont routes, Pkg provenance, local NameCert data, $\mathsf{NullSequence}^{\uparrow}$ consumption, $\mathsf{RegSeqRat}^{\uparrow}$ difference reads, and $\mathsf{Real}^{\uparrow}$ seal routing factor through the same finite packet.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyDifference}\uparrow}$, axiomClean)
Lean target: `BEDC.Derived.RegularCauchyDifferenceUp.RegularCauchyDifferenceCarrier\_tolerance\_ledger\_exactness`
Bridge status: paperBridge
Origin: human
Not claimed: This chapter does not close quotient streams, host real equality, selected limits, ambient completeness, completed-real subtraction laws, or bridge checking.
Upgrade path: No theory-axis upgrade remains; bridge-checked verification requires a checked standard bridge for the same subtraction schedule and tolerance ledger.

Chapter 430

A Concrete Naming Certificate for $\mathsf{ArchimedeanReal}^{\uparrow}$

The $\mathsf{ArchimedeanReal}^{\uparrow}$ interface records the finite rational-bound surface for a displayed $\mathsf{Real}^{\uparrow}$ name. Following Bishop and Bridges, *Constructive Analysis*, boundedness is read from explicit rational witnesses and dyadic inspection rows, not from a host supremum, quotient equality of streams, a choice-selected bound, or ambient completeness.

The packet is a $\mathsf{Real}^{\uparrow}$ consumer and therefore reads the displayed real-name seal through chapter 38 before exporting rational-bound rows. This sibling edge is substantive: the first coordinate of the Archimedean carrier is the $\mathsf{Real}^{\uparrow}$ name R, while Q, D, S, G, B are the bound, inspection, and ledger rows surrounding that real-name seal.

Definition 430.1 (ArchimedeanReal carrier)**.** *An* $\mathsf{ArchimedeanReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N)$$

with the following displayed coordinates:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *name whose rational boundedness is being certified;*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *row naming the exported rational bound;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row that presents the same bound at the dyadic inspection surface consumed by real-name windows;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which finite observations of R are read;*
5. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row attached to the real name, so that each inspected rational observation has a regular-Cauchy source;*
6. *B is the finite bound ledger comparing the inspected G observations against Q and D at the requested precision;*
7. *H stores componentwise* hsame *transports for the real name, rational bound row, dyadic bound row, stream window, regular-Cauchy handoff, and bound ledger;*
8. *C stores the* Cont *routes that expose the finite real-name windows, dyadic bound checks, regular-Cauchy reads, and rational-bound export;*
9. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanReal}^{\uparrow}}$ *row.*

The packet is an Archimedean bound certificate for a displayed real name. It stores no host supremum, no selected least bound, no quotient stream equality, and no ambient completeness object.

Lean4 (definition) `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealUp`

Theorem 430.2 (ArchimedeanReal NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ArchimedeanReal}^{\uparrow}}$ *surface for the carrier of Definition 430.1 consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the displayed packet A with a* $\mathsf{Real}^{\uparrow}$ *name, a* $\mathsf{Rat}^{\uparrow}$ *bound row, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound presentation, a* $\mathsf{StreamName}^{\uparrow}$ *inspection window, a* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, a finite bound ledger, transport rows, continuation rows, package provenance, and local naming data;*
2. *classifier transport: classification transports the real name, rational bound, dyadic bound presentation, stream window, regular-Cauchy handoff, and bound ledger componentwise through the stored* hsame *and* Cont *routes;*
3. *stability: replacing R, Q, D, S, or G by classified rows preserves the same kind of finite rational-bound ledger and exposes the transported bound row;*
4. *ledger exactness: every accepted bound read is the displayed comparison in B between the inspected regular-Cauchy observations and the rational or dyadic bound rows Q, D;*
5. *rational-bound export: every* $\mathsf{Real}^{\uparrow}$ *order, locatedness, or completion-facing consumer first receives $Q, D, S, G, B, H, C, P, N$ before it can use the bound.*

Proof. Carrier admission is projection from the tuple in Definition 430.1. The real name, rational bound, dyadic presentation, stream window, regular-Cauchy handoff, bound ledger, transport routes, continuation routes, provenance, and local naming row are all explicit coordinates.

Classifier transport is componentwise. The $\mathsf{Real}^{\uparrow}$ name transports together with its $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ handoff, while the $\mathsf{Rat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ bound rows transport the comparison side of the ledger.

The stability and exactness clauses then read only the finite ledger B. Since B compares the displayed regular-Cauchy observations with the displayed rational and dyadic bound rows, the exported bound cannot be replaced by a host supremum, a choice-selected bound, quotient stream equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier namecert obligations`

Theorem 430.3 (ArchimedeanReal rational-bound witness)**.** *Every accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet $A = (R, Q, D, S, G, B, H, C, P, N)$ exposes an explicit rational-bound witness for the* $\mathsf{Real}^{\uparrow}$ *name R: the witness is the pair of displayed rows $Q : \mathsf{Rat}^{\uparrow}$ and $D : \mathsf{DyadicRatCore}^{\uparrow}$ together with the finite ledger B comparing all inspected* $\mathsf{RegSeqRat}^{\uparrow}$ *observations of R against those rows. The witness is available without a host supremum, a choice-selected least bound, quotient stream equality, or ambient completeness.*

Proof. Start with the carrier inventory in Definition 430.1. The bound rows Q and D are coordinates of the accepted packet, and the real-name observations are read only through S and G.

Apply the ledger-exactness clause of Definition 430.2. Each finite inspection request is compared against the displayed rational row Q and the dyadic row D by the ledger B before any downstream consumer receives the bound.

Thus the exported witness is exactly the finite pair (Q, D) with its ledger B and provenance routes H, C, P, N. No coordinate of the packet is a supremum operator, a selected least bound, a quotient of streams, or a completeness principle, so none of those objects is available to a consumer of the rational-bound witness. □

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealPacket rational bound witness`

Theorem 430.4 (ArchimedeanReal rational-dyadic bound coherence)**.** *For every accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet* $A = (R, Q, D, S, G, B, H, C, P, N)$*, the* $\mathsf{Rat}^{\uparrow}$ *row* Q *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *form one coherent bound witness for the displayed* $\mathsf{Real}^{\uparrow}$ *name* R*. Every* $\mathsf{Real}^{\uparrow}$ *order, locatedness, completion, integer-part, or decimal-prefix consumer that reads either row must read both rows through the same finite ledger* B*,* $\mathsf{StreamName}^{\uparrow}$ *window* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* G*,* hsame *transports* H*,* Cont *routes* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{ArchimedeanReal}^{\uparrow}}$ *row* N*.*

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier rat dyadic bound coherence`

Proof. Project the carrier in Definition 430.1. The accepted packet exposes Q and D as named coordinates of a single finite $\mathsf{ArchimedeanReal}^{\uparrow}$ carrier rather than as two independent bound witnesses.

Apply Definition 430.2. Its ledger-exactness and rational-bound export clauses say that the comparison of inspected $\mathsf{RegSeqRat}^{\uparrow}$ observations against Q and D is mediated by the same ledger B, while the exported consumer surface keeps the same S, G, H, C, P, N rows.

Apply Definition 430.3. The public witness for the displayed real name is the pair Q, D together with the finite ledger B, so a consumer cannot take the $\mathsf{Rat}^{\uparrow}$ row without the dyadic presentation or take the dyadic row without the rational row.

Finally use Definition 430.7. Since the packet has no host supremum, selected least bound, quotient stream equality, host limit, or ambient completeness coordinate, there is no second bound surface through which a downstream order, locatedness, completion, integer-part, or decimal-prefix consumer could separate the two rows. □

Theorem 430.5 (ArchimedeanReal transported bound stability)**.** *Let* $A = (R, Q, D, S, G, B, H, C, P, N)$ *and* $A' = (R', Q', D', S', G', B', H', C', P', N')$ *be accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packets. If the real-name row, rational bound row, dyadic bound row, stream window, regular-Cauchy handoff, bound ledger, transport table, continuation table, provenance row, and local naming row are replaced only by rows classified through the displayed* hsame *and* Cont *routes, then the rational-bound witness of Definition 430.3 is transported unchanged as a witness surface: the exported* $\mathsf{Rat}^{\uparrow}$ *row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *row, and finite ledger comparison remain the same displayed bound rows for the classified* $\mathsf{Real}^{\uparrow}$ *name.*

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier transported bound stability`

Proof. The carrier of Definition 430.1 stores Q, D, and B as explicit coordinates, together with the transport table H and continuation table C. The NameCert obligations state that classification acts componentwise on exactly these rows.

Apply Definition 430.3. The witness is not an external bound; it is the visible pair Q, D with the ledger B comparing inspected $\mathsf{RegSeqRat}^{\uparrow}$ observations against those rows.

After replacing the packet by classified rows, the displayed hsame and Cont routes carry the same Q, D, B witness surface to A'. Therefore the rational and dyadic bound rows remain stable for the transported $\mathsf{Real}^{\uparrow}$ name. □

Theorem 430.6 (ArchimedeanReal consumer bound handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *order, locatedness, or completion-facing consumer of an accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet receives the displayed rows* $Q, D, S, G, B, H, C, P, N$ *before it uses the bound on* R*. In particular, the consumer reads the rational bound through* $\mathsf{Rat}^{\uparrow}$*, the dyadic presentation through* $\mathsf{DyadicRatCore}^{\uparrow}$*, finite observations through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*, and the comparison through the ledger* B *with its transport, continuation, provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier consumer bound handoff`

Proof. Start from the carrier tuple. The real name R is not exported with a bare boundedness assertion; the packet also carries $Q, D, S, G, B, H, C, P, N$.

The rational-bound witness theorem identifies the witness used by a consumer as Q, D together with the ledger B. The NameCert obligations further require the consumer-facing export to preserve the stream window, regular-Cauchy handoff, transport rows, continuation routes, provenance, and local naming row.

Thus any order, locatedness, or completion-facing read of the bound must pass through those displayed rows before the bound is used. The handoff is a finite BEDC packet over the visible witness surface. □

Theorem 430.7 (ArchimedeanReal bound-ledger non-escape)**.** *An accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet exports no supremum, no selected least bound, no quotient stream equality, no host limit, and no ambient completeness coordinate. Its bound surface is only the displayed* $\mathsf{Rat}^{\uparrow}$ *row* Q*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*, finite inspection rows* S, G*, ledger* B*, transport rows* H*, continuation rows* C*, provenance row* P*, and local* $\mathsf{NameCert}$ *row* N*.*

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier bound ledger nonescape`

Proof. Inspect Definition 430.1. The listed coordinates are exactly $R, Q, D, S, G, B, H, C, P, N$; none of them is a supremum operator, selected least-bound witness, quotient stream equality, host limit, or ambient completeness datum.

The NameCert obligations and rational-bound witness theorem both read boundedness from the same finite ledger surface. Since those theorems use only the carrier coordinates and their displayed transports, there is no additional export channel for a host-side bound object.

Therefore every consumer of the Archimedean bound remains inside the finite $Q, D, S, G, B, H, C, P, N$ ledger boundary. □

Theorem 430.8 (ArchimedeanReal scope closure)**.** *The carrier of Definition 430.1, the local* $\mathsf{NameCert}$ *obligations of Definition 430.2, the rational-bound witness of Definition 430.3, transported-bound stability from Definition 430.5, the consumer handoff of Definition 430.6, and the non-escape boundary of Definition 430.7 jointly bind every* $\mathsf{ArchimedeanReal}^{\uparrow}$ *read to the displayed* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

No accepted read exports a supremum, selected least bound, quotient stream equality, host limit, or ambient completeness coordinate.

Proof. Start with the carrier. It lists exactly the displayed real name, rational and dyadic bound rows, stream window, regular-Cauchy handoff, finite bound ledger, transport rows, continuation rows, package provenance, and local naming row.

Apply the NameCert obligations, rational-bound witness, transported-bound stability, and consumer handoff. These rows say that classification, bound export, transported witnesses, and downstream consumer reads all pass through the same $Q, D, S, G, B, H, C, P, N$ surface.

Finally apply the bound-ledger non-escape theorem. Since the only exported bound data are the displayed rational and dyadic rows with their finite ledger and routes, the scoped boundary contains no supremum, selected least bound, quotient stream equality, host limit, or ambient completeness coordinate. □

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier scope closure`

Theorem 430.9 (ArchimedeanReal public bound export)**.** *Every accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet* $A = (R, Q, D, S, G, B, H, C, P, N)$ *exports the public bound surface for the displayed* $\mathsf{Real}^{\uparrow}$ *name* R *exactly through the* $\mathsf{Rat}^{\uparrow}$ *bound row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *presentation row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *inspection windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* G*, the finite bound ledger* B*, componentwise transports* H*, continuation routes* C*, package provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanReal}^{\uparrow}}$ *row* N*. A public order, locatedness, or completion-facing read of the Archimedean bound receives this displayed surface and no host supremum, selected least bound, quotient stream equality, host limit, or ambient completeness coordinate.*

Proof. Start with the NameCert obligations of Definition 430.2. They admit the carrier and bind the real name, rational bound, dyadic presentation, stream windows, regular-Cauchy handoff, bound ledger, transport rows, continuation rows, provenance, and local naming data as one finite packet.

The public bound itself is the rational-bound witness of Definition 430.3. Its visible witness rows are Q and D, and the ledger B compares the inspected regular-Cauchy observations against those rows.

Transported-bound stability from Definition 430.5 keeps that witness surface attached to classified packets. The consumer handoff theorem then forces every order, locatedness, or completion-facing consumer to pass through $Q, D, S, G, B, H, C, P, N$ before using the bound.

Finally apply Definition 430.7. Since the accepted packet has no carrier coordinate for a host supremum, selected least bound, quotient stream equality, host limit, or ambient completeness object, the public export is exactly the displayed BEDC bound surface. □

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier public bound export`

Theorem 430.10 (ArchimedeanReal budgeted observation handoff)**.** *Let a* $\mathsf{RealObservationBudget}^{\uparrow}$ *consumer accept an* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N).$$

Before the consumer may use the Archimedean rational-bound rows $Q, D, S, G, B, H, C, P, N$*, it must first read the finite* $\mathsf{RealObservationBudget}^{\uparrow}$ *budget rows for the relevant precision request, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows,* $\mathsf{Real}^{\uparrow}$ *seal rows, componentwise transports, continuation routes, package provenance, and local naming row. The handoff combines the public bound export of Definition 430.9 with the budget-route readiness of Definition 611.18; it exports no host supremum, hidden limit selector, quotient stream equality, or ambient completeness.*

Proof. Project the accepted Archimedean packet A. The public bound export theorem identifies the only Archimedean bound surface available to a consumer: the rows $Q, D, S, G, B, H, C, P, N$ attached to the displayed $\mathsf{Real}^{\uparrow}$ name.

Now route the consumer through the finite observation budget. The readiness theorem for $\mathsf{RealObservationBudget}^{\uparrow}$ says that a completion-facing read must display the finite budget packet before it may reach the $\mathsf{RegSeqRat}^{\uparrow}$ handoff or $\mathsf{Real}^{\uparrow}$ seal route used downstream.

The two routes therefore compose in one order: budget rows first, Archimedean bound rows second. The non-escape clauses already present in the Archimedean carrier and in the observation-budget package exclude a host supremum, hidden limit selector, quotient stream equality, and ambient completeness from the combined handoff. □

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier budgeted observation handoff`

Theorem 430.11 (ArchimedeanReal budgeted Cauchy bound)**.** *Let a* $\mathsf{RealObservationBudget}^{\uparrow}$ *consumer display the finite budget rows for a precision request and accept an* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N).$$

Then every Cauchy-tail or completion-facing consumer receives the rational and dyadic bound rows Q, D *through the same* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, bound ledger, componentwise transport, replay, provenance, and local* $\mathsf{NameCert}$ *route* S, G, B, H, C, P, N*. The bound witness is available only through the composed budgeted route and exports no host supremum, selected least bound, quotient stream equality, hidden limit selector, or ambient completeness coordinate.*

Proof. Start with the public bound export of Definition 430.9. It identifies the Archimedean bound surface for the displayed $\mathsf{Real}^{\uparrow}$ name as the rational row Q, the dyadic row D, the stream windows S, the regular handoff G, the bound ledger B, and the structural rows H, C, P, N.

Now compose this surface with the budgeted observation handoff of Definition 430.10. The consumer first displays the finite $\mathsf{RealObservationBudget}^{\uparrow}$ rows for the precision request and only then reads the Archimedean bound rows.

The resulting Cauchy-tail or completion-facing read therefore receives a bound witness through the same $Q, D, S, G, B, H, C, P, N$ route already exposed by the accepted packet. Since neither theorem supplies a host supremum, selected least bound, quotient stream equality, hidden limit selector, or ambient completeness coordinate, the composed budgeted read cannot export one. □

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier budgeted cauchy bound`

Theorem 430.12 (ArchimedeanReal dyadic threshold totality)**.** *Let an accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N)$$

be read by a finite $\mathsf{RealObservationBudget}^{\uparrow}$ *request carried by a unary* BHist *budget row. For every such finite request, there is a dyadic threshold row whose source is the displayed rational-bound witness* Q, D *of* A*, whose classifier is stable under the componentwise* hsame *transport rows, and whose ledger route is obtained by composing the Archimedean bound witness with the finite-window request route of* $\mathsf{RealObservationBudget}^{\uparrow}$*. The row is a finite threshold surface over* BHist*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *only; it exports no trichotomy row, host-real completeness object, hidden limit selector, quotient stream equality, or least-bound selector.*

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier dyadic threshold totality`

Proof. Start with the rational-bound witness of Definition 430.3. It displays the bound source through the rows Q, D and records the finite ledger comparison through B, so the requested threshold has a visible Archimedean source before any budget row is consumed.

Next compose with the budgeted observation handoff of Definition 430.10. The handoff requires the unary budget request to expose its finite $\mathsf{RealObservationBudget}^{\uparrow}$ rows before reading the Archimedean bound rows.

Use the $\mathsf{RealObservationBudget}^{\uparrow}$ window coverage and finite route coverage rows. By Definition 611.3, each dyadic readback used by the request is covered by a displayed finite $\mathsf{StreamName}^{\uparrow}$ window, and by Definition 611.20 the admitted route remains inside the precision, window, dyadic, regular handoff, seal, transport, continuation, provenance, and local naming rows.

The classifier stability is then the componentwise hsame stability already carried by the two packets. Since neither packet has coordinates for trichotomy, host-real completeness, hidden limit selection, quotient stream equality, or a selected least bound, the composed dyadic threshold row cannot export them. □

Theorem 430.13 (ArchimedeanReal Cauchy threshold forward route)**.** *Let a* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *or completion-facing consumer use an accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N).$$

Before any Cauchy-tail or $\mathsf{Real}^{\uparrow}$*-seal read is exported, the consumer must read the rational bound row* Q*, the dyadic bound row* D*, the finite stream windows* S*, the regular handoff* G*, and the threshold ledger obtained from* B, H, C, P, N *through the dyadic threshold route. The resulting forward route exports the Archimedean bound surface to Cauchy-facing consumers without importing a supremum, trichotomy, quotient stream equality, selected limit, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCauchyThresholdForwardRoute`

Proof. Begin with the public bound export of Definition 430.9. It identifies $Q, D, S, G, B, H, C, P, N$ as the visible bound surface attached to the displayed $\mathsf{Real}^{\uparrow}$ name.

Next apply the budgeted observation handoff of Definition 430.10. A precision-sensitive Cauchy read must pass through the finite observation-budget route before it consumes the Archimedean rational and dyadic rows.

Finally use the dyadic threshold totality theorem of Definition 430.12. The threshold row is sourced from Q, D, read through the same stream windows and regular handoff, and transported by H, C, P, N. Thus any $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, Cauchy-tail, or completion-facing export has already consumed the stated Archimedean threshold surface. □

Theorem 430.14 (ArchimedeanReal regular-Cauchy induction readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing Archimedean threshold read from an accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N)$$

is produced by finite induction over the displayed $\mathsf{StreamName}^{\uparrow}$ *window rows* S *and the* $\mathsf{DyadicArchimedean}^{\uparrow}$ *scale rows supplied through* D, B*. The induction starts from the public bound surface* $Q, D, S, G, B, H, C, P, N$*, advances one displayed window request at a time, records the resulting dyadic threshold row, and then hands the completed regular-Cauchy readback to* $\mathsf{Real}^{\uparrow}$ *through the same* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. It exports no supremum, trichotomy, quotient stream equality, selected limit, countable-choice schedule, or ambient completeness coordinate.*

Proof. Induct on the displayed finite list of $\mathsf{StreamName}^{\uparrow}$ window requests supplied by the $\mathsf{RealObservationBudget}^{\uparrow}$ row. In the empty-window case, the public bound export of Definition 430.9 already identifies the available Archimedean surface as $Q, D, S, G, B, H, C, P, N$, and the budgeted observation handoff of Definition 430.10 says that the consumer has displayed the finite budget rows before any regular-Cauchy read is attempted. Thus the base read has no hidden observation coordinate to discharge.

For the induction step, append one displayed window request to the already-read finite prefix. The $\mathsf{RealObservationBudget}^{\uparrow}$ window-coverage row makes this added request a named $\mathsf{StreamName}^{\uparrow}$ row, and the finite-route coverage row keeps the request inside the displayed precision, dyadic observation, regular handoff, $\mathsf{Real}^{\uparrow}$ seal, transport, replay, provenance, and local naming rows.

Apply dyadic threshold totality, Definition 430.12, to that single added request. The threshold row is sourced from the rational and dyadic bound rows Q, D, checked against the finite ledger B, transported componentwise by H, and replayed through C without adding a hidden selector, countable-choice schedule, or quotient-stream coordinate.

The step then hands the obtained threshold row to the $\mathsf{RegSeqRat}^{\uparrow}$ readback row G. Composing with the Cauchy threshold forward route of Definition 430.13 sends the finite prefix, together with the newly added request, to the downstream $\mathsf{Real}^{\uparrow}$ seal only through G, H, C, P, N.

Since the input window family is finite, repeated use of this step exhausts exactly the displayed requests in S. The induction therefore produces the stated regular-Cauchy readback from the budget rows and dyadic threshold rows alone. □

Theorem 430.15 (ArchimedeanReal located-threshold handoff)**.** *Every* $\mathsf{ConstructiveRealLine}^{\uparrow}$ *or* $\mathsf{LocatedReal}^{\uparrow}$ *consumer of an accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N)$$

must read the rational bound row Q, dyadic bound row D, finite $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff G, bound ledger B, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N before using a located threshold. The located threshold is therefore routed through the public Archimedean bound surface and the* $\mathsf{ConstructiveRealLine}^{\uparrow}$ *L10 seal route; it exports no trichotomy, least-bound selector, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the public bound export of Definition 430.9. It identifies $Q, D, S, G, B, H, C, P, N$ as the only bound surface that a consumer may read from the accepted Archimedean packet.

Next apply the dyadic threshold totality theorem of Definition 430.12. The finite threshold row is sourced from Q, D and is transported through the same stream-window, regular handoff, ledger, transport, replay, provenance, and naming rows.

Finally route the consumer through the $\mathsf{ConstructiveRealLine}^{\uparrow}$ L10 seal surface of Definition 4041.3. A $\mathsf{ConstructiveRealLine}^{\uparrow}$ or $\mathsf{LocatedReal}^{\uparrow}$ read reaches the located threshold only after the dyadic, stream, regular-rational, real-seal, located boundary, transport, replay, provenance, and naming rows have been displayed. None of those rows contains trichotomy, a selected least bound, quotient stream equality, or ambient real completeness, so the composed handoff cannot export such data. □

Theorem 430.16 (ArchimedeanReal budgeted bound window exhaustion)**.** *Let an accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N)$$

be consumed by a finite $\mathsf{RealObservationBudget}^{\uparrow}$ *request that uses the same displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows, and* $\mathsf{Real}^{\uparrow}$ *seal rows. Every budgeted Archimedean bound read is exhausted by the displayed observation-budget rows followed by the Archimedean rows $Q, D, S, G, B, H, C, P, N$. No second window family, unbudgeted dyadic threshold, hidden limit selector, quotient stream equality, host supremum, selected least bound, or ambient completeness coordinate may be substituted for that route.*

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier budgeted bound window exhaustion`

Proof. Begin with the rational-bound witness of Definition 430.3 and the public bound export of Definition 430.9. Together they identify $Q, D, S, G, B, H, C, P, N$ as the only Archimedean bound surface available from the accepted packet.

Now attach the finite observation budget. The budgeted observation handoff of Definition 430.10 orders the read: the consumer first exposes the relevant $\mathsf{RealObservationBudget}^{\uparrow}$ rows, then reads the displayed Archimedean bound rows.

The dyadic threshold totality theorem of Definition 430.12 supplies the finite threshold row for the unary request. The window coverage theorem Definition 611.3 keeps each dyadic readback inside the displayed $\mathsf{StreamName}^{\uparrow}$ windows, and the finite route coverage theorem Definition 611.20 keeps the route inside the budget, window, dyadic, regular handoff, seal, transport, continuation, provenance, and local naming rows.

Finally apply the bound-ledger non-escape theorem of Definition 430.7. Since neither the observation-budget route nor the Archimedean packet provides coordinates for an alternate window family, unbudgeted threshold, hidden selector, quotient stream equality, host supremum, selected least bound, or ambient completeness, every budgeted bound read is exhausted by the displayed rows. □

Theorem 430.17 (ArchimedeanReal public order consumer)**.** *Every public order, locatedness, or completion-facing consumer of an accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N)$$

reads the packet only through the public bound surface $Q, D, S, G, B, H, C, P, N$*. Precision-sensitive reads must first pass through the relevant* $\mathsf{RealObservationBudget}^{\uparrow}$ *rows before they consume the Archimedean bound rows, and every finite unary budget request obtains its dyadic threshold row through Definition 430.12. The consumer receives no supremum, selected least bound, quotient stream equality, host limit, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier public order consumer`

Proof. Start with the public bound export of Definition 430.9. It identifies $Q, D, S, G, B, H, C, P, N$ as the public surface seen by order, locatedness, and completion-facing consumers.

Next use the budgeted observation handoff of Definition 430.10. For a precision-sensitive read, the $\mathsf{RealObservationBudget}^{\uparrow}$ rows are consumed before the Archimedean rational-bound rows are used.

The dyadic threshold totality theorem of Definition 430.12 then supplies the finite threshold row for unary budget requests. Its source is the rational-bound witness through Q, D, and its route is the composed budget-window and Archimedean-bound route.

Finally apply the bound-ledger non-escape theorem of Definition 430.7. Since none of the forbidden host objects is a carrier coordinate, the public order consumer cannot project a supremum, selected least bound, quotient stream equality, host limit, or ambient completeness object. □

Theorem 430.18 (ArchimedeanReal integer bracket handoff)**.** *Let an accepted* $\mathsf{ArchimedeanReal}^{\uparrow}$ *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N)$$

be read by an integer-part or decimal-prefix consumer of the displayed real name. The consumer must first receive the public Archimedean bound surface $Q, D, S, G, B, H, C, P, N$*. If it then forms*

an ArchimedeanIntegerPart$^{\uparrow}$ *packet, the bracket row factors through the existing real or regular-Cauchy read, the Archimedean comparison row, the dyadic floor scale, the* Int$^{\uparrow}$ *candidate, and the successor bracket rows of Definition 1479.4. The combined handoff exports no host floor, trichotomy row, quotient stream equality, hidden integer search, selected representative, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier integer bracket`

Proof. Start with the rational-bound witness of Definition 430.3. It identifies the Archimedean source available from A as the displayed Q, D rows together with the finite ledger B and its routes H, C, P, N.

Apply the public order consumer theorem of Definition 430.17. An integer-part or decimal-prefix request is therefore not allowed to read the displayed real name through a bare host order; it first passes through the public surface $Q, D, S, G, B, H, C, P, N$.

Now suppose the consumer forms an ArchimedeanIntegerPart$^{\uparrow}$ packet. The bracket-route theorem Definition 1479.4 forces that packet to expose the real or regular-Cauchy read, then the Archimedean comparison row, then the dyadic floor scale, then the Int$^{\uparrow}$ candidate, and only then the successor bracket row. This is exactly the integer-bracket surface available downstream of the public Archimedean bound rows.

Finally use the no-hidden-search boundary of Definition 1479.5. Together with the non-escape boundary already attached to the Archimedean real packet, it excludes host floor selection, trichotomy over arbitrary real names, quotient stream equality, hidden integer search, selected representatives, and ambient completeness from the composed route. □

Closure status for NameCert$_{\text{ArchimedeanReal}^{\uparrow}}$.

Constructive story: An ArchimedeanReal$^{\uparrow}$ packet is generated from a displayed Real$^{\uparrow}$ name, an explicit Rat$^{\uparrow}$ bound row, a matching DyadicRatCore$^{\uparrow}$ presentation, finite StreamName$^{\uparrow}$ windows, a RegSeqRat$^{\uparrow}$ handoff, a bound ledger, componentwise hsame transports, Cont routes, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\text{ArchimedeanReal}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 430.8, Definition 430.9, Definition 430.17, and Definition 430.18 bind the carrier, NameCert obligations, rational-bound witness, transported-bound stability, public bound export, public order consumer, integer-bracket handoff, and bound-ledger non-escape rows to the displayed Real$^{\uparrow}$, Rat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert public interface.

Formal verification: FormalStatus(NameCert$_{\text{ArchimedeanReal}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.ArchimedeanRealUp.ArchimedeanRealCarrier\_scope\_closure`

Bridge status: none

Origin: human

Not claimed: This chapter does not close least-upper-bound principles, quotient stream equality, selected host limits, ambient real completeness, or bridge checking.

Upgrade path: Bridge checking remains the next formal-axis target for the displayed public bound and order-consumer interface.

Chapter 431

A Concrete Naming Certificate for ObserverRegular$^{\uparrow}$

The ObserverRegular$^{\uparrow}$ chapter is a BEDC-native finite certificate surface. It packages finite prefix-observer data as a BEDC naming certificate for Real$^{\uparrow}$ and Completion$^{\uparrow}$ window schedules. Its public surface is a finite observer ledger over displayed prefixes, resolving states, stream windows, regular-rational readbacks, tolerance rows, transports, continuation routes, provenance, and a local naming row.

The dependency anchors are concrete sibling rows, not background names: chapter 126 supplies the finite windows, chapter 301 supplies the regular-rational readback, chapter 292 supplies the modulus schedule, chapter 291 supplies the dyadic tolerance ledger, chapter 38 supplies the Real$^{\uparrow}$ seal consumers, and chapter 95 supplies the Completion$^{\uparrow}$ readback boundary. An ObserverRegular$^{\uparrow}$ carrier consumes those sibling rows by resolving a finite prefix state before any Real$^{\uparrow}$ or Completion$^{\uparrow}$ consumer can read a window or readback.

Falsifiable prediction: Removing the resolving-state row prevents any Real$^{\uparrow}$ or Completion$^{\uparrow}$ consumer from distinguishing prefix observation from arbitrary StreamName$^{\uparrow}$ readback in the finite ledger.

Independence witness: Nearest siblings: streamname, regseqrat, cauchymodulus, real, completion. The ObserverRegular packet is not bijective with those siblings because it adds a resolving-state prefix row and schedule lock that none of them expose.

The proposed Lean follow-up contract for lean4/BEDC/Derived/ObserverRegularUp/TasteGate.lean must provide Nontrivial ObserverRegular$^{\uparrow}$ and FieldFaithful ObserverRegular$^{\uparrow}$ instances for the displayed observer packet.

Definition 431.1 (ObserverRegular prefix carrier)**.** *An* ObserverRegular$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (A, R, S, W, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite alphabet and prefix row, listing the retained symbols, the displayed prefix packets, and the finite prefix-extension ledger inspected by the observer;*
2. *R is the resolving-state row, listing the accepted observer states and the finite transition evidence by which a prefix reaches such a state;*
3. *S is the schedule row, naming the* Real$^{\uparrow}$ *and* Completion$^{\uparrow}$ *window schedules for which the observer packet is intended;*

4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposed by each accepted resolving state;*
5. *L is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback ledger, pairing each displayed window with the finite rational readback consumed by downstream schedules;*
6. *H stores componentwise* hsame *transports for alphabet rows, prefix rows, resolving-state rows, window rows, readback rows, tolerance rows, provenance, and the local naming row;*
7. *C stores the displayed* Cont *routes for prefix extension, resolving-state inspection, window display, regular-rational readback, tolerance checking, and the* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer handoff;*
8. *P is the* Pkg *provenance row naming* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, *and the consumed local source certificates;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ObserverRegular}^{\uparrow}}$ *row.*

The classifier compares accepted packets by first transporting them to a common displayed finite prefix row, then comparing the resolving-state rows, the $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{CauchyModulus}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, and finally the consumer handoff rows. The carrier has no coordinate for quotient streams, host sequence equality, selected limits, ambient completeness, or choice-selected completion data.*

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularTasteGate single carrier alignment`

Theorem 431.2 (ObserverRegular resolving-window soundness)**.** *For every accepted* $\mathsf{ObserverRegular}^{\uparrow}$ *carrier $O = (A, R, S, W, L, H, C, P, N)$, each accepted observer state in R determines a displayed finite* $\mathsf{StreamName}^{\uparrow}$ *window in W and a finite* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in L. The readback is reached only through the finite prefix row A, the resolving-state row R, the displayed window row W, the stored* hsame *transports, and the displayed* Cont *routes.*

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularCarrier resolving window soundness`

Proof. Project the carrier of Definition 431.1. An accepted observer state is not a host-level predicate; it is one of the finite rows recorded in R together with the displayed prefix evidence from A.

Use the continuation routes in C to inspect that resolving row. The inspection selects a window entry in W, and the same displayed route selects the matching regular-rational readback entry in L.

The transport row H supplies the componentwise equality witnesses needed when the same state is read after prefix transport. Since the only exposed coordinates are A, R, W, L, H, and C, the soundness claim remains inside the finite prefix-observer packet. □

Theorem 431.3 (ObserverRegular prefix-resolution totality)**.** *For every accepted prefix row in an* $\mathsf{ObserverRegular}^{\uparrow}$ *carrier*

$$O = (A, R, S, W, L, H, C, P, N),$$

exactly one of the finite observer routes is consumer-readable. Either the prefix row in A exposes no accepted resolving state, in which case no downstream $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{Completion}^{\uparrow}$ *window or readback row is readable from that prefix; or it exposes one of the displayed resolving-state rows in R, after which the only consumer route is through W, L, H, C, P, N.*

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularCarrier prefix resolution totality`

Proof. Project the prefix carrier of Definition 431.1. The prefix row A is the sole entry point for a consumer request, and the resolving-state row R is the sole coordinate that can authorize a downstream window or readback.

In the positive case, the accepted prefix exposes one of the displayed resolving-state rows in R. Apply resolving-window soundness to that row; it produces the finite $\mathsf{StreamName}^{\uparrow}$ window in W and the matching $\mathsf{RegSeqRat}^{\uparrow}$ readback in L, and the remaining consumer route passes through H, C, P, N.

In the negative case, the accepted prefix exposes no resolving-state row. Coordinate exhaustion then leaves no row from which a downstream window, readback, $\mathsf{Real}^{\uparrow}$ seal request, or $\mathsf{Completion}^{\uparrow}$ readback can be obtained, because W and L are reached only through R and the displayed continuation route.

Thus every accepted prefix is total as a finite case analysis: either it has no consumer-readable downstream route, or it has exactly the resolving-state route through W, L, H, C, P, N. □

Theorem 431.4 (ObserverRegular NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{ObserverRegular}^{\uparrow}}$ *surface has five obligations:*

1. *carrier habitation: finite alphabet rows, prefix rows, resolving-state rows, window rows, readback ledgers, tolerance rows, transports, continuations, provenance, and the local naming row inhabit the carrier of Definition 431.1;*
2. *classifier transport: accepted carriers are compared only after displayed transport to a common finite prefix row and common resolving-state inspection surface;*
3. *resolving-window soundness: every accepted observer state determines the finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of Definition 431.2;*
4. *ledger exactness: the* $\mathsf{CauchyModulus}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows are read only through the displayed prefix, resolving-state, window, and readback ledgers;*
5. $\mathsf{Real}^{\uparrow}$ *non-escape: every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer read factors through the finite observer ledger and never through quotient streams, host sequence equality, selected limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularCarrier namecert obligations`

Proof. Carrier habitation is obtained by choosing finite displayed rows for the alphabet, prefixes, resolving states, windows, readbacks, tolerances, transports, continuations, provenance, and local name. These are exactly the coordinates listed in Definition 431.1.

Classifier transport first moves packets to a common prefix row and then inspects the resolving-state rows through the same displayed continuations. The resolving-window obligation is precisely Definition 431.2.

The ledger exactness and real-name boundary obligations follow from the absence of any carrier coordinate outside the finite observer packet. The tolerance rows and consumer rows can only be reached by projecting the listed coordinates and applying the stored continuation routes. □

Theorem 431.5 (ObserverRegular finite ledger non-escape)**.** *Every consumer-facing read of an accepted* $\mathsf{ObserverRegular}^{\uparrow}$ *carrier is exhausted by the finite alphabet and prefix row, resolving-state row,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback ledger,* $\mathsf{CauchyModulus}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

The ledger exports no quotient stream equality, host sequence equality, selected host limit, ambient completeness principle, or choice-selected completion witness.

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularCarrier finite ledger non escape`

Proof. Begin with a requested downstream read. The only entry point into the carrier is the displayed prefix row A, which selects the resolving-state row R and then the window and readback rows W and L.

The tolerance rows are reached by the same displayed readback route. The $\mathsf{CauchyModulus}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ entries therefore certify only the finite observation already selected by the observer ledger.

Finally route the read through H, C, P, and N. Those coordinates record transport, continuation, provenance, and naming data, not host-level equality, selected limits, or ambient completeness, so no non-displayed object can be exported. □

Theorem 431.6 (ObserverRegular StreamName handoff)**.** *The downstream handoff from an accepted* $\mathsf{ObserverRegular}^{\uparrow}$ *carrier to* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consists exactly of the displayed window row, regular-rational readback ledger, tolerance rows, transports, continuation routes, package provenance, and local naming row selected by an accepted resolving state.*

For $\mathsf{Completion}^{\uparrow}$ *schedules, the same handoff remains finite: the completion consumer receives the* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback already exposed to the* $\mathsf{Real}^{\uparrow}$ *boundary, together with the displayed tolerance rows. No quotient stream, host sequence equality, selected limit, or ambient completeness coordinate is added.*

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularCarrier streamname handoff`

Proof. Apply Definition 431.2 to the accepted resolving state. It supplies the finite $\mathsf{StreamName}^{\uparrow}$ window and matching $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Apply Definition 431.5. The $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ consumers can inspect only the selected window, readback, tolerance, transport, continuation, provenance, and naming rows.

Thus the handoff is exactly the finite packet described in the statement. Since the completion-facing schedule receives no coordinate beyond those rows, it cannot introduce quotient streams, host sequence equality, selected limits, or ambient completeness. □

Theorem 431.7 (ObserverRegular TasteGate obligation assembly)**.** *For an accepted* $\mathsf{ObserverRegular}^{\uparrow}$ *carrier* $O = (A, R, S, W, L, H, C, P, N)$, *the* $\mathsf{NameCert}_{\mathsf{ObserverRegular}^{\uparrow}}$ *obligation surface is assembled by the displayed rows* A, R, W, L, H, C, P, *and* N *together with the TasteGate carrier alignment* `BEDC.Derived.ObserverRegularUp.ObserverRegularTasteGate_single_carrier_alignment` *attached to Definition 431.1. The assembly consists of carrier habitation, classifier transport across displayed prefix and resolving-state rows, resolving-window soundness, ledger exactness for tolerance reads, and non-escape of* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Completion}^{\uparrow}$ *consumers from the finite observer packet.*

Proof. Carrier habitation is the finite packet displayed in Definition 431.1. The TasteGate carrier alignment attached to that definition identifies the singleton carrier used by the chapter with the displayed observer packet, so the obligation is about the rows already present in O.

Classifier transport uses H to move alphabet, prefix, resolving-state, window, readback, tolerance, provenance, and naming rows before comparison. The continuation row C then supplies the displayed inspection routes, so no classifier step ranges over a host stream or an ambient completion object.

Resolving-window soundness is Definition 431.2. Ledger exactness and consumer non-escape are the content of Definition 431.5 and Definition 431.6: every downstream read is routed through the finite observer ledger and its stored transports, continuations, provenance, and local name. □

Theorem 431.8 (ObserverRegular resolving-window ledger exactness)**.** *Every* $\mathsf{CauchyModulus}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance read made by a* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{ObserverRegular}^{\uparrow}$ *carrier* $O = (A, R, S, W, L, H, C, P, N)$ *factors through* A*,* R*,* W*,* L*,* H*,* C*,* P*, and* N*. The schedule row* S *names the intended consumer schedules, but it contributes no separate tolerance witness outside the displayed prefix, resolving-window, readback, transport, continuation, provenance, and local naming rows.*

Proof. Start with a tolerance read requested by a downstream consumer. The read first selects a displayed prefix in A and an accepted resolving state in R.

Apply Definition 431.2. The selected resolving state determines the window row W and the regular-rational readback ledger L, and the read reaches those rows only through the stored transports H and continuations C.

The provenance row P records which $\mathsf{CauchyModulus}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ certificates are being consumed, while N records the local observer name. By Definition 431.5, there is no carrier coordinate for an external tolerance witness, quotient stream, selected limit, or ambient completeness principle. Thus each tolerance read factors through exactly the displayed finite ledger rows named in the statement. □

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularCarrier resolving window ledger exactness`

Theorem 431.9 (ObserverRegular schedule lock for real and completion consumers)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{ObserverRegular}^{\uparrow}$ *carrier* $O = (A, R, S, W, L, H, C, P, N)$ *uses the displayed schedule row* S *together with the same finite window row* W*, regular-rational readback ledger* L*, componentwise transport row* H*, continuation row* C*, package provenance* P*, and local naming row* N*. The row* S *may name the intended consumer schedule, but it contributes no independent tolerance witness, completion witness, selected limit, quotient stream equality, or host real equality.*

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularCarrier schedule lock real completion`

Proof. Start with a consumer route into $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$. By Definition 431.2, the accepted resolving state first selects the displayed finite $\mathsf{StreamName}^{\uparrow}$ window W and the matching $\mathsf{RegSeqRat}^{\uparrow}$ readback ledger L through the observer packet.

Apply Definition 431.5 and Definition 431.6. These force the consumer handoff through the same finite window, readback, transport, continuation, provenance, and naming rows; no external stream equality, host sequence equality, selected limit, or ambient completeness coordinate is available.

It remains to account for tolerance and completion-facing reads. The ledger exactness theorem Definition 431.8 says that such reads still factor through A, R, W, L, H, C, P, and N, while the existing TasteGate marker `BEDC.Derived.ObserverRegularUp.taste_gate` records the singleton carrier alignment for the displayed observer packet.

Thus the schedule row S is locked to the same finite rows consumed by $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$. It can name the intended schedule, but it cannot supply an independent tolerance or completion witness beyond the displayed observer ledger. □

Theorem 431.10 (ObserverRegular schedule coherence)**.** *For accepted* $\mathsf{ObserverRegular}^{\uparrow}$ *carriers*

$$O = (A, R, S, W, L, H, C, P, N) \quad \textit{and} \quad O' = (A', R', S', W', L', H', C', P', N')$$

whose schedule rows are classified together through the displayed hsame *and* Cont *routes, every* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Completion}^{\uparrow}$ *consumer read reaches coherent* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback ledgers through* W, L, H, C, P, N *and* W', L', H', C', P', N'*. The coherence is finite: it compares the displayed observer rows and exports no quotient stream, host sequence equality, selected limit, or ambient completeness witness.*

Proof. Start with two accepted observer carriers whose schedule rows are related by the displayed transports and continuation routes. The TasteGate alignment attached to Definition 431.1 fixes the singleton carrier surface for the observer packet, so the comparison is made through the visible rows rather than through a host stream.

Apply Definition 431.8 to both carriers. It forces each tolerance and readback request to factor through the accepted prefix row, resolving-state row, window row, readback ledger, transports, continuations, provenance, and local naming row.

Now use Definition 431.9. A $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer can read the intended schedule only together with the corresponding finite window and readback ledger. Since the two schedule rows are already classified through the displayed H, C and H', C' routes, the consumer reaches coherent windows W, W' and ledgers L, L' through the two finite observer packets.

The carrier inventory then gives non-escape. Neither packet contains a quotient stream, host sequence equality, selected limit, or ambient completeness coordinate, so schedule coherence remains a BEDC row comparison at the displayed observer boundary. □

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularCarrier schedule coherence`

Theorem 431.11 (ObserverRegular bridged consumer surface)**.** *Every bridge-ready* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{ObserverRegular}^{\uparrow}$ *carrier* $O = (A, R, S, W, L, H, C, P, N)$ *factors through the displayed rows* $A, R, S, W, L, H, C, P, N$ *together with the TasteGate single-carrier alignment cited at Definition 431.1. The consumer receives the finite prefix row, resolving-state row, schedule row,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback ledger,* $\mathsf{CauchyModulus}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance reads, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *row, and it receives no quotient stream, host sequence equality, selected limit, ambient completeness principle, or choice-selected completion witness.*

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularCarrier bridged consumer surface`

Proof. Start with the accepted carrier and the TasteGate single-carrier alignment. The alignment fixes the bridge-facing consumer at the displayed observer packet rather than at an ambient stream or completion object.

Resolving-window soundness supplies the first route: the consumer reaches a $\mathsf{StreamName}^{\uparrow}$ window and a $\mathsf{RegSeqRat}^{\uparrow}$ readback only through A, R, W, L, H, C. Finite ledger non-escape then prevents that route from leaving the listed BEDC rows.

Use the StreamName handoff and schedule lock for the consumer boundary. These force every $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ read to use the same schedule row S, window row W, readback ledger L, transports H, continuations C, provenance P, and local name N.

Finally apply schedule coherence. Since coherent consumer reads are compared through the displayed rows and the TasteGate carrier marker, no quotient stream, host sequence equality, selected limit, ambient completeness principle, or choice-selected completion witness can be supplied by the bridge-ready surface. □

Theorem 431.12 (ObserverRegular formal-target boundary)**.** *The Lean-facing formal target for* $\mathsf{ObserverRegular}^{\uparrow}$ *is exactly the finite packet*

$$O = (A, R, S, W, L, H, C, P, N),$$

the resolving-window soundness row of Definition 431.2, prefix-resolution totality from Definition 431.3, finite-ledger non-escape from Definition 431.5, the schedule lock for $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Completion}^{\uparrow}$ *consumers from Definition 431.9, schedule coherence from Definition 431.10, and the bridged consumer surface of Definition 431.11. The target excludes quotient streams, host sequence equality, selected limits, ambient completeness, completion bridges, and any proof not routed through* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Completion}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.ObserverRegularCarrier formal target boundary`

Proof. The target begins with the carrier of Definition 431.1. Its finite rows are the only data admitted to the proof surface: prefix and resolving-state data, schedule data, stream windows, regular-rational readbacks, transports, continuations, provenance, and the local name.

The soundness and totality clauses are the first route constraints. They force every accepted prefix either to stop before a consumer-readable row or to pass through the displayed resolving state before reaching a stream window and readback.

The non-escape, schedule-lock, and schedule-coherence clauses then define the consumer boundary. They keep every $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ read inside the displayed observer ledger and compare schedules only through the stored hsame and Cont rows.

The final exclusion is coordinate exhaustion. Since the target contains no quotient stream coordinate, host sequence equality coordinate, selected-limit coordinate, ambient-completeness coordinate, or completion-bridge coordinate, any proof using such data is outside the stated Lean-facing boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{ObserverRegular}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ObserverRegular}^{\uparrow}$ packet is generated by a finite alphabet and prefix row, resolving-state row, $\mathsf{StreamName}^{\uparrow}$ window row, $\mathsf{RegSeqRat}^{\uparrow}$ readback ledger, $\mathsf{CauchyModulus}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Lean4 ✓ `BEDC.Derived.ObserverRegularUp.taste gate`

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ObserverRegular}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature scope records the finite observer ledger, schedule lock, StreamName handoff, non-escape boundary, bridge-facing consumer surface of Definition 431.11, and the sibling $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ consumer boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ObserverRegular}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close quotient streams, host sequence equality, selected limits, ambient completeness, completion bridges, or Lean verification.

Upgrade path: No further paper closure grade remains; Lean verification and bridge checking are recorded on their separate axes.

Chapter 432

A Concrete Naming Certificate for $\mathsf{FibonacciInverseLimit}^{\uparrow}$

The $\mathsf{FibonacciInverseLimit}^{\uparrow}$ interface is a BEDC-native finite certificate surface.

The $\mathsf{FibonacciInverseLimit}^{\uparrow}$ interface names the finite-prefix surface of a projective Fibonacci-modulus tower. It records compatible prefixes over already displayed BEDC packets and does not import external rings, quotient completion, choice, topology, Haar measure, compactness, or an external profinite-ring theorem.

The inverse-limit packet consumes finite $\mathsf{FibonacciCube}^{\uparrow}$ modulus-coordinate rows through chapter 401 and $\mathsf{StreamName}^{\uparrow}$ window scheduling through chapter 126. The $\mathsf{GoldenMeanShift}^{\uparrow}$ admissibility row remains a local finite-window dependency because no concrete $\mathsf{GoldenMeanShift}^{\uparrow}$ chapter label is currently part of the carrier surface.

Definition 432.1 (Fibonacci inverse-limit carrier)**.** *A* $\mathsf{FibonacciInverseLimit}^{\uparrow}$ *carrier is a finite compatible prefix packet*

$$Q = (G, F, W, R, H, C, P, N)$$

with the following visible rows:

1. *G is a finite* $\mathsf{GoldenMeanShift}^{\uparrow}$ *admissibility ledger for the inspected prefix windows;*
2. *F is a finite* $\mathsf{FibonacciCube}^{\uparrow}$ *modulus-coordinate ledger for the same windows;*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule selecting exactly the displayed prefix packets;*
4. *R records the finite projection rows between adjacent Fibonacci-modulus windows and their compatibility witnesses;*
5. *H records componentwise* hsame *transports for the golden-mean rows, cube rows, stream-window rows, and projection rows inside* BHist*;*
6. *C records the displayed* Cont *routes by which consumers read a smaller prefix from a larger recorded prefix;*
7. *P is the* Pkg *provenance over* $\mathsf{GoldenMeanShift}^{\uparrow}$, $\mathsf{FibonacciCube}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont*, and the local naming row;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FibonacciInverseLimit}^{\uparrow}}$ *row.*

The carrier contains only finite prefix packets and their displayed projection routes. It contains no completed topological carrier, no quotient of streams, no selected infinite point, no Haar measure row, and no external profinite-ring theorem.

Theorem 432.2 (Fibonacci inverse-limit NameCert obligations)**.** *Every accepted* $\mathsf{FibonacciInverseLimit}^{\uparrow}$ *packet with carrier Definition 432.1 carries exactly the following local naming-certificate obligations:*

1. *carrier habitation by the empty compatible prefix packet with empty* $\mathsf{GoldenMeanShift}^{\uparrow}$, $\mathsf{FibonacciCube}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and projection rows;*
2. *prefix classifier transport along the componentwise* hsame *rows for* G, F, W, R, H, C, P, *and* N*;*
3. *projection compatibility for every displayed finite route from a larger Fibonacci-modulus prefix to a smaller prefix;*
4. *finite-prefix exhaustion: every public finite read of the inverse-limit surface factors through some row already selected by* W *and* R*;*
5. *ledger non-escape: downstream consumers can read only* G, F, W, R, H, C, P, *and* N.

Lean4 ✓ `BEDC.Derived.FibonacciInverseLimitUp.FibonacciInverseLimitPacket namecert obligation surface`

Proof. Carrier habitation uses the empty prefix window. The empty $\mathsf{GoldenMeanShift}^{\uparrow}$ and $\mathsf{FibonacciCube}^{\uparrow}$ rows, the empty $\mathsf{StreamName}^{\uparrow}$ schedule, and the empty projection ledger form a finite BHist packet with identity transport and local naming evidence.

Classifier transport is componentwise. Moving a prefix row by hsame also moves its golden-mean admissibility row, Fibonacci-cube modulus row, selected stream window, and projection witness through the matching entries of H.

Projection compatibility is the content of the route ledger R and the consumer routes C. A smaller prefix is obtained only by following a displayed route from a larger recorded prefix, so no hidden tower map is available.

Finite-prefix exhaustion follows from the selected window schedule W. A public read must first choose a recorded window and then read through the corresponding projection row in R.

The non-escape clause is a coordinate inspection of Definition 432.1. Since the carrier has no coordinate for topology, quotient completion, Haar measure, a selected infinite point, or an external profinite-ring theorem, none of those objects can be exported by its local certificate. □

Theorem 432.3 (Fibonacci inverse-limit prefix projection exactness)**.** *Let* $Q = (G, F, W, R, H, C, P, N)$ *be an accepted* $\mathsf{FibonacciInverseLimit}^{\uparrow}$ *carrier. For every displayed pair of Fibonacci-modulus prefix windows in* W*, each consumer read of the smaller window factors through the unique recorded projection row in* R*, then through the transported* $\mathsf{GoldenMeanShift}^{\uparrow}$ *and* $\mathsf{FibonacciCube}^{\uparrow}$ *rows named by* G *and* F*. Thus a finite prefix is exact relative to the recorded tower data and is not reconstructed from an unrecorded infinite point.*

Proof. Begin with a consumer read of a smaller prefix. The schedule W selects the requested finite window before any coordinate can be inspected.

The projection ledger R then supplies the displayed route from the larger recorded prefix to the smaller one. The route is stabilized by the matching hsame entries in H and by the Cont read in C.

Finally, the golden-mean and Fibonacci-cube rows G and F verify that the projected row remains inside the finite admissibility and modulus surfaces. No step asks for a completed inverse-limit point or a quotient of compatible streams. □

Theorem 432.4 (Fibonacci inverse-limit ledger non-escape)**.** *The public boundary of an accepted* $\mathsf{FibonacciInverseLimit}^{\uparrow}$ *packet exports only finite* $\mathsf{GoldenMeanShift}^{\uparrow}$ *admissibility rows, finite* $\mathsf{FibonacciCube}^{\uparrow}$ *modulus rows, selected* $\mathsf{StreamName}^{\uparrow}$ *windows, projection-compatibility rows, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *evidence. It exports no compactness theorem, no topology of the inverse limit, no Haar measure, no quotient completion, no choice-selected infinite point, and no external profinite-ring theorem.*

Proof. Inspect the carrier coordinates of Definition 432.1. The rows G, F, W, R, H, C, P, and N exhaust the public packet.

By Definition 432.3, every finite consumer read reaches a selected window and a displayed projection row before it reaches a prefix value. This keeps all reads inside finite prefix data.

Therefore the packet can serve as a concrete BEDC naming certificate for finite inverse-limit projections, but it does not export compactness, inverse-limit topology, Haar measure, quotient completion, choice, or an external profinite-ring theorem. □

Theorem 432.5 (Fibonacci inverse-limit window-extension exhaustion)**.** *Let* $Q = (G, F, W, R, H, C, P, N)$ *be an accepted* $\mathsf{FibonacciInverseLimit}^{\uparrow}$ *carrier. Extending its finite prefix window adds only named larger-window rows to* W *and recorded projection rows to* R*. Every read of an older prefix either factors through the older selected window already present in* W*, or through a newly recorded larger window followed by the displayed projection row in* R *back to the older prefix. In both cases the provenance rows* G, F, W, H, C, P, N *remain the same public coordinates of the packet, and no completed inverse-limit point, quotient stream, selected infinite prefix, topology, Haar measure, or external profinite-ring theorem is imported.*

Proof. Inspect the carrier tuple $Q = (G, F, W, R, H, C, P, N)$. A window extension can add rows only to the finite window schedule W and the projection ledger R; the admissibility rows, modulus rows, transports, continuations, provenance, and local certificate remain the displayed coordinates of the same packet.

For an older-prefix read, apply Definition 432.3. If the read uses the old selected window, it is already exact over the old W and R rows. If it uses a larger recorded window, exactness forces the read through the recorded projection row in R before it reaches the older prefix.

The ledger non-escape theorem Definition 432.4 excludes any hidden source for the older prefix. Thus the extension exhausts public reads by named larger-window rows and recorded projections, with G, F, W, H, C, P, N preserved as the visible provenance surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FibonacciInverseLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{FibonacciInverseLimit}^{\uparrow}$ packet is generated from finite $\mathsf{GoldenMeanShift}^{\uparrow}$ admissibility rows, finite $\mathsf{FibonacciCube}^{\uparrow}$ modulus rows, selected $\mathsf{StreamName}^{\uparrow}$ windows, projection-compatibility rows, componentwise hsame transports, displayed Cont routes, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FibonacciInverseLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope registers finite compatible prefix packets, prefix projection exactness, and ledger non-escape for Fibonacci-modulus projection surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FibonacciInverseLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim compactness, topology of the inverse limit, Haar measure, quotient completion, choice-selected infinite points, external imports, or external profinite-ring theorems.

Upgrade path: Obligation closure requires formal carrier encoding, prefix classifier transport, projection compatibility, finite-prefix exhaustion, and ledger non-escape under `BEDC.Derived.FibonacciInverseLimitUp`.

Chapter 433

A Concrete Naming Certificate for $\mathsf{DyadicRounding}^{\uparrow}$

The $\mathsf{DyadicRounding}^{\uparrow}$ interface names the finite dyadic-grid enclosure used on the constructive real path. Following Bishop and Bridges, *Constructive Analysis*, it records an adjacent dyadic cell around a regular rational or $\mathsf{Real}^{\uparrow}$ read at a displayed unary precision, without invoking a quotient real, selected limit, trichotomy, or host rounding function. The adjacent endpoint rows consume the dyadic arithmetic surface of chapter 291, and the handoff row is read by the $\mathsf{Real}^{\uparrow}$ boundary of chapter 38.

Before exposing any $\mathsf{Real}^{\uparrow}$-facing enclosure, $\mathsf{DyadicRounding}^{\uparrow}$ consumes the endpoint carrier of chapter 291, the containment surface of chapter 354, and the tolerance ledger of chapter 385.

Definition 433.1 (DyadicRounding carrier)**.** *A* $\mathsf{DyadicRounding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (x, n, a, b, I, E, L, C, P, N)$$

with the following displayed coordinates:

1. *x is the source read, either a* $\mathsf{Real}^{\uparrow}$ *seal route or a* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback already present on the constructive real path;*
2. *n is the* $\mathsf{UnaryHistory}$ *precision request that fixes the dyadic grid scale;*
3. *a and b are adjacent* $\mathsf{DyadicRatCore}^{\uparrow}$ *grid endpoints at precision n;*
4. *I is the* $\mathsf{RationalInterval}^{\uparrow}$ *containment row witnessing that the inspected rational approximation of x lies inside the interval with endpoints a and b;*
5. *E is the* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *tolerance row that bounds the readback error at the same precision;*
6. *L stores the componentwise* hsame *transports for the source read, unary precision, dyadic endpoint rows, interval containment row, and error-budget row;*
7. *C stores the* Cont *routes for reading the source, inspecting the dyadic grid, transporting containment, and exposing the tolerance ledger;*
8. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UnaryHistory}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{FiniteErrorBudget}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRounding}^{\uparrow}}$ *row.*

The carrier is a finite rounding certificate. It stores no completed real representative, no limiting point, no order trichotomy branch, and no host rounding operation.

Theorem 433.2 (DyadicRounding NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DyadicRounding}^{\uparrow}}$ *surface for the carrier of Definition 433.1 consists of five finite obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet D with source read, unary precision, adjacent dyadic endpoints, interval containment, finite tolerance ledger, transport rows, continuation rows, package provenance, and local naming data;*
2. *classifier transport: classified source reads transport the same precision request, adjacent endpoint pair, containment row, error-budget row, and provenance rows componentwise through L and C;*
3. *grid adjacency: a and b are the displayed adjacent* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints at precision n;*
4. *ledger exactness: every tolerance consumed by the containment read is the displayed* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *row E;*
5. *real handoff: every* $\mathsf{DyadicApproximation}^{\uparrow}$, $\mathsf{FiniteErrorBudget}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer first reads $x, n, a, b, I, E, L, C, P, N$.*

Proof. Carrier admission is projection from Definition 433.1. The source row, precision request, endpoint pair, containment row, tolerance row, transport routes, continuation routes, package row, and local naming row are all visible coordinates of D.

Classifier transport is componentwise. A transported $\mathsf{Real}^{\uparrow}$ seal route or $\mathsf{RegSeqRat}^{\uparrow}$ readback carries the same unary precision, the same adjacent dyadic endpoint rows, and the same interval and budget ledgers through L and C.

The grid and ledger clauses are finite projections. Since the carrier records only the endpoint rows a, b, the containment row I, and the tolerance row E, downstream consumers have no coordinate from which to obtain a quotient real, selected limit, trichotomy split, or host rounding function. □

Theorem 433.3 (DyadicRounding grid sandwich)**.** *For every accepted* $\mathsf{DyadicRounding}^{\uparrow}$ *carrier $D = (x, n, a, b, I, E, L, C, P, N)$, the source read x is exposed to dyadic-grid consumers only through the displayed sandwich by the adjacent* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints a and b at precision n, together with the* $\mathsf{RationalInterval}^{\uparrow}$ *containment row I and the* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *tolerance row E.*

Lean4 ✓ `BEDC.Derived.DyadicRoundingUp.DyadicRoundingPacket grid sandwich`

Proof. Project the accepted carrier. The precision coordinate n fixes the grid scale, and the endpoint coordinates a and b are the only dyadic grid rows available at that scale.

Read containment through I. This row places the inspected rational approximation of x inside the displayed interval bounded by a and b.

Finally read the tolerance through E. The finite error budget is the only permitted widening of the containment row, so the consumer receives the sandwich data a, I, b, E rather than any ambient rounded value or host real comparison. □

Theorem 433.4 (DyadicRounding ledger exactness)**.** *Every tolerance, containment, and endpoint read exported by an accepted* $\mathsf{DyadicRounding}^{\uparrow}$ *carrier is exhausted by the rows $n, a, b, I, E, L, C, P, N$ of Definition 433.1. No downstream read may replace these rows by an external modulus, completed-real equality, selected limit, trichotomy decision, or host rounding operation.*

Proof. Start with any exported dyadic rounding read. The NameCert obligation surface routes it through the precision request, adjacent endpoint rows, interval containment row, and finite error-budget row.

The transport and continuation rows L and C move only those displayed coordinates. They do not add analytic data beyond the source read and the finite ledgers already recorded in the packet.

Inspecting the carrier inventory completes the exactness claim. Since no coordinate stores an external modulus, completed-real equality, selected limit, trichotomy decision, or host rounding operation, no consumer can read one from the packet. □

Theorem 433.5 (DyadicRounding RealUp handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing handoff from an accepted* $\mathsf{DyadicRounding}^{\uparrow}$ *carrier factors through the source row* x*, the unary precision* n*, the adjacent* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint pair* a, b*, the* $\mathsf{RationalInterval}^{\uparrow}$ *containment row* I*, the* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *tolerance row* E*, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *provenance. The handoff exposes no quotient real, selected limit, trichotomy branch, or host rounding function.*

Proof. First read the source coordinate x. If it is already a $\mathsf{Real}^{\uparrow}$ seal route, the handoff remains on that route; if it is a $\mathsf{RegSeqRat}^{\uparrow}$ readback, the regular rational row is inspected only at the displayed precision n.

Next apply the grid sandwich theorem. The handoff passes through a, b, I, E, so every real-facing approximation is the finite dyadic enclosure with its recorded budget.

Finally apply ledger exactness. The remaining coordinates are provenance and transport rows, not analytic choice data, so the $\mathsf{Real}^{\uparrow}$ consumer receives exactly the finite rounding packet and nothing outside it. □

Theorem 433.6 (DyadicRounding transport stability)**.** *Let* $D = (x, n, a, b, I, E, L, C, P, N)$ *be an accepted* $\mathsf{DyadicRounding}^{\uparrow}$ *carrier. If each displayed coordinate is transported componentwise along the* hsame *rows stored in* L *and then read along the* Cont *routes stored in* C*, the resulting packet is accepted by the same* $\mathsf{NameCert}_{\mathsf{DyadicRounding}^{\uparrow}}$ *surface and preserves the source read* x*, unary precision* n*, adjacent endpoints* a, b*, containment row* I*, finite budget row* E*, transport ledger* L*, continuation ledger* C*, package provenance* P*, and local naming row* N*.*

Proof. Start from the carrier inventory in Definition 433.1. The only movable data are the displayed source read, unary precision, endpoint pair, containment row, finite budget row, and provenance rows.

Apply Definition 433.3 after transport. The same transported precision row still selects the adjacent endpoint pair, and the same containment and budget rows provide the finite sandwich.

Apply Definition 433.4 and Definition 433.5. The transported packet exposes no extra rounding operation or real comparison, so the original NameCert obligations are preserved componentwise. □

Theorem 433.7 (DyadicRounding finite-grid coverage)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *read at unary precision* n *from a* $\mathsf{DyadicRounding}^{\uparrow}$ *carrier is covered by the displayed adjacent* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints* a, b *together with the* $\mathsf{RationalInterval}^{\uparrow}$ *containment row* I *and the* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *row* E *of Definition 433.1. No accepted read at that precision can require a dyadic endpoint, interval witness, or tolerance ledger outside the displayed packet.*

Proof. First use Definition 433.3. It places the source read at precision n between the adjacent dyadic endpoints a and b through the containment row I.

Next use Definition 433.4. The only widening of that interval read is the finite budget row E, and every tolerance consumed by the read is exhausted by the displayed ledger.

Finally apply Definition 433.5. A $\mathsf{Real}^{\uparrow}$ read and a $\mathsf{RegSeqRat}^{\uparrow}$ read both pass through the same finite enclosure data before any downstream consumer sees them, so the displayed grid covers every accepted read at precision n. □

Theorem 433.8 (DyadicRounding carrier scope)**.** *The carrier of Definition 433.1 has no coordinate for order trichotomy, host rounding, quotient reals, or selected limits. Its complete analytic surface is the finite grid sandwich of Definition 433.3, the ledger exactness boundary of Definition 433.4, and the* $\mathsf{Real}^{\uparrow}$ *handoff of Definition 433.5.*

Proof. Inspect the packet $D = (x, n, a, b, I, E, L, C, P, N)$ from Definition 433.1. Each coordinate is a finite source, precision, dyadic endpoint, interval, budget, transport, continuation, package, or naming row.

The grid sandwich and ledger exactness theorems identify all analytic data available to consumers: adjacent endpoints, containment, and a finite error budget at the displayed precision.

The $\mathsf{Real}^{\uparrow}$ handoff theorem then accounts for the real-facing route. Since the carrier inventory contains no further coordinate, trichotomy, host rounding, quotient-real data, and selected limits are outside the scoped surface. □

Theorem 433.9 (DyadicRounding mature finite-grid envelope)**.** *For every accepted* $\mathsf{DyadicRounding}^{\uparrow}$ *carrier* $D = (x, n, a, b, I, E, L, C, P, N)$*, the mature finite-grid envelope is exactly the carrier row of Definition 433.1, the finite grid sandwich of Definition 433.3, the ledger exactness row of Definition 433.4, the* $\mathsf{Real}^{\uparrow}$ *handoff of Definition 433.5, and the carrier scope of Definition 433.8. Every rounded read is therefore confined to the displayed source, precision, adjacent dyadic endpoints, containment, finite error budget, transport, continuation, provenance, and local naming rows.*

The envelope exports no quotient real, selected limit, trichotomy branch, host rounding operation, or additional paper-side theory obligation.

Proof. Start with the carrier row. The packet displays only $x, n, a, b, I, E, L, C, P, N$, so every accepted read begins inside the named finite inventory.

Apply the grid sandwich and ledger exactness theorems. They bind the analytic content of the rounded read to the adjacent dyadic endpoints, interval containment, and finite error budget at the requested precision.

Use the $\mathsf{Real}^{\uparrow}$ handoff theorem to route any real-facing consumer through the same finite enclosure before it sees the source read. The carrier scope theorem then rules out every absent analytic coordinate, so no additional paper-side theory row remains outside the finite-grid envelope. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRounding}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicRounding}^{\uparrow}$ packet is generated from a displayed source read, unary precision request, adjacent dyadic endpoint rows, interval containment, finite error budget, componentwise transports, continuation routes, package provenance, and a local naming row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicRounding}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 433.1, Definition 433.2, Definition 433.3, Definition 433.4, Definition 433.5, Definition 433.8, and Definition 433.9 bind the source read, unary precision, dyadic endpoints, interval containment, finite error budget, BHist, hsame, Cont, Pkg, and NameCert rows of the displayed rounding packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicRounding}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.DyadicRoundingUp.DyadicRoundingPacket\_grid\_sandwich`

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient reals, selected limits, trichotomy of host order, host rounding operations, or a public standard bridge.

Upgrade path: No paper-side theory upgrade remains; only future machine bridge checking can raise the verification bridge grade.

Chapter 434

A Concrete Naming Certificate for $\mathsf{SubshiftOfFiniteType}^{\uparrow}$

Following Lind and Marcus symbolic dynamics, the $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ interface is a BEDC finite certificate surface. It packages finite BHist words, forbidden-window ledgers, shift-window reads, and regular-language handoff rows, not an ambient shift space or an external symbolic-dynamics object.

The singleton forbidden-adjacency instance is consumed by chapter 370, so the finite forbidden-ledger carrier here is not isolated from the symbolic-dynamics branch.

434.1 Finite adjacency windows

Definition 434.1 (Subshift of finite type carrier)**.** *A* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, W, F, L, R, H, C, P, N)$$

with the following displayed coordinates:

1. *A is the finite visible alphabet row, specialized here to the displayed zero and one bit rows when the GoldenMean sibling is read;*
2. *W is a finite word row over A, recorded as a list of visible* BHist *letter rows;*
3. *F is the finite forbidden-window ledger whose rows are displayed words of one fixed positive length and whose binary adjacency specialization is the forbidden-pair ledger;*
4. *L is the admissibility ledger recording, for every displayed window of W, that the window is absent from F;*
5. *R is the shift-window row recording the left and right one-step windows of W and the finite* $\mathsf{StreamName}^{\uparrow}$ *observation through which those windows are read;*
6. *H records componentwise* hsame *transport for alphabet rows, word rows, forbidden-window rows, admissibility rows, shift-window rows, replay rows, provenance rows, and local naming rows;*
7. *C records displayed* Cont *replay from the finite word to its subwindows and from the subwindows to the admissibility ledger;*
8. *P records the finite prefix, restriction,* $\mathsf{FiniteAutomaton}^{\uparrow}$, $\mathsf{RegularLanguage}^{\uparrow}$, *and row-transport provenance through* Cont *and* Pkg*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{SubshiftOfFiniteType}^{\uparrow}}$ *row for the componentwise visible-word classifier.*

The classifier compares two carriers componentwise by hsame *on the alphabet row, each visible word row, the forbidden-window ledger, the admissibility ledger, the shift-window row, the* Cont *replay row, the provenance row, and the local certificate row. Acceptance is exactly finite ledger inspection: every fixed-length window displayed by W must be rejected by no row of F and certified in L as allowed.*

Lean4 ✓ `BEDC.Derived.SubshiftOfFiniteTypeUp.SubshiftOfFiniteTypeTasteGate single carrier alignment`

Theorem 434.2 (Subshift of finite type NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{SubshiftOfFiniteType}^{\uparrow}}$ *obligation surface consists of five finite obligations:*

1. *carrier habitation: the empty word and every word shorter than the displayed forbidden-window length are accepted, because they display no forbidden window;*
2. *classifier laws: reflexivity, symmetry, and transitivity are inherited componentwise from* hsame *on visible alphabet rows, word rows, forbidden-window rows, admissibility rows, shift-window rows, replay rows, provenance rows, and certificate rows;*
3. *forbidden-window transport: displayed* hsame, Cont, Pkg, *and* NameCert *routes transport accepted carriers exactly when transported finite windows remain outside the transported forbidden ledger;*
4. *finite-prefix restriction: every displayed prefix, suffix, shift-window, or finite restriction of W retains the corresponding subledger of F, L, R, C, P, N and remains accepted;*
5. *non-escape: every accepted row is justified only by the finite visible alphabet, word, forbidden-window ledger, admissibility ledger, shift-window row, replay row, provenance row, and local certificate rows.*

Thus the certificate is a BEDC-native finite-window object over BHist *rows.*

Proof. For habitation, choose the empty word or any displayed word shorter than the forbidden-window length. There is no full forbidden window to inspect, so the admissibility ledger is empty and no forbidden window can be witnessed.

For the classifier laws, read each coordinate of Definition 434.1 componentwise. The visible rows are compared by hsame, and the packet has no further coordinate on which another classifier could act.

For forbidden-window transport, move the alphabet, word, forbidden-window ledger, admissibility ledger, shift-window row, replay row, provenance row, and certificate row through the displayed hsame, Cont, Pkg, and NameCert routes. The transported carrier is accepted exactly when every transported window remains absent from the transported forbidden ledger, because acceptance is defined by that finite inspection.

For finite-prefix restriction, select an initial segment, suffix segment, or one-step shift window of the word through the recorded Cont route and restrict the ledgers to windows that still appear in the segment. A retained window was already accepted in the original word, so the restricted admissibility ledger certifies it again.

Non-escape follows by projection of the carrier coordinates. The packet exposes no entropy row, inverse-limit object, quotient coordinate, infinite sequence carrier, or host symbolic-dynamics theorem, so a downstream NameCert consumer can cite only the displayed finite ledger rows and their routes. □

Lean4 ✓ `BEDC.Derived.SubshiftfinitetypeUp.SubshiftFiniteTypeCarrier semantic name certificate`

Theorem 434.3 (Golden mean instance)**.** *The* $\mathsf{GoldenMeanShift}^{\uparrow}$ *finite-window carrier is the one-forbidden-word instance of* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ *obtained by taking the visible alphabet row* $A = \{0, 1\}$ *and the forbidden-adjacency ledger*

$$F = \{11\}.$$

For this instance, a finite word is accepted precisely when every neighboring pair is zero-zero, zero-one, or one-zero, and the inherited NameCert *obligations are the GoldenMeanShift carrier habitation, local stability, fold-prefix closure, adjacency-ledger exhaustion, and non-escape obligations.*

Proof. Specialize Definition 434.1 to the binary alphabet row and the singleton forbidden ledger whose only row is the adjacent pair 11. A neighboring pair is accepted exactly when the finite ledger inspection does not find that row.

The remaining adjacent binary pairs are zero-zero, zero-one, and one-zero. These are exactly the accepted adjacency rows used by the $\mathsf{GoldenMeanShift}^{\uparrow}$ carrier, and the componentwise hsame classifier is the same visible-word classifier.

The NameCert obligations restrict along the same finite ledgers. Habitation is witnessed by the empty word, one-letter words, and the all-zero word; local transport preserves acceptance by transporting the singleton forbidden row; prefix restriction deletes neighboring checks without adding any; and non-escape is inherited from the absence of any coordinate beyond the finite BHist word and ledger rows.

This one-forbidden-word instance is the sibling dependency consumed by chapter 370: $\mathsf{GoldenMeanShift}^{\uparrow}$ reads the same binary alphabet row and singleton forbidden adjacency ledger rather than introducing a separate symbolic-dynamics carrier. □

Theorem 434.4 (Subshift finite type adjacency carrier transport)**.** *For accepted* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ *carriers, componentwise* hsame *transport of the visible alphabet row, finite word row, forbidden-adjacency ledger, acceptance ledger,* Cont *routes,* Pkg *provenance, and local* NameCert *row preserves the finite adjacency carrier whenever the forbidden-pair ledger is transported with the same rows.*

Proof. Project the carrier of Definition 434.1. The carrier predicate is stated only in terms of the displayed alphabet, word, forbidden-window ledger, admissibility ledger, shift-window row, replay row, provenance row, and local certificate rows.

Transport the forbidden-pair ledger and the admissibility ledger along the same componentwise hsame routes. Every neighboring pair in the transported word is the length-two image of a window already inspected by the original finite ledger.

The Cont routes and Pkg provenance then repack the transported rows into the same carrier shape. Since no further coordinate participates in the predicate, the transported packet remains an accepted finite adjacency carrier. □

Theorem 434.5 (Subshift finite type forbidden-word ledger exhaustion)**.** *Every accepted neighboring-pair decision in a* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ *carrier is read from the displayed allowed and forbidden adjacency ledgers, as the length-two specialization of the forbidden-window surface. No decision is supplied by entropy, inverse limits, quotient shift spaces, external imports, or an ambient symbolic-dynamics theorem.*

Proof. Take a neighboring-pair decision in an accepted word row. By the carrier definition, acceptance is recorded by the finite admissibility ledger and by absence from the finite forbidden-window ledger specialized to length two.

The provenance row records only Cont and Pkg routes between the displayed rows. These routes name how the finite rows are read; they do not introduce any entropy value, inverse-limit object, quotient carrier, or host symbolic-dynamics theorem.

Thus the decision is exhausted by the local adjacency ledgers. A downstream consumer can recover the decision by projecting the word, forbidden-ledger, admissibility-ledger, shift-window, replay, provenance, and local NameCert coordinates. □

Theorem 434.6 (Subshift finite type golden-mean scope)**.** *The singleton forbidden one-one row recovers the existing* $\mathsf{GoldenMeanShift}^{\uparrow}$ *instance as a scoped* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ *packet: its accepted neighboring pairs are exactly zero-zero, zero-one, and one-zero, and its rejected neighboring pair is exactly one-one.*

Proof. Specialize the visible alphabet row to zero and one, and specialize the forbidden-adjacency ledger to the single row one-one. The acceptance ledger inspects each neighboring pair of the displayed finite word against that singleton row.

If the pair is zero-zero, zero-one, or one-zero, it is absent from the forbidden ledger and is accepted by the displayed finite decision row. If the pair is one-one, it is present in the forbidden ledger and is rejected.

This is exactly the finite-window $\mathsf{GoldenMeanShift}^{\uparrow}$ classifier used in Definition 434.3. The Cont routes, Pkg provenance, and local NameCert row repack the same scoped packet without adding an infinite shift carrier. □

Theorem 434.7 (Subshift finite type window-language route)**.** *Every accepted* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ *carrier factors its admissible-word decision through the finite route*

$$\mathsf{BHist} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{FiniteAutomaton}^{\uparrow} \longrightarrow \mathsf{RegularLanguage}^{\uparrow}$$

before any symbolic-dynamics consumer can read the word as a language element. The BHist *row supplies the displayed finite word, the* $\mathsf{StreamName}^{\uparrow}$ *row supplies the inspected finite windows, the* $\mathsf{FiniteAutomaton}^{\uparrow}$ *row replays the forbidden-window scan as a finite-state run, and the* $\mathsf{RegularLanguage}^{\uparrow}$ *row records the accepted-language endpoint. No infinite shift space, quotient presentation, entropy coordinate, invariant measure, or ambient compactness theorem is inserted into this route.*

Proof. Project the accepted carrier to $A, W, F, L, R, H, C, P, N$. The rows W, F, L give the finite word, the forbidden-window ledger, and the admissibility ledger; R names the shift-window observations of the same finite word.

Read R through the $\mathsf{StreamName}^{\uparrow}$ finite-window surface. This only exposes the inspected windows as finite BHist observations, so the consumer still has no access to an infinite sequence or quotient shift space.

Replay the same window scan as a $\mathsf{FiniteAutomaton}^{\uparrow}$ run whose states remember the finite suffix needed to test the forbidden ledger. The accepting endpoint is then a $\mathsf{RegularLanguage}^{\uparrow}$ row for the language of finite words avoiding F.

Finally, H, C, P, N transport and name that route componentwise. Since every coordinate used by the consumer is one of these displayed rows, the accepted word decision is exhausted by the finite window-language route. □

Theorem 434.8 (Subshift finite type scoped obligation package)**.** *The carrier of Definition 434.1, the five* $\mathsf{NameCert}_{\mathsf{SubshiftOfFiniteType}^{\uparrow}}$ *obligations of Definition 434.2, adjacency carrier transport, forbidden-word ledger exhaustion, the finite window-language route, and the* $\mathsf{GoldenMeanShift}^{\uparrow}$

singleton-forbidden scope form one scoped package over the displayed alphabet row, finite word row, forbidden ledger, admissibility ledger, shift-window row, BHist, StreamName$^{\uparrow}$, FiniteAutomaton$^{\uparrow}$, RegularLanguage$^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert. *The package exports no entropy coordinate, inverse-limit object, quotient shift-space, external import, or ambient symbolic-dynamics theorem.*

Proof. Project the carrier coordinates $A, W, F, L, R, H, C, P, N$. They supply the visible alphabet row, finite word row, forbidden-window ledger, admissibility ledger, shift-window row, transport, replay, provenance, and local naming row that support the scoped package.

Use the five local obligations of Definition 434.2. Habitation, classifier laws, forbidden-window transport, finite-prefix restriction, and non-escape are all stated over the displayed finite rows and their hsame, Cont, Pkg, and NameCert routes.

Next apply adjacency carrier transport, forbidden-word ledger exhaustion, and the finite window-language route from Definition 434.4, Definition 434.5, and Definition 434.7. These rows keep accepted packets within the same finite adjacency surface, identify every neighboring-pair decision with the displayed ledgers, and route finite words through StreamName$^{\uparrow}$, FiniteAutomaton$^{\uparrow}$, and RegularLanguage$^{\uparrow}$ before any language consumer reads them.

Finally specialize by Definition 434.6. The singleton forbidden one-one row gives the Golden-Mean finite-window scope inside the same packet, while the non-escape clauses rule out entropy, inverse limits, quotient shift spaces, external imports, and ambient symbolic-dynamics data. □

Closure status for NameCert$_{\text{SubshiftOfFiniteType}^{\uparrow}}$.

Constructive story: A SubshiftOfFiniteType$^{\uparrow}$ packet is generated from a visible alphabet row, a finite BHist word row, a finite forbidden-window ledger, an admissibility ledger for inspected windows, a shift-window row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SubshiftOfFiniteType}^{\uparrow}}$, obligation)

Scope closed: The obligation surface names the finite forbidden-window carrier, its five local NameCert obligations, adjacency-carrier transport, forbidden-ledger exhaustion, the finite window-language route, and the GoldenMeanShift$^{\uparrow}$ singleton-forbidden-ledger scope.

Formal verification: FormalStatus(NameCert$_{\text{SubshiftOfFiniteType}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.SubshiftfinitetypeUp.SubshiftFiniteTypeCarrier\_semantic\_name\_certificate`

Bridge status: none

Origin: human

Not claimed: This chapter does not close entropy, inverse limits, quotient presentations, infinite shift spaces, invariant measures, external imports, or a public standard bridge.

Upgrade path: Scoped closure requires complete Lean coverage of adjacency-carrier transport, forbidden-ledger exhaustion, the finite window-language route, and the singleton-forbidden-row GoldenMeanShift$^{\uparrow}$ scope.

UniformCauchyCriterion$^{\uparrow}$ reads its shared finite-family threshold route through chapter 126, chapter 301, chapter 291, and chapter 38 before the child files expose the Cauchy-limit and Real-completion consumers. The packet exports no quotient stream, selected limit, host equality, countable choice, or ambient completeness row.

Chapter 435

A Concrete Naming Certificate for UniformCauchyCriterion$^{\uparrow}$

The UniformCauchyCriterion$^{\uparrow}$ interface names the finite family-level Cauchy test used in the Bishop–Bridges constructive reading of uniform convergence. It records one displayed dyadic tail criterion shared by a finite family of StreamName$^{\uparrow}$ windows. The certificate is a consumer surface for RegSeqRat$^{\uparrow}$, CauchyModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, DyadicTailBound$^{\uparrow}$, and Real$^{\uparrow}$, and it withholds quotient streams, host real equality, selected limits, and ambient completeness.

The sibling UniformLimit$^{\uparrow}$ dossier consumes this criterion through the shared-threshold tail ledger recorded in chapter 463: its endpoint route reads the same windowwise family data, then passes through the UniformCauchyCriterion$^{\uparrow}$ row before the RegSeqRat$^{\uparrow}$ handoff. Locally, the dependency route is grounded in StreamName$^{\uparrow}$ finite windows and RegSeqRat$^{\uparrow}$ regular-sequence readback, so the criterion is a concrete-instance bridge between source windows and the uniform-limit consumer rather than a kernel-only tail predicate.

Definition 435.1 (UniformCauchyCriterion carrier)**.** *A* UniformCauchyCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite family index ledger naming the members whose windows are compared;*
2. *W is the shared finite* StreamName$^{\uparrow}$ *window family, indexed by I, through which every source observation is read;*
3. *M is one* CauchyModulus$^{\uparrow}$ *schedule used uniformly for all indices in I;*
4. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance row whose dyadic budget is used by the family test;*
5. *T is the finite* DyadicTailBound$^{\uparrow}$ *tail-comparison ledger recording all accepted comparisons beyond the threshold selected by M and inside the windows named by W;*
6. *E is the* Real$^{\uparrow}$ *seal handoff row reached after the finite family tail criterion has been accepted;*
7. *H records the componentwise* hsame *rows for the family ledger, window family, modulus schedule, tolerance row, tail ledger, and seal handoff;*
8. *C records the displayed* Cont *routes by which a consumer reads the family index row, shared windows, uniform modulus, tolerance, finite tail ledger, and real seal;*

9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyCriterion}^{\uparrow}}$ *provenance row.*

The classifier compares two accepted carriers only through these displayed coordinates, their componentwise transports, their continuation routes, and their package and local naming provenance.

Lean4 (definition) `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionCarrier`

This carrier consumes the finite $\mathsf{StreamName}^{\uparrow}$ window interface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-tail readback surface of chapter 301, and the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. These sibling dependencies are exactly the horizontal lattice edges used by the shared-window, tail-ledger, and seal-handoff obligations below: the criterion is a finite family tail service between source windows and Real-facing consumers, not a kernel-only Cauchy predicate.

Theorem 435.2 (UniformCauchyCriterion NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{UniformCauchyCriterion}^{\uparrow}}$ *surface for the carrier of Definition 435.1 consists exactly of five rows:*

1. *carrier habitation by the displayed packet $U = (I, W, M, Q, T, E, H, C, P, N)$;*
2. *classifier transport by componentwise* hsame *and displayed* Cont *routes over the finite family ledger, shared window family, modulus schedule, tolerance row, tail ledger, seal handoff, package provenance, and local naming row;*
3. *uniform window stability, requiring every transported precision request to keep the same I-indexed* $\mathsf{StreamName}^{\uparrow}$ *window family and the same shared modulus row M before tail comparisons are read;*
4. $\mathsf{Real}^{\uparrow}$ *seal handoff, requiring the family tail ledger to pass through T and the real-facing row E after the shared threshold and dyadic tolerance have been displayed;*
5. *non-escape from quotient streams, host real equality, selected limits, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket namecert obligations`

Proof. Carrier habitation is projection from the finite packet in Definition 435.1. The family index ledger, window family, shared modulus, dyadic tolerance, finite tail ledger, real seal, transport rows, continuation routes, package row, and local naming row are all visible coordinates.

Classifier transport is componentwise. The hsame rows in H move the family ledger, windows, modulus, tolerance, tail ledger, and seal row, while the Cont rows in C replay the same read order for a consumer.

The uniform window row is the key obligation: every member named by I is inspected through the same W family and the same threshold schedule M. The seal handoff then reads Q and T before reaching E, and no remaining coordinate can export quotient streams, host real equality, selected limits, or ambient completeness. □

Theorem 435.3 (UniformCauchyCriterion window stability)**.** *Let $U = (I, W, M, Q, T, E, H, C, P, N)$ and $U' = (I', W', M', Q', T', E', H', C', P', N')$ be accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *carriers related by the displayed classifier. Every transported family precision request preserves the same finite index ledger, the same* $\mathsf{StreamName}^{\uparrow}$ *window family up to the componentwise* hsame *rows, and the same shared* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule up to the transported row. Thus every tail comparison in the transported carrier is still read through one uniform threshold and one displayed dyadic tolerance row for all family members.*

Proof. Project both carriers through Definition 435.1. The classifier has access only to $I, W, M, Q, T, E, H, C, P, N$ and to the corresponding rows of U'.

Transport the family index and window rows first. The rows in H compare the finite family ledger and the window family componentwise, and the routes in C describe how the consumer reaches those rows before any tail ledger is inspected.

Now transport the shared modulus row. Since M is a single coordinate of the packet rather than an index-dependent family of moduli, the transported request still reaches one threshold schedule before reading Q and T.

The tail ledger can therefore record only comparisons inside the transported window family and beyond the transported threshold. Repacking these projections gives the stated window stability and leaves no coordinate for a host-level pointwise criterion. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket window stability`

Theorem 435.4 (UniformCauchyCriterion RealUp seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *carrier factors through the finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

The route first fixes the finite family ledger, then reads the shared $\mathsf{StreamName}^{\uparrow}$ *windows, then applies the single* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule, then reads the dyadic tolerance row and the finite tail-comparison ledger before reaching the seal row. The seal exposes no completed family limit, no quotient of streams, no host real equality, and no ambient completeness principle.*

Proof. Start with a real-facing consumer request. By carrier projection, the request must first identify the finite family ledger I and the shared window family W that supplies the inspected observations.

Apply Definition 435.3. The request reaches the shared modulus row M before any comparison in T can be used, so the threshold is uniform over the displayed family.

The tolerance coordinate Q and the finite ledger T are then read in the same packet. These rows provide the accepted dyadic tail comparison, while H, C, P, N keep the transport, continuation, package, and local naming provenance visible.

Finally the seal coordinate E is reached only after that route has been completed. Since none of the carrier coordinates is a completed family limit, quotient stream, host real equality, or completeness theorem, the exported seal read cannot bypass the displayed finite criterion. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real seal handoff`

Theorem 435.5 (UniformCauchyCriterion shared-window obligation)**.** *Let I be a finite family ledger, W a* $\mathsf{StreamName}^{\uparrow}$ *window family over I, M a* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule, Q a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, T a* $\mathsf{DyadicTailBound}^{\uparrow}$ *tail ledger, E a* $\mathsf{Real}^{\uparrow}$ *seal row, and H, C, P, N the displayed* hsame, Cont, Pkg, *and local* NameCert *rows of an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every family tail comparison admitted by this packet first fixes I, W, M, Q and then records its comparison in T; no comparison may be read through a quotient stream family, host real equality, selected limit, or ambient completeness object.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket shared window obligation`

Proof. Use Definition 435.3 to fix the finite family ledger and shared window family before a tail row is inspected.

Then apply Definition 435.9. It places every accepted comparison after the single threshold schedule and dyadic tolerance row.

Finally use Definition 435.8. The excluded objects are not rows of the packet, so the shared-window obligation is exhausted by $I, W, M, Q, T, H, C, P, N$. □

Theorem 435.6 (UniformCauchyCriterion seal-route obligation)**.** *For accepted rows $I, W, M, Q, T, E, H, C, P, N$ of a* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, every* $\mathsf{Real}^{\uparrow}$ *seal read follows the displayed finite route from I through W, M, Q, T to E. The route may transport and replay through H, C, P, N, but it has no coordinate for quotient streams, host real equality, selected limits, or ambient completeness.*

Proof. Begin with Definition 435.4. It identifies the route to E as the finite family ledger, shared windows, threshold schedule, dyadic tolerance, and tail ledger.

The structural rows H, C, P, N only transport, replay, package, and name that same route. By Definition 435.72, there is no second seal path inside the accepted packet. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket seal route obligation`

Theorem 435.7 (UniformCauchyCriterion non-escape obligation)**.** *The current-phase* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *obligation surface for rows $I, W, M, Q, T, E, H, C, P, N$ is exactly the shared-window tail route and the seal route displayed above. A consumer can inspect finite family comparisons and seal handoff through those rows only; it cannot obtain quotient streams, host real equality, selected limits, or ambient completeness from the criterion.*

Proof. Combine Definition 435.5 with Definition 435.6. The first theorem exhausts family tail comparisons, and the second exhausts real-seal reads.

Apply Definition 435.8 to the combined surface. Since all consumer reads have already been routed through $I, W, M, Q, T, E, H, C, P, N$, the excluded analytic objects remain outside the packet. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket nonescape obligation`

Theorem 435.8 (UniformCauchyCriterion non-escape boundary)**.** *An accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *carrier exports only the finite family index ledger, the shared* $\mathsf{StreamName}^{\uparrow}$ *windows, the uniform* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the finite* $\mathsf{DyadicTailBound}^{\uparrow}$ *comparison ledger, the* $\mathsf{Real}^{\uparrow}$ *seal handoff, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows. It exports no quotient stream family, no host real equality, no selected family of limits, and no ambient completeness object.*

Proof. Inspect the carrier coordinates of Definition 435.1. Each row is a finite ledger, a displayed dependency certificate, a transport row, a continuation route, package provenance, or local naming provenance.

The window-stability theorem keeps every transported read inside the finite I, W, M, Q, T surface. The real-seal handoff theorem then forces every $\mathsf{Real}^{\uparrow}$ read to pass through that same surface before reaching E.

No excluded analytic object is a coordinate of the packet or a result of the displayed route. Therefore a downstream Weierstrass, completion, or real-seal chapter can consume the uniform Cauchy criterion only as the finite NameCert package described here. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket non escape boundary`

Theorem 435.9 (UniformCauchyCriterion tail-ledger exactness)**.** *Every accepted finite-family tail comparison in a* UniformCauchyCriterion$^{\uparrow}$ *carrier factors through the displayed packet*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

of Definition 435.1 and through one shared dyadic tolerance ledger. More precisely, the comparison first reads the finite family ledger I, the shared StreamName$^{\uparrow}$ *window family W, the single* CauchyModulus$^{\uparrow}$ *threshold schedule M, and the* DyadicRatCore$^{\uparrow}$ *tolerance row Q; it then records the accepted tail comparison in T before any* Real$^{\uparrow}$ *seal row E can be consumed. The transport rows H, read routes C, package row P, and local naming row N are the only provenance by which the comparison is replayed.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket tail ledger exactness`

Proof. Start with an accepted tail comparison. By Definition 435.2, the comparison is read from the carrier of Definition 435.1, so its available rows are exactly $I, W, M, Q, T, E, H, C, P, N$.

Apply Definition 435.3. The transported request keeps the same finite family ledger, the same shared window family, and one shared threshold schedule before the tail ledger is inspected.

The dyadic tolerance row Q and the comparison ledger T therefore form one displayed tolerance route for all accepted family comparisons. Finally Definition 435.4 places any real seal read after this route, and Definition 435.8 blocks any hidden completion or host equality escape. □

Theorem 435.10 (UniformCauchyCriterion shared-threshold transport)**.** *Let $U = (I, W, M, Q, T, E, H, C, P, N)$ and $U' = (I', W', M', Q', T', E', H', C', P', N')$ be accepted* UniformCauchyCriterion$^{\uparrow}$ *carriers related by the displayed classifier. Classifier transport preserves the single shared threshold schedule: every transported family-index read reaches M' as the transported image of the one schedule M, not as a family of independently selected indexwise schedules. Consequently all transported tail comparisons for indices in I' use the same threshold route before reading Q' and T'.*

Proof. Project the two carriers through Definition 435.1. The classifier can compare only the displayed coordinates and their recorded hsame, Cont, Pkg, and NameCert provenance.

Use the classifier-transport row of Definition 435.2. It transports the family ledger and window family componentwise, while the modulus coordinate is one row of the packet.

Now apply Definition 435.3. Since there is only one modulus coordinate before the tolerance and tail rows, the transported carrier can supply only the transported shared schedule M' for all family indices. The tail-ledger exactness route then forces Q' and T' to be read after that same schedule. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket shared threshold transport`

Theorem 435.11 (UniformCauchyCriterion RegSeqRat tail equivalence)**.** *For every accepted* UniformCauchyCriterion$^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N),$$

the finite tail-ledger route through the shared StreamName$^{\uparrow}$ *window family W, the single* CauchyModulus$^{\uparrow}$ *schedule M, the* DyadicRatCore$^{\uparrow}$ *tolerance row Q, and the* DyadicTailBound$^{\uparrow}$ *comparison ledger T is equivalent, as a BEDC consumer surface, to the* RegSeqRat$^{\uparrow}$ *finite-window regularity route whose* Real$^{\uparrow}$ *seal is E. Thus a consumer can reconstruct the same accepted finite evidence from either surface, and neither route introduces a quotient stream, selected limit, host real equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.RegSeqRatTailEquivalence.UniformCauchyCriterionPacket regseqrat tail equivalence`

Proof. For the forward direction, begin with a consumer read of the tail ledger. By Definition 435.9, the read passes through I, W, M, Q, T before any seal row is consumed. By Definition 435.10, the threshold row remains one shared M-schedule across all transported family indices.

Now attach the regular-rational handoff. The carrier already stores the seal row E, and Definition 435.4 forces the real-facing read to pass through the same finite route before reaching E. The $\mathsf{RegSeqRat}^{\uparrow}$ regularity window therefore receives exactly the stream windows, shared modulus, dyadic tolerance, and accepted tail comparisons displayed in the packet.

For the reverse direction, start with the $\mathsf{RegSeqRat}^{\uparrow}$ finite-window regularity route whose seal is E. Unpack its window read through the same carrier coordinates: the stream observations are the family windows W, the threshold schedule is the displayed modulus row M, and the dyadic tolerance budget is Q.

Repack those rows into the comparison ledger T. The transport and read routes H and C preserve the displayed coordinates, while P and N keep the package and local naming provenance attached. This reconstructs the finite $\mathsf{DyadicTailBound}^{\uparrow}$ ledger without adding any excluded completion, limit-selection, quotient, or host-equality object. □

Theorem 435.12 (UniformCauchyCriterion finite-tail-filter Real-window handoff)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any finite-family tail route of* U *consumed by a* $\mathsf{RealWindowBudget}^{\uparrow}$ *or Real-completion consumer must factor through the displayed* $\mathsf{FiniteTailFilter}^{\uparrow}$ *packet of chapter 1119 before the Real-window selector reads the route.*

Concretely, the consumer first reads the shared $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the uniform modulus row* M*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* Q*, and the tail ledger* T *as the UniformCauchyCriterion tail surface; the same read is then repacked as the* $\mathsf{FiniteTailFilter}^{\uparrow}$ *cofinal-tail packet carrying the displayed stream-window, dyadic,* $\mathsf{RegSeqRat}^{\uparrow}$*, tail-budget,* $\mathsf{CauchyTailComparison}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows; only after that packet is displayed may the* $\mathsf{RealWindowBudget}^{\uparrow}$ *selector consume the Real-facing route.*

This handoff does not assert quotient stream equality, selected limits, host real equality, countable choice, ambient completeness, or any standard bridge row.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite tail filter real window handoff`

Proof. Start with tail-ledger exactness, Definition 435.9. It places every accepted finite-family tail comparison of U after the displayed index, window, modulus, dyadic tolerance, and tail-ledger rows I, W, M, Q, T.

Next attach the UniformCauchyCriterion Real seal route, Definition 435.4. The Real-facing read reaches E only after the same finite tail surface has been consumed, with H, C, P, N replaying transport, continuation, provenance, and local naming.

Now pass to the FiniteTailFilter packet. The finite-tail-filter Real-window consumer theorem, Definition 1119.6, reads the displayed cofinal-tail packet through its stream-window, dyadic, regular-sequence, tail-budget, common-tail, Real seal, transport, continuation, package, and local naming rows.

Finally apply the Real-window selector bridge, Definition 1119.8. It lets the $\mathsf{RealWindowBudget}^{\uparrow}$ selector read only after the $\mathsf{FiniteTailFilter}^{\uparrow}$ route is displayed, and it refuses a private selector,

detached dyadic ledger, selected limit, quotient stream, host real equality, countable-choice row, ambient completeness coordinate, or bridge row. Hence every Real-window or completion-facing consumer of U factors through the finite-tail-filter packet before the selector reads the route. □

Theorem 435.13 (UniformCauchyCriterion Real-completion window exhaustion)**.** *For every accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N),$$

any $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer route from finite family observations into a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and then into the* $\mathsf{Real}^{\uparrow}$ *seal factors through exactly the finite observation rows* I, W, M, Q, T, E*, with structural replay through* H, C, P, N*. Conversely, this displayed route supplies the full admissible finite evidence consumed by the* $\mathsf{RegSeqRat}^{\uparrow}$*-to-*$\mathsf{Real}^{\uparrow}$ *handoff. No such route may pass through quotient streams, selected limits, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion window exhaustion`

Proof. Start from the finite family observations. By Definition 435.3, any accepted transported read remains inside the shared $\mathsf{StreamName}^{\uparrow}$ window family W. By Definition 435.10, the same read uses the single modulus schedule M, not an indexwise choice of thresholds.

The tail side is then forced. Tail-ledger exactness sends each accepted comparison through the dyadic tolerance row Q and the finite comparison ledger T. The RegSeqRat tail equivalence theorem repackages exactly this finite route as the $\mathsf{RegSeqRat}^{\uparrow}$ regularity readback whose seal row is E.

Now attach the seal. The $\mathsf{Real}^{\uparrow}$ seal handoff consumes the displayed finite rows before any real-facing boundary is reached, while H, C, P, N replay the classifier transport, continuation, package provenance, and local naming structure already present in the accepted packet.

For the converse direction, begin with the displayed route $I, W, M, Q, T, E, H, C, P, N$. The same cited window, threshold, tail-ledger, RegSeqRat, and seal results reconstruct the admissible finite evidence in the order required by the $\mathsf{RegSeqRat}^{\uparrow}$-to-$\mathsf{Real}^{\uparrow}$ handoff. The non-escape boundary excludes quotient streams, selected limits, host real equality, and ambient completeness, so no additional completion object can be part of the handoff route. □

Theorem 435.14 (UniformCauchyCriterion obligation assembly)**.** *The carrier of Definition 435.1, Definition 435.2, Definition 435.3, Definition 435.9, Definition 435.10, Definition 435.4, and Definition 435.8 assemble the full* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *obligation package. The package consists of carrier habitation, classifier transport, shared-window stability, exact finite tail ledger readback,* $\mathsf{Real}^{\uparrow}$ *seal handoff, and non-escape from quotient streams, host real equality, selected family limits, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket obligation assembly`

Proof. First bind carrier habitation. The finite packet $U = (I, W, M, Q, T, E, H, C, P, N)$ supplies the family ledger, shared windows, uniform modulus, dyadic tolerance, finite tail ledger, real seal, transport rows, read routes, package provenance, and local naming row.

Next bind transport and stability. The NameCert obligation theorem gives componentwise classifier transport, and the window-stability theorem keeps every transported family request inside the same window family and shared modulus route.

Now bind the tail and threshold rows. Tail-ledger exactness forces every accepted comparison through I, W, M, Q, T, while shared-threshold transport preserves the single M schedule across all transported family indices.

Finally attach the seal and boundary rows. The real-seal handoff routes each $\mathsf{Real}^{\uparrow}$ read through the same finite path, and the non-escape theorem states that no coordinate exports quotient streams, host real equality, selected limits, or ambient completeness. These rows are exactly the displayed obligation package. □

Theorem 435.15 (UniformCauchyCriterion subfamily restriction)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose J is a displayed finite subfamily ledger whose every read factors through the index ledger I by visible* hsame *comparisons and* Cont *rows. Then the restricted packet $U|_J$ is again an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *carrier over the same shared schedule M, tolerance row Q, tail ledger route, real seal row E, package row P, and local* $\mathsf{NameCert}$ *row N.*

The restricted carrier reads only the displayed subfamily windows selected by J and inherits the hsame *and* Cont *rows already present in H and C. It does not introduce a quotient stream, selected limit, host equality row, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket subfamily restriction`

Proof. First apply Definition 435.3. Each transported request from J factors through I, so the restricted window read stays inside the same finite window family W and uses the same shared schedule M.

Next apply Definition 435.9. The tail evidence read by the subfamily is the displayed subledger of T reached through I, W, M, Q, so no separate tolerance row or tail route is created.

The shared threshold is preserved by Definition 435.10. Since every J-read reaches the original packet through visible hsame and Cont rows, the restricted packet keeps the single schedule M rather than indexwise schedules.

Finally use Definition 435.4. The real-facing row remains E, and the package and local naming provenance are the inherited rows P and N. The construction has no carrier coordinate for quotient streams, selected limits, host equality, or ambient completeness, so none is added by the restriction. □

Theorem 435.16 (UniformCauchyCriterion RegSeqRat consumer package)**.** *For every accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N),$$

each $\mathsf{RegSeqRat}^{\uparrow}$ *consumer route factors through the finite family index ledger I, the shared* $\mathsf{StreamName}^{\uparrow}$ *window family W, the single* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule M, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row Q, the finite* $\mathsf{DyadicTailBound}^{\uparrow}$ *comparison ledger T, the* $\mathsf{Real}^{\uparrow}$ *seal E, the transport row H, the continuation route C, the package provenance P, and the local* $\mathsf{NameCert}$ *row N.*

Proof. First use Definition 435.14. It binds the carrier, local classifier transport, shared-window stability, finite tail ledger, real seal, and non-escape boundary as one obligation package.

Next apply Definition 435.11. The regular-rational read is the same finite evidence as the tail-ledger route, so the consumer must pass through I, W, M, Q, T before reading the real seal.

Finally use Definition 435.10 and Definition 435.4. The shared threshold and seal rows keep the consumer path inside H, C, P, N and expose no additional completion object. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket regseqrat consumer package`

Theorem 435.17 (UniformCauchyCriterion finite-family window exhaustion)**.** *Every transported request made to an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet uses the same finite index ledger, the same* $\mathsf{StreamName}^{\uparrow}$ *window family, the same shared modulus schedule, the same dyadic tolerance row, and the same finite tail ledger. Transport may rename the displayed rows through* hsame *and read them through* Cont*, but it cannot split the family into indexwise schedules or add a selected limit for any member of the family.*

Proof. Start from the NameCert obligations in Definition 435.2. They make classifier transport componentwise over the displayed packet coordinates.

Use Definition 435.3 to keep each transported request inside the same window family W. Then use Definition 435.10 to keep the threshold schedule as the one shared row M.

It remains to account for tolerance and tails. By Definition 435.9, every accepted comparison reads through Q and T after the shared window and modulus coordinates. The non-escape theorem then rules out indexwise schedules and selected limits because those objects have no carrier coordinate. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family window exhaustion`

Theorem 435.18 (UniformCauchyCriterion Real seal completion boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal or completion-facing consumer of an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet reaches the seal only after the finite family route through* $I, W, M, Q, T, E, H, C, P, N$*. The route supplies a finite uniform Cauchy certificate for the named family windows, but it does not supply quotient stream families, host real equality, selected family limits, or ambient completeness.*

Proof. First apply Definition 435.4. It sends every Real-facing read through the finite index ledger, shared windows, modulus, dyadic tolerance, and tail comparison ledger before the seal row E is consumed.

Next combine Definition 435.16 with Definition 435.17. These package the regular-rational and transported family reads over the same finite rows.

Finally use Definition 435.8 and Definition 435.14. The completion consumer receives the displayed finite certificate surface and no quotient stream family, host equality, selected limit, or completeness principle. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real seal completion boundary`

Definition 435.19 (UniformCauchyCriterion public export surface)**.** *The public export surface of an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet is the finite row package*

$$\mathsf{Pub}(U) = (I, W, M, Q, T, E, H, C, P, N)$$

read from the carrier of Definition 435.1. It exposes the finite family index ledger I*, shared* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, single* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule* M*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* Q*, finite* $\mathsf{DyadicTailBound}^{\uparrow}$ *tail ledger* T*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*, transport rows* H*, continuation routes* C*, package provenance* P*, and local naming row* N*.*

The surface is public only as this finite row package. It contains no quotient stream family, no host real equality, no selected family limits, and no ambient completeness object.

Lean4 (definition) `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPublicExportSurface`

Theorem 435.20 (UniformCauchyCriterion public export package)**.** *Every accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet exports the public surface of Definition 435.19. The export is assembled from the carrier, NameCert obligations, window stability, tail-ledger exactness, shared-threshold transport, RegSeqRat consumer package, finite-family window exhaustion, and the* $\mathsf{Real}^{\uparrow}$ *seal completion boundary.*

Proof. First project the carrier of Definition 435.1. This supplies exactly the rows $I, W, M, Q, T, E, H, C, P, N$ named by the public export surface.

Next attach the local certificate obligations. The NameCert obligation theorem gives carrier habitation and classifier transport, while window stability and shared-threshold transport keep every transported family request inside the same shared window and modulus rows.

Now attach the tail and consumer rows. Tail-ledger exactness routes every accepted comparison through I, W, M, Q, T, the RegSeqRat consumer package reads the same finite evidence, and finite-family window exhaustion prevents indexwise schedules or selected limits from entering the route.

Finally apply the $\mathsf{Real}^{\uparrow}$ seal completion boundary. The seal is reached only after the finite public rows have been displayed, and the non-escape clauses exclude quotient stream families, host real equality, selected family limits, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPublicExportSurface package closure`

Theorem 435.21 (UniformCauchyCriterion downstream Real consumer export)**.** *Every downstream* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or completion-facing consumer of an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet can read only the public export surface* $\mathsf{Pub}(U) = (I, W, M, Q, T, E, H, C, P, N)$. *The consumer route factors through the shared threshold, finite tail ledger, RegSeqRat consumer package, finite-family window exhaustion, and the* $\mathsf{Real}^{\uparrow}$ *seal completion boundary before any real-facing row is available.*

Proof. Start with a downstream consumer read. By Definition 435.16, a regular-rational consumer must pass through the family ledger, shared windows, shared modulus, dyadic tolerance, tail ledger, real seal, transport rows, continuation routes, package row, and local naming row.

The same route is preserved for real-facing consumers. Shared-threshold transport keeps the modulus coordinate single, and finite-family window exhaustion keeps every request inside the displayed window family.

The completion-facing step is then the seal boundary of Definition 435.18. Since the boundary exposes only the finite public surface before E is read, the downstream consumer receives no quotient streams, host real equality, selected family limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket downstream real consumer export`

Theorem 435.22 (UniformCauchyCriterion finite-family Real seal route determinacy)**.** *Let* $U = (I, W, M, Q, T, E, H, C, P, N)$ *be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. The Real-facing seal route of* U *is uniquely determined by the finite family ledger* I*, the shared* $\mathsf{StreamName}^{\uparrow}$ *window family* W*, the single modulus schedule* M*, the dyadic tolerance row* Q*, and the tail ledger* T*.*

In particular, any downstream consumer that reaches the seal row E *through the same displayed rows* I, W, M, Q, T *reaches the same finite BEDC route through* E, H, C, P, N*. The route has no quotient stream family, host real equality, selected family limit, ambient completeness object, or choice schedule.*

Proof. Begin with the carrier of Definition 435.1. It displays exactly the finite packet rows $I, W, M, Q, T, E, H, C, P, N$, so the family ledger, shared windows, modulus schedule, dyadic tolerance, and tail ledger are public route coordinates rather than external analytic data.

Apply Definition 435.3. The shared StreamName windows remain the same family under the allowed transports. Then use Definition 435.4 to route every Real-facing read through the displayed rows before the seal row E is consumed.

Next apply Definition 435.9. Once I, W, M, Q, T are fixed, every accepted tail comparison reads through the same finite tolerance and tail ledger, so a consumer reaching E through those rows has not introduced a second route.

Finally use Definition 435.8. Since quotient stream families, host real equality, selected family limits, ambient completeness, and choice schedules are not packet coordinates, they cannot distinguish two consumers that display the same I, W, M, Q, T rows and the same seal handoff through E, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family real seal route determinacy`

Theorem 435.23 (UniformCauchyCriterion endpoint budget reflector)**.** *Let $U = (I, W, M, Q, T, E, H, C, P, N)$ be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any downstream endpoint-budget request on the Real-facing route reflects back to the same finite family ledger I, shared window family W, modulus schedule M, dyadic tolerance row Q, and tail ledger T before the seal row E is read. The reflected endpoint budget has no quotient stream, selected family limit, host real equality, ambient completeness object, or choice schedule.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket endpoint budget reflector`

↪ variant `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family endpoint budget reflector`

Proof. Begin with the finite-family Real seal route determinacy theorem, Definition 435.22. It identifies the route to the seal from the displayed rows I, W, M, Q, T and no external analytic coordinate.

Now use tail-ledger exactness, Definition 435.9. Any endpoint-budget request that reaches the Real-facing seal must first pass through the same tail comparison ledger and dyadic tolerance row.

Finally apply the public non-escape export, Definition 435.24. Since quotient streams, selected family limits, host real equality, ambient completeness, and choice schedules are absent from the public packet, the reflected endpoint budget can only be the finite I, W, M, Q, T readback before E. □

Theorem 435.24 (UniformCauchyCriterion public non-escape export)**.** *The public export surface of* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *is finite and non-escaping: it exports exactly $I, W, M, Q, T, E, H, C, P, N$ and excludes quotient stream families, host real equality, selected family limits, and ambient completeness. Any downstream consumer that claims one of the excluded objects is outside the public package.*

Proof. Inspect the definition of the public export surface. It contains only the ten displayed rows copied from the accepted carrier.

Use the NameCert obligations and the non-escape boundary to rule out extra coordinates. The certificate admits classifier transport, window stability, tail-ledger exactness, and real-seal handoff only through the rows already present in the carrier.

The downstream Real consumer export does not add a new object. It merely replays the RegSeqRat consumer package, finite-family window exhaustion, shared-threshold transport, and Real seal completion boundary. Therefore the public surface remains finite and cannot export quotient streams, host real equality, selected family limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket public non escape export`

Theorem 435.25 (UniformCauchyCriterion L10 exit public non-escape)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. The L10 exit consumer read of* U *is public exactly through the finite export surface*

$$\mathsf{Pub}(U) = (I, W, M, Q, T, E, H, C, P, N),$$

the $\mathsf{RegSeqRat}^{\uparrow}$ *tail-equivalence route, the* $\mathsf{Real}^{\uparrow}$ *seal handoff, and, when the finite-observation comparison is displayed, the* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *diagonal-budget pullback route.*

Equivalently, preserving these rows and routes is sufficient for the L10 exit consumer read; conversely every L10 exit consumer read factors back through these rows before any completion-facing endpoint is available. The read therefore exports no quotient stream family, selected family limit, countable choice schedule, host real equality, or ambient completeness object.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket l10 exit public nonescape`

Proof. For sufficiency, first read the public surface through Definition 435.19 and Definition 435.20. These identify the accepted packet with the displayed finite rows $I, W, M, Q, T, E, H, C, P, N$ and place all carrier, NameCert, stability, tail-ledger, and seal data on that surface.

Next attach the exit routes. The tail read is the $\mathsf{RegSeqRat}^{\uparrow}$ route of Definition 435.11, while the completion-facing endpoint reaches the seal only along the displayed public rows. If a finite-observation selector is displayed, the pullback theorem Definition 435.26 places the same W, Q, T, E read inside that finite selector surface.

For necessity, start with any L10 exit consumer read. Apply Definition 435.24. Since the public export is exactly $\mathsf{Pub}(U)$ and has no excluded completion or host coordinate, the consumer must factor through $I, W, M, Q, T, E, H, C, P, N$ before any endpoint read can be interpreted.

Finally use Definition 435.76. The late-boundary route exhausts the no-choice completion side by the same public rows together with the displayed tail-equivalence and finite-budget routes. Thus preserving those rows is exactly the public L10 exit condition, and every such consumer read factors back through them. □

Theorem 435.26 (UniformCauchyCriterion finite-observation budget pullback)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let*

$$B = (B_s, S, W_B, D, R, E_B, H_B, C_B, P_B, N_B)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet whose displayed window, dyadic ledger, regular readback, and seal rows agree componentwise with* W, Q, T, E *through the carried* hsame *and*

Cont *routes. Then every* UniformCauchyCriterion$^{\uparrow}$ *Real-facing or completion-facing consumer pulls back through the finite observation budget selector surface before E is read.*

The pullback route is the public non-escaping route of Definition 435.24, the finite-family Real seal route of Definition 435.22, and the shared selector route of Definition 782.20 inside chapter 782. Hence the consumer cannot read a quotient stream, selected host limit, choice schedule, host equality, or ambient completeness object from either packet.

Proof. Project the accepted packet U. The public non-escape export exposes only $I, W, M, Q, T, E, H, C, P, N$, and the finite-family Real seal route determinacy theorem locks the Real-facing route to I, W, M, Q, T before the seal row E is consumed.

Project the accepted selector packet B. By hypothesis, the selector rows W_B, D, R, E_B agree componentwise with the UniformCauchyCriterion rows W, Q, T, E through the carried hsame and Cont routes. Thus the displayed window, dyadic budget, regular readback, and seal rows are the same consumer surface up to the recorded BEDC transports.

Now attach the finite-observation selector pullback from Definition 782.20. It places the shared W, Q, T, E route inside the selector surface before any Real-facing endpoint can be read.

Finally apply non-escape on both packets. The UniformCauchyCriterion public export and the finite selector route exclude quotient streams, selected host limits, choice schedules, host equality, and ambient completeness. Therefore every Real-facing or completion-facing consumer of U must pass through the finite observation budget selector surface before E is read. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite observation budget pullback`

Theorem 435.27 (UniformCauchyCriterion finite-tail-filter alignment)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted UniformCauchyCriterion$^{\uparrow}$ *packet. The shared-window route through $I, W, M, Q, T, E, H, C, P, N$ determines a* FiniteTailFilter$^{\uparrow}$ *cofinal-tail packet exactly when the displayed tail ledger factors through the same* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *tolerance row,* RegSeqRat$^{\uparrow}$ *readback,* DyadicTailBound$^{\uparrow}$ *budget,* CauchyTailComparison$^{\uparrow}$ *row, and* Real$^{\uparrow}$ *seal.*

Equivalently, a Real-facing or Completion-facing consumer of U is a finite-tail-filter consumer precisely when its route reads the common windows and dyadic tolerance from W and Q, reads the regular sequence tail from T, reads the finite tail budget and comparison row through the tail ledger certified by T, and reaches the seal row E only through the displayed structural rows H, C, P, N. Under this alignment the consumer receives no quotient stream family, host real equality, selected family limit, ambient completeness object, or choice schedule.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite tail filter alignment`

Proof. Start with tail-ledger exactness, Definition 435.9. It places every accepted tail comparison of U after the same shared StreamName$^{\uparrow}$ windows and DyadicRatCore$^{\uparrow}$ tolerance row, so the candidate finite-tail-filter route has no second window family or tolerance ledger.

Use the RegSeqRat tail equivalence of Definition 435.11. The regular-sequence readback carried by T is therefore the same readback used by the shared-window tail comparison. The finite-tail-filter tail-window exactness theorem, Definition 1119.4, then identifies the cofinal-tail packet rows with the displayed W, Q, T route.

Next apply the Real seal and completion boundary, Definition 435.18. The seal-facing part of the UniformCauchyCriterion route reaches E through the public rows H, C, P, N and does not expose a quotient stream, selected limit, host equality, ambient completeness object, or choice schedule.

Finally use the finite-tail-filter Real seal handoff, Definition 1119.5, and sibling tail handoff, Definition 1119.9. The first carries the same cofinal-tail packet to Real and Completion consumers; the second prevents a sibling consumer from substituting another tail selector, comparison row, or seal route. Hence the shared-window route of U determines exactly the finite-tail-filter cofinal-tail packet described above, and the reverse implication is obtained by reading the same packet rows back through W, Q, T, E, H, C, P, N. □

Theorem 435.28 (UniformCauchyCriterion finite-window Real-seal extraction)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Its* $\mathsf{Real}^{\uparrow}$*-seal route is extracted from exactly the finite window family* W*, the dyadic tolerance row* Q*, the tail ledger* T*, and the structural rows* H, C, P, N*. The extraction exposes no quotient stream family, host real equality, selected family limit, choice schedule, or ambient completeness.*

Proof. Start with Definition 435.27. It identifies the Real-facing route with the shared finite-window route through W, Q, T, E, H, C, P, N and excludes any second window family or tail selector.

Apply Definition 435.18. The seal row E is read only after the public rows H, C, P, N have carried the finite tail and tolerance data to the Real-facing boundary.

Finally use Definition 435.24. Since the public route is already exhausted by $I, W, M, Q, T, E, H, C, P, N$, the extracted Real-seal route has no coordinate for quotient stream families, host real equality, selected family limits, choice schedules, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionFiniteWindowRealSealExtraction`

Theorem 435.29 (UniformCauchyCriterion finite-window selector uniqueness)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

and

$$U' = (I', W', M', Q', T', E', H', C', P', N')$$

be accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packets. Suppose their finite family ledgers,* $\mathsf{StreamName}^{\uparrow}$ *window families, shared modulus rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail readbacks,* $\mathsf{Real}^{\uparrow}$ *seal rows, and structural* hsame, Cont, Pkg, *and* NameCert *rows agree componentwise along the displayed BEDC transports.*

Then every $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of* U *reads the same finite-window selector surface as the corresponding consumer of* U' *before reaching the seal. The common surface is exactly the route through the finite family ledger,* $W, M, Q, T, E, H, C, P, N$*, equivalently through the matched route* $W', M', Q', T', E', H', C', P', N'$*. It has no coordinate for quotient stream families, selected limits, host real equality, choice schedules, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite window selector uniqueness`

Proof. Start with tail-ledger exactness, Definition 435.9. It places every accepted comparison of each packet after the displayed finite family ledger, the $\mathsf{StreamName}^{\uparrow}$ window row, the shared modulus row, and the dyadic tolerance row. The componentwise agreement hypotheses therefore identify the two tail-ledger routes before any consumer reaches a seal-facing row.

Next apply shared-threshold transport, Definition 435.10. The transported threshold request remains the same M-route, or the matched M'-route, under the recorded hsame and Cont rows. Thus a consumer cannot distinguish the packets by choosing another modulus schedule or by moving the tolerance read outside the displayed transport.

Now use RegSeqRat tail equivalence, Definition 435.11. The regular rational readback carried by T is the same tail evidence already fixed by the window and tolerance route, and the same statement holds for T'. Since the readbacks agree componentwise, the two packets present a single $\mathsf{RegSeqRat}^{\uparrow}$ selector surface to downstream consumers.

Finally apply finite-window Real-seal extraction, Definition 435.28. The $\mathsf{Real}^{\uparrow}$ seal row is reached only through the finite window family, dyadic tolerance row, tail readback, and structural rows. The matched H, C, P, N and H', C', P', N' rows carry the same hsame, Cont, Pkg, and $\mathsf{NameCert}$ evidence, so the Real-facing and completion-facing consumers read one finite-window selector surface before E or E' is consumed.

The excluded objects are not rows of that surface. Quotient stream families, selected limits, host real equality, choice schedules, and ambient completeness cannot supply an alternate selector, so the componentwise matched packets are indistinguishable to every Real-facing or completion-facing consumer up to the seal. □

Theorem 435.30 (UniformCauchyCriterion diagonal uniqueness exit)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose its terminal rows are consumed through an accepted* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *selector-budget route and through an accepted* $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$ *comparison route, with both routes reading the same displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *faces.*

Then every Phase Real and Completion exit read of U factors through that same finite route. The terminal read uses the stream windows carried by W, the regular rational readback carried by T, the dyadic tolerance ledger carried by Q, and the Real seal carried by E, together with the structural rows H, C, P, N. No exit read has access to quotient streams, host real equality, selected limits, choice data, ambient completeness, or a second completion source.

Proof. Start with the public export of U. By Definition 435.24, every downstream consumer is already exhausted by the finite rows $I, W, M, Q, T, E, H, C, P, N$, so the exit read has no hidden analytic coordinate before the terminal rows are interpreted.

Next apply the terminal seal envelope, the completion–Real correspondence, and the finite-window extraction route. The envelope keeps the terminal seal downstream of the displayed rows, the correspondence identifies the Real-facing and Completion-facing endpoint reads on the same seal route, and Definition 435.28 extracts the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces from W, T, Q, E.

Now attach the diagonal selector-budget route. The diagonal compatibility surface supplies the same finite faces to the UniformCauchyCriterion terminal rows, while the uniqueness-seal comparison consumes those faces through the same selector budget. By Definition 646.207, the terminal consumer and the uniqueness-seal consumer collapse to one finite pullback route rather than two endpoint sources.

Finally combine this pullback with the non-escape clauses on both sides. Since the shared route has no coordinate for quotient streams, host equality, selected limits, choice data, ambient completeness, or an independent completion object, every Phase Real and Completion exit read of U factors through the same finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket diagonal uniqueness exit`

Theorem 435.31 (UniformCauchyCriterion diagonal exit classifier)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose two terminal exit reads of* U*, one Phase Real-facing and one Completion-facing, consume the same displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *faces, the same accepted* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *selector-budget route, and the same accepted* $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$ *comparison rows.*

Then the two terminal Real-facing classifier rows are hsame-equivalent. In particular, no second completion source, quotient-stream equality, host real equality, selected limit, choice datum, ambient completeness coordinate, or independent endpoint witness can distinguish the two terminal classifier reads.

Proof. Apply Definition 435.30 to the two exit reads. Both reads factor through the common finite route carried by $I, W, M, Q, T, E, H, C, P, N$, so neither route has an extra source from which a different terminal classifier could be read.

The public rows are exhausted by Definition 435.24. The Real-seal part of the route is exhausted by Definition 435.28, which reads the displayed stream name, regular rational sequence, dyadic tolerance core, and Real seal from W, T, Q, E.

Now compare the selector and uniqueness consumers. The shared $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ route and the shared $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$ comparison rows are collapsed by Definition 646.207, so the Phase Real-facing and Completion-facing classifier consumers lie over the same finite pullback route.

The classifier conclusion is therefore forced at the level of $BHist$ rows. Since *hsame* identifies terminal rows read from the same finite pullback route, the two terminal Real-facing classifier rows are *hsame*-equivalent, and the excluded coordinates have no remaining slot through which to separate them. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket diagonal exit classifier`

Theorem 435.32 (UniformCauchyCriterion diagonal exit nonescape)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose terminal exit reads share the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$*, and* $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$ *rows.*

Then every classifier distinction visible at the diagonal exit is witnessed inside the finite rows $BHist$*, hsame,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *carried by* H, C, P, N *and the terminal route* I, W, M, Q, T, E*. Quotient streams, host real equality, selected limits, choice data, ambient completeness, metric-completeness data, and independent completion sources are outside the accepted diagonal exit classifier.*

Proof. Apply Definition 435.30. The Phase Real-facing and Completion-facing terminal reads already factor through the same finite pullback route, whose displayed coordinates are the stream name, regular rational readback, dyadic tolerance ledger, Real seal, and structural rows H, C, P, N.

Next apply Definition 435.31. It identifies any two terminal classifier reads over that shared route at the level of *hsame*, so a visible distinction must be carried by the finite $BHist$ and classifier rows rather than by an external analytic separator.

The diagonal-limit pullback, Definition 646.207, supplies no separate selector route, and the real-limit uniqueness side is bounded by the same non-escape surface used above for the $\mathsf{Real}^{\uparrow}$ seal. Hence quotient streams, host real equality, selected limits, choice data, ambient completeness, metric-completeness data, and independent completion sources have no route slot in the accepted diagonal exit classifier. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket diagonal exit nonescape`

Theorem 435.33 (UniformCauchyCriterion diagonal budget extraction)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose terminal exit is read through the same displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, *and* $\mathsf{RealLimitUniquenessSea}$ *rows. Then the accepted terminal exit extracts exactly the finite budget route*

$$W, Q, T, E, H, C, P, N$$

for its Phase Real and Completion-facing consumers. No quotient stream, selected limit, host equality, choice row, ambient completeness witness, or independent completion datum can replace that route.

Proof. First use Definition 435.30. It places every terminal exit read of U on the shared finite route carried by the stream window, dyadic tolerance ledger, regular rational readback, Real seal, and structural rows.

Next apply Definition 435.31 and Definition 435.32. The classifier is forced inside the same $BHist$, *hsame*, Cont, Pkg, and local $\mathsf{NameCert}$ rows, and the non-escape boundary removes the listed host or completion-side coordinates.

Now pull the selector budget back through Definition 646.206. Under the shared $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads, the UniformCauchyCriterion terminal consumer receives precisely the displayed rows W, Q, T, E, H, C, P, N.

Finally use Definition 1120.6. The Phase Real and Completion exit sees only the four completion-facing faces and their structural budget rows, so the extracted route is finite and no external stream quotient, host-selected endpoint, choice principle, ambient completeness row, or detached completion datum remains available. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket diagonal budget extraction`

Theorem 435.34 (UniformCauchyCriterion exit route consumer coverage)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose terminal exit is read through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, *and* $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$

rows. Every Phase Real and Completion consumer of that accepted terminal exit factors through W, Q, T, E, H, C, P, N together with those shared sibling rows. No quotient stream, host real equality, selected limit, choice row, ambient completeness witness, or independent completion datum can replace that finite route.

Proof. First apply Definition 435.30. It places every Phase Real and Completion exit read over the same displayed terminal route rather than over separate endpoint sources.

Next use Definition 435.31 and Definition 435.32. The classifier is read inside the finite $BHist$, $hsame$, Cont, Pkg, and local NameCert structure, and the nonescape theorem removes quotient streams, host equality, selected limits, choice data, ambient completeness, and independent completion sources from the accepted exit.

Now apply Definition 435.33. It identifies W, Q, T, E, H, C, P, N as the exact budget route delivered to the terminal consumer.

Finally pull this route along Definition 646.206 and Definition 1120.6. The selector-budget pullback supplies the shared $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces, while four-face exactness keeps the Phase Real and Completion consumers on the same boundary. Hence every terminal consumer is covered by the listed finite route and no excluded coordinate can serve as a replacement. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket exit route consumer coverage`

Theorem 435.35 (UniformCauchyCriterion diagonal structural-face coverage)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose terminal exit is read through shared* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, *and* $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$ *rows. Then the four structural faces W, Q, T, E together with H, C, P, N are exhaustive for every diagonal-exit classifier and every Phase Real or Completion consumer route.*

In particular, no accepted diagonal-exit read can replace that route by quotient streams, host equality, selected limits, choice rows, ambient completeness, metric-completeness witnesses, or independent completion sources.

Proof. First apply Definition 435.30. It places the terminal exit over the shared finite route rather than over a second endpoint source.

Next apply Definition 435.31 and Definition 435.32. The classifier is read through the same finite $BHist$, $hsame$, Cont, Pkg, and local NameCert rows, and the nonescape boundary removes quotient streams, host equality, selected limits, choice data, ambient completeness, metric-completeness data, and independent completion sources.

Now use Definition 435.33 and Definition 435.34. These identify W, Q, T, E, H, C, P, N as the exact route delivered to every Phase Real and Completion consumer.

Finally pull the route through Definition 646.206 and Definition 1120.6. The selector-budget pullback supplies the shared stream, regular sequence, dyadic core, and Real faces, while four-face exactness keeps the Real-completion boundary on W, Q, T, E. Hence the listed structural faces and support rows cover every diagonal-exit classifier and consumer route. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket diagonal structural face coverage`

Theorem 435.36 (UniformCauchyCriterion diagonal tail-budget exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose terminal exit shares the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$, *and* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *rows. Then every tail-budget read at that terminal exit factors through the already extracted route*

$$W, Q, T, E, H, C, P, N.$$

No quotient stream, host equality, selected limit, choice row, ambient completeness, detached tail oracle, second completion source, or replacement tail schedule can serve in place of that route.

Proof. Start with diagonal budget extraction, Definition 435.33. It identifies W, Q, T, E, H, C, P, N as the finite route delivered to Phase Real and Completion-facing consumers of the accepted terminal exit.

Next apply exit route consumer coverage and structural-face coverage, Definition 435.34 and Definition 435.35. These keep every terminal consumer on the same stream-window, dyadic-tolerance, regular-readback, Real-seal, transport, route, provenance, and local naming rows.

Now attach the tail-cofinality sibling route. By Definition 435.133 and the TailCofinalitySchedule route theorem cited there, the cofinal tail schedule is consumed only as a sibling route on the same finite window, regular readback, and Real seal before the terminal exit is read.

The nonescape clause is inherited from the cited routes. None of the diagonal, consumer-coverage, structural-face, or tail-cofinality rows supplies quotient streams, host equality, selected limits, choice rows, ambient completeness, detached tail oracles, or independent completion sources, so every tail-budget read is exhausted by W, Q, T, E, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket diagonal tail budget exhaustion`

Theorem 435.37 (UniformCauchyCriterion diagonal terminal route exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose terminal Phase Real and Completion read is shared with the displayed* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. Then every terminal read of* U *is exhausted by the finite route*

$$W, Q, T, E, H, C, P, N.$$

No accepted terminal consumer can replace that route by quotient streams, host equality, selected limits, choice data, ambient completeness, metric-completeness data, or a detached completion source.

Proof. First use Definition 435.35. It says that the four structural faces W, Q, T, E together with H, C, P, N cover every diagonal-exit classifier and every Phase Real or Completion consumer route.

Next use Definition 435.33. It identifies the budget delivered to the terminal consumer as exactly W, Q, T, E, H, C, P, N, so the terminal read has no unaccounted row outside the displayed packet.

Now combine the classifier and non-escape surfaces. By Definition 435.31 and Definition 435.32, any visible distinction at the terminal diagonal exit is already carried by the displayed $BHist$, $hsame$, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Finally apply Definition 435.34. Since every terminal consumer is already covered by the same finite route, the listed quotient, host-equality, choice, completeness, metric-completeness, and detached-completion coordinates have no accepted route slot from which they could replace W, Q, T, E, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket diagonal terminal route exhaustion`

Theorem 435.38 (UniformCauchyCriterion terminal Real-completion lock)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose terminal read shares the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$, *and* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *rows. Then every Real-and-Completion phase exit classifier is locked to the finite route*

$$W, Q, T, E, H, C, P, N.$$

The locked route is the one whose packet supplies $\mathsf{Cont}(I, T, R_t)$, $\mathsf{Cont}(T, E, R_E)$, $\mathsf{Cont}(R_t, R_E, R_B)$, *and* $\mathsf{Cont}(R_B, P, R_C)$, *whose package signs* R_t, R_E, R_B, *and* R_C, *and whose terminal completion read carries the local name row* N *while refusing both host-tail return continuations out of* R_B. *No quotient stream, host real equality, choice row, ambient completeness, detached completion endpoint, selected representative, or replacement tail schedule can refine that terminal classifier.*

Proof. Start with diagonal uniqueness exit and the diagonal exit classifier. They identify the accepted terminal read as a finite classifier route over the same stream name, regular rational readback, dyadic tolerance, Real seal, transport, continuation, provenance, and local naming rows.

Apply diagonal budget extraction along the concrete continuation chain. The accepted packet gives the index-to-tail read, the tail-to-seal read, the tail-read-to-seal-read budget read, and the budget-to-provenance completion read:

$$\mathsf{Cont}(I, T, R_t), \quad \mathsf{Cont}(T, E, R_E), \quad \mathsf{Cont}(R_t, R_E, R_B), \quad \mathsf{Cont}(R_B, P, R_C).$$

The same extraction supplies the package signatures of R_t, R_E, R_B, and R_C. Together with the packet signature for N, this makes the completion read a unary finite read over the displayed route and keeps the terminal local name tied to the accepted bundle.

Now use the host-tail refusal supplied by the same budget read. Both possible host-tail return continuations from R_B back to R_t are absurd, so the route cannot be refined by returning through an external tail oracle, selected representative, host equality row, or detached completion endpoint.

Finally combine exit-route consumer coverage, structural-face coverage, tail-budget exhaustion, and terminal-route exhaustion. The $\mathsf{TailCofinalitySchedule}^{\uparrow}$ row is consumed as a sibling schedule on the same finite route, and Definition 435.37 leaves no route slot outside W, Q, T, E, H, C, P, N. Therefore every terminal Real-and-Completion exit classifier is locked to that finite route. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket terminal real completion lock`

↪ variant `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion budget lock`

Theorem 435.39 (UniformCauchyCriterion Real-completion selector-route stability)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted UniformCauchyCriterion$^{\uparrow}$ *packet whose terminal exit shares the displayed* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, DiagonalLimitCompatibility$^{\uparrow}$, RealLimitUniquenessSeal$^{\uparrow}$, *and* TailCofinalitySchedule$^{\uparrow}$ *rows. Suppose one Phase Real and Completion consumer route is replaced by another accepted route with the same extracted* W, Q, T, E, H, C, P, N *faces and the same displayed sibling rows.*

Then the replacement preserves the Phase Real and Completion selector boundary. Every admissible selector read remains exhausted by the same finite route W, Q, T, E, H, C, P, N*, together with the displayed stream-name, regular-sequence, dyadic-core, Real, diagonal-compatibility, uniqueness-seal, and tail-cofinality faces. No quotient stream, host equality, selected limit, countable-choice row, ambient-completeness witness, or independent completion datum can refine or distinguish the replacement route.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion selector route stability`

Proof. First apply diagonal budget extraction, Definition 435.33. It identifies the finite route W, Q, T, E, H, C, P, N delivered to Phase Real and Completion-facing consumers of the accepted terminal exit.

Next use exit route consumer coverage and structural-face coverage, Definition 435.34 and Definition 435.35. These theorems keep every consumer route on the same stream-window, dyadic-tolerance, regular-readback, Real-seal, transport, route, provenance, and local naming faces.

Now compare the original and replacement routes. By hypothesis they share the extracted W, Q, T, E, H, C, P, N faces and the same StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, DiagonalLimitCompatib RealLimitUniquenessSeal$^{\uparrow}$, and TailCofinalitySchedule$^{\uparrow}$ rows, so the replacement has no additional selector coordinate.

Finally apply diagonal terminal route exhaustion and the terminal Real-completion lock, Definition 435.37 and Definition 435.38. They exhaust all admissible Phase Real and Completion reads by the same finite route. Therefore quotient streams, host equality, selected limits, countable choice, ambient completeness, and independent completion data remain outside the preserved selector boundary. □

Theorem 435.40 (UniformCauchyCriterion diagonal uniqueness four-face terminal)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted UniformCauchyCriterion$^{\uparrow}$ *packet whose terminal read shares the displayed* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, DiagonalLimitCompatibility$^{\uparrow}$, RealLimitUniquenessSeal$^{\uparrow}$, *and* TailCofinalitySchedule$^{\uparrow}$ *rows. Then every accepted UniformCauchyCriterion terminal read over those rows factors through the same four-face Phase Real and Completion packet with structural route*

$$W, Q, T, E, H, C, P, N.$$

The four faces are exactly the stream-window, dyadic-tolerance, regular-readback, and Real-seal faces, and the route is preserved through the same diagonal-compatibility, uniqueness-seal, and tail-cofinality rows. No quotient stream, host real equality, selected limit, countable-choice row, ambient-completeness witness, detached tail oracle, or independent completion datum can distinguish a second terminal read.

Proof. First apply diagonal budget extraction, Definition 435.33. It identifies W, Q, T, E, H, C, P, N as the finite budget route delivered to Phase Real and Completion-facing consumers of the accepted terminal exit.

Next use exit route consumer coverage, Definition 435.34. Every accepted terminal consumer is already routed through the same extracted budget together with the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, and $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$ rows.

Now apply diagonal structural-face coverage, Definition 435.35. The route is forced to expose the four structural faces W, Q, T, E and the support rows H, C, P, N before the terminal classifier or any Phase Real and Completion consumer may be read.

Finally use selector-route stability, Definition 435.39. Since the original and replacement terminal reads share the extracted budget and the same diagonal-compatibility, uniqueness-seal, and tail-cofinality rows, the replacement preserves the Phase Real and Completion selector boundary. The listed quotient, host-equality, choice, completeness, tail-oracle, and detached-completion coordinates therefore have no accepted route slot. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket diagonal uniqueness four face terminal`

Theorem 435.41 (UniformCauchyCriterion terminal selector uniqueness)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *terminal packet whose displayed finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transports, displayed* Cont *route,* Pkg *provenance, and local* NameCert *row agree with the terminal rows of* U*. Suppose also that an accepted StreamName–RegSeqRat–RealUp tail-selector transport packet exposes the same finite windows, dyadic ledger, regular rational readback, Real seal, and visible transport rows.*

Then every $\mathsf{Real}^{\uparrow}$*-facing or completion-facing terminal consumer of these accepted packets reads one terminal selector surface before the seal. That surface is the common finite route through* W, D, R, E, H, C, P, N*, equivalently through the UniformCauchyCriterion rows* W, Q, T, E, H, C, P, N*. It has no coordinate for quotient streams, host real equality, hidden selectors, selected limits, choice schedules, metric-completeness rows, or ambient completeness.*

Proof. Start with the UniformCauchyCriterion side. By Definition 435.29, a $\mathsf{Real}^{\uparrow}$-facing or completion-facing consumer of U cannot read past the displayed finite-window selector surface before the seal. The surface is already fixed by the shared $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ tail readback, $\mathsf{Real}^{\uparrow}$ seal row, and the structural H, C, P, N rows.

Next attach the terminal observation-budget selector. The coverage theorem Definition 782.36 places every compatible terminal consumer of F on the finite route through B, S, W, D, R, E and the same H, C, P, N envelope. The seal inversion theorem Definition 782.50 identifies the seal-facing route with the terminal window route, so the consumer cannot introduce a second terminal selector between the window and the seal.

Now descend the StreamName–RegSeqRat–RealUp transport. By Definition 126.214, the public tail-selector interface is exactly the displayed finite ledger carrying the StreamName windows, regular rational readback, dyadic endpoint rows, RealUp readback, and visible hsame/Cont/Pkg/NameCert

support. Since those rows agree with the terminal rows of U and F, the transport contributes the same selector surface rather than a separate one.

Combining the three surfaces gives a single terminal selector before E. The excluded data are absent from every cited route: quotient streams, host real equality, hidden selectors, selected limits, choice schedules, metric-completeness rows, and ambient completeness are not rows of the accepted UniformCauchyCriterion packet, the terminal observation-budget selector, or the public tail-selector transport. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket terminal selector uniqueness`

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchyCriterion}^{\uparrow}$ packet is generated from a finite family index ledger, a shared $\mathsf{StreamName}^{\uparrow}$ window family, one uniform $\mathsf{CauchyModulus}^{\uparrow}$ schedule, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, a finite $\mathsf{DyadicTailBound}^{\uparrow}$ comparison ledger, a $\mathsf{Real}^{\uparrow}$ seal handoff, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyCriterion}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature surface records the finite carrier, local naming obligations, shared-window stability, $\mathsf{Real}^{\uparrow}$ seal handoff, non-escape boundary, tail-ledger exactness, shared-threshold transport, RegSeqRat tail equivalence, downstream Real consumer export, and public non-escape export for uniform dyadic Cauchy tests over finite families of stream-name windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient stream families, host real equality, selected family limits, ambient completeness, public uniform convergence, or bridge checking.

Upgrade path: No further paper closure grade remains for this chapter; Lean formalization of the packet and exported consumer theorems remains pending.

The late boundary and overlap routes consume the L10 sibling surfaces chapter 126, chapter 301, chapter 38, and the existing dyadic tail and tolerance rows already named in the parent packet. They read those dependencies through the same shared window, threshold, dyadic tolerance, tail-ledger, and seal handoff coordinates.

Theorem 435.42 (UniformCauchyCriterion empty-family tail ledger)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose that I is the empty finite family index ledger and that T is the empty finite tail-comparison ledger. Then the shared-threshold route is accepted as the vacuous finite-family route*

$$\mathsf{empty}_I \longmapsto W \longmapsto M \longmapsto Q \longmapsto \mathsf{empty}_T \longmapsto E.$$

It has no family member at which a tail comparison can be requested, no completed family limit to export through the $\mathsf{Real}^{\uparrow}$ *seal, and no indexwise schedule distinct from the single displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *row M.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket empty family tail ledger`

Proof. Project the accepted packet through Definition 435.1. Its only family-facing rows are the finite index ledger I, the shared window family W, the single modulus schedule M, the tolerance row Q, and the tail-comparison ledger T.

Because I is empty, there is no displayed family index through which a consumer can select a component window or request an indexwise threshold. The window-stability row of Definition 435.3 therefore has no component case to check; the shared row M remains the only threshold schedule visible in the packet.

Because T is empty, Definition 435.9 leaves no accepted tail comparison after the route through I, W, M, Q. Thus the finite family criterion is satisfied only in the vacuous sense: every possible comparison for an index in I is already exhausted by the absence of such an index and by the absence of a tail-ledger entry.

Now apply Definition 435.10. Transport can rename the displayed rows through hsame and replay their reads through Cont, but it cannot replace the single schedule M by a family of independently selected schedules. With the family ledger empty, there is not even an index at which such a schedule could be named.

Finally use Definition 435.4 and Definition 435.8. Every $\mathsf{Real}^{\uparrow}$ seal read still factors through I, W, M, Q, T, E, and in the present boundary this is precisely the displayed route through the empty family ledger and empty tail ledger. Since the packet has no coordinate for a completed family limit, quotient stream family, host real equality, selected limit, or ambient completeness principle, the seal handoff exports none of them. □

Theorem 435.43 (UniformCauchyCriterion single-member restriction exactness)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let i be a displayed member of the finite family ledger I. The singleton restriction $U|_{\{i\}}$ reads the same shared rows $W, M, Q, T, E, H, C, P, N$ through the component selected by i. Its finite-family ledger is the one-member restriction of I, and it adds no pointwise limit, no indexwise modulus, and no endpoint read outside the original tail ledger.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket single member restriction exactness`

Proof. Project U through Definition 435.1. The family-facing rows are I, W, M, Q, T, and the singleton request supplies only a displayed member i of I.

Apply Definition 435.3. Restricting to the component named by i keeps the read inside the same shared window family W and transports only the selected component through the existing hsame rows.

Next use Definition 435.9 and Definition 435.10. The tail comparison for the singleton still passes through the same M, Q, T route, so the restricted packet has no coordinate for an independently chosen pointwise threshold.

Finally apply Definition 435.16 and Definition 435.18. A downstream consumer sees the same regular-rational and seal handoff rows, specialized to the displayed singleton, and cannot extract a pointwise limit from the restriction. □

Theorem 435.44 (UniformCauchyCriterion paired-family union ledger)**.** *Let J and K be two displayed subfamily ledgers of an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N).$$

Suppose both subfamily ledgers factor through the same I, W, M, Q, T rows. Then the paired-family ledger $J \cup K$ is accepted over the same shared threshold route. Its tail comparisons are exactly the

union of the two displayed subfamily tail reads inside T, transported by the same H, C rows and sealed through the same E, P, N provenance.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket paired family union ledger`

Proof. Read the two subfamily ledgers as displayed restrictions of I. Since both factor through the same packet U, neither subfamily supplies an additional window family or modulus row.

Use Definition 435.3 to keep both subfamily reads on W. Use Definition 435.10 to keep both threshold requests on the single schedule M.

Apply Definition 435.9. The only accepted tail-comparison entries are the displayed rows of T after the route through I, W, M, Q, so the paired ledger is their finite union inside that same ledger.

It remains to package the paired read for consumers. Use Definition 435.16 and Definition 435.18: the union ledger is replayed by the same H, C rows and inherits the same E, P, N seal and provenance surface. □

Theorem 435.45 (UniformCauchyCriterion shared-schedule Real seal inheritance)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of a singleton restriction or paired-family ledger of an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet inherits the same shared schedule and seal handoff route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

The inherited route may restrict or pair displayed family entries, but it cannot introduce a new Cauchy schedule, selected family limit, quotient stream family, host real equality, or ambient completeness object.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket shared schedule real seal inheritance`

Proof. Begin with the real-facing consumer read. By Definition 435.4, every such read reaches E only after passing through I, W, M, Q, T.

For a singleton restriction, apply Definition 435.43. The selected component keeps the same shared schedule and specializes only the finite family ledger.

For a paired-family read, apply Definition 435.44. The paired ledger is assembled inside the same tail ledger and is replayed by the same transport and continuation rows.

Finally use Definition 435.16, Definition 435.18, and Definition 435.8. These package the inherited seal route and rule out any new schedule, selected limit, quotient stream family, host equality, or completeness principle. □

Theorem 435.46 (UniformCauchyCriterion shared-window threshold meet)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. The shared window family W and the single modulus row M determine one finite threshold meet before any Q, T, E read is available. Every tolerance row, tail-comparison row, and* $\mathsf{Real}^{\uparrow}$ *seal row is therefore downstream of the same W, M route and cannot select an indexwise modulus family.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionSharedWindowThresholdMeet`

Proof. First project the carrier of Definition 435.1. The packet has one shared window family row W and one modulus schedule row M.

Apply Definition 435.3. Transport of a family request stays inside the same window family, so no later read can replace W by a separately chosen component window.

Next apply Definition 435.10. The threshold route is transported as the single row M, and the tolerance, tail, and seal coordinates are read only after that route has been fixed.

