Proof. Start with terminal consumer readiness. It places every terminal normalization or closed-substitution read behind the displayed packet R, so O is consumed as a row with the branch, descent, audit, boundary, and naming data still attached.

Apply boundary factorization. Any public route from O into a ClosedTermSubstitutionBoundary$^{\uparrow}$ or MetaCICNormalizationFrontier$^{\uparrow}$ consumer passes through B, D, A, H, C, P, G, N after the generator admission rows I, E, M have fixed the authorized surface.

Use normalization consumer nonescape to restrict the target consumer. The normalization frontier receives the recursor-generated output only as the authorized finite route already consumable by the closed-substitution boundary, and not as hidden induction, unchecked generation, detached normalization, subject reduction, host equality, or external proof production.

Finally apply the strict obstruction corollary. A proposed reuse that bypasses one of the listed rows is exactly a local obstruction at the named terminal route. Therefore the admissible MetaCIC reuse is precisely the factored boundary route, while detached subject reduction, host equality, hidden generator, and proof-producing-channel readings are rejected. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalOutputMetaCICReus`

Theorem 525.102 (AuthorizedGeneratorRecursor root carrier route)**.** *Every closed-substitution-facing route from an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet factors through the displayed packet rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The route may expose the accepted signature, emitted recursor, motive, branch package, descent row, output row, audit row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, ground-compiler boundary, and local* NameCert *row, but it has no route coordinate outside that finite carrier.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootCarrierRoute`

Proof. Start from the carrier of Definition 525.1. It lists exactly the packet rows $I, E, M, B, D, O, A, H, C, P, G, N$, so a closed-substitution-facing consumer begins from the same finite route used by the root recursor surface.

Apply Definition 525.50. The normalization and closed-substitution consumers receive O only after signature admission, branch coverage, structural descent, audit provenance, and the ground-compiler boundary have been displayed.

Finally use Definition 525.48 and Definition 525.7. These identify the consumer route with the same BHist, hsame, Cont, Pkg, boundary, and NameCert rows, leaving no additional carrier for an off-packet substitution read. □

Theorem 525.103 (AuthorizedGeneratorRecursor closed substitution gate)**.** *For a sibling* ClosedTermSubstitutionB *consumer, the output row O of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet is reachable only after the signature rows I, E, M, branch row B, descent row D, audit row A, componentwise transport row H, displayed continuation row C, package row P, ground-compiler boundary row G, and local naming row N have all been carried in the same finite packet. In particular, the consumer reaches O through* Cont, Pkg, *and* NameCert *rows rather than through a detached substitution principle.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorClosedSubstitutionGate`

Proof. First invoke Definition 525.102. It places every closed-substitution-facing route inside the displayed packet before any consumer reads the output row.

Next apply Definition 525.50. This forces the output read behind accepted signatures, branch coverage, structural descent, audit provenance, and the sibling closed-substitution boundary rows.

The remaining rows are the transport and naming rows. By Definition 525.48, the route exposes H, C, P, G, N as componentwise hsame transport, displayed Cont replay, Pkg provenance, ground-compiler boundary, and local NameCert data. Thus the sibling consumer reaches O only after the stated route has been displayed. □

Theorem 525.104 (AuthorizedGeneratorRecursor audit ledger nonescape)**.** *The audit ledger exported by an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet carries no hidden generator, host induction principle, external axiom, unaudited dependency route, or off-packet substitution channel. Every audit-facing closed-substitution read remains inside the route*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

and inside the local BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows displayed by that packet.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorAuditLedgerNonescape`

Proof. Begin with the carrier route of Definition 525.102. Since every closed-substitution-facing route factors through the finite packet, the audit ledger has no independent source row from which to export a hidden generator or host induction principle.

Next use the closed substitution gate of Definition 525.103. The output row is reachable only after the signature, branch, descent, audit, transport, continuation, package, boundary, and local naming rows have been displayed.

Finally apply Definition 525.7. The handoff consumes the same finite carrier and supplies no external axiom, unaudited dependency route, or off-packet substitution channel. Therefore the audit ledger remains nonescaping for the displayed authorized-generator packet. □

Corollary 525.105 (AuthorizedGeneratorRecursor root route strict obstruction)**.** *Let an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet be read by a* ClosedTermSubstitutionBoundary$^{\uparrow}$ *consumer through the root route of Definition 525.102. Any consumer-facing use of the obstruction recorded by Definition 525.104 is strict and local: it can block only the named converse or reuse route that tries to read the output row O without the displayed packet rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Equivalently, the obstruction is confined to the failure of an off-packet closed-substitution, hidden-generator, host-induction, unaudited-dependency, or detached-output route. It cannot be reinterpreted as a global impossibility theorem, a host theorem, or hidden external validation of any coordinate outside the accepted AuthorizedGeneratorRecursor$^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootRouteStrictObstructio`

Proof. Read the root carrier route first. By Definition 525.102, every closed-substitution-facing route from the accepted packet factors through exactly the finite carrier

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The same statement identifies the exposed data as the accepted signature, emitted recursor, motive, branch package, descent row, output row, audit row, componentwise hsame transport, displayed Cont replay, Pkg provenance, ground-compiler boundary, and local NameCert row. Hence a consumer-facing route has no independent coordinate from which to read a second generator, a detached substitution principle, a host induction principle, or an external theorem.

Now apply Definition 525.104. The audit ledger carries no hidden generator, host induction principle, external axiom, unaudited dependency route, or off-packet substitution channel, and every audit-facing closed-substitution read remains inside the displayed carrier and inside the local BHist, hsame, Cont, Pkg, and NameCert rows. Thus a displayed failure, refusal, separation, or countermodel row can only deny the attempted converse or reuse route at the packet coordinate where that route asks to leave the carrier.

The remaining interpretations are outside the finite route. A global impossibility theorem would quantify beyond the accepted packet; a host theorem would add semantic strength not carried by $I, E, M, B, D, O, A, H, C, P, G, N$; hidden external validation would require an extra validating row not present among A, H, C, P, G, N. Since the cited carrier and ledger theorems give no such coordinate, the obstruction has exactly its local blocking force against the named converse or reuse route and no wider export surface. □

Theorem 525.106 (AuthorizedGeneratorRecursor acceptance totality)**.** *Every accepted* AuthorizedGeneratorRecurs *carrier exposes its branch, descent, audit, output, and local* NameCert *rows through the finite route*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The branch row B, descent row D, audit row A, output row O, displayed BHist *carrier, componentwise* hsame *transport H, displayed* Cont *route C,* Pkg *provenance P, ground boundary row G, and local* NameCert *row N are all available from the accepted packet and no consumer may read a detached recursor surface before these rows have been displayed.*

Proof. Start from the carrier of Definition 525.1. Its accepted packet lists exactly the signature, emitted recursor, motive, branch, descent, output, audit, transport, continuation, provenance, boundary, and naming rows.

Apply Definition 525.102. It places every closed-substitution-facing read inside the same finite route and makes the branch, descent, audit, and output rows visible only as packet coordinates.

The naming and replay coordinates are supplied by Definition 525.48 and Definition 525.7. These identify H, C, P, G, N as the displayed BHist, hsame, Cont, Pkg, and NameCert support for the same accepted carrier. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCarrier acceptance totality`

Theorem 525.107 (AuthorizedGeneratorRecursor output stability)**.** *For two accepted* AuthorizedGeneratorRecurso *packets whose displayed branch, descent, audit, transport, continuation, provenance, boundary, and local naming rows are related by the shown* hsame *and* Cont *routes, every output read of O is stable along those routes. The output cannot be separated from the branch package B, descent row D, audit row A,* Pkg *provenance P, ground boundary G, and local* NameCert *row N that present it.*

Proof. First expose the output through Definition 525.106. The read of O begins only after the branch, descent, audit, transport, continuation, provenance, boundary, and naming rows have been displayed in the same finite packet.

Next apply Definition 525.112. It prevents an output consumer from detaching O from A, G, N or from replacing the accepted audit route with a host-side read.

The displayed hsame and Cont rows then transport the same packet surface componentwise. Since no off-packet generator coordinate is exported, any output read along those routes is the same accepted output read carried by B, D, A, P, G, N. □

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCarrier output stability

Theorem 525.108 (AuthorizedGeneratorRecursor ledger separation)**.** *Audit-ledger reads of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet do not import host recursion, hidden generators, or closed-substitution facts not already present in*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Every audit read factors through the displayed branch, descent, output, transport, continuation, provenance, ground-boundary, and local NameCert *rows of the packet.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCarrier ledger separation

Proof. Begin with Definition 525.104. The audit ledger has no independent source for hidden generators, host induction, external axioms, unaudited dependencies, or off-packet substitution channels.

Use Definition 525.103. Closed-substitution-facing reads reach the output only after the accepted signature, branch, descent, audit, transport, continuation, provenance, boundary, and naming rows have been carried together.