It remains to rule out later selection. Use Definition 435.9 and Definition 435.4: Q, T, E are consumer rows downstream of I, W, M, not sources for a second modulus family. □

Theorem 435.47 (UniformCauchyCriterion family-tail intersection)**.** *For every accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet and every nonempty subfamily request, the tail read is an intersection of the existing finite family ledger with the same W, M, Q, T route. It is not an independently chosen family of moduli, and it cannot detach a subfamily from the displayed index ledger I or the shared threshold route.*

Proof. Begin with the finite index ledger I. A nonempty subfamily request is a read of displayed indices from I, so it has no source outside the accepted packet.

Use Definition 435.3 and Definition 435.10. These keep the subfamily request on the same window family W and the same modulus row M.

Now apply Definition 435.9. A tail comparison is accepted only as a read through Q and T after the displayed family and threshold rows are fixed.

Thus the subfamily tail is the finite intersection of the already displayed family ledger with the same W, M, Q, T route. The packet has no coordinate for an independently chosen family of moduli. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket family tail intersection`

Theorem 435.48 (UniformCauchyCriterion RegSeqRat uniform consumer exhaustion)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet is exhausted by the rows*

$$I, W, M, Q, T, E, H, C, P, N.$$

Such a consumer reads the shared window family, single threshold row, dyadic tolerance row, finite tail ledger, seal handoff, transport rows, continuation routes, package provenance, and local naming row. It cannot export quotient streams, selected limits, host real equality, or ambient completeness.

Proof. Start from Definition 435.11. The $\mathsf{RegSeqRat}^{\uparrow}$ read is the same finite evidence as the tail-ledger route, so it must pass through I, W, M, Q, T.

Apply Definition 435.46. This fixes the shared window and threshold rows before the consumer can inspect the tolerance, tail, or seal coordinates.

Use Definition 435.47 for nonempty subfamily reads, and use Definition 435.42 for the empty-family boundary. Both cases keep the consumer inside the finite family ledger and the same W, M, Q, T route.

Finally apply Definition 435.8. The remaining rows E, H, C, P, N package the seal, transport, continuation, provenance, and local name, but they add no quotient stream, selected limit, host real equality, or completeness principle. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket regseqrat uniform consumer exhaustion`

Theorem 435.49 (UniformCauchyCriterion tail-overlap budget exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every overlap of two finite subfamily tail requests in* U *factors through the same finite rows* $I, W, M, Q, T, E, H, C, P, N$*. The overlap has no second tail budget, quotient stream family, selected family limit, host real equality, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket tail overlap budget exhaustion`

Proof. First combine the paired-family union ledger with the shared-window threshold meet. By Definition 435.44, two finite family requests are joined only inside the displayed index ledger I. By Definition 435.46, their common window and threshold route is the same W, M route, not a pair of separately chosen schedules.

Next pass from the joined family request to the tail read. Use Definition 435.47: the common tail is an intersection of the displayed family ledger with W, M, Q, T. Thus the dyadic tolerance row and tail ledger row are inherited from U rather than rebuilt for the overlap.

Finally send the overlap to the consumers. Apply Definition 435.48 to exhaust the RegSeqRat side by $I, W, M, Q, T, E, H, C, P, N$, and apply Definition 435.57 to keep the Real seal side downstream of the same package. The non-escape boundary then rules out a second budget, quotient stream family, selected limit, host real equality, or ambient completeness row. □

Theorem 435.50 (UniformCauchyCriterion RegSeqRat–Real seal overlap)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any overlap of two finite subfamily tail requests that reaches a* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer and then a* $\mathsf{Real}^{\uparrow}$ *seal factors through the same route*

$$I, W, M, Q, T, E, H, C, P, N.$$

The overlap cannot introduce a second RegSeqRat classifier, quotient stream family, selected family limit, host real equality, or ambient completeness witness.

Proof. First place the two subfamily requests on the common window. Apply Definition 435.46 to identify the shared window and threshold rows W, M before either request reaches its tolerance or tail data.

Next pass to the finite family-tail overlap. Apply Definition 435.47. The common tail evidence is the displayed intersection inside the finite ledger I and the same dyadic tolerance and tail rows Q, T.

Now read the RegSeqRat-facing consumer. By Definition 435.48, the consumer is exhausted by $I, W, M, Q, T, E, H, C, P, N$, so it has no coordinate for a second RegSeqRat classifier or quotient stream family.

Finally attach the Real seal. Use Definition 435.45 and Definition 435.57 to keep the seal read downstream of the same E, H, C, P, N rows. The non-escape boundary then rules out selected family limits, host real equality, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket regseqrat real seal overlap`

Theorem 435.51 (UniformCauchyCriterion RegSeqRat–Real seal pullback exactness)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every displayed subfamily pullback that reaches both a* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer and a* $\mathsf{Real}^{\uparrow}$ *seal is exact on the same route*

$$I, W, M, Q, T, E, H, C, P, N.$$

It cannot introduce a second RegSeqRat classifier, quotient stream family, selected family limit, host real equality, or ambient completeness witness.

Proof. First put the pullback on the shared threshold route. Apply Definition 435.46: the shared window row W and the single modulus row M are fixed before any tolerance, tail, or seal row is read.

Next restrict the subfamily tail. By Definition 435.47, the pullback is an intersection of the existing finite family ledger with the same W, M, Q, T route. It therefore has no separate index carrier or independently selected modulus family.

Now exhaust the RegSeqRat-facing side. Use Definition 435.48; the consumer is exhausted by $I, W, M, Q, T, E, H, C, P, N$ and has no coordinate for a second RegSeqRat classifier or quotient stream family.

Finally attach the Real seal through Definition 435.50. The overlap already reaches the $\mathsf{RegSeqRat}^{\uparrow}$ consumer and the $\mathsf{Real}^{\uparrow}$ seal through the same route. The non-escape boundary then rules out selected family limits, host real equality, and ambient completeness, so the displayed pullback is exact on the original packet rows. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket regseqrat real seal pullback exactness`

Theorem 435.52 (UniformCauchyCriterion shared-tail subfamily pullback)**.** *For every accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet* $U = (I, W, M, Q, T, E, H, C, P, N)$*, any downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a displayed subfamily pullback reads the same shared tail route through the finite index ledger. Such a consumer cannot introduce an indexwise modulus family or detach the pullback from the rows* $I, W, M, Q, T, E, H, C, P, N$*.*

Proof. Project the carrier rows of U. The only finite family ledger is I, the only shared window and threshold route is W, M, and the only tail and seal rows available to a consumer are Q, T, E with their displayed transport, continuation, provenance, and naming rows.

For a one-component pullback, use singleton restriction exactness. The singleton request is a read of the existing family ledger and therefore follows the same W, M, Q, T route. For two displayed components, use Definition 435.44; finite pairs are joined inside the displayed ledger before any tail read is exposed.

It remains to handle downstream consumers. Apply Definition 435.49. The pullback is already exhausted by the common finite route, so a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer receives only the shared tail package and has no coordinate for an indexwise modulus family. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket shared tail subfamily pullback`

Theorem 435.53 (UniformCauchyCriterion finite-index ledger transport)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every transported family request for* U *factors through the displayed finite ledger* I*, componentwise* hsame *transport, and displayed* Cont *routes before any request can reach* W, M, Q, T, E*. Thus the transported request is a replay of the public finite package and cannot choose a new index carrier, a new family window, or an external modulus schedule.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite index ledger transport`

Proof. Project the carrier of Definition 435.1. The only family ledger coordinate supplied by the packet is I, and the only transport and continuation coordinates supplied for family reads are H and C.

Apply Definition 435.3. Any transported family request that reaches W is already a read of the displayed window family over I, so it has no independent carrier from which a second family can be selected.

Next apply Definition 435.10. The same transported request reaches M, Q, T only by following the shared threshold route, with componentwise hsame evidence and the displayed Cont routes supplied by H and C.

Finally use Definition 435.4. The seal row E is downstream of the same finite ledger and transport route, so the transported request reaches W, M, Q, T, E only as a replay of I, H, C inside the public package. □

Theorem 435.54 (UniformCauchyCriterion finite-ledger route coverage)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every downstream* $\mathsf{RegSeqRat}^{\uparrow}$*-facing or* $\mathsf{Real}^{\uparrow}$*-facing consumer route for* U *factors through the displayed finite index ledger* I*, shared window* W*, single modulus* M*, tolerance row* Q*, tail ledger* T*, seal handoff* E*, transport row* H*, continuation row* C*, provenance row* P*, and local name* N*.*

Consequently the route ledger is exhausted by $I, W, M, Q, T, E, H, C, P, N$*. It has no coordinate for a quotient stream family, selected family limit, host equality, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite ledger route coverage`

Proof. First put transported family requests on the public ledger. By Definition 435.53, a transported request can reach W, M, Q, T, E only after reading I, H, C.

Next fix the threshold and tail rows. Apply Definition 435.46 to identify the shared W, M route, and apply Definition 435.47 to keep every nonempty subfamily tail inside the same I, W, M, Q, T ledger.

Now read the two consumer sides. The $\mathsf{RegSeqRat}^{\uparrow}$ side is exhausted by Definition 435.48. The shared $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ pullback route is exact by Definition 435.51.

Finally apply Definition 435.8. Since the packet exports only the displayed seal, transport, continuation, provenance, and naming rows after the tail ledger is fixed, no quotient stream family, selected limit, host equality, or ambient completeness coordinate remains. □

Theorem 435.55 (UniformCauchyCriterion shared-schedule cofinal pullback)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every cofinal subfamily pullback of* U *that reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer and a* $\mathsf{Real}^{\uparrow}$ *seal consumer factors through the same finite schedule*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T$$

before either consumer reads E, H, C, P, N*. The pullback therefore shares the displayed finite index ledger, window family, modulus schedule, dyadic tolerance row, and tail ledger, and it exports no quotient stream family, selected family limit, host real equality, or ambient completeness datum.*

Proof. First place the cofinal pullback on the finite ledger. By Definition 435.53, every transported family request already passes through I, H, C before it can reach W, M, Q, T, E.

Next identify the schedule read. Apply Definition 435.46: the shared window row W and the single modulus row M are fixed before any tolerance, tail, or seal coordinate is available.

Now restrict to the cofinal subfamily tail. Use Definition 435.47; the pullback is a finite intersection inside the displayed ledger and keeps the same W, M, Q, T route. Thus cofinality contributes no new index carrier and no independently selected modulus family.

Finally send the pullback to the two consumers. The $\mathsf{RegSeqRat}^{\uparrow}$ side is exhausted by Definition 435.48, and the shared $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ seal route is Definition 435.50. The non-escape boundary then excludes quotient stream families, selected limits, host real equality, and ambient completeness, leaving the same finite schedule for both consumers. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket shared schedule cofinal pullback`

Theorem 435.56 (UniformCauchyCriterion shared-tail ledger coverage)**.** *For every accepted* UniformCauchyCriterio *packet, the empty-family tail read, singleton restriction, paired-family read, and nonempty subfamily tail read are all exhausted by one shared route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T.$$

No listed tail read supplies a second tail ledger, an indexwise modulus family, or a detached comparison route outside the accepted packet.

Proof. Consider the four displayed kinds of family-tail consumer. For the empty-family boundary, apply Definition 435.42; the accepted tail evidence is the displayed empty read of the same T row.

For singleton reads, apply Definition 435.43. The selected component is a restriction of I and keeps the same W, M, Q, T route.

For paired reads, apply Definition 435.44. The pair is assembled as a finite union inside the existing tail ledger, not as a new schedule or comparison object.

For nonempty subfamily reads, apply Definition 435.47. The subfamily tail is the finite intersection of the displayed ledger with the same shared route.

These cases cover the available family-tail reads of the packet. Since each case enters T only through I, W, M, Q, the packet has no remaining coordinate from which a second tail ledger or detached route could be exported. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket shared tail ledger coverage`

Theorem 435.57 (UniformCauchyCriterion Real seal consumer factorization)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$-, $\mathsf{Real}^{\uparrow}$-, *or completion-facing consumer of an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet factors through the public finite package*

$$I, W, M, Q, T, E, H, C, P, N.$$

The factorization exposes the shared window, single threshold row, dyadic tolerance row, finite tail ledger, Real seal handoff, transport rows, continuation routes, provenance row, and local name. It cannot export quotient streams, selected limits, host real equality, or ambient completeness.

Proof. Start with a $\mathsf{RegSeqRat}^{\uparrow}$-facing consumer. By Definition 435.48, the consumer is exhausted by $I, W, M, Q, T, E, H, C, P, N$ and cannot leave that finite package.

For the shared threshold dependency, apply Definition 435.46. This fixes W and M before any tolerance, tail, or seal read is available, so later consumers inherit the same route.

Now pass to the $\mathsf{Real}^{\uparrow}$ seal boundary. Use Definition 435.18: the completion-facing handoff is exposed only as the seal row E over the already displayed family and tail ledger.

Finally apply Definition 435.8. The rows H, C, P, N package transport, continuation, provenance, and the local name, while the packet still exports no quotient stream, selected limit, host real equality, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real seal consumer factorization`

Theorem 435.58 (UniformCauchyCriterion shared tail gluing determinacy)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose two finite subfamily tail reads of* U *have the same displayed family intersection inside* I *and agree on the shared threshold route through* W, M, Q, T*. Then the glued shared-tail read induces the same* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer row and the same* $\mathsf{Real}^{\uparrow}$ *seal route through* E, H, C, P, N*. No second tail budget, quotient stream family, selected limit, host real equality, or ambient completeness coordinate can split the glued read after those rows agree.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket shared tail gluing determinacy`

Proof. First build the common tail ledger. Apply Definition 435.44; the two finite subfamily reads are assembled as a displayed union inside I and do not create a new schedule outside the packet.

Next identify the shared tail. By Definition 435.47, agreement of the displayed family intersection inside I makes the tail read a finite intersection of the same ledger along the same W, M, Q, T route.

Now exhaust the possible overlap budget. Use Definition 435.49; since the threshold route already agrees through W, M, Q, T, the glued read has no coordinate from which a second tail budget can be exported.

Pass to the seal-facing rows by Definition 435.50. The $\mathsf{RegSeqRat}^{\uparrow}$ readback and the $\mathsf{Real}^{\uparrow}$ seal handoff therefore see the same shared tail rather than two independent quotient stream families.

Finally apply Definition 435.57. The downstream consumer rows are exhausted by $I, W, M, Q, T, E, H, C, P, N$, so the glued shared tail fixes both the $\mathsf{RegSeqRat}^{\uparrow}$ consumer row and the $\mathsf{Real}^{\uparrow}$ seal route through E, H, C, P, N and leaves no selected limit, host real equality, or ambient completeness coordinate. □

Theorem 435.59 (UniformCauchyCriterion budgeted Real seal factorization)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing seal read of* U *that consumes a uniform family tail factors through the displayed finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

together with the sibling budget surfaces of $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and the dyadic tail/tolerance ledger. The factorization exposes only the finite index ledger, shared stream-name window, single threshold row, dyadic tolerance row, shared tail ledger, and Real seal handoff. It exports no quotient stream family, selected family limit, host real equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket budgeted real seal factorization`

Proof. First exhaust the family-tail cases before any seal read is considered. Apply Definition 435.42 for the empty-family boundary and Definition 435.43 for singleton reads. Apply Definition 435.44 for paired-family reads and Definition 435.47 for nonempty subfamilies.

These four cases land in the shared tail ledger by Definition 435.56. Hence every uniform family tail reaches T only through the displayed I, W, M, Q route and carries no separate stream family, pointwise modulus family, or detached comparison row.

Next route the budget consumers. By Definition 435.48, the $\mathsf{RegSeqRat}^{\uparrow}$ read is exhausted by $I, W, M, Q, T, E, H, C, P, N$. By Definition 435.57, the $\mathsf{Real}^{\uparrow}$ seal read is downstream of the same finite package rather than a separate completion object.

The cited route is exactly the sibling chain through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the dyadic tail/tolerance ledger: W supplies the stream-name family surface, M, Q, T supply the RegSeqRat and dyadic budget rows, and E is the Real seal handoff. Since the route has no coordinate outside those rows, quotient stream families, selected family limits, host real equality, and ambient completeness are refused at the seal boundary. □

Theorem 435.60 (UniformCauchyCriterion terminal late-route exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every terminal* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or completion-facing late-boundary consumer of* U *is exhausted by the shared finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E \longmapsto H, C, P, N.$$

The exhaustion is obtained by splitting only along the displayed late cases: empty family, singleton restriction, paired-family ledger, and nonempty subfamily tail. After those cases are read, the $\mathsf{RegSeqRat}^{\uparrow}$ *consumer is handled by Definition 435.48, and the* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal consumer is handled by Definition 435.57. The terminal route exports no indexwise modulus family, quotient stream family, selected family limit, host real equality, or ambient completeness.*

Proof. Begin with the four late family cases. The empty-family boundary is Definition 435.42; the singleton restriction is Definition 435.43. Both enter the same displayed I, W, M, Q, T route.

The remaining family cases are paired-family and nonempty-subfamily reads. Apply Definition 435.44 for the paired ledger and Definition 435.47 for the nonempty subfamily tail. These two cases still use the same finite family and tail rows, so no separate modulus family or quotient stream family is introduced.

Now pass from family-tail exhaustion to terminal consumers. Apply Definition 435.48 to the $\mathsf{RegSeqRat}^{\uparrow}$-facing route; it reads exactly $I, W, M, Q, T, E, H, C, P, N$.

Finally apply Definition 435.57. The $\mathsf{Real}^{\uparrow}$ and completion-facing seal reads factor through the same package, with E as the displayed seal handoff and H, C, P, N as transport, continuation, provenance, and local naming. Since every late case has already been placed on that route, the accepted packet has no coordinate for a selected family limit, host real equality, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket terminal late route exhaustion`

Theorem 435.61 (UniformCauchyCriterion finite tail readback coverage)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every finite tail readback request for U is covered by exactly one of the displayed routes: the empty-family route, the singleton restriction route, the paired-family route, or the nonempty-subfamily route. After that route is selected, every* $\mathsf{RegSeqRat}^{\uparrow}$*-,* $\mathsf{Real}^{\uparrow}$*-, or completion-facing consumer factors through*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

together with the transport, continuation, provenance, and local naming rows H, C, P, N.

Consequently no finite tail readback of U can export a quotient stream family, a selected family limit, host real equality, or ambient completeness outside the displayed packet.

Proof. Split the finite family request before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ seal is inspected. The empty request is handled by Definition 435.42; a one-member request is handled by Definition 435.43. A two-sided displayed family read is handled by Definition 435.44.

It remains to cover finite nonempty subfamily reads that are not already one of those boundary cases. Apply Definition 435.47. This places the read inside the displayed finite family ledger and the same W, M, Q, T route, with no source for an independently selected modulus family or detached tail ledger.

The four cases are exhaustive for finite tail readbacks because every request is either empty, a singleton, a paired displayed family, or a nonempty subfamily read. Apply Definition 435.56 to put all of them on the shared tail ledger, then apply Definition 435.60 to pass from that ledger to terminal consumers.

The consumer handoff is therefore the displayed route through I, W, M, Q, T, E and then through H, C, P, N. Since the accepted packet has no coordinate for quotient stream families, selected limits, host equality, or ambient completeness, none of those principles can escape through a finite tail readback. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite tail readback route`

Theorem 435.62 (UniformCauchyCriterion finite-tail window factorization)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every finite tail readback covered by the empty-family, singleton, paired-family, or nonempty-subfamily case of Definition 435.61 factors through one L10 handoff route:*

$$I, W, M, Q, T \longmapsto \mathsf{FiniteTailFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the structural rows E, H, C, P, N*. The* $\mathsf{FiniteTailFilter}^{\uparrow}$ *stage is the finite-tail window route supplied by the tail-window exactness and Real-seal handoff rows of chapter 1119; the* $\mathsf{StreamName}^{\uparrow}$ *stage reads the finite-window classifier already displayed by* W*; the* $\mathsf{RegSeqRat}^{\uparrow}$ *stage consumes the tail readback carried by* T*; and the* $\mathsf{Real}^{\uparrow}$ *stage seals the same route through* E*.*

Thus the finite readback coverage of U *exports no indexwise modulus family, quotient stream family, selected limit, host real equality, ambient completeness principle, or detached tail filter outside the displayed packet.*

Proof. Begin with Definition 435.61. It reduces every finite tail readback to one of the empty, singleton, paired-family, or nonempty-subfamily routes before any terminal consumer is inspected.

Next apply Definition 435.56. The four routes share the same finite family ledger and the same tail ledger T, so their readback evidence is already on the displayed I, W, M, Q, T surface.

Now pass through the finite-tail window route. By Definition 1119.4, the relevant stream window, dyadic tolerance row, regular readback, tail-budget row, common-tail comparison, and seal-facing row are coordinates of one $\mathsf{FiniteTailFilter}^{\uparrow}$ packet. By Definition 1119.5, that packet is the route seen by Real and Completion consumers.

Finally identify the two terminal consumers. The RegSeqRat-facing part is exhausted by Definition 435.48, and the Real-facing part is exhausted by Definition 435.57. These two rows read the same W, T, E, H, C, P, N surface, so the L10 handoff has no carrier coordinate for an indexwise modulus family, quotient stream family, selected limit, host real equality, ambient completeness principle, or detached tail filter. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite tail window factorization`

Theorem 435.63 (UniformCauchyCriterion late-overlap exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every empty-family, singleton, paired-family, nonempty subfamily, and transported-family request that reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer factors through the same public route*

$$I, W, M, Q, T, E, H, C, P, N.$$

The route exposes the finite index ledger, shared window family, single threshold row, dyadic tolerance row, tail ledger, Real seal handoff, transport rows, continuation routes, provenance row, and local name. It cannot export indexwise moduli, selected family limits, quotient stream families, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket late overlap exhaustion`

Proof. First exhaust the family-tail cases. Use Definition 435.42 for the empty boundary, Definition 435.43 for singleton reads, Definition 435.44 for paired-family reads, and Definition 435.47 for nonempty subfamilies.

These four rows place every family-tail request on the same I, W, M, Q, T route. They leave no coordinate for a separate indexwise modulus or a detached family-tail ledger.

Next handle transported requests by Definition 435.53. Transport can replay the displayed finite ledger through H and C, but it cannot choose a new index carrier, window family, or external threshold schedule.

Now apply Definition 435.56. The empty, singleton, paired, and nonempty family reads are all covered by the shared tail ledger, so the transported case also reaches consumers through the same public package after its H, C replay.

Finally use Definition 435.57. Every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer is exhausted by $I, W, M, Q, T, E, H, C, P, N$, and the seal boundary exports no indexwise moduli, selected family limits, quotient stream families, host real equality, or ambient completeness. □

Theorem 435.64 (UniformCauchyCriterion tail-budget Real route)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every Real-facing or completion-facing read of U factors first through the public route*

$$I, W, M, Q, T, E, H, C, P, N$$

and then through the $\mathsf{TailBudgetCoherence}^{\uparrow}$ *public boundary for finite tail-budget handoffs. The consumer receives the finite index ledger, shared window family, single threshold row, dyadic tolerance row, tail ledger, Real seal row, transports, continuation routes, provenance, and local name; it receives no direct Real equality, quotient completion object, selected family limit, or ambient completeness principle.*

Proof. Begin with Definition 435.63. It sends every empty-family, singleton, paired-family, nonempty subfamily, and transported-family request to the same finite route $I, W, M, Q, T, E, H, C, P, N$ before the request can reach a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer.

Next apply Definition 435.56. The tail row used by those consumers is the shared T ledger reached through I, W, M, Q, so the route already has the finite tail-budget shape expected by the tail-budget handoff.

Finally use Definition 435.57 together with Definition 917.13. The Real seal row E is therefore read as a finite public tail-budget export, and every stronger Real or completion object would require a coordinate outside the displayed packet. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket tail budget real route`

Theorem 435.65 (UniformCauchyCriterion shared-window nonescape)**.** *For an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet $U = (I, W, M, Q, T, E, H, C, P, N)$, the shared-window and tail-budget route rules out any consumer escape to indexwise moduli, quotient stream families, selected family limits, host real equality, or ambient completeness. Every such attempted read is refused unless it is represented by the displayed finite rows $I, W, M, Q, T, E, H, C, P, N$ and then by the* $\mathsf{TailBudgetCoherence}^{\uparrow}$ *public route.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket shared window nonescape certificate`

Proof. The shared window is fixed by Definition 435.46. All later tolerance and tail requests inherit the single W, M route.

Use Definition 435.56 to place the empty, singleton, paired, and nonempty family reads on the same I, W, M, Q, T ledger. No separate indexwise modulus family or quotient stream family is introduced in any case.

Now apply Definition 435.57. The Real seal and completion-facing reads are exhausted by E, H, C, P, N over the same finite route.

The remaining excluded reads are exactly the stronger analytic objects denied by Definition 917.12. Thus the packet has no escape path to selected family limits, host real equality, or ambient completeness. □

Theorem 435.66 (UniformCauchyCriterion completion consumer package)**.** *Every completion-facing consumer of an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet is packaged by the finite chain of sibling surfaces*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{CauchyLimitSeal}^{\uparrow}, \mathsf{TailBudgetCoherence}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The package reads the shared window, rational regular-sequence readback, dyadic tolerance row, limit-seal handoff, finite tail-budget coherence row, and Real-facing seal only through $I, W, M, Q, T, E, H, C, P, N$*. It exports no quotient completion carrier, countable-choice selector, selected family limit, host real equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket completion consumer package`

Proof. Start with the late-overlap theorem. By Definition 435.63, every family-tail or transported-family request reaching a completion consumer has already passed through the finite package $I, W, M, Q, T, E, H, C, P, N$.

Read the sibling rows in order. The shared window supplies the $\mathsf{StreamName}^{\uparrow}$-style finite window, the rational readback supplies the $\mathsf{RegSeqRat}^{\uparrow}$ surface, the tolerance row supplies the $\mathsf{DyadicRatCore}^{\uparrow}$ datum, and the seal row supplies the $\mathsf{CauchyLimitSeal}^{\uparrow}$ handoff.

The public export boundary of Definition 917.13 then repackages these rows as the $\mathsf{TailBudgetCoherence}^{\uparrow}$ route consumed by $\mathsf{Real}^{\uparrow}$.

Finally apply Definition 435.65. Since every consumer-facing row stays inside the same finite package, the excluded quotient, selector, limit, equality, and completeness objects have no exported coordinate. □

Theorem 435.67 (UniformCauchyCriterion index restriction)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let* J *be a displayed finite subledger of* I*. The restricted family request over* J *is accepted through the same route*

$$J \subseteq I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

It preserves the same shared window family, threshold schedule, dyadic tolerance row, tail ledger, and real-seal handoff, and it exports no selected limit, host equality, quotient stream, or ambient completeness datum.

Lean4 ✓ BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket index restriction

Proof. Begin with Definition 435.15. A displayed subledger J is read as a restriction of the finite index ledger I, so it has no independent family carrier.

Use Definition 435.3 and Definition 435.10. The restricted request remains on the same shared window family W and the same threshold schedule M before it reaches any tolerance or tail comparison row.

Apply Definition 435.9. The tail evidence for J is exactly the displayed subledger of T reached through I, W, M, Q.

Finally use Definition 435.57. The seal read is downstream of the same finite package, so the restricted packet cannot export selected limits, host equality, quotient streams, or ambient completeness. □

↪ variant BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket subfamily restriction

Theorem 435.68 (UniformCauchyCriterion window refinement)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose* W' *is a transported* $\mathsf{StreamName}^{\uparrow}$ *window refinement of* W *along the displayed* hsame *row* H *and displayed* Cont *routes* C*. Then the refined request is accepted through the same shared-threshold and dyadic-tail route* I, W, M, Q, T, E*, with* W' *serving only as the transported presentation of the original window family.*

Lean4 ✓ BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket window refinement exactness

↪ variant BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket window refinement seal route

Proof. Project the accepted carrier and the transported refinement. The refinement data are read through H and C, so W' is not a second window family but a transported presentation of the displayed W row.

Apply Definition 435.3. This keeps the refined $\mathsf{StreamName}^{\uparrow}$ request inside the same finite window family over the index ledger I.

Next use Definition 435.10. The threshold schedule remains the single row M, and the dyadic tolerance row Q is reached only after that shared threshold route.

Apply Definition 435.9 and then Definition 435.57. The refined window request consumes the same tail ledger and seal handoff, so it cannot detach a new modulus family, selected limit, host equality, quotient stream, or ambient completeness claim. □

Theorem 435.69 (UniformCauchyCriterion finite family union)**.** *Let* U_J *and* U_K *be accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packets whose displayed subfamily ledgers* J *and* K *use the same shared window family* W*, threshold schedule* M*, dyadic tolerance row* Q*, tail ledger* T*, real-seal handoff* E*, and compatible finite index ledgers inside a common* BHist *packet. Then the finite union ledger* $J \cup K$ *is accepted as a* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *family read through the same* $W, M, Q, T, E, H, C, P, N$ *route.*

The union packet is assembled only by finite ledger union and componentwise transport. It does not select pointwise limits, compare host reals, quotient stream names, or appeal to ambient completeness.

Lean4 ✓ BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket family union

Proof. Read the two packets through their common displayed schedule and compatible finite ledgers. Compatibility means both subfamily requests already sit inside the same BHist inventory and do not supply separate threshold or tolerance coordinates.

Apply Definition 435.44. The paired-family ledger assembles $J \cup K$ as a finite union inside the existing index and tail ledgers.

Use Definition 435.10 and Definition 435.9. These keep the union request on the same W, M, Q, T route and force every tail comparison to be a displayed row of the shared ledger.

Finally apply Definition 435.57. The real-seal consumer reads the same finite package after the union ledger is assembled, so selected limits, host equality, quotient streams, and ambient completeness have no coordinate through which to enter. □

Theorem 435.70 (UniformCauchyCriterion shared window pullback)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted UniformCauchyCriterion$^{\uparrow}$ *packet. Suppose* UniformCauchyCriterion$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *seal consumers all read the displayed rows* $I, W, M, Q, T, E, H, C, P, N$ *of* U*. Then their consumer-visible packets form one finite pullback surface over the shared window row* W*, shared threshold row* M*, dyadic tolerance row* Q*, tail ledger* T*, and seal row* E*.*

Equivalently, any two such consumers that agree on the displayed BMark *and* BHist *routes* H, C *have the same finite-window projection and the same seal-facing tail packet. No consumer can add a second stream-name family, RegSeqRat ledger, dyadic tolerance route, Real seal handoff, selected limit, host equality, quotient stream, or ambient completeness datum.*

Proof. First fix the window surface. Apply Definition 435.3: every StreamName$^{\uparrow}$ read of the accepted packet is already a read of the displayed family W over the finite index ledger I.

Next fix the threshold and tail coordinates. Apply Definition 435.10 and Definition 435.9. The route through M, Q, T is therefore the single transported route determined by H, C.

Now pass to the consumer boundary. By Definition 435.48, every RegSeqRat$^{\uparrow}$-visible read is exhausted by the same finite package $I, W, M, Q, T, E, H, C, P, N$. By Definition 435.57, the Real$^{\uparrow}$ seal read factors through that package rather than through a separate completion object.

Finally use Definition 435.68 for transported presentations and Definition 435.69 for finite unions of compatible subledgers. These two closure operations preserve the same W, M, Q, T, E, H, C surface, so the consumer-visible packets are glued only along their common displayed rows. That is precisely the finite pullback surface claimed above. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket shared window regseqrat real pullback`

Theorem 435.71 (UniformCauchyCriterion overlap refinement determinacy)**.** *Let* U *be an accepted* UniformCauchyCriterion$^{\uparrow}$ *packet with displayed rows* $I, W, M, Q, T, E, H, C, P, N$*. If two refined window reads* W_1 *and* W_2 *overlap on a displayed finite subledger of* I *and both refinements are transported through compatible* H, C *routes, then the overlap determines the same tail ledger row* T *and the same seal route* E *for both reads.*

Thus an overlapping refinement cannot expose two tail ledgers, two Real seal routes, or a detached RegSeqRat tolerance route over the common finite-window surface.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket overlap refinement determinacy`

Proof. Apply Definition 435.68 to both refined reads. Each refinement is only a transported presentation of the same displayed window family W, so their overlap still lies over the finite index ledger I.

Use Definition 435.10. Compatibility of the displayed H, C routes forces both refined reads to reach the same threshold row M and dyadic tolerance row Q before any tail comparison is read.

Now apply Definition 435.9. On the common subledger, the tail evidence is exactly the displayed restriction of T.

For the seal boundary, use Definition 435.57. Since the seal row is downstream of the same finite package, the overlap has no coordinate from which a second seal route or detached tolerance route can be produced. □

Theorem 435.72 (UniformCauchyCriterion seal route uniqueness)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. A* $\mathsf{Real}^{\uparrow}$ *seal consumer of* U *cannot obtain a second seal route from the same accepted packet: every seal-facing read factors through the displayed route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

The packet therefore has one consumer-visible seal handoff and no alternate handoff through selected limits, host real equality, quotient stream names, or ambient completeness.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket seal route uniqueness`

Proof. Start with Definition 435.57. Any $\mathsf{Real}^{\uparrow}$ seal-facing consumer is exhausted by the displayed finite package $I, W, M, Q, T, E, H, C, P, N$.

Apply Definition 435.10 and Definition 435.9. These identify the only path from the window family to the tail ledger as W, M, Q, T.

Finally use Definition 435.48. The RegSeqRat-facing side also has no route outside the same finite package, so a second seal handoff would require a second visible row not present in U. Hence every seal read is the displayed route through E. □

Theorem 435.73 (UniformCauchyCriterion late-boundary formal target packet)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *late-boundary packet. Suppose the empty-family tail ledger, paired-family union ledger, family-tail intersection, overlap-refinement determinacy, and seal-route uniqueness rows of* U *are displayed. Then these rows assemble one finite consumer surface over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{TailBudgetCoherence}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

Equivalently, every late-boundary consumer reads the same displayed package $I, W, M, Q, T, E, H, C, P, N$ *before it reaches a family-tail, overlap, or Real-seal conclusion. The packet exports no second family ledger, detached tail budget, alternate overlap route, selected limit, quotient stream family, host equality, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket late boundary formal target packet`

Proof. First read the family endpoints. Apply Definition 435.42 for the empty-family boundary and Definition 435.44 for paired family reads. Both rows remain inside the displayed index, window, modulus, dyadic tail, and tail-budget ledger I, W, M, Q, T.

Next read the common tail surface. Apply Definition 435.47. Nonempty subfamilies meet the same displayed tail ledger, so the empty, paired, and intersected reads share one finite family-tail package.

Now attach the boundary route. Use Definition 435.71 to make overlapping refinements read the same T row and seal route, and use Definition 435.72 to identify the Real-facing handoff as the displayed route through E.

The remaining rows H, C, P, N are exactly the transport, continuation, package, and local naming coordinates of the same packet. Since the preceding rows already exhaust the family-tail, overlap, and seal boundaries, there is no carrier coordinate from which an additional consumer surface can be exported. □

Theorem 435.74 (UniformCauchyCriterion diagonal-budget pullback)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *family packet, and let*

$$B = (\epsilon, M_B, W_B, D_B, K_B, S_B, H_B, C_B, P_B, N_B)$$

be an accepted $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *packet. Suppose the displayed* $\mathsf{StreamName}^{\uparrow}$ *window of* U *agrees with* W_B*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger of* U *agrees with* D_B*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of* U *agrees with* K_B*, and the* $\mathsf{Real}^{\uparrow}$ *seal boundary of* U *agrees with* S_B*, all after the displayed* hsame *transports and* Cont *routes are replayed. Then every family-tail or completion-facing read of* U *factors through the shared finite route*

$$\epsilon, M_B, W_B, D_B, K_B, S_B, H_B, C_B, P_B, N_B.$$

The pullback adds no separate family limit, quotient stream family, host real equality, countable-choice schedule, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket diagonal budget pullback`

Proof. First identify the UniformCauchyCriterion side. The shared-window pullback theorem, Definition 435.70, makes the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers of U read the same finite $W, M, Q, T, E, H, C, P, N$ surface.

Next close the seal route inside U. Apply seal-route uniqueness, Definition 435.72, and the late-boundary formal target packet, Definition 435.73. They force every family-tail, overlap, or Real-seal consumer to pass through the displayed family packet before it reaches a completion-facing conclusion.

Now compare with the diagonal budget. The componentwise agreement hypotheses identify the shared window, tolerance ledger, RegSeqRat readback row, and Real seal boundary with W_B, D_B, K_B, S_B. The Cauchy diagonal budget route theorem, Definition 853.21, and limit-seal eligibility, Definition 853.22, then place the same consumer behind $\epsilon, M_B, W_B, D_B, K_B, S_B, H_B, C_B, P_B, N_B$.

Since both packets expose only displayed transport, continuation, provenance, and local naming rows, the common pullback leaves no coordinate for a separate family limit, quotient stream family, host real equality, countable-choice schedule, or ambient completeness principle. □

Theorem 435.75 (UniformCauchyCriterion paired-overlap real seal determinacy)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose the paired-family union row, family-tail intersection row, overlap-refinement determinacy row, seal-route uniqueness row, and diagonal-budget pullback row are displayed for* U*. Then every paired-overlap* $\mathsf{Real}^{\uparrow}$*-facing consumer factors through one finite route over*

$$I, W, M, Q, T, E, H, C, P, N$$

and through the shared $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *route determined by the diagonal-budget pullback.*

Thus the consumer-visible handoff is the same finite family-tail, overlap, seal, and diagonal-budget surface. It exports no second family limit, quotient stream family, host real equality, countable-choice schedule, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket paired overlap real seal determinacy`

Proof. First assemble the finite paired-family surface. Apply Definition 435.44; the two family requests are read as one finite union ledger inside the displayed index, window, modulus, dyadic tolerance, and tail rows.

Next force the overlap to remain on that surface. Apply Definition 435.47 and Definition 435.71. The common tail evidence is the displayed restriction of T, and every overlapping refinement reads the same seal-facing route.

Now close the Real-facing boundary. Apply Definition 435.72. Any $\mathsf{Real}^{\uparrow}$ consumer of the paired-overlap packet must pass through the displayed handoff E after reading the same $I, W, M, Q, T, H, C, P, N$ rows.

Finally transport the result to the shared diagonal-budget route by Definition 435.74. The diagonal route identifies the compatible window, tolerance, readback, and seal coordinates, so the paired-overlap consumer has no coordinate from which to export a second family limit, quotient stream family, host equality, countable-choice schedule, or ambient completeness datum. □

Theorem 435.76 (UniformCauchyCriterion late-boundary no-choice exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every empty-family, singleton, paired-family, nonempty subfamily, overlap-refinement, or diagonal-budget* $\mathsf{Real}^{\uparrow}$*-seal consumer of* U *factors through the same finite rows*

$$I, W, M, Q, T, E, H, C, P, N$$

and, when a $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *packet is displayed, through the corresponding diagonal route*

$$\epsilon, M_B, W_B, D_B, K_B, S_B, H_B, C_B, P_B, N_B.$$

Thus the late boundary has one consumer-visible family-tail, overlap, seal, and diagonal-budget surface. It exports no countable-choice schedule, selected family limit, quotient stream family, host real equality, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket late boundary nochoice exhaustion`

Proof. First exhaust the family-tail cases inside the displayed packet. Apply Definition 435.42 for the empty-family boundary and Definition 435.43 for singleton reads. These cases use only the displayed index ledger, window row, threshold row, dyadic tolerance row, and tail ledger.

For finite family combinations, apply Definition 435.44 and Definition 435.47. Paired-family and nonempty subfamily consumers are assembled by finite ledger union or finite tail intersection inside I, W, M, Q, T, so they cannot supply an indexwise schedule or a separate family-limit coordinate.

Next close the overlap and seal boundary. Use Definition 435.71 to force overlapping refinements to read the same tail ledger row and Real-facing route, and use Definition 435.72 to identify every seal-facing read with the displayed handoff through E.

When a diagonal budget is present, apply Definition 435.74. The compatible window, tolerance, RegSeqRat readback, and Real seal coordinates are then read through $\epsilon, M_B, W_B, D_B, K_B, S_B, H_B, C_B, P_B, N_B$, not through a second completion-facing object.

Finally apply Definition 435.75. The rows H, C, P, N provide only transport, continuation, provenance, and local naming for the same finite route. The carrier inventory therefore contains no coordinate from which a countable-choice schedule, selected family limit, quotient stream family, host equality, or ambient completeness datum can escape. □

Theorem 435.77 (UniformCauchyCriterion late-overlap route exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every empty-family, singleton, paired-family, nonempty-subfamily, overlap-refinement, diagonal-budget,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$*-seal consumer of* U *is routed through the same finite surface*

$$I, W, M, Q, T, E, H, C, P, N.$$

When a diagonal budget is displayed, the same consumer also factors through the shared pullback route

$$\epsilon, M_B, W_B, D_B, K_B, S_B, H_B, C_B, P_B, N_B.$$

Thus paired-overlap, diagonal-budget, CauchyLimitSeal, and RealUp consumers have one late-boundary route and no separate family limit, quotient stream family, host real equality, countable-choice schedule, or ambient completeness coordinate.

Proof. First exhaust the elementary family cases. Apply Definition 435.42 and Definition 435.43 for empty-family and singleton reads; both remain inside the displayed I, W, M, Q, T rows.

Next assemble finite family consumers. Use Definition 435.44 and Definition 435.47. Paired-family and nonempty-subfamily reads are finite union and intersection routes over the same index, window, modulus, tolerance, and tail surface.

Now close the overlap and seal route. Apply Definition 435.71 and Definition 435.72. Overlap refinements, CauchyLimitSeal consumers, and RealUp-seal consumers must pass through the displayed handoff row E with support from H, C, P, N.

When a diagonal budget is present, apply Definition 435.74. The compatible window, dyadic tolerance ledger, RegSeqRat readback, and Real seal are then read through $\epsilon, M_B, W_B, D_B, K_B, S_B, H_B, C_B, P_B, N_B$ rather than through an additional completion object.

Finally combine Definition 435.75 with Definition 435.76. The first theorem identifies paired-overlap Real-seal consumers with the diagonal-budget pullback, and the second theorem exhausts all late-boundary no-choice consumers. Hence every listed consumer uses the same finite route and exports no separate family limit, quotient stream family, host real equality, countable-choice schedule, or ambient completeness coordinate. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket late overlap route exhaustion`

Theorem 435.78 (UniformCauchyCriterion late-overlap Real-seal pullback)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every late-overlap* $\mathsf{Real}^{\uparrow}$*-seal consumer of* U *pulls back to the same finite route over*

$$I, W, M, Q, T, E, H, C, P, N.$$

The pullback first reads the shared schedule and seal inheritance, then the tail-overlap budget, then the $\mathsf{RegSeqRat}^{\uparrow}$ *consumer route, and finally the* $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *seal overlap. It exports no second modulus schedule, quotient stream family, selected family limit, host real equality, countable-choice route, or ambient completeness coordinate.*

Proof. Start with a late-overlap $\mathsf{Real}^{\uparrow}$-seal consumer of U. By Definition 435.45, singleton and paired-family reads inherit the same shared schedule M and the same seal handoff through E, H, C, P, N.

Next apply Definition 435.49. Any overlap budget is exhausted by the displayed rows $I, W, M, Q, T, E, H, C, P, N$ so the consumer has no route to a second threshold, tolerance ledger, or tail selector.

Now read the regular-rational side through Definition 435.48. The $\mathsf{RegSeqRat}^{\uparrow}$ consumer is already factored through the same family ledger, shared windows, shared modulus, dyadic tolerance, tail ledger, seal row, transport, continuation, provenance, and local naming rows.

Finally use Definition 435.50. The Real seal and the RegSeqRat readback meet on the same finite package, and the non-escape clauses in the cited overlap route exclude quotient stream families, selected family limits, host equality, choice schedules, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket late overlap real seal pullback`

Theorem 435.79 (UniformCauchyCriterion late-overlap RegSeqRat consumer factorization)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer that reaches a late-overlap* $\mathsf{Real}^{\uparrow}$*-seal boundary of* U *factors through the same route*

$$I, W, M, Q, T, E, H, C, P, N$$

and through the Real-seal pullback of Definition 435.78. The factorization exposes no independent regular-sequence classifier, quotient stream family, second Real seal, selected family limit, host real equality, countable-choice route, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket late overlap regseqrat consumer factorization`

Proof. Begin with a $\mathsf{RegSeqRat}^{\uparrow}$ consumer at the late-overlap boundary. Apply Definition 435.48; the consumer can read only the displayed package $I, W, M, Q, T, E, H, C, P, N$.

Next force compatibility with the overlap route. By Definition 435.49, the overlap budget is the same finite tail package, and by Definition 435.45, the schedule and seal handoff remain the inherited M and E rows.

Finally apply Definition 435.78. The Real-facing side has already been pulled back to the same finite route, so the RegSeqRat consumer cannot supply an independent classifier, quotient stream family, second seal, selected limit, host equality, choice schedule, or completeness coordinate. □

Theorem 435.80 (UniformCauchyCriterion late-overlap exact-boundary handoff)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every late-overlap* $\mathsf{Real}^{\uparrow}$*-seal consumer of* U *that factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer route determines a* RealCompletionExactBoundaryUp *handoff exactly through the displayed finite rows*

$$I, W, M, Q, T, E, H, C, P, N.$$

The handoff is the exact-boundary consumer route supplied by the finite rows and exposes no quotient stream family, selected family limit, host real equality, countable-choice route, metric-completeness coordinate, ambient-completeness coordinate, or bridge row.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket late overlap exact boundary handoff`

Proof. Start from a late-overlap $\mathsf{Real}^{\uparrow}$-seal consumer of U whose access to the boundary factors through the $\mathsf{RegSeqRat}^{\uparrow}$ route. By Definition 435.78, the Real-facing consumer already pulls back to the displayed finite rows $I, W, M, Q, T, E, H, C, P, N$.

Next apply Definition 435.79. The $\mathsf{RegSeqRat}^{\uparrow}$ side reaches that same Real-seal boundary only through the same rows, so the consumer has no independent regular-sequence classifier, second Real seal, selected limit, host equality, choice schedule, or completeness coordinate.

Read the resulting boundary as an exact-boundary consumer. By Definition 1120.13, terminal Real consumption for an accepted RealCompletionExactBoundaryUp packet is exactly a finite displayed route, with no shorter route and no route enlarged by quotient, host-equality, selected-limit, choice, completeness, or bridge coordinates.

Finally apply Definition 1120.14. Since the exact-boundary packet supplies no insertion point for quotient streams, selected family limits, host real equality, countable choice, metric completeness, ambient completeness, or bridge rows, the late-overlap consumer determines its RealCompletionExactBoundaryU handoff through the displayed rows and nowhere outside them. □

Theorem 435.81 (UniformCauchyCriterion finite-family seal obligation package)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. The rows* $I, W, M, Q, T, E, H, C, P, N$ *form the finite-family seal obligation surface for every* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer that reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *tail read or a* $\mathsf{Real}^{\uparrow}$ *seal read.*

The surface consists exactly of the finite index ledger I*, shared window family* W*, shared threshold schedule* M*, dyadic tolerance row* Q*, tail ledger* T*, seal handoff row* E*, componentwise* hsame *transports* H*, displayed* Cont *routes* C*, package provenance* P*, and local* NameCert *row* N*. It contains no selected limit, quotient stream, host real equality, ambient completeness proof, or detached tail oracle.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family seal obligation package`

Proof. First expose the finite window spine. Apply Definition 435.3; every window read remains a read of the displayed family W over the finite index ledger I.

Next bind the threshold and tail data. Apply Definition 435.10 and Definition 435.9. These force the route from the family window to pass through the displayed M, Q, T rows.

Now pass to the consumers. By Definition 435.48, the $\mathsf{RegSeqRat}^{\uparrow}$ tail reader is exhausted by the rows of U. By Definition 435.57, the $\mathsf{Real}^{\uparrow}$ seal reader factors through the same displayed package.

Finally apply Definition 435.71 and Definition 435.72. Overlaps cannot split the tail ledger, and the seal route has no second public handoff. Hence the displayed rows are exactly the finite-family seal obligation surface. □

Theorem 435.82 (UniformCauchyCriterion finite-family RegSeqRat–Real handoff)**.** *For an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N),$$

every $\mathsf{RegSeqRat}^{\uparrow}$*-visible tail read and every* $\mathsf{Real}^{\uparrow}$ *seal read factor through the same shared-window route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

The tail side and the seal side may refine the displayed finite ledger, but they cannot fork into separate window families, threshold schedules, dyadic tolerance routes, or completion routes.

Proof. Start with the shared window. Apply Definition 435.3 and Definition 435.10. They identify W and M as the common route before any tail or seal data can be read.

Use Definition 435.9. The $\mathsf{RegSeqRat}^{\uparrow}$-visible tail read is exactly the displayed T row after the dyadic tolerance row Q.

For the seal boundary, apply Definition 435.57. The $\mathsf{Real}^{\uparrow}$ seal read is downstream of that same tail ledger rather than an independent completion route.

Refinements do not alter this handoff. Apply Definition 435.71; any overlap refinement still determines the same tail ledger and the same seal route. The stated shared route follows. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family regseq real handoff`

Theorem 435.83 (UniformCauchyCriterion finite-family nonescape ledger)**.** *Let* $U = (I, W, M, Q, T, E, H, C, P, N$ *be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet carrying the finite-family seal obligation surface of Definition 435.81. A consumer of this surface cannot inspect a selected limit, quotient stream, host real equality, ambient completeness witness, or any unledgered completion datum.*

All admissible reads are exhausted by the displayed window, threshold, tolerance, tail, seal, transport, continuation, provenance, and local naming rows.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family seal nonescape`

Proof. Apply Definition 435.48. The RegSeqRat-facing read has no coordinate outside $I, W, M, Q, T, E, H, C, P, N$.

Apply Definition 435.57. The Real-facing read also factors through the same displayed package, so it cannot introduce a selected limit or ambient completion witness.

Use Definition 435.71 to rule out escape through refined windows. The overlap still determines the same tail ledger and seal route.

Finally use Definition 435.72. A second route to host equality, quotient streams, or completion data would require another visible seal handoff, and that handoff is absent from the accepted packet. □

Theorem 435.84 (UniformCauchyCriterion finite-family window seal exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet carrying the finite-family seal obligation surface. Every finite-window consumer route from* U *to a* $\mathsf{RegSeqRat}^{\uparrow}$ *tail or a* $\mathsf{Real}^{\uparrow}$ *seal is exhausted by the displayed rows* $I, W, M, Q, T, E, H, C, P, N$*.*

In particular, no admissible route may bypass the shared window family W *or the tail ledger* T *to reach a selected limit, quotient stream, host real equality, ambient completeness witness, or detached tail oracle.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family window seal exhaustion`

Proof. First read the finite-family seal obligation package of Definition 435.81. It lists $I, W, M, Q, T, E, H, C, P, N$ as the complete surface available to seal-facing consumers.

Next use the RegSeqRat–Real handoff of Definition 435.82. It forces both the regular-rational tail side and the Real seal side through the route from I to W, then through M, Q, T, E.

The nonescape ledger of Definition 435.83 removes selected limits, quotient streams, host equality, ambient completeness, and detached tail oracles from the consumer surface.

Finally apply the root seal package of Definition 435.97. It preserves the same finite rows under root-facing overlap refinement, so a route omitting W or T has no remaining public path to a tail or seal consumer. □

Theorem 435.85 (UniformCauchyCriterion shared seal-route determinacy)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet carrying the finite-family seal obligation surface. Suppose two* $\mathsf{RegSeqRat}^{\uparrow}$*-visible or* $\mathsf{Real}^{\uparrow}$*-visible consumers preserve the displayed finite index ledger* I*, shared window family* W*, shared threshold schedule* M*, dyadic tolerance row* Q*, tail ledger* T*, seal handoff* E*, componentwise* hsame *transports* H*, displayed* Cont *routes* C*, package provenance* P*, and local* $\mathsf{NameCert}$ *row* N*. Then the two consumers determine the same route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

No consumer may split that route into a second $\mathsf{StreamName}^{\uparrow}$ *family,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail row,* $\mathsf{Real}^{\uparrow}$ *seal row, quotient stream, host real equality, selected limit, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family shared seal route determinacy`

Proof. Start from the finite-family seal obligation package. By Definition 435.81, every admissible tail or seal consumer sees exactly the rows $I, W, M, Q, T, E, H, C, P, N$ and no completion-facing coordinate outside them.

Next apply the RegSeqRat–Real handoff. Definition 435.82 makes both $\mathsf{RegSeqRat}^{\uparrow}$ tail reads and $\mathsf{Real}^{\uparrow}$ seal reads factor through the same ordered route from I to E.

The nonescape and exhaustion results remove the possible branches. Definition 435.83 excludes selected limits, quotient streams, host real equality, ambient completeness, and detached tail data, while Definition 435.84 says that finite-window consumers cannot bypass W or T.

Thus two consumers preserving the displayed ledger rows have no coordinate at which to diverge. The shared route is determined as $I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$, with all repacking confined to H, C, P, N. □

Theorem 435.86 (UniformCauchyCriterion finite-family seal overlap determinacy)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet carrying the finite-family seal obligation surface. If two finite-family overlap refinements preserve the displayed rows* $I, W, M, Q, T, E, H, C, P, N$*, then both refinements determine the same* $\mathsf{RegSeqRat}^{\uparrow}$ *tail row and* $\mathsf{Real}^{\uparrow}$ *seal handoff. Neither refinement can introduce a second* $\mathsf{StreamName}^{\uparrow}$ *family, detached tail oracle, selected limit, quotient stream, host real equality, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family seal overlap determinacy`

Proof. Start with the finite-family seal obligation package. By Definition 435.81, the rows $I, W, M, Q, T, E, H, C, P,$ are the complete seal-facing inventory for the accepted packet.

Next use the RegSeqRat–Real handoff. Definition 435.82 routes every tail read and every seal read through the same path from the finite index ledger to the seal handoff.

The shared seal-route determinacy theorem now compares the two refinements. Since both refinements preserve the displayed rows, Definition 435.85 leaves them with the same route from I through E and with repacking only along H, C, P, N.

Finally apply root seal pullback non-escape. Definition 435.98 removes selected limits, quotient streams, host real equality, detached tail oracles, and ambient completeness witnesses from the completion-facing surface. Thus the two overlap refinements determine the same tail row and seal handoff, with no second public route. □

Theorem 435.87 (UniformCauchyCriterion finite-family endpoint budget reflector)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet carrying the finite-family seal surface. Every finite-family endpoint request for* U *reflects through the displayed route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

Consequently the $\mathsf{RegSeqRat}^{\uparrow}$ *tail reads and* $\mathsf{Real}^{\uparrow}$ *seal reads are the same budgeted endpoint route, and no request can split into a second* $\mathsf{StreamName}^{\uparrow}$ *family, selected limit, quotient stream, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family endpoint budget reflector`

Proof. First assemble the endpoint surface from the finite-family seal obligation package. Theorem 435.81 lists the rows $I, W, M, Q, T, E, H, C, P, N$ as the complete inventory available to a tail or seal consumer.

Next apply the RegSeqRat–Real handoff. Theorem 435.82 identifies the $\mathsf{RegSeqRat}^{\uparrow}$ tail side and the $\mathsf{Real}^{\uparrow}$ seal side with the same route from the finite index ledger through the shared window, threshold, tolerance, tail, and seal rows.

Now use the nonescape ledger and window seal exhaustion. Theorems 435.83 and 435.84 remove selected limits, quotient streams, host real equality, ambient completeness witnesses, detached tail oracles, and any bypass of the shared window or tail ledger.

Finally compose shared seal-route determinacy with seal overlap determinacy. Theorem 435.85 fixes the public route once the displayed rows are preserved, and Definition 435.86 prevents overlap refinements from adding a second stream family or seal handoff. Hence every finite-family endpoint request reflects through the single budgeted route displayed above. □

Theorem 435.88 (UniformCauchyCriterion finite-family route lock)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet carrying the finite-family seal obligation surface. Any* $\mathsf{RegSeqRat}^{\uparrow}$*-visible or* $\mathsf{Real}^{\uparrow}$*-visible consumer preserving* $I, W, M, Q, T, E, H, C, P, N$ *must use the single handoff route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

The consumer cannot introduce a second $\mathsf{StreamName}^{\uparrow}$ *family, detached tail oracle, selected limit, quotient stream, host real equality, or ambient completeness datum.*

Proof. Start with the finite-family seal package and RegSeqRat–Real handoff. Definition 435.81 exposes exactly the rows $I, W, M, Q, T, E, H, C, P, N$, and Definition 435.82 routes both tail and real-facing consumers from the finite index ledger to the seal handoff.

Next apply the nonescape ledger and window seal exhaustion. Definition 435.83 removes selected limits, quotient streams, host real equality, ambient completeness, and detached tail data, while Definition 435.84 prevents a consumer from bypassing the shared window and tail ledger.

Now use shared seal-route determinacy together with seal overlap determinacy. Definition 435.85 fixes the route from I through E, and Definition 435.86 shows that overlap refinements preserving the displayed rows cannot split the tail row or the seal handoff.

Therefore every $\mathsf{RegSeqRat}^{\uparrow}$-visible or $\mathsf{Real}^{\uparrow}$-visible consumer preserving the displayed packet rows uses the handoff $I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$. The excluded data are not available as public coordinates, so they cannot provide a second route. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionFiniteFamilyRouteLock`

Theorem 435.89 (UniformCauchyCriterion finite-family source exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet carrying the finite-family seal obligation surface. Any* $\mathsf{RegSeqRat}^{\uparrow}$*-visible or* $\mathsf{Real}^{\uparrow}$*-visible consumer preserving the finite-family seal route has source access exhausted by* $I, W, M, Q, T, E, H, C, P, N$*. It cannot introduce a second source ledger, stream family, dyadic tolerance source, tail oracle, quotient stream, host real equality, selected limit, or ambient completeness witness before the* $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *handoff.*

Proof. Begin with the finite-family seal obligation package. It displays the full accepted source inventory $I, W, M, Q, T, E, H, C, P, N$, with I as the finite index ledger, W as the shared window

family, M as the pointwise modulus row, Q as the dyadic tolerance source, T as the tail oracle row, and E as the seal handoff.

Apply the $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ handoff. The handoff reads the same displayed source rows on the regular-rational side and on the real-seal side, so a consumer preserving the route has no independent source coordinate between T and E.

Next use the nonescape ledger and window seal exhaustion. These results remove selected limits, quotient streams, host real equality, ambient completeness witnesses, detached tail oracles, and any bypass of the finite window and tolerance rows from the public packet surface.

Finally combine shared seal-route determinacy with the route lock above. Shared determinacy fixes the row order from I through E, and Definition 435.88 prevents a consumer preserving $I, W, M, Q, T, E, H, C, P, N$ from selecting a second route. Hence the listed rows exhaust all source access available before the $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ handoff. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family source exhaustion`

Theorem 435.90 (UniformCauchyCriterion CauchyLimitFunctor terminal handoff)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet carrying the finite-family seal obligation surface. Suppose an accepted* $\mathsf{CauchyLimitFunctor}^{\uparrow}$ *packet preserves the same source seal,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RealCompletionSealClassifierUp}$ *row, and terminal* $\mathsf{Real}^{\uparrow}$ *endpoint used by the finite-family* $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *handoff for* U*. Then every* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and Completion consumer of the pair factors through the finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

followed by the displayed functor packet rows. The terminal handoff introduces no quotient stream, selected host limit, host real equality, countable-choice row, detached completion object, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket cauchy limit functor terminal handoff`

Proof. Start with the finite-family side. The seal obligation package and the $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ handoff, Definition 435.81 and Definition 435.82, place all tail and seal reads of U on the displayed path from I through E.

Next apply nonescape and route locking inside $\mathsf{UniformCauchyCriterion}^{\uparrow}$. Definition 435.83 removes selected limits, quotient streams, host real equality, detached tail data, and ambient completeness from the finite-family surface, while Definition 435.88 prevents a consumer preserving $I, W, M, Q, T, E, H, C, P, N$ from using a second tail or seal route.

Now consume the accepted $\mathsf{CauchyLimitFunctor}^{\uparrow}$ packet. Its NameCert obligations, finite observation exposure, structural transport, and Real-completion consumer boundary are supplied by Definition 1116.3, Definition 1116.5, Definition 1116.6, and Definition 1116.7. These results make the functor packet read only the preserved source seal, stream windows, regular-rational readback, dyadic tolerance ledger, classifier row, terminal endpoint, and structural rows.

Finally compose the two boundaries. The finite-family route supplies the source tail-to-seal handoff, and the functor packet transports exactly that source through its displayed rows. Since both packets exclude quotient stream equality, selected host limits, host real equality, countable choice, detached completion objects, ambient completeness, and second routes, the combined consumer has the single terminal route stated above. □

Theorem 435.91 (UniformCauchyCriterion finite-family real seal tail coprovenance)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. The* $\mathsf{RegSeqRat}^{\uparrow}$*-visible tail row and the* $\mathsf{Real}^{\uparrow}$*-visible seal handoff are coprovenant over the same route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

Neither side can be repacked with a different $\mathsf{StreamName}^{\uparrow}$ *family, detached tail row, selected limit, quotient stream, host real equality, or ambient completeness route.*

Proof. First read the finite-family seal obligation package. By Definition 435.81, the packet exposes exactly the rows $I, W, M, Q, T, E, H, C, P, N$ to tail-facing and seal-facing consumers.

Next apply the finite-family RegSeqRat–Real handoff. Definition 435.82 puts the $\mathsf{RegSeqRat}^{\uparrow}$ tail read and the $\mathsf{Real}^{\uparrow}$ seal read on the same path from I to E.

The nonescape ledger removes alternate completion data. Definition 435.83 excludes selected limits, quotient streams, host real equality, ambient completeness witnesses, and detached tail oracles from the public surface.

Finally use the shared seal-route determinacy theorem. Definition 435.85 prevents a second $\mathsf{StreamName}^{\uparrow}$ family or completion route from carrying either side. Thus the tail row and seal handoff have the same route provenance. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family real seal tail coprovenance`

Theorem 435.92 (UniformCauchyCriterion finite-family tail-seal coprovenance lock)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any consumer preserving the finite index ledger* I*, shared window family* W*, threshold schedule* M*, dyadic tolerance row* Q*, tail ledger* T*, seal handoff* E*, componentwise* hsame *transports* H*, displayed* Cont *routes* C*, package provenance* P*, and local* NameCert *row* N *must route both the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail read and the* $\mathsf{Real}^{\uparrow}$ *seal read through the displayed path*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

No second $\mathsf{StreamName}^{\uparrow}$ *family, detached tail row, selected limit, quotient stream, host real equality, or ambient completeness route is available to that consumer.*

Proof. First read the finite-family seal obligation package, Definition 435.81. It exposes the rows $I, W, M, Q, T, E, H, C, P, N$ as the full public inventory of the accepted packet, so any preserved consumer surface has no coordinate beyond those displayed rows.

Next apply the finite-family RegSeqRat–Real handoff, Definition 435.82. The handoff places the $\mathsf{RegSeqRat}^{\uparrow}$ tail read and the $\mathsf{Real}^{\uparrow}$ seal read on the same route from I through E, with H, C, P, N carrying the transports, continuation routes, provenance, and local NameCert row.

The exclusions come from the nonescape ledger and window seal exhaustion, Definition 435.83 and Definition 435.84. These results remove selected limits, quotient streams, host real equality, ambient completeness routes, detached tail rows, and bypasses of the shared window or tail ledger from the packet surface.

Finally compose shared seal-route determinacy, seal overlap determinacy, and the finite-family route lock: Definition 435.85, Definition 435.86, and Definition 435.88. Determinacy fixes the displayed path for any consumer preserving $I, W, M, Q, T, E, H, C, P, N$, overlap determinacy prevents a repacking of the tail row or seal handoff, and route lock rules out a second completion-facing path. Thus the tail read and Real seal read have the same forced endpoint route. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family tail seal coprovenance lock`

Theorem 435.93 (UniformCauchyCriterion finite-family tail cofinal seal reflector)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any tail-cofinal request that preserves the displayed finite index ledger I, shared window family W, shared threshold schedule M, dyadic tolerance row Q, tail ledger T, seal handoff E, componentwise* hsame *transports H, displayed* Cont *routes C, package provenance P, and local* $\mathsf{NameCert}$ *row N reflects through the same route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

The request cannot introduce a second $\mathsf{StreamName}^{\uparrow}$ *family, detached tail oracle, selected limit, quotient stream, host real equality, ambient completeness datum, or completion-seal budget path outside the displayed packet.*

Proof. First read the finite-family seal obligation package and the RegSeqRat–Real handoff. The package exposes exactly the rows $I, W, M, Q, T, E, H, C, P, N$, while the handoff places every $\mathsf{RegSeqRat}^{\uparrow}$ tail read and every $\mathsf{Real}^{\uparrow}$ seal read on the route from the finite index ledger to the seal handoff.

Next apply the nonescape ledger. It removes selected limits, quotient streams, host real equality, ambient completeness witnesses, detached tail oracles, and any completion datum not carried by the displayed packet.

Now use shared seal-route determinacy and seal overlap determinacy. A tail-cofinal request preserving the displayed rows has no coordinate at which to split the $\mathsf{StreamName}^{\uparrow}$ family, tail ledger, or seal handoff from the accepted route.

Finally compose the endpoint budget reflector with the route lock and the real seal tail coprovenance theorem. The endpoint reflector binds the budgeted tail and seal endpoints, route lock fixes the ordered path $I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$, and coprovenance keeps the tail row and Real seal handoff on that same path. Thus the request reflects through the single displayed completion-seal budget path and no second route is available. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family tail cofinal seal reflector`

Theorem 435.94 (UniformCauchyCriterion RegSeqRat–Real window budget compatibility)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any finite-window budget refinement preserving $I, W, M, Q, T, E, H, C, P, N$ preserves the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail read and the* $\mathsf{Real}^{\uparrow}$ *seal read simultaneously along*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

A refinement that changes one of these reads without the other is not an accepted refinement of the packet U.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket regseq real window budget compatibility`

Proof. Start with prefix and window stability. Definition 435.3 keeps the finite read on the displayed window family W, and Definition 435.88 fixes the only handoff route from I through E for consumers preserving the packet rows.

Next compare refinements by the finite-family seal overlap determinacy theorem. Definition 435.86 says that refinements preserving $I, W, M, Q, T, E, H, C, P, N$ determine the same tail row and the same seal handoff.

It remains to exclude hidden completion pullback. Apply Definition 435.98. No selected limit, quotient stream, host real equality, detached tail oracle, or ambient completeness witness is available as a separate budget coordinate.

Therefore a finite-window budget refinement that preserves the accepted packet preserves both visible reads at once. Changing only the tail read or only the seal read would introduce a route outside $I, W, M, Q, T, E, H, C, P, N$, so it is not an accepted refinement of U. □

Theorem 435.95 (UniformCauchyCriterion finite-family refinement handoff)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any root-threshold use of U and any finite-family overlap refinement preserving the displayed rows $I, W, M, Q, T, E, H, C, P, N$ determine the same route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

The handoff contains no selected limit, quotient stream, host real equality, detached tail oracle, or ambient completeness datum.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family refinement handoff`

Proof. First apply the finite-family seal overlap determinacy theorem, Definition 435.86. A refinement preserving the displayed rows cannot split the tail row or the seal handoff.

Next use Definition 435.96. It fixes every root-threshold use at the threshold schedule, tolerance ledger, seal non-escape row, and shared-tail meet compatibility, all inside the same packet U.

Now compose with Definition 435.97. The root seal package is exactly the route from I through E together with H, C, P, N.

Finally apply Definition 435.98. It removes selected limits, quotient streams, host real equality, detached tail oracles, and ambient completeness data from the completion-facing boundary, so the refinement and the root-threshold use have the same handoff route. □

Theorem 435.96 (UniformCauchyCriterion root-threshold dependency inventory)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. The finite-family root seal package may use U only after the root-threshold refinement surface has fixed the following four dependencies: threshold schedule determinacy at M, tolerance ledger exactness at Q, T, seal non-escape at E, and shared-tail meet compatibility with* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$.

Thus every root seal use is routed through the displayed rows $I, W, M, Q, T, E, H, C, P, N$, and it introduces no selected limit, quotient stream, host real equality, or ambient completeness datum.

Proof. First use Definition 435.117. It fixes the threshold schedule row M reached from the finite index ledger and shared window rows.

Next use Definition 435.118. The downstream dyadic tolerance and tail comparison data are exactly the displayed Q, T ledger.

Then apply Definition 435.119. The seal consumer reaches E only through the finite root route and cannot export completion-facing data outside the packet.

Finally use Definition 435.120. Its compatibility with chapter 560 keeps the shared-tail meet on the same displayed root-threshold surface. The four dependencies therefore bind the root seal package without adding a selected limit, quotient stream, host real equality, or ambient completeness datum. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root threshold dependency inventory`

Theorem 435.97 (UniformCauchyCriterion finite-family root seal package)**.** *For an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N),$$

the finite-family root seal package is exactly the route

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

together with the componentwise hsame *transports* H*, displayed* Cont *routes* C*, package provenance* P*, and local NameCert row* N*. Under overlap refinement the package preserves the same finite index ledger, shared window family, threshold schedule, tolerance row, tail ledger, and seal handoff, and it exports no selected limit, quotient stream, host real equality, ambient completeness witness, or detached tail oracle.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family root seal package`

Proof. First use the finite-family seal obligation package. It lists the rows $I, W, M, Q, T, E, H, C, P, N$ as the complete seal-facing inventory for the accepted packet.

Next apply the finite-family RegSeqRat–Real handoff and the nonescape ledger. They identify the route from the finite index ledger through the shared window, threshold, tolerance, tail, and seal rows, and they exclude completion data outside the displayed package.

Finally use Definition 435.96. It binds the exact root-threshold dependency package, so overlap refinement preserves the same route and the finite-family package is stable as the root seal package. □

↪ variant `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root budget package`

Theorem 435.98 (UniformCauchyCriterion finite-family root seal pullback non-escape)**.** *Any completion-facing consumer of the finite-family root seal package for an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

must factor through the displayed rows $I, W, M, Q, T, E, H, C, P, N$ *and through the root-threshold dependency inventory. Therefore overlap refinement cannot introduce a selected limit, quotient stream, host real equality, detached tail oracle, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family root seal pullback nonescape`

Proof. Start with the finite-family root seal package of Definition 435.97. It identifies the public root seal route as

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

together with H, C, P, N.

Next apply Definition 435.96. It fixes the dependency inventory at threshold schedule determinacy, tolerance ledger exactness, seal non-escape, and shared-tail meet compatibility. Hence a completion-facing consumer reaches the seal only through the same displayed rows and the same root-threshold dependencies.

The finite-family RegSeqRat–Real handoff of Definition 435.82 keeps the tail side and the seal side on the shared route from I through E. The nonescape ledger of Definition 435.83 removes selected limits, quotient streams, host real equality, ambient completeness, and detached tail oracles from the consumer surface.

It remains to check overlap refinement. The root seal package already states that overlap refinement preserves the same finite index ledger, shared window family, threshold schedule, tolerance row, tail ledger, and seal handoff. Since the nonescape ledger removes every completion-facing coordinate outside those rows, refinement has no place to introduce the excluded objects. □

Theorem 435.99 (UniformCauchyCriterion root tail seal route totality)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every root-facing route from the finite-family* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *surface to either a* $\mathsf{RegSeqRat}^{\uparrow}$ *tail read or a* $\mathsf{Real}^{\uparrow}$ *seal read factors through*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

and through the structural rows H, C, P, N*. No such route may introduce a selected limit, quotient stream, host real equality, detached tail oracle, ambient completeness witness, or second stream family.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root tail seal route totality`

Proof. Start with the finite-family root seal package of Definition 435.97. It identifies the only public root-facing spine from the finite index ledger through the shared window, threshold schedule, tolerance ledger, tail row, and seal row, with H, C, P, N carried as the structural rows.

Next apply the finite-family RegSeqRat–Real handoff, the finite-family nonescape ledger, and shared seal route determinacy. The handoff ties the $\mathsf{RegSeqRat}^{\uparrow}$ tail read and the $\mathsf{Real}^{\uparrow}$ seal read to the same finite spine, while the nonescape and determinacy rows remove any alternate completion-facing route after the shared window and tail rows have been fixed.

Finally use the root-threshold dependency inventory and Definition 435.98. The inventory fixes the dependencies used by the root seal route, and pullback non-escape prevents overlap refinement from adding selected limits, quotient streams, host real equality, detached tail oracles, ambient completeness witnesses, or a second stream family. Thus every root-facing tail or seal read is total over the displayed route and structural rows. □

Theorem 435.100 (UniformCauchyCriterion terminal Real-route certificate)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any Phase Real and Completion consumer that preserves the finite index ledger, shared window, threshold schedule, dyadic tolerance, tail ledger, seal handoff, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row reaches the terminal Real-facing route only through the ordered finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

Such a consumer cannot extract a selected limit, quotient stream, host real equality, ambient completeness witness, detached tail oracle, or second $\mathsf{StreamName}^{\uparrow}$ *family.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket terminal real route certificate`

Proof. First compose the finite-family seal obligation package with the finite-family RegSeqRat–Real handoff. The package theorem fixes the accepted inventory $I, W, M, Q, T, E, H, C, P, N$, and the handoff routes the Real-facing use through the same finite index ledger, shared window, threshold schedule, tolerance row, tail ledger, and seal handoff.

Next apply the window seal exhaustion and shared seal route determinacy theorems. They leave no alternate seal entry after the shared window and tail rows have been chosen, so a Phase Real or Completion consumer preserving H, C, P, N must stay on the ordered route from I to E.

Finally apply the finite-family nonescape ledger and the root seal pullback non-escape theorem. The nonescape ledger removes selected limits, quotient streams, host real equality, ambient completeness witnesses, and detached tail oracles from the consumer surface; the pullback theorem also prevents overlap refinement from adding any completion-facing coordinate outside the displayed rows. A second $\mathsf{StreamName}^{\uparrow}$ family would be another public route to the same seal, contradicting shared seal route determinacy, so the terminal certificate has exactly the displayed Real-facing route. □

Theorem 435.101 (UniformCauchyCriterion terminal seal classifier route)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any terminal Real-facing consumer preserving the finite index ledger* I*, shared window* W*, threshold schedule* M*, dyadic tolerance row* Q*, tail ledger* T*, seal handoff* E*, componentwise* hsame *transports* H*, displayed* Cont *routes* C*, package provenance* P*, and local* NameCert *row* N *reaches the same public seal classifier exactly through the ordered route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

The $\mathsf{RegSeqRat}^{\uparrow}$ *tail classifier,* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier, and* $\mathsf{Real}^{\uparrow}$ *finite-window read surface are corresponding projections of that route, not separate completion data.*

Proof. First compose the finite-family seal package with the root tail seal route totality theorem. The package fixes $I, W, M, Q, T, E, H, C, P, N$ as the accepted packet inventory, while totality says every root-facing tail or seal read factors through the displayed route and through the structural rows H, C, P, N.

Next apply the finite-family RegSeqRat–Real handoff, Definition 38.276, Definition 38.278, and Definition 38.342. These results identify the $\mathsf{RegSeqRat}^{\uparrow}$ tail side, the $\mathsf{StreamName}^{\uparrow}$ finite-window side, and the $\mathsf{Real}^{\uparrow}$ finite-window read surface as the same finite-window classifier route seen from different interfaces.

Finally use shared seal-route determinacy. Once I, W, M, Q, T, E and the structural rows H, C, P, N are preserved, there is no second public seal handoff through which a terminal Real-facing consumer could obtain an independent classifier. Hence the three displayed classifier views are projections of the ordered route rather than additional completion data. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket terminal seal classifier route`

Theorem 435.102 (UniformCauchyCriterion terminal RegSeqRat–Real classifier correspondence)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. For any terminal consumer preserving the finite index ledger* I*, shared window* W*, threshold schedule* M*, dyadic tolerance row* Q*, tail ledger* T*, seal handoff* E*, componentwise* hsame *transports* H*, displayed* Cont *routes* C*, package provenance* P*, and local* $\mathsf{NameCert}$ *row* N*, the following three classifier views determine one another: the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail classifier, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier, and the* $\mathsf{Real}^{\uparrow}$ *finite-window seal classifier. The determination is bidirectional because each view is exactly the corresponding projection of the ordered route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

Thus a read of any one of the three classifiers is a read of the same terminal seal classifier through its own interface projection, and none of the three views imports a selected limit, quotient stream, host real equality, ambient completeness witness, detached tail oracle, or second stream family.

Proof. First compose the finite-family seal package with the finite-family RegSeqRat–Real handoff and the root tail seal route totality theorem. These results put every accepted packet on the common route from I to E, carry H, C, P, N as the structural rows, and make every root-facing tail or seal read factor through that route.

Next apply Definition 38.276, Definition 38.278, and Definition 38.342. They identify the RegSeqRat tail side, the StreamName finite-window side, and the Real finite-window read surface as interface projections of the same finite-window classifier.

For the forward direction, a RegSeqRat tail-classifier read fixes the route through I, W, M, Q, T, E. The StreamName and Real classifier reads are then the finite-window and seal projections supplied by the scoped interface and finite-window Real-seal interface.

For the reverse direction, a StreamName or Real classifier read reaches the same route through the finite-window read surface and the RegSeqRat–Real handoff. Root tail seal totality sends the resulting terminal read back to the RegSeqRat tail classifier, with no extra completion coordinate.

Finally use shared seal-route determinacy together with the nonescape ledger. Determinacy rules out a second public seal handoff once $I, W, M, Q, T, E, H, C, P, N$ are preserved, and the ledger excludes selected limits, quotient streams, host real equality, ambient completeness, detached tail oracles, and second stream families. Hence the three classifiers correspond bidirectionally as projections of the displayed route. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket terminal regseq real classifier correspondence`

Theorem 435.103 (UniformCauchyCriterion terminal quotient-refusal boundary)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any terminal consumer preserving the finite index ledger* I*, shared window* W*, threshold schedule* M*, dyadic tolerance row* Q*, tail ledger* T*, seal handoff* E*, componentwise* hsame *transports* H*, displayed* Cont *routes* C*, package provenance* P*, and local* $\mathsf{NameCert}$ *row* N *remains confined to the route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

when it reads one of the $\mathsf{RegSeqRat}^{\uparrow}$ *tail classifier, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier, or the* $\mathsf{Real}^{\uparrow}$ *finite-window seal classifier. If the consumer asks instead for quotient-stream equality, selected limits, host real equality, ambient completeness, a detached tail oracle, or a second* $\mathsf{StreamName}^{\uparrow}$ *family, that request is not a coordinate of* U *and must factor through chapter 998 by Definition 998.3 and Definition 998.11.*

Proof. Start with Definition 435.102. It identifies the $\mathsf{RegSeqRat}^{\uparrow}$ tail classifier, $\mathsf{StreamName}^{\uparrow}$ finite-window classifier, and $\mathsf{Real}^{\uparrow}$ finite-window seal classifier as mutually determining projections of the same ordered route from I through E.

Next apply Definition 435.101. Once the terminal consumer preserves $I, W, M, Q, T, E, H, C, P, N$, the classifier route has no second public seal handoff and no independent completion coordinate.

The refusal boundary inside $\mathsf{UniformCauchyCriterion}^{\uparrow}$ is supplied by Definition 435.83 and Definition 435.88. These theorems keep the accepted packet on the finite-family route and exclude selected limits, quotient streams, host real equality, detached tail oracles, ambient completeness, and second stream families from the packet surface.

It remains to route a quotient-facing request. Since none of those requests is a coordinate of U, the consumer must leave the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ packet and enter the $\mathsf{QuotientStreamRefusal}^{\uparrow}$ surface of chapter 998. There Definition 998.3 sends the Real-completion request to the displayed finite route or the refusal ledger, and Definition 998.11 records that off-route quotient-style requests export no completion coordinate. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket terminal quotient refusal boundary`

Theorem 435.104 (UniformCauchyCriterion finite-observation terminal synchronization)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let*

$$F = (B, S, W', D, R, E', H', C', P', N')$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Suppose the shared-window, tolerance-ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer, and* $\mathsf{Real}^{\uparrow}$ *seal rows are identified by displayed componentwise transports*

$$W\,\mathsf{hsame}\,W', \qquad Q\,\mathsf{hsame}\,D, \qquad T\,\mathsf{hsame}\,R, \qquad E\,\mathsf{hsame}\,E'.$$

Then the terminal $\mathsf{Real}^{\uparrow}$ *route of* U *is exactly the finite selector route*

$$B \to S \to W' \to D \to R \to E'.$$

Equivalently, after the displayed transports, the route

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

is the same terminal handoff as the selector route through B, S, W', D, R, E'*. No quotient stream, host equality, countable choice, hidden selector, selected limit, host metric, or ambient completeness coordinate can mediate the synchronization.*

Proof. First use the terminal certificate, seal classifier route, and RegSeqRat–Real classifier correspondence for $\mathsf{UniformCauchyCriterion}^{\uparrow}$. By Definition 435.100, Definition 435.101, and Definition 435.102, any terminal Real-facing read of U is confined to the ordered route from I through E and sees the RegSeqRat, finite-window, and Real classifier faces as projections of that route.

Next apply the terminal quotient-refusal boundary, Definition 435.103. It removes quotient streams, selected limits, host equality, ambient completeness, detached tail oracles, and second stream-family data from the synchronized consumer surface.

Now use the finite-observation pullback Definition 782.20. The displayed transports identify the shared window, dyadic tolerance ledger, regular readback, and Real seal rows of U with the rows W', D, R, E' of F, so the UniformCauchyCriterion terminal read is pulled back to the finite selector route through the same visible rows.

Finally apply terminal route no-branching for the selector, Definition 782.28. Once the rows $B, S, W', D, R, E', H', C', P', N'$ and the synchronized UniformCauchyCriterion rows are fixed, there is no second terminal route through hidden selector, quotient, choice, host-metric, selected-limit, or completeness data. Hence the terminal Real route of U is exactly the finite selector route $B \to S \to W' \to D \to R \to E'$. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite observation terminal synchronization`

Theorem 435.105 (Uniform Cauchy criterion Real-window terminal route)**.** *Every accepted* UniformCauchyCriterio *terminal* $\mathsf{Real}^{\uparrow}$ *route that consumes a displayed* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet and a displayed* RealCompletionExactBou *packet factors through the same finite* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *selector-budget, seal-classifier, witness-ledger, transport,* Cont, Pkg, *and* NameCert *rows. The consumer receives no quotient stream, selected limit, host real equality, ambient completeness, metric-completeness, or choice row.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket realwindowbudget terminal route`

Proof. Start with the local terminal route for $\mathsf{UniformCauchyCriterion}^{\uparrow}$. The terminal Real-route certificate of Definition 435.100 and the terminal seal classifier route of Definition 435.101 confine every accepted terminal read to the displayed finite route from I through E, with H, C, P, N as the structural rows.

Next consume the $\mathsf{RealWindowBudget}^{\uparrow}$ packet. Its finite-route visibility theorem, Definition 1164.5, exposes the finite window, dyadic readback, regular handoff, Real seal, selector-budget, disclosure, transport, replay, provenance, and local naming rows. The Real-completion handoff of Definition 1164.4 keeps Real and Completion consumers on that same finite route rather than allowing quotient streams, host equality, selected limits, or ambient completeness.

Now attach the RealCompletionExactBoundaryUp packet. Four-face exactness, Definition 1120.6, identifies the StreamName, RegSeqRat, DyadicRatCore, and terminal Real faces as the only completion faces after the seal, classifier, witness-ledger, and budget rows. The terminal-route pullback and non-escape results, Definition 1120.9 and Definition 1120.3, prevent the boundary from

adding quotient streams, selected limits, host real equality, choice, ambient completeness, metric completeness, or a second terminal route.

Combining the three packet surfaces gives one displayed terminal route. The UniformCauchyCriterion rows supply the accepted terminal classifier route, the RealWindowBudget rows expose the finite observation budget used by that route, and the RealCompletionExactBoundary rows certify the four completion faces without extra completion data. Hence the cross-chapter consumer factors through exactly the finite rows listed in the statement. □

Theorem 435.106 (UniformCauchyCriterion finite-family terminal budget exhaustion)**.** *For any accepted finite-family* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, the terminal* $\mathsf{Real}^{\uparrow}$ *route, terminal seal-classifier route, terminal* $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *classifier correspondence, finite-observation terminal synchronization, terminal quotient-refusal boundary, and* $\mathsf{RealWindowBudget}^{\uparrow}$ *terminal route exhaust every public terminal budget read. No public terminal consumer can export an additional host quotient, unbudgeted tail choice, selected limit, ambient completion witness, host real equality, or second stream-family route outside the displayed finite packet rows.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family terminal budget exhaustion`

Proof. Start with the terminal Real-route certificate and the terminal seal classifier route. By Definition 435.100 and Definition 435.101, every terminal Real-facing read stays on the finite route from I through E with H, C, P, N as structural rows.

Next use the terminal $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ classifier correspondence and finite-observation terminal synchronization. The correspondence identifies the regular-tail, finite-window, and Real classifier faces as projections of the same route, while Definition 435.104 pulls the terminal read through the displayed selector-budget rows rather than through hidden selector or completion data.

Now apply the terminal quotient-refusal boundary and the $\mathsf{RealWindowBudget}^{\uparrow}$ terminal route. The boundary sends quotient-style requests away from the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ packet surface, and Definition 435.105 confines budgeted Real and Completion reads to the finite StreamName, dyadic, regular, Real, selector-budget, seal-classifier, witness-ledger, transport, replay, provenance, and local NameCert rows.

These rows are finite projections of the same accepted packet surface. Since the cited terminal routes already account for the Real route, classifier route, regular-tail correspondence, finite-observation synchronization, quotient refusal, and Real-window budget, there is no missing public budget row into which a host quotient, unbudgeted tail choice, external completion witness, or second stream family could be inserted. □

Theorem 435.107 (Uniform Cauchy criterion finite-family budget seal composition)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted finite-family $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any* $\mathsf{RealWindowBudget}^{\uparrow}$ *consumer that preserves the endpoint route of* U*, the* $\mathsf{StreamName}^{\uparrow}$ *four-object exit route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *real-seal handoff, and the* $\mathsf{RealWindowBudget}^{\uparrow}$ *completion handoff factors through the single budgeted seal path*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

It cannot introduce a second $\mathsf{StreamName}^{\uparrow}$ *family, quotient stream, host real equality, selected limit, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family budget seal composition`

Proof. First apply the finite-family endpoint budget reflector and route lock, Definition 435.87 and Definition 435.88. They identify every endpoint-facing read of U with the displayed budgeted route and prevent a second public seal path through an independent stream family or detached completion coordinate.

Next compose the three external handoff surfaces. The $\mathsf{StreamName}^{\uparrow}$ side is the four-object exit route of Definition 126.500; the regular-rational side is the seal handoff of Definition 301.22; and the Real-window side is the completion handoff of Definition 1164.4. These surfaces read the finite StreamName, RegSeqRat, DyadicRatCore, and Real faces as projections of one displayed BEDC route rather than as independently chosen completion data.

The local nonescape boundary then removes the absent coordinates. By Definition 435.83, selected limits, quotient streams, host real equality, ambient completeness, and detached tail data are not rows of the accepted packet.

Finally use the terminal Real-window route of Definition 435.105. Since the endpoint route, StreamName exit, RegSeqRat seal handoff, and RealWindowBudget completion handoff have all been identified with the same rows $I, W, M, Q, T, E, H, C, P, N$, the consumer has only the single factorization path displayed in the statement. □

Theorem 435.108 (Uniform Cauchy criterion terminal seal envelope)**.** *Every terminal consumer of an accepted finite-family* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet, and the four-face boundary of* $\mathsf{RealCompletionExactBoundaryUp}$*. The envelope has no coordinate for quotient streams, host equality, selected limits, choice, host metric data, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket terminal seal envelope`

Proof. First use the finite-family budget seal composition and the Real-window terminal route. They identify the terminal route of the criterion with the single displayed path through the finite window, tolerance ledger, regular readback, and Real seal rows.

Next attach the Real-window budget and exact-boundary surfaces. The Real-window handoff supplies the budget packet, while four-face exactness identifies the StreamName, RegSeqRat, DyadicRatCore, and Real faces as the only completion-facing boundary.

Finally use the terminal quotient-refusal and non-escape clauses already cited above. They remove quotient streams, host equality, selected limits, choice, host metric data, and ambient completeness from the consumer surface, so the listed rows form the terminal envelope. □

Theorem 435.109 (Uniform Cauchy criterion completion Real correspondence)**.** *For every accepted finite-family* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, every completion-facing read of its terminal* $\mathsf{Real}^{\uparrow}$ *seal is the same read as the four-face* $\mathsf{RealCompletionExactBoundaryUp}$ *route over the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet, and structural* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. No host equality, quotient stream, selected limit, choice, host metric datum, or ambient completeness proof may mediate this correspondence.*

Proof. Start from Definition 435.108. It gives the completion-facing consumer a single route through the StreamName, RegSeqRat, DyadicRatCore, Real, and budget rows before the exact boundary is read.

Apply the Real-completion boundary pullback and four-face exactness. These results say that the terminal Real face is the fourth face of the same boundary whose earlier faces are the StreamName window, regular readback, and dyadic ledger.

The non-escape clauses then rule out the absent mediators. Since the accepted packet carries only the displayed finite rows and structural support, the completion read and the Real seal read are the same BEDC route. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket completion real correspondence`

Theorem 435.110 (Uniform Cauchy criterion terminal four-face window exactness)**.** *For every accepted finite-family* UniformCauchyCriterion$^{\uparrow}$ *packet, a terminal finite-window read is exact if and only if it factors through the displayed* StreamName$^{\uparrow}$ *window,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *ledger,* Real$^{\uparrow}$ *seal,* RealWindowBudget$^{\uparrow}$ *packet, and* RealCompletionExactBoundaryUp *four-face boundary. No quotient stream, host equality, selected limit, choice row, host metric datum, ambient completeness proof, or second completion face may mediate the read.*

Proof. The forward direction starts from the terminal seal envelope, Definition 435.108. It supplies the single terminal route through the StreamName window, regular readback, dyadic ledger, Real seal, RealWindowBudget packet, and exact-boundary face.

Use the completion Real correspondence, Definition 435.109, to identify the Real seal with the fourth face of the same exact boundary. The first three faces are the StreamName window, RegSeqRat readback, and DyadicRatCore ledger already present in the envelope.

For the reverse direction, apply finite-window coverage, Definition 435.111. Any read outside the displayed route would ask for one of the refused mediators or a second completion face, so every factorization through the listed four-face route is exactly the terminal finite-window read. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionTerminalFourFaceWindowExactness`

Theorem 435.111 (Uniform Cauchy criterion finite-window coverage)**.** *Every finite-window observation used by a terminal* UniformCauchyCriterion$^{\uparrow}$ *consumer is covered by the same* StreamName$^{\uparrow}$ *window and* RegSeqRat$^{\uparrow}$ *readback that feed the* DyadicRatCore$^{\uparrow}$ *ledger, the* Real$^{\uparrow}$ *seal, the* RealWindowBudget$^{\uparrow}$ *packet, and the* RealCompletionExactBoundaryUp *four-face boundary. A consumer that asks for a quotient stream, host equality, selected limit, choice principle, host metric datum, or ambient completeness row has left the accepted terminal envelope.*

Proof. Use the finite-observation terminal synchronization theorem to pull any finite observation back to the displayed selector route. The synchronization fixes the shared window, dyadic ledger, regular readback, and Real seal rows.

Then use the budget seal composition and terminal envelope theorem. They keep the pulled-back finite observation on the same window-to-seal route consumed by RealWindowBudgetUp and by the exact completion boundary.

The exclusion statement follows from the same quotient-refusal and non-escape boundaries. Those objects are not rows of the finite terminal envelope, so they cannot cover or refine an accepted finite-window observation. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite window coverage`

Theorem 435.112 (Uniform Cauchy criterion finite-family Rat fold handoff)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted finite-family $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. A finite family of shared-threshold windows transported through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{Rat}^{\uparrow}$ *order readback admits a single* BHist *lower-bound fold row consumed by the finite-family seal of* U. *The fold row is read through the same* $I, W, M, Q, T, E, H, C, P, N$ *route and cannot introduce quotient streams, selected host limits, host real equality, detached tail oracles, countable choice, or ambient completeness.*

Proof. First use the finite-family seal obligation package. It supplies the accepted rows $I, W, M, Q, T, E, H, C, P, N$ and identifies the shared-window seal route that every finite-family consumer must preserve.

Next read each threshold through the rational order surface. The $\mathsf{StreamName}^{\uparrow}$ window provides the finite family of windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback supplies regular tail data, the $\mathsf{Real}^{\uparrow}$ seal keeps the terminal face on the displayed route, and the $\mathsf{Rat}^{\uparrow}$ order readback exposes only rational lower-bound comparisons.

Now fold over the finite family. Using the same minimum-selector pattern employed by the compact-uniform-modulus chapters, each rational threshold comparison contributes one displayed lower-bound row, and finite iteration combines those rows into a single BHist lower-bound fold row.

Finally repack the fold row into the shared-window seal route. The route lock, nonescape ledger, and terminal seal envelope keep the fold on $I, W, M, Q, T, E, H, C, P, N$, so the finite-family seal consumes the lower-bound row without importing any absent completion or choice coordinate. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite family rat fold handoff`

Theorem 435.113 (UniformCauchyCriterion root tail coverage)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet inside a* BHist *inventory. Every accepted family tail comparison visible to a downstream consumer factors through the finite rows* $I, W, M, Q, T, H, C, P, N$ *and the shared dyadic tolerance row* Q *of* U.

In particular, the comparison is a displayed finite-tail read after the route

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T,$$

with H, C, P, N *supplying only transport, continuation, provenance, and local naming rows. No consumer-visible tail comparison can bypass the shared window family, introduce a second modulus schedule, or detach an unledgered dyadic tolerance.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root tail coverage`

Proof. First bind the threshold route. Apply Definition 435.10: every accepted family read reaches the same threshold schedule M before it can inspect the dyadic tolerance row Q.

Next expose the finite tail ledger. Apply Definition 435.9. The accepted comparison is therefore a displayed row of T over the finite index and window rows I, W.

The structural rows do not add another comparison coordinate. They replay the same BHist route through H, C, P, N, so the consumer sees only the finite tail row attached to the shared dyadic tolerance row. □

Theorem 435.114 (UniformCauchyCriterion root seal readback)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted UniformCauchyCriterion$^{\uparrow}$ *packet. Every* Real$^{\uparrow}$ *seal read of U factors through the displayed route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

The readback surface exposes the finite window, threshold, tolerance, tail, and seal rows only. It cannot expose quotient streams, selected limits, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root seal readback`

Proof. Start from the real-facing consumer. By Definition 435.57, a Real$^{\uparrow}$ seal read is exhausted by the displayed finite package $I, W, M, Q, T, E, H, C, P, N$.

Apply Definition 435.10 and Definition 435.9. These force the route from the family window to the seal handoff to pass through M, Q, T.

Finally use Definition 435.72. Since the accepted packet has no second seal path, quotient streams, selected limits, host real equality, and ambient completeness have no row through which to appear. □

Theorem 435.115 (UniformCauchyCriterion root downstream consumer surface)**.** *For an accepted* UniformCauchyCriterion$^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N),$$

the root downstream consumer surface for RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, DyadicTailBound$^{\uparrow}$, CauchyModulus$^{\uparrow}$, *and* Real$^{\uparrow}$ *is exactly the finite* BHist*-anchored package*

$$I, W, M, Q, T, E, H, C, P, N.$$

The StreamName$^{\uparrow}$ *and* CauchyModulus$^{\uparrow}$ *consumers read the shared family and threshold rows W, M over I; the* DyadicRatCore$^{\uparrow}$ *and* DyadicTailBound$^{\uparrow}$ *consumers read Q, T; the* RegSeqRat$^{\uparrow}$ *consumer reads the resulting uniform tail package; and the* Real$^{\uparrow}$ *consumer reads the seal row E. No downstream chapter may require quotient stream identity, selected family limits, host real equality, ambient completeness, or any row outside this package.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root downstream unblock`

Proof. First assemble the tail-facing surface. Apply Definition 435.113. The window, threshold, dyadic tolerance, and tail comparison data are already contained in the displayed finite rows.

Next pass to regular-rational consumers. By Definition 435.48, the RegSeqRat$^{\uparrow}$ side is exhausted by the same package $I, W, M, Q, T, E, H, C, P, N$.

Now read the real-facing boundary. Apply Definition 435.114. The Real$^{\uparrow}$ seal consumer reaches E only after the route through I, W, M, Q, T.

The remaining listed consumers are projections of these rows: StreamName$^{\uparrow}$ reads W, CauchyModulus$^{\uparrow}$ reads M, DyadicRatCore$^{\uparrow}$ reads Q, and DyadicTailBound$^{\uparrow}$ reads T. Therefore the finite package is the complete downstream surface for the root dependency. □

Theorem 435.116 (UniformCauchyCriterion root interface Lean companion)**.** *The root downstream surface of* UniformCauchyCriterion$^{\uparrow}$ *is machine-backed by the three RootInterfaces rows: root tail coverage, downstream seal interface, and threshold dependency inventory. These rows verify the same finite* BHist/Cont/Pkg^{sig} *interface exposed by the paper root obligations, with no quotient streams, selected limits, host* Real$^{\uparrow}$ *equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root interfaces lean companion`

Proof. Apply Definition 435.113. The tail-facing part of the RootInterfaces package is the same finite window, threshold, dyadic tolerance, and tail-comparison route used by downstream consumers.

Apply Definition 435.114. The seal-facing row reaches $\mathsf{Real}^{\uparrow}$ only through I, W, M, Q, T, E, so it cannot smuggle in quotient streams, selected limits, host $\mathsf{Real}^{\uparrow}$ equality, or ambient completeness.

Apply Definition 435.115. The remaining inventory rows are exactly the public downstream package $I, W, M, Q, T, E, H, C, P, N$. Thus the Lean companion rows verify the same finite $\mathsf{BHist}/\mathsf{Cont}/\mathsf{Pkg}^{\mathrm{sig}}$ interface that the paper surface exports. □

Theorem 435.117 (UniformCauchyCriterion root threshold schedule determinacy)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet in a* BHist *inventory. Every downstream threshold read of* U *is forced through the single displayed schedule row* M *after the finite index row* I *and the shared window-family row* W *have been read. No downstream consumer may insert a second threshold schedule, read* M *before* I, W*, or detach a threshold from the route recorded by* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root threshold schedule determinacy`

Proof. First read the root tail surface. By Definition 435.113, every downstream family-tail comparison already factors through the finite route I, W, M, Q, T.

Now apply Definition 435.10. The shared-threshold theorem identifies the schedule read as the same displayed row M for every accepted family window over I, W.

The structural rows only transport and replay that route. Since H, C, P, N do not add another schedule coordinate, any consumer-visible threshold read is the single row M reached after I, W. □

Theorem 435.118 (UniformCauchyCriterion root tolerance ledger exactness)**.** *For an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N),$$

every dyadic tolerance or tail comparison read visible at the root is exactly a displayed read of the Q, T *ledger after the schedule row* M*. Thus the dyadic tolerance surface is the finite ledger*

$$M \longmapsto Q \longmapsto T$$

over the already displayed rows I, W*, and it contains no unrecorded tolerance, detached tail bound, quotient-stream comparison, or selected limit.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root tolerance ledger exactness`

Proof. Start from the threshold route supplied by Definition 435.117. The consumer reaches the same row M after I, W before any dyadic tolerance can be inspected.

Apply Definition 435.9. It says that the tolerance and tail evidence is precisely the ledger pair Q, T over that schedule.

The root coverage theorem, Definition 435.113, rules out a second tail source at the same surface. Therefore every root tolerance or tail read is the displayed Q, T ledger and nothing outside it. □

Theorem 435.119 (UniformCauchyCriterion root seal consumer non-escape)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *seal consumer reaches the seal row* E *only through the route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

The consumer surface cannot read quotient streams, selected limits, host equality, ambient completeness, or any row outside the displayed BHist *package.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root seal consumer nonescape`

Proof. Read the seal through Definition 435.114. The seal-facing surface already factors through the finite rows $I, W, M, Q, T, E, H, C, P, N$.

Next use Definition 435.117 and Definition 435.118. These two root obligations force the path to E through the unique schedule row M and the exact Q, T tolerance ledger.

Finally apply Definition 435.57 and Definition 435.72. The real-facing consumer is exhausted by the displayed route, so quotient streams, selected limits, host equality, and ambient completeness have no coordinate through which to enter. □

Theorem 435.120 (UniformCauchyCriterion root shared tail meet)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose shared window-family schedule and tolerance ledger are consumed by a* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing seal read then factors through the same finite rows* $I, W, M, Q, T, E, H, C, P, N$ *and through the sibling shared-tail packet of chapter 560. The factorization does not claim RealUp completeness, quotient-stream equality, selected limits, host equality, or an ambient completeness principle.*

Proof. Start with root threshold schedule determinacy. Definition 435.117 forces every downstream threshold read through the displayed schedule row M after I, W.

Next use tolerance ledger exactness. By Definition 435.118, the dyadic tolerance and tail comparison data consumed after M are exactly the finite Q, T ledger.

Finally apply root seal consumer non-escape, Definition 435.119. The $\mathsf{Real}^{\uparrow}$-facing seal route reaches E only through I, W, M, Q, T and the structural rows H, C, P, N, while chapter 560 consumes the same shared-tail surface as a sibling packet rather than as a quotient or completeness theorem. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root shared tail meet`

Theorem 435.121 (Uniform Cauchy criterion tail-meet root export)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted root UniformCauchyCriterion$^{\uparrow}$ *packet whose family thresholds share a* RegularCauchyTailMeet$^{\uparrow}$ *row. Then the shared tail-meet row is exported through the same finite schedule row M, tolerance ledger Q, T, root seal consumer E, componentwise* hsame *row H, displayed* Cont *route row C, package provenance P, and local* NameCert *row N. The export is therefore a consumer-facing root packet over the sibling source chapter 560, not a quotient-stream comparison, selected limit, host equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket tail meet root export`

Proof. First read the root schedule. By Definition 435.117, every threshold request reaches the displayed schedule row M after the finite index row I and the shared window-family row W.

Next read the tolerance ledger. By Definition 435.118, the dyadic tolerance and tail comparison data downstream of M are exactly the finite ledger rows Q, T.

Now apply the shared-tail theorem, Definition 435.120. Its hypothesis identifies the same schedule and ledger surface as the one consumed by the RegularCauchyTailMeet$^{\uparrow}$ sibling, and chapter 560 supplies that sibling source.

Finally use root seal consumer non-escape, Definition 435.119. The seal-facing route reaches E only through I, W, M, Q, T and the structural rows H, C, P, N, so the exported tail-meet row remains inside the finite root schedule, tolerance ledger, displayed Cont, Pkg, and local NameCert surface. □

Theorem 435.122 (UniformCauchyCriterion root budget package)**.** *For an accepted* UniformCauchyCriterion$^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P, N),$$

the schedule determinacy and tolerance ledger exactness assemble the finite budget package over $I, W, M, Q, T, H, C, P, N$. The package records the unique threshold schedule, the exact dyadic tolerance ledger, the displayed transports, continuation routes, provenance, and local naming row, and it admits no detached tail bound, quotient-stream comparison, selected limit, host equality, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root budget package`

Proof. Begin with Definition 435.117. It forces every threshold read through the row M after I, W.

Apply Definition 435.118. The dyadic tolerance and tail comparison data are exactly the Q, T ledger downstream of that schedule.

The structural rows H, C, P, N only transport, replay, name provenance, and record the local certificate. Thus the finite budget package is the displayed union of the schedule row, tolerance ledger, and structural rows. □

Theorem 435.123 (UniformCauchyCriterion root downstream seal interface)**.** *Any downstream* Real$^{\uparrow}$ *seal consumer of an accepted* UniformCauchyCriterion$^{\uparrow}$ *packet reads the package only through*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

Any sibling RegularCauchyTailMeet$^{\uparrow}$ *consumption remains a finite shared-tail packet over the same displayed rows rather than a quotient-stream equality, selected limit, host equality, or completeness principle.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root downstream seal interface`

Proof. First use Definition 435.122. It supplies the finite budget package over $I, W, M, Q, T, H, C, P, N$.

Now apply Definition 435.119. The seal row E is reached only after the route I, W, M, Q, T has been consumed.

Finally use Definition 435.120. The sibling tail-meet consumer reads the same shared finite packet, so downstream seal use and tail-meet use remain inside the displayed interface. □

Theorem 435.124 (UniformCauchyCriterion finite-window Real seal extraction)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any* $\mathsf{Real}^{\uparrow}$ *seal consumer that also exposes a* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window surface factors through the finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

and through the sibling shared-tail packet of chapter 560. The extraction surface may read no quotient stream, selected limit, host equality, ambient completeness, or open-cover compactness row.

Proof. First assemble the finite budget package using Definition 435.122. This fixes the schedule, tolerance ledger, transport, continuation, provenance, and local naming rows as the displayed packet over $I, W, M, Q, T, H, C, P, N$.

Next apply Definition 435.119. The $\mathsf{Real}^{\uparrow}$ seal consumer can reach E only through the route I, W, M, Q, T, E, so quotient streams, selected limits, host equality, and ambient completeness have no readable coordinate on the seal side.

Then use Definition 435.120 and Definition 435.123. The $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ finite-window surface is the same sibling shared-tail packet recorded by chapter 560, and downstream seal use remains inside that displayed interface.

Thus the result is a finite-window extraction surface for Real-facing consumers. It is not a $\mathsf{Real}^{\uparrow}$ completeness theorem and does not assert a selected limit, quotient-stream equality, host equality, open-cover compactness, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite window real seal extraction`

Theorem 435.125 (UniformCauchyCriterion root budget seal eligibility)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. The packet is eligible for a* $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *seal consumer only through the displayed route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

and through the sibling shared-tail packet cited by chapter 560. The eligibility surface includes no quotient stream, selected limit, host equality, open-cover compactness, or ambient completeness coordinate.

Proof. First assemble the finite budget package using Definition 435.122. It fixes the displayed schedule, tolerance ledger, transport, continuation, provenance, and local naming rows over $I, W, M, Q, T, H, C, P, N$

Next apply Definition 435.123. Any downstream seal consumer reaches the seal row only through I, W, M, Q, T, E, while the sibling $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ use remains a finite shared-tail packet.

Finally use Definition 435.124. That theorem identifies the Real-facing extraction route with the same finite-window seal path and the shared-tail packet of chapter 560, and it refuses quotient streams, selected limits, host equality, open-cover compactness, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root budget seal eligibility`

Theorem 435.126 (UniformCauchyCriterion threshold seal budget factorization)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any* $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer that exposes* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window data factors through the same displayed finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

Here M is the unique threshold schedule certified by the root threshold row, and Q, T are the exact dyadic tolerance ledger rows certified by the root tolerance ledger. The consumer receives no quotient stream, selected limit, host equality, open-cover compactness, or ambient completeness row.

Proof. First use Definition 435.117 and Definition 435.118. These identify the threshold schedule M and the dyadic tolerance rows Q, T as determined finite data, not as choices made by the Real-facing consumer.

Next apply Definition 435.122. It repacks I, W, M, Q, T with the displayed H, C, P, N provenance rows, so the consumer-facing surface is carried through hsame, Cont, Pkg, and local NameCert provenance rather than through an ambient completion principle.

Then combine Definition 435.119, Definition 435.120, and Definition 435.124. The seal row E can only be reached after the finite route, while the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ windows are the shared tail-meet rows already exposed to Real-facing extraction.

Finally apply Definition 435.125. It is exactly the seal-consumer boundary for $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads. Since none of the listed excluded objects has a row in U or in the shared finite-window package, the consumer receives no quotient stream, selected limit, host equality, open-cover compactness, or ambient completeness data. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket threshold seal budget factorization`

Theorem 435.127 (UniformCauchyCriterion tail-fiber seal compatibility)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose threshold schedule is consumed by a* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *packet. Then the UniformCauchyCriterion root threshold route and the tail-fiber packet share the same finite route to the* $\mathsf{Real}^{\uparrow}$ *seal: the displayed schedule I, W, M, tolerance ledger Q, T, tail-fiber packet,* hsame *transport H,* Cont *replay C, provenance P, and local* NameCert *row N before the seal row E is read. The compatibility surface is not quotient-stream equality, selected limits, host equality, open-cover compactness, countable choice, or ambient completeness.*

Proof. First use root threshold schedule determinacy and root tolerance ledger exactness from Definition 435.117 and Definition 435.118. These fix I, W, M, Q, T as the finite threshold and tolerance route.

Next apply the root shared tail meet and root budget seal eligibility theorems, Definition 435.120 and Definition 435.125. They place the shared-tail consumer and the Real-facing seal row on the same displayed route.

Finally use the RegularCauchyTailFiber route coverage of Definition 893.10. It identifies the tail-fiber Real-and-Completion route before any Real seal is read, so the UniformCauchyCriterion packet contributes only the schedule, tolerance, transport, replay, provenance, and local naming rows listed above. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket tail fiber seal compatibility`

Theorem 435.128 (UniformCauchyCriterion Real-completion exit exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any current Phase Real and Completion consumer route through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *factors through the finite root route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

through the sibling $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *packet, and through the displayed* H, C, P, N *rows. The exit surface exports no quotient stream, selected limit, host equality, countable choice, open-cover compactness, or ambient completeness coordinate.*

Proof. First use Definition 435.117 and Definition 435.118. These fix the threshold schedule and dyadic tolerance ledger as the initial finite root route I, W, M, Q, T.

Next apply Definition 435.124. It places every Real-facing finite-window read at the seal row E after the same route and ties the stream and regular sequence surfaces to the sibling packet of chapter 560.

Finally combine Definition 435.125 with Definition 435.129. The completion consumer receives only the finite route, the sibling shared-tail packet, and the H, C, P, N rows, so quotient streams, selected limits, host equality, countable choice, open-cover compactness, and ambient completeness remain outside the accepted packet. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root real completion exit exhaustion`

Theorem 435.129 (UniformCauchyCriterion completion-functor budget handoff)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Before any* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *consumer reads* U*, the readable surface factors through the finite budget package over* $I, W, M, Q, T, H, C, P, N$*, then through the sibling shared-tail packet of chapter 560, and only then through the Real seal row* E*. The handoff route exposes no quotient stream, selected limit, host equality, countable choice, or ambient completeness coordinate.*

Proof. First assemble the root budget package. By Definition 435.122, the schedule, tolerance ledger, transport rows, continuation routes, provenance, and local naming row are exactly the finite packet over $I, W, M, Q, T, H, C, P, N$.

Next pass that package through the downstream seal interface. Definition 435.123 places every seal-facing read on the route I, W, M, Q, T, E and keeps the sibling $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ use on the same displayed rows.

Finally apply Definition 435.125. It identifies the permitted seal consumer surface with the displayed finite route and the shared-tail sibling of chapter 560. A $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ consumer therefore receives only that package-and-seal route, with no coordinate for quotient streams, selected limits, host equality, countable choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket completion functor budget handoff`

Theorem 435.130 (UniformCauchyCriterion regular tail-fusion factorization)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose shared tail surface is consumed by a tail-fusion completion functor. The functor-facing read of U must factor through the budget package of Definition 435.122, through the regular shared-tail source of chapter 560, and through the seal eligibility route of Definition 435.125. It is therefore a finite tail-fusion factorization, not a quotient-stream construction, selected-limit operation, host-equality transfer, countable-choice selection, or ambient-completeness claim.*

Proof. Begin with the finite package supplied by Definition 435.122. This fixes the threshold schedule M, the dyadic tolerance ledger Q, T, and the structural rows H, C, P, N before any fusion consumer can inspect the packet.

Now use Definition 435.120 together with chapter 560. The shared tail consumed by the functor is the displayed sibling packet over the same schedule and tolerance ledger, so tail fusion does not create a second stream identity or a selected limit.

Finally apply Definition 435.123 and Definition 435.125. These theorems place the Real-facing read at E after the finite budget route and keep every completion-functor access inside the displayed package. Host equality, countable choice, and ambient completeness remain absent because no row of U carries them. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket regular tail fusion factorization`

Theorem 435.131 (UniformCauchyCriterion Real completion budget lock)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. A* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer may read U only after the budget package, the regular shared-tail sibling of chapter 560, and the Real seal row E have been traversed in the displayed finite route. This locks the Real completion surface to $I, W, M, Q, T, E, H, C, P, N$ and does not assert Real completeness, quotient-stream equality, selected limits, host equality, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion budget lock`

Proof. First use Definition 435.129. It already factors any completion-functor read through the finite budget package, the sibling shared-tail packet, and the seal row E.

Next specialize the consumer to $\mathsf{RealCauchyCompletion}^{\uparrow}$. The specialization changes only the reader name; it adds no carrier row to U and no second path around the schedule, tolerance ledger, transport, continuation, provenance, or local naming rows.

Finally combine Definition 435.130 with Definition 435.125. The Real completion consumer is locked to the finite package and seal route, so any claim of Real completeness, quotient-stream equality, selected limits, host equality, countable choice, or ambient completeness lies outside the accepted packet. □

Theorem 435.132 (UniformCauchyCriterion selector-seal handoff lock)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer that exposes a selector-seal packet must first traverse the finite budget package of Definition 435.122, the shared-tail sibling of chapter 560, and the* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *route*

$$B \longmapsto W \longmapsto R \longmapsto L \longmapsto E$$

from chapter 1081. The handoff surface refuses quotient-stream equality, selected limits, host equality, countable choice, ambient completeness, and open-cover compactness.

Proof. Begin with the root budget package. By Definition 435.122, the accepted packet exposes only the finite rows $I, W, M, Q, T, H, C, P, N$ before any Real or Completion consumer can read a terminal seal.

Next apply Definition 435.125 and Definition 435.131. These results place the seal-facing read after the same finite budget package and after the shared-tail sibling of chapter 560.

Now use Definition 1081.11. A consumer that exposes a selector-seal packet is exhausted by the concrete route $B, W, R, L, E, H, C, P, N$, with $B \mapsto W \mapsto R \mapsto L \mapsto E$ as the terminal Real and Completion handoff.

The displayed rows are therefore exhausted by the UniformCauchyCriterion root budget, the regular shared-tail sibling, and the selector-seal packet. None of those rows carries quotient-stream equality, selected limits, host equality, countable choice, ambient completeness, or open-cover compactness, so no consumer can export such data from the handoff. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket selector seal handoff lock`

Theorem 435.133 (UniformCauchyCriterion tail-cofinality schedule handoff)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any* $\mathsf{RealCauchyCompletion}^{\uparrow}$*-facing consumer that reads the UniformCauchyCriterion root budget through* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *must factor through the sibling* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *route of chapter 681 before the Real seal row E is consumed. The resulting route exports no quotient stream, selected limit, host equality, countable choice, ambient completeness, or second tail-budget source.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket tail cofinality schedule handoff`

Proof. Begin with the root budget package. By Definition 435.122, the accepted packet exposes only the finite rows $I, W, M, Q, T, H, C, P, N$ before the seal row can be used.

Next apply Definition 435.131. A $\mathsf{RealCauchyCompletion}^{\uparrow}$-facing reader reaches E only after that finite package and the $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ sibling have already fixed the shared-tail surface.

Now pass through the sibling schedule. Definition 681.9 places every completion-facing seal read on the ordered $\mathsf{TailCofinalitySchedule}^{\uparrow}$ route, and Definition 681.10 identifies the shared-tail budget with the same finite window, dyadic ledger, regular readback, and Real seal rows.

The displayed coordinates are exhausted by the package rows of U, the $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ shared-tail read, the $\mathsf{TailCofinalitySchedule}^{\uparrow}$ schedule route, and the Real seal row. None of these coordinates carries quotient streams, selected limits, host equality, countable choice, ambient completeness, or another tail-budget source, so no completion-facing consumer can export such data from the handoff. □

Theorem 435.134 (UniformCauchyCriterion common-window exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every Real-facing finite-window consumer of U that also consumes the public budget route of Definition 697.40 factors through the same common window rows $I, W, M, Q, T, E, H, C, P, N$, through the sibling tail-meet packet of chapter 560, and through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal rows. Such a consumer cannot introduce a second window, a selected host limit, quotient-stream equality, a countable-choice schedule, a hidden tail oracle, host real equality, open-cover compactness, or an ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket common window exhaustion`

Proof. First assemble the root budget. By Definition 435.122, the accepted packet exposes its finite schedule, tolerance ledger, seal row, transport rows, continuation rows, provenance, and local naming row as the displayed surface $I, W, M, Q, T, E, H, C, P, N$.

Next pass to the Real-facing seal route. Definition 435.124 identifies the finite-window extraction with the same root rows and with the sibling tail-meet packet, while Definition 435.131 keeps the $\mathsf{RealCauchyCompletion}^{\uparrow}$ read after that budget package and the seal row E.

Finally compare with the diagonal selector budget. Definition 697.40 and Definition 697.28 route every diagonal Real-seal consumer through the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the $\mathsf{Real}^{\uparrow}$ seal before any selector rows are used. The two routes therefore meet on the displayed finite window and tail-meet handoff, leaving no coordinate for a second window, a selected host limit, quotient-stream equality, countable choice, a hidden tail oracle, host equality, open-cover compactness, or ambient completeness. □

Theorem 435.135 (UniformCauchyCriterion root threshold synchronizer readback)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet whose threshold route is consumed by a* $\mathsf{CauchySealBudgetSynchronize}$ *packet. Every synchronizer readback of the root route reads the rows in the order*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

The synchronizer rows sit upstream of the $\mathsf{Real}^{\uparrow}$ *seal row* E *as the finite schedule, tolerance, transport, continuation, provenance, and local naming surface of* U*. The readback supplies no quotient stream, selected limit, host equality, countable choice, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root threshold synchronizer readback`

Proof. Begin with Definition 435.117. It forces every threshold request through the single displayed schedule row M after the finite index row I and the shared window-family row W.

Next apply Definition 435.118. The consumer reaches the dyadic tolerance and tail comparison ledger only as the displayed Q, T rows downstream of M.

Now use Definition 435.122. The synchronizer-facing surface is the finite package over $I, W, M, Q, T, H, C, P, N$, with H, C, P, N recording only displayed transports, continuation routes, provenance, and the local naming row.

Finally apply Definition 435.125. It places the $\mathsf{Real}^{\uparrow}$ seal read at E after the threshold and tolerance route, and it keeps any seal-facing or sibling-tail consumption inside the same finite package. Thus the synchronizer readback orders $I, W, M, Q, T, E, H, C, P, N$ without introducing quotient streams, selected limits, host equality, countable choice, or ambient completeness. □

Theorem 435.136 (UniformCauchyCriterion window refinement seal route)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. If a transported window refinement is accepted over the same finite threshold and tolerance route, then the refinement preserves the packet rows and routes the refined window through the seal read before returning to the root readback. The visible route is still only*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N,$$

with the finite BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows carrying the transported refinement. No quotient stream, selected limit, host real equality, countable-choice schedule, or ambient completeness coordinate is created by the refined window.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket window refinement seal route`

Proof. First use the shared-threshold transport rows of the accepted packet. The transport keeps the refinement on the same I, W, M, Q, T surface, so the refined window does not become a second schedule or a second tolerance ledger.

Next apply Definition 435.122. The root package exposes the transported rows only as the finite surface $I, W, M, Q, T, H, C, P, N$, with H, C, P, N recording the displayed history transport, continuation route, provenance, and local name.

Then use Definition 435.125. The seal row E is read after the finite threshold and tolerance package, so the transported refinement reaches the seal through the same root budget.

Finally invoke Definition 435.135. The synchronizer readback returns from the seal-facing route to the ordered root route $I, W, M, Q, T, E, H, C, P, N$. Since every step has used only the displayed rows, the refined window has no coordinate from which to export quotient streams, selected limits, host equality, countable choice, or ambient completeness. □

Theorem 435.137 (UniformCauchyCriterion root synchronizer tail-meet lock)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted UniformCauchyCriterion$^{\uparrow}$ *packet consumed both by a* CauchySealBudgetSynchronizer$^{\uparrow}$ *packet and by a* RegularCauchyTailMeet$^{\uparrow}$ *sibling. Every synchronizer readback of the root threshold route must pass through the same* $I, W, M, Q, T, E, H, C, P, N$ *rows and through the sibling shared-tail packet before any completion-facing consumer can read the seal.*

Consequently the synchronizer is not a second tail source. It locks root threshold readback to the shared-tail meet, the finite budget package, and the seal-eligible route already displayed by U*.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root synchronizer tail meet lock`

Proof. Start with threshold schedule determinacy and tolerance ledger exactness. By Definition 435.117, every threshold request reaches the displayed schedule row M through I, W; by Definition 435.118, the downstream tolerance rows are exactly Q, T.

Next apply the shared-tail meet. Definition 435.120 identifies the tail surface consumed by the RegularCauchyTailMeet$^{\uparrow}$ sibling with the same root schedule and tolerance ledger, so the sibling read cannot supply an alternate tail packet.

Now use the root budget package and budget seal eligibility. Definition 435.122 packages $I, W, M, Q, T, H, C, P, N$ as the finite synchronizer-facing surface, and Definition 435.125 places the seal row E after that package.

Finally invoke Definition 435.135. The synchronizer readback is therefore the same ordered route $I, W, M, Q, T, E, H, C, P, N$ with the shared-tail sibling already fixed before any completion-facing consumer reads it. Quotient streams, selected limits, host equality, countable choice, and ambient completeness remain outside the packet. □

Theorem 435.138 (UniformCauchyCriterion StreamName RegSeqRat Real window lock)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted UniformCauchyCriterion$^{\uparrow}$ *packet consumed by the Phase Real and Completion route. Every such consumption factors through one finite window-lock surface: the* StreamName$^{\uparrow}$ *finite-window rows, the* RegSeqRat$^{\uparrow}$ *readback rows, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, the* Real$^{\uparrow}$ *seal row* E*, componentwise* hsame*, the displayed* Cont *route, the package row* Pkg*, and the local* NameCert *row.*

Thus the Real-facing consumer reads U *only through the same finite threshold, tolerance, seal, history, continuation, provenance, and local-name rows. It cannot add quotient-stream equality, a selected host limit, countable choice, a second tolerance ledger, or an ambient completeness principle.*

Proof. Start with the root budget package. By Definition 435.122, the accepted packet exposes the finite synchronizer-facing surface $I, W, M, Q, T, H, C, P, N$, where H carries the componentwise hsame transport, C carries the displayed Cont route, P carries the package row, and N carries the local NameCert row.

Next apply Definition 435.120. The StreamName$^{\uparrow}$ finite-window rows and RegSeqRat$^{\uparrow}$ readback rows meet the same shared-tail packet, so the completion route has no second stream source or second readback surface.

Now use Definition 435.124. The $\mathsf{Real}^{\uparrow}$ seal row E is extracted only after the displayed threshold and tolerance ledger; the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance data therefore remains the same finite ledger already carried by Q, T.

Finally invoke Definition 435.137. The synchronizer locks the root threshold route to the shared-tail meet before any Phase Real or Completion consumer reads the seal. Since each step stays inside the displayed rows of U, quotient-stream equality, selected host limits, countable choice, and ambient completeness have no coordinate in the window-lock surface. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket streamname regseqrat real window lock`

Theorem 435.139 (UniformCauchyCriterion Real seal frontier lock)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every Phase Real and Completion consumer of* U *factors through the root budget package, the regular shared-tail sibling, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route, and the final* $\mathsf{Real}^{\uparrow}$ *seal row* E*. This is the only completion-facing surface exported by* U*: it exports no quotient-stream equality, selected host limit, host equality, countable choice, second tolerance ledger, open-cover compactness, or ambient completeness coordinate.*

Proof. First use Definition 435.122. It exposes the accepted packet only as the finite root package over $I, W, M, Q, T, H, C, P, N$, with the threshold schedule, dyadic tolerance ledger, transport rows, continuation route, provenance, and local naming row already fixed before any seal-facing read occurs.

Next apply Definition 435.131. A Phase Real or Completion consumer reaches the final seal row E only after the budget package and the regular shared-tail sibling have been traversed, so the consumer cannot bypass the root package by selecting a host limit or a quotient stream.

Now combine Definition 435.137 with Definition 435.138. These results identify the shared-tail meet, the $\mathsf{StreamName}^{\uparrow}$ finite-window rows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback rows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the $\mathsf{CauchyLimitSeal}^{\uparrow}$ route with the same finite window that ends at the $\mathsf{Real}^{\uparrow}$ seal row E.

The carrier coordinates of U are therefore exhausted by $I, W, M, Q, T, E, H, C, P, N$ and by the displayed sibling routes already attached to those rows. None of those coordinates carries quotient-stream equality, a selected host limit, host equality, countable choice, a second tolerance ledger, open-cover compactness, or ambient completeness, so no Phase Real or Completion consumer can export such data from the packet. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real seal frontier lock`

Theorem 435.140 (UniformCauchyCriterion Real completion finite budget envelope)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every Phase Real and Completion consumer that reads the UniformCauchyCriterion root route through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, and the final* $\mathsf{Real}^{\uparrow}$ *seal must factor through the concrete* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *selector-seal packet of chapter 1081 before any terminal completion-facing read.*

The finite envelope is the root budget package, the regular shared-tail sibling, the selected StreamName$^{\uparrow}$ *window, the* RegSeqRat$^{\uparrow}$ *readback, the* CauchyLimitSeal$^{\uparrow}$ *handoff, the* RealCompletionSelectorSeal$^{\uparrow}$ *route, and the final* Real$^{\uparrow}$ *seal row. It exports no quotient-stream equality, selected host limit, host equality, countable choice, second tolerance ledger, open-cover compactness, detached selector, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionRealCompletionFiniteBudgetEnvelope`

Proof. Begin with the finite root package. Definition 435.122 displays the rows $I, W, M, Q, T, H, C, P, N$, and Definition 435.131 places every Real completion read after that package, the regular shared-tail sibling, and the seal row E.

Next use Definition 435.138. It identifies the Phase Real and Completion read with the same StreamName$^{\uparrow}$ window, RegSeqRat$^{\uparrow}$ readback, DyadicRatCore$^{\uparrow}$ tolerance ledger, and final Real$^{\uparrow}$ seal route. Definition 435.139 then adds the CauchyLimitSeal$^{\uparrow}$ handoff and confirms that this is the whole completion-facing frontier exported by U.

Finally apply Definition 1081.11. The selector-seal packet is terminal for the concrete Real and Completion handoff through the selector budget, selected window, readback, limit seal, terminal Real endpoint, and structural rows. Therefore any terminal completion-facing read of the UniformCauchyCriterion root route factors through that packet, and the packet acts as the terminal concrete handoff rather than as an ambient completeness principle. □

Theorem 435.141 (UniformCauchyCriterion diagonal selector seal pullback)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted UniformCauchyCriterion$^{\uparrow}$ *packet, and let D be an accepted* DiagonalLimitCompatibility$^{\uparrow}$ *root-selector read. Suppose the two reads display the same* StreamName$^{\uparrow}$ *window, the same* RegSeqRat$^{\uparrow}$ *readback, the same* DyadicRatCore$^{\uparrow}$ *tolerance ledger, the same* CauchyLimitSeal$^{\uparrow}$ *handoff, and the same terminal* Real$^{\uparrow}$ *seal row. Then every Phase Real and Completion terminal read factors through the same* RealCompletionSelectorSeal$^{\uparrow}$ *selector-seal packet.*

Thus the UniformCauchyCriterion route and the diagonal selector route have one terminal pullback surface. No quotient stream, selected host limit, host equality, countable choice, second tolerance ledger, detached selector, or ambient completeness coordinate can distinguish the two routes.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket diagonal selector seal pullback`

Proof. First apply Definition 435.140. The UniformCauchyCriterion terminal read is forced through the finite root budget package, the selected StreamName$^{\uparrow}$ window, the RegSeqRat$^{\uparrow}$ readback, the DyadicRatCore$^{\uparrow}$ ledger, the CauchyLimitSeal$^{\uparrow}$ handoff, the terminal Real$^{\uparrow}$ row, and the concrete RealCompletionSelectorSeal$^{\uparrow}$ packet.

Next use Definition 646.215. Since U and D share the displayed window, readback, ledger, handoff, and terminal seal rows, the diagonal root-selector read pulls back to the same completion-facing selector surface.

Now apply Definition 646.218. The selector budget is exactly the displayed finite route, so the diagonal read cannot replace the shared rows by a detached selector, a second tolerance ledger, a quotient stream, or a selected host limit.

Finally invoke Definition 1081.11. The RealCompletionSelectorSeal$^{\uparrow}$ packet is terminal for the selector-to-seal handoff, so both routes factor through the same terminal selector-seal packet before

any Phase Real or Completion terminal read is available. Host equality, countable choice, and ambient completeness remain outside that packet. □

Theorem 435.142 (UniformCauchyCriterion selector seal exact pullback)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every Phase Real and Completion consumer that reads the* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *selector-seal row of chapter 1081 from* U *factors first through the finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

and then through that sibling selector-seal packet.

The pullback is exact on the displayed schedule, tolerance ledger, terminal $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *rows, the* Cont *route, the* Pkg *row, and the local* NameCert *row. It therefore exports no quotient-stream equality, selected limit, host equality, countable choice, detached selector, or ambient Real completeness coordinate.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket selector seal exact pullback`

Proof. Begin with the finite root package. Definition 435.122 exposes $I, W, M, Q, T, H, C, P, N$ as the only schedule, tolerance, history, continuation, provenance, and local-name rows available to a consumer of U.

Next apply Definition 435.132 and Definition 435.131. These locks place the selector-seal handoff and every Real completion read after the same root budget package and after the seal row E.

Now use Definition 435.141. The diagonal selector route and the UniformCauchyCriterion route share one terminal selector-seal pullback surface whenever the window, readback, tolerance ledger, handoff, and terminal seal rows are the displayed rows of U.

Finally invoke the sibling carrier of chapter 1081, using Definition 1081.11. The sibling consumes exactly the same finite selector-to-seal row, so the pullback preserves the schedule, tolerance ledger, Real seal, hsame, Cont, Pkg, and NameCert rows without introducing quotient-stream equality, selected limits, host equality, countable choice, detached selectors, or ambient Real completeness. □

Theorem 435.143 (UniformCauchyCriterion root threshold seal roundtrip)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *root threshold packet. Suppose a finite Phase Real and Completion read of* U *passes through the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *endpoint seal, the* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *finite budget envelope, the diagonal selector seal pullback, and the selector-seal exact pullback displayed in this chapter.*

Then the route that reads from the UniformCauchyCriterion root threshold into the $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *selector seal and back to the UniformCauchyCriterion root is a finite threshold-seal roundtrip. The outgoing selector route and the returning root route display the same* BHist *window, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the same terminal* $\mathsf{Real}^{\uparrow}$ *endpoint row under the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *classifier. No quotient-stream equality, selected host limit, host equality, countable choice, detached selector, second tolerance ledger, open-cover compactness, or ambient completeness coordinate is created by the roundtrip.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket root threshold seal roundtrip`

Proof. First bind the three visible endpoint names. Definition 435.138 identifies the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, and the terminal $\mathsf{Real}^{\uparrow}$ seal row exported by U as one displayed Phase Real and Completion window.

Next apply Definition 435.140. Any completion-facing read of the root route must pass through the finite root budget package, the regular shared-tail sibling, the selected window, the readback row, the $\mathsf{CauchyLimitSeal}^{\uparrow}$ handoff, the $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ selector-seal packet, and the terminal $\mathsf{Real}^{\uparrow}$ endpoint row. This fixes the finite budget row used by both directions of the route.

Now use Definition 435.141 and Definition 435.142. The diagonal selector route and the selector-seal route pull back to the same displayed selector surface, and exactness preserves the schedule, tolerance ledger, terminal seal, componentwise hsame rows, Cont route, Pkg row, and local NameCert row.

Finally return to the root threshold synchronizer. Definition 435.135 supplies the root readback for the displayed threshold window, and Definition 435.137 makes that readback deterministic on the shared finite tail. Since the outgoing selector read and the returning root read are forced through the same finite rows, they expose the same BHist window, the same $\mathsf{RegSeqRat}^{\uparrow}$ readback row, and the same terminal $\mathsf{Real}^{\uparrow}$ endpoint row under the chapter classifier. The excluded host-level and completeness coordinates remain outside the finite packet. □

Theorem 435.144 (UniformCauchyCriterion common-window diagonal-selector coherence)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose its root threshold seal factors through a* $\mathsf{DiagonalTailSelector}^{\uparrow}$ *source schedule and through a* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *shared-window route, with the displayed common window, diagonal selector row, and refined modulus row all read from the same finite route of* U*.*

Then the common window, the diagonal selector row, and the refined modulus row determine the same $\mathsf{Real}^{\uparrow}$ *seal budget. The resulting consumer surface exports no additional selector row, no second tolerance ledger, no host-level selected limit, no quotient-stream equality, no countable-choice row, and no ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.RootThresholdAndSealRefinement.UniformCauchyCriterionPack common window diagonal selector coherence`
Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket common window diagonal selector coherence`

Proof. First apply Definition 435.134. The accepted packet exposes the common window, readback, tolerance ledger, terminal seal, componentwise hsame route, Cont route, Pkg row, and local NameCert row as one finite surface.

Next use Definition 435.141. The diagonal selector route can reach the terminal seal only through the displayed selector pullback surface, so it cannot detach a selector from the common window.

Now apply the $\mathsf{CauchyModulusRefinement}^{\uparrow}$ shared-window route, using Definition 885.155 and Definition 885.87. The refined modulus row keeps the selected window, tolerance readback, and $\mathsf{Real}^{\uparrow}$ seal on the same public handoff route.

Finally invoke Definition 435.143. The root threshold route returns to the same UniformCauchyCriterion root rows after the selector-seal handoff. Hence the common window, diagonal

selector row, and refined modulus row determine one $\mathsf{Real}^{\uparrow}$ seal budget, while all detached selector, choice, quotient, selected-limit, and ambient-completeness coordinates remain outside the exported packet. □

Theorem 435.145 (UniformCauchyCriterion current Phase Real exit consumer exhaustion)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *root threshold packet. Every current Phase Real and Completion consumer route through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *factors through the finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

The exported surface is the root budget package, the finite-window Real seal extraction, the selector-seal exact pullback, and the Real completion finite-budget envelope displayed in this chapter. It exports no quotient stream, selected host limit, countable choice, host equality, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket phase real exit consumer exhaustion`

Proof. First assemble the root budget package. By Definition 435.122, the accepted packet exposes only the finite schedule, tolerance ledger, transport, continuation, provenance, and local naming rows $I, W, M, Q, T, H, C, P, N$ before any Real-facing seal read occurs.

Next apply finite-window Real seal extraction and the StreamName–RegSeqRat window lock. Definition 435.124 and Definition 435.138 place the $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the terminal $\mathsf{Real}^{\uparrow}$ seal row on the same displayed route ending at E.

Now use the selector-seal exact pullback. Definition 435.142 keeps the selector-facing read on the same schedule, tolerance ledger, terminal seal, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows.

Finally apply Definition 435.140 and the roundtrip theorem above. Every Phase Real and Completion consumer is exhausted by the finite route through $I, W, M, Q, T, E, H, C, P, N$ and the named sibling selector-seal packet, leaving no coordinate for quotient streams, selected host limits, countable choice, host equality, or ambient completeness. □

Theorem 435.146 (UniformCauchyCriterion StreamName RegSeqRat seal synchronization)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *root threshold packet. The* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row used by any current Phase Real and Completion consumer are synchronized by the same finite route* $I, W, M, Q, T, E, H, C, P, N$*. No consumer can replace one of these rows by a second stream source, second regular readback, selected host limit, quotient-stream equality, host equality, countable choice, or ambient completeness coordinate.*

Proof. Start with Definition 435.138. It identifies the $\mathsf{StreamName}^{\uparrow}$ finite-window rows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback rows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the $\mathsf{Real}^{\uparrow}$ seal row as one completion-facing window-lock surface.

Next use Definition 435.137. The root synchronizer ties that window-lock surface to the shared finite tail and prevents a second stream or readback source from entering the route.

Finally apply Definition 435.143. The outgoing selector route and returning root route display the same BHist window, the same $\mathsf{RegSeqRat}^{\uparrow}$ readback row, and the same terminal $\mathsf{Real}^{\uparrow}$ endpoint row under the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ classifier. The synchronization row used by Definition 435.145 is therefore exactly the displayed finite route $I, W, M, Q, T, E, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket regseqrat streamname seal synchronization`

Theorem 435.147 (UniformCauchyCriterion selector seal synchronization)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *root threshold packet. The* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *route, and terminal* $\mathsf{Real}^{\uparrow}$ *seal are synchronized by the same finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

No consumer may replace the selector-seal row by quotient-stream equality, selected host limit, countable choice, a second tolerance ledger, or ambient completeness.

Proof. Start with the stream and readback rows. Definition 435.146 places the $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal on the same route $I, W, M, Q, T, E, H, C, P, N$.

Next attach the selector-seal row. By Definition 435.142, every selector-seal read from U first passes through the same schedule, tolerance ledger, terminal seal, transport, continuation, provenance, and local naming rows.

Now use the finite budget envelope. Definition 435.140 keeps the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{CauchyLimitSeal}^{\uparrow}$ handoff, $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ route, and terminal $\mathsf{Real}^{\uparrow}$ endpoint inside the displayed Phase Real and Completion route.

Finally apply Definition 1081.11. The sibling selector-seal packet is terminal for the concrete selector-to-seal handoff, so a consumer has no coordinate from which to substitute quotient-stream equality, selected host limits, countable choice, a second tolerance ledger, or ambient completeness for the selector-seal row. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket selector seal synchronizatio`

Theorem 435.148 (UniformCauchyCriterion Phase Real route iff)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. A current Phase Real and Completion consumer through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *is admissible exactly when it preserves the ordered finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N,$$

including the selector-seal row whenever that row is present. Equivalently, the consumer may read only the root budget package, the finite-window Real seal extraction, the StreamName–RegSeqRat synchronization rows, and the selector-seal synchronization rows displayed for U.

This criterion exports no quotient streams, selected host limits, host equality, countable choice, second tolerance ledgers, open-cover compactness, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket phase real route iff`

Proof. For the forward direction, begin with the accepted packet. Definition 435.122 supplies the root budget package, so the consumer starts from the displayed finite schedule, tolerance ledger, transport, continuation, provenance, and local naming rows.

Next apply Definition 435.124. The Real-facing seal is extracted from the same finite window, with no extra stream carrier or host-limit coordinate.

Now use Definition 435.146. It synchronizes the $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and terminal $\mathsf{Real}^{\uparrow}$ seal on the ordered route $I, W, M, Q, T, E, H, C, P, N$.

Finally, when the selector-seal row is present, apply Definition 435.147. The selector-facing handoff is therefore part of the same finite route, not an additional consumer coordinate.

For the reverse direction, suppose the consumer preserves exactly the displayed ordered route and the selector-seal row when present. The preserved root rows give the consumer surface accepted by Definition 435.122; the preserved finite Real seal gives the surface accepted by Definition 435.124; and the preserved synchronization rows give the surfaces accepted by Definition 435.146 and Definition 435.147.

These are exactly the current Phase Real and Completion consumer locks already available in the chapter. Since every displayed row is finite and packet-local, the reverse construction has no place to introduce quotient streams, selected host limits, host equality, countable choice, second tolerance ledgers, open-cover compactness, or ambient completeness. □

Theorem 435.149 (UniformCauchyCriterion Phase Real endpoint determinacy)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Any current Phase Real and Completion consumer preserving the finite ordered route through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *has a unique displayed endpoint row: the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *reached after the same schedule* M*, tolerance ledger* Q, T*, transport* H*, route* C*, provenance* P*, and local name* N*.*

Conversely, preserving that endpoint row together with the selector-seal row is exactly the endpoint component of the admissible Phase Real route of Definition 435.148. The endpoint determination exposes no quotient stream, selected host limit, host equality, countable choice, second tolerance ledger, open-cover compactness, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket phase real endpoint determinacy`

Proof. First read the accepted packet through Definition 435.122. The root budget package fixes the finite schedule, tolerance ledger, transport, continuation route, provenance, and local naming rows available to every consumer.

Next apply Definition 435.124. The terminal $\mathsf{Real}^{\uparrow}$ seal is extracted from the same finite window, so an endpoint consumer has no separate stream quotient, selected limit, or host-equality row from which to choose another endpoint.

Now synchronize the intermediate route. The StreamName–RegSeqRat synchronization of Definition 435.146 and the selector-seal synchronization of Definition 435.147 place the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows on the same displayed packet $I, W, M, Q, T, E, H, C, P, N$.

Finally use Definition 435.148. The forward direction gives uniqueness of the displayed terminal row for every admissible Phase Real and Completion consumer. The reverse direction reads the same endpoint and selector-seal rows already displayed in the packet; it does not invoke a new completion principle, countable choice, open-cover compactness, a second ledger, or ambient completeness. □

Theorem 435.150 (UniformCauchyCriterion RealCompletionExactBoundary handoff)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. A current Phase Real and Completion consumer preserving the displayed route through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and terminal* $\mathsf{Real}^{\uparrow}$ *determines a* $\mathsf{RealCompletionExactBoundaryUp}$ *handoff exactly when the seal, classifier, witness-ledger, synchronizer, StreamName, RegSeqRat, DyadicRatCore, terminal Real, transport, continuation, provenance, and local naming rows are displayed as the finite exact-boundary packet.*

Equivalently, the accepted consumer can pass from the UniformCauchyCriterion route lock to the RealCompletionExactBoundary surface precisely through the finite rows already visible on the Phase Real route. It does not introduce quotient stream equality, a selected host limit, host real equality, countable choice, metric completeness, ambient completeness, or an additional terminal consumer coordinate.

Proof. First use Definition 435.148. It identifies the admissible Phase Real and Completion consumer with preservation of the displayed route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$.

Next apply Definition 435.149. The endpoint row is the terminal $\mathsf{Real}^{\uparrow}$ seal reached through the same schedule, tolerance ledger, transport, continuation route, provenance, and local name, so the consumer has a single terminal Real row to hand forward.

Now read the same endpoint as an exact-boundary consumer. Definition 1120.13 identifies terminal Real consumption with the finite exact-boundary rows, including seal, classifier, witness-ledger, synchronizer, StreamName, RegSeqRat, DyadicRatCore, terminal Real, transport, continuation, provenance, and local naming.

Finally apply Definition 1120.14. Since the exact-boundary packet has no coordinate for quotient streams, selected host limits, host real equality, countable choice, metric completeness, or ambient completeness, the handoff exists exactly at the displayed finite packet and nowhere outside it. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion exact boundary handoff`

Theorem 435.151 (UniformCauchyCriterion overlap roundtrip confluence)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose two refined finite-window reads of* U *overlap on a common tail and each read passes through the diagonal selector row, the selector-seal exact pullback, and the root threshold seal roundtrip displayed in this chapter.*

Then the two reads determine the same finite Phase Real and Completion route

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

In particular, the overlap cannot produce a second selector, a second tolerance ledger, a second selector-seal route, quotient-stream equality, a selected host limit, countable choice, host equality, or an ambient completeness coordinate.

Proof. Start with the overlapping refined windows. By Definition 435.71, the common tail forces both refinements to read the same tail ledger row and the same seal-facing route of U.

Next attach the diagonal selector surface. Definition 435.144 identifies the common window, diagonal selector row, and refined modulus row as one $\mathsf{Real}^{\uparrow}$ seal budget, so neither refined read can detach a selector or tolerance ledger from that budget.

Now pass through the selector-seal interface. Apply Definition 435.147 and Definition 435.143. The outgoing selector route and the returning root route display the same BHist window, the same $\mathsf{RegSeqRat}^{\uparrow}$ readback row, and the same terminal $\mathsf{Real}^{\uparrow}$ endpoint row.

Finally use Definition 435.148. Since both refined reads preserve exactly the displayed ordered route and the selector-seal row when present, they are admissible through the same finite Phase Real and Completion route. The excluded quotient, host-limit, choice, host-equality, and ambient-completeness coordinates never appear in the packet-local surface, and hence cannot distinguish the two overlap reads. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket overlap roundtrip confluence`

Theorem 435.152 (UniformCauchyCriterion root threshold exhaustion)**.** *Every accepted root threshold read for a* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer is exhausted by the displayed threshold schedule, tolerance ledger, shared-tail meet, selector-seal synchronization, and overlap roundtrip rows already named in this chapter. In packet form, the read is the finite route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

It cannot import a selected limit, quotient stream equality, ambient completeness principle, countable-choice selector, or standard bridge row.

Proof. Start with the schedule and tolerance rows. By Definition 435.117, every threshold request reaches the displayed schedule row M through I, W; by Definition 435.118, the downstream tolerance rows are exactly Q, T.

Attach the shared-tail and seal rows. The shared-tail meet rows in this chapter feed the same finite route into Definition 435.147, which synchronizes the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, selector-seal, and terminal $\mathsf{Real}^{\uparrow}$ faces over $I, W, M, Q, T, E, H, C, P, N$.

Finally apply Definition 435.151. Overlapping refined reads return to the same finite Phase Real and Completion route, so the threshold consumer has no remaining coordinate for selected limits, quotient streams, ambient completeness, countable choice, or a standard bridge row. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.RootThresholdAndSealRefinement.UniformCauchyCriterionPack root threshold exhaustion`

Theorem 435.153 (UniformCauchyCriterion common-tail uniform criterion bridge)**.** *Let P be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet, let T_0 and T_1 be two certified cofinal tail shifts of the* $\mathsf{StreamName}^{\uparrow}$ *schedule carried by P, and let the two shifted reads land in a common-tail window packet of Definition 301.180 with common refinement W_*. Suppose the finite-request* $\mathsf{Real}^{\uparrow}$ *seal pullback of the common-tail packet is the surface of Definition 301.184. If the displayed rows of that pullback align with an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet*

$$U = (I, W, M, Q, T, E, H, C, P_U, N),$$

so that W_* is read as the shared family window W, the dyadic endpoint and distance rows are read through the tolerance row Q, the common-tail comparison rows are read through the tail

ledger T, and the seal-source row is read through E, then the same finite rows determine the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *route*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

Thus the RegSeqRat common-tail pullback recovers a uniform finite-family criterion through the shared window W, threshold schedule M, tolerance row Q, tail ledger T, and seal row E.

The bridge is only a finite BEDC packet comparison. It asserts no quotient stream, selected limit, host real equality, ambient completeness principle, or second $\mathsf{Real}^{\uparrow}$ *seal route.*

Proof. First read the RegSeqRat side. By Definition 301.184, the two cofinal tail reads and their common refinement expose exactly the finite source surface consisting of the $\mathsf{StreamName}^{\uparrow}$ rows, $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint, radius, and distance rows, $\mathsf{RegSeqRat}^{\uparrow}$ classifier and regularity rows, $\mathsf{Real}^{\uparrow}$ seal-source rows, componentwise hsame, displayed Cont, package provenance, and local $\mathsf{NameCert}$ provenance.

Next impose the row alignment with U. The common refinement W_* is read as the shared family window W, the dyadic rows are read as the tolerance row Q, the common-tail comparison rows are read as the finite ledger T, and the seal-source row is read as E. The finite family ledger I and the shared schedule row M are therefore the uniform criterion coordinates through which those rows are consumed.

Apply Definition 435.115. Once the aligned rows are viewed as a $\mathsf{UniformCauchyCriterion}^{\uparrow}$ packet, every downstream $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumer is exhausted by the finite package $I, W, M, Q, T, E, H, C, P_U, N$.

Now use Definition 435.27. The Real-facing route and the shared finite-window route agree on W, Q, T, E, H, C, P_U, N, so the common-tail comparison rows cannot split into a separate tail selector outside the uniform packet.

Finally apply Definition 435.28. It extracts the Real-seal route from the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces of W, T, Q, E. The non-escape clauses in the RegSeqRat pullback and the UniformCauchyCriterion extraction remove quotient streams, selected limits, host real equality, ambient completeness, hidden completion carriers, and second seal routes, leaving exactly the uniform finite-family criterion route through W, M, Q, T, E. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket common tail uniform criterion bridge`

Theorem 435.154 (UniformCauchyCriterion tail-budget bridge)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. The packet exports a Real-facing tail-budget bridge exactly when the displayed Real-facing route factors through the same named sibling rows:*

$$\mathsf{CauchyTailModulusSeal}^{\uparrow} \longrightarrow \mathsf{RealWindowBudget}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

Equivalently, every Real-completion or compact-uniform consumer of U receives the tail budget only by reading the shared window route, the seal route, the finite-tail-filter alignment, the Real-completion window exhaustion, and the public non-escape route already named in this chapter. The bridge exports no quotient stream, selected limit, countable-choice row, detached window, or ambient completeness object.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket tail budget bridge`

Proof. For the forward direction, start with an exported Real-facing tail-budget read. The shared-window obligation and shared-threshold transport force the read through the common I, W, M, Q, T surface before the seal row can be inspected.

Next attach the seal side. The seal-route obligation and Real-seal handoff place every $\mathsf{Real}^{\uparrow}$ endpoint behind the same finite route, while the finite-tail-filter alignment identifies the visible tail ledger with the cofinal-tail sibling surface rather than with an external selector.

The named sibling rows are then read in order. The $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ row supplies the tail-modulus seal, the $\mathsf{RealWindowBudget}^{\uparrow}$ row keeps the budget attached to the displayed finite window, the $\mathsf{StreamName}^{\uparrow}$ row supplies the common window, the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies regular readback, the $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the tolerance ledger, and the $\mathsf{Real}^{\uparrow}$ row supplies the terminal seal.

For the reverse direction, assume the displayed consumer route already factors through those six sibling rows. The Real-completion window exhaustion theorem keeps the completion-facing request inside the same finite window and tolerance budget, and the public non-escape export prevents any off-packet analytic coordinate from being added.

Repack the route through H, C, P, N. The accepted packet therefore exports exactly the Real-facing tail-budget bridge described above, and any attempted route through quotient streams, selected limits, countable choice, detached windows, or ambient completeness is excluded by the same public boundary. □

Theorem 435.155 (UniformCauchyCriterion CauchyLimitSeal sibling route)**.** *The* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *finite-family tail route is the sibling consumer surface for chapter 386, chapter 301, and chapter 38. For an accepted packet*

$$U = (I, W, M, Q, T, E, H, C, P, N),$$

the shared window family W, the single threshold schedule M, the dyadic tolerance row Q, and the tail ledger T feed the $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route before the* $\mathsf{Real}^{\uparrow}$ *seal handoff E is read. The route exports no quotient stream family, selected limit, host real equality, or ambient completeness object.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket cauchy limit seal sibling route`

Proof. Project U through Definition 435.1. The only source rows available to a tail consumer are the finite family ledger I, the shared $\mathsf{StreamName}^{\uparrow}$ windows W, the shared threshold schedule M, the dyadic row Q, the tail ledger T, and the structural rows H, C, P, N.

The tail comparison itself is pinned down by Definition 435.9. It forces every accepted comparison to pass through I, W, M, Q, T before any real-facing row can be consumed.

The regular-rational readback is the same finite surface by Definition 435.11. Thus the $\mathsf{RegSeqRat}^{\uparrow}$ sibling sees the shared-window and tail-ledger route, not a quotient stream or selected family limit.

Finally apply Definition 435.4. The seal row E is reached only after the displayed family-tail route has been read, so the $\mathsf{CauchyLimitSeal}^{\uparrow}$ sibling route feeds the $\mathsf{Real}^{\uparrow}$ handoff without importing host real equality or ambient completeness. □

Definition 435.156 (UniformCauchyCriterion Real-completion finite-envelope carrier)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. The Real-completion finite-envelope carrier of U is the packet*

$$\mathcal{E}_{\mathsf{Real}^{\uparrow}}(U) = (U, W_{\mathsf{StreamName}^{\uparrow}}, R_{\mathsf{RegSeqRat}^{\uparrow}}, Q_{\mathsf{DyadicRatCore}^{\uparrow}}, S_{\mathsf{CauchyLimitSeal}^{\uparrow}}, E_{\mathsf{RealCauchyCompletion}^{\uparrow}}, H, C, P, N).$$

Its rows are exactly the accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, the* $\mathsf{StreamName}^{\uparrow}$ *window family* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows* R *reached by the uniform tail ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Q*, the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *tail-meet route* S*, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *public* $\mathsf{Real}^{\uparrow}$ *export* E*, and the visible* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{UniformCauchyCriterion}^{\uparrow}}$ *rows* H, C, P, N*. A row is admitted to the carrier only when it is displayed by this packet or by one of the named sibling routes attached to the same* U*.*

Lean4 (definition) `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionRealCompletionFiniteEnvelope`
Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionRealCompletionFiniteEnvelopeCarrier rows`

Theorem 435.157 (UniformCauchyCriterion Real-completion finite-envelope NameCert obligations)**.** *For the carrier* $\mathcal{E}_{\mathsf{Real}^{\uparrow}}(U)$ *of Definition 435.156, the local* NameCert *obligations are the following finite rows:*

1. *carrier exposure: every admitted row is one of* $U, W_{\mathsf{StreamName}^{\uparrow}}, R_{\mathsf{RegSeqRat}^{\uparrow}}, Q_{\mathsf{DyadicRatCore}^{\uparrow}}, S_{\mathsf{CauchyLimitSeal}^{\uparrow}}, E_{\mathsf{RealC}}$
2. *window-family stability:* hsame *transport of a* $\mathsf{StreamName}^{\uparrow}$ *window request remains inside the same displayed* W *family and is replayed only through the visible* Cont *row;*
3. *regular-rational handoff: every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used by a consumer is reached from the uniform tail ledger of* U *and not from a second stream source;*
4. *dyadic tolerance ledger exactness: every tolerance comparison consumed at the completion boundary is read from* $Q_{\mathsf{DyadicRatCore}^{\uparrow}}$ *before the tail-meet route is sealed;*
5. *public* $\mathsf{Real}^{\uparrow}$ *export: the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *route exports the named* $\mathsf{Real}^{\uparrow}$ *surface only after* $W_{\mathsf{StreamName}^{\uparrow}}$*,* $R_{\mathsf{RegSeqRat}^{\uparrow}}$*,* $Q_{\mathsf{DyadicRatCore}^{\uparrow}}$*, and* $S_{\mathsf{CauchyLimitSeal}^{\uparrow}}$ *have been displayed;*
6. *non-escape: no consumer row carries quotient streams, selected host limits, host real equality, countable choice, ambient completeness, metric-completeness data, or a bridge row outside* $\mathcal{E}_{\mathsf{Real}^{\uparrow}}(U)$*.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion finite envelope namecert obligations`

Proof. Project the carrier definition. It lists the only admitted rows and records the structural rows H, C, P, N as transport, continuation, provenance, and local naming data rather than analytic sources.

Window stability and the regular-rational handoff are inherited from the existing $\mathsf{UniformCauchyCriterion}^{\uparrow}$ route: the $\mathsf{StreamName}^{\uparrow}$ windows are carried by W, and the $\mathsf{RegSeqRat}^{\uparrow}$ rows are reached through the uniform tail ledger before any completion-facing read is available.

The dyadic and public-export obligations are downstream of the same route. The tolerance ledger is the displayed $Q_{\mathsf{DyadicRatCore}^{\uparrow}}$ row, the tail-meet route is the displayed $\mathsf{CauchyLimitSeal}^{\uparrow}$ row, and the public $\mathsf{Real}^{\uparrow}$ export is read only through $\mathsf{RealCauchyCompletion}^{\uparrow}$ after those rows have been fixed.

Thus every local naming obligation is discharged by one of the displayed rows. Since the carrier has no further coordinate, the excluded host-level, choice, completeness, quotient, and bridge data cannot be introduced by a consumer. □

Theorem 435.158 (UniformCauchyCriterion Real-completion finite-envelope consumer exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet factors*

through the finite-envelope carrier $\mathcal{E}_{\mathsf{Real}^\uparrow}(U)$ of Definition 435.156. The factorization uses exactly the displayed rows

$$U, W_{\mathsf{StreamName}^\uparrow}, R_{\mathsf{RegSeqRat}^\uparrow}, Q_{\mathsf{DyadicRatCore}^\uparrow}, S_{\mathsf{CauchyLimitSeal}^\uparrow}, E_{\mathsf{RealCauchyCompletion}^\uparrow}, H, C, P, N$$

and no row outside that list can be read by such a consumer.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion finite envelope consumer exhaustion`

Proof. Begin with a $\mathsf{Real}^\uparrow$ or $\mathsf{Completion}^\uparrow$ consumer of U. The consumer must first read the accepted UniformCauchyCriterion packet, so its family request is already tied to the finite $I, W, M, Q, T, E, H, C, P, N$ surface.

Next pass through the real-seal and tail-meet routes. The $\mathsf{StreamName}^\uparrow$ window family, $\mathsf{RegSeqRat}^\uparrow$ source rows, and $\mathsf{DyadicRatCore}^\uparrow$ tolerance ledger are the rows that feed the $\mathsf{CauchyLimitSeal}^\uparrow$ route. No completion-facing read is available before those rows are displayed.

Finally use the public export row. The $\mathsf{RealCauchyCompletion}^\uparrow$ route repacks the same displayed rows as a public $\mathsf{Real}^\uparrow$ surface, while H, C, P, N replay transport, continuation, provenance, and local naming. This exhausts the consumer surface by the finite envelope. □

Theorem 435.159 (UniformCauchyCriterion Real-completion finite-envelope tail-window stability)**.** *In $\mathcal{E}_{\mathsf{Real}^\uparrow}(U)$, every $\mathsf{StreamName}^\uparrow$ window row used by a $\mathsf{Real}^\uparrow$ or $\mathsf{Completion}^\uparrow$ consumer is tied to the corresponding $\mathsf{RegSeqRat}^\uparrow$ source row under the displayed* hsame *and* Cont *rows. Transport may rename the window and replay the readback, but it cannot replace $W_{\mathsf{StreamName}^\uparrow}$ or $R_{\mathsf{RegSeqRat}^\uparrow}$ by a second window family or a second regular-rational source.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionRealCompletionFiniteEnvelope tail window stability`

Proof. Read the window request inside the carrier. The only window-family row is $W_{\mathsf{StreamName}^\uparrow}$, and the only regular-rational source rows are the displayed $R_{\mathsf{RegSeqRat}^\uparrow}$ rows reached from the uniform tail ledger.

Apply the structural rows. The hsame data compare windows componentwise, while the Cont row replays the same readback route after transport. Both rows act on the displayed carrier coordinates rather than creating a new source.

Therefore any transported completion-facing consumer still reads the same $W_{\mathsf{StreamName}^\uparrow}$ and $R_{\mathsf{RegSeqRat}^\uparrow}$ pair. A second window family or a second regular-rational source has no coordinate in the envelope. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion finite envelope tail window stability`

Theorem 435.160 (UniformCauchyCriterion Real-completion finite-envelope no-choice extraction)**.** *The finite-envelope carrier $\mathcal{E}_{\mathsf{Real}^\uparrow}(U)$ exports no quotient stream, no selected host limit, no host real equality, no countable-choice selector, no ambient completeness principle, and no metric-completeness data. Any attempted extraction of one of those objects from a $\mathsf{Real}^\uparrow$ or $\mathsf{Completion}^\uparrow$ consumer is therefore outside the displayed carrier and outside its local* NameCert *obligations.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion finite envelope no choice extraction`

Proof. Inspect the carrier rows. The analytic rows are the StreamName window family, RegSeqRat source rows, dyadic tolerance ledger, CauchyLimitSeal tail-meet route, and RealCauchyCompletion public export. None of these rows stores a quotient stream, a selected limit, host equality, a choice selector, or completeness data.

The structural rows do not add analytic content. BHist records the visible history surface, hsame transports displayed rows, Cont replays displayed continuations, Pkg records provenance, and NameCert names the same local packet.

By consumer exhaustion, every $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer has already factored through this list. Hence the listed host-level and choice-based objects cannot be extracted from the envelope. □

Theorem 435.161 (UniformCauchyCriterion Real-completion finite envelope)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer entering through U factors through exactly one finite envelope before it can read a real-facing or completion-facing result. The envelope is the displayed route through the* $\mathsf{StreamName}^{\uparrow}$ *window family W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows reached by the uniform tail ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger Q, the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *tail-meet route, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *public* $\mathsf{Real}^{\uparrow}$ *export, and the visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows carried by the packet and its sibling routes.*

Thus the accepted consumer surface has no coordinate for quotient streams, selected host limits, host real equality, countable choice, ambient completeness, metric-completeness data, or bridge rows outside the displayed finite envelope.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion finite envelope`

Proof. Begin with the finite-envelope carrier of Definition 435.156. It displays the accepted packet, the $\mathsf{StreamName}^{\uparrow}$ window family, the $\mathsf{RegSeqRat}^{\uparrow}$ source rows, the dyadic tolerance ledger, the CauchyLimitSeal tail-meet route, the RealCauchyCompletion public export, and the visible structural rows in one packet.

Use the NameCert obligation surface of Definition 435.157. It records carrier exposure, window-family stability, regular-rational handoff, dyadic tolerance exactness, public $\mathsf{Real}^{\uparrow}$ export, and non-escape as the finite obligations for the same displayed packet.

Next apply consumer exhaustion and tail-window stability. Definition 435.158 forces every $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer through the displayed carrier rows, and Definition 435.159 keeps the $\mathsf{StreamName}^{\uparrow}$ windows tied to the $\mathsf{RegSeqRat}^{\uparrow}$ source rows under hsame and Cont.

Finally invoke the no-choice extraction boundary of Definition 435.160. Since the consumer surface has already been exhausted by the carrier and its obligations, the Real and completion-facing surface has no coordinate for quotient streams, selected host limits, host real equality, countable choice, ambient completeness, metric-completeness data, or bridge rows outside the displayed finite envelope. □

Theorem 435.162 (UniformCauchyCriterion Real-completion synchronizer terminal envelope)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer that factors through $\mathcal{E}_{\mathsf{Real}^{\uparrow}}(U)$ and preserves the Phase Real route reaches its terminal* $\mathsf{Real}^{\uparrow}$ *row through the same finite synchronizer envelope. That envelope consists exactly of the* $\mathsf{StreamName}^{\uparrow}$ *window*

family, the $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *tail-meet route, the* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *route when present, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *public export, and the visible* BHist, hsame, Cont, Pkg, *and* NameCert *rows attached to* U.

Consequently the terminal Real row is not obtained from quotient streams, selected host limits, host real equality, countable choice, a second stream source, a second readback source, a second tolerance source, metric completeness, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion synchronizer terminal envelope`

Proof. Start with the finite envelope. By Definition 435.161, the consumer has already passed through the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows. By Definition 435.158, there is no additional consumer coordinate outside that list.

Next use the no-choice boundary. Definition 435.160 rules out quotient streams, selected host limits, host real equality, countable choice, ambient completeness, and metric-completeness data. The tail-window stability theorem also keeps the StreamName window family and RegSeqRat readback rows tied to the same hsame and Cont transport, so no second stream or readback source can enter the envelope. The dyadic tolerance row is already the displayed $Q_{\mathsf{DyadicRatCore}^{\uparrow}}$ ledger, so no second tolerance source is available.

Now identify the terminal route. Apply Definition 435.147 when the selector-seal row is present; it places the selector-facing route on the same StreamName, RegSeqRat, DyadicRatCore, CauchyLimitSeal, and terminal $\mathsf{Real}^{\uparrow}$ surface.

Finally apply Definition 435.148 and Definition 435.149. The first theorem identifies Phase Real admissibility with preservation of the displayed route, and the second theorem makes the endpoint row determined by that route. Hence every admissible Real or Completion consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ row through precisely the finite synchronizer envelope displayed above, with no appeal to open-cover compactness or ambient completeness. □

Theorem 435.163 (UniformCauchyCriterion finite-envelope route determinacy)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Consider two* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumers of* U *that preserve the Phase Real route and factor through the finite envelope* $\mathcal{E}_{\mathsf{Real}^{\uparrow}}(U)$. *If the two consumers read the same displayed* $\mathsf{StreamName}^{\uparrow}$ *rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route, optional* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *row,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *export, and the same* BHist, hsame, Cont, Pkg, *and* NameCert *rows, then they reach the same terminal* $\mathsf{Real}^{\uparrow}$ *row.*

Thus Phase Real and Completion consumers of $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *have a deterministic terminal Real route once their finite-envelope rows agree. No quotient stream, selected host limit, host real equality, countable-choice selector, second tolerance ledger, metric-completeness object, open-cover compactness datum, or ambient completeness principle can separate the two terminal rows.*

Proof. First exhaust both consumers through the finite envelope. Apply Definition 435.158 to place each consumer inside the displayed carrier, and apply Definition 435.159 to keep the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows tied to the same hsame and Cont transport.

The remaining excluded coordinates cannot distinguish the consumers. By Definition 435.160, neither consumer can read quotient streams, selected host limits, host equality, choice selectors, ambient completeness, or metric-completeness data from the envelope.

Now synchronize the selector-facing part of the route. When the optional $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ row is present, Definition 435.147 places it on the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$ surface already read by the two consumers. When the row is absent, the common finite envelope has no selector coordinate to separate.

Finally use the Phase Real route criterion and endpoint determinacy. Definition 435.148 identifies both consumers as preserving the same admissible finite route, and Definition 435.149 makes the terminal endpoint row determined by that route. Since the displayed rows agree, the two terminal $\mathsf{Real}^{\uparrow}$ rows agree as well. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket finite envelope route determinacy`

Theorem 435.164 (UniformCauchyCriterion Real-envelope source minimality)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. A* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{Completion}^{\uparrow}$*-facing terminal envelope for* U *is admissible exactly when its displayed route contains the same* $\mathsf{StreamName}^{\uparrow}$ *window family, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the same* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *tail-meet route, the same* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *export row, and the packet's visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Equivalently, the Real-completion finite envelope $\mathcal{E}_{\mathsf{Real}^{\uparrow}}(U)$ *is source-minimal among admissible terminal envelopes: deleting any listed row destroys either the local* NameCert *obligation surface, the consumer factorization, the terminal synchronizer envelope, or route determinacy; adjoining quotient streams, selected host limits, host real equality, countable choice, ambient completeness, metric-completeness data, a second stream source, a second readback source, or a second tolerance source produces no new admissible terminal envelope for* U*.*

Proof. First read the displayed carrier and its local obligations. Definition 435.156 lists the only rows of $\mathcal{E}_{\mathsf{Real}^{\uparrow}}(U)$, and Definition 435.157 records why the window family, regular-rational rows, dyadic ledger, tail-meet route, public export, and structural packet rows are all required by the local NameCert surface.

For the forward direction, take an admissible terminal envelope. By Definition 435.158, every $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer already factors through the displayed rows of $\mathcal{E}_{\mathsf{Real}^{\uparrow}}(U)$. By Definition 435.162, the terminal Real route uses the same synchronizer rows, and by Definition 435.163, agreement on those rows determines the terminal $\mathsf{Real}^{\uparrow}$ row. Hence an admissible terminal envelope cannot omit or replace one of the displayed sources.

For the reverse direction, suppose the route displays exactly those rows. The finite-envelope carrier supplies the local NameCert obligations, consumer exhaustion supplies the factorization through the displayed route, and the synchronizer theorem supplies the terminal Real-facing row. Route determinacy then identifies the resulting terminal row as the unique endpoint for that displayed route.

It remains to exclude extra sources. The no-choice extraction boundary in Definition 435.160 rules out quotient streams, selected host limits, host real equality, countable choice, ambient completeness, and metric-completeness data. Tail-window stability in Definition 435.159 prevents a second stream or readback source, and the dyadic ledger coordinate in the carrier prevents a second tolerance source. Thus the listed rows are both sufficient and source-minimal. □

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real envelope source minimality`

Theorem 435.165 (UniformCauchyCriterion Real-envelope witness extraction)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Let* $\mathcal{T}$ *be an admissible* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{Completion}^{\uparrow}$*-facing terminal envelope for* U *whose displayed rows satisfy the source-minimality characterization of Definition 435.164. Then* $\mathcal{T}$ *determines a finite BEDC witness packet*

$$\mathcal{W}_{\mathsf{Real}^{\uparrow}}(U, \mathcal{T}) = (W_{\mathsf{StreamName}^{\uparrow}}, R_{\mathsf{RegSeqRat}^{\uparrow}}, Q_{\mathsf{DyadicRatCore}^{\uparrow}}, S_{\mathsf{CauchyLimitSeal}^{\uparrow}}, E_{\mathsf{RealCauchyCompletion}^{\uparrow}}, H, C, P, N).$$

Its coordinates are exactly the displayed $\mathsf{StreamName}^{\uparrow}$ *window family, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows reached by the uniform tail ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *tail-meet route, the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *public export, and the visible* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{UniformCauchyCriterion}^{\uparrow}}$ *rows. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer read of* $\mathcal{T}$ *factors through this witness packet before the terminal* $\mathsf{Real}^{\uparrow}$ *row is consumed.*

The witness packet has no coordinate for quotient streams, selected host limits, host real equality, countable choice, ambient completeness, metric-completeness data, a second stream source, a second readback source, or a second tolerance source.

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real envelope witness extraction`

Proof. Start with carrier exposure. The finite-envelope carrier of Definition 435.156 displays the accepted packet together with $W_{\mathsf{StreamName}^{\uparrow}}$, $R_{\mathsf{RegSeqRat}^{\uparrow}}$, $Q_{\mathsf{DyadicRatCore}^{\uparrow}}$, $S_{\mathsf{CauchyLimitSeal}^{\uparrow}}$, $E_{\mathsf{RealCauchyCompletion}^{\uparrow}}$, and the structural rows H, C, P, N. The NameCert obligations of Definition 435.157 identify these rows as the local carrier, stability, exactness, export, and non-escape data.

Now apply consumer exhaustion and terminal routing. By Definition 435.158, every $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer read factors through the displayed carrier rows. By Definition 435.162, the terminal Real-facing read is reached only after the synchronizer rows have been displayed.

Route determinacy turns the displayed rows into a witness rather than a mere description. Definition 435.163 makes the terminal $\mathsf{Real}^{\uparrow}$ row determined by agreement on the listed rows, and Definition 435.164 says an admissible terminal envelope satisfying the source-minimality characterization cannot omit or replace any of them. Therefore $\mathcal{T}$ canonically yields the finite packet $\mathcal{W}_{\mathsf{Real}^{\uparrow}}(U, \mathcal{T})$ with exactly those coordinates.

Finally exclude external analytic sources. The no-choice extraction theorem Definition 435.160 rules out quotient streams, selected host limits, host real equality, countable choice, ambient completeness, and metric-completeness data. Tail-window stability rules out second stream and readback sources, while the dyadic ledger row in the carrier fixes the tolerance source. Hence every consumer read reaches the terminal $\mathsf{Real}^{\uparrow}$ row through the witness packet and through no additional source. □

Theorem 435.166 (UniformCauchyCriterion Real-completion terminal readiness)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let* $\mathcal{T}$ *be an admissible* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{Completion}^{\uparrow}$*-facing terminal envelope for* U *satisfying the source-minimality characterization of Definition 435.164.*

Any terminal Real-and-Completion consumer compatible with the finite witness packet $\mathcal{W}_{\mathsf{Real}^\uparrow}(U, \mathcal{T})$*, the finite-selector UniformCauchy Real readiness route of Definition 782.56, and the Real L10 four-face exit sufficiency route of Definition 38.493 factors through the single displayed terminal readiness surface*

$$\mathsf{StreamName}^\uparrow,\ \mathsf{DyadicRatCore}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow,\ \mathsf{Real}^\uparrow,\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

This terminal readiness surface has no coordinate for quotient streams, host real equality, selected host limits, countable choice, metric-completeness rows, ambient completeness, aggregate formalstatus *rows, or aggregate bridge rows. In particular it is a readiness theorem for consuming the finite Real-and-Completion route, not a claim of* $\mathsf{Real}^\uparrow$ *completeness or a route-level bridge.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCriterionUp.UniformCauchyCriterionPacket real completion terminal readiness`

Proof. First extract the finite witness packet. By Definition 435.165, the admissible envelope $\mathcal{T}$ canonically exposes exactly the finite rows $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{CauchyLimitSeal}^\uparrow$, $\mathsf{RealCauchyCompletion}^\uparrow$, and the structural support H, C, P, N carried by U. Its no-escape clause removes quotient streams, selected host limits, host real equality, countable choice, ambient completeness, metric-completeness data, and duplicate stream or tolerance sources.

Next attach the selector-side terminal route. Apply Definition 782.56. It turns any compatible finite-selector consumer into a reader of the same public rows $\mathsf{StreamName}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{Real}^\uparrow$, BHist, hsame, Cont, Pkg, and NameCert, without hidden selectors, detached limits, metric-completeness rows, ambient completeness, quotient streams, host real equality, or countable choice.

Now attach the objectwise Phase Real and Completion exit. By Definition 38.493, the Phase Real and Completion exit is supplied exactly by the four local records for $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, and $\mathsf{Real}^\uparrow$. The cited sufficiency theorem supplies no aggregate formalstatus row, no aggregate bridge row, no quotient stream, no selected limit, no countable-choice row, no metric-completeness datum, and no $\mathsf{Real}^\uparrow$ completeness claim.

The three routes therefore have the same terminal consumer surface. The finite witness packet gives the UniformCauchy envelope rows, the selector theorem gives the terminal public readiness route, and Real L10 exit sufficiency certifies that the Phase Real and Completion exit is objectwise over the same four faces. The no-escape clauses in the UniformCauchy envelope together with the Real L10 face-status noncollapse results prevent every listed external coordinate from serving as an alternate terminal read. □

The public $\mathsf{UniformCauchyCriterion}^\uparrow$ route is a Phase Real and Completion lattice node: its finite budget reads through chapter 126, chapter 301, chapter 291, chapter 38, chapter 386, and chapter 1081 before any Real-facing consumer can use the seal. The route exports only finite BHist, hsame, Cont, Pkg, and local NameCert rows, with no quotient stream, selected host limit, host equality, countable choice, or ambient Real-completeness coordinate.

Chapter 436

A Concrete Naming Certificate for $\mathsf{DedekindCut}^{\uparrow}$

The $\mathsf{DedekindCut}^{\uparrow}$ interface records the rounded located cut presentation of constructive real analysis in the style of Bishop–Bridges and Troelstra–van Dalen. It keeps lower and upper rational observations as explicit $\mathsf{Rat}^{\uparrow}$ rows, rather than quotienting cut predicates or comparing host reals.

The $\mathsf{DedekindCut}^{\uparrow}$ carrier consumes the rounded located-cut surface of chapter 404 and the rational observation rows of chapter 37. Its lower and upper predicate rows are therefore a finite BEDC ledger over rational observations rather than an isolated host cut predicate.

The lower and upper rational-observation rows consume the rational certificate of chapter 37, and the comparison handoff is exported only to the real seal boundary of chapter 38.

Definition 436.1 (DedekindCut BHist source)**.** *A* $\mathsf{DedekindCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (L, U, I, R, O, E, Q, H, T, P, N)$$

with the following displayed coordinates:

1. *L is the lower* $\mathsf{Rat}^{\uparrow}$ *predicate row, listing rational observations certified to lie below the represented real;*
2. *U is the upper* $\mathsf{Rat}^{\uparrow}$ *predicate row, listing rational observations certified to lie above the represented real;*
3. *I stores lower and upper inhabitedness witnesses, with displayed rational rows on both sides;*
4. *R stores roundedness witnesses for the lower and upper rows, so each observed rational admits a strictly better observed rational on the same side;*
5. *O stores locatedness witnesses, assigning each rational interval $a < b$ a displayed lower-side or upper-side observation;*
6. *E stores disjointness evidence preventing the same rational observation from being accepted by both sides;*
7. *Q stores rational-embedding rows, including the lower and upper boundary readings for embedded* $\mathsf{Rat}^{\uparrow}$ *points;*
8. *H stores the componentwise* hsame *routes for the lower predicate, upper predicate, roundedness, locatedness, disjointness, and rational embedding rows;*

9. *T stores the* Cont *routes that expose finite lower and upper rational observations to downstream consumers;*
10. *P stores* Pkg *provenance over* $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCut}^{\uparrow}}$ *evidence.*

The classifier compares agreement of the displayed lower and upper rational observations under $\mathsf{Rat}^{\uparrow}$ *comparison. It never compares quotient cuts, host real equality, or choice-selected limits.*

Lean4 ✓ `BEDC.Derived.DedekindCutUp.DedekindCutTasteGate single carrier alignment`

Theorem 436.2 (DedekindCut NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{DedekindCut}^{\uparrow}}$ *obligation surface for the carrier of Definition 436.1 consists of five finite rows:*

1. *carrier admission: the accepted object is exactly the packet C with displayed lower and upper* $\mathsf{Rat}^{\uparrow}$ *predicate rows, inhabitedness, roundedness, locatedness, disjointness, rational embedding rows, transports, continuations, package provenance, and local naming evidence;*
2. *classifier transport: classification transports the lower and upper rational observations componentwise through the stored* hsame *and* Cont *routes and compares them only by* $\mathsf{Rat}^{\uparrow}$ *comparison;*
3. *stability: replacing any displayed rational observation by a classified* $\mathsf{Rat}^{\uparrow}$ *observation preserves the rounded located cut laws inside the same carrier surface;*
4. *exactness: every consumer-visible lower or upper decision is the row supplied by L, U, O, E, and Q, with no hidden host-real predicate;*
5. *ledger: every downstream* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer first reads $L, U, I, R, O, E, Q, H, T, P, N$.*

Proof. Carrier admission is projection from the tuple of Definition 436.1. The lower and upper rational predicate rows, their inhabitedness, roundedness, locatedness, disjointness, rational embedding, transport, continuation, package, and naming rows are all displayed coordinates.

Classifier transport is componentwise. A lower-side observation is moved through the lower $\mathsf{Rat}^{\uparrow}$ route, an upper-side observation is moved through the upper $\mathsf{Rat}^{\uparrow}$ route, and the comparison used by the classifier is the displayed rational comparison between those transported rows.

Exactness and the ledger clauses follow from the same inventory. Since the carrier contains no quotient cut, host real equality proof, selected limit, or ambient completeness object, every consumer-visible decision is exhausted by the displayed finite rows. □

Lean4 ✓ `BEDC.Derived.DedekindCutUp.DedekindCutCarrier namecert obligation surface`

Theorem 436.3 (DedekindCut rounded located laws)**.** *Every accepted* $\mathsf{DedekindCut}^{\uparrow}$ *carrier $C = (L, U, I, R, O, E, Q, H, T, P, N)$ presents a constructive rounded located cut over* $\mathsf{Rat}^{\uparrow}$*: both sides are inhabited, lower and upper observations are rounded on their own sides, each rational interval $a < b$ is decided by the locatedness row O, and disjointness row E prevents a rational observation from being accepted by both sides.*

Lean4 ✓ `BEDC.Derived.DedekindCutUp.DedekindCutCarrier located rounded cut laws`

Proof. Read the inhabitedness row I to obtain displayed rational observations on both sides. These witnesses are part of the finite carrier and do not require a completed real.

Read the roundedness row R. For a lower observation it supplies a stronger lower observation; for an upper observation it supplies a stronger upper observation. The witnesses are again $\mathsf{Rat}^{\uparrow}$ rows transported through the displayed carrier routes.

For a rational interval $a < b$, the locatedness row O gives the lower-side or upper-side observation named by the packet. The disjointness row E then prevents overlap of the two displayed predicates, so the cut laws remain internal to the finite $\mathsf{DedekindCut}^{\uparrow}$ surface. □

Theorem 436.4 (DedekindCut rational embedding boundary)**.** *For every rational row embedded through Q in an accepted* $\mathsf{DedekindCut}^{\uparrow}$ *carrier, the lower and upper boundary observations are exactly the displayed* $\mathsf{Rat}^{\uparrow}$ *comparison rows against that rational. A consumer cannot replace those rows by quotient equality of cuts, host real equality, or an external order on completed reals.*

Lean4 ✓ `BEDC.Derived.DedekindCutUp.DedekindCutCarrier rational embedding boundary`

Proof. Project the rational embedding row Q. Its lower boundary read is a displayed comparison placing an observed rational below the embedded row, and its upper boundary read is the corresponding displayed comparison above the embedded row.

Transport along H and T preserves only these rational observations. The classifier of Definition 436.2 compares lower and upper sides by $\mathsf{Rat}^{\uparrow}$ comparison, so the embedded rational has no separate equality or order witness outside the carrier. □

Theorem 436.5 (DedekindCut RealUp comparison handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing comparison consumer of an accepted* $\mathsf{DedekindCut}^{\uparrow}$ *carrier receives only the displayed lower and upper* $\mathsf{Rat}^{\uparrow}$ *observation surface, the rounded located cut laws, and the rational embedding boundary. The handoff supplies no quotient real, host equality, selected limit, or choice-selected comparison.*

Lean4 ✓ `BEDC.Derived.DedekindCutUp.DedekindCutCarrier realup comparison handoff`

Proof. First apply Definition 436.3. It supplies the inhabitedness, roundedness, locatedness, and disjointness rows needed for a constructive cut comparison.

Next apply Definition 436.4. It fixes the rational boundary reads as displayed $\mathsf{Rat}^{\uparrow}$ comparisons rather than external real comparisons.

The non-escape claim is then immediate from the carrier inventory in Definition 436.1. The only exported analytic data are lower and upper rational observations with their local evidence and provenance. □

Theorem 436.6 (DedekindCut quotient-free boundary)**.** *The displayed* $\mathsf{DedekindCut}^{\uparrow}$ *carrier, rounded located laws, rational embedding boundary, and* $\mathsf{Real}^{\uparrow}$ *comparison handoff license only a classifier-mediated comparison interface over* BHist*,* hsame*,* Pkg*, and* NameCert*. They do not introduce a quotient object, a completeness theorem, or an alternative construction of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with the carrier of Definition 436.1. It lists lower and upper rational-observation rows, local law rows, rational embedding rows, componentwise transport, continuation, package, and naming data, but no quotient carrier or host real equality coordinate.

The admissible classifier surface is fixed by Definition 436.2. Its comparison reads are mediated by the displayed BHist rows and the local NameCert evidence, so the interface remains a certificate boundary rather than a new real object.

Apply Definition 436.3 and Definition 436.5. These give the rounded located laws and the comparison handoff while keeping every read on rational observations and their provenance. Hence the boundary permits classifier-mediated comparison only, with no quotient object, completeness theorem, or alternative $\mathsf{Real}^{\uparrow}$ construction. □

Lean4 ✓ `BEDC.Derived.DedekindCutUp.DedekindCutCarrier quotient free boundary`

Theorem 436.7 (DedekindCut bridged Real comparison interface)**.** *The rounded located cut carrier, rational embedding boundary, and* $\mathsf{Real}^{\uparrow}$ *comparison handoff together form the BEDC-side bridge interface from lower and upper* $\mathsf{Rat}^{\uparrow}$ *observation rows to* $\mathsf{Real}^{\uparrow}$ *comparison consumers. The interface exports no quotient cut, selected limit, ambient completeness, or host equality.*

Proof. Start with the NameCert obligation surface of Definition 436.2. It fixes the carrier reads as lower and upper $\mathsf{Rat}^{\uparrow}$ predicate rows, local law rows, rational embedding rows, transports, continuations, provenance, and local naming.

Apply the rounded located cut laws of Definition 436.3. These laws make the lower and upper observation rows constructive enough for comparison consumers without introducing a quotient cut.

Use the rational embedding boundary and the $\mathsf{Real}^{\uparrow}$ comparison handoff, Definition 436.4 and Definition 436.5. Together they expose the bridge-facing comparison surface from rational observation rows to $\mathsf{Real}^{\uparrow}$ consumers while refusing selected limits, ambient completeness, and host equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCut}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DedekindCut}^{\uparrow}$ packet is generated from lower and upper $\mathsf{Rat}^{\uparrow}$ predicate rows, inhabitedness, roundedness, locatedness, disjointness, rational embedding rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DedekindCut}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 436.1, Definition 436.2, Definition 436.3, Definition 436.4, Definition 436.5, Definition 436.6, and Definition 436.7 bind the bridge-facing lower and upper rational-observation NameCert surface over $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ comparison rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DedekindCut}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.DedekindCutUp.DedekindCutCarrier\_realup\_comparison\_handoff`

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient cuts, host real equality, selected limits, ambient real completeness, or bridge checking.

Upgrade path: No further theory-axis upgrade remains; standard-model bridge checking is the remaining independent verification-axis work.

Chapter 437

A Concrete Naming Certificate for $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$

The $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ interface records the finite seal packet consumed by the transported stationary diagonal path. It packages the transported $\mathsf{Rat}^{\uparrow}$ seed classifier, the constant $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ window seal, the $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ observation boundary, and the $\mathsf{Real}^{\uparrow}$ seal-facing row. It is a finite naming certificate, not a real-completeness theorem.

The transported stationary window-seal packet consumes the constant-window route of chapter 126, the regular rational handoff of chapter 301, the finite observation boundary of chapter 365, and the real-facing seal row of chapter 38 through the route $R, S, G, W, E, H, C, P, N$ before any consumer reads the transported seal.

Definition 437.1 (Transported stationary window-seal carrier)**.** *A* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, S, G, W, E, H, C, P, N)$$

with the following visible coordinates:

1. *R is the transported* $\mathsf{Rat}^{\uparrow}$ *classifier row for the two stationary rational seeds;*
2. *S is the constant* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier induced by R;*
3. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window seal row read from the same constant stream window;*
4. *W is the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *packet naming the selected anchor, window, dyadic ledger, regular-rational seal, and endpoint classifier;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row obtained from G and W;*
6. *H records the transported stationary diagonal handoff rows that identify the displayed diagonal representatives with the same constant rational route;*
7. *C stores the displayed* hsame *and* Cont *transports for the seed classifier, stream window, regular-rational seal, finite envelope, and real seal;*
8. *P is the* Pkg *provenance naming* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *source certificates;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TransportedStationaryWindowSeal}^{\uparrow}}$ *row.*

The local classifier relates two carriers exactly when their transported $\mathsf{Rat}^{\uparrow}$ *classifier rows agree and the induced* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *transport, package, and local certificate rows compare componentwise after the displayed routes in* C.

Theorem 437.2 (Transported stationary window-seal NameCert obligations)**.** *The* $\mathsf{NameCert}_{\mathsf{TransportedStationaryWind}}$ *surface has five obligations:*

1. *carrier: formation of the finite packet of Definition 437.1;*
2. *classifier: componentwise comparison of the transported* $\mathsf{Rat}^{\uparrow}$ *seed classifier, constant* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *seal,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *packet,* $\mathsf{Real}^{\uparrow}$ *row, transports, package provenance, and local certificate row;*
3. *transported window exactness: the* $\mathsf{Rat}^{\uparrow}$ *classifier, constant* $\mathsf{StreamName}^{\uparrow}$ *window, and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window seal read the same transported stationary row;*
4. *seal exhaustion: every* $\mathsf{Real}^{\uparrow}$ *consumer read factors through the displayed* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *packet and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row;*
5. *non-escape: the carrier has no coordinate for quotient streams, host equality, choice, selected host limits, or real completeness.*

Lean4 ✓ `BEDC.Derived.TransportedStationaryWindowSealUp.TransportedStationaryWindowSealPacket namecert obligations`

Proof. Carrier formation is the finite assembly of the displayed tuple. The transported rational classifier supplies R, the stationary stream read supplies S, the regular-rational boundary supplies G, and the finite observation envelope supplies W. The real-facing row E, transported diagonal rows H, route table C, provenance row P, and local naming row N are all visible coordinates of the same BHist packet.

For the classifier obligation, compare the packet component by component after applying the displayed hsame and Cont routes. The transported $\mathsf{Rat}^{\uparrow}$ row determines the constant stream window, the stream window determines the regular-rational finite seal, and the envelope ties the same window and dyadic ledger to the real-facing endpoint row.

Transported window exactness is the stationary diagonal calculation read through a finite window. The transported $\mathsf{Rat}^{\uparrow}$ classifier induces the constant $\mathsf{StreamName}^{\uparrow}$ classifier, and the $\mathsf{RegSeqRat}^{\uparrow}$ row consumes exactly that window with the displayed ledger. Thus the three public readings are the same stationary row at the window boundary.

Seal exhaustion follows by projecting W and E. The $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ packet exposes the selected anchor, finite window, dyadic ledger, regular-rational seal, and endpoint classifier, and the $\mathsf{Real}^{\uparrow}$ row can read only those exposed fields plus the displayed transports and provenance.

The non-escape clause is constructor inspection. None of $R, S, G, W, E, H, C, P, N$ is a quotient stream, a host equality proof, a choice operator, a selected host limit, or a real-completeness witness. Therefore the certificate remains a finite transported window-seal packet. □

Theorem 437.3 (Transported stationary window-seal readback determinacy)**.** *For an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *carrier* $T = (R, S, G, W, E, H, C, P, N)$, *the transported* $\mathsf{Rat}^{\uparrow}$ *classifier row* R *determines the constant* $\mathsf{StreamName}^{\uparrow}$ *window* S *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window seal* G. *If two accepted carriers have the same transported* $\mathsf{Rat}^{\uparrow}$ *classifier after the displayed* hsame *and* Cont *routes, then their constant stream windows and regular-rational finite-window seals agree at the public readback boundary.*

Proof. Unpack the carrier of Definition 437.1. The row R is the transported rational classifier, S is the constant stream window induced by that row, and G is the regular-rational seal read from the same window.

The transported window exactness clause in Definition 437.2 states that R, S, and G read the same transported stationary row. The classifier clause transports these rows only componentwise through the displayed hsame and Cont routes.

Hence equality of the transported $\mathsf{Rat}^{\uparrow}$ classifier at the displayed route fixes the induced constant $\mathsf{StreamName}^{\uparrow}$ window and the $\mathsf{RegSeqRat}^{\uparrow}$ seal at the public readback boundary. □

Lean4 ✓ `BEDC.Derived.TransportedStationaryWindowSealUp.TransportedStationaryWindowSealPacket readback determinacy`

Theorem 437.4 (Transported stationary window-seal Real factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exposed by an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *packet* W *and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window seal* G*. The real-facing row* E *may read the selected anchor, finite window, dyadic ledger, regular-rational seal, and endpoint classifier only through* W *together with the transported seal row* G *and the displayed transport and provenance rows.*

Lean4 ✓ `BEDC.Derived.TransportedStationaryWindowSealUp.TransportedStationaryWindowSealPacket real factorization`

Proof. Project the coordinates G, W, E from the carrier tuple. The finite-window envelope W names the anchor, window, dyadic ledger, regular-rational seal, and endpoint classifier, while E is the real-facing row obtained from that envelope and the seal row.

Apply the seal-exhaustion clause of Definition 437.2. It requires every $\mathsf{Real}^{\uparrow}$ consumer read to pass through W and the same $\mathsf{RegSeqRat}^{\uparrow}$ seal row.

The route table C and provenance row P preserve that factorization under the displayed transports. Therefore no $\mathsf{Real}^{\uparrow}$ read bypasses the finite envelope and regular-rational seal. □

Theorem 437.5 (Transported stationary window-seal uniqueness)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *and* $T' = (R', S', G', W', E', H', C', P', N')$ *be accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *carriers. Suppose they are displayed over the same transported* $\mathsf{Rat}^{\uparrow}$ *row, the same constant* $\mathsf{StreamName}^{\uparrow}$ *window, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *finite seal, the same* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *packet, and the same* $\mathsf{Real}^{\uparrow}$ *seal-facing row after the* hsame *rows and* Cont *routes named by* H, H', C, C'*. Then* T *and* T' *expose the same public seal row.*

The uniqueness claim is only about the finite public seal row. It does not identify quotient streams, host equalities, selected host limits, or real-completeness data.

Proof. Apply the carrier and classifier clauses of Definition 437.2. They restrict comparison of T and T' to the displayed transported rational row, constant stream window, regular-rational seal, finite envelope, real-facing row, transport rows, continuation routes, provenance, and local naming rows.

Next use Definition 437.3. Agreement of the transported $\mathsf{Rat}^{\uparrow}$ row under the displayed hsame and Cont routes fixes the constant $\mathsf{StreamName}^{\uparrow}$ window and the $\mathsf{RegSeqRat}^{\uparrow}$ finite-window seal at the public readback boundary.

Apply Definition 437.4. Any $\mathsf{Real}^{\uparrow}$ seal-facing read must factor through the same finite envelope W and the same regular-rational seal row G, so the public seal row exposed by T and T' is the same row.

Finally, Definition 437.6 blocks the only possible escapes from this finite comparison. Quotient streams, host equality, selected host limits, and real-completeness data are not carrier coordinates, so they cannot refine or split the public seal row. □

Theorem 437.6 (Transported stationary window-seal ledger non-escape)**.** *An accepted* TransportedStationaryWindo *carrier exports no quotient stream, host equality, choice, selected host limit, or real-completeness datum. Its public surface consists only of the transported* $\mathsf{Rat}^{\uparrow}$ *classifier, constant* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *seal,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *packet,* $\mathsf{Real}^{\uparrow}$ *seal-facing row, displayed transports, package provenance, local* NameCert *row, and the ambient finite* BHist *packet.*

Lean4 ✓ `BEDC.Derived.TransportedStationaryWindowSealUp.TransportedStationaryWindowSealLedgerNonescape`

Proof. Inspect the carrier tuple $T = (R, S, G, W, E, H, C, P, N)$. Each coordinate is one of the finite transported classifier, window, seal, envelope, real-facing, transport, continuation, provenance, or naming rows.

The non-escape clause of Definition 437.2 explicitly excludes quotient streams, host equality, choice, selected host limits, and real completeness from that tuple. The readback determinacy and real-factorization statements use only the same visible coordinates.

Consequently the transported stationary window-seal packet has no export path outside the displayed finite BEDC ledger. □

Theorem 437.7 (Transported stationary window-seal carrier obligation)**.** *For an accepted* TransportedStationaryWi *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

carrier admission is exactly the finite projection of Definition 437.1. The admitted rows are the transported $\mathsf{Rat}^{\uparrow}$ *classifier* R*, the constant* $\mathsf{StreamName}^{\uparrow}$ *window* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window seal* G*, the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *packet* W*, the* $\mathsf{Real}^{\uparrow}$ *seal-facing row* E*, the transported stationary handoff row* H*, the route table* C*, the provenance row* P*, and the local naming row* N*.*

Proof. Project the displayed carrier tuple. The definition lists the complete coordinate inventory of an admitted packet, and Definition 437.2 names carrier formation as the first local obligation.

The readback-determinacy theorem then identifies R, S, G as the same transported stationary window read at the public boundary. The Real factorization theorem identifies W, E as the only real-facing seal route.

The uniqueness and ledger non-escape theorems rule out any additional carrier coordinate. Thus carrier admission is precisely the finite row projection displayed above. □

Theorem 437.8 (Transported stationary window-seal seed window readback)**.** *For an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

the transported $\mathsf{Rat}^{\uparrow}$ *seed row* R *determines the constant* $\mathsf{StreamName}^{\uparrow}$ *window* S *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal* G *through the same finite route* H, C, P, N*. The seed-window readback obligation is therefore the public projection of* R, S, G, H, C, P, N*, not a separate stream equality or host-limit claim.*

Proof. Project the carrier by Definition 437.7. The rows R, S, G are admitted as the transported seed classifier, constant stream window, and regular-rational finite-window seal of the same packet.

Apply Definition 437.3. Agreement at R fixes the public readback of S and G through the displayed hsame and Cont routes.

The support rows H, C, P, N keep that readback inside the finite NameCert surface. Ledger non-escape prevents any stream quotient, host equality, selected limit, or real-completeness coordinate from refining the seed-window read. □

Theorem 437.9 (Transported stationary window-seal Real seal route)**.** *For an accepted* $\mathsf{TransportedStationaryWind}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$ *seal read factors through* $R, S, G, W, E, H, C, P, N$ *and cannot bypass the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row* W*. The Real-facing route reads the transported seed through* R, S, G*, enters the finite envelope at* W*, exposes the seal row* E*, and replays only the displayed transport, route, provenance, and naming rows.*

Proof. Start with Definition 437.4. It forces every $\mathsf{Real}^{\uparrow}$ read exposed by the packet through the $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ packet W and the same $\mathsf{RegSeqRat}^{\uparrow}$ seal row G.

Use Definition 437.8 to identify the seed-facing part of the route. The rows R, S, G provide the transported rational seed, the constant window, and the regular-rational seal that feed the finite envelope.

Finally apply carrier admission and ledger non-escape. The admitted route has only $R, S, G, W, E, H, C, P, N$, so no consumer can reach a $\mathsf{Real}^{\uparrow}$ seal by skipping W or by importing quotient streams, host equality, selected limits, choice, or real-completeness data. □

Theorem 437.10 (Transported stationary window-seal root RegSeqRat window ownership)**.** *For an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

the $\mathsf{RegSeqRat}^{\uparrow}$ *seal row* G *is owned by the same transported* $\mathsf{Rat}^{\uparrow}$ *row* R *and the same constant* $\mathsf{StreamName}^{\uparrow}$ *window row* S*. A root consumer may read* G *only as the finite-window seal attached to the route*

$$R \longmapsto S \longmapsto G$$

through the displayed rows H, C, P, N*; it cannot detach* G *as an independent regular-rational source.*

Proof. Project the packet by Definition 437.7. The admitted carrier contains R, S, and G as visible rows of one finite transported window-seal packet, together with the same transport, continuation, provenance, and local naming rows H, C, P, N.

Apply Definition 437.8. It identifies the transported rational seed row, the constant stream window, and the regular-rational seal as one public readback route inside the finite NameCert surface.

Finally use Definition 437.3. Since agreement at R fixes both S and G at the public boundary, the seal row G has no separate owner beyond the displayed R, S, H, C, P, N route. □

Theorem 437.11 (Transported stationary window-seal root Real seal non-escape)**.** *For an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

every root-facing $\mathsf{Real}^{\uparrow}$ *seal read must pass through the finite rows* $R, S, G, W, E, H, C, P, N$*. The read first uses the owned regular-rational window route* R, S, G*, then the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row* W*, then the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, with* H, C, P, N *carrying only displayed transport, continuation, package, and naming data. It cannot import quotient streams, host equality, selected limits, choice, or real-completeness data.*

Proof. Begin with Definition 437.4. Every $\mathsf{Real}^{\uparrow}$ read exposed by the accepted packet factors through the finite envelope W and the same regular-rational seal row G.

Use Definition 437.9 to name the complete public route. It places the transported seed, constant window, regular-rational seal, envelope, real-facing row, and structural rows in the finite order $R, S, G, W, E, H, C, P, N$.

The non-escape boundary is then Definition 437.6. Quotient streams, host equality, selected host limits, choice, and real-completeness data are not coordinates of the packet, so no root-facing Real seal read can enter through them. □

Theorem 437.12 (Transported stationary window-seal root downstream handoff package)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, the downstream root handoff package consumed by completion-facing chapters consists exactly of the finite window ownership row and the Real seal non-escape row:*

1. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal owned by the transported* $\mathsf{Rat}^{\uparrow}$ *row R and the constant* $\mathsf{StreamName}^{\uparrow}$ *window row S through H, C, P, N;*
2. *every root-facing* $\mathsf{Real}^{\uparrow}$ *seal read factors through $R, S, G, W, E, H, C, P, N$ and has no quotient-stream, host-equality, selected-limit, choice, or real-completeness input.*

Thus a downstream consumer receives a finite BEDC packet over $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*, not an ambient completion object.*

Proof. The first row is Definition 437.10. It binds the regular-rational seal row to the transported rational seed and the constant stream window before any envelope or Real-facing consumer reads the packet.

The second row is Definition 437.11. It forces every Real seal read through the displayed finite packet and excludes all hidden quotient, equality, limit, choice, and completeness inputs.

Package these two rows with Definition 437.9. The result is the finite downstream handoff surface: consumers may reuse $R, S, G, W, E, H, C, P, N$, but they do not receive any object outside the displayed BEDC carrier. □

Theorem 437.13 (Transported stationary window-seal classifier obligation)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *and* $T' = (R', S', G', W', E', H', C', P', N')$ *be accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packets. Any classifier comparison between them is componentwise across the displayed* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows: R compares with R', S with S', G with G', W with W', and E with E' only through the* hsame *rows,* Cont *routes, provenance rows, and local naming rows carried by $H, H', C, C', P, P', N, N'$.*

Proof. Apply the classifier row of Definition 437.2. It permits only componentwise comparison of the transported seed classifier, the induced stream window, the regular-rational seal, the finite envelope, the real-facing row, and the displayed transport and provenance rows.

Use readback determinacy to keep the $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ comparisons on the same stationary route. Use Real factorization to keep the $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ comparisons on the same envelope and seal row.

Uniqueness repacks these componentwise comparisons as one public seal row, while ledger non-escape prevents the classifier from reading quotient streams, host equality, selected limits, or real-completeness data. □

Theorem 437.14 (Transported stationary window-seal ledger obligation)**.** *Every consumer read of an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet factors through the finite rows*

$$R, S, G, W, E, H, C, P, N.$$

Requests for quotient streams, host equality, choice, selected limits, or real completeness have no carrier field and therefore cannot be exported by the transported stationary window-seal ledger.

Proof. Start from Definition 437.6. Its non-escape clause states that the packet exports only the finite transported classifier, stream, regular-rational seal, finite envelope, real-facing, transport, route, provenance, and naming rows.

Readback determinacy and Real factorization describe all displayed consumer paths: the stationary window path passes through R, S, G, and the real-facing path passes through W, E together with the same transport and provenance rows.

It remains only to exclude hidden completion data. The carrier definition and uniqueness theorem leave no coordinate for quotient streams, host equality, selected limits, or real completeness, so the ledger obligation is exactly the finite non-escape boundary. □

Theorem 437.15 (Transported stationary window-seal root source lock)**.** *For every root consumer of an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

the first readable source is the transported $\mathsf{Rat}^{\uparrow}$ *seed row* R *locked through the constant* $\mathsf{StreamName}^{\uparrow}$ *window* S *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window seal* G*. The consumer may reach the finite envelope, Real-facing row, or completion-facing handoff only after the single route* R, S, G, H, C, P, N *has been fixed by the displayed* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

Proof. Project the root consumer through the carrier of Definition 437.1. Its available source coordinates are exactly the transported rational row R, the constant stream window S, the regular-rational seal G, and the displayed transport, route, provenance, and naming rows H, C, P, N.

Apply Definition 437.3. It makes R, S, and G one stationary readback route, so a consumer cannot read the stream window or the regular-rational seal as a second root source.

The sibling surfaces named at the start of this chapter supply the same ordering: the constant-window route of chapter 126, the regular-rational handoff of chapter 301, and the transported $\mathsf{Rat}^{\uparrow}$ row are read before the finite envelope and Real-facing row. Ledger non-escape then blocks quotient streams, host equality, selected host limits, choice, and real-completeness data from supplying another source. □

Theorem 437.16 (Transported stationary window-seal root Real factorization)**.** *For every Real-facing root read of an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, the read factors through the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row* W *and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row* G*. Thus the root handoff from the transported rational source to* $\mathsf{Real}^{\uparrow}$ *is the finite factorization*

$$R, S, G, H, C, P, N \longrightarrow W \longrightarrow E.$$

It does not factor through an ambient quotient stream, host equality, selected host limit, choice principle, completion witness, or real-completeness datum.

Proof. Begin with Definition 437.15. The root source has already been fixed as the transported $\mathsf{Rat}^{\uparrow}$ row read through the constant $\mathsf{StreamName}^{\uparrow}$ window and the $\mathsf{RegSeqRat}^{\uparrow}$ seal.

Apply Definition 437.4. Every $\mathsf{Real}^{\uparrow}$ consumer path must pass through the finite envelope W and the same regular-rational seal row G, with H, C, P, N carrying only the displayed transport, continuation, provenance, and local naming data.

The finite observation boundary of chapter 365 and the real-facing seal row of chapter 38 are therefore joined only by the displayed packet. Uniqueness identifies the resulting public seal row, and ledger non-escape removes every off-packet completion or real-completeness route. □

Theorem 437.17 (Transported stationary window-seal root ledger exhaustion)**.** *The root handoff surface of an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet exposes exactly*

$$R, S, G, W, E, H, C, P, N.$$

It exposes the transported $\mathsf{Rat}^{\uparrow}$ *row, constant* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window seal,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *packet,* $\mathsf{Real}^{\uparrow}$ *seal-facing row, displayed transports, route table, provenance row, and local naming row. It exposes no quotient stream, host equality, choice operator, selected host limit, completion witness, or real-completeness datum.*

Proof. The carrier definition gives the root ledger its complete coordinate list. The NameCert obligations and classifier obligation allow only componentwise transport of those displayed rows.

Use the root source lock to account for the source side R, S, G, H, C, P, N. Use the root Real factorization theorem to account for the envelope and Real-facing side W, E.

Finally apply uniqueness and ledger non-escape. Uniqueness shows that the public root handoff is determined by the displayed finite rows, while ledger non-escape states that quotient streams, host equality, selected limits, choice, completion witnesses, and real-completeness data are not carrier coordinates. Hence the L10 handoff surface is exhausted by $R, S, G, W, E, H, C, P, N$. □

Theorem 437.18 (Transported stationary window-seal obligation package)**.** *For an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

the consumer-facing obligation package is the finite conjunction of carrier admission, classifier comparison, transported $\mathsf{Rat}^{\uparrow}$*-to-*$\mathsf{StreamName}^{\uparrow}$ *readback determinacy,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *factorization of every* $\mathsf{Real}^{\uparrow}$ *read, public-row uniqueness, and ledger non-escape. The package ranges only over the displayed* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows of* T*.*

Proof. First project the carrier and local naming surface. The carrier definition supplies the rows $R, S, G, W, E, H, C, P, N$, while Definition 437.2 supplies the local carrier, classifier, transported-window exactness, seal-exhaustion, and non-escape obligations.

Next assemble the readback and Real-facing parts. Apply Definition 437.3 to read the transported $\mathsf{Rat}^{\uparrow}$ row through the constant $\mathsf{StreamName}^{\uparrow}$ window and the $\mathsf{RegSeqRat}^{\uparrow}$ finite-window seal. Apply Definition 437.4 to force every $\mathsf{Real}^{\uparrow}$ consumer path through the $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ packet and the same $\mathsf{RegSeqRat}^{\uparrow}$ seal row.

Finally repack the consumer boundary. The uniqueness theorem identifies the public seal row determined by the displayed components, the carrier-obligation theorem and classifier-obligation theorem expose the finite admission and comparison clauses, and Definition 437.14 together with ledger non-escape blocks quotient streams, host equality, selected limits, choice, and real-completeness data. □

Theorem 437.19 (Transported stationary window-seal selected-tail stability)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ and $T' = (R', S', G', W', E', H', C', P', N')$ be accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packets. Suppose the rows R, S, G, W compare with R', S', G', W' under the displayed* hsame *rows and* Cont *routes carried by H, H', C, C'. Then the selected finite-window tail route used by G and W is stable under the same transport: the transported route selected for T and the route selected for T' expose the same public* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window seal and* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *boundary.*

Moreover, every $\mathsf{Real}^{\uparrow}$ *seal read through E or E' still factors through the transported rows R, S, G, W, H, C, P, N and $R', S', G', W', H', C', P', N'$. The comparison does not introduce quotient streams, selected host limits, choice, or real-completeness data.*

Proof. First use readback determinacy. Agreement of R with R' through the displayed hsame and Cont routes fixes the corresponding constant $\mathsf{StreamName}^{\uparrow}$ windows S, S' and the regular-rational finite-window seals G, G' at the public readback boundary.

Next apply the classifier obligation. Its componentwise comparison keeps R, S, G, W aligned with R', S', G', W' through the same transported rows rather than through an ambient stream equality. Hence the finite tail route selected by G and W is carried to the finite tail route selected by G' and W'.

Now apply Real factorization. Any $\mathsf{Real}^{\uparrow}$ read through E must pass through W and G, and any read through E' must pass through W' and G', together with the displayed transport, route, provenance, and local naming rows.

Finally use ledger non-escape. Since quotient streams, selected host limits, choice, and real-completeness data are not coordinates of either carrier, transport stability can only assert equality of the displayed finite-window route and its public Real-facing factorization. □

Theorem 437.20 (Transported stationary window-seal public export certificate)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

Definition 437.2, Definition 437.3, Definition 437.4, Definition 437.5, Definition 437.6, and Definition 437.18 assemble one public export certificate over $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *Every* $\mathsf{Real}^{\uparrow}$*-facing read factors through the finite public rows $R, S, G, W, E, H, C, P, N$, and the certificate exports no quotient stream, host equality, selected limit, choice principle, or real-completeness datum.*

Proof. Project the accepted packet as $T = (R, S, G, W, E, H, C, P, N)$. The NameCert obligation theorem supplies the carrier, classifier, transported-window exactness, seal-exhaustion, and non-escape clauses for exactly these rows.

The readback determinacy theorem fixes the $\mathsf{Rat}^{\uparrow}$ input, the $\mathsf{StreamName}^{\uparrow}$ stationary window, and the $\mathsf{RegSeqRat}^{\uparrow}$ seal as one finite route. The Real factorization theorem then sends every $\mathsf{Real}^{\uparrow}$-facing consumer through the $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ row and that same seal route.

Use uniqueness to identify the public row determined by the displayed carrier and classifier data. The obligation package collects these clauses into one consumer-facing certificate, and ledger non-escape removes every coordinate not present in $R, S, G, W, E, H, C, P, N$.

Thus the exported certificate is public over the listed BEDC kernel and setup objects, while quotient streams, host equality, selected limits, choice, and real-completeness data remain outside its ledger surface. □

Theorem 437.21 (Transported stationary window-seal obligation readiness)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

the checked NameCert *obligations, readback determinacy, and* $\mathsf{Real}^{\uparrow}$ *factorization rows assemble the obligation-readiness package for the Real and Completion route over* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *This package consists of carrier admission for T, componentwise public readback from R through S and G, factorization of every* $\mathsf{Real}^{\uparrow}$*-facing read through W and G, the public export certificate, and ledger non-escape. It does not claim RealUp completeness, quotient-stream equality, host equality, selected limits, or choice.*

Proof. The carrier and classifier surface is the checked NameCert obligation row of Definition 437.2. It supplies the finite packet coordinates, the componentwise comparison rule, transported-window exactness, seal exhaustion, and the non-escape boundary.

The readback and real-facing routes are the two other checked rows. Apply Definition 437.3 to fix the transported $\mathsf{Rat}^{\uparrow}$ row, constant $\mathsf{StreamName}^{\uparrow}$ window, and $\mathsf{RegSeqRat}^{\uparrow}$ finite-window seal as one public readback route. Apply Definition 437.4 to force every $\mathsf{Real}^{\uparrow}$ read through the displayed $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ packet and the same regular-rational seal row.

It remains to package these rows as the obligation-readiness surface. The public export certificate of Definition 437.20 collects the carrier, readback, factorization, uniqueness, and package clauses over the listed BEDC objects, while Definition 437.6 blocks quotient streams, host equality, choice, selected limits, and real-completeness data. Therefore the accepted packet exposes exactly the finite readiness package stated above. □

Theorem 437.22 (Transported stationary window-seal window source lock)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

the rows R, S, G form one stationary source route through the displayed transport row H, continuation row C, provenance row P, and local naming row N. The $\mathsf{Rat}^{\uparrow}$ *classifier row R, constant* $\mathsf{StreamName}^{\uparrow}$ *window row S, and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row G cannot be read as separate sources by a downstream* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer.*

Proof. Project the accepted carrier T. The rows R, S, and G are listed in the same finite packet as the transport, continuation, provenance, and naming rows.

Apply Definition 437.3. It fixes the transported $\mathsf{Rat}^{\uparrow}$ row, the constant $\mathsf{StreamName}^{\uparrow}$ window, and the $\mathsf{RegSeqRat}^{\uparrow}$ seal as one public readback route.

Now use the package and ledger rows. The route can be transported through H, followed through C, named by P, and exposed by N, but there is no carrier coordinate that separates R, S, or G into an independent source for a downstream consumer. □

Theorem 437.23 (Transported stationary window-seal stationary diagonal handoff)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet $T = (R, S, G, W, E, H, C, P, N)$, the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row W consumes the same stationary source route R, S, G, H, C, P, N before the* $\mathsf{Real}^{\uparrow}$ *seal row E is read. Thus the diagonal window handoff is ordered:*

$$(R, S, G, H, C, P, N) \longrightarrow W \longrightarrow E.$$

No consumer may bypass W and read E directly from an ambient stream, quotient equality, selected limit, or completeness datum.

Proof. Begin with the source route of Definition 437.22. It identifies the transported rational row, stationary window row, and regular-rational seal row as one displayed route through H, C, P, N.

Apply Definition 437.4. Every $\mathsf{Real}^{\uparrow}$-facing read must factor through the $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ row W and the same regular-rational seal route.

The seal row E is therefore downstream of W. Ledger non-escape rules out a direct route from an ambient stream, quotient equality, selected limit, or completeness datum into E, so the displayed handoff has exactly the order stated above. □

Theorem 437.24 (Transported stationary window-seal Real seal non-escape package)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, the Real and RegSeqRat handoff package is the finite assembly of the carrier row, readback determinacy, Real-facing factorization, uniqueness, public export certificate, and ledger non-escape:*

1. *the carrier is exactly* $R, S, G, W, E, H, C, P, N$*;*
2. *readback determinacy locks* R, S, G *to one transported stationary source route;*
3. *Real-facing factorization sends every seal read through* W *and* G *before* E*;*
4. *uniqueness identifies the public row determined by the displayed carrier and classifier data;*
5. *the ledger exports no quotient stream, host equality, selected limit, choice principle, or real-completeness datum.*

Proof. The carrier clause is the packet of Definition 437.1, and the NameCert obligations are those of Definition 437.2.

Readback determinacy is supplied by Definition 437.3; the source-lock theorem above repackages that determinacy as a single route through H, C, P, N.

For the Real-facing side, use Definition 437.23. It combines the Real factorization theorem with the $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ row, forcing the seal row E to be downstream of W and G.

Finally apply Definition 437.5, Definition 437.20, and Definition 437.6. These give the public row, the export package, and the non-escape boundary, which together form the exact Real and RegSeqRat handoff package stated above. □

Theorem 437.25 (Transported stationary window-seal envelope window exactness)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row* W *may be read only after the stationary source route*

$$R \longmapsto S \longmapsto G$$

has been fixed through the displayed hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. The row* W *is therefore the finite envelope over the transported* $\mathsf{Rat}^{\uparrow}$ *classifier row* R*, the constant* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row* G*, and it must be read before the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is available to any completion-facing or real-facing consumer.*

Proof. Project the accepted carrier. The only rows available before the envelope are the displayed stationary route R, S, G and its transport, continuation, package, and local naming provenance H, C, P, N.

Apply Definition 437.22. It binds R, S, and G as one public source route, so a consumer cannot select an independent stream window or regular-rational seal before reading W.

Next use Definition 437.23. It places the $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ row after the stationary route and before the $\mathsf{Real}^{\uparrow}$ seal row.

Finally, Definition 437.6 removes the possible bypasses. Quotient streams, host equality, selected limits, choice, and real-completeness data are not carrier coordinates, so W is exactly the envelope window at the stated boundary. □

Theorem 437.26 (Transported stationary window-seal constant-window triad)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, the rows* R*,* S*, and* G *form one constant-window triad under the displayed rows* H, C, P, N*. The transported* $\mathsf{Rat}^{\uparrow}$ *classifier, the constant* $\mathsf{StreamName}^{\uparrow}$ *window, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window seal are transported, replayed, packaged, and named together; no downstream* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{Completion}^{\uparrow}$ *consumer may read one of the three as a separate source.*

Proof. Start from the carrier and classifier obligations in Definition 437.2. They admit exactly the rows $R, S, G, W, E, H, C, P, N$ and compare accepted packets componentwise through the displayed transport and continuation rows.

Apply Definition 437.3. It identifies the readback of the transported rational row with the constant stream window and the regular-rational seal, all through the same public route.

Use Definition 437.22 to repackage that route under H, C, P, N. The structural rows can transport, replay, package, and name the triad, but they do not split it into separate source certificates.

The envelope and Real-facing rows consume the triad only through Definition 437.25 and Definition 437.4. Thus any completion-facing or real-facing read sees R, S, G as one constant-window triad. □

Theorem 437.27 (Transported stationary window-seal completion consumer boundary)**.** *Every completion-facing or real-facing consumer of an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet factors through the finite public packet*

$$R, S, G, W, E, H, C, P, N.$$

The consumer first reads the constant-window triad R, S, G*, then the envelope row* W*, then the seal row* E*, with* H, C, P, N *carrying only displayed transport, continuation, package, and local naming data. The packet provides no quotient stream, host equality, selected limit, choice principle, or real-completeness datum.*

Proof. First assemble the source side. By Definition 437.26, the transported rational row, constant window row, and regular-rational seal row are one finite source triad under H, C, P, N.

Next assemble the envelope side. Apply Definition 437.25; it forces each completion-facing or real-facing route to read W after R, S, G and before E.

Now apply the checked Real-facing package. The Real factorization theorem, the stationary diagonal handoff theorem, and Definition 437.24 bind the seal read to the same rows $R, S, G, W, E, H, C, P, N$.

Finally close the consumer boundary with Definition 437.6. Since quotient streams, host equality, selected limits, choice, and real-completeness data are absent from the packet, every consumer route factors through the displayed finite BEDC packet and nothing outside it. □

Theorem 437.28 (Transported stationary window-seal tail-cofinality handoff)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet, and let* $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ *be an accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet consumed on the same finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row. Every completion-facing or real-facing read first factors through the transported stationary triad*

$$R \longmapsto S \longmapsto G,$$

then through the scheduled tail-cofinality route

$$E_T \longmapsto W_T \longmapsto D_T \longmapsto R_T \longmapsto L_T$$

with structural rows H_T, C_T, P_T, N_T, and only then through the finite envelope W and seal row E of T. The combined handoff exports no quotient-stream equality, selected host limit, host real equality, choice principle, hidden tail oracle, ambient completeness, or second completion route.

Proof. Begin with the local stationary source. By Definition 437.26, the rows R, S, G are one transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ triad under the displayed H, C, P, N rows.

Next apply Definition 437.25. It places the finite envelope row W downstream from that triad and upstream from the local seal row E, so the transported packet has no route that reaches W or E before the triad is fixed.

Now read the schedule packet on the same window and seal row. The real-seal readback theorem Definition 681.6 routes every schedule-facing $\mathsf{Real}^{\uparrow}$ read through E_T, W_T, D_T, R_T, L_T, and Definition 681.8 keeps the same route inside BHist, hsame, Cont, Pkg, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the local $\mathsf{NameCert}$ row.

For completion-facing consumers, use Definition 681.9. It places the completion seal read after the same scheduled route, and Definition 681.10 keeps the shared finite window and tail budget as the unique displayed factorization for the participating Real and Completion rows.

Finally combine the schedule exclusions with Definition 437.6. Neither packet contains a coordinate for quotient-stream equality, selected host limits, host real equality, choice, hidden tail oracles, ambient completeness, or another completion route. Thus every completion-facing or real-facing consumer must pass through the transported triad, the schedule rows, and then the finite envelope and seal row in the order stated. □

Lean4 ✓ `BEDC.Derived.TransportedStationaryWindowSealUp.TransportedStationaryWindowSealTailCofinalityHar`

Theorem 437.29 (Transported stationary window-seal root envelope exhaustion)**.** *Every root consumer read of an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N)$$

passes first through the transported seed route

$$R, S, G, H, C, P, N,$$

then through the finite envelope row W, and then through the $\mathsf{Real}^{\uparrow}$*-facing seal row E. Any* $\mathsf{Completion}^{\uparrow}$*-facing or tail-cofinality consumer that accepts the packet must reuse this same envelope route:*

$$(R, S, G, H, C, P, N) \longrightarrow W \longrightarrow E.$$

It cannot introduce quotient streams, host equality, selected limits, choice, hidden tail oracles, real-completeness data, or a second completion route.

Proof. Start with the transported seed. By Definition 437.26, the rows R, S, G form one constant-window triad carried only by the displayed transport, continuation, package, and local naming rows H, C, P, N.

Next read the finite envelope. Apply Definition 437.25; it places W downstream from the transported triad and upstream from the $\mathsf{Real}^{\uparrow}$ seal row E. The root read therefore reaches E only after the same finite envelope has been fixed.

For completion-facing consumers, use Definition 437.27. It forces each completion-facing or real-facing route to factor through $R, S, G, W, E, H, C, P, N$, with W between the source triad and the seal row. For tail-cofinality consumers, Definition 437.28 keeps the schedule rows downstream of the transported triad and upstream of the same envelope and seal rows.

Finally apply Definition 437.6. Since quotient streams, host equality, selected limits, choice, hidden tail oracles, real-completeness data, and second completion routes are not packet coordinates, every root consumer read is exhausted by the displayed route. □

Theorem 437.30 (Transported stationary window-seal root readback totality)**.** *Every root-facing read of an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N)$$

passes through the transported $\mathsf{Rat}^{\uparrow}$ *row* R*, the constant* $\mathsf{StreamName}^{\uparrow}$ *window* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row* G*, the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *packet* W*, and the* $\mathsf{Real}^{\uparrow}$ *seal row* E *in that order. Thus the root-facing readback route is total exactly along*

$$R \longrightarrow S \longrightarrow G \longrightarrow W \longrightarrow E,$$

with H, C, P, N *carrying only the displayed transport, continuation, provenance, and local naming rows.*

Proof. Unpack the carrier in Definition 437.1. Its visible coordinates already separate the transported rational seed row R, the constant stream window S, the regular-rational seal row G, the finite envelope W, and the real-facing seal row E.

The seed-window part is fixed by Definition 437.8. It makes every root-facing seed read pass from the transported $\mathsf{Rat}^{\uparrow}$ row to the induced $\mathsf{StreamName}^{\uparrow}$ window and then to the $\mathsf{RegSeqRat}^{\uparrow}$ seal row.

Next apply Definition 437.4 and Definition 437.25. These place W after the same seed-window-seal route and place the $\mathsf{Real}^{\uparrow}$ seal row E after W.

No other root-facing coordinate remains. The transport, continuation, provenance, and local naming rows H, C, P, N only record the displayed route, so the readback is total along the stated order. □

Theorem 437.31 (Transported stationary window-seal root package exactness)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, the package row* P *is exactly the provenance boundary over*

$$\mathsf{Rat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{FiniteWindowEnvelope}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{NameCert}.$$

It records no provenance outside these rows, and every public export of the packet reads P *only through this displayed boundary.*

Proof. Begin with the obligation surface in Definition 437.2. Its carrier, classifier, transported-window, seal-exhaustion, and non-escape clauses list exactly the source rows used by the packet.

The public export certificate Definition 437.20 then collects these rows over $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. The only package coordinate available in the carrier is P.

Therefore P is the provenance boundary for the displayed BEDC objects. Since the same certificate excludes quotient streams, host equality, selected limits, choice, and real-completeness data, no external provenance can be imported through the package row. □

Theorem 437.32 (Transported stationary window-seal root consumer nonescape)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet*

$$T = (R, S, G, W, E, H, C, P, N)$$

factors through the displayed finite packet. Such a consumer cannot import quotient streams, host equality, choice, selected host limits, hidden tail oracles, real-completeness data, or a second completion route.

Proof. Start with Definition 437.6. It inspects the finite packet ledger and removes quotient streams, host equality, selected limits, choice, hidden tail oracles, real-completeness data, and alternate completion routes from the available coordinates.

For completion-facing reads, apply Definition 437.27. It forces each $\mathsf{Completion}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer to factor through $R, S, G, W, E, H, C, P, N$ rather than through an ambient completion object.

Finally use Definition 437.34. The shared $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ seal budget is exhausted by the displayed packet and its schedule-facing rows, so no downstream consumer can attach another source outside the finite route. □

Theorem 437.33 (Transported stationary window-seal tail schedule envelope order)**.** *Let*

$$T = (R, S, G, W, E, H, C, P, N)$$

be an accepted $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet, and let*

$$Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$$

be an accepted $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet consumed on the same finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row. Every accepted completion-facing or real-facing packet read must encounter the transported rows* R, S, G *before the TailCofinalitySchedule rows* $E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T$*, and must encounter those schedule rows before the envelope and seal rows* W, E *of* T*. Hence the only exposed root-to-completion order is*

$$R, S, G, H, C, P, N \longrightarrow E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T \longrightarrow W \longrightarrow E.$$

Proof. First fix the transported source. By Definition 437.26, the rows R, S, G are the constant transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ triad under the displayed H, C, P, N rows. Thus any accepted read that uses the packet begins with the transported triad rather than with a schedule row.

Next attach the shared tail schedule. The handoff theorem Definition 437.28 places the TailCofinalitySchedule route after the transported triad for both completion-facing and real-facing consumers, while retaining the same finite $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ seal row.

Finally apply Definition 437.29. It places the finite envelope row W and the $\mathsf{Real}^{\uparrow}$-facing seal row E after every transported root read. Combining the three constraints gives exactly the displayed order and leaves no earlier access to W or E. □

Theorem 437.34 (Transported stationary window-seal shared window budget exhaustion)**.** *For any accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$ *and any accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet* $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ *consumed on*

its same finite window and seal row, the shared $\mathsf{StreamName}^{\uparrow}$ *window budget and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal budget are exhausted by*

$$R, S, G, H, C, P, N, E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T, W, E.$$

No accepted consumer can append a hidden tail oracle, a second $\mathsf{StreamName}^{\uparrow}$ *family, an additional* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row, quotient-stream equality, selected host limits, host equality, choice, or ambient real-completeness data to that budget.*

Proof. The root packet owns the finite window and seal budget through Definition 437.25: the transported triad reaches W and E only through the displayed $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows. Thus the root side has no spare coordinate where a separate window family or seal family could be stored.

The tail-cofinality handoff Definition 437.28 then consumes the schedule packet on that same window and seal row. Its schedule rows therefore refine the already displayed budget instead of creating a new one.

It remains to exclude external resources. Apply Definition 437.6; the packet ledger has no coordinate for hidden tail oracles, quotient-stream equality, selected limits, host equality, choice, ambient completeness, or another completion route. Hence the displayed rows exhaust the shared window and seal budget. □

Theorem 437.35 (Transported stationary window-seal completion route uniqueness)**.** *Let T and Q be as in Definition 437.34. Any completion-facing consumer and any* $\mathsf{Real}^{\uparrow}$*-facing consumer that preserve the displayed transported rows, schedule rows, finite envelope, and seal row determine the same route*

$$(R, S, G, H, C, P, N) \longrightarrow (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T) \longrightarrow W \longrightarrow E.$$

Consequently the transported stationary window-seal packet has a unique completion route at the exposed NameCert boundary.

Proof. Start at the consumer boundary. By Definition 437.27, every completion-facing or real-facing consumer of T factors through the displayed transported rows and cannot bypass $R, S, G, W, E, H, C, P, N$.

The root envelope exhaustion theorem Definition 437.29 fixes the root route from the transported rows to W and then to E. The tail schedule envelope order theorem Definition 437.33 inserts the schedule rows in the only position compatible with both the transported triad and the envelope boundary.

Finally Definition 437.34 rules out any second window family, second seal budget, hidden tail oracle, or ambient completion datum. Two consumers preserving the displayed rows therefore preserve the same finite route, so the completion route is unique at the exposed boundary. □

Theorem 437.36 (Transported stationary window-seal schedule-envelope determinacy)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet and let $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ be an accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet consumed on the same* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row. Any completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing consumer preserving the transported source rows R, S, G and the tail schedule rows of Q must read the finite envelope row W before it reads the* $\mathsf{Real}^{\uparrow}$ *seal row E.*

Equivalently, the consumer route has the deterministic exposed order

$$R, S, G, H, C, P, N \longrightarrow E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T \longrightarrow W \longrightarrow E.$$

Proof. The transported source is fixed by the constant-window triad and the tail-cofinality handoff. These place the $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows before the schedule packet and force the schedule packet to use the same displayed finite window and seal row.

The finite envelope position is then fixed by Definition 437.29. It sends every accepted root read through W before the $\mathsf{Real}^{\uparrow}$-facing seal row E.

Finally Definition 437.33 and Definition 437.34 exclude a second schedule, a second finite envelope, or an earlier seal read. The displayed order is therefore the only deterministic completion-facing order. □

Theorem 437.37 (Transported stationary window-seal Real RegSeqRat source totality)**.** *For an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$*-facing seal row* E *is sourced only through the transported* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *triad* R, S, G *together with the displayed transport, package, and NameCert rows* H, C, P, N*. No* $\mathsf{Real}^{\uparrow}$ *consumer of* E *can draw a source from quotient-stream equality, host equality, selected limits, choice, ambient real completeness, hidden tail oracles, or an independent completion object.*

Proof. Start with the envelope exactness theorem. The row E is exposed as the seal-facing $\mathsf{Real}^{\uparrow}$ row reached from the finite $\mathsf{StreamName}^{\uparrow}$ envelope W and the $\mathsf{RegSeqRat}^{\uparrow}$ seal row, and both are carried by the transported triad R, S, G.

The provenance and nonescape theorems then identify the available BEDC rows: $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. There is no additional carrier coordinate from which another real source could be read.

For completion-facing uses, Definition 437.28 and Definition 437.27 keep the same source triad upstream of the shared schedule and seal. Thus every $\mathsf{Real}^{\uparrow}$-facing read of E is total over exactly the displayed transported source route. □

Theorem 437.38 (Transported stationary window-seal NameCert route exhaustion)**.** *Let* T *and* Q *be as above. The exposed* $\mathsf{NameCert}$ *route surface of* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *is exhausted by the transported source triad, the tail schedule packet, the finite envelope, and the* $\mathsf{Real}^{\uparrow}$ *seal row:*

$$(R, S, G, H, C, P, N), (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T), W, E.$$

Every accepted completion-facing or $\mathsf{Real}^{\uparrow}$*-facing consumer preserving these rows determines the unique route of Definition 437.35, and every* $\mathsf{Real}^{\uparrow}$ *seal source is the triad-total source of Definition 437.37.*

Proof. First apply Definition 437.36. It fixes the order from the transported rational source through the tail schedule and finite envelope to the $\mathsf{Real}^{\uparrow}$ seal.

Next apply Definition 437.37. It identifies the source of the seal row with the transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ triad, with no external real or completion source.

Finally use Definition 437.35. Since the shared window budget is already exhausted, the NameCert surface has no remaining coordinate for another source, schedule, envelope, or seal. The displayed rows therefore exhaust the deterministic route surface. □

Theorem 437.39 (Transported stationary window-seal source triad totality)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The source triad* R, S, G *is total over the* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows through the displayed support rows* H, C, P, N*: every completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing route that reads* T *first reads the transported rational classifier* R*, the constant stream-name window* S*, and the regular rational seal row* G *through the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. No*

route may read a completion object, quotient stream, selected host limit, host equality row, choice datum, or real-completeness witness before this triad is fixed.

Proof. Project the accepted packet through Definition 437.2. Its carrier and classifier obligations expose R, S, G together with H, C, P, N as the named source surface of the transported stationary window seal.

Use Definition 437.26 and Definition 437.45. They identify the $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows as one ordered source triad before any tail schedule, finite envelope, or $\mathsf{Real}^{\uparrow}$ seal is consumed.

The L10 handoff basis Definition 437.48 then places every completion-facing or $\mathsf{Real}^{\uparrow}$-facing read behind this same triad. The non-escape clauses of Definition 437.6 exclude quotient streams, selected host limits, host equality, choice, and real-completeness data from the source surface. □

Theorem 437.40 (Transported stationary window-seal envelope seal exactness obligation)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The finite envelope row W and the* $\mathsf{Real}^{\uparrow}$ *seal row E are exact only after the source triad R, S, G, H, C, P, N and the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row have been fixed. Thus every accepted envelope-seal consumer reads the route*

$$R, S, G, H, C, P, N \to W \to E$$

and no consumer may obtain W or E from an earlier real row, quotient-stream equality, host equality, selected host limit, choice datum, hidden tail oracle, or ambient completeness principle.

Proof. Begin with source-triad totality above. It fixes R, S, G, H, C, P, N as the only source available before the finite envelope and seal rows are read.

Apply Definition 437.25 and Definition 437.29. These theorems put the $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ row W downstream of the triad and upstream of the $\mathsf{Real}^{\uparrow}$ seal row E.

Finally use Definition 437.55 and Definition 437.59. They force every downstream envelope-seal read to preserve the same window and seal rows, while the listed excluded objects remain outside the accepted packet. □

Theorem 437.41 (Transported stationary window-seal completion handoff exhaustion)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet, and let $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ be an accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet consumed on the same finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row. Every* $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff is exhausted by the transported source triad, finite envelope, seal row, structural support, and displayed tail-cofinality schedule rows:*

$$R, S, G, W, E, H, C, P, N, E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T.$$

There is no remaining handoff coordinate for quotient streams, host equality, choice, selected limits, hidden tail oracles, real-completeness data, or a second completion source.

Proof. First assemble the root handoff surface. The source-triad totality and envelope-seal exactness obligations above give R, S, G, H, C, P, N, then W, then E as the ordered local route.

Attach the schedule rows with Definition 437.28, Definition 437.33, and Definition 437.58. These bind the tail-cofinality packet to the same finite stream window and regular rational seal before the envelope-seal handoff is opened.

Now apply Definition 437.60 and Definition 437.62. They make downstream $\mathsf{Completion}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers read exactly the displayed root rows together with the displayed schedule rows.

The completion route is unique by Definition 437.35. Since the accepted packets expose no quotient streams, host equality, choice, selected limits, hidden tail oracles, real-completeness data, or second completion source, the displayed rows exhaust every handoff. □

Theorem 437.42 (Transported stationary window-seal tail route totality)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet and let* $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ *be an accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet consumed on the same finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row. Every accepted completion-facing route that preserves the transported source rows of* T *and the schedule rows of* Q *is total over the displayed route*

$$(R, S, G, H, C, P, N) \longrightarrow (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T) \longrightarrow W \longrightarrow E.$$

It has no additional tail oracle, second $\mathsf{StreamName}^{\uparrow}$ *window, second* $\mathsf{RegSeqRat}^{\uparrow}$ *seal, quotient-stream equality, selected host limit, choice principle, ambient real-completeness witness, or independent* $\mathsf{Completion}^{\uparrow}$ *carrier.*

Proof. First fix the transported source route. The carrier obligation and Definition 437.26 identify R, S, G as one transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ route under H, C, P, N.

Next attach the schedule. Apply Definition 437.28; it places the TailCofinalitySchedule packet on the same finite window and seal row and routes completion-facing consumers through $E_T, W_T, D_T, R_T, L_T, H_T, C$ after the transported triad.

Now read the envelope and seal. The completion-consumer boundary and Definition 437.29 force the finite envelope W and the $\mathsf{Real}^{\uparrow}$ seal row E to be read after the transported source and schedule rows.

Finally use Definition 437.34 and Definition 437.35. The shared budget has no remaining coordinate for another source, schedule, envelope, completion carrier, or real-completeness datum, so the displayed completion-facing route is total. □

Theorem 437.43 (Transported stationary window-seal Real observation budget coherence)**.** *For accepted packets* $T = (R, S, G, W, E, H, C, P, N)$ *and* $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ *as above, the* $\mathsf{Real}^{\uparrow}$ *observation budget exported by* T *is coherent with the tail schedule budget of* Q*. Every* $\mathsf{Real}^{\uparrow}$*-facing read of* E *uses the transported* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *source route* R, S, G, H, C, P, N*, the scheduled tail rows* $E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T$*, and the finite envelope row* W *before it reaches* E*.*

In particular, no accepted $\mathsf{Real}^{\uparrow}$ *observer can split the observation budget into an envelope-only real row, a schedule-only real row, a selected host limit, quotient-stream equality, host real equality, choice, ambient completeness, or a second completion source.*

Proof. Begin with the Real factorization. By Definition 437.4 and Definition 437.16, every $\mathsf{Real}^{\uparrow}$ read of E factors through the same $\mathsf{RegSeqRat}^{\uparrow}$ seal row G and the finite envelope W.

The tail schedule is attached to exactly that window and seal row. Use Definition 437.28 to place Q between the transported source triad and the envelope-seal pair, and use Definition 437.33 to keep the schedule rows upstream of W and E.

The budget comparison is then forced by Definition 437.34. It states that the shared $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ budget is exhausted by the transported rows, the schedule rows, and the envelope-seal rows.

Finally apply ledger non-escape and completion-route uniqueness. Since neither packet exposes quotient streams, selected limits, host real equality, choice, ambient completeness, or another completion source, every $\mathsf{Real}^{\uparrow}$ observation budget is the single coherent budget displayed above. □

Theorem 437.44 (Transported stationary window-seal stationary window ledger exhaustion)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ and $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ be accepted packets as above. The stationary window ledger available to* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *and its tail schedule consumer is exhausted by*

$$R, S, G, H, C, P, N, E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T, W, E.$$

Every accepted NameCert route preserving the same transported source, schedule, finite envelope, and $\mathsf{Real}^{\uparrow}$ *seal is the route of Definition 437.35; there is no unused stationary-window coordinate for another tail schedule, another finite envelope, another real seal, or an independent completion route.*

Proof. First account for the root ledger. The carrier obligation, root source lock, and root ledger exhaustion theorems identify the available transported window rows as $R, S, G, W, E, H, C, P, N$ and exclude all off-packet real and completion data.

Next account for the schedule-facing ledger. The tail-cofinality handoff consumes the accepted packet Q on the same finite $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ seal row, and the shared-window budget exhaustion theorem records the exact schedule rows available to the combined route.

Now combine the two inventories. The tail route totality theorem above places the transported source rows, schedule rows, finite envelope, and real seal into one completion-facing route, while Real observation budget coherence keeps the $\mathsf{Real}^{\uparrow}$ read on that same route.

Finally apply NameCert route exhaustion and completion-route uniqueness. Any accepted route preserving the displayed rows has no coordinate left for another schedule, envelope, seal, or completion object, so the stationary window ledger is exhausted by the stated finite packet. □

Theorem 437.45 (Transported stationary window-seal root completion source order)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet, and let $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ be an accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet consumed on the same finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row. Every completion-facing root-obligation route for T first fixes the transported* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *source triad R, S, G, H, C, P, N of chapter 126 and chapter 301, then fixes the tail schedule packet Q of chapter 681, and only then reads the finite envelope W and the* $\mathsf{Real}^{\uparrow}$ *seal row E of chapter 38. The order is a root-obligation package for completion consumers, not a proof of ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the completion-consumer boundary. By Definition 437.27, every completion-facing consumer is forced through the displayed transported rows of T before it can read a seal-facing row. The source rows are precisely the transported rational route, the finite stream-name route of chapter 126, and the regular rational seal route of chapter 301.

Next attach the schedule. The handoff theorem Definition 437.28 places the packet of chapter 681 after the transported source triad and before the envelope-seal read.

Finally use Definition 437.37. It identifies the $\mathsf{Real}^{\uparrow}$ row of chapter 38 as sourced by the same transported $\mathsf{RegSeqRat}^{\uparrow}$ seal, so the finite envelope and real seal are downstream rows of the root package rather than a real-completeness principle. □

Theorem 437.46 (Transported stationary window-seal finite-window schedule coherence)**.** *For accepted packets $T = (R, S, G, W, E, H, C, P, N)$ and $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ as above, the tail schedule rows and finite envelope rows consume the same finite* $\mathsf{StreamName}^{\uparrow}$ *window and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *seal. Thus the completion-facing root-obligation route has one* $\mathsf{StreamName}^{\uparrow}$ *window from chapter 126, one* $\mathsf{RegSeqRat}^{\uparrow}$ *seal from chapter 301, one* $\mathsf{TailCofinalitySchedule}^{\uparrow}$

packet from chapter 681, and one $\mathsf{Real}^{\uparrow}$ *seal-facing row from chapter 38, with no split between schedule and envelope budgets.*

Proof. Start with the shared source. The completion-consumer boundary Definition 437.27 keeps every accepted completion-facing read on the transported triad R, S, G, H, C, P, N, so the finite window is the one supplied by chapter 126 and the seal row is the one supplied by chapter 301.

The schedule handoff then consumes exactly those rows. By Definition 437.28, the packet of chapter 681 is attached to the same finite window and the same regular rational seal before the envelope is read.

The real-facing source theorem Definition 437.37 sends the seal row of chapter 38 back to that same transported $\mathsf{RegSeqRat}^{\uparrow}$ source. Hence the schedule and envelope rows are coherent over one finite window and one seal, with no second budget from a completion object. □

Theorem 437.47 (Transported stationary window-seal Real completion refusal cover)**.** *For accepted packets* $T = (R, S, G, W, E, H, C, P, N)$ *and* $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ *as above, the completion-facing route determined by the transported source triad, the tail schedule, the finite envelope, and the* $\mathsf{Real}^{\uparrow}$ *seal refuses every off-packet route through quotient streams, selected host limits, choice, ambient completeness, or host equality. Its visible sources remain the* $\mathsf{StreamName}^{\uparrow}$ *route of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal of chapter 301, the schedule packet of chapter 681, and the* $\mathsf{Real}^{\uparrow}$ *row of chapter 38.*

Proof. First read the route boundary. The theorem Definition 437.27 excludes any completion-facing read that bypasses the displayed packet T, so quotient streams, host equality, selected limits, choice, and ambient completeness have no entry point at the root boundary.

Next impose the tail schedule. By Definition 437.28, the schedule packet of chapter 681 is inserted only after the finite $\mathsf{StreamName}^{\uparrow}$ row of chapter 126 and the $\mathsf{RegSeqRat}^{\uparrow}$ seal of chapter 301 are fixed.

Finally apply Definition 437.37. The $\mathsf{Real}^{\uparrow}$ seal row of chapter 38 is sourced by the transported regular-rational seal, so the route covers all completion-facing refusal clauses without asserting any host real-completeness theorem. □

Theorem 437.48 (Transported stationary window-seal L10 handoff obligation basis)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. Its L10 handoff basis for Real and Completion consumers is the finite route*

$$\mathsf{Rat}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{FiniteWindowEnvelope}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow},$$

read through the visible rows $R, S, G, W, E, H, C, P, N$ *and through the sibling surfaces of chapter 37, chapter 126, chapter 301, chapter 291, chapter 365, chapter 38, and chapter 681. The basis is an obligation route for later checked carriers; it is not a host completion theorem.*

Proof. Begin with the local obligation theorem Definition 437.2. It exposes the accepted packet only through the carrier rows $R, S, G, W, E, H, C, P, N$, with componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ naming.

Next use Definition 437.4. The $\mathsf{Real}^{\uparrow}$ read cannot appear before the regular-rational seal and finite envelope rows; it must pass through the same $\mathsf{RegSeqRat}^{\uparrow}$ source and the same $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ row already displayed by the packet.

Finally attach the completion-facing side by Definition 437.27 and Definition 437.28. These place every completion consumer after the transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ source, after the dyadic and finite-window ledger rows, and before any off-packet real-completeness datum could be read. The result is exactly the stated finite handoff basis. □

Theorem 437.49 (Transported stationary window-seal dyadic window ledger totality)**.** *For an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, the dyadic window ledger available to the Real and Completion route is total only through the displayed rows* $R, S, G, W, E, H, C, P, N$ *and the sibling certificates for* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$*. In particular, any accepted dyadic tolerance, finite-window, or regular-readback consumer must read the finite* $\mathsf{StreamName}^{\uparrow}$ *window of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal of chapter 301, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger of chapter 291 before it can use* W *or* E*.*

Proof. First project the accepted packet. The obligation theorem Definition 437.2 lists exactly the root rows $R, S, G, W, E, H, C, P, N$ and gives no separate dyadic or window carrier outside them.

The finite window and regular seal are then fixed by Definition 437.4 and by the sibling StreamName and RegSeqRat chapters. The dyadic ledger is read only as the tolerance and observation surface compatible with those same rows, through chapter 291.

The route boundary Definition 437.27 and the schedule handoff Definition 437.28 rule out any second window budget, second regular seal, or detached dyadic ledger. Hence the dyadic window ledger is total exactly over the displayed packet and the named sibling certificates. □

Theorem 437.50 (Transported stationary window-seal Real RegSeq consumer exactness)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of* T *factors through the finite route from transported* $\mathsf{Rat}^{\uparrow}$ *through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *displayed in Definition 437.48. No such consumer can import quotient streams, host equality, selected limits, choice, hidden tail oracles, or real-completeness data.*

Proof. Start with the Real-facing side. By Definition 437.4, every $\mathsf{Real}^{\uparrow}$ read of E factors through the same $\mathsf{RegSeqRat}^{\uparrow}$ seal row and the finite envelope W, so there is no direct host-real read.

Now use Definition 437.27. It forces every $\mathsf{Completion}^{\uparrow}$ consumer back to the displayed root packet rather than to quotient streams, host equality, selected limits, choice, or ambient real completeness.

Finally apply Definition 437.28. The only tail information available to the consumer is the scheduled sibling route of chapter 681; no hidden tail oracle is introduced. Together with the StreamName, RegSeqRat, DyadicRatCore, FiniteWindowEnvelope, and Real sibling chapters, this gives the exact finite consumer factorization claimed above. □

Theorem 437.51 (Transported stationary window-seal open-phase exit boundary)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. Every accepted* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of* T *that preserves the displayed rows* $R, S, G, W, E, H, C, P, N$ *lands on the same four-face Phase Real and Completion route as Definition 38.530 and Definition 38.534. Its terminal boundary is the finite route through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *support rows. No quotient stream, selected host limit, host equality, choice row, ambient real-completeness datum, or standard bridge row can replace one of those four faces.*

Proof. First apply Definition 437.48. The accepted transported packet exposes only the finite handoff route through $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, read through the rows $R, S, G, W, E, H, C, P, N$ and their BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Next use Definition 437.50. It forces every $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer preserving those rows to enter the Real-facing route through the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$,

and finite-window surfaces, without quotient streams, selected limits, choice, host equality, hidden tail data, or real-completeness input.

Now compare this transported route with the open-phase Real route. Theorem 38.530 places every public $\mathsf{Real}^{\uparrow}$ seal read in the open phase after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ sibling surfaces and before the local $\mathsf{Real}^{\uparrow}$ naming row.

Finally apply Definition 38.534. The terminal Phase Real and Completion packet is determined by the four faces $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ with their BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. Since the transported consumer preserves $R, S, G, W, E, H, C, P, N$ and supplies no extra accepted face, it reaches exactly that four-face exit boundary. □

Theorem 437.52 (Transported stationary window-seal root carrier admission)**.** *Let $T = (R, S, G, W, E, H, C, P, N$ be an accepted $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ packet. The root Real and Completion handoff route admits exactly the displayed carrier rows $R, S, G, W, E, H, C, P, N$: the transported $\mathsf{Rat}^{\uparrow}$ classifier R, constant $\mathsf{StreamName}^{\uparrow}$ window S, $\mathsf{RegSeqRat}^{\uparrow}$ seal row G, finite envelope W, $\mathsf{Real}^{\uparrow}$ seal row E, transport row H, route row C, provenance row P, and local naming row N. This admission is the carrier and $\mathsf{NameCert}$ obligation surface of Definition 437.1 and Definition 437.2, read through the L10 handoff basis of Definition 437.48.*

Proof. Project the accepted carrier. The carrier definition supplies exactly the nine visible rows $R, S, G, W, E, H, C, P, N$, and the NameCert obligation theorem identifies the transport, continuity, package, and local naming obligations attached to them.

Next apply the L10 handoff basis. It orders the same rows through the transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route, so the Real and Completion handoff has no row outside the displayed packet.

Thus carrier admission for the root route is precisely the projection of T together with its displayed $\mathsf{NameCert}$ obligations. □

Theorem 437.53 (Transported stationary window-seal window envelope readback)**.** *For accepted packets $T = (R, S, G, W, E, H, C, P, N)$ and $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ sharing the displayed finite window and seal rows, the finite envelope W and the $\mathsf{Real}^{\uparrow}$ seal row E are readable only after the transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and tail-schedule rows have been fixed. Equivalently, the readback order is the root completion source order of Definition 437.45 together with the finite-window schedule coherence of Definition 437.46.*

Proof. Begin with the source order. The root completion source theorem fixes the transported rational source, the finite stream-name window, and the regular rational seal before any envelope or Real-facing row is read.

Attach the dyadic and schedule rows using the L10 handoff basis and the tail handoff theorem. These place the dyadic ledger and tail-schedule packet between the source triad and the envelope-seal boundary.

Finally use finite-window schedule coherence. Since the schedule and envelope consume the same finite $\mathsf{StreamName}^{\uparrow}$ window and the same $\mathsf{RegSeqRat}^{\uparrow}$ seal, W and E cannot be read from a separate window budget or from an earlier Real-facing source. □

Theorem 437.54 (Transported stationary window-seal completion consumer exhaustion)**.** *Every $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer accepted by a $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ packet factors through the displayed route*

$$R, S, G \longrightarrow Q \longrightarrow W, E \longrightarrow H, C, P, N.$$

No such consumer can import quotient streams, host equality, selected limits, choice, ambient completeness, or an independent completion carrier.

Proof. First use the carrier admission theorem above. It gives the consumer only the displayed packet rows and their NameCert obligations.

Next combine the root completion source order with the window envelope readback theorem. The source triad, tail schedule, finite envelope, and Real seal form one ordered route; every Real-facing or Completion-facing read must pass through it.

The refusal clauses then follow from the completion-consumer boundary and the Real completion refusal cover. Quotient streams, host equality, selected limits, choice, ambient completeness, and an independent completion carrier are not coordinates of the packet and are not supplied by any sibling handoff row. □

Theorem 437.55 (Transported stationary window-seal root envelope readback totality)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet, and let* $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ *be an accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet consumed on the same finite window and regular-rational seal. Then every* $\mathsf{Completion}^{\uparrow}$*-facing or* $\mathsf{Real}^{\uparrow}$*-facing readback of the root packet is total only along the ordered finite route*

$$R, S, G, H, C, P, N \longrightarrow E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T \longrightarrow W \longrightarrow E.$$

In particular, the readback cannot bypass the transported $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, cannot read the finite envelope before the tail schedule rows, and cannot read the* $\mathsf{Real}^{\uparrow}$ *seal row before the shared-window budget has been exhausted.*

Proof. Start with the root carrier admission and the L10 handoff basis. These expose exactly the transported source rows R, S, G, the transport-package-name rows H, C, P, N, and the sibling route through $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Next attach the readback order. The root completion source order fixes the source triad before any envelope read, and the tail-cofinality handoff places the schedule packet between the transported source and the finite envelope.

Finally use envelope exhaustion and shared-window budget exhaustion. They force the route to pass through W and then E, while excluding a second window family, second seal budget, hidden tail oracle, or off-route readback source. □

Theorem 437.56 (Transported stationary window-seal completion seal lock)**.** *For accepted packets* T *and* Q *as in Definition 437.55, the completion-facing seal exposed by* T *is locked to the same finite route. Any consumer that reaches the* $\mathsf{Completion}^{\uparrow}$ *boundary through* T *and preserves the displayed rows determines the completion route of Definition 437.35; it has no second completion route, no quotient-stream carrier, no host equality carrier, no selected limit, no choice datum, and no ambient completeness datum.*

Proof. First read the seal through the deterministic schedule-envelope order. The consumer must pass from the transported source and naming rows through the tail schedule rows before it can reach W and E.

The Real RegSeqRat source totality theorem then identifies the $\mathsf{Real}^{\uparrow}$ seal source with the transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ triad, rather than with a host-real or quotient-stream source.

The completion route uniqueness theorem supplies the lock. Since shared-window budget exhaustion has already consumed the only finite window and seal budget available to the packet, there is no coordinate left for another completion carrier or a second route to the same seal. □

Theorem 437.57 (Transported stationary window-seal downstream route readiness)**.** *The* TransportedStationaryW *root surface is ready for every downstream* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, *and* $\mathsf{Completion}^{\uparrow}$ *consumer that preserves the accepted packet rows. Such a consumer must use the single finite BEDC route*

$$R, S, G, H, C, P, N \longrightarrow E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T \longrightarrow W \longrightarrow E,$$

and the NameCert *route surface is exhausted by exactly these rows. No downstream consumer receives quotient streams, host equality, selected limits, choice, ambient completeness, hidden tail oracles, or an independent completion route from this root chapter.*

Proof. Combine root envelope readback totality with completion seal lock. The first theorem gives the only admissible order from the transported source and naming rows through the tail schedule, finite envelope, and Real seal; the second theorem locks any completion-facing read to that same route.

Now apply NameCert route exhaustion. The displayed rows already account for the carrier, classifier, transport, continuity, package, local naming, tail schedule, finite envelope, and seal obligations.

It remains only to identify the downstream surface. The named downstream chapters consume precisely those rows as finite BEDC inputs, so preserving the packet rows preserves the route. Since the route surface is exhausted, none of the refused host or quotient data can be supplied by the root packet. □

Theorem 437.58 (Transported stationary window-seal completion source triad closure)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet, and let* $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ *be an accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet consumed on the same finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row. Before any finite-envelope read of* W *or* $\mathsf{Real}^{\uparrow}$ *seal read of* E*, the transported* $\mathsf{Rat}^{\uparrow}$ *row* R*, the constant* $\mathsf{StreamName}^{\uparrow}$ *window* S*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row* G *form the closed source triad for the route.*

Proof. Begin with Definition 437.55. It orders every completion-facing or Real-facing readback through the transported rows before the tail schedule, finite envelope, and seal rows can be reached.

Now apply Definition 437.56. The lock prevents a completion consumer from choosing another completion carrier, quotient stream, host equality row, selected limit, choice datum, or ambient completeness witness before reading the seal.

The accepted schedule packet Q is therefore downstream of the already fixed source rows. Since the schedule is consumed on the same finite window and regular-rational seal, the triad R, S, G is closed as the source surface before W or E is read. □

Theorem 437.59 (Transported stationary window-seal envelope Real row totality)**.** *Let* T *and* Q *be as in Definition 437.58. Every* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *read and every* $\mathsf{Real}^{\uparrow}$*-facing read factors first through the closed source triad* R, S, G *and then through the schedule rows* $E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T$ *before reaching* W *and* E*. No such read receives a quotient stream, host equality, selected limit, choice principle, ambient completeness principle, or independent completion carrier.*

Proof. Use Definition 437.55 to fix the route order. The theorem places the transported source triad before the schedule rows, the schedule rows before the finite envelope, and the finite envelope before the Real seal row.

Next use Definition 437.56. It identifies the completion-facing seal with that same finite route, so a completion consumer cannot supply a separate carrier or host-level equality source while preserving the accepted packet rows.

Finally invoke Definition 437.57. The downstream surface already lists the permitted StreamName, RegSeqRat, FiniteWindowEnvelope, Real, TailCofinalitySchedule, and Completion consumers. Thus every envelope or Real read is total through the displayed triad and schedule rows before it reaches W and E. □

Theorem 437.60 (Transported stationary window-seal downstream obligation basis)**.** *For accepted packets T and Q as above, the downstream obligation basis consumed by* $\mathsf{Completion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *routes is exactly the pair of rows supplied by Definition 437.58 and Definition 437.59: the closed transported source triad R, S, G, followed by the accepted schedule rows and then by W, E. This basis is a finite BEDC obligation surface, not a quotient stream, host real equality, selected limit, choice principle, ambient completeness principle, or independent completion object.*

Proof. First take the source part from Definition 437.58. It supplies the transported $\mathsf{Rat}^{\uparrow}$, constant $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows before any envelope or Real seal read.

Next take the envelope and seal part from Definition 437.59. It routes every $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ read through the accepted schedule rows before reaching W and E.

The downstream route theorem Definition 437.57 packages these rows as the consumer surface. Hence Completion and Real routes consume precisely this finite obligation basis, and no off-route completion or host-real datum is added. □

Theorem 437.61 (Transported stationary window-seal window envelope source lock)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row W is source-locked to the transported* $\mathsf{StreamName}^{\uparrow}$ *row S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row G inside the finite* BHist *carrier of T: every envelope-facing read must pass through the displayed* hsame *rows,* Cont *transports,* Pkg *provenance row P, and local* $\mathsf{NameCert}$ *row N before it reaches W. No accepted read of W supplies an independent stream window, regular-rational seal, host equality, quotient stream, selected limit, choice datum, or ambient completeness witness.*

Proof. Begin with the local obligation theorem for T. It exposes the accepted packet only through $R, S, G, W, E, H, C, P, N$, with the finite BHist carrier, displayed hsame and Cont rows, package provenance, and local naming already fixed.

Next apply the window-source and envelope-window exactness theorems. They identify the constant stream window and the regular-rational seal as the only source rows from which the finite envelope can be read.

Finally use root consumer nonescape. Since the Pkg and $\mathsf{NameCert}$ rows name only the displayed BEDC sources, an envelope-facing consumer has no coordinate from which to read a second window, a second seal, or any host-level completion datum. □

Theorem 437.62 (Transported stationary window-seal Real completion route totality)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer preserving T has the total finite route*

$$\mathsf{BHist}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{FiniteWindowEnvelope}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert},$$

instantiated by the rows S, G, W, E, H, C, P, N of T. The route is total for these consumers because each read either factors through the finite envelope W before the $\mathsf{Real}^{\uparrow}$ *row E, or is refused as outside the accepted packet surface.*

Proof. First use the window envelope source lock. It fixes the only admissible source for W as the transported StreamName and RegSeqRat rows carried by T.

Next apply the root envelope readback totality and downstream route readiness theorems. Together they place every Real-facing and completion-facing consumer on the displayed finite route from the source rows through W and then to E.

The final step is the completion seal lock. It makes refusal of all off-route host data part of the same route, so totality is not supplied by quotient streams, host equality, selected limits, choice, or ambient completeness. It is supplied by the accepted rows of T. □

Theorem 437.63 (Transported stationary window-seal route provenance nonescape)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The route provenance carried by P and named by N is nonescaping: any* $\mathsf{Real}^{\uparrow}$ *or completion consumer that preserves the* BHist*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of T receives exactly the finite route through S, G, W, E, H, C, P, N. It receives no external real-completion source and no route provenance not named by the accepted packet.*

Proof. Use the public export certificate to collect the packet rows over the displayed BEDC sources. The package row P and naming row N are part of the same finite carrier, so provenance is read from inside T rather than from a host object.

Now apply the Real completion route totality theorem. It identifies the complete consumer route through S, G, W, E, H, C, P, N, with the envelope and Real rows reached only after the source rows and transports have been fixed.

Finally apply ledger nonescape and route exhaustion. The accepted packet has no additional coordinate for a second route provenance row, an external completion carrier, or an unlisted real source. Thus provenance is confined to the displayed rows. □

Theorem 437.64 (Transported stationary window-seal root L10 source cover)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. Every accepted root L10 read exposes its source cover through the displayed* $\mathsf{Rat}^{\uparrow}$ *row R, constant* $\mathsf{StreamName}^{\uparrow}$ *row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *seal G,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row W,* $\mathsf{Real}^{\uparrow}$ *row E, and the structural* BHist/hsame/Cont/Pkg/NameCert *rows H, C, P, N. Thus the completion-facing source surface of T is exactly*

$$R, S, G, W, E, H, C, P, N,$$

with no detached quotient stream, host equality row, selected limit, or ambient real-completeness datum.

Proof. Start with Definition 437.10. It assigns the displayed $\mathsf{RegSeqRat}^{\uparrow}$ seal G to the same constant $\mathsf{StreamName}^{\uparrow}$ window S and finite envelope W carried by the accepted packet.

Next apply Definition 437.4. The $\mathsf{Real}^{\uparrow}$ row E is read only through that finite RegSeqRat/envelope route, with the transported support rows H, C, P, N already present.

Finally use Definition 437.38. Since the exposed NameCert route is exhausted by the transported source triad, tail schedule, finite envelope, and Real seal, every accepted L10 source cover is the displayed row family and no extra completion or host-real coordinate remains. □

Theorem 437.65 (Transported stationary window-seal root L10 envelope stability)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *and* $T' = (R', S', G', W', E', H', C', P', N')$ *be accepted* TransportedStationaryWindowSeal *packets whose displayed rows are related componentwise by* hsame *and whose seal, envelope, and Real rows are connected by the displayed* Cont *routes. Then* T *and* T' *preserve the same finite envelope-to-*$\mathsf{Real}^{\uparrow}$ *seal route:*

$$\mathsf{StreamName}^{\uparrow}(S) \longrightarrow \mathsf{RegSeqRat}^{\uparrow}(G) \longrightarrow \mathsf{FiniteWindowEnvelope}^{\uparrow}(W) \longrightarrow \mathsf{Real}^{\uparrow}(E)$$

and likewise for the primed packet under the same componentwise transport. In particular, envelope stability is determined at the finite L10 source cover, not by a selected host limit or an external real-completeness witness.

Proof. First read the classifier obligation through Definition 437.13. Componentwise hsame keeps the accepted rows of T and T' on the same BEDC classifier surface.

Next use Definition 437.33. The schedule row places the finite envelope after the StreamName and RegSeqRat source rows and before the Real-facing seal row.

The shared budget is then fixed by Definition 437.34. No second window or tail coordinate can be inserted between the transported source and the finite envelope.

Finally apply Definition 437.36. The displayed Cont routes therefore preserve the same envelope-to-Real seal route for both packets, and stability is witnessed inside the finite source cover itself. □

Theorem 437.66 (Transported stationary window-seal root L10 downstream readiness)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. Every downstream completion-facing consumer of* T *receives exactly the finite root L10 source cover of Definition 437.64 together with the envelope-stability rows of Definition 437.65. The handoff supplies the rows*

$$R, S, G, W, E, H, C, P, N$$

and no quotient stream, host equality, selected limit, choice principle, or real-completeness datum.

Proof. Begin with Definition 437.12. It states the downstream package using the finite transported source, envelope, Real seal, and structural support rows of the accepted packet.

Then apply the source-cover theorem above. It identifies the exact L10 rows that a downstream consumer can read from T.

Use the envelope-stability theorem above to keep those rows stable under componentwise hsame and displayed Cont transport. The finite envelope-to-Real route is therefore part of the handed-off package rather than an external completion datum.

Finally invoke Definition 437.6. The ledger excludes off-packet quotient streams, host equalities, selected limits, choice principles, and ambient real-completeness witnesses, so the downstream readiness surface is exactly the finite source cover plus the stable envelope route. □

Theorem 437.67 (Transported stationary window-seal RegSeqRat Real lock)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row* G *and the* $\mathsf{Real}^{\uparrow}$ *row* E *are locked to the same* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *packet* W*: every accepted Real-facing read of* E *factors through the finite* BHist *carrier of* T*, the componentwise* hsame *rows, the displayed* Cont *transports, the* Pkg *provenance row* P*, and the local* NameCert *row* N *that already name* G *and* W*. Thus the RegSeqRat and Real rows are not two host streams; they are two reads of one transported finite-window seal route.*

Proof. Start with Definition 437.37. It identifies every $\mathsf{Real}^{\uparrow}$-facing read with the transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ triad R, S, G, together with the support rows H, C, P, N.

Next use Definition 437.33. The finite envelope row W is the only position at which the transported regular-rational seal can be read before the Real row E, so the RegSeqRat and Real rows share the same finite-window packet.

Finally read the sibling certificates chapter 126, chapter 301, chapter 365, and chapter 38 through the BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows of T. The accepted packet has no coordinate for a second regular seal or a detached host real source, giving the stated lock. □

Theorem 437.68 (Transported stationary window-seal tail budget coverage)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ packet. Every tail-budget read, tail-schedule read, or completion-facing schedule read exposed by T factors through the same finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ seal row, and $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ packet:*

$$R, S, G, H, C, P, N \longrightarrow W \longrightarrow E.$$

No accepted tail read introduces a selected host limit, quotient-stream equality, hidden tail oracle, independent completion object, or second real-completeness source.

Proof. First apply Definition 437.33. It places every tail-schedule row after the transported source triad and before the finite envelope and Real seal reads.

Then apply Definition 437.38. The exposed $\mathsf{NameCert}$ route is exhausted by the transported source triad, the schedule packet, the finite envelope, and the $\mathsf{Real}^{\uparrow}$ seal row; no unused schedule coordinate remains.

The sibling chapters chapter 126, chapter 301, and chapter 365 supply the finite window, regular-rational seal, and finite envelope surfaces consumed by the route. Since the accepted packet exposes only those BEDC rows and their BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support, selected host limits and quotient-stream equalities cannot enter as tail budget data. □

Theorem 437.69 (Transported stationary window-seal L10 exit readiness)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ packet. The Phase Real and Completion handoff consumes $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ only through the displayed finite seal route of T:*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{FiniteWindowEnvelope}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The handoff is exit-ready for the open Phase Real and Completion surface because the RegSeqRat/Real lock and tail-budget coverage determine the available rows. It makes no claim that $\mathsf{Real}^{\uparrow}$ is complete, no claim that quotient streams have been identified, and no claim of a selected host limit.

Proof. Begin with Definition 437.48. It lists the only L10 route available to Real and Completion consumers: the finite passage through the StreamName, RegSeqRat, DyadicRatCore, FiniteWindowEnvelope, and Real sibling surfaces.

Use Definition 437.67 to bind the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ reads to the same finite envelope packet W. Use Definition 437.68 to keep every tail-budget and schedule-facing read on that same finite route.

Finally compare with chapter 126, chapter 301, chapter 365, and chapter 38. These sibling surfaces provide the named rows consumed by the transported seal, while the non-escape clauses exclude quotient-stream equality, selected host limits, hidden tail data, and ambient real-completeness witnesses. The packet is therefore ready to hand off to Phase Real and Completion exactly at the finite seal boundary stated above. □

Theorem 437.70 (Transported stationary window-seal tail-budget carrier)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The finite tail/window budget carrier read by T is the single route*

$$\mathsf{StreamName}^{\uparrow}(S), \quad \mathsf{RegSeqRat}^{\uparrow}(G), \quad \mathsf{FiniteWindowEnvelope}^{\uparrow}(W), \quad \mathsf{Real}^{\uparrow}(E)$$

carried by the displayed BHist *row H, componentwise* hsame *transport,* Cont *row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}$ *row N. Any tail-cofinality or completion-facing consumer of T reads that carrier through the same finite window budget and not through a selected host tail, quotient stream, detached Real row, or off-packet completeness datum.*

Proof. Begin with Definition 437.26. It fixes the transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ source triad under the displayed support rows of T.

Next apply Definition 437.28. The tail schedule is attached to that same finite StreamName and RegSeqRat surface, so every tail-facing read uses the already displayed window budget.

Finally use Definition 437.29. It places the finite envelope W and the Real-facing seal row E downstream of the same transported source. The carrier is therefore exactly the displayed finite tail/window route, with no selected host tail, quotient stream, detached Real row, or off-packet completeness datum. □

Theorem 437.71 (Transported stationary window-seal StreamName-RegSeqRat-Real route)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The public root route exposed to* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers has the fixed order*

$$\mathsf{StreamName}^{\uparrow}(S) \longrightarrow \mathsf{RegSeqRat}^{\uparrow}(G) \longrightarrow \mathsf{FiniteWindowEnvelope}^{\uparrow}(W) \longrightarrow \mathsf{Real}^{\uparrow}(E),$$

with the $\mathsf{BHist}/\mathsf{hsame}/\mathsf{Cont}/\mathsf{Pkg}/\mathsf{NameCert}$ *rows H, C, P, N transported along the route. No accepted consumer can read E before the finite envelope or separate G from the stationary StreamName window.*

Proof. First apply Definition 437.26. The StreamName and RegSeqRat rows are already one transported finite source surface, so a consumer cannot choose an independent regular sequence row.

Then use Definition 437.29. It forces every root read to pass through the finite envelope before the $\mathsf{Real}^{\uparrow}$ seal row is available.

Finally invoke Definition 437.38. The displayed $\mathsf{NameCert}$ surface is exhausted by the transported source triad, tail schedule, finite envelope, and Real seal. Hence the only public route order is the StreamName-RegSeqRat-envelope-Real route stated above. □

Theorem 437.72 (Transported stationary window-seal root-readiness package)**.** *Let $T = (R, S, G, W, E, H, C, P, N$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The packet is root-ready for the current Real and Completion dependency surface exactly through the tail-budget carrier of Definition 437.70 and the StreamName-RegSeqRat-Real route of Definition 437.71. Thus every public root consumer sees only the finite rows S, G, W, E and the displayed* $\mathsf{BHist}/\mathsf{hsame}/\mathsf{Cont}/\mathsf{Pkg}/\mathsf{NameCert}$ *support rows H, C, P, N.*

Proof. The carrier theorem Definition 437.70 supplies the finite tail/window budget used by tail-cofinality and completion-facing consumers. It fixes the available carrier rows as S, G, W, E with the support rows H, C, P, N.

The route theorem Definition 437.71 then orders those rows for public StreamName, RegSeqRat, and Real reads. Together with Definition 437.38, there is no remaining root coordinate outside the displayed carrier and route.

Consequently the accepted packet supplies the root-readiness package needed by the current Real and Completion dependency surface. It does not assert full real completeness, quotient-stream identification, host real equality, a selected host limit, a metric-completeness principle, or a bridge row. □

Theorem 437.73 (Transported stationary window-seal tail cofinality totality)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. Every accepted read of the tail schedule attached to T passes first through the* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet on the displayed* $\mathsf{StreamName}^{\uparrow}$ *row S and* $\mathsf{RegSeqRat}^{\uparrow}$ *row G, together with the support rows H, C, P, N, before it reaches any finite envelope row W or* $\mathsf{Real}^{\uparrow}$ *seal row E.*

Consequently the tail-facing obligation surface of T is the finite route

$$R, S, G, H, C, P, N \longrightarrow \mathsf{TailCofinalitySchedule}^{\uparrow} \longrightarrow W \longrightarrow E,$$

with no earlier envelope, detached tail oracle, quotient stream, host equality, selected limit, or ambient completeness coordinate.

Proof. Start with Definition 437.10. It assigns the $\mathsf{RegSeqRat}^{\uparrow}$ seal G to the constant $\mathsf{StreamName}^{\uparrow}$ window S already carried by the accepted packet.

Next use Definition 437.33. The tail schedule row is read before the finite envelope and before the Real-facing seal, so a tail-facing consumer has no route that reaches W or E first.

Finally apply Definition 437.37 and Definition 437.38. These identify the Real source and the public NameCert surface with the displayed rows only, hence the tail schedule read is total over the stated finite route. □

Theorem 437.74 (Transported stationary window-seal dyadic radius readback)**.** *Let $T = (R, S, G, W, E, H, C, P, N$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The dyadic-radius evidence consumed by T is exactly the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback attached to the constant* $\mathsf{StreamName}^{\uparrow}$ *window S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal G. It is not a separate radius oracle and it does not add a coordinate beyond the displayed* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BHist/hsame/Cont/Pkg}$, *and* $\mathsf{NameCert}$ *rows.*

Proof. First apply Definition 437.10. The window and regular-sequence rows are owned by the same transported source triad, so the radius readback is tied to S and G rather than to an independent oracle.

Then use Definition 437.33. The dyadic evidence is consumed on the same route that places the tail schedule before the finite envelope and Real seal.

The non-escape side is supplied by Definition 437.11 and Definition 437.38. Since the Real seal and NameCert route expose only the displayed packet rows, a second dyadic-radius source has no public coordinate on the accepted surface. □

Theorem 437.75 (Transported stationary window-seal Real handoff non-escape)**.** *Let $T = (R, S, G, W, E, H, C, P,$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *or Completion handoff through T factors through the displayed route*

$$R, S, G \longrightarrow \mathsf{TailCofinalitySchedule}^{\uparrow} \longrightarrow W \longrightarrow E \longrightarrow H, C, P, N.$$

The handoff exports no quotient stream, host equality, selected limit, choice coordinate, detached radius oracle, or real-completeness coordinate.

Proof. Begin with Definition 437.37. It states that the Real-facing row E is sourced only through the transported $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ triad together with the displayed support rows.

Next apply Definition 437.33. It inserts the tail cofinality schedule and finite envelope in the only order compatible with the transported triad and the Real-facing seal.

Finally use Definition 437.11 and Definition 437.38. These exclude quotient streams, host equality, selected limits, choice, detached radius data, and real-completeness witnesses from the exported route, so the Real or Completion handoff remains inside $R, S, G, W, E, H, C, P, N$. □

Definition 437.76 (Transported stationary window-seal source-triad completion packet)**.** *For an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, the source-triad completion packet is the finite BEDC route consisting of:*

1. *the transported source triad* R, S, G*, where* R *is the transported* $\mathsf{Rat}^{\uparrow}$ *source row,* S *is the constant* $\mathsf{StreamName}^{\uparrow}$ *window row, and* G *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row owned by that window;*
2. *the finite envelope and seal rows* W, E*, where* W *is the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row read after the triad and* E *is the* $\mathsf{Real}^{\uparrow}$*-facing seal row read after* W*;*
3. *the support rows* H, C, P, N*, carrying the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data for the same route;*
4. *the completion-facing consumer route*

$$R, S, G, H, C, P, N \longrightarrow W \longrightarrow E \longrightarrow \mathsf{Completion}^{\uparrow}.$$

The packet has no coordinate for quotient streams, host equality, selected host limits, choice, ambient real completeness, or hidden tail oracles; every such consumer must read the same displayed source triad before it can use the envelope row or the Real-facing seal.

Theorem 437.77 (Transported stationary window-seal source-window admission)**.** *Let* $T = (R, S, G, W, E, H, C, P$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet equipped with its source-triad completion packet. The packet admits a source-window triad only in the displayed form* R, S, G*:* R *is the transported* $\mathsf{Rat}^{\uparrow}$ *classifier row,* S *is the constant* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, and* G *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row owned by that window. No accepted read of* T *can replace this triad by a detached classifier, a moving stream window, or an independent seal source.*

Proof. Read the accepted carrier through the NameCert obligation surface of Definition 437.2. Its coordinates are exactly $R, S, G, W, E, H, C, P, N$, and the source side is exposed before the envelope and Real-facing rows.

The seed-window readback fixes the finite-window coordinate. By Definition 437.10, the $\mathsf{RegSeqRat}^{\uparrow}$ seal G is owned by the same constant $\mathsf{StreamName}^{\uparrow}$ row S, while R supplies the transported $\mathsf{Rat}^{\uparrow}$ classifier for that row.

Ledger non-escape then excludes alternate admissions. The package and naming rows P, N, together with the displayed BHist, hsame, and Cont support in H, C, leave no coordinate from which a detached classifier, moving window, or independent $\mathsf{RegSeqRat}^{\uparrow}$ source could be read. □

Theorem 437.78 (Transported stationary window-seal stationary transport coherence)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet equipped with its source-triad completion packet. The stationary handoff row* H *and route table* C *preserve the same* $R \to S \to G$ *route componentwise under* hsame *and* Cont*. Hence transport through* H, C *cannot create a detached* $\mathsf{RegSeqRat}^{\uparrow}$ *source or a second stream-name route for the seal.*

Proof. Readback determinacy first fixes the order of the source side. The route table can be consumed only after the accepted packet has exposed R, S, G, and Definition 437.55 keeps every later envelope read downstream from that source route.

The root window-ownership clause controls the seal coordinate. By Definition 437.10, the row G is a $\mathsf{RegSeqRat}^{\uparrow}$ seal on the same constant $\mathsf{StreamName}^{\uparrow}$ row S, so componentwise hsame may identify transported presentations of that row but cannot allocate a new source for G.

Finally, the Real-seal route forces coherence through completion-facing use. Apply Definition 437.4 and Definition 437.11: the Cont data in C carries the displayed source route into W and E, and no detached $\mathsf{RegSeqRat}^{\uparrow}$ row is available outside that route. □

Theorem 437.79 (Transported stationary window-seal completion handoff nonescape)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ packet equipped with its source-triad completion packet. Every completion-facing consumer of T must pass through the displayed rows $R, S, G, W, E, H, C, P, N$. In particular, such a consumer cannot import quotient streams, host equality, choice, selected limits, or ambient real-completeness data in place of the transported $\mathsf{Rat}^{\uparrow}$ classifier, constant $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{RegSeqRat}^{\uparrow}$ seal, finite envelope, Real-facing seal, and support rows.*

Proof. The downstream handoff package is rooted in the displayed packet. Use Definition 437.48 and Definition 437.57: they expose the completion-facing route only through the source triad, finite envelope, Real-facing seal, and the rows H, C, P, N.

The Real seal supplies no external escape. By Definition 437.11 and Definition 437.37, the row E is read from the finite $\mathsf{RegSeqRat}^{\uparrow}$ route through W, not from host equality, selected limits, choice, or real-completeness assumptions.

NameCert route exhaustion handles the remaining consumers. Apply Definition 437.38: the local name and package rows N, P, together with BHist, hsame, and Cont in H, C, enumerate the accepted handoff coordinates, so any completion-facing consumer that preserves T has no off-route coordinate for quotient streams or independent completion data. □

Theorem 437.80 (Transported stationary window-seal envelope RealUp totality)**.** *Let $T = (R, S, G, W, E, H, C, P$ be an accepted $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ packet equipped with its source-triad completion packet. Every $\mathsf{Real}^{\uparrow}$-facing read of E and every completion-facing read that preserves E factors through the $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ source triad and the $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ row before the Real seal. More precisely, the read route is determined by*

$$R, S, G \longrightarrow W \longrightarrow E,$$

together with the displayed support rows H, C, P, N.

Proof. First use the carrier and NameCert obligation surface of Definition 437.2. It exposes the accepted packet only through $R, S, G, W, E, H, C, P, N$, with componentwise transport, package provenance, and local naming.

Next apply Definition 437.10. This fixes the $\mathsf{RegSeqRat}^{\uparrow}$ row G as a seal on the same finite $\mathsf{StreamName}^{\uparrow}$ row S, so the route cannot reach a finite envelope before the source triad has been read.

Finally use Definition 437.4, Definition 437.29, and the L10 handoff basis of Definition 437.48. These place the finite envelope row W between the source triad and the Real-facing row E, and they keep completion consumers on that same finite route. □

Theorem 437.81 (Transported stationary window-seal completion route nonescape)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet equipped with its source-triad completion packet. No completion-facing consumer preserving* T *can import quotient streams, host equality, selected limits, choice, ambient real completeness, or a hidden tail oracle. Such a consumer has access only to the transported source triad, the finite envelope, the Real seal row, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *support rows.*

Proof. Begin with readback determinacy, using Definition 437.55. It orders every accepted completion-facing read through the transported rows before the finite envelope and the Real seal can be consumed.

The Real side is controlled by Definition 437.11 and Definition 437.37. These rule out host equality, selected limits, choice, and ambient real completeness as sources for the seal row, because E is sourced by the displayed $\mathsf{RegSeqRat}^{\uparrow}$ route and the finite envelope.

It remains to exclude off-route completion data. Apply Definition 437.27, Definition 437.28, and Definition 437.50. The sibling L10 handoff files force any tail or completion consumer back through the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route, leaving no coordinate for a hidden tail oracle or independent completion source. □

Theorem 437.82 (Transported stationary window-seal source triad completion)**.** *Let* $T = (R, S, G, W, E, H, C, P,$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet equipped with the source-triad completion packet of Definition 437.76. The accepted route completes the* $\mathsf{Rat}^{\uparrow}$–$\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$ *source triad before any finite-envelope,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{Completion}^{\uparrow}$ *consumer can read the packet:*

$$R, S, G, H, C, P, N \longrightarrow W \longrightarrow E.$$

The completed triad is carried by the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows only; it has no quotient-stream coordinate, host equality row, selected limit, choice datum, or ambient-completeness witness.*

Proof. Start with the carrier and NameCert obligation surface of Definition 437.2. It exposes the accepted packet exactly as the rows $R, S, G, W, E, H, C, P, N$, with local naming and package provenance attached to the same route.

Apply the root source lock Definition 437.15. It fixes R, S, G as one transported source route, so the stream window and regular-rational seal cannot be read as detached sources.

Finally combine readback determinacy with Definition 437.80. The finite envelope and Real-facing rows are reachable only after the completed triad has been read, and the non-escape clauses remove quotient streams, host equality, selected limits, choice, and ambient completeness from the route. □

Theorem 437.83 (Transported stationary window-seal tail-filter source triad handoff)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet and let* $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ *be an accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *packet consumed on the same finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row. The finite-tail-filter and cofinal-tail surface receives exactly the completed source triad* R, S, G *together with its support rows* H, C, P, N*, then hands it through the schedule rows of* Q *before the route reaches* W *and* E*.*

Equivalently, every accepted tail-filter or cofinal-tail read preserving the packet is routed through

$$R, S, G, H, C, P, N \longrightarrow E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T \longrightarrow W \longrightarrow E.$$

No such handoff exports a quotient stream, host equality, selected limit, hidden tail oracle, choice principle, ambient-completeness datum, or independent completion carrier.

Proof. First use Definition 437.82. It supplies the completed $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ source triad before any envelope or Real-facing read.

Next attach the tail surface. Apply Definition 437.73 and Definition 437.28; these place the accepted schedule packet Q on the same finite window and regular-rational seal row, downstream of R, S, G, H, C, P, N and upstream of W, E.

The completion boundary is then determined by Definition 437.58 and Definition 437.60. They identify the consumer-facing obligation basis with the same completed triad and schedule rows, so no separate tail oracle or completion carrier remains available.

Finally apply Definition 437.81. It excludes quotient streams, host equality, selected limits, choice, ambient completeness, and hidden tail data from the exported handoff. □

Theorem 437.84 (Transported stationary window-seal L10 exit source triad readiness)**.** *For accepted packets $T = (R, S, G, W, E, H, C, P, N)$ and $Q = (E_T, W_T, D_T, R_T, L_T, H_T, C_T, P_T, N_T)$ as above, the completed source-triad route exposes exactly the L10 Phase Real and Completion faces*

$$\mathsf{Rat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{TailCofinalitySchedule}^{\uparrow}, \mathsf{FiniteWindowEnvelope}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Completion}^{\uparrow}$$

The exposure is through the finite route R, S, G, H, C, P, N, the schedule rows of Q, and the envelope-seal rows W, E. It is therefore exit-ready for later L10 Real and Completion formalization, while making no claim of quotient-stream equality, host equality, selected limits, choice, or ambient real completeness.

Proof. Begin with the source-triad completion theorem above. It closes the $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ source side of the route inside the accepted packet rows.

Use Definition 437.83 to pass that completed source side through the finite-tail-filter and cofinal-tail surface. The handoff supplies the $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{TailCofinalitySchedule}^{\uparrow}$ faces only as downstream reads of the same finite window and regular-rational seal.

Now apply Definition 437.48, Definition 437.67, and Definition 437.69. These identify the Phase Real and Completion exit surface with the finite envelope row W, the Real-facing seal row E, and the same displayed support rows.

The non-escape boundary is inherited from Definition 437.81 and Definition 437.75. Since the accepted route has no coordinate for quotient streams, host equality, selected limits, choice, or ambient completeness, the L10 exit surface consists exactly of the displayed Phase Real and Completion faces. □

Theorem 437.85 (Transported stationary window-seal checked obligation basis)**.** *For an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet $T = (R, S, G, W, E, H, C, P, N)$, the obligation basis is the triple already isolated by the checked NameCert rows:*

1. *the* $\mathsf{NameCert}_{\mathsf{TransportedStationaryWindowSeal}^{\uparrow}}$ *obligation surface of Definition 437.2;*
2. *the transported readback determinacy of Definition 437.3;*
3. *the* $\mathsf{Real}^{\uparrow}$ *factorization of Definition 437.4.*

Equivalently, the basis is the finite route

$$R, S, G, W, E, H, C, P, N$$

together with the componentwise BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows that the three checked theorems expose.*

Proof. The NameCert obligation theorem supplies the carrier, classifier, transported-window exactness, seal-exhaustion, and non-escape rows for T.

Readback determinacy then fixes the public $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ seal after the transported $\mathsf{Rat}^{\uparrow}$ classifier row is fixed through the displayed routes.

Finally, Real factorization forces every $\mathsf{Real}^{\uparrow}$ read to pass through the same finite envelope W and seal row G. These three rows are exactly the accepted obligation basis, and no additional carrier coordinate is introduced. □

Theorem 437.86 (Transported stationary window-seal formal target boundary)**.** *The formal target boundary for* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *obligation closure is exactly the checked Lean NameCert obligation theorem cited by the chapter closure row. It covers the finite carrier, componentwise classifier, transported-window exactness, seal exhaustion, and non-escape clauses for* $R, S, G, W, E, H, C, P, N$*. It does not include quotient streams, host equality, choice, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The target boundary is read from the NameCert obligation theorem rather than from an ambient real or completion object. Its inputs are the visible packet rows and their displayed structural support.

The readback and Real-factorization theorems remain companion checked rows, but they do not enlarge the target boundary beyond the NameCert obligation theorem. They only show that the existing boundary determines the stationary window readback and the Real-facing factorization.

The excluded objects are not carrier coordinates of T and are not supplied by the theorem boundary. Hence they cannot be part of the formal target recorded for obligation closure. □

Theorem 437.87 (Transported stationary window-seal obligation-closure handoff)**.** *The obligation-closure handoff from* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *to downstream Real and Completion consumers is carried by the already displayed rows for* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. Every accepted downstream read must enter through that finite row set before it can use the checked obligation basis of Definition 437.85.*

Proof. Begin with the source route. The transported $\mathsf{Rat}^{\uparrow}$ row, constant $\mathsf{StreamName}^{\uparrow}$ window, and $\mathsf{RegSeqRat}^{\uparrow}$ seal row give the source triad for the packet.

Next attach the finite envelope and Real-facing rows. The finite envelope supplies the observation boundary, and the Real row can only read it through the checked factorization.

The remaining rows BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provide the structural support and provenance for the same route. Therefore the downstream handoff is exactly the displayed finite row set, with no extra quotient, host, choice, selected-limit, or completeness input. □

Theorem 437.88 (Transported stationary window-seal constant-window exactness)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, the constant* $\mathsf{StreamName}^{\uparrow}$ *window row* S *is read only from the transported* $\mathsf{Rat}^{\uparrow}$ *row* R *and then from the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row* G*. No completion-facing consumer may read* S *from a quotient stream, host equality, selected limit, choice principle, ambient real completeness object, hidden tail oracle, or second completion carrier.*

Proof. The carrier row of Definition 437.7 exposes exactly the displayed packet coordinates $R, S, G, W, E, H, C, P, N$

Apply the seed-window row Definition 437.8. It places the constant $\mathsf{StreamName}^{\uparrow}$ read at S after the transported $\mathsf{Rat}^{\uparrow}$ source row R and before the $\mathsf{RegSeqRat}^{\uparrow}$ seal row G.

Readback determinacy, Definition 437.3, then fixes the same order for every accepted consumer. Since no further carrier coordinate is present, the displayed R, S, G route is the exact constant-window route. □

Theorem 437.89 (Transported stationary window-seal Real seal factorization)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal read reaches* E *only through the finite route*

$$R, S, G, W, H, C, P, N.$$

The row W *is the finite-window envelope through which the transported* $\mathsf{Rat}^{\uparrow}$*, constant* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows become available to the* $\mathsf{Real}^{\uparrow}$*-facing seal row* E*.*

Proof. Begin with envelope exactness. The row Definition 437.25 identifies W as the finite $\mathsf{StreamName}^{\uparrow}$ envelope carried by the transported source rows.

The completion-consumer boundary of Definition 437.27 then permits a completion-facing read of E only after the same source rows have passed through W.

Finally, the Real factorization row Definition 437.4 supplies the $\mathsf{Real}^{\uparrow}$ seal-facing endpoint. Thus every Real seal read factors through R, S, G, W, H, C, P, N, with W as the finite-window envelope. □

Theorem 437.90 (Transported stationary window-seal completion source nonescape)**.** *For every accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet* $T = (R, S, G, W, E, H, C, P, N)$*, no completion-facing consumer may import quotient-stream equality, host real equality, selected limits, choice, hidden tail oracle, real-completeness data, or a second completion carrier outside the displayed packet. Every admissible source for such a consumer must be read from the packet rows* $R, S, G, W, E, H, C, P, N$ *and their displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *support.*

Proof. The ledger nonescape row, Definition 437.6, excludes quotient-stream equality, host equality, selected limits, choice, and ambient completeness data from the packet ledger.

The shared-window budget is already exhausted by Definition 437.34. Hence there is no remaining finite-window coordinate from which a hidden tail oracle or second completion carrier could be read.

Root consumer nonescape, Definition 437.32, applies the same exclusion to downstream completion-facing consumers. Therefore every admissible source is one of the displayed packet rows together with its structural BEDC support. □

Theorem 437.91 (Transported stationary window-seal constant StreamName classifier coverage)**.** *Let* $T = (R, S, G, W, E, H, C, P, N)$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The transported* $\mathsf{Rat}^{\uparrow}$ *classifier row* R *covers the constant* $\mathsf{StreamName}^{\uparrow}$ *window* S *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite seal* G *through the same displayed route*

$$R, S, G, H, C, P, N.$$

Every read of the constant window or its finite seal is therefore a read of this transported classifier route, with the support rows H, C, P, N *carrying the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *data.*

Proof. Begin with the carrier and NameCert obligation surface of Definition 437.2. It exposes the accepted packet only through $R, S, G, W, E, H, C, P, N$, so the source side has no coordinate outside the transported rational classifier, constant stream name, and RegSeqRat seal rows.

Next apply readback determinacy, Definition 437.3. The constant $\mathsf{StreamName}^{\uparrow}$ row S is read after R and before the finite seal row G, and the same order is preserved by the displayed support rows.

Finally use route exhaustion, Definition 437.38. Since the exposed route surface is exhausted by the transported source triad and its support rows, the classifier coverage for the constant window and finite seal is exactly R, S, G, H, C, P, N. □

Theorem 437.92 (Transported stationary window-seal finite envelope handoff exhaustion)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing handoff through the finite envelope W and seal row E is exhausted by the same finite route*

$$R, S, G \longrightarrow W \longrightarrow E$$

together with the support rows H, C, P, N. Such a handoff cannot import quotient streams, host equality, choice, hidden tail oracles, selected limits, or ambient real completeness.

Proof. First apply Definition 437.4. It places every $\mathsf{Real}^{\uparrow}$ seal read behind the transported $\mathsf{Rat}^{\uparrow}$, constant $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and finite envelope rows.

Then use Definition 437.36. The schedule fixes the envelope W between the source triad and the Real-facing row E, so a handoff preserving W, E must preserve the same finite route.

It remains to exclude off-route sources. Apply Definition 437.38: the support rows H, C, P, N enumerate the accepted route surface, leaving no coordinate for quotient streams, host equality, choice, hidden tail data, selected limits, or ambient real completeness. □

Theorem 437.93 (Transported stationary window-seal Real completion exit readiness)**.** *Let $T = (R, S, G, W, E, H, C, P, N)$ be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet. The displayed route*

$$R, S, G, W, E, H, C, P, N$$

is the exact $\mathsf{Real}^{\uparrow}/\mathsf{Completion}^{\uparrow}$ *exit-readiness packet consumed by downstream L10 chapters: R supplies the transported rational classifier, S supplies the constant stream-name window, G supplies the RegSeqRat finite seal, W supplies the finite envelope, E supplies the Real-facing row, and H, C, P, N supply the BEDC support, package, and naming rows.*

Proof. Start with the constant-window coverage theorem above. It identifies the source side of the packet as the finite transported route R, S, G, H, C, P, N.

Next use the finite-envelope handoff theorem above. It extends the same route through W and E while excluding quotient-stream, host-equality, choice, hidden-tail, selected-limit, and ambient-completeness sources.

Finally combine Definition 437.3, Definition 437.4, and Definition 437.36. These rows fix the read order from the transported classifier through the finite seal and envelope to the Real-facing endpoint. Thus downstream L10 consumers receive exactly $R, S, G, W, E, H, C, P, N$ as their $\mathsf{Real}^{\uparrow}/\mathsf{Completion}^{\uparrow}$ exit-readiness packet. □

Definition 437.94 (Transported stationary window-seal scoped route)**.** *For an accepted* TransportedStationaryWind *packet*

$$T = (R, S, G, W, E, H, C, P, N),$$

the scoped route is the finite dependency packet that reads R as the transported $\mathsf{Rat}^{\uparrow}$ *classifier, S as the induced* $\mathsf{StreamName}^{\uparrow}$ *finite window, G as the* $\mathsf{RegSeqRat}^{\uparrow}$ *seal on that window, W as the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *observation packet with its* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, E as the* $\mathsf{Real}^{\uparrow}$*-facing completion boundary, H as the transported handoff row, C as the displayed* hsame *and* Cont *route table, P as the* Pkg *provenance row, and N as the local* NameCert *row.*

Its dependency basis is exactly the sibling surface

$\mathsf{Rat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{FiniteWindowEnvelope}^{\uparrow}, \mathsf{TailCofinalitySchedule}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Completion}^{\uparrow}$

The route supplies a finite $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Completion}^{\uparrow}$ *handoff boundary; it does not add quotient streams, host equality, selected limits, choice, or full real-completeness data.*

Theorem 437.95 (Transported stationary window-seal scoped dependency basis)**.** *Let* $T = (R, S, G, W, E, H, C, P,$ *be an accepted* $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ *packet equipped with the scoped route of Definition 437.94. Every public read of* T *factors through the displayed rows* $R, S, G, W, E, H, C, P, N$ *and through the named dependencies* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *No public read of the packet has a further dependency coordinate.*

Proof. Start with the carrier and naming surface. The carrier definition and Definition 437.2 expose only the rows $R, S, G, W, E, H, C, P, N$, with the componentwise classifier, displayed BHist support, hsame comparisons, Cont transports, Pkg provenance, and local $\mathsf{NameCert}$ row.

Next apply the source-triad completion packet and the L10 handoff basis. Theorems 437.82 and 437.48 place the public route through $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Completion}^{\uparrow}$ in that finite order.

Finally use the Real and completion boundary theorems. Theorems 437.11, 437.27, and 437.38 rule out quotient streams, host equality, selected limits, choice, ambient real completeness, and hidden completion carriers. Thus every public read factors through exactly the scoped dependency basis displayed above. □

Theorem 437.96 (Transported stationary window-seal source-triad scope exhaustion)**.** *In the scoped route of Definition 437.94, the source triad* R, S, G *cannot be detached from the* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{R}$ *route. The row* R *determines the constant stream window* S*, the row* S *owns the regular-rational seal* G*, and every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *read of* W *or* E *must consume that same triad before it reaches the finite envelope or the seal row.*

Proof. First read the transported source side. The readback determinacy and root window-ownership theorems identify R as the transported $\mathsf{Rat}^{\uparrow}$ row, S as the induced constant $\mathsf{StreamName}^{\uparrow}$ window, and G as the $\mathsf{RegSeqRat}^{\uparrow}$ seal owned by that window.

Next attach the completion packet. The source-triad completion packet and the tail-filter handoff theorem keep R, S, G upstream of the tail schedule, dyadic ledger, finite envelope, and Real-facing seal.

It remains to exclude detached sources. Apply Definition 437.37, Definition 437.45, and Definition 437.38. These theorems identify every Real and Completion consumer with the same source triad and leave no public coordinate for a moving stream window, independent regular-rational seal, or off-route real source. □

Theorem 437.97 (Transported stationary window-seal real-completion boundary)**.** *The scoped route of Definition 437.94 supplies only the finite* $\mathsf{Real}^{\uparrow}$*-facing completion boundary determined by* $R, S, G, W, E, H, C, P, N$*. It does not supply quotient streams, host equality, selected limits, choice, full real completeness, or an independent* $\mathsf{Completion}^{\uparrow}$ *carrier beyond the finite handoff named by the packet.*

Proof. Begin with the Real-facing seal. By Definition 437.4 and Definition 437.11, the row E is read only through the finite envelope W, the regular-rational seal G, and the displayed transport and provenance rows.

Next use the completion handoff controls. Theorems 437.54, 437.75, and 437.50 force every completion-facing consumer back to the same finite source triad, tail schedule, envelope, and Real seal.

Finally apply route exhaustion. The NameCert route exhaustion theorem enumerates the visible packet rows and support rows, so there is no remaining coordinate for quotient streams, host equality, selected host limits, choice, full real completeness, or an independent completion carrier. The route therefore supplies exactly the finite Real-facing completion boundary and nothing stronger. □

Closure status for $\mathsf{NameCert}_{\mathsf{TransportedStationaryWindowSeal}\uparrow}$.

Constructive story: A $\mathsf{TransportedStationaryWindowSeal}^{\uparrow}$ packet is generated from a transported RatUp classifier, constant StreamNameUp finite window, RegSeqRatUp seal row, FiniteWindowEnvelopeUp observation packet, RealUp seal-facing row, displayed transports, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TransportedStationaryWindowSeal}\uparrow}, \mathsf{scopedClosed})$

Scope closed: The scoped route is closed over RatUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, FiniteWindowEnvelopeUp, TailCofinalityScheduleUp, RealUp, CompletionUp, BHist, hsame, Cont, Pkg, and NameCert, read through the finite packet rows $R, S, G, W, E, H, C, P, N$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TransportedStationaryWindowSeal}\uparrow}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.TransportedStationaryWindowSealUp.TransportedStationaryWindowSealPacket\_namecert\_obli`

Bridge status: none

Origin: human

Not claimed: This chapter does not close full real completeness, quotient-stream equality, host real equality, selected host limits, or choice principles.

Upgrade path: Public closure requires a public export theorem for this scoped transported window-seal route.

Chapter 438

A Concrete Naming Certificate for $\mathsf{MonotoneCauchy}^{\uparrow}$

The $\mathsf{MonotoneCauchy}^{\uparrow}$ interface records the finite surface through which a located monotone Cauchy packet is read by interval and real-seal consumers. In the Bishop–Bridges constructive-analysis reading, monotone convergence is exposed through displayed Cauchy windows, located upper bounds, and interval enclosures rather than by trichotomy, quotient reals, open-cover compactness, or a choice of a limiting representative.

The located enclosure row I consumes the interval surface of chapter 394: its lower endpoint, upper endpoint, and location proof are the interval rows read by the monotone packet. The finite tail-window and shared-threshold discipline follows the same RegularCauchy tail route recorded in chapter 560, so the monotone schedule and modulus rows are consumed as displayed tail data rather than as a hidden limiting representative.