Finally apply Definition 525.110. The ground-compiler consumer reads the same finite packet, so the audit ledger cannot import a recursion principle or substitution fact absent from $I, E, M, B, D, O, A, H, C, P,$ □

Corollary 525.109 (AuthorizedGeneratorRecursor acceptance obstruction locality)**.** *Let an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet be read through the acceptance-totality surface. Any displayed failure, refusal, separation, or countermodel row cited from the route*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

blocks only the named converse or reuse route whose read would detach O from the displayed branch, descent, audit, transport, continuation, provenance, boundary, or local naming rows. The same row cannot be reinterpreted as a global impossibility result, a host theorem, or hidden external validation for a coordinate absent from the displayed packet.

Proof. By Definition 525.106, every accepted read begins from the finite packet $I, E, M, B, D, O, A, H, C, P, G, N$. Thus a consumer-facing obstruction has access only to the listed signature, emitted recursor, motive, branch, descent, output, audit, transport, continuation, provenance, boundary, and local NameCert coordinates.

Apply Definition 525.108. It says that audit-ledger reads of the same packet do not import host recursion, hidden generators, external axioms, unaudited dependencies, or closed-substitution facts beyond the displayed rows, and that every audit read factors through the branch, descent, output, transport, continuation, provenance, ground-boundary, and local NameCert rows. Therefore a cited separation or refusal row can obstruct only a read that asks for one of the excluded off-packet

coordinates. Reading it as a global impossibility theorem, a host theorem, or an external validation certificate would require exactly the kind of unlisted coordinate that ledger separation rejects.

It remains to check that the obstruction is strict for output reuse. By Definition 525.107, every accepted output read of O is stable only along the displayed hsame and Cont routes and cannot be separated from B, D, A, P, G, N. Hence a converse or reuse route that omits or replaces those rows is not another interpretation of the accepted output; it is the named failed route blocked at the displayed packet boundary. The obstruction therefore stays local to that coordinate and exports no additional impossibility, host-side theorem, or hidden validation principle. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorAcceptanceObstructionLoca`

Theorem 525.110 (AuthorizedGeneratorRecursor ground compiler authorization)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet, any ground-compiler consumer of the recursor output must read the packet through the displayed rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The consumer may reach O only after the accepted signature row I, emitted eliminator row E, motive row M, branch row B, structural descent row D, audit row A, BHist *carrier row, displayed* Cont *row C, package row* Pkg *at P, boundary row G, and local* NameCert *row N have all been retained in the same route.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor ground compiler authorization`

Proof. Start with the carrier of Definition 525.1. It presents the accepted recursor output as one row of the finite BHist packet, so the ground compiler has no initial read outside $I, E, M, B, D, O, A, H, C, P, G, N$.

The computational rows are fixed by the existing branch and descent obligations. Apply Definition 525.2 and Definition 525.5; the branch row is exhausted by the displayed constructors, and the recursive use is local to the motive and descent rows.

The audit and naming side is fixed by Definition 525.6, Definition 525.79, and Definition 525.7. These rows retain audit provenance, carrier admission, boundary exhaustion, Pkg provenance, and the local NameCert certificate before any ground-compiler consumer may read O. □

Theorem 525.111 (AuthorizedGeneratorRecursor finite route exposure)**.** *Every public route exposed by an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet is exhausted by the finite packet rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Consequently the public surface cannot introduce an unregistered branch, a hidden induction channel, or an off-packet generator path beyond the accepted signature, eliminator, motive, branch, descent, output, audit, transport, continuation, package, boundary, and local certificate rows.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorFiniteRouteExposure`

Proof. Read the route from Definition 525.102. It already factors every closed-substitution-facing public route through the displayed packet and leaves no carrier coordinate outside the finite row list.

Branch exposure is exhausted by Definition 525.2. A public route can name only the branch package associated with the accepted constructors and the emitted eliminator, so an unregistered branch has no row from which to enter.

The remaining escape routes are closed by descent locality and ledger descent. Use Definition 525.5, Definition 525.104, and Definition 525.7; together they keep recursive use, audit provenance, and ground-compiler consumption inside the same finite packet. □

Theorem 525.112 (AuthorizedGeneratorRecursor output audit nonescape)**.** *For every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *root packet, the output row O cannot be consumed apart from the audit provenance row A, the ground-compiler boundary row G, and the local certificate row N. Any consumer of O must preserve the same displayed route through audit provenance, boundary exposure, and* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *certification.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorOutputAuditNonescape`

Proof. Begin with Definition 525.6. It attaches public exposure of O to the audit and provenance rows, so the output cannot be read as an isolated generator result.

The boundary side is supplied by Definition 525.79. The row G is exhausted by the displayed packet and cannot export a hidden proof generator, external axiom, or detached induction channel.

Finally apply Definition 525.110. Since every ground-compiler consumer reads O only after the carrier, audit, boundary, package, and local $\mathsf{NameCert}$ rows are retained, the output row has no nonescaping consumer route apart from A, G, N and the finite packet that carries them. □

Corollary 525.113 (AuthorizedGeneratorRecursor ground-compiler authorization strict obstruction)**.** *Let an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *root packet be read by a ground-compiler consumer. Suppose a displayed failure, refusal, separation, or countermodel row is cited against a named converse or reuse route for the output row O. Then the row is a strict local obstruction: it blocks only the named route whose consumer-facing use tries to read, omit, detach, replace, or bypass one of the displayed packet rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

In particular every permitted consumer-facing use of the cited row factors through the audit row A, the componentwise transport row H, the displayed Cont *row C, the package row P, the ground-compiler boundary row G, and the local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row N before it can speak about O. The same row cannot be reinterpreted as a global impossibility theorem, a host theorem, hidden external validation, or a certificate for any coordinate not displayed by the accepted packet.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorGroundCompilerAuthorizati`

Proof. Start with finite route exposure. By Definition 525.111, every public route exposed by the accepted packet is exhausted by

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The theorem also excludes an unregistered branch, a hidden induction channel, and an off-packet generator path beyond the accepted signature, eliminator, motive, branch, descent, output, audit, transport, continuation, package, boundary, and local certificate rows. Hence any consumer-facing use of a displayed failure, refusal, separation, or countermodel row has no public coordinate outside that finite list.

Now apply output-audit nonescape, Definition 525.112. A consumer of O cannot detach the output row from audit provenance A, boundary exposure G, and local certification N; it must preserve the same displayed route through those rows. Together with the ground-compiler authorization route already displayed in the chapter, this forces the consumer-facing readback through

A, H, C, P, G, N, where H carries componentwise transport, C carries the displayed Cont replay, P carries package provenance, G carries the ground-compiler boundary, and N carries the local name certificate.

Consider the cited displayed row. If the named converse or reuse route asks to read O while omitting, replacing, detaching, or bypassing one of the rows above, the two cited theorems place the obstruction exactly at that missing packet coordinate. Thus the row blocks that named route and no other route that remains inside the displayed carrier.

It remains to rule out stronger readings. A global impossibility theorem would require a public conclusion not confined to the accepted packet and not indexed by the named failed route. A host theorem would require a host-facing theorem coordinate not among $I, E, M, B, D, O, A, H, C, P, G, N$. Hidden external validation would require an extra validation or certificate row outside A, H, C, P, G, N. Finite route exposure gives no such coordinate, and output-audit nonescape prevents O from being read apart from the displayed audit, boundary, transport, continuation, package, and local naming route. Therefore the obstruction remains strict and local to the named ground-compiler converse or reuse route. □

Theorem 525.114 (AuthorizedGeneratorRecursor root signature totality)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N),$$

the accepted signature is total over the displayed constructor row I, emitted recursor row E, motive row M, branch package row B, structural descent row D, output row O, audit row A, componentwise hsame *row H, displayed* Cont *row C,* Pkg *row P, boundary row G, and local* NameCert *row N. Thus the signature cannot be read apart from the finite carrier described by Definition 525.1.*

Proof. Start with carrier admission and acceptance totality. They expose the finite packet $R = (I, E, M, B, D, O, A, H, C, P, G, N)$ and require every accepted signature read to pass through the same displayed constructor, recursor, motive, branch, descent, output, audit, transport, continuation, package, boundary, and local naming rows.

Next use the finite route exposure and root authorization obligations. The generator route is not a hidden host eliminator; it is the accepted signature carried by I, checked by the local NameCert surface, and replayed through the displayed Cont and Pkg rows.

Finally attach the ground compiler authorization. Since the compiler-facing route reads only the displayed packet, no unchecked generator row or unregistered recursion principle can supply a second signature source. The accepted signature is therefore total over the displayed root rows. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootSignatureTotality`

Theorem 525.115 (AuthorizedGeneratorRecursor root branch descent ledger)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet $R = (I, E, M, B, D, O, A, H, C, P, G, N)$, every root branch descent that reaches the output row O is routed through the branch package row B and the structural descent row D before O is available. The ledger admits no proof-producing branch source, hidden host induction, or external recursive call outside the displayed carrier.*

Proof. Read the branch package first. Branch exhaustion and root branch package coverage keep every branch consumption on the accepted constructor signature, emitted recursor, motive, and branch package rows.