Definition 438.1 (Monotone Cauchy carrier)**.** *A* $\mathsf{MonotoneCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

with the following visible coordinates:

1. *F is a displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *rational-name row carrying the inspected monotone Cauchy observations;*
2. *σ is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that selects the finite windows read from F;*
3. *μ is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row that routes each requested dyadic tolerance to a finite tail window;*
4. *λ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger of tolerance rows, monotone comparison rows, and located upper-bound readbacks;*
5. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *enclosure row that records the lower endpoint, upper endpoint, and location proof consumed by interval handoff readers;*
6. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row reached from the same regular sequence, schedule, modulus, dyadic ledger, and located interval enclosure;*
7. *H records componentwise* hsame *transports for the regular sequence, schedule, modulus, dyadic ledger, located interval, and real-seal rows;*
8. *C records the displayed* Cont *routes by which consumers inspect those rows;*

9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *source certificates;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneCauchy}^{\uparrow}}$ *row.*

The monotonicity ledger is the displayed dyadic comparison row

$$\lambda_{\mathrm{mono}}(i,j) : i \le j \Rightarrow F_i \le F_j,$$
$$\lambda_{\mathrm{cau}}(\varepsilon) : \sigma(\mu(\varepsilon)) \text{ is a tail window below } \varepsilon.$$

The located upper-bound and interval ledger is

$$\lambda_{\mathrm{loc}}(\varepsilon) : F_{\sigma(\mu(\varepsilon))} \le I^{+} \text{ and } I^{-} \le F_{\sigma(\mu(\varepsilon))},$$
$$I(\varepsilon) = [I^{-}(\varepsilon), I^{+}(\varepsilon)] \text{ is the located interval row read by } Q.$$

The carrier contains no quotient-name equality, selected representative, host real equality, ambient completeness theorem, trichotomy row, or choice operator.

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier carrier admission window`
Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier interval real seal route certificate`

Theorem 438.2 (Monotone Cauchy NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{MonotoneCauchy}^{\uparrow}}$ *surface consists exactly of five rows:*

1. *carrier admission for the displayed packet of Definition 438.1;*
2. *classifier by common finite windows selected from the schedule σ and compared through the same regular-sequence, modulus, tolerance, interval, and seal rows;*
3. *monotone-row transport, stating that the displayed monotonicity ledger is preserved by the componentwise* hsame *rows in H and by the consumer routes in C;*
4. *located interval handoff, stating that every accepted interval read reaches the displayed upper-bound and enclosure ledger before any real-seal read;*
5. $\mathsf{Real}^{\uparrow}$ *seal non-escape, stating that the seal row Q consumes only $F, \sigma, \mu, \lambda, I, H, C, P, N$ and no hidden completion coordinate.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier namecert obligation surface`

Proof. Carrier admission is projection of the finite packet in Definition 438.1. Each coordinate is a displayed history row, transport row, continuation route, package row, or local naming row.

The classifier is by common finite windows. Two accepted packets are compared only after their schedules select the same requested tail window and their dyadic tolerance, monotone comparison, located interval, and real-seal rows have been transported componentwise.

Monotone-row transport uses the hsame rows in H to move the displayed comparisons and the Cont routes in C to replay the same reads. The located interval handoff is then the projection of the ledger λ_{loc} and the enclosure row I.

Finally, the real-seal boundary is the row Q. Since the carrier has no quotient-name equality, selected representative, host real equality, trichotomy row, ambient completeness row, or choice operator, no such coordinate can be read by a downstream consumer. □

Theorem 438.3 (Monotone Cauchy located interval handoff)**.** *Let*

$$M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{MonotoneCauchy}^{\uparrow}$ *carrier. Every* $\mathsf{LocatedInterval}^{\uparrow}$ *consumer read of* M *factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row* F*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* σ*, the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail row* μ*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and upper-bound ledger* λ*, and the located interval row* I*, transported only by* H *and* C *with provenance* P, N*.*

The handoff asserts a finite located enclosure for the monotone Cauchy packet; it does not assert a selected limiting representative, host real equality, trichotomy, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier located interval handoff`

Proof. Project the carrier. The interval coordinate is I, and every route to it first exposes the scheduled regular-rational observations F, the selected window σ, the modulus row μ, and the dyadic ledger λ.

The located ledger records the lower and upper enclosure rows used by the interval consumer. Transporting an accepted packet moves those rows componentwise through H and replays only the displayed routes in C.

Thus the interval handoff is exhausted by $F, \sigma, \mu, \lambda, I, H, C, P, N$. None of the excluded analytic objects is present as a carrier coordinate, so no interval consumer can read it from this packet. □

Theorem 438.4 (Monotone Cauchy Real seal boundary)**.** *For an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet, every* $\mathsf{Real}^{\uparrow}$ *seal read factors through the same displayed regular sequence* F*, schedule* σ*, Cauchy modulus* μ*, dyadic monotonicity and located upper-bound ledger* λ*, located interval row* I*, transport row* H*, continuation row* C*, package row* P*, and local* $\mathsf{NameCert}_{\mathsf{MonotoneCauchy}^{\uparrow}}$ *row* N*.*

Consequently the real seal receives a finite monotone Cauchy and located-interval surface, not quotient-name equality, a selected representative, host real equality, trichotomy, open-cover compactness, ambient completeness, or choice.

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier real seal boundary`

Proof. Use the NameCert obligation surface to force each consumer route onto a common finite window and to preserve the monotone row under transport.

Apply Definition 438.3. The located interval row is reached only after the regular sequence, schedule, modulus, dyadic ledger, transports, continuations, package, and local certificate have already been read.

The seal coordinate Q consumes that same finite surface. Since no excluded completion or host-real coordinate occurs in Definition 438.1, the real-seal boundary cannot escape the displayed packet. □

Theorem 438.5 (Monotone Cauchy ledger exhaustion)**.** *Every public read of an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *carrier is exhausted by the displayed monotonicity ledger, Cauchy tail ledger, located upper-bound ledger, located interval row, real-seal row,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row of Definition 438.1.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier ledger exhaustion`

Proof. Inspect the carrier coordinates. The regular rational observations, stream schedule, Cauchy modulus, dyadic comparison rows, located interval row, and real-seal row are all explicit fields of the same finite BHist packet.

The transport and continuation fields account for all permitted movement of those rows. The package and local naming rows account for provenance, but they do not add analytic data.

Therefore every public monotone Cauchy, located interval, or real-seal read has already appeared in the displayed ledger. There is no remaining coordinate for quotient equality, a selected representative, host real equality, trichotomy, open-cover compactness, ambient completeness, or choice. □

Theorem 438.6 (Monotone Cauchy common-window classifier)**.** *Let*

$$M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted MonotoneCauchy$^{\uparrow}$ *carrier. Any classifier comparison of M with another accepted carrier is made after both packets expose a common finite window selected through the* StreamName$^{\uparrow}$ *schedule σ and the* CauchyModulus$^{\uparrow}$ *row μ. On that window the classifier compares only the* RegSeqRat$^{\uparrow}$ *observations, the* DyadicRatCore$^{\uparrow}$ *tolerance and monotonicity ledger, the* LocatedInterval$^{\uparrow}$ *enclosure, the* Real$^{\uparrow}$ *seal row, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Project the classifier row from Definition 438.2. It requires common finite windows before accepted packets are compared.

The window is selected by σ and μ. Once the window is fixed, the regular rational observations in F and the dyadic ledger λ supply the tolerance, monotonicity, and located upper-bound rows available for comparison.

The interval row I and seal row Q are downstream of that same window. The transport and continuation rows H and C replay only the displayed reads, while P and N name the same local package, so no quotient or host-real comparison is introduced. □

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier common window classifier`

Theorem 438.7 (Monotone Cauchy modulus tail stability)**.** *For every accepted carrier $M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$, transporting M by the componentwise* hsame *rows in H preserves the finite tail comparison selected by μ. The monotone row and Cauchy tail row in λ therefore remain attached to the same* RegSeqRat$^{\uparrow}$ *observations and the same* StreamName$^{\uparrow}$ *window route before any located interval or real-seal consumer reads them.*

Proof. Read the tail ledger in Definition 438.1. The row $\lambda_{\mathrm{cau}}(\varepsilon)$ ties the requested tolerance to the scheduled window $\sigma(\mu(\varepsilon))$, and the monotone row λ_{mono} compares observations on that displayed window.

Transport the packet through H. Componentwise transport moves F, σ, μ, and λ together, and the continuation routes in C replay the same window read before exposing interval or seal data.

Apply the ledger exhaustion theorem Definition 438.5. Since every public read is already exhausted by the displayed ledger, the transported tail comparison cannot detach from the modulus route or acquire an additional completion premise. □

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier modulus tail stability`

Theorem 438.8 (Monotone Cauchy Real seal factorization obligation)**.** *Let $M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *seal read of Q factors through the common finite-window classifier, the modulus tail route, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *located ledger, and the* $\mathsf{LocatedInterval}^{\uparrow}$ *row I before any completion-facing read is consumed. The factorization exports no quotient real, selected representative, host real equality, trichotomy, open-cover compactness, ambient completeness, or choice operator.*

Proof. Use Definition 438.6 to place the comparison on a common finite window. The regular sequence, stream schedule, modulus row, and dyadic ledger are all visible before the seal row is compared.

Next apply Definition 438.7. The Cauchy tail and monotone comparison rows remain attached to the same modulus-selected window under transport, so the downstream located interval row consumes the same finite ledger.

Finally apply Definition 438.3. The real-seal boundary of Definition 438.4 then reads Q only after I and its upstream ledger have been displayed, and the carrier contains none of the excluded analytic objects. □

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier real seal factorization obligation`

Theorem 438.9 (Monotone Cauchy located trap certificate)**.** *Let $M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *carrier. The monotone ledger row and Cauchy modulus row determine a finite* $\mathsf{LocatedInterval}^{\uparrow}$ *trap row for the tail window selected by σ and μ. The trap certificate uses only F, σ, μ, λ, I, H, C, P, and N, and it records the lower observation, upper guard, tolerance, and transport route before any* $\mathsf{Real}^{\uparrow}$ *seal read is available.*

No quotient real, selected representative, host real order, trichotomy, open-cover compactness, ambient completeness, or choice operator is part of this certificate.

Proof. Project the carrier through Definition 438.1. The rows F, σ, μ, and λ display the regular rational observations, the selected finite window, the modulus tail, and the monotone located upper-bound ledger.

Apply Definition 438.6. The trap is built on the same common finite window used by classifier comparisons, so every row needed for the located interval is already visible before interval handoff.

Next use Definition 438.7. Transport through H keeps the Cauchy tail and monotone comparison rows attached to the same scheduled observations, and C replays the window read without adding a completion premise.

Finally apply Definition 438.3 and Definition 438.5. The located row I receives exactly the displayed trap data, while P and N name the same local package. The carrier contains no coordinate from which the excluded analytic objects could enter. □

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier located trap certificate`

Theorem 438.10 (Monotone Cauchy tail-window Real seal certificate)**.** *For every accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet $M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$, each* $\mathsf{Real}^{\uparrow}$ *seal read of Q factors through the finite located trap certificate and the same modulus-selected tail window before reaching Q. The seal-facing path is therefore*

$$(F, \sigma, \mu, \lambda) \quad \textit{then} \quad I \quad \textit{then} \quad Q,$$

with componentwise transport supplied by H and displayed continuation supplied by C.

The path does not branch through quotient equality, a selected real representative, host real order, open-cover compactness, ambient completeness, or choice.

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier tail window real seal certificate`

Proof. Start with Definition 438.9. It gives a finite located trap whose rows are already selected by the stream schedule, the Cauchy modulus, and the monotone dyadic ledger.

Apply Definition 438.8. Every seal-facing read must pass through the common finite-window classifier, the modulus tail route, the dyadic located ledger, and the located interval row before it consumes Q.

Use Definition 438.4 for the final handoff. The boundary reads only the displayed located interval and the seal row, and Definition 438.5 rules out any additional hidden coordinate for the excluded analytic objects. □

Theorem 438.11 (Monotone Cauchy located interval cell coherence)**.** *Let*

$$M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet. Every located interval cell read in I is coherent with the same finite* $\mathsf{StreamName}^{\uparrow}$ *window selected by σ and μ, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *observations in F, and the same dyadic ledger λ before the* $\mathsf{Real}^{\uparrow}$ *seal row Q is read. The lower and upper endpoint rows of the located interval, the rational or dyadic cell row being inspected, and the seal-facing route therefore form one finite window:*

$$(F, \sigma, \mu, \lambda) \quad \textit{then} \quad I \quad \textit{then} \quad Q.$$

The coherence statement uses only the displayed BHist *surface, the componentwise* hsame *transports in H, the* Cont *routes in C, the* Pkg *provenance row P, and the local* NameCert *row N. It does not invoke a quotient real, selected representative, host real order, trichotomy, ambient completeness principle, or choice row.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier located interval cell coherence`

Proof. Project the packet through Definition 438.1. The only tail-window rows visible before the interval and seal stages are F, σ, μ, λ together with their displayed transport, continuation, provenance, and naming rows.

Apply Definition 438.9. It binds the located interval row I to the regular rational observations in F, the finite window selected by σ and μ, and the monotone dyadic ledger λ before any $\mathsf{Real}^{\uparrow}$ seal row is available.

Use Definition 394.35 for the endpoint-cell step. The lower endpoint row, upper endpoint row, rational or dyadic cell ledger, endpoint windows, regular readbacks, and seal-facing rows of the located interval remain a single finite route, so a cell read in I cannot detach from the displayed endpoint rows.

Finally apply Definition 438.10. The seal row Q consumes the same located trap and the same modulus-selected finite window, so the interval cell, endpoint rows, regular observations, dyadic ledger, and Real seal are read from one carrier surface. Since the carrier has no coordinate for quotient reals, selected representatives, host real order, trichotomy, ambient completeness, or choice, none of those objects can enter the coherence route. □

Theorem 438.12 (Monotone Cauchy CauchyCriterion seal handoff)**.** *Let $M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet. Suppose the* $\mathsf{Real}^{\uparrow}$ *seal row Q is consumed by an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet through the same displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$,

$\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. Then every such consumer route factors through the finite Monotone Cauchy tail-window certificate and then through the CauchyCriterion finite criterion route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{CauchyModulus}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The handoff remains on the same finite BHist *surface, with the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *rows. It cannot introduce quotient equality, selected representatives, host real equality, trichotomy, countable choice, ambient completeness, or any separate completion oracle.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier cauchycriterion seal handoff`

Proof. Apply Definition 438.10. It forces each $\mathsf{Real}^{\uparrow}$ seal read of Q through the located trap, the modulus-selected tail window, and the displayed StreamName, dyadic, regular rational, transport, continuation, provenance, and naming rows of M.

Next use Definition 392.7. A CauchyCriterion consumer can read a regular rational source and the $\mathsf{Real}^{\uparrow}$ seal only through its displayed source window, modulus threshold, dyadic tolerance, tail ledger, and seal row. The shared-row hypothesis identifies those rows with the route already exposed by the Monotone Cauchy certificate.

Finally apply Definition 392.8. The StreamName presentation, dyadic tail coverage, regular shared threshold, and seal row remain one finite shared-tail route, so repacking through BHist, hsame, Cont, Pkg, and NameCert preserves the same seal surface. None of the participating carriers contains a coordinate for quotient equality, selected representatives, host real equality, trichotomy, countable choice, ambient completeness, or an independent completion oracle. □

Theorem 438.13 (Monotone Cauchy located Real-completion handoff)**.** *Let* $M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet. Every Real-and-Completion consumer of* M *that reads the* $\mathsf{Real}^{\uparrow}$ *seal* Q *factors through the finite located trap certificate, the CauchyCriterion route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{CauchyModulus}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow},$$

and the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows before the seal is read.*

The consumer boundary therefore exposes only the finite rows $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ *together with the accepted CauchyCriterion handoff surface. It does not export quotient equality, selected representatives, host real equality, trichotomy, countable choice, ambient completeness, or a separate completion oracle.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier located real completion handoff`

Proof. First apply Definition 438.9. It places the located read behind the common finite window, the monotone dyadic ledger, and the displayed located interval row.

Next use Definition 438.10. The $\mathsf{Real}^{\uparrow}$ seal Q can be consumed only after the located trap, modulus-selected tail window, and transport rows have been displayed.

Now apply Definition 438.12. The Real-and-Completion consumer is forced through the CauchyCriterion route from $\mathsf{StreamName}^{\uparrow}$ through $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$.

Finally use the ledger-exhaustion rows, including Definition 438.5. They repack the same finite route through BHist, hsame, Cont, Pkg, and NameCert, leaving no carrier coordinate for quotient equality, selected representatives, host real equality, trichotomy, countable choice, ambient completeness, or an independent completion oracle. □

Theorem 438.14 (Monotone Cauchy public seal window determinacy)**.** *Let*

$$M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N) \quad \textit{and} \quad M' = (F', \sigma', \mu', \lambda', I', Q', H', C', P', N')$$

be accepted $\mathsf{MonotoneCauchy}^{\uparrow}$ *packets. Suppose their* F, σ, μ, λ *tail-window rows are displayed on the same finite window, and their* I, Q, H, C, P, N *rows are transported componentwise by the shown* hsame *data. Then any public* $\mathsf{Real}^{\uparrow}$ *seal read of* Q *and any public* $\mathsf{Real}^{\uparrow}$ *seal read of* Q' *factor through the same finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{CauchyModulus}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{LocatedInterval}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before reaching the seal row.

Consequently the two public seal reads determine the same finite tail-window seal surface under the displayed hsame *transport. They cannot diverge through quotient equality, selected representatives, host real equality, trichotomy, open-cover compactness, ambient completeness, or choice.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier public seal window determinacy`

Proof. First apply Definition 438.6. The two accepted packets are compared only after the schedule and modulus rows expose the same finite tail window for the displayed F, σ, μ, λ data.

Next use Definition 438.7. The componentwise hsame transport keeps the Cauchy and monotone rows attached to that shared window, so neither packet can move the seal read to a different tail route.

The interval stage is supplied by Definition 438.9. The located trap consumes the transported dyadic ledger and produces the same $\mathsf{LocatedInterval}^{\uparrow}$ surface before any $\mathsf{Real}^{\uparrow}$ seal row is read.

Finally apply Definition 438.10 and Definition 438.5. The former forces each public seal read through the displayed tail-window route, and the latter says that every public read has already appeared in the finite ledger. Since no excluded quotient, representative, host-real, compactness, completeness, or choice coordinate occurs in the carrier, the two transported seal reads have the same finite seal surface. □

Theorem 438.15 (Monotone Cauchy window tail-cofinality handoff)**.** *Let* $M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet. Any* $\mathsf{Real}^{\uparrow}$ *seal consumer of* M *that also uses a* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *route must pass through the displayed monotone ledger, the Cauchy modulus row, the located trap certificate, the finite tail-window schedule, the dyadic threshold ledger, and the located interval row before the seal row* Q *is readable. The handoff supplies no host real order, quotient equality, selected representative, ambient completeness, open-cover compactness, or choice operator.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier window tail cofinality handoff`

Proof. Begin with Definition 438.9. The rows F, σ, μ, λ expose the monotone ledger and Cauchy modulus data, and the located trap certificate places the finite interval row I on that same selected tail window.

Next use Definition 438.10. It forces every seal-facing read of Q through the located trap and the modulus-selected tail window before the $\mathsf{Real}^{\uparrow}$ seal row can be consumed.

Finally apply Definition 681.3 to the sibling schedule route. Its finite route carries the tail window through the dyadic threshold ledger before any downstream $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read, and the two carriers contain none of the excluded analytic or choice coordinates. □

Theorem 438.16 (Monotone Cauchy obligation package)**.** *The rows F, σ, μ, λ, I, Q, H, C, P, and N of an accepted* MonotoneCauchy$^{\uparrow}$ *carrier assemble into the five-row* NameCert *obligation package for located monotone Cauchy data: carrier admission, classifier by common finite windows, monotone-row transport through the modulus tail, located interval handoff, and* Real$^{\uparrow}$ *seal non-escape. Each row is read from the displayed packet and its local* Pkg *and* NameCert *data.*

The package claims only this displayed finite-window obligation surface. It does not close quotient reals, selected representatives, host real equality, trichotomy, open-cover compactness, ambient completeness, or choice.

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier obligation package`

Proof. Carrier admission is the displayed carrier of Definition 438.1. It exposes the regular sequence, stream schedule, modulus, dyadic ledger, located interval, real seal, transport, continuation, package, and naming rows.

For classification, apply Definition 438.6. Accepted packets are compared only after the common finite window selected by σ and μ is displayed.

For transport, apply Definition 438.7. The monotone and Cauchy rows in λ remain attached to the same scheduled observations under the componentwise hsame rows in H.

For the downstream rows, apply Definition 438.9 and Definition 438.10. The located interval row consumes the finite trap, and every real-seal read remains inside that same tail window.

Finally use Definition 438.5. Since every public read has already appeared in the displayed ledger, the five obligation rows are exhausted by the packet data and do not import any excluded completion or choice principle. □

Theorem 438.17 (Monotone Cauchy scoped tail-window package)**.** *For an accepted* MonotoneCauchy$^{\uparrow}$ *carrier, the common finite window, the* CauchyModulus$^{\uparrow}$ *row μ, the* DyadicRatCore$^{\uparrow}$ *monotone ledger λ, the* LocatedInterval$^{\uparrow}$ *trap I, the* Real$^{\uparrow}$ *seal Q, and the displayed* hsame, Cont, Pkg, *and* NameCert *rows form a single scoped packet. Tail-window readers and* Real$^{\uparrow}$ *readers consume the packet only through*

$$F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

No such reader can pass through quotient reals, selected representatives, host real equality, trichotomy, open-cover compactness, ambient completeness, or choice.

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier scoped tail window package`

Proof. First expose the common finite window by applying Definition 438.6. The stream schedule σ and modulus row μ determine the finite observations of F that any accepted comparison may read.

Next apply Definition 438.7. The CauchyModulus$^{\uparrow}$ tail and the DyadicRatCore$^{\uparrow}$ monotone ledger remain attached to that same finite window under the componentwise hsame rows in H.

The located part is supplied by Definition 438.9. It turns the monotone ledger and upper-bound rows into the displayed located interval trap I without introducing any ambient completeness datum.

For Real$^{\uparrow}$ readers, use Definition 438.10. The seal row Q consumes the common window, modulus tail, dyadic ledger, located trap, transport rows, continuation routes, package provenance, and local naming row.

Finally apply Definition 438.5. Every permitted reader has already appeared in the displayed rows $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so the scoped packet has no hidden route to the excluded analytic or choice principles. □

Theorem 438.18 (Monotone Cauchy located scope package)**.** *For an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *carrier, the located interval trap is a scoped packet over* $F, \sigma, \mu, \lambda, I, H, C, P, N$*. Every located read first passes through the common finite tail window, the monotone dyadic ledger, and the located trap certificate before it reaches the displayed interval row.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier located scope package`

Proof. Start with Definition 438.6. It selects the common finite window through the schedule σ and modulus μ before any accepted packets are compared.

Apply Definition 438.9. The located trap is read from the dyadic monotonicity and upper-bound ledger λ over the same finite tail window.

Finally use Definition 438.3. The interval row I is reached only through the displayed regular sequence, schedule, modulus, ledger, transport, continuation, package, and naming rows. □

Theorem 438.19 (Monotone Cauchy tail-window scope lock)**.** *The tail-window classifier of an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet is locked to the finite* BHist *rows selected by* σ *and* μ*. Tail stability, located interval transport, and consumer-visible classifier reads are routed only through* H*,* C*,* P*, and* N*, with no quotient real, selected representative, host order, or choice operator.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier tail window scope lock`

Proof. Use Definition 438.6 to expose the common finite tail window. The classifier compares only the scheduled $\mathsf{RegSeqRat}^{\uparrow}$ observations and the dyadic tolerance, monotonicity, interval, and seal rows visible on that window.

Apply Definition 438.7. The monotone and Cauchy rows remain attached to the scheduled observations under the componentwise hsame transport in H.

The continuation routes in C replay the same finite reads, and Definition 438.5 excludes every hidden analytic coordinate. Thus the tail-window classifier is locked to the displayed packet. □

Theorem 438.20 (Monotone Cauchy Real seal scope package)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet factors through the located scope package and the tail-window classifier. The seal uses only* $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$*, so RealUp-facing consumers receive a displayed regular rational sequence, a finite tail window, a located interval trap, and the local* $\mathsf{NameCert}$ *provenance.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier real seal scope package`

Proof. Apply Definition 438.8. It factors each seal-facing path through the common finite-window classifier, the modulus tail route, the dyadic located ledger, and the located interval row.

Use Definition 438.18 to bind the located trap and interval handoff to the displayed rows $F, \sigma, \mu, \lambda, I, H, C, P, N$.

Finally apply Definition 438.19 and Definition 438.4. The seal row Q consumes the same finite surface and has no route to quotient reals, selected representatives, host real equality, ambient completeness, or choice. □

Theorem 438.21 (Monotone Cauchy public tail-window certificate)**.** *The scoped tail-window classifier, located scope package, and* $\mathsf{Real}^{\uparrow}$ *seal scope package assemble a single public* $\mathsf{NameCert}_{\mathsf{MonotoneCauchy}^{\uparrow}}$ *export over rows* $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$*. The public certificate exposes the finite tail-window schedule, monotone and Cauchy modulus rows, located interval trap, real-seal row, componentwise transports, continuation routes, package provenance, and local naming row, and exports no quotient real, selected representative, host real equality, ambient completeness, or choice principle.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier public tail window certificate`

Proof. Start with Definition 438.6. It identifies the finite tail window through which the scheduled observations F, σ, μ are read.

Use Definition 438.18 and Definition 438.19. The located rows λ and I remain attached to the same tail window, while the lock prevents consumer reads from moving outside H, C, P, N.

Finally apply Definition 438.20 and Definition 438.5. The real-seal row Q is repacked through the displayed finite surface, and the ledger excludes every route to quotient reals, selected representatives, host real equality, ambient completeness, or choice. □

Theorem 438.22 (Monotone Cauchy bridge-facing certificate)**.** *Let $M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet. If M is consumed through a* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet, or if a* $\mathsf{Real}^{\uparrow}$ *seal consumer reads M through Q, then both consumers read the same finite tail-window surface: the regular rational row F, scheduled windows σ, modulus row μ, dyadic ledger λ, located trap I, seal row Q, transport rows H, continuation routes C, package provenance P, and local naming row N. Neither consumer may replace that surface by quotient real equality, selected representatives, ambient completeness, or choice-selected tails.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier bridge facing certificate`

Proof. Apply Definition 438.21. It already assembles the public $\mathsf{NameCert}_{\mathsf{MonotoneCauchy}^{\uparrow}}$ export over exactly $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and excludes every hidden analytic coordinate.

For the $\mathsf{Real}^{\uparrow}$ seal consumer, use Definition 438.20. The seal row Q factors through the located scope package and the tail-window classifier, so its read is the same finite surface exported by the public certificate.

For the bounded monotone witness consumer, use chapter 535. That chapter reads the monotone source, witness rows, located trap, and seal handoff through the displayed route $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. Restricting to the $\mathsf{MonotoneCauchy}^{\uparrow}$ component leaves exactly $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so both consumers share the same tail-window surface. □

Theorem 438.23 (Monotone Cauchy public route classifier handoff)**.** *Let*

$$M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet. Every public completion-facing classifier read and every* $\mathsf{Real}^{\uparrow}$ *seal-facing classifier read of M factors through the same ordered surface: the located interval trap I, the monotone tail-window certificate over λ, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row F, the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail-stability row μ, and the* $\mathsf{Real}^{\uparrow}$ *seal row Q, together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows in H, C, P, N. No public route may replace this surface by a quotient stream, host sequence equality, selected limit, ambient completeness principle, trichotomy row, or choice datum.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier public route classifier handoff`

Proof. Begin with the carrier of Definition 438.1. It displays $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ as the only regular sequence, schedule, modulus, located ledger, interval, seal, transport, continuation, provenance, and naming rows available to a public classifier.

Apply Definition 438.3 and Definition 438.7. The located interval row I is reached only after the regular sequence, scheduled window, modulus row, monotone dyadic ledger, componentwise hsame transport, continuation routes, package row, and local naming row have been displayed; the Cauchy and monotone tail rows remain attached to that same window.

Next use Definition 438.8 and Definition 438.22. Seal-facing and completion-facing consumers therefore read the same ordered surface before reaching Q, and the bounded witness route restricts to the $\mathsf{MonotoneCauchy}^{\uparrow}$ rows without changing the tail-window classifier.

Finally apply Definition 438.5 and the scope package of Definition 438.17. Every public coordinate has already appeared in the displayed ledger $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so no unlisted quotient stream, host sequence equality, selected limit, ambient completeness principle, trichotomy row, or choice datum can serve as a replacement route. □

Theorem 438.24 (Monotone Cauchy mature route summary)**.** *For an accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet*

$$M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N),$$

the carrier, common-window classifier, modulus-tail stability, located interval handoff, $\mathsf{Real}^{\uparrow}$ *seal boundary, public tail-window certificate, and bridge-facing certificate assemble one finite located monotone Cauchy route over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *The route exposes the displayed regular rational sequence, scheduled tail window, modulus row, located dyadic ledger, located interval row, seal row, transports, continuations, provenance, and naming row, and it excludes quotient reals, selected representatives, host real equality, trichotomy, open-cover compactness, ambient completeness, and choice.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier mature route summary`

Proof. Begin with the carrier of Definition 438.1. It displays $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ as the only regular sequence, schedule, modulus, located ledger, interval, seal, transport, continuation, provenance, and naming rows.

Apply Definition 438.6 and Definition 438.7. The common-window classifier fixes the finite observations of F through σ and μ, while modulus-tail stability keeps the Cauchy and monotone rows attached to that window under H and C.

Next use Definition 438.3 and Definition 438.4. The located interval row I and the seal row Q are therefore read only after the finite tail-window and dyadic ledger have been displayed.

Finally apply Definition 438.21 and Definition 438.22. These certificates package the same finite surface for public and bridge-facing consumers and exclude quotient reals, selected representatives, host real equality, trichotomy, open-cover compactness, ambient completeness, and choice. □

Theorem 438.25 (Monotone Cauchy bounded-witness tail factorization)**.** *Let*

$$M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet. If an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet consumes the tail-window rows, located interval rows, and* $\mathsf{Real}^{\uparrow}$ *seal rows of* M*, then every bounded-witness public tail read factors through the* $\mathsf{MonotoneCauchy}^{\uparrow}$ *common-window classifier, the located-interval handoff, the* $\mathsf{Real}^{\uparrow}$ *seal boundary, and the ledger-exhaustion rows before it reaches the bounded-witness surface.*

Thus the bounded witness receives the displayed rows $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ *as a finite tail-window route, not as a quotient real, host equality, trichotomy row, ambient completeness coordinate, or selected limiting representative.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier bounded witness tail factorization`

Proof. First expose the tail window by applying Definition 438.6. The scheduled observations F, σ and the modulus row μ determine the finite window through which any accepted bounded-witness tail read can inspect M.

Next apply Definition 438.3. The located interval row I is reached only after the regular sequence, scheduled window, modulus, dyadic ledger, transports, continuations, package row, and local certificate have already been displayed.

For the seal side, use Definition 438.4 and the bounded-witness handoff surface cited in Definition 438.22. The seal row Q is therefore consumed through the same tail-window and located-interval route that the bounded-witness packet reads.

Finally apply Definition 438.5. Every public coordinate has already appeared in the displayed rows $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so the bounded-witness consumer has no remaining route to a quotient real, host equality, trichotomy row, ambient completeness coordinate, or selected limiting representative. □

Theorem 438.26 (Monotone Cauchy diagonal terminal pullback handoff)**.** *Let*

$$M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet whose public* $\mathsf{Real}^{\uparrow}$ *seal is consumed by an accepted* DiagonalLimitCompatibili *terminal packet. Then every completion-facing classifier read and every* $\mathsf{Real}^{\uparrow}$ *seal-facing classifier read of* M *factors through the same terminal finite pullback over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the monotone tail-window rows* F, σ, μ, λ, *the located-interval row* I, *and the displayed* BHist/hsame/Cont/Pkg/NameCert *support rows in* H, C, P, N.

The handoff exports no quotient stream, host real equality, selected limit, trichotomy row, ambient completeness principle, metric-completeness datum, bridge row, or choice datum.

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier diagonal terminal pullback handoff`

Proof. First apply Definition 438.23. The public completion-facing classifier and the $\mathsf{Real}^{\uparrow}$ seal-facing classifier of M already read the same located interval trap, monotone tail-window certificate, $\mathsf{RegSeqRat}^{\uparrow}$ row, $\mathsf{CauchyModulus}^{\uparrow}$ tail-stability row, $\mathsf{Real}^{\uparrow}$ seal row, and support rows.

Next use Definition 438.25. It keeps the bounded tail-window and located-interval reads downstream of the same $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ surface, so the monotone source cannot contribute a second consumer route through a quotient real, trichotomy row, or selected limiting representative.

Now compose that surface with the diagonal terminal packet by applying Definition 646.173. The consumer hypothesis identifies the public $\mathsf{Real}^{\uparrow}$ seal of M with the terminal $\mathsf{Real}^{\uparrow}$ read exported by the diagonal packet, so the two packets share one finite seal handoff over the displayed support rows.

Finally apply Definition 646.172 and Definition 126.504. The diagonal terminal route is complete exactly through its finite terminal route, and the L10 exit boundary identifies all completion-facing and Real-seal-facing reads with the terminal pullback over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the displayed support rows. The cited non-escape clauses exclude quotient streams, host real equality, selected limits, trichotomy, ambient completeness, metric-completeness data, bridge rows, and choice. □

Theorem 438.27 (Monotone Cauchy cofinal criterion seal readback)**.** *Let*

$$M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{MonotoneCauchy}^{\uparrow}$ *packet. Suppose its* $\mathsf{Real}^{\uparrow}$ *seal row* Q *is consumed both through a* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *route and through an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *finite criterion route, and*

suppose the same seal-facing read is also visible to the diagonal terminal pullback route. Then every seal-facing read of M factors through the single finite route $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, together with the sibling finite-window, dyadic-threshold, shared-tail, and criterion rows.

The readback has no quotient stream, selected representative, host real equality, trichotomy row, ambient completeness principle, metric-completeness datum, bridge row, or choice datum. Its entire public surface is the displayed BHist, hsame, Cont, Pkg, *and* NameCert *support over the finite Monotone Cauchy, tail-cofinality, CauchyCriterion, and diagonal terminal rows.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyUp.MonotoneCauchyCarrier cofinal criterion seal readback`

Proof. First apply Definition 438.15. The $\mathsf{TailCofinalitySchedule}^{\uparrow}$ consumer must read the seal through the monotone ledger, Cauchy modulus row, located trap, finite tail-window schedule, dyadic threshold ledger, and located interval row before Q becomes available.

Next use Definition 438.12. The accepted $\mathsf{CauchyCriterion}^{\uparrow}$ consumer reads the same $\mathsf{Real}^{\uparrow}$ seal only through the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ chain, with the shared-tail and criterion rows still attached to the finite carrier surface.

Now apply Definition 438.26. The diagonal terminal packet identifies the completion-facing and Real-seal-facing classifier reads with the same finite terminal pullback, so the cofinal schedule and criterion consumers cannot split into a second completion or representative route.

Finally use Definition 438.5. Every public read has already appeared in the displayed rows $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and their sibling finite-window, dyadic-threshold, shared-tail, criterion, and terminal rows. Since those carriers expose no coordinate for the excluded analytic or choice data, the composite seal readback is exhausted by the displayed BEDC ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{MonotoneCauchy}^{\uparrow}$ packet is generated from a displayed regular rational sequence, a stream schedule, a Cauchy modulus row, dyadic monotonicity and located upper-bound ledgers, a located interval row, a real-seal row, componentwise transport, displayed continuation routes, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MonotoneCauchy}^{\uparrow}}$, maturePackageClosed)

Scope closed: The obligation scope registers carrier admission, common finite-window classification, monotone-row transport, located interval handoff, $\mathsf{Real}^{\uparrow}$ seal non-escape, ledger exhaustion, and the mature route summary of Definition 438.24 for located monotone Cauchy packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MonotoneCauchy}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient reals, selected representatives, host real equality, trichotomy, open-cover compactness, ambient completeness, or choice.

Upgrade path: No further paper-side theory-axis work remains; the remaining work is formal and bridge verification of the same finite tail-window, located-interval, real-seal, transport, package, and naming rows.

Chapter 439

A Concrete Naming Certificate for $\mathsf{IsometricEmbedding}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and the metric-space treatment in Kreyszig, *Introductory Functional Analysis*, the $\mathsf{IsometricEmbedding}^{\uparrow}$ interface records a distance-preserving injection only as a finite BEDC certificate. It is a completion-boundary object for $\mathsf{Real}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, and $\mathsf{HausdorffCompletion}^{\uparrow}$: downstream consumers see displayed metric and distance rows, not a host function equality or a quotient map.

Definition 439.1 (IsometricEmbedding carrier)**.** *An* $\mathsf{IsometricEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, Y, F, D_X, D_Y, R, T, Q, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *carrier and classifier row;*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *carrier and classifier row;*
3. *F is the graph row displaying the embedding as a finite BEDC relation from source observations to target observations;*
4. *D_X is the source* MetricDistanceWitness *row for displayed source endpoints;*
5. *D_Y is the target* MetricDistanceWitness *row for the displayed target endpoints selected by F;*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *distance-reflection row comparing the real-distance read from D_X with the real-distance read from D_Y;*
7. *T stores the componentwise* hsame *transports for X, Y, F, D_X, D_Y, and R;*
8. *Q stores the* Cont *routes for source reads, graph reads, target reads, and real-distance reflection reads;*
9. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, MetricDistanceWitness, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{IsometricEmbedding}^{\uparrow}}$ *row.*

The carrier contains no quotient map, no host function object, no selected representative of a completion class, and no external completion theorem.

Lean4 (definition) `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier`

Definition 439.2 (IsometricEmbedding classifier)**.** *For accepted* $\mathsf{IsometricEmbedding}^{\uparrow}$ *carriers* I *and* I'*, the classifier* $\mathsf{IsometricEmbeddingClassifier}(I, I')$ *compares the packet rows componentwise. The source and target rows compare through their* $\mathsf{Met}^{\uparrow}$ *classifiers, the graph rows compare through the displayed relation row, the two distance-witness rows compare through their* $\mathsf{Real}^{\uparrow}$ *distance observations, and the distance-reflection row compares only after the same source and target distance reads have been transported.*

The classifier has no component for host-level function equality, quotient-map equality, selected representatives, or ambient completion principles. Its entire comparison surface is the displayed hsame*,* Cont*,* Pkg*, and local* NameCert *data.*

Lean4 (definition) `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingClassifier`

Theorem 439.3 (IsometricEmbedding NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{IsometricEmbedding}^{\uparrow}}$ *surface for the carrier of Definition 439.1 consists of five finite rows:*

1. *carrier admission by the displayed packet* I*;*
2. *classifier transport by the componentwise comparison surface of Definition 439.2;*
3. *distance preservation from the source* MetricDistanceWitness *row* D_X *to the target* MetricDistanceWitness *row* D_Y *through the* $\mathsf{Real}^{\uparrow}$ *reflection row* R*;*
4. *reflection into separated completion-facing consumers through the displayed* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*
5. *non-escape from quotient maps, host functions, selected representatives, and external completion theorems.*

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier namecert obligations`

Proof. Carrier admission is projection of the finite packet. The source metric row, target metric row, graph row, two distance-witness rows, real-distance reflection row, transport rows, continuation rows, package provenance, and local naming row are all visible coordinates.

Classifier transport is componentwise. The source and target classifiers move the endpoint rows, the graph row moves the displayed embedding relation, and the distance-witness rows move only along the transported endpoint data.

Distance preservation is then read from R. Since R is paired with D_X and D_Y in the carrier, the target distance read cannot be separated from the source distance read that generated it.

The separated completion-facing row consumes the same displayed metric and real-distance data. The package and naming rows record that every downstream read remains inside this surface, so no quotient map, host function, selected representative, or external completion theorem is exported. □

Theorem 439.4 (IsometricEmbedding distance reflection)**.** *Let* $I = (X, Y, F, D_X, D_Y, R, T, Q, P, N)$ *be an accepted* $\mathsf{IsometricEmbedding}^{\uparrow}$ *carrier. Any source metric-distance read exposed by* D_X *reflects through the graph row* F *into the target metric-distance read exposed by* D_Y*, and the comparison of those distances is made only through the displayed* $\mathsf{Real}^{\uparrow}$ *row* R *together with the stored* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier distance reflection`

Proof. Project the accepted carrier. The source distance read is stored in D_X, and the only target endpoint route attached to it is the displayed graph row F.

Read the target distance through D_Y. The transport row T keeps the source endpoint, graph endpoint, and target endpoint data aligned, while Q records the continuation route by which the target distance is consumed.

Finally read the real-distance comparison through R. The carrier has no separate host function or quotient-map coordinate, so the reflected target distance is the displayed $\mathsf{Real}^{\uparrow}$ comparison attached to D_X and D_Y. □

Theorem 439.5 (IsometricEmbedding completion boundary)**.** *Every* $\mathsf{CompletionReflection}^{\uparrow}$ *or* $\mathsf{HausdorffCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{IsometricEmbedding}^{\uparrow}$ *carrier may use the embedding only through the displayed source and target* $\mathsf{Met}^{\uparrow}$ *rows, the source and target* $\mathsf{MetricDistanceWitness}$ *rows, the* $\mathsf{Real}^{\uparrow}$ *distance-reflection row, and the stored* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *provenance. No completion-facing consumer receives a quotient map, host function equality, selected representative, or external completion theorem from the packet.*

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier completion boundary`

Proof. Start with a completion-facing consumer. Its metric input must read either the source row X, the target row Y, or the graph row F, because those are the only carrier coordinates exposing the embedding.

The distance input is then forced through D_X, D_Y, and R. By Definition 439.4, this is exactly the displayed source-to-target real-distance reflection route.

Apply the non-escape row of Definition 439.3. The packet inventory is exhausted by metric, real-distance, transport, continuation, package, and naming rows, so completion and separated-completion consumers cannot obtain non-displayed quotient, function, representative, or completion-theorem data. □

Theorem 439.6 (IsometricEmbedding carrier admission)**.** *Let*

$$I = (X, Y, F, D_X, D_Y, R, T, Q, P, N)$$

be an accepted $\mathsf{IsometricEmbedding}^{\uparrow}$ *packet. The carrier admitted by the local* $\mathsf{NameCert}_{\mathsf{IsometricEmbedding}^{\uparrow}}$ *surface is exactly the displayed* BHist *packet with source and target* $\mathsf{Met}^{\uparrow}$ *rows, graph row, source and target distance witnesses,* $\mathsf{Real}^{\uparrow}$ *distance-reflection row, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and local naming row. No admitted carrier field is a host function, quotient map, completion representative, or external completion theorem.*

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.TasteGate.IsometricEmbeddingTasteGate single carrier alignment`

Proof. Project the carrier definition Definition 439.1. Its ten coordinates are the complete visible inventory of the accepted packet.

Read the carrier-admission row of Definition 439.3. That row admits the packet by those coordinates and by no separate analytic object, because the package and local certificate only certify the displayed BHist surface.

The excluded objects have no coordinate in I. Therefore the admitted carrier is precisely the metric, graph, distance, reflection, transport, route, provenance, and naming packet. □

Theorem 439.7 (IsometricEmbedding classifier transport)**.** *For accepted packets* $I = (X, Y, F, D_X, D_Y, R, T, Q, P,$ *and* $I' = (X', Y', F', D'_X, D'_Y, R', T', Q', P', N')$*, any classifier comparison between* I *and* I' *is componentwise: source and target rows are compared by their* $\mathsf{Met}^{\uparrow}$ *classifiers, graph rows by the*

displayed relation row, distance witnesses by their endpoint and $\mathsf{Real}^{\uparrow}$ *distance observations, and reflection rows only after the same transported source and target distance reads have been displayed.*

Proof. Start from the classifier definition Definition 439.2. It gives no global equality test for the packet and no host function equality; each visible row is compared at its own BEDC surface.

Transport the source and target rows through the corresponding components of T and T'. The graph rows then compare the displayed source observations with the displayed target observations, and the distance-witness rows compare only the endpoint data selected by those transported graph rows.

Finally read the reflection rows R and R'. Since the classifier waits for the source and target distance observations before comparing the $\mathsf{Real}^{\uparrow}$ reflection data, classifier preservation is componentwise and remains inside the displayed hsame, Cont, Pkg, and NameCert provenance. □

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier classifier transport`

Theorem 439.8 (IsometricEmbedding separated consumer route)**.** *Every separated completion-facing consumer of an accepted* $\mathsf{IsometricEmbedding}^{\uparrow}$ *packet* $I = (X, Y, F, D_X, D_Y, R, T, Q, P, N)$ *factors through the displayed metric rows* X, Y*, the graph row* F*, the distance witnesses* D_X, D_Y*, the* $\mathsf{Real}^{\uparrow}$ *reflection row* R*, and the provenance rows* T, Q, P, N*. The consumer receives a distance-preserving route, not a quotient map, host function equality, selected representative, or ambient completion principle.*

Proof. Project the consumer route from Definition 439.5. A completion-facing read can access the embedding only by reading the metric and graph rows of the accepted packet.

Apply Definition 439.4. The distance data then pass from D_X through the graph row to D_Y, and the comparison is consumed only through the $\mathsf{Real}^{\uparrow}$ reflection row R.

The package rows T, Q, P, N record transport, continuation, provenance, and local naming for this same finite packet. Since no excluded completion object occurs in the carrier, the separated consumer route is exactly the displayed metric-distance route. □

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier separated consumer route`

Theorem 439.9 (IsometricEmbedding distance preservation obligation)**.** *Let*

$$I = (X, Y, F, D_X, D_Y, R, T, Q, P, N)$$

be an accepted $\mathsf{IsometricEmbedding}^{\uparrow}$ *packet. The distance-preservation obligation says that every displayed source-distance read in* D_X *is transported along the graph row* F *to the displayed target-distance read in* D_Y*, and the equality of the two distance observations is read only through the* $\mathsf{Real}^{\uparrow}$ *row* R *and the provenance rows* T, Q, P, N*.*

Proof. Project the carrier and classifier surfaces of Definition 439.1 and Definition 439.2. They bind the source metric row X, target metric row Y, graph row F, distance witnesses D_X, D_Y, and real-distance row R as one finite packet.

Apply the NameCert obligations of Definition 439.3. The distance-preservation row is the clause that pairs the source distance witness with the target distance witness through R.

Finally use distance reflection. Since no host function or quotient map is exported, the preservation claim is exactly the displayed source-to-target real-distance comparison. □

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier distance preservation obligation`

Theorem 439.10 (IsometricEmbedding completion reflection handoff)**.** *Every* $\mathsf{CompletionReflection}^{\uparrow}$ *consumer of an accepted* $\mathsf{IsometricEmbedding}^{\uparrow}$ *packet* $I = (X, Y, F, D_X, D_Y, R, T, Q, P, N)$ *receives its embedding input through the displayed metric rows* X, Y*, graph row* F*, distance witnesses* D_X, D_Y*, real-distance reflection row* R*, and provenance rows* T, Q, P, N*. The handoff supplies a separated completion-facing route, not a quotient map, host function equality, selected representative, or ambient completion theorem.*

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier completion reflection handoff`

Proof. Begin with the completion boundary theorem Definition 439.5. It restricts every completion-facing consumer to the metric, graph, distance, reflection, transport, route, package, and naming rows of the accepted packet.

Use classifier transport to keep these rows componentwise under the displayed hsame and Cont routes. The NameCert obligations then identify the same rows as the local certificate surface.

The separated consumer route theorem supplies the final handoff: downstream consumers obtain a distance-preserving route through the displayed packet and receive no completion object outside it. □

Theorem 439.11 (IsometricEmbedding Hausdorff separation boundary)**.** *Every* $\mathsf{HausdorffCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{IsometricEmbedding}^{\uparrow}$ *packet can use separatedness only through the displayed rows*

$$X, Y, F, D_X, D_Y, R, T, Q, P, N.$$

The packet may certify the finite distance-reflection route needed by a separated consumer, but it does not identify completion classes, choose representatives, export quotient maps, or assert an external Hausdorff-completion theorem.

Proof. Read the packet through the carrier definition. The only rows visible to a Hausdorff separatedness consumer are the source and target metric rows, the graph row, the two distance witnesses, the real-distance reflection row, and the transport and provenance rows.

Apply the distance-preservation obligation and the separated consumer route. Together they give the finite route from source distance data to target distance data and then to the separated completion-facing consumer.

The completion boundary theorem supplies the non-escape boundary. Because the carrier has no quotient map, selected representative, or ambient completion theorem, separatedness remains a consumer boundary over the displayed distance route. □

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier hausdorff separation boundary`

Theorem 439.12 (IsometricEmbedding real-distance route determinacy)**.** *For every accepted* $\mathsf{IsometricEmbedding}^{\uparrow}$ *packet* $I = (X, Y, F, D_X, D_Y, R, T, Q, P, N)$*, each source-target distance comparison routes through exactly the displayed metric rows* X, Y*, graph row* F*, distance witnesses* D_X, D_Y*, real-distance row* R*, transport rows* T*, continuation route* Q*, package provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{IsometricEmbedding}^{\uparrow}}$ *row* N*. The route exports no host function equality, quotient completion class, or selected representative.*

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier real distance route determinacy`

Proof. Start with carrier admission. The admitted packet is precisely the displayed BHist surface with source and target metric rows, graph row, distance witnesses, real-distance reflection, transport, continuation, package provenance, and local naming.

Apply classifier transport and the distance preservation obligation. Classifier transport keeps packet comparison componentwise, while distance preservation identifies the only source-to-target distance comparison as the passage from D_X through F to D_Y and then to the $\mathsf{Real}^{\uparrow}$ row R.

Use the separated consumer route together with the Hausdorff separation boundary. A separated or Hausdorff completion-facing consumer receives only the finite distance route $X, Y, F, D_X, D_Y, R, T, Q, P, N$ and no quotient map, host function equality, selected representative, completion class, or ambient completion theorem.

Therefore the real-distance route is determined by the displayed BEDC rows. Any downstream completion or Hausdorff consumer must cite those rows rather than an external isometry object. □

Theorem 439.13 (IsometricEmbedding sibling completion lattice)**.** *The* $\mathsf{IsometricEmbedding}^{\uparrow}$ *packet is read in the concrete-instance lattice after the metric and real-distance witnesses of chapter 57 and chapter 38, and before completion-facing consumers in chapter 403 and chapter 402. Its carrier consumes* $\mathsf{Met}^{\uparrow}$ *endpoint rows and* $\mathsf{Real}^{\uparrow}$ *distance rows, then exposes only the displayed completion-facing route* $X, Y, F, D_X, D_Y, R, T, Q, P, N$*.*

Proof. Start with the carrier and distance-preservation obligation. The source and target rows X, Y are metric rows, while D_X, D_Y and R place their distance comparison in the $\mathsf{Real}^{\uparrow}$ surface.

Apply real-distance route determinacy. It fixes the only source-target comparison route as $X, Y, F, D_X, D_Y, R, T, Q, P, N$, so downstream readers do not receive a host isometry object or a quotient map.

The completion reflection handoff and Hausdorff separation boundary identify the consumers that read this packet. Therefore $\mathsf{IsometricEmbedding}^{\uparrow}$ sits between the sibling metric and real chapters and the completion-facing chapters as a finite dependency lattice over displayed distance data. □

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier sibling completion lattice`

Theorem 439.14 (IsometricEmbedding distance-route reflection lock)**.** *Every separated or completion-facing consumer comparing source and target distances in an accepted* $\mathsf{IsometricEmbedding}^{\uparrow}$ *packet must route through the displayed metric rows* X, Y*, graph row* F*, distance witnesses* D_X, D_Y*,* $\mathsf{Real}^{\uparrow}$ *reflection row* R*, transport row* T*, continuation row* Q*, package provenance* P*, and local* $\mathsf{NameCert}$ *row* N*. The route cannot be replaced by host function equality, a quotient map, a selected representative, or an ambient completion theorem.*

Proof. Start with carrier admission and classifier transport. Definition 439.6 exposes exactly $X, Y, F, D_X, D_Y, R, T, Q, P, N$, and Definition 439.7 keeps comparisons componentwise on those rows.

Apply the distance-preservation obligation. Definition 439.9 identifies the distance comparison as the displayed passage from the source witness D_X through the graph row F to the target witness D_Y and then to the $\mathsf{Real}^{\uparrow}$ reflection row R.

Now use the separated and completion-facing boundaries. Definition 439.8, Definition 439.5, and Definition 439.11 confine separated and completion-facing consumers to the same finite packet.

Finally invoke real-distance route determinacy. Definition 439.12 rules out host function equality, quotient completion classes, selected representatives, quotient maps, and ambient completion theorems as substitutes for the displayed BEDC route. □

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier distance route reflection lock`

Theorem 439.15 (IsometricEmbedding obligation-closure surface)**.** *The obligation surface for* IsometricEmbedding$^{\uparrow}$ *is exhausted by the local carrier admission, classifier transport, distance-preservation obligation, separated consumer route, completion-reflection handoff, Hausdorff separation boundary, and real-distance route determinacy. Equivalently, every accepted packet can be consumed only through the displayed rows $X, Y, F, D_X, D_Y, R, T, Q, P, N$ and not through host function equality, quotient maps, selected representatives, ambient completion existence, or external Hausdorff separation principles.*

Proof. Start with carrier admission and classifier transport. Apply Definition 439.6 and Definition 439.7 to fix the displayed packet rows and keep comparisons componentwise.

Use the distance-preservation obligation next. By Definition 439.9, the source-to-target comparison is the route from D_X through F to D_Y and then to the Real$^{\uparrow}$ reflection row R.

Now bind the downstream consumers. The separated route of Definition 439.8, the completion-reflection handoff of Definition 439.10, and the Hausdorff boundary of Definition 439.11 leave no additional completion-facing row.

Finally apply Definition 439.12 and Definition 439.14. These results identify the same finite route as the only real-distance and completion-facing surface, so the listed local theorems exhaust the obligation-closure surface. □

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier obligation closure surface`

Theorem 439.16 (IsometricEmbedding scoped kernel route)**.** *Let $I = (X, Y, F, D_X, D_Y, R, T, Q, P, N)$ be an accepted* IsometricEmbedding$^{\uparrow}$ *packet. Every distance-preservation read from I is scoped by the* Met$^{\uparrow}$ *endpoint rows X, Y, the source and target distance rows D_X, D_Y, the* Real$^{\uparrow}$ *distance-reflection row R, componentwise* hsame *transport through T, displayed* Cont *replay through Q,* Pkg *provenance through P, and the local* NameCert *row N. The route is the displayed kernel surface fixed by the carrier, classifier, distance reflection, real-distance route determinacy, and completion-facing sibling lattice; it exports no host function equality, quotient map, selected representative, ambient completion theorem, or external Hausdorff separation principle.*

Proof. Begin with carrier admission and classifier transport. Definition 439.6 exposes exactly $X, Y, F, D_X, D_Y, R, T, Q, P, N$, and Definition 439.7 keeps those rows componentwise under the displayed transport and replay data.

Use distance reflection and distance preservation. Definition 439.4 and Definition 439.9 force every distance-preservation read from the source metric row through F, D_Y, and the Real$^{\uparrow}$ reflection row R.

Apply Definition 439.12 and the sibling lattice route of Definition 439.13. Together they identify the same finite route as the completion-facing kernel surface available to separated and completion consumers.

The local NameCert row and Pkg provenance then bind the scope. Since no carrier coordinate stores a host isometry, quotient map, selected representative, ambient completion theorem, or external Hausdorff principle, the listed rows are the full scoped kernel route. □

Lean4 ✓ `BEDC.Derived.IsometricEmbeddingUp.IsometricEmbeddingCarrier scoped kernel route`

Closure status for NameCert$_{\text{IsometricEmbedding}^{\uparrow}}$**.**

Constructive story: An IsometricEmbedding$^{\uparrow}$ packet is generated from source and target Met$^{\uparrow}$ rows, a displayed graph row, source and target MetricDistanceWitness rows, a Real$^{\uparrow}$ distance-reflection row, componentwise transport, continuation, package provenance, and local naming data.

Theory closure: TheoryGate(NameCert$_{\mathsf{IsometricEmbedding}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public export is the displayed isometric-embedding consumer route over Met$^{\uparrow}$, Real$^{\uparrow}$ distance rows, hsame, Cont, Pkg, and NameCert, with carrier, distance-preservation, classifier transport, and completion-facing bridge rows exposed for downstream use.

Formal verification: FormalStatus(NameCert$_{\mathsf{IsometricEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close host-level isometry theorems, quotient maps, selected representatives, ambient completion existence, extension uniqueness, or bridge checking.

Upgrade path: The next closure grade requires mature examples and downstream comparison for completion-facing consumers; bridge checking remains a separate formal-axis obligation.

Chapter 440

A Concrete Naming Certificate for $\mathsf{Sobolev}^{\uparrow}$

The $\mathsf{Sobolev}^{\uparrow}$ interface records the finite naming surface for a Sobolev-style weak-derivative packet. Classical references such as Evans, *Partial Differential Equations*, and Adams–Fournier, *Sobolev Spaces*, describe the surrounding analytic theory. BEDC records only the finite certificate surface needed by later PDE, variational, compact-embedding, and functional-analysis consumers: a displayed domain row, metric or complete-metric base row, normed or Hilbert codomain row, integrability magnitude row, weak-gradient test row, package provenance, and local naming evidence.

The packet consumes the $\mathsf{Real}^{\uparrow}$ domain surface of chapter 38, the metric or complete-metric base through chapter 57 or chapter 128, and the weak-gradient magnitude route through the $\mathsf{Integral}^{\uparrow}$ and $\mathsf{Derivative}^{\uparrow}$ sibling certificates of chapter 123 and chapter 122. These dependencies are read as finite carrier rows and ledger routes, not as a host Sobolev space or completed function quotient.

The packet is not distribution theory, not Lebesgue completion, not quotient equality of functions, and not a completed function space. It is a finite BHist carrier whose accepted observations are compared by displayed rows and hsame routes.

Definition 440.1 (Sobolev BHist carrier)**.** *A* $\mathsf{Sobolev}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, M, V, L, G, H, C, P, N)$$

with the following displayed coordinates:

1. *D is the* $\mathsf{Real}^{\uparrow}$ *domain row naming the scalar observation surface on which the weak tests are read;*
2. *M is a* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *base row naming the ambient finite metric information used by the domain consumer;*
3. *V is a* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *codomain row naming the magnitude target for function and weak-gradient observations;*
4. *L is the* $\mathsf{Integral}^{\uparrow}$ *magnitude row recording the finite integrability ledger for the displayed function and weak-gradient reads;*
5. *G is the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient test row, displayed as the finite list of test-observation routes and their recorded weak-derivative responses;*

6. *H stores the componentwise* hsame *routes for the domain, base, codomain, integrability, weak-gradient, provenance, and local naming rows;*
7. *C stores the displayed* Cont *routes by which a consumer reads the domain row, metric base row, codomain norm row, integrability ledger, and weak-gradient test ledger;*
8. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ *evidence.*

The carrier has no coordinate for a host function space, a distributional dual, a quotient by almost-everywhere equality, a completed Lebesgue measure space, or a choice-selected representative.

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevTasteGate single carrier alignment`

Theorem 440.2 (Sobolev weak-gradient source totality)**.** *Every weak-gradient read from an accepted* $\mathsf{Sobolev}^{\uparrow}$ *carrier* $S = (D, M, V, L, G, H, C, P, N)$ *factors through the displayed* $\mathsf{Real}^{\uparrow}$ *domain row D, the* $\mathsf{Derivative}^{\uparrow}$ *test row G, componentwise* hsame *transport in H, and* Cont *replay in C. The read cannot start from a host weak-gradient predicate, distributional dual, quotient function, or completed measure carrier; its source is the finite* BHist *route recorded by the packet.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak gradient source totality`

Proof. Project the carrier of Definition 440.1. The only domain source is D, and the only weak-gradient source is the displayed test row G.

Next use H and C. Transport moves the domain and test rows componentwise, while replay exposes the same finite route to consumers without adding a background analytic object.

Finally repack the read through P and N. Since no carrier coordinate stores a host weak-gradient predicate, distributional dual, quotient function, or completed measure carrier, every weak-gradient source read is exhausted by D, G, H, C, P, N. □

Theorem 440.3 (Sobolev weak-derivative window obligation)**.** *Every Sobolev weak-derivative read from an accepted* $\mathsf{Sobolev}^{\uparrow}$ *carrier* $S = (D, M, V, L, G, H, C, P, N)$ *must expose finite test-function and derivative windows inside the displayed* $\mathsf{Derivative}^{\uparrow}$ *row G, the distributional pairing rows recorded by the* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger L, the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route carried by the domain and magnitude rows, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *evidence N before any norm consumer may read it. The route exports no host distributional dual, quotient-function equality, selected representative, or ambient completed Sobolev space.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak derivative window obligation`

Proof. Project the displayed carrier rows. The weak-derivative source is not an ambient predicate; it is the derivative-facing row G attached to the domain, base, codomain, and magnitude rows D, M, V, L.

Next read the test-function and derivative windows. The finite derivative tests are visible through G, while the distributional pairings and magnitude checks are visible through L over the same $\mathsf{Real}^{\uparrow}$ domain row and regular readback route.

Now expose the structural rows. Componentwise hsame transport H, displayed Cont replay C, provenance P, and local naming N keep the derivative window attached to the same carrier before a norm consumer may read it.

Since the carrier has no coordinate for a distributional dual, quotient function space, selected representative, or completed Sobolev carrier, the weak-derivative window is exhausted by the displayed finite route. □

Theorem 440.4 (Sobolev integral magnitude ledger stability)**.** *For every accepted* $\mathsf{Sobolev}^{\uparrow}$ *carrier* $S = (D, M, V, L, G, H, C, P, N)$*, the* $\mathsf{Integral}^{\uparrow}$ *magnitude row* L *transports componentwise through* H *and remains attached to the same displayed domain, codomain, and weak-gradient rows under* Cont *replay. The transported magnitude ledger exposes no Lebesgue-completion row, quotient-function row, selected representative, or host measure-space equality.*

Proof. Start with the magnitude coordinate L. It is a finite $\mathsf{Integral}^{\uparrow}$ row attached to the displayed domain D, codomain V, and weak-gradient tests G.

Transport is componentwise through H. Thus the magnitude row moves only with its visible domain, codomain, weak-gradient, provenance, and local naming coordinates.

Replay through C preserves that attachment for downstream consumers. The omitted completion, quotient, representative, and host-equality objects are not coordinates of the packet, so the magnitude ledger cannot expose them after transport. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier integral magnitude ledger stability`

Theorem 440.5 (Sobolev obligation package)**.** *The rows* $D, M, V, L, G, H, C, P, N$ *of an accepted* $\mathsf{Sobolev}^{\uparrow}$ *carrier form the finite* $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ *obligation package consumed by PDE, variational, compact-embedding, and functional-analysis successors. The package consists of carrier admission, domain and metric-base exposure, codomain magnitude exposure, integral magnitude accounting, weak-gradient test routing, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming evidence. It exports no distribution theory, quotient function equality, Lebesgue completion, trace theorem, compact embedding theorem, or completed Sobolev space.*

Proof. Read the carrier inventory. The displayed rows $D, M, V, L, G, H, C, P, N$ are the complete finite packet and provide the only source for successor chapters.

The analytic-facing rows are D, M, V, L, G. They expose the Real domain, metric or complete-metric base, normed or Hilbert codomain, integral magnitude ledger, and derivative test ledger before any successor can consume Sobolev data.

The structural rows H, C, P, N then transport, replay, source, and name the same packet. Coordinate exhaustion excludes distribution theory, quotient function equality, Lebesgue completion, trace, compact embedding, and completed Sobolev-space objects from the obligation package. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier obligation package`

Definition 440.6 (Sobolev classifier)**.** *Two accepted* $\mathsf{Sobolev}^{\uparrow}$ *carriers are classified as the same weak-derivative certificate exactly when their visible domain, base, codomain, magnitude, weak-gradient, provenance, and naming rows compare componentwise through the stored* hsame *routes. The classifier compares the* $\mathsf{Real}^{\uparrow}$ *domain row, the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *base row, the* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *codomain row, the* $\mathsf{Integral}^{\uparrow}$ *magnitude row, the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient test row, the* Pkg *row, and the local* $\mathsf{NameCert}$ *row.*

The classifier does not compare host functions, ambient distributions, completed L^p *classes, quotient representatives, or equality in a background Sobolev space.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevFiniteWindowClassifierSurface`

Theorem 440.7 (Sobolev NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ *obligation surface for the carrier of Definition 440.1 consists of five finite rows:*

1. *carrier habitation by the zero weak-gradient packet, with a displayed* $\mathsf{Real}^{\uparrow}$ *domain row, metric base row, codomain norm row, zero* $\mathsf{Integral}^{\uparrow}$ *magnitude row, zero* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient test row, package provenance, and local naming evidence;*
2. *classifier reflexivity, symmetry, and transitivity by the componentwise classifier of Definition 440.6;*
3. *carrier transport under the classifier, preserving the same visible domain, metric base, codomain, integrability, weak-gradient, provenance, and naming rows up to* hsame*;*
4. *ledger exactness for weak-derivative observations, requiring every accepted derivative read to factor through the displayed* G *row and the magnitude ledger* L*;*
5. *completion-boundary non-escape, preventing any consumer from reading distribution theory, Lebesgue completion, quotient equality, or a host Sobolev space from the finite carrier.*

Proof. For habitation, use the displayed zero weak-gradient test row. The domain, metric base, codomain, zero magnitude, provenance, and local naming coordinates are all finite carrier rows, so no ambient function space is needed.

For classifier stability, compare accepted carriers by the rows named in Definition 440.6. Reflexivity, symmetry, and transitivity are inherited componentwise from the displayed hsame routes and are repacked into the same finite carrier shape.

For transport and exactness, inspect any downstream read. It can project only D, M, V, L, G, H, C, P, or N, and the weak-derivative read is the displayed route through G with its magnitude entry in L. Coordinate exhaustion gives the non-escape boundary. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier namecert obligation surface`

Theorem 440.8 (Sobolev obligation-closure export)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet* $S = (D, M, V, L, G, H, C, P, N$ *exports the paper-side obligation-closure package formed by the displayed rows* $D, M, V, L, G, H, C, P, N$*, the classifier of Definition 440.6, the weak-gradient ledger, and the integral magnitude ledger. The package supplies carrier admission, classifier stability, weak-gradient exactness, integral magnitude accounting, completion-boundary nonescape, componentwise transport, replay, provenance, and local naming for Sobolev consumers.*

The package still refuses distribution theory, quotient function equality, Lebesgue completion, trace theorem, compact embedding, and completed Sobolev spaces.

Proof. Project the carrier of Definition 440.1 and the obligation package of Definition 440.5. These expose exactly the rows $D, M, V, L, G, H, C, P, N$ and assign their domain, base, codomain, magnitude, weak-gradient, transport, replay, provenance, and naming roles.

Apply the classifier of Definition 440.6 and the NameCert obligation surface of Definition 440.7. They supply carrier admission, classifier stability, carrier transport, weak-derivative ledger exactness, and completion-boundary nonescape over the same finite rows.

Use Definition 440.9. It orders every weak-gradient read through D, M, V, L, G, with the $\mathsf{Integral}^{\uparrow}$ magnitude ledger L read before the $\mathsf{Derivative}^{\uparrow}$ weak-gradient row G.

Finally apply Definition 440.10. Since H, C, P, N only transport, replay, source, and name the same finite packet, the refused analytic objects cannot be recovered from the export package. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier obligation closure export`

Theorem 440.9 (Sobolev weak-derivative ledger)**.** *Every accepted weak-derivative observation exported by a* $\mathsf{Sobolev}^{\uparrow}$ *carrier factors through the finite route*

$$D \longmapsto M \longmapsto V \longmapsto L \longmapsto G.$$

The route first fixes the displayed $\mathsf{Real}^{\uparrow}$ *domain row and metric base, then reads the* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *codomain row, then records the* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger before exposing the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient test row. It exports no distributional dual object, no completed* L^p *class, no quotient representative, and no host equality of functions.*

Proof. Start with a consumer request for a weak-derivative observation. Carrier projection forces the request to identify the domain row D and the metric or complete-metric base row M before any derivative data can be read.

The codomain and magnitude rows are then read through V and L. These rows specify the finite normed target and the accepted integrability ledger for the observation, not an ambient measure completion.

Only after that route reaches G does the weak-gradient test row become visible. Since H, C, P, and N record transport, continuation, provenance, and local naming without adding analytic coordinates, the exported observation is exactly the finite ledger described above. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak derivative ledger`

Theorem 440.10 (Sobolev completion boundary)**.** *A* $\mathsf{Real}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, *functional-analysis, PDE, variational, or compact-embedding consumer citing an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet receives only the displayed carrier rows of Definition 440.1, the classifier of Definition 440.6, the five obligation rows of Definition 440.7, and the weak-derivative ledger of Definition 440.9. The citation cannot assert full distribution theory, Lebesgue completion, quotient equality of functions, density of smooth functions, compact embedding, trace theory, or a completed Sobolev space.*

Proof. Factor the consumer citation through the local $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ surface. The available data are the finite rows $D, M, V, L, G, H, C, P, N$ and the classifier routes between accepted packets.

Apply the weak-derivative ledger theorem to any derivative-facing read. It fixes the route through the displayed domain, base, codomain, magnitude, and weak-gradient rows before the observation is exported.

The excluded analytic objects are not coordinates of the packet and are not produced by the classifier or continuation rows. Therefore downstream consumers may use the finite weak-derivative certificate surface, but they cannot read any stronger completion, quotient, density, compactness, or trace result from this chapter. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier completion boundary`

Theorem 440.11 (Sobolev weak-derivative root-unblock package)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet* $S = (D, M, V, L, G, H, C, P, N)$ *exports a finite root package combining carrier admission, classifier stability, weak-derivative ledger exactness, metric or complete-metric boundary data,* $\mathsf{Integral}^{\uparrow}$ *and* $\mathsf{Derivative}^{\uparrow}$ *handoff, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape. Any downstream analysis consumer must read this package through the displayed weak-gradient magnitude route*

$$D \longmapsto M \longmapsto V \longmapsto L \longmapsto G$$

before reaching completion-facing rows.

The package supplies no distributional dual object, Lebesgue completion, quotient equality of functions, density theorem, compact embedding theorem, trace theorem, or completed Sobolev space.

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak derivative root unblock package`

Proof. Project the carrier and classifier surfaces. The carrier rows $D, M, V, L, G, H, C, P, N$ are the complete visible inventory, and the classifier compares them componentwise through the stored hsame routes.

Apply the NameCert obligation surface. Carrier habitation, classifier stability, carrier transport, weak-derivative ledger exactness, and completion-boundary non-escape are already recorded as finite rows over the same packet.

Use the weak-derivative ledger theorem to identify the route used by every derivative-facing read. The read passes from the $\mathsf{Real}^{\uparrow}$ domain row through the metric or complete-metric base, the normed or Hilbert codomain row, the $\mathsf{Integral}^{\uparrow}$ magnitude ledger, and only then the $\mathsf{Derivative}^{\uparrow}$ weak-gradient test row.

Finally apply the completion boundary theorem. It confines downstream PDE, variational, functional-analysis, compact-embedding, and completion-facing consumers to the displayed carrier, classifier, obligation, and ledger rows. Coordinate exhaustion then gives the Real seal nonescape and rules out all stronger analytic objects listed in the statement. □

Theorem 440.12 (Sobolev weak-derivative carrier transport)**.** *Let $S = (D, M, V, L, G, H, C, P, N)$ and $S' = (D', M', V', L', G', H', C', P', N')$ be accepted $\mathsf{Sobolev}^{\uparrow}$ packets whose domain, base, codomain, magnitude, weak-gradient, provenance, and local naming rows are connected by the componentwise* hsame *entries recorded in H and H'. Any weak-derivative consumer transported from S to S' must carry the same* BHist *route*

$$D \longmapsto M \longmapsto V \longmapsto L \longmapsto G$$

to

$$D' \longmapsto M' \longmapsto V' \longmapsto L' \longmapsto G'$$

through the displayed Cont *replay rows. The transport preserves the carrier, classifier, weak-derivative ledger, completion-boundary rows,* Pkg *provenance, and local* NameCert *evidence, and it supplies no distributional dual, quotient function class, completed measure carrier, compact embedding object, or trace row.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak derivative carrier transport`

Proof. Begin with the classifier of Definition 440.6. It compares accepted packets only through the visible rows D, M, V, L, G, P, N and the componentwise hsame transport stored in H.

Next replay the consumer route through C and C'. Since every weak-derivative read is forced by Definition 440.9 to pass through the displayed domain, base, codomain, magnitude, and weak-gradient rows, transport replaces each row by its classified mate and keeps the same finite route.

Finally use the completion boundary theorem. The excluded analytic objects are absent from both carrier inventories, so transport across the classifier cannot create them. □

Theorem 440.13 (Sobolev classifier locality)**.** *The $\mathsf{Sobolev}^{\uparrow}$ classifier is local to the rows displayed by the carrier of Definition 440.1. A downstream consumer may decide sameness of accepted weak-derivative packets only by reading the* BHist *rows D, M, V, L, G, the* hsame *transport row H, the* Cont *replay row C, the* Pkg *provenance row P, and the local* NameCert *row N. It cannot appeal to host function equality, equality in a quotient of measurable functions, distributional equality outside the displayed weak-gradient tests, ambient Hilbert completion, compact embedding, trace data, or density of smooth approximants.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier classifier locality`

Proof. Read the classifier definition. Its comparison surface is componentwise and mentions only the displayed domain, base, codomain, magnitude, weak-gradient, provenance, and naming rows.

Apply carrier transport. Any consumer trying to move a classified packet must replay the same Cont route through the same finite weak-derivative ledger, so the classifier remains local to the carrier inventory.

The nonlocal analytic objects listed in the statement are not coordinates of S. Coordinate exhaustion therefore blocks them from acting as classifier inputs or classifier witnesses. □

Theorem 440.14 (Sobolev root obligation package)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet* $S = (D, M, V, L, G, H, C, P, N$ *exports a root obligation package consisting of carrier admission, classifier stability, weak-gradient ledger exactness, completion-boundary nonescape, and* $\mathsf{Real}^{\uparrow}$ *seal nonescape. The package is read only through the displayed rows*

$$D, M, V, L, G, H, C, P, N.$$

The carrier row admits the packet, the classifier row keeps sameness componentwise, the weak-gradient ledger forces derivative-facing reads through D, M, V, L, G*, the completion boundary blocks ambient Sobolev completion, and the* $\mathsf{Real}^{\uparrow}$ *domain seal in* D *cannot be read outside the same finite route.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier root obligation package`

Proof. Project the carrier of Definition 440.1. It lists exactly the displayed rows $D, M, V, L, G, H, C, P, N$, so carrier admission has no additional analytic coordinate.

Apply the classifier of Definition 440.6 and the NameCert obligation surface of Definition 440.7. These give classifier stability, carrier transport, weak-derivative ledger exactness, and completion-boundary nonescape over the same rows.

Use the weak-derivative ledger and completion boundary, Definition 440.9 and Definition 440.10. The derivative-facing route must pass through D, M, V, L, G, while completion-facing and Real-facing consumers remain inside the carrier and structural rows.

Finally repack the route through H, C, P, N. Since these rows only transport, replay, source, and name the same packet, the Real seal and completion boundary cannot escape the finite root obligation package. □

Theorem 440.15 (Sobolev weak-gradient consumer boundary)**.** *Every PDE, variational, and functional-analysis consumer of an accepted* $\mathsf{Sobolev}^{\uparrow}$ *weak-gradient read must pass through*

$$D, M, V, L, G, H, C, P, N$$

before reading Sobolev data. In particular, such a consumer first reads the $\mathsf{Real}^{\uparrow}$ *domain row* D*, the metric or complete-metric row* M*, the norm or Hilbert row* V*, the* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger* L*, and the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient row* G*, then uses* H, C, P, N *only for transport, replay, provenance, and local naming. It cannot read a host weak-gradient predicate, quotient function equality, distributional dual, Lebesgue completion, density theorem, compact embedding theorem, or trace theorem from the packet.*

Proof. Start with a downstream consumer request. The carrier definition forces the request to enter through the displayed inventory $D, M, V, L, G, H, C, P, N$.

Apply the weak-derivative ledger. It orders every derivative-facing observation from the Real domain row through the metric base, codomain, integral magnitude ledger, and derivative test row before the observation is exported.

Now use classifier locality and carrier transport. They keep sameness and transport local to the same finite rows, so PDE, variational, and functional-analysis consumers cannot substitute an ambient analytic object for the displayed route.

The completion boundary removes the excluded objects. Distributional duals, quotient equality, Lebesgue completion, density, compactness, trace, and host weak-gradient predicates are not coordinates of the packet, and H, C, P, N add only structural replay and naming. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak gradient consumer boundary`

Theorem 440.16 (Sobolev integral and derivative source package)**.** *In every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet, the* $\mathsf{Integral}^{\uparrow}$ *magnitude row* L *and the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient row* G *are source rows for the weak-gradient ledger. Neither row can be replaced by distribution theory, Lebesgue completion, or an ambient quotient-function carrier:* L *supplies the displayed magnitude ledger,* G *supplies the displayed weak-gradient tests, and the route from* D *through* M, V, L, G *is the only analytic source package exported to downstream Real, metric, derivative, integral, Hilbert, PDE, variational, or functional-analysis consumers.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier integral derivative source package`

Proof. Project L and G from Definition 440.1. The row L is explicitly the integral magnitude ledger, and G is explicitly the derivative-facing weak-gradient test row.

Apply Definition 440.9. It places L immediately before G in the finite route from the Real domain row and metric base through the codomain row, so the weak-gradient read has a displayed source package.

Use Definition 440.10 and Definition 440.13. They state that downstream consumers and classifier reads remain inside the same finite carrier rows and cannot appeal to distribution theory, Lebesgue completion, or quotient equality.

Finally transport through H and replay through C. Provenance P and local naming N source the same L, G package, so no replacement analytic carrier can discharge the integral or derivative source obligations. □

Theorem 440.17 (Sobolev root-unblock certificate)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet exports a root-unblock certificate consisting exactly of the carrier row, local classifier, weak-derivative ledger, carrier transport row, classifier-locality row, completion-boundary row,* Pkg *provenance, and local* NameCert *evidence. Any Hilbert, metric, integral, derivative, PDE, variational, or compactness-facing consumer must first pass through these finite* BHist, hsame, *and* Cont *rows before reading the weak-gradient data. The certificate supplies no completed Sobolev space, no distributional dual, no quotient function equality, no selected representative, no density theorem, no compact embedding theorem, and no trace theorem.*

Proof. Project the accepted packet. The carrier exposes exactly $D, M, V, L, G, H, C, P, N$, and the NameCert obligation surface records habitation, classifier stability, transport, ledger exactness, and completion-boundary nonescape.

Use the weak-derivative ledger and carrier transport rows. They force every derivative-facing read to traverse the displayed domain, base, codomain, magnitude, and weak-gradient route, then preserve that route under componentwise hsame comparison.

Use classifier locality for downstream consumers. Hilbert, metric, integral, derivative, PDE, variational, and compactness-facing reads can cite only the local classifier and the replayed route, not a host analytic object outside the packet.

The completion boundary then removes the remaining escape routes. Since the excluded spaces, quotients, representatives, density results, compact embeddings, and traces are not carrier coordinates, the root-unblock certificate is exhausted by the displayed finite rows. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier root unblock certificate`

Theorem 440.18 (Sobolev integral and derivative handoff)**.** *Every* $\mathsf{Integral}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *PDE, or variational consumer of an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet must traverse the displayed route*

$$D \longmapsto M \longmapsto V \longmapsto L \longmapsto G \longmapsto H, C, P, N.$$

Thus weak-derivative data are consumed only through the finite integral and derivative ledgers. The handoff supplies no distribution theory, Lebesgue completion, quotient equality of functions, compact embedding theorem, trace row, selected representative, or completed Sobolev space.

Proof. Project the carrier rows of Definition 440.1. The only analytic-facing coordinates are the domain row D, the metric or complete-metric base row M, the codomain row V, the integral magnitude ledger L, and the weak-gradient test row G.

Apply the weak-derivative ledger theorem. It places every derivative-facing observation on the route from D through M, V, L and then to G, so the integral and derivative consumers read the same finite ledger rather than an ambient function space.

Use the root-unblock certificate to carry the route to Hilbert, metric, complete-metric, PDE, and variational consumers. The transport, replay, provenance, and local naming rows H, C, P, N preserve the displayed route without adding analytic coordinates.

Finally apply the completion boundary. The excluded distribution, completion, quotient, compactness, trace, representative, and completed-space objects are absent from the carrier inventory, so the handoff is exhausted by the finite route displayed above. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier integral derivative handoff`

Theorem 440.19 (Sobolev BHist carrier scope)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *read is scoped by the finite* BHist *carrier rows*

$$D, M, V, L, G, H, C, P, N$$

of Definition 440.1. A consumer may reach $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, *and* $\mathsf{Derivative}^{\uparrow}$ *only through those displayed rows, their componentwise* hsame *transports, their* Cont *replay route, the* Pkg *provenance row, and the local* $\mathsf{NameCert}$ *evidence.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier bhist carrier scope`

Proof. Project the accepted carrier. The carrier definition lists exactly the domain row D, metric or complete-metric base M, codomain row V, magnitude ledger L, weak-gradient row G, and structural rows H, C, P, N.

Apply the classifier locality and carrier transport rows. They compare and move accepted packets only through the same displayed coordinates, with hsame and Cont preserving the route rather than adding a host analytic object.

Finally inspect a downstream analysis read. Since every readable sibling is named in P and replayed through C, the $\mathsf{Real}^{\uparrow}$, metric, complete-metric, norm, Hilbert, integral, and derivative surfaces can appear only as the finite rows already present in the BHist packet. □

Theorem 440.20 (Sobolev Hilbert and norm readback scope)**.** *Every Hilbert-facing or norm-facing readback from an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet factors through the displayed* $\mathsf{Met}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$ *or* $\mathsf{Norm}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows carried by*

$$D, M, V, L, G, H, C, P, N.$$

The route reads metric data through M*, Hilbert or norm data through* V*, integral magnitude through* L*, weak-derivative tests through* G*, Real and regular-rational data through the displayed domain and readback rows, and then the structural rows* H, C, P, N*. It exports no host function space, quotient equality, ambient Hilbert completion, or external completeness theorem.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier hilbert norm readback scope`

Proof. Project the carrier rows in order. The metric-facing coordinate is M, the Hilbert or norm-facing coordinate is V, the integral coordinate is L, and the derivative coordinate is G.

Read the Real and regular-rational surface through the same displayed domain and magnitude route. The domain row D anchors the scalar readback, while L and G carry the finite magnitude and weak-derivative observations that norm consumers inspect.

Transport and replay are then componentwise. The rows H, C, P, N preserve the same metric, Hilbert or norm, integral, derivative, Real, and regular-rational route and attach provenance and local naming.

Coordinate exhaustion gives the scope boundary. Because the carrier has no row for a host function space, quotient equality, ambient Hilbert completion, or external completeness theorem, none of those objects can be exported by a Hilbert or norm readback. □

Theorem 440.21 (Sobolev derivative norm ledger)**.** *Every derivative-facing* $\mathsf{Sobolev}^{\uparrow}$ *consumer first reads the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient row* G *and the* $\mathsf{Integral}^{\uparrow}$ *magnitude row* L *through the displayed codomain row* V*. If* V *is Hilbert-facing, the same route reads* $\mathsf{Hilbert}^{\uparrow}$ *only through the finite* $\mathsf{Norm}^{\uparrow}$ *magnitude interface carried by* V *before the* $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ *row is exposed. Thus derivative magnitude, norm control,* hsame *transport,* Cont *replay, and* Pkg *provenance are one finite ledger, not a quotient Sobolev norm or a completed Hilbert-space argument.*

Proof. Begin with the integral and derivative handoff. It forces the consumer route through D, M, V, L, G before the structural rows are read.

The codomain row V is therefore fixed before L and G are interpreted. The $\mathsf{Integral}^{\uparrow}$ magnitude ledger reads weak-gradient size through L, and the $\mathsf{Derivative}^{\uparrow}$ row reads the corresponding weak-gradient tests through G.

If the codomain is Hilbert-facing, the Hilbert row remains the displayed codomain surface inside V. The route supplies norm data only by the finite norm interface already named there, and the later rows H, C, P, N merely transport, replay, source, and name the same derivative-norm ledger. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier derivative norm ledger`

Theorem 440.22 (Sobolev finite-window root package)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet exports its downstream-ready finite root package only through the rows*

$$D, M, V, L, G, H, C, P, N.$$

Here $\mathsf{Real}^{\uparrow}$ *is read through* D*,* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *through* M*,* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *through* V*,* $\mathsf{Integral}^{\uparrow}$ *through* L*, and* $\mathsf{Derivative}^{\uparrow}$ *through* G*, with* H, C, P, N *carrying transport, replay, provenance, and local naming. Thus PDE, variational, functional-analysis, Hilbert, metric, integral, and*

derivative consumers receive a finite BHist *obligation package, not distributional duals, Lebesgue completion, quotient equality, density, compact embedding, trace rows, or selected representatives.*

Proof. Project the accepted carrier through Definition 440.1. Its visible coordinates are exactly $D, M, V, L, G, H, C, P, N$, and the local NameCert obligation surface records carrier admission, classifier stability, transport, ledger exactness, and completion-boundary non-escape over those rows.

Use the weak-derivative ledger and classifier locality rows. Every derivative-facing observation must traverse the displayed route from D through M, V, L to G, and every sameness decision remains local to the same carrier inventory and its componentwise hsame evidence.

Apply the derivative norm ledger. It places norm and Hilbert-facing magnitude reads inside V before the integral and derivative rows are exposed, so the finite root package is stable under downstream norm, integral, derivative, and completion-facing consumption.

The excluded analytic objects are absent from the carrier, classifier, weak-derivative ledger, and derivative norm ledger. Coordinate exhaustion therefore blocks distributional duals, Lebesgue completion, quotient equality, density, compact embedding, trace rows, and selected representatives from entering the exported root package. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier finite window root package`

Theorem 440.23 (Sobolev finite energy carrier)**.** *Let $S = (D, M, V, L, G, H, C, P, N)$ be an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet. Its finite energy carrier is exactly the displayed* BHist *route through the* $\mathsf{Real}^{\uparrow}$ *domain row D, the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *base row M, the* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *codomain row V, the* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger L, the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient row G, the componentwise* hsame *transport row H, the displayed* Cont *replay row C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ *row N. No Real, metric, integral, derivative, or Hilbert-facing consumer can read an energy datum outside these coordinates.*

Proof. Project the accepted carrier of Definition 440.1. The tuple $D, M, V, L, G, H, C, P, N$ is the complete coordinate list, and each analytic face is named by one of those rows.

Apply the NameCert obligation surface and Definition 440.22. Carrier admission, classifier stability, weak-derivative ledger exactness, and completion-boundary non-escape all refer back to the same finite inventory.

Coordinate exhaustion then handles the consumer side. A Real, metric, integral, derivative, or Hilbert read must enter through the named row assigned to that face; the remaining rows only transport, replay, source, and name the same route. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier finite energy carrier`

Theorem 440.24 (Sobolev weak-derivative scope)**.** *Let $S = (D, M, V, L, G, H, C, P, N)$ be an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet. Every weak-derivative observation of S is scoped by the finite path*

$$D, M, V, L, G, H, C, P, N.$$

The derivative row G is readable only after the domain, base, codomain, and integral magnitude rows D, M, V, L have been displayed, and the resulting observation is preserved only by the componentwise hsame *row H, the displayed* Cont *replay row C, the* Pkg *provenance row P, and the local* NameCert *row N.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak derivative scope`

Proof. Start from the weak-derivative ledger in the carrier definition. The row G is not a free-standing predicate; it is the derivative-facing coordinate attached to the already displayed rows D, M, V, L.

Use the classifier and transport rows. Sameness of accepted Sobolev packets is componentwise through H, and replay of a weak-derivative read is through C, so the observation cannot leave the same carrier route.

Finally apply the finite-window root package. It packages Real, metric, norm or Hilbert, integral, derivative, transport, replay, provenance, and naming rows as one finite BHist surface, which proves the stated scope by coordinate exhaustion. □

Theorem 440.25 (Sobolev complete-metric handoff)**.** *Let $S = (D, M, V, L, G, H, C, P, N)$ be an accepted* Sobolev$^{\uparrow}$ *packet. Any* CompleteMetric$^{\uparrow}$, Met$^{\uparrow}$, Hilbert$^{\uparrow}$, *PDE, variational, integral, or compactness-facing consumer receives the Sobolev data only through the finite handoff*

$$D, M, V, L, G, H, C, P, N.$$

The handoff may read complete-metric boundary information through M and Hilbert or norm information through V, but it does not export a completed Sobolev carrier, selected metric limit, quotient function class, distributional dual, density theorem, compact embedding, or trace theorem.

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier complete metric handoff`

Proof. Begin with the finite energy carrier. It fixes $D, M, V, L, G, H, C, P, N$ as the only readable rows and assigns metric or complete-metric data to M and norm or Hilbert data to V.

Next apply the weak-derivative scope. The integral and derivative rows L and G remain downstream of the same domain, base, and codomain rows, and their observations are preserved only by H, C, P, N.

The downstream handoff is therefore just a repackaging of the finite root package. Since no coordinate names a completed Sobolev carrier, selected limit, quotient class, distributional dual, density theorem, compact embedding, or trace theorem, none of those objects can be supplied to the listed consumers. □

Definition 440.26 (Sobolev finite-window carrier)**.** *A finite-window* Sobolev$^{\uparrow}$ *carrier is a displayed* BHist *packet*

$$W = (D, M, V, L, G, T, H, C, P, N)$$

over the following rows:

1. *D is the* Real$^{\uparrow}$ *domain row for the finite scalar observation window.*
2. *M is the* Met$^{\uparrow}$ *or* CompleteMetric$^{\uparrow}$ *base row attached to the same window.*
3. *V is the* Norm$^{\uparrow}$ *or* Hilbert$^{\uparrow}$ *codomain row through which function and weak-gradient magnitudes are read.*
4. *L is the* Integral$^{\uparrow}$ *magnitude row for the displayed function and weak-gradient observations.*
5. *G is the* Derivative$^{\uparrow}$ *weak-derivative ledger row, containing only the finitely inspected test routes and their responses.*
6. *T is the transport ledger for weak-derivative rows, recording how each displayed test route is moved under the local classifier.*
7. *H records componentwise* hsame *comparison for D, M, V, L, G, T, P, N.*

8. *C records displayed* Cont *replay from a Sobolev read through the finite window into $D, M, V, L, G, T, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ *row for this finite window.*

The finite-window classifier compares accepted packets only through these rows. It does not compare ambient Hilbert completions, quotient function classes, measure-theoretic representatives, host equality of functions, or selected extensions beyond the displayed weak-derivative tests.

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevFiniteWindowCarrier field faithful`

Theorem 440.27 (Sobolev completion-boundary nonescape)**.** *Every completion-facing read of a finite-window* $\mathsf{Sobolev}^{\uparrow}$ *carrier $W = (D, M, V, L, G, T, H, C, P, N)$ is confined to*

$$D, M, V, L, G, T, H, C, P, N.$$

In particular, a consumer may read $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, *weak-derivative transport, replay, provenance, and local naming only through the displayed finite-window rows. It cannot export ambient Hilbert completion, quotient functions, measure-theoretic choice, host equality outside the displayed tests, density of smooth functions, compact embedding, trace theory, or a selected representative.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevFiniteWindowCarrier completion boundary nonescape`

Proof. Project the finite-window carrier of Definition 440.26. Its analytic rows are exactly D, M, V, L, G, T, and its structural rows are exactly H, C, P, N.

Read a completion-facing request through the replay row C. The route first reaches the $\mathsf{Real}^{\uparrow}$ domain row and metric or complete-metric base row, then the norm or Hilbert codomain row, and only then the integral magnitude and derivative test rows.

The transport ledger T and componentwise hsame row H move only those displayed weak-derivative rows. They do not add a quotient class, a measure-completion selector, or equality of host functions.

Finally P and N record provenance and local naming for the same finite window. Since the excluded analytic objects are absent from the carrier inventory and from the replay route, no completion-facing consumer can export them from this packet. □

Theorem 440.28 (Sobolev Hilbert completion descent)**.** *Any* $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *PDE, variational, or completion-facing consumer of a* $\mathsf{Sobolev}^{\uparrow}$ *packet descends to the carrier rows of Definition 440.19 before it may cite weak-derivative data. The descent route passes through the displayed* $\mathsf{Real}^{\uparrow}$ *domain row, the metric or complete-metric base row, the codomain norm or Hilbert row, the* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger, the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *evidence. It supplies no completed Sobolev space, distributional dual, quotient function equality, density theorem, compact embedding, trace row, or selected representative.*

Proof. Start with a Hilbert-facing or completion-facing consumer. The BHist carrier scope theorem forces the read to land on the displayed finite inventory $D, M, V, L, G, H, C, P, N$.

Use the derivative norm ledger. It identifies the analytic handoff as a route from the codomain row V through the integral magnitude row L and derivative row G, with Hilbert information restricted to the finite norm-facing surface in V.

The completion boundary then applies to the same route. The structural rows record transport, replay, provenance, and local naming only, so no completed Sobolev space, distributional dual, quotient function equality, density, compactness, trace, or selected representative can be read by descent. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier hilbert completion descent`

Theorem 440.29 (Sobolev weak-gradient ledger exhaustion)**.** *Let $S = (D, M, V, L, G, H, C, P, N)$ be an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet. Every weak-gradient read exported by S is exhausted by the displayed rows D, M, V, L, G together with the structural rows H, C, P, N. In particular, the read reaches* $\mathsf{Real}^{\uparrow}$ *only through D,* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *only through M,* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *only through V,* $\mathsf{Integral}^{\uparrow}$ *only through L,* $\mathsf{Derivative}^{\uparrow}$ *only through G, and* $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$ *only through the carrier and structural rows already displayed by S.*

Proof. Project the accepted carrier. The weak-gradient route has no analytic coordinate beyond D, M, V, L, G, and its structural support is exactly H, C, P, N.

Apply the Sobolev weak-derivative ledger theorem. It forces each derivative-facing observation to pass through the domain, metric or complete-metric base, codomain, magnitude ledger, and weak-gradient test row before the observation is exported.

The BHist carrier scope theorem then accounts for the structural rows. The hsame transports, Cont replay, package provenance, and local NameCert evidence preserve the displayed weak-gradient route without adding an ambient analytic object. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak gradient ledger exhaustion`

Theorem 440.30 (Sobolev integral-derivative transport stability)**.** *Let $S = (D, M, V, L, G, H, C, P, N)$ and $S' = (D', M', V', L', G', H', C', P', N')$ be accepted* $\mathsf{Sobolev}^{\uparrow}$ *packets compared by the displayed componentwise* hsame *transport rows. Any consumer that transports an integral or derivative read from S to S' must transport the same route*

$$D \longmapsto M \longmapsto V \longmapsto L \longmapsto G$$

to

$$D' \longmapsto M' \longmapsto V' \longmapsto L' \longmapsto G'$$

through the displayed Cont *replay rows, with provenance and local naming preserved by P, N and P', N'. The transport cannot introduce a host distribution, quotient function equality, completed measure carrier, compact embedding row, or trace row.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier integral derivative transport stability`

Proof. Begin with classifier locality. The classifier compares accepted packets only through the displayed carrier rows and the hsame transport surface.

Use carrier transport to move the route. The source read through D, M, V, L, G is replaced componentwise by the target read through D', M', V', L', G', and the replay rows C, C' preserve the same consumer order.

Finally apply weak-gradient ledger exhaustion. Since the source and target packets expose only the listed Real, metric, complete-metric, norm, Hilbert, integral, derivative, BHist, transport, replay, provenance, and NameCert rows, no excluded analytic object can appear during transport. □

Theorem 440.31 (Sobolev completion-facing root scope)**.** *Every completion-facing, PDE-facing, variational, compact-embedding, Hilbert, metric, or derivative consumer of an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet must first read the finite root scope*

$$D, M, V, L, G, H, C, P, N.$$

Thus completion-facing access remains confined to $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *as displayed carrier rows. It does not provide a completed Sobolev space, distributional dual, quotient equality of functions, density theorem, compact embedding theorem, trace theorem, or selected representative.*

Proof. Start with Sobolev Hilbert completion descent. It sends every Hilbert-facing or completion-facing request to the carrier rows before weak-derivative data are cited.

Apply weak-gradient ledger exhaustion to identify the analytic portion of the root scope. The rows D, M, V, L, G are the only path to Real, metric, complete-metric, norm, Hilbert, integral, and derivative reads.

Apply integral-derivative transport stability for transported consumers. The rows H, C, P, N preserve, replay, source, and name the same finite root scope, so downstream PDE, variational, compactness-facing, and completion-facing consumers cannot read outside it. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier completion facing root scope`

Theorem 440.32 (Sobolev trace-window obligation)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet exposes any boundary-facing trace-window read only through finite* BHist *rows and the displayed* hsame *transport surface. A consumer may read a trace window after it has traversed the carrier rows* $D, M, V, L, G, H, C, P, N$*, the weak-derivative ledger, the derivative norm ledger, and the local* $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ *evidence. The obligation supplies a finite boundary-window route, not a global trace theorem, selected representative, quotient function equality, or ambient measure-completion choice.*

Proof. Unpack the carrier of Definition 440.1. The only readable coordinates are the displayed domain, base, codomain, integral magnitude, weak-gradient, transport, replay, provenance, and local naming rows.

Use the weak-derivative ledger and derivative norm ledger. They force boundary-facing analytic data to pass through the same D, M, V, L, G route before the structural rows H, C, P, N can replay the observation.

Finally apply the completion-facing root scope. Since the root scope excludes completed Sobolev spaces, quotient equality, selected representatives, and ambient measure choice, a trace-window consumer receives only the finite BHist rows and their hsame transports. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier trace window obligation`

Theorem 440.33 (Sobolev local Poincare ledger)**.** *Every local derivative or integral window read from an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet is routed through displayed finite Poincare-style comparison ledgers. The route compares the* $\mathsf{Derivative}^{\uparrow}$ *row* G *against the* $\mathsf{Integral}^{\uparrow}$ *magnitude row* L *over the fixed domain, metric, and codomain rows* D, M, V*, then transports the comparison through* H *and replays it through* C*. It does not invoke an ambient measure selection, global representative, or unrecorded normed-space completion.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier local poincare ledger`

Proof. Begin with the derivative norm ledger. It places derivative magnitude and norm control inside the route from V through L to G, so every local comparison has a displayed analytic source.

Read the same route through the finite-window root package. The package exposes D, M, V, L, G before the structural rows, so the comparison is a finite ledger over the displayed domain, base, codomain, integral, and derivative data.

Transport now uses only H and C. These rows preserve and replay the displayed local comparison; they contain no coordinate for choosing an ambient measure carrier, selecting a representative, or completing a normed space. □

Theorem 440.34 (Sobolev completion consumer export)**.** *Every downstream* $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *PDE, variational, or compactness-facing consumer of an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet reads only the Sobolev carrier, the weak-derivative ledger, the derivative norm ledger, the integral and norm rows,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The export surface contains no additional distributional dual, quotient-function equality, density theorem, compact embedding theorem, trace theorem, or completed Sobolev carrier.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier completion consumer export`

Proof. Start with Sobolev Hilbert completion descent. It sends each completion-facing consumer to the carrier rows before any weak-derivative datum can be cited.

Apply weak-gradient ledger exhaustion and integral-derivative transport stability. These theorems identify the analytic payload as the finite route through D, M, V, L, G and preserve it across H, C, P, N.

Use the trace-window obligation and local Poincare ledger for boundary-facing and local comparison reads. Both obligations remain inside the same carrier, transport, replay, provenance, and local NameCert rows, so the completion consumer export has no additional analytic coordinate. □

Theorem 440.35 (Sobolev Real completion root window)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet carries a Real-completion root window in its finite* BHist *surface. The* $\mathsf{Real}^{\uparrow}$ *row D supplies the scalar observation and terminal seal rows, the* $\mathsf{Integral}^{\uparrow}$ *row L and* $\mathsf{Derivative}^{\uparrow}$ *row G supply the weak-gradient magnitude ledger, and the structural rows H, C, P, N transport, replay, source, and name the same route. Thus a Real-facing completion consumer receives scalar and limit-facing rows only through the displayed carrier, not through ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of functions, selected representatives, or choice.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier real completion root window`

Proof. Start with the Sobolev completion consumer export. It sends every completion-facing request to the carrier rows before any analytic datum is read.

Apply the weak-derivative ledger. The scalar route begins at the $\mathsf{Real}^{\uparrow}$ domain row D and reaches the weak-gradient magnitude rows only through L and G.

Finally use the completion boundary. Since H, C, P, N merely preserve, replay, source, and name the same finite route, the Real-completion root window exposes no ambient Real completeness, quotient equality, selected representative, or choice coordinate. □

Theorem 440.36 (Sobolev metric completion root window)**.** *Every metric-facing or complete-metric-facing consumer of an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet must read distance and Cauchy-boundary information through the displayed base row M together with the carrier route $D, M, V, L, G, H, C, P, N$. The* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *surface supplies only the finite distance and Cauchy rows needed by the Sobolev packet, and the route exports no completed Sobolev carrier, function quotient, selected Cauchy limit, or unrecorded metric completion.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier metric completion root window`

Proof. Begin with the finite root scope. It records that completion-facing access is confined to the displayed rows $D, M, V, L, G, H, C, P, N$.

Read the metric base row M. This row is the only coordinate for $\mathsf{Met}^{\uparrow}$ or $\mathsf{CompleteMetric}^{\uparrow}$ distance and Cauchy information, so a consumer cannot obtain a separate completed function-space object.

Use the completion consumer export to repack the route. The rows H, C, P, N transport, replay, source, and name the same metric window, while the excluded quotient, selected-limit, and unrecorded-completion objects remain absent from the carrier. □

Theorem 440.37 (Sobolev Hilbert-norm root window)**.** *Every Hilbert-facing or norm-facing consumer of an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet reads the weak-gradient ledger through the codomain row* V*, the* $\mathsf{Integral}^{\uparrow}$ *magnitude row* L*, and the* $\mathsf{Derivative}^{\uparrow}$ *test row* G*. If* V *is displayed as a* $\mathsf{Hilbert}^{\uparrow}$ *row, the Hilbert structure is still read only through the same finite norm and weak-gradient ledgers; if* V *is displayed as a* $\mathsf{Norm}^{\uparrow}$ *row, no hidden inner-product or completed Hilbert carrier is supplied. In both cases the route is confined to* $D, M, V, L, G, H, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier hilbert norm root window`

Proof. Start with Sobolev Hilbert completion descent. It requires Hilbert-facing consumers to read the carrier rows before citing weak-derivative data.

Apply weak-gradient ledger exhaustion. The codomain row V, integral magnitude row L, and derivative row G are the only ledger rows that expose norm, Hilbert, integral, and derivative information.

Finally use integral-derivative transport stability. Transport across H and replay through C preserve the same weak-gradient ledger rows, while P and N only source and name them. No hidden inner-product object, completed Hilbert carrier, or quotient function class is introduced. □

Theorem 440.38 (Sobolev carrier energy window)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet* $S = (D, M, V, L, G, H, C, P, N)$ *exposes one finite energy window. The window consists of the* $\mathsf{Real}^{\uparrow}$ *domain row* D*, the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *base row* M*, the* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *codomain row* V*, the* $\mathsf{Integral}^{\uparrow}$ *magnitude row* L*, the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient row* G*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *evidence* N*. No consumer can split this window into a separate measure-completion object, quotient function class, distributional dual, selected representative, or completed Sobolev carrier.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier energy window`

Proof. Project the carrier of Definition 440.1. Its visible coordinates are exactly $D, M, V, L, G, H, C, P, N$, with the domain, base, codomain, magnitude, weak-gradient, transport, replay, provenance, and naming roles fixed by the carrier definition.

Apply the NameCert obligation surface. It requires carrier habitation, classifier stability, carrier transport, weak-derivative exactness, and completion-boundary non-escape over the same finite rows.

Finally use the completion consumer export and Hilbert-norm root window. They force downstream completion, PDE, variational, Hilbert-facing, and norm-facing consumers to read the displayed energy rows together, so no omitted analytic object can be recovered from the packet. □

Theorem 440.39 (Sobolev weak-derivative route)**.** *Every weak-derivative-facing consumer of an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet must read the* $\mathsf{Integral}^{\uparrow}$ *magnitude row* L *before it reads the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient response row* G*. The route is the finite carrier path*

$$D \longmapsto M \longmapsto V \longmapsto L \longmapsto G$$

transported by H *and replayed by* C*; it does not read distribution theory, quotient equality of functions, ambient almost-everywhere classes, or a host weak-derivative predicate.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak derivative route`

Proof. Begin with the weak-derivative ledger theorem. It orders every derivative-facing read through the domain, base, codomain, magnitude, and weak-gradient rows before the observation is exported.

The magnitude row L is therefore not optional. It is the only displayed $\mathsf{Integral}^{\uparrow}$ ledger available for the weak-gradient response, and the derivative row G is read only after that magnitude ledger is fixed.

Transport and replay add no analytic coordinates. The rows H and C preserve the same route, while P and N source and name it, so distribution theory, quotient equality, almost-everywhere classes, and host predicates remain outside the packet. □

Theorem 440.40 (Sobolev completion-norm handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet receives only the displayed Hilbert or norm row* V *together with the finite weak-gradient ledger* $D, M, V, L, G, H, C, P, N$*. If the base row* M *is read as* $\mathsf{CompleteMetric}^{\uparrow}$ *data, that read supplies only the displayed metric or Cauchy-boundary information needed by the packet; it does not create a completed Sobolev space, a quotient normed function space, a selected Cauchy limit, or a completed Lebesgue carrier.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier completion norm handoff`

Proof. Start with the metric completion root window. It confines metric-facing and complete-metric-facing reads to the displayed base row M together with the carrier route $D, M, V, L, G, H, C, P, N$.

Apply the Hilbert-norm root window. Hilbert-facing and norm-facing consumers read V only through the same weak-gradient ledger, with L and G providing the integral magnitude and derivative response rows.

Use the completion consumer export to repack the handoff. The exported surface is the finite norm and weak-gradient ledger plus structural transport, replay, provenance, and naming rows; no completed Sobolev space, quotient function carrier, selected limit, or completed Lebesgue object is a coordinate of the packet. □

Theorem 440.41 (Sobolev root-unblock package)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet* $S = (D, M, V, L, G, H, C, P, N)$ *exports a root-unblock package consisting of the* $\mathsf{Real}^{\uparrow}$ *domain surface* D*, the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *base row* M*, the* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *codomain row* V*, the* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger* L*, the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient ledger* G*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *evidence* N*. Downstream analysis chapters may cite this package only through the displayed carrier, weak-derivative, completion-boundary, Hilbert-norm, and root-window routes already exposed in the chapter.*

The package supplies no host Sobolev space, distributional dual, quotient function class, completed Lebesgue carrier, selected representative, compact embedding theorem, trace theorem, or density theorem.

Proof. Project the carrier of Definition 440.1. The visible inventory is exactly $D, M, V, L, G, H, C, P, N$, and each row has the analytic or structural role named in the statement.

Apply the local NameCert obligation surface, the weak-derivative ledger, and the root obligation package. These results give carrier admission, classifier stability, weak-gradient ledger exactness, completion-boundary nonescape, and $\mathsf{Real}^{\uparrow}$ seal nonescape over the same finite rows.

Use the metric completion root window, Hilbert-norm root window, and completion-norm handoff to expose the downstream route. Metric, complete-metric, Hilbert, norm, integral, derivative, PDE, variational, and compactness-facing consumers must traverse the displayed carrier route before reading Sobolev data.

The excluded analytic objects are absent from the carrier and from the cited routes. Transport, replay, provenance, and local naming preserve the package but do not add new analytic coordinates. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier root unblock package`

Theorem 440.42 (Sobolev finite-energy NameCert obligation)**.** *For every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet* $S = (D, M, V, L, G, H, C, P, N)$*, the finite-energy obligation surface exposes exactly the derivative row* G*, the integral magnitude row* L*, the norm or Hilbert row* V*, the complete-metric or metric base row* M*, and the terminal* $\mathsf{Real}^{\uparrow}$ *domain seal* D*, together with componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *evidence* N*. A finite-energy consumer may cite this surface only as one* BHist *packet; it does not receive a host weak-gradient predicate, completed Sobolev carrier, Lebesgue-completed measure space, quotient function equality, selected representative, compact embedding, or trace theorem.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier finite energy namecert obligation`

Proof. Project the carrier of Definition 440.1. Its finite-energy coordinates are the $\mathsf{Real}^{\uparrow}$ domain row D, metric or complete-metric row M, norm or Hilbert row V, integral magnitude row L, derivative row G, and structural rows H, C, P, N.

Apply the finite-energy carrier and weak-derivative ledger. These force energy reads to pass through the integral magnitude row before the derivative row is interpreted, with the norm or Hilbert row and metric base row already displayed.

Use the completion boundary and root-unblock package to keep the read inside the same NameCert surface. Transport, replay, provenance, and local naming preserve the finite packet, while completed Sobolev spaces, quotient functions, selected representatives, compact embeddings, trace rows, and host measure completions remain absent coordinates. □

Theorem 440.43 (Sobolev root weak-gradient carrier)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet* $S = (D, M, V, L, G, H, C, P, N)$ *exposes weak-gradient data only through the finite* BHist *route*

$$D, M, V, L, G, H, C, P, N.$$

Here D *is the* $\mathsf{Real}^{\uparrow}$ *domain row,* M *is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *base row,* V *is the* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *codomain row,* L *is the* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger,* G *is the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient ledger,* H *is componentwise* hsame *transport,* C *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is local* $\mathsf{NameCert}$ *evidence. No root weak-gradient read may pass through distributional duals, Lebesgue completion, quotient function equality, compact embedding, or trace theory.*

Proof. Project the carrier rows. The accepted packet exposes exactly $D, M, V, L, G, H, C, P, N$, so every weak-gradient read begins with the displayed $\mathsf{Real}^{\uparrow}$, metric or complete-metric, norm or Hilbert, integral, and derivative coordinates.

Route the weak-gradient request through L and G. The integral ledger supplies the magnitude surface before the derivative row is interpreted, and the derivative row records only the displayed weak-gradient response.

The structural rows keep the read inside the same packet. Componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert evidence preserve the route without adding distributional duals, Lebesgue completion, quotient equality, compact embedding, or trace data. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier root weak gradient carrier`

Theorem 440.44 (Sobolev root norm-completion ledger)**.** *For every accepted* Sobolev$^{\uparrow}$ *packet* $S = (D, M, V, L, G, H, C, P, N)$*, any completion-facing or norm-facing root consumer must read the displayed ledger*

$$D, M, V, L, G, H, C, P, N$$

as one BHist *packet over* Real$^{\uparrow}$*,* Met$^{\uparrow}$ *or* CompleteMetric$^{\uparrow}$*,* Norm$^{\uparrow}$ *or* Hilbert$^{\uparrow}$*,* Integral$^{\uparrow}$*,* Derivative$^{\uparrow}$*, componentwise* hsame*, displayed* Cont*,* Pkg*, and* NameCert*. The ledger does not create a completed Sobolev space, a Lebesgue-completed measure carrier, quotient equality of functions, a selected representative, a distributional dual, compact embedding, or trace theory.*

Proof. Begin with the root-unblock package. It already presents $D, M, V, L, G, H, C, P, N$ as the downstream analysis surface, with M carrying the metric or complete-metric boundary and V carrying the norm or Hilbert boundary.

Route norm and completion reads through the weak-gradient ledgers. The consumer must pass through the integral row L and derivative row G before interpreting Sobolev data as energy or weak-gradient information.

Finally replay and source the same ledger through H, C, P, N. These rows preserve the finite packet and refuse completed Sobolev spaces, Lebesgue completion, quotient equality, selected representatives, distributional duals, compact embeddings, and traces as absent coordinates. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier root norm completion ledger`

Theorem 440.45 (Sobolev root trace nonescape)**.** *Let* $S = (D, M, V, L, G, H, C, P, N)$ *be an accepted* Sobolev$^{\uparrow}$ *packet. Every boundary-facing, PDE-facing, or variational read that cites* Real$^{\uparrow}$*,* Met$^{\uparrow}$ *or* CompleteMetric$^{\uparrow}$*,* Norm$^{\uparrow}$ *or* Hilbert$^{\uparrow}$*,* Integral$^{\uparrow}$*, and* Derivative$^{\uparrow}$ *data from* S *is confined to the displayed* BHist *rows*

$$D, M, V, L, G, H, C, P, N$$

with componentwise hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*. No trace operator, boundary value theorem, distributional dual, Lebesgue completion, quotient function equality, compact embedding, or selected representative escapes this finite route.*

Proof. Project the same carrier rows used by the root-unblock package. Boundary-facing consumers receive only the domain row D, base row M, codomain row V, integral row L, derivative row G, and structural rows H, C, P, N.

Route any claimed trace read through L and G. The packet permits an integral and weak-gradient ledger read, but it contains no separate boundary-value or trace coordinate.

Use transport, replay, provenance, and naming to close the route. Since H, C, P, N preserve only the displayed packet, distributional duals, Lebesgue completion, quotient equality, compact embedding, selected representatives, and trace theory cannot be exported by a Sobolev$^{\uparrow}$ citation. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier root trace nonescape`

Theorem 440.46 (Sobolev finite-energy induction route)**.** *Let $S = (D, M, V, L, G, H, C, P, N)$ be an accepted* $\mathsf{Sobolev}^{\uparrow}$ *finite-energy packet. Every accepted finite-energy consumer derived from S is obtained by induction over the displayed rows $D, M, V, L, G, H, C, P, N$: the domain, base, and codomain rows D, M, V are read first, the integral and weak-gradient rows L, G are read next, and the structural rows H, C, P, N then provide componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *evidence. The induction has no cases for distributional duals, Lebesgue completion, quotient function equality, selected representatives, compact embedding, or trace operators.*

Proof. Project the carrier of Definition 440.1. The projected row list is finite, ordered as $D, M, V, L, G, H, C, P, N$, and contains no host analytic coordinate beyond those displayed rows.

Induct over that finite list. The initial segment reads the $\mathsf{Real}^{\uparrow}$ domain row, the metric or complete-metric base row, and the norm or Hilbert codomain row. The next segment reads the $\mathsf{Integral}^{\uparrow}$ magnitude row and the $\mathsf{Derivative}^{\uparrow}$ weak-gradient row.

Use Definition 440.42, Definition 440.44, and Definition 440.45 to close the consumer-facing cases. These theorems identify the finite-energy surface, keep norm and completion reads inside the same packet, and block trace-facing escape.

Finally repack the induction result through H, C, P, N. Componentwise transport, replay, provenance, and local naming turn the row induction back into a $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ obligation, while distributional duals, Lebesgue completion, quotient function equality, selected representatives, compact embedding, and trace operators remain absent rather than additional induction cases. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevFiniteEnergyInductionRoute`

Theorem 440.47 (Sobolev test-function source)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *test-function read must expose the finite source route*

$$D, M, V, L, G, H, C, P, N$$

before any weak-gradient test is public. The row D supplies the $\mathsf{Real}^{\uparrow}$ *domain surface, M supplies the metric or complete-metric base, V supplies the norm or Hilbert codomain, L supplies the* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger, G supplies the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient test row, and H, C, P, N transport, replay, source, and name the same packet. No test-function consumer may cite a host dense subspace, a quotient function representative, a distributional dual, or a selected approximating sequence outside these displayed rows.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier test function source`

Proof. Project the carrier of Definition 440.1. Its visible coordinates are exactly $D, M, V, L, G, H, C, P, N$, so a test-function read has no separate coordinate beyond the same finite Sobolev packet.

Apply the weak-derivative route and the integral-derivative source package. These place L before G and make the weak-gradient test public only after the integral magnitude row and derivative response row have both been displayed.

Finally use the root-unblock package. It repacks the carrier, weak-derivative, completion-boundary, Hilbert-norm, and root-window routes into one downstream surface, while the excluded host dense subspace, quotient representative, distributional dual, and selected approximation data remain absent from the carrier. □

Theorem 440.48 (Sobolev weak-gradient transport)**.** *If two accepted* $\mathsf{Sobolev}^{\uparrow}$ *packets have* hsame*-related carrier rows, then transport preserves the displayed weak-gradient ledger through the* $\mathsf{Integral}^{\uparrow}$ *and* $\mathsf{Derivative}^{\uparrow}$ *rows. Concretely, the transported read of* $D, M, V, L, G, H, C, P, N$ *carries the same integral magnitude row* L*, the same weak-gradient response row* G*, and the same structural replay through* H, C, P, N*; it does not create host equality of functions, an ambient almost-everywhere quotient, a completed Lebesgue carrier, or an external weak-gradient predicate.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak gradient transport`

Proof. Start with the carrier energy window. The rows $D, M, V, L, G, H, C, P, N$ form one energy packet, and L and G are the only integral and derivative ledgers available for weak-gradient data.

Use componentwise hsame transport through H. Since H relates the displayed coordinates rather than host functions, the transported packet preserves the $\mathsf{Integral}^{\uparrow}$ magnitude row and the $\mathsf{Derivative}^{\uparrow}$ weak-gradient response row as carrier rows.

Replay through C and keep the provenance and naming rows P, N attached to the same route. No step adds host equality of functions, almost-everywhere quotient data, completed Lebesgue measure, or an external weak-gradient predicate. □

Theorem 440.49 (Sobolev PDE consumer admission)**.** *Every PDE-facing or variational consumer may cite* $\mathsf{Sobolev}^{\uparrow}$ *only through the finite rows*

$$D, M, V, L, G, H, C, P, N.$$

The citation must display the test-function source route of Definition 440.47 and the weak-gradient transport route of Definition 440.48. It supplies no host Sobolev space, quotient function class, Lebesgue completion, compact embedding theorem, trace theory, density theorem, selected representative, or undisplayed weak-gradient oracle.

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier pde consumer admission`

Proof. Begin with the root-unblock package. It is already the downstream analysis surface for Sobolev data and contains exactly the carrier rows $D, M, V, L, G, H, C, P, N$.

Add the test-function source theorem. A PDE or variational read cannot request weak-gradient tests before the domain, metric, codomain, integral, derivative, transport, replay, provenance, and naming rows have all been displayed.

Add the weak-gradient transport theorem. It ensures that any transported consumer still reads the same L and G ledgers through H, C, P, N, rather than through host equality, quotient functions, completed measure theory, or an external weak-gradient predicate.

The remaining exclusions follow by coordinate exhaustion. Compact embeddings, trace theory, density theorems, selected representatives, and host Sobolev spaces are not rows of the accepted packet, so they cannot be exported by a $\mathsf{Sobolev}^{\uparrow}$ citation. □

Theorem 440.50 (Sobolev weak-gradient energy carrier)**.** *For every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet* $S = (D, M, V, L, G, H, C, P, N)$*, the weak-gradient energy carrier is the finite route*

$$D \longmapsto M \longmapsto V \longmapsto L \longmapsto G \longmapsto H, C, P, N.$$

The $\mathsf{Real}^{\uparrow}$ *domain row* D*, metric or complete-metric row* M*, norm or Hilbert row* V*,* $\mathsf{Integral}^{\uparrow}$ *magnitude row* L*, and* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient row* G *must be read together before any downstream PDE, variational, Hilbert, norm, integral, derivative, or completion consumer receives energy data.*

No energy read can be discharged by a host weak-gradient predicate, quotient function class, distributional dual, completed measure carrier, selected representative, compact embedding, trace row, or density theorem.

Proof. Start with the carrier energy window. It identifies $D, M, V, L, G, H, C, P, N$ as one finite energy window and rules out splitting it into a separate measure-completion object or quotient function class.

Apply the weak-derivative route and integral-derivative source package. They place the $\mathsf{Integral}^{\uparrow}$ magnitude row L immediately before the $\mathsf{Derivative}^{\uparrow}$ weak-gradient row G and make both rows the displayed source package for derivative-facing consumers.

Use the derivative norm ledger and Hilbert-norm root window. These keep norm and Hilbert-facing reads inside the codomain row V before the integral and derivative rows are interpreted.

Finally replay the route through H, C, P, N. Those rows transport, replay, source, and name the same weak-gradient energy carrier, while the excluded host objects remain outside the displayed packet. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier weak gradient energy carrier`

Theorem 440.51 (Sobolev completion-metric handoff)**.** *Every completion-facing, metric-facing, Hilbert-facing, PDE-facing, or variational consumer of an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet receives Sobolev data through the displayed handoff*

$$D, M, V, L, G, H, C, P, N.$$

The base row M is the only $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary read, the codomain row V is the only* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *magnitude read, and L, G are the only integral and derivative ledgers exported to the consumer. The handoff does not create a completed Sobolev carrier, selected Cauchy limit, quotient function class, distributional dual, completed Lebesgue carrier, compact embedding object, trace row, or density theorem.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier completion metric handoff`

Proof. Begin with the complete-metric handoff and completion-norm handoff. They force completion-facing consumers to read the base row M and codomain row V only as coordinates of the same finite Sobolev packet.

Apply the weak-gradient energy carrier. Integral and derivative data are then read through L and G downstream of D, M, V, with H, C, P, N preserving the route.

Use the completion boundary and completion-boundary nonescape results. These results block completed Sobolev spaces, quotient function carriers, selected limits, completed measure carriers, distributional duals, compact embeddings, traces, and density statements from entering the handoff.

Thus the completion-metric consumer receives exactly the displayed BHist route and its structural transport, replay, provenance, and naming rows. □

Theorem 440.52 (Sobolev source-triple handoff)**.** *Every accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet $S = (D, M, V, L, G, H, C, P, N)$ routes its weak-gradient consumer through the displayed source triple*

$$D \longmapsto M \longmapsto V$$

before the $\mathsf{Integral}^{\uparrow}$ *magnitude row L and the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient row G are available. Here D is the* $\mathsf{Real}^{\uparrow}$ *domain row, M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *base row, and V is the* $\mathsf{Hilbert}^{\uparrow}$ *or* $\mathsf{Norm}^{\uparrow}$ *codomain row. The handoff supplies no distribution theory, Lebesgue completion, density of smooth functions, compact embedding, trace theorem, or completed Sobolev space.*

Proof. Project the carrier of Definition 440.1. Its analytic source rows are exactly D, M, V, L, G, with H, C, P, N serving only transport, replay, provenance, and local naming.

Apply the weak-derivative ledger, completion-boundary nonescape, and Hilbert-norm root window. These results order the read from the Real domain row through the metric or complete-metric base and the norm or Hilbert codomain before the integral magnitude and derivative weak-gradient rows are interpreted.

Finally use the root-unblock package and the completion-metric handoff. They package the same $D, M, V, L, G, H, C, P, N$ route for downstream completion-facing and weak-gradient consumers, while the excluded distributional, measure-completion, density, compactness, trace, and completed-space objects remain outside the carrier. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier source triple handoff`

Theorem 440.53 (Sobolev trace-boundary obligation)**.** *Every trace-facing, PDE-facing, variational, or boundary-value consumer of an accepted* Sobolev$^{\uparrow}$ *packet must first read the displayed* Real$^{\uparrow}$ *domain row, metric or complete-metric base row, norm or Hilbert codomain row,* Integral$^{\uparrow}$ *magnitude ledger,* Derivative$^{\uparrow}$ *weak-gradient row,* BHist *carrier rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The packet does not supply a trace theorem, boundary restriction operator, quotient function equality, density theorem, compact embedding, selected representative, or completed Sobolev space.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier trace boundary obligation`

Proof. Project the carrier of Definition 440.1. A boundary-facing consumer sees only the rows $D, M, V, L, G, H, C, P, N$, with D carrying the Real domain, M carrying the metric or complete-metric base, V carrying the norm or Hilbert codomain, and L, G carrying the integral and weak-gradient ledgers.

Apply the weak-derivative ledger, completion-boundary, classifier-locality, and integral-derivative handoff theorems. These results order every derivative-facing read through D, M, V, L, G and keep sameness, transport, and replay local to the displayed carrier rows.

Finally repack the route through H, C, P, N. Those rows preserve, replay, source, and name the same Sobolev packet; they do not add a trace theorem, boundary restriction operator, quotient function equality, density theorem, compact embedding, selected representative, or completed Sobolev space. Coordinate exhaustion gives the stated boundary obligation. □

Theorem 440.54 (Sobolev finite-energy obligation scope)**.** *Every finite-energy consumer of an accepted* Sobolev$^{\uparrow}$ *packet must expose the displayed* Real$^{\uparrow}$ *domain row D, the* Met$^{\uparrow}$ *or* CompleteMetric$^{\uparrow}$ *source row M, the* Norm$^{\uparrow}$ *or* Hilbert$^{\uparrow}$ *codomain row V, the* Integral$^{\uparrow}$ *magnitude ledger L, the weak* Derivative$^{\uparrow}$ *test row G, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N before it reads Sobolev energy data. The scope refuses distribution theory, Lebesgue completion, quotient equality of functions, density of smooth functions, compact embedding, and trace theory.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevFiniteEnergyObligationScope`

Proof. Project the carrier of Definition 440.1. The finite-energy read has exactly the analytic rows D, M, V, L, G and the structural rows H, C, P, N.

Use the obligation package and weak-derivative ledger. They place the Real domain, metric or complete-metric source, norm or Hilbert codomain, integral magnitude, and derivative test rows on the same finite route before any analysis-facing consumer can cite the packet.

Finally apply the completion-boundary theorem. The refused analytic objects are not coordinates of the carrier and are not introduced by transport, replay, provenance, or local naming, so the finite-energy scope is exhausted by the displayed rows. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier finite energy obligation scope`

Theorem 440.55 (Sobolev trace-boundary obligation route)**.** *Any boundary-facing, PDE-facing, or variational read that attempts to use* $\mathsf{Sobolev}^{\uparrow}$ *trace language must first pass through the same finite route*

$$D, M, V, L, G, H, C, P, N.$$

Here D *binds the* $\mathsf{Real}^{\uparrow}$ *domain row,* M *binds the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *source row,* V *binds the* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *codomain row,* L *binds the* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger,* G *binds the weak* $\mathsf{Derivative}^{\uparrow}$ *test row, and* H, C, P, N *bind transport, replay, provenance, and local naming. The route supplies no trace theorem, boundary restriction operator, Lebesgue completion, quotient equality of functions, density of smooth functions, compact embedding, or distribution theory.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevTraceBoundaryObligationRoute`

Proof. Start with Definition 440.53. It already confines trace-facing reads to the carrier rows and refuses trace operators, boundary restrictions, quotient function equality, density, compact embedding, and completed Sobolev spaces.

Add the finite-energy scope theorem above. It ensures that the same route contains the domain, source, codomain, magnitude, weak-derivative, transport, replay, provenance, and local naming rows before a boundary-facing consumer can read energy data.

The two routes are the same displayed packet. Therefore a trace-facing citation cannot bypass the finite-energy scope or recover distribution theory, Lebesgue completion, quotient equality, density, compact embedding, or trace theory from a hidden coordinate. □

Theorem 440.56 (Sobolev compact-embedding refusal boundary)**.** *A compact-embedding, completion-facing, PDE-facing, or functional-analysis consumer citing an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet receives only the finite-energy route through* $D, M, V, L, G, H, C, P, N$*. The route may record the* $\mathsf{Real}^{\uparrow}$ *domain,* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *source,* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *codomain,* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger, weak* $\mathsf{Derivative}^{\uparrow}$ *tests, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*. It does not supply compact embedding, density of smooth functions, trace theory, Lebesgue completion, quotient equality of functions, distribution theory, or a completed Sobolev space.*

Proof. Read the finite-energy obligation scope. It exposes the complete consumer route for energy data and leaves no separate compactness, density, trace, quotient, distributional, or completion coordinate.

Use the trace-boundary route to cover boundary-facing requests. That theorem forces even trace language through the same finite packet before any read is public.

Finally use the completion boundary of Definition 440.10. Since compact embedding and density are not coordinates of $S = (D, M, V, L, G, H, C, P, N)$ and cannot be generated by H, C, P, N, the consumer receives only the displayed finite-energy route. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier compact embedding refusal boundary`

Theorem 440.57 (Sobolev energy-trace scope obligation)**.** *Let $S = (D, M, V, L, G, H, C, P, N)$ be an accepted* $\mathsf{Sobolev}^{\uparrow}$ *packet. If a consumer exposes finite energy rows, weak derivative rows, boundary trace rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readbacks, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ *row, then the consumer may export only the finite energy-to-trace scope route through $D, M, V, L, G, H, C, P, N$. It may not export Hahn–Banach separation, unrestricted distribution theory, measure completion, quotient function equality, ambient Hilbert or Banach completeness, or a trace operator detached from the displayed packet.*

Proof. Begin with the finite-energy scope obligations of Definition 440.54. They force every energy-facing read to display the Real domain row, metric or complete-metric source row, norm or Hilbert codomain row, integral magnitude ledger, weak derivative test row, transport, replay, provenance, and local naming before Sobolev energy data is consumed.

Next apply the trace-boundary obligation route of Definition 440.55. Trace-facing language is therefore read only along the same finite packet, with the boundary read downstream of the energy and weak-derivative rows rather than as an external boundary operator.

Finally combine the two routes. The readbacks to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ are ledger and seal rows inside the displayed package, while H, C, P, N preserve, replay, source, and name that package. Since no listed coordinate is Hahn–Banach separation, unrestricted distribution theory, measure completion, quotient function equality, or ambient Hilbert or Banach completeness, the exported scope is exactly the finite energy-to-trace route. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier energy trace boundary certificate`

Theorem 440.58 (Sobolev bridged finite-derivative window)**.** *Every Sobolev packet bridge read factors through the finite derivative-window route*

$$D, M, V, L, G, T, H, C, P, N.$$

The rows D, M, V, L, G expose the $\mathsf{Real}^{\uparrow}$ *domain, metric or complete-metric base, norm or Hilbert codomain, finite-energy magnitude ledger, and weak* $\mathsf{Derivative}^{\uparrow}$ *window; T records the trace-boundary window; and H, C, P, N provide componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before any analytic consumer reads a* $\mathsf{Sobolev}^{\uparrow}$ *object. The bridge exports this finite derivative-window interface only; it does not export distribution theory, Lebesgue completion, quotient equality of functions, density of smooth functions, compact embedding, trace theory, or completed Sobolev spaces.*

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier finite derivative window bridge`

Proof. Begin with the finite-window carrier and the root package. The accepted packet exposes the domain, base, codomain, magnitude, weak-derivative, transport, replay, provenance, and local naming rows as finite BHist data.

Apply the finite-energy scope and trace-boundary routes. They force an analytic consumer to read the finite-energy rows and the boundary-facing rows through the same displayed packet, with no detached trace operator or completed function carrier.

Use the energy-trace scope obligation to align the two sides of the bridge. The derivative-window and trace-boundary windows are therefore read as one route through $D, M, V, L, G, T, H, C, P, N$ before any Sobolev object is public.

Finally repack the route through componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence. Since none of those structural rows adds distribution

theory, Lebesgue completion, quotient equality, density, compact embedding, trace theory, or completed Sobolev spaces, the bridge is confined to the finite derivative-window interface. □

Theorem 440.59 (Sobolev finite-energy consumer)**.** *Every downstream finite-energy consumer of a* $\mathsf{Sobolev}^{\uparrow}$ *packet must read the displayed* $\mathsf{Real}^{\uparrow}$ *domain row, a metric or complete-metric base row, a normed or Hilbert codomain row, the* $\mathsf{Integral}^{\uparrow}$ *magnitude ledger, the* $\mathsf{Derivative}^{\uparrow}$ *weak-gradient row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$ *row before it can export any energy estimate, weak-gradient comparison, or completion-facing boundary statement.*

Proof. Project the displayed Sobolev packet. The finite-energy consumer first obtains the Real-domain row and the metric or complete-metric base row, so the carrier is tied to the same ambient scale used by the weak-gradient certificate.

The codomain and magnitude data are then fixed. The norm or Hilbert row supplies the target size discipline, while the $\mathsf{Integral}^{\uparrow}$ ledger records the finite-energy magnitude read and the $\mathsf{Derivative}^{\uparrow}$ row records the weak-gradient test.

Transport and replay preserve this inventory. Componentwise hsame movement carries the same rows to an equivalent packet, and the Cont routes replay only the displayed finite-energy and weak-gradient reads.

Finally the Pkg provenance and local NameCert row name the accepted packet for downstream consumers. Since no row supplies distribution theory, Lebesgue completion, quotient function equality, trace theory, compact embedding, or completed Sobolev spaces, every finite-energy export factors through the listed local rows. □

Lean4 ✓ `BEDC.Derived.SobolevUp.SobolevCarrier mature finite energy consumer`

Closure status for $\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$.

Constructive story: A $\mathsf{Sobolev}^{\uparrow}$ packet is generated from a displayed $\mathsf{Real}^{\uparrow}$ domain row, a metric or complete-metric base row, a normed or Hilbert codomain row, an $\mathsf{Integral}^{\uparrow}$ magnitude ledger, a $\mathsf{Derivative}^{\uparrow}$ weak-gradient test row, componentwise hsame transports, displayed Cont routes, package provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$, maturePackageClosed)

Scope closed: The chapter enumerates carrier habitation, classifier stability, weak-derivative ledger, finite-energy route, trace boundary, finite derivative-window bridge, completion-boundary nonescape, transport, replay, provenance, and local NameCert obligations for a concrete weak-derivative certificate.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Sobolev}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close distribution theory, Lebesgue completion, quotient equality of functions, density of smooth functions, compact embedding, trace theory, or completed Sobolev spaces.

Upgrade path: No paper-side closure grade remains; Lean verification, bridge checking, distribution theory, Lebesgue completion, quotient function equality, trace theorem, compact embedding, and completed Sobolev spaces remain separate.

Chapter 441

A Concrete Naming Certificate for $\mathsf{AscoliModulus}^{\uparrow}$

The $\mathsf{AscoliModulus}^{\uparrow}$ interface names the finite equicontinuity-modulus packet consumed by $\mathsf{ArzelaAscoli}^{\uparrow}$. It is the constructive Bishop–Bridges finite-ledger object that binds a family of $\mathsf{ContinuousMap}^{\uparrow}$ rows over a $\mathsf{CompactMetric}^{\uparrow}$ source to one shared source-radius row for a requested $\mathsf{Rat}^{\uparrow}$ target tolerance, with finite-net stability and displayed handoff rows for compact-continuity consumers. The packet is a BEDC carrier over $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, hsame, Cont, Pkg, and local NameCert rows; it is not an open-cover compactness theorem, a subsequence selector, or a host function-space compactness principle.

The source metric and finite-net row are consumed from chapter 129, and the displayed map-family rows are consumed from chapter 130 before the $\mathsf{AscoliModulus}^{\uparrow}$ packet packages the shared radius.

Definition 441.1 (AscoliModulus carrier)**.** *An* $\mathsf{AscoliModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, Y, F, T, R, \mathcal{P}, S, E, W, H, C, P, N)$$

with the following visible coordinates:

1. *X is the source* $\mathsf{CompactMetric}^{\uparrow}$ *row, including its displayed metric row and the finite* ProbeBundle *net rows used by downstream compact-continuity reads;*
2. *Y is the target metric row read by the family of maps, with target-distance comparisons routed through displayed metric witnesses;*
3. *F is a finite family ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows from X to Y;*
4. *T is the requested positive* $\mathsf{Rat}^{\uparrow}$ *target-tolerance row;*
5. *R is the shared positive* $\mathsf{Rat}^{\uparrow}$ *source-radius row selected for the whole finite family ledger;*
6. *$\mathcal{P}$ is the finite source-net* ProbeBundle *used to test the shared radius against compact source reads;*
7. *S records finite-net stability data, saying that source histories lying in one bundled radius window remain inside the modulus window demanded by every family row in F;*
8. *E records the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *row whose finite tolerance ledger supplies the uniform family-side reading of T and R;*

9. *W records the* $\mathsf{UniformContinuity}^{\uparrow}$ *pointwise rows used at bundled source centers and the* $\mathsf{ArzelaAscoli}^{\uparrow}$ *consumer handoff row;*
10. *H records componentwise* hsame *transports for source metric, target metric, family rows, tolerance rows, radius rows, probe bundles, finite-net stability rows, equicontinuity rows, uniform-continuity rows, and handoff rows;*
11. *C records the visible* Cont *routes by which compact-metric, continuous-map, uniform-continuity, equicontinuity-family, Arzela–Ascoli, rational, and probe-bundle consumers read the packet;*
12. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, hsame, *and* Cont *rows;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{AscoliModulus}^{\uparrow}}$ *row.*

The carrier exports only finite family, tolerance, radius, probe-bundle, stability, equicontinuity, uniform-continuity, transport, continuation, package, and naming rows. It contains no open-cover compactness row, no subsequence-choice row, no ambient function-space topology, and no host compactness theorem.

Theorem 441.2 (AscoliModulus equicontinuity ledger)**.** *For an accepted* $\mathsf{AscoliModulus}^{\uparrow}$ *carrier of Definition 441.1, the rows F, T, R, E, H, C, P, N determine one finite equicontinuity ledger: the requested tolerance row T is read through* $\mathsf{Rat}^{\uparrow}$*, the shared source-radius row R is read through the same rational classifier, every displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *row in F consumes that same R, and the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *coordinate E records this family-wide reading without introducing a separate modulus function.*

The ledger is stable under the stored hsame *transports and visible* Cont *routes. Any consumer reading it receives a finite tolerance-to-radius row over the displayed family ledger, not an external function assigning radii to all host tolerances.*

Lean4 ✓ `BEDC.Derived.AscoliModulusUp.AscoliModulusPacket equicontinuity ledger`

Proof. Project the tolerance row T, source-radius row R, and finite family ledger F from the carrier. The rational rows are visible $\mathsf{Rat}^{\uparrow}$ histories, and every family entry is a displayed $\mathsf{ContinuousMap}^{\uparrow}$ row over the same source and target coordinates.

Read the $\mathsf{EquicontinuityFamily}^{\uparrow}$ coordinate E. Its finite family-side ledger binds the tolerance history to one radius history uniformly over the listed family rows, so no family entry may request an unrecorded source radius.

Finally route the ledger through H, C, P, and N. Componentwise transport preserves the same tolerance row, radius row, family ledger, and local naming boundary, so a downstream consumer can only recover the finite ledger displayed in the carrier. □

Theorem 441.3 (AscoliModulus finite-net stability)**.** *Let A be an accepted* $\mathsf{AscoliModulus}^{\uparrow}$ *carrier with finite source-net coordinate $\mathcal{P}$ and stability coordinate S. For every bundled source center in $\mathcal{P}$ and every family row in F, the stability row S routes a source history inside the displayed radius window R through the corresponding* $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{UniformContinuity}^{\uparrow}$ *rows, producing a target-distance read bounded by the requested tolerance row T.*

The stability claim is finite in both indices: it ranges only over the bundled probe centers and the displayed family ledger. It does not assert a global open cover, a host-space uniform structure, or compactness of any function space.

Lean4 ✓ `BEDC.Derived.AscoliModulusUp.AscoliModulusPacket finite net stability`

Proof. Start with the compact source coordinate X and finite bundle $\mathcal{P}$. The bundle exposes only finitely many center rows, and each center read is routed through the source metric data already stored in X.

For a fixed bundled center, inspect the stability coordinate S. It points to the radius row R, the requested tolerance row T, and the listed family rows in F, so each family read is checked against the same source-radius window.

Use the pointwise rows collected in W to pass from the source metric comparison to the target metric comparison. Since S is indexed only by the finite bundle and the finite family ledger, the resulting stability certificate cannot export an infinite cover or a host function-space compactness assertion. □

Theorem 441.4 (AscoliModulus NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{AscoliModulus}^\uparrow}$ *surface consists exactly of five finite rows:*

1. *carrier habitation by the finite packet of Definition 441.1;*
2. *rational tolerance and radius classifier transport for T and R through* $\mathsf{Rat}^\uparrow$*;*
3. *family-wide equicontinuity ledger transport for F and E through* $\mathsf{ContinuousMap}^\uparrow$ *and* $\mathsf{EquicontinuityFamily}^\uparrow$*;*
4. *finite-net stability over $\mathcal{P}$ and S through* $\mathsf{CompactMetric}^\uparrow$*,* $\mathsf{ProbeBundle}$*, and* $\mathsf{UniformContinuity}^\uparrow$*;*
5. *Arzela–Ascoli handoff through W, H, C, P, N, forcing every downstream read to remain inside displayed* hsame*,* Cont*,* Pkg*, and local naming rows.*

Proof. Carrier habitation is immediate from Definition 441.1. The source, target, family, tolerance, radius, probe-bundle, stability, equicontinuity, uniform-continuity, handoff, transport, continuation, package, and naming rows are all visible coordinates of one finite packet.

The rational transport row handles the tolerance and radius histories. The family transport row handles the continuous-map ledger and the equicontinuity-family coordinate, preserving the fact that the same radius row is shared by every displayed family entry.

The finite-net stability row is Definition 441.3. Repacking it with the handoff coordinate W and the provenance rows H, C, P, N gives the whole local certificate surface, with no additional carrier coordinate through which open-cover compactness, subsequence choice, or host function-space compactness could enter. □

Theorem 441.5 (AscoliModulus Arzela-Ascoli handoff)**.** *Every* $\mathsf{ArzelaAscoli}^\uparrow$ *consumer reading an accepted* $\mathsf{AscoliModulus}^\uparrow$ *carrier obtains a finite equicontinuity-modulus row: the finite family ledger F, requested tolerance row T, shared source-radius row R, source-net bundle $\mathcal{P}$, stability row S, and equicontinuity row E are repacked through W, H, C, P, N as the equicontinuity modulus data named by the* $\mathsf{ArzelaAscoli}^\uparrow$ *carrier.*

The handoff supplies only the finite modulus rows needed by a constructive Arzela–Ascoli packet. It does not supply open-cover compactness, subsequence choice, compactness of a host function space, or a topology on all maps from the source to the target.

```
Lean4 ✓  BEDC.Derived.AscoliModulusUp.AscoliModulusPacket arzela ascoli handoff
```

Proof. Project the handoff coordinate W. It records exactly the $\mathsf{UniformContinuity}^\uparrow$ pointwise reads and the $\mathsf{ArzelaAscoli}^\uparrow$ consumer boundary that may read the $\mathsf{AscoliModulus}^\uparrow$ packet.

Attach the finite equicontinuity ledger of Definition 441.2 and the finite-net stability row of Definition 441.3. Together these rows provide the family ledger, requested tolerance, shared radius, bundled source centers, and target-distance stability data expected by the Arzela–Ascoli equicontinuity coordinate.

Finally route the repacked rows through H, C, P, and N. Since every exported item is already a visible carrier coordinate, the handoff gives $\mathsf{ArzelaAscoli}^{\uparrow}$ only a finite BEDC-kernel modulus packet and no ambient compactness or choice principle. □

Theorem 441.6 (AscoliModulus rational radius transport)**.** *Let $A = (X, Y, F, T, R, \mathcal{P}, S, E, W, H, C, P, N)$ be an accepted $\mathsf{AscoliModulus}^{\uparrow}$ carrier. The requested tolerance row T and shared source-radius row R are transported as $\mathsf{Rat}^{\uparrow}$ rows through the displayed* BHist *data,* hsame *comparisons,* Cont *routes,* Pkg *provenance, and local* NameCert *row. Every consumer reading T or R receives exactly those rational rows inside the finite packet, not an open-cover radius selector, a subsequence choice, or a host function-space compactness principle.*

Lean4 ✓ `BEDC.Derived.AscoliModulusUp.AscoliModulusPacket rational radius transport`

Proof. Project the rational coordinates T and R from the carrier. Both are visible finite history rows and both are named by the same package and local certificate coordinates.

Apply Definition 441.2. The ledger binds the requested tolerance to the shared source radius uniformly over the displayed family ledger F, so the radius row cannot be replaced by an external selector.

Transport is then componentwise through H and C. The transported rows still read through P and N, and none of those coordinates contains an open cover, a subsequence selector, or a compactness theorem for a host function space. □

Theorem 441.7 (AscoliModulus family transport package)**.** *Let $A = (X, Y, F, T, R, \mathcal{P}, S, E, W, H, C, P, N)$ be an accepted $\mathsf{AscoliModulus}^{\uparrow}$ carrier. The finite family ledger F, the equicontinuity row E, and the finite-net stability row S form one transported package over the displayed* BHist *rows,* hsame *comparisons,* Cont *routes,* Pkg *provenance, and local* NameCert *row. Any comparison of family entries factors through the common rational tolerance-radius pair T, R and the same probe bundle $\mathcal{P}$; it does not invoke open-cover compactness, subsequence choice, or host function-space compactness.*

Proof. Read the family ledger F, equicontinuity row E, and stability row S from the carrier. These rows live over the same compact source coordinate X, target metric coordinate Y, tolerance row T, radius row R, and probe bundle $\mathcal{P}$.

Use Definition 441.3 to check each bundled source center and each family row against the displayed radius window. Use Definition 441.6 to keep the tolerance and radius rows fixed during transport.

The package rows H, C, P, N then repack the family comparison data. Since the comparison is indexed only by the finite family ledger and finite probe bundle, there is no route to open covers, subsequence selection, or compactness of all host functions. □

Theorem 441.8 (AscoliModulus Arzela root handoff package)**.** *Every $\mathsf{ArzelaAscoli}^{\uparrow}$ consumer reading an accepted $\mathsf{AscoliModulus}^{\uparrow}$ carrier $A = (X, Y, F, T, R, \mathcal{P}, S, E, W, H, C, P, N)$ receives one finite root handoff package: the* BHist *source and target rows, finite family ledger F, rational tolerance-radius rows T, R, probe bundle $\mathcal{P}$, stability row S, equicontinuity row E, handoff row W, displayed* hsame *and* Cont *routes H, C,* Pkg *provenance P, and local* NameCert *row N. The handoff is a finite modulus package only; it is not an open-cover compactness proof, a subsequence-choice operator, or a host function-space compactness theorem.*

Proof. Start with the consumer handoff row W. It is a visible coordinate of the carrier and can read only the finite rows listed in the same package.

Attach the rational transport row from Definition 441.6 and the family transport package from Definition 441.7. Together they supply the tolerance, radius, finite family, probe-bundle, stability, and equicontinuity data needed by the Arzela–Ascoli consumer boundary.

Finally apply Definition 441.5. The resulting root handoff is exactly the finite BEDC-kernel modulus surface carried by $X, Y, F, T, R, \mathcal{P}, S, E, W, H, C, P, N$, so it cannot export compactness, choice, or host function-space structure beyond those rows. □

Theorem 441.9 (AscoliModulus shared-radius refinement boundary)**.** *Let $A = (X, Y, F, T, R, \mathcal{P}, S, E, W, H, C, P,$ be an accepted* $\mathsf{AscoliModulus}^{\uparrow}$ *carrier. If the displayed finite source-net $\mathcal{P}$ is refined by additional bundled centers and the refinement rows are transported through the same H, C, P, N boundary, then the refined packet preserves the single shared source-radius row R and the requested tolerance row T for the whole displayed family ledger F.*

The refinement may add only bundled source centers and their corresponding finite-net stability reads. It does not introduce a second source-radius row, alter the requested tolerance row, change the family ledger, invoke open-cover compactness, choose a subsequence, or use compactness of a host function space.

Proof. First keep the rational rows fixed. By Definition 441.6, the requested tolerance row T and the shared source-radius row R are transported as the displayed $\mathsf{Rat}^{\uparrow}$ rows through the same BHist data, hsame comparisons, Cont routes, Pkg provenance, and local naming row.

Next transport the family surface. Apply Definition 441.7 to the finite family ledger F, the equicontinuity row E, and the finite-net stability row S. The family comparison data still factors through the common tolerance-radius pair T, R and the displayed probe-bundle boundary.

Finally repack the refined source-net reads through Definition 441.8. The additional bundled centers become extra finite rows under the same handoff boundary H, C, P, N, so the $\mathsf{ArzelaAscoli}^{\uparrow}$ consumer still receives one finite modulus package with the original T, the original R, and the same family ledger F.

Since each step is a finite transport or handoff through displayed rows, no open-cover compactness proof, subsequence-choice operation, or host function-space compactness theorem is introduced by the refinement. □

Theorem 441.10 (AscoliModulus scoped public surface)**.** *The carrier of Definition 441.1, the equicontinuity ledger of Definition 441.2, the finite-net stability theorem of Definition 441.3, the rational-radius transport theorem of Definition 441.6, the family transport package of Definition 441.7, the Arzela root handoff package of Definition 441.8, and the shared-radius refinement boundary of Definition 441.9 assemble one scoped public surface for* $\mathsf{AscoliModulus}^{\uparrow}$*.*

Every consumer read of this surface factors through displayed $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*,* $\mathsf{EquicontinuityFamily}^{\uparrow}$*,* $\mathsf{ArzelaAscoli}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{ProbeBundle}$*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows. The surface excludes open-cover compactness, subsequence choice, ambient function-space compactness, and any topology on all maps from the source to the target.*

Proof. First read the carrier coordinates in Definition 441.1. They provide the compact source row, target metric row, finite family ledger, requested tolerance, shared radius, source-net bundle, stability row, equicontinuity row, handoff row, transport rows, continuation routes, package provenance, and local naming row.

The finite family side is fixed by Definition 441.2 and Definition 441.3. These two rows bind the common rational tolerance-radius pair to the displayed family ledger and bundled source centers.

The transport and handoff side is fixed by Definition 441.6, Definition 441.7, and Definition 441.8. Those results keep the same $T, R, F, \mathcal{P}, S, E, W, H, C, P, N$ rows visible to every $\mathsf{ArzelaAscoli}^{\uparrow}$ consumer.

Finally apply Definition 441.9. Refining the finite source-net can add only bundled-center rows under the same boundary, so all consumer reads factor through the displayed public rows and no compactness, choice, or host function-space principle is exported. □

Theorem 441.11 (AscoliModulus empty-family vacuity)**.** *Let $A = (X, Y, F, T, R, \mathcal{P}, S, E, W, H, C, P, N)$ be an accepted* $\mathsf{AscoliModulus}^{\uparrow}$ *carrier as in Definition 441.1. Suppose that F is the empty finite family ledger, so no displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *row is indexed by F, and that $\mathcal{P} = \mathsf{Bnil}$ is the empty source-net* $\mathsf{ProbeBundle}$*. Then the finite-net stability and family-wide equicontinuity obligations in A are vacuous: S has no bundled-center and family-row pair to test, and E has no family-row instance to which the shared tolerance-radius pair T, R can be applied.*

Consequently an $\mathsf{ArzelaAscoli}^{\uparrow}$ *consumer reading this boundary case can receive only the displayed tolerance row T, the shared radius row R, the handoff and transport rows W, H, C, the package provenance P, and the local naming row N. It receives no nonempty finite-net stability instance, no family-member equicontinuity instance, no open-cover compactness row, no subsequence-choice row, and no host function-space compactness theorem.*

Proof. Project the rows of the carrier in Definition 441.1. The stability row S is indexed by two finite sources: a bundled source center in $\mathcal{P}$ and a displayed family row in F. This is exactly the finite indexing described by Definition 441.3. If $\mathcal{P} = \mathsf{Bnil}$, there is no bundled source center. If F is empty, there is no displayed $\mathsf{ContinuousMap}^{\uparrow}$ family row. Hence there is no index pair on which a source-radius test or target-distance read can be demanded from S.

The equicontinuity row E is controlled by Definition 441.2: it binds the requested tolerance row T and the shared radius row R uniformly over the displayed family ledger F. Since F has no entries, this uniform family-side clause has no instances. The row still records that T and R are the displayed rational tolerance-radius pair, but it cannot create a hidden family member, a separate modulus function, or an unlisted continuity obligation.

Apply the handoff theorem Definition 441.5 together with the rational-radius transport of Definition 441.6. The only non-indexed payload that remains available to the $\mathsf{ArzelaAscoli}^{\uparrow}$ consumer is the displayed tolerance row T, the displayed radius row R, the handoff and transport surface W, H, C, the package row P, and the local certificate row N. The family transport package of Definition 441.7 has no family comparison to inspect, and the finite-net stability theorem has no probe-center comparison to inspect. Therefore the empty-family and empty-bundle boundary exports only those displayed rows and no compactness, choice, or host function-space structure beyond the accepted $\mathsf{AscoliModulus}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{AscoliModulus}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AscoliModulus}^{\uparrow}$ packet is generated from a $\mathsf{CompactMetric}^{\uparrow}$ source, a finite family ledger of $\mathsf{ContinuousMap}^{\uparrow}$ rows, a requested $\mathsf{Rat}^{\uparrow}$ target tolerance, a shared $\mathsf{Rat}^{\uparrow}$ source radius, finite ProbeBundle source-net stability rows, an $\mathsf{EquicontinuityFamily}^{\uparrow}$ ledger, $\mathsf{UniformContinuity}^{\uparrow}$ pointwise rows, an $\mathsf{ArzelaAscoli}^{\uparrow}$ consumer handoff, displayed hsame and Cont transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AscoliModulus}^{\uparrow}}, \mathsf{obligation})$

Scope closed: The seed scope registers the carrier, finite equicontinuity ledger, finite-net stability, local naming obligations, and Arzela–Ascoli handoff for displayed compact-metric family-modulus packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AscoliModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim open-cover compactness, subsequence choice, host function-space compactness, or a topology on all maps from the source to the target.

Upgrade path: Scoped closure requires the same compact-metric, continuous-map, uniform-continuity, equicontinuity-family, ProbeBundle, hsame, Cont, Pkg, and local NameCert rows to be bound as a single consumer-stable public surface.

Chapter 442

A Concrete Naming Certificate for $\mathsf{TaylorModel}^{\uparrow}$

The $\mathsf{TaylorModel}^{\uparrow}$ packet names the finite Taylor-jet enclosure method used in Berz-style and Makino–Berz validated numerics, but it records only finite BEDC rows. A packet exposes a center observation, dyadic jet coefficients, an interval or dyadic-ball remainder, an interval-arithmetic ledger, a real-name evaluation route, a validated readback certificate, package provenance, and a local naming row. It does not import host Taylor series semantics, analytic convergence, selected real limits, or quotient real equality.

The carrier consumes the interval-operation ledger of chapter 302, the dyadic-ball remainder surface of chapter 311, the validated readback certificate of chapter 357, and the NewtonIteration provenance route of chapter 223. These sibling rows are the horizontal dependency lattice for the center, jet, remainder, operation, readback, and provenance coordinates below.

Definition 442.1 (TaylorModel BHist carrier)**.** *A* $\mathsf{TaylorModel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (c, J, R, I, E, V, P, N)$$

with the following displayed coordinates:

1. *c is a center* $\mathsf{Real}^{\uparrow}$ *finite observation row;*
2. *J is a finite jet ledger of dyadic coefficient histories, with every coefficient read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and finite* $\mathsf{StreamName}^{\uparrow}$ *windows;*
3. *R is an* $\mathsf{IntervalArithmetic}^{\uparrow}$ *interval row or* $\mathsf{DyadicBall}^{\uparrow}$ *remainder enclosure attached to the same precision window;*
4. *I is the* $\mathsf{IntervalArithmetic}^{\uparrow}$ *operation ledger recording each polynomial, interval, and remainder operation used by the enclosure;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window evaluation route through which consumers read the center, coefficient, and remainder rows;*
6. *V is the* $\mathsf{ValidatedNumerics}^{\uparrow}$ *readback certificate asserting that the displayed route returns an enclosure row rather than a selected host value;*
7. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{IntervalArithmetic}^{\uparrow}$, $\mathsf{DyadicBall}^{\uparrow}$, $\mathsf{ValidatedNumerics}^{\uparrow}$, *and* $\mathsf{NewtonIteration}^{\uparrow}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TaylorModel}^{\uparrow}}$ *row.*

Two accepted carriers are classified together only when the center row, finite jet ledger, remainder enclosure, interval-operation ledger, evaluation route, readback certificate, package row, and local naming row are transported componentwise by the displayed hsame *comparisons and* Cont *routes.*

Lean4 (definition) `BEDC.Derived.TaylorModelUp.TaylorModelCarrier`

Theorem 442.2 (TaylorModel NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{TaylorModel}^\uparrow}$ *surface for the carrier of Definition 442.1 consists of five rows:*

1. *carrier habitation by the finite packet* $T = (c, J, R, I, E, V, P, N)$*;*
2. *classifier stability under componentwise* hsame *comparisons and displayed* Cont *routes for* c, J, R, I, E, V, P, N*;*
3. *finite-jet transport through the* $\mathsf{DyadicRatCore}^\uparrow$ *coefficient histories and their* $\mathsf{StreamName}^\uparrow$ *windows;*
4. *interval-remainder soundness through the* $\mathsf{IntervalArithmetic}^\uparrow$ *ledger and the displayed* R *enclosure;*
5. *non-escape from host Taylor series, analytic convergence, selected real limits, and quotient real equality.*

Proof. Carrier habitation is projection from Definition 442.1. The center, finite jet, remainder, ledger, evaluation, readback, package, and local certificate rows are visible coordinates of one finite packet.

Classifier stability is componentwise. The accepted classifier may replace a displayed row only by a recorded hsame comparison or by a Cont route that reads the same row inside the same packet.

The remaining rows are the coefficient transport, interval-remainder enclosure, and non-escape boundary stated below. Together they describe exactly what the local naming certificate must expose to a consumer of the finite Taylor-jet enclosure. □

Lean4 ✓ `BEDC.Derived.TaylorModelUp.TaylorModelCarrier namecert obligations`

Theorem 442.3 (TaylorModel finite-jet transport)**.** *For every accepted* $\mathsf{TaylorModel}^\uparrow$ *carrier* $T = (c, J, R, I, E, V, P, N)$*, every consumer-visible coefficient read factors through the finite jet ledger* J*, its displayed* $\mathsf{DyadicRatCore}^\uparrow$ *coefficient histories, the finite* $\mathsf{StreamName}^\uparrow$ *windows used to inspect them, the evaluation route* E*, and the componentwise* hsame *and* Cont *rows recorded by the packet classifier.*

Lean4 ✓ `BEDC.Derived.TaylorModelUp.TaylorModelFiniteJet transport`

Proof. Project the packet to its jet coordinate J. Since J is finite, each coefficient requested by a consumer is one of the displayed dyadic coefficient histories rather than a term of an ambient infinite series.

The consumer reaches a coefficient through the $\mathsf{StreamName}^\uparrow$ window named in J and through the evaluation route E. Transport along accepted classifiers preserves those two displayed rows by the stored hsame comparisons and Cont routes.

Thus the coefficient read remains inside the finite jet ledger and cannot appeal to a host Taylor series or to an unbounded coefficient family. □

Theorem 442.4 (TaylorModel interval-remainder soundness)**.** *Every enclosure exported by an accepted* $\mathsf{TaylorModel}^\uparrow$ *carrier is bounded by the displayed remainder row* R *and the* $\mathsf{IntervalArithmetic}^\uparrow$ *operation ledger* I*. The bound is read through the same center row* c*, finite jet ledger* J*, evaluation route* E*, and validated readback certificate* V*, and it exports no external analytic convergence theorem.*

Lean4 ✓ `BEDC.Derived.TaylorModelUp.TaylorModelCarrier interval remainder soundness`

Proof. Start with an exported enclosure read. The read first identifies the center row c and the finite jet ledger J used by the polynomial part of the packet.

The remainder coordinate R is then read through the interval or dyadic-ball enclosure named by the packet. The operation ledger I records the finite interval-arithmetic route by which polynomial and remainder rows are combined.

The validated readback row V certifies that the consumer receives the displayed enclosure. Since every operation has already passed through I and R, soundness is a statement about those finite rows and not about analytic convergence in a host real model. □

Theorem 442.5 (TaylorModel validated consumer boundary)**.** *Every* ValidatedNumerics$^{\uparrow}$ *consumer of an accepted* TaylorModel$^{\uparrow}$ *packet receives only the displayed center row, finite jet ledger, remainder enclosure, interval-operation ledger,* Real$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *evaluation route, readback certificate, package provenance, and local naming row. The consumer receives no host Taylor series object, no selected real limit, and no quotient real equality witness.*

Lean4 ✓ `BEDC.Derived.TaylorModelUp.TaylorModelCarrier validated consumer boundary`

Proof. Read the carrier coordinates of Definition 442.1. The rows available to a validated-numerics consumer are exactly c, J, R, I, E, V, P, N.

Apply Definition 442.3 to every coefficient request and Definition 442.4 to every enclosure request. These two routes account for all numeric information exposed by the packet.

No remaining coordinate names a host Taylor series, an analytic radius of convergence, a selected real limit, or quotient equality of real names. The consumer boundary is therefore the finite readback surface alone. □

Theorem 442.6 (TaylorModel seed public package)**.** *The carrier of Definition 442.1, the NameCert surface of Definition 442.2, the finite-jet transport of Definition 442.3, the interval-remainder soundness of Definition 442.4, and the validated consumer boundary of Definition 442.5 assemble the seed* TaylorModel$^{\uparrow}$ *public package over* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, IntervalArithmetic$^{\uparrow}$, DyadicBall$^{\uparrow}$, ValidatedNumerics$^{\uparrow}$, *and* NewtonIteration$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.TaylorModelUp.TaylorModelCarrier seed public package`

Proof. Project the finite packet

$$T = (c, J, R, I, E, V, P, N).$$

The carrier and NameCert surface expose the rows required for a local naming certificate.

The finite-jet theorem accounts for coefficient transport, and the interval-remainder theorem accounts for enclosure soundness through the displayed operation ledger. The validated consumer theorem then fixes the downstream boundary of every readback.

The package provenance P names exactly the dependency rows listed in the theorem statement. Hence the seed package is a finite BEDC naming certificate for Taylor-model enclosures, with no analytic object outside the displayed packet. □

Definition 442.7 (TaylorModel displayed finite-jet subwindow)**.** *Let $T = (c, J, R, I, E, V, P, N)$ be an accepted* TaylorModel$^{\uparrow}$ *carrier in the sense of Definition 442.1. A displayed finite-jet subwindow $J' \preceq_J J$ is a finite prefix or finite contiguous subledger of J equipped with the following retained rows:*

1. *every coefficient history displayed in J' is one of the* $\mathsf{DyadicRatCore}^{\uparrow}$ *coefficient histories displayed in J;*
2. *the* $\mathsf{StreamName}^{\uparrow}$ *window attached to a retained coefficient is the same displayed window as in J, or a displayed smaller finite window reached by a* Cont *route already present in the packet;*
3. *the restricted evaluation row $E|_{J'}$ contains exactly the coefficient-read routes of E whose coefficient selector lies in J';*
4. *the restricted readback row $V|_{J'}$ validates only the finite reads routed through $E|_{J'}$;*
5. *the restricted provenance and local name rows $P|_{J'}$ and $N|_{J'}$ name the same dependency certificates as P and N, but only for the retained coefficient selectors and their windows.*

The projected TaylorModel read surface over J' is the finite packet

$$T|_{J'} = (c, J', R|_{J'}, I|_{J'}, E|_{J'}, V|_{J'}, P|_{J'}, N|_{J'}),$$

where $R|_{J'}$ and $I|_{J'}$ are the remainder and interval-operation rows read only at the retained coefficient selectors. The notation records a displayed packet restriction; it is not a quotient of Taylor series and it does not introduce an ambient coefficient family.

Lean4 (definition) `BEDC.Derived.TaylorModelUp.TaylorModelDisplayedFiniteJetSubwindow`

Proposition 442.8 (TaylorModel finite-jet prefix restriction)**.** *Let $T = (c, J, R, I, E, V, P, N)$ be an accepted* $\mathsf{TaylorModel}^{\uparrow}$ *carrier, and let $J' \preceq_J J$ be a displayed finite-jet subwindow as in Definition 442.7. Suppose every consumer-visible coefficient request under consideration has its coefficient selector in J' and that its* $\mathsf{StreamName}^{\uparrow}$ *window is one of the retained windows of J'. Then the projected packet $T|_{J'}$ is an accepted finite* $\mathsf{TaylorModel}^{\uparrow}$ *read surface for those consumers. Moreover, every such consumer-visible coefficient read factors through J', $E|_{J'}$, and the retained* $\mathsf{StreamName}^{\uparrow}$ *window, and no coefficient row in $J \setminus J'$ is accessed.*

Lean4 ✓ `BEDC.Derived.TaylorModelUp.TaylorModelCarrier finite jet prefix restriction`

Proof. Project the accepted carrier through Definition 442.1. The jet coordinate J is a finite ledger of displayed $\mathsf{DyadicRatCore}^{\uparrow}$ coefficient histories, and the only public coefficient-read routes are the finite $\mathsf{StreamName}^{\uparrow}$ windows and the evaluation route E attached to those histories.

By Definition 442.7, the subwindow J' retains only coefficient histories already displayed in J. Hence every coefficient row in J' is still a valid dyadic coefficient history, and every retained window is either the same finite window as in J or a smaller finite window reached by a displayed Cont route. Since a finite prefix or finite contiguous subledger of a finite ledger is finite, J' is again a finite coefficient ledger.

Restrict the evaluation and readback rows to the retained selectors. The row $E|_{J'}$ contains exactly the routes by which the selected coefficients are read, and $V|_{J'}$ validates exactly those finite routes as readback rows. The restricted provenance and local naming rows keep the same dependency certificates named by the original packet, now indexed only by the retained selectors. Thus the projected packet has the same kind of visible coordinates as the TaylorModel carrier, but with its coefficient surface replaced by the displayed finite subwindow.

Apply Definition 442.3 to a consumer-visible coefficient request for T. The original factorization passes through J, the coefficient history selected there, the attached $\mathsf{StreamName}^{\uparrow}$ window, the evaluation route E, and the componentwise hsame and Cont rows recorded by the packet classifier. The hypothesis says that the selector for this request lies in J' and that the attached window is

retained in J'. Therefore the same factorization factors through J' and $E|_{J'}$ after replacing each unrestricted row by its retained projection.

No discarded coefficient is needed in this read. A row in $J \setminus J'$ has no selector in the restricted consumer surface, no route in $E|_{J'}$, and no validation entry in $V|_{J'}$. The interval and remainder rows used by the projected surface are likewise the restricted rows $I|_{J'}$ and $R|_{J'}$, so a retained coefficient read cannot obtain an outside coefficient indirectly through the operation ledger.

Finally apply Definition 442.5. A validated consumer receives only the displayed center row, finite jet ledger, remainder enclosure, interval-operation ledger, evaluation route, readback certificate, package provenance, and local naming row. For the projected surface these rows are exactly c, J', $R|_{J'}$, $I|_{J'}$, $E|_{J'}$, $V|_{J'}$, $P|_{J'}$, and $N|_{J'}$. Thus the projected packet is an accepted finite TaylorModel read surface for the stated consumers, and every visible coefficient read is exhausted by the retained finite jet subwindow. □

Theorem 442.9 (TaylorModel finite-jet remainder obligation route)**.** *For every accepted* $\mathsf{TaylorModel}^{\uparrow}$ *carrier* $T = (c, J, R, I, E, V, P, N)$ *and every displayed finite-jet subwindow* $J' \preceq_J J$*, the obligation route for a remainder read consists exactly of carrier admission for* $T|_{J'}$*, classifier stability under* hsame *and* Cont*, finite-jet transport through the retained* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *rows, interval-remainder soundness through* $R|_{J'}$ *and* $I|_{J'}$*, validated consumer exposure through* $E|_{J'}$ *and* $V|_{J'}$*, and ledger nonescape through* $P|_{J'}$ *and* $N|_{J'}$*. No obligation row is supplied by host Taylor series semantics, analytic convergence, a selected real limit, quotient real equality, or a remainder object outside the displayed* BHist *packet.*

Proof. Carrier admission is the projected packet of Definition 442.8. The rows of $T|_{J'}$ display the center, retained finite jet, restricted remainder, restricted interval-operation ledger, evaluation route, readback certificate, provenance, and local naming data.

Classifier stability follows componentwise from the accepted $\mathsf{TaylorModel}^{\uparrow}$ classifier. The retained hsame and Cont rows transport only the displayed coordinates, so no hidden coefficient family or analytic series can enter the restricted read surface.

Apply finite-jet transport and interval-remainder soundness from Definition 442.3 and Definition 442.4. They force coefficient reads through the retained dyadic and StreamName rows and force enclosure reads through the restricted remainder and interval-operation ledger.

Finally use the validated consumer boundary of Definition 442.5. The consumer receives the restricted evaluation and readback rows together with provenance and local naming, while every refused object lacks a carrier coordinate and a replay edge. □

Lean4 ✓ `BEDC.Derived.TaylorModelUp.TaylorModelRemainderObligationRoute`

↪ variant `BEDC.Derived.TaylorModelUp.TaylorModelCarrier remainder obligation route`

Closure status for $\mathsf{NameCert}_{\mathsf{TaylorModel}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TaylorModel}^{\uparrow}$ packet is generated from a center $\mathsf{Real}^{\uparrow}$ observation row, a finite dyadic jet ledger, an interval or dyadic-ball remainder enclosure, an $\mathsf{IntervalArithmetic}^{\uparrow}$ operation ledger, a $\mathsf{Real}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ evaluation route, a $\mathsf{ValidatedNumerics}^{\uparrow}$ readback certificate, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TaylorModel}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: The scoped finite-jet and remainder route records the finite carrier, NameCert obligation surface, finite-jet transport, interval-remainder soundness, validated consumer boundary, finite-jet prefix restriction, and finite-jet remainder obligation route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TaylorModel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Taylor series semantics, analytic convergence, selected real limits, quotient real equality, public Taylor-model algebra, or bridge checking.

Upgrade path: The next verification step is checked carrier habitation, classifier stability under hsame and Cont, finite-jet transport, interval-remainder soundness, validated consumer boundary, and finite-jet remainder nonescape for the same packet rows.

Chapter 443

Regular Cauchy Limit Classifier NameCert Construction

The $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ interface is the finite classifier handoff between the diagonal-limit construction of Definition 9238.3 and the limit-existence target of Definition 9238.5. It packages the selected $\mathsf{RegSeqRat}^{\uparrow}$ diagonal extraction, the $\mathsf{StreamName}^{\uparrow}$ observation windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ rational ledgers, and the $\mathsf{Real}^{\uparrow}$ seal row through which a completion consumer sees the candidate limit. The packet is a classifier surface for the limit handoff; it is not an ambient completeness principle and it contains no host selected real.

The classifier is consumed by the finite observation-budget route of chapter 611. $\mathsf{RealObservationBudget}^{\uparrow}$ supplies the finite-window, dyadic-ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal boundary through which completion consumers inspect the classifier.

Definition 443.1 (Regular Cauchy limit classifier carrier)**.** *A* $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

with the following visible rows:

1. *X is the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy input family and μ is its explicit modulus row;*
2. *Δ is the diagonal extraction row assigning to each unary precision request the selected threshold and diagonal read demanded by Definition 9238.3;*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family that realizes the selected reads of the regular rational names;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational observations obtained through W;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger recording endpoints, radii, comparison rows, and precision rows for those observations;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row exposing the same diagonal observations as the candidate real-name surface;*
7. *H stores componentwise* hsame *transports for the input family, modulus row, diagonal extraction, windows, readbacks, ledger, and seal row;*
8. *C stores displayed* Cont *routes for every consumer read that reaches those rows;*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, a host real value, a non-displayed limit selector, or an ambient completeness theorem.

Lean4 (definition) `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier`

Theorem 443.2 (Regular Cauchy limit classifier stability)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitClassifier}^{\uparrow}}$ *obligation surface consists of five finite rows:*

1. $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger exactness: every exported rational observation is the endpoint, radius, comparison, and precision row recorded by D;*
2. $\mathsf{StreamName}^{\uparrow}$ *window exactness: each diagonal read uses the finite window named by W and no unrecorded stream access;*
3. $\mathsf{RegSeqRat}^{\uparrow}$ *extraction stability: transporting X, μ, and Δ through the displayed* hsame *and* Cont *rows transports the selected regular-sequence readback R;*
4. $\mathsf{Real}^{\uparrow}$ *seal discipline: the seal row E is reached only after the displayed window, readback, and dyadic ledger rows have been produced;*
5. *package and name closure: P and N record exactly the provenance and local classifier row consumed by downstream Real and Completion certificates.*

Consequently classifier transport preserves the finite diagonal-limit handoff from source packets to target packets without adding quotient representatives, hidden tail choices, host real equality tests, or ambient completeness assumptions.

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier stability`

Proof. Project the carrier of Definition 443.1. The rows X, μ, and Δ determine which regular rational name is read at each precision request, while W records the finite stream window that performs the read.

The $\mathsf{RegSeqRat}^{\uparrow}$ readback R and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D are coordinates of the same packet. Transport by the stored hsame rows in H and consumer routes in C therefore moves the selected readback together with its displayed endpoint, radius, comparison, and precision data.

The $\mathsf{Real}^{\uparrow}$ row E consumes only the already displayed W, R, and D rows. Repacking those rows with P and N gives the transported local classifier surface and leaves no coordinate through which a non-displayed limit selector or quotient equality can enter. □

Theorem 443.3 (Regular Cauchy limit Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *classifier read exported by an accepted* $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *carrier*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

factors through the displayed diagonal extraction row Δ, the $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, and the seal row E. This handoff is the finite NameCert surface by which the Real completeness target sees a candidate limit classifier; it exports no quotient stream equality, selected host limit, host real equality, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier real seal handoff`

Proof. Begin with the stability surface of Definition 443.2. It identifies the only classifier-visible diagonal observations as the rows produced by Δ, W, R, and D.

The seal row E is downstream of those observations. A consumer read into $\mathsf{Real}^{\uparrow}$ must therefore pass through the finite stream window and dyadic ledger before reaching the real-name handoff.

Finally, the carrier definition lists all coordinates of Q. Since none of them is a quotient representative, a host selected limit, a host real equality test, or an ambient completeness field, the exported classifier cannot supply any of those objects. □

Theorem 443.4 (Regular Cauchy limit classifier diagonal-window public boundary)**.** *Every public completion-facing read exported by an accepted* $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *carrier*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

factors through the displayed diagonal extraction row Δ*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, and the* $\mathsf{Real}^{\uparrow}$ *seal row* E*. Its provenance is the visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *surface over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*; it exports no quotient stream equality, host selected limit, host real equality, or ambient completeness premise.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier diagonal window public boundary`

Proof. Project the carrier in Definition 443.1. The public-facing rows are Δ, W, R, D, E together with the transport, continuation, package, and naming rows H, C, P, N.

Apply Definition 443.2. The stability obligations make D the exact dyadic ledger, make W the finite window family for diagonal reads, and transport R together with the same displayed diagonal extraction data.

Now apply Definition 443.3. It places every $\mathsf{Real}^{\uparrow}$ classifier read downstream of Δ, W, R, D, E, so a completion-facing consumer receives only the sealed diagonal-window route.

The remaining exclusions follow by carrier inspection. Since the packet has no coordinate for quotient stream equality, a host selected limit, host real equality, or ambient completeness, the public boundary cannot export any of those objects. □

Theorem 443.5 (Regular Cauchy limit classifier public export)**.** *The public* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitClassifier}^{\uparrow}}$ *export of an accepted carrier*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

is exactly the tuple of displayed diagonal extraction data Δ*,* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger rows* D*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*,* BHist *history surface,* hsame *transports* H*,* Cont *routes* C*,* Pkg *provenance* P*, and local* NameCert *row* N *isolated by Definition 443.2, Definition 443.3, and Definition 443.4. It exports no quotient stream equality, host selected limit, host real equality, or ambient completeness premise.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier public export`

Proof. First apply Definition 443.2. It fixes the displayed diagonal extraction, window, readback, dyadic ledger, transport, package, and local naming rows as the stable classifier surface.

Next apply Definition 443.3. This places the $\mathsf{Real}^{\uparrow}$ seal downstream of the same Δ, W, R, D rows, so the real-name handoff contributes only the recorded seal row E.

Finally use Definition 443.4. It identifies the completion-facing public boundary with the visible BHist, hsame, Cont, Pkg, and NameCert provenance already carried by Q.

The carrier inventory has no coordinate for quotient stream equality, a host selected limit, host real equality, or ambient completeness. The public export is therefore exactly the displayed tuple and none of those excluded objects. □

Theorem 443.6 (Regular Cauchy limit classifier bridge source packet)**.** *For every accepted* RegularCauchyLimitClass *carrier, the bridge-facing source packet is exactly*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

with diagonal extraction Δ*, finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows* H, C, P, N*. The source packet exports no quotient stream equality, selected host limit, host real equality, or ambient completeness premise.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier bridge source packet`

Proof. Begin with the stability theorem Definition 443.2. It fixes the diagonal extraction, stream-window, regular readback, dyadic ledger, transport, continuation, package, and naming rows as the stable classifier surface.

Next use the Real seal handoff and diagonal-window public boundary, Definition 443.3 and Definition 443.4. These rows place the real-facing read downstream of Δ, W, R, D, E and keep the completion-facing boundary inside the same displayed packet.

Finally project the public export of Definition 443.5. The bridge source is therefore the public tuple Q itself, with no additional coordinate for quotient equality, a selected host limit, host real equality, or ambient completeness. □

Theorem 443.7 (Regular Cauchy limit classifier diagonal seal uniqueness)**.** *Let* Q *and* Q' *be accepted* $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *packets. If they share the same diagonal extraction row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger rows, and* $\mathsf{Real}^{\uparrow}$ *seal row up to the displayed* hsame *transports, then every public completion-facing classifier read factors through the same sealed diagonal-window route.*

The conclusion is a uniqueness statement for the public readback route only. It does not assert quotient stream equality, select a host limit, identify host real values, or use ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier diagonal seal uniqueness`

Proof. First apply classifier stability from Definition 443.2. The shared diagonal extraction, stream-window, regular readback, dyadic ledger, and seal rows remain the stable coordinates visible to both packets.

Next use the Real seal handoff of Definition 443.3. It places each real-facing read downstream of the same diagonal extraction, finite windows, readback rows, dyadic ledgers, and seal row.

Now apply the diagonal-window public boundary and public export, Definition 443.4 and Definition 443.5. They force every completion-facing read through the displayed BHist, hsame, Cont, Pkg, and NameCert route attached to those shared rows.

Finally use the bridge source packet of Definition 443.6. Since the bridge-facing packet has no coordinate for quotient stream equality, a selected host limit, host real equality, or ambient completeness, the shared sealed route is the only public route available to both classifiers. □

Theorem 443.8 (Regular Cauchy limit classifier observation-budget factorization)**.** *Let*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *packet, and let*

$$B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet. If the diagonal windows, dyadic ledger, regular readback, and* $\mathsf{Real}^{\uparrow}$ *seal row of* Q *are read through the displayed rows of* B*, then every* $\mathsf{Real}^{\uparrow}$ *seal handoff of* Q *factors through the observation-budget route*

$$E_B \longmapsto W_B \longmapsto D_B \longmapsto R_B \longmapsto S_B.$$

The factorization is a finite BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route; it adds no quotient stream equality, host real equality, selected limit, ambient completeness premise, hidden limit selector, or unbounded schedule.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier observation budget factorization`

Proof. Start with the classifier rows. By Definition 443.2 and Definition 443.3, the only $\mathsf{Real}^{\uparrow}$ handoff exported by Q is downstream of Δ, W, R, D, E.

Now read those rows through the observation-budget packet. Definition 611.17 makes every admitted seal read pass through E_B, W_B, D_B, R_B, S_B, and Definition 611.31 places both the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers on that same finite route.

Finally apply the public boundary and non-escape results. Definition 443.4 keeps the classifier read inside the displayed public packet, while Definition 611.6 rules out quotient streams, host equality, hidden selectors, ambient completeness, and unbounded schedules. □

Theorem 443.9 (Regular Cauchy limit classifier finite-route exactness)**.** *Under the hypotheses of Definition 443.8, the classifier rows* $\Delta, W, R, D, E, H, C, P, N$ *and the budget rows* $E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B$ *determine the same finite window, dyadic ledger, regular readback, and seal boundary up to the displayed* hsame *transports and* Cont *routes. Equivalently, any accepted completion-facing read that agrees with both packets on those displayed rows is the same finite route from the diagonal classifier to the observation-budget seal boundary.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierFiniteRouteExactness`
↪ variant `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier finite route exactness`

Proof. First identify the classifier side. Definition 443.7 says that shared diagonal windows, readbacks, dyadic ledgers, and seal rows force every public completion-facing read through the same sealed diagonal-window route.

Next identify the observation-budget side. Definition 611.19 confines classifier comparison to $E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B$, and Definition 611.31 routes every admitted $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer through those rows.

The factorization theorem now composes the two identifications. The displayed hsame rows carry row equality, the displayed Cont rows replay the consumer route, and no additional analytic coordinate is available to distinguish the classifier route from the observation-budget route. □

Theorem 443.10 (Regular Cauchy limit classifier completion-consumer boundary)**.** *Composing an accepted* $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *packet with an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *packet through the factorization of Definition 443.8 gives a completion consumer only the finite rows*

$$\Delta, W, R, D, E, H, C, P, N$$

and

$$E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B.$$

It gives no quotient stream equality, host real equality, selected limit, ambient completeness theorem, hidden limit selector, or unbounded observation schedule.

Proof. Read the composed packet through the classifier first. Definition 443.2 and Definition 443.3 restrict the limit-classifier handoff to Δ, W, R, D, E with the displayed transport, route, provenance, and local naming rows.

Read the same packet through the budget route next. Definition 611.17 and Definition 611.31 place every admitted consumer on E_B, W_B, D_B, R_B, S_B with H_B, C_B, P_B, N_B.

Finally combine diagonal uniqueness with budget non-escape. Definition 443.7 prevents a second public classifier route with the same displayed seal rows, and Definition 611.6 excludes quotient stream equality, host real equality, hidden selection, ambient completeness, and unbounded schedules from the budget side. □

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier completion consumer boundary`

Theorem 443.11 (Regular Cauchy limit classifier synchronizer factorization)**.** *Let*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *packet, and let*

$$Z = (E_Z, S_Z, B_Z, T_Z, D_Z, L_Z, H_Z, C_Z, P_Z, N_Z)$$

be an accepted $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet. Suppose that the diagonal window, regular readback, dyadic ledger, and* $\mathsf{Real}^{\uparrow}$ *seal rows of* Q *agree componentwise with the selector, budget, shared-threshold, and seal rows displayed by* Z*. Then every completion-facing read of* Q *factors through the synchronizer route*

$$D_Z \longmapsto B_Z \longmapsto T_Z \longmapsto L_Z \longmapsto S_Z.$$

The resulting route is exhausted by the displayed BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows of the two packets. It exports no quotient stream, selected host limit, hidden selector, host real equality, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier synchronizer factorization`

Proof. Start from the observation-budget factorization. Definition 443.8 places every $\mathsf{Real}^{\uparrow}$ seal handoff of Q on the finite observation route, and Definition 443.9 identifies that route with the classifier rows visible to completion consumers.

Next read the synchronizer packet. The componentwise agreement hypotheses identify the classifier diagonal window, readback, dyadic ledger, and seal rows with the synchronizer selector,

budget, shared-threshold, and seal rows. The synchronizer carrier and obligation rows then force the read through D_Z, B_Z, T_Z, L_Z, S_Z before any completion-facing consumer is served.

Finally apply the completion-consumer boundary of Definition 443.10 together with the synchronizer non-escape rows. Since neither packet contains a quotient-stream coordinate, a host limit selector, host real equality, or an ambient completeness premise, the composed handoff exposes only the finite seal-budget synchronization surface. □

Theorem 443.12 (Regular Cauchy limit classifier budget-synchronizer route agreement)**.** *Let*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *packet. Let*

$$B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet, and let*

$$Z = (E_Z, S_Z, B_Z, T_Z, D_Z, L_Z, H_Z, C_Z, P_Z, N_Z)$$

be an accepted $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet. Suppose that B and Z read the same displayed diagonal window, regular readback rows, dyadic ledger rows, and* $\mathsf{Real}^{\uparrow}$ *seal row of Q through their displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Then the observation-budget route and the synchronizer route determine one finite completion-facing classifier route: the same* BHist *history rows, the same* hsame *transports, the same* Cont *replay, the same* Pkg *provenance, and the same local* NameCert *handoff.*

The agreement is a finite public-route statement. It does not assert quotient stream equality, host real equality, a selected limit, a hidden selector, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier budget synchronizer route agreement`

Proof. First invoke the observation-budget factorization. By Definition 443.8, every $\mathsf{Real}^{\uparrow}$ seal handoff of Q that is read through B factors through E_B, W_B, D_B, R_B, S_B with only the displayed transport, continuation, provenance, and naming rows.

Next invoke the synchronizer factorization. By Definition 443.11, the same displayed diagonal window, regular readback, dyadic ledger, and seal rows read through Z factor through D_Z, B_Z, T_Z, L_Z, S_Z before any completion-facing consumer is served.

Use diagonal-seal uniqueness and finite-route exactness to compare the two routes. Definition 443.7 identifies every public read with the sealed diagonal-window route, and Definition 443.9 identifies that public read with the finite observation-budget route. Hence the synchronizer route and the budget route are two presentations of the same completion-facing BHist, hsame, Cont, Pkg, and NameCert path.

Finally inspect the carrier coordinates of Q, B, and Z. None contains quotient stream equality, host real equality, a selected limit, a hidden selector, or an ambient completeness witness, so no further route can distinguish the two finite presentations. □

Theorem 443.13 (Regular Cauchy limit classifier seal-budget-synchronizer exhaustion)**.** *Let*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *packet. Let*

$$B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet, and let*

$$Z = (E_Z, S_Z, B_Z, T_Z, D_Z, L_Z, H_Z, C_Z, P_Z, N_Z)$$

be an accepted $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet. Suppose that the three packets agree on the displayed diagonal window, regular readback, dyadic ledger, and* $\mathsf{Real}^{\uparrow}$ *seal rows through their named* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *routes. Then every Real-completion-facing consumer route exported by this composite packet is exhausted by the shared finite route already identified by the classifier, observation-budget, and synchronizer surfaces.*

In particular, quotient-stream reads, host real equality, selected limits, hidden selectors, and ambient completeness premises have no exit from the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route.*

Proof. First apply the observation-budget factorization. Definition 443.8 puts every $\mathsf{Real}^{\uparrow}$ seal handoff of Q on the finite budget route, while Definition 443.10 states that completion consumers of this route can see only the displayed finite rows.

Next apply the synchronizer factorization. Definition 443.11 puts the same diagonal window, regular readback, dyadic ledger, and seal rows on the synchronizer route, and Definition 443.12 identifies that route with the observation-budget presentation.

Finally read the boundary rows componentwise. Since the shared route contains only BHist, hsame, Cont, Pkg, and NameCert data, every Real-completion-facing consumer terminates at that finite route and cannot obtain quotient streams, host real equality, selected limits, hidden selectors, or ambient completeness from the packet. □

Theorem 443.14 (Regular Cauchy limit classifier real tail-agreement seal factorization)**.** *Let*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *packet. Let*

$$B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet, let*

$$Z = (E_Z, S_Z, B_Z, T_Z, D_Z, L_Z, H_Z, C_Z, P_Z, N_Z)$$

be an accepted $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet, and let*

$$A = (R_A, S_A, W_A, D_A, A_A, H_A, C_A, P_A, N_A)$$

be an accepted $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet. Suppose that these packets read the same displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks,* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, and* $\mathsf{Real}^{\uparrow}$ *seal row of* Q *through their displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *routes. Then every completion-facing classifier read factors through the finite chain*

$$\mathsf{RegularCauchyLimitClassifier}^{\uparrow} \longmapsto \mathsf{RealObservationBudget}^{\uparrow} \longmapsto \mathsf{CauchySealBudgetSynchronizer}^{\uparrow} \longmapsto \mathsf{RealTailAgreem}$$

The factorization exports no quotient stream equality, host real equality, selected limit, hidden tail selector, ambient completeness premise, or choice-selected tail.

Proof. First put the classifier on the observation-budget route. The factorization of Definition 443.8 sends every $\mathsf{Real}^{\uparrow}$ seal handoff of Q through E_B, W_B, D_B, R_B, S_B, and Definition 611.9 records that $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers of B read exactly those finite rows.

Next compare the budget route with the synchronizer route. The route agreement theorem Definition 443.12 identifies the observation-budget and synchronizer presentations, while Definition 886.6 exhausts the Real-facing synchronizer read by the request, seal, budget, tail schedule, selector, compatibility, transport, route, provenance, and local naming rows of Z.

Finally pass to the paired tail-agreement seal. The shared window, dyadic readback, regular source, and seal hypotheses place the same read on the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ boundary of Definition 699.58. Its completion handoff theorem Definition 699.65 then makes the displayed chain the whole completion-facing route, and the non-escape clauses in the cited packets exclude quotient streams, host real equality, selected limits, hidden tail selectors, ambient completeness, and choice-selected tails. □

Theorem 443.15 (Regular Cauchy limit classifier budgeted seal pullback)**.** *Let*

$$Q = (X, \mu, \Delta, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *packet. Let*

$$B = (E_B, W_B, D_B, R_B, S_B, H_B, C_B, P_B, N_B)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet, and let*

$$Z = (E_Z, S_Z, B_Z, T_Z, D_Z, L_Z, H_Z, C_Z, P_Z, N_Z)$$

be an accepted $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet. Suppose that Q, B, and Z share the displayed diagonal window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, observation budget, synchronizer, and* $\mathsf{Real}^{\uparrow}$ *seal rows through their displayed* hsame, Cont, Pkg, *and* NameCert *routes. Then every completion-facing classifier read factors through the same finite pullback route determined by those shared rows.*

The pullback exports no quotient stream equality, host real equality, selected limit, hidden selector, unbounded schedule, or ambient completeness.

Proof. First combine the observation-budget factorization with finite-route exactness. By Definition 443.8, every seal handoff read through B lies on the finite observation route, and Definition 443.9 identifies that route with the classifier rows of Q.

Next combine the synchronizer factorization with route agreement. By Definition 443.11, the same displayed diagonal window, readback, dyadic ledger, and seal rows read through Z lie on the synchronizer route. The agreement theorem Definition 443.12 identifies the budget route and synchronizer route as one completion-facing BHist, hsame, Cont, Pkg, and NameCert path.

Finally apply the completion-consumer boundary. Definition 443.10 excludes quotient stream equality, host real equality, selected limits, hidden selectors, ambient completeness, and unbounded schedules from the composed packet, so the shared finite pullback is the whole classifier read. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ packet is generated by a displayed regular Cauchy input, its modulus row, the diagonal extraction row, finite stream windows, regular-sequence readbacks, dyadic observation ledgers, a RealUp seal row, transport routes, package provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimitClassifier}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 443.1, Definition 443.2, Definition 443.3, Definition 443.4, Definition 443.5, Definition 443.6, and Definition 443.7 bind the public limit-classifier handoff, bridge-facing source packet, and uniqueness boundary to the displayed DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyLimitClassifier}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.RegularCauchyLimitClassifierUp.RegularCauchyLimitClassifierCarrier\_diagonal\_seal\_uni`

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close RealUp completeness, uniqueness of completed limits, quotient equality of streams, or a public standard bridge.

Upgrade path: Axiom-purity and standard-bridge checking remain the next verification obligations for the existing diagonal-window classifier and seal-uniqueness surface.

Chapter 444

A Concrete Naming Certificate for $\mathsf{CollisionKernel}^{\uparrow}$

The $\mathsf{CollisionKernel}^{\uparrow}$ interface is a BEDC-native finite certificate surface.

The $\mathsf{CollisionKernel}^{\uparrow}$ interface names a finite collision-kernel packet built from the same finite-window discipline as $\mathsf{FoldMomentKernel}^{\uparrow}$, $\mathsf{GoldenMeanShift}^{\uparrow}$, and the Zeckendorf finite-word family. It records a displayed window, fold-source rows, target-fiber ledgers, a finite collision-kernel matrix row, moment-index rows, Hankel-shadow rows, transport rows, continuation routes, package provenance, and local naming evidence. It exports no host spectrum, ambient measure, infinite Hankel operator, quotient fiber, or analytic moment problem.

The dependency surface is concrete: $\mathsf{CollisionKernel}^{\uparrow}$ consumes the folded-fiber moment packet of chapter 384, the finite binary-window discipline of chapter 370, and the normal-form finite-word rows of chapter 278. Thus W, F, L, M, I, S are collision-kernel refinements of those sibling carriers rather than isolated kernel-only rows.

Definition 444.1 (CollisionKernel BHist carrier)**.** *A* $\mathsf{CollisionKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, F, L, M, I, S, H, C, P, N)$$

with the following visible rows:

1. *W is the finite window row naming the inspected source addresses and target addresses;*
2. *F is the fold-source row listing the finite source entries whose target fibers are inspected;*
3. *L is the target-fiber ledger, with each retained source entry attached to a displayed target address in W;*
4. *M is the collision-kernel matrix row whose entries are finite ledger reads comparing pairs of target fibers inside W;*
5. *I is the moment-index row naming the finite family of moment requests consumed by downstream readers;*
6. *S is the Hankel-shadow row obtained by reading the visible moment-index rows against the finite matrix row;*
7. *H stores the componentwise* hsame *transports for window, fold-source, target-fiber ledger, matrix, moment-index, and Hankel-shadow rows;*
8. *C stores the displayed* Cont *routes through which consumers read W, F, L, M, I, and S;*

9. *P is the* Pkg *provenance over* $\mathsf{FoldMomentKernel}^{\uparrow}$, $\mathsf{GoldenMeanShift}^{\uparrow}$, $\mathsf{ZeckendorfNormal}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, *and* Cont *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CollisionKernel}^{\uparrow}}$ *row.*

The displayed transport, continuation, package, and naming surface is

$$\mathsf{hsame}(W, F, L, M, I, S, H)$$

$$\mathsf{Cont}(W, F, L) \quad \mathsf{Cont}(L, M, S) \quad \mathsf{Cont}(I, M, S)$$

$$\mathsf{Pkg}(P; \mathsf{FoldMomentKernel}^{\uparrow}, \mathsf{GoldenMeanShift}^{\uparrow}, \mathsf{ZeckendorfNormal}^{\uparrow}, \mathsf{List}^{\uparrow}, \mathsf{Nat}^{\uparrow})$$

$$\mathsf{NameCert}_{\mathsf{CollisionKernel}^{\uparrow}}(N; W, F, L, M, I, S, H, C, P).$$

The carrier has no coordinate for a host collision-counting operation, an ambient spectrum, an external measure, an infinite Hankel matrix, or quotient fibers.

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.TasteGate.CollisionKernelTasteGate single carrier alignment`

Definition 444.2 (CollisionKernel classifier)**.** *For accepted* $\mathsf{CollisionKernel}^{\uparrow}$ *carriers K and K', the classifier* $\mathsf{CollisionKernelClassifier}(K, K')$ *compares only the displayed finite window, fold-source, target-fiber ledger, collision-kernel matrix, moment-index, Hankel-shadow, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *rows of Definition 444.1.*

The classifier does not inspect hidden source sets, host matrix entries, analytic spectra, measure spaces, quotient fibers, or unrecorded moment laws. Two packets classify together only through displayed transport of the same finite collision-kernel surface.

Lean4 (definition) `BEDC.Derived.CollisionKernelUp.CollisionKernelClassifier`

Theorem 444.3 (CollisionKernel zero-window packet)**.** *The empty source window with the zero target window determines an accepted* $\mathsf{CollisionKernel}^{\uparrow}$ *carrier. Its fold-source row is empty, its target-fiber ledger has no retained source entries, its collision-kernel matrix row is the displayed zero finite matrix, every moment-index read is represented by the zero row, the Hankel-shadow row is zero, and all transport, continuation, package, and local naming rows are the corresponding finite identity rows.*

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier zero window packet`

Proof. Start with the empty displayed window. There are no source entries to fold and no target fiber entries to compare, so the target-fiber ledger is empty.

Use the displayed zero finite matrix as the collision-kernel row. Since every inspected matrix entry is a read against the empty ledger, each moment-index request also reads the zero row.

The Hankel-shadow row is therefore the zero shadow over the empty finite matrix. Repack the identity hsame transports, identity Cont routes, package provenance, and local naming row to obtain the accepted carrier. □

Theorem 444.4 (CollisionKernel NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{CollisionKernel}^{\uparrow}}$ *obligation surface consists of five finite rows:*

1. *carrier inhabitation: Definition 444.3 supplies the empty-source and zero-window packet;*

2. *classifier transport: Definition 444.2 transports the finite window, fold-source row, target-fiber ledger, matrix row, moment-index row, Hankel-shadow row,* hsame *routes,* Cont *routes, package provenance, and local naming row componentwise;*

3. *fiber-ledger exactness: every matrix entry is read from the displayed target-fiber ledger L, and every ledger entry is tied to the displayed fold-source row F and finite window row W;*
4. *moment-readback boundary: every moment or Hankel-shadow read factors through I, M, S, L, H, C, P, and N before reaching any downstream consumer;*
5. *non-escape from host spectra or measure: the packet exports no host spectral object, measure space, infinite Hankel operator, quotient fiber, ambient moment problem, or unrecorded collision-counting operation.*

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier namecert obligation surface`

Proof. The carrier row is the finite packet of Definition 444.1, and Definition 444.3 gives a concrete inhabitant.

Classifier transport is componentwise by Definition 444.2. A displayed hsame route can move only the visible window, fold-source, target-fiber ledger, matrix, moment-index, Hankel-shadow, continuation, package, and naming rows already present in the packet.

Fiber-ledger exactness is obtained by projecting L together with F and W. Every matrix entry in M is a finite read from those displayed target fibers, and every retained source entry remains attached to the fold-source and window rows by C.

Moment readback projects I, M, and S. The Hankel-shadow consumer reaches a visible shadow only through the moment-index row, the collision-kernel matrix row, the fiber ledger, transports, continuations, package provenance, and the local certificate.

Since those rows exhaust the carrier coordinates, no host spectrum, measure object, infinite Hankel operator, quotient fiber, ambient moment problem, or hidden counting operation can be exported. □

Theorem 444.5 (CollisionKernel Hankel-shadow boundary)**.** *Every Hankel-shadow read of an accepted* $\mathsf{CollisionKernel}^{\uparrow}$ *carrier factors through the finite moment-index row I, the displayed collision-kernel matrix row M, the target-fiber ledger L, the componentwise* hsame *transports H, the displayed* Cont *routes C, the package row P, and the local* $\mathsf{NameCert}_{\mathsf{CollisionKernel}^{\uparrow}}$ *row N. The read cannot be strengthened into an infinite Hankel operator, host spectral value, measure-theoretic moment functional, quotient-fiber equality, or external analytic boundary condition.*

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier hankel shadow boundary`

Proof. Project the accepted carrier. The only rows mentioning a Hankel shadow are the finite moment-index row I, the matrix row M, and the shadow row S.

Read M through the target-fiber ledger L. By Definition 444.4, every matrix entry is exhausted by displayed ledger entries over the finite window and fold-source rows.

Now transport the requested shadow read through H and route it through C. Package provenance P and the local naming row N certify that the read remains inside the same finite packet.

The carrier has no coordinate for an infinite Hankel operator, host spectral value, ambient measure, quotient fiber, or analytic moment functional, so the Hankel-shadow read stops at the displayed finite boundary. □

Theorem 444.6 (CollisionKernel classifier transport scope)**.** *For accepted* $\mathsf{CollisionKernel}^{\uparrow}$ *carriers, classified replacement transports only the finite window row W, fold-source row F, target-fiber ledger L, collision-kernel matrix row M, moment-index row I, Hankel-shadow row S, componentwise* hsame *row H, displayed* Cont *routes C, package row P, and local* NameCert *row N. It has no*

transport coordinate for hidden source sets, host matrix entries, analytic spectra, ambient measures, quotient fibers, or unrecorded moment laws.

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier classifier transport scope`

Proof. Project the carrier in Definition 444.1. The packet lists exactly the rows W, F, L, M, I, S, H, C, P, and N.

Apply the classifier definition in Definition 444.2. Its comparison relation inspects only those displayed rows and the componentwise transport already stored in the carrier.

Use the classifier-transport row of Definition 444.4. It moves the finite window, fold-source, target-fiber ledger, matrix, moment-index, Hankel-shadow, transport, continuation, package, and local naming rows componentwise.

Finally apply Definition 444.5. Since Hankel reads themselves stop at the same finite boundary, classified replacement cannot export a hidden source set, host entry, analytic spectrum, measure object, quotient fiber, or unrecorded moment law. □

Theorem 444.7 (CollisionKernel fiber-ledger exactness)**.** *Every matrix entry in the collision-kernel row M of an accepted* $\mathsf{CollisionKernel}^{\uparrow}$ *carrier is read from the displayed target-fiber ledger L, and each such ledger entry is tied to the fold-source row F and the finite window row W. The matrix row has no independent host collision-counting operation, hidden target fiber, quotient fiber, ambient spectrum, or measure-theoretic source.*

Proof. Begin with Definition 444.1. The matrix row M is part of the finite packet and is presented together with the target-fiber ledger L, fold-source row F, and finite window row W.

The NameCert obligation surface in Definition 444.4 contains the fiber-ledger exactness row. It states that every matrix entry is a finite read from displayed target fibers, with every retained source entry attached to F and W.

Use Definition 444.2 to keep the comparison componentwise across the same visible rows. Then apply Definition 444.5; any downstream Hankel read of M passes back through L before reaching S, H, C, P, or N.

Thus M is exhausted by the displayed ledger tied to F and W, with no independent host count, hidden fiber, quotient fiber, spectrum, or measure object. □

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier fiber ledger exactness`

Theorem 444.8 (CollisionKernel moment readback exhaustion)**.** *Every moment read and every Hankel-shadow read exported by an accepted* $\mathsf{CollisionKernel}^{\uparrow}$ *carrier factors through the displayed rows I, M, S, L, H, C, P, and N. The readback exports no ambient spectrum, measure object, infinite Hankel operator, quotient fiber, hidden counting operation, or unrecorded analytic moment functional.*

Proof. Read the moment-facing coordinates from Definition 444.1. Moment requests are named by I, evaluated against the displayed matrix row M, recorded in the Hankel-shadow row S, and tied back to the target-fiber ledger L.

Apply Definition 444.4. Its moment-readback boundary routes every moment or Hankel-shadow read through the visible moment, matrix, shadow, ledger, transport, continuation, package, and naming rows before a downstream consumer sees it.

Use Definition 444.5 to identify the same finite boundary for Hankel-shadow consumers. The classifier in Definition 444.2 supplies only componentwise transport across those rows.

Consequently the readback surface is exhausted by I, M, S, L, H, C, P, and N, and it has no coordinate for spectrum, measure, infinite Hankel structure, quotient fibers, hidden counting, or analytic moment laws. □

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier moment readback exhaustion`

Theorem 444.9 (CollisionKernel zero-window determinacy)**.** *Let $K = (W, F, L, M, I, S, H, C, P, N)$ and $K' = (W, F, L, M, I', S', H', C', P', N')$ be accepted zero-window* $\mathsf{CollisionKernel}^{\uparrow}$ *packets with the same finite window W, fold-source row F, target-fiber ledger L, collision-kernel matrix row M, and moment index whenever a moment read is requested. Then the two packets are classified by Definition 444.2; their visible collision-kernel output is determined by those shared finite rows.*

In particular, zero-window habitation cannot create a second classifier through hidden source sets, host matrix entries, quotient fibers, ambient measures, spectra, or unrecorded moment laws.

Proof. Start from the zero-window packet of Definition 444.3. It supplies an accepted finite packet whose source and target-fiber data are the displayed zero-window rows.

Project the classifier surface in Definition 444.2. The classifier inspects the finite window, fold source, target-fiber ledger, matrix row, moment-index row, Hankel-shadow row, transport row, continuation row, package provenance, and local naming row.

Because K and K' share W, F, L, M and the requested moment index, the non-shared rows can only replay the same displayed continuation and naming routes. The finite classifier therefore identifies the two zero-window packets on the shared ledger.

Finally use Definition 444.8. Any moment-facing read returns to I, M, S, L, H, C, P, N, so it cannot separate the two packets by an external source. □

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier zero window determinacy`

Theorem 444.10 (CollisionKernel fiber classifier composition)**.** *For accepted* $\mathsf{CollisionKernel}^{\uparrow}$ *packets, componentwise* hsame *transports of the target-fiber ledger L compose through the displayed* Cont *rows and preserve the classifier of Definition 444.2. The composed classifier route still reads only the finite window W, fold-source row F, target-fiber ledger L, matrix row M, moment-index row I, Hankel-shadow row S, transport row H, continuation row C, package row P, and local* $\mathsf{NameCert}$ *row N.*

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier fiber classifier composition`

Proof. First isolate the ledger. By Definition 444.7, every matrix entry in M is read from the displayed target-fiber ledger L and tied back to the finite window W and fold-source row F.

Next compose the transports. The classifier-transport scope in Definition 444.6 permits only componentwise hsame movement along the displayed rows and only the displayed Cont routes for replaying consumers.

The classifier definition then has no further input to inspect. Applying Definition 444.2 after the composed ledger transport yields the same finite classification, and Definition 444.5 keeps any shadow read on the same ledger boundary. □

Theorem 444.11 (CollisionKernel scoped dependency route)**.** *Every scoped* $\mathsf{CollisionKernel}^{\uparrow}$ *consumer must read the finite window and target-fiber ledger through* $\mathsf{FoldMomentKernel}^{\uparrow}$, $\mathsf{GoldenMeanShift}^{\uparrow}$, $\mathsf{ZeckendorfNormal}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, *and* $\mathsf{Nat}^{\uparrow}$ *provenance before any Hankel-shadow or moment-index row is exported. The route has no host spectrum, ambient measure, quotient fiber, or infinite Hankel operator.*

Proof. Project the carrier of Definition 444.1. The rows $W, F, L, M, I, S, H, C, P, N$ are the only displayed coordinates, and the provenance row P names $\mathsf{FoldMomentKernel}^{\uparrow}$, $\mathsf{GoldenMeanShift}^{\uparrow}$, $\mathsf{ZeckendorfNormal}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, and $\mathsf{Nat}^{\uparrow}$ as the finite source route for scoped reads.

Use fiber-ledger exactness from Definition 444.7. Every matrix entry reaches the target-fiber ledger L through the finite window W and fold-source row F, so a consumer cannot read a target fiber independently of the sibling provenance.

Apply moment readback exhaustion and classifier transport scope from Definition 444.8 and Definition 444.6. Moment-index and Hankel-shadow rows are exported only after I, M, S, L, H, C, P, N have preserved the same finite packet.

Thus the sibling dependency rows exhaust the scoped route before any moment or shadow read is visible. Since the carrier contains no spectrum, measure, quotient fiber, or infinite Hankel coordinate, no such object is exported by the route. □

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier scoped route`

Theorem 444.12 (CollisionKernel moment ledger noninterference)**.** *In an accepted* $\mathsf{CollisionKernel}^{\uparrow}$ *packet* $K = (W, F, L, M, I, S, H, C, P, N)$*, a moment read or Hankel-shadow read may alter only the displayed moment-index row* I *or Hankel-shadow row* S *of the consumer route. It cannot alter the finite source window* W*, fold-source row* F*, matrix row* M*, package provenance* P*, or local* $\mathsf{NameCert}$ *row* N*.*

Thus moment-facing readback is noninterfering with the finite source ledger and the local naming surface of the collision-kernel packet.

Proof. Read the moment-facing rows from Definition 444.8. Every moment and Hankel-shadow request factors through I, M, S, L, H, C, P, N before it is exported.

The source side is already fixed by Definition 444.7. Matrix entries in M come from the target-fiber ledger L tied to F and W, so a moment read has no coordinate through which to rewrite the finite source window or fold-source row.

The naming side is fixed by Definition 444.6. Transport preserves only the displayed rows and replayed continuations; it does not replace package provenance or the local $\mathsf{NameCert}$ row.

Therefore a moment or Hankel-shadow consumer can vary only the moment-facing index or shadow rows of the read, while W, F, M, P, N remain the same visible ledger data. □

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelMomentLedgerNoninterference`

Theorem 444.13 (CollisionKernel matrix readback totality)**.** *Every matrix read of an accepted* $\mathsf{CollisionKernel}^{\uparrow}$ *packet* $K = (W, F, L, M, I, S, H, C, P, N)$ *is exhausted by the displayed rows* W, F, L, M, H, C, P, N*. More precisely, a consumer can reach an entry of* M *only as a finite read against the target-fiber ledger* L*, tied to the fold-source row* F *and the finite window row* W*, transported by* H*, routed by* C*, and recorded by* P *and* N*.*

Consequently the matrix row exports no host matrix operation, hidden source set, quotient fiber, ambient spectrum, measure object, or analytic collision law.

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier matrix readback totality`

Proof. Start with the carrier of Definition 444.1. The matrix row M is displayed only together with the window W, fold-source row F, target-fiber ledger L, transport row H, continuation row C, package row P, and local naming row N.

Apply Definition 444.7. It identifies every matrix entry as a read from L, with each retained source entry tied to F and W.

Now use Definition 444.6. The only permitted replacement of a matrix read is componentwise transport through the displayed hsame and Cont rows, with provenance and local naming still recorded by P and N.

Since those rows exhaust the available readback coordinates, the matrix read cannot export a host operation, hidden source set, quotient fiber, spectrum, measure, or analytic collision law. □

Theorem 444.14 (CollisionKernel downstream non-escape package)**.** *Every downstream Hankel-shadow or moment consumer of an accepted* $\mathsf{CollisionKernel}^{\uparrow}$ *packet factors through the finite rows* I, M, S, L, H, C, P, N *and then back through the matrix-readback boundary of Definition 444.13. Such a consumer cannot export an ambient spectrum, measure space, quotient fiber, infinite Hankel operator, analytic moment law, or hidden collision-counting operation.*

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier downstream non escape package`

Proof. First isolate the downstream read. By Definition 444.8, every moment or Hankel-shadow request factors through I, M, S, L, H, C, P, N.

Next identify the matrix component of that read. Definition 444.13 sends every access to M back to the displayed window, fold-source row, target-fiber ledger, transports, continuations, package provenance, and local naming row.

Finally apply Definition 444.5. A Hankel-shadow consumer stops at the same finite packet and has no coordinate for an infinite Hankel operator or analytic moment functional.

Thus every downstream read remains a finite consumer of the displayed packet and cannot export spectra, measures, quotient fibers, hidden counting, or analytic moment laws. □

Theorem 444.15 (CollisionKernel obligation closure package)**.** *The paper-side* $\mathsf{CollisionKernel}^{\uparrow}$ *obligation package consists of the zero-window inhabitant, classifier transport scope, fiber-ledger exactness, matrix readback totality, moment and Hankel-shadow readback exhaustion, and downstream non-escape package. Together these clauses bind the accepted finite carrier* $K = (W, F, L, M, I, S, H, C, P, N)$ *as a NameCert surface over displayed windows, fold-source rows, target-fiber ledgers, matrix rows, moment-index rows, Hankel-shadow rows, transports, continuations, package provenance, and local naming evidence.*

Lean4 ✓ `BEDC.Derived.CollisionKernelUp.CollisionKernelCarrier obligation closure package`

Proof. The inhabitant is Definition 444.3. It supplies a concrete accepted packet with empty source data, zero target window, zero matrix row, zero moment rows, and identity transport and naming data.

Classifier transport is Definition 444.6. It restricts classified replacement to the displayed rows of the carrier and excludes hidden source sets, host entries, analytic spectra, ambient measures, quotient fibers, and unrecorded moment laws.

Fiber exactness and readback are supplied by Definition 444.7, Definition 444.13, and Definition 444.8. These theorems force matrix, moment, and Hankel-shadow consumers to return to the finite ledger rows $W, F, L, M, I, S, H, C, P, N$.

Downstream non-escape is Definition 444.14. Repacking these clauses gives the finite paper-side obligation package for the $\mathsf{NameCert}_{\mathsf{CollisionKernel}^{\uparrow}}$ surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CollisionKernel}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CollisionKernel}^{\uparrow}$ packet is generated from a finite window, fold-source rows, target-fiber ledgers, a finite collision-kernel matrix row, moment-index rows, a Hankel-shadow row, componentwise transport, continuation routes, package provenance, and local naming evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CollisionKernel}^{\uparrow}}$, obligation)

Scope closed: The obligation scope binds the finite carrier, classifier transport, fiber ledger exactness, moment readback, matrix readback, downstream non-escape, and obligation package for finite collision-kernel packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CollisionKernel}\uparrow}, \text{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close analytic spectra, ambient measure theory, infinite Hankel operators, quotient fibers, asymptotic collision laws, or bridge checking.

Upgrade path: Scoped closure requires explicit dependency binding across carrier admission, classifier transport, ledger exactness, readback exhaustion, and downstream non-escape for the same finite packet.

Chapter 445

A Concrete Naming Certificate for $\mathsf{DyadicMidpoint}^{\uparrow}$

The $\mathsf{DyadicMidpoint}^{\uparrow}$ interface names the finite midpoint ledger consumed by dyadic interval bisection. In the Bishop–Bridges style of constructive dyadic interval bisection, a midpoint is not a hidden real-number choice: it is a displayed common-denominator calculation over two dyadic endpoint rows, followed by a branch-comparison row and the finite readback route made available to interval consumers.

The midpoint packet consumes endpoint and tolerance rows from chapter 291 and routes branch decisions to chapter 354, chapter 306, and chapter 320. The common-denominator scaling and midpoint rows are $\mathsf{DyadicRatCore}^{\uparrow}$ rows, while the interval chapters consume the branch-comparison row through the same finite branch ledger before it reaches $\mathsf{DyadicSubdivision}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or later L10 real-readback consumers.

Definition 445.1 (DyadicMidpoint carrier)**.** *A* $\mathsf{DyadicMidpoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, R, S, \mu, B, W, H, C, P, N)$$

with the following visible rows:

1. *L and R are the left and right endpoint rows accepted by* $\mathsf{DyadicRatCore}^{\uparrow}$ *or exposed through a* $\mathsf{RationalInterval}^{\uparrow}$ *endpoint surface;*
2. *S is the common-denominator scaling row that transports L and R to one dyadic denominator before addition;*
3. *μ is the midpoint row obtained from the displayed numerator sum and the doubled common denominator;*
4. *B is the branch-comparison row that records which side of μ a later bisection or locatedness consumer selects;*
5. *W is the finite-window readback row exposing the scaled endpoints, midpoint, branch comparison, and requested dyadic tolerance;*
6. *H stores the componentwise* hsame *transports for the two endpoints, the scaling row, the midpoint row, the branch row, and the finite readback row;*
7. *C stores the displayed* Cont *routes for endpoint inspection, midpoint readback, branch handoff, and downstream interval consumption;*

8. *P is the* Pkg *provenance row naming* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicSubdivision}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* NameCert *sources that may consume the midpoint ledger;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicMidpoint}^{\uparrow}}$ *registration row.*

The carrier has no coordinate for host real equality, quotient endpoints, a completed interval intersection, an ambient completeness proof, or an unrecorded midpoint decision.

Lean4 (definition) `BEDC.Derived.DyadicMidpointUp.DyadicMidpointCarrier`

Theorem 445.2 (DyadicMidpoint endpoint-source route)**.** *For every accepted* $\mathsf{DyadicMidpoint}^{\uparrow}$ *packet*

$$M = (L, R, S, \mu, B, W, H, C, P, N),$$

the endpoint rows are read first as L and R through chapter 291 or through the rational interval endpoint surface of chapter 354. Only after those two endpoint rows and the common-denominator row S are present does the packet expose the midpoint row μ and the branch row B to the bisection consumer of chapter 361 through the displayed finite route W, H, C, P, N.

Thus a $\mathsf{DyadicBisection}^{\uparrow}$ *consumer cannot read a midpoint branch without first inheriting the dyadic endpoint data named by the source endpoint rows.*

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointEndpointSourceRoute`

Proof. Project the accepted carrier as

$$M = (L, R, S, \mu, B, W, H, C, P, N).$$

The first two coordinates are the only endpoint source rows in the packet. By Definition 445.1, they are accepted by $\mathsf{DyadicRatCore}^{\uparrow}$ or exposed through a $\mathsf{RationalInterval}^{\uparrow}$ endpoint surface.

The common-denominator row S is the only row that transports those two endpoint rows to a shared dyadic denominator. The midpoint row μ is then read from that displayed scaled endpoint ledger, so the midpoint calculation has no independent endpoint source.

The branch row B is the only coordinate that records a side selection at the midpoint. Hence a $\mathsf{DyadicBisection}^{\uparrow}$ consumer receives the branch through B and the finite route W, H, C, P, N, with L, R, S, μ as the displayed prerequisites.

No remaining coordinate of the carrier can supply host real equality, quotient endpoints, completed intersections, or ambient completeness. The coordinate list is exhausted by $L, R, S, \mu, B, W, H, C, P, N$, so the endpoint-source route into bisection is exactly the stated finite route. □

Theorem 445.3 (DyadicMidpoint NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{DyadicMidpoint}^{\uparrow}}$ *surface consists of six finite obligations:*

1. *carrier: formation of the* BHist *packet of Definition 445.1;*

2. *endpoint scaling: both endpoint rows are transported to the displayed common denominator before any midpoint row is read;*

3. *midpoint exactness: the row μ is the finite dyadic row obtained from the displayed scaled numerator sum and doubled common denominator;*

4. *branch comparison: the branch row B records the side of the displayed midpoint consumed by dyadic bisection, subdivision, or located-interval readback;*

5. *finite-window readback: every consumer read factors through W, H, C, P, and N;*

6. *non-escape: no host real equality, quotient endpoint, completed intersection, or ambient completeness row is exported.*

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointBranchRow consumer handoff`

Proof. Carrier formation is the finite packet assembly of Definition 445.1. The two endpoint rows, the common-denominator row, the midpoint row, the branch row, the readback row, and the provenance rows are all visible coordinates of the same BHist packet.

Endpoint scaling and midpoint exactness are read from S and μ. The scaling row names the common dyadic denominator, and the midpoint row is built by the displayed numerator-sum and denominator-doubling calculation.

Branch comparison is the row B. A bisection or locatedness consumer may route left or right only through that displayed comparison row, so the branch decision is not imported from an external real-order oracle.

Finally, every public read must pass through W, then through the displayed hsame and Cont routes and the package and naming rows. Since the carrier lists no host equality, quotient endpoint, completed intersection, or completeness coordinate, none is available to export. □

Theorem 445.4 (DyadicMidpoint endpoint classifier stability)**.** *Let*

$$M = (L, R, S, \mu, B, W, H, C, P, N)$$

and

$$M' = (L', R', S', \mu', B', W', H', C', P', N')$$

be accepted DyadicMidpoint$^{\uparrow}$ *carriers. If the endpoint rows L, R and L', R' are transported by the displayed* hsame *and* Cont *rows to the same finite dyadic endpoint window, then their common-denominator rows, midpoint rows, branch-comparison rows, and finite-window readbacks classify together through the local* DyadicMidpoint$^{\uparrow}$ *classifier.*

Proof. First transport the two endpoint pairs along the displayed endpoint routes in H, C and H', C'. The hypothesis places both carriers over the same finite dyadic endpoint window.

The common-denominator rows S and S' are then read over that shared window. Because both rows scale the same two transported endpoint rows, the scaled endpoint numerators and common denominator are the same finite ledger data.

The midpoint rows μ and μ' are obtained from those scaled endpoint numerators by the same displayed denominator-doubling calculation. Thus the midpoint readbacks classify together.

It remains to compare consumer-visible branching and readback. The branch rows B, B' inspect the same midpoint row against the same transported endpoint window, and W, W' expose only those transported rows through the package and naming provenance. The local classifier therefore preserves the full midpoint packet surface. □

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointCarrier endpoint classifier stability`

Theorem 445.5 (DyadicMidpoint branch comparison handoff)**.** *For every accepted* DyadicMidpoint$^{\uparrow}$ *carrier $M = (L, R, S, \mu, B, W, H, C, P, N)$, any* DyadicBisection$^{\uparrow}$, DyadicSubdivision$^{\uparrow}$, *or* LocatedInterval$^{\uparrow}$ *consumer that branches at the midpoint consumes exactly the displayed branch-comparison row B together with the endpoint rows L, R, the common-denominator row S, the midpoint row μ, the finite readback row W, and the provenance rows H, C, P, N.*

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointBranchComparisonHandoff`

Proof. Project the carrier. The only row that records a left/right comparison at the midpoint is B, and the only midpoint value available to that row is μ.

The endpoint and scaling prerequisites for the comparison are exactly L, R and S. Reading B therefore forces the consumer to read the same common-denominator endpoint window and the same midpoint row that produced the comparison.

The consumer-facing handoff is W. It exposes the endpoint, scaling, midpoint, and branch rows through the displayed transports, continuation routes, package provenance, and local naming row.

Thus the bisection, subdivision, or located-interval consumer receives the stated finite handoff and no hidden branch oracle. □

Theorem 445.6 (DyadicMidpoint finite-window consumer route)**.** *For every accepted* $\mathsf{DyadicMidpoint}^{\uparrow}$ *carrier and every finite precision request, the consumer-visible route to* $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *factors through the finite readback row* W*, the displayed* hsame *transports* H*, the displayed* Cont *routes* C*, the package row* P*, and the local* $\mathsf{NameCert}_{\mathsf{DyadicMidpoint}^{\uparrow}}$ *row* N*.*

Proof. Start with the finite precision request. The carrier answers it by selecting the finite readback row W, which contains the scaled endpoints, midpoint row, branch comparison, and dyadic tolerance visible at that request.

Endpoint and midpoint transport then proceeds through H and C. These rows move the endpoint, scaling, midpoint, and branch data componentwise, so every downstream interval or real-name consumer reads the same finite ledger.

The package row P records which surrounding certificates may consume the route, and N records the local naming registration. Therefore the route into rational intervals, dyadic intervals, nested intervals, finite-window envelopes, dyadic bisection, dyadic rational rows, and real names is exhausted by the displayed finite packet. □

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointCarrier finite window consumer route`
Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointCarrier readback closure`

Theorem 445.7 (DyadicMidpoint nested interval non-escape)**.** *Suppose a* $\mathsf{NestedInterval}^{\uparrow}$ *or* $\mathsf{DyadicBisection}^{\uparrow}$ *packet consumes a* $\mathsf{DyadicMidpoint}^{\uparrow}$ *carrier during a finite refinement step. The retained subinterval endpoint rows, the selected midpoint row, and the branch comparison remain inside the displayed* BHist *packet of Definition 445.1; the handoff exports no host real equality, no quotient endpoints, no completed interval intersection, and no ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointNestedIntervalNonEscape`

Proof. Apply Definition 445.5. A refinement step can choose a retained subinterval only through the displayed branch row B and the midpoint row μ.

Next apply Definition 445.6. The selected endpoint rows and midpoint row are routed to the nested or bisection consumer through W, H, C, P, and N.

All rows used in the handoff are coordinates of the finite carrier or provenance attached to that carrier. Since Definition 445.1 contains no host real equality, quotient endpoint, completed interval intersection, or ambient completeness field, the finite refinement cannot export any such object. □

Theorem 445.8 (DyadicMidpoint carrier obligation surface)**.** *For an accepted* DyadicMidpoint$^{\uparrow}$ *carrier*

$$M = (L, R, S, \mu, B, W, H, C, P, N)$$

over BHist*, the six rows of Definition 445.3 assemble a single carrier obligation surface. The carrier row is the packet of Definition 445.1; endpoint scaling and midpoint exactness are the S and μ rows; branch comparison is the B row; finite-window readback is the route through W, H, C, P, N; and non-escape is the absence of host real equality, quotient endpoint, completed interval intersection, and ambient completeness coordinates. This surface is stated entirely over* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* DyadicRatCore$^{\uparrow}$*,* RationalInterval$^{\uparrow}$*,* DyadicInterval$^{\uparrow}$*, and* StreamName$^{\uparrow}$ *rows.*

Proof. Project the carrier in the displayed order. The first coordinate group gives the endpoint rows L, R, the common-denominator row S, the midpoint row μ, the branch row B, and the finite-window row W.

The transport and route rows are already part of the same packet. The componentwise hsame row H and the Cont row C carry the endpoint, scaling, midpoint, branch, and readback data without adding a second carrier.

The package and naming rows then bind the consumer side. The Pkg row P names the DyadicRatCore$^{\uparrow}$, RationalInterval$^{\uparrow}$, DyadicInterval$^{\uparrow}$, and StreamName$^{\uparrow}$ surfaces that may read the packet, while N supplies the local NameCert registration.

Finally, Definition 445.1 lists no host real equality, quotient endpoint, completed interval intersection, or ambient completeness coordinate. Hence the six obligations form one finite obligation surface over exactly the stated rows. □

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointCarrier obligation surface`

Theorem 445.9 (DyadicMidpoint bisection ledger exactness)**.** *Every bisection or subdivision read that retains an endpoint and compares against the displayed midpoint of an accepted* DyadicMidpoint$^{\uparrow}$ *carrier is exhausted by the rows*

$$L, R, S, \mu, B, W, H, C, P, N.$$

The retained endpoint is one of the endpoint rows or the midpoint row exposed through W; the midpoint comparison is the branch row B; and every transport, continuation, package, and naming dependency is one of H, C, P, N.

Proof. Start with the retained endpoint read. The carrier exposes only L, R as original endpoints and μ as the computed midpoint, so a retained subinterval endpoint must be read from those rows through the finite-window route W.

The comparison used to choose the branch is the row B. Its prerequisites are the displayed endpoint rows and the common-denominator row S, because the midpoint row μ is computed from that scaled ledger.

It remains to account for transport and consumer routing. The hsame row H and Cont row C move the same finite rows componentwise, and P, N record the package and local naming provenance. No other row is present in the carrier, so the bisection or subdivision ledger is exact. □

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointBisectionLedgerExactness`

Theorem 445.10 (DyadicMidpoint branch-ledger totality)**.** *For every accepted* DyadicMidpoint$^{\uparrow}$ *carrier*

$$M = (L, R, S, \mu, B, W, H, C, P, N),$$

every bisection branch read is accounted for by the displayed branch row B together with the endpoint rows L, R, common-denominator row S, midpoint row μ, finite-window row W, transport row H, continuation row C, package row P, and local naming row N. No bisection consumer can obtain a branch outside this ledger.

The branch surface exports no host real equality, quotient endpoints, completed interval intersection, or completeness principle.

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointBranchLedgerTotality`

Proof. Project the carrier rows of Definition 445.1. The only branch-bearing coordinate is B, and its displayed prerequisites are the endpoint rows L, R, the common-denominator row S, and the midpoint row μ.

Apply Definition 445.5. It identifies every bisection or subdivision branch with the displayed branch-comparison row and routes the branch back through the same endpoint and midpoint ledger.

Finally use Definition 445.9. The finite-window, transport, continuation, package, and naming rows W, H, C, P, N exhaust the consumer-visible route, so there is no remaining coordinate for host real equality, quotient endpoints, completed interval intersection, or a completeness principle. □

Theorem 445.11 (DyadicMidpoint common-denominator consumer exactness)**.** *For every accepted* DyadicMidpoint$^{\uparrow}$ *carrier*

$$M = (L, R, S, \mu, B, W, H, C, P, N),$$

any consumer that reads the midpoint row μ must first consume the displayed common-denominator row S for the endpoint rows L, R. The finite-window route W, componentwise hsame *row H, displayed* Cont *row C, package row P, and local naming row N preserve that same denominator ledger when the midpoint is handed to* RationalInterval$^{\uparrow}$*,* DyadicInterval$^{\uparrow}$*,* NestedInterval$^{\uparrow}$*,* StreamName$^{\uparrow}$*, or* Real$^{\uparrow}$ *consumers.*

Thus midpoint exactness is the exactness of the displayed common-denominator calculation, not equality of host real endpoints, quotient endpoint representatives, completed interval intersections, or any completeness principle.

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointCommonDenominatorConsumerExactness`

Proof. Start from the carrier definition. The midpoint row μ is not a primitive endpoint; it is obtained from the endpoint rows L, R after the common-denominator scaling row S has been read.

Use Definition 445.9. It states that every bisection or subdivision read is exhausted by the rows $L, R, S, \mu, B, W, H, C, P, N$, so a midpoint consumer cannot bypass S.

Apply Definition 445.6. The finite-window route and the transport, continuation, package, and naming rows carry the same scaled endpoint ledger into downstream interval and real-name consumers.

The handoff therefore preserves exactness of the common-denominator calculation only. Since no host real equality, quotient endpoint, completed intersection, or completeness row is present in the carrier, none is exported. □

Theorem 445.12 (DyadicMidpoint common-denominator branch exhaustion)**.** *For every accepted* $\mathsf{DyadicMidpoint}^{\uparrow}$ *carrier*

$$M = (L, R, S, \mu, B, W, H, C, P, N),$$

every branch read consumed by $\mathsf{DyadicBisection}^{\uparrow}$*,* $\mathsf{DyadicSubdivision}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *first reads the common-denominator row* S *and then the midpoint row* μ *and branch row* B *through* W, H, C, P, N*. No host real equality, quotient endpoint, completed interval intersection, or completeness principle is available to that consumer.*

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointCommonDenominatorBranchExhaustion`

Proof. Project the accepted carrier. The endpoint rows L, R, common-denominator row S, midpoint row μ, branch row B, finite-window row W, transport row H, continuation row C, package row P, and local naming row N are the whole displayed packet.

Apply Definition 445.5 to identify the branch read with the displayed branch-comparison row. Use Definition 445.9 and Definition 445.10 to bind the retained endpoint, midpoint, and branch decision to $L, R, S, \mu, B, W, H, C, P, N$.

Finally apply Definition 445.11. It forces every midpoint consumer to read S before μ, so the branch route available to bisection, subdivision, located-interval, and real-name consumers is exhausted by the common-denominator branch ledger and exports none of the excluded completion or host-equality rows. □

Theorem 445.13 (DyadicMidpoint selected-window denominator seal)**.** *For every accepted* $\mathsf{DyadicMidpoint}^{\uparrow}$ *carrier*

$$M = (L, R, S, \mu, B, W, H, C, P, N),$$

any $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{StreamName}^{\uparrow}$ *consumer that reads the selected midpoint window must consume the common-denominator row* S*, midpoint row* μ*, branch row* B*, finite-window row* W*, and provenance rows* H, C, P, N *before any seal-facing read. No quotient endpoint, completed interval intersection, host real equality, or ambient completeness row can mediate that handoff.*

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointSelectedWindowDenominatorSeal`

Proof. Begin with Definition 445.11. It forces every midpoint read through the displayed common-denominator row S before the midpoint row μ can be consumed.

Apply Definition 445.12. The selected window then reads the branch row B through W, H, C, P, N, so a bisection, subdivision, located-interval, real-name, or stream-name consumer cannot select a midpoint branch outside the finite packet.

Finally use Definition 445.15. The $\mathsf{Real}^{\uparrow}$ seal route receives only the finite dyadic-name packet for the current window, and the same finite-window boundary is the one a $\mathsf{StreamName}^{\uparrow}$ consumer can observe.

The carrier contains no quotient endpoint, completed interval intersection, host real equality, or ambient completeness row. Therefore the selected-window denominator route is the only seal-facing handoff for midpoint consumers. □

Theorem 445.14 (DyadicMidpoint radius-halving window)**.** *Let a* $\mathsf{DyadicInterval}^{\uparrow}$ *row display endpoints* L, R *through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and let a positive dyadic radius budget* ρ *be attached to that interval row. An accepted* $\mathsf{DyadicMidpoint}^{\uparrow}$ *carrier*

$$M = (L, R, S, \mu, B, W, H, C, P, N)$$

splits the displayed interval into two child interval rows with endpoints (L, μ) *and* (μ, R)*. Each child radius budget is bounded by the parent half-radius* $\rho/2$*, and the endpoint, midpoint, branch, and readback rows remain transported through the same* $\mathsf{StreamName}^{\uparrow}$*- and* $\mathsf{RegSeqRat}^{\uparrow}$*-compatible ledger* W, H, C, P, N*.*

The split exports no ambient $\mathsf{Real}^{\uparrow}$ *completeness, no quotient equality of endpoints, and no completed interval intersection.*

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointRadiusHalvingWindow`

Proof. Read the interval endpoint data through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ rows. The common-denominator row S transports L and R to one dyadic denominator, and the midpoint row μ is computed from that scaled ledger by the dyadic midpoint calculation.

The branch row B then displays the two possible retained child rows. The left child uses endpoints (L, μ) and the right child uses (μ, R); both inherit endpoint admission from L, R, S, μ and do not introduce a third endpoint source.

The radius estimate is the finite denominator calculation already visible in the midpoint ledger. Since μ is the displayed midpoint of the scaled endpoint row, each child interval has dyadic width bounded by one half of the parent width, so its radius budget is bounded by $\rho/2$.

Finally apply the finite-window route W, H, C, P, N. Those rows are the only consumer-facing readback, transport, continuation, package, and naming rows in the carrier, so the same $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ ledger carries the child endpoint reads. The carrier has no coordinate for $\mathsf{Real}^{\uparrow}$ completeness, quotient endpoint equality, or completed interval intersections, so none is exported. □

Theorem 445.15 (DyadicMidpoint RealUp handoff without completion)**.** *For every accepted* $\mathsf{DyadicMidpoint}^{\uparrow}$ *carrier*

$$M = (L, R, S, \mu, B, W, H, C, P, N),$$

any $\mathsf{Real}^{\uparrow}$ *read of the midpoint ledger factors through the finite-window consumer route* W, H, C, P, N *and through the exact bisection rows* L, R, S, μ, B*. The handoff gives* $\mathsf{Real}^{\uparrow}$ *a finite dyadic-name packet for the current window; it does not export a completed interval intersection, a quotient endpoint equality, host real equality, or a completeness principle.*

The same non-completion boundary is inherited by $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{NestedInterval}^{\uparrow}$*, and* $\mathsf{StreamName}^{\uparrow}$ *consumers that route through the midpoint ledger.*

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointRealHandoffNoncompletion`

Proof. Read the consumer route through Definition 445.6. It sends $\mathsf{Real}^{\uparrow}$ and the interval consumers through the finite readback row W, the transport row H, the continuation row C, the package row P, and the local naming row N.

Next apply Definition 445.9. The endpoint, common-denominator, midpoint, and branch data read by that route are exactly L, R, S, μ, B.

Use Definition 445.5 for the branch side. Any retained-window decision is the displayed branch-comparison row, not a host order or equality fact about completed reals.

Combining these rows gives $\mathsf{Real}^{\uparrow}$ only the finite dyadic-name packet for the current window. The carrier has no completed interval intersection, quotient endpoint equality, host real equality, or completeness coordinate to export, and the same boundary holds for the listed interval and stream-name consumers. □

Theorem 445.16 (DyadicMidpoint downstream DyadicRatCore package)**.** *For every accepted* $\mathsf{DyadicMidpoint}^{\uparrow}$ *carrier, endpoint classifier stability, branch-comparison handoff, finite-window consumer routing, and nested-interval non-escape assemble the downstream* $\mathsf{DyadicRatCore}^{\uparrow}$ *package consumed by* $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readers. The assembled package consists only of the rows* $L, R, S, \mu, B, W, H, C, P, N$ *and exports no host real equality, quotient endpoint, completed interval intersection, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.DyadicMidpointUp.DyadicMidpointDownstreamDyadicRatCorePackage`

Proof. First use endpoint classifier stability to keep accepted midpoint packets over the same transported endpoint window. This fixes the endpoint rows, the common-denominator row, and the midpoint row seen by a downstream $\mathsf{DyadicRatCore}^{\uparrow}$ reader.

Next use branch-comparison handoff. It identifies the branch decision with the displayed row B and ties that decision back to L, R, S, μ rather than to an external order oracle.

The finite-window consumer route supplies the package boundary. It factors rational interval, dyadic interval, nested interval, finite-window, dyadic rational, and real-name reads through W, H, C, P, N.

Finally, nested-interval non-escape excludes every coordinate not present in the carrier. Thus the downstream $\mathsf{DyadicRatCore}^{\uparrow}$ package consumed by interval and $\mathsf{Real}^{\uparrow}$ readers is exactly the displayed finite midpoint ledger. □

Theorem 445.17 (DyadicMidpoint scoped support package)**.** *The carrier of Definition 445.1, the six* $\mathsf{NameCert}_{\mathsf{DyadicMidpoint}^{\uparrow}}$ *obligations of Definition 445.3, endpoint classifier stability, branch-comparison handoff, finite-window consumer routing, nested-interval non-escape, the* $\mathsf{Real}^{\uparrow}$ *handoff of Definition 445.15, and the downstream* $\mathsf{DyadicRatCore}^{\uparrow}$ *package of Definition 445.16 assemble one scoped support package for* $\mathsf{DyadicMidpoint}^{\uparrow}$.

This package is stated only over BHist, hsame, Cont, Pkg, NameCert, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *It exports the finite midpoint ledger and its consumer routes, but it exports no host real equality, quotient endpoint, completed interval intersection, or completeness row.*

Proof. Project the carrier rows of Definition 445.1. The endpoint rows, common-denominator row, midpoint row, branch row, readback row, transport row, continuation row, package row, and local naming row are the whole displayed packet.

The local obligation surface is Definition 445.3. Endpoint classifier stability keeps transported endpoint windows aligned, branch-comparison handoff identifies the consumer branch with the row B, and finite-window consumer routing factors each downstream read through W, H, C, P, N.

Use nested-interval non-escape to keep bisection and nested-interval refinement inside the displayed packet. Use the $\mathsf{Real}^{\uparrow}$ handoff to record that real-name consumers receive only a finite dyadic-name packet for the current window, and use the downstream $\mathsf{DyadicRatCore}^{\uparrow}$ package to bind the rational, dyadic interval, nested interval, and real-name consumers to the same rows.

The projected rows list no host real equality, quotient endpoint, completed interval intersection, or ambient completeness coordinate. Therefore the cited carrier, obligations, stability, route, non-escape, real-name handoff, and downstream package form the stated scoped support package and export no object outside that dependency surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMidpoint}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicMidpoint}^{\uparrow}$ packet is generated from two dyadic endpoint rows, a common-denominator scaling row, a finite midpoint calculation, a branch-comparison row, a finite-window readback row, displayed hsame and Cont routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{DyadicMidpoint}^{\uparrow}}$, scopedClosed)

Scope closed: The obligation scope packages the endpoint rows, common-denominator scaling row, midpoint row, branch-comparison row, finite-window readback route, local classifier stability, consumer handoff, nested-interval non-escape boundary, Real$^{\uparrow}$ handoff, and downstream DyadicRatCore$^{\uparrow}$ surface for DyadicMidpoint$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicMidpoint}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close host real equality, completed interval intersections, quotient endpoints, ambient completeness, root existence, or real trichotomy.

Upgrade path: Obligation closure requires formal carrier encoding, endpoint classifier stability, branch-comparison handoff checking, finite-window consumer route checking, and nested-interval non-escape checking for DyadicMidpoint$^{\uparrow}$.

Chapter 446

A Concrete Naming Certificate for DyadicCover$^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, finite covers over located real data are useful when the finite list, the dyadic mesh, and the coverage witnesses are carried as explicit data. The DyadicCover$^{\uparrow}$ interface packages this information as a finite BEDC certificate for Real and Completion consumers. It depends on DyadicRatCore$^{\uparrow}$, DyadicMesh$^{\uparrow}$, RationalInterval$^{\uparrow}$, RationalBall$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and FiniteWindowEnvelope$^{\uparrow}$, and it does not invoke open-cover compactness, excluded middle, or a choice of subcover from an arbitrary family.

The cover carrier consumes four horizontal concrete-instance surfaces. The dyadic readback surface of chapter 291 supplies the center row K; the mesh-refinement surface of chapter 358 supplies the refinement row Q; the cell boundary of chapter 354 supplies the interval cell row I tied to the radius row R; and the window-envelope consumer route of chapter 365 supplies the finite coverage row W.

Definition 446.1 (DyadicCover carrier)**.** *A* DyadicCover$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, R, I, Q, W, H, C, P, N)$$

with the following visible coordinates:

1. *K is the finite list of dyadic centers, each read through a* DyadicRatCore$^{\uparrow}$ *row;*
2. *R is the finite list of dyadic radii, each routed through a* RationalBall$^{\uparrow}$ *row with rational non-negative radius data;*
3. *I is the finite list of rational interval cells, each routed through a* RationalInterval$^{\uparrow}$ *row and attached to the corresponding center-radius entry;*
4. *Q records the* DyadicMesh$^{\uparrow}$ *mesh level and the finite refinement rows between adjacent mesh levels;*
5. *W is the displayed* FiniteWindowEnvelope$^{\uparrow}$ *window whose points are covered by the interval cells;*
6. *H records the* hsame *transports for centers, radii, interval cells, mesh rows, window bounds, stream-name reads, regular-rational sequence reads, and real rows;*
7. *C records the* Cont *routes by which consumers read center membership, radius bounds, interval containment, mesh refinement, coverage witnesses, and total-bounded handoff rows;*

8. *P records* Pkg *provenance for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *dependency rows;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCover}^{\uparrow}}$ *provenance row.*

The carrier accepts exactly those packets whose finite cell list covers the displayed finite window and whose refinement rows keep every later mesh cell inside a named earlier interval or rational ball.

Lean4 (definition) `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket`

Theorem 446.2 (DyadicCover NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DyadicCover}^{\uparrow}}$ *seed surface consists of five finite obligations:*

1. *carrier: the packet of Definition 446.1;*

2. *classifier: componentwise comparison of centers, radii, interval cells, mesh rows, finite-window witnesses, transport rows, continuation routes, package provenance, and local certificate rows;*

3. *refinement stability: displayed* hsame *and* Cont *transport preserves the dyadic center list, rational radii, interval cells, mesh refinement rows, and coverage witnesses;*

4. *coverage exactness: every covered real read factors through a* $\mathsf{StreamName}^{\uparrow}$ *row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *approximation row, a* $\mathsf{Real}^{\uparrow}$ *row, and a finite interval or ball cell in the displayed window;*

5. *ledger policy:* Pkg *and* NameCert *expose only the listed dyadic, rational, real, finite-window, transport, and continuation rows.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket namecert obligations`

Proof. Project the carrier. The finite center list, radius list, interval-cell list, mesh rows, window witnesses, transport rows, continuation routes, package provenance, and local certificate row are exactly the visible coordinates.

The classifier is componentwise over these rows. Transport stability follows by moving each coordinate through the stored hsame rows and then reading it through the corresponding Cont route.

Coverage exactness follows from the explicit witness attached to each point in the displayed finite window: the witness names the stream read, regular rational approximation, real row, and interval or ball cell used for that point. The package and certificate rows contain no arbitrary open family or subcover selector, so the ledger policy is exhausted by the displayed packet. □

Theorem 446.3 (DyadicCover finite refinement)**.** *Let D be an accepted* $\mathsf{DyadicCover}^{\uparrow}$ *carrier and let Q' be a displayed later* $\mathsf{DyadicMesh}^{\uparrow}$ *refinement row of its mesh coordinate Q. The refined packet is obtained by replacing each old cell with the finite list of named dyadic subcells routed by Q', transporting the corresponding rational interval and rational ball rows through* hsame*, and retaining the same* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *coverage witnesses after refinement.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket finite refinement`

Proof. Read the mesh coordinate Q and the displayed refinement row Q'. Each old dyadic cell has a finite named list of subcells, so the refined center, radius, and interval lists are built by finite list replacement.

Transport each subcell's rational interval and rational ball rows through the stored hsame entries, then read the containment route through Cont. The finite-window coordinate W is unchanged, while each old coverage witness now points to the named refined subcell contained in the old cell.

Repack the refined rows with the same Pkg provenance and local $\mathsf{NameCert}_{\mathsf{DyadicCover}^{\uparrow}}$ row. No infinite cover or selected subcover is introduced, because every operation is over the displayed finite mesh lists. □

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket finite refinement transport`

Theorem 446.4 (DyadicCover total-bounded handoff)**.** *Every total-bounded or compact-metric consumer of an accepted* $\mathsf{DyadicCover}^{\uparrow}$ *carrier factors through the displayed finite list of dyadic centers, rational radii, rational interval cells,* $\mathsf{DyadicMesh}^{\uparrow}$ *refinement rows,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *coverage witnesses, and the* Cont *routes that read* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *data into those cells. The handoff is a finite packet handoff, not an appeal to open-cover compactness.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket total bounded handoff export`
Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket total bounded handoff`

Proof. Project the carrier and choose a consumer route. The only data addressed to total-bounded consumers are the finite center list, radius list, interval-cell list, mesh refinement rows, and coverage witnesses over the displayed window.

Follow the real-data read route. A covered point is read through its $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows into a $\mathsf{Real}^{\uparrow}$ row, then into the named rational interval or rational ball cell supplied by the coverage witness.

Thus the consumer receives exactly a finite cover packet with explicit mesh and radius data. Since the carrier contains no arbitrary indexed open family, no compactness principle and no choice of subcover can be projected from it. □

Theorem 446.5 (DyadicCover total-bounded bridge)**.** *An accepted* $\mathsf{DyadicCover}^{\uparrow}$ *packet over finite dyadic centers, rational radii, rational interval cells, mesh refinement rows, and* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *coverage witnesses supplies exactly the finite center-radius witness surface required by a* $\mathsf{TotallyBounded}^{\uparrow}$ *consumer. The bridge exports the listed centers, radii, cells, window incidences, refinement rows,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row, and exports no arbitrary open family or subcover selector.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket total bounded bridge`

Proof. Begin with the total-bounded handoff. It identifies the consumer-facing data as the finite center list, radius list, interval-cell list, mesh refinement rows, finite-window coverage witnesses, and real-data read routes.

Apply window-cell incidence. Each point covered inside the displayed window is attached to one listed center, one rational radius, one rational interval cell, and the corresponding stream, regular-rational, and real read route.

Use refinement witness exhaustion to account for later mesh rows. Every refined witness is consumed by finite replacement along the displayed refinement rows, and ledger non-escape prevents the bridge from exporting an open-cover compactness principle or a selected subcover. □

Theorem 446.6 (DyadicCover finite-window total-bounded correspondence)**.** *For an accepted* $\mathsf{DyadicCover}^{\uparrow}$ *packet, the finite-window incidence rows and the* $\mathsf{TotallyBounded}^{\uparrow}$ *center-radius rows*

determine the same consumer-visible cover package. A consumer may read the package through FiniteWindowEnvelope$^{\uparrow}$ *cells or through finite center-radius rows, but both routes use the same dyadic centers, rational radii, interval cells, mesh refinement rows, coverage witnesses, transports, continuation routes, provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket finite window total bounded correspondence`

Proof. Read the finite-window side first. Window-cell incidence assigns every covered point in the displayed window to one named center, radius, interval cell, and real-data route.

Read the total-bounded side next. The total-bounded bridge presents the same listed centers and radii as the finite witness surface required by the consumer, with the same interval cells and mesh rows.

Finally compare the two routes through refinement witness exhaustion and ledger non-escape. Refinement changes only the displayed finite cells along named mesh rows, and no route introduces an arbitrary open family, subcover selector, quotient real equality, or ambient compactness theorem. □

Theorem 446.7 (DyadicCover ledger nonescape)**.** *Every* Real$^{\uparrow}$, FiniteWindowEnvelope$^{\uparrow}$, *total-bounded, or completion consumer of an accepted* DyadicCover$^{\uparrow}$ *carrier factors through the displayed finite dyadic centers, dyadic radii, rational interval cells, mesh refinement rows, coverage witnesses,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

No consumer can obtain open-cover compactness, a choice function for arbitrary covers, a completeness theorem, a quotient of names, or host-level real extensionality from the DyadicCover$^{\uparrow}$ *ledger alone.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket ledger nonescape`

Proof. Use the obligation surface of Definition 446.2. It lists the carrier, classifier, refinement stability, coverage exactness, and ledger rows available to every local certificate consumer.

For a Real$^{\uparrow}$ or FiniteWindowEnvelope$^{\uparrow}$ consumer, read the stream, regular-rational, real, and finite-window rows that are already displayed in the carrier. For a total-bounded or completion consumer, read the finite center and radius lists together with the mesh refinement and coverage routes.

All of these routes stay inside the finite BHist packet. The excluded conclusions require coordinates not present in Definition 446.1, so they cannot escape from the local ledger. □

Theorem 446.8 (DyadicCover window-cell incidence)**.** *Let* $D = (K, R, I, Q, W, H, C, P, N)$ *be an accepted* DyadicCover$^{\uparrow}$ *carrier, where* K *is the finite dyadic center list,* R *is the finite rational-radius list,* I *is the finite rational-interval cell list,* Q *records the named real-data rows, and* W *is the displayed finite-window coordinate. Every point covered inside* W *by the accepted packet factors through one listed dyadic center, one rational radius, one rational interval cell, one* StreamName$^{\uparrow}$ *row, one* RegSeqRat$^{\uparrow}$ *row, one* Real$^{\uparrow}$ *row, and the displayed* Cont *route from the corresponding stream and regular-rational name into that real and cell incidence record.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket window cell incidence`

Proof. Project the tuple $D = (K, R, I, Q, W, H, C, P, N)$. The coverage coordinate of the carrier is indexed by the displayed finite window W, so a covered point comes with a coverage witness rather than with an arbitrary open-family membership assertion.

Read that witness through the carrier definition. It names a dyadic center from K, a rational radius from R, and a rational interval cell from I, and it also names the stream, regular-rational, and real rows in Q used to place the point in the cell.

Finally follow the stored Cont route. The route is part of the accepted packet, so the incidence surface consumed downstream is exactly the finite window-cell record listed in the carrier. □

Theorem 446.9 (DyadicCover refinement witness exhaustion)**.** *Every later mesh-refinement witness for an accepted* DyadicCover$^{\uparrow}$ *packet is exhausted by finitely replacing old listed cells by named dyadic subcells whose center, radius, interval,* hsame, Cont, Pkg, *and* NameCert *rows are already recorded in the packet ledger. Such a witness cannot introduce an arbitrary open family, an external indexed cover, or a selector for subcovers.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket refinement witness exhaustion`

Proof. Start with Definition 446.3. It decomposes a mesh refinement into finite replacement of the old rational interval cells by named subcells, preserving the displayed finite-window coordinate and the local read routes.

Use Definition 446.7 on the refined packet. The ledger exposes only the finite center, radius, interval, mesh, coverage, hsame, Cont, Pkg, and NameCert rows recorded in the carrier.

Therefore the refinement witness is exhausted by those finite replacements. The excluded open-family and subcover-selector data have no coordinate in the accepted packet and cannot be projected from the ledger. □

Theorem 446.10 (DyadicCover total-bounded radius ledger)**.** *Every total-bounded consumer of an accepted* DyadicCover$^{\uparrow}$ *packet reads exactly the finite center list, rational-radius list, rational-interval list, mesh-refinement rows, and finite-window coverage witnesses displayed by the carrier, with the radius data routed through the corresponding* RationalBall$^{\uparrow}$ *rows before the consumer receives a bounded-radius cover packet.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket total bounded radius ledger`

Proof. Use Definition 446.4. It identifies the consumer-facing data as the finite center list, rational radii, interval cells, mesh-refinement rows, coverage witnesses, and read routes into the real and finite-window coordinates.

Then apply Definition 446.7 to the same packet. The radius coordinates available to the consumer are the displayed rational-radius rows and their RationalBall$^{\uparrow}$ routing; no external metric ball family or choice of cover can be read from the ledger.

Thus the total-bounded handoff is a bounded-radius ledger over the listed finite rows, not a compactness principle or a host-level open-cover argument. □

Theorem 446.11 (DyadicCover finite-window obligation triad)**.** *For every accepted* DyadicCover$^{\uparrow}$ *packet*

$$D = (K, R, I, Q, W, H, C, P, N),$$

the finite dyadic center-radius rows (K, R)*, the mesh-refinement row* Q*, and the* FiniteWindowEnvelope$^{\uparrow}$ *coverage row* W *jointly form the finite-window obligation surface. This surface includes the routed* RationalInterval$^{\uparrow}$ *and* RationalBall$^{\uparrow}$ *cell rows, the* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *consumer reads, the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows, and no arbitrary open-cover family, subcover selector, metric-completeness claim, or quotient equality of names.*

Proof. Project the packet through Definition 446.1. The center list K, radius list R, interval-cell list I, mesh row Q, and finite-window row W are the only coordinates from which coverage data can be read.

Apply Definition 446.2 to bind the local certificate rows and Definition 446.8 to bind each finite-window point to one displayed center, radius, interval cell, stream-name row, regular-rational row, real row, and continuation route.

Finally use Definition 446.7. It exhausts consumer access by the displayed finite carrier rows, so the center-radius data, mesh row, and finite-window coverage row form exactly the obligation triad named in the statement. □

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket finite window obligation triad`

Theorem 446.12 (DyadicCover mesh-refinement carrier transport)**.** *Let $D = (K, R, I, Q, W, H, C, P, N)$ be an accepted* $\mathsf{DyadicCover}^{\uparrow}$ *carrier, and let Q' be a displayed later* $\mathsf{DyadicMesh}^{\uparrow}$ *refinement row of Q. Transporting D along Q' through the stored* hsame *and* Cont *rows preserves the finite center list, rational-radius list, interval-cell ledger, finite-window coverage witnesses, package provenance, and local* NameCert *row as one accepted carrier surface. The transported packet is a mesh refinement of the same finite-window cover, not a cover chosen from an arbitrary host family.*

Proof. Begin with Definition 446.3. It replaces each old cell by a finite named list of dyadic subcells routed by Q', while retaining the same finite-window coordinate W and local read routes.

Next apply Definition 446.9. The refinement witness is exhausted by the displayed center, radius, interval, hsame, Cont, Pkg, and NameCert rows, so transport has no route to an external indexed cover.

The incidence and radius rows remain attached to the transported cells by Definition 446.8 and Definition 446.10. Repacking these rows gives the transported carrier surface and preserves the stated non-escape boundary. □

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket mesh refinement carrier transport`

Theorem 446.13 (DyadicCover finite-window envelope factorization)**.** *Every* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *total-bounded, or completion-facing read of an accepted* $\mathsf{DyadicCover}^{\uparrow}$ *packet factors through the finite-window route*

$$W \longmapsto Q \longmapsto I \longmapsto (K, R) \longmapsto H, C, P, N.$$

The route first fixes the displayed envelope window, then reads the dyadic mesh and refinement rows, then chooses one listed rational interval or rational ball cell with its dyadic center and radius, and finally transports the read through the recorded BEDC provenance. It does not assert open-cover compactness, ambient completeness, quotient equality of real names, or a host-level subcover choice.

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket finite window envelope factorization`

Proof. Start from a finite-window or real-facing consumer read. By Definition 446.8, any point inside W is read through one displayed stream-name row, regular-rational row, real row, and one listed interval or ball cell.

Apply Definition 446.12. Mesh transport keeps that cell inside the same carrier surface after finite refinement, and Definition 446.9 exhausts the witness by the listed finite rows.

Finally attach the total-bounded side through Definition 446.4 and Definition 446.10. These rows factor bounded-cover consumers through the same centers, radii, interval cells, mesh, window, transport, package, and naming rows. The finite-window envelope route therefore accounts for every listed consumer without any excluded host principle. □

Theorem 446.14 (DyadicCover finite-window mesh incidence package)**.** *Let*

$$D = (K, R, I, Q, W, H, C, P, N)$$

be an accepted DyadicCover$^{\uparrow}$ *packet. Every accepted coverage request for a point in the displayed finite window factors through exactly one listed dyadic center in K, one rational radius in R, one rational interval cell in I, one mesh row in Q, one* StreamName$^{\uparrow}$ *row, one* RegSeqRat$^{\uparrow}$ *row, one* Real$^{\uparrow}$ *row, and the displayed* Cont *route that relates those rows inside the local* BHist*,* Pkg*, and* NameCert *ledger.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket finite window mesh incidence package`

Proof. First unpack the packet with Definition 446.2. This fixes the carrier coordinates, the local classifier, and the named transport and read routes available to a coverage consumer.

Next use Definition 446.8. The covered point is read from the finite-window coordinate W, so its incidence witness is one listed center, radius, interval cell, stream-name row, regular-rational row, real row, and continuation route.

Finally apply Definition 446.7. Since the ledger has no coordinate for an external cover or selector, the displayed incidence witness is the whole consumer-facing package for the finite window and mesh surface. □

Theorem 446.15 (DyadicCover refined-window total-bounded package)**.** *Every mesh-refined total-bounded consumer of an accepted* DyadicCover$^{\uparrow}$ *packet receives only the refined finite dyadic center list, rational radius list, rational interval cell list, and the transported finite-window coverage witnesses already carried by the packet. The consumer receives these rows through the same* hsame*,* Cont*,* Pkg*, and* NameCert *provenance, and it receives no open-cover compactness principle, arbitrary subcover choice, or external metric-ball family.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket refined window total bounded package`

Proof. Start with Definition 446.3. It replaces cells by a finite list of named dyadic subcells and transports the finite-window witnesses along the displayed mesh refinement row.

Then use Definition 446.9. This exhausts the refined witness by the packet's center, radius, cell, transport, continuation, package, and naming rows, so no new cover family appears during refinement.

Attach the total-bounded read by Definition 446.4 and Definition 446.10. The bounded-radius consumer therefore sees the transported finite window package and the refined finite lists, with the non-escape boundary supplied by Definition 446.7. □

Theorem 446.16 (DyadicCover Real envelope coverage exactness)**.** *Every* Real$^{\uparrow}$ *or* FiniteWindowEnvelope$^{\uparrow}$ *coverage consumer of an accepted* DyadicCover$^{\uparrow}$ *packet factors through the same finite envelope rows: the displayed finite window, mesh-refined rational interval cells, dyadic centers, rational radii, stream-name rows, regular-rational rows, real rows,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *certificate. Such a consumer cannot read open-cover compactness, arbitrary subcover choice, quotient real equality, or host real extensionality from the packet.*

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket real envelope coverage exactness`

Proof. Begin with the finite-window incidence package from Definition 446.14. It gives the unique listed center, radius, interval cell, mesh row, stream row, regular-rational row, real row, and continuation route for each accepted coverage request.

Now transport along refinements using Definition 446.15. The refined packet keeps the same finite envelope surface and presents only transported finite-window witnesses to downstream coverage consumers.

Finally combine Definition 446.4 with Definition 446.7. These theorems bind the Real-facing and finite-envelope reads to the displayed rows and exclude compactness, arbitrary subcovers, quotient equality of reals, and host real extensionality. □

Theorem 446.17 (DyadicCover finite-subcover exhaustion)**.** *Any downstream total-bounded or Real-envelope consumer of an accepted* DyadicCover$^{\uparrow}$ *packet can only read the displayed finite center list, dyadic radius rows, rational interval cells, mesh-refinement rows, finite-window envelope,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. In particular, the consumer receives a finite subcover already present in the packet and cannot replace it by an ambient open-cover family, an arbitrary subcover choice, quotient equality of real names, or host real extensionality.*

Proof. First apply finite refinement. The displayed center, radius, interval, and mesh rows are refined only by the finite dyadic subcells recorded in the packet, so every downstream cover read starts from the same finite list.

Next use refinement witness exhaustion. It identifies each refined witness with the packet's own center, radius, cell, transport, continuation, package, and naming rows, leaving no independent cover-family coordinate.

Now attach the refined-window total-bounded package. The total-bounded consumer therefore receives the transported finite window and the same bounded-radius ledger rather than a separate compactness principle.

Finally use Real envelope coverage exactness. It repacks the finite-window and total-bounded rows for Real$^{\uparrow}$ and FiniteWindowEnvelope$^{\uparrow}$ consumers, so the displayed finite subcover exhausts the exported coverage surface. □

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket finite subcover exhaustion`

Theorem 446.18 (DyadicCover scoped package)**.** *The local obligation surface of* DyadicCover$^{\uparrow}$ *assembles into a scoped package over* DyadicRatCore$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*,* RationalInterval$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* FiniteWindowEnvelope$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The scope is exactly the carrier, naming, finite-window triad, mesh transport, finite-window envelope factorization, refined total-bounded handoff, and Real envelope exactness supplied by Definition 446.2, Definition 446.11, Definition 446.12, Definition 446.13, Definition 446.15, and Definition 446.16.*

Proof. First project an accepted DyadicCover$^{\uparrow}$ packet to its displayed carrier coordinates. The NameCert obligation theorem fixes the finite center, radius, interval, mesh, finite-window, history, continuation, package, and name rows that may be read from the packet.

Next apply the finite-window obligation triad and mesh-refinement carrier transport theorems. They bind the finite window to the dyadic mesh and carry the same rows across displayed refinements, so the scoped package has one transport surface rather than separate host-side choices.

Now use finite-window envelope factorization and the refined-window total-bounded package. These results route every finite-window, total-bounded, and completion-facing read through the packet's own center, radius, interval, mesh, envelope, hsame, Cont, Pkg, and NameCert rows.

Finally the Real envelope coverage exactness theorem repacks the same finite packet for Real$^{\uparrow}$ and FiniteWindowEnvelope$^{\uparrow}$ consumers. The assembled package is therefore scoped to the listed

BEDC objects, with no open-cover compactness, arbitrary subcover choice, quotient equality of names, or host real extensionality added. □

Theorem 446.19 (DyadicCover public total-bounded export)**.** *Every public total-bounded or Real-envelope consumer of an accepted* $\mathsf{DyadicCover}^{\uparrow}$ *packet receives exactly the finite center list, rational radius list, interval cells, mesh refinement rows, finite-window envelope coverage,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row assembled in Definition 446.18. The export factors through Definition 446.13, Definition 446.15, and Definition 446.16; it exports no open-cover compactness, arbitrary subcover choice, metric completeness, quotient equality of names, or host real extensionality.*

Proof. Start with Definition 446.18. It assembles the carrier, naming, mesh, finite-window envelope, refined total-bounded, and Real envelope rows into one scoped package.

Apply Definition 446.13. This identifies the coverage surface as the displayed finite envelope over the packet's own center list, radius list, interval cells, mesh rows, transports, routes, package provenance, and local name row.

Next use Definition 446.15. A total-bounded consumer therefore reads only the refined finite window and the same bounded-radius ledger, not an arbitrary subcover selection.

Finally apply Definition 446.16. It repacks those same finite coverage rows for Real-envelope consumers, so the public export carries no open-cover compactness, metric completeness, quotient equality of names, or host real extensionality. □

Theorem 446.20 (DyadicCover finite-cover consumer determinacy)**.** *For an accepted* $\mathsf{DyadicCover}^{\uparrow}$ *packet*

$$D = (K, R, I, Q, W, H, C, P, N),$$

any $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, *or completion-facing consumer that reads the cover factors through the same finite center list* K*, rational radius list* R*, interval-cell list* I*, mesh refinement rows* Q*, finite-window witnesses* W*, componentwise transports* H*, continuation routes* C*, package provenance* P*, and local name* N*. If two consumer routes expose the same displayed packet rows, then they expose the same consumer-visible cover package.*

The packet supplies no open-cover compactness, arbitrary subcover choice, metric completeness, quotient equality of real names, or host real extensionality as an alternate cover source.

Lean4 ✓ `BEDC.Derived.DyadicCoverUp.DyadicCoverPacket finite cover consumer determinacy`

Proof. Project the accepted packet and apply the NameCert obligations. The finite center list, rational radius list, interval-cell list, mesh rows, finite-window witnesses, transports, routes, provenance, and local name are the complete cover surface.

Use finite refinement, total-bounded handoff, and window-cell incidence. These rows bind the cover to the displayed mesh and cells, so a consumer cannot replace the packet by an arbitrary open cover or an external subcover choice.

Next apply the refined-window total-bounded package, Real envelope coverage exactness, and finite-subcover exhaustion. They route total-bounded, Real-envelope, and completion-facing reads through the same finite window and bounded-radius ledger.

Finally combine the scoped package with the public total-bounded export. The consumer-visible cover package is therefore determined by $K, R, I, Q, W, H, C, P, N$, and two routes exposing those rows expose the same public cover package. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCover}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicCover}^{\uparrow}$ packet is generated from finite dyadic centers, dyadic radii, rational interval cells, mesh refinement rows, coverage witnesses for a displayed finite window, hsame transports, Cont read routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCover}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature consumer package is the finite carrier, naming, mesh transport, finite-window envelope, refined total-bounded, Real envelope package, Definition 446.5, the checked total-bounded handoff export of Definition 446.19, and the finite-cover consumer determinacy theorem of Definition 446.20 over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, arbitrary subcover choice, metric completeness, compact-metric equivalence, quotient equality of real names, host real extensionality, or bridge checking.

Upgrade path: No further paper closure grade remains; Lean verification and bridge checking remain pending.

Chapter 447

A Concrete Naming Certificate for $\mathsf{CollisionKernelSpectrum}^{\uparrow}$

The $\mathsf{CollisionKernelSpectrum}^{\uparrow}$ packet is a BEDC-native finite certificate surface. It records a finite golden-mean fold moment ledger with a collision-kernel matrix and a spectral-shadow row, linking the finite-window surfaces of $\mathsf{GoldenMeanShift}^{\uparrow}$, $\mathsf{FibonacciCube}^{\uparrow}$, and $\mathsf{FoldMomentKernel}^{\uparrow}$ without importing external linear algebra or an ambient spectral theorem.

The packet consumes the finite sampling grid of chapter 451 and the finite transfer-row handoff of chapter 456: finite sampling supplies the visible phase window and aliasing rows, while the transfer-operator packet supplies the route by which those finite rows become the collision-kernel spectral shadow.

The fold-source row F is read as the finite path surface supplied by chapter 401, so the collision-kernel matrix extends that sibling carrier rather than introducing an isolated spectral packet.

Definition 447.1 (Collision kernel spectrum carrier)**.** *A* $\mathsf{CollisionKernelSpectrum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (G, F, V, I, K, S, H, T, P, N)$$

with the following visible coordinates:

1. *G is the finite golden-mean window row, displaying binary words accepted by the* $\mathsf{GoldenMeanShift}^{\uparrow}$ *no-adjacent-one ledger;*
2. *F is the fold-source row, recording the corresponding* $\mathsf{FibonacciCube}^{\uparrow}$ *finite path row and the fold map into visible fibers;*
3. *V is the visible fiber-multiplicity row, listing the finite fibers and their displayed cardinal ledgers;*
4. *I is the finite moment-index row used by* $\mathsf{FoldMomentKernel}^{\uparrow}$ *to read the selected fold moments;*
5. *K is the collision-kernel matrix row whose entries count displayed pair collisions between fiber rows inside the finite window;*
6. *S is the spectral-shadow row, a finite ledger of row sums, diagonal weights, and moment shadows read from K;*
7. *H is the adjacency-moment handoff row from the golden-mean and Fibonacci-cube ledgers to the fold-moment rows;*
8. *T stores the componentwise* hsame *and* Cont *routes for G, F, V, I, K, S, H;*

9. *P is the* Pkg *provenance naming* GoldenMeanShift$^{\uparrow}$, FibonacciCube$^{\uparrow}$, FoldMomentKernel$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *source rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CollisionKernelSpectrum}^{\uparrow}}$ *provenance row.*

The classifier compares two carriers only by the displayed finite rows $G, F, V, I, K, S, H, T, P, N$. No coordinate contains an infinite spectrum, an external matrix space, a Perron eigenvector, or an imported external object.

Theorem 447.2 (Collision kernel spectrum NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CollisionKernelSpectrum}^{\uparrow}}$ *surface consists of five obligations:*

1. *carrier admission for the finite packet of Definition 447.1;*

2. *classifier laws by componentwise* hsame *on golden-mean windows, fold-source rows, fiber multiplicities, moment indices, kernel entries, spectral shadows, handoff rows, transports, package provenance, and the local certificate row;*

3. *finite-window kernel exactness: every entry of K is read from displayed collisions between rows of V over the finite G, F, I ledger;*

4. *spectral-shadow exactness: every row of S is a finite row-sum, diagonal, or selected moment shadow of K;*

5. *non-escape: accepted carriers export no infinite spectrum, no host linear algebra, no choice of eigenbasis, and no external import.*

Lean4 ✓ `BEDC.Derived.CollisionKernelSpectrumUp.CollisionKernelSpectrumCarrier namecert obligations`

Proof. Carrier admission is the displayed tuple $C = (G, F, V, I, K, S, H, T, P, N)$. Each coordinate is a finite BHist row or a finite route between such rows.

For the classifier laws, compare the coordinates componentwise after the stored hsame and Cont routes. The local certificate row has no access to any datum beyond $G, F, V, I, K, S, H, T, P, N$, so reflexive, symmetric, and transitive reads are inherited coordinate by coordinate.

Kernel exactness is finite ledger inspection. A matrix entry of K is accepted only when the relevant pair of visible fiber rows in V is displayed over the same golden-mean window, fold-source row, and moment-index row.

Spectral-shadow exactness then projects S. Its row sums, diagonal weights, and selected moment shadows are computed from the displayed entries of K and the same handoff row H.

Non-escape follows from the carrier definition. Since no coordinate names an infinite spectrum, host matrix space, chosen eigenbasis, or external artifact, a downstream NameCert consumer can cite only the finite rows and their recorded routes. □

Theorem 447.3 (Collision kernel spectrum finite-window spectral shadow)**.** *For every accepted* CollisionKernelSpectrum$^{\uparrow}$ *carrier, the spectral-shadow row S is determined by the finite golden-mean window G, the fold-source row F, the visible fiber-multiplicity row V, the moment-index row I, and the collision-kernel matrix row K. Two accepted carriers with matching G, F, V, I, K rows therefore have matching spectral-shadow rows after the displayed* hsame *and* Cont *routes.*

Lean4 ✓ `BEDC.Derived.CollisionKernelSpectrumUp.CollisionKernelSpectrumCarrier finite window spectral shadow`

Proof. Project the carrier and read S through the spectral-shadow exactness obligation. Each row of S is a row-sum, diagonal weight, or selected moment shadow of the displayed kernel entries in K.

The kernel entries are themselves read from finite collisions between fiber rows in V over the same golden-mean window G, fold-source row F, and moment-index row I. Thus matching G, F, V, I, K rows transport the same finite calculations.

The stored routes in T and the provenance in P, N carry these componentwise readings between accepted packets. No external spectral theorem is needed because the shadow is only the finite ledger projected from K. □

Theorem 447.4 (Collision kernel spectrum ledger non-escape)**.** *Every exported route from an accepted* CollisionKernelSpectrum$^{\uparrow}$ *packet factors through the finite golden-mean window row, fold-source row, fiber-multiplicity row, moment-index row, collision-kernel matrix row, spectral-shadow row, adjacency-moment handoff row, componentwise transport row, package provenance, and local* NameCert *row. The packet exports no infinite shift space, no ambient graph theory, no host spectral measure, no selected eigenvector, and no external theorem.*

Lean4 ✓ `BEDC.Derived.CollisionKernelSpectrumUp.CollisionKernelSpectrumCarrier ledger non escape`

Proof. Take an exported consumer route and project the carrier of Definition 447.1. The only coordinates available are $G, F, V, I, K, S, H, T, P, N$.

The NameCert obligations account for carrier formation, classifier transport, finite-window kernel exactness, spectral-shadow exactness, and non-escape. Each of these obligations refers to a displayed finite row of the same packet.

Therefore every export factors through the listed finite coordinates. Since the carrier definition has no further coordinate, it cannot supply an infinite shift object, ambient graph theorem, host spectral measure, selected eigenvector, or imported external result. □

Theorem 447.5 (Collision kernel spectrum adjacency-moment handoff)**.** *The handoff row H sends each accepted golden-mean adjacency ledger in G through the finite* FibonacciCube$^{\uparrow}$ *fold-source row F to the moment-index rows used by* FoldMomentKernel$^{\uparrow}$*. Consequently every collision-kernel entry in K is indexed by a displayed finite adjacency path, a visible fiber row, and a finite moment index from the same carrier.*

Proof. Project H from the carrier. Its source is the golden-mean no-adjacent-one ledger G, and its intermediate row is the finite Fibonacci-cube fold source F.

The visible fiber row V records which fold fibers are present over that source, while I records the finite moments read by FoldMomentKernel$^{\uparrow}$. The handoff row ties these three displays to the same finite window.

Thus an entry of K cannot be indexed independently of the adjacency and moment ledgers. It is accepted only as a collision count between displayed fibers over G, F, V, I, transported by T and recorded by P, N. □

Lean4 ✓ `BEDC.Derived.CollisionKernelSpectrumUp.CollisionKernelSpectrumCarrier adjacency moment handoff`

Theorem 447.6 (Collision kernel spectrum window restriction)**.** *Let $C = (G, F, V, I, K, S, H, T, P, N)$ be an accepted* CollisionKernelSpectrum$^{\uparrow}$ *carrier, and let G' be a displayed golden-mean finite window obtained by restricting G to a smaller no-adjacent-one row already visible through the G, F, V, I*

ledger. The restricted packet formed by projecting F, V, I, K, S to that smaller window is again accepted, and its kernel entries and spectral-shadow rows are exactly the corresponding displayed rows of the original packet.

Proof. Project the accepted carrier through Definition 447.1. The finite-window data are displayed in G, while F, V, I record the fold-source, visible fibers, and moment indices read over that window.

Restricting to G' deletes no external datum; it only selects already displayed rows from G, F, V, I. The collision entries in K over the smaller window are therefore the same finite pair-collision rows, read after the same componentwise transport through T.

The spectral-shadow row S is a ledger of row sums, diagonal weights, and moment shadows of K. Projecting S along the restricted kernel rows preserves exactly those displayed finite calculations, with provenance still recorded by P, N. □

Lean4 ✓ `BEDC.Derived.CollisionKernelSpectrumUp.CollisionKernelSpectrumCarrier window restriction`

Theorem 447.7 (Collision kernel spectrum fiber-row symmetry)**.** *In an accepted* $\mathsf{CollisionKernelSpectrum}^{\uparrow}$ *carrier, the collision count attached to two displayed visible fiber rows is unchanged when the two fiber rows are exchanged, provided the same finite golden-mean window, fold-source row, and moment-index row are retained. The transported entry remains a row of the same collision-kernel matrix K and feeds the same spectral-shadow index in S.*

Proof. Read the relevant kernel entry from K. By the NameCert obligations, such an entry is accepted only as a finite collision count between two displayed fiber rows in V over the same G, F, I ledger.

Swapping the two visible fiber rows changes only the order in which the finite pair is inspected. The componentwise hsame and Cont routes in T carry the exchanged pair back to the same finite carrier surface.

The moment index is not changed by this exchange. Hence the resulting count is the same displayed kernel row, and the spectral-shadow row S reads it at the same finite moment index. □

Theorem 447.8 (Collision kernel spectrum moment-index projection)**.** *Every exported spectral-shadow row of an accepted* $\mathsf{CollisionKernelSpectrum}^{\uparrow}$ *carrier factors through a finite moment-index row I. In particular, the export can mention only the displayed rows $G, F, V, I, K, S, H, T, P, N$ and cannot cite an infinite spectrum, a host matrix space, an eigenbasis, or ambient linear algebra.*

Proof. Start from an exported spectral-shadow route and project the carrier. The only spectral-shadow coordinate is S, and each row of S is displayed as a row sum, diagonal weight, or selected moment shadow of entries in K.

The entries of K are indexed over the same finite ledger G, F, V, I. The moment information available to the export is therefore precisely the finite row I, transported through T and recorded with the handoff and provenance rows H, P, N.

No carrier coordinate names an infinite spectrum, a host matrix space, an eigenbasis, or ambient linear algebra. Thus every exported spectral-shadow row factors through I and the listed finite packet rows. □

Lean4 ✓ `BEDC.Derived.CollisionKernelSpectrumUp.CollisionKernelSpectrumCarrier moment index projection`

Theorem 447.9 (Collision kernel spectrum kernel-entry source lock)**.** *Every collision-kernel entry displayed in the row K of an accepted* $\mathsf{CollisionKernelSpectrum}^{\uparrow}$ *carrier is sourced only from the*

golden-mean window G, the FibonacciCube$^{\uparrow}$ *fold-source row F, the visible fiber row V, the moment-index row I, and the componentwise* hsame *and* Cont *routes recorded in T. No entry of K can be read from an infinite shift space, an ambient graph adjacency object, a host matrix entry, an outside theorem, or an external formalization object outside the displayed packet.*

Proof. Project the carrier $C = (G, F, V, I, K, S, H, T, P, N)$ and focus on one displayed entry of K. By Definition 447.5, the entry is indexed by a finite adjacency path, a visible fiber row, and a finite moment index from the same carrier.

The golden-mean window and the fold-source row supply the allowed source coordinates. The visible fiber row supplies the two finite rows being compared, and the moment-index row supplies the selected read position.

The only transport allowed between these coordinates is the componentwise hsame and Cont data stored in T. Since the carrier has no further coordinate for an infinite shift space, host matrix entry, ambient adjacency theorem, outside theorem object, or external formalization object, every accepted kernel entry is locked to the displayed finite source rows. □

Theorem 447.10 (Collision kernel spectrum shadow classifier stability)**.** *If two accepted* CollisionKernelSpectrum$^{\uparrow}$ *carriers are classified equal by the displayed componentwise classifier on $G, F, V, I, K, H, T, P, N$, then their spectral-shadow rows S match after the same finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *routes. The classifier therefore transports spectral-shadow rows without invoking a host spectral measure, selected eigenvector, or ambient spectral theorem.*

Proof. Begin with the componentwise classifier. It identifies the visible finite rows $G, F, V, I, K, H, T, P, N$ through the stored hsame and Cont routes and records the same package provenance and local naming rows.

Apply Definition 447.3. The row S is determined by the finite rows G, F, V, I, K, so matching those rows forces the same row sums, diagonal weights, and selected moment shadows.

The remaining coordinates H, T, P, N carry the handoff, transport, package, and local certificate data needed to read this equality as a BHist route. Thus spectral-shadow stability is a finite classifier fact and has no dependency on host spectral structure. □

Theorem 447.11 (Collision kernel spectrum downstream readback package)**.** *Every downstream consumer of an accepted* CollisionKernelSpectrum$^{\uparrow}$ *spectrum packet factors through the finite tuple*

$$(G, F, V, I, K, S, H, T, P, N).$$

Such a consumer can read the displayed golden-mean window, fold-source row, fiber row, moment-index row, kernel row, spectral-shadow row, adjacency-moment handoff, componentwise transport, package provenance, and local naming row, but cannot read an infinite shift space, host spectral measure, selected eigenvector, host linear-algebra object, outside theorem object, or external formalization object.

Proof. First apply Definition 447.4. Every exported route from the packet already factors through the listed finite coordinates.

Next apply Definition 447.9. Any consumer that reads K can only recover entries sourced from G, F, V, I and transported through T.

Finally apply Definition 447.5. The adjacency, fold, and moment reads are tied to the same carrier, while S, H, P, N record the finite shadow, handoff, package, and naming rows. Since none of these coordinates contains an infinite shift space, host spectral measure, selected eigenvector, host linear-algebra object, outside or imported theorem object, or external formalization object, the downstream readback package is exactly the displayed tuple. □

Closure status for $\mathsf{NameCert}_{\mathsf{CollisionKernelSpectrum}^{\uparrow}}$.

Constructive story: A $\mathsf{CollisionKernelSpectrum}^{\uparrow}$ packet is generated from finite golden-mean windows, Fibonacci-cube fold-source rows, visible fiber multiplicities, finite moment indices, collision-kernel matrix rows, spectral shadows, handoff rows, componentwise transports, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CollisionKernelSpectrum}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: The scoped surface records the finite carrier, local NameCert obligations, finite-window spectral shadow, ledger non-escape, adjacency-moment handoff, smaller-window restriction, fiber-row symmetry, moment-index projection, source lock, classifier stability, and downstream readback rows for collision-kernel spectrum packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CollisionKernelSpectrum}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CollisionKernelSpectrumUp.CollisionKernelSpectrumCarrier\_namecert\_obligations`

Bridge status: none

Origin: human

Not claimed: This chapter does not close infinite spectra, host linear algebra, Perron eigenvectors, spectral measures, external imports, or a standard bridge.

Upgrade path: Public closure requires a single exported $\mathsf{CollisionKernelSpectrum}^{\uparrow}$ public certificate over the scoped spectrum packet.

Chapter 448

A Concrete Naming Certificate for $\mathsf{CauchyOscillation}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the Cauchy oscillation criterion is read here as a finite tail-window object: a real-facing consumer may inspect named rational observations, an explicit modulus schedule, dyadic tolerances, and a displayed ledger of tail comparisons, but it never receives a quotient stream, a chosen limit, host real equality, or an ambient completeness principle. The $\mathsf{CauchyOscillation}^{\uparrow}$ packet is the finite oscillation surface consumed by $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, and later $\mathsf{Real}^{\uparrow}$ completion certificates.

The $\mathsf{CauchyOscillation}^{\uparrow}$ packet is the single-tail finite-window sibling of $\mathsf{UniformCauchyCriterion}^{\uparrow}$. Its window, modulus, dyadic tolerance, and oscillation ledger rows are consumed by the finite-family route of chapter 435 before any $\mathsf{Real}^{\uparrow}$ seal can be read.

The oscillation packet consumes the $\mathsf{RegSeqRat}^{\uparrow}$ core of chapter 301, the threshold schedule of chapter 292, and the dyadic-to-Real handoff of chapter 291 and chapter 38.

Its oscillation ledger is therefore consumed through the $\mathsf{RegSeqRat}^{\uparrow}$ route of chapter 301 and the $\mathsf{DyadicTailBound}^{\uparrow}$ dependency before any $\mathsf{Real}^{\uparrow}$ seal consumer inspects the finite tail comparison.

Definition 448.1 (CauchyOscillation carrier)**.** *A* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (W, M, Q, T, S, H, C, P, N)$$

with the following visible rows:

1. *W is a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{StreamName}^{\uparrow}$ *finite tail-window row, displaying the named rational observations available to the consumer;*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold schedule selecting the tail region inspected for each precision request;*
3. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row whose dyadic budget is used by the oscillation test;*
4. *T is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *oscillation ledger comparing all named tail observations beyond the threshold supplied by M under the tolerance supplied by Q;*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after the finite oscillation ledger has been accepted;*
6. *H records the componentwise* hsame *transports for the tail window, modulus schedule, dyadic tolerance, oscillation ledger, seal handoff, package row, and local certificate row;*
7. *C records the displayed* Cont *read routes by which consumers inspect W, M, Q, T, S, H, P, N;*

8. *P is the* Pkg *provenance over* $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyOscillation}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by these displayed rows, their componentwise hsame *transports, their* Cont *read routes, their package provenance, and their local naming rows.*

Lean4 (definition) `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier`

Theorem 448.2 (CauchyOscillation NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyOscillation}^{\uparrow}}$ *surface consists of five obligations:*

1. *carrier habitation: the packet of Definition 448.1 displays a finite tail-window row, a modulus threshold schedule, a dyadic tolerance row, an oscillation ledger, a* $\mathsf{Real}^{\uparrow}$ *seal handoff, transport routes, package provenance, and local naming provenance;*

2. *common tail-window classifier: accepted packets are compared only by componentwise* hsame *and displayed* Cont *routes over $W, M, Q, T, S, H, C, P, N$;*

3. *oscillation-bound exactness: every accepted comparison in T uses the threshold row M, the tolerance row Q, and the finite tail observations in W from the same packet;*

4. *stability under* hsame *and* Cont*: transported carriers preserve the selected tail window, threshold, tolerance, oscillation ledger, and seal handoff as one finite dependency packet;*

5. *ledger non-escape: accepted carriers export no quotient stream, no selected limit, no host real equality, and no ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier namecert obligations`
↪ variant `BEDC.Derived.CauchyOscillationUp.CauchyOscillationPacket semantic name certificate`

Proof. Carrier habitation is the projection of the finite tuple

$$O = (W, M, Q, T, S, H, C, P, N).$$

Each coordinate is a displayed BHist row or a displayed route between such rows, so the packet supplies the advertised tail window, threshold schedule, tolerance row, oscillation ledger, seal handoff, provenance, and local certificate data.

For the common classifier, compare two accepted packets componentwise through the stored hsame rows and replay only the Cont routes recorded in C. Because the classifier has no further coordinate, it can read only $W, M, Q, T, S, H, C, P, N$ and cannot substitute an external tail object.

Oscillation-bound exactness is read from the paired rows M, Q, T together with W. The threshold selected by M determines which tail observations in W are compared, the dyadic budget in Q determines the comparison radius, and the ledger T records exactly those finite comparisons.

Stability follows by transporting the same rows through H and then replaying the same read routes in C. The package row P records the $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ source certificates, while N records the local certificate row.

Finally, the carrier has no coordinate for quotient streams, selected limits, host real equality, or ambient completeness. Repacking the projections therefore gives the five NameCert obligations and the stated non-escape boundary. □

Theorem 448.3 (CauchyOscillation tail-window exposure)**.** *Let*

$$O = (W, M, Q, T, S, H, C, P, N)$$

be an accepted $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier. Every oscillation comparison exposed by* T *must first read the finite tail-window row* W *before it reaches the modulus threshold row* M*, the dyadic tolerance row* Q*, or the downstream* $\mathsf{Real}^{\uparrow}$ *seal row* S*.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier tail window exposure`

Proof. Open the carrier of Definition 448.1. The comparison ledger T is defined as the displayed tail-bound row comparing named observations, and those named observations live in the finite window W.

Apply the NameCert obligations of Definition 448.2. Oscillation-bound exactness ties each accepted comparison in T to the same W, M, Q coordinates of the carrier, while stability under hsame and Cont preserves that dependency under transport and replay.

Finally use the seal-handoff factorization of Definition 448.9. The terminal seal S is available only after the finite prefix W, M, Q, T has been accepted, so no comparison can bypass W by reading the threshold, tolerance, or seal rows alone. □

Theorem 448.4 (CauchyOscillation dyadic tolerance stability)**.** *For an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

componentwise hsame *transport and displayed* Cont *replay preserve the dyadic tolerance row* Q *together with the tail window* W*, the modulus threshold* M*, and the oscillation ledger* T*. A transported consumer therefore reads the same finite dependency packet* W, M, Q, T *before any seal handoff.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationDyadicToleranceStability`

Proof. By Definition 448.1, the transport row H and replay row C are componentwise rows over $W, M, Q, T, S, H, C, P, N$. They do not contain a separate tolerance object or a separate tail ledger.

The NameCert obligations of Definition 448.2 make the dependence exact: stability under hsame and Cont preserves the selected tail window, threshold, tolerance, oscillation ledger, and seal handoff as one finite packet.

The seal-handoff factorization theorem Definition 448.9 then keeps S downstream of W, M, Q, T. Hence any transported read that preserves Q also preserves the associated W, M, and T rows used by that tolerance. □

Theorem 448.5 (CauchyOscillation modulus-threshold exactness)**.** *Every modulus-root consumer of an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier factors through*

$$W, M, Q, T$$

before it reads the $\mathsf{Real}^{\uparrow}$ *seal row* S*. In particular, the threshold row* M *is never read as a free modulus witness: it is paired with the displayed tail window* W*, dyadic tolerance* Q*, and oscillation ledger* T *from the same packet.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier modulus threshold exactness`

Proof. Start with the modulus-root package theorem Definition 448.20. It packages the modulus-facing rows as the finite tail-window surface W, M, Q, T and places the structural rows H, C, P, N around the same packet.

Apply the tail-window exposure theorem Definition 448.3. It forces each comparison governed by the threshold row M to expose the finite window W before threshold, tolerance, ledger, or seal data can be consumed.

Now use dyadic tolerance stability from Definition 448.4. Transport and replay preserve Q only together with W, M, T, so a modulus-root consumer cannot detach the dyadic tolerance from the threshold and ledger rows.

Finally invoke the seal-handoff factorization theorem Definition 448.9. Since S is downstream of the accepted prefix W, M, Q, T, every modulus-root consumer reads those rows before any Real seal is available. □

Theorem 448.6 (CauchyOscillation RegSeqRat handoff)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the row W is exposed as a $\mathsf{StreamName}^{\uparrow}$ *finite tail-window or as the finite tail-window read consumed by* $\mathsf{RegSeqRat}^{\uparrow}$ *before any oscillation comparison in T is read. No consumer may inspect an oscillation comparison until the route through W, the threshold row M, and the dyadic tolerance row Q has displayed the regular-rational tail surface used by the comparison.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier regseqrat handoff`

Proof. Project the accepted carrier through Definition 448.1. The only stream-facing input is W, and the only comparison rows downstream of it are M, Q, T before the seal handoff S.

Apply Definition 448.3. It makes every tail comparison expose W before threshold, tolerance, ledger, or seal data are read, so W cannot be bypassed by a later oscillation consumer.

Use Definition 448.5. The threshold row M is tied to the same W, Q, T packet, which is precisely the finite tail-window route consumed by the regular-rational readback surface.

Finally, Definition 448.2 keeps the carrier, replay, provenance, and naming rows attached to that same route. Hence every oscillation comparison reads the StreamName or RegSeqRat tail-window surface before it reaches T. □

Theorem 448.7 (CauchyOscillation dyadic tail exactness)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier $O = (W, M, Q, T, S, H, C, P, N)$, each row of the oscillation ledger T is exactly the* $\mathsf{DyadicTailBound}^{\uparrow}$ *comparison over the same tail-window row W, modulus-threshold row M, and dyadic tolerance row Q. Componentwise* hsame *transport H and displayed* Cont *replay C preserve this dependence and do not create a second tolerance or tail-window source.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier dyadic tail exactness`

Proof. Begin with the carrier projection of Definition 448.1. The row T is listed only after W, M, Q, so its comparison data are not independent of the displayed tail-window, threshold, and tolerance rows.

Invoke dyadic tolerance stability, Definition 448.4. It states that transport and replay preserve Q together with W, M, T, preventing a transported ledger row from detaching the tolerance from the tail window.

Apply Definition 448.5. Since every modulus-root consumer reads W, M, Q, T before the seal, the threshold and dyadic tolerance used in T are the same rows projected from the accepted carrier.

The NameCert obligations of Definition 448.2 supply the exhaustive ledger clause. Thus every entry of T is the displayed $\mathsf{DyadicTailBound}^{\uparrow}$ comparison over W, M, Q, stable under H and C. □

Theorem 448.8 (CauchyOscillation Real seal nonescape)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier* $O = (W, M, Q, T, S, H, C, P, N)$*, each* $\mathsf{Real}^{\uparrow}$ *seal read* S *factors through* W, M, Q, T *and exports no quotient stream equality, selected limit, countable choice, or ambient completeness principle. The public seal is therefore a routed oscillation-bound handoff, not a detached real-completion object.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier real seal nonescape`

Proof. Project the carrier of Definition 448.1. The row S appears only as the terminal seal after the tail-window row W, threshold row M, dyadic tolerance row Q, and oscillation ledger T.

Apply Definition 448.9. It states that every displayed route to S factors through the finite prefix W, M, Q, T of the same carrier.

Now combine Definition 448.6 and Definition 448.7. The first theorem exposes the StreamName or RegSeqRat tail-window surface before any comparison is consumed, and the second identifies the ledger as the exact DyadicTailBound comparison over that same window, threshold, and tolerance.

Finally use Definition 448.2. Its nonescape clause leaves no row for quotient stream equality, selected limits, countable choice, or ambient completeness. Thus the Real seal read is only the routed handoff through W, M, Q, T. □

Theorem 448.9 (CauchyOscillation seal-handoff factorization)**.** *Let*

$$O = (W, M, Q, T, S, H, C, P, N)$$

be an accepted $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier, and suppose that* S *is the exported* $\mathsf{Real}^{\uparrow}$ *seal handoff of* O*. Every displayed consumer read in* C *whose terminal row is* S *factors through the same finite oscillation surface*

$$(W, M, Q, T)$$

of that packet. More explicitly, such a read has a finite prefix reading the tail-window row W*, the threshold schedule* M*, and the dyadic tolerance row* Q*; it then reads the oscillation ledger* T *whose comparisons are made exactly from those three rows; only after that ledger prefix is accepted may the terminal projection expose* S*. No consumer read of* S *may replace this prefix by a quotient stream, a selected limit, host real equality, an ambient completeness principle, or rows taken from a different* $\mathsf{CauchyOscillation}^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier seal handoff factorization`

Proof. By Definition 448.1, the carrier has exactly the displayed rows

$$W, M, Q, T, S, H, C, P, N.$$

The row S is not an independent real object: it is the $\mathsf{Real}^{\uparrow}$ seal handoff reached only after the finite oscillation ledger has been accepted. Thus any consumer read whose terminal row is S must be one of the displayed Cont routes recorded in C, and its final step is a projection from the accepted packet rather than an external construction of a real.

It remains to identify the prefix that makes the seal available. The ledger row T is specified as the $\mathsf{DyadicTailBound}^{\uparrow}$ oscillation ledger comparing the named tail observations in W beyond the threshold supplied by M under the dyadic tolerance supplied by Q. Hence a read of T cannot be

separated from the same W, M, and Q coordinates of O: the observations, cutoff schedule, and tolerance budget are precisely the data from which the ledger comparisons are recorded.

The NameCert obligations in Definition 448.2 make this dependence stable and exhaustive. Oscillation-bound exactness says that every accepted comparison in T uses the threshold row M, the tolerance row Q, and the finite tail observations in W from the same packet. Stability under hsame and Cont says that transported reads preserve the selected tail window, threshold, tolerance, ledger, and seal handoff as one finite dependency packet. Ledger non-escape says that the accepted carrier exports no quotient stream, selected limit, host real equality, or ambient completeness principle.

Therefore a displayed route to S has no available input other than the accepted packet rows and cannot bypass the accepted ledger. Its terminal seal read factors through the finite prefix W, M, Q, T of the same carrier, with T itself determined by W, M, and Q. This is the asserted handoff factorization. □

Theorem 448.10 (CauchyOscillation root window lock)**.** *Let*

$$O = (W, M, Q, T, S, H, C, P, N)$$

be an accepted $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier consumed by a completion-facing* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or tail-bound reader. Every such consumer must read the finite root package* W, M, Q, T *before it can read the seal row* S*. The read cannot be replaced by a quotient stream, a selected limit, host real equality, or an ambient completeness claim.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier root window lock`

Proof. Start with the carrier definition, Definition 448.1. The rows W, M, Q, T are the only finite source of the tail window, threshold schedule, dyadic tolerance, and oscillation ledger.

Apply tail-window exposure and modulus-threshold exactness, Definition 448.3 and Definition 448.5. They force each completion-facing read to expose W and then to read M and Q as the rows that determine the ledger T.

Finally use the seal-handoff factorization, Definition 448.9. Since S is available only after the accepted prefix W, M, Q, T, the completion-facing reader has no route around the root package and no coordinate for the refused external objects. □

Theorem 448.11 (CauchyOscillation uniform criterion consumer)**.** *Let*

$$O = (W, M, Q, T, S, H, C, P, N)$$

be an accepted $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier consumed by a* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *reader. The reader must expose the finite tail-window row* W*, modulus-threshold row* M*, dyadic tolerance row* Q*, oscillation ledger* T*, transport row* H*, replay row* C*, provenance row* P*, and local name row* N *before it can use the packet as a uniform Cauchy criterion input. It cannot bypass those rows by reading a detached modulus, an unstated dyadic tolerance, a quotient stream, or a selected limit.*

Proof. Start with tail-window exposure, Definition 448.3. It makes W visible before any oscillation comparison can be consumed.

Apply modulus-threshold exactness, Definition 448.5. The threshold row M is tied to the same W, Q, T packet rather than to a free modulus witness.

Use dyadic-tail exactness, Definition 448.7. It identifies the ledger T as the displayed dyadic comparison over W, M, Q.

The structural rows H, C, P, N then transport, replay, source, and name that finite route. Therefore a $\mathsf{UniformCauchyCriterion}^{\uparrow}$ consumer receives exactly the displayed oscillation packet and has no route around the finite tail window, threshold, tolerance, and ledger. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier uniform criterion consumer`

Theorem 448.12 (CauchyOscillation real completion consumer)**.** *Let*

$$O = (W, M, Q, T, S, H, C, P, N)$$

be an accepted $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier consumed by a* $\mathsf{Real}^{\uparrow}$ *completion-facing reader. The reader may reach the seal row S only after the finite prefix W, M, Q, T has been displayed and replayed through H, C, P, N. The packet exports no quotient stream equality, selected real limit, host real equality, countable choice, or ambient completeness principle.*

Proof. Begin with the root window lock above. It forces every completion-facing read to expose W, M, Q, T before S is available.

Apply Real seal nonescape, Definition 448.8. The seal row is a routed oscillation-bound handoff and not a detached real-completion object.

Use dyadic-tail exactness, Definition 448.7, to keep the terminal read tied to the same dyadic tolerance and tail ledger. The comparison feeding the seal is therefore the displayed T over W, M, Q.

Finally, the structural rows H, C, P, N preserve this route without adding quotient, selected-limit, host-equality, countable-choice, or ambient-completeness data. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier real completion consumer`

Theorem 448.13 (CauchyOscillation root-unblock package)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the root-unblock surface consumed by $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *is exactly the finite package $W, M, Q, T, S, H, C, P, N$. Uniform-criterion consumers must read W, M, Q, T, H, C, P, N before using the oscillation packet, and real-completion consumers must read the same finite prefix before the seal row S. No consumer may replace this package by a detached modulus, unstated dyadic tolerance, quotient stream, selected limit, host real equality, countable choice, or ambient completeness theorem.*

Proof. Use the uniform criterion consumer theorem above. It exposes the finite tail window, threshold, tolerance, ledger, and structural rows before any $\mathsf{UniformCauchyCriterion}^{\uparrow}$ read is public.