Now attach descent. Structural descent locality, branch descent totality, and root descent-audit coupling require recursive branch use to pass through D before the output row O and audit row A can be read.

The terminal branch descent exactness then supplies the root ledger boundary. A route that skipped B or D would need either a proof-producing branch source or a hidden host induction coordinate, but neither coordinate is present in R. □

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootBranchDescentLedger

Theorem 525.116 (AuthorizedGeneratorRecursor root output audit exactness)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet* $R = (I, E, M, B, D, O, A, H, C, P, G, N)$*, output audit exactness keeps the output row* O*, audit row* A*, transport row* H*, continuation row* C*, package row* P*, boundary row* G*, and local* NameCert *row* N *attached inside the same finite packet. No terminal or root consumer may detach* O *from* A, H, C, P, G, N *by appealing to hidden host induction, unregistered recursion, unchecked generator rows, or proof-producing branch sources.*

Proof. Begin with output-audit non-escape and root output audit totality. These results bind O to audit provenance, boundary exposure, package provenance, and local NameCert certification rather than to a detached generator authority.

Next use root host boundary NameCert exhaustion together with terminal audit NameCert non-escape. The output-facing route remains visible only through A, H, C, P, G, N and the displayed rows that carry them.

Finally apply terminal generator admission. Since terminal normalization, closed-substitution, and generator-audit consumers read O only as part of $I, E, M, B, D, O, A, H, C, P, G, N$, the excluded host-induction, unregistered-recursion, unchecked-generator, and proof-producing branch sources have no packet row through which to enter. □

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootOutputAuditExactness

Theorem 525.117 (AuthorizedGeneratorRecursor terminal generator admission)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, every terminal generator-facing consumer route is admitted only through the displayed packet rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

In particular, a terminal normalization, closed-substitution, or generator-audit consumer may read the output row O *only as a row of this finite carrier and never as a detached generator authority.*

Proof. Start with the carrier admission and total route surface. By Definition 525.34, Definition 525.106, and Definition 525.111, the accepted packet displays exactly the signature, eliminator, motive, branch, descent, output, audit, transport, continuation, provenance, boundary, and local naming rows.

Next use terminal consumer readiness. Definition 525.97 keeps terminal normalization and closed-substitution consumers behind the same displayed carrier, while Definition 525.110 gives the ground compiler no read outside the same packet rows.

Finally apply output-audit nonescape. By Definition 525.112, the terminal consumer cannot detach O from the audit, boundary, and local NameCert rows, so admission is exhausted by $I, E, M, B, D, O, A, H, C, P, G, N$. □

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalGeneratorAdmissio

Theorem 525.118 (AuthorizedGeneratorRecursor terminal branch descent exactness)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, any terminal branch consumption that reaches the output row* O *must first pass through the branch row* B *and the structural-descent row* D*. No terminal route may consume a branch, recursive call, or output-facing generator result unless the branch is carried by* B *and the descent evidence is carried by* D *inside the same displayed packet.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalBranchDescentExac

Proof. Read the branch surface first. Definition 525.2 and Definition 525.69 force every public branch read to stay on the accepted constructor list and the displayed branch package.

Now attach descent locality. By Definition 525.5, Definition 525.13, and Definition 525.61, a recursive read is public only when its descent evidence is recorded in D together with the accepted signature, emitted eliminator, motive, and branch row.

The terminal step is supplied by Definition 525.97 and Definition 525.110. Since terminal consumers read O only after the finite packet has been displayed, a branch route that skipped either B or D would require a packet coordinate that the carrier does not expose. □

Theorem 525.119 (AuthorizedGeneratorRecursor terminal audit NameCert nonescape)**.** *For every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet, terminal output cannot be consumed apart from the audit row A, the ground-boundary row G, and the local* $\mathsf{NameCert}$ *row N. The terminal route exports no output consumer outside the audit ledger, boundary exposure, and local certificate carried by the same packet.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalAuditNameCertNone

Proof. Begin with the output-audit row. Definition 525.112 binds any consumer of O to audit provenance, boundary exposure, and local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ certification.

Next use the output and boundary readiness results. Definition 525.46, Definition 525.79, and Definition 525.110 keep terminal output consumption on the displayed audit, boundary, package, and local naming rows.

Finally apply terminal consumer readiness. Definition 525.97 leaves no terminal normalization, closed-substitution, or generator-audit route outside the finite packet, so O has no consumer apart from A, G, N and the displayed rows that carry them. □

Corollary 525.120 (AuthorizedGeneratorRecursor terminal generator strict obstruction)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. Suppose a displayed failure, refusal, separation, or countermodel row is cited against a named terminal-generator converse or reuse route in the terminal generator obligation surface of R. Then the row is a strict local obstruction: it blocks only the named route whose consumer-facing use tries to read, omit, detach, replace, or bypass one of the displayed packet coordinates*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Every permitted terminal-generator use of the row factors through the same route block I, E, M, B, D, O, A, the componentwise transport row H, the displayed continuation readback row C, the provenance row P, the ground-boundary row G, and the local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row N. The same displayed row cannot be reinterpreted as a global impossibility theorem, a host theorem about generators, hidden external validation, or an obstruction to any terminal consumer route that still remains inside those displayed rows.*

Proof. Start with terminal generator admission, Definition 525.117. It admits every terminal generator-facing consumer route only through the finite packet rows

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

It also states that terminal normalization, closed-substitution, and generator-audit consumers may read O only as a row of this finite carrier and never as detached generator authority. Hence a consumer-facing use of the cited failure, refusal, separation, or countermodel row has no initial terminal-generator coordinate outside the displayed packet.

Now apply terminal audit NameCert nonescape, Definition 525.119. Terminal output cannot be consumed apart from the audit row A, the ground-boundary row G, and the local NameCert row N carried by the same packet. Thus any terminal use that speaks about O must retain the route rows that carry the output and audit, the transport and continuation rows H, C, the provenance row P, and the boundary-certificate rows G, N.

Consider the named converse or reuse route against which the displayed row is cited. If that route tries to read O before the route block I, E, M, B, D, O, A is present, or tries to omit the transport row H, the continuation readback row C, the provenance row P, the ground-boundary row G, or the local certificate row N, the two cited theorems locate the obstruction at that missing displayed coordinate. Therefore the row blocks precisely that named terminal-generator route, namely the route whose consumer-facing use fails to remain inside the admitted finite carrier and the audit-certificate nonescape route.

It remains to exclude stronger readings. A global impossibility theorem would require a conclusion not indexed by the accepted packet R and not confined to the named failed route. A host theorem about generators would require a host-facing generator coordinate outside $I, E, M, B, D, O, A, H, C, P, G, N$. Hidden external validation would require an additional validation or certificate row beyond A, G, N and the same displayed packet rows that carry them. Terminal generator admission exposes no such coordinate, and terminal audit NameCert nonescape prevents O from being read apart from the displayed audit, boundary, provenance, transport, continuation, and local naming data. Hence the obstruction is strict and local to the named terminal-generator converse or reuse route. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalGeneratorStrictOb`

Theorem 525.121 (AuthorizedGeneratorRecursor terminal authorized output cover)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, terminal authorized output is exposed only through the displayed generator, branch, output, audit, route, provenance, and local* NameCert *rows. More precisely, any terminal consumer of the output row O must remain inside the finite* BHist *carrier*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

with componentwise hsame *transport at H, displayed* Cont *replay at C, package provenance at* Pkg *on P, audit provenance at A, boundary exposure at G, and local naming evidence at N.*

Proof. Start from terminal generator admission. By Definition 525.117, every terminal generator-facing consumer route is admitted only through the displayed packet rows, and the output row is not available as detached generator authority.

Next attach the ground compiler surface. Definition 525.110 forces any ground-compiler consumer of O to retain the signature, eliminator, motive, branch, descent, audit, BHist, Cont, Pkg, boundary, and local NameCert rows in the same route.

Finally use the existing audit and terminal nonescape facts. Definition 525.112 binds O to audit provenance, boundary exposure, and local certification, while Definition 525.119 keeps terminal output consumption on the displayed audit, boundary, package, and naming rows. Thus terminal authorized output is covered exactly by the displayed rows listed above. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCarrier terminal authorized output cover`

Theorem 525.122 (AuthorizedGeneratorRecursor terminal branch ledger lock)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, the terminal branch ledger is locked to the closed-substitution and ground-compiler authorization rows already displayed by the chapter. A terminal consumer may read a branch, recursive call, or output-facing generator result only through the branch row B, descent row D, audit row A, componentwise* hsame *row H, displayed* Cont *row C, package provenance row P, ground-boundary row G, and local* NameCert *row N carried by the same finite packet.*

Proof. First read the branch ledger through the terminal branch exactness result. Definition 525.118 requires every terminal branch consumption that reaches O to pass through B and D inside the displayed packet.

Next lock this branch route to closed substitution. By Definition 525.103, a sibling closed-substitution consumer reaches O only after the signature, branch, descent, audit, transport, continuation, package, boundary, and local naming rows have all been carried in one finite route.