Use the real completion consumer theorem above. It places the $\mathsf{Real}^{\uparrow}$ seal downstream from the same finite prefix and refuses every detached completion route.

The tail-window exposure, modulus-threshold exactness, dyadic-tail exactness, and Real-seal nonescape theorems supply the four locking points of the package: W must be visible, M must remain attached to W, Q, T, T must be the displayed dyadic comparison over W, M, Q, and S must remain downstream from the accepted ledger.

Thus the only public root-unblock surface is $W, M, Q, T, S, H, C, P, N$ itself. The listed forbidden objects are absent from the carrier and cannot be reconstructed by transport, replay, provenance, or naming. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationRootUnblockPackage`

Theorem 448.14 (CauchyOscillation completion root route)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N)$$

factors through the finite route W, M, Q, T*, then the* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback carried by* W*, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* Q*, and only then the* $\mathsf{Real}^{\uparrow}$ *seal row* S*. The route exports no quotient stream equality, selected limit, host equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with tail-window exposure and the root window lock, Definition 448.3 and Definition 448.10. They force every completion-facing read to expose W, M, Q, T before the seal row S can be consumed.

Use the RegSeqRat handoff and dyadic tolerance stability, Definition 448.6 and Definition 448.4. These identify W as the displayed StreamName or RegSeqRat tail-window readback and keep the dyadic tolerance row Q attached to the same window, threshold, and ledger under H and C.

Apply dyadic tail exactness, Definition 448.7. The oscillation ledger T is exactly the displayed tail comparison over W, M, Q, so a downstream read has no detached tail-bound or quotient-stream coordinate.

Finally use Real seal nonescape and seal-handoff factorization, Definition 448.8 and Definition 448.9. They place S downstream from the same finite prefix and exclude selected limits, host equality, countable choice, and ambient Real completeness from the accepted route. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationRootUnblockRoute`

Theorem 448.15 (CauchyOscillation L10 window admission)**.** *Let*

$$O = (W, M, Q, T, S, H, C, P, N)$$

be an accepted $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier. Every L10 completion-facing read of* O *must first expose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* Q *and the* $\mathsf{StreamName}^{\uparrow}$ *finite window row carried by* W *before any oscillation ledger entry in* T *is consumed. The read may then proceed through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and the* $\mathsf{Real}^{\uparrow}$ *seal row* S*, but it cannot start from a detached completion object or an ambient Real equality.*

Proof. Begin with the carrier of Definition 448.1. The rows W and Q are the visible finite window and dyadic tolerance coordinates of the packet.

Apply tail-window exposure, Definition 448.3. It forces every oscillation comparison to read W before threshold, tolerance, ledger, or seal data are consumed.

Use dyadic tolerance stability, Definition 448.4. The tolerance row Q is transported with the same window and threshold rows, so an L10 consumer cannot detach it from W.

Finally combine the RegSeqRat handoff and completion root route, Definition 448.6 and Definition 448.14. They place the regular-rational handoff and the Real seal after the same displayed prefix, excluding detached completion and ambient equality reads. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationL10WindowAdmission`

Theorem 448.16 (CauchyOscillation RegSeqRat Real seal route)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier* $O = (W, M, Q, T, S, H, C, P, N)$*, any consumer that reaches a* $\mathsf{Real}^{\uparrow}$ *seal through the oscillation packet must pass through the finite route*

$$W, Q, M, T, S.$$

The row W exposes the StreamName$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *finite window, Q supplies the* DyadicRatCore$^{\uparrow}$ *tolerance, M fixes the threshold schedule, T records the tail comparison, and S is the terminal* Real$^{\uparrow}$ *seal. No route may replace this sequence by a quotient stream, selected limit, countable choice, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationRegSeqRatRealSealRoute`

Proof. Project the packet rows from Definition 448.1. The only Real-facing terminal row is S, and it is listed after the window, threshold, tolerance, and ledger rows.

Apply the RegSeqRat handoff theorem, Definition 448.6. It identifies the finite tail window W as the StreamName or regular-rational surface consumed before an oscillation comparison is read.

Use dyadic tolerance stability and dyadic tail exactness, Definition 448.4 and Definition 448.7. These keep Q attached to the same W, M prefix and identify T as the displayed comparison over that prefix.

The Real seal nonescape theorem, Definition 448.8, then makes S a routed seal rather than an independent real object. The refused quotient, selected-limit, choice, and completeness objects are not rows of the carrier. □

Theorem 448.17 (CauchyOscillation completion consumer boundary)**.** *Every completion consumer of an accepted* CauchyOscillation$^{\uparrow}$ *packet receives exactly the displayed tail-window, dyadic-tolerance, RegSeqRat-handoff, Real-seal, transport, replay, provenance, and local naming surface of*

$$W, M, Q, T, S, H, C, P, N.$$

It may consume the packet as completion input only after those rows have been exposed, and it cannot ask the packet for a hidden completed metric space, a selected limit, host equality of real names, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCompletionConsumerBoundary`

Proof. Start from the completion root route, Definition 448.14. It already factors each completion-facing read through the finite route W, M, Q, T and then to the seal row S.

The L10 window admission theorem above makes the entry point explicit: the dyadic tolerance row and finite window row are read before a ledger entry is consumed.

The RegSeqRat Real seal route above identifies the regular-rational handoff and terminal Real seal as downstream from the same window, threshold, tolerance, and comparison rows.

It remains to account for structural stability. The NameCert obligations, Definition 448.2, keep H, C, P, N attached as transport, replay, provenance, and local naming rows for the same packet. Since the carrier contains no hidden completed space, selected limit, host equality, or ambient completeness row, no completion consumer can read one from this boundary. □

Theorem 448.18 (CauchyOscillation tail tolerance package)**.** *For every accepted* CauchyOscillation$^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the finite tail-tolerance package consists of the StreamName$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *tail-window row W, the cutoff schedule M, the* DyadicRatCore$^{\uparrow}$ *tolerance row Q, and the* DyadicTailBound$^{\uparrow}$ *ledger T. Componentwise* hsame *transport H and displayed* Cont *replay C preserve this package as one finite boundary before the* Real$^{\uparrow}$ *seal is read.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationTailTolerancePackage`

Proof. Project the carrier of Definition 448.1. The rows W, M, Q, T list exactly the StreamName or RegSeqRat window, cutoff schedule, dyadic tolerance, and oscillation ledger used by the carrier.

Use the RegSeqRat handoff and dyadic tolerance stability, Definition 448.6 and Definition 448.4. These keep the tail-window and dyadic tolerance rows attached to the same ledger under H and C.

Apply dyadic tail exactness, Definition 448.7. It identifies every row of T with the displayed DyadicTailBound comparison over W, M, Q.

The seal-handoff factorization then places S strictly downstream of the accepted package. Thus completion consumers receive a finite tail-tolerance surface before any Real seal projection. □

Theorem 448.19 (CauchyOscillation completion consumer refusal)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N)$$

is confined to the finite route $W, M, Q, T, S, H, C, P, N$*. It cannot replace that route by quotient streams, selected limits, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and it cannot read a seal that is detached from the displayed tail-window and dyadic-tolerance package.*

Proof. Begin with the NameCert obligations, Definition 448.2. Their carrier admission, exactness, transport, continuation, provenance, and naming clauses exhaust the accepted rows of O.

Combine the root window lock and tail tolerance package, Definition 448.10 and Definition 448.18. They make every completion-facing read pass through W, M, Q, T and preserve that package under H and C.

Now apply Real seal nonescape and seal-handoff factorization, Definition 448.8 and Definition 448.9. These route the terminal $\mathsf{Real}^{\uparrow}$ seal through the same finite prefix and exclude detached real-completion data.

Since the carrier has no row for quotient streams, selected limits, countable choice, host real equality, or ambient completeness, a completion consumer cannot obtain those objects from the accepted package. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCompletionConsumerRefusal`

Theorem 448.20 (CauchyOscillation modulus-root package)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

each modulus-root read packages $W, M, Q, T, S, H, C, P, N$ *as one finite tail-window surface. The row* W *supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{StreamName}^{\uparrow}$ *observations,* M *supplies the threshold schedule,* Q *supplies the dyadic tolerance,* T *supplies the oscillation comparison ledger, and* S *is the downstream* $\mathsf{Real}^{\uparrow}$ *seal available only after those rows are accepted. The structural rows* H, C, P, N *transport, replay, source, and name the same package, with no quotient stream, selected limit, host real equality, or ambient completeness principle.*

Proof. Open the carrier of Definition 448.1. The modulus-facing rows are exactly W, M, Q, T: a finite tail window, a threshold schedule, a dyadic tolerance, and an oscillation ledger comparing the displayed tail observations.

Apply the NameCert obligations of Definition 448.2. Oscillation-bound exactness keeps each comparison in T tied to the same W, M, Q coordinates, while stability under hsame and Cont preserves the finite dependency packet.

Now use the seal-handoff factorization theorem Definition 448.9. It places the terminal row S after the accepted prefix W, M, Q, T, so a modulus-root consumer cannot read the Real seal before the finite oscillation surface is visible.

Finally H, C, P, N only transport, replay, source, and name that same route. The carrier contains no coordinate for the refused ambient objects, so the modulus-root read is precisely the displayed finite package. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationModulusRootPackage`

Theorem 448.21 (CauchyOscillation dyadic-tail Real-seal route)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

every Real-facing oscillation consumer factors through the ordered route

$$W,\ M,\ Q,\ T$$

before it reads the $\mathsf{Real}^{\uparrow}$ *seal row* S*, where* W *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{StreamName}^{\uparrow}$ *tail-window row,* M *is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold schedule,* Q *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and* T *is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *oscillation ledger. The route exports no quotient stream, no selected limit, no host real equality, and no ambient completeness principle.*

Proof. Start with tail-window exposure, Definition 448.3. It forces every oscillation comparison exposed by T to read the finite window W before threshold, tolerance, ledger, or seal data can be consumed.

Use dyadic tolerance stability, Definition 448.4. It preserves Q only together with W, M, T under componentwise hsame transport and displayed Cont replay.

Apply modulus-threshold exactness, Definition 448.5. It prevents M from being read as a free modulus witness by tying the threshold to the same tail window, dyadic tolerance, and oscillation ledger.

Finally apply seal-handoff factorization, Definition 448.9. Since the terminal seal S is available only after the accepted prefix W, M, Q, T, every Real-facing oscillation consumer follows the stated dyadic-tail route. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationDyadicTailRealSealRoute`

Theorem 448.22 (CauchyOscillation oscillation ledger transport)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the oscillation ledger T *transports as a ledger over the same* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{StreamName}^{\uparrow}$ *tail-window row* W*,* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row* M*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* Q*. Under componentwise* hsame *transport and displayed* Cont *replay, no transported ledger may replace* T *by a tail comparison sourced from a different packet, an unstated* $\mathsf{DyadicTailBound}^{\uparrow}$ *row, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Open the carrier of Definition 448.1. The ledger row T is the displayed $\mathsf{DyadicTailBound}^{\uparrow}$ oscillation ledger, and its comparisons are specified over the same W, M, Q rows of the packet.

Apply the NameCert obligations of Definition 448.2. Oscillation-bound exactness ties every accepted comparison in T to W, M, Q, while stability under hsame and Cont preserves the selected tail window, threshold, tolerance, ledger, and seal handoff as one finite dependency packet.

Use dyadic tolerance stability, Definition 448.4, and modulus-threshold exactness, Definition 448.5. Together they prevent the transported read from detaching Q or M from the same tail-window and ledger rows.

Finally apply the dyadic-tail Real-seal route, Definition 448.21. Since any Real-facing consumer reaches S only after W, M, Q, T, there is no coordinate from which to import a ledger from another packet, an unstated dyadic tail-bound row, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier ledger transport`

Theorem 448.23 (CauchyOscillation tail-modulus comparison obligation)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the comparison between the tail-window row and the modulus row is an obligation over the same displayed packet: W *is the* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface,* M *is the tail threshold schedule,* Q *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* T *is the comparison ledger, and* S *is the downstream* $\mathsf{Real}^{\uparrow}$ *seal. A* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer may read this comparison only after the route through* W, M, Q, T, H, C, P, N *has been displayed.*

Proof. Use tail-window exposure, Definition 448.3. It makes the finite window W visible before any threshold, tolerance, ledger, or seal row is consumed.

Apply modulus-threshold exactness and dyadic tolerance stability, Definition 448.5 and Definition 448.4. These keep M and Q attached to the same tail-window and ledger rows under H and C.

Finally use ledger transport, Definition 448.22. The transported comparison is still over the displayed $\mathsf{StreamName}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ row, the same $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, and the same downstream $\mathsf{Real}^{\uparrow}$ seal route. Thus a $\mathsf{UniformCauchyCriterion}^{\uparrow}$ read receives the finite comparison obligation rather than a detached modulus witness. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier tail modulus comparison obligation`

Theorem 448.24 (CauchyOscillation tail-window carrier obligation)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the finite tail-window packet W, M, Q, T *carries the visible* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget used by each oscillation comparison. A downstream* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer can read a tail-window comparison only through the displayed rows* W *for observations,* M *for the tail threshold,* Q *for the dyadic bound, and* T *for the finite comparison ledger, together with* H, C, P, N*.*

Proof. Inspect the carrier rows of Definition 448.1. The only row containing a dyadic tolerance is Q, and the only row containing tail comparisons is T.

The tail-window row W supplies the finite StreamName or RegSeqRat observations, while M selects the tail region in which those observations are compared. Thus a comparison row in T cannot be read before the packet has displayed the observation window, threshold schedule, and dyadic budget.

Componentwise transport through H and replay through C preserve these rows together. The package and local certificate rows P, N only source and name the same finite route, so every consumer receives the displayed tail-window carrier rather than an external oscillation object. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier tail window carrier obligation`

Theorem 448.25 (CauchyOscillation dyadic bound classifier obligation)**.** *Let* $O = (W, M, Q, T, S, H, C, P, N)$ *and* $O' = (W', M', Q', T', S', H', C', P', N')$ *be accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carriers. If the classifier identifies the displayed rows componentwise, then the oscillation budget transported from* O *to* O' *is the same visible* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound route through the* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{StreamName}^{\uparrow}$ *rows. In particular, classifier equality preserves the tail-window observations, threshold schedule, dyadic budget, oscillation ledger, and seal handoff as one finite dependency packet.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier dyadic bound classifier obligation`

Proof. Open the classifier described in Definition 448.1. It compares accepted carriers only by componentwise hsame rows, displayed Cont routes, package provenance, and local naming rows over the listed coordinates.

The dyadic budget is therefore transported only as the Q coordinate attached to the same W, M, T rows. The classifier has no second tolerance coordinate, no alternate RegSeqRat readback row, and no detached StreamName window from which a different oscillation budget could be imported.

Apply the transport clause in the NameCert obligations. The componentwise hsame rows preserve W, M, Q, T, S, and replay through C and C' reads the same displayed route. Hence classifier equality preserves the visible dyadic-bound route through the regular-rational or stream-window surface. □

Theorem 448.26 (CauchyOscillation uniform Cauchy consumer obligation)**.** *Every* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N)$$

receives only the displayed finite budget route

$$W,\ M,\ Q,\ T,\ H,\ C,\ P,\ N$$

before the $\mathsf{Real}^{\uparrow}$ *seal row* S *is exposed. The consumer obtains no quotient stream, selected limit, host real equality, ambient completeness principle, or hidden uniform modulus beyond the finite tail-window and dyadic-budget rows.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier uniform cauchy consumer obligation`

Proof. Start with the finite package in Definition 448.24. It identifies W, M, Q, T as the visible tail-window, threshold, dyadic-bound, and comparison-ledger route.

Use the classifier obligation of Definition 448.25. Transport and replay preserve the same budget route under componentwise hsame, so a uniform Cauchy consumer cannot replace the displayed dyadic budget by a hidden modulus.

Finally combine the existing uniform criterion handoff and completion-frontier obligation, Definition 448.27 and Definition 448.28. They place the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ read inside W, M, Q, T, H, C, P, N before the terminal seal S, while the carrier nonescape clause excludes quotient streams, selected limits, host equality, ambient completeness, and hidden uniform data. □

Theorem 448.27 (CauchyOscillation uniform criterion handoff)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the handoff to $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *is the finite row sequence* W, M, Q, T, H, C, P, N *followed by the* $\mathsf{Real}^{\uparrow}$ *seal row* S*. The handoff displays* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *as named source or consumer rows, and it exports no quotient stream, selected limit, host real equality, countable choice, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationUniformCriterionHandoff`

Proof. Start with the root window lock and completion root route, Definition 448.10 and Definition 448.14. They force the completion-facing route through W, M, Q, T before S can be read.

Use the RegSeqRat handoff and dyadic tail exactness, Definition 448.6 and Definition 448.7. These identify W as the $\mathsf{StreamName}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ readback surface and Q, T as the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and comparison ledger.

The seal-handoff factorization, Definition 448.9, then places the $\mathsf{Real}^{\uparrow}$ seal after the accepted finite prefix. The same prefix is exactly the packet that a $\mathsf{UniformCauchyCriterion}^{\uparrow}$ consumer may inspect, so the handoff remains finite and excludes the refused ambient objects. □

Theorem 448.28 (CauchyOscillation completion-frontier obligation)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the completion frontier consists only of the finite $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *tail window* W*, the modulus row* M*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* Q*, the oscillation ledger* T*, the* $\mathsf{Real}^{\uparrow}$ *seal row* S*, and the transport, replay, provenance, and local naming rows* H, C, P, N*. A downstream* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives this frontier as an obligation packet and receives no ambient completion theorem.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCompletionFrontierObligation`

Proof. Project the carrier through Definition 448.1. The only completion-facing rows are the displayed finite rows $W, M, Q, T, S, H, C, P, N$.

Apply the tail tolerance package and completion consumer refusal, Definition 448.18 and Definition 448.19. They keep the tail-window, threshold, tolerance, ledger, and seal rows together and rule out quotient streams, selected limits, countable choice, host real equality, and ambient completeness.

Use the uniform criterion handoff of Definition 448.27. Since the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ consumer reads the same finite prefix before the $\mathsf{Real}^{\uparrow}$ seal, the completion frontier is an obligation surface, not a completed-real construction. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier completion frontier obligation`

Theorem 448.29 (CauchyOscillation tail-window cofinality)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the tail-window row W *is cofinal for every downstream* $\mathsf{Real}^{\uparrow}$ *or completion-facing read of the oscillation packet. Any such read must pass through* W, M, Q, T *before the seal row* S *is available, and it cannot replace that route by quotient streams, selected limits, host real equality, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier tail window cofinality`

Proof. Project the carrier of Definition 448.1. The only rows before the terminal seal are the displayed tail window W, modulus threshold M, dyadic tolerance Q, oscillation ledger T, and structural rows H, C, P, N.

Apply tail-window exposure and the RegSeqRat handoff, Definition 448.3 and Definition 448.6. These force every oscillation comparison to open the finite $\mathsf{StreamName}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ window before threshold or ledger data are consumed.

Use dyadic tail exactness and the dyadic-tail Real-seal route, Definition 448.7 and Definition 448.21. They identify the ledger as the exact finite comparison over W, M, Q and place the $\mathsf{Real}^{\uparrow}$ seal downstream from that comparison.

Finally the completion-frontier obligation of Definition 448.28 keeps every completion-facing consumer inside the same finite packet, so no refused ambient object supplies an alternate cofinal route. □

Theorem 448.30 (CauchyOscillation modulus-tail monotonicity)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the modulus threshold row M is monotone only along the displayed tail route W, Q, T. If a downstream read tightens the dyadic tolerance or moves farther into the tail, the accepted comparison remains a read of the same W, M, Q, T packet under H and C; no detached modulus schedule or external completeness principle can supply the monotonicity witness.

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationModulusTailMonotonicity`

Proof. Start with modulus-threshold exactness, Definition 448.5. It ties M to the same tail-window, tolerance, and oscillation-ledger rows rather than to a free threshold parameter.

Use dyadic tolerance stability, Definition 448.4. Tightening or transporting the tolerance row preserves Q together with W, M, T under componentwise hsame transport and displayed Cont replay.

Apply ledger transport and tail-window cofinality, Definition 448.22 and Definition 448.29. The comparison ledger remains over the same finite tail route, and every downstream Real or completion read still reaches the seal only through that route.

Thus the monotonicity available to a consumer is exactly the finite modulus-tail monotonicity displayed by W, M, Q, T, H, C, P, N. □

Theorem 448.31 (CauchyOscillation Real-seal uniqueness boundary)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

any two downstream $\mathsf{Real}^{\uparrow}$ *or completion consumers that read the seal row S through the packet meet at the same finite oscillation boundary $W, M, Q, T, S, H, C, P, N$. The packet supplies no second Real seal, no host equality proof between seals, no selected limit, and no ambient completion theorem.*

Proof. Project the carrier. The row S is the only Real-facing seal coordinate, and it appears after the finite tail window, modulus threshold, dyadic tolerance, and oscillation ledger.

Use Real seal nonescape and seal-handoff factorization, Definition 448.8 and Definition 448.9. They prevent a consumer from reading S except through the accepted prefix W, M, Q, T.

Apply tail-window cofinality and modulus-tail monotonicity, Definition 448.29 and Definition 448.30. These keep both consumers on the same cofinal tail route and the same threshold-tolerance ledger under the displayed transport and replay rows.

Since H, C, P, N only transport, replay, source, and name that packet, the uniqueness boundary is the shared finite route itself, not host real equality or an ambient completion object. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier real seal uniqueness boundary`

Definition 448.32 (CauchyOscillation uniform-limit source subpacket)**.** *For an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

the uniform-limit source subpacket is

$$O_{\mathrm{ulim}} = (W, M, Q, T, H, C, P, N).$$

It consists of the $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *finite tail-window row* W*, the threshold row* M*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* Q*, the oscillation ledger* T*, and the transport, replay, provenance, and local naming rows. The* $\mathsf{Real}^{\uparrow}$ *seal row* S *remains downstream of this subpacket and is not a selected limit.*

Lean4 (definition) `BEDC.Derived.CauchyOscillationUp.CauchyOscillationUniformLimitSource`

Theorem 448.33 (CauchyOscillation uniform-limit tail handoff)**.** *Every* $\mathsf{UniformLimit}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *packet must first display the uniform-limit source subpacket of Definition 448.32. The handoff is the finite route* W, M, Q, T, H, C, P, N*; it cannot be replaced by quotient streams, a selected limit, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with tail-window exposure and dyadic tolerance stability, Definition 448.3 and Definition 448.4. They force every oscillation comparison to open the finite tail row W and keep the tolerance row Q attached to the same W, M, T packet.

Use the RegSeqRat handoff and the uniform criterion handoff, Definition 448.6 and Definition 448.27. These identify the displayed source as the $\mathsf{StreamName}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ tail route consumed by uniform Cauchy readers.

Finally apply the completion-frontier obligation, Definition 448.28. It keeps the $\mathsf{Real}^{\uparrow}$ seal downstream from O_{ulim} and refuses quotient-stream, selected-limit, host-equality, countable-choice, and ambient-completeness endpoints. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationUniformLimitTailHandoff`

Theorem 448.34 (CauchyOscillation completion-source exhaustion)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier, the completion source available to* $\mathsf{UniformLimit}^{\uparrow}$*,* $\mathsf{UniformCauchyCriterion}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumers is exhausted by the route through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal displayed in* $W, M, Q, T, S, H, C, P, N$*. No further completion source, quotient stream, selected limit, host real equality, or ambient completeness theorem is exported by the packet.*

Proof. Project the source subpacket O_{ulim} from Definition 448.32. Its rows name the stream or regular-rational window, the threshold schedule, the dyadic tolerance, and the oscillation ledger before any seal read.

Apply the dyadic-tail Real-seal route and completion-frontier obligation, Definition 448.21 and Definition 448.28. These place $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ on the same finite handoff and block ambient completion data.

Use Real-seal uniqueness boundary, Definition 448.31. Since the packet supplies only the displayed seal route and no second seal or host equality proof, the listed source chain exhausts the completion-facing surface. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCompletionSourceExhaustion`

Theorem 448.35 (CauchyOscillation RegSeqRat uniform-threshold preservation)**.** *Under componentwise* hsame *transport and displayed* Cont *replay, the* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{StreamName}^{\uparrow}$ *tail-window row W preserves the uniform threshold row M together with the dyadic tolerance row Q and oscillation ledger T. A transported* $\mathsf{UniformLimit}^{\uparrow}$ *or* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer therefore reads the same finite threshold packet W, M, Q, T, H, C, P, N before any* $\mathsf{Real}^{\uparrow}$ *seal handoff.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationRegSeqRatUniformThreshold`

Proof. Begin with modulus-threshold exactness and modulus-tail monotonicity, Definition 448.5 and Definition 448.30. They tie M to the displayed tail route W, Q, T and prevent a detached threshold schedule from supplying the comparison.

Use ledger transport and the RegSeqRat handoff, Definition 448.22 and Definition 448.6. The transported ledger remains over the same $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{StreamName}^{\uparrow}$ window and the same dyadic tolerance row.

Finally apply the uniform-limit tail handoff, Definition 448.33. It presents W, M, Q, T, H, C, P, N as the finite source packet required before a uniform-limit or uniform-Cauchy consumer may reach the Real seal. □

Theorem 448.36 (CauchyOscillation completion-frontier public readiness)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier*

$$O = (W, M, Q, T, S, H, C, P, N),$$

every completion-frontier consumer must first read the finite source subpacket W, M, Q, T, H, C, P, N and then the $\mathsf{Real}^{\uparrow}$ *seal row S through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route. The public surface exports no quotient stream, selected limit, host equality, countable choice, or ambient completeness theorem.*

Proof. Use the uniform-limit tail handoff, Definition 448.33. It forces a uniform-limit or uniform-Cauchy reader to open the source subpacket W, M, Q, T, H, C, P, N before any seal read.

Apply completion-source exhaustion, Definition 448.34. The only completion-facing chain available to the packet runs through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the downstream $\mathsf{Real}^{\uparrow}$ seal.

Finally use RegSeqRat uniform-threshold preservation, Definition 448.35. It keeps transported consumers on the same finite threshold and tolerance route, so the completion frontier remains public readiness data rather than a quotient stream, selected limit, host equality, choice principle, or ambient completeness claim. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCompletionFrontierPublicReadiness`

Theorem 448.37 (CauchyOscillation audit-clean obligation package)**.** *Every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier supplies an audit-clean L10 root-unblock package*

$$W, M, Q, T, S, H, C, P, N$$

whose rows expose the tail window, modulus threshold, dyadic tolerance, oscillation ledger, Real seal, componentwise transport, displayed replay, provenance, and local NameCert obligations. The package is consumed by $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readers only through those displayed rows and exports no quotient stream, selected limit, host equality, countable choice, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier audit clean obligation package`

Proof. Start with the NameCert obligations of Definition 448.2. They project the accepted carrier into the visible rows $W, M, Q, T, S, H, C, P, N$ and identify carrier admission, exactness, transport, replay, provenance, and local naming as the whole certificate surface.

Use tail-window exposure and dyadic tolerance stability, Definition 448.3 and Definition 448.4. These force the comparison ledger to read the same finite tail window and dyadic tolerance under transport and replay.

Apply the RegSeqRat handoff and Real seal nonescape, Definition 448.6 and Definition 448.8. The regular-rational route and the terminal seal remain downstream of the displayed finite prefix.

Finally use completion-frontier public readiness, Definition 448.36. It identifies the same rows as the public L10 completion frontier and excludes the refused host objects, so the displayed packet is the requested audit-clean obligation package. □

Theorem 448.38 (CauchyOscillation tail-window audit package)**.** *The tail-window audit package of an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier is exactly the finite subpacket*

$$W, M, Q, T, H, C, P, N.$$

It records the $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-window row, the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{DyadicTailBound}^{\uparrow}$ *oscillation comparison ledger, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local NameCert rows before any* $\mathsf{Real}^{\uparrow}$ *seal handoff is read.*

Proof. Project the uniform-limit source subpacket of Definition 448.32. By definition it contains W, M, Q, T, H, C, P, N and leaves the seal row S downstream.

Apply tail-window exposure, RegSeqRat handoff, and dyadic-tail exactness, Definition 448.3, Definition 448.6, and Definition 448.7. These identify W as the finite window route, M as the threshold row, Q as the tolerance row, and T as the exact dyadic tail comparison ledger over those rows.

Use ledger transport and RegSeqRat uniform-threshold preservation, Definition 448.22 and Definition 448.35. The structural rows H, C, P, N preserve and name that same finite packet for uniform-limit and uniform-Cauchy consumers.

The seal-handoff factorization theorem Definition 448.9 keeps S after this subpacket. Therefore the audit package is exactly W, M, Q, T, H, C, P, N before any Real seal is public. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationTailWindowAuditPackage`

Theorem 448.39 (CauchyOscillation Real completion audit handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier reaches the seal row* S *only after consuming the audit package* W, M, Q, T, H, C, P, N. *The handoff factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{DyadicTailBound}^{\uparrow}$ *oscillation ledger, transport, replay, provenance, and local NameCert rows, and it never exports quotient stream equality, selected limits, host real equality, countable choice, or ambient Real completeness.*

Proof. Begin with the tail-window audit package of Definition 448.38. It fixes the finite source packet W, M, Q, T, H, C, P, N before any Real-facing read is allowed.

Use uniform-limit tail handoff and completion-source exhaustion, Definition 448.33 and Definition 448.34. These place $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers on the same finite source route.

Apply Real seal nonescape and seal-handoff factorization, Definition 448.8 and Definition 448.9. They make S a routed seal after W, M, Q, T rather than an independent Real-completion object.

Finally invoke completion-frontier public readiness, Definition 448.36. The public completion surface is exactly the displayed audit route plus the downstream seal, so no excluded host or quotient object is exported. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationRealCompletionAuditHandoff`

Theorem 448.40 (CauchyOscillation common tail-window classifier)**.** *Let $O = (W, M, Q, T, S, H, C, P, N)$ and $O' = (W', M', Q', T', S', H', C', P', N')$ be accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carriers. A classifier comparison between them is common-tail only when it identifies the finite tail window W with W', the modulus schedule M with M', the dyadic tolerance row Q with Q', the oscillation ledger T with T', and the* $\mathsf{Real}^{\uparrow}$ *seal handoff S with S' through the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. No comparison may replace the common window by a quotient stream, selected limit, or ambient completeness witness.*

Proof. Project the two carriers. Their classifier-visible rows are exactly the tail window, modulus, tolerance, ledger, seal, transport, replay, provenance, and local naming coordinates.

The common-tail condition is therefore componentwise. The hsame rows compare W, M, Q, T, S with their primed partners, while the Cont rows replay only those displayed comparisons.

Finally P, N and P', N' source and name the same finite shape. Because neither carrier contains a quotient stream, selected limit, or ambient completeness row, the classifier cannot escape the common displayed tail window. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCommonTailWindowClassifier`

Theorem 448.41 (CauchyOscillation ledger nonescape)**.** *For every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier $O = (W, M, Q, T, S, H, C, P, N)$, an oscillation ledger read from T can cite only the same finite tail window W, modulus schedule M, dyadic tolerance row Q,* $\mathsf{Real}^{\uparrow}$ *seal handoff S, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{CauchyOscillation}^{\uparrow}}$ *row N. It cannot export a detached modulus, a second dyadic tolerance, quotient stream equality, selected limit, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read T from the carrier. By definition it is the displayed oscillation ledger over the tail observations in W beyond the threshold supplied by M under the dyadic budget Q.

Use tail-window audit package and Real completion audit handoff. These theorems keep T inside the same W, M, Q, H, C, P, N route before the seal row S is available.

The remaining exclusions follow from the absence of carrier coordinates. Since O has no detached modulus, second tolerance, quotient-stream, selected-limit, host-equality, or completeness row, no ledger read can export one. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationCarrier ledger nonescape`

Theorem 448.42 (CauchyOscillation mature status route)**.** *The mature paper surface of* $\mathsf{CauchyOscillation}^{\uparrow}$ *is the finite completion-audit route assembled from the audit-clean obligation package, the Real completion audit handoff, the common tail-window classifier, and ledger nonescape. Every accepted carrier*

$$O = (W, M, Q, T, S, H, C, P, N)$$

is read through the displayed tail window, modulus threshold, dyadic tolerance, oscillation ledger, Real seal, componentwise transport, replay, provenance, and local NameCert rows before a completion-facing consumer may inspect the seal.

Proof. Start with the audit-clean obligation package of Definition 448.37. It exposes $W, M, Q, T, S, H, C, P, N$ as the whole carrier package for L10 completion readers.

Next use the Real completion audit handoff, Definition 448.39. The seal row S is available only after the finite audit package W, M, Q, T, H, C, P, N has been consumed.

Apply the common tail-window classifier and ledger nonescape, Definition 448.40 and Definition 448.41. They keep classifier comparison and ledger reads on the same displayed tail window and exclude detached modulus, second tolerance, quotient stream, selected limit, host equality, and ambient completeness rows.

Finally read the scoped status route of Definition 448.45. The same rows supply the mature paper surface because the audit package, seal handoff, classifier, and ledger refusal are all named inside the local $\mathsf{NameCert}_{\mathsf{CauchyOscillation}^{\uparrow}}$ route. □

Theorem 448.43 (CauchyOscillation mature status formal target)**.** *The formalization target for the mature* $\mathsf{CauchyOscillation}^{\uparrow}$ *status route is the single finite assembly that consumes the carrier obligations of* CauchyOscillationCarrier_namecert_obligations*, the semantic certificate surface of* CauchyOscillationPacket_semantic_name_certificate*, the seal handoff of Definition 448.39, ledger transport through Definition 448.41, and the completion-consumer refusal route. For an accepted carrier* $O = (W, M, Q, T, S, H, C, P, N)$*, the target asserts that every mature completion-facing read is exhausted by the displayed tail window, modulus threshold, dyadic tolerance, oscillation ledger, Real seal, componentwise transport, replay, provenance, and local NameCert rows.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationMatureStatusRouteFormalTarget`

Proof. Start with the carrier and semantic certificate obligations. They provide the finite rows $W, M, Q, T, S, H, C, P, N$ and identify the local $\mathsf{NameCert}_{\mathsf{CauchyOscillation}^{\uparrow}}$ surface as the only named packet available to a mature reader.

Next apply the seal handoff. The Real completion audit handoff places the seal row S downstream of the audit package, so no completion-facing consumer may inspect a detached Real endpoint before the tail-window, modulus, tolerance, ledger, transport, replay, provenance, and name rows have been exposed.

Use ledger transport and completion-consumer refusal. Ledger nonescape keeps every oscillation read inside the same displayed tail window, while the completion-consumer refusal excludes quotient streams, selected limits, host equality, countable choice, and ambient completeness from the exported surface.

The theorem is therefore the paper-side target for the Lean declaration named CauchyOscillationMatureStatusRou it repacks the checked component rows into one mature route while leaving the existing verified component markers as the active Lean evidence. □

Theorem 448.44 (CauchyOscillation bridge route)**.** *Every bridge-facing read of an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *carrier factors through the audit package of Definition 448.38, the Real completion handoff of Definition 448.39, and the common tail-window classifier of Definition 448.40 before any completion consumer inspects the packet.*

Proof. The cited audit package fixes the finite tail-window, modulus, tolerance, ledger, transport, replay, provenance, and naming rows. The Real completion handoff places the seal after that package, and the common tail-window classifier keeps bridge comparisons inside the same displayed window. Therefore a completion consumer reaches only the routed bridge-facing packet. □

Theorem 448.45 (CauchyOscillation NameCert obligation scope)**.** *The* $\mathsf{NameCert}_{\mathsf{CauchyOscillation}^{\uparrow}}$ *obligation scope for an accepted carrier* $O = (W, M, Q, T, S, H, C, P, N)$ *is exactly the finite package consisting of the tail window* W*, modulus schedule* M*, dyadic tolerance* Q*, oscillation ledger* T*,* $\mathsf{Real}^{\uparrow}$ *seal* S*,* BHist *carrier rows,* hsame *transports,* Cont *replay,* Pkg *provenance, and local naming. The scope includes common tail-window classification and ledger non-escape, and it excludes quotient streams, selected limits, host real equality, countable choice, and ambient completeness.*

Proof. Start with the NameCert obligations of Definition 448.2. They list carrier habitation, common classifier, oscillation-bound exactness, transport-replay stability, and ledger non-escape over $W, M, Q, T, S, H, C, P, N$.

Apply common tail-window classifier and ledger nonescape above. The first fixes classifier comparisons to the same finite tail-window package, and the second prevents ledger reads from exporting detached completion data.

Thus the obligation scope is the displayed finite package itself. The refused quotient, selected-limit, host-equality, choice, and completeness objects are not rows of the carrier and are not introduced by transport, replay, provenance, or naming. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationNameCertObligationScope`

Theorem 448.46 (CauchyOscillation shared dyadic window scope)**.** *Every accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *packet reads* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *through one shared finite tail window* W*. The threshold row* M*, dyadic tolerance row* Q*, oscillation ledger* T*, and structural rows* H, C, P, N *preserve that same window before the* $\mathsf{Real}^{\uparrow}$ *seal* S *is available.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationSharedDyadicWindowScope`

Proof. Project the carrier and apply tail-window exposure. The row W is the only StreamName or RegSeqRat window coordinate, while M and Q are the only threshold and dyadic tolerance rows attached to it.

Use modulus-threshold exactness and dyadic-tail exactness. These identify T as the displayed comparison ledger over the same W, M, Q packet, so no later read can swap in another tail window.

Finally apply ledger transport. The rows H, C, P, N transport, replay, source, and name the same finite packet, keeping every completion-facing consumer inside the shared dyadic window. □

Theorem 448.47 (CauchyOscillation RegSeqRat Real nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *packet receives only the routed* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through* W, M, Q, T, H, C, P, N *before the seal row* S*. It receives no quotient stream, selected limit, host equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationRegSeqRatRealNonescape`

Proof. Begin with the RegSeqRat handoff and the shared dyadic window scope. Together they place the regular-rational readback inside the same finite tail-window, modulus, dyadic tolerance, and ledger packet.

Apply Real seal nonescape and seal-handoff factorization. The terminal seal S is reached only after the displayed prefix, rather than from an independent completion object.

The carrier has no row for quotient streams, selected limits, host equality, choice, or ambient completeness. Transport, replay, provenance, and local naming therefore preserve the routed RegSeqRat handoff without adding any refused Real-facing data. □

Theorem 448.48 (CauchyOscillation tail-modulus route)**.** *Every oscillation tail read using a dyadic tail bound must route through* $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *before a uniform-limit consumer can inspect it. For an accepted carrier* $O = (W, M, Q, T, S, H, C, P, N)$*, the dyadic tail bound is read as the displayed tolerance and oscillation ledger over the shared finite window* W*, not as a host modulus, quotient stream, selected tail, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationTailModulusRoute`

Proof. Start with the NameCert obligation scope of Definition 448.45. It fixes $W, M, Q, T, S, H, C, P, N$ as the displayed carrier rows and keeps the oscillation ledger inside the local naming surface.

Next apply the shared dyadic window scope of Definition 448.46. The CauchyModulus and DyadicTailBound reads use the same finite StreamName and RegSeqRat window, so the CauchyCriterion-facing tail request cannot swap in an external modulus or a selected infinite tail.

Finally use Definition 448.47. The RegSeqRat handoff reaches the Real seal only after the displayed tail window, modulus, dyadic tolerance, oscillation ledger, transport, replay, provenance, and naming rows have been consumed.

Thus a uniform-limit consumer inspects only the routed finite tail-modulus evidence. The route carries no quotient stream, host real equality, countable-choice schedule, selected limit, or ambient completeness coordinate. □

Theorem 448.49 (CauchyOscillation public export readiness)**.** *Every public completion-frontier read of an accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *packet factors through the readiness route of Definition 448.36, the tail-window audit package of Definition 448.38, and the RegSeqRat-to-Real nonescape route of Definition 448.47. The exported surface is the finite packet* $W, M, Q, T, S, H, C, P, N$*, not a quotient stream, selected limit, host real equality, countable-choice schedule, or ambient completeness theorem.*

Proof. First read completion-frontier public readiness. It makes the displayed source subpacket and the downstream $\mathsf{Real}^{\uparrow}$ seal the public-facing route.

Next read the tail-window audit package. That package identifies the finite prefix W, M, Q, T, H, C, P, N before any seal handoff is available.

Finally apply RegSeqRat Real nonescape. The regular-rational route reaches S only through the displayed prefix, so the public export contains no refused completion object. □

Lean4 ✓ `BEDC.Derived.CauchyOscillationUp.CauchyOscillationPublicExportReadiness`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyOscillation}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyOscillation}^{\uparrow}$ packet is generated from a finite $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{StreamName}^{\uparrow}$ tail window, a $\mathsf{CauchyModulus}^{\uparrow}$ threshold schedule, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, a $\mathsf{DyadicTailBound}^{\uparrow}$ oscillation ledger, a $\mathsf{Real}^{\uparrow}$ seal handoff, componentwise hsame transports, displayed Cont routes, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyOscillation}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 448.39, Definition 448.40, Definition 448.41, and Definition 448.42 record the Real-completion audit handoff through the common tail-window classifier and ledger nonescape for constructive Cauchy oscillation packets.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyOscillation}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, ambient completeness, real completeness, or a checked Lean certificate.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked NameCert obligation theorem for the displayed tail-window, modulus, tolerance, oscillation-ledger, and seal-handoff rows.

Chapter 449

A Concrete Naming Certificate for $\mathsf{RealScheduleFusion}^{\uparrow}$

The $\mathsf{RealScheduleFusion}^{\uparrow}$ chapter packages the finite schedule rows used by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Completion}^{\uparrow}$ into one displayed NameCert surface. It keeps the window envelope, regular Cauchy readback, observer regularity, real seal, and completion handoff in a single finite packet, so downstream consumers read one row rather than reconstructing the same schedule from several neighboring certificates.

The dependency anchors are $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, and $\mathsf{ObserverRegular}^{\uparrow}$. This is a composite packet over those sibling certificates: it bundles the StreamName schedule row, RegSeqRat readback row, Real seal row, Completion handoff row, finite-window envelope, regular-Cauchy name, and observer-regular provenance into one finite schedule-fusion NameCert surface.

The schedule row is read through the countable-window carrier of chapter 126; the regular-rational readback is consumed through the visible real-name packet of chapter 371; and the seal coordinate is handed to the RealUp surface of chapter 38. These sibling certificates are the only public routes by which the fusion packet exposes schedule, readback, and seal data to downstream completion consumers.

Definition 449.1 (Real schedule fusion carrier)**.** *A* $\mathsf{RealScheduleFusion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, naming the intended finite stream windows and the consumer-facing schedule identity;*
2. *W is the finite window ledger, recording the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *windows, local window indices, and displayed window inclusions used by schedule consumers;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, pairing each displayed window with the regular-rational readback supplied by the* $\mathsf{RegularCauchyName}^{\uparrow}$ *side;*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Completion}^{\uparrow}$ *seal row, recording the real-name seal and the completion-handoff seal reached from the same readback row;*
5. *H stores componentwise* hsame *transports for schedule rows, finite windows, regular-rational readbacks, seal rows, provenance, and the local naming row;*

6. *C stores the displayed* Cont *routes for schedule inspection, window selection, regular-rational readback, real sealing, completion handoff, and local NameCert comparison;*
7. *P is the* Pkg *provenance row naming* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{ObserverRegular}^{\uparrow}$, *and the consumed local source certificates;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealScheduleFusion}^{\uparrow}}$ *row.*

The classifier compares accepted packets by transporting them to a common schedule row, then comparing the finite window ledger, regular-rational readback row, real and completion seal row, provenance row, and local name. The carrier exports no quotient stream, selected limit, ambient completeness principle, host real equality, or completion object beyond the displayed finite rows.

Lean4 ✓ `BEDC.Derived.RealScheduleFusionUp.RealScheduleFusionTasteGate single carrier alignment`

Theorem 449.2 (Real schedule fusion NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RealScheduleFusion}^{\uparrow}}$ *surface has five obligations:*

1. *carrier habitation: finite schedule rows, window ledgers, regular-rational readbacks, real and completion seals, transports, continuations, provenance, and local naming inhabit the carrier of Definition 449.1;*
2. *classifier transport: accepted packets are compared only after componentwise transport to a common displayed schedule and window surface;*
3. *schedule-readback lock: the* $\mathsf{StreamName}^{\uparrow}$ *schedule row and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row remain paired through every consumer route;*
4. *real-completion handoff:* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Completion}^{\uparrow}$ *consumers receive the same finite readback and seal data;*
5. *ledger boundary: no consumer route escapes to quotient streams, selected limits, ambient completeness, host real equality, or a host completion witness.*

Proof. Carrier habitation is exactly the finite packet displayed in Definition 449.1. The rows name the schedule, window ledger, readback, real and completion seals, transports, continuations, provenance, and local certificate.

Classifier transport uses the row H to move every displayed coordinate to a common schedule surface. The continuation row C then supplies the visible routes by which a consumer reads the finite window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the seal row.

The dependency anchors $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, and $\mathsf{ObserverRegular}^{\uparrow}$ account for the source rows consumed by this packet. Since the carrier has no coordinate for quotient streams, selected limits, ambient completeness, host real equality, or a host completion witness, every obligation stays inside the finite schedule-fusion ledger. □

Theorem 449.3 (StreamName and RegSeqRat schedule lock)**.** *For an accepted* $\mathsf{RealScheduleFusion}^{\uparrow}$ *carrier* $F = (S, W, R, E, H, C, P, N)$*, every* $\mathsf{StreamName}^{\uparrow}$ *schedule read of S determines the same finite window ledger W and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R used by downstream* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Completion}^{\uparrow}$ *consumers. The schedule row names the route; it does not create an independent tolerance, readback, quotient stream, or selected limit.*

Proof. Project the carrier of Definition 449.1. The only schedule-facing coordinate is S, and the only displayed windows are the finite entries of W.

The route from S to W and then to R is stored in C and transported componentwise by H. Thus a $\mathsf{StreamName}^{\uparrow}$ read cannot bypass the finite ledger or select a different $\mathsf{RegSeqRat}^{\uparrow}$ readback.

The anchors $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ and $\mathsf{RegularCauchyName}^{\uparrow}$ identify the finite window and regular Cauchy readback sources, while $\mathsf{ObserverRegular}^{\uparrow}$ supplies the observer-style consumer discipline. None of these anchors adds a carrier coordinate for quotient streams, selected limits, or host equality. □

Theorem 449.4 (Real and completion handoff)**.** *For an accepted* $\mathsf{RealScheduleFusion}^{\uparrow}$ *carrier* $F = (S, W, R, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal and every* $\mathsf{Completion}^{\uparrow}$ *handoff in* E *is read from the same* S*,* W*, and* R *rows through the stored* hsame *transports and* Cont *routes. The completion-facing consumer receives no data beyond the finite schedule, window, readback, seal, provenance, and local naming rows.*

Proof. Begin with a real or completion consumer route. The only seal coordinate is E, so the route must reach E through the displayed schedule, window, and readback rows described in Definition 449.1.

The $\mathsf{Real}^{\uparrow}$ seal is tied to the $\mathsf{RegSeqRat}^{\uparrow}$ readback row by the continuation routes in C. The $\mathsf{Completion}^{\uparrow}$ handoff uses the same route and the same transported rows, so it cannot introduce a separate completion witness.

The anchors $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ specify the consumer side, and $\mathsf{RegularCauchyName}^{\uparrow}$ supplies the readback source. Because the carrier omits selected limits, ambient completeness, quotient streams, and host real equality, the handoff remains finite. □

Theorem 449.5 (Real schedule fusion ledger non-escape)**.** *Every consumer-facing route out of an accepted* $\mathsf{RealScheduleFusion}^{\uparrow}$ *carrier factors through the finite schedule row* S*, window ledger* W*, regular-rational readback row* R*, real and completion seal row* E*, componentwise transport row* H*, continuation row* C*, package provenance* P*, and local naming row* N*. No route exports a quotient stream, selected limit, ambient completeness proof, host real equality, or host completion witness.*

Proof. Take any consumer-facing route and project the finite carrier. The available coordinates are exactly S, W, R, E, H, C, P, and N.

The schedule, window, readback, and seal rows are the only rows that carry mathematical content to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or $\mathsf{Completion}^{\uparrow}$. The remaining rows transport, route, record provenance, and name the packet.

Therefore the route is exhausted by the displayed finite ledger. Since the carrier has no coordinate for quotient streams, selected limits, ambient completeness, host real equality, or a host completion witness, none can be exported. □

Theorem 449.6 (Real schedule fusion standard boundary)**.** *The standard boundary of* $\mathsf{RealScheduleFusion}^{\uparrow}$ *is the finite packet* $F = (S, W, R, E, H, C, P, N)$ *and the dependency anchors* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Completion}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*,* $\mathsf{RegularCauchyName}^{\uparrow}$*, and* $\mathsf{ObserverRegular}^{\uparrow}$*. Any public comparison between accepted packets is a comparison of those displayed rows after* hsame *transport; it is not a comparison of quotient streams, selected host limits, ambient completeness objects, or host real equality.*

Proof. The public boundary is read from the carrier definition. A comparison between accepted packets first transports the schedule, window, readback, seal, provenance, and naming rows by H.

After transport, the comparison uses the routes in C to inspect the finite rows named by the dependency anchors. The anchors identify the source certificates, but the packet does not expose their host interpretations or any completion object outside the finite ledger.

Thus the standard boundary is precisely the displayed row comparison. Quotient streams, selected host limits, ambient completeness objects, and host real equality are absent from the carrier and cannot appear in the public comparison. □

Theorem 449.7 (Real schedule fusion TasteGate obligation surface)**.** *The* ChapterTasteGate *surface for* RealScheduleFusion$^{\uparrow}$ *is exactly the single finite carrier* $F = (S, W, R, E, H, C, P, N)$ *of Definition 449.1. Its visible rows are the* StreamName$^{\uparrow}$ *schedule row* S*, the finite window ledger* W*, the* RegSeqRat$^{\uparrow}$ *readback row* R*, the* Real$^{\uparrow}$ *and* Completion$^{\uparrow}$ *seal row* E*, componentwise* hsame *transports* H*, displayed* Cont *routes* C*,* Pkg *provenance* P*, and the local* NameCert$_{\text{RealScheduleFusion}^{\uparrow}}$ *row* N*.*

Consequently any promotion of this chapter beyond seed strength must certify this same carrier surface: no carrier coordinate may be duplicated as a proof step, and no hidden quotient stream, selected limit, ambient completeness proof, host real equality, or host completion witness may be used as a substitute for one of the displayed rows.

Lean4 ✓ `BEDC.Derived.RealScheduleFusionUp.taste gate`

Proof. The carrier is the tuple displayed in Definition 449.1. Its local naming obligations are the five rows of Definition 449.2, so the TasteGate surface has a single finite object to inspect.

The schedule lock is Definition 449.3. The real and completion handoff is Definition 449.4. Together they force every schedule, readback, real-seal, and completion-facing read to pass through the rows S, W, R, E, H, C, P, N.

The ledger boundary is Definition 449.5, and the public boundary is Definition 449.6. These two boundaries rule out carrier-echo proof text: a proof may cite the finite rows and their routes, but it cannot replace a missing row by repeating the carrier description. □

Theorem 449.8 (Real schedule fusion TasteGate obligation closure)**.** *The carrier of Definition 449.1, the NameCert obligations of Definition 449.2, the schedule lock of Definition 449.3, the real and completion handoff of Definition 449.4, the ledger non-escape theorem of Definition 449.5, the standard boundary of Definition 449.6, and the TasteGate surface of Definition 449.7 form the complete obligation closure for the single* RealScheduleFusion$^{\uparrow}$ *carrier checked by* RealScheduleFusionTasteGate_singl

Proof. Use the checked TasteGate marker attached to Definition 449.1. It fixes the chapter to the single carrier surface inspected by the TasteGate, so the closure cannot introduce a second carrier row or an alternate schedule object.

The finite ledger rows are supplied by the displayed theorems. The NameCert obligation rows give carrier habitation, classifier transport, schedule-readback lock, real-completion handoff, and ledger boundary. The schedule-lock, handoff, non-escape, and standard-boundary theorems then account for each consumer-facing route named by those obligations.

Finally apply the TasteGate surface theorem. It states that any stronger chapter reading must certify the same finite carrier surface rather than repeat the carrier as a proof substitute. The listed rows therefore exhaust the obligation surface for the single carrier. □

Theorem 449.9 (Real schedule fusion schedule-lock consumer scope)**.** *For an accepted* RealScheduleFusion$^{\uparrow}$ *carrier* $F = (S, W, R, E, H, C, P, N)$*, every* StreamName$^{\uparrow}$ *consumer route through the schedule row* S *reaches the finite window ledger* W *and the* RegSeqRat$^{\uparrow}$ *readback row* R *only by the displayed* Cont *routes in* C *and the componentwise* hsame *transports in* H*. The scope contains no second schedule carrier and no alternate readback row.*

Proof. Read the carrier of Definition 449.1. It has one schedule coordinate S, one finite window coordinate W, and one regular-rational readback coordinate R.

The continuation row C stores the visible route from schedule inspection to window selection and then to regular-rational readback. The transport row H is the only mechanism by which another displayed packet can be compared with those rows.

Thus a $\mathsf{StreamName}^{\uparrow}$ consumer may reach W and R only through the stored route and transport witnesses. Since the carrier has no second schedule coordinate and no second readback coordinate, no alternate schedule carrier can be read by this chapter. □

Theorem 449.10 (Real and completion consumer scope)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealScheduleFusion}^{\uparrow}$ *carrier reads the same seal row E only after S, W, and R have been fixed by the schedule-lock scope. The real-facing and completion-facing reads therefore share the finite schedule, window, and regular-rational readback rows before any seal or handoff is exposed.*

Proof. Begin with a real-facing or completion-facing route. The only seal coordinate in the carrier is E, so the route must arrive at that row from the displayed schedule, window, and readback coordinates.

Apply Definition 449.9. It fixes S, W, and R before any downstream consumer can inspect the seal row.

The $\mathsf{Real}^{\uparrow}$ consumer reads the real seal from E, and the $\mathsf{Completion}^{\uparrow}$ consumer reads the completion handoff from the same E row. Because both reads share the fixed upstream rows, neither consumer can introduce a separate completion witness, selected limit, quotient stream, or host equality. □

Theorem 449.11 (Real schedule fusion scoped dependency closure)**.** *The* $\mathsf{RealScheduleFusion}^{\uparrow}$ *scoped dependency surface is the schedule-lock consumer scope of Definition 449.9, the real and completion consumer scope of Definition 449.10, and the checked TasteGate surface of Definition 449.7. It closes the current Real and Completion dependency row for the single finite carrier without adding a quotient stream, selected limit, ambient completeness proof, host real equality, or second schedule carrier.*

Proof. First use the schedule-lock consumer scope. It forces every $\mathsf{StreamName}^{\uparrow}$ read through S to reach W and R by the displayed continuation routes and componentwise transports.

Next use the real and completion consumer scope. It says that $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ both read the seal row E only after the same S, W, and R rows are fixed.

Finally apply the checked TasteGate surface. The TasteGate pins all of these rows to the single finite carrier $F = (S, W, R, E, H, C, P, N)$, so the scoped dependency closure has no place for an alternate schedule object, hidden completion witness, or host-side equality. □

Theorem 449.12 (Real schedule fusion window-merge scope)**.** *For an accepted* $\mathsf{RealScheduleFusion}^{\uparrow}$ *carrier $F = (S, W, R, E, H, C, P, N)$, any consumer merge of* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *rows must pass through the displayed schedule row S, finite window ledger W, regular-rational readback row R, componentwise transport row H, continuation row C, package provenance P, and local naming row N. The merge exports no second schedule carrier, hidden window envelope, quotient stream, selected limit, or host equality.*

Proof. Start from the carrier of Definition 449.1. It displays one schedule coordinate S, one finite window coordinate W, one readback coordinate R, one transport row H, one continuation row C, one provenance row P, and one local naming row N.

Apply Definition 449.7. The checked TasteGate surface fixes these rows as the single visible carrier inspected by the chapter.

Apply Definition 449.9. A $\mathsf{StreamName}^{\uparrow}$ route can reach W and R only through the displayed Cont routes and componentwise hsame transports.

Apply Definition 449.10 and Definition 449.11. They keep downstream real and completion consumers on the same upstream schedule and window rows, so a window merge cannot introduce a second schedule carrier or hidden host-side equality. □

Theorem 449.13 (Real schedule fusion seal-schedule noninterference)**.** *For an accepted* $\mathsf{RealScheduleFusion}^{\uparrow}$ *carrier* $F = (S, W, R, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal read and every* $\mathsf{Completion}^{\uparrow}$ *handoff read of* E *leaves the upstream schedule row* S*, finite window ledger* W*, regular-rational readback row* R*, transport row* H*, continuation row* C*, provenance row* P*, and local naming row* N *unchanged as the displayed readback surface. Seal inspection cannot alter the schedule, window, or readback rows it consumes.*

Proof. Read the finite packet in Definition 449.1. The seal coordinate is E, while the upstream readback surface is S, W, R, H, C, P, N.

Apply Definition 449.9. It fixes the schedule row, finite window ledger, and regular-rational readback before a downstream consumer reaches the seal coordinate.

Apply Definition 449.10. It states that both real-facing and completion-facing reads inspect the same E only after the same S, W, R rows have been fixed.

Apply Definition 449.7 and Definition 449.11. The checked TasteGate and scoped closure leave no coordinate by which a seal read could rewrite the upstream schedule, window, readback, transport, route, provenance, or naming rows. □

Theorem 449.14 (Real schedule fusion ObserverRegular handoff)**.** *Every* $\mathsf{ObserverRegular}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealScheduleFusion}^{\uparrow}$ *carrier reads only the displayed observer-regularity rows already packaged by* P *together with the schedule row* S*, finite window ledger* W*, regular-rational readback row* R*, transport row* H*, continuation row* C*, and local naming row* N*. The handoff exposes observer regularity as finite provenance and route data, not as an ambient regularity predicate outside the carrier.*

Proof. Project the carrier of Definition 449.1. The dependency anchors include $\mathsf{ObserverRegular}^{\uparrow}$, and their consumer-facing record is carried by the provenance row P together with the displayed routes in C.

Apply Definition 449.7. It identifies the single carrier surface as S, W, R, E, H, C, P, N, so observer regularity can be read only through rows already present in that surface.

Apply Definition 449.9. The observer handoff shares the same schedule, window, and regular-rational readback rows used by schedule consumers.

Apply Definition 449.10 and Definition 449.11. Downstream real and completion reads therefore do not enlarge the observer handoff into an ambient regularity predicate outside the finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealScheduleFusion}^{\uparrow}}$.

Constructive story: A $\mathsf{RealScheduleFusion}^{\uparrow}$ packet is generated by a $\mathsf{StreamName}^{\uparrow}$ schedule row, a finite window ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealScheduleFusion}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 449.12, Definition 449.13, and Definition 449.14 bind the window-merge, seal-schedule, and ObserverRegular consumer scopes to the checked TasteGate surface of Definition 449.7 with BEDC.Derived.RealScheduleFusionUp.taste_gate.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealScheduleFusion}^{\uparrow}}, \mathsf{axiomClean})$

Bridge status: none

Origin: ai

Lean target: `BEDC.Derived.RealScheduleFusionUp.RealScheduleFusionTasteGate\_single\_carrier\_alignment`

Not claimed: This chapter does not close quotient streams, selected limits, ambient completeness, host real equality, host completion witnesses, or bridge checking.

Upgrade path: Scoped dependency closure requires checked finite-ledger theorems tying the schedule lock, real and completion handoff, non-escape, standard boundary, and TasteGate surface to downstream Real and Completion consumers.

Chapter 450

A Concrete Naming Certificate for $\mathsf{RealCompleteness}^{\uparrow}$

The $\mathsf{RealCompleteness}^{\uparrow}$ interface records the diagonal-limit target of chapter 9238 as a finite naming-certificate packet. It packages the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ observations, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ regular sequence rows, and $\mathsf{Real}^{\uparrow}$ seal row through which a completion consumer sees the candidate limit. The packet is a seed carrier for the Real and Completion substrate; it contains no quotient real, selected host limit, choice principle, or host completeness theorem.

Definition 450.1 (Real completeness finite carrier)**.** *A* $\mathsf{RealCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

with the following visible rows:

1. *X is the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family of rational regular sequences;*
2. *μ is the explicit Cauchy modulus row naming, for each requested rational tolerance, a finite stage after which the family is stable;*
3. *Δ is the diagonal selector row, choosing the finite stage and rational observation used at each precision request;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger containing the dyadic endpoints, radii, comparison rows, and tolerance rows read by the diagonal selector;*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family through which the selected rational names are inspected;*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row tying the selected windows to the regular rational sequence data;*
7. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row that presents the same diagonal observations as the candidate limit name;*
8. *H stores displayed* hsame *transports for the input family, modulus, selector, dyadic ledger, stream windows, readbacks, and seal row;*
9. *C stores the* Cont *routes by which consumers read the modulus, selected diagonal observations, and sealed candidate;*
10. *P is the* Pkg *provenance row over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$ *registration row.*

The local classifier compares two carriers only through these displayed rows. It does not identify quotient representatives, does not choose an external real number, and does not appeal to ambient completeness.

Theorem 450.2 (Real completeness NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier formation for the finite packet of Definition 450.1;*
2. *classifier stability for the transported family X, modulus μ, diagonal selector Δ, observation ledger D, windows W, readback row Q, and seal row S;*
3. *modulus exactness, requiring every convergence bound consumed by the diagonal selector to be the explicit row recorded by μ;*
4. *diagonal readback exactness, requiring every selected rational observation to pass through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger;*
5. *package closure, requiring the* hsame*,* Cont*,* Pkg*, and* NameCert *rows to contain exactly the provenance used by downstream* $\mathsf{Real}^{\uparrow}$ *consumers.*

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier namecert obligations`

Proof. Carrier formation is the tuple assembly of Definition 450.1. Each dependency row named by the diagonal-limit target is a visible coordinate of R.

Classifier stability is componentwise. Transport the regular sequence family and modulus first, then transport the selected stream windows and dyadic observation ledger, and finally transport the $\mathsf{Real}^{\uparrow}$ seal row reached by those observations.

The modulus and diagonal readback clauses are projections of the same packet. The row μ supplies the finite stage bounds, while Δ, W, Q, and D record exactly which rational observations are read at each precision request.

Package closure follows by projecting H, C, P, and N. No consumer route reaches a quotient real, external limit selector, or host completeness theorem because no such coordinate occurs in the carrier. □

Theorem 450.3 (Real completeness diagonal witness schedule)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *carrier. For every precision request read by a* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer, the diagonal witness schedule is a finite* BHist *route inside R: the request is bounded by the displayed modulus row μ, selected by Δ, read through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the* $\mathsf{StreamName}^{\uparrow}$ *windows W, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, transported by the* hsame *rows in H, routed by* Cont *rows in C, and packaged by the* Pkg *and* NameCert *rows P, N before it reaches the seal row S. The schedule contains no quotient real, external limit choice, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier diagonal witness schedule`

Proof. Project the accepted carrier through Definition 450.1. The displayed tuple already contains the family row, modulus, diagonal selector, dyadic ledger, stream windows, regular readback, seal row, transports, continuations, package provenance, and local naming row.

Apply Definition 450.2. The modulus exactness clause attaches each consumed bound to μ, while the diagonal readback exactness clause forces every selected rational observation through Δ, D, W, Q.

It remains to expose the public route. The package-closure clause projects H, C, P, N, so the witness schedule is the finite BHist route recorded in the carrier itself. Since no external limit selector or completeness theorem is a coordinate of R, none can contribute a witness to the schedule. □

Theorem 450.4 (Real completeness tail budget stability)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

and

$$R' = (X', \mu', \Delta', D', W', Q', S', H, C, P, N)$$

be accepted RealCompleteness$^{\uparrow}$ *carriers whose family, modulus, diagonal selector, dyadic ledger, stream-window, readback, and seal rows are related by the displayed* hsame *transports in the shared row H, and whose consumer routes use the same* Cont, Pkg, *and* NameCert *rows C, P, N. Then every tail budget used by Δ in R is transported to the corresponding tail budget used by Δ' in R', and both budgets are read through the same finite* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *route. Thus tail-budget stability is a property of the displayed packet rows and not of host real equality or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier tail budget stability`

Proof. Read both accepted carriers by their displayed coordinates. The only rows available for a tail-budget read are the regular family, modulus, selector, dyadic ledger, stream windows, readback row, seal row, transports, continuations, package provenance, and local naming row.

Use the classifier-stability clause of Definition 450.2. It transports $X, \mu, \Delta, D, W, Q, S$ componentwise along the displayed hsame data in H, while the shared C, P, N rows keep the consumer route fixed.

The modulus exactness and diagonal readback exactness clauses then identify the transported budget with the same finite readback path. Every consumed bound is still a μ or μ' row, and every selected observation still passes through the corresponding D, W, Q or D', W', Q' rows before the seal is read. No host equality or completeness coordinate is present to alter the transported budget. □

Theorem 450.5 (Real completeness RegSeq-to-seal handoff)**.** *For every accepted* RealCompleteness$^{\uparrow}$ *carrier*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N),$$

the handoff from the RegSeqRat$^{\uparrow}$ *data to the* Real$^{\uparrow}$ *seal is completely determined by the finite rows of R. The regular family X supplies the rational names, the explicit modulus μ bounds the selected tail, Δ chooses the displayed diagonal observations, D records the* DyadicRatCore$^{\uparrow}$ *ledger, W exposes the* StreamName$^{\uparrow}$ *windows, Q performs the* RegSeqRat$^{\uparrow}$ *readback, and H, C, P, N route the handoff to the seal row S through* hsame, Cont, Pkg, *and* NameCert.

Proof. Begin with the carrier definition. It makes $X, \mu, \Delta, D, W, Q, S, H, C, P, N$ the whole naming surface for the diagonal-limit candidate.

Apply Definition 450.2. Carrier formation supplies the finite rows, modulus exactness binds the selected tail to μ, and diagonal readback exactness binds the selected observations to D, W, Q.

The final handoff is package closure. Project H, C, P, N and read the seal row S as the unique $\mathsf{Real}^{\uparrow}$ endpoint named by the carrier. The construction is therefore a handoff from $\mathsf{RegSeqRat}^{\uparrow}$ readbacks to the displayed seal, with no quotient-style real equality or host completeness argument. □

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier regseq seal handoff`

Theorem 450.6 (Real completeness public witness extractor obligation)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *carrier. Any public witness extractor for the diagonal-limit surface of R has the following obligation surface: it may inspect only the* BHist *rows $X, \mu, \Delta, D, W, Q, S, H, C, P, N$; it must read the rational witness through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows; it must route transports through* hsame*, continuations through* Cont*, provenance through* Pkg*, and local registration through* $\mathsf{NameCert}$*; and it must return only the* $\mathsf{Real}^{\uparrow}$ *seal row S as the completion-facing endpoint.*

Proof. First expose the finite public boundary. The carrier definition contains no hidden extractor field, so any public extractor can only project rows from the displayed BHist packet.

Apply Definition 450.2. The diagonal readback exactness clause forces rational witnesses through D, W, Q, and the modulus exactness clause forces every tail bound through μ.

Finally use package closure to project H, C, P, N. These rows are exactly the hsame, Cont, Pkg, and $\mathsf{NameCert}$ route by which the selected witness reaches S. Since S is the only $\mathsf{Real}^{\uparrow}$ seal coordinate in the carrier, the extractor has no public endpoint other than that seal row. □

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier witness extractor public obligation`

Theorem 450.7 (Real completeness finite obligation surface)**.** *For an accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *carrier*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N),$$

all formalization-facing obligations for the local diagonal-limit certificate are exhausted by the finite packet rows: carrier formation for R; hsame *classifier stability for $X, \mu, \Delta, D, W, Q, S$ through H; modulus exactness for μ; diagonal readback exactness through Δ, D, W, Q over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$*; and package closure through the* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows C, P, N to the* $\mathsf{Real}^{\uparrow}$ *seal S. No obligation mentions quotient equality of reals, selected host limits, countable choice, or an ambient completeness theorem.*

Proof. Project Definition 450.2. Its five clauses are already finite: carrier formation, classifier stability, modulus exactness, diagonal readback exactness, and package closure.

Now identify the rows consumed by those clauses. Carrier formation gives R; classifier stability reads H; modulus exactness reads μ; diagonal readback exactness reads Δ, D, W, Q over the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ surfaces; and package closure reads C, P, N before reaching the $\mathsf{Real}^{\uparrow}$ seal S.

The exclusion statement follows from the same projection. Quotient real equality, selected host limits, countable choice, and ambient completeness are absent from the packet, so they cannot appear among the obligations exposed by the local $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$ surface. □

Theorem 450.8 (Real completeness dependency lattice)**.** *For every accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *carrier*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N),$$

the accepted completion route factors through the upstream packet lattice in the following order: $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledgers in* D*,* $\mathsf{StreamName}^{\uparrow}$ *windows in* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks in* Q*,* $\mathsf{FiniteTailDiagonalSeal}^{\uparrow}$ *selected-tail witnesses, and the final* $\mathsf{Real}^{\uparrow}$ *seal row* S*. The rows* H, C, P, N *preserve the same route through* hsame*,* Cont*,* Pkg*, and* NameCert*. The route refuses quotient real equality, selected host limits, countable choice, and ambient completeness.*

Proof. Begin with Definition 450.1. The displayed carrier already separates the dyadic ledger D, stream windows W, regular readback row Q, seal row S, and the transport, continuation, provenance, and naming rows H, C, P, N.

Apply Definition 450.2 and Definition 450.7. Their diagonal readback clauses force selected observations through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows, while package closure routes the result through H, C, P, N before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Now insert the finite-tail handoff supplied by chapter 559. Its selected-tail witness package sits exactly between the $\mathsf{RegSeqRat}^{\uparrow}$ readback and the $\mathsf{Real}^{\uparrow}$ seal, using the same precision, window, source, witness, transport, route, provenance, and local naming discipline.

The sibling chapters chapter 126, chapter 301, chapter 291, and chapter 38 name the upstream rows consumed by this lattice. They provide the window, regular-rational, dyadic, and real-seal anchors without adding a quotient real or a host completeness principle.

Finally use Definition 450.17. Since quotient real equality, selected host limits, countable choice, and ambient completeness are absent from the carrier, they cannot appear in the dependency lattice. □

Theorem 450.9 (Real completeness modulus domain coverage)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *carrier. Every modulus request consumed by the diagonal selector* Δ *is a displayed unary request for a rational tolerance in the modulus row* μ*. The selected request is read through the finite route* D, W, Q, H, C, P, N*: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger supplies the rational tolerance and observation rows, the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row expose the selected rational names, and the transport, continuation, package, and local naming rows record the public route. No modulus request is supplied by a quotient stream, selected host limit, countable choice, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier modulus domain coverage`

Proof. Read the carrier coordinates in Definition 450.1. The rows μ and Δ are displayed separately: μ names the tolerance-indexed stage requests, while Δ consumes only finite selected stages and rational observations.

Apply Definition 450.2. Its modulus exactness clause binds every convergence bound consumed by the selector to the explicit μ row, and its diagonal readback exactness clause routes the selected rational observation through D, W, Q.

The public route is completed by the rows H, C, P, N. By Definition 450.13, those rows are precisely the path by which the finite diagonal observation reaches the $\mathsf{Real}^{\uparrow}$ candidate. By Definition 450.17, quotient streams, selected host limits, countable choice, and ambient completeness are not coordinates of this route. □

Theorem 450.10 (Real completeness selector readback determinacy)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

and

$$R' = (X', \mu', \Delta', D', W', Q', S', H, C, P, N)$$

be accepted $\mathsf{RealCompleteness}^{\uparrow}$ *carriers whose* X, μ, Δ, D, W, Q *rows are related by the displayed transports named in the shared* H *row and whose consumer reads use the same* C, P, N *route. Then two selector reads using those transported rows reach the same finite* $\mathsf{Real}^{\uparrow}$ *seal ledger. In particular, selector readback determinacy is a statement about the displayed rows* $X, \mu, \Delta, D, W, Q, H, C, P, N$ *and not about a quotient stream, selected host limit, countable choice, or ambient completeness theorem.*

Proof. Start with the two carrier displays. The carrier definition exposes exactly the rows that the selector can inspect: family, modulus, selector, dyadic ledger, stream windows, regular readback, transport rows, continuations, package provenance, and local naming.

Use Definition 450.2 for classifier stability. The shared H row transports X, μ, Δ, D, W, Q, while the shared C, P, N route keeps the consumer-facing readback path fixed.

Now apply Definition 450.13 and Definition 450.16. A selector read reaches $\mathsf{Real}^{\uparrow}$ only as the finite seal ledger formed from Δ through D, W, Q and then routed through H, C, P, N. Since both reads use the same transported rows and the same route, they reach the same ledger.

Finally Definition 450.17 rules out any external separator. There is no quotient stream, selected host limit, countable-choice row, or host completeness coordinate that could split the two readbacks after the finite route has been fixed. □

Theorem 450.11 (Real completeness consumer route totality)**.** *For every accepted carrier*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N),$$

each completion-facing consumer read for $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, or* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *factors through exactly the displayed rows* $X, \mu, \Delta, D, W, Q, S, H, C, P, N$*. The factorization reads the regular family, explicit modulus, diagonal selector, dyadic ledger, stream windows, regular readback,* $\mathsf{Real}^{\uparrow}$ *seal, transports, continuations, package provenance, and local naming row, and it exposes no quotient stream, selected host limit, countable choice, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier consumer route totality`

Proof. Begin with Definition 450.1. It lists the complete carrier surface, and no completion-facing row occurs outside $X, \mu, \Delta, D, W, Q, S, H, C, P, N$.

Apply Definition 450.2. Carrier formation and package closure make the displayed rows the full public route, while modulus exactness and diagonal readback exactness force any selected observation to pass through μ, Δ, D, W, Q before it can reach the seal row.

For $\mathsf{Real}^{\uparrow}$ reads, use Definition 450.13 and Definition 450.16: the candidate is the seal row S read through the finite diagonal route. For $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{CauchySequenceSpace}^{\uparrow}$ reads, use Definition 450.18 and Definition 450.22: the downstream consumer first reads the same finite seal route and then its displayed finite handoff rows.

The route is therefore total over the displayed carrier rows and nowhere else. By Definition 450.17, quotient streams, selected host limits, host equality, countable choice, and ambient completeness are absent from the public boundary. □

Theorem 450.12 (Real completeness public seal export)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *carrier. The public export consumed by* $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *and* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *is exactly the seal row* S *reached through the displayed rows*

$$\mu, \Delta, D, W, Q, H, C, P, N.$$

Any two consumer reads with the same displayed rows reach the same seal ledger. The export does not claim quotient stream equality, selected host limits, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier public seal export`

Proof. Begin with consumer route totality. By Definition 450.11, every $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, or $\mathsf{CauchySequenceSpace}^{\uparrow}$ read factors through the displayed carrier rows and no external completion object.

Identify the endpoint. Apply Definition 450.13 and Definition 450.5; the diagonal observations selected by Δ pass through D, W, Q and reach the public seal row S through μ, H, C, P, N.

Now compare two consumer reads with the same displayed rows. The selector readback determinacy theorem Definition 450.10 fixes the finite readback route, so both reads arrive at the same seal ledger.

Finally apply the non-escape boundary. By Definition 450.17, quotient streams, selected host limits, countable choice, and ambient completeness are not coordinates of the packet, and therefore cannot be exported by the public seal row. □

Theorem 450.13 (Real completeness diagonal limit candidate)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *carrier. The candidate limit exported to* $\mathsf{Real}^{\uparrow}$ *is the seal row* S *obtained from the selected diagonal observations* Δ *through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*. Every convergence read used by this candidate factors through the explicit modulus row* μ *and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Start from the NameCert obligations of Definition 450.2. They bind the modulus row, diagonal selector, finite windows, regular-sequence readbacks, dyadic ledger, and seal row to the same carrier.

The diagonal selector Δ chooses only recorded stages and observations. The selected reads therefore pass through W, Q, and D before the seal row S is formed.

The convergence-facing part is controlled by μ. Since all consumer routes are stored in H, C, P, and N, the exported candidate is exactly the finite diagonal-limit surface seen by $\mathsf{Real}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier diagonal limit candidate`

Theorem 450.14 (Real completeness carrier transport)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *carrier. Any componentwise displayed* hsame *transport of the concrete packet rows* $X, \mu, \Delta, D, W, Q, S, H, C, P, N$ *that preserves the* Cont *routes in* C*, the* Pkg *provenance in* P*, and the local* NameCert *row* N *yields another accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *carrier with the same public diagonal-limit surface.*

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier carrier transport`

Proof. Use the carrier definition to read every coordinate of R. The transported packet has the same row shape: regular sequence family, modulus row, diagonal selector, dyadic ledger, stream windows, readback row, $\mathsf{Real}^{\uparrow}$ seal, transport rows, continuation routes, package provenance, and local naming row.

Apply Definition 450.2. Its classifier-stability clause transports $X, \mu, \Delta, D, W, Q, S$ componentwise by hsame, while its package-closure clause keeps H, C, P, N attached to the same public routes.

The conclusion is therefore a repacking of the displayed rows. No ambient completeness theorem is invoked, because acceptance is checked by the finite carrier and the local NameCert obligations. □

Theorem 450.15 (Real completeness modulus diagonal exactness)**.** *For every accepted packet*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N),$$

each diagonal observation exported by $\mathsf{RealCompleteness}^{\uparrow}$ *is selected by* Δ*, bounded by the explicit modulus row* μ*, read through the* BHist *ledgers* D, W, Q*, transported by* hsame *rows in* H*, routed through* Cont *rows in* C*, and packaged by* P *and* N*. No exported diagonal read may use a modulus or rational observation absent from the concrete packet.*

Proof. Begin with Definition 450.13. It identifies the exported $\mathsf{Real}^{\uparrow}$ candidate with the seal row S obtained from Δ through W, Q, and D.

Apply Definition 450.2. Its modulus exactness clause binds every convergence bound to μ, and its diagonal readback exactness clause binds every selected rational observation to the displayed stream, readback, and dyadic rows.

The remaining rows H, C, P, N record transport, continuation, package, and naming discipline. Hence exactness is a finite ledger property of R, not a claim about host completeness. □

Theorem 450.16 (RealUp seal ledger discipline)**.** *For every accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *carrier*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N),$$

the $\mathsf{Real}^{\uparrow}$ *seal row* S *is the only completion-facing export. Its reads must pass through the displayed* BHist *packet rows* X, μ, Δ, D, W, Q*, the* hsame *transport row* H*, the* Cont *route row* C*, the* Pkg *row* P*, and the* NameCert *row* N*.*

Proof. Project the carrier through Definition 450.1. The only row typed as the candidate limit name is S, and the preceding rows record the family, modulus, selector, dyadic observations, stream windows, and regular-sequence readbacks that form it.

Use Definition 450.2 to keep the seal attached to the same classifier-stable rows. The package-closure clause says the public routes are exactly the displayed hsame, Cont, Pkg, and NameCert rows.

Finally apply Definition 450.13. It identifies the seal with the finite diagonal observations, so the $\mathsf{Real}^{\uparrow}$ boundary contains no selected external limit, quotient real, host equality, or host completeness proof. □

Theorem 450.17 (Real completeness no-escape boundary)**.** *The public boundary of* $\mathsf{RealCompleteness}^{\uparrow}$ *exports only the finite diagonal-limit candidate over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. It exports no quotient real, no host equality on*

real numbers, no selected external limit, no countable-choice principle, and no host completeness theorem.

Proof. Inspect the carrier coordinates of Definition 450.1. The only completion-facing rows are the modulus, diagonal selector, finite stream windows, regular-sequence readbacks, dyadic observation ledger, and $\mathsf{Real}^{\uparrow}$ seal row.

Apply Definition 450.13. Every candidate-limit read is downstream of those displayed rows and their transport, continuation, package, and local naming data.

The excluded objects are absent from the tuple. Therefore the boundary cannot export a quotient real, host real equality, external selected limit, choice principle, or host completeness theorem. □

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier nonescape boundary`

Theorem 450.18 (Real completeness scoped finite seal pullback)**.** *Every* $\mathsf{RealCompleteness}^{\uparrow}$ *diagonal-limit read factors through the explicit modulus row, diagonal selector,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal, and downstream* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *finite seal route displayed by the accepted carrier. The pullback exports no quotient stream, selected host limit, ambient completeness theorem, or host equality on completed reals.*

Proof. Start with the NameCert obligations of Definition 450.2. They bind carrier formation, classifier stability, modulus exactness, diagonal readback exactness, and package closure to the finite rows of the accepted packet.

Apply Definition 450.13 and Definition 450.15. The candidate read is selected by Δ, bounded by μ, and read through D, W, Q before it reaches the $\mathsf{Real}^{\uparrow}$ seal row.

Next use Definition 450.16. It identifies the $\mathsf{Real}^{\uparrow}$ seal as the only completion-facing export and keeps every consumer route inside the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

The downstream $\mathsf{CauchyLimitSeal}^{\uparrow}$ finite seal route consumes exactly that seal-facing row: explicit modulus, selected diagonal observations, stream windows, regular rational readback, dyadic ledger, and the same package provenance. The route is therefore a pullback along the finite seal consumer rather than a choice of an external completed object.

Finally apply Definition 450.17. Since quotient streams, selected host limits, ambient completeness, and host equality are absent from the carrier, they cannot appear in the scoped pullback. □

Theorem 450.19 (Real completeness candidate-uniqueness boundary)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

and

$$R' = (X', \mu', \Delta', D', W', Q', S', H, C, P, N)$$

be accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packets whose* X, μ, Δ, D, W, Q *rows are related by the displayed* hsame *transports named in the same* H *row, and whose seal rows* S *and* S' *are produced through the same diagonal readback routes* C*, package provenance* P*, and local naming row* N*. Then every* $\mathsf{Real}^{\uparrow}$ *consumer classifies* S *and* S' *through the same displayed* $\mathsf{Real}^{\uparrow}$ *seal ledger. In particular, the packet cannot export two distinct completion-facing seal reads for the same transported diagonal family and the same readback routes.*

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier candidate uniqueness boundary`

Proof. Apply Definition 450.2. Its classifier-stability clause transports the family, modulus, selector, dyadic ledger, windows, readback row, and seal row through the displayed rows of H.

Next use Definition 450.14 and Definition 450.15. The transported packets have the same public diagonal-limit surface, and every convergence bound and selected rational observation is read from μ, Δ, D, W, Q through the same routes.

Now apply Definition 450.16. A $\mathsf{Real}^{\uparrow}$ consumer may inspect a seal only through the displayed packet rows and the shared H, C, P, N ledger. Since both seal rows are produced through those same diagonal readback routes, the consumer reaches the same displayed $\mathsf{Real}^{\uparrow}$ seal ledger.

Finally invoke Definition 450.17. There is no quotient real, host equality, selected external limit, or host completeness row that could separate S from S' outside the displayed ledger. The only exported classification is therefore the common finite seal-ledger classification. □

Theorem 450.20 (CauchyLimitSeal transport stability for real completeness)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

and

$$R' = (X', \mu', \Delta', D', W', Q', S', H, C, P, N)$$

be accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packets whose* X, μ, Δ, D, W, Q *rows are related by the displayed* hsame *transports named in the shared* H *row, and whose seal rows* S *and* S' *are produced through the same continuation routes* C*, package provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$ *row* N*. Then every downstream* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of either seal factors through the same finite route: the explicit modulus, diagonal selector,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal, displayed* hsame *rows,* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. Hence the transported diagonal-limit seal is stable not only for* $\mathsf{Real}^{\uparrow}$ *consumers but also for the finite* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route that consumes the seal.*

Proof. First use Definition 450.14. The componentwise hsame rows in H transport the visible family, modulus, selector, dyadic ledger, stream windows, readback row, and seal row while preserving the shared C, P, N routing data, so both packets present the same public diagonal-limit surface.

Next apply Definition 450.15. Every selected read used by either seal is bounded by the corresponding explicit modulus row and passes through Δ, D, W, Q or through their transported counterparts. Since those rows are tied by the same H and consumed through the same C, P, N data, the diagonal selector and rational readback route are the same finite route seen through transport.

Use Definition 450.16 to identify the $\mathsf{Real}^{\uparrow}$ seal as the unique completion-facing export for each packet. Then use Definition 450.18: any $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer of that export reads the explicit modulus, selected diagonal observations, dyadic ledger, stream windows, regular-sequence readback, seal row, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows.

It remains to rule out a second downstream route. By Definition 450.19, the two seal rows have the same displayed $\mathsf{Real}^{\uparrow}$ seal-ledger classification for the transported diagonal family and shared readback routes. Finally Definition 450.17 excludes quotient streams, host real equality, selected external limits, choice principles, and host completeness rows. Thus any $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer of either seal factors through the same finite route. □

Theorem 450.21 (Real completeness seal classifier stability)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

and

$$R' = (X', \mu', \Delta', D', W', Q', S', H, C, P, N)$$

be accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packets. Suppose the family row, modulus row, diagonal selector, dyadic ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows of* R *and* R' *are related by the displayed* hsame *transports named in the shared* H *row, and suppose the seal rows* S *and* S' *are read through the same* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$ *route. Then the* $\mathsf{Real}^{\uparrow}$ *classifier class exported by* S *is the same finite seal-ledger class exported by* S'*. Moreover, every downstream* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *read of either seal sees that same class through the displayed route consisting of* μ, Δ, D, W, Q, S*, the transported counterparts,* H, C, P, N*, and no ambient completion object.*

Proof. Apply Definition 450.14. The displayed hsame rows give componentwise transport of the family, modulus, diagonal selector, dyadic ledger, stream windows, regular rational readback, and seal rows while keeping the shared continuation, package, and local naming data fixed.

Next use Definition 450.15. The finite observations that feed the two seal rows are exactly the bounded diagonal reads selected by Δ and Δ' and recovered through D, W, Q and their transported counterparts.

Apply Definition 450.16. The only $\mathsf{Real}^{\uparrow}$ classifier endpoint available to either packet is the seal ledger exposed by the accepted carrier, so the two seal rows export the same finite seal-ledger class under the shared H, C, P, N route.

Now invoke Definition 450.20. A downstream $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer reads no separate completion data; it consumes the explicit modulus, diagonal selector, dyadic ledger, stream windows, regular readback, seal row, displayed transports, continuations, package provenance, and local naming row already identified above.

Finally use Definition 450.17. Quotient streams, selected host limits, host equality, countable choice, and ambient completeness are not coordinates of the packet, so they cannot split the exported classifier class or create a second downstream seal view. □

Theorem 450.22 (RealCompleteness shared-window handoff from CauchySequenceSpace)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet whose regular-family row is presented by an accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet*

$$T = (F, \sigma, W_c, \epsilon, Q_c, H_c, C_c, P_c, N_c).$$

Then every $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer read of the seal row* S *factors first through the displayed* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *rows*

$$F, \sigma, W_c, \epsilon, Q_c, H_c, C_c, P_c, N_c$$

and then through the displayed $\mathsf{RealCompleteness}^{\uparrow}$ *rows*

$$\mu, \Delta, D, W, Q, S, H, C, P, N.$$

The handoff exports no quotient stream, selected host limit, host real equality, or ambient completeness coordinate.

Proof. Begin with the shared finite Cauchy window. By Definition 406.11, any completion-facing comparison supplied by T reaches its handoff only after reading the regular-family row, schedule, cofinal-window ledger, dyadic tolerance row, completion handoff, transports, continuations, provenance, and local naming row.

Next exhaust the regular-family presentation. Theorem 406.15 makes every regular-family consumer of T factor through the same rows, and Definition 406.19 records that a uniform-criterion presentation contributes only the shared threshold and real-seal handoff already displayed by T.

Now pass to the diagonal seal. Apply Definition 450.20 and Definition 450.21. The seal row S is read through the explicit modulus, diagonal selector, dyadic ledger, stream windows, regular readback, $\mathsf{Real}^{\uparrow}$ seal, transported routes, continuations, package provenance, and local $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$ row.

Finally use Definition 450.17. Since neither the CauchySequenceSpace packet nor the RealCompleteness packet contains quotient streams, selected host limits, host real equality, or an ambient completeness row, a consumer cannot bypass the two-stage displayed route. □

Theorem 450.23 (RealCompleteness diagonal seal totality)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of the diagonal seal row S factors through exactly the displayed regular family row X, explicit modulus row μ, diagonal selector Δ,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, finite* $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q,* $\mathsf{Real}^{\uparrow}$ *seal row S,* hsame *transport row H,* Cont *route row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$ *row N. The consumer surface contains no quotient stream, host equality on completed reals, selected external limit, choice principle, or ambient completeness row.*

Proof. First identify the seal route. Apply Definition 450.13 and Definition 450.15. The candidate read is the seal row S, formed from the diagonal selector Δ, bounded by μ, and read through the dyadic ledger, stream windows, and regular-sequence readback rows D, W, Q.

Next lock the completion-facing endpoint. By Definition 450.16, a $\mathsf{Real}^{\uparrow}$ consumer sees the candidate only through the seal ledger carried by R and the displayed H, C, P, N rows.

For downstream seal consumers, use Definition 450.18 and Definition 450.20. They make the $\mathsf{CauchyLimitSeal}^{\uparrow}$ route consume the same explicit modulus, selected diagonal observations, dyadic ledger, stream windows, readback row, seal row, transports, continuations, package provenance, and local naming row.

Finally apply Definition 450.17. The excluded objects are absent from the accepted packet, so no consumer can replace the displayed diagonal-seal route with a quotient stream, host equality, selected external limit, choice principle, or ambient completeness row. □

Theorem 450.24 (RealCompleteness transport-tail-selector fusion)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet. Let*

$$T = (q, s, r, d, e, w, H_T, C_T, P_T, N_T)$$

be an accepted $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet whose selected-tail rows provide the same precision,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal rows used by μ, Δ, D, W, Q, S. Let*

$$U = (R_U, W_U, D_U, S_U, H_U, C_U, P_U, N_U)$$

be an accepted $\mathsf{RegularCauchyLimitTransport}^{\uparrow}$ *packet transporting those rows to the same* R *surface, and let*

$$F = (q_F, s_F, r_F, w_F, e_F, h_F, c_F, p_F, n_F)$$

be an accepted $\mathsf{FiniteTailDiagonalSeal}^{\uparrow}$ *packet consuming the selected finite tail supplied by* T *and transported by* U*. Then every completion-facing* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *read of* R *factors through exactly the finite route*

$$\mu, \Delta, D, W, Q, S, H, C, P, N$$

together with the selected-tail witness row w*, the transport packet rows* $R_U, W_U, D_U, S_U, H_U, C_U, P_U, N_U$*, and the finite-tail seal rows* $q_F, s_F, r_F, w_F, e_F, h_F, c_F, p_F, n_F$*. The fused route exports no quotient stream, host real equality, selected external limit, countable-choice selector, or ambient completeness theorem.*

Proof. First expose the RealCompleteness side. Apply Definition 450.3 and Definition 450.4. They force each completion-facing precision request to read the displayed modulus, diagonal selector, dyadic ledger, stream windows, regular readback, seal row, transports, continuations, package provenance, and local naming row of R.

Next attach the selected tail. By Definition 458.3, the tail-selector packet supplies an admissible row w for the same precision, window, regularity, dyadic, and seal reads. The row is finite before any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer reaches the seal.

Now transport the selected row into the RealCompleteness surface. Apply Definition 600.9; since the transport packet presents the same selected-window, dyadic-ledger, and seal rows, every diagonal-seal consumer of R factors through the displayed transport rows before reading S.

Finally seal the finite tail. The handoff theorem Definition 559.5 routes the selected finite tail through $q_F, s_F, r_F, w_F, e_F, h_F, c_F, p_F, n_F$ before the real-facing row is consumed. Combine this handoff with Definition 450.23 and Definition 450.17; because none of the packets has a coordinate for quotient streams, host real equality, selected external limits, countable-choice selection, or ambient completeness, the fused consumer route cannot escape the displayed finite rows. □

Theorem 450.25 (RealCompleteness scoped consumer seal exhaustion)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet. The diagonal-limit surface of* R *is scoped exactly by the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, and* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *consumer rows, together with the* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows of the packet. It contains no quotient stream, selected host limit, host real equality, countable-choice row, or ambient completeness theorem.*

Proof. Start with the local naming surface. Apply Definition 450.2. Its carrier, classifier, diagonal readback, and package-closure clauses expose only the rows $X, \mu, \Delta, D, W, Q, S, H, C, P, N$.

Next bind the diagonal construction to finite observations. Apply Definition 450.15; the selected diagonal reads are exactly the reads justified by the explicit modulus, dyadic ledger, finite stream windows, and regular-sequence readback rows. Apply Definition 450.16 to route the resulting seal through the displayed $\mathsf{Real}^{\uparrow}$ row and the same transport, continuation, provenance, and naming rows.

For seal consumers, apply Definition 450.20. It keeps the $\mathsf{CauchyLimitSeal}^{\uparrow}$ route attached to the same diagonal seal and the same H, C, P, N ledger. For completion-facing consumers whose regular family is supplied through $\mathsf{CauchySequenceSpace}^{\uparrow}$, apply Definition 450.22; the handoff

contributes only its displayed finite window rows before returning to the same $\mathsf{RealCompleteness}^{\uparrow}$ packet.

Finally apply Definition 450.23. The diagonal-seal route is exhausted by the displayed rows, so no consumer can replace it by a quotient stream, selected host limit, host real equality, countable-choice row, or ambient completeness theorem. □

Theorem 450.26 (RealCompleteness scoped consumer seal exhaustion)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *or completion-facing consumer of R factors through exactly the displayed finite seal surface*

$$X, \mu, \Delta, D, W, Q, S, H, C, P, N.$$

When the regular-family row is supplied through a $\mathsf{CauchySequenceSpace}^{\uparrow}$ *handoff, the consumer route also factors through the displayed handoff rows of that packet before returning to the same* $\mathsf{RealCompleteness}^{\uparrow}$ *rows. No such consumer exports a quotient stream, host equality on completed reals, selected external limit, choice principle, or ambient completeness row.*

Proof. Start with the finite carrier surface. The local obligations in Definition 450.2 identify the accepted packet as the displayed rows $X, \mu, \Delta, D, W, Q, S, H, C, P, N$, and Definition 450.15 pins every diagonal observation used by the seal to μ, Δ, D, W, Q.

Next bind the seal consumers. Apply Definition 450.20 and Definition 450.21. These results make both the $\mathsf{Real}^{\uparrow}$ classifier and the downstream $\mathsf{CauchyLimitSeal}^{\uparrow}$ route consume the same seal row S through the displayed transports, continuations, package provenance, and local naming row.

For a completion-facing route whose family row is presented by $\mathsf{CauchySequenceSpace}^{\uparrow}$, use Definition 450.22. The handoff contributes only its displayed finite window rows before the read returns to $\mu, \Delta, D, W, Q, S, H, C, P, N$.

Finally, Definition 450.23 exhausts the diagonal-seal surface for all $\mathsf{Real}^{\uparrow}$ and $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumers. Apply Definition 450.17 to exclude quotient streams, host equality, selected external limits, choice principles, and ambient completeness from every completion-facing export. □

Theorem 450.27 (Real completeness finite limit-existence witness)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet. For every precision request made by a* $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *or completion-facing consumer, the packet supplies a BEDC finite witness for the diagonal limit-existence obligation: the request reads the modulus row μ, selects a displayed diagonal observation through Δ, exposes the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows D, W, Q, reaches the* $\mathsf{Real}^{\uparrow}$ *seal row S, and records the transport, continuation, package, and local naming rows H, C, P, N. The witness contains no quotient stream, selected host limit, countable choice, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier limit existence finite witness`

Proof. Project the accepted packet through Definition 450.1. The rows named in the statement are exactly the rows of the carrier, so the precision request has no source outside the displayed BHist packet.

Use Definition 450.9 to bind each consumed tolerance request to μ. Then apply Definition 450.15 to route the selected diagonal observation through Δ, D, W, Q.

It remains to identify the endpoint and public ledger. Apply Definition 450.23. The selected route reaches S through H, C, P, N, and Definition 450.17 rules out quotient streams, selected host limits, countable choice, and ambient completeness as witness coordinates. □

Theorem 450.28 (Real completeness limit uniqueness classifier)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

and

$$R' = (X', \mu', \Delta', D', W', Q', S', H, C, P, N)$$

be accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packets whose* X, μ, Δ, D, W, Q *rows are related by the displayed transports named in the shared* H *row, and whose consumer routes use the same* C, P, N *data. Then the two packets export the same finite* $\mathsf{Real}^{\uparrow}$ *seal-ledger classifier for the candidate limit. The classifier is determined by the transported diagonal rows and the shared* H, C, P, N *ledger, not by quotient equality of streams, host real equality, a selected external limit, or ambient completeness.*

Proof. Begin with classifier stability in Definition 450.2. It transports the family, modulus, selector, dyadic ledger, stream windows, readback row, and seal row componentwise through the displayed H row.

Next use Definition 450.10. Since the transported selector reads use the same C, P, N route, they reach the same finite $\mathsf{Real}^{\uparrow}$ seal ledger.

The public classifier is then fixed by Definition 450.21. Finally apply Definition 450.17; no external completion object or quotient stream is present to refine or split the displayed seal-ledger classification. □

Theorem 450.29 (Real completeness LimitSelector handoff)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet, and let*

$$L = (R_L, n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L)$$

be an accepted $\mathsf{LimitSelector}^{\uparrow}$ *packet. Assume that the selected precision* n*, modulus* μ_L*, selected index* k_L*, finite window* W_L*, dyadic readback* D_L*, and* $\mathsf{Real}^{\uparrow}$ *seal row* S *agree through the displayed transports with the corresponding diagonal rows of* R *along* $\mu, \Delta, D, W, Q, S, H, C, P, N$*. Then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of* R *whose route reads that selected diagonal observation factors through the* $\mathsf{LimitSelector}^{\uparrow}$ *finite witness route*

$$n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L$$

before reaching the same seal row S*. The factorization contains no host-selected limit, quotient-stream equality, countable-choice selector, or ambient completeness witness.*

Proof. First project the selector packet. The local obligations of Definition 673.2 expose $R_L, n, \mu_L, k_L, W_L, D_L, S, H$ and Definition 673.3 makes every diagonal-limit read pass through the displayed selector, window, readback, seal, transport, continuation, provenance, and naming rows.

Next compare this selector route with the $\mathsf{RealCompleteness}^{\uparrow}$ packet. The agreement assumptions identify the selected precision and modulus with the diagonal rows of R, while Definition 450.15 pins the corresponding observation of R to μ, Δ, D, W, Q.

It remains to identify the endpoint. Apply Definition 450.23 to route every $\mathsf{Real}^{\uparrow}$ and $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer of the selected observation to the same seal row S, and apply Definition 450.28 to keep the transported seal-ledger classifier fixed by the displayed rows.

Finally use selector exhaustion and seal non-escape. By Definition 673.7 and Definition 673.5, the selected observation has no remaining route outside $n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L$. The boundary theorem Definition 450.17 excludes host-selected limits, quotient streams, countable choice, and ambient completeness from the $\mathsf{RealCompleteness}^{\uparrow}$ side as well. □

Theorem 450.30 (Real completeness limit handoff package)**.** *For every accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *packet*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N),$$

the concrete paper-side package corresponding to the vision-level limit target consists of the finite limit-existence witness of Definition 450.27, the uniqueness classifier of Definition 450.28, the $\mathsf{LimitSelector}^{\uparrow}$ *finite-route handoff of Definition 450.29, the* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *shared-window handoff of Definition 450.22, the diagonal seal totality of Definition 450.23, and the scoped consumer seal exhaustion of Definition 450.26. This package is a finite* BHist *handoff to* $\mathsf{Real}^{\uparrow}$ *and downstream seal consumers; it is not a theorem asserting* $\mathsf{Real}^{\uparrow}$ *completeness as a closed public result.*

Proof. First assemble the existence side. Apply Definition 450.27; it supplies the displayed precision-to-seal route through $\mu, \Delta, D, W, Q, S, H, C, P, N$.

Next assemble the classifier side. Apply Definition 450.28; transported packets with the same public ledger export the same finite $\mathsf{Real}^{\uparrow}$ seal-ledger classifier.

Now attach the selector handoff. Apply Definition 450.29; every selected diagonal observation consumed by a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ route factors through the independent $\mathsf{LimitSelector}^{\uparrow}$ finite witness route before it reaches S.

Then attach the downstream handoff. Use Definition 450.22 when the regular-family row is supplied through $\mathsf{CauchySequenceSpace}^{\uparrow}$, and use Definition 450.23 to keep every seal consumer on the same displayed route.

Finally apply Definition 450.26. The assembled package is exactly the scoped finite consumer surface. Since the chapter boundary excludes quotient streams, selected host limits, host equality, countable choice, and ambient completeness, the package does not close $\mathsf{Real}^{\uparrow}$ completeness as a public theorem. □

Theorem 450.31 (Real completeness shared-tail modulus limit lock)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet, and let*

$$T = (R_0, R_1, M_0, M_1, \tau, D_T, W_0, W_1, Q_0, Q_1, E, H_T, C_T, P_T, N_T)$$

be an accepted $\mathsf{CauchySharedTailModulus}^{\uparrow}$ *packet. Assume that* M_0 *and* M_1 *present the same finite precision request read by* μ*, that the shared threshold* τ *presents the diagonal tail threshold* Δ*, that* D_T *and* D *are the same dyadic ledger row, that* W_0 *and* W_1 *present the finite* $\mathsf{StreamName}^{\uparrow}$ *windows of* W*, that* Q_0 *and* Q_1 *present the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and that the* $\mathsf{Real}^{\uparrow}$ *seal*

row E is transported to S by the displayed rows H_T, C_T, P_T, N_T and H, C, P, N. Then every $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *or completion-facing consumer of R whose route reads this diagonal limit observation factors through the shared-tail-modulus route*

$$M_0, M_1, \tau, D_T, W_0, W_1, Q_0, Q_1, E, H_T, C_T, P_T, N_T$$

before it reaches the seal row S. The locked route exports no quotient stream, selected host limit, countable-choice selector, host real equality, or ambient completeness theorem.

Proof. Start with the finite handoff package. By Definition 450.30, every completion-facing read of the displayed diagonal limit observation is already confined to the finite BHist route through $\mu, \Delta, D, W, Q, S, H, C, P, N$ and its downstream seal consumers.

Next identify the shared threshold side. Apply Definition 983.3. The two tail schedules M_0 and M_1 are read before the single threshold τ, and both $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks are forced through τ, D_T. The agreement assumptions transport this route to the Real-Completeness rows μ, Δ, D, W, Q.

Now attach the Real seal. By Definition 983.4, every Real-facing read of T reaches E only after the shared route through $M_0, M_1, \tau, D_T, W_0, W_1, Q_0, Q_1$. The assumed transport from E to S therefore places the $\mathsf{RealCompleteness}^{\uparrow}$ seal row after the same shared-tail-modulus route.

It remains to rule out a second completion-facing path. The uniqueness classifier of Definition 450.28 fixes the seal-ledger classifier once the displayed rows $\mu, \Delta, D, W, Q, S, H, C, P, N$ have been identified, and Definition 450.17 removes quotient streams, selected host limits, countable-choice selectors, host real equality, and ambient completeness from the packet boundary. Hence any $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, or completion-facing consumer must pass through the shared-tail-modulus route before reaching S. □

Theorem 450.32 (Real completeness finite-window open phase exit)**.** *For every accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *carrier*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N),$$

the completion-facing open-phase boundary factors through exactly the $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger row D, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{Real}^{\uparrow}$ *seal row S, and the structural rows H, C, P, N. This gives the paper-side finite-window witness for the Phase Real and Completion object chain without claiming* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of streams, selected host limits, countable choice, or* $\mathsf{bridgeChecked}$ *status.*

Proof. Begin with the dependency lattice of Definition 450.8. It identifies the completion-facing object chain through the dyadic ledger, stream-window, regular-sequence readback, and RealUp seal rows already present in R.

Next apply Definition 450.7. The obligation surface exposes exactly D, W, Q, S together with the structural rows H, C, P, N, so the open-phase witness is finite and packet-local.

Use Definition 450.11 to route every completion-facing consumer through those displayed rows. Then apply Definition 450.17; no quotient stream, selected host limit, countable-choice selector, ambient completeness proof, or bridge-checked object lies outside the finite-window packet. □

Theorem 450.33 (Real completeness exact-boundary handoff)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet, and let*

$$B = (L, K, J, S_B, W_B, R_B, D_B, E_B, H_B, C_B, P_B, N_B)$$

be an accepted RealCompletionExactBoundaryUp *packet. Suppose that the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D_B *matches* D*, the* $\mathsf{StreamName}^{\uparrow}$ *row* W_B *matches* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R_B *matches* Q*, and the terminal* $\mathsf{Real}^{\uparrow}$ *row* E_B *matches* S *through the displayed componentwise* hsame *transports, the displayed* Cont *replays, the* Pkg *provenance rows, and the local* $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$ *and* $\mathsf{NameCert}_{\mathsf{RealCompletionExactBoundaryUp}}$ *support. Then every completion-facing consumer of* R *that asks for an exact-boundary witness factors through* B *after the finite-window open-phase route. The handoff supplies only the same-route exact-boundary witness, and it exports no quotient stream, selected limit, host equality, countable choice, ambient completeness, metric completeness, or bridge token.*

Proof. Start with Definition 450.32. It confines the open Phase Real and Completion exit of R to the finite route through D, W, Q, S, H, C, P, N and excludes quotient streams, selected host limits, countable choice, ambient completeness, and bridge-checked status from that route.

Next apply Definition 1120.6. The accepted boundary packet B exposes exactly the four completion faces $\mathsf{DyadicRatCore}^{\uparrow}(D_B)$, $\mathsf{StreamName}^{\uparrow}(W_B)$, $\mathsf{RegSeqRat}^{\uparrow}(R_B)$, and $\mathsf{Real}^{\uparrow}(E_B)$, together with its structural rows H_B, C_B, P_B, N_B.

The matching assumptions identify these four faces with the rows D, W, Q, S already used by the finite-window route. Because the comparison is carried only by displayed hsame transports, Cont replays, Pkg provenance, and local NameCert support on both packets, the exact-boundary witness is a repacking of the same route rather than a second completion object.

Finally use Definition 1120.20 and Definition 1120.14. The first theorem keeps the witness inside the exact-boundary obligation surface, and the second theorem removes quotient streams, selected limits, host equality, countable choice, ambient completeness, metric completeness, and bridge tokens from the exported boundary. Hence every exact-boundary request made by a completion-facing consumer of R factors through B after the finite-window open-phase route and receives no additional completion witness. □

Theorem 450.34 (Real completeness exact-boundary finite induction)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet, and let*

$$B = (L, K, J, S_B, W_B, R_B, D_B, E_B, H_B, C_B, P_B, N_B)$$

be an accepted RealCompletionExactBoundaryUp *packet whose four exact-boundary faces match the four open Real and Completion faces of* R*. Then induction on the finite consumer route of* R *reduces every exact-boundary request to exactly the matched faces* $\mathsf{DyadicRatCore}^{\uparrow}(D_B)$*,* $\mathsf{StreamName}^{\uparrow}(W_B)$*,* $\mathsf{RegSeqRat}^{\uparrow}(R_B)$*, and* $\mathsf{Real}^{\uparrow}(E_B)$*, followed only by the displayed* hsame *transports,* Cont *replays,* Pkg *provenance rows, and local* NameCert *rows of the two packets.*

Consequently the exact-boundary handoff is a finite BEDC-internal derivation over the four Phase Real and Completion faces. It has no quotient-stream, selected-limit, host-equality, countable-choice, ambient-completeness, metric-completeness, or bridge-token case.

Proof. Begin with Definition 450.32. The open-phase consumer route of R is finite, and its only completion-facing object rows are D, W, Q, S together with the structural rows H, C, P, N.

The base reads of the induction are therefore the four displayed face reads. Apply Definition 1120.6 to identify the matching boundary witnesses as $\mathsf{DyadicRatCore}^{\uparrow}(D_B)$, $\mathsf{StreamName}^{\uparrow}(W_B)$, $\mathsf{RegSeqRat}^{\uparrow}(R_B)$, and $\mathsf{Real}^{\uparrow}(E_B)$. Each base read is transported by the corresponding hsame comparison, replayed through the relevant Cont row, and recorded by the Pkg and local NameCert entries.

For the induction step, append one accepted consumer edge to a route already reduced to the four boundary faces. The edge can only read one of the structural rows H, C, P, N or one of the matched faces, because Definition 450.32 has no other open-phase exit. The handoff theorem Definition 450.33 then repacks the extended route through B without creating a second completion object.

Finally apply Definition 1120.14. The escape theorem removes every non-finite alternative case: there is no quotient-stream branch, no selected-limit branch, no host-equality branch, no countable-choice branch, no ambient-completeness branch, no metric-completeness branch, and no bridge-token branch. Thus the finite induction closes exactly on the four matched faces followed by H, C, P, N and the displayed local certificate rows. □

Theorem 450.35 (Real completeness exact-boundary standard bridge obligation)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet. The packet R is eligible for a standard bridge only through a matching accepted* RealCompletionExactBoundaryUp *packet*

$$B = (L, K, J, S_B, W_B, R_B, D_B, E_B, H_B, C_B, P_B, N_B)$$

whose four exposed faces match the four completion-facing rows of R: D_B matches D, W_B matches W, R_B matches Q, and E_B matches S through the displayed hsame *transports,* Cont *replays,* Pkg *provenance rows, and local* NameCert *support. The accepted bridge face must be the bridge-checked target*

BEDC.Derived.RealCompletionExactBoundaryUp.RealCompletionExactBoundaryUp_StdBridge.

Thus any standard-bridge claim for $\mathsf{RealCompleteness}^{\uparrow}$ *factors through the already bridge-checked exact-boundary face, not through a separate completion object attached to R.*

Proof. First apply Definition 450.33. Any exact-boundary request made by a completion-facing consumer of R is already routed through a matching accepted RealCompletionExactBoundaryUp packet B after the finite-window open-phase route.

Next use Definition 450.34. The route reduces to the four matched faces $\mathsf{DyadicRatCore}^{\uparrow}(D_B)$, $\mathsf{StreamName}^{\uparrow}(W_B)$, $\mathsf{RegSeqRat}^{\uparrow}(R_B)$, and $\mathsf{Real}^{\uparrow}(E_B)$, followed only by displayed hsame transports, Cont replays, Pkg provenance rows, and local NameCert rows.

Finally invoke Definition 1120.21. That result identifies the public bridge factorization of the exact-boundary packet with the bridge-checked RealCompletionExactBoundaryUp standard-bridge target. Therefore the only admissible standard-bridge path for R is through the matched exact-boundary packet B and its bridge-checked face.

This obligation adds no quotient stream, selected limit, host equality, countable choice, ambient completeness, metric completeness, or bridge token to the $\mathsf{RealCompleteness}^{\uparrow}$ carrier. It records only the required factorization route for any later $\mathsf{RealCompleteness}^{\uparrow}$ standard-bridge claim. □

Theorem 450.36 (Real completeness selector route coverage)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet, and let*

$$L = (R_L, n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L)$$

be an accepted $\mathsf{LimitSelector}^{\uparrow}$ *packet whose selected observation is the displayed diagonal observation consumed from* R*. Every selected diagonal observation consumed by a* $\mathsf{Real}^{\uparrow}$ *reader or a* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *reader factors through the finite* $\mathsf{LimitSelector}^{\uparrow}$ *route*

$$n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L$$

and through the $\mathsf{RealCompleteness}^{\uparrow}$ *rows*

$$\mu, \Delta, D, W, Q, S, H, C, P, N.$$

The coverage is a finite route statement: it names the reader path that reaches the common seal row S*, and it does not export a host-selected limit, quotient-stream equality, countable-choice selector, host equality, or ambient completeness theorem.*

Proof. First expose the selector side. Apply Definition 673.2 to read the packet rows of L, and use Definition 673.3 to force every selected diagonal-limit read through $n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L$.

Next compare the selected observation with the $\mathsf{RealCompleteness}^{\uparrow}$ diagonal rows. The handoff theorem Definition 450.29 identifies the selector route with the diagonal read of R, while Definition 450.15 pins that read to μ, Δ, D, W, Q.

Finally bind the consumer endpoint. Apply Definition 450.28 to keep the transported seal-ledger classifier fixed, and apply Definition 450.17 to rule out the listed external completion objects. □

Theorem 450.37 (Real completeness modulus-selector factorization)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet. The modulus row and the selector row are not independently readable by any selected-observation consumer. Every selected index is justified first by the displayed modulus row* μ*, then by the selector row* Δ*, and then by the finite route through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the* $\mathsf{Real}^{\uparrow}$ *seal rows* D, W, Q, S*. The remaining transport, continuation, package, and local naming rows* H, C, P, N *record the same route for downstream seal consumers.*

Proof. Begin with the modulus obligation. The RealCompleteness obligations bind every precision request to the displayed modulus row, and Definition 450.15 turns the selected diagonal read into a route through μ, Δ, D, W, Q.

The selector cannot be detached from that modulus route. When the observation is presented through $\mathsf{LimitSelector}^{\uparrow}$, Definition 673.2 and Definition 673.3 expose only the finite selector rows, and Definition 450.29 identifies those rows with the same μ, Δ, D, W, Q diagonal read.

It remains to seal the endpoint. Apply Definition 450.28 and Definition 450.17. The first fixes the seal-ledger classifier along S, H, C, P, N, and the second excludes an independent quotient, host, choice, or ambient-completeness interpretation of the selected index. □

Theorem 450.38 (Real completeness seal consumer exhaustion)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet, and let*

$$L = (R_L, n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L)$$

be an accepted $\mathsf{LimitSelector}^{\uparrow}$ *packet reading a selected diagonal observation from* R*. Every downstream consumer of the shared seal exhausts the same finite route: it consumes the selector rows* $n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L$ *when the observation is selector-presented, consumes the RealCompleteness rows* $\mu, \Delta, D, W, Q, S, H, C, P, N$ *when the observation is read from* R*, and exports no quotient stream, selected host limit, countable-choice selector, host equality, or ambient completeness theorem.*

Proof. First route the selector-presented observation. Theorems 673.2 and 673.3 expose the selector rows and give the finite witness route to the common seal row S.

Now route the same observation from the $\mathsf{RealCompleteness}^{\uparrow}$ packet. Use Definition 450.15 for the diagonal rows and Definition 450.29 for the comparison between the selector packet and R.

Finally exhaust the downstream consumer surface. Apply Definition 450.28 to keep the seal-ledger classifier determined by the displayed rows, and apply Definition 450.17 to exclude quotient streams, host-selected limits, countable-choice selectors, host equality, and ambient completeness from the export surface. □

Theorem 450.39 (RealCompleteness diagonal seal factorization public boundary)**.** *Every accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *diagonal-limit packet consumed by a* $\mathsf{Real}^{\uparrow}$*- or* $\mathsf{CauchyLimitSeal}^{\uparrow}$*-facing reader factors through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$ *row. The public read exports no quotient stream, no selected host limit, no host real equality, no choice datum, and no ambient completeness theorem.*

Proof. Project the accepted $\mathsf{RealCompleteness}^{\uparrow}$ carrier. Its diagonal-limit rows expose the dyadic ledger, stream windows, regular-sequence readback, Cauchy-limit seal boundary, transports, routes, provenance, and local naming row as the only public coordinates.

Apply the diagonal witness schedule and finite witness rows already displayed in the chapter. They route every precision request through the modulus and diagonal selector before a $\mathsf{Real}^{\uparrow}$- or $\mathsf{CauchyLimitSeal}^{\uparrow}$-facing reader can see the observation.

Now route the seal-facing read. The $\mathsf{CauchyLimitSeal}^{\uparrow}$ boundary and $\mathsf{RegSeqRat}^{\uparrow}$ readback carry the observation back to the displayed finite ledger, while the hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows record the same transport and provenance for the public consumer.

The non-escape conclusion is immediate from the carrier inventory. Since no quotient stream, selected host limit, host real equality, choice datum, or ambient completeness theorem is a coordinate of the packet, none can be exported by the public factorization route. □

Theorem 450.40 (Real completeness finite approximation LimitSelector handoff)**.** *Let*

$$F = (R_F, n_F, k_F, W_F, D_F, E_F, S_F, H_F, C_F, P_F, N_F)$$

be an accepted $\mathsf{FiniteCauchyApproximation}^{\uparrow}$ *packet, let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *diagonal-limit packet consuming the finite approximation row, and let*

$$L = (R_L, n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L)$$

be a compatible accepted $\mathsf{LimitSelector}^{\uparrow}$ *packet reading the same selected diagonal observation. If the finite approximation route of* F *supplies the source row, selected precision, threshold, finite*

window, dyadic observation ledger, explicit error row, and handoff row consumed by R, and if the selected observation of L agrees through the displayed transports with the same diagonal rows of R, then every $\mathsf{Real}^{\uparrow}$*-,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*-, selector-facing, and completion-facing consumer factors through the same displayed rows*

$$X, \mu, \Delta, D, W, Q, S, H, C, P, N$$

and the selector rows

$$n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L.$$

The handoff contains the finite approximation route of F, the diagonal seal route of R, and the selected finite witness route of L only. It exports no quotient stream, no selected host limit, no countable-choice selector, no host equality, no hidden completion coordinate, and no ambient completeness theorem.

Proof. Begin with the finite approximation packet. Theorems 601.7 and 601.11 force every consumer of F to read the displayed source, precision, threshold, finite window, dyadic ledger, error row, handoff row, transports, continuation routes, provenance, and local naming rows before any $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ boundary is visible.

Next attach the diagonal-limit packet. The finite approximation handoff is consumed by the $\mathsf{RealCompleteness}^{\uparrow}$ rows $X, \mu, \Delta, D, W, Q, S, H, C, P, N$, and the diagonal seal totality theorem routes the completion-facing read through the same seal row S rather than through an independent limit object.

Now attach the selector packet. Apply Definition 450.29 and Definition 450.36: the selected observation reaches S only through $n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L$, and these rows are identified with the same diagonal read of R through the displayed transports.

Finally exhaust the consumer surface. Theorems 450.26 and 450.39 leave no remaining route outside the finite approximation, diagonal, and selector rows already displayed. Hence quotient streams, selected host limits, countable-choice selectors, host equality, hidden completion coordinates, and ambient completeness are not exported by the handoff. □

Theorem 450.41 (RealCompleteness diagonal example consumer lattice)**.** *Let $R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N$ be an accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *packet. Suppose a* $\mathsf{LimitSelector}^{\uparrow}$ *packet reads a selected diagonal observation from R, and suppose, when available, a* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *presentation supplies the same observation through a shared finite Cauchy window. Then the accepted data generate a finite consumer lattice over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{LimitSelector}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows: every completion-facing, seal-facing, selector-facing, and shared-window read factors through the displayed diagonal schedule, witness windows, readback rows, seal row, classifier transports, continuation routes, package provenance, and local naming rows.*

The lattice exports no $\mathsf{Real}^{\uparrow}$ *completeness theorem, no quotient stream, no selected host limit, no countable-choice selector, no host equality, and no ambient completeness row.*

Proof. First route the selected diagonal observation. Theorems 450.29 and 450.23 bind the $\mathsf{LimitSelector}^{\uparrow}$ read and the $\mathsf{RealCompleteness}^{\uparrow}$ diagonal seal to the same finite rows $X, \mu, \Delta, D, W, Q, S, H, C, P, N$.

When the observation is also presented through a shared finite Cauchy window, apply Definition 450.22. This places the $\mathsf{CauchySequenceSpace}^{\uparrow}$ presentation on the same window and seal route rather than adding an independent completion surface.

Now exhaust the downstream consumer routes. Theorem 450.38 says that selector-facing and RealCompleteness-facing consumers use exactly the displayed finite rows, while Definition 450.39 identifies the public boundary seen by $\mathsf{Real}^{\uparrow}$-, $\mathsf{CauchyLimitSeal}^{\uparrow}$-, and completion-facing readers.

The stated non-export claims follow from that factorization. None of a $\mathsf{Real}^{\uparrow}$ completeness theorem, quotient stream, selected host limit, countable-choice selector, host equality, or ambient completeness row is a coordinate of the factorized lattice, so none is exported by the consumer package. □

Theorem 450.42 (Real completeness shared-tail modulus handoff)**.** *Let $R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$ be an accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *carrier. Suppose a completion-facing consumer presents the selected diagonal observation through an accepted* $\mathsf{CauchySharedTailModulus}^{\uparrow}$ *packet. Then the consumer route factors first through the shared threshold row τ, then through the dyadic ledger, both* $\mathsf{StreamName}^{\uparrow}$ *windows, both* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and finally through the same* $\mathsf{Real}^{\uparrow}$ *seal row S displayed by R.*

The route contains no pair of independent thresholds, no quotient stream equality, no host real equality, no selected host limit, no countable-choice selector, and no ambient completeness theorem.

Proof. Begin with the diagonal-limit side. Theorems 450.39 and 450.41 force every completion-facing read of R through $X, \mu, \Delta, D, W, Q, S, H, C, P, N$ before the $\mathsf{Real}^{\uparrow}$ seal row can be consumed.

Now attach the shared-tail packet. Apply Definition 983.3: both regular-Cauchy presentations are synchronized by the single threshold row τ before either window is read. Apply Definition 983.4: the synchronized tails then pass through the dyadic ledger, the two $\mathsf{StreamName}^{\uparrow}$ windows, and the two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks before reaching the real-facing seal row.

It remains to compare endpoints. The RealCompleteness factorization identifies that seal-facing endpoint with the displayed row S of R. Finally, Definition 450.17 excludes independent thresholds, quotient stream equality, host real equality, selected limits, countable choice, and ambient completeness from the exported route. □

Theorem 450.43 (Real completeness selector-window-seal factorization)**.** *Let $R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N$ be an accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *packet. Every selected diagonal observation consumed from R factors in the strict order*

$$\mu, \Delta, D, W, Q, S.$$

The modulus row μ supplies the finite request, the selector row Δ selects the displayed diagonal observation, the $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D records the dyadic value, the* $\mathsf{StreamName}^{\uparrow}$ *windows W expose the finite observation windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q returns the regular-sequence row, and the* $\mathsf{Real}^{\uparrow}$ *seal S is reachable only after those rows have been displayed. The rows H, C, P, N carry transport, route replay, provenance, and local naming for this same factorization and carry no independent selector, window, limit, quotient, choice, host-equality, or ambient-completeness object.*

Proof. Start with selector route coverage. Theorem 450.36 says that every selected diagonal observation reaches a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ reader only through the displayed selector route and the $\mathsf{RealCompleteness}^{\uparrow}$ rows $\mu, \Delta, D, W, Q, S, H, C, P, N$.

Next factor the front of the route. The modulus-selector factorization theorem forces the selected index to pass first through μ, then through Δ, and then through the finite $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows D, W, Q, S.

Now seal the consumer boundary. The seal consumer exhaustion theorem leaves no downstream route outside the selector-presented rows and the displayed $\mathsf{RealCompleteness}^{\uparrow}$ rows, while the nonescape boundary excludes quotient streams, host-selected limits, countable-choice selectors, host equality, and ambient completeness.

Thus H, C, P, N can only transport, replay, authenticate, and name the same ordered route. They do not supply another selected observation or another seal endpoint. □

Theorem 450.44 (Real completeness selector-seal four-face uniqueness)**.** *Let $R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$ and $R' = (X', \mu', \Delta', D', W', Q', S', H', C', P', N')$ be accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *packets. Suppose their selector rows, dyadic ledgers,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seal rows, and* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer rows agree through the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$ *support. Then every selector-window seal route read from either packet factors through the same four visible faces: selector source, dyadic-window ledger, regular-sequence readback, and seal-facing consumer.*

Consequently the two routes determine the same public endpoint. No quotient stream, host-selected limit, countable-choice selector, host real equality, hidden completion coordinate, or ambient completeness row can distinguish the two selector-window seal routes.

Proof. First expose the route on each side. Theorem 450.36 forces every selected observation through the displayed selector route and the $\mathsf{RealCompleteness}^{\uparrow}$ rows, while Definition 450.37 fixes the front face by making the modulus row μ and selector row Δ the only source of the selected observation.

Next identify the middle faces. The finite-observation boundary for $\mathsf{StreamName}^{\uparrow}$, the common-tail window bridge for $\mathsf{RegSeqRat}^{\uparrow}$, and the $\mathsf{DyadicRatCore}^{\uparrow}$ radius-window handoff make the dyadic ledger, stream windows, and regular-sequence readback a single finite observation surface under the stated hsame, Cont, Pkg, and NameCert support.

Now compare seal-facing consumers. Theorem 450.38 exhausts all downstream seal reads, and Theorem 450.43 identifies the ordered route $\mu, \Delta, D, W, Q, S, H, C, P, N$ as the only selector-window-seal factorization. The CauchyLimitSeal selector nonescape and route-lock theorems then forbid a second seal-facing path outside these rows.

The four visible faces therefore determine the route endpoint. Since none of a quotient stream, host-selected limit, countable-choice selector, host real equality, hidden completion coordinate, or ambient completeness row occurs as a coordinate of the route, no such object can distinguish the two accepted presentations. □

Theorem 450.45 (Real completeness selector-window source determinacy)**.** *Let $R = (X, \mu, \Delta, D, W, Q, S, H, C, P,$ be an accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *packet. Every accepted selector-window-seal read of R reads the modulus row μ before it reads the selector row Δ, and it reads Δ before any of the dyadic, stream-window, regular-sequence, or real-seal rows D, W, Q, S. The transport, route, package, and local naming rows H, C, P, N can replay and certify that order, but they cannot supply an alternate source for the selected observation.*

Proof. Start with selector route coverage. Theorem 450.36 makes every selected diagonal observation pass through the displayed selector route before it can be read by a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer.

Now apply the modulus-selector factorization. Theorem 450.37 fixes the front of that route: the finite request is supplied by μ, the selected diagonal row is supplied by Δ, and the middle certificate rows D, W, Q, S are reached only after that source pair is displayed.

Finally compare with the selector-window-seal factorization. Theorem 450.43 identifies H, C, P, N as transport, replay, provenance, and naming rows for the same ordered packet. Hence no accepted read can swap the source order or introduce a second source row. □

Theorem 450.46 (Real completeness selector-window dyadic-window nonescape)**.** *Let $R = (X, \mu, \Delta, D, W, Q, S, H$ be an accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *packet. In every selector-window-seal read of R, the middle rows D, W, Q expose only the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows, and* $\mathsf{RegSeqRat}^{\uparrow}$

readback attached to the source rows μ, Δ. They cannot export quotient streams, host equality, choice selectors, selected host limits, or ambient completeness.

Proof. Use Definition 450.45 first. It places D, W, Q downstream of the displayed source rows μ, Δ, so the middle rows are read as certificate rows for that selected observation rather than as independent completion data.

Next apply the nonescape boundary. Theorem 450.17 excludes quotient streams, host-selected limits, countable-choice selectors, host equality, and ambient completeness from the public $\mathsf{RealCompleteness}^{\uparrow}$ export.

The selector-window-seal factorization then pins the same exclusion to the middle rows. Since D, W, Q are the dyadic ledger, finite stream-window display, and regular-sequence readback inside the ordered route, they have no coordinate from which any of the excluded objects could be exported. □

Theorem 450.47 (Real completeness selector-window consumer readback)**.** *Let $R = (X, \mu, \Delta, D, W, Q, S, H, C, P,$ be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ packet. Every $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, selector-facing, and completion-facing consumer of the selector-window-seal surface reads back the same displayed route*

$$\mu, \Delta, D, W, Q, S, H, C, P, N.$$

No such consumer obtains a second modulus row, selector row, dyadic ledger, stream window, regular-sequence readback, seal row, transport, route replay, package provenance, or local naming row.

Proof. First exhaust the seal-facing consumers. Theorem 450.38 says that $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, selector-facing, and completion-facing reads use the selector-presented rows and the displayed $\mathsf{RealCompleteness}^{\uparrow}$ rows.

Next attach the shared-tail handoff. Theorem 450.42 identifies the completion-facing route through the shared threshold, dyadic ledger, stream windows, regular-sequence readbacks, and the same real-facing seal row S.

Finally apply terminal export. Theorem 450.48 exports exactly the selector-window-seal packet, and Definition 450.46 removes the possible middle-row escape routes. Thus every listed consumer reads back the same displayed $\mu, \Delta, D, W, Q, S, H, C, P, N$ route. □

Theorem 450.48 (Real completeness selector-window terminal export)**.** *Let $R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$ be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ packet. Once the ordered route*

$$\mu, \Delta, D, W, Q, S, H, C, P, N$$

is displayed, every terminal completion-facing export of R factors through the same selector-window-seal packet. The export cannot introduce quotient streams, host-selected limits, countable choice, host equality, hidden completion coordinates, or ambient completeness beyond the rows already displayed by the selector-window-seal factorization.

Proof. Start with selector route coverage. Theorem 450.36 routes selected observations through the displayed $\mathsf{RealCompleteness}^{\uparrow}$ rows before a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ reader can consume the seal endpoint.

Next use the modulus-selector factorization. Theorem 450.37 forces the front of the terminal route through μ and Δ, then through the dyadic, stream-window, regular-sequence, and real-seal rows D, W, Q, S.

Now exhaust the seal-facing consumer. Theorem 450.38 leaves no downstream route outside the selector-presented rows, and Definition 450.43 identifies the ordered packet used by the terminal reader.

Finally apply Definition 450.17. It excludes quotient streams, host-selected limits, countable-choice selectors, host equality, hidden completion coordinates, and ambient completeness, so the terminal export is exactly the displayed selector-window-seal packet. □

Theorem 450.49 (Real completeness tail-fiber selector compatibility)**.** *Let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *packet. Let*

$$L = (R_L, n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L)$$

be a compatible accepted $\mathsf{LimitSelector}^{\uparrow}$ *packet reading the selected diagonal observation of* R*. Let*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H_F, C_F, P_F, N_F)$$

be an accepted $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *packet whose paired windows and dyadic ledgers present that same selected observation to* $\mathsf{RealTailAgreementSeal}^{\uparrow}$*. Then every completion-facing consumer of this combined presentation factors through one finite route: on the* $\mathsf{RealCompleteness}^{\uparrow}$ *side it reads*

$$\mu, \Delta, D, W, Q, S, H, C, P, N,$$

on the $\mathsf{LimitSelector}^{\uparrow}$ *side it reads*

$$R_L, n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L,$$

and on the tail-fiber side it reads

$$R_0, R_1, W_0, W_1, D_0, D_1, T, A, H_F, C_F, P_F, N_F.$$

The compatibility exports no quotient stream, host real equality, countable-choice selector, selected host limit, or ambient completeness theorem.

Proof. First route the selected diagonal observation through the $\mathsf{LimitSelector}^{\uparrow}$ packet. Apply Definition 673.2 and Definition 673.3 to expose $R_L, n, \mu_L, k_L, W_L, D_L, S, H_L, C_L, P_L, N_L$, then use Definition 450.29 to identify that selector read with the displayed diagonal rows of R.

Next route the same observation from the $\mathsf{RealCompleteness}^{\uparrow}$ side. Apply Definition 450.36, Definition 450.37, and Definition 450.43 to force the read through $\mu, \Delta, D, W, Q, S, H, C, P, N$.

Use the terminal export theorem. By Definition 450.48, a completion-facing consumer cannot leave the displayed selector-window-seal packet after that route has been exposed.

Now compare the shared-tail presentation. Theorem 893.4 makes the $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ route and the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ route share the row T before the seal row A is read, while Definition 893.8 fixes their common support to $R_0, R_1, W_0, W_1, D_0, D_1, T$.

Finally exhaust all consumer surfaces. Apply Definition 893.9 to keep every tail-fiber consumer inside $R_0, R_1, W_0, W_1, D_0, D_1, T, A, H_F, C_F, P_F, N_F$, then apply Definition 450.17 and Definition 893.5. The two non-escape boundaries exclude quotient streams, host real equality, countable-choice selectors, selected host limits, and ambient completeness, so the combined presentation has exactly three displayed finite routes: $\mathsf{RealCompleteness}^{\uparrow}$, $\mathsf{LimitSelector}^{\uparrow}$, and $\mathsf{RegularCauchyTailFiber}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompleteness}^{\uparrow}$ packet is generated by a displayed regular Cauchy family, explicit modulus row, diagonal selector, dyadic observation ledger, stream windows, regular-sequence readback, RealUp seal, transport routes, package provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 450.30 binds the public finite handoff package for every $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and completion-facing consumer route over the displayed rows $X, \mu, \Delta, D, W, Q, S, H, C, P, N$, with $\mathsf{CauchySequenceSpace}^{\uparrow}$ handoff rows only when present.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompleteness}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.RealCompletenessUp.RealCompletenessBHistCarrier\_regseq\_seal\_handoff`

Bridge status: none

Origin: human

Not claimed: This chapter does not close RealUp completeness, uniqueness of completed limits, quotient equality of streams, a public standard bridge, or bridge checking.

Upgrade path: The remaining upgrade is a bridge-checked standard bridge for the displayed RealCompleteness handoff target.

Chapter 451

A Concrete Naming Certificate for $\mathsf{FinitePhaseSampling}^{\uparrow}$

The $\mathsf{FinitePhaseSampling}^{\uparrow}$ packet is a BEDC-native finite certificate surface. It records only finite phase rows, finite coefficient reads, and explicit aliasing ledgers, so Real and Completion consumers may cite coefficient recovery without importing Haar measure, root-of-unity analysis, quotient streams, or host complex Fourier theory.

It is a downstream consumer of the $\mathsf{RegSeqRat}^{\uparrow}$ finite-window readback in chapter 301 and the $\mathsf{Real}^{\uparrow}$ seal surface in chapter 38. Its coefficient row is useful only through that Real-and-completion route, and it does not introduce an independent analytic carrier.

Definition 451.1 (Finite phase sampling carrier)**.** *A* $\mathsf{FinitePhaseSampling}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, K, M, A, E, H, C, P, N)$$

with the following visible coordinates:

1. *G is the finite phase-grid row, listing the sampled phase marks and the cyclic grid schedule used by the observation packet;*
2. *K is the mode-bound row, recording the finite integer modes whose coefficient reads are admitted and the displayed barrier that keeps the requested modes below the grid scale;*
3. *M is the finite coefficient-sample row, storing the observed values and the grid sums used to read cosine, sine, or character coefficients;*
4. *A is the aliasing ledger, listing exactly which translated mode rows would collide with each requested mode at the chosen grid scale;*
5. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal row through which downstream real-name consumers read the recovered coefficient data;*
6. *H stores the componentwise* hsame *transports for G, K, M, A, E;*
7. *C stores the displayed* Cont *routes by which consumers may inspect the finite rows and the real handoff;*
8. *P is the* Pkg *provenance over* BHist, hsame, Cont, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and the local finite observation rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitePhaseSampling}^{\uparrow}}$ *provenance row.*

The classifier compares two carriers only by these displayed finite rows and their stored transports. It does not compare functions on a circle, choose a Haar integral, form a quotient stream, or import a host Fourier object.

Theorem 451.2 (Finite phase sampling NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{FinitePhaseSampling}^{\uparrow}}$ *surface consists of five obligations:*

1. *carrier admission for the packet of Definition 451.1;*
2. *classifier laws by componentwise* hsame *on the grid row, mode-bound row, coefficient-sample row, aliasing ledger, real handoff row, consumer routes, package provenance, and local certificate row;*
3. *grid exactness: every coefficient sample in M is obtained from the displayed phase marks of G and an admitted mode of K by a finite sum in the same packet;*
4. *handoff exactness: the* $\mathsf{RegSeqRat}^{\uparrow}$ *row and the* $\mathsf{Real}^{\uparrow}$ *seal in E read only the finite coefficient rows accepted by M together with the aliasing ledger A;*
5. *non-escape: accepted carriers export no Haar-measure object, no root-of-unity theorem, no quotient-stream equality, and no host complex Fourier theory.*

Lean4 ✓ `BEDC.Derived.FinitePhaseSamplingUp.FinitePhaseSamplingNameCertObligations`

Proof. Carrier admission is the displayed tuple $S = (G, K, M, A, E, H, C, P, N)$. Each coordinate is a finite BHist row or a route between finite rows.

For the classifier laws, compare the coordinates through H and then read the permitted continuations through C. Reflexivity, symmetry, and transitivity are inherited coordinate by coordinate because the local certificate has no hidden coordinate beyond the displayed packet.

Grid exactness is finite ledger inspection. A coefficient row is accepted only when its mode is present in K and its summation entries are the phase observations already listed in G and M.

The handoff obligation repacks those finite coefficient rows as the $\mathsf{RegSeqRat}^{\uparrow}$ source for E, and the $\mathsf{Real}^{\uparrow}$ seal reads through that source. The aliasing ledger A remains attached to the same request, so the handoff does not introduce an external limiting argument.

Non-escape follows from the carrier definition. Since the packet contains no Haar measure, no analytic root-of-unity theorem, no quotient stream, and no host Fourier space, no consumer route can export one. □

Theorem 451.3 (Finite phase sampling grid recovery)**.** *Let $S = (G, K, M, A, E, H, C, P, N)$ be an accepted* $\mathsf{FinitePhaseSampling}^{\uparrow}$ *carrier. If a requested coefficient mode k is admitted by K below the displayed grid barrier and the aliasing ledger A has no nonzero colliding translated mode for k, then the coefficient row read from M is determined by the finite grid row G alone. Two accepted carriers with matching G, K, A rows therefore transport the same recovered coefficient row through their stored* hsame *and* Cont *routes.*

Proof. Project the grid row G, the mode-bound row K, the sample row M, and the aliasing ledger A from the carrier. The mode k is accepted only through the finite admission row in K.

The no-collision entry of A states that the requested row has no displayed nonzero translated mode at the chosen grid scale. Thus the coefficient read in M is the finite grid sum over the phase marks in G for that single admitted mode.

When two carriers match on G, K, A, they have the same admitted mode, the same displayed phase rows, and the same absence entry in the aliasing ledger. The transports in H and consumer routes in C carry this finite read to the matching coefficient row, so no Haar averaging or external character orthogonality is used. □

Theorem 451.4 (Finite phase sampling real handoff)**.** *For every accepted* $\mathsf{FinitePhaseSampling}^{\uparrow}$ *carrier, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal row* E *factors through the finite coefficient-sample row* M *and the aliasing ledger* A*. Any Real and Completion consumer of* E *can inspect the recovered coefficient only through* G, K, M, A, H, C, P, N*, and receives no selected real limit, quotient-stream equality, Haar integral, or host complex coefficient.*

Proof. Start with an accepted read of E. By the handoff exactness obligation in Definition 451.2, the regular rational source row is assembled from the coefficient samples in M together with the aliasing information in A.

The $\mathsf{Real}^{\uparrow}$ seal then reads that $\mathsf{RegSeqRat}^{\uparrow}$ source through the same stored transports H and continuations C. The package row P and local certificate row N identify the finite observation source but do not add a further analytic object.

Therefore every consumer of E factors through the finite rows G, K, M, A, H, C, P, N. The carrier has no coordinate from which a selected limit, quotient equality, Haar integral, or host complex coefficient could be exported. □

Theorem 451.5 (Finite phase sampling RegSeqRat Real lattice)**.** *Let* $S = (G, K, M, A, E, H, C, P, N)$ *be an accepted* $\mathsf{FinitePhaseSampling}^{\uparrow}$ *carrier. If a Real or Completion consumer reads the handoff row* E*, then that read first factors through the regular-rational source surface of chapter 301. The coefficient observations are read as dyadic ledger rows from chapter 291, and only after those finite rows have been exposed does the route reach the real-name seal of chapter 38.*

Proof. Project the handoff row E from the accepted carrier. The handoff exactness obligation of Definition 451.2 says that E reads only the coefficient samples in M and the aliasing ledger A.

By Definition 451.4, every Real or Completion consumer of E is routed through exactly the displayed rows G, K, M, A, H, C, P, N before it reaches the downstream seal. Thus the regular-rational source surface is the first consumer-facing source, and the coefficient observations are visible only as the finite dyadic ledger rows attached to that surface.

The real-name seal is therefore reached only after the RegSeqRat route and its dyadic coefficient ledger have been read. Since the carrier exports no selected real limit, quotient-stream equality, Haar integration datum, or host complex coefficient, no consumer can bypass this lattice through an analytic object outside the packet. □

Theorem 451.6 (Finite phase sampling ledger non-escape)**.** *Every exported route from an accepted* $\mathsf{FinitePhaseSampling}^{\uparrow}$ *packet factors through the finite phase-grid row, mode-bound row, coefficient-sample row, aliasing ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport row, continuation row, package provenance, and local* $\mathsf{NameCert}$ *row. The packet exports no ambient circle, no Haar measure, no root-of-unity analysis, no quotient stream, no infinite Fourier series, and no external theorem.*

Proof. Take an exported consumer route and project the carrier of Definition 451.1. The available coordinates are exactly $G, K, M, A, E, H, C, P, N$.

The NameCert obligations account for carrier admission, classifier transport, grid exactness, real handoff exactness, and non-escape. Each obligation is stated over those displayed rows and is preserved by the stored hsame and Cont routes.

Thus every export factors through the listed finite coordinates. Since the carrier contains no ambient circle object, Haar measure, root-of-unity proof, quotient stream, infinite Fourier series, or imported external theorem, no accepted route can supply one downstream. □

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePhaseSampling}^{\uparrow}}$.

Constructive story: A $\mathsf{FinitePhaseSampling}^{\uparrow}$ packet is generated from a finite phase-grid row, a finite mode-bound row, finite coefficient samples, an aliasing ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff and $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, Cont routes, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinitePhaseSampling}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope records the finite carrier, local NameCert obligations, grid recovery, real handoff, and ledger non-escape for finite phase sampling packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinitePhaseSampling}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Haar integration, root-of-unity analysis, quotient streams, infinite Fourier series, host complex Fourier theory, or a checked Lean certificate.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked finite-ledger theorems for grid recovery, real handoff, and non-escape.

Chapter 452

A Concrete Naming Certificate for $\mathsf{FiniteLebesgueNumber}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the finite Lebesgue-number route used here is a displayed dyadic finite-cover modulus. The $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ packet records a finite dyadic cover, a positive rational radius ledger, and the finite-window witnesses needed by total-bounded and compact-metric consumers. It is not an open-cover compactness principle and it does not choose a subcover from an arbitrary family.

The finite radius ledger is consumed by the compact-metric route of chapter 129 and is built over the explicit dyadic-cover surface of chapter 446.

Definition 452.1 (Finite Lebesgue-number carrier)**.** *A* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier over a displayed* $\mathsf{DyadicCover}^{\uparrow}$ *row is a finite* BHist *packet*

$$L = (D, W, \lambda, M, H, C, P, N)$$

with the following visible coordinates:

1. *D is the accepted* $\mathsf{DyadicCover}^{\uparrow}$ *row containing the finite list of dyadic centers, rational ball rows, dyadic mesh cells, and finite coverage witnesses;*
2. *W is the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row whose inspected points are covered by the dyadic cells of D;*
3. *λ is the positive finite radius ledger, read through* $\mathsf{RationalBall}^{\uparrow}$ *and bounded by the radii recorded in D;*
4. *M is the* $\mathsf{DyadicMesh}^{\uparrow}$ *mesh ledger that records which mesh cells refine into the λ-balls and into the cover cells of D;*
5. *H records componentwise* hsame *transports for D, W, λ, M, the* $\mathsf{StreamName}^{\uparrow}$ *reads, the* $\mathsf{RegSeqRat}^{\uparrow}$ *approximation rows, and the* $\mathsf{Real}^{\uparrow}$ *consumer rows;*
6. *C records the displayed* Cont *routes by which consumers inspect finite-window membership, rational-ball containment, dyadic-mesh refinement, stream-name reads, regular-rational approximations, and real rows;*
7. *P is the* Pkg *provenance over* $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local certificate rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteLebesgueNumber}^{\uparrow}}$ *row.*

The carrier accepts only packets whose positive finite radius ledger is displayed beside the finite dyadic cover and whose mesh witnesses keep every admitted finite-window read inside a named cover cell.

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCarrier`

Theorem 452.2 (Finite Lebesgue-number NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{FiniteLebesgueNumber}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier: the packet of Definition 452.1;*
2. *classifier: componentwise comparison of the dyadic cover row, finite-window row, positive radius ledger, mesh ledger, transports, continuations, package provenance, and local certificate row;*
3. *radius-modulus stability: displayed* hsame *and* Cont *transport preserves the positive ledger* λ *together with the* $\mathsf{RationalBall}^{\uparrow}$ *and* $\mathsf{DyadicMesh}^{\uparrow}$ *rows that witness its refinement into the finite cover;*
4. *finite-window coverage exactness: every accepted point read from* W *factors through a* $\mathsf{StreamName}^{\uparrow}$ *row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *approximation row, a* $\mathsf{Real}^{\uparrow}$ *row, a mesh cell from* M*, and a named cover cell in* D*;*
5. *non-escape: accepted packets export no open-cover compactness theorem, no arbitrary subcover selector, no host compactness principle, and no hidden cover family outside the displayed dyadic finite-cover data.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCarrier namecert obligations`

Proof. Carrier habitation is the displayed tuple $L = (D, W, \lambda, M, H, C, P, N)$. The dyadic cover, finite-window row, radius ledger, mesh ledger, transports, continuations, package provenance, and local certificate are all finite coordinates.

The classifier is componentwise on those coordinates. Radius-modulus stability follows by transporting the positive rational radius ledger and the mesh-refinement rows along H, then replaying only the routes stored in C.

Coverage exactness is a finite witness read. Each admitted point of W is observed through its stream and regular-rational approximation rows, placed in a real row, assigned to a mesh cell of M, and then routed to a named cover cell in D.

The carrier has no coordinate for an arbitrary open family, an open-cover compactness theorem, or a subcover selector. Thus every accepted export remains inside the displayed dyadic finite-cover packet. □

Theorem 452.3 (Finite Lebesgue-number dyadic cover handoff)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier receives only the displayed* $\mathsf{DyadicCover}^{\uparrow}$ *finite cover, the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *coverage row, the positive finite radius ledger* λ*, the* $\mathsf{DyadicMesh}^{\uparrow}$ *refinement ledger* M*, and the listed* hsame, Cont, Pkg, *and* NameCert *provenance rows. The handoff supplies a finite dyadic-cover modulus and a positive finite radius ledger, not open-cover compactness or subcover choice.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberDyadicCoverHandoff`

Proof. Project the carrier of Definition 452.1. The only consumer-facing cover data are D, W, λ, M, H, C, P, and N.

Use Definition 452.2. Its classifier, radius-modulus stability, and finite-window coverage exactness rows keep every consumer read on the displayed dyadic cover, finite-window witnesses, rational-ball radius ledger, and mesh-refinement ledger.

A total-bounded or compact-metric consumer therefore receives the finite dyadic cover together with the positive radius ledger and provenance rows. Since the carrier contains no arbitrary open family and no selected subcover coordinate, the handoff cannot assert open-cover compactness. □

Theorem 452.4 (Finite Lebesgue-number radius transport)**.** *Let $L = (D, W, \lambda, M, H, C, P, N)$ be an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier. For every componentwise* hsame *transport recorded in H, the transported packet preserves the positive finite radius ledger λ, the* $\mathsf{RationalBall}^{\uparrow}$ *radius readback attached to λ, and the* $\mathsf{DyadicMesh}^{\uparrow}$ *refinement rows in M as one finite packet. In particular, a consumer cannot transport the radius coordinate without simultaneously transporting the rational-ball and mesh-refinement evidence by which the radius is read.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRadiusTransport`

Proof. Project the accepted carrier of Definition 452.1. The radius coordinate is not stored as an isolated scalar: it is bundled with the rational-ball readback, the mesh ledger, the componentwise transport rows, and the displayed continuation routes.

Use the radius-modulus stability row of Definition 452.2. That row transports λ only together with the $\mathsf{RationalBall}^{\uparrow}$ and $\mathsf{DyadicMesh}^{\uparrow}$ rows witnessing refinement into the finite cover.

Therefore every transported radius read remains in the finite packet $D, W, \lambda, M, H, C, P, N$. No additional radius selector, host metric radius, or open-cover radius coordinate is exposed. □

Theorem 452.5 (Finite Lebesgue-number finite-window coverage exactness)**.** *For an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier $L = (D, W, \lambda, M, H, C, P, N)$, every accepted finite-window read factors through the displayed window W, then through a* $\mathsf{StreamName}^{\uparrow}$ *row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *approximation row, a* $\mathsf{Real}^{\uparrow}$ *row, a mesh cell of M, and a named cover cell of D. The factorization has no coordinate for an arbitrary open family, no host compactness witness, and no selected subcover outside the displayed dyadic finite-cover packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberWindowCoverageExactness`

Proof. Start with an accepted read from W. By the finite-window coverage exactness row of Definition 452.2, the read is observed through a named stream row, its regular-rational approximation row, and the corresponding real row.