The ground-compiler side supplies the same authorization surface. Definition 525.110 allows the consumer to reach O only after those displayed rows have been retained. Therefore the terminal branch ledger has no independent branch authority beyond the closed-substitution and ground-compiler rows already exposed by the packet. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalBranchLedgerLock`

Theorem 525.123 (AuthorizedGeneratorRecursor terminal reader nonescape)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, terminal consumers cannot read hidden generator state, host evaluation, unchecked recursion, or private audit routes. Every terminal read of generator output, branch evidence, descent evidence, audit provenance, continuation replay, package provenance, or local naming data remains inside the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of the packet.*

Proof. Begin with the finite route surface. Definition 525.111 exhausts public routes by

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Hence a terminal reader has no carrier coordinate for hidden generator state or host evaluation outside the displayed packet.

Now use the audit ledger and terminal generator facts. Definition 525.104 blocks hidden generators, host induction principles, external axioms, unaudited dependency routes, and off-packet substitution channels, while Definition 525.117 keeps terminal generator-facing routes on the displayed carrier.

It remains to exclude private terminal audit routes. Definition 525.119 attaches terminal output consumption to the audit, boundary, package, and local NameCert rows, and Definition 525.103 keeps closed-substitution reads behind hsame, Cont, Pkg, and NameCert data. Thus terminal consumers cannot escape to hidden generator state, host evaluation, unchecked recursion, or private audit routes. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalReaderNonescape`

Corollary 525.124 (AuthorizedGeneratorRecursor terminal authorize strict obstruction)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted AuthorizedGeneratorRecursor$^{\uparrow}$ *packet. Suppose a displayed failure, refusal, separation, or countermodel row is attached to a named terminal-authorize converse, reuse, or readback*

route in the terminal authorized-output surface of R. Then the row is a strict local obstruction: it blocks only the named route whose consumer-facing use tries to read, omit, replace, detach, or bypass one of the displayed terminal coordinates

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Every permitted terminal-authorize use factors through the displayed branch, descent, output, audit, transport, continuation, package provenance, ground-boundary, and local NameCert *rows of the same packet. The same displayed row cannot be reinterpreted as a global impossibility theorem, a host theorem about recursors, hidden external validation of the failed route, an unchecked generator, hidden generator state, host evaluation, unchecked recursion, a private audit route, or an obstruction to any terminal consumer route that still factors through those displayed rows.*

Proof. Fix the accepted packet R. By Definition 525.123, every terminal read of generator output, branch evidence, descent evidence, audit provenance, continuation replay, package provenance, or local naming data remains inside the displayed BHist, hsame, Cont, Pkg, and NameCert rows of R. The same theorem also excludes hidden generator state, host evaluation, unchecked recursion, and private audit routes. Thus a consumer-facing terminal-authorize use has no coordinate outside

$$I, E, M, B, D, O, A, H, C, P, G, N$$

from which to obtain an alternate generator, host evaluator, private audit path, or external certificate.

Apply Definition 525.122 to the branch side of the same terminal use. A terminal consumer may read a branch, recursive call, or output-facing generator result only through the branch row B, descent row D, audit row A, componentwise hsame row H, displayed Cont row C, package provenance row P, ground-boundary row G, and local NameCert row N carried by the same finite packet. Hence the terminal branch ledger supplies no independent branch authority and no second authorization route beyond the closed-substitution and ground-compiler rows already displayed by R.

Now consider the displayed failure, refusal, separation, or countermodel row. If the row is attached to a named terminal-authorize converse, reuse, or readback route, the reader nonescape theorem forces any consumer-facing use of that row to remain on the displayed reader coordinates, while the branch ledger lock forces the branch, recursive-call, and output-facing parts of the use to remain on B, D, A, H, C, P, G, N. Therefore the row can obstruct only the named local route at the coordinate where that route tries to read, omit, replace, detach, or bypass one of the displayed packet rows.

A stronger reading would require data that neither cited theorem exposes. A global impossibility theorem would require a theorem surface beyond the finite terminal packet; a host theorem about recursors would require host evaluation or host recursion data; hidden external validation would require an external certificate route; an unchecked generator, hidden generator state, unchecked recursion, or private audit route would require exactly the off-packet coordinates ruled out by terminal reader nonescape; and an independent branch authorization would contradict the terminal branch ledger lock. Since every permitted terminal consumer still factors through the displayed rows of R, the obstruction is strict and local to the named terminal-authorize route. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalAuthorizeStrictOb`

Theorem 525.125 (AuthorizedGeneratorRecursor root source)**.** *Every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *recursor route exposes the generator source, authorization token, boundary row, displayed* Cont

route, Pkg *provenance, ledger row, and local* NameCert *row before a consumer may read the output. Concretely, the route remains inside the finite* BHist *packet*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

where I names the accepted source signature, E names the emitted generator row, B names the authorized branch package, G names the boundary row, C names the displayed continuation route, P names package provenance, and N names the local certificate.

Proof. Start from carrier admission in Definition 525.34. It identifies the accepted recursor route with the displayed finite BHist packet and leaves no separate generator-source coordinate.

Use the route authorization surface of Definition 525.93. The source signature, emitted recursor, motive, branch package, descent row, output row, audit row, and local certificate are all read through the same accepted route.

Finally apply the boundary and terminal output rows. Theorems 525.74 and 525.121 force any output-facing read to pass through G, C, P, N together with the displayed ledger and package rows. Hence generator source, authorization token, boundary, continuation, provenance, ledger, and local naming are exposed before output consumption. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootSource`

Theorem 525.126 (AuthorizedGeneratorRecursor boundary closure)**.** *Every closed substitution or generator-normalization consumer of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *output must pass through the displayed source, authorization, boundary,* Cont*,* Pkg*, ledger,* hsame*, and* NameCert *rows before reading O. The consumer may use the output only as a row of the packet $I, E, M, B, D, O, A, H, C, P, G$, not as a detached substitution rule or host generator.*

Proof. First use the closed-substitution handoff. Definition 525.86 requires every closed-substitution consumer to remain inside the displayed BHist, hsame, Cont, Pkg, and NameCert route.

Next use terminal readiness. Definition 525.84 states that O is available only after the signature, emitted recursor, motive, branch package, descent, audit, transport, continuation, provenance, boundary, and local certificate rows have all been retained.

The generator-normalization side is therefore not a separate host route. By Definition 525.122, every terminal branch read is locked to the closed-substitution and ground-compiler authorization rows already displayed by the packet. Thus closed substitution and generator normalization pass through the displayed boundary before reading the output. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorBoundaryClosure`

Theorem 525.127 (AuthorizedGeneratorRecursor ledger nonescape)**.** *No ledger of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet can export an unlicensed generator, host recursion oracle, or hidden substitution step. Every ledger-facing read of generator source, authorization, boundary evidence, continuation replay, package provenance, componentwise* hsame *transport, or local naming data remains inside the displayed* BHist*,* Cont*,* Pkg*, and* NameCert *rows of the same packet.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorLedgerNonescape`

Proof. Begin with the root source theorem above. It exposes generator source, authorization, boundary, continuation, provenance, ledger, and local naming as displayed rows of one finite packet.

Apply boundary closure. Any closed substitution or generator-normalization consumer that reaches O has already passed through the displayed boundary, hsame, Cont, Pkg, and NameCert rows.

It remains to exclude hidden authority. Theorems 525.36 and 525.123 rule out hidden generator state, host evaluation, unchecked recursion, and private audit routes. Therefore the ledger has no coordinate from which to export an unlicensed generator, host recursion oracle, or hidden substitution step. □

Theorem 525.128 (AuthorizedGeneratorRecursor root-unblock carrier admission)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, root-unblock carrier admission exposes exactly the rows*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

before any output-facing read. These rows are the accepted source signature, emitted generator, motive, branch package, structural descent, output, audit, componentwise transport, continuation, provenance, boundary, and local NameCert *rows of the displayed* BHist *packet.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootUnblockCarrierAdmissi`

Proof. Start from the carrier admission theorem Definition 525.34. It identifies an accepted root packet with the displayed finite BHist carrier and gives no row outside $I, E, M, B, D, O, A, H, C, P, G, N$.

Use the root source theorem above to place generator source, authorization token, boundary, continuation, provenance, ledger, and local naming on the same admitted packet. Thus the output row O is not visible before the surrounding admission rows have been displayed.

Finally apply boundary closure. The boundary, hsame, Cont, Pkg, and NameCert rows stay attached to the same carrier before any closed-substitution or generator-normalization consumer may read O, so the carrier admission is exhausted by the stated finite packet. □

Theorem 525.129 (AuthorizedGeneratorRecursor root-unblock route totality)**.** *Every output-facing root-unblock route for an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet passes through the source signature, emitted generator, motive, branch package, descent, output, audit, transport, continuation, provenance, boundary, and local* NameCert *rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

No output-facing route skips one of these rows or reads O through a detached generator route.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootUnblockRouteTotality`

Proof. First read route authorization, Definition 525.93. It places accepted signature, emitted recursor, motive, branch package, descent row, output row, audit row, and local certificate on one accepted route.

Next use the root-unblock carrier admission just established. It supplies the remaining displayed transport, continuation, provenance, and boundary rows as part of the same BHist packet before output consumption.

Finally apply the boundary and terminal cover rows: Definition 525.126, Definition 525.74, and Definition 525.121. These force every output-facing route through A, H, C, P, G, N after I, E, M, B, D and keep O inside the displayed carrier rather than on a detached generator channel. □

Theorem 525.130 (AuthorizedGeneratorRecursor root-unblock ledger nonescape)**.** *No ledger read of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root-unblock packet exports an unlicensed generator, host recursion oracle, detached substitution step, or hidden authorization. Every ledger-facing read remains inside the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootUnblockLedgerNonescap`

Proof. Begin with ledger nonescape above. It already rules out unlicensed generators, host recursion oracles, and hidden substitution steps for ledger-facing reads of generator source, authorization, boundary evidence, continuation replay, package provenance, transport, and local naming data.

Then apply root-unblock route totality. Every output-facing route has already passed through the source signature, emitted generator, motive, branch package, descent, output, audit, transport, continuation, provenance, boundary, and local NameCert rows, so no ledger read can obtain a second authorization route.

It remains to exclude detached substitution. Boundary closure and the terminal reader nonescape theorem Definition 525.123 keep closed-substitution, generator-normalization, and terminal output reads inside the same displayed packet. Hence the ledger has no coordinate from which to export hidden authorization or a substitution step outside the root-unblock packet. □

Corollary 525.131 (AuthorizedGeneratorRecursor root source strict obstruction)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted AuthorizedGeneratorRecursor$^{\uparrow}$ *recursor route. Suppose a displayed failure, refusal, separation, or countermodel row is attached to a named converse, reuse, or readback route at the root-source surface of R. Then the row is a strict local obstruction: it blocks only the named route whose consumer-facing use tries to read the generator source, authorization token, boundary row, displayed* Cont *route,* Pkg *provenance, ledger row, componentwise* hsame *transport, or local* NameCert *row away from the displayed packet coordinates*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Every permitted consumer-facing use factors through the root-source exposure rows and then through the ledger-facing BHist*,* Cont*,* Pkg*,* hsame*, and* NameCert *rows of the same packet. The same displayed row cannot be reinterpreted as a global impossibility theorem for recursors, a host theorem, hidden external validation of the failed route, an unlicensed generator, a host recursion oracle, a detached substitution step, a private authorization channel, or any obstruction to a consumer route that still factors through the displayed rows of R.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootSourceStrictObstructi`

Proof. Fix an accepted recursor route R. By Definition 525.125, the generator source, authorization token, boundary row, displayed Cont route, Pkg provenance, ledger row, and local NameCert row are exposed before a consumer may read the output, and they are exposed only inside the finite BHist packet

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Thus a consumer-facing use of the root source has no independent source coordinate, no authorization token outside the route, no boundary row outside G, no continuation route outside C, no provenance row outside P, and no local certificate outside N.

Apply Definition 525.127 to the ledger side of the same route. Every ledger-facing read of generator source, authorization, boundary evidence, continuation replay, package provenance, componentwise hsame transport, or local naming data remains inside the displayed BHist, Cont, Pkg, and NameCert rows of the packet. The ledger therefore exports no unlicensed generator, host recursion oracle, or hidden substitution step.

Now consider the displayed failure, refusal, separation, or countermodel row. If it is attached to a named converse, reuse, or readback route, the first cited theorem forces the attempted consumer-facing use to pass through the root-source packet coordinates, while the second cited theorem forces its ledger component to remain on the displayed transport, continuation, provenance, boundary, and local-name rows. Hence the row can block only the local route at the coordinate where that route tries to read, omit, replace, detach, or bypass one of those displayed rows.

Any stronger interpretation would require a coordinate not supplied by the packet. A global impossibility theorem would require a theorem surface beyond the finite root-source carrier; a host theorem would require host recursion or host evaluation data; hidden external validation would require an external certificate route; an unlicensed generator, host recursion oracle, detached substitution step, or private authorization channel would require exactly the exports ruled out by ledger nonescape. Since neither cited theorem exposes such a coordinate, the obstruction remains strict and local to the named converse, reuse, or readback route, and it does not block any consumer route that continues to factor through the displayed rows of R. □

Theorem 525.132 (AuthorizedGeneratorRecursor grounded acceptance surface)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *carrier, the generator-row input is admitted only as a displayed* BHist *row of the same root packet*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The accepted surface reads E through the source signature I, branch package B, structural descent row D, componentwise hsame *row H, displayed* Cont *replay row C,* Pkg *provenance row P, boundary and ledger row G, and local* NameCert *row N. Hence no acceptance read can treat the generator as a detached host recursor, an abstract carrier equivalence, or an unstated authorization token.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor grounded acceptance surface`

Proof. Start with the root-unblock carrier admission of Definition 525.128. It identifies the accepted generator-row input with the finite BHist packet $I, E, M, B, D, O, A, H, C, P, G, N$ and gives no off-packet coordinate for generator admission.

Next use route totality, Definition 525.129. The output-facing route must pass through the source signature, emitted generator, motive, branch package, descent, output, audit, transport, continuation, provenance, boundary, and local certificate rows before any consumer may read the output.

Finally apply the root carrier and route surfaces in Definition 525.144 and Definition 525.145. These keep the ground-compiler and TasteGate-facing reads attached to the same finite packet, so acceptance is grounded in concrete BHist, hsame, Cont, Pkg, and NameCert rows rather than in carrier-equivalence transport. □

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorLedgerNonescapeSurface

Theorem 525.133 (AuthorizedGeneratorRecursor readback provenance surface)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, any readback of the generated output O is provenance-preserving: it must pass through the componentwise* hsame *row H, the displayed* Cont *replay row C, the* Pkg *row P, the boundary ledger G, and the local* NameCert *row N of the same* BHist *carrier. A readback therefore cannot replace O by a hidden generator output, a host normalization result, or a package whose provenance is detached from I, E, M, B, D, A.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorReadbackProvenanceSurface

Proof. Begin with the ledger provenance closure of Definition 525.146. It keeps audit ledger and output provenance inside A, H, C, P, G, N before any closed-substitution, normalization-frontier, or operational-membrane consumer reads O.

The readback route is then the same displayed replay route. By Definition 525.126, closed-substitution and generator-normalization consumers pass through the displayed source, authorization, boundary, Cont, Pkg, ledger, hsame, and NameCert rows before reading the output.

Use root-unblock route totality to recover the source side of the packet. Since I, E, M, B, D remain attached to O through H, C, P, G, N, the readback has a concrete provenance surface and cannot be substituted by a detached output package. □

Theorem 525.134 (AuthorizedGeneratorRecursor ledger nonescape surface)**.** *No ledger-facing read of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet can export an unlicensed generator, hidden authorization, host recursion oracle, detached substitution step, or provenance-free output. Every such read remains inside the displayed* BHist *packet and its* hsame*,* Cont*,* Pkg*, boundary, and* NameCert *rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The ledger therefore records nonescape for generator-row input, readback, continuation replay, package provenance, local naming, and boundary evidence on the existing AuthorizedGenerator-Recursor root carrier surface.

Proof. First apply the root-unblock ledger nonescape theorem, Definition 525.130. It rules out unlicensed generators, host recursion oracles, detached substitution steps, and hidden authorization for ledger-facing reads of the displayed root-unblock packet.

Next attach output provenance through the readback surface above. Any read of O has already passed through H, C, P, G, N together with the source and branch rows, so the ledger cannot export a provenance-free output.

Finally combine consumer nonescape with terminal readiness. Theorems 525.36, 525.123, and 525.84 keep closed-substitution, terminal output, and ground-compiler-facing consumers inside the same displayed carrier. Thus the ledger has no escape coordinate beyond the concrete Authorized-GeneratorRecursor root carrier surface. □

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootLedgerNonescapeSurfac

Corollary 525.135 (AuthorizedGeneratorRecursor grounded acceptance strict obstruction)**.** *Let an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet be read through the grounded acceptance surface. If a displayed failure, refusal, separation, or countermodel row is cited against a converse or reuse route for that packet, then the obstruction is strict local data: it blocks only the named route whose read leaves one of the displayed coordinates*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Equivalently, the obstruction applies only to a read that tries to detach the generator row E, the output row O, the componentwise hsame *row H, the displayed* Cont *replay row C, the* Pkg *provenance row P, the boundary ledger row G, or the local* NameCert *row N from the same root packet. It cannot be read as a global impossibility theorem, a host theorem, or hidden external validation for any coordinate not displayed by the packet.*

Proof. By Definition 525.132, grounded acceptance admits the generator-row input only as a displayed BHist row of the same root packet. The accepted read of E is therefore routed through the source signature I, branch package B, structural descent row D, componentwise hsame row H, displayed Cont replay row C, Pkg provenance row P, boundary ledger row G, and local NameCert row N. This already fixes the domain of any consumer-facing objection: it may inspect the shown packet rows, but it has no separate host recursor, carrier-equivalence route, or unstated authorization token to inspect.