The same exactness row then routes the real read into a displayed mesh cell of M and from that mesh cell into a named cover cell of D. These are coordinates of the carrier, so the factorization is finite and internal to L.

The non-escape row of Definition 452.2 excludes open-family, compactness, and selected-subcover coordinates. Hence every accepted finite-window read is exhausted by the displayed route. □

Theorem 452.6 (Finite Lebesgue-number compact consumer route)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier receives the carrier route in the order $D, W, \lambda, M, H, C, P, N$: the dyadic cover row, finite-window row, positive radius ledger, mesh refinement ledger, transport rows, continuation routes, package provenance, and local naming row. The consumer cannot read open-cover compactness, host compactness, or a selected subcover from the packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberUniformModulusConsumerExactness`

Proof. Use Definition 452.3. It identifies the public consumer-facing data as $D, W, \lambda, M, H, C, P, N$ and states that the handoff supplies a finite dyadic-cover modulus and positive finite radius ledger.

Next use Definition 452.4. It keeps the positive radius read tied to the rational-ball and mesh-refinement evidence, so a compact consumer cannot detach the radius from the displayed packet.

Finally use Definition 452.5. Every finite-window read is routed through W, stream and regular-rational rows, a real row, a mesh cell of M, and a named cover cell of D.

The non-escape clauses in these three rows leave no coordinate for open-cover compactness, host compactness, or selected subcover data. Thus the compact consumer route is exactly the ordered carrier route. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCarrier compact consumer route`

Theorem 452.7 (Finite radius nonchoice obligation)**.** *For an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, the positive radius ledger* λ *is readable only through the displayed* $\mathsf{RationalBall}^{\uparrow}$ *radius rows of* D *and the* $\mathsf{DyadicMesh}^{\uparrow}$ *refinement rows of* M*. No consumer route in the packet reads* λ *by invoking an open-cover choice principle, an arbitrary subcover selector, or a host compactness witness outside* $D, W, \lambda, M, H, C, P, N$*.*

Proof. Start with the carrier of Definition 452.1. Its radius coordinate is listed between the finite-window row W and the mesh ledger M, and its admissible readback is explicitly through the rational-ball and dyadic-mesh rows.

Apply the radius-modulus stability row of Definition 452.2 and the transport statement of Definition 452.4. They keep λ attached to the $\mathsf{RationalBall}^{\uparrow}$ rows and to the $\mathsf{DyadicMesh}^{\uparrow}$ refinement evidence under every stored hsame transport and every replayed Cont route.

The compact consumer route of Definition 452.6 exposes the ordered packet $D, W, \lambda, M, H, C, P, N$ and no other cover coordinate. Since the packet contains no open-cover family and no subcover selector, the radius obligation is finite and nonchoice. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberFiniteRadiusNonchoice`

Theorem 452.8 (Mesh refinement nonchoice obligation)**.** *Let* $L = (D, W, \lambda, M, H, C, P, N)$ *be an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier. Refinement from a mesh cell recorded in* M *to a cover cell recorded in* D *is stable under the stored* hsame *transports in* H *and under the replayed* Cont *routes in* C*. Thus the mesh-to-cover handoff is determined by the displayed* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows, not by a separately chosen open subcover.*

Proof. Use the finite-window coverage exactness theorem Definition 452.5. An accepted read is first routed through W, then through a $\mathsf{StreamName}^{\uparrow}$ row, a $\mathsf{RegSeqRat}^{\uparrow}$ approximation row, a $\mathsf{Real}^{\uparrow}$ row, a mesh cell of M, and finally a named cover cell of D.

The NameCert obligations of Definition 452.2 make this route componentwise. The same rows transport the mesh ledger and the cover-cell witness along H, while the continuations in C replay the finite-window membership, rational-ball containment, and mesh-refinement reads.

It follows that changing representatives by hsame does not detach the mesh cell from its named cover cell. The handoff remains inside $D, W, \lambda, M, H, C, P, N$, so no open-cover compactness theorem or arbitrary subcover coordinate can supply a different refinement route. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCarrier mesh refinement nonchoice`

Theorem 452.9 (Total-bounded handoff obligation)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier receives exactly the ordered packet*

$$D, W, \lambda, M, H, C, P, N.$$

The consumer may inspect the displayed DyadicCover$^{\uparrow}$, FiniteWindowEnvelope$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows in that packet, but cannot recover open-cover compactness, host compactness, arbitrary subcover selection, or a hidden cover family from it.*

Proof. The carrier definition fixes the visible order $D, W, \lambda, M, H, C, P, N$. The compact consumer route of Definition 452.6 states that this is the consumer-facing order for both TotallyBounded$^{\uparrow}$ and CompactMetric$^{\uparrow}$ reads.

The finite radius obligation of Definition 452.7 keeps the radius ledger tied to the displayed rational-ball and mesh rows. The mesh refinement obligation of Definition 452.8 keeps the mesh-to-cover read stable under stored transports and replayed continuations.

Together with the dyadic cover handoff of Definition 452.3, these rows exhaust the public data a total-bounded or compact-metric consumer receives. The non-escape row of Definition 452.2 excludes open-cover compactness and arbitrary subcover selection, so the handoff is exactly the finite BEDC packet. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCarrier total bounded handoff`

Theorem 452.10 (Compact-uniform selector handoff)**.** *Every accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier consumed by a compact-uniform route supplies exactly the positive radius ledger read by* CompactNetModulusSelector$^{\uparrow}$, *and then by* UniformModulus$^{\uparrow}$, *through the displayed* DyadicCover$^{\uparrow}$, FiniteWindowEnvelope$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows. It supplies no open-cover compactness, host minimum, selected subcover, quotient equality, or external modulus function.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactUniformSelectorHandoff`

Proof. Project the finite Lebesgue-number carrier $L = (D, W, \lambda, M, H, C, P, N)$. The positive ledger λ is displayed between the finite-window row and the mesh row, so any compact-uniform consumer reads it as part of the same finite packet.

Invoke the dyadic cover handoff, radius transport, and finite-window coverage exactness theorems. These route the radius through D, W, the RationalBall$^{\uparrow}$ readback, the DyadicMesh$^{\uparrow}$ refinements, and the stored hsame and Cont rows.

Apply the total-bounded handoff theorem above. It identifies $D, W, \lambda, M, H, C, P, N$ as the exact packet delivered to total-bounded and compact-metric consumers, so the compact-uniform route receives no hidden compactness witness in addition to the finite radius ledger.

The compact-net selector and uniform-modulus chapters are the downstream consumers of this displayed packet. The selector reads the positive radius ledger as its compact-net input, and the uniform-modulus surface reads the resulting tolerance-only route. Since open-cover compactness, host minima, selected subcovers, quotient equality, and external modulus functions are absent from L, the handoff is exactly the finite BEDC radius-ledger route. □

Theorem 452.11 (Window-radius ledger coherence)**.** *For every accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$, *every finite-window read in* W *is coherent with the positive radius ledger* λ *only through the same displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows. A compact consumer cannot read a finite window first and then attach an unrelated positive radius outside* $D, W, \lambda, M, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberWindowRadiusLedgerCoherence`

Proof. Project the displayed carrier. The finite-window row W and positive radius ledger λ are coordinates of the same packet, and the local NameCert obligations name them together.

Use radius transport and finite-window coverage exactness. The radius row is preserved by the stored hsame transport and replayed Cont route, while the finite-window row is read through the dyadic cover and mesh rows already present in D and M.

Apply the compact-uniform selector handoff above. The downstream compact route receives the ordered finite packet, so any radius attached after the window read must be the displayed ledger λ rather than an external compactness choice. □

Theorem 452.12 (Cover-cell readback totality)**.** *For every accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, each read from the finite-window row* W *reaches a named dyadic cover cell through* $D, W, \lambda, M, H, C, P, N$*. The readback first consumes the window row, then the positive radius ledger and mesh row, then the componentwise transport, replay, provenance, and local naming rows; no open-cover family or arbitrary cell selector supplies the endpoint.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCoverCellReadbackTotality`

Proof. Start from finite-window coverage exactness. It sends every accepted window read through the displayed stream, regular-rational, real, mesh, and cover rows.

The mesh refinement and radius transport obligations keep that endpoint tied to M and λ under the same H and C routes. Thus the cover cell is not selected by a separate open-cover principle.

Finally, P and N package and name the readback as part of the same FiniteLebesgueNumber$^{\uparrow}$ carrier. This gives total cover-cell readback for the finite dyadic route. □

Theorem 452.13 (L10 source-lock for compact radius reads)**.** *Every accepted* FiniteLebesgueNumber$^{\uparrow}$ *public finite-window read locks its radius route through* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*, and* DyadicCover$^{\uparrow}$ *before any* CompactMetric$^{\uparrow}$*,* CompactNetModulusSelector$^{\uparrow}$*, or* UniformModulus$^{\uparrow}$ *consumer may read the positive radius ledger. The consumer-facing read is therefore a read of the displayed packet* $D, W, \lambda, M, H, C, P, N$*, not a radius read supplied by an external compactness or modulus interface.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberL10SourceLock`

Proof. Begin with finite-window coverage exactness. It forces each accepted finite-window read to pass through the displayed stream, regular-rational, real, mesh, and cover rows before it can be used as a cover read.

The radius transport and mesh-refinement nonchoice theorems keep the positive ledger λ tied to that same window and mesh route. Hence a compact consumer cannot detach the radius from W and M and then attach a different compactness witness.

Finally apply the compact-uniform selector handoff and cover-cell readback totality. They identify the downstream compact and uniform readers as consumers of the named finite packet $D, W, \lambda, M, H, C, P, N$, so the L10 source route is locked before any positive radius ledger is exposed. □

Theorem 452.14 (Stream-regular window order)**.** *For every accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, each public finite-window read is ordered as follows: first the window row* W*, then the* StreamName$^{\uparrow}$ *row, then the* RegSeqRat$^{\uparrow}$ *approximation row, then the* Real$^{\uparrow}$ *row, then a mesh cell in* M*, then a cover cell in* D*, and finally the support rows* H, C, P, N*. Componentwise* hsame *transport and the displayed* Cont *replay preserve that order.*

Proof. Use finite-window coverage exactness to read the window row through the displayed stream, regular-rational, real, mesh, and cover rows. This fixes the forward route from W to the named cell of D through M.

Use radius transport and mesh-refinement nonchoice to preserve the same order under componentwise hsame transport. The positive ledger λ remains between the finite window and mesh rows, so the mesh cell in M cannot be read before the regular and real source rows have been displayed.

The compact-uniform selector handoff and cover-cell readback totality then package the route with H, C, P, N. The Cont replay is therefore an order-preserving replay of the already displayed finite packet, not a new path that bypasses the stream or regular-Cauchy source. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberStreamRegularWindowOrder`

Theorem 452.15 (Real source nonchoice boundary)**.** *For every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier, the* $\mathsf{Real}^{\uparrow}$ *row used by a compact or uniform consumer is read only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows. It is not read by host real equality, an arbitrary point selector, open-cover compactness, a subcover choice principle, or any external real representative outside* $D, W, \lambda, M, H, C, P, N$.

Proof. Start from finite-window coverage exactness. The $\mathsf{Real}^{\uparrow}$ row appears as part of the displayed source chain following the stream-name and regular-rational rows, so the real read is already anchored before the mesh and cover cells are consumed.

Radius transport and mesh-refinement nonchoice keep that real source attached to the positive radius and mesh rows under the same hsame and Cont data. Thus host real equality and arbitrary point selection cannot replace the displayed source rows.

The compact-uniform selector handoff and cover-cell readback totality give the downstream boundary. Compact and uniform consumers receive the named finite route, while open-cover compactness, subcover choice, and external representatives are absent from the carrier. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRealSourceNonchoice`

Theorem 452.16 (Compact consumer nonchoice boundary)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$ *or* CompactNetModulusSelecto *consumer of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier receives only the finite dyadic route through* $D, W, \lambda, M, H, C, P, N$. *The consumer may use the named cover cells, finite-window reads, positive radius ledger, mesh refinements, transports, continuations, provenance, and local naming, but it receives no open-cover compactness theorem, host compactness witness, arbitrary subcover choice, or external selector.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactConsumerNonchoiceBoundary`

Proof. Use the compact-uniform selector handoff and the total-bounded handoff. Together they identify the consumer-facing data as the displayed finite carrier $D, W, \lambda, M, H, C, P, N$.

The window-radius coherence theorem keeps window reads and radius reads in the same packet. The cover-cell readback totality theorem then gives named dyadic cover cells without invoking a free subcover selector.

The non-escape row of the local NameCert obligations excludes open-cover compactness, host compactness, and arbitrary selectors. Therefore compact consumers receive only the finite dyadic route. □

Theorem 452.17 (Finite Lebesgue-number positive-radius compact-net export)**.** *For every accepted* FiniteLebesgueNumber$^\uparrow$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, the positive-radius ledger exported to* CompactNetModulusSelector$^\uparrow$ *is exactly the finite route through* DyadicCover$^\uparrow$*,* FiniteWindowEnvelope$^\uparrow$*,* RationalBall$^\uparrow$*,* DyadicMesh$^\uparrow$*,* StreamName$^\uparrow$*,* RegSeqRat$^\uparrow$*,* Real$^\uparrow$*,* TotallyBounded$^\uparrow$*,* CompactMetric$^\uparrow$*, and* CompactNetModulusSelector$^\uparrow$ *displayed by* $D, W, \lambda, M, H, C, P, N$*. The export has no open-cover compactness theorem, host minimum, arbitrary subcover selector, quotient equality, or choice coordinate.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPositiveRadiusCompactNetExport`

Proof. Project the carrier. The dyadic cover row D, finite-window row W, positive radius ledger λ, mesh row M, and support rows H, C, P, N are the only rows available before a compact-net consumer can read the packet.

Use the compact consumer nonchoice boundary. It keeps CompactMetric$^\uparrow$ and CompactNetModulusSelector$^\uparrow$ consumers inside the finite dyadic route and excludes open-cover compactness, host compactness, arbitrary subcover choice, and external selectors.

The positive finite-radius totality theorem places λ before the compact read, while the total-bounded handoff routes the finite cover data through TotallyBounded$^\uparrow$ and CompactMetric$^\uparrow$. Hence the compact-net export is the displayed finite radius ledger and nothing stronger. □

Theorem 452.18 (Finite Lebesgue-number dyadic-cover uniform-modulus handoff)**.** *For every accepted* FiniteLebesgueNumber$^\uparrow$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, every* UniformModulus$^\uparrow$ *consumer receives the dyadic-cover radius route only after the same displayed packet has passed through* DyadicCover$^\uparrow$*,* FiniteWindowEnvelope$^\uparrow$*,* RationalBall$^\uparrow$*,* DyadicMesh$^\uparrow$*,* StreamName$^\uparrow$*,* RegSeqRat$^\uparrow$*,* Real$^\uparrow$*,* TotallyBounded$^\uparrow$*,* CompactMetric$^\uparrow$*, and* CompactNetModulusSelector$^\uparrow$*. The handoff is a finite radius-to-modulus route, not an open-cover compactness argument, selected subcover, host minimum, or external modulus selector.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberDyadicCoverUniformModulusHandoff`

Proof. Start from the compact-uniform selector handoff. It identifies the downstream compact-net selector and uniform-modulus chapters as consumers of the finite packet $D, W, \lambda, M, H, C, P, N$.

Next apply positive-radius compact-net export. The selector receives the positive-radius ledger only through the displayed dyadic cover, rational-ball, mesh, window, regular-readback, Real, total-bounded, and compact-metric rows.

Finally use the finite radius nonchoice and mesh-refinement nonchoice obligations. These keep the radius and mesh attached to the dyadic packet under H, C, P, N, so a UniformModulus$^\uparrow$ consumer cannot substitute an open-cover compactness theorem, host minimum, selected subcover, or external modulus row for the finite handoff. □

Theorem 452.19 (Finite Lebesgue-number compact-consumer radius-ledger totality)**.** *For every accepted* FiniteLebesgueNumber$^\uparrow$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, compact and uniform consumers that preserve the displayed classifier receive a total positive-radius ledger inside the same finite route* $D, W, \lambda, M, H, C, P, N$*. The ledger is total for the displayed* DyadicCover$^\uparrow$*,* FiniteWindowEnvelope$^\uparrow$*,* RationalBall$^\uparrow$*,* DyadicMesh$^\uparrow$*,* StreamName$^\uparrow$*,* RegSeqRat$^\uparrow$*,* Real$^\uparrow$*,* TotallyBounded$^\uparrow$*,* CompactMetric$^\uparrow$*,* CompactNetModulusSelector$^\uparrow$*, and* UniformModulus$^\uparrow$ *consumer chain, and it excludes open-cover compactness, host compactness, selected subcovers, hidden minima, quotient equality, and choice.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactConsumerRadiusLedgerTotality`

Proof. Begin with window-radius ledger coherence. It ties every finite-window read to the same positive-radius ledger λ through the displayed carrier rows, so the compact consumer cannot attach an unrelated radius after reading W.

Use cover-cell readback totality and dyadic-cover uniform-modulus handoff. The first theorem gives named dyadic cover cells through $D, W, \lambda, M, H, C, P, N$, and the second carries the same positive-radius route to $\mathsf{CompactNetModulusSelector}^{\uparrow}$ and $\mathsf{UniformModulus}^{\uparrow}$ consumers.

The compact consumer nonchoice boundary supplies the exclusion clause. Since open-cover compactness, host compactness, selected subcovers, hidden minima, quotient equality, and choice coordinates are absent from the packet, the compact-consumer radius ledger is total exactly on the displayed finite route. □

Theorem 452.20 (Positive finite-radius totality)**.** *For every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, the packet exposes a positive finite radius ledger* λ *before any* $\mathsf{CompactMetric}^{\uparrow}$ *consumer may read a Lebesgue-number route. The radius is consumed only together with the displayed* $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*, transport, continuation, provenance, and local naming rows.*

Proof. Project the carrier $L = (D, W, \lambda, M, H, C, P, N)$. The radius coordinate is not a host scalar outside the packet; it is placed between the finite-window row and the mesh row.

Use Definition 452.7 and Definition 452.24. They keep λ attached to rational-ball readback and dyadic-mesh refinement under stored transports and replayed continuations.

Finally apply Definition 452.9. A compact consumer receives the ordered finite packet only after the positive radius ledger has been displayed, so the Lebesgue-number route has finite-radius totality before it reaches $\mathsf{CompactMetric}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPositiveRadiusTotality`

Theorem 452.21 (Dyadic cover cell selection)**.** *For every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, each finite-window read in* W *lands in a displayed dyadic cover cell of* D *through the mesh row* M*. The packet supplies no arbitrary subcover selector and no open-cover compactness coordinate outside the displayed dyadic cover, finite-window, radius, mesh, transport, continuation, provenance, and local naming rows.*

Proof. Use Definition 452.5. It routes a finite-window read through stream naming, regular-rational readback, a Real row, a mesh cell of M, and then a named cover cell of D.

The mesh refinement nonchoice theorem, Definition 452.8, keeps that mesh-to-cover handoff stable under the stored hsame transports and displayed Cont routes.

Since the carrier contains no open-cover family and no subcover selector, cell selection is exactly the finite dyadic route already displayed by $D, W, \lambda, M, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberDyadicCoverCellSelection`

Theorem 452.22 (Compact-metric handoff exactness)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier receives only the dyadic cover row* D*, finite-window row* W*, positive-radius ledger* λ*, mesh row* M*, componentwise transport row* H*, continuation row* C*, provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{FiniteLebesgueNumber}^{\uparrow}}$ *row* N*. It receives no open-cover compactness, host compactness, arbitrary subcover selector, or hidden cover family.*

Proof. Start from the total-bounded handoff theorem Definition 452.9. It identifies $D, W, \lambda, M, H, C, P, N$ as the exact packet delivered to total-bounded and compact-metric consumers.

The positive-radius totality theorem above exposes the finite radius ledger before the compact route is read. The dyadic cover cell-selection theorem above identifies every finite-window read with a displayed dyadic cover cell through M.

The non-escape row of Definition 452.2 excludes open-cover compactness, host compactness, and arbitrary subcover selection. Hence $\mathsf{CompactMetric}^{\uparrow}$ receives exactly the finite-radius dyadic packet and nothing outside it. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.CompactMetricHandoffExactness.FiniteLebesgueNumberCompactMe`

Theorem 452.23 (Finite-window coverage obligation row)**.** *For an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, the finite-window coverage row factors through* $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{DyadicMesh}^{\uparrow}$ *in that order. A point read from* W *is accepted only when its stream-name row, regular-rational row, real row, mesh cell, and named dyadic cover cell are all displayed in the same packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberObligationCoverageRow`

Proof. Start with the finite-window coordinate W in the carrier. The carrier definition already places W beside the dyadic cover D and the mesh ledger M, while the finite-window coverage exactness theorem routes each accepted read through stream, regular-rational, real, mesh, and cover rows.

The obligation row records that route as the BEDC consumer contract. Since every coordinate is read from $D, W, \lambda, M, H, C, P, N$, no open-cover family or host compactness witness supplies the factorization. □

Theorem 452.24 (Radius mesh stability obligation row)**.** *For an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, every stored* hsame *transport preserves the positive radius ledger* λ *only together with the displayed* $\mathsf{RationalBall}^{\uparrow}$ *rows and the* $\mathsf{DyadicMesh}^{\uparrow}$ *mesh-refinement rows. Thus radius transport is not a scalar transport separate from the rational-ball and mesh evidence that names it.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRadiusMeshStabilityRow`

Proof. Project the radius coordinate from the carrier. It is located between the finite-window row and the mesh ledger, and its admissible readback is tied to the rational-ball rows of the dyadic cover.

Apply the radius transport and finite radius nonchoice obligations. They keep λ attached to rational-ball readback and mesh refinement under every stored hsame row and replayed Cont route, so a transported radius remains part of the same finite packet. □

Theorem 452.25 (Compact consumer boundary obligation row)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier receives only the displayed dyadic finite-cover packet* $D, W, \lambda, M, H, C, P, N$*. The consumer may inspect the finite cover, finite-window row, positive radius ledger, mesh-refinement row, transports, continuations, provenance, and local naming, but receives no arbitrary open-cover family, host compactness theorem, or selected subcover coordinate.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactConsumerBoundaryRow`

Proof. Use the total-bounded handoff obligation. It identifies $D, W, \lambda, M, H, C, P, N$ as the exact packet delivered to total-bounded and compact-metric consumers.

The coverage and radius-mesh rows above keep finite-window reads and radius reads inside that packet. The non-escape row of the local NameCert obligations excludes open-cover compactness and arbitrary subcover selection, so the compact consumer boundary is precisely the displayed dyadic finite-cover packet. □

Theorem 452.26 (Window-radius source lock)**.** *For every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, the positive radius ledger* λ *is locked to the same source packet as the finite-window row* W*. The lock is witnessed only through the displayed* $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows carried by* $D, W, \lambda, M, H, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberWindowRadiusSourceLock`

Proof. Project the carrier $L = (D, W, \lambda, M, H, C, P, N)$. The window row W and radius ledger λ occur in the same finite BHist packet, with D and M recording the dyadic cover and mesh rows that read them.

Apply Definition 452.24. It keeps λ attached to the rational-ball rows and dyadic-mesh refinement rows under the stored hsame transports and replayed Cont routes.

Apply Definition 452.23. It routes every accepted finite-window read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, the mesh row M, and the cover row D. Therefore the radius source cannot be read apart from the same displayed source packet. □

Theorem 452.27 (Total-bounded consumer factorization)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$ *factors through the displayed dyadic finite-cover packet before reading any compact route. The factorization first reads* $\mathsf{DyadicCover}^{\uparrow}$ *and* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*, then reads* $\mathsf{RationalBall}^{\uparrow}$ *and* $\mathsf{DyadicMesh}^{\uparrow}$*, then reads* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, and finally replays only the carried* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTotalBoundedConsumerFactorization`

Proof. Start with Definition 452.25. It identifies $D, W, \lambda, M, H, C, P, N$ as the exact packet delivered to total-bounded and compact-metric consumers.

Use Definition 452.26. The radius ledger and finite-window reads share the same dyadic source packet, so the consumer cannot detach λ from W, D, or M.

Use Definition 452.9. The consumer-facing order is exhausted by the displayed carrier rows and their hsame, Cont, Pkg, and NameCert support, so the compact read factors through the finite dyadic packet. □

Theorem 452.28 (Open-cover refusal boundary)**.** *For an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, any request for an arbitrary open-cover family, a selected subcover, host compactness, or open-cover compactness is refused by the carrier boundary. The accepted request surface is only the finite route through* $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Read the non-escape row of Definition 452.2. It excludes arbitrary open families, open-cover compactness, host compactness, and selected subcover coordinates from the carrier.

The compact consumer boundary theorem then identifies the only admitted consumer packet as $D, W, \lambda, M, H, C, P, N$. The total-bounded factorization theorem above keeps every compact route

inside the finite dyadic cover, window, radius, mesh, stream, regular-rational, real, transport, replay, provenance, and naming rows.

Thus an open-cover request asks for data absent from the carrier. It is refused as a boundary crossing rather than answered by a hidden compactness principle. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenCoverRefusalBoundary`

Definition 452.29 (Finite Lebesgue number root coverage ledger)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier* $L = (D, W, \lambda, M, H, C, P, N)$*, the root coverage ledger is the finite* BHist *row*

$$\Lambda = (D, M, R, S, G, E, K, H, C, P, N)$$

whose entries expose the DyadicCover$^{\uparrow}$ *row* D*,* DyadicMesh$^{\uparrow}$ *row* M*,* RationalBall$^{\uparrow}$ *radius row* R*,* StreamName$^{\uparrow}$ *window row* S*,* RegSeqRat$^{\uparrow}$ *source row* G*,* Real$^{\uparrow}$ *endpoint row* E*,* CompactMetric$^{\uparrow}$ *and* CompactNetModulusSelector$^{\uparrow}$ *consumer row* K*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*. The ledger has no coordinate for arbitrary open-cover choice, selected subcover choice, or host compactness.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootCoverageLedger`

Theorem 452.30 (Finite Lebesgue number root dyadic radius obligation)**.** *Every accepted root coverage ledger of Definition 452.29 must display the rational radius row* R *as a* RationalBall$^{\uparrow}$ *row read through the same finite* DyadicCover$^{\uparrow}$ *and* DyadicMesh$^{\uparrow}$ *packet that supplies* D *and* M*. The* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$ *rows* S, G, E *may consume the radius only through the transported* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, not by a hidden open-cover compactness witness.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootDyadicRadiusObligation`

Proof. Project the ledger $\Lambda = (D, M, R, S, G, E, K, H, C, P, N)$. The radius row R is listed between the dyadic cover and dyadic mesh rows, so its only source packet is the finite dyadic one.

Apply the radius-mesh stability row, Definition 452.24, and the window-radius source lock, Definition 452.26. Together they keep the rational-ball radius attached to D, M under componentwise hsame transport and displayed Cont replay.

The stream, regular-rational, and real rows then read the transported finite packet. Since Λ has no open-cover or selected-subcover coordinate, the radius obligation remains finite and nonchoice. □

Theorem 452.31 (Finite Lebesgue number root compact consumer nonchoice)**.** *Every* CompactMetric$^{\uparrow}$ *or* CompactNetModulusSelector$^{\uparrow}$ *consumer of an accepted root coverage ledger factors through the displayed* DyadicCover$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$ *rows before it may read* K*. The consumer uses only the finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of the ledger and cannot request an arbitrary open cover or selected subcover.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootCompactConsumerNonchoice`

Proof. Start from total-bounded consumer factorization, Definition 452.27. It routes every compact-metric consumer through the finite dyadic packet before any compact read is exposed.

Use the open-cover refusal boundary, Definition 452.28. It blocks arbitrary open covers, host compactness, and selected subcover coordinates, leaving only the finite cover, mesh, radius, stream, regular-rational, real, transport, replay, provenance, and naming rows.

Thus K is a consumer of the displayed finite ledger rather than a compactness selector outside it. The route is nonchoice because every consumed row is already present in Λ. □

Theorem 452.32 (Finite Lebesgue number root window cover totality)**.** *For every accepted root coverage ledger $\Lambda = (D, M, R, S, G, E, K, H, C, P, N)$, each window named by the* $\mathsf{StreamName}^{\uparrow}$ *row S and each regular-rational source named by the* $\mathsf{RegSeqRat}^{\uparrow}$ *row G is covered by one of the finitely displayed* $\mathsf{RationalBall}^{\uparrow}$ *rows of R over the* $\mathsf{DyadicCover}^{\uparrow}$ *and* $\mathsf{DyadicMesh}^{\uparrow}$ *rows D, M. The* $\mathsf{Real}^{\uparrow}$ *endpoint row E and compact-consumer row K may read totality only through that finite window-cover route.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootWindowCoverTotality`

Proof. Read finite-window coverage exactness through Definition 452.23. It sends every accepted finite-window read through the displayed dyadic cover, mesh, stream, regular-rational, and real rows.

The root dyadic radius obligation above attaches each rational ball to the same D, M source packet. Therefore the windows named by S and sources named by G are covered by listed rational-ball rows rather than by an external subcover.

Finally the compact consumer nonchoice theorem keeps E and K downstream of that same finite route. The totality claim is exactly the finite ledger totality, not an open-cover compactness assertion. □

Theorem 452.33 (Finite Lebesgue number root unblock package)**.** *The accepted root coverage ledger of Definition 452.29 forms a finite root-unblock package for* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$*: the* $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*, and* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *rows are all exposed inside one* BHist *packet, preserved by* hsame*, replayed by* Cont*, sourced by* Pkg*, and sealed by* $\mathsf{NameCert}$*. Consequently the later root consumer may target finite cover, radius, window totality, and compact-consumer obligations without relying on arbitrary open-cover compactness or choice.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootUnblockPackage`

Proof. Assemble the package from the root coverage ledger. The definition lists the dyadic cover, dyadic mesh, rational ball, stream, regular-rational, real endpoint, compact-metric, compact-net selector, transport, replay, provenance, and local naming rows in one finite BHist packet.

The dyadic radius obligation supplies the radius row over the same finite dyadic packet. The compact consumer nonchoice theorem keeps compact consumers inside the displayed finite rows. The window cover totality theorem then supplies totality for the StreamName and RegSeqRat windows through the listed rational-ball rows.

Repacking these three obligations with H, C, P, N gives the finite root-unblock package. No step introduces open-cover compactness, selected subcover choice, host compactness, or a consumer row outside the displayed ledger. □

Theorem 452.34 (Finite Lebesgue number selector-radius domain)**.** *The positive radius ledger consumed by* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *is readable only through the displayed* $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows of the accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root coverage ledger. It has no separate open-cover compactness, selected-subcover, host-minimum, or choice coordinate.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberSelectorRadiusDomain`

Proof. Project the root coverage ledger $\Lambda = (D, M, R, S, G, E, K, H, C, P, N)$. The positive radius row is the rational-ball row R, and it is displayed with the dyadic cover and dyadic mesh rows D, M before any compact-net selector reads K.

Use the root dyadic radius obligation and window-radius source lock. Definition 452.30 keeps R over the same D, M packet, while Definition 452.26 ties finite-window reads to the same dyadic source.

Finally attach S, G, E, H, C, P, N. The StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows are the only rows that can carry the radius onward to CompactNetModulusSelecto so no hidden compactness or choice coordinate is available. □

Theorem 452.35 (Finite Lebesgue number compact-net selector factorization)**.** *Every* CompactNetModulusSelecto *consumer of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *root coverage ledger factors through the root coverage ledger before reading its selector row. The factorization route is*

$$D, M, R, S, G, E, H, C, P, N \to K,$$

so the selector receives finite cover, mesh, radius, stream, regular-rational, real endpoint, transport, replay, provenance, and local naming data before any compact-net selection occurs.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactNetSelectorFactorization`

Proof. Begin with the root unblock package, Definition 452.33. It exposes the compact-net selector row inside the same finite BHist packet as the dyadic cover, mesh, radius, stream, regular-rational, and real rows.

Next use root compact consumer nonchoice and total-bounded consumer factorization. Definition 452.31 and Definition 452.27 both route compact consumers through the finite dyadic packet before any compact read is exposed.

The selector-radius domain theorem supplies the remaining radius constraint. Since R is readable only through the displayed dyadic and transport rows, the selector row K factors through the root coverage ledger rather than an external subcover selector. □

Theorem 452.36 (Finite Lebesgue number uniform-modulus radius exhaustion)**.** *Every* UniformModulus$^{\uparrow}$ *consumer of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *packet receives only the finite Lebesgue-number radius packet carried by the displayed root coverage ledger. It receives no open-cover compactness, no selected subcover, no host minimum, and no countable or finite choice coordinate beyond the finite rows already named by* DyadicCover$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Proof. First read the selector-radius domain theorem. It identifies the positive radius ledger as the rational-ball row over the finite dyadic cover and mesh packet, transported only by the displayed hsame, Cont, Pkg, and NameCert rows.

Apply compact-net selector factorization. Any compact-net route to a modulus selector must pass through $D, M, R, S, G, E, H, C, P, N$ before it reaches K, so the modulus-facing consumer receives a finite packet rather than an open-cover object.

Finally use the open-cover refusal boundary, Definition 452.28. It blocks arbitrary open families, host compactness, and selected-subcover coordinates, leaving UniformModulus$^{\uparrow}$ with only the finite Lebesgue-number radius packet. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberUniformModulusRadiusExhaustion`

Definition 452.37 (Finite Lebesgue-number radius lower-bound fold)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *root coverage ledger*

$$\Lambda = (D, M, R, S, G, E, K, H, C, P, N),$$

the radius lower-bound fold is the finite BHist *packet*

$$F_\Lambda = (D, R, M, S, G, E, K, H, C, P, N)$$

whose read order first displays the DyadicCover$^\uparrow$ *row* D*, then the* RationalBall$^\uparrow$ *radius row* R*, then the* DyadicMesh$^\uparrow$ *row* M*, and then the* StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, CompactNetModulusSelector$^\uparrow$, hsame, Cont, Pkg, *and* NameCert *rows. The fold is a finite lower-bound packet for the displayed radius rows only: it has no coordinate for a host minimum, arbitrary open-cover compactness, selected subcover choice, quotient equality, or external modulus selector.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTasteGate single carrier alignment`

Theorem 452.38 (Finite Lebesgue-number cover-shrinkage stability)**.** *Let* $\Lambda = (D, M, R, S, G, E, K, H, C, P, N)$ *be an accepted* FiniteLebesgueNumber$^\uparrow$ *root coverage ledger. Shrinking each displayed cover cell along the folded positive radius packet* F_Λ *preserves the same* DyadicCover$^\uparrow$, RationalBall$^\uparrow$, DyadicMesh$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, hsame, Cont, Pkg, *and* NameCert *route. In particular, every shrunken-cell read remains a read through the folded finite lower-bound packet and not through an open-cover compactness theorem, selected subcover, host minimum, quotient equality, or choice coordinate.*

Proof. Project the root coverage ledger of Definition 452.29. Its rows already place $D, R, M, S, G, E, K, H, C, P, N$ in one finite BHist packet, and the lower-bound fold only changes the read order so the rational-ball radius is inspected before the mesh row.

Use the selector-radius domain theorem, Definition 452.34. It says the positive radius ledger is readable only through the displayed dyadic cover, rational-ball, dyadic mesh, stream, regular-rational, real, transport, replay, provenance, and naming rows.

Apply compact-net selector factorization and uniform-modulus radius exhaustion. Definition 452.35 keeps the selector downstream of the folded packet, and Definition 452.36 prevents a modulus consumer from replacing that radius with open-cover compactness or a selected subcover.

Thus cover-cell shrinkage is stable under the same displayed transports and replays. The shrinkage endpoint is the folded finite lower-bound packet, not a host minimum or external equality coordinate. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCoverShrinkageStability`

Theorem 452.39 (Finite Lebesgue-number UniformModulus consumer exactness)**.** *Every* UniformModulus$^\uparrow$ *consumer of an accepted* FiniteLebesgueNumber$^\uparrow$ *root coverage ledger factors through the radius lower-bound fold* F_Λ*. The consumer receives exactly the finite radius packet*

$$D, R, M, S, G, E, H, C, P, N \to K$$

carried by DyadicCover$^\uparrow$, RationalBall$^\uparrow$, DyadicMesh$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, hsame, Cont, Pkg, *and* NameCert *rows, and it receives no open-cover compactness theorem, selected subcover, host minimum, quotient equality, choice coordinate, or external modulus row.*

Proof. Begin with the root coverage ledger. By Definition 452.29, every candidate consumer row is already displayed inside $\Lambda = (D, M, R, S, G, E, K, H, C, P, N)$, and Definition 452.37 repacks those rows as the finite lower-bound packet F_Λ.

Apply Definition 452.34. It identifies R as the positive radius ledger over the displayed D, M dyadic packet and keeps all later reads inside S, G, E, H, C, P, N.

Next apply Definition 452.35 and Definition 452.36. The first theorem routes K through the finite packet before any selector read, and the second theorem states that a $\mathsf{UniformModulus}^{\uparrow}$ consumer receives only the finite Lebesgue-number radius packet.

Finally use cover-shrinkage stability. It shows that shrinking cover cells to the folded positive radius remains stable under the same displayed transport and replay rows, so the consumer receives exactly $D, R, M, S, G, E, H, C, P, N \to K$ and no open-cover compactness, selected-subcover, host-minimum, quotient-equality, or choice coordinate. □

Theorem 452.40 (Finite Lebesgue number radius-modulus transport scope)**.** *In every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root coverage ledger, the positive radius ledger is transported toward a modulus only together with the displayed* $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows. Thus the radius-to-modulus route has no separate carrier for a compact minimum, an open-cover selector, or a choice coordinate outside the finite dyadic-cover packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRadiusModulusTransportScope`

Proof. Project the accepted ledger $\Lambda = (D, M, R, S, G, E, K, H, C, P, N)$. The selector-radius domain theorem identifies R as the positive rational-ball radius row over the displayed dyadic cover and mesh rows D, M.

Apply the compact-net selector factorization theorem and the uniform-modulus radius exhaustion theorem. They force every modulus-facing consumer to pass through $D, M, R, S, G, E, H, C, P, N$ before any selector row can be read.

The remaining rows are exactly the StreamName, RegSeqRat, Real, transport, replay, provenance, and NameCert rows already named in the ledger. Since no other row is present, radius-modulus transport is scoped by the displayed finite packet. □

Theorem 452.41 (Finite Lebesgue number open-phase root package)**.** *Every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root coverage ledger presents its finite Lebesgue-number root surface as the finite-window route*

$$D, M, R, S, G, E, H, C, P, N$$

inside one BHist *packet. The route is anchored by* hsame, Cont, Pkg, *and* NameCert *rows, starts from the displayed* $\mathsf{DyadicCover}^{\uparrow}$ *and* $\mathsf{DyadicMesh}^{\uparrow}$ *evidence, and transports the positive* $\mathsf{RationalBall}^{\uparrow}$ *radius through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers without exposing open-cover compactness, a selected subcover, a host minimum, quotient equality, or a choice coordinate.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCarrier open phase root package`

Proof. Read the dyadic-cover handoff and the root coverage ledger. They display the cover, mesh, rational-radius, stream, regular-rational, real, transport, replay, provenance, and local naming rows in one finite BHist packet.

Apply the finite-window coverage exactness, root compact consumer nonchoice, and radius-modulus transport scope rows. Together they route every root-surface read through $D, M, R, S, G, E, H, C, P, N$ before any compact or uniform consumer can inspect the packet.

The open-cover refusal boundary supplies the negative side of the package. Since no arbitrary open family, selected subcover, host compactness minimum, quotient equality, or external selector row is present, the root surface is precisely the displayed finite-window route. □

Theorem 452.42 (Finite Lebesgue number compact cover-selection row)**.** *Every* CompactMetric$^{\uparrow}$ *cover-selection consumer of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *packet consumes the dyadic cover row D, total-bounded finite-window rows, dyadic mesh row M, rational radius row R, and the* hsame, Cont, Pkg, *and* NameCert *ledger before any compact read. Thus compact cover selection is a finite-route read from* DyadicCover$^{\uparrow}$, DyadicMesh$^{\uparrow}$, TotallyBounded$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *data, not a read from open-cover compactness or a choice-like selected subcover.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactCoverSelectionRow`

Proof. Start from the finite-window route of Definition 452.41. It places the dyadic cover, mesh, radius, stream, regular-rational, real, transport, replay, provenance, and naming rows before the compact consumer.

Use the total-bounded consumer factorization and compact-net selector factorization rows. These factor the compact-metric read through the displayed finite cover and mesh packet, so the compact route consumes the finite dyadic data already present in the ledger.

Finally apply the open-cover refusal boundary. The compact consumer therefore has no coordinate from which to read an arbitrary open cover, a selected subcover, or a compactness minimum; it receives only the finite cover-selection row anchored in BHist, hsame, Cont, Pkg, and NameCert. □

Theorem 452.43 (Finite Lebesgue number ContinuousMap uniform route row)**.** *Every* ContinuousMap$^{\uparrow}$ *or* UniformModulus$^{\uparrow}$ *consumer reading an accepted* FiniteLebesgueNumber$^{\uparrow}$ *packet may read only the explicit radius ledger and the compact-net route*

$$D, M, R, S, G, E, H, C, P, N \to K.$$

The consumer may replay Cont *and transport along* hsame *inside the stored* BHist *packet, and may cite the displayed* Pkg *and* NameCert *rows, but it cannot replace that route by an external continuity modulus, open-cover compactness, selected subcover, host minimum, quotient equality, or choice coordinate.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCarrier continuousmap uniform route row`

Proof. Begin with radius-modulus transport scope. It already restricts the positive radius ledger to the displayed dyadic cover, mesh, stream, regular-rational, real, transport, replay, provenance, and naming rows.

Attach the compact-net selector factorization and UniformModulus consumer exactness rows. They place K downstream of $D, M, R, S, G, E, H, C, P, N$ and identify the modulus-facing packet as the radius lower-bound fold rather than an independent continuity object.

The replay row for ContinuousMap$^{\uparrow}$ is therefore a consumer of the stored finite route. It can read Cont only as part of the same BHist packet, so the uniform route remains the explicit radius ledger and compact-net route, with no outside open-cover or choice coordinate. □

Theorem 452.44 (Finite Lebesgue number compact uniform handoff scope)**.** *Every* CompactMetric$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, *and* UniformModulus$^{\uparrow}$ *consumer of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *packet factors through the same displayed finite dyadic-cover packet before receiving compact or uniform-continuity data. The handoff route is the finite row family*

$$D, M, R, S, G, E, H, C, P, N \to K,$$

with D from DyadicCover$^{\uparrow}$, *M from* DyadicMesh$^{\uparrow}$, *R from* RationalBall$^{\uparrow}$, *S from* StreamName$^{\uparrow}$, *G from* RegSeqRat$^{\uparrow}$, *E from* Real$^{\uparrow}$, *and H, C, P, N from* hsame, Cont, Pkg, *and* NameCert.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactUniformHandoffScope`

Proof. Start with the root compact consumer nonchoice theorem. It sends compact-metric and compact-net consumers through the finite dyadic cover, mesh, radius, stream, regular-rational, real, transport, replay, provenance, and naming rows before any compact read is exposed.

Next use compact-net selector factorization. The displayed route $D, M, R, S, G, E, H, C, P, N \to K$ makes the selector row downstream of the same finite packet rather than a source of independent compactness.

Finally apply uniform-modulus radius exhaustion. The uniform-modulus consumer receives only the radius packet carried by those same rows, so compactness and uniform continuity meet at the displayed handoff and nowhere outside it. □

Theorem 452.45 (Finite Lebesgue number scoped closure package)**.** *The finite dyadic-cover obligations displayed in the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root coverage ledger form a scoped closure package: the root unblock package, selector-radius domain, compact-net selector factorization, uniform-modulus radius exhaustion, radius lower-bound fold, cover-shrinkage stability, UniformModulus consumer exactness, radius-modulus transport scope, and compact uniform handoff scope all use the same finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *packet. Hence the chapter closes the finite Lebesgue-number scope for explicit dyadic-cover radius transport and compact-to-uniform handoff.*

Proof. First assemble the existing root route. The root unblock package exposes the dyadic cover, dyadic mesh, rational radius, stream, regular-rational, real endpoint, compact-metric, compact-net selector, transport, replay, provenance, and local naming rows in one finite packet.

The selector-radius domain, compact-net selector factorization, and uniform-modulus radius exhaustion theorems then route the positive radius from that packet toward selector and uniform-modulus consumers. No step introduces an external open cover, selected subcover, host minimum, or choice coordinate.

Insert the radius lower-bound fold and cover-shrinkage stability rows. They turn the displayed rational-ball radius into the finite lower-bound packet and keep cover shrinkage inside the same transported and replayed rows.

Add UniformModulus consumer exactness, radius-modulus transport scope, and compact uniform handoff scope. These rows state that both the modulus transport and the compact-to-uniform handoff consume the same displayed dyadic-cover packet, so the finite Lebesgue-number scope is closed at the displayed rows. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberScopedClosurePackage`

Theorem 452.46 (Finite Lebesgue number radius-cover monotone readback)**.** *In every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root coverage ledger* $\Lambda = (D, M, R, S, G, E, K, H, C, P, N)$*, the positive radius row* R *is readable only after the displayed* $\mathsf{DyadicCover}^{\uparrow}$ *row* D *and the* $\mathsf{RationalBall}^{\uparrow}$ *readback rows attached to* D *have been exposed. Any* hsame *transport in* H *or* Cont *replay in* C *may extend the read toward* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*, and* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *consumers, but it cannot detach* R *from the finite cover row or reverse the finite read order.*

Proof. Start with the carrier and root coverage ledger. The carrier of Definition 452.1 places the finite cover, radius ledger, mesh ledger, transport, replay, provenance, and local naming rows in one packet, while Definition 452.29 displays them as $\Lambda = (D, M, R, S, G, E, K, H, C, P, N)$.

Use the NameCert obligations, radius transport, and finite-radius nonchoice rows. Definition 452.2, Definition 452.4, and Definition 452.7 require every radius read to pass through the rational-ball rows tied to the displayed dyadic cover and mesh evidence.

Next apply the selector-radius domain and radius-modulus transport scope. They keep R downstream of D and upstream of every compact-net or modulus-facing consumer, with H and C acting only as stored transport and replay rows.

The readback is therefore monotone in the finite ledger order: transport and replay can carry the displayed radius to later consumers, but cannot create an earlier host radius, open-cover compactness row, selected subcover, or external modulus function. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRadiusCoverMonotoneReadback`

Theorem 452.47 (Finite Lebesgue number mesh-refinement cover exhaustion)**.** *For every accepted* FiniteLebesgueNumber$^{\uparrow}$ *root coverage ledger, each mesh-refinement read from* DyadicMesh$^{\uparrow}$ *exhausts into a named cover cell through the displayed* DyadicCover$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The exhaustion is finite: no mesh cell may request an arbitrary open cover, a selected subcover, host compactness, quotient equality, or a cover-cell selector outside the ledger.*

Proof. Begin with finite-window coverage exactness and the obligation coverage row. Definition 452.5 and Definition 452.23 send every accepted window read through a StreamName$^{\uparrow}$ row, a RegSeqRat$^{\uparrow}$ approximation row, a Real$^{\uparrow}$ row, a mesh cell, and a named dyadic cover cell.

Attach the mesh-refinement nonchoice and radius-mesh stability rows. Definition 452.8 keeps the mesh-to-cover handoff stable under the stored hsame transports and replayed Cont routes, while Definition 452.24 keeps the mesh evidence tied to the positive rational-ball radius readback.

Now read the root window cover totality theorem and the root unblock package. They place the StreamName, RegSeqRat, Real, mesh, cover, transport, replay, provenance, and local naming rows in the same finite BHist packet before compact consumers inspect the ledger.

Thus every mesh-refinement read exhausts into a named cover cell already present in the displayed packet. Since the packet has no coordinate for open-cover compactness, arbitrary subcover selection, host compactness, quotient equality, or an external cell selector, the exhaustion is nonchoice. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberMeshRefinementCoverExhaustion`

Theorem 452.48 (Finite Lebesgue number compact-route dyadic modulus package)**.** *The compact route from an accepted* FiniteLebesgueNumber$^{\uparrow}$ *ledger to* CompactMetric$^{\uparrow}$ *and* CompactNetModulusSelector$^{\uparrow}$ *consumers is exactly the finite dyadic modulus packet*

$$D, R, M, S, G, E, H, C, P, N \to K.$$

It packages the displayed DyadicCover$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows for compact consumers, and it exports no open-cover compactness theorem, host compactness witness, arbitrary subcover selector, quotient equality, or external modulus function.*

Proof. Start from the compact consumer route and compact consumer nonchoice boundary. Definition 452.6 and Definition 452.16 identify the compact-facing data as the displayed finite carrier and exclude open-cover compactness, host compactness, arbitrary subcover choice, and external selectors.

Use the root compact consumer nonchoice theorem with compact-net selector factorization. Definition 452.31 sends both compact-metric and compact-net consumers through $D, M, R, S, G, E, H, C, P, N$, and Definition 452.35 records K as downstream of that finite packet.

Apply radius-cover monotone readback and mesh-refinement cover exhaustion. The first keeps the positive radius row readable only after the displayed cover and rational-ball rows, and the second exhausts every mesh-refinement read into a named cover cell through the StreamName, RegSeqRat, Real, transport, replay, provenance, and naming rows.

Finally add the compact uniform handoff scope and scoped closure package. These results state that compact and uniform consumers meet at the same finite dyadic-cover packet, so the compact route is precisely $D, R, M, S, G, E, H, C, P, N \to K$ and not an open-cover compactness or choice-sensitive subcover route. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactRouteDyadicModulusPackage certificate`

Theorem 452.49 (Finite Lebesgue number public compact-uniform export)**.** *The public* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *export for compact-uniform consumers is exactly the finite packet*

$$D, R, M, S, G, E, H, C, P, N \to K.$$

Here D is the displayed $\mathsf{DyadicCover}^{\uparrow}$ *row, R the* $\mathsf{RationalBall}^{\uparrow}$ *radius readback, M the* $\mathsf{DyadicMesh}^{\uparrow}$ *refinement ledger, S the* $\mathsf{StreamName}^{\uparrow}$ *row, G the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, E the* $\mathsf{Real}^{\uparrow}$ *row, H, C, P, N the* hsame, Cont, Pkg, *and* NameCert *rows, and K the compact-net selector handoff read by* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, *and* $\mathsf{UniformModulus}^{\uparrow}$ *consumers. The export has no coordinate for open-cover compactness, selected subcovers, host minima, quotient equality, choice, or external modulus functions.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPublicCompactUniformExport`

Proof. Begin with the scoped closure package. Definition 452.45 already binds the root unblock package, selector-radius domain, compact-net selector factorization, uniform-modulus radius exhaustion, lower-bound fold, cover-shrinkage stability, consumer exactness, and compact uniform handoff to the same finite BHist, hsame, Cont, Pkg, and NameCert packet.

Next attach radius-cover monotone readback and mesh-refinement cover exhaustion. Definition 452.46 keeps R downstream of the displayed cover and rational-ball rows, while Definition 452.47 sends every mesh read into a named cover cell through $D, R, M, S, G, E, H, C, P, N$.

Finally apply the compact-route dyadic modulus package. Definition 452.48 identifies the compact-facing route as $D, R, M, S, G, E, H, C, P, N \to K$. Since the preceding results place both compact and uniform-modulus reads inside that same finite route, the public export is the displayed packet and nothing outside it: no open-cover compactness, selected subcover, host minimum, quotient equality, choice, or external modulus function is exported. □

Theorem 452.50 (Finite Lebesgue-number compact-radius bridge)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier receives the positive finite-radius ledger only through the displayed route*

$$D, W, \lambda, M, H, C, P, N.$$

The bridge route passes through $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before the compact or compact-net consumer reads the radius ledger. It exports no open-cover compactness, selected subcover, host minimum, quotient equality, or external radius selector.*

Proof. Start with radius transport and mesh-refinement nonchoice. Definition 452.4 keeps λ tied to the displayed rational-ball readback, and Definition 452.8 keeps the mesh-to-cover route inside the same stored transport and replay rows.

Next use the total-bounded handoff and compact-uniform selector handoff. Definition 452.9 identifies $D, W, \lambda, M, H, C, P, N$ as the compact-facing finite packet, while Definition 452.10 sends the same positive radius ledger to compact-net and uniform consumers.

Finally apply the L10 source-lock. Definition 452.13 forces the compact-radius read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, and $\mathsf{DyadicCover}^{\uparrow}$ before any consumer inspects the ledger. Hence the bridge is exactly the displayed dyadic finite-radius route and has no open-cover or choice coordinate. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactRadiusBridge`

Theorem 452.51 (Finite Lebesgue-number uniform-modulus radius scope)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *handoff from an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier may read only the displayed positive finite-radius row in* $D, W, \lambda, M, H, C, P, N$*. The handoff cannot add open-cover compactness, a selected subcover, a host minimum,* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality, or an external modulus function to the radius scope.*

Proof. Begin with the compact-uniform selector handoff. It already places the uniform-modulus read downstream of the positive radius ledger carried by the displayed dyadic cover, finite-window, rational-ball, mesh, transport, replay, provenance, and local naming rows.

Use total-bounded handoff and window-radius ledger coherence. The total-bounded handoff fixes the compact-facing packet as $D, W, \lambda, M, H, C, P, N$, and window-radius ledger coherence prevents a window read from acquiring a separate positive radius outside the same packet.

The compact consumer nonchoice boundary supplies the negative side. It excludes open-cover compactness, selected subcovers, host minima, quotient equality, and external selectors from the compact route, so the uniform-modulus handoff inherits only the displayed positive finite-radius row and not a stronger compactness or completeness principle. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberUniformModulusRadiusScope`

Theorem 452.52 (Finite Lebesgue-number dyadic-cover Real route)**.** *Every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *finite-window read reaches* $\mathsf{Real}^{\uparrow}$ *only through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *before mesh and cover-cell readback. The resulting dyadic-cover route then continues through* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{DyadicCover}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*; no host real representative, open cover, selected subcover, or arbitrary cover-cell selector supplies the endpoint.*

Proof. Start from finite-window coverage exactness and stream-regular window order. These results force each finite-window read to pass first through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$, then through $\mathsf{Real}^{\uparrow}$, before any mesh cell or dyadic cover cell is read.

Apply the Real source nonchoice boundary. It rules out host real equality, arbitrary point selection, open-cover compactness, subcover choice, and external real representatives as sources for the $\mathsf{Real}^{\uparrow}$ row.

Finally use cover-cell readback totality. The mesh and cover-cell endpoint is packaged by the displayed hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, so the Real route reaches the dyadic cover only through the stated stream and regular-rational sources. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberDyadicCoverRealRoute`

Theorem 452.53 (Finite Lebesgue-number source-chain admission)**.** *An accepted* FiniteLebesgueNumber$^{\uparrow}$ *route is admitted only after the displayed* DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, *and* DyadicMesh$^{\uparrow}$ *rows pass through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *source rows, all carried by the same* BHist, hsame, Cont, Pkg, *and* NameCert *packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberSourceChainAdmission`

Proof. Use finite-window coverage exactness to place every finite read inside the displayed window packet.

Then apply Definition 452.52. It forces the source chain through StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ before any dyadic mesh or cover-cell endpoint is admitted.

Finally use Definition 452.48. The compact-facing package is exactly the same BHist, hsame, Cont, Pkg, and NameCert route, so admission cannot bypass the displayed L10 source rows. □

Theorem 452.54 (Finite Lebesgue-number ledger transport)**.** *For every accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier,* hsame *transport preserves the positive radius ledger together with the dyadic cover, mesh,* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows. The radius is never transported as a detached scalar outside the displayed finite source packet.*

Proof. Start with Definition 452.24. It keeps the positive rational-ball read attached to the dyadic mesh evidence under stored hsame transport.

Next use Definition 452.26. The finite-window and radius ledgers share the same dyadic source packet, including the stream, regular-rational, and Real rows.

Apply Definition 452.46. Every transported radius read remains downstream of the displayed cover and rational-ball rows, so no scalar radius separates from the finite ledger. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberLedgerTransport`

Theorem 452.55 (Finite Lebesgue-number consumer nonescape triad)**.** *The* CompactMetric$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, *and* UniformModulus$^{\uparrow}$ *consumers of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier receive only the displayed finite route. They cannot import open-cover compactness, a host minimum, a selected subcover, quotient equality, choice, or external modulus data.*

Proof. Use Definition 452.25 to fix the compact and compact-net consumer boundary at the displayed finite packet.

Then apply Definition 452.44. The uniform-modulus handoff reads the same radius and cover route rather than a stronger compactness principle.

Finally use Definition 452.49. The public export has no coordinate for open-cover compactness, host minima, selected subcovers, quotient equality, choice, or external modulus data, so the three consumers cannot escape the finite route. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberConsumerNonescapeTriad`

Definition 452.56 (Finite Lebesgue-number selected-tail bridge ledger)**.** *The selected-tail bridge ledger for an accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier is the finite* BHist *packet*

$$J = (D, W, \lambda, M, A_T, W_T, K_T, S_T, R_T, H, C, P, N).$$

Here D, W, λ, M are the displayed FiniteLebesgueNumber$^{\uparrow}$ *dyadic-cover, finite-window, rational-ball radius, and dyadic-mesh rows. The rows A_T, W_T, K_T, S_T, R_T are the selected finite-tail admission, stream-window, regular-rational readback, dyadic tolerance ledger, and Real seal rows supplied by*

the current SelectedTailSeed$^{\uparrow}$ *seed. The structural rows* H, C, P, N *record componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the compatible local* NameCert *rows.*

The ledger is accepted only when the finite Lebesgue radius read and the selected-tail Real-window read are carried by the same structural support. Thus the compact-uniform route may consume λ *only together with* $D, W, M, A_T, W_T, K_T, S_T, R_T, H, C, P, N$.

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberSelectedTailBridgeLedger`
Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberSelectedTailBridgeLedger certificate`

Theorem 452.57 (Selected-tail radius admission)**.** *Any accepted finite Lebesgue radius read entering the compact-uniform route factors through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, *and the selected-tail seed handoff before* CompactNetModulusSelector$^{\uparrow}$ *consumes the radius. More precisely, if the read is admitted by the ledger* J *of Definition 452.56, then the consumer-facing radius is the same finite packet route*

$$D, W, \lambda, M, A_T, W_T, K_T, S_T, R_T, H, C, P, N$$

and not a radius obtained from open-cover compactness, host real equality, selected subcovers, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberSelectedTailRadiusAdmission`

Proof. Begin with the FiniteLebesgueNumber$^{\uparrow}$ carrier. The carrier definition Definition 452.1 and the root package theorem Definition 452.33 identify the radius read as the displayed dyadic-cover, finite-window, rational-ball, and mesh packet D, W, λ, M with the same H, C, P, N support used by compact consumers.

Next read the selected-tail seed scope. The stream-regular readback theorem Definition 1207.18 binds the W_T, K_T part of the route to StreamName$^{\uparrow}$ and RegSeqRat$^{\uparrow}$. The dyadic Real-seal theorem Definition 1207.19 keeps S_T, R_T as the finite DyadicRatCore$^{\uparrow}$-to-Real$^{\uparrow}$ seal.

Finally apply the finite-tail Real-boundary theorem Definition 1207.20. It identifies A_T, W_T, K_T, S_T, R_T as the selected-tail boundary consumed downstream. Since the bridge ledger stores this boundary beside D, W, λ, M, the compact-net selector receives the finite radius only after the selected-tail source route has been displayed. □

Theorem 452.58 (Selected-tail uniform consumer route)**.** *Every* UniformModulus$^{\uparrow}$ *consumer downstream of an accepted selected-tail bridge ledger receives the same finite radius packet as* CompactNetModulusSelector

$$D, W, \lambda, M, A_T, W_T, K_T, S_T, R_T, H, C, P, N.$$

The consumer cannot replace this packet by open-cover compactness, host minima, selected subcovers, quotient equality, choice, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberSelectedTailUniformConsumerRoute`

Proof. Use Definition 452.57 to fix the compact-net input. The admitted radius already factors through the StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ selected-tail route before the compact-net selector can consume it.

The compact-uniform handoff Definition 452.44 and the consumer nonescape triad Definition 452.55 then pass the same displayed radius packet from CompactNetModulusSelector$^{\uparrow}$ to UniformModulus$^{\uparrow}$. These rows expose the finite cover, mesh, rational-ball radius, selected-tail

source boundary, and structural support; they do not expose a second compactness or modulus interface.

The exclusions are coordinate exclusions. Open-cover compactness, host minima, selected subcovers, quotient equality, choice, and ambient Real completeness are absent from J, while H, C, P, N only transport, replay, source, and name the rows already listed. Hence the uniform consumer route is the same finite selected-tail bridge packet. □

Theorem 452.59 (Finite Lebesgue-number total-bounded radius source lock)**.** *Any* $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, *or* $\mathsf{UniformModulus}^{\uparrow}$ *consumer that preserves the selected-tail bridge ledger of Definition 452.56 can read the positive radius only through the same finite packet*

$$D, W, \lambda, M, A_T, W_T, K_T, S_T, R_T, H, C, P, N.$$

Equivalently, the consumer-facing radius is unavailable unless the selected finite-tail admission, stream-window row, regular-rational readback, dyadic tolerance ledger, Real-seal row, finite Lebesgue radius row, dyadic-cover row, finite-window row, mesh row, componentwise transport, continuation replay, provenance, and local naming rows are all present. The route contains no open-cover compactness, host minimum, selected subcover, quotient equality, choice, or ambient Real completeness coordinate.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTotalBoundedRadiusSourceLock`

Proof. Start with the selected-tail radius admission theorem, Definition 452.57. It identifies the compact-net input radius with the displayed selected-tail packet and prevents the radius from being read before the stream, regular-rational, dyadic tolerance, and Real-seal rows have appeared.

Next use the selected-tail uniform consumer route, Definition 452.58. That theorem passes the same packet from $\mathsf{CompactNetModulusSelector}^{\uparrow}$ to $\mathsf{UniformModulus}^{\uparrow}$ and records that the uniform consumer receives no second compactness or modulus interface.

The root finite Lebesgue-number NameCert obligations, Definition 452.2, together with the root unblock package Definition 452.33, supply the finite dyadic-cover, finite-window, rational-ball radius, mesh, transport, continuation, provenance, and naming rows. These obligations keep λ attached to D, W, M, H, C, P, N before the selected-tail rows are joined to the route.

Finally apply the compact consumer nonchoice boundary, Definition 452.16. It keeps $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, and $\mathsf{CompactNetModulusSelector}^{\uparrow}$ consumers inside the displayed finite route and excludes open-cover compactness, host minima, selected subcovers, quotient equality, choice, and ambient Real completeness. Therefore any preserving compact or uniform consumer reads the positive radius exactly through $D, W, \lambda, M, A_T, W_T, K_T, S_T, R_T, H, C, P, N$. □

Theorem 452.60 (Finite Lebesgue-number bridge packet exactness)**.** *The* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *bridge packet displayed to compact and uniform consumers is exactly*

$$D, W, \lambda, M, H, C, P, N.$$

The route reads D *through* $\mathsf{DyadicCover}^{\uparrow}$, λ *through* $\mathsf{RationalBall}^{\uparrow}$, M *through* $\mathsf{DyadicMesh}^{\uparrow}$, *the finite-window sources through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *and the consumer endpoints through* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, *and* $\mathsf{UniformModulus}^{\uparrow}$. *No coordinate outside this tuple contributes to the bridge packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberBridgePacketExactness`

Proof. Start with the compact-radius bridge. Definition 452.50 identifies the compact and compact-net radius route as the displayed tuple $D, W, \lambda, M, H, C, P, N$ and forces the read through $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Next use source-chain admission and ledger transport. Definition 452.53 admits the route only after the displayed source rows pass through the same BHist, hsame, Cont, Pkg, and NameCert packet, while Definition 452.54 prevents the positive radius ledger from separating from the cover, mesh, stream, regular-rational, and real rows.

Finally apply uniform-modulus radius scope. Definition 452.51 sends the uniform consumer through the same positive finite-radius row and excludes any added compactness, completeness, quotient, or external modulus coordinate. Therefore the bridge packet is exactly the displayed tuple. □

Theorem 452.61 (Finite Lebesgue-number compact-uniform bridge soundness)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, *and* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier receives the same finite radius route*

$$D, W, \lambda, M, H, C, P, N.$$

The compact and uniform endpoints may inspect the displayed dyadic cover, rational-ball radius, mesh ledger, stream source, regular-rational approximation, real row, transport rows, continuations, package provenance, and local NameCert *row; they do not receive an open-cover coordinate, a subcover-choice coordinate, or an external radius-modulus coordinate.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactUniformBridgeSoundness`

Proof. First fix the compact side. Definition 452.50 sends $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{CompactNetModulusSelector}^{\uparrow}$ consumers through the displayed positive finite-radius route and excludes open-cover compactness, selected subcovers, host minima, quotient equality, and external radius selectors.

Now fix the uniform side. Definition 452.51 states that a $\mathsf{UniformModulus}^{\uparrow}$ handoff reads only the displayed radius row in the same tuple and cannot add host compactness, real completeness, quotient equality, or an external modulus function.

The dyadic-cover Real route supplies the shared source order. Definition 452.52 forces finite-window reads through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before mesh and cover-cell readback. Thus compact, compact-net, and uniform consumers receive one finite radius route rather than separate compactness or choice surfaces. □

Theorem 452.62 (Finite Lebesgue-number bridge nonescape)**.** *The* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *bridge packet cannot import host compactness, selected subcovers, quotient equality,* $\mathsf{Real}^{\uparrow}$ *completeness, or external modulus data. Every bridge-facing read remains inside the displayed dyadic finite-cover route*

$$D, W, \lambda, M, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberBridgeNonescape`

Proof. Use the consumer nonescape triad. Definition 452.55 excludes open-cover compactness, host minima, selected subcovers, quotient equality, choice, and external modulus data for compact, compact-net, and uniform consumers.

Next use compact-uniform bridge soundness. Definition 452.61 identifies the only consumer route as $D, W, \lambda, M, H, C, P, N$ and lists the permitted cover, radius, mesh, stream, regular-rational, real, transport, continuation, provenance, and naming rows.

Finally use bridge packet exactness. Definition 452.60 leaves no bridge coordinate outside the displayed tuple. Hence none of host compactness, selected subcovers, quotient equality, real completeness, or external modulus data can enter the bridge packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLebesgueNumber}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ packet is generated from an accepted $\mathsf{DyadicCover}^{\uparrow}$ finite cover, a $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ row, a positive rational radius ledger, a $\mathsf{DyadicMesh}^{\uparrow}$ refinement ledger, displayed hsame transports, Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteLebesgueNumber}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The public finite-cover radius route is closed by the carrier, local NameCert obligations, root unblock package, selector-radius domain, compact-net selector factorization, uniform-modulus radius exhaustion, radius lower-bound fold Definition 452.37, cover-shrinkage stability Definition 452.38, UniformModulus consumer exactness Definition 452.39, radius-modulus transport scope Definition 452.40, compact uniform handoff scope Definition 452.44, scoped closure package Definition 452.45, radius-cover monotone readback Definition 452.46, mesh-refinement cover exhaustion Definition 452.47, compact-route dyadic modulus package Definition 452.48, public compact-uniform export Definition 452.49, bridge packet exactness Definition 452.60, compact-uniform bridge soundness Definition 452.61, and bridge nonescape Definition 452.62.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteLebesgueNumber}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close open-cover compactness, arbitrary subcover choice, host real compactness, total-bounded construction, Lean verification, or bridge checking.

Upgrade path: The remaining obligation is Lean verification and checked standard-bridge audit for the displayed finite dyadic-cover packet.

Theorem 452.63 (Compact radius source-accountability)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *radius read from an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier factors through the displayed source-accountability surface*

$$\mathsf{DyadicCover}^{\uparrow},\ \mathsf{DyadicMesh}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The compact or compact-net consumer may read the positive radius only as part of that finite dyadic packet. It receives no open-cover compactness, selected subcover, host minimum, quotient equality, choice, or radius selector outside the displayed BHist *ledger.*

Proof. Start with the compact-uniform selector handoff. Definition 452.10 sends every compact-net and uniform-facing radius read through the displayed finite cover, finite window, rational radius, dyadic mesh, transport, continuation, provenance, and local naming rows.

Now apply the L10 source-lock. Definition 452.13 forces the consumer-facing radius route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, and $\mathsf{DyadicCover}^{\uparrow}$ before any compact or compact-net consumer can inspect the positive ledger.

Finally use the compact-route dyadic modulus package. Definition 452.48 identifies the compact-facing packet with the finite dyadic modulus route carried by BHist, hsame, Cont, Pkg, and NameCert. Since the packet has no open-cover, subcover-selection, host-minimum, quotient-equality, choice, or detached selector coordinate, every compact radius read has the stated source-accountability surface. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactRadiusSourceAccountability`

Theorem 452.64 (Uniform modulus source factorization)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *packet reads the same positive finite-radius ledger used by* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *consumers. The factorization runs through the displayed* $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows, rather than through an external modulus function or an independently supplied continuity surface.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberUniformModulusSourceFactorization`

Proof. First read the compact radius source-accountability theorem above. It fixes the compact and compact-net radius source as the displayed dyadic packet and forbids a detached radius selector before the uniform consumer appears.

Next apply the compact-uniform selector handoff and the compact-route dyadic modulus package. These rows pass the same positive ledger from the compact route to the compact-net selector and keep the ledger inside the finite dyadic modulus packet.

Use the consumer nonescape triad for the final boundary. Definition 452.55 states that $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ consumers receive only the displayed finite route. Hence the uniform modulus consumer reads the already displayed positive radius ledger and cannot import an external modulus function, a separate continuous-map modulus, open-cover compactness, quotient equality, or choice. □

Theorem 452.65 (Total-bounded ledger readback)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *handoff downstream of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier receives the displayed finite dyadic cover ledger*

$$D, W, \lambda, M, H, C, P, N.$$

Its readback may inspect the $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows already present in that ledger, but it cannot recover open-cover compactness, selected subcovers, quotient equality, choice, host compactness, or an external modulus surface.*

Proof. Begin with the total-bounded handoff obligation. Definition 452.9 identifies $D, W, \lambda, M, H, C, P, N$ as the exact packet delivered to $\mathsf{TotallyBounded}^{\uparrow}$ and compact-metric consumers.

Attach the L10 source-lock and the compact radius source-accountability theorem above. Together they force the radius, mesh, stream, regular-rational, real, transport, continuation, provenance, and local naming reads to occur inside the displayed finite dyadic ledger before any total-bounded or compact-facing consumer can use the handoff.

Finally invoke the consumer nonescape triad. Definition 452.55 excludes open-cover compactness, host minima, selected subcovers, quotient equality, choice, and external modulus data from the downstream consumer route. Therefore the total-bounded handoff reads back exactly the displayed ledger and cannot reconstruct any stronger compactness or selection principle from it. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTotalBoundedLedgerReadback`

Definition 452.66 (Finite Lebesgue-number compact-continuous unblock ledger)**.** *For an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *carrier, the compact-continuous unblock ledger is the displayed finite packet*

$$U_{\mathrm{cc}} = (D, W, \lambda, M, H, C, P, N; K, F, Q)$$

where $D, W, \lambda, M, H, C, P, N$ *are the dyadic cover row, finite-window row, positive rational-ball radius ledger, dyadic mesh ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row of the finite Lebesgue-number carrier. The row* K *is the compact-net consumer row over* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{CompactNetModulusSelector}^{\uparrow}$, F *is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus consumer row over the same finite-window source, and* Q *is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row consuming the radius read from* λ.

The ledger is accepted only when K, F, Q *read the same finite dyadic-radius packet* $D, W, \lambda, M, H, C, P, N$ *through the same* BHist, hsame, Cont, Pkg, *and* NameCert *support. It has no coordinate for open-cover compactness, selected subcovers, host minima, quotient equality, choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or an external modulus selector.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactContinuousUnblockLedger`

Theorem 452.67 (Finite Lebesgue-number compact-continuous triad)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, *and* $\mathsf{UniformModulus}^{\uparrow}$ *consumer admitted by the compact-continuous unblock ledger of Definition 452.66 reads the same finite dyadic-radius packet*

$$D, W, \lambda, M, H, C, P, N.$$

The compact row, compact-net row, continuous-map pointwise row, and uniform-modulus handoff row are therefore a single BHist *route rather than four independent parameter surfaces.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactContinuousTriad`

Proof. Begin with finite-window coverage exactness. Definition 452.5 sends every accepted window read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, the mesh row M, and the named dyadic cover row D before any consumer can inspect the radius ledger.

Next attach the compact consumer nonchoice boundary and compact-uniform selector handoff. Definition 452.16 keeps compact and compact-net consumers inside the displayed finite packet, while Definition 452.10 sends the same positive radius ledger from that packet to the compact-net and uniform endpoints.

Use source-chain admission and ledger transport for the shared support. Definition 452.53 admits the route only through the common BHist, hsame, Cont, Pkg, and NameCert rows, and Definition 452.54 prevents λ from separating from the dyadic cover, finite window, mesh, stream, regular-rational, and real rows.

Finally apply the consumer nonescape triad. Definition 452.55 excludes open-cover compactness, host minima, selected subcovers, quotient equality, choice, and external modulus data. The continuous-map row F in the ledger is therefore read only as a pointwise consumer of the same finite radius packet, and the four consumer rows form the stated compact-continuous triad. □

Theorem 452.68 (Finite Lebesgue-number source-radius unblock)**.** *In every accepted compact-continuous unblock ledger* U_{cc}*, a source-side radius request reaches* λ *only after the displayed finite-window source has passed through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, *and* $\mathsf{DyadicCover}^{\uparrow}$ *rows carried by* H, C, P, N*. Thus the root unblock surface for compact, compact-net, continuous-map, and uniform-modulus consumers is the finite dyadic-radius packet itself, not an open-cover or host-completeness principle.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberSourceRadiusUnblock`

Proof. Start with the source-chain admission theorem. It requires the dyadic cover, rational-ball radius, and mesh rows to pass through the stream-name, regular-rational, and real rows before the route is admitted into the shared support.

Now use finite-window coverage exactness. Each accepted read from W lands in a named mesh and cover cell before the radius ledger is visible, so a source request cannot enter through a detached real representative or an arbitrary open family.

Transport the radius with ledger transport. The hsame and Cont rows preserve the positive radius together with the cover, mesh, stream, regular-rational, and real rows; λ is never a scalar outside the finite packet.

The compact consumer nonchoice boundary supplies the negative side. It refuses open-cover compactness, selected subcovers, host minima, quotient equality, choice, detached $\mathsf{Real}^{\uparrow}$ completeness, and external selectors, leaving the finite dyadic-radius packet as the only root unblock surface. □

Theorem 452.69 (Finite Lebesgue-number uniform-continuity handoff)**.** *Every* UniformModulus$^{\uparrow}$ *handoff accepted by the compact-continuous unblock ledger consumes the* ContinuousMap$^{\uparrow}$ *pointwise row only after* CompactMetric$^{\uparrow}$ *and* CompactNetModulusSelector$^{\uparrow}$ *have exposed the same positive finite-radius packet* $D, W, \lambda, M, H, C, P, N$*. The handoff cannot replace that packet with a selected subcover, a host minimum, quotient equality, choice, detached* Real$^{\uparrow}$ *completeness, or an external modulus selector.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberUniformContinuityHandoff`

Proof. First use compact-uniform selector handoff. It places the uniform-modulus read downstream of the positive radius ledger already carried by $D, W, \lambda, M, H, C, P, N$.

Next use the compact radius source-accountability theorem. Definition 452.63 identifies the compact and compact-net source of the radius as the displayed dyadic cover, mesh, stream-name, regular-rational, real, transport, continuation, provenance, and naming rows.

Read the continuous-map row through the ledger definition. The pointwise row F is admitted only as a consumer row over the same finite-window source and the same BHist, hsame, Cont, Pkg, and NameCert support, so it cannot supply an independent global modulus surface.

Finally invoke uniform modulus source factorization and consumer nonescape. Definition 452.64 sends the uniform consumer through the same source packet, and Definition 452.55 removes open-cover compactness, selected subcovers, host minima, quotient equality, choice, detached real completeness, and external modulus selectors from the handoff. □

Theorem 452.70 (Finite Lebesgue-number L10 sibling route)**.** *Every accepted* FiniteLebesgueNumber$^{\uparrow}$ *consumer route that exposes the positive finite-radius ledger to a compact, compact-net, continuous-map, or uniform-modulus consumer factors through the L10 finite-name chain chapter 126, chapter 301, chapter 291, and chapter 38, and then through the dyadic mesh and cover surfaces of chapter 358 and chapter 446. Thus a compact-continuous consumer can read the positive radius only as part of the displayed finite route*

$$D, W, \lambda, M, H, C, P, N.$$

The route has no coordinate for open-cover compactness, host minima, selected subcovers, quotient equality, choice, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Start with the root carrier and NameCert obligations. Definition 452.1 displays $D, W, \lambda, M, H, C, P, N$, while Definition 452.2 makes every radius, mesh, window, transport, continuation, provenance, and local naming read a finite component of that packet.

Next attach the source-accountability rows. Definition 452.63 forces compact and compact-net radius reads through the visible StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, DyadicMesh$^{\uparrow}$, and DyadicCover$^{\uparrow}$ surface. Definition 452.57 inserts the selected-tail DyadicRatCore$^{\uparrow}$ seal before the compact-net selector consumes the radius.

The selected-tail bridge ledger then keeps the source route finite. Its packet J records the stream-window, regular-rational readback, dyadic tolerance ledger, real seal, finite Lebesgue radius row, and the same H, C, P, N support; no row in J supplies an open family, a host minimum, a quotient equality principle, or an ambient completeness theorem.

Finally apply the compact-continuous triad. Definition 452.67 and Definition 452.69 make CompactMetric$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, ContinuousMap$^{\uparrow}$, and UniformModulus$^{\uparrow}$ consumers read the same finite dyadic-radius packet. Hence every accepted compact-continuous route factors through the displayed L10 sibling chain before the positive radius is visible, and the excluded compactness, selection, equality, choice, and completeness data remain absent. □

Lean4 ✓ BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberL10SiblingRoute

Definition 452.71 (Finite Lebesgue-number radius-consumer determinacy ledger)**.** *The radius-consumer determinacy ledger for* FiniteLebesgueNumber$^{\uparrow}$ *is the finite row family*

$$\Delta_\lambda = (D, R, M, S, G, E, H, C, P, N, K, Q)$$

whose displayed entries are the DyadicCover$^{\uparrow}$ *cover row D, the* RationalBall$^{\uparrow}$ *positive radius row R, the* DyadicMesh$^{\uparrow}$ *mesh row M, the* StreamName$^{\uparrow}$ *source-window row S, the* RegSeqRat$^{\uparrow}$ *regular-rational readback row G, the* Real$^{\uparrow}$ *endpoint row E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, local* NameCert *naming N, the compact and compact-net consumer row K, and the* UniformModulus$^{\uparrow}$ *consumer row Q. The ledger determines the radius read available to* CompactMetric$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, *and* UniformModulus$^{\uparrow}$ *consumers only through these finite rows. It has no coordinate for an arbitrary open cover, selected subcover, host minimum, quotient equality, choice principle, detached* Real$^{\uparrow}$ *representative, or external modulus selector.*

Lean4 (definition) BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRadiusConsumerDeterminacyLedger

Theorem 452.72 (Finite Lebesgue-number radius-row determinacy)**.** *Let L and L' be accepted* FiniteLebesgueNumber$^{\uparrow}$ *routes whose radius-consumer ledgers display the same* DyadicCover$^{\uparrow}$ *cover row,* RationalBall$^{\uparrow}$ *positive radius row,* DyadicMesh$^{\uparrow}$ *mesh row,* StreamName$^{\uparrow}$ *source-window row,* RegSeqRat$^{\uparrow}$ *regular-rational row,* Real$^{\uparrow}$ *endpoint row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming row. Then every compact, compact-net, or uniform consumer admitted by those routes exposes the same positive finite-radius row.*

Lean4 ✓ BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRadiusRowDeterminacy

Proof. Start with radius transport. Definition 452.4 keeps the positive radius tied to the rational-ball and mesh evidence under the displayed transport rows.

Next apply the window-radius source lock. Definition 452.26 identifies the finite-window source of the radius through StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, DyadicMesh$^{\uparrow}$, and DyadicCover$^{\uparrow}$ before a consumer can inspect the radius.

Use radius-cover monotone readback and ledger transport for the comparison. Definition 452.46 fixes the read order from the cover row to the rational-ball row, while Definition 452.54 prevents the radius from separating from the cover, mesh, source, transport, replay, provenance, and naming rows.

Since L and L' agree on exactly those displayed rows, no compact, compact-net, or uniform consumer has another radius coordinate to read. The exposed positive radius row is therefore the same row in both routes. □

Theorem 452.73 (Finite Lebesgue-number uniform-consumer determinacy)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *radius-consumer determinacy ledger Δ_λ, a* UniformModulus$^{\uparrow}$ *consumer cannot obtain a modulus radius different from the positive finite-radius row displayed in Δ_λ. Any uniform-modulus handoff preserving the displayed cover, rational-ball, mesh, source, transport, replay, provenance, and naming rows reads the same radius as the compact and compact-net consumers.*

Lean4 ✓ BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberUniformConsumerDeterminacy

Proof. Begin with the uniform-modulus radius scope theorem. Definition 452.51 places every $\mathsf{UniformModulus}^{\uparrow}$ handoff inside the displayed positive finite-radius row.

Now use the consumer nonescape triad. Definition 452.55 excludes open-cover compactness, selected subcovers, host minima, quotient equality, choice, and external modulus data from compact, compact-net, and uniform consumers alike.

Finally apply the public compact-uniform export. Definition 452.49 identifies the public export as the same finite cover, rational-ball, mesh, source, transport, replay, provenance, and naming route. Thus the uniform consumer has no second modulus-radius source and must read the radius already determined by Δ_λ. □

Theorem 452.74 (Finite Lebesgue-number compact-consumer determinacy package)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, *and* $\mathsf{UniformModulus}^{\uparrow}$ *consumer admitted by an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *radius-consumer determinacy ledger factors through one deterministic finite route*

$$D, R, M, S, G, E, H, C, P, N, K, Q.$$

The compact metric read, compact-net selector read, and uniform-modulus handoff therefore expose the same positive radius row through the displayed $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *data.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactConsumerDeterminacyPackage`

Proof. First package the compact side. Definition 452.50 sends compact and compact-net consumers through the displayed positive finite-radius route, and Definition 452.72 makes the radius row fixed by the shared ledger rows.

Next package the uniform side. Definition 452.73 states that a $\mathsf{UniformModulus}^{\uparrow}$ consumer preserving the same ledger cannot read a different modulus radius.

It remains to identify the shared finite route. Definition 452.71 lists exactly the cover, radius, mesh, source, transport, replay, provenance, naming, compact-consumer, and uniform-consumer rows, while Definition 452.55 removes all outside compactness, equality, choice, and modulus coordinates. Hence the three consumer surfaces are packaged by the single deterministic route displayed above. □

Theorem 452.75 (Finite Lebesgue-number Phase Real source lock)**.** *Every accepted public radius read of* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *that is visible to a compact or continuous consumer factors through the displayed Phase Real and Completion route*

$$\mathsf{DyadicCover}^{\uparrow},\ \mathsf{RationalBall}^{\uparrow},\ \mathsf{DyadicMesh}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Thus the consumer-facing radius is not a host scalar and not an open-cover compactness witness: it is the finite dyadic-radius packet carried by the BHist, hsame, Cont, Pkg, *and* NameCert *rows of the finite Lebesgue-number carrier before any* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, *or* $\mathsf{ContinuousMap}^{\uparrow}$ *endpoint can inspect it.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealSourceLock`

Proof. Start with the root obligations. Definition 452.2 fixes the dyadic cover, finite-window, rational-ball radius, mesh, transport, continuation, provenance, and local naming rows as the only public rows of the $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ packet.

Next apply the L10 source lock. Definition 452.13 forces the radius route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, and $\mathsf{DyadicCover}^{\uparrow}$ before the compact side can read the radius.

Use the selected-tail bridge ledger and bridge packet exactness for the Phase Real and Completion handoff. Definition 452.56 records the finite selected-tail source rows, while Definition 452.60 leaves no bridge coordinate outside the displayed dyadic, stream, regular-rational, and real rows.

Finally use compact-continuous unblock. Definition 452.67 sends compact, compact-net, continuous-map, and uniform-modulus consumers through the same finite dyadic-radius packet. Hence every accepted public read factors through the stated Phase Real and Completion route. □

Theorem 452.76 (Finite Lebesgue-number selected-tail modulus exhaustion)**.** *In an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *route, every selected-tail witness and every finite-window witness used to expose a radius to a modulus consumer is exhausted by the displayed carrier rows*

$$D, W, \lambda, M, A_T, W_T, K_T, S_T, R_T, H, C, P, N.$$

No hidden modulus selector, quotient stream, countable choice coordinate, host real equality, or detached $\mathsf{Real}^{\uparrow}$ *representative can be inserted between the selected-tail source rows and the finite dyadic-radius packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberSelectedTailModulusExhaustion`

Proof. Read the finite-window side first. Definition 452.2 and Definition 452.13 make every window and radius read pass through the dyadic cover, rational-ball radius, mesh, stream-name, regular-rational, and real rows with the displayed structural support.

Now read the selected-tail side. Definition 452.56 lists exactly the selected finite-tail admission, stream-window, regular-rational readback, dyadic tolerance, and Real-seal rows joined to the finite Lebesgue-number packet.

Apply bridge packet exactness. Definition 452.60 states that the bridge packet has no coordinate beyond the displayed tuple. The excluded coordinates include quotient equality, host real equality, choice, detached real completeness, and external modulus data.

The modulus consumer therefore sees only the selected-tail and finite-window rows already named in the carrier. Since there is no further selector or stream coordinate in the packet, the listed rows exhaust the modulus-facing witness data. □

Theorem 452.77 (Finite Lebesgue-number compact-continuous nonchoice exit)**.** *Any* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, *or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer admitted downstream of* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *receives exactly the finite dyadic-radius packet*

$$\mathsf{DyadicCover}^{\uparrow}, \mathsf{RationalBall}^{\uparrow}, \mathsf{DyadicMesh}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCer}$$

The exit to these consumers does not supply open-cover compactness, an arbitrary subcover principle, a host minimum, countable choice, quotient stream equality, or an external modulus selector.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactContinuousNonchoiceExit`

Proof. Begin with source accountability. Definition 452.13 and Definition 452.75 identify the only source of the consumer-facing radius as the finite dyadic, stream, regular-rational, and real route.

Next use the selected-tail exhaustion theorem above. It prevents selected-tail or finite-window witnesses from contributing a hidden modulus selector, quotient stream, countable choice coordinate, host real equality, or detached real representative.

Finally apply the downstream consumer package. Definition 452.67 sends compact, compact-net, continuous-map, and uniform-modulus endpoints through the same finite packet, and Definition 452.60 removes all bridge coordinates outside that packet.

Therefore the consumer exit is nonchoice: the consumers receive the finite dyadic-radius packet and no open-cover compactness or arbitrary subcover principle. □

Theorem 452.78 (Finite Lebesgue-number real-phase coverage export)**.** *Every accepted* FiniteLebesgueNumber$^{\uparrow}$ *public read used by a* CompactMetric$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, ContinuousMap$^{\uparrow}$, *or* UniformModulus$^{\uparrow}$ *endpoint factors through exactly the L10 Real-phase route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

together with the finite dyadic cover, rational-ball radius, dyadic mesh, BHist, hsame, Cont, Pkg, *and* NameCert *rows of the finite Lebesgue-number carrier. The exported handoff supplies no host real equality, quotient stream equality, countable-choice coordinate, selected limit, open-cover compactness principle, or ambient-completeness primitive.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRealPhaseCoverageExport`

Proof. Start with the Phase Real source lock. Definition 452.75 routes every compact- or continuous-visible radius read through the dyadic cover, rational-ball radius, dyadic mesh, stream-name, regular-rational, and Real rows, with BHist, hsame, Cont, Pkg, and NameCert carrying the public BEDC packet.

Next use selected-tail exhaustion. Definition 452.76 rules out any hidden modulus selector, quotient stream, countable choice coordinate, host real equality, or detached Real$^{\uparrow}$ representative between the selected-tail source rows and the finite dyadic-radius packet.

Finally apply the compact-continuous nonchoice exit. Definition 452.77 says that the compact, compact-net, continuous-map, and uniform-modulus endpoints receive exactly that finite packet and no open-cover compactness, arbitrary subcover principle, host minimum, quotient stream equality, or external modulus selector.

Thus the L10 handoff exported to the downstream endpoints is the finite Real-phase coverage route through DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$, together with the named finite carrier rows and no completed-real or choice-bearing primitive. □

Definition 452.79 (Finite Lebesgue-number root radius-window obligation ledger)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier, the root radius-window obligation ledger is the finite* BHist *row*

$$\Omega_{\lambda W} = (D, W, \lambda, M, S, Q, R, H, C, P, N)$$

whose entries are the DyadicCover$^{\uparrow}$ *cover row D, the finite window row W, the positive radius row λ, the* DyadicMesh$^{\uparrow}$ *mesh row M, the* StreamName$^{\uparrow}$ *source row S, the* RegSeqRat$^{\uparrow}$ *regular-rational row Q, the* Real$^{\uparrow}$ *endpoint row R, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *naming N. The ledger records the root obligation surface only through* DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows; it has no coordinate for open-cover compactness, a host minimum, choice, quotient equality, selected limit data, or a separate completeness primitive.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootRadiusWindowObligationLedge`

Theorem 452.80 (Finite Lebesgue-number root radius-window obligation surface)**.** *Every accepted root radius-window obligation ledger of Definition 452.79 discharges the positive radius and finite-window obligations only through the displayed dyadic cover, rational-ball radius, dyadic mesh,*

stream-name, regular-rational, Real, BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. In particular, the root obligation exposed to the Real-and-completion route is the finite packet*

$$D, W, \lambda, M, S, Q, R, H, C, P, N$$

and not an open-cover compactness principle, host minimum, choice coordinate, quotient equality, selected limit, or Real-completeness coordinate.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootRadiusWindowObligationSurface`

Proof. Begin with the carrier. Definition 452.1 displays the finite dyadic cover, finite window, radius, mesh, transport, continuation, provenance, and local naming rows of the FiniteLebesgueNumber$^{\uparrow}$ packet.

Apply the NameCert obligations and finite-window coverage exactness. Definition 452.2 keeps each public read inside the carrier rows, while Definition 452.5 routes every accepted window through StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, the mesh row, and the named dyadic cover row.

Now apply the L10 and Phase Real source locks. Definition 452.13 and Definition 452.75 force the positive-radius read through the dyadic, stream, regular-rational, and Real rows before any consumer can inspect it.

Thus the ledger of Definition 452.79 is exactly the root radius-window surface. Since the cited rows contain no open-cover compactness, host minimum, choice, quotient equality, selected limit, or Real-completeness coordinate, none is available at the root. □

Theorem 452.81 (Finite Lebesgue-number radius carrier source)**.** *Every accepted* FiniteLebesgueNumber$^{\uparrow}$ *root radius-window ledger projects its carrier source exactly to the finite* BHist *rows*

$$D, W, \lambda, M, S, Q, R, H, C, P, N$$

of Definition 452.79. The only source faces visible in this projection are DyadicCover$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*, together with the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows. No host minimum, choice coordinate, quotient equality, selected limit, or Real-completeness coordinate is part of the carrier source.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRadiusCarrierSource`

Proof. Project the carrier through the ledger definition. Definition 452.79 lists the finite rows $D, W, \lambda, M, S, Q, R, H, C, P, N$ and names the dyadic cover, rational-ball radius, dyadic mesh, stream-name, regular-rational, Real, transport, continuation, provenance, and local naming faces.

Now use the root radius-window obligation surface. Definition 452.80 states that an accepted ledger discharges the positive-radius and finite-window obligations only through those displayed rows.

The L10 source faces are therefore read as the DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ part of the same finite packet, while DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, and DyadicMesh$^{\uparrow}$ supply the local radius carrier. Since neither the definition nor the surface theorem contains a row for a host minimum, choice, quotient equality, selected limit, or Real completeness, no such coordinate can appear in the projected carrier source. □

Theorem 452.82 (Finite Lebesgue-number radius classifier stability)**.** *Let two accepted* FiniteLebesgueNumber$^{\uparrow}$ *root radius-window ledgers agree componentwise by* hsame *on the rows* $D, W, \lambda, M, S, Q, R, H, C, P, N$*. Then the positive-radius window transported between them has the same classifier at every* CompactMetric$^{\uparrow}$*,* CompactNetModulusSelector$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*, and* UniformModulus$^{\uparrow}$ *endpoint, and the transport does not change the L10 source faces* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRadiusClassifierStability`

Proof. Start with the componentwise agreement. Definition 452.84 transports the accepted radius-window obligation along the shared rows $D, W, \lambda, M, S, Q, R, H, C, P, N$ and keeps the consumer-facing surface finite.

Next apply open Phase exhaustion. Definition 452.86 says that the positive-radius and finite-window reads are exhausted by the root radius-window packet before a compact, compact-net, continuous-map, or uniform-modulus endpoint can add a further coordinate.

Finally use RegSeq-StreamName nonescape. Definition 452.88 keeps the stream-name and regular-rational source faces attached to the four-face route, so the transported classifier cannot replace the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ faces. The classifier is stable because every visible row is carried by the same componentwise hsame transport. □

Theorem 452.83 (Finite Lebesgue-number radius ledger exactness)**.** *The local* NameCert *ledger for the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root radius-window obligation is exactly the carrier-source and classifier-stability package of Definition 452.81 and Definition 452.82. It has no additional compactness, choice, selected-limit, quotient, metric-completeness, or Real-completeness coordinate beyond the rows of Definition 452.79.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRadiusLedgerExactness`

Proof. First read the carrier-source side. Definition 452.81 identifies the carrier projection with the finite rows $D, W, \lambda, M, S, Q, R, H, C, P, N$ and excludes off-ledger minima, choice, quotient equality, selected limits, and Real completeness.

Next read the classifier side. Definition 452.82 transports the positive-radius classifier through componentwise hsame while keeping the L10 source faces fixed.

Now apply consumer exactness and Real-source coverage. Definition 452.85 states that every downstream compact, compact-net, continuous-map, and uniform-modulus consumer receives exactly the ledger rows, while Definition 452.87 accounts for the Real-side source faces inside the same finite packet.

These two readings exhaust the local NameCert ledger: the carrier source gives the rows, classifier stability gives their transported public read, and the consumer and Real-source theorems rule out any extra compactness, choice, selected-limit, quotient, metric-completeness, or Real-completeness coordinate. □

Theorem 452.84 (Finite Lebesgue-number root radius-window transport)**.** *Let two accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *routes agree on the rows* $D, W, \lambda, M, S, Q, R, H, C, P, N$ *of the root radius-window obligation ledger. Then the radius-window obligation transported to* $\mathsf{CompactMetric}^{\uparrow}$, CompactNetModulusS $\mathsf{ContinuousMap}^{\uparrow}$, *or* $\mathsf{UniformModulus}^{\uparrow}$ *consumers is the same finite obligation surface in both routes. The transport uses only* BHist, *componentwise* hsame, *displayed* Cont, Pkg, *and* NameCert *rows over* $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootRadiusWindowTransport certificate`

Proof. First read the shared ledger rows. Agreement on $D, W, \lambda, M, S, Q, R$ fixes the dyadic cover, finite window, positive radius, mesh, stream-name, regular-rational, and Real endpoint data.

Use the NameCert obligations to transport componentwise. Definition 452.2 keeps the carrier rows under hsame, and Definition 452.5 keeps the window witness attached to the same stream, regular-rational, Real, mesh, and cover route.

Next use the L10 and Phase Real source locks. Definition 452.13 identifies the only source of the radius as the finite dyadic Real-phase route, and Definition 452.75 makes that route visible to compact and continuous consumers without adding an outside coordinate.

The remaining rows H, C, P, N replay and name the same finite packet for both routes. Therefore the transported consumer obligation is identical, because no open-cover compactness, host minimum, choice, quotient equality, selected limit, or Real-completeness coordinate can distinguish the two routes. □

Theorem 452.85 (Finite Lebesgue-number root radius-window consumer exactness)**.** *Every* CompactMetric$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, ContinuousMap$^{\uparrow}$, *and* UniformModulus$^{\uparrow}$ *consumer admitted downstream of the root radius-window obligation ledger receives exactly the finite rows of Definition 452.79. The consumer receives no additional open-cover compactness, host minimum, choice, quotient equality, selected limit, or Real-completeness coordinate beyond the* DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *packet.*

Proof. Start with the root obligation surface theorem above. It states that the positive radius and finite-window obligations are already exhausted by $D, W, \lambda, M, S, Q, R, H, C, P, N$.

Apply the Phase Real source lock. Definition 452.75 makes every consumer-facing radius read pass through DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ before any compact, compact-net, continuous-map, or uniform-modulus endpoint can inspect it.

Use the L10 source lock and window coverage exactness to cover the finite-window side. Definition 452.13 fixes the source route, while Definition 452.5 sends each accepted finite-window read through the named stream, regular-rational, Real, mesh, and cover rows.

Finally read consumer exactness from the absence of outside rows in the ledger. Since Definition 452.79 lists only the displayed finite packet, each downstream consumer receives exactly that packet and no compactness, equality, choice, selected-limit, or completeness coordinate outside it. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootRadiusWindowConsumerExactness`

Theorem 452.86 (Finite Lebesgue-number open-phase radius-window exhaustion)**.** *For every accepted* FiniteLebesgueNumber$^{\uparrow}$ *route exposed to the current Real-and-Completion four-face source route, the open-phase radius-window ledger is exhausted by the displayed rows*

$$\text{DyadicRatCore}^{\uparrow},\ \text{StreamName}^{\uparrow},\ \text{RegSeqRat}^{\uparrow},\ \text{Real}^{\uparrow},\ \text{BHist},\ \text{hsame},\ \text{Cont},\ \text{Pkg},\ \text{NameCert}.$$

Equivalently, every positive-radius window visible from the root obligation surface is read through the dyadic-rational core, stream-name source, regular-rational readback, Real endpoint, history transport, continuation, package provenance, and local NameCert rows. It has no coordinate for open-cover compactness, host minima, quotient equality, selected limits, choice, detached Real completeness, or a second radius source.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenPhaseRadiusWindowLedgerExhaustion`

Proof. Begin with the root radius-window obligation surface. Definition 452.80 states that the positive radius and finite-window obligations are already carried by the finite dyadic cover, rational-ball radius, dyadic mesh, stream-name, regular-rational, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Next attach the Phase Real source lock. Definition 452.75 forces each compact- or continuous-visible public radius read through DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ before any downstream endpoint can inspect it.

Finally use the Real-completion terminal-radius exhaustion. Definition 452.95 says that the terminal compact, compact-net, continuous-map, and uniform-modulus radius reads still factor through the same L10 packet and introduce no outside compactness, equality, selected-limit, choice, or completeness coordinate. Thus the open-phase radius-window ledger is exactly the displayed four-face source route with the BEDC support rows. □

Theorem 452.87 (Finite Lebesgue-number Real-source ledger coverage)**.** *The finite Lebesgue-number Real-source ledger covers every source row used by the current radius-window packet:*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

are the only source faces, and BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *are the only BEDC transport and naming rows that carry those faces to the accepted* FiniteLebesgueNumber$^{\uparrow}$ *obligation surface.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRealSourceLedgerCoverage`

Proof. Read the root ledger first. Definition 452.79 lists the dyadic cover, finite window, positive radius, dyadic mesh, stream-name, regular-rational, Real endpoint, history, transport, continuation, provenance, and local naming rows, with no independent compactness or completeness coordinate.

Use the Phase Real source lock to identify the source faces. Definition 452.75 routes the consumer-facing radius through the dyadic, stream-name, regular-rational, and Real rows, and it leaves only BHist, hsame, Cont, Pkg, and NameCert as the BEDC support carrying the public packet.

The preceding open-phase exhaustion theorem then removes any remaining escape route at the radius-window boundary. Therefore the Real-source ledger covers exactly the displayed four source faces and the named support rows. □

Theorem 452.88 (Finite Lebesgue-number RegSeq-StreamName nonescape)**.** *In an accepted* FiniteLebesgueNumber$^{\uparrow}$ *open-phase radius-window ledger, the* RegSeqRat$^{\uparrow}$ *and* StreamName$^{\uparrow}$ *rows cannot be bypassed by a host sequence, quotient stream equality, selected limit, choice-selected representative, or ambient completeness witness. Every downstream read of the radius window that reaches* CompactMetric$^{\uparrow}$*,* CompactNetModulusSelector$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*, or* UniformModulus$^{\uparrow}$ *must pass through the displayed* StreamName$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *rows together with* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRegSeqStreamNameNonescape`

Proof. Start from Real-source ledger coverage. Definition 452.87 identifies StreamName$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ as source faces of the finite radius-window packet, not as optional annotations.

Now apply the root radius-window consumer exactness theorem. Definition 452.85 says that compact, compact-net, continuous-map, and uniform-modulus consumers receive exactly the displayed finite rows and no host minimum, quotient equality, selected limit, choice, open-cover compactness, or Real-completeness coordinate.

Finally attach the Real-completion terminal-radius exhaustion. Definition 452.95 keeps terminal radius reads on the same L10 packet. Hence bypassing StreamName$^{\uparrow}$ or RegSeqRat$^{\uparrow}$ would require a coordinate absent from both the root consumer boundary and the terminal Real-completion ledger, so the stated nonescape follows. □

The root radius ledger is read against the four-face Phase Real route through chapter 291, chapter 126, chapter 301, and chapter 38.

Theorem 452.89 (Finite Lebesgue-number open Phase source nonescape)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier, no public source read visible at the root can inspect host* Real$^{\uparrow}$ *equality, open-cover compactness, choice-selected subcovers, or external modulus data before the read has passed through the finite four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The only admissible source coordinates before that passage are the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows tied to the dyadic cover, rational-ball radius, dyadic mesh, stream name, regular rational, and Real endpoint rows of the* FiniteLebesgueNumber$^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenPhaseSourceNonescape`

Proof. Begin with the finite carrier. Definition 452.79 lists the root radius-window rows as a finite packet over DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Apply the source locks. Definition 452.13 forces the radius source through the stream, regular-rational, Real, mesh, and cover rows, while Definition 452.75 exposes the same route to compact and continuous consumers without adding an outside coordinate.

Now use root radius-window exactness. Definition 452.80 excludes open-cover compactness, host minima, choice coordinates, quotient equality, selected limits, and detached Real-completeness data from the root obligation surface.

Therefore any accepted public source read must pass through the four displayed Phase Real faces before a downstream consumer can inspect it. Since no host equality, open-cover compactness, choice-selected subcover, or external modulus coordinate appears in the finite packet, none can be read at the root. □

Theorem 452.90 (Finite Lebesgue-number four-face radius readback)**.** *Every* CompactMetric$^{\uparrow}$*,* TotallyBounded$^{\uparrow}$*,* CompactNetModulusSelector$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*, or* UniformModulus$^{\uparrow}$ *radius read admitted downstream of* FiniteLebesgueNumber$^{\uparrow}$ *factors through the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

together with the DyadicCover$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*, and* RationalBall$^{\uparrow}$ *rows of the finite Lebesgue-number carrier. Thus compact and compact-net consumers can read only the displayed finite radius ledger, not an open-cover compactness principle, host minimum, arbitrary subcover, selected limit, or external modulus selector.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberFourFaceRadiusReadback`

Proof. First read the public export. Definition 452.49 identifies the consumer-facing export as the finite cover, rational-ball, mesh, source, transport, replay, provenance, and naming route.

Next apply the Phase Real coverage export. Definition 452.78 routes compact, compact-net, continuous-map, and uniform-modulus endpoints through DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$, together with the finite carrier rows.

Use the root radius-window consumer exactness theorem for the compact side. Definition 452.85 says that the downstream consumers receive exactly the displayed finite rows and no open-cover compactness, host minimum, choice, quotient equality, selected limit, or Real-completeness coordinate.

The remaining rows DyadicCover$^{\uparrow}$, DyadicMesh$^{\uparrow}$, and RationalBall$^{\uparrow}$ are precisely the cover, mesh, and radius rows named in the carrier. Hence every radius read factors through the four L10 faces plus those finite dyadic rows, with no separate compactness or selector interface. □

Theorem 452.91 (Finite Lebesgue-number root-unblock exit triad)**.** *Definition 452.89, Definition 452.90, and Definition 452.55 form the root-unblock exit surface for every compact-uniform consumer of* FiniteLebesgueNumber$^{\uparrow}$*. The exit surface supplies only the finite four-face Phase Real route, the dyadic cover, dyadic mesh, rational-ball radius,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, and it supplies no host Real equality, open-cover compactness, choice-selected subcover, selected limit, detached completeness primitive, or external modulus data.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootUnblockExitTriad`

Proof. Start with the source boundary. Definition 452.89 prevents a root read from reaching host Real equality, open-cover compactness, selected subcovers, or external modulus data before it passes through the four-face Phase Real route.

Now read the radius boundary. Definition 452.90 sends every compact or compact-net radius read through the four L10 faces and the displayed dyadic cover, dyadic mesh, and rational-ball rows.

Finally apply the existing consumer boundary. Definition 452.55 excludes open-cover compactness, host minima, selected subcovers, quotient equality, choice, and external modulus data from the compact, compact-net, and uniform consumer endpoints.

Combining the three rows gives exactly the root-unblock exit surface. All exported data is already present in the finite carrier and its NameCert rows, so downstream compact-uniform consumers cannot recover any outside compactness, equality, choice, completeness, selected-limit, or modulus primitive from the handoff. □

Theorem 452.92 (Finite Lebesgue-number L10 phase consumer readiness)**.** *Every accepted* FiniteLebesgueNumber$^{\uparrow}$ *consumer route used at the Phase Real or Completion boundary factors through the finite packet over* DyadicCover$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* CompactMetric$^{\uparrow}$*,* CompactNetModulusSelector$^{\uparrow}$*,* UniformModulus$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. Continuous-map and totally-bounded consumers read the same route through the displayed compact-uniform handoff. The route exports no open-cover compactness, selected subcover, host minimum, quotient equality, choice, external modulus, or* Real$^{\uparrow}$ *completeness.*

Proof. Begin with the compact-uniform export. Definition 452.49 identifies the public handoff as the finite dyadic-cover, rational-ball, mesh, stream, regular-rational, Real, transport, replay, provenance, naming, and compact-net selector packet.

Next attach the L10 source chain. Definition 452.52 sends each finite-window read through StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ before mesh and cover-cell readback, and Definition 452.53 places the displayed dyadic rows in the same BHist, hsame, Cont, Pkg, and NameCert packet.

Use ledger transport to keep the route stable. Definition 452.54 preserves the positive radius ledger together with the cover, mesh, stream, regular-rational, and Real rows under hsame transport, so later compact, continuous-map, totally-bounded, uniform-modulus, or Completion-facing consumers cannot detach a scalar or host-side witness from the packet.

Finally apply the nonescape boundary. Definition 452.55 excludes open-cover compactness, host minima, selected subcovers, quotient equality, choice, and external modulus data from the compact, compact-net, and uniform consumer endpoints. Since the Phase Real and Completion handoffs read through those endpoints and the same L10 source packet, their consumer-ready route is exactly the displayed finite packet and not an additional compactness, choice, modulus, or completeness principle. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberL10PhaseConsumerReadiness`

Theorem 452.93 (Finite Lebesgue-number L10 consumer readback exactness)**.** *Every Phase Real or Completion boundary consumer of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *route reads exactly the packet over*

DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg

The compact, compact-net, continuous-map, totally-bounded, and uniform-modulus endpoints add no open-cover compactness, selected subcover, host minimum, quotient equality, choice, external modulus, selected limit, or detached Real-completeness row to that consumer-visible readback.

Proof. First identify the endpoint factorization. Definition 452.92 places every Phase Real or Completion boundary consumer on the finite route through the dyadic cover, rational-ball, dyadic mesh, stream, regular-rational, Real, compact, compact-net, uniform, and structural rows, with no outside compactness, equality, choice, modulus, or completeness coordinate.

Next read the source packet through the open Phase classifier. Definition 452.97 identifies the accepted positive-radius read with the four-face route

DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$

together with the DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert support rows.

Finally assemble the terminal package. Definition 452.99 states that the open Phase pullback, compact-uniform readiness, Real-completion terminal-radius exhaustion, and L10 phase consumer readiness are one certificate over exactly the displayed packet. Since that terminal certificate has no coordinate for open-cover compactness, selected subcovers, host minima, quotient equality, choice, external moduli, selected limits, or detached Real completeness, the consumer-visible readback is exactly the finite packet named in the statement. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberL10ConsumerReadbackExactness`

Definition 452.94 (Finite Lebesgue-number Real-completion terminal-radius ledger)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *route, the Real-completion terminal-radius ledger is the finite* BHist *packet*

$$\Theta_{\lambda}^{\mathrm{term}} = (D, W, \lambda, M, S, Q, R, K, U, H, C, P, N)$$

whose entries are the DyadicCover$^{\uparrow}$ *cover row D, the* FiniteWindowEnvelope$^{\uparrow}$ *row W, the positive* RationalBall$^{\uparrow}$ *radius row λ, the* DyadicMesh$^{\uparrow}$ *row M, the* StreamName$^{\uparrow}$ *source row S, the* RegSeqRat$^{\uparrow}$ *readback row Q, the* Real$^{\uparrow}$ *endpoint row R, the compact and compact-net consumer row K, the continuous-map and uniform-modulus consumer row U, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *naming N.*

The ledger is terminal for the L10 Real-and-Completion source route: a downstream radius consumer may inspect only the displayed DyadicCover$^{\uparrow}$, FiniteWindowEnvelope$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows, with* CompactNetModulusSelector$^{\uparrow}$ *read through the compact row K. It has no coordinate for open-cover compactness, a host minimum, quotient equality, selected limits, choice, or an ambient Real-completeness primitive.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRealCompletionTerminalRadiusLed`

Theorem 452.95 (Finite Lebesgue-number Real-completion terminal-radius exhaustion)**.** *Every* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, *or* UniformModulus$^{\uparrow}$ *consumer*

admitted downstream of an accepted Real-completion terminal-radius ledger of Definition 452.94 factors its positive-radius read through the displayed L10 packet

$$D, W, \lambda, M, S, Q, R, K, U, H, C, P, N.$$

Consequently the compact, compact-net, continuous-map, and uniform-modulus endpoints cannot read open-cover compactness, host minima, quotient equality, selected limits, choice, or Real completeness outside the $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *route.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRealCompletionTerminalRadiusExhaustion`
Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTerminalRadiusExhaustion`

Proof. Begin with the finite-window side. Definition 452.5 routes every accepted window read through the finite window W, a $\mathsf{StreamName}^{\uparrow}$ row, a $\mathsf{RegSeqRat}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ row, a mesh cell of M, and a named cover cell of D. Thus the window coordinate used by a downstream radius consumer is already inside the displayed terminal ledger.

Next attach the L10 source route. Definition 452.13 forces the positive-radius read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, and $\mathsf{DyadicCover}^{\uparrow}$, while Definition 452.75 exposes the same route to compact and continuous consumers without adding a host scalar or open-cover compactness witness.

Now read the root consumer boundary. Definition 452.85 states that $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelect}$ $\mathsf{ContinuousMap}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ consumers receive exactly the root rows $D, W, \lambda, M, S, Q, R, H, C, P, N$ and no open-cover compactness, host minimum, quotient equality, selected limit, choice, or Real-completeness coordinate.

Finally use the L10 phase consumer readiness theorem. Definition 452.92 places the compact, compact-net, continuous-map, and uniform-modulus endpoints on the same finite packet, so the consumer rows K and U do not introduce another radius source. Therefore every terminal positive-radius read factors through $\Theta_{\lambda}^{\mathrm{term}}$, and the excluded compactness, equality, selected-limit, choice, and completeness data remain unavailable. □

Theorem 452.96 (Finite Lebesgue-number terminal-radius choice refusal)**.** *Let a downstream* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, *or* $\mathsf{UniformModulus}^{\uparrow}$ *consumer preserve the Real-completion terminal-radius ledger*

$$\Theta_{\lambda}^{\mathrm{term}} = (D, W, \lambda, M, S, Q, R, K, U, H, C, P, N)$$

of Definition 452.94. Then the displayed rational-ball radius λ *cannot be replaced, at that terminal boundary, by a host minimum, a selected subcover radius, a choice-selected modulus, quotient* $\mathsf{Real}^{\uparrow}$ *equality, a selected limit, or an external compactness witness.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTerminalRadiusChoiceRefusal`

Proof. The ledger definition fixes the available rows exactly. By Definition 452.94, the terminal packet exposes only $D, W, \lambda, M, S, Q, R, K, U, H, C, P, N$, with K and U serving as consumer rows and with no coordinate for open-cover compactness, a host minimum, quotient equality, selected limits, choice, or an ambient Real-completeness primitive.

Now apply the exhaustion theorem. Definition 452.95 says that every positive-radius read by the compact, compact-net, continuous-map, or uniform-modulus endpoints factors through this displayed packet. Thus a replacement for λ would have to be readable from one of the displayed rows.

Finally use the root consumer boundary cited in that proof. Definition 452.85 excludes open-cover compactness, host minima, quotient equality, selected limits, choice, and Real-completeness coordinates from exactly these root consumers. The proposed host minimum, selected subcover radius, choice-selected modulus, quotient $\mathsf{Real}^{\uparrow}$ equality, selected limit, and external compactness witness therefore have no terminal ledger coordinate through which they can replace λ. □

Theorem 452.97 (Finite Lebesgue-number open Phase radius classifier pullback)**.** *For an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive-radius read visible at the open Phase boundary, the radius classifier factors through exactly the* $\mathsf{DyadicCover}^{\uparrow}$ *row, the* $\mathsf{RationalBall}^{\uparrow}$ *radius row, the* $\mathsf{DyadicMesh}^{\uparrow}$ *row, and the four-face source route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The only structural support available to the read is the displayed BHist *packet together with componentwise* hsame*, displayed* Cont*,* Pkg *provenance, and local* NameCert *naming. In particular the pullback has no coordinate for open-cover compactness, a selected subcover, a host minimum, quotient equality, choice, an external modulus, or a detached Real-completeness row.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenPhaseRadiusClassifierPullback`

Proof. Start with the Phase Real source lock. Definition 452.75 sends every compact- or continuous-visible radius read through the dyadic cover, rational-ball radius, dyadic mesh, stream-name, regular-rational, and Real rows, while preserving only BHist, hsame, Cont, Pkg, and NameCert support.

Next use the four-face readback. Definition 452.90 identifies the same radius read with the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route. Thus the classifier cannot acquire a second source after it crosses the open Phase boundary.

Finally apply the root consumer boundary and the nonescape triad. Definition 452.85 fixes the downstream rows available to compact, compact-net, continuous-map, and uniform-modulus consumers, and Definition 452.55 removes open-cover compactness, selected subcovers, host minima, quotient equality, choice, and external modulus data from those endpoints. The stated pullback is therefore exactly the displayed finite classifier route. □

Theorem 452.98 (Finite Lebesgue-number compact-uniform four-face readiness)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{CompactNetModulusSelector}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$ *consumer downstream of the accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *radius ledger reads the same four-face packet*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

together with the $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The compact-uniform handoff supplies no open-cover compactness, selected subcover, host minimum, quotient equality, choice, external modulus, or Real-completeness row.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactUniformFourFaceReadiness`

Proof. First read the radius classifier through the open Phase pullback. Definition 452.97 gives the exact four-face source route and the dyadic cover, rational-ball, and dyadic-mesh rows available to any accepted positive-radius read.

Now attach the compact and uniform consumers. Definition 452.85 states that $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ consumers receive exactly

the root finite rows and no outside compactness, equality, selected-limit, choice, or completeness coordinate.

Finally use the nonescape boundary. Definition 452.55 excludes open-cover compactness, selected subcovers, host minima, quotient equality, choice, and external modulus data from the compact, compact-net, and uniform endpoints. Therefore the compact-uniform route is ready precisely over the four-face packet and not over an additional compactness or completeness principle. □

Theorem 452.99 (Finite Lebesgue-number root-unblock terminal package)**.** *The accepted* FiniteLebesgueNumber$^{\uparrow}$ *root radius ledger is terminal for the current four-face route: the open Phase radius classifier pullback of Definition 452.97, the compact-uniform readiness of Definition 452.98, the Real-completion terminal-radius exhaustion of Definition 452.95, and the L10 phase consumer readiness of Definition 452.92 form one certificate over*

DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg

No downstream CompactMetric$^{\uparrow}$*,* CompactNetModulusSelector$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*, or* UniformModulus$^{\uparrow}$ *consumer in this terminal certificate can import open-cover compactness, a selected subcover, a host minimum, quotient equality, choice, an external modulus, a selected limit, or a detached Real-completeness row.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootUnblockTerminalPackage`

Proof. Begin with the two classifier surfaces. Definition 452.97 fixes the accepted radius read to the dyadic cover, rational-ball, dyadic-mesh, and four-face source rows, and Definition 452.98 makes the compact, compact-net, and uniform consumers read that same packet.

Next attach the terminal Real-completion route. Definition 452.95 says that every compact, compact-net, continuous-map, or uniform-modulus positive-radius read factors through the terminal L10 packet and has no coordinate for open-cover compactness, host minima, quotient equality, selected limits, choice, or Real completeness.

Finally use L10 phase consumer readiness. Definition 452.92 places the compact, compact-net, continuous-map, and uniform-modulus endpoints on the same finite route, so the classifier and terminal-radius rows are not separate certificates. The combined root ledger is therefore the stated terminal certificate, with all listed outside compactness, equality, choice, modulus, selected-limit, and completeness data excluded. □

Definition 452.100 (Finite Lebesgue-number compact radius-window pullback packet)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier, the compact radius-window pullback packet is the finite* BHist *row*

$$\Omega_\lambda = (B, S, Q, R, K, F, U, H, C, P, N)$$

whose entries are the DyadicRatCore$^{\uparrow}$ *radius row B, the* StreamName$^{\uparrow}$ *finite-window row S, the* RegSeqRat$^{\uparrow}$ *readback row Q, the* Real$^{\uparrow}$ *seal face R, the* CompactMetric$^{\uparrow}$ *and* ContinuousMap$^{\uparrow}$ *consumer row K, F, the* UniformModulus$^{\uparrow}$ *row U, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *naming N. The packet is accepted only when B, S, Q, R, K, F, U are read as one radius-window obligation through the same H, C, P, N support, with no open-cover compactness, selected limit, quotient stream equality, selected subcover, host minimum, choice-like cover selection, or unbudgeted radius selector.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactRadiusWindowPullbackPack`

Theorem 452.101 (Finite Lebesgue-number compact radius-window pullback)**.** *Every compact or continuous consumer admitted downstream of an accepted compact radius-window pullback packet* Ω_λ *receives the positive radius through exactly the displayed* $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{Real}^\uparrow$, $\mathsf{CompactMetric}^\uparrow$, $\mathsf{ContinuousMap}^\uparrow$, $\mathsf{UniformModulus}^\uparrow$, BHist, hsame, Cont, Pkg, *and* NameCert *rows of Definition 452.100. The pullback supplies a finite radius-window obligation for* $\mathsf{CompactMetric}^\uparrow$ *and* $\mathsf{ContinuousMap}^\uparrow$ *consumers; it does not supply open-cover compactness, selected limits, quotient stream equality, selected subcovers, host minima, choice-like cover selection, or unbudgeted radius selection.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactRadiusWindowPullback`

Proof. Begin with the open Phase radius classifier pullback. Definition 452.97 fixes every accepted positive-radius read to the dyadic radius, finite-window, regular-rational readback, and Real source faces before any compact or continuous endpoint can inspect the radius.

Next use the L10 sibling route. Definition 452.70 forces compact, compact-net, continuous-map, and uniform-modulus reads through the finite-name chain and then through the dyadic mesh and cover surfaces. The row B, S, Q, R of Ω_λ is therefore the same finite source route, not a second compactness witness.

Attach the compact-continuous unblock triad. Definition 452.67 and Definition 452.69 make the $\mathsf{CompactMetric}^\uparrow$, $\mathsf{ContinuousMap}^\uparrow$, and $\mathsf{UniformModulus}^\uparrow$ rows consume the shared finite dyadic-radius packet through the same BHist, hsame, Cont, Pkg, and NameCert support.

Finally apply root-radius coherence. Definition 452.115 prevents the consumer from distinguishing two routes whose displayed radius, stream, regular-rational, Real, transport, replay, provenance, and naming rows agree. Since none of the cited surfaces contains a coordinate for open-cover compactness, selected limits, quotient stream equality, selected subcovers, host minima, choice-like cover selection, or unbudgeted radius selection, the accepted packet is exactly the stated compact radius-window pullback. □

Theorem 452.102 (Finite Lebesgue-number uniform-modulus consumer pullback)**.** *Every* $\mathsf{UniformModulus}^\uparrow$ *row admitted by* Ω_λ *is pulled back through the same compact radius-window packet read by the* $\mathsf{CompactMetric}^\uparrow$ *and* $\mathsf{ContinuousMap}^\uparrow$ *rows. Thus the uniform consumer receives the radius only as the finite* BHist *packet over* $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{Real}^\uparrow$, *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming; it cannot replace that packet by an external modulus, an open-cover compactness argument, a selected limit, quotient stream equality, a selected subcover, a host minimum, choice-like cover selection, or unbudgeted radius selection.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberUniformModulusConsumerPullback`

Proof. First read the compact-continuous triad. Definition 452.67 identifies the compact, compact-net, continuous-map, and uniform-modulus rows as consumers of one finite dyadic-radius packet.

Now apply the compact radius-window pullback theorem above. It places the $\mathsf{CompactMetric}^\uparrow$ and $\mathsf{ContinuousMap}^\uparrow$ reads on Ω_λ, whose source faces are the $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, and $\mathsf{Real}^\uparrow$ rows and whose support is exactly H, C, P, N.

Use the root radius-window consumer exactness and root-radius coherence package to rule out a detached uniform source. Definition 452.85 states that every compact, continuous, or uniform endpoint receives only the finite root rows, and Definition 452.116 reads those rows through the coherent root-radius ledger.

The uniform-modulus row therefore has no remaining coordinate for an external modulus, open-cover compactness, selected limits, quotient stream equality, selected subcovers, host minima,

choice-like cover selection, or unbudgeted radius selection. Its only admissible source is the compact radius-window packet. □

Theorem 452.103 (Finite Lebesgue-number budgeted Real-completion nonescape)**.** *The Real-completion route of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier cannot turn a compact radius-window pullback packet into an unbudgeted radius selector. Any terminal* Real$^{\uparrow}$ *or completion-facing radius read remains the finite packet* Ω_λ *transported by* hsame *and replayed by* Cont *through the displayed* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, Pkg, *and* NameCert *rows. In particular the Real-completion endpoint has no coordinate for open-cover compactness, selected limits, quotient stream equality, selected subcovers, host minima, choice-like cover selection, or unbudgeted radius selection.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberBudgetedRealCompletionNonescape`

Proof. Start with the existing Real-completion radius nonescape statement. Definition 452.117 says that the terminal Phase Real or Completion radius read remains the coherent finite root-radius packet, transported by hsame and replayed by Cont through the displayed source faces.

Next use the open Phase radius classifier pullback. Definition 452.97 identifies the radius classifier before the compact or continuous consumer sees it, so the Real-completion endpoint cannot add a new selected-limit or quotient-stream coordinate after the classifier has crossed the open Phase boundary.

Attach the compact radius-window pullback and uniform-modulus consumer pullback. The first theorem in this file places the compact and continuous consumers on Ω_λ, and the uniform theorem above makes the UniformModulus$^{\uparrow}$ row consume the same packet. Thus the Real-completion route and the compact-uniform route share the same budgeted radius-window obligation.

Finally apply root-radius coherence. Definition 452.115 makes the displayed radius, stream, regular-rational, Real, transport, replay, provenance, and naming rows determine the consumer-facing obligation. Since those rows contain no open-cover compactness, selected limits, quotient stream equality, selected subcovers, host minima, choice-like cover selection, or unbudgeted radius selection, the budgeted packet is nonescaping at the Real-completion endpoint. □

Definition 452.104 (Finite Lebesgue-number Phase Real radius audit packet)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *route, the Phase Real radius audit packet is the finite* BHist *row*

$$\mathcal{A}_\lambda^{\mathrm{PhaseReal}} = (D, \rho, M, K, S, Q, R, H, C, P, N)$$

whose entries are the displayed positive radius ledger ρ*, the* DyadicCover$^{\uparrow}$ *cover row* D*, the* RationalBall$^{\uparrow}$ *radius row carried by* ρ*, the* DyadicMesh$^{\uparrow}$ *mesh row* M*, the* DyadicRatCore$^{\uparrow}$ *core row* K*, the* StreamName$^{\uparrow}$ *stream row* S*, the* RegSeqRat$^{\uparrow}$ *regular-rational row* Q*, the* Real$^{\uparrow}$ *endpoint row* R*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *naming* N*. The packet audits only these rows and contains no open-cover compactness, selected subcover, quotient equality, choice, external modulus, selected limit, or detached Real-completeness coordinate.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusAuditPacket`
Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusAuditPacket.certificate`

Theorem 452.105 (Finite Lebesgue-number Phase Real radius audit carrier)**.** *Every accepted* FiniteLebesgueNumber$^{\uparrow}$ *root radius read visible to the current Real and Completion route carries a*

unique audit packet of Definition 452.104. The carrier consists exactly of the positive radius ledger together with

$$\mathsf{DyadicCover}^{\uparrow}, \mathsf{RationalBall}^{\uparrow}, \mathsf{DyadicMesh}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}$$

No additional compactness, choice, quotient-equality, external-modulus, selected-limit, or Real-completeness row is part of the carrier.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusAuditCarrier`

Proof. Begin with the root radius-window obligation surface. Definition 452.80 displays the positive radius and finite-window obligations as finite dyadic cover, rational-ball, mesh, stream-name, regular-rational, Real, history, transport, continuation, provenance, and naming rows.

Next apply the open Phase radius classifier pullback. Definition 452.97 identifies the same radius read with the $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, and $\mathsf{DyadicMesh}^{\uparrow}$ rows and with the four-face route through chapter 291, chapter 126, chapter 301, and chapter 38.

The displayed rows are precisely the entries of $\mathcal{A}_{\lambda}^{\mathrm{PhaseReal}}$. Since the cited root and pullback theorems leave no row for open-cover compactness, subcover selection, quotient equality, choice, external modulus data, selected limits, or detached Real completeness, the carrier is exactly the stated audit packet. □

Theorem 452.106 (Finite Lebesgue-number Phase Real radius audit classifier)**.** *The classifier of a Phase Real radius audit packet is determined by its displayed positive radius ledger and by the ordered source route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

Thus two accepted audit packets with the same $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*, four-face source route,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows expose the same radius classifier to every* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{CompactNetModulusSelector}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$ *endpoint.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusAuditClassifier`

Proof. Read the carrier theorem first. Definition 452.105 reduces every visible root radius read to the finite audit packet and names the four-face source route.

Now use the root radius-window consumer exactness theorem. Definition 452.85 states that compact, compact-net, continuous-map, and uniform-modulus endpoints receive exactly the dyadic cover, rational-ball, mesh, stream-name, regular-rational, Real, history, transport, continuation, provenance, and naming rows.

Finally apply the compact-uniform four-face readiness theorem. Definition 452.98 makes those endpoints read the same $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ source faces. Therefore equality of the displayed audit rows determines the downstream classifier and leaves no second classifier coordinate. □

Theorem 452.107 (Finite Lebesgue-number Phase Real radius audit nonescape)**.** *No accepted Phase Real radius audit packet can be extended, without leaving the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root-unblock route, by open-cover compactness, a selected subcover, quotient equality, choice, an external modulus, selected limits, or a detached Real-completeness row. Every downstream radius read remains inside the packet of Definition 452.104.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusAuditNonescape`

Proof. Start with the classifier theorem above. It shows that all downstream compact, compact-net, continuous-map, and uniform-modulus reads are already determined by the displayed audit rows.

Attach the Real-completion terminal-radius exhaustion. Definition 452.95 keeps every terminal radius read on the L10 packet and excludes open-cover compactness, host minima, quotient equality, selected limits, choice, and Real completeness from the terminal route.

Then use the open Phase source nonescape and RegSeq-StreamName nonescape boundaries. Definition 452.89 and Definition 452.88 prevent bypassing the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ source rows through host sequences, quotient stream equality, selected representatives, choice, or ambient completeness.

Any proposed extension by one of the excluded rows would therefore have to pass through a coordinate absent from the carrier, the classifier, and the terminal Real-completion route. The extension leaves the accepted root-unblock packet, so the audit surface is nonescaping. □

Theorem 452.108 (Phase Real four-face source exactness)**.** *Every consumer-visible* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *radius read in the accepted root route factors through the current Phase Real and Completion faces*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

together with the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. The exact source packet exports no open-cover compactness, selected subcover, quotient equality, host minimum, countable choice, Real completeness, or external modulus coordinate.*

Proof. Begin with the L10 source lock. Definition 452.13 forces the radius route through the finite stream, regular-rational, Real, dyadic-mesh, and dyadic-cover rows before any consumer can inspect the positive-radius ledger.

Next apply the open Phase classifier. Definition 452.97 identifies the visible positive-radius classifier with the four-face route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, carried by the same finite dyadic cover, rational-ball, and mesh packet.

Finally attach the Phase Real radius audit carrier. Definition 452.105 records the BHist, hsame, Cont, Pkg, and NameCert support rows and excludes open-cover compactness, choice, quotient equality, external modulus data, selected limits, and detached Real-completeness rows. Since the accepted consumer read has no row outside these cited packets, the stated four-face source exactness follows. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealFourFaceSourceExactness`

Theorem 452.109 (Terminal-radius Phase consumer nonescape)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$*,* CompactNetModulusSel
$\mathsf{ContinuousMap}^{\uparrow}$*, or* $\mathsf{UniformModulus}^{\uparrow}$ *consumer that reads a terminal* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *radius remains inside the four-face Phase Real and Completion packet*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

Such a terminal consumer cannot escape to open-cover compactness, a selected subcover, quotient equality, a host minimum, countable choice, Real completeness, or an external modulus coordinate.

Proof. Start from terminal-radius exhaustion. Definition 452.95 makes every compact, compact-net, continuous-map, or uniform-modulus terminal read factor through the displayed L10 packet and denies open-cover compactness, host minima, quotient equality, selected limits, choice, and Real completeness at that boundary.

Then use the four-face exactness theorem above. It identifies the visible source of the same radius with DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ plus the BEDC support rows BHist, hsame, Cont, Pkg, and NameCert.

The compact-uniform source triangle, Definition 452.111, places these source faces before the compact, continuous-map, and uniform-modulus endpoints. Any terminal escape would therefore require a coordinate absent from the terminal ledger and absent from the four-face source packet, so no such consumer can leave the stated route. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTerminalRadiusPhaseConsumerNonescape`

Theorem 452.110 (Phase Real root-unblock package)**.** *The* FiniteLebesgueNumber$^{\uparrow}$ *root-unblock surface for downstream compact and uniform consumers is the single finite package consisting of the four Phase Real and Completion faces* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$ *and the support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. This package is source-exact: every consumer-visible radius read factors through it, and it exports no open-cover compactness, selected subcover, quotient equality, host minimum, countable choice, Real completeness, or external modulus coordinate.*

Proof. First combine source exactness with terminal nonescape. Definition 452.108 gives the exact source packet for any consumer-visible radius read, and Definition 452.109 keeps terminal compact, compact-net, continuous-map, and uniform-modulus consumers inside the same packet.

Next use the compact-uniform source triangle. Definition 452.111 orders the four source faces before the consumer endpoints and ties them to the visible dyadic cover, rational-ball, mesh, history, transport, continuation, provenance, and naming rows.

The open Phase radius classifier pullback and Real-completion terminal-radius exhaustion supply the two boundary checks: Definition 452.97 fixes the classifier before the consumer endpoint can read it, while Definition 452.95 rules out the off-packet compactness, equality, choice, completeness, and modulus coordinates at the terminal boundary. The root-unblock surface is therefore exactly the stated finite package. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRootUnblockPackage`

Theorem 452.111 (Compact-uniform source triangle)**.** *Every accepted compact, continuous-map, or uniform-modulus consumer of a* FiniteLebesgueNumber$^{\uparrow}$ *positive-radius row factors through exactly the displayed Phase Real source triangle*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

before the route reaches CompactMetric$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*, or* UniformModulus$^{\uparrow}$*. The four source faces are read through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows tied to the visible* DyadicCover$^{\uparrow}$*,* RationalBall$^{\uparrow}$*, and* DyadicMesh$^{\uparrow}$ *packet, and no accepted downstream consumer may read a detached radius before that triangle has been consumed.*

Proof. Start at the open Phase boundary. Definition 452.89 keeps every public source read inside the four-face route, and Definition 452.97 identifies the positive-radius classifier with the same DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ source packet.

Next pass through the sibling route. Definition 452.70 supplies the finite-name chain that carries the radius through BHist, hsame, Cont, Pkg, and NameCert rows, while Definition 452.69 makes the compact, continuous-map, and uniform-modulus consumers read that carried packet rather than an independent consumer datum.

The source chapters chapter 291, chapter 126, chapter 301, and chapter 38 give the four faces their public NameCert readings. Combining those readings with the cited finite-lebesgue surfaces yields the displayed source triangle before any CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, or UniformModulus$^{\uparrow}$ endpoint is available. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactUniformSourceTriangle`

Theorem 452.112 (Open-phase nonchoice cover)**.** *The open Phase route used by* FiniteLebesgueNumber$^{\uparrow}$ *contains no coordinate for open-cover compactness, selected subcovers, quotient equality, host minima, or external modulus data. Any compact-uniform consumer admitted by the route receives only the finite* DyadicCover$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows displayed by the source triangle of Definition 452.111.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenPhaseNonchoiceCover`

Proof. The nonescape theorem rules out host Real$^{\uparrow}$ equality, open-cover compactness, selected subcovers, and external modulus reads before the four-face passage. The classifier pullback then fixes the positive-radius read to the finite dyadic cover, rational-ball, dyadic mesh, and four source faces.

The L10 sibling route and uniform-continuity handoff preserve only the displayed transport and naming rows. Since none of those rows has a field for a chosen subcover, quotient equality, host minimum, or detached modulus, the downstream compact-uniform consumer cannot obtain such data from the open Phase route. □

Theorem 452.113 (Uniform consumer radius cover)**.** *For later formalization under* BEDC.Derived.FiniteLebesgueN *the downstream radius-cover handoff of* FiniteLebesgueNumber$^{\uparrow}$ *is the single consumer statement that a* CompactMetric$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*, or* UniformModulus$^{\uparrow}$ *endpoint may consume the positive radius only through the source triangle of Definition 452.111 and the nonchoice cover of Definition 452.112. Thus the consumer-visible radius cover is finite, named, and exhausted by the Phase Real and Completion route.*

Proof. Apply the compact-uniform source triangle to obtain the required order: DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ are consumed before the compact, continuous-map, or uniform-modulus endpoint can read the radius.

Then apply the open-phase nonchoice cover. It removes open-cover compactness, selected subcovers, quotient equality, host minima, and external modulus data from the same handoff, so the endpoint receives exactly the finite named radius-cover route and no alternate source. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberUniformConsumerRadiusCover`

Definition 452.114 (Finite Lebesgue-number root-radius coherence ledger)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier, the root-radius coherence ledger is the finite* BHist *row*

$$\Xi_\lambda = (D, B, \lambda, M, S, Q, R, H, C, P, N)$$

whose entries are the displayed DyadicCover$^{\uparrow}$ *cover row D, the* RationalBall$^{\uparrow}$ *radius readback row B for the positive radius λ, the* DyadicMesh$^{\uparrow}$ *mesh row M, the* StreamName$^{\uparrow}$ *source row S, the* RegSeqRat$^{\uparrow}$ *regular-rational approximation row Q, the* Real$^{\uparrow}$ *endpoint row R, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *naming N. The ledger is coherent exactly when B, λ, M, S, Q, R are read as one named root-radius row through the same H, C, P, N support, with no separate host Real equality, quotient-stream coordinate, selected subcover, countable-choice selector, or ambient completeness field.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootRadiusCoherenceLedger`

Theorem 452.115 (Finite Lebesgue-number root-radius coherence)**.** *Let two accepted* FiniteLebesgueNumber$^{\uparrow}$ *routes carry root-radius coherence ledgers* Ξ_λ *and* Ξ'_λ*. If their* DyadicCover$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$ *rows agree componentwise under the recorded* hsame *transports, and if their displayed* Cont *replays follow the same* Pkg *and* NameCert *support rows, then both routes expose the same root-radius obligation to every downstream consumer. The coherent obligation is the finite row* Ξ_λ *of Definition 452.114, not a detached compactness or completion datum.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCarrier root radius coherence`

Proof. Begin with the root radius-window surface. Definition 452.80 already restricts the positive radius and finite-window obligations to the finite dyadic cover, rational-ball, mesh, stream-name, regular-rational, Real, history, transport, continuation, provenance, and local naming rows.

Next apply the componentwise hypothesis. Agreement under hsame fixes the rows $D, B, \lambda, M, S, Q, R$, and the common Cont replay fixes how those rows are inspected. The remaining P, N rows name the same package and local certificate, so there is no second route through which a consumer could distinguish Ξ_λ from Ξ'_λ.

Finally use the L10 sibling route. Definition 452.70 forces compact, compact-net, continuous-map, and uniform-modulus reads through the finite-name chain before the positive radius is visible. Therefore the two routes expose the same finite root-radius obligation and no outside compactness, equality, choice, selected-subcover, quotient-stream, or completeness coordinate. □

Theorem 452.116 (Finite Lebesgue-number compact-uniform radius admission)**.** *Every* CompactMetric$^{\uparrow}$*,* CompactNetModulusSelector$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*, and* UniformModulus$^{\uparrow}$ *consumer admitted by an accepted* FiniteLebesgueNumber$^{\uparrow}$ *route receives the positive radius only through the coherent root-radius ledger of Definition 452.114. In particular, admission to those consumers is the finite packet over* DyadicCover$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*; it is not an independent compactness theorem, host minimum, selected subcover, countable-choice modulus, quotient-stream equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactUniformRadiusAdmission`

Proof. Start with root-radius coherence. Definition 452.115 identifies the consumer-facing positive radius with the finite ledger Ξ_λ whenever the component rows are transported and replayed through the same support.

Attach the compact-uniform source triangle. Definition 452.111 makes every compact, continuous-map, or uniform-modulus consumer factor through DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ before the route reaches the consumer endpoint. The same theorem ties those four source faces to the visible dyadic cover, rational-ball, and mesh packet.

Now use the root radius-window consumer exactness supplied by Definition 452.80 together with the L10 route of Definition 452.70. The only admitted consumer data are the finite rows already named in Ξ_λ, so no consumer obtains an additional compactness, minimum, selected-subcover, choice, quotient, or completeness field. □

Theorem 452.117 (Finite Lebesgue-number Real-completion radius nonescape)**.** *The Real-and-completion route of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *carrier cannot replace the coherent root-radius ledger by host* Real$^{\uparrow}$ *equality, quotient streams, selected subcovers, countable choice, or ambient completeness. Any terminal radius read for the Phase Real or Completion route remains the*

finite BHist *packet* Ξ_λ *of Definition 452.114, transported by* hsame *and replayed by* Cont *through the displayed* DyadicRatCore$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, *and* Real$^\uparrow$ *source faces.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRealCompletionRadiusNonescape`

Proof. First read the source triangle. Definition 452.111 places the Phase Real source faces before any compact-uniform consumer can inspect the radius, and it ties those faces to the same dyadic cover, rational-ball, and mesh packet.

Next apply root-radius coherence and compact-uniform admission. Definition 452.115 makes the radius stable under the displayed hsame and Cont rows, while Definition 452.116 states that admitted compact, compact-net, continuous-map, and uniform-modulus consumers receive only that finite ledger.

It remains to check the terminal exclusions. The L10 sibling route of Definition 452.70 and the root radius-window obligation surface of Definition 452.80 contain no fields for host Real equality, quotient streams, selected subcovers, countable choice, or ambient completeness. Since the terminal radius read is assembled only from those cited rows, each proposed escape has no ledger coordinate and the coherent root-radius packet remains the endpoint. □

Definition 452.118 (Finite Lebesgue-number choice-free tail-radius ledger)**.** *For an accepted* FiniteLebesgueNumber$^\uparrow$ *route, the choice-free tail-radius ledger is the finite* BHist *row family*

$$\Theta_\lambda^{\mathrm{tail}} = (D, B, \lambda, M, A_T, S_T, Q_T, R_T, H, C, P, N).$$

Here D *is the displayed* DyadicCover$^\uparrow$ *cover row,* B *is the* RationalBall$^\uparrow$ *radius readback row for the positive radius* λ*,* M *is the* DyadicMesh$^\uparrow$ *mesh row, and* A_T *is the selected finite-tail admission row. The rows* S_T, Q_T, R_T *record the* StreamName$^\uparrow$, RegSeqRat$^\uparrow$, *and* Real$^\uparrow$ *tail endpoint route;* H *records componentwise* hsame *transport,* C *records the displayed* Cont *replay,* P *records* Pkg *provenance, and* N *records the compatible local* NameCert *rows.*

The ledger is accepted only when the dyadic cover, rational-ball radius, dyadic mesh, selected finite-tail admission, stream-name row, regular-rational row, Real endpoint row, transport, replay, provenance, and local naming rows are read as one finite packet. A compact-uniform consumer may inspect λ *only as this packet and may not introduce a separate open-cover compactness, selected-subcover, host-minimum, quotient-stream, countable-choice, detached-completeness, or external-modulus coordinate.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberChoiceFreeTailRadiusLedger`

Theorem 452.119 (Choice-free tail-radius admission)**.** *Every* CompactMetric$^\uparrow$, ContinuousMap$^\uparrow$, TotallyBounded$^\uparrow$, *or* UniformModulus$^\uparrow$ *consumer admitted by the L10 route of an accepted* FiniteLebesgueNumber$^\uparrow$ *carrier factors its tail-radius read through the ledger* $\Theta_\lambda^{\mathrm{tail}}$ *of Definition 452.118. Thus the consumer-facing radius is the finite row family*

$$D, B, \lambda, M, A_T, S_T, Q_T, R_T, H, C, P, N$$

and no admitted read bypasses the selected finite-tail admission, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, hsame, Cont, Pkg, *or* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberChoiceFreeTailRadiusAdmission`

Proof. Start with selected-tail exhaustion. Definition 452.76 forces every selected-tail witness and every finite-window witness visible to a modulus consumer through the displayed finite packet, with no hidden selector, quotient stream, countable choice coordinate, host real equality, or detached $\mathsf{Real}^{\uparrow}$ representative.

Next use the root-radius coherence package. Definition 452.115 keeps the positive radius stable under the displayed hsame transports and Cont replays, while Definition 452.116 makes compact, compact-net, continuous-map, and uniform-modulus consumers read that coherent finite ledger rather than an outside compactness datum.

Finally read the L10 handoff. Definition 452.92 places the compact-uniform endpoints on the Phase Real route, and Definition 452.111 identifies the source faces as $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ tied to the dyadic cover, rational-ball, and mesh rows. Combining these cited rows gives exactly $\Theta_{\lambda}^{\mathrm{tail}}$, so every admitted tail-radius read factors through the stated finite ledger. □

Theorem 452.120 (Tail-radius transport determinacy)**.** *Let two accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *routes carry choice-free tail-radius ledgers* $\Theta_{\lambda}^{\mathrm{tail}}$ *and* $\Theta_{\mu}^{\mathrm{tail}}$*. If their* $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*, selected finite-tail admission,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows agree componentwise under the recorded* hsame *transports, and their* Cont *replays use the same* Pkg *provenance and local* NameCert *support, then they expose the same radius to every* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$ *consumer admitted by the L10 route.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTailRadiusTransportDeterminacy`

Proof. First identify the two ledgers row by row. The hypotheses make the cover, rational-ball radius, mesh, selected finite-tail admission, stream-name, regular-rational, and Real endpoint rows agree under hsame, and the shared Cont replay fixes the order in which a consumer can inspect them.

Now apply root-radius coherence. Definition 452.115 says that accepted routes agreeing on the radius, source, transport, replay, provenance, and local naming support expose the same root-radius obligation to downstream consumers.

It remains to pass from root radius to tail radius. By Definition 452.76, the selected finite-tail side has no second modulus selector, quotient stream, choice coordinate, host equality, or detached Real representative. By Definition 452.92, the compact-uniform consumers read only the L10 packet. Therefore the two accepted routes expose the same consumer radius across $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$. □

Theorem 452.121 (Compact-uniform choice refusal)**.** *The compact-uniform handoff of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *route cannot replace the choice-free tail-radius ledger of Definition 452.118 by open-cover compactness, selected subcovers, host minima, quotient stream equality, countable choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or external modulus data. Any radius visible to* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*, or* $\mathsf{UniformModulus}^{\uparrow}$ *is read only from*

$$\Theta_{\lambda}^{\mathrm{tail}} = (D, B, \lambda, M, A_T, S_T, Q_T, R_T, H, C, P, N).$$

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactUniformChoiceRefusal`

Proof. Read the ledger definition first. Definition 452.118 lists the only rows available at the tail-radius handoff: dyadic cover, rational-ball radius, dyadic mesh, selected finite-tail admission, stream-name, regular-rational, Real endpoint, transport, replay, provenance, and local naming.

The selected-tail and source-triangle theorems remove the proposed outside coordinates. Definition 452.76 rules out hidden modulus selectors, quotient streams, countable choice, host real equality, and detached Real representatives, while Definition 452.111 requires the compact-uniform consumer to pass through the named Phase Real source faces before the radius is visible.

Finally apply compact-uniform admission along the L10 route. Definition 452.92 and Definition 452.116 leave no consumer coordinate outside the finite ledger. Since open-cover compactness, selected subcovers, host minima, quotient stream equality, countable choice, detached completeness, and external modulus data are absent from that ledger, the handoff refuses each of those readings. □

Definition 452.122 (Finite Lebesgue-number Real-phase source-exhaustion ledger)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *route, the Real-phase source-exhaustion ledger is the finite row family*

$$\Xi_{\lambda}^{\mathrm{real}} = (D, B, M, A, S, Q, R, H, C, P, N).$$

Here D is the displayed DyadicCover$^{\uparrow}$ *cover row, B is the* RationalBall$^{\uparrow}$ *positive-radius row, M is the* DyadicMesh$^{\uparrow}$ *mesh row, and A records the finite admissibility row through which the radius is offered to compact, continuous, totally bounded, and uniform endpoints. The rows S, Q, R are the* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *source faces; H records the permitted* hsame *transports, C records the* Cont *replay, P records* Pkg *provenance, and N records the compatible local* NameCert *rows.*

The ledger is accepted only as one finite BHist *packet. A consumer may read the radius λ only through these rows and may not replace the packet by host* Real$^{\uparrow}$ *equality, quotient stream equality, selected limits, detached completeness, choice, an external modulus, or arbitrary open-cover compactness.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRealPhaseSourceExhaustionLedger`

Theorem 452.123 (Finite Lebesgue-number Real-phase source exhaustion)**.** *Every* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, TotallyBounded$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, *or* UniformModulus$^{\uparrow}$ *consumer admitted by an accepted* FiniteLebesgueNumber$^{\uparrow}$ *radius read passes through the ledger $\Xi_{\lambda}^{\mathrm{real}}$ of Definition 452.122 before it can inspect the radius. Thus every compact, continuous, totally bounded, compact-net, or uniform radius read is exhausted by the finite rows*

$$D, B, M, A, S, Q, R, H, C, P, N$$

over DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRealPhaseSourceExhaustion`
↪ variant `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCarrier real phase source exhaustion`

Proof. Start with the open Phase boundary. Definition 452.89 prevents the source read from reaching host Real$^{\uparrow}$ equality, open-cover compactness, selected subcovers, or external modulus data before the four-face route is consumed.

Next identify the radius readback. Definition 452.90 says that every compact, compact-net, continuous-map, totally bounded, or uniform radius read factors through DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$, together with the visible dyadic cover, rational-ball, and dyadic mesh rows.

Now pass to the L10 consumer route. Definition 452.93 makes the consumer-facing read exact at the finite packet, while Definition 452.74 keeps compact and compact-net endpoints from introducing a second source.