Apply Definition 525.134. Ledger-facing reads of the same accepted packet cannot export an unlicensed generator, hidden authorization, host recursion oracle, detached substitution step, or provenance-free output. Every such read remains inside the displayed BHist packet and its hsame, Cont, Pkg, boundary, and NameCert rows. Hence any cited failure, refusal, separation, or countermodel row has force only at the coordinate where the attempted converse or reuse route leaves those rows.

Now suppose the same displayed row were reinterpreted as a global impossibility theorem, a host theorem, or hidden external validation. Such a reinterpretation would have to supply a conclusion beyond the grounded acceptance packet: either a host-side theorem not routed through $I, E, M, B, D, O, A, H, C, P, G, N$, an impossibility claim not indexed by the named failed route, or a validation certificate not carried by H, C, P, G, N. The grounded acceptance surface gives no such coordinate, and ledger nonescape forbids exporting one from the ledger. Therefore the obstruction remains strict and local to the named converse or reuse route. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorGroundedAcceptanceStrict(`

Theorem 525.136 (AuthorizedGeneratorRecursor acceptance budget cover)**.** *Every accepted* AuthorizedGeneratorR *output exposes source, branch, budget, audit, and local* NameCert *rows before any consumer route may read the terminal output. Concretely, the consumer-facing output route remains inside the finite carrier*

$$I, E, M, B, D, O, A, H, C, P, G, N,$$

where I, E, M name the source signature, emitted eliminator, and checked motive, B, D name branch and descent budget rows, A names audit, G names the ground-compiler boundary, and N names the local certificate.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorAcceptanceBudgetCover`

Proof. Begin with carrier admission. By Definition 525.1 and Definition 525.144, every accepted output row O is already a row of the displayed packet $I, E, M, B, D, O, A, H, C, P, G, N$.

The source and budget rows are retained by route totality. Apply Definition 525.89: the public route cannot reach O without the accepted signature, emitted eliminator, motive, branch package, structural descent, audit, continuation, package, boundary, and local naming rows.

Finally attach the ground and public-consumer constraints. The ground-compiler handoff of Definition 525.7, the ledger nonescape theorem Definition 525.104, and the public-consumer boundary Definition 525.18 keep the consumer route on the same finite carrier. Hence accepted output is covered by source, branch, budget, audit, and NameCert rows before it is public. □

Theorem 525.137 (AuthorizedGeneratorRecursor ground-route refusal surface)**.** *Any* AuthorizedGeneratorRecurso *route that lacks the ground-compiler witness row G is retained as* GAP*-ledger content rather than exported as a public ground route. Such a route may name source, branch, output, audit, continuation, and provenance data, but it cannot be consumed as a ground-compiler handoff until G is present in the same carrier.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorGroundRouteRefusalSurface`

Proof. Read the ground-compiler handoff theorem. Definition 525.7 places every compiler-facing read behind the carrier row G together with the audit, continuation, package, and local naming rows.

If G is absent, the route fails the same admission test used by Definition 525.145. The route may still be recorded by the audit ledger, but the ledger nonescape theorem Definition 525.104 prevents ledger data from becoming a compiler handoff.

Therefore the route remains at the refusal surface. The public-consumer boundary of Definition 525.18 can read O only through the saturated carrier, so a carrier missing G is not exported as a ground route. □

Theorem 525.138 (AuthorizedGeneratorRecursor terminal output readback totality)**.** *The terminal output readback of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet is exhausted by the displayed carrier, ledger, audit, and boundary rows. Every terminal read of O factors through $I, E, M, B, D, O, A, H, C, P, G, N$ and no terminal consumer receives a hidden generator, detached branch budget, unaudited output, off-packet boundary witness, or external recursion principle.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalOutputReadbackTot`

Proof. Start with the displayed carrier. Root carrier admission and Definition 525.157 place every terminal output route inside $I, E, M, B, D, O, A, H, C, P, G, N$.

Next use the ledger and audit rows. Definition 525.104 confines audit-facing reads to the displayed ledger, while Definition 525.91 keeps output exposure behind the same audit and route data.

Finally use the boundary rows. The ground-compiler handoff and public-consumer boundary theorems keep G, N attached to any terminal readback. Since the carrier has no coordinate for a hidden generator, detached branch budget, unaudited output, off-packet boundary witness, or external recursion principle, the displayed rows exhaust the terminal readback surface. □

Corollary 525.139 (AuthorizedGeneratorRecursor acceptance budget strict obstruction)**.** *In the acceptance-budget surface for* AuthorizedGeneratorRecursor$^{\uparrow}$*, a ground-route attempt missing the boundary row G is a strict local obstruction. It blocks exactly the attempted converse or reuse route that reads O as a public ground-compiler handoff through the displayed carrier*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

It does not assert that accepted recursor output is globally impossible, that the host has supplied an independent theorem, or that hidden external validation has been found. Any such reading would require a coordinate outside the accepted source, branch, budget, audit, transport, continuation, package, boundary, and local NameCert *rows.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorAcceptanceBudgetStrictObs

Proof. By Definition 525.136, every consumer-facing read of an accepted output factors through the finite carrier $I, E, M, B, D, O, A, H, C, P, G, N$ before O is public. Thus a consumer route can use source data through I, E, M, branch and descent budget data through B, D, output and audit data through O, A, transport and continuation data through H, C, package provenance through P, boundary data through G, and the local certificate through N; there is no additional consumer coordinate in the acceptance-budget cover.

Now apply Definition 525.137. When G is absent, the named route is retained as GAP-ledger content and is not exported as a public ground route. The refusal therefore attaches to the single missing boundary coordinate required for ground-compiler consumption. It leaves the listed source, branch, output, audit, continuation, provenance, and naming rows in their ledger roles, but it denies the readback that would reuse those rows as a completed ground-compiler handoff.

The obstruction is strict because both cited theorems keep the argument on the same finite packet. A global impossibility claim would need a row saying that no accepted AuthorizedGeneratorRecursor$^{\uparrow}$ output can exist, but the acceptance-budget cover instead starts from accepted output and lists its required rows. A host theorem reading would need a coordinate that exports a theorem outside the carrier, while the refusal surface exports only when G is present in that carrier. A hidden external validation reading would need an off-packet certificate or validation row, but the displayed carrier ends at the local NameCert row N. Hence the failure blocks only the named ground-route converse or reuse attempt and cannot be reinterpreted as a global impossibility, a host theorem, or hidden external validation. □

Theorem 525.140 (AuthorizedGeneratorRecursor accepted signature route)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet with displayed carrier*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N),$$

any public read that consumes the output row O must first expose the accepted signature row I, emitted recursor row E, checked motive row M, authorized branch package B, and structural-descent row D. The route may then read O only as the output row of the same carrier; it has no detached branch table, motive-free recursive channel, hidden generator source, or off-packet signature route.

Proof. Project the carrier of Definition 525.1. It places I, E, M, B, D before O in one finite BHist packet, so the public consumer begins with the displayed signature, recursor, motive, branch, and descent rows rather than with a separate generator source.

Use Definition 525.34 and Definition 525.93. These results identify accepted route consumption with the same finite carrier and require the route to retain the source signature, emitted recursor, motive, branch package, descent row, output row, audit row, and local certificate together.

Finally apply branch exhaustion and descent locality. Theorems 525.2 and 525.5 keep the branch package on the accepted constructor list and keep recursive use local to the motive and descent rows. Therefore O is reached only after I, E, M, B, D have become visible on the accepted signature route. □

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorAcceptedSignatureRoute

Theorem 525.141 (AuthorizedGeneratorRecursor output boundary totality)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet with displayed carrier*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N),$$

the output row O becomes public only while the audit row A, componentwise hsame *transport H, displayed* Cont *route C,* Pkg *provenance P, boundary row G, and local* NameCert *row N are retained. The public output boundary exports no hidden generator, free induction principle, external axiom channel, or unaudited dependency route outside R.*

Proof. Start with the output side of the displayed packet. The rows O, A, H, C, P, G, N are not separate public surfaces; they are the output, audit, transport, continuation, provenance, boundary, and local naming coordinates of the same carrier.

Apply Definition 525.74. It exhausts the output boundary ledger by $I, E, M, B, D, O, A, H, C, P, G, N$ and rules out a hidden generator, unaudited dependency route, external axiom channel, host-kernel completeness claim, or naming certificate outside the displayed packet.

Use Definition 525.121 for terminal consumption. That theorem keeps terminal readers on the same authorized output rows, so public exposure of O cannot discard A, H, C, P, G, N while retaining an output name. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor output boundary totality`

Theorem 525.142 (AuthorizedGeneratorRecursor audit NameCert lock)**.** *Every downstream closed-substitution, ground-compiler, or TasteGate-facing consumer of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *output is locked to the displayed packet*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The lock is the composite of accepted signature exposure, output boundary totality, the chapter's TasteGate handoff, and the OperationalMembrane$^{\uparrow}$ *audit route; it permits no closed-substitution read, ground-compiler read, or local* NameCert *read through a row outside that packet.*

Proof. First combine Definition 525.140 with Definition 525.141. The first theorem exposes I, E, M, B, D before output consumption, and the second retains O, A, H, C, P, G, N at the public boundary.

Next add the closed-substitution and ground-compiler consumers. Theorems 525.86 and 525.110 require both consumer families to read the output only through the displayed BHist, hsame, Cont, Pkg, boundary, and NameCert rows.

Finally synchronize the audit route with the operational membrane and the TasteGate handoff already cited by the chapter. Apply Definition 525.12, Definition 533.6, and the checked carrier handoff named by `BEDC.Derived.AuthorizedGeneratorRecursorUp.taste_gate`. These identify the audit and carrier-alignment reads with the same displayed packet, so downstream consumers cannot replace $I, E, M, B, D, O, A, H, C, P, G, N$ by an off-packet route. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorAuditNameCertLock`

Lemma 525.143 (AuthorizedGeneratorRecursor accepted signature downstream coverage)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet with displayed carrier*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N),$$

every accepted local consumer of the accepted signature output is exhausted by the finite rows displayed in R. More precisely, the consumer can read only an admission alternative among I, E, M, B, D, an output-boundary ledger row among O, A, H, C, P, G, N, or the same-packet coverage obtained by keeping those two surfaces coupled inside the carrier. A request for a detached branch table, motive-free recursive channel, hidden generator source, off-packet signature route, free induction principle, external axiom channel, unaudited dependency route, or naming certificate outside R remains outside the accepted BEDC *packet.*

Proof. Fix an accepted root packet and project the displayed carrier R. By Definition 525.140, any public read that consumes O must first expose the accepted signature row I, emitted recursor row E, checked motive row M, authorized branch package B, and structural-descent row D. The same theorem also says that the subsequent read of O is a read of the output row of this carrier, with no detached branch table, motive-free recursive channel, hidden generator source, or off-packet signature route. Thus the admission side of any accepted local consumer is already exhausted by the finite alternatives I, E, M, B, D.

Now apply Definition 525.141 to the output side. Once O is public, the audit row A, componentwise hsame transport H, displayed Cont route C, Pkg provenance P, boundary row G, and local NameCert row N remain attached to the same carrier. Hence a downstream consumer that passes the admission side can only proceed through the displayed output-boundary ledger O, A, H, C, P, G, N.

Combining the two cited theorems leaves no third source of consumer-facing data. A local consumer either stops on the admission alternatives I, E, M, B, D, reads the output-boundary ledger O, A, H, C, P, G, N, or uses their same-packet coupling as the coverage row for R. The alternatives excluded by the accepted signature route are absent before O, and the alternatives excluded by output boundary totality are absent after O. Therefore every unlisted coordinate remains outside the accepted BEDC packet. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorAcceptedSignatureDownstre`

Theorem 525.144 (AuthorizedGeneratorRecursor root carrier admission)**.** *Every accepted* AuthorizedGeneratorRec *root packet exposes only the carrier rows*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

before any root-unblock, ground-compiler, or output-facing consumer may read it. Here I is the accepted signature, E the emitted eliminator, M the motive, B the branch package, D the structural descent row, O the output row, A the audit row, H the componentwise transport row, C the displayed continuation route, P the package provenance, G the boundary row, and N the local NameCert *row.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootCarrierAdmission`

Proof. Project the carrier of Definition 525.1. Its displayed BHist packet is exactly $I, E, M, B, D, O, A, H, C, P, G, N$ and the definition gives no coordinate for an off-packet generator, hidden branch source, or detached output name.

Branch and descent exposure are already exhausted by the local root obligations. Theorems 525.2 and 525.5 keep every public recursive read on the signature, emitted eliminator, motive, branch package, and structural descent rows.

Finally attach audit and handoff data. The audit boundary of Definition 525.4 keeps output exposure behind audit provenance, and Definition 525.7 reads the checked carrier alignment only as the same finite packet. Hence the accepted root carrier exposes no rows beyond the displayed list. □

Theorem 525.145 (AuthorizedGeneratorRecursor ground-compiler route totality)**.** *Every ground-compiler or TasteGate-facing route out of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet factors through the signature row I, eliminator row E, motive row M, branch row B, descent row D, audit row A, continuation row C, package row P, boundary row G, and local certificate row N, together with the output row O and componentwise transport row H of the same carrier.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorGroundCompilerRouteTotali`

Proof. Start from root carrier admission above. The ground-compiler route begins with the same finite packet $I, E, M, B, D, O, A, H, C, P, G, N$ and has no separate compiler-facing carrier.

The computational part is forced through the signature, eliminator, motive, branch, and descent rows. Apply Definition 525.2 and Definition 525.5; together they rule out an unlisted constructor case, detached branch table, or non-structural recursion channel.

The public handoff is then routed through audit, continuation, package, boundary, and naming rows. Theorems 525.4 and 525.7 place the TasteGate-facing read behind the finite NameCert packet rather than behind a separate proof-producing generator. Thus every ground-compiler route is total over the displayed rows. □

Theorem 525.146 (AuthorizedGeneratorRecursor ledger provenance closure)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, the audit ledger and output provenance close inside* A, H, C, P, G, N *before any* ClosedTermSubstitutionBoundary$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, *or* OperationalMembrane$^{\uparrow}$ *consumer reads* O*. Such a consumer receives the output only as a row of the finite packet* $I, E, M, B, D, O, A, H, C, P$

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorLedgerProvenanceClosure`

Proof. Begin with the root carrier admission theorem. It places the output row O inside the admitted carrier and keeps the audit, transport, continuation, provenance, boundary, and local certificate rows attached to that output.

Next use the branch and descent obligations. Branch exhaustion and structural-descent locality keep the recursive source of O on I, E, M, B, D, so a downstream consumer cannot replace the output by a detached generator or hidden substitution step.

Finally apply audit boundary and ground-compiler handoff. The audit ledger is closed by Definition 525.4, while Definition 525.7 confines the compiler-facing handoff to the same NameCert carrier. Therefore closed-substitution, normalization-frontier, and operational-membrane consumers read only the closed provenance packet, not an off-route output. □

Lemma 525.147 (AuthorizedGeneratorRecursor root admission downstream coverage)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet, every local downstream consumer admitted by the root carrier is covered by the finite consumer interface of Definition 525.145. More explicitly, a consumer-facing use is exhausted by one of the displayed roles: the accepted signature row* I*, emitted eliminator row* E*, motive row* M*, branch package row* B*, structural descent row* D*, output row* O*, audit row* A*, componentwise transport row* H*, displayed continuation row* C*, package provenance row* P*, boundary row* G*, or local* NameCert *row* N*. An unlisted constructor alternative, detached branch source, non-structural recursion channel, unaudited ledger, detached output name, or external compiler certificate is therefore not an accepted coordinate of the* AuthorizedGeneratorRecursor$^{\uparrow}$ *BEDC packet.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootAdmissionDownstreamCo`

Proof. Start with root carrier admission, Definition 525.144. It presents the accepted root carrier as the displayed packet of signature, eliminator, motive, branch, descent, output, audit, transport, continuation, provenance, boundary, and local certificate rows, and it gives no additional coordinate for an off-packet generator, hidden branch source, or detached output name.

Now apply ground-compiler route totality, Definition 525.145. Any ground-compiler or TasteGate-facing route out of the accepted packet factors through exactly those named roles. The computational alternatives are therefore exhausted by the accepted signature row I, emitted eliminator row

E, motive row M, branch package row B, and structural descent row D; a purported constructor case or recursive branch not admitted by those rows has no consumer-facing route.

It remains to account for ledger, readback, and output use. The same totality theorem keeps public output and readback on O, A, H, C, P, G, N: the output row O is read only together with audit row A, componentwise transport row H, displayed continuation row C, package provenance row P, boundary row G, and local NameCert row N. Thus every accepted local consumer factors through the finite alternatives, ledger rows, and coverage rows already displayed by the root carrier admission theorem. Since the admitted carrier has no coordinate beyond those roles, every excluded alternative remains outside the BEDC packet rather than becoming a hidden consumer route. □

Definition 525.148 (AuthorizedGeneratorRecursor readiness route obligation packet)**.** *An* AuthorizedGeneratorRec *readiness route is the finite* BHist *packet*

$$Q = (U, J, K, O, L, H, C, P, N)$$

read from the admitted carrier of Definition 525.1. The authorization row U records the accepted constructor signature, emitted eliminator, checked motive, complete branch package, and structural descent rows I, E, M, B, D; the generator row J records the authorized recursor call; the ground-compiler recognition row K records that the route reaches the compiler boundary only through G; the output row O is the displayed public name; the refusal ledger L records the audit row A together with the refusal of unlisted branches, non-structural recursion, external axioms, hidden generators, and unaudited dependency channels; H is componentwise hsame *transport; C is the displayed* Cont *replay route; P is the* Pkg *provenance row; and N is the local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row.*

Lean4 (definition) `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorReadinessRoute`

Theorem 525.149 (AuthorizedGeneratorRecursor ground compiler admission)**.** *Every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *readiness route factors its generator output through the authorization row U and the ground-compiler recognition row K. Equivalently, no route may expose O to a ground-compiler consumer unless the same finite packet retains the accepted signature, emitted eliminator, motive, branch package, structural descent, audit provenance, boundary row, transports, continuation replay, package provenance, and local NameCert row.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor ground compiler admission`

↪ variant `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorGroundCompilerAdmission`

Proof. Start with root carrier admission. By Definition 525.144, the accepted packet exposes only $I, E, M, B, D, O, A, H, C, P, G, N$ before a ground-compiler or output-facing consumer may read it.