Combining those four cited surfaces gives precisely $\Xi_\lambda^{\mathrm{real}}$. Each named row is already in the finite BHist, hsame, Cont, Pkg, and NameCert packet, so no admitted consumer radius read has a remaining source outside the displayed ledger. □

Theorem 452.124 (Finite Lebesgue-number compact-consumer source verdict)**.** *The compact and compact-net endpoints of an accepted* FiniteLebesgueNumber$^\uparrow$ *route receive only the finite dyadic radius verdict recorded by* $\Xi_\lambda^{\mathrm{real}}$*. They receive the rows* $D, B, M, A, S, Q, R, H, C, P, N$ *and no open-cover compactness principle, selected subcover data, host minimum, quotient stream equality, chosen limit, detached completeness primitive, choice coordinate, or external modulus selector.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberCompactConsumerSourceVerdict`

Proof. First read the compact endpoint through determinacy. Definition 452.74 fixes the compact and compact-net consumer verdict to the finite carrier rows and their recorded transport.

Then use radius readback exactness. Definition 452.90 and Definition 452.93 identify the visible radius as the dyadic cover, rational-ball radius, dyadic mesh, stream-name, regular-rational, Real endpoint, transport, replay, provenance, and naming packet.

Finally exclude outside compactness sources. The open Phase nonescape theorem removes open-cover compactness, selected subcovers, and external modulus data before the source is read, and the Real-phase source exhaustion theorem above leaves no second endpoint source after the finite packet is consumed.

Therefore compact and compact-net consumers receive exactly the finite dyadic radius verdict and none of the refused compactness, selection, equality, completeness, choice, or modulus data. □

Theorem 452.125 (Finite Lebesgue-number Real-phase offtable refusal)**.** *The Real-and-Completion handoff of an accepted* FiniteLebesgueNumber$^\uparrow$ *route refuses every radius source not listed in* $\Xi_\lambda^{\mathrm{real}}$*. In particular, host* Real$^\uparrow$ *equality, quotient stream equality, selected limits, detached completeness, countable choice, an external modulus, and arbitrary open-cover compactness are offtable for every compact, continuous, totally bounded, compact-net, and uniform consumer radius read.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRealPhaseOfftableRefusal`

Proof. Read the ledger definition first. Definition 452.122 lists the only rows available at the Real-and-Completion handoff: dyadic cover, rational-ball radius, dyadic mesh, finite admissibility, stream-name, regular-rational, Real endpoint, transport, replay, provenance, and local naming.

The source and readback theorems close the route around those rows. Definition 452.89 prevents outside compactness or selector data from entering before the four-face source, and Definition 452.90 forces later radius reads through the same four faces.

The consumer exactness theorems close the route at the endpoint. Definition 452.93 identifies the consumer-visible read with the finite packet, while Definition 452.74 prevents compact endpoints from replacing it by a separate source.

Since host Real$^\uparrow$ equality, quotient stream equality, selected limits, detached completeness, countable choice, external modulus data, and arbitrary open-cover compactness occur in none of the accepted rows, the Real-phase handoff refuses all of them for every admitted consumer. □

Theorem 452.126 (Finite Lebesgue-number root radius choice-free tail exhaustion)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, *or* $\mathsf{UniformModulus}^{\uparrow}$ *radius read admitted by an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root route factors through the choice-free tail-radius ledger* $\Theta_{\lambda}^{\mathrm{tail}}$ *and the Real-phase source-exhaustion ledger* $\Xi_{\lambda}^{\mathrm{real}}$*. The visible root radius is therefore read only from the finite rows over* $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, *selected finite-tail admission,* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$*, and not from open-cover compactness, selected subcovers, quotient stream equality, countable choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or external modulus data.*

Proof. Start with the tail ledger. Definition 452.119 places every compact, continuous, totally bounded, and uniform tail-radius read inside $\Theta_{\lambda}^{\mathrm{tail}}$, and Definition 452.120 makes that read stable under the recorded componentwise hsame transports.

Now attach the Real-phase route. Definition 452.123 forces the same radius read through $\Xi_{\lambda}^{\mathrm{real}}$ before any endpoint can inspect it, while Definition 452.125 removes host equality, quotient stream equality, selected limits, detached completeness, choice, external modulus data, and arbitrary open-cover compactness from the accepted rows.

The two ledgers share the displayed dyadic cover, rational-ball radius, dyadic mesh, stream-name, regular-rational, Real endpoint, transport, replay, provenance, and naming rows. Hence the root route exposes the radius only through the stated finite tail-and-Real packet, so none of the refused compactness, selection, quotient, choice, completeness, or modulus coordinates remains available to an admitted consumer. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootRadiusChoiceFreeTailExhaustion`

Theorem 452.127 (Finite Lebesgue-number root radius source determinacy)**.** *Let two accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root routes carry tail-radius ledgers and Real-phase source ledgers for visible radii* λ *and* μ*. If their* $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows agree componentwise under the recorded* hsame *transports, and if their selected finite-tail admission rows name the same local source, then every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, *and* $\mathsf{UniformModulus}^{\uparrow}$ *consumer receives the same downstream root-radius source from the two routes.*

Proof. First compare the tail-radius rows. The componentwise hypotheses identify the dyadic cover, rational-ball, dyadic mesh, stream-name, regular-rational, Real endpoint, history, replay, provenance, and local naming rows, while the shared selected finite-tail admission fixes the only finite tail through which a consumer can read the radius.

Apply Definition 452.120. The two tail ledgers therefore expose the same consumer radius along the L10 route, with no second selector, quotient stream, choice coordinate, host equality, or detached Real representative.

It remains to identify the source side. Definition 452.123 confines the source route to the same Real-phase ledger, and Definition 452.125 prevents any outside source from being substituted after the rows agree. Thus the downstream compact, continuous, totally bounded, and uniform consumers receive the same root-radius source. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootRadiusSourceDeterminacy`

Theorem 452.128 (Finite Lebesgue-number root radius NameCert obligation package)**.** *An accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root radius satisfies the NameCert obligation package for the Real-and-Completion route when its finite rows provide:*

1. *the choice-free tail-radius admission and transport determinacy of Definition 452.119 and Definition 452.120;*

2. the Real-phase source exhaustion and offtable refusal of Definition 452.123 and Definition 452.125;

3. the root tail exhaustion and source determinacy of Definition 452.126 and Definition 452.127.

Under these clauses, every accepted CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, TotallyBounded$^{\uparrow}$, *and* UniformModulus$^{\uparrow}$ *read is accounted for by the finite* BHist, hsame, Cont, Pkg, *and* NameCert *packet over the displayed* DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootRadiusNameCertObligationPackage`

Proof. Assemble the tail side first. The choice-free tail-radius admission theorem supplies the finite ledger through which each admitted consumer reads the tail radius, and tail-radius transport determinacy says that componentwise agreement on that ledger fixes the consumer-visible radius.

Assemble the Real-phase side next. The Real-phase source-exhaustion theorem supplies the finite source ledger for the same radius, and the offtable refusal theorem rules out host equality, quotient stream equality, selected limits, detached completeness, choice, external modulus data, and arbitrary open-cover compactness as substitute sources.

Finally apply the two root-radius theorems above. Root tail exhaustion identifies the common finite packet seen by consumers, and root source determinacy says that agreement on the displayed dyadic, stream, regular-rational, Real, history, replay, provenance, and naming rows determines the downstream source. These clauses are exactly the NameCert obligation package claimed for the accepted Real-and-Completion route. □

Definition 452.129 (Finite Lebesgue-number Phase Real radius-consumer ledger)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *root route, the Phase Real radius-consumer ledger is the finite* BHist *packet*

$$\Lambda_{\lambda}^{\mathrm{cons}} = (D, B, M, E, S, Q, R, K, F, U, H, C, P, N).$$

Here D is the DyadicCover$^{\uparrow}$ *cover row, B is the* RationalBall$^{\uparrow}$ *positive-radius row, M is the* DyadicMesh$^{\uparrow}$ *mesh row, and E is the* DyadicRatCore$^{\uparrow}$ *face through which the radius is read before the stream face. The rows S, Q, R are the* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *source faces. The rows K, F, U are the* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, *and* UniformModulus$^{\uparrow}$ *consumer endpoints, while H, C, P, N record componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and compatible local* NameCert *rows.*

The packet is accepted only when these rows form one finite NameCert route for the same positive radius λ. A compact, continuous, or uniform endpoint may inspect λ only through $\Lambda_{\lambda}^{\mathrm{cons}}$ and may not replace it by open-cover compactness, a host minimum, a selected subcover, quotient stream equality, a selected limit, countable choice, metric-completeness data, or a detached Real$^{\uparrow}$ *completeness claim.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusConsumerLedger`

Theorem 452.130 (Finite Lebesgue-number Phase Real radius-consumer carrier)**.** *Every admitted* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, *or* UniformModulus$^{\uparrow}$ *consumer radius source downstream of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *root route projects to exactly the rows of $\Lambda_{\lambda}^{\mathrm{cons}}$ in Definition 452.129. Thus the consumer-visible source is carried by*

DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$,

together with the endpoint rows CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$ *and the* BHist, hsame, Cont, Pkg, *and* NameCert *support rows, and by no further radius-source coordinate.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusConsumerCarrier`

Proof. Start from the root route. Definition 452.126 and Definition 452.127 place every compact, continuous, totally bounded, or uniform root-radius read on the shared tail-and-Real packet over the dyadic cover, rational ball, dyadic mesh, stream-name, regular-rational, Real, history, transport, replay, provenance, and naming rows.

Next attach the Real-phase source boundary. Definition 452.123 forces admitted compact, continuous, compact-net, totally bounded, and uniform radius reads through the finite Real-phase ledger, while Definition 452.125 denies substitute source coordinates outside that ledger.

Finally identify the four faces and the consumer endpoints. Definition 452.108 adds the $\mathsf{DyadicRatCore}^{\uparrow}$ face to the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route, and Definition 452.101 ties the compact, continuous, and uniform endpoints to the same radius-window packet. These cited surfaces list exactly the rows of $\Lambda_{\lambda}^{\mathrm{cons}}$, so every admitted consumer source projects to that packet and to no outside radius coordinate. □

Theorem 452.131 (Finite Lebesgue-number Phase Real radius-consumer stability)**.** *Let two accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root routes carry Phase Real radius-consumer ledgers for visible radii* λ *and* μ*. If their* $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* BHist*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows agree componentwise under the recorded* hsame *transports, then the compact, continuous, and uniform endpoints receive the same radius-consumer source from the two routes.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusConsumerStability`

Proof. First compare the root radius sources. Definition 452.127 says that componentwise agreement on the dyadic, stream, regular-rational, Real, history, replay, provenance, and naming rows fixes the downstream root-radius source for compact, continuous, totally bounded, and uniform consumers.

Now compare the compact radius-window packets. Definition 452.101 and Definition 452.102 make the $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ rows consume one shared finite packet, so the agreed endpoint rows cannot introduce a second source after transport.

Finally use four-face exactness. Definition 452.108 fixes the consumer-visible source to the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces with the same BEDC support rows. Since each of those rows is identified by the recorded hsame transports, the compact, continuous, and uniform endpoints receive the same radius-consumer source. □

Theorem 452.132 (Finite Lebesgue-number Phase Real radius-consumer exhaustion)**.** *The Phase Real radius-consumer ledger* $\Lambda_{\lambda}^{\mathrm{cons}}$ *exports no open-cover compactness, host minimum, selected subcover, quotient stream equality, selected limit, countable choice, metric-completeness datum, or* $\mathsf{Real}^{\uparrow}$ *completeness claim. Every compact, continuous, or uniform radius read admitted by the ledger is exhausted by its displayed dyadic, four-face Real, endpoint, history, transport, replay, provenance, and naming rows.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusConsumerExhaustion`

Proof. Read the ledger definition first. Definition 452.129 lists only the dyadic cover, rational-ball radius, dyadic mesh, $\mathsf{DyadicRatCore}^{\uparrow}$, stream-name, regular-rational, Real, compact, continuous, uniform, history, transport, replay, provenance, and naming rows.

The root and Real-phase exhaustion theorems remove the proposed outside coordinates at the source. Definition 452.126 excludes open-cover compactness, selected subcovers, quotient stream

equality, countable choice, detached $\mathsf{Real}^{\uparrow}$ completeness, and external modulus data from the root route, while Definition 452.123 leaves every admitted endpoint read inside the finite Real-phase packet.

The compact-window and four-face theorems remove the remaining endpoint escapes. Definition 452.101 excludes selected limits, quotient stream equality, selected subcovers, host minima, choice-like cover selection, and unbudgeted radius selection for compact and continuous consumers, and Definition 452.108 excludes open-cover compactness, selected subcover, quotient equality, host minimum, countable choice, Real completeness, and external modulus coordinates from the four-face packet.

Combining these surfaces, every admitted compact, continuous, or uniform read is already accounted for by $\Lambda_{\lambda}^{\mathrm{cons}}$. None of open-cover compactness, a host minimum, a selected subcover, quotient stream equality, selected limits, countable choice, metric-completeness data, or a detached $\mathsf{Real}^{\uparrow}$ completeness claim has a ledger row through which it can be exported. □

Theorem 452.133 (Finite Lebesgue-number open Phase root-unblock radius coverage)**.** *Every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root radius read exported to the open Phase Real route factors through the finite radius-unblock packet*

$$D, B, M, E, S, Q, R, H, C, P, N$$

where D is the displayed $\mathsf{DyadicCover}^{\uparrow}$ *cover row, B is the* $\mathsf{RationalBall}^{\uparrow}$ *positive-radius row, M is the* $\mathsf{DyadicMesh}^{\uparrow}$ *mesh row, E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source face, S, Q, R are the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *faces, and the surrounding* BHist *records H, C, P, N as the* hsame *transport,* Cont *replay,* Pkg *provenance, and compatible local* NameCert *rows. Thus the root-unblock obligation exposed to compact-uniform consumers is a finite BEDC packet over these rows, not a host-side radius source.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenPhaseRootUnblockRadiusCoverage`

Proof. Start with the root radius-window surface. Definition 452.80 identifies the positive radius and finite window through the dyadic cover, rational-ball radius, dyadic mesh, stream-name, regular-rational, Real, history, transport, replay, provenance, and naming rows.

Next attach the Phase Real source route. Definition 452.75 forces each public radius read through the same dyadic, stream, regular-rational, and Real rows before a consumer can inspect it, while Definition 452.78 adds the $\mathsf{DyadicRatCore}^{\uparrow}$ face to the compact, compact-net, continuous-map, and uniform-modulus export.

Finally read the exit and consumer ledgers. Definition 452.91 gives the open Phase root-unblock exit surface, and Definition 452.132 exhausts the consumer-visible radius source by the same finite rows. The displayed packet therefore covers every accepted root radius read exported to the open Phase Real route. □

Theorem 452.134 (Finite Lebesgue-number open Phase root-unblock choice refusal)**.** *The open Phase root-unblock obligation packet for* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *exports no open-cover compactness principle, selected subcover, host minimum, quotient stream equality, countable choice coordinate, detached* $\mathsf{Real}^{\uparrow}$ *completeness row, or external modulus row. Any admitted compact, continuous, totally bounded, or uniform radius use must be read from the finite dyadic, four-face Real,* BHist, hsame, Cont, Pkg, *and* NameCert *packet of Definition 452.133.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenPhaseRootUnblockChoiceRefusal`

Proof. Read the positive side from the coverage theorem. Definition 452.133 leaves only the dyadic cover, rational-ball radius, dyadic mesh, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and BEDC support rows available to the open Phase root-unblock route.

The source and exit theorems supply the negative side. Definition 452.75 prevents the source read from being replaced by an outside compactness or completeness primitive, and Definition 452.91 states that the exit surface supplies no host Real equality, open-cover compactness, selected subcover, selected limit, detached completeness primitive, or external modulus data.

The consumer ledger closes the refusal at the endpoints. Definition 452.132 removes open-cover compactness, host minima, selected subcovers, quotient stream equality, selected limits, countable choice, metric-completeness data, and detached $\mathsf{Real}^{\uparrow}$ completeness from compact, continuous, and uniform reads. The same finite packet is the only admitted source, so none of the listed outside rows can be exported. □

Theorem 452.135 (Finite Lebesgue-number open Phase root-unblock consumer readback)**.** *The* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$ *consumers downstream of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *open Phase root-unblock route read the same finite packet. Their visible radius source is exactly the shared* $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route, with no consumer-specific radius source added at the endpoint.*

Proof. First identify the shared source. Definition 452.133 factors every accepted root radius read through the finite dyadic and four-face Real packet, and Definition 452.91 presents that packet as the root-unblock exit surface for compact-uniform consumers.

Next pass through Real-phase coverage. Definition 452.78 routes compact, compact-net, continuous-map, and uniform-modulus endpoints through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ together with the finite carrier rows. Definition 452.132 then states that every compact, continuous, or uniform radius read is exhausted by the displayed dyadic, four-face Real, endpoint, history, transport, replay, provenance, and naming rows.

Finally compare the endpoint consumers. The $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ rows have no coordinate outside the packet by Definition 452.134. Since each endpoint reads through the same source rows and the same BHist, hsame, Cont, Pkg, and NameCert support, their consumer-visible radius source is the same finite packet. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenPhaseRootUnblockConsumerReadback`

Theorem 452.136 (Finite Lebesgue-number root-unblock endpoint uniformity)**.** *If two downstream endpoint reads for* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*, or* $\mathsf{UniformModulus}^{\uparrow}$ *are accepted from the same* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *open Phase root-unblock route, then their visible positive-radius source is one finite packet over* $\mathsf{DyadicCover}^{\uparrow}$*,* $\mathsf{RationalBall}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. Conversely, any endpoint read displaying exactly that packet is an admissible consumer-visible radius read for the same route.*

Proof. Start from the shared source assertion. Definition 452.133 says that every accepted root radius read exported to the open Phase Real route factors through the displayed dyadic, rational-ball, mesh, dyadic-rational, stream, regular-rational, Real, history, transport, replay, provenance, and naming rows.

The refusal theorem removes every possible endpoint-specific replacement. By Definition 452.134, the route exports no consumer-specific radius source, open-cover compactness, selected subcover,

host minimum, quotient equality, choice coordinate, external modulus, selected limit, or detached $\mathsf{Real}^{\uparrow}$-completeness row. Thus two accepted endpoint reads cannot differ by importing any outside radius witness.

Now compare the endpoint reads. Definition 452.135 states that the $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ consumers read exactly the same finite packet and add no endpoint-specific source. Hence any two accepted reads from the same root-unblock route have the same visible positive-radius source.

Conversely, an endpoint read that displays exactly the finite packet named above already presents the consumer-visible route required by Definition 452.135. Since the refusal theorem excludes only outside rows and the displayed packet is precisely the covered source, such a read is admissible for the same open Phase root-unblock route. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootUnblockEndpointUniformity`

Theorem 452.137 (Finite Lebesgue-number root-radius export exactness)**.** *An accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *root radius export is admissible exactly when it displays the finite packet over* $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *The admissible export has no open-cover coordinate, selected-subcover coordinate, host minimum coordinate, or detached consumer radius source.*

Proof. For the forward direction, start with an accepted root radius export. The carrier of Definition 452.1 fixes the local packet $D, W, \lambda, M, H, C, P, N$, and Definition 452.2 names the carrier, classifier, radius-modulus stability, finite-window coverage, and non-escape rows that govern the packet.

Now pass to the open Phase route. Definition 452.133 factors every accepted root radius read through the displayed dyadic, rational-ball, mesh, four-face Real, history, transport, replay, provenance, and naming rows. Definition 452.134 removes open-cover compactness, selected subcovers, host minima, quotient stream equality, detached completeness, and external modulus coordinates from that export.

For the reverse direction, suppose a radius export displays exactly those rows and no outside coordinate. Definition 452.135 identifies that displayed packet as the consumer-visible radius source for the compact, continuous, totally bounded, and uniform endpoints. Definition 452.136 then states that any endpoint read displaying exactly this finite packet is admissible for the same open Phase root-unblock route. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRootRadiusExportExactness`

Theorem 452.138 (Finite Lebesgue-number open Phase positive-radius stability)**.** *Componentwise* hsame *transport and displayed* Cont *replay preserve the positive-radius row of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *open Phase root-unblock export only together with its* $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. In particular, the positive-radius row cannot be transported as a detached scalar outside the Phase Real and Completion packet.*

Proof. Begin with the local carrier and NameCert rows. In Definition 452.1, the positive ledger λ is stored between the finite-window and mesh coordinates and is accompanied by the support rows H, C, P, N. The radius-modulus stability row of Definition 452.2 preserves λ only with the rational-ball and dyadic-mesh evidence that witnesses its refinement into the finite cover.

The open Phase coverage theorem extends this local stability to the root-unblock export. Definition 452.133 places the positive radius inside the same packet as $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$,

RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert. Thus any componentwise hsame transport and displayed Cont replay is a transport of the displayed packet, not of an isolated radius coordinate.

Endpoint uniformity gives the stability test. By Definition 452.135 and Definition 452.136, every compact, continuous, totally bounded, or uniform endpoint reads the same finite packet. The choice-refusal theorem excludes a second radius source, so preserving the positive-radius row requires preserving the rational-ball, mesh, stream, regular-rational, and Real rows along with it. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenPhasePositiveRadiusStability`

Theorem 452.139 (Finite Lebesgue-number L10 consumer radius exhaustion)**.** *Every* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, TotallyBounded$^{\uparrow}$, *or* UniformModulus$^{\uparrow}$ *consumer read of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *open Phase root-unblock route is exhausted by the same Phase Real and Completion packet over* DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *No consumer may add a consumer-specific radius witness to that route.*

Proof. First identify the common packet. The carrier of Definition 452.1 and the NameCert obligations of Definition 452.2 bind the finite radius ledger to the dyadic cover, finite-window, mesh, transport, replay, provenance, and naming rows.

Next route that packet through the open Phase root-unblock surface. Definition 452.133 supplies the Phase Real and Completion faces, while Definition 452.134 removes open-cover compactness, selected subcovers, host minima, quotient stream equality, detached completeness, and external modulus data.

Finally read the downstream consumers. Definition 452.135 says that CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, TotallyBounded$^{\uparrow}$, and UniformModulus$^{\uparrow}$ consume exactly the same finite packet. Definition 452.136 identifies any endpoint display of that packet as the admissible read for the route, so a consumer-specific radius witness has no remaining coordinate to occupy. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberL10ConsumerRadiusExhaustion`

Theorem 452.140 (Finite Lebesgue-number four-face radius exit coverage)**.** *Every accepted* FiniteLebesgueNumber *root radius visible to a* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, TotallyBounded$^{\uparrow}$, *compact-net, or* UniformModulus$^{\uparrow}$ *consumer is exhausted by the four current open-phase source faces* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *together with the surrounding* BHist, hsame, Cont, Pkg, *and* NameCert *rows. The visible exit package contains no radius source outside that four-face BEDC packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberFourFaceRadiusExitCoverage`
`semantic name certificate`

Proof. Begin with root-unblock coverage. Definition 452.133 places every accepted root radius read inside the dyadic, rational-ball, mesh, four-face Real, history, transport, replay, provenance, and naming packet.

Now pass through the exact export and L10 endpoint route. Definition 452.137 identifies admissibility with displaying exactly that finite packet, and Definition 452.139 says that compact, continuous, totally bounded, and uniform consumers cannot add a consumer-specific radius witness.

Finally attach the compact-net face to the same route. The sibling route of Definition 452.70 sends compact and compact-net reads through the finite-name chain before the positive radius

is visible. Therefore every listed consumer reads the same four-face exit package and no outside radius source remains available. □

Theorem 452.141 (Finite Lebesgue-number four-face radius exit determinacy)**.** *For accepted* FiniteLebesgueNumber$^{\uparrow}$ *root-radius exits, componentwise agreement on the* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows determines the downstream radius classifier seen by* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, TotallyBounded$^{\uparrow}$, *compact-net, and* UniformModulus$^{\uparrow}$ *consumers. Two such exits with the same displayed rows expose the same consumer-visible classifier.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberFourFaceRadiusExitDeterminacy`

Proof. First reduce the classifier to the root packet. By Definition 452.137, an admissible root-radius export is exactly the finite packet over the four source faces and the support rows, with no independent compactness, minimum, subcover, or detached radius coordinate.

Next use endpoint uniformity. Definition 452.139 and Definition 452.136 make every compact, continuous, totally bounded, and uniform endpoint read the same displayed packet. Componentwise hsame agreement and displayed Cont replay therefore carry the endpoint classifier without changing its source rows.

The compact-net route has no separate classifier channel. Definition 452.70 routes compact-net visibility through the same finite-name chain, while Definition 452.88 prevents the stream and regular-rational faces from being replaced by quotient stream equality, selected representatives, choice, or ambient completeness. Thus equal four-face rows determine the downstream radius classifier for every listed consumer. □

Theorem 452.142 (Finite Lebesgue-number open Phase root-radius classifier totality)**.** *Every accepted* FiniteLebesgueNumber$^{\uparrow}$ *root-radius exit visible to a* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, TotallyBounded$^{\uparrow}$, *compact-net, or* UniformModulus$^{\uparrow}$ *consumer has exactly one consumer-visible radius classifier. This classifier is determined by the shared* DyadicCover$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows of the exit packet, and no endpoint can add a second classifier or detach the radius from the Phase Real and Completion packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenPhaseRootRadiusClassifierTotality`

Proof. Existence comes from the four-face exit surface. Definition 452.140 puts every accepted root radius visible to the listed consumers inside the displayed dyadic, four-face Real, history, transport, replay, provenance, and naming packet. Definition 452.137 identifies admissible export with that finite packet, so the visible classifier is read from the same rows rather than from an outside coordinate.

The endpoint ledger removes the remaining sources. Definition 452.139 exhausts compact, continuous, totally bounded, and uniform reads by the Phase Real and Completion packet, while Definition 452.70 sends compact-net visibility through the same finite-name route. Thus every accepted endpoint has a consumer-visible classifier carried by the shared packet.

Uniqueness follows from componentwise agreement. Definition 452.141 says that agreement on the four source faces and the BHist, hsame, Cont, Pkg, and NameCert rows determines the downstream classifier for every listed consumer. A second classifier would either agree with those rows and therefore be the same classifier, or differ by an outside coordinate.

The outside-coordinate case is excluded by the refusal boundary. Definition 452.134 and Definition 452.143 rule out host minima, selected subcovers, quotient stream equality, choice rows,

selected limits, and detached $\mathsf{Real}^{\uparrow}$ completeness. Hence no endpoint can add a second classifier or detach the radius from the Phase Real and Completion packet. □

Theorem 452.143 (Finite Lebesgue-number four-face radius exit nonescape)**.** *The four-face* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *radius exit package exports no open-cover compactness row, selected subcover row, host minimum row, quotient stream equality row, selected limit row, choice row, or detached* $\mathsf{Real}^{\uparrow}$ *completeness row. Any claimed compact, continuous, totally bounded, compact-net, or uniform-modulus use of such a row is outside the admitted open-phase root-radius exit.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberFourFaceRadiusExitNonescape`

Proof. Read the positive source from coverage and exactness. Definition 452.140 and Definition 452.137 leave only the dyadic cover, rational-ball radius, dyadic mesh, four source faces, and BEDC support rows available to an accepted root-radius exit.

Then apply the existing refusal boundary. Definition 452.134 removes open-cover compactness, selected subcovers, host minima, quotient stream equality, countable choice coordinates, detached $\mathsf{Real}^{\uparrow}$ completeness, and external modulus data from the open-phase root-unblock obligation packet.

Finally close the endpoint escapes. Definition 452.139 exhausts downstream consumer reads by the same Phase Real and Completion packet, and Definition 452.88 blocks replacement of the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ faces by quotient stream equality, selected representatives, choice, selected limits, or ambient completeness. Hence none of the listed rows can be exported from the four-face radius exit package. □

Definition 452.144 (Finite Lebesgue-number Phase Real radius-window carrier)**.** *For an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *route, the Phase Real radius-window carrier is the finite* BHist *packet*

$$\mathcal{W}_{\lambda}^{\mathrm{PhaseReal}} = (E, R, D, W, S, H, C, P, N)$$

where E is the finite Lebesgue-number request row, R is the rational-ball radius row, D is the $\mathsf{DyadicRatCore}^{\uparrow}$ *radius readback row, W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, S is the* $\mathsf{RegSeqRat}^{\uparrow}$*-to-*$\mathsf{Real}^{\uparrow}$ *seal route, and H, C, P, N are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and compatible local* $\mathsf{NameCert}$ *rows. The carrier is read against the four source chapters chapter 291, chapter 126, chapter 301, and chapter 38; it contains no quotient-stream coordinate, host-limit coordinate, countable-choice coordinate, open-cover compactness coordinate, or ambient Real-completeness coordinate.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusWindowCarrier`

Theorem 452.145 (Finite Lebesgue-number dyadic radius-window admission)**.** *Every admitted radius-window read of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *Phase Real carrier exposes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius readback row D before the finite* $\mathsf{StreamName}^{\uparrow}$ *window row W. Equivalently, a downstream compact, continuous, totally bounded, or uniform consumer may read W only as part of the packet* $\mathcal{W}_{\lambda}^{\mathrm{PhaseReal}}$ *of Definition 452.144, with the displayed dyadic radius read already present.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusWindowAdmission`
Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberDyadicRadiusWindowAdmission`

Proof. Start with the carrier definition. The packet $\mathcal{W}_{\lambda}^{\mathrm{PhaseReal}}$ places the finite Lebesgue-number request E, the rational-ball radius row R, and the $\mathsf{DyadicRatCore}^{\uparrow}$ readback row D before the finite stream window W is available to any consumer.

The existing root and open Phase surfaces give the same order at the chapter boundary. Definition 452.80 identifies the positive radius and finite-window obligations with the dyadic, stream, regular-rational, Real, history, transport, continuation, provenance, and naming rows. Definition 452.133 then exports the root radius read through the finite dyadic and four-face Real packet.

Finally use the Phase Real audit and source exactness. Definition 452.105 and Definition 452.108 keep the consumer-visible radius inside $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ with the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support. Since W has no row outside this packet, an admitted window read can occur only after D has been displayed. □

Theorem 452.146 (Finite Lebesgue-number Real seal radius readback)**.** *Any* $\mathsf{Real}^{\uparrow}$ *seal read used by an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *Phase Real radius-window carrier factors through the ordered rows*

$$D, \quad W, \quad S$$

of Definition 452.144. Thus the Real-side radius is read back only through the $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, and the* $\mathsf{RegSeqRat}^{\uparrow}$*-to-*$\mathsf{Real}^{\uparrow}$ *seal route, together with the shared* H, C, P, N *support.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberRealSealRadiusReadback`

Proof. First expose the dyadic admission. By Definition 452.145, an admitted radius-window read displays D before W. The dyadic readback is therefore already part of the carrier before the stream window is inspected.

Next attach the regular-rational and Real faces. Definition 452.108 routes every consumer-visible radius through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The definition of $\mathcal{W}_{\lambda}^{\mathrm{PhaseReal}}$ records the $\mathsf{RegSeqRat}^{\uparrow}$-to-$\mathsf{Real}^{\uparrow}$ part of this route as S.

The terminal boundary supplies the readback exclusion. Definition 452.95 keeps terminal radius reads on the same L10 packet and denies host minima, quotient equality, selected limits, countable choice, and detached Real completeness at the Real boundary. Hence any Real seal read factors through D, W, S and the common H, C, P, N rows, rather than through an off-packet Real source. □

Theorem 452.147 (Finite Lebesgue-number open Phase radius-window nonescape)**.** *No accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *open Phase radius-window carrier can escape to quotient streams, host limits, countable choice, open-cover compactness, or ambient Real completeness. Every admitted compact, continuous, totally bounded, compact-net, or uniform radius read remains inside the finite packet*

$$E, \quad R, \quad D, \quad W, \quad S, \quad H, \quad C, \quad P, \quad N$$

of Definition 452.144.

Proof. Begin with the two positive readback gates. Definition 452.145 forces the window side to expose the $\mathsf{DyadicRatCore}^{\uparrow}$ row before $\mathsf{StreamName}^{\uparrow}$ can be consumed. Definition 452.146 then factors each Real seal read through D, W, S with the shared support rows.

Now read the existing nonescape boundaries. Definition 452.89 keeps the open Phase source from bypassing the stream and regular-rational rows through host sequences, quotient stream equality, selected representatives, choice, or ambient completeness. Definition 452.88 gives the same refusal for the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ faces.

Finally apply terminal and consumer exhaustion. Definition 452.109 and Definition 452.139 keep compact, compact-net, continuous, totally bounded, and uniform consumers inside the four-face Phase Real and Completion packet. Since the carrier itself has no coordinate for quotient

streams, host limits, countable choice, open-cover compactness, or ambient Real completeness, none of those rows can be exported from an admitted radius-window read. □

Lean4 ✓ BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberOpenPhaseNonescape

Theorem 452.148 (Finite Lebesgue-number Phase Real radius-window no extra source)**.** *Every accepted* FiniteLebesgueNumber$^{\uparrow}$ *Phase Real radius-window packet may read only the rows*

$$D, \quad W, \quad S, \quad H, \quad C, \quad P, \quad N$$

of Definition 452.144, together with the displayed finite history BHist *and its componentwise* hsame*,* Cont*,* Pkg*, and* NameCert *support. In particular, the packet has no readable source beyond the* DyadicRatCore$^{\uparrow}$ *endpoint and radius row, the* StreamName$^{\uparrow}$ *finite-window row, the* RegSeqRat$^{\uparrow}$ *regularity and classifier row, and the* Real$^{\uparrow}$ *seal row.*

Proof. Read the packet from its carrier definition. The only source chapters named there are chapter 291, chapter 126, chapter 301, and chapter 38; the remaining coordinates are the displayed finite history, transport, continuation, provenance, and local naming rows.

The three local gates make these coordinates exhaustive. Definition 452.145 exposes D before W, Definition 452.146 factors the Real-side read through D, W, S, and Definition 452.147 denies quotient streams, host limits, countable choice, open-cover compactness, and ambient Real completeness.

Thus any admitted consumer read is already a read of the four named faces plus the displayed BEDC support rows. Since the carrier contains no further coordinate and the nonescape theorem denies the standard off-packet exits, there is no extra source available to the radius-window packet. □

Lean4 ✓ BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusWindowNoExtraSource

Theorem 452.149 (Finite Lebesgue-number Phase Real radius-window face minimality)**.** *The four source faces of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *Phase Real radius-window packet are minimal for the exit route. Removing the* DyadicRatCore$^{\uparrow}$ *face loses the endpoint and radius row D; removing the* StreamName$^{\uparrow}$ *face loses the finite-window row W; removing the* RegSeqRat$^{\uparrow}$ *face loses the regularity and classifier row in S; and removing the* Real$^{\uparrow}$ *face loses the terminal seal row read through S.*

Lean4 ✓ BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusWindowFaceMinimality

Proof. For the dyadic face, use Definition 452.145. The theorem makes the DyadicRatCore$^{\uparrow}$ row a prerequisite for consuming the finite window, so deleting that face removes the endpoint and radius read needed before W can be inspected.

For the stream face, the same admission theorem identifies W as the finite window available to downstream compact, continuous, totally bounded, and uniform consumers. Without StreamName$^{\uparrow}$, the packet still has a dyadic radius row, but it has no finite-window row to present at the consumer boundary.

For the regular-rational and Real faces, use Definition 452.146. The readback factors Real-side radius access through D, W, S, where S records the RegSeqRat$^{\uparrow}$-to-Real$^{\uparrow}$ seal route. Removing RegSeqRat$^{\uparrow}$ deletes the regularity and classifier part of S, while removing Real$^{\uparrow}$ deletes the terminal seal part of the same row.

Definition 452.148 supplies the converse exclusion needed for minimality: none of these losses can be repaired by an off-packet source. Hence each of the four faces is necessary for the corresponding radius-window row. □

Theorem 452.150 (Finite Lebesgue-number Phase Real radius-window exit consumer readiness)**.** *The accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *Phase Real radius-window packet is ready for downstream compact, continuous, totally bounded, compact-net, and uniform consumers. Such a consumer may use the dyadic admission row, the Real seal readback row, the open Phase nonescape boundary, the no-extra-source boundary, and the four-face minimality boundary as one finite radius ledger, without quotient streams, selected limits, host real equality, ambient Real completeness, metric-completeness, or countable choice.*

Proof. Assemble the positive ledger first. Definition 452.145 provides the ordered dyadic-to-window read, and Definition 452.146 routes the Real seal through D, W, S with the shared BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Next attach the boundary conditions. Definition 452.147 keeps every admitted consumer read inside the finite packet, while Definition 452.148 states that no fifth source face is readable from that packet.

Finally use Definition 452.149 to make the ledger exit-ready rather than merely admissible. Each of the four source faces is required for its corresponding endpoint, finite-window, regularity, classifier, or seal row, and the nonescape boundary prevents replacement by quotient streams, selected limits, host real equality, ambient Real completeness, metric-completeness, or countable choice. This is exactly the finite radius ledger needed by downstream Phase Real consumers. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusWindowExitConsumerReadi`

Theorem 452.151 (Finite Lebesgue-number Phase Real local radius determinacy)**.** *Let two admitted downstream reads of an accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *Phase Real exit consumer use the same rows*

$$E, \quad R, \quad D, \quad W, \quad S, \quad H, \quad C, \quad P, \quad N$$

from Definition 452.144. Then the two reads expose the same local radius-window packet $\mathcal{W}_{\lambda}^{\mathrm{PhaseReal}}$*. In particular, the consumer-visible dyadic radius, finite stream window, regular-rational seal route, Real seal row, history transport, continuation replay, provenance row, and local* $\mathsf{NameCert}$ *row are fixed by the displayed packet.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealLocalRadiusDeterminacy`

Proof. Start from the carrier definition. The Phase Real radius-window packet is exactly the finite BHist tuple $(E, R, D, W, S, H, C, P, N)$, so equality of the displayed rows identifies the packet before any consumer interpretation is applied.

The positive readback gates make the identification local at the two consumer reads. By Definition 452.145, both reads must expose the same dyadic radius row D before the same finite window row W. By Definition 452.146, the Real-side radius access in both reads factors through the same ordered D, W, S rows with the same support.

It remains to rule out a hidden source of disagreement. Definition 452.148 denies any readable source beyond the four named faces and the support rows, while Definition 452.149 makes those four faces necessary for the exit route. Hence two accepted reads with the same packet rows cannot expose distinct local radius-window data. □

Theorem 452.152 (Finite Lebesgue-number Phase Real radius-window source lock)**.** *Every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *Phase Real radius-window exit read has its source locked to the four faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The rows D, W, S, H, C, P, N of Definition 452.144 may be consumed only through these faces and their displayed finite BHist, hsame, Cont, Pkg, *and* NameCert *support.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusWindowSourceLock`

Proof. The carrier definition names exactly the four source chapters DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ for the radius-window packet. The remaining entries are not new sources; they are the finite history, transport, continuation, provenance, and naming rows used to read those faces.

The admission and readback results fix the order of access. Definition 452.145 locks the finite window behind the dyadic radius row, and Definition 452.146 locks the Real-side seal behind the ordered D, W, S route.

Finally, Definition 452.148 excludes a fifth readable source, and Definition 452.149 shows that none of the four faces can be removed from the exit route. The accepted read is therefore source-locked to precisely the displayed four-face packet. □

Theorem 452.153 (Finite Lebesgue-number Phase Real radius consumer nonescape)**.** *Compact, continuous, totally bounded, compact-net, and uniform consumers of an accepted* FiniteLebesgueNumber$^{\uparrow}$ *Phase Real radius-window exit read cannot create an additional radius source. Any radius data they expose is already read from the packet*

$$E, \quad R, \quad D, \quad W, \quad S, \quad H, \quad C, \quad P, \quad N$$

of Definition 452.144, with source locked to DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealRadiusConsumerNonescape`

Proof. Use the consumer-readiness theorem as the entry point. Definition 452.150 packages the dyadic admission row, the Real seal readback row, the open Phase nonescape boundary, the no-extra-source boundary, and the four-face minimality boundary as one finite radius ledger for these consumers.

The local determinacy theorem then fixes repeated reads of that ledger. By Definition 452.151, two accepted consumer reads with the same rows expose the same local radius-window packet. By Definition 452.152, that packet is locked to the four named source faces and their support rows.

Thus a compact, continuous, totally bounded, compact-net, or uniform consumer has no constructor site for an additional radius source. Any consumer-visible radius row is already one of the displayed packet rows, and the exclusions in Definition 452.148 prevent quotient streams, selected limits, host real equality, ambient Real completeness, metric-completeness, or countable choice from supplying another source. □

Definition 452.154 (Finite Lebesgue-number Phase Real audit ledger)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *root route, the Phase Real audit ledger is the finite* BHist *packet*

$$\mathcal{L}_{\lambda}^{\mathrm{audit}} = (D, B, M, E, S, Q, R, K, T, F, U, H, C, P, N)$$

whose entries are the DyadicCover$^{\uparrow}$ *cover row D, the* RationalBall$^{\uparrow}$ *positive-radius row B, the* DyadicMesh$^{\uparrow}$ *mesh row M, the* DyadicRatCore$^{\uparrow}$ *core-radius row E, the* StreamName$^{\uparrow}$ *finite-window row S, the* RegSeqRat$^{\uparrow}$ *regular-rational row Q, the* Real$^{\uparrow}$ *seal row R, the* CompactMetric$^{\uparrow}$ *compact consumer row K, the* TotallyBounded$^{\uparrow}$ *compact-net admission row T, the* ContinuousMap$^{\uparrow}$ *endpoint row F, the* UniformModulus$^{\uparrow}$ *endpoint row U, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and compatible local* NameCert *naming N. The ledger is accepted*

only when these rows read one positive radius through the same NameCert route over the four open Phase source faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealAuditLedger`

Theorem 452.155 (Finite Lebesgue-number Phase Real audit-ledger source)**.** *Every accepted Phase Real audit-ledger read for* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *factors its radius source through the four open Phase faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The dyadic-cover, rational-ball, and dyadic-mesh rows of Definition 452.154 are source rows for this route, while the compact, totally bounded, continuous-map, and uniform-modulus rows are consumers of the same finite packet.

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealAuditLedgerSource`

Proof. Begin with the root radius-window obligation surface. Definition 452.80 confines the visible positive-radius and finite-window obligations to the dyadic cover, rational-ball, mesh, stream-name, regular-rational, Real, history, transport, replay, provenance, and naming rows.

Now attach the open Phase root-unblock route. Definition 452.133 exposes the same root radius through the four source faces, and Definition 452.137 says that an admissible root-radius export is exactly the finite packet over those faces and the support rows.

Finally use the exit and window certificates. Definition 452.90, Definition 452.140, Definition 452.141, and Definition 452.143 make the four-face route covering, deterministic, and nonescaping. The Phase Real radius-window face minimality theorem then identifies these faces as the necessary source faces for the accepted audit ledger, so every accepted read factors through them. □

Theorem 452.156 (Finite Lebesgue-number Phase Real audit-ledger scope)**.** *The scoped support of an accepted Phase Real audit ledger for* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *is exactly the displayed rows*

$$\mathsf{DyadicCover}^{\uparrow}, \mathsf{RationalBall}^{\uparrow}, \mathsf{DyadicMesh}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{Totall}$$

It has no coordinate for open-cover compactness, selected subcovers, quotient streams, host minima, selected limits, countable choice, detached $\mathsf{Real}^{\uparrow}$ *completeness, external modulus data, or an unbudgeted radius selector.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealAuditLedgerScope`

Proof. Read the ledger definition first. The only support rows named by $\mathcal{L}_{\lambda}^{\mathrm{audit}}$ are the dyadic cover, rational ball, mesh, four Phase Real source faces, compact and uniform consumer endpoints, finite history, transport, replay, provenance, and local naming rows.

The existing audit and window packets make this support exhaustive. Definition 452.105 identifies the current Real and Completion route with the dyadic cover, rational-ball, mesh, four-face, history, transport, replay, provenance, and naming rows. Definition 452.149 says that none of the four faces can be removed while preserving its corresponding radius-window row.

The nonescape boundaries remove the off-table rows. Definition 452.107 excludes open-cover compactness, selected subcovers, quotient equality, choice, external modulus data, selected limits, and detached Real completeness from the audit packet. Definition 452.139 keeps downstream consumers inside the same Phase Real and Completion packet, so host minima, quotient streams, selected limits, and unbudgeted radius selection have no scope row in the accepted ledger. □

Theorem 452.157 (Finite Lebesgue-number Phase Real audit-ledger readiness)**.** *The Phase Real audit ledger of Definition 452.154 is ready for* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, TotallyBounded$^{\uparrow}$, *compact-net, and* UniformModulus$^{\uparrow}$ *consumers. Each of these consumers reads the same finite ledger through the root radius-window obligation surface, the open Phase root-unblock coverage, the root-radius export, the L10 consumer exhaustion, the four-face exit package, and the Phase Real radius-window face minimality boundary; none receives a private radius source.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealAuditLedgerReadiness`

Proof. Assemble the source side first. Definition 452.155 routes every accepted audit-ledger read through the four open Phase faces, and Definition 452.156 fixes the support rows available to the route.

Now attach the downstream endpoints. Definition 452.98 places compact, compact-net, and uniform consumers on the same four-face packet. Definition 452.139 extends the same exhaustion to compact, continuous, totally bounded, compact-net, and uniform radius reads along the Phase Real and Completion route.

The readiness claim follows from the absence of a second source coordinate. The root radius-window obligation surface, the open Phase root-unblock radius coverage, the root-radius export exactness, the four-face exit coverage, determinacy, and nonescape theorems, and the Phase Real radius-window face minimality theorem leave the consumers with precisely the rows of $\mathcal{L}_{\lambda}^{\mathrm{audit}}$. Since the scoped ledger excludes open-cover compactness, selected subcovers, quotient streams, host minima, selected limits, countable choice, detached Real completeness, external modulus data, and unbudgeted radius selection, no consumer can read a private radius source. □

452.1 Finite Lebesgue-number Phase Real terminal radius readiness

Definition 452.158 (Finite Lebesgue-number Phase Real terminal radius readiness ledger)**.** *For an accepted* FiniteLebesgueNumber$^{\uparrow}$ *route, the Phase Real terminal radius readiness ledger is the finite* BHist *packet*

$$\mathcal{T}_{\lambda}^{\mathrm{ready}} = (D, B, M, E, S, Q, R, K, F, T, U, H, C, P, N)$$

whose entries are the DyadicCover$^{\uparrow}$ *cover row D, the* RationalBall$^{\uparrow}$ *positive-radius row B, the* DyadicMesh$^{\uparrow}$ *mesh row M, the* DyadicRatCore$^{\uparrow}$ *core-radius face E, the* StreamName$^{\uparrow}$ *window face S, the* RegSeqRat$^{\uparrow}$ *regular-rational face Q, the* Real$^{\uparrow}$ *endpoint face R, the* CompactMetric$^{\uparrow}$ *compact consumer row K, the* ContinuousMap$^{\uparrow}$ *continuous endpoint row F, the* TotallyBounded$^{\uparrow}$ *finite-net consumer row T, the* UniformModulus$^{\uparrow}$ *uniform endpoint row U, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and compatible local* NameCert *naming N.*

The ledger is accepted only when the compact, continuous, totally bounded, compact-net, and uniform consumers read one terminal positive-radius verdict through the same dyadic and four-face Phase Real packet. In particular, the verdict is carried by the displayed DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *faces and by the same* BHist, hsame, Cont, Pkg, *and* NameCert *support rows; it is not a host minimum, an open-cover compactness row, a selected subcover, a quotient stream equality, a selected limit, countable choice, detached* Real$^{\uparrow}$ *completeness, or an external modulus datum.*

Lean4 (definition) `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealTerminalRadiusReadiness`

Theorem 452.159 (Finite Lebesgue-number Phase Real terminal radius readiness)**.** *Every accepted terminal radius consumer for* FiniteLebesgueNumber$^{\uparrow}$ *factors through the ledger of Definition 452.158. Equivalently, each* CompactMetric$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*,* TotallyBounded$^{\uparrow}$*, compact-net, or* UniformModulus$^{\uparrow}$ *consumer visible at the Phase Real terminal boundary receives the same finite packet*

$$D, B, M, E, S, Q, R, K, F, T, U, H, C, P, N$$

and receives no private positive-radius source outside that packet.

Proof. Start with the root-unblock surface. Definition 452.133 puts every accepted root radius read inside the finite dyadic cover, rational-ball, dyadic-mesh, four-face Real, history, transport, replay, provenance, and naming packet, while Definition 452.137 identifies admissible root-radius export with displaying exactly that packet.

Next attach the terminal consumer rows. Definition 452.139 exhausts compact, continuous, totally bounded, and uniform radius reads by the same Phase Real and Completion packet. Definition 452.140 adds the compact-net consumer to the same four-face exit package, so every listed endpoint reads the displayed dyadic and Phase Real rows before any consumer verdict is available.

Finally use the audit readiness boundary. Definition 452.157 states that compact, continuous, totally bounded, compact-net, and uniform consumers read the same finite ledger through the root radius-window obligation surface, open Phase root-unblock coverage, root-radius export, L10 consumer exhaustion, four-face exit package, and Phase Real radius-window face minimality boundary. These are precisely the rows of $\mathcal{T}_{\lambda}^{\mathrm{ready}}$, so every accepted terminal consumer factors through the readiness ledger and cannot add a private positive-radius source. □

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealTerminalRadiusReadiness`

Theorem 452.160 (Finite Lebesgue-number Phase Real terminal radius stability)**.** *Componentwise* hsame *transport and displayed* Cont *replay preserve the terminal radius verdict of Definition 452.158 exactly when they preserve the displayed* DyadicCover$^{\uparrow}$*,* RationalBall$^{\uparrow}$*,* DyadicMesh$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* CompactMetric$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*,* TotallyBounded$^{\uparrow}$*,* UniformModulus$^{\uparrow}$*,* BHist*,* Pkg*, and* NameCert *rows componentwise. Under such transport, the compact, continuous, totally bounded, compact-net, and uniform consumers read the same terminal verdict.*

Proof. First reduce the verdict to the root packet. By Definition 452.137, an admissible root-radius export is exactly the finite packet over the dyadic cover, rational-ball, mesh, four source faces, and BEDC support rows. Definition 452.138 then says that componentwise hsame transport and displayed Cont replay preserve the positive-radius row only together with its rational-ball, mesh, stream, regular-rational, and Real rows.

Next compare the consumer endpoints. Definition 452.141 makes agreement on the four source faces and the BHist, hsame, Cont, Pkg, and NameCert rows determine the downstream radius classifier seen by compact, continuous, totally bounded, compact-net, and uniform consumers. Thus componentwise transport of the rows listed in $\mathcal{T}_{\lambda}^{\mathrm{ready}}$ transports the consumer-visible verdict as one packet.

The converse is forced by nonescape. If the terminal verdict were preserved while one displayed source or support row changed, the endpoint would require an unrecorded replacement coordinate for the missing row. Definition 452.143 and Definition 452.156 exclude precisely those outside coordinates. Hence terminal verdict stability is exactly componentwise hsame and displayed Cont stability of the ledger rows. □

Lean4 ✓ BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealTerminalRadiusStability

Theorem 452.161 (Finite Lebesgue-number Phase Real terminal radius nonescape)**.** *The Phase Real terminal radius readiness ledger exports no open-cover compactness row, selected-subcover row, host-minimum row, quotient stream equality row, selected-limit row, countable-choice row, detached* $\mathsf{Real}^{\uparrow}$ *completeness row, or external-modulus row. Any compact, continuous, totally bounded, compact-net, or uniform-modulus terminal use of such a row lies outside the accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *terminal radius route.*

Proof. Read the positive source first. Definition 452.134 removes open-cover compactness, selected subcovers, host minima, quotient stream equality, countable choice coordinates, detached $\mathsf{Real}^{\uparrow}$ completeness, and external modulus data from the open Phase root-unblock obligation packet.

Now pass through the four-face exit package. Definition 452.143 excludes open-cover compactness, selected subcovers, host minima, quotient stream equality, selected limits, choice rows, and detached $\mathsf{Real}^{\uparrow}$ completeness from the four-face radius exit. Definition 452.139 keeps compact, continuous, totally bounded, and uniform consumers inside the same Phase Real and Completion packet.

Finally attach the terminal ledger. Definition 452.156 lists exactly the dyadic, four-face Real, compact, continuous, totally bounded, uniform, history, transport, replay, provenance, and naming rows available to the audit route, and Definition 452.159 makes every accepted terminal consumer factor through those rows. Since none of the excluded objects has a coordinate in $\mathcal{T}_{\lambda}^{\mathrm{ready}}$, no accepted terminal consumer can export or inspect such an object. □

Lean4 ✓ BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealTerminalRadiusNonescape

Theorem 452.162 (Finite Lebesgue-number Phase Real terminal radius choice-free finality)**.** *For* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$*, every accepted Phase Real terminal radius verdict is final exactly as the finite packet* $D, B, M, E, S, Q, R, K, F, T, U, H, C, P, N$ *of Definition 452.158. If another accepted terminal verdict is visible at the same boundary, then it agrees componentwise on the* $\mathsf{DyadicCover}^{\uparrow}$ *cover row,* $\mathsf{RationalBall}^{\uparrow}$ *positive-radius row,* $\mathsf{DyadicMesh}^{\uparrow}$ *mesh row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *core-radius face,* $\mathsf{StreamName}^{\uparrow}$ *window face,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational face,* $\mathsf{Real}^{\uparrow}$ *endpoint face,* $\mathsf{CompactMetric}^{\uparrow}$ *compact consumer row,* $\mathsf{ContinuousMap}^{\uparrow}$ *continuous endpoint row,* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row,* $\mathsf{UniformModulus}^{\uparrow}$ *uniform endpoint row,* BHist *transport ledger, displayed continuation row,* Pkg *provenance row, and compatible* $\mathsf{NameCert}$ *row. No compact, continuous, totally bounded, compact-net, or uniform endpoint may refine that final verdict by open-cover compactness, selected subcover, host minimum, quotient stream equality, countable choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or an external modulus.*

Lean4 ✓ BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberPhaseRealTerminalRadiusChoiceFreeFinali

Proof. First force every terminal verdict through the readiness packet. By Definition 452.159, an accepted compact, continuous, totally bounded, compact-net, or uniform endpoint reads the terminal positive-radius verdict only through the displayed rows $D, B, M, E, S, Q, R, K, F, T, U, H, C, P, N$.

Now compare two accepted terminal verdicts. Definition 452.160 says that preservation of the terminal verdict is exactly componentwise preservation of the dyadic cover, rational ball, dyadic mesh, DyadicRatCore, StreamName, RegSeqRat, Real, compact, continuous, totally bounded, uniform, history, provenance, and NameCert rows together with the displayed transport and continuation data. Thus two accepted terminal verdicts at the same boundary agree precisely when these coordinates agree.

The remaining visible classifier is unique. Definition 452.142 supplies the total visible root-radius classifier for the open Phase boundary, so there is no second consumer-facing classifier through which the same terminal packet could be reread as a different verdict.

Finally exclude all proposed refinements outside the packet. Definition 452.161 refuses open-cover compactness, selected subcover, host minimum, quotient stream equality, countable choice, detached $\mathsf{Real}^{\uparrow}$ completeness, and external modulus rows at this terminal boundary. Hence the accepted terminal radius verdict is final in the choice-free Phase Real sense: every second accepted verdict is the same componentwise packet, and every outside endpoint refinement is unavailable to the route. □

Theorem 452.163 (Finite Lebesgue-number terminal-readiness face projection)**.** *Every accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *terminal readiness ledger projects componentwise to the four displayed Phase Real exit faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

and to the support rows BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The projection keeps the dyadic-cover, rational-ball, dyadic-mesh, compact, continuous, totally bounded, compact-net, and uniform endpoint rows only as coordinates of the same finite terminal packet; it does not introduce a second radius source.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTerminalReadinessFaceProjection`

Proof. Read the terminal ledger first. Definition 452.159 makes every accepted compact, continuous, totally bounded, compact-net, or uniform terminal consumer factor through the displayed packet $D, B, M, E, S, Q, R, K, F, T, U, H, C, P, N$.

The four source faces are then forced by the exit package. Definition 452.140 covers the accepted root radius read by the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces, and Definition 452.108 identifies those faces together with BHist, hsame, Cont, Pkg, and NameCert as the exact source packet for consumer-visible reads.

Finally compare transported ledgers. Definition 452.160 says terminal verdict stability is exactly componentwise stability of these displayed coordinates. Hence every accepted terminal readiness ledger has the stated componentwise projection, and the consumer rows remain downstream coordinates of the same packet rather than private positive-radius sources. □

Theorem 452.164 (Finite Lebesgue-number terminal-readiness exit handoff)**.** *The componentwise projection of Definition 452.163 is exactly the Phase Real and Completion exit handoff consumed by the* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*, compact-net, and* $\mathsf{UniformModulus}^{\uparrow}$ *endpoints. At the terminal boundary, these endpoints receive the same four-face radius packet and the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTerminalReadinessExitHandoff`

Proof. First identify the packet being handed off. The face projection theorem above gives the four Phase Real and Completion faces and the BEDC support rows as componentwise coordinates of the accepted terminal readiness ledger.

Next attach the endpoint consumers. Definition 452.139 exhausts compact, continuous, totally bounded, compact-net, and uniform radius reads by the same Phase Real and Completion packet, while Definition 452.141 makes agreement on the four source faces and support rows determine the downstream radius classifier.

The remaining boundary is the visible classifier. Definition 452.142 supplies the total root-radius classifier for the open Phase boundary. Therefore the projected terminal readiness packet is not merely compatible with the endpoints: it is the exact exit handoff those endpoints consume. □

Theorem 452.165 (Finite Lebesgue-number terminal-readiness no-completeness promotion)**.** *The terminal-readiness exit handoff of Definition 452.164 cannot promote to an open-cover compactness row, a selected subcover, a host minimum, a quotient stream equality, countable choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, metric completeness, or an external modulus. Any such datum lies outside the accepted* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *Phase Real terminal radius route.*

Lean4 ✓ `BEDC.Derived.FiniteLebesgueNumberUp.FiniteLebesgueNumberTerminalReadinessNoCompletenessPromotio`

Proof. Start with the terminal boundary. Definition 452.161 excludes open-cover compactness, selected subcovers, host minima, quotient stream equality, selected limits, countable choice, detached $\mathsf{Real}^{\uparrow}$ completeness, and external modulus rows from accepted terminal radius use.

The four-face exit gives the same refusal before the handoff reaches any endpoint. Definition 452.143 removes open-cover compactness, selected subcovers, host minima, quotient stream equality, selected limits, choice rows, and detached $\mathsf{Real}^{\uparrow}$ completeness from the Phase Real radius exit itself.

Metric completeness and external moduli have no independent coordinate in the projected packet. The handoff theorem above passes only the four Phase Real and Completion faces plus BHist, hsame, Cont, Pkg, and NameCert support rows to the compact, continuous, totally bounded, compact-net, and uniform endpoints. Thus the handoff is a finite BEDC exit packet, not a compactness, completeness, or external-modulus surrogate. □

Chapter 453

A Concrete Naming Certificate for $\mathsf{DoCalculus}^{\uparrow}$

Following Pearl, *Causality*, 2009, the intervention calculus used here is recorded as a finite certificate surface rather than as an external semantic oracle. The $\mathsf{DoCalculus}^{\uparrow}$ packet keeps the intervention ledger, observed variable rows, adjustment-set witnesses, distribution rows, conditional independence certificates, and conditional-expectation handoff rows visible as BEDC data. It does not claim a host probability space, a full structural causal model, graphical completeness of do-calculus, or a selected counterfactual semantics.

The finite intervention ledger consumes already certified probability-facing rows rather than creating a host causal model. Its probability-space export surface is the one isolated by chapter 184; its conditional independence certificates are read through chapter 187; its displayed distribution handoff is the surface of chapter 186; and its conditional-expectation row is routed through chapter 188. Thus $\mathsf{DoCalculus}^{\uparrow}$ only packages finite intervention reads through those certified probability-facing rows.

Definition 453.1 (DoCalculus carrier)**.** *A* $\mathsf{DoCalculus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, V, A, M, R, J, E, H, C, P, N)$$

with the following visible coordinates:

1. *I is the finite intervention ledger, whose rows name the intervened variables, the displayed intervention marks, and the finite order in which the intervention rows are read;*
2. *V is the finite observed-variable row, listing the outcome, treatment, covariate, and auxiliary observation names that are visible to the certificate;*
3. *A is the adjustment-set ledger, containing only finite rows that name which observed variables are admitted as adjustment coordinates for the displayed query;*
4. *M records the intervention-modified distribution rows, including the pre-intervention observational row, the post-intervention row, and the finite conditioning rows exposed to consumers;*
5. *R records conditional-independence certificates used by the intervention ledger and the adjustment-set ledger;*
6. *J is the conditional-expectation handoff row, whose input is the displayed adjusted distribution row and whose output is the query-facing expectation row;*

7. *E records the probability-facing export row consumed by downstream probability chapters;*
8. *H records the componentwise* hsame *transports for intervention rows, observed-variable rows, adjustment ledgers, distribution rows, independence certificates, conditional-expectation rows, and probability exports;*
9. *C records the displayed* Cont *routes by which consumers read intervention admission, adjustment-set membership, independence certificates, distribution handoffs, and conditional-expectation exports;*
10. *P records* Pkg *provenance over* BHist, hsame, Cont, *finite variable rows, finite ledger rows, probability handoff rows, and local naming rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DoCalculus}^{\uparrow}}$ *provenance row.*

The carrier accepts exactly finite intervention-ledger packets whose consumers can read every causal query through the displayed adjustment, independence, distribution, and expectation rows.

Lean4 ✓ `BEDC.Derived.DoCalculusUp.DoCalculusUpTasteGate single carrier alignment`

Theorem 453.2 (DoCalculus NameCert obligation surface)**.** *Every accepted* $\mathsf{DoCalculus}^{\uparrow}$ *packet with carrier Definition 453.1 carries five local naming obligations:*

1. *carrier admission: the tuple $D = (I, V, A, M, R, J, E, H, C, P, N)$ is admitted as one finite* BHist *packet;*
2. *classifier transport: componentwise* hsame *and* Cont *transport preserves the intervention, observed-variable, adjustment, distribution, independence, expectation, package, and naming rows;*
3. *adjustment ledger exactness: the adjustment row A lists exactly the observed coordinates allowed to mediate the displayed intervention query;*
4. *intervention non-escape: every consumer-visible intervention read passes through $I, V, A, M, R, H, C, P, N$ and cannot project an unlisted intervention, hidden counterfactual, or host causal model;*
5. *probability handoff: every probability-facing read passes through the conditional-expectation row J and the export row E after the finite adjustment and independence rows have been displayed.*

These five rows are the complete local $\mathsf{NameCert}_{\mathsf{DoCalculus}^{\uparrow}}$ *surface for the finite intervention calculus packet.*

Lean4 ✓ `BEDC.Derived.DoCalculusUp.DoCalculusPacket namecert obligation surface`

Proof. Project the accepted carrier. Its coordinates are the finite rows $I, V, A, M, R, J, E, H, C, P, N$, so carrier admission is just the displayed BHist packet.

For classifier transport, move each coordinate through its stored hsame row and then read it through the corresponding Cont route. Because the carrier is componentwise, no transported row can introduce a variable, intervention, distribution, or handoff coordinate not already listed in the tuple.

Adjustment exactness is read from A: it names only observed variables from V, and the distribution rows in M consume exactly those names for the displayed query. The intervention non-escape clause follows because every intervention-facing route has to pass through I and the same finite ledger rows before a consumer can read it.

Finally, probability-facing data are exported only through J and E. The conditional-independence certificates in R and the adjustment ledger A are therefore visible before the expectation handoff is consumed, which keeps the handoff finite and internal to the packet. □

Theorem 453.3 (DoCalculus adjustment ledger exactness)**.** *For every accepted* $\mathsf{DoCalculus}^{\uparrow}$ *packet* $D = (I, V, A, M, R, J, E, H, C, P, N)$*, the adjustment-set ledger* A *is exhausted by the finite observed-variable rows in* V *and by the conditional-independence certificates in* R *that justify their use for the displayed intervention query. No variable outside* V *and no unstored independence assertion can be read as part of the adjustment set.*

Lean4 ✓ `BEDC.Derived.DoCalculusUp.DoCalculusPacket adjustment ledger exactness`

Proof. Read the observed-variable coordinate V. It gives the finite list of outcome, treatment, covariate, and auxiliary observation names available to the packet.

Next read the adjustment ledger A. Each adjustment entry is indexed by one of those observed names and points to an independence certificate in R used by the displayed query.

Thus the adjustment surface is exhausted by V, A, R, H, C, P, N. A hidden variable or unstored independence assertion would require a coordinate absent from Definition 453.1, so it cannot be projected from the accepted packet. □

Theorem 453.4 (DoCalculus intervention non-escape)**.** *Every intervention-facing consumer of an accepted* $\mathsf{DoCalculus}^{\uparrow}$ *packet* $D = (I, V, A, M, R, J, E, H, C, P, N)$ *factors through the intervention ledger* I*, the observed-variable row* V*, the adjustment ledger* A*, the distribution rows* M*, the independence certificates* R*, the transport rows* H*, the continuation routes* C*, the package provenance* P*, and the local* $\mathsf{NameCert}$ *row* N*. Such a consumer cannot obtain a hidden intervention, an unlisted causal graph, a counterfactual selector, or a host structural causal model from the packet.*

Lean4 ✓ `BEDC.Derived.DoCalculusUp.DoCalculusPacket intervention non escape`

Proof. Use the carrier definition to inspect an intervention read. The read begins at the finite ledger I, and each intervention mark is paired with visible observed-variable data in V.

The route then passes through the adjustment ledger, the modified distribution rows, and the named independence certificates. Transport and consumer access are only the displayed H and C rows, with provenance kept in P and N.

The excluded objects have no coordinate in the carrier. Since consumer routes are finite projections from the displayed packet, none of those objects can escape through an intervention-facing read. □

Theorem 453.5 (DoCalculus probability handoff)**.** *Every probability-facing read from an accepted* $\mathsf{DoCalculus}^{\uparrow}$ *packet factors through the adjusted distribution rows* M*, the conditional-independence certificates* R*, the conditional-expectation handoff row* J*, and the export row* E*. The handoff is a finite certificate route into probability chapters, not a claim of host measure theory, graphical completeness, or selected counterfactual semantics.*

Proof. Project the distribution coordinate M and the independence coordinate R. They display the observational, post-intervention, and conditioning rows available to the query together with the finite certificates that justify the adjustment route.

Read the conditional-expectation handoff J. Its input is the adjusted distribution row already exposed by M and R, and its output is the probability-facing row later exported by E.

Therefore the probability chapter receives only the finite handoff packet M, R, J, E, H, C, P, N. No ambient probability space, completeness theorem for do-calculus, or counterfactual selector is supplied by this route. □

Lean4 ✓ `BEDC.Derived.DoCalculusUp.DoCalculusPacket probability handoff`

Definition 453.6 (DoCalculus displayed prefix subledger)**.** *Let $D = (I, V, A, M, R, J, E, H, C, P, N)$ be an accepted* $\mathsf{DoCalculus}^{\uparrow}$ *packet as in Definition 453.1. A displayed prefix subledger of D is a finite packet*

$$D_{\leq k} = (I_{\leq k}, V_{\leq k}, A_{\leq k}, M_{\leq k}, R_{\leq k}, J_{\leq k}, E_{\leq k}, H_{\leq k}, C_{\leq k}, P_{\leq k}, N_{\leq k})$$

obtained by retaining an initial segment $I_{\leq k}$ of the displayed finite order on the intervention ledger I and retaining exactly the observed-variable, adjustment, distribution, independence, conditional-expectation, export, transport, continuation, package, and local naming rows whose route entries are used by intervention reads from that initial segment. Rows of I strictly after the displayed prefix are called later intervention rows for $D_{\leq k}$.

Lean4 (definition) `BEDC.Derived.DoCalculusUp.DoCalculusDisplayedPrefixSubledger`

Theorem 453.7 (DoCalculus intervention prefix locality)**.** *Let $D = (I, V, A, M, R, J, E, H, C, P, N)$ be an accepted* $\mathsf{DoCalculus}^{\uparrow}$ *packet, and let $D_{\leq k}$ be a displayed prefix subledger of D in the sense of Definition 453.6. Every intervention-facing consumer whose displayed intervention mark lies in $I_{\leq k}$ factors through*

$$I_{\leq k}, V_{\leq k}, A_{\leq k}, M_{\leq k}, R_{\leq k}, H_{\leq k}, C_{\leq k}, P_{\leq k}, N_{\leq k}.$$

In particular, such a consumer cannot read any later intervention row of I.

Proof. By Definition 453.1, the intervention ledger I is finite and carries a displayed order for the intervention rows. The prefix subledger retains an initial segment $I_{\leq k}$ of that order together with exactly the route rows attached to interventions in that segment.

Apply the intervention non-escape theorem Definition 453.4 to the accepted packet D. Any intervention-facing read in D factors through the displayed intervention ledger, observed-variable row, adjustment ledger, distribution rows, independence certificates, transport rows, continuation routes, package provenance, and local naming row:

$$I, V, A, M, R, H, C, P, N.$$

For a read whose intervention mark lies in the prefix $I_{\leq k}$, the definition of displayed prefix subledger says that the relevant observed-variable, adjustment, distribution, independence, transport, continuation, package, and naming entries are exactly the retained rows

$$V_{\leq k}, A_{\leq k}, M_{\leq k}, R_{\leq k}, H_{\leq k}, C_{\leq k}, P_{\leq k}, N_{\leq k}.$$

Thus restricting the non-escape factorization to the displayed prefix gives the stated factorization through the retained prefix rows.

It remains to exclude later intervention rows. A later row is, by definition, a row of I outside the initial segment $I_{\leq k}$. Since the consumer route has already been restricted to the retained prefix route family $C_{\leq k}$ and its retained provenance rows, no projection in that route has a source coordinate in the later part of I. Reading such a later row would require leaving the retained prefix packet and using an intervention coordinate not present in $D_{\leq k}$. This is impossible for an intervention-facing read that factors through the displayed prefix subledger. Therefore no later intervention row can be read. □

Lean4 ✓ `BEDC.Derived.DoCalculusUp.DoCalculusPacket intervention prefix locality`

Theorem 453.8 (DoCalculus scoped closure route)**.** *The displayed* DoCalculus$^{\uparrow}$ *packet closes the following scoped surface: finite* BHist *intervention ledgers, componentwise* hsame *transport, displayed* Cont *replay, adjustment ledgers, intervention non-escape rows, probability-facing handoff rows, displayed prefix subledgers, prefix-locality routes,* Pkg *provenance, and local* NameCert *rows. The scope is witnessed exactly by Definition 453.1, Definition 453.2, Definition 453.3, Definition 453.4, Definition 453.5, Definition 453.6, and Definition 453.7.*

Within this scope, every intervention-facing read is a finite packet route through the displayed causal ledger and its retained probability-facing rows. No read in the scoped surface supplies a hidden intervention, host causal graph, selected counterfactual, ambient probability equality, or adjustment row outside the finite ledger.

Proof. Start from the carrier of Definition 453.1. It lists exactly the intervention ledger, observed-variable rows, adjustment ledger, modified distribution rows, independence certificates, conditional-expectation row, export row, transport row, continuation row, package provenance, and local naming row. The NameCert obligation surface of Definition 453.2 then identifies carrier admission, classifier transport, adjustment exactness, intervention non-escape, and probability handoff as the local naming obligations.

The adjustment ledger is bounded by Definition 453.3: only observed rows from V and stored independence certificates from R can mediate the displayed query. The intervention-facing side is bounded by Definition 453.4, which forces every consumer route through $I, V, A, M, R, H, C, P, N$ before any intervention read is visible.

The probability-facing side is bounded by Definition 453.5. It routes adjusted distribution rows and independence certificates through the conditional-expectation row and the export row, so the probability chapter receives a finite handoff rather than an ambient model.

Finally use the prefix interface. The displayed subledger of Definition 453.6 retains an initial intervention segment together with exactly its dependent observed-variable, adjustment, distribution, independence, transport, continuation, package, and naming rows. The locality theorem Definition 453.7 says that reads from the retained prefix cannot inspect later intervention rows. These witnesses assemble the stated scoped closure over BHist, hsame, Cont, finite intervention ledgers, probability-facing rows, and NameCert. □

Lean4 ✓ `BEDC.Derived.DoCalculusUp.DoCalculusPacket scoped closure route`

Closure status for NameCert$_{\text{DoCalculus}^{\uparrow}}$.

Constructive story: A DoCalculus$^{\uparrow}$ packet is generated from a finite intervention ledger, observed-variable rows, adjustment-set ledger, modified distribution rows, conditional-independence certificates, conditional-expectation rows, export rows, componentwise hsame transport, displayed Cont routes, package provenance, and local naming. The classifier reads an intervention only through the same finite causal ledger and its adjustment and probability-facing handoff rows. The prefix subledger story is constructive locality: an initial intervention segment generates its own retained packet, and later intervention rows cannot be read through routes that were restricted to the displayed prefix. No causal oracle or hidden intervention is introduced.

Theory closure: TheoryGate(NameCert$_{\text{DoCalculus}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 453.8 binds the DoCalculus carrier, NameCert obligation surface, adjustment ledger exactness, intervention non-escape, probability handoff, displayed prefix subledger, and intervention prefix locality for DoCalculus$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{DoCalculus}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.DoCalculusUp.DoCalculusPacket\_scoped\_closure\_route`

Bridge status: none

Origin: human

Not claimed: It does not claim hidden interventions, host graphical causal semantics, causal oracles, external probability equality, or adjustment rows outside the finite ledger.

Upgrade path: To reach obligationClosure, the intervention ledger and prefix-locality results must be assembled into a checked finite-carrier closure theorem.

Chapter 454

LocatedModulusCompletion NameCert Construction

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedModulusCompletion}^{\uparrow}$ interface records a completion-side read of a located real name only through explicit regular Cauchy data, a displayed modulus, and a finite limit seal. It belongs to the same Real and Completion phase as $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{LocatedReal}^{\uparrow}$: the packet exposes finite readback and seal rows, not a quotient of Cauchy streams or a selected host real value.

The packet consumes the regular source of chapter 301, the real seal of chapter 38, the modulus row of chapter 292, the limit-facing seal of chapter 386, and the located evidence of **??**. The located modulus row is not an ambient completeness principle: it transports finite $\mathsf{StreamName}^{\uparrow}$ windows through $\mathsf{RegSeqRat}^{\uparrow}$ regularity and $\mathsf{Real}^{\uparrow}$ seal rows, with $\mathsf{CauchyModulus}^{\uparrow}$ supplying the displayed threshold budget.

Definition 454.1 (LocatedModulusCompletion carrier)**.** *A* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, Q, M, S, E, H, C, P, N)$$

with the following visible coordinates:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose rational observations supply the regular Cauchy name;*
2. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row read from that regular source;*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row assigning each requested precision a finite threshold for the same source row;*
4. *S is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row recording the finite limit-facing seal consumed by completion readers;*
5. *E is the* $\mathsf{LocatedReal}^{\uparrow}$ *evidence row, listing the located read windows and rational separation or enclosure rows attached to the same real-name read;*
6. *H stores componentwise* hsame *transports for the regular source, real seal, modulus row, limit seal, located evidence row, package provenance, and local naming row;*
7. *C stores the displayed* Cont *routes for reading the source windows, applying the modulus threshold, reaching the limit seal, and exposing the located real evidence;*
8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedModulusCompletion}^{\uparrow}}$ *row.*

The packet is a finite completion-side read certificate. It carries no quotient of Cauchy names, no selected completed value, no host equality of real numbers, and no ambient completeness principle.

Theorem 454.2 (LocatedModulusCompletion NameCert obligations)**.** *For the carrier of Definition 454.1, the local* $\mathsf{NameCert}_{\mathsf{LocatedModulusCompletion}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the displayed packet $L = (R, Q, M, S, E, H, C, P, N)$;*
2. *classifier transport by componentwise* hsame *over the* $\mathsf{RegSeqRat}^{\uparrow}$ *source,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{CauchyModulus}^{\uparrow}$ *row,* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row, and* $\mathsf{LocatedReal}^{\uparrow}$ *evidence;*
3. *regular-seal routing, which requires every completion-facing read to pass through the displayed regular source R, modulus row M, and limit seal S before reaching Q or E;*
4. *ledger exactness, which records that the precision threshold used by a read is exactly the threshold displayed by M for that request;*
5. *non-escape, which excludes quotient streams, selected host limits, host real equality, trichotomy, and ambient completeness from the packet surface.*

Lean4 ✓ `BEDC.Derived.LocatedModulusCompletionUp.LocatedModulusCompletionCarrier namecert obligations`

Proof. Carrier admission is the direct projection of the finite tuple in Definition 454.1. The listed rows are all displayed in the same BHist packet and are named by the local certificate row.

Classifier transport is componentwise. The regular source, real seal, modulus row, limit seal, and located evidence each move through the stored hsame rows and are read through the corresponding Cont route.

For routing and exactness, inspect a requested precision. The continuation first reads the threshold row of M, then uses that finite threshold to reach the source window in R, the limit-facing row in S, and the visible real or located rows Q and E.

The non-escape clause follows from the carrier inventory. Since no coordinate stores a quotient stream, selected limit, host equality, trichotomy, or completeness theorem, no consumer route can project one. □

Theorem 454.3 (LocatedModulusCompletion regular seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{LocatedReal}^{\uparrow}$ *read exported by an accepted* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *carrier factors through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source row R, the same* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row M, and the same* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *limit-facing row S. The real seal Q and located evidence E therefore share one finite completion route over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Proof. Start with the consumer route to Q or E. By the carrier definition, both routes are stored in C and both are packaged with the same provenance row P.

Read the requested precision through M. The threshold selected by the modulus row determines which finite source window in R is inspected before any real-seal or located-evidence row is exposed.

Finally read the limit-facing row S. It is the completion-side seal attached to the same source and threshold, so the exported real and located reads share the same finite route and do not choose an independent completed value. □

Lean4 ✓ `BEDC.Derived.LocatedModulusCompletionUp.LocatedModulusCompletionCarrier regular seal`

Theorem 454.4 (LocatedModulusCompletion classifier stability)**.** *Let $L = (R, Q, M, S, E, H, C, P, N)$ and $L' = (R', Q', M', S', E', H', C', P', N')$ be accepted* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *carriers whose displayed rows are related componentwise by the stored* hsame *transports. If the transported modulus rows assign matching threshold reads and the transported limit seals remain attached to the transported regular sources, then every* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{LocatedReal}^{\uparrow}$ *consumer route from L transports to the corresponding route from L'.*

Proof. Project the componentwise transports. The rows R, Q, M, S, E have separate hsame comparisons, and the package and naming rows record that those comparisons belong to one carrier.

Use the modulus comparison first. Matching threshold reads ensure that a requested precision reaches corresponding source windows in R and R'.

Next use the seal comparison. The transported $\mathsf{CauchyLimitSeal}^{\uparrow}$ row remains attached to the transported regular source, so the real-seal and located-evidence routes keep the same source-threshold-limit order.

Repack the transported rows with C', P', N'. The resulting consumer route is exactly the corresponding route from L', and no hidden equality of completed real values is used. □

Theorem 454.5 (LocatedModulusCompletion ledger exactness)**.** *For every accepted* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *carrier and every displayed precision request, the threshold consumed by the* $\mathsf{RegSeqRat}^{\uparrow}$ *source read, the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row, the* $\mathsf{Real}^{\uparrow}$ *seal row, and the* $\mathsf{LocatedReal}^{\uparrow}$ *evidence row is the threshold recorded by the carrier's* $\mathsf{CauchyModulus}^{\uparrow}$ *row for that request. No downstream consumer may replace it by an unrecorded modulus, a host convergence rate, or a choice-selected tail.*

Proof. Inspect the precision request in the carrier. The only threshold coordinate is the displayed row M, and the continuation route C reads that row before it reaches any source, seal, or located-evidence coordinate.

The regular source route consumes the threshold selected by M. The limit seal, real seal, and located evidence are downstream of that same source read, so their tolerance ledger is the one already selected by the modulus row.

An unrecorded modulus or host convergence rate would require an additional carrier coordinate. Since Definition 454.1 lists none, the displayed ledger is exact for every accepted route. □

Theorem 454.6 (LocatedModulusCompletion public scope)**.** *The public surface of a* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *seed packet is precisely the finite route through* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *named in Definition 454.1. It exposes located modulus-controlled completion reads and excludes quotient-real construction, selected limits, host order completeness, trichotomy, and equality of completed real representatives.*

Proof. Project the carrier and collect its consumer-facing rows. The visible data are the regular source, real seal, modulus threshold row, limit seal, located evidence, transports, continuation routes, package provenance, and local naming row.

Apply the regular-seal theorem to route real and located reads through the same source, modulus, and limit-seal rows. Apply classifier stability to transport those rows componentwise, and apply ledger exactness to identify the threshold consumed by each precision request.

The public scope is exhausted by those finite rows. None of the excluded objects is present as a carrier coordinate, so the seed packet states only the located modulus-controlled completion surface. □

Theorem 454.7 (LocatedModulusCompletion obligation routing package)**.** *The carrier of Definition 454.1, the regular seal of Definition 454.3, classifier stability of Definition 454.4, ledger exactness of Definition 454.5, and public scope of Definition 454.6 assemble the five* $\mathsf{NameCert}_{\mathsf{LocatedModulusCompletion}^{\uparrow}}$ *obligations for carrier admission, classifier transport, regular-seal routing, modulus ledger exactness, and public non-escape.*

Proof. First project the carrier packet $L = (R, Q, M, S, E, H, C, P, N)$. The displayed coordinates provide carrier admission, and the local naming row N names the certificate surface over that same finite packet.

Next attach transport and routing. Classifier stability supplies componentwise transport through the stored hsame rows, while the regular-seal theorem routes every $\mathsf{Real}^{\uparrow}$ and $\mathsf{LocatedReal}^{\uparrow}$ consumer through R, M, S before it reaches Q or E.

Finally attach exactness and scope. Ledger exactness identifies the consumed threshold with the displayed row M for each precision request, and public scope rules out quotient-real construction, selected completed limits, host order completeness, trichotomy, and equality of completed representatives. □

Theorem 454.8 (LocatedModulusCompletion modulus seal ledger scope)**.** *For every accepted* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *carrier and every displayed precision request, the route to either the* $\mathsf{Real}^{\uparrow}$ *seal row* Q *or the* $\mathsf{LocatedReal}^{\uparrow}$ *evidence row* E *passes through the same* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M *and the same* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row* S*. Thus the modulus ledger and limit-facing seal are shared by all completion-side reads of the packet.*

Proof. Begin with the requested precision. The carrier exposes only one modulus coordinate, namely M, and the continuation inventory reads M before any route reaches a real or located consumer row.

After the modulus threshold is read, the same route reaches the limit-facing seal row S. The regular source row R and the seal row S are packaged with the same provenance P and local certificate row N.

Apply Definition 454.5 to identify the threshold used by every downstream read, and apply Definition 454.3 to factor the routes to Q and E through R, M, S. Hence both consumer rows share the same modulus and seal ledger. □

Theorem 454.9 (LocatedModulusCompletion located-real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer and every* $\mathsf{LocatedReal}^{\uparrow}$ *consumer exported by a* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *carrier receives the same finite source, modulus, and limit-seal packet*

$$(R, M, S)$$

before reading Q *or* E*. The located-real handoff therefore adds located evidence to the displayed completion route without changing the source row, replacing the modulus row, or selecting an external completed value.*

Proof. Project the two consumer rows from the carrier. The $\mathsf{Real}^{\uparrow}$ row is Q and the $\mathsf{LocatedReal}^{\uparrow}$ evidence row is E, and both are downstream of the route inventory stored in C.

Use Definition 454.8. It forces any route to either consumer through the same modulus row M and limit-seal row S, with the same regular source row R read before the consumer boundary.

The located evidence row E therefore extends the real-seal route by visible located-read data only. Since the carrier has no coordinate for a selected completed value or an alternate source/modulus packet, the handoff preserves the same finite packet (R, M, S) for both consumers. □

Theorem 454.10 (LocatedModulusCompletion schedule seal)**.** *For every accepted* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *precision request, the consumer schedule first reads the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row* M*, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* R*, then the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row* S*, before either the* $\mathsf{Real}^{\uparrow}$ *seal row* Q *or the* $\mathsf{LocatedReal}^{\uparrow}$ *evidence row* E *is exposed. This schedule is stable under the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows and cannot be replaced by a quotient stream, a selected completed value, host equality, trichotomy, or ambient completeness.*

Proof. Start with the precision request. By Definition 454.5, the consumed threshold is exactly the one recorded by the displayed modulus row M, so the route cannot begin from an unrecorded convergence rate.

Apply Definition 454.8. After the threshold is read, every route to Q or E passes through the same regular source row R and the same limit-facing seal row S.

Use Definition 454.3 and Definition 454.9 to expose the two possible consumer faces. The real seal and located evidence are downstream of the same packet (R, M, S).

The stability and non-escape clauses are then inherited from the carrier rows. Componentwise hsame transports, displayed Cont routes, Pkg provenance, and the local NameCert row replay the same schedule, while the carrier has no coordinate for quotient streams, selected completed values, host equality, trichotomy, or ambient completeness. □

Theorem 454.11 (LocatedModulusCompletion observation-budget handoff)**.** *Let* $L = (R, Q, M, S, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *carrier, and let*

$$B = (E_0, W, D, R_0, S_0, H_0, C_0, P_0, N_0)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet whose regular-sequence row* R_0 *and* $\mathsf{Real}^{\uparrow}$ *seal row* S_0 *agree with the displayed rows* R *and* Q *of* L*. Then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{LocatedReal}^{\uparrow}$ *consumer route of* L *first factors through the finite budget route*

$$E_0 \longmapsto W \longmapsto D \longmapsto R_0 \longmapsto S_0$$

and then through the displayed modulus row M *and limit-seal row* S *before the consumer reads* Q *or* E*. The handoff consumes only the finite observation-budget packet and the displayed located-modulus ledger; it cannot read quotient streams, selected host limits, ambient completeness, host equality, or an unbounded schedule.*

Proof. Start from the accepted budget packet. By Definition 611.17, every admitted $\mathsf{Real}^{\uparrow}$ seal read of B is reached through E_0, W, D, R_0, S_0 with the displayed transport, route, provenance, and local naming rows.

Use the row agreement hypotheses to identify the budget handoff with the displayed source and real-seal rows of L. Then Definition 611.9 says that the regular-sequence and real-facing consumers have exactly the finite packet rows supplied by B, with no additional analytic coordinate.

Now attach the located completion route. Definition 454.10 forces every consumer route of L to read M, then R, then S, before Q or E is exposed; the agreement with R_0 and S_0 places this schedule downstream of the finite budget route.

Finally apply Definition 454.15. It preserves the same modulus and limit-seal ledger under classifier transport, so the combined route has no coordinate for quotient streams, selected host limits, ambient completeness, host equality, or an unbounded schedule. □

Theorem 454.12 (LocatedModulusCompletion real observation-budget route)**.** *Let $L = (R, Q, M, S, E, H, C, P, N$ be an accepted* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *carrier, and let*

$$B = (E_0, W, D, R_0, S_0, H_0, C_0, P_0, N_0)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet whose regular-sequence row R_0 and* $\mathsf{Real}^{\uparrow}$ *seal row S_0 agree with the displayed rows R and Q of L. Then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{LocatedReal}^{\uparrow}$ *read of L first factors through the accepted observation-budget rows*

$$E_0, W, D, R_0, S_0$$

and only then through the displayed modulus row M and limit-seal row S before reaching Q or E.

Proof. Project the carrier from Definition 454.1. The only consumer-facing rows are the $\mathsf{Real}^{\uparrow}$ seal row Q and the $\mathsf{LocatedReal}^{\uparrow}$ evidence row E, and both are attached to the same displayed packet R, M, S, H, C, P, N.

Apply Definition 454.11. It routes every real or located-real consumer through the accepted budget packet E_0, W, D, R_0, S_0 before the located-modulus rows are read.

Use Definition 454.3 and Definition 454.10. The regular source, modulus threshold, and limit-seal route are consumed in the displayed order before Q or E is exposed.

Finally apply Definition 454.5 and Definition 454.15. They identify the consumed threshold with the displayed ledger row and preserve that ledger under classifier transport, so the route is exactly the finite observation-budget packet followed by M, S and then the consumer row. □

Theorem 454.13 (LocatedModulusCompletion threshold source coherence)**.** *Under the hypotheses of Definition 454.12, the modulus threshold row consumed by R is the same threshold ledger routed through the observation-budget window. It cannot be replaced by an unrecorded convergence rate, an alternate modulus packet, or a source row outside the displayed agreement between R_0 and R.*

Proof. Start with the accepted carrier and budget packet. The observation-budget handoff fixes the regular-sequence row by the agreement between R_0 and R, and Definition 454.12 places the subsequent located-modulus read downstream of that finite packet.

Apply Definition 454.5. The threshold used by the route is the one recorded in the displayed modulus row M, not a hidden convergence rate.

Use Definition 454.10. It reads M before the regular source row is consumed by the seal-facing route and then carries the same source through S before Q or E is exposed.

The carrier of Definition 454.1, the regular-seal theorem, and the classifier-ledger seal leave no coordinate for a second threshold ledger. Hence the threshold consumed by R is coherent with the observation-budget window and cannot be exchanged for an unrecorded rate. □

Theorem 454.14 (LocatedModulusCompletion consumer-window non-escape)**.** *For every accepted pair (B, L) satisfying the agreement hypotheses of Definition 454.12, the combined consumer window exports only the observation-budget rows E_0, W, D, R_0, S_0 followed by the located-modulus rows M, S, Q, E and the displayed* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *data. It exports no quotient stream, selected completed value, host equality, trichotomy, ambient completeness principle, or unbounded schedule.*

Proof. Project the accepted carrier and budget packet. Their visible rows are the finite observation-budget packet, the located modulus and limit-seal rows, the two consumer rows, and the displayed transport, continuation, provenance, and naming data.

Apply Definition 454.11 and Definition 454.12. These theorems force each real or located-real read through E_0, W, D, R_0, S_0 and then through M, S before Q or E can be consumed.

Use Definition 454.13. The threshold row is the recorded ledger row for the same source route, so the consumer cannot switch to an unrecorded convergence schedule.

Finally combine Definition 454.3, Definition 454.5, Definition 454.10, and Definition 454.15. These results exhaust the displayed route and preserve it under classifier transport, while the carrier contains no row for quotient streams, selected completed values, host equality, trichotomy, ambient completeness, or unbounded schedules. □

Theorem 454.15 (LocatedModulusCompletion classifier ledger seal)**.** *Let $L = (R, Q, M, S, E, H, C, P, N)$ and $L' = (R', Q', M', S', E', H', C', P', N')$ be accepted* $\mathsf{LocatedModulusCompletion}^{\uparrow}$ *carriers whose displayed rows are related componentwise by the stored* hsame *transports. If the modulus row M transports to M' request by request, and the limit-seal attachment S transports to the limit-seal attachment S' for the transported regular source, then every transported route to Q' or E' consumes the transported threshold from M' and the transported seal S'. Hence classifier transport preserves the same modulus row and limit-seal ledger, and no quotient stream, selected completed value, host equality, trichotomy, or ambient completeness principle can enter through the transported classifier.*

Proof. Project the two carrier rows from Definition 454.1. The displayed classifier data are the regular source, real seal, modulus row, limit seal, located evidence, componentwise transports, continuation routes, provenance, and local naming row.

Use Definition 454.5 to identify the consumed threshold with the row supplied by the modulus ledger. Under the assumed transport from M to M', the transported route must therefore read the corresponding threshold in M'.

Next apply Definition 454.8 and Definition 454.9. These force both the real-seal route and the located-evidence route through the same regular source, transported modulus row, and transported limit seal before either Q' or E' is exposed.

Finally apply Definition 454.10. The route order remains threshold, source, limit seal, and then consumer row, so the transported classifier has no coordinate from which a quotient stream, selected completed value, host equality, trichotomy, or ambient completeness principle could be read. □

Theorem 454.16 (LocatedModulusCompletion scoped route closure)**.** *The carrier of Definition 454.1, the NameCert obligations of Definition 454.2, the regular-seal route of Definition 454.3, classifier stability of Definition 454.4, ledger exactness of Definition 454.5, public scope of Definition 454.6, modulus-seal ledger scope of Definition 454.8, located-real handoff of Definition 454.9, schedule seal of Definition 454.10, and classifier-ledger seal of Definition 454.15 assemble the complete obligation surface for $L = (R, Q, M, S, E, H, C, P, N)$.*

Every $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{LocatedReal}^{\uparrow}$ *consumer is forced through* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. No quotient stream, selected completed value, host equality, trichotomy, or ambient completeness coordinate is available inside the scoped route.*

Proof. Project the carrier and local naming rows from Definition 454.1 and Definition 454.2. These provide carrier admission and the five displayed certificate obligations over $R, Q, M, S, E, H, C, P, N$.

Next assemble the consumer route. Apply Definition 454.3, Definition 454.8, Definition 454.9, and Definition 454.10 to force every real or located read through the regular source, modulus threshold, and limit-facing seal before Q or E is exposed.

Finally attach transport, exactness, and scope. The classifier stability and classifier-ledger seal theorems preserve the same displayed route under hsame, while ledger exactness and public scope

rule out every excluded completion coordinate. Hence the listed local theorems exhaust the scoped obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedModulusCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedModulusCompletion}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source row, a $\mathsf{Real}^{\uparrow}$ seal row, a $\mathsf{CauchyModulus}^{\uparrow}$ threshold row, a $\mathsf{CauchyLimitSeal}^{\uparrow}$ limit-facing row, $\mathsf{LocatedReal}^{\uparrow}$ evidence, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedModulusCompletion}^{\uparrow}}, \mathsf{obligation})$

Scope closed: The seed scope records the finite carrier, local naming obligations, regular-seal route, classifier stability surface, ledger exactness, and public located-modulus completion boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedModulusCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient-real construction, selected completed limits, host order completeness, trichotomy, equality of completed real representatives, or a checked Lean certificate.

Upgrade path: Obligation closure requires checked carrier admission, modulus ledger exactness, classifier stability, regular-seal routing, and public non-escape for the located completion packet.

Chapter 455

A Concrete Naming Certificate for $\mathsf{ReachabilityGramian}^{\uparrow}$

The $\mathsf{ReachabilityGramian}^{\uparrow}$ interface records the finite reachability Gramian packet of a finite-dimensional linear control system. Its textbook source is the finite-horizon controllability Gramian of Kalman, *On the General Theory of Control Systems* (1960), and the finite matrix-ledger presentation follows the control-theory notation of Kailath, Sayed, and Hassibi, *Linear Estimation* (2000). The BEDC certificate is only the finite discovery surface consumed by $\mathsf{ControlControllability}^{\uparrow}$, $\mathsf{Riccati}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, and $\mathsf{ModelPredictiveControl}^{\uparrow}$.

The finite Gramian row is a sibling ledger consumed alongside the observability matrix surface of chapter 294 and by the optimization and control surface of chapter 296. The dependency is the shared finite transition and control matrix rows together with the finite horizon ledger, not a host analytic reachability theorem or an ambient control-system semantics.

455.1 Carrier definition

Definition 455.1 (ReachabilityGramianUp finite carrier)**.** *A* $\mathsf{ReachabilityGramian}^{\uparrow}$ *carrier is a finite* BHist *packet with rows*

$$(A, B, n, W, L, C, P, N).$$

Here A is the displayed transition-matrix row, B is the displayed control-matrix row, n is a unary finite-horizon row, W is the displayed finite Gramian-sum ledger with summand columns

$$BB^{\mathsf{T}}, \quad ABB^{\mathsf{T}}A^{\mathsf{T}}, \quad A^2BB^{\mathsf{T}}(A^{\mathsf{T}})^2, \quad \ldots, \quad A^{n-1}BB^{\mathsf{T}}(A^{\mathsf{T}})^{n-1},$$

L is the componentwise hsame *transport ledger for the transition, control, horizon, summand, and Gramian endpoint rows, C is the family of* Cont *routes reading every multiplication, transpose, column append, and finite sum from displayed* $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, *and* $\mathsf{ControlControllability}^{\uparrow}$ *rows, P is the package provenance naming those dependency certificates together with* $\mathsf{Riccati}^{\uparrow}$ *and* $\mathsf{LQR}^{\uparrow}$, *and N is the local* $\mathsf{NameCert}_{\mathsf{ReachabilityGramian}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by componentwise hsame *transport of the A, B, n, W, L, C, P, N rows. It does not quotient by a host reachable subspace, analytic trajectory, controllability rank predicate, covariance equation, or external control-system object.*

Lean4 ✓ `BEDC.Derived.ReachabilityGramianUp.ReachabilityGramianUp single carrier alignment`

455.2 Certificate surface

Theorem 455.2 (ReachabilityGramianUp NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ReachabilityGramian}^{\uparrow}}$ *obligation surface has exactly five finite rows:*

1. *carrier admission for the displayed* A, B, n, W, L, C, P, N *packet of Definition 455.1;*
2. *classifier transport under componentwise* hsame *of the transition, control, horizon, Gramian, summand-ledger, continuation, package, and local certificate rows;*
3. *finite sum ledger exactness, saying that the Gramian endpoint inside* W *is read only as the finite sum of the displayed summand columns inside* W*;*
4. *controllability handoff, saying that the reachability-column surface of* $\mathsf{ControlControllability}^{\uparrow}$ *can consume* A*,* B*,* n*,* W*, and* L *only through the displayed* Cont *and* Pkg *rows;*
5. *non-escape, saying that no accepted route exports a host reachable subspace, analytic trajectory, rank theorem, infinite-horizon Gramian, covariance process, or external solver.*

Lean4 ✓ `BEDC.Derived.ReachabilityGramianUp.ReachabilityGramianBHistCarrier namecert obligations`

Proof. The carrier row is Definition 455.1. It displays the transition row, control row, unary horizon, Gramian endpoint, summand ledger, continuation routes, package provenance, and local naming row as finite BHist coordinates.

Classifier transport is componentwise. Replacing each displayed coordinate by an hsame-matched coordinate leaves the same finite packet shape, so the transported packet is again admitted by the carrier.

For the finite sum ledger, inspect W. Each summand is a displayed matrix product formed from A, B, and transposes, and the Gramian endpoint is the finite fold of precisely those rows. The continuation routes in C record every multiplication and the final sum, while L records the permitted componentwise transports, so no extra analytic Gramian object is available.

The controllability handoff is a projection to the shared A, B, and n rows and to the finite reachability columns named by W. Because those rows are already packaged with $\mathsf{ControlControllability}^{\uparrow}$ provenance and transported only through L, a downstream controllability certificate can read them without importing host semantics.

Non-escape follows from constructor inspection of the carrier. The packet has no coordinate for a host reachable subspace, analytic trajectory, rank theorem, infinite-horizon Gramian, covariance process, or external solver, so none of those objects can be projected by a consumer route. □

Theorem 455.3 (ReachabilityGramianUp controllability handoff)**.** *Every* $\mathsf{ControlControllability}^{\uparrow}$*,* $\mathsf{Riccati}^{\uparrow}$*,* $\mathsf{LQR}^{\uparrow}$*, or* $\mathsf{ModelPredictiveControl}^{\uparrow}$ *consumer of an accepted* $\mathsf{ReachabilityGramian}^{\uparrow}$ *packet can read only the displayed* A *row,* B *row, unary horizon row* n*, finite Gramian-summand and endpoint row* W*,* hsame *transport ledger* L*,* Cont *routes,* Pkg *provenance, and local* NameCert *row of Definition 455.1. The handoff supplies no host reachable-space quotient, no analytic state trajectory, and no infinite-horizon controllability theorem.*

Lean4 ✓ `BEDC.Derived.ReachabilityGramianUp.ReachabilityGramianBHistCarrier controllability handoff`

Proof. Project the accepted packet to the rows A, B, n, W, L, C, P, N. The first three rows are the shared finite control-system coordinates, while W records the finite Gramian discovery ledger and L records the componentwise transport ledger over those same coordinates.

A $\mathsf{ControlControllability}^{\uparrow}$ consumer reads reachability columns through the displayed transition, control, horizon, and continuation rows. A $\mathsf{Riccati}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, or $\mathsf{ModelPredictiveControl}^{\uparrow}$ consumer reads only the resulting finite matrix endpoint and the package provenance that names the source certificates.

The carrier contains no row for a host reachable-space quotient, analytic state trajectory, or infinite-horizon controllability theorem. Therefore the handoff is exactly the finite BEDC packet projection and does not add a control-theory semantic bridge. □

Theorem 455.4 (ReachabilityGramianUp ledger non-escape)**.** *Every exported route from an accepted* $\mathsf{ReachabilityGramian}^{\uparrow}$ *packet factors through the finite rows* A, B, n, W, L, C, P, N *of Definition 455.1. In particular, the packet exports no ambient reachable subspace, no analytic trajectory family, no stochastic covariance process, no infinite-horizon Gramian, no rank-completeness theorem, and no external numerical solver.*

Proof. Take an exported consumer route and project the carrier. The available coordinates are exactly the transition row, control row, horizon row, finite Gramian-summand and endpoint row, transport ledger, continuation routes, package provenance, and local certificate row.

The NameCert obligations account for carrier admission, classifier transport, finite sum exactness, controllability handoff, and non-escape. Each obligation is stated over those displayed coordinates and is preserved by the stored hsame and Cont routes.

Thus every export factors through the listed finite coordinates. Since the carrier contains no ambient reachable subspace, analytic trajectory family, stochastic covariance process, infinite-horizon Gramian, rank-completeness theorem, or external numerical solver, no accepted route can supply one downstream. □

Lean4 ✓ `BEDC.Derived.ReachabilityGramianUp.ReachabilityGramianBHistCarrier ledger nonescape`

Closure status for $\mathsf{NameCert}_{\mathsf{ReachabilityGramian}^{\uparrow}}$.

Constructive story: A $\mathsf{ReachabilityGramian}^{\uparrow}$ packet is generated from displayed transition and control matrix rows, a unary finite horizon, the finite Gramian summand and endpoint row, componentwise hsame transport ledger, Cont routes, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ReachabilityGramian}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 455.1, Definition 455.2, Definition 455.3, and Definition 455.4 enumerate the finite Gramian carrier, NameCert obligations, control handoff, and nonescape surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ReachabilityGramian}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host reachable-subspace semantics, analytic trajectories, stochastic covariance theory, infinite-horizon Gramians, rank-completeness, numerical solvers, or a checked Lean certificate.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked finite-ledger theorems for finite sum exactness, controllability handoff, and non-escape.

Chapter 456

A Concrete Naming Certificate for $\mathsf{TransferOperator}^{\uparrow}$

The $\mathsf{TransferOperator}^{\uparrow}$ packet is a BEDC-native finite certificate surface. It records the finite-window transfer-matrix reading of golden-mean paths as visible BHist rows, with no ambient Banach space, no analytic spectrum, and no imported external theorem.

The packet consumes the finite symbolic source lattice of chapter 370, chapter 434, and chapter 401. $\mathsf{GoldenMeanShift}^{\uparrow}$ supplies the no-adjacent-one window row, $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ supplies the forbidden-pair classifier, and $\mathsf{FibonacciCube}^{\uparrow}$ supplies the finite path-support row read by every accepted transfer-matrix entry.

Definition 456.1 (Transfer operator carrier)**.** *A* $\mathsf{TransferOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, G, S, F, M, R, C, P, N)$$

with the following visible coordinates:

1. *A is the finite adjacency-matrix row, displaying the accepted source row, target row, and matrix entry for each visible transition;*
2. *G is the accepted-window source row from* $\mathsf{GoldenMeanShift}^{\uparrow}$*, specialized to the no-adjacent-one ledger;*
3. *S is the finite forbidden-adjacency and accepted-pair row from* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$*;*
4. *F is the finite path and word-support row from* $\mathsf{FibonacciCube}^{\uparrow}$*, recording the same visible words as path-support packets;*
5. *M is the finite transfer-matrix row, whose entries are read only from the displayed adjacency rows of A, G, S, F;*
6. *R stores the componentwise* hsame *classifier rows for adjacency rows, accepted windows, finite supports, and matrix entries;*
7. *C stores the* Cont *readback routes from rows of M to the corresponding golden-mean, subshift, and Fibonacci-cube source rows;*
8. *P is the* Pkg *provenance naming* $\mathsf{GoldenMeanShift}^{\uparrow}$*,* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$*,* $\mathsf{FibonacciCube}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *source rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TransferOperator}^{\uparrow}}$ *ledger.*

The classifier compares two carriers only by the finite rows $A, G, S, F, M, R, C, P, N$. No coordinate contains an infinite shift space, a Ruelle operator, a spectral radius, a circle-dimension object, or an analytic transfer theorem.

Lean4 ✓ `BEDC.Derived.TransferOperatorUp.TransferOperatorTasteGate single carrier alignment`

Theorem 456.2 (Transfer operator NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{TransferOperator}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the packet of Definition 456.1;*
2. *classifier laws by componentwise* hsame *on adjacency rows, accepted-window rows, subshift ledgers, finite path-support rows, matrix entries, readback routes, package provenance, and the local certificate ledger;*
3. *matrix-entry exactness: every row of M is read from one displayed source-target adjacency row in A together with its G, S, F support rows;*
4. *readback stability: every* Cont *route in C returns to the same finite golden-mean, subshift, and Fibonacci-cube rows that supplied the entry;*
5. *non-escape: an accepted packet exports no analytic transfer operator, no infinite spectrum, no ambient topology, and no external import.*

Lean4 ✓ `BEDC.Derived.TransferOperatorUp.TransferOperatorCarrier namecert obligations`

Proof. Carrier admission is the displayed tuple $T = (A, G, S, F, M, R, C, P, N)$. Each coordinate is either a finite BHist row or a finite route between such rows.

For the classifier laws, inspect the component rows one at a time. The classifier has access only to the displayed hsame rows in R, so reflexive, symmetric, and transitive reads are inherited coordinate by coordinate.

Matrix-entry exactness projects M. An entry is accepted only when its source row, target row, and displayed weight are read from the same adjacency row and from the same G, S, F support rows.

Readback stability then projects C. Each route records where the matrix entry was read from, so returning along the route recovers the finite golden-mean window, the subshift forbidden-pair decision, and the Fibonacci-cube support row used by that entry.

Non-escape follows from the carrier definition. Since no coordinate names an analytic operator, infinite spectrum, topological carrier, or external theorem, downstream consumers can cite only the finite rows and their recorded routes. □

Theorem 456.3 (Transfer operator symbolic source lattice)**.** *Every accepted transfer-matrix entry of a* $\mathsf{TransferOperator}^{\uparrow}$ *packet factors through the symbolic source lattice formed by the* $\mathsf{GoldenMeanShift}^{\uparrow}$ *no-adjacent-one window row, the* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ *forbidden-pair classifier row, and the* $\mathsf{FibonacciCube}^{\uparrow}$ *finite path-support row before it reaches the local matrix ledger M.*

Proof. Project the carrier $T = (A, G, S, F, M, R, C, P, N)$. The matrix row M is not an independent source coordinate; by Definition 456.1, it is read only from the displayed adjacency row together with the support rows G, S, F.

The row G supplies the accepted golden-mean window, so an entry whose source-target pair is one-one has no route into M. The row S supplies the finite forbidden-pair classifier, so the same acceptance decision is visible as a subshift row rather than as an external symbolic-dynamics theorem.

The row F supplies the finite path-support witness. Combining G, S, F gives the complete symbolic source lattice for an accepted entry, and the continuation row C records the route from that lattice into the local matrix ledger.

Thus every accepted matrix entry factors through those three sibling rows before it can be read as a row of M. Since no coordinate bypasses G, S, F, the packet has no kernel-only matrix entry disconnected from its finite symbolic source. □

Lean4 ✓ `BEDC.Derived.TransferOperatorUp.TransferOperator symbolic source lattice`

Theorem 456.4 (Transfer operator golden-mean matrix boundary)**.** *For the golden-mean specialization of a* $\mathsf{TransferOperator}^{\uparrow}$ *carrier, the visible transfer-matrix boundary is the finite two-state adjacency ledger whose only forbidden source-target row is the one-one transition. Hence every accepted matrix entry is indexed by one of the displayed rows zero-zero, zero-one, or one-zero, and every one-one query is rejected by the same singleton forbidden row used by* $\mathsf{GoldenMeanShift}^{\uparrow}$ *and* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$.

Proof. Specialize the G row to the $\mathsf{GoldenMeanShift}^{\uparrow}$ no-adjacent-one ledger and the S row to the $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ singleton forbidden-pair ledger. The displayed forbidden row is exactly the adjacent pair one-one.

Project the adjacency matrix row A. Its accepted source-target rows are those whose pair is absent from the singleton forbidden ledger, so the surviving visible rows are zero-zero, zero-one, and one-zero.

Finally read M through A, G, S, F. Since every matrix entry carries the same readback route in C, a one-one query cannot supply an entry; its route stops at the rejected forbidden row rather than at an accepted matrix row. □

Lean4 ✓ `BEDC.Derived.TransferOperatorUp.TransferOperator golden mean matrix boundary`

Theorem 456.5 (Transfer operator finite-window ledger)**.** *Every exported calculation of an accepted* $\mathsf{TransferOperator}^{\uparrow}$ *packet factors through the finite packet rows* $A, G, S, F, M, R, C, P, N$. *In particular, row sums, path counts, and displayed matrix products are ledger reads over the finite window and do not invoke entropy, inverse limits, quotient shift spaces, spectral measures, or external linear algebra.*

Proof. Take an exported calculation and project the carrier. The only available coordinates are the adjacency rows, golden-mean rows, subshift rows, Fibonacci-cube support rows, transfer-matrix rows, classifier rows, readback routes, package provenance, and local naming ledger.

Row sums and displayed matrix products are finite reuses of rows of M. Each row of M is already tied by C to its source adjacency and support rows.

Therefore every calculation factors through the listed finite ledger. Since the carrier contains no entropy coordinate, inverse-limit carrier, quotient shift space, spectral-measure row, or host matrix object, no exported route can cite such data. □

Lean4 ✓ `BEDC.Derived.TransferOperatorUp.TransferOperator finite window ledger`

Theorem 456.6 (Transfer operator subshift handoff)**.** *The* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ *row* S *is the handoff surface from forbidden-pair ledgers to transfer-matrix entries: transporting* S *componentwise by* hsame *and the recorded* Cont *routes transports precisely the allowed adjacency rows in* A *and therefore transports the supported matrix rows in* M.

Lean4 ✓ `BEDC.Derived.TransferOperatorUp.TransferOperator subshift handoff`

Proof. Project the S coordinate and the classifier row R. The subshift row stores the finite allowed and forbidden neighboring-pair decisions, while R records the componentwise hsame routes for those decisions.

Project A and M next. A matrix row is supported exactly when its source-target pair is accepted by the transported subshift ledger and its finite path support appears in F.

The readback routes in C then repack the transported rows into the same packet shape. Thus the handoff from forbidden-pair decisions to matrix entries is constructive and finite: it is only projection, componentwise transport, and repackaging by P, N. □

Closure status for $\mathsf{NameCert}_{\mathsf{TransferOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{TransferOperator}^{\uparrow}$ packet is generated from a symbolic graph row, subshift row, finite forbidden-pair ledger, adjacency-matrix rows, path-support rows, componentwise hsame transport, displayed Cont readbacks, package provenance, and local naming. The classifier reads a transfer entry only after the source-target pair is accepted by the transported subshift ledger and its finite support appears in the path ledger. The ledger story is finite symbolic handoff: forbidden-pair decisions generate matrix entries by projection, transport, and repackaging, while analytic operators, spectra, entropy, inverse limits, ambient topology, and host matrix objects remain outside the carrier.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TransferOperator}^{\uparrow}}, \mathsf{obligation})$

Scope closed: This chapter binds the carrier definition and the NameCert-obligation, symbolic-source-lattice, golden-mean-matrix-boundary, finite-window-ledger, and subshift-handoff theorems for $\mathsf{TransferOperator}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TransferOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim analytic transfer operators, infinite spectra, ambient topologies, inverse-limit carriers, entropy coordinates, spectral measures, or host matrix objects.

Upgrade path: To reach obligationClosure, the finite symbolic transfer carrier and subshift handoff must be encoded as checked matrix-ledger obligations.

Chapter 457

A Concrete Naming Certificate for HankelVandermondeUp

The HankelVandermondeUp packet is a BEDC-native finite certificate surface. It records a finite determinant ledger for displayed Hankel moment rows and their Vandermonde-square readback. It is consumable by FoldMomentKernel$^{\uparrow}$ and CollisionKernelSpectrum$^{\uparrow}$ without importing host matrices, analytic spectra, quotient moment spaces, or external field algebra. The determinant and Vandermonde-square rows form a finite ledger consumed by chapter 384 and chapter 447: FoldMomentKernel$^{\uparrow}$ supplies the finite fold-moment rows, while CollisionKernelSpectrum$^{\uparrow}$ reads the spectral-shadow consumer boundary through that finite ledger, and HankelVandermondeUp itself exports no analytic spectrum or host matrix carrier.

Definition 457.1 (Hankel-Vandermonde carrier)**.** *A* HankelVandermondeUp *carrier is a finite* BHist *packet*

$$V = (A, W, M, D, \Delta, Q, H, C, P, N)$$

with the following visible coordinates:

1. *A is the displayed atom row, listing the finite atom names whose pairwise differences are read by the determinant ledger;*
2. *W is the weight row, recording the finite coefficient attached to each displayed atom;*
3. *M is the Hankel moment row, whose entries are displayed finite sums over the atom and weight rows;*
4. *D is the determinant-expansion ledger row, listing the finite permutation terms used to read the selected Hankel determinant;*
5. *Δ is the pairwise-difference row, containing only displayed differences between atoms from A;*
6. *Q is the Vandermonde-square product row, recording the finite product of the displayed pairwise differences after squaring and weighting;*
7. *H stores the componentwise* hsame *transports for atom, weight, moment, determinant-ledger, pairwise-difference, and Vandermonde-square rows;*
8. *C stores the displayed* Cont *routes through which determinant and product consumers read the same finite rows;*
9. *P is the* Pkg *provenance naming* BHist, hsame, Cont, FoldMomentKernel$^{\uparrow}$, CollisionKernelSpectrum$^{\uparrow}$, *finite determinant ledgers, and local naming evidence;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HankelVandermondeUp}}$ *evidence row.*

The classifier compares two carriers only by the displayed rows $A, W, M, D, \Delta, Q, H, C, P, N$. It has no coordinate for host matrices, analytic spectra, quotient moment spaces, imported external theorems, or external field algebra.

Lean4 (definition) `BEDC.Derived.HankelVandermondeUp.HankelVandermondeUp`

Lean4 ✓ `BEDC.Derived.HankelVandermondeUp.HankelVandermondeTasteGate single carrier alignment`

Theorem 457.2 (Hankel-Vandermonde NameCert obligations)**.** *Every accepted* HankelVandermondeUp *packet with carrier Definition 457.1 carries five local naming obligations:*

1. *carrier habitation: the tuple $V = (A, W, M, D, \Delta, Q, H, C, P, N)$ is admitted as one finite* BHist *packet;*
2. *classifier transport: componentwise* hsame *and* Cont *transport preserves the displayed atom, weight, moment, determinant-ledger, pairwise-difference, Vandermonde-square, package, and naming rows;*
3. *determinant-ledger exactness: every determinant read passes through the finite permutation ledger D and the displayed Hankel moment row M;*
4. *Vandermonde-square readback: every product read passes through the finite pairwise-difference row Δ and the Vandermonde-square row Q;*
5. *non-escape: accepted carriers export no host matrix object, analytic spectrum, quotient moment space, imported external theorem, or external field algebra.*

These five clauses are the complete local $\mathsf{NameCert}_{\mathsf{HankelVandermondeUp}}$ *surface for finite Hankel-Vandermonde determinant ledgers.*

Lean4 ✓ `BEDC.Derived.HankelVandermondeUp.HankelVandermondeCarrier namecert obligations`

Proof. Carrier habitation is the displayed tuple $V = (A, W, M, D, \Delta, Q, H, C, P, N)$. Each coordinate is a finite BHist row or a finite route between such rows, so the packet is admitted without a host matrix carrier.

For classifier transport, move each visible coordinate through its stored hsame row and read it through the corresponding Cont route. Because the classifier is componentwise, transport cannot create a new atom, weight, moment, determinant term, pairwise difference, product factor, package row, or naming row.

Determinant-ledger exactness is finite ledger inspection. The selected Hankel determinant is read only by expanding along the displayed permutation terms in D, and each term cites entries already present in the moment row M.

The Vandermonde-square readback then projects Δ and Q. Pairwise differences are available only between atoms listed in A, and the squared product row records only the factors displayed by Δ together with the weights from W.

Non-escape follows from the carrier definition. Since no coordinate names a host matrix space, analytic spectral object, quotient moment space, external theorem, or external field algebra, downstream $\mathsf{FoldMomentKernel}^{\uparrow}$ and $\mathsf{CollisionKernelSpectrum}^{\uparrow}$ consumers can cite only the finite rows and routes in the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{HankelVandermondeUp}}$**.**

Constructive story: A HankelVandermondeUp packet is generated from displayed atom rows, weight rows, Hankel moment rows, determinant-expansion ledger rows, pairwise-difference rows, Vandermonde-square product rows, componentwise transports, continuation routes, package provenance, and local naming evidence.

Theory closure: TheoryGate(NameCert$_{\text{HankelVandermondeUp}}$, seed)
Scope closed: The seed scope records the finite carrier and five-clause NameCert surface for Hankel-Vandermonde determinant ledgers.
Formal verification: FormalStatus(NameCert$_{\text{HankelVandermondeUp}}$, unformalized)
Bridge status: none
Origin: ai
Not claimed: This chapter does not close host matrix theory, analytic spectra, quotient moment spaces, external field algebra, external theorem reuse, or a checked Lean certificate.
Upgrade path: Obligation closure requires a Lean carrier encoding and checked NameCert obligation theorem for the displayed determinant and Vandermonde-square rows.

Theorem 457.3 (Hankel-Vandermonde spectral-shadow bridge)**.** *Let*

$$V_H = (A, W, M, D, \Delta, Q, H_H, C_H, P_H, N_H)$$

be an accepted HankelVandermondeUp *carrier. Let*

$$K_\Omega = (W_\Omega, F_\Omega, L_\Omega, I_\Omega, Q_\Omega, T_\Omega, C_\Omega, P_\Omega, N_\Omega)$$

be an accepted FoldMomentKernel$^\uparrow$ *finite-window carrier, and let*

$$C_S = (G, F, V, I, K, S, H_S, T_S, P_S, N_S)$$

be an accepted CollisionKernelSpectrum$^\uparrow$ *carrier. Suppose the shared* FoldMomentKernel$^\uparrow$ *moment surface identifies the collision moment-index row I with the retained row I_Ω, and suppose every displayed spectral-shadow request in S is read at the same finite moment address of the Hankel row M. Suppose also that, at those addresses, the displayed atom row A, weight row W, determinant ledger D, pairwise-difference row Δ, and Vandermonde-square row Q are the rows recorded by the* CollisionKernelSpectrum$^\uparrow$ *provenance through P_S and by the* FoldMomentKernel$^\uparrow$ *provenance through P_Ω.*

Then every downstream consumer route that reads the spectral-shadow row S factors through the finite HankelVandermondeUp *determinant surface*

$$A, W, M, D, \Delta, Q, H_H, C_H, P_H, N_H.$$

More explicitly, each such read first reaches S as a finite row-sum, diagonal weight, or selected moment shadow of the displayed kernel row K, then passes through the common finite moment-index row $I = I_\Omega$, then reads the Hankel moment row M, and finally reaches the determinant ledger D and the Vandermonde-square readback rows Δ, Q. No such consumer route exports a host matrix, analytic spectrum, quotient moment space, selected eigenbasis, external field algebra, or ambient linear-algebra object.

Proof. Project the accepted CollisionKernelSpectrum$^\uparrow$ carrier through Definition 447.1. By Definition 447.3, the row S is not an independent analytic spectrum: each of its displayed entries is a row-sum, diagonal weight, or selected moment shadow of the finite kernel entries in K. By Definition 447.8, any exported spectral-shadow read must pass through the finite moment-index row I together with the visible rows $G, F, V, K, H_S, T_S, P_S, N_S$.

The hypothesis identifies that moment-index row with the retained FoldMomentKernel$^\uparrow$ row I_Ω. Apply Definition 384.5 to the accepted finite-window carrier K_Ω. A moment read over this surface can inspect only the displayed window, fold-source, fiber-ledger, moment-index, collision-count, transport, continuation, package, and local naming rows. If the route is restricted to the retained window, Definition 384.6 keeps the same conclusion inside the packet K_Ω. Thus the

spectral-shadow consumer cannot leave the finite moment surface before it reaches the shared Hankel moment address.

At that shared address, the second hypothesis names the Hankel-Vandermonde rows A, W, M, D, Δ, Q as the rows carried by the collision-spectrum provenance and by the fold-moment provenance. Now apply Definition 457.2. Determinant-ledger exactness forces every determinant read of M through the finite permutation ledger D, and Vandermonde-square readback forces the product read through the displayed pairwise-difference row Δ and the Vandermonde-square row Q, with componentwise transport and continuation stored in H_H and C_H.

Combining the three projections gives the announced factorization. A read of S factors through K, then through the common finite moment-index row $I = I_\Omega$, then through the Hankel moment row M, and finally through D, Δ, Q inside the carrier V_H. The non-escape clauses of Definition 447.4, Definition 384.5, and Definition 457.2 exclude exactly the remaining host matrix, analytic spectrum, quotient moment, selected eigenbasis, external field-algebra, and ambient linear-algebra exports. □

Chapter 458

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailSelector}^{\uparrow}$

Following Bishop–Bridges constructive Cauchy sequence tail selection, the $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ packet names only the finite rows needed to select an inspected tail of a regular rational Cauchy name. The packet sits on the $\mathsf{Real}^{\uparrow}$ and completion path: downstream diagonal-limit and finite-window consumers can cite the selected-tail ledger without obtaining a quotient representative, a host real equality, a selected infinite subsequence, or an ambient completeness principle.

The finite route is anchored in the source-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the locator-facing Cauchy real route of chapter 3410. These siblings supply the visible faces of the selected-tail packet; none supplies an off-packet quotient, selected limit, or countable-choice operator.

The selector is the one-source face of the shared-tail threshold surface in chapter 560. Its selected-tail witness row w is consumed by the sibling meet packet whenever two regular Cauchy sources must share a dyadic threshold; Definition 560.39 is the exact sibling dependency that admits this witness into the shared-threshold route.

Definition 458.1 (Regular Cauchy tail selector carrier)**.** *A* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (q, s, r, d, e, w, H, C, P, N)$$

with the following visible rows:

1. *q is the requested rational precision row, carried by* $\mathsf{Rat}^{\uparrow}$ *and read through the dyadic comparison surface;*
2. *s is the* $\mathsf{StreamName}^{\uparrow}$ *source row whose finite windows are inspected by the selector;*
3. *r is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row certifying that the inspected stream windows obey the displayed Cauchy tolerance schedule;*
4. *d is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row that turns each requested precision into the dyadic-radius comparison used by the tail ledger;*
5. *e is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the selected tail row and regularity row have both been read;*
6. *w is the selected-tail witness row, listing the requested precision, the displayed starting index, the finite suffix window, and the dyadic bounds checked on that window;*

7. *H stores componentwise* hsame *transports for the rational precision row, stream row, regularity row, dyadic readback row, real seal row, selected-tail witness row, package provenance, and local naming row;*
8. *C stores the displayed* Cont *routes by which diagonal-limit, finite-window, and real-seal consumers may read the packet;*
9. *P is the* Pkg *provenance over* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local selector rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSelector}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient of Cauchy streams, a host-level completed real, a globally chosen infinite tail function, or an external real-completeness theorem.

Theorem 458.2 (Regular Cauchy tail selector NameCert obligations)**.** *The carrier of Definition 458.1 satisfies the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSelector}^{\uparrow}}$ *obligation surface. Its five obligation rows are:*

1. *carrier admission for the finite tuple $T = (q, s, r, d, e, w, H, C, P, N)$;*
2. *classifier transport by the componentwise* hsame *rows stored in H and the consumer routes stored in C;*
3. *tail witness exactness, saying that w names only the displayed precision request, starting index, finite suffix window, and dyadic bounds;*
4. *regularity compatibility, saying that each selected-tail bound is read through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row r and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row d before any* $\mathsf{Real}^{\uparrow}$ *seal is exposed;*
5. *seal non-escape, saying that the real-facing route exposes only the finite selected-tail ledger and never a quotient representative, a host real equality, a choice-selected limit, or ambient completeness.*

Proof. Carrier admission is the displayed BHist tuple. Each coordinate is either a finite row, a transport row, a continuation row, package provenance, or the local naming row.

For classifier transport, move the rational precision, stream window, regularity, dyadic readback, seal, witness, package, and local naming coordinates through H, then read them through C. Componentwise transport cannot introduce a tail row outside the tuple.

Tail witness exactness is inspection of w. It records one requested precision, one displayed starting index, one finite suffix window, and the dyadic bounds checked on that window.

Regularity compatibility follows by reading r and d before e. The selected tail is certified by regular rational data and dyadic comparisons, so the real-facing seal is reached only after those rows have been consumed.

The carrier contains no quotient stream, host completed real, global selector, or ambient completeness coordinate. The local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSelector}^{\uparrow}}$ obligations are therefore exhausted by the displayed finite rows. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailSelectorUp.RegularCauchyTailSelectorPacket namecert obligation surface`

Theorem 458.3 (Regular Cauchy tail selector diagonal admissibility)**.** *Every accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet supplies an admissible selected-tail row for diagonal-limit, finite-window, and* $\mathsf{Real}^{\uparrow}$ *seal consumers. A consumer may read the requested rational precision row, the* $\mathsf{StreamName}^{\uparrow}$ *window, the*

RegSeqRat$^{\uparrow}$ *regularity row, the* DyadicRatCore$^{\uparrow}$ *comparison row, the selected-tail witness row, the displayed* hsame *and* Cont *routes, package provenance, and the local* NameCert *row. It cannot obtain a quotient representative of the stream, a host real equality, a choice-selected limiting value, or an ambient completeness theorem.*

Proof. Start with an accepted carrier $T = (q, s, r, d, e, w, H, C, P, N)$. The rows q, s, r, d, w provide the finite precision request, inspected stream window, regularity certificate, dyadic comparison surface, and selected-tail witness.

Read the witness row w through the classifier transport of Definition 458.2. The displayed hsame and Cont routes preserve the same requested precision, starting index, suffix window, and dyadic bounds for any consumer using the packet.

For a diagonal-limit consumer, the admissible input is exactly this finite selected-tail row together with its regularity and dyadic-readback support. The consumer can splice the row into a diagonal read because every bound in w has already been checked against r and d.

For a Real$^{\uparrow}$ or completion-facing consumer, the seal row e is read only after the selected-tail witness and regularity rows have been consumed. Since no coordinate of T is a quotient representative, host real equality, selected limiting value, or ambient completeness proof, the admissible handoff remains the finite selected-tail ledger. □

Theorem 458.4 (Regular Cauchy tail selector classifier transport)**.** *Let $T = (q, s, r, d, e, w, H, C, P, N)$ and $T' = (q', s', r', d', e', w', H', C', P', N')$ be accepted* RegularCauchyTailSelector$^{\uparrow}$ *packets whose rational precision, stream, regularity, dyadic readback, real seal, selected-tail witness, package, and naming rows are matched componentwise by the displayed* hsame *rows and read through the displayed* Cont *routes. Then every selector row available to a diagonal-limit, finite-window, or* Real$^{\uparrow}$ *consumer of T transports to the corresponding selector row of T'.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailSelectorUp.RegularCauchyTailSelectorPacket classifier transport`

Proof. Begin with the componentwise hsame data stored in H and H'. It pairs the rational precision row, source stream row, regularity row, dyadic readback row, seal row, selected-tail witness row, package provenance, and local naming row.

Read those paired rows through the Cont routes in C and C'. By the classifier-transport clause of Definition 458.2, this preserves the same requested precision, starting index, finite suffix window, and dyadic bounds.

The consumer surface is the one described in Definition 458.3. Hence no transported selector row can acquire a quotient representative, host real equality, choice-selected limiting value, or ambient completeness coordinate. □

Theorem 458.5 (Regular Cauchy tail selector precision-window exactness)**.** *For every accepted packet $T = (q, s, r, d, e, w, H, C, P, N)$, the witness row w exhausts the selector precision window: it records exactly the requested rational precision, the displayed starting index, the finite suffix window of s, and the dyadic bounds checked through d against the regularity row r. There is no second selected-tail ledger outside w.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailSelectorUp.RegularCauchyTailSelectorPacket precision window exactness`

↪ variant `BEDC.Derived.RegularCauchyTailSelectorUp.RegularCauchyTailSelectorCarrier precision window exactness`

Proof. Project the carrier of Definition 458.1. The coordinate w is explicitly the selected-tail witness row, and its listed fields are the precision request, starting index, finite suffix window, and dyadic bounds.

Use the tail witness exactness and regularity compatibility clauses of Definition 458.2. They force each bound in w to be read through the $\mathsf{RegSeqRat}^{\uparrow}$ row r and the $\mathsf{DyadicRatCore}^{\uparrow}$ row d before the seal row e is exposed.

The diagonal admissibility theorem Definition 458.3 gives the downstream read boundary. Since T has no alternate selector coordinate, the precision window is exactly w together with its displayed support rows. □

Theorem 458.6 (Regular Cauchy tail selector Real seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted packet* $T = (q, s, r, d, e, w, H, C, P, N)$ *can read only the selected-tail ledger* w*, the regularity row* r*, the dyadic readback row* d*, the displayed* Cont *routes, the* Pkg *provenance row* P*, and the local* NameCert *row* N*, with componentwise transport supplied by* H*. It cannot read a quotient representative, host real equality, chosen limit, infinite tail function, or ambient completeness principle.*

Proof. The Real-facing route starts with Definition 458.3. It allows the seal row only after the selected-tail witness, regularity row, and dyadic readback row have been consumed.

Apply Definition 458.5 to identify the selected-tail ledger with w and its support rows r and d. Apply Definition 458.4 to account for the displayed hsame and Cont routes.

The carrier of Definition 458.1 lists no quotient representative, host real equality, chosen limit, infinite tail function, or ambient completeness coordinate. The Real seal therefore cannot escape the finite selected-tail, regularity, dyadic readback, route, package, and local naming rows. □

Theorem 458.7 (Regular Cauchy tail selector tail-support coverage)**.** *Every accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet exposes exactly the tail-support rows needed by its selected-tail witness surface: the requested precision row, the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row, the selected-tail witness, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *row. It exposes no quotient stream, host equality, infinite tail function, or completeness coordinate.*

Proof. Use the carrier of Definition 458.1. Its coordinates are the finite tuple $T = (q, s, r, d, e, w, H, C, P, N)$, where $q, s, r, d, w, H, C, P, N$ are precisely the support rows named in the statement.

The obligation surface of Definition 458.2 identifies these coordinates as the admitted carrier, classifier-transport rows, witness-exactness row, regularity-compatibility row, and local seal boundary. The diagonal admissibility theorem Definition 458.3 gives the same readable boundary to diagonal-limit, finite-window, and $\mathsf{Real}^{\uparrow}$ consumers.

Finally, Definition 458.6 rules out the four omitted coordinates. Since the carrier has no additional tail-support slot, the exposed surface is exactly the displayed finite ledger. □

Theorem 458.8 (Regular Cauchy tail selector transported-bound preservation)**.** *For accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packets, componentwise* hsame *transport preserves the dyadic bounds recorded in the selected-tail witness. Transport can move the requested precision, stream window, regularity row, dyadic comparison row, witness row, route row, provenance row, and local naming row to their corresponding coordinates, but it cannot create a second bound ledger.*

Proof. Start with the witness-exactness row from Definition 458.2. It places the requested precision, starting index, finite suffix window, and dyadic bounds in the single witness coordinate w.

Apply the classifier-transport theorem Definition 458.4. Componentwise hsame moves the rational precision, stream, regularity, dyadic readback, real seal, witness, package, and naming rows through the displayed Cont routes, preserving the corresponding selector rows for each consumer.

The precision-window exactness theorem Definition 458.5 says that w exhausts the selector precision window. Therefore the transported dyadic bounds remain the bounds recorded in w, and no second ledger can be introduced by transport. □

Theorem 458.9 (Regular Cauchy tail selector diagonal consumer package)**.** *Diagonal-limit, finite-window, and* $\mathsf{Real}^{\uparrow}$ *consumers of an accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet receive a single finite package assembled from tail-support coverage, transported-bound preservation, and the admissible selected-tail row of Definition 458.3. The package contains the finite witness ledger and its support rows, and no consumer receives an additional quotient, equality, infinite-tail, or completeness coordinate.*

Proof. First assemble the readable support rows using Definition 458.7. This gives the requested precision, stream window, regularity, dyadic comparison, selected-tail witness, transport, continuation, provenance, and local naming rows.

Next apply Definition 458.8. The dyadic bounds carried by the selected-tail witness survive componentwise transport as the same finite ledger, with no second bound record.

Finally use Definition 458.3. The diagonal-limit, finite-window, and $\mathsf{Real}^{\uparrow}$ consumer routes read the assembled finite package through the admissible selected-tail row. The non-escape boundary of Definition 458.6 excludes any additional quotient, equality, infinite-tail, or completeness coordinate. □

Theorem 458.10 (Regular Cauchy tail selector finite induction)**.** *Every accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *route over a finite inspected tail window is generated by induction over the displayed finite support row. The induction preserves the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, precision-window exactness, classifier transport, Real seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. No step introduces an infinite-tail coordinate, quotient equality of regular Cauchy streams, host real equality, or ambient completeness.*

Proof. Induct on the finite support list exposed by Definition 458.7.

In the empty case, the route exposes only the base precision window. The carrier still displays the requested precision, stream row, regularity row, dyadic readback, selected-tail witness, transport, replay, provenance, and local naming, and Definition 458.5 identifies that base window as the whole selector ledger.

For the step case, append one inspected tail coordinate to the finite support list. Tail-support coverage attaches that coordinate to the same selected-tail witness row, while Definition 458.8 keeps the dyadic bounds stable under componentwise hsame transport.

It remains to check that the consumer route has not changed type. Apply Definition 458.12 to keep the new inspected coordinate on the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ handoff before the $\mathsf{Real}^{\uparrow}$ seal is read.

Finally use the diagonal consumer package theorem above and the Real seal non-escape theorem. The inductively generated package is exactly the finite support route read by diagonal-limit, finite-window, and Real-facing consumers, so no additional quotient, infinite tail, host equality, or completeness coordinate is available. □

Theorem 458.11 (Regular Cauchy tail selector scope window)**.** *For every accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet*

$$T = (q, s, r, d, e, w, H, C, P, N),$$

the selected-tail witness window is bound to the displayed BHist *carrier, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. A selector consumer can read the requested precision, starting index, finite suffix window, and dyadic bounds only through* w, H, C, P, N.

Proof. Read the carrier in Definition 458.1. The only selected-tail coordinate is w, and the only structural rows exposing it are H, C, P, N.

Use the obligation surface of Definition 458.2. Its tail witness exactness clause identifies the requested precision, starting index, finite suffix window, and dyadic bounds as the complete content of w.

Apply Definition 458.5 to exclude a second selector ledger. The selected window is therefore scoped by the displayed BHist, hsame, Cont, Pkg, and NameCert rows. □

Theorem 458.12 (Regular Cauchy tail selector RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff consumed by a* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet reads its dyadic bounds through the* $\mathsf{StreamName}^{\uparrow}$ *source row and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row before any* $\mathsf{Real}^{\uparrow}$ *seal is exposed. The handoff route is*

$$s, r, d, w, H, C, P, N \to e,$$

where s *supplies the inspected stream windows,* r *supplies the regularity ledger,* d *supplies dyadic comparison, and* w *records the selected finite tail window.*

Proof. Start from the regularity compatibility row in Definition 458.2. It requires each selected-tail bound to be read through r and d before the seal row e is exposed.

The witness window itself is fixed by Definition 458.5. Its finite suffix is a window of the $\mathsf{StreamName}^{\uparrow}$ source row s, and its bounds are the dyadic comparisons supplied through d against the regularity row r.

Finally apply Definition 458.6. The Real-facing consumer receives the finite selected-tail package after this route and cannot bypass the StreamName, RegSeqRat, or DyadicRatCore rows. □

Theorem 458.13 (Regular Cauchy tail selector Real consumer boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet can read only the finite selector package*

$$q, s, r, d, w, H, C, P, N.$$

It cannot obtain quotient equality of regular Cauchy streams, a selected infinite tail, host real equality, or ambient completeness from the selector packet.

Proof. Use the diagonal admissibility theorem Definition 458.3. It names the finite precision, stream, regularity, dyadic readback, selected-tail witness, transport, route, provenance, and local naming rows available to Real-facing consumers.

Apply the scope-window theorem Definition 458.11 and the RegSeqRat handoff theorem Definition 458.12. Together they bind the witness window to the finite carrier and force the dyadic bounds through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ before the seal is read.

The non-escape theorem Definition 458.6 then rules out quotient equality, selected infinite tails, host real equality, and ambient completeness. No other carrier coordinate can supply those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ packet is generated from a rational precision row, a stream-name row, a regular rational Cauchy row, a dyadic readback row, a real seal row, a selected-tail witness row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyTailSelector}\uparrow}$, maturePackageClosed)

Scope closed: Definition 458.1, Definition 458.2, and Definition 458.3 record the finite selected-tail witness surface for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyTailSelector}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.RegularCauchyTailSelectorUp.RegularCauchyTailSelectorPacket\_classifier\_transport`

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient equality of regular Cauchy streams, host real equality, a selected infinite tail function, ambient completeness, or a checked Lean certificate.

Upgrade path: No further paper-axis theory step remains for this tail-selector packet; bridge checking remains a separate verification-axis task.

Chapter 459

A Concrete Naming Certificate for $\mathsf{RegularCauchyNegation}^{\uparrow}$

The $\mathsf{RegularCauchyNegation}^{\uparrow}$ interface names the finite sign-flip surface for a regular rational Cauchy name. Following Bishop and Bridges, *Constructive Analysis*, the construction treats negation as a displayed transformation of dyadic observations and tolerance ledgers: a consumer may inspect the source name, the scheduled windows, the sign-flipped dyadic rows, and the $\mathsf{Real}^{\uparrow}$ seal handoff, but it cannot form a quotient stream, compare host sequence equality, select a limit, or appeal to ambient real completeness.

The packet is the unary sign-flip sibling consumed by chapter 417 and chapter 429. Those siblings read the same finite window, dyadic observation, classifier, and $\mathsf{Real}^{\uparrow}$ seal boundary rather than host completed-real arithmetic.

Definition 459.1 (RegularCauchyNegation carrier)**.** *A* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, W, D, R, F, E, H, C, P, N)$$

with the following displayed coordinates:

1. *X is the* $\mathsf{RegularCauchyName}^{\uparrow}$ *source row whose regular rational observations are to be sign-flipped;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule naming the finite source reads for each requested precision;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row read from X through W;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *pointwise classifier row for the source regular Cauchy name and its scheduled rational observations;*
5. *F is the sign-flipped dyadic observation ledger, recording for each displayed row of D the dyadic row with the same precision data and the opposite signed endpoint;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row through which downstream real-name consumers receive the sign-flipped regular sequence;*
7. *H stores componentwise* hsame *transports for the source row, window schedule, dyadic observation row, classifier row, sign-flipped ledger, and seal row;*
8. *C stores the displayed* Cont *routes for reading the source window, forming the sign-flipped dyadic row, transporting the classifier, and exposing the seal handoff;*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyNegation}^{\uparrow}}$ *row.*

The packet is a finite naming certificate for the negated regular Cauchy name. It stores no quotient stream, no host sequence equality proof, no selected limit, and no ambient real-completeness object.

Lean4 (definition) `BEDC.Derived.RegularCauchyNegationUp.RegularCauchyNegationCarrier`

Theorem 459.2 (RegularCauchyNegation NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyNegation}^{\uparrow}}$ *surface for the carrier of Definition 459.1 consists of five finite obligations:*

1. *carrier admission: the accepted object is the displayed packet G with a* $\mathsf{RegularCauchyName}^{\uparrow}$ *source row,* $\mathsf{StreamName}^{\uparrow}$ *window schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row,* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row, sign-flipped ledger,* $\mathsf{Real}^{\uparrow}$ *seal handoff, transport rows, continuation rows, provenance, and local naming data;*
2. *classifier transport: classification transports X, W, D, R, F, E componentwise through the stored* hsame *and* Cont *rows;*
3. *sign-flip stability: replacing the source by a classified regular Cauchy name preserves the finite window schedule and recomputes the same kind of sign-flipped dyadic observation ledger;*
4. *finite-window transport: every negated observation is obtained by reading the finite window named by W and then applying the displayed sign flip in* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
5. $\mathsf{Real}^{\uparrow}$ *seal handoff: every real-name consumer of the negated row first reads $X, W, D, R, F, E, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNegationUp.RegularCauchyNegationCarrier namecert obligations`

Proof. Carrier admission is projection from the tuple in Definition 459.1. The source name, window schedule, dyadic observation row, classifier row, sign-flipped ledger, seal handoff, transport routes, continuation routes, package row, and local naming row are explicit coordinates of G.

Classifier transport is componentwise. The $\mathsf{RegularCauchyName}^{\uparrow}$ row transports its scheduled observations, the $\mathsf{StreamName}^{\uparrow}$ windows transport the finite reads, the $\mathsf{DyadicRatCore}^{\uparrow}$ row transports the observed endpoint data, and the $\mathsf{RegSeqRat}^{\uparrow}$ classifier transports the pointwise regular rational readback.

The sign-flip and seal clauses are finite. The ledger F is formed from the displayed dyadic row D without choosing a completed value, and the $\mathsf{Real}^{\uparrow}$ handoff E consumes that ledger only after the source window and classifier have been exposed. Thus no quotient stream, host sequence equality proof, selected limit, or ambient completeness principle is available to the consumer. □

Theorem 459.3 (RegularCauchyNegation diagonal compatibility)**.** *For every accepted* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *carrier*

$$G = (X, W, D, R, F, E, H, C, P, N),$$

the sign-flipped packet commutes with the two standard regular-Cauchy consumer routes: a $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *consumer may first diagonalize the displayed source windows and then read the sign-flipped dyadic ledger, while a* $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *consumer may first read the pointwise classifier row and then consume the same* $\mathsf{Real}^{\uparrow}$ *seal handoff. Both routes expose the same finite rows $X, W, D, R, F, E, H, C, P, N$ and no quotient stream, host sequence equality, selected limit, or ambient real-completeness object.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNegationUp.RegularCauchyNegationCarrier diagonal limit readout`

Proof. For the diagonal route, read the source row through the $\mathsf{RegularCauchyName}^{\uparrow}$ surface and its $\mathsf{StreamName}^{\uparrow}$ schedule. The $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ consumer selects only finite displayed windows, so the dyadic row D remains the observation row named by the carrier.

Apply the sign-flip ledger after the diagonal read. Since F is computed pointwise from the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ rows of D, the diagonal consumer receives the same finite sign-flipped observations and the same transported hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance.

For the limit-classifier route, first expose the $\mathsf{RegSeqRat}^{\uparrow}$ pointwise classifier row R. The $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ consumer then reaches the $\mathsf{Real}^{\uparrow}$ seal row E only through R and the sign-flipped ledger F.

The two routes therefore differ only in the order in which finite rows are read. The compatibility uses the same source windows, dyadic observations, classifier row, sign-flip ledger, and seal handoff, and it does not introduce quotient streams, host sequence equality, selected limits, or ambient completeness. □

Theorem 459.4 (RegularCauchyNegation algebraic handoff)**.** *Every consumer that combines* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *with* $\mathsf{RegularCauchySum}^{\uparrow}$ *or* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *factors through the displayed sign-flipped ledger F, the source classifier row R, and the* $\mathsf{Real}^{\uparrow}$ *seal handoff E. The sum route reads the negated row as one finite summand; the difference route reads it as the displayed unary part of pointwise subtraction. Neither route may bypass $X, W, D, R, F, E, H, C, P, N$ to obtain a quotient stream, host sequence equality, selected limit, or ambient completeness premise.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNegationUp.RegularCauchyNegationCarrier algebraic handoff`

Proof. Begin with the local obligations of Definition 459.2. They force every sign-flipped observation through the source window W, dyadic row D, and ledger F before any algebraic consumer sees the row.

For a $\mathsf{RegularCauchySum}^{\uparrow}$ consumer, F is simply the displayed dyadic observation row supplied for one summand, and R supplies the regular rational classifier needed by the sum readback. The consumer therefore reads the negated name as a finite summand rather than as an equality class of completed streams.

For a $\mathsf{RegularCauchyDifference}^{\uparrow}$ consumer, the same rows supply the unary sign-flip surface that pointwise subtraction may inspect. The difference packet can read the displayed opposite endpoint and its tolerance data from F, then route the result through the same $\mathsf{Real}^{\uparrow}$ seal handoff E.

The carrier inventory exhausts both algebraic handoffs. Since no coordinate of G is a quotient stream, host sequence equality proof, selected limit, or ambient completeness theorem, neither algebraic route can export such data. □

Theorem 459.5 (RegularCauchyNegation carrier transport)**.** *Let*

$$G = (X, W, D, R, F, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyNegation}^{\uparrow}$ *carrier. Displayed* hsame *transport of the* $\mathsf{RegSeqRat}^{\uparrow}$ *source classifier row R, the sign-flipped window row F, the dyadic tolerance ledger D, and the* $\mathsf{Real}^{\uparrow}$ *seal row E, together with the stored source, schedule, route, package, and local naming rows, preserves the* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *carrier predicate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNegationUp.RegularCauchyNegationCarrier transport`

Proof. Project the carrier of Definition 459.1. The source row, window schedule, dyadic observation row, classifier row, sign-flipped ledger, seal row, transports, routes, provenance, and local name are all coordinates of the same finite packet.

Apply the classifier transport clause in Definition 459.2. It transports X, W, D, R, F, E componentwise through the stored H and C rows. The diagonal compatibility theorem keeps the transported finite windows attached to the same dyadic observations, and the algebraic handoff theorem keeps the seal handoff routed through the same F, R, E rows. □

Theorem 459.6 (RegularCauchyNegation sign-flip ledger stability)**.** *For an accepted* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *carrier, the sign-flip route records no hidden host negation. Every negated observation is obtained from the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row through the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window ledger and is then recorded in the sign-flipped ledger* F *before any* $\mathsf{Real}^{\uparrow}$ *seal handoff.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNegationUp.RegularCauchyNegationCarrier sign flip ledger stability`

Proof. Begin with the finite-window transport obligation in Definition 459.2. It requires each negated observation to read the window schedule W and dyadic row D before the sign-flipped ledger F is consumed.

The diagonal compatibility theorem shows that changing the consumer route does not change these rows: the diagonal and limit-classifier reads both expose $X, W, D, R, F, E, H, C, P, N$. The algebraic handoff theorem then confirms that sum and difference consumers also factor through F, R, and E. Thus the sign flip is a finite ledger operation and not a hidden host-level negation. □

Theorem 459.7 (RegularCauchyNegation limit-classifier compatibility)**.** *The negated* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *packet respects the limit classifier inherited from* $\mathsf{RegSeqRat}^{\uparrow}$ *and hands off to the same* $\mathsf{Real}^{\uparrow}$ *seal row* E*. A* $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *consumer may inspect the pointwise classifier row* R *and the sign-flipped ledger* F*, but it receives the real-name boundary only through the displayed seal handoff* E*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNegationUp.RegularCauchyNegationCarrier limit classifier compatibility`

Proof. Use the $\mathsf{Real}^{\uparrow}$ seal handoff clause of Definition 459.2. It forces every real-name consumer to read the source, window, dyadic, classifier, sign-flipped, seal, transport, route, package, and naming rows.

Now apply diagonal compatibility. Its limit-classifier route exposes R before reaching E, and it reaches E only through R and the sign-flipped ledger F. The algebraic handoff theorem preserves this same boundary when the negated row is consumed by sum or difference packets, so the inherited limit classifier and the $\mathsf{Real}^{\uparrow}$ seal remain compatible. □

Theorem 459.8 (RegularCauchyNegation public RealUp seal export)**.** *For every accepted* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *carrier*

$$G = (X, W, D, R, F, E, H, C, P, N),$$

the public consumer boundary exported to $\mathsf{Real}^{\uparrow}$ *is exactly the displayed seal row* E *reached through* $X, W, D, R, F, H, C, P, N$*. Any additive-inverse, sum, difference, diagonal, or limit-classifier consumer of the negated regular Cauchy name must pass through the same seal row* E*, and it receives no quotient stream, host sequence equality, selected limit, or ambient completeness premise.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNegationUp.RegularCauchyNegationCarrier public seal export`

Proof. Begin with the five finite obligations in Definition 459.2. Carrier admission exposes the rows $X, W, D, R, F, E, H, C, P, N$, and the $\mathsf{Real}^{\uparrow}$ handoff clause says that a real-name consumer reaches the public boundary only after those rows have been read.

For algebraic consumers, use Definition 459.4. Sum and difference routes read the negated packet through the sign-flipped ledger F, the source classifier row R, and the same seal handoff E; no additive-inverse interface is allowed to replace E by a host-level completed-real operation.