The authorization row U is obtained by grouping the signature, eliminator, motive, branch, and descent rows. Theorems 525.2 and 525.5 keep the authorized generator call on those rows, so J cannot be read as a detached proof-producing source.

Now attach compiler recognition. The ground-compiler authorization theorem and the handoff theorem, Definition 525.110 and Definition 525.7, force any compiler-facing read of O to retain G, H, C, P, N with the audit row. Thus the output reaches the compiler only through U and K inside the displayed readiness packet. □

Theorem 525.150 (AuthorizedGeneratorRecursor output refusal route)**.** *Any request against an* AuthorizedGeneratorRecursor$^{\uparrow}$ *readiness route that omits either the authorization row U or the refusal ledger L remains* GAP*-ledger content. Such a request is not exported as the public output row O and is not consumed as a ground-compiler route.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor output refusal`

Proof. First read the refusal side of the carrier. The GAP boundary refusal theorem, Definition 525.24, places external axioms, hidden generators, non-structural recursion, and unlisted branches behind the boundary row G and the audit row A.

If U is absent, the request has no accepted signature, eliminator, motive, branch package, or structural descent row from which a recursor output can be formed. Root authorization obligations and root ground-compiler authorization therefore leave the request at the boundary rather than at O.

If L is absent, the request has no source-refusal, dependency-refusal, or hidden-generator ledger attached to the output route. The audit dependency refusal theorem and the root output boundary package keep such a request in the GAP ledger until the refusal rows are restored.

Finally apply root output saturation. Since Definition 525.157 exports O only through the saturated carrier route, a request missing U or L cannot be the exported output and cannot be read as a compiler-recognized route. □

Theorem 525.151 (AuthorizedGeneratorRecursor NameCert obligation exhaustion)**.** *The rows of the readiness route obligation packet exhaust the local carrier, classifier, stability, ledger, and non-escape obligations for* AuthorizedGeneratorRecursor$^{\uparrow}$*. Carrier admission is supplied by U, J, K, O; classifier visibility is supplied by C, N; stability is supplied by H and P; the refusal ledger is supplied by L; and non-escape is supplied by the joint retention of U, K, L, H, C, P, N around O.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorNameCertObligationExhaust`

Proof. Carrier exhaustion is already finite. The carrier admission packet supplies $I, E, M, B, D, O, A, H, C, P, G, N$, and the readiness route only repackages these rows as authorization, generator, ground-compiler recognition, output, refusal, transport, replay, provenance, and local naming rows.

Classifier and stability obligations are retained by the public surface. The NameCert surface of Definition 525.3 classifies the route through the same packet, while output-name stability keeps O attached to H, C, P, G, N and to the authorization rows.

The ledger obligations are exhausted by refusal and audit rows. Use Definition 525.30, Definition 525.78, and Definition 525.24; together they place source refusal, dependency refusal, and hidden-generator refusal in L before output exposure.

It remains to rule out escape. Root carrier admission, root output route saturation, and ground-compiler admission above keep every consumer-facing read inside the same finite packet. Therefore the readiness rows exhaust the local carrier, classifier, stability, ledger, and non-escape obligations without adding an off-packet route. □

Corollary 525.152 (AuthorizedGeneratorRecursor readiness-route public-admission strict obstruction)**.** *Let*

$$Q = (U, J, K, O, L, H, C, P, N)$$

be an AuthorizedGeneratorRecursor$^{\uparrow}$ *readiness route. Suppose a displayed failure, refusal, separation, or countermodel row is cited against a named public-admission converse or reuse route for the*

output row O. Then the cited row is a strict local obstruction: it blocks only the named route whose consumer-facing read omits, replaces, or bypasses one of the displayed readiness coordinates

$$U, J, K, O, L, H, C, P, N.$$

In particular, its force is confined to the authorization row U, the generator-call row J, the ground-compiler recognition row K, the output row O, the refusal ledger L, componentwise hsame *transport H, the* Cont *replay route C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row N. It cannot be reinterpreted as a global impossibility theorem, a host theorem, hidden external validation, or an off-packet certificate for any coordinate not displayed by Q.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorReadinessRoutePublicAdmis`

Proof. Read the packet from Definition 525.148. The readiness route has exactly the displayed finite coordinates $U, J, K, O, L, H, C, P, N$. The row U is the only authorization package for the accepted signature, eliminator, motive, branch package, and structural descent rows; J is only the authorized recursor call; K reaches the compiler boundary only through the displayed boundary row; L is the refusal ledger for unlisted branches, non-structural recursion, external axioms, hidden generators, and unaudited dependency channels; and H, C, P, N are respectively the displayed transport, replay, provenance, and local naming rows. Thus a consumer-facing use of the public output has no coordinate from which to read a detached converse route, a second generator route, a host theorem, or an external validation certificate.

Now apply Definition 525.150. Any request against the readiness route that omits U or L remains GAP-ledger content. It is not exported as O and is not consumed as a ground-compiler route. Hence a displayed refusal, failure, separation, or countermodel row can affect a public-admission converse or reuse attempt only at the precise coordinate where that attempt omits, replaces, or bypasses the authorization package or the refusal ledger.

It remains to exclude stronger readings. Interpreting the same row as a global impossibility theorem would require a theorem surface not indexed by the named failed route. Interpreting it as a host theorem would require a host-facing recursion, induction, equality, or completion coordinate outside the packet. Interpreting it as hidden external validation would require a certificate channel not carried by H, C, P, N and not audited by L. None of these coordinates appears in Q, and the output-refusal route leaves every request missing U or L at the local GAP boundary. Therefore the obstruction is strict and local to the named public-admission converse or reuse route. □

Theorem 525.153 (AuthorizedGeneratorRecursor root carrier totality)**.** *Every accepted* AuthorizedGeneratorRecur *readiness route exposes its root carrier only through the finite* BHist *rows*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

and through the repackaged readiness rows

$$U, J, K, O, L, H, C, P, N.$$

The accepted carrier, generator authorization row, boundary row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row are therefore read together. No hidden generator, external axiom, host induction principle, detached branch table, unchecked recursive call, or off-packet substitution source is a carrier coordinate.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootCarrierTotality`

Proof. Start with root carrier admission. By Definition 525.144, the admitted packet is exactly the finite route through $I, E, M, B, D, O, A, H, C, P, G, N$ before any compiler, normalization, or closed-substitution consumer may read the output.

Next use the readiness route definition. Definition 525.148 repackages the signature, emitted eliminator, motive, branch, descent, output, audit, boundary, transport, replay, provenance, and naming rows as $U, J, K, O, L, H, C, P, N$ without adding a further carrier source.

Finally apply NameCert obligation exhaustion, Definition 525.151. The carrier, classifier, stability, refusal-ledger, and non-escape clauses are all discharged by the displayed rows, so any route omitting one of them remains outside the accepted root carrier. □

Theorem 525.154 (AuthorizedGeneratorRecursor closed-substitution source exposure)**.** *Every closed-substitution consumer of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *route must preserve the source rows that authorize the generator output: the accepted signature row I, emitted recursor row E, checked motive row M, branch package B, structural descent row D, audit row A, ground-boundary row G, componentwise* hsame *row H, displayed* Cont *route C,* Pkg *provenance P, refusal ledger L, and local* NameCert *row N. A closed-substitution read that omits any of these rows remains boundary content and is not an admitted output handoff.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorClosedSubstitutionSourceE`

Proof. First read the closed-substitution gate. Definition 525.103 places every output read for a closed-substitution consumer after the signature, branch, descent, audit, transport, continuation, package, boundary, and local naming rows have been displayed.

Next attach the closed-substitution handoff. Definition 525.86 keeps the handoff inside $I, E, M, B, D, O, A, H, C$ and treats the sibling closed-substitution boundary as finite BEDC boundary rows rather than as an unrestricted substitution calculus.

Finally use output refusal and closed-substitution admission, Definition 525.150 and Definition 525.169. The refusal ledger and generator authorization rows determine whether the request reaches O or remains in the GAP ledger, so the closed-substitution source exposure is exactly the displayed finite packet. □

Theorem 525.155 (AuthorizedGeneratorRecursor terminal output non-escape)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *readiness route, terminal normalization, closed-substitution, and ground-compiler consumers may read the output row O only through the displayed generator authorization row U, refusal ledger L, ground-compiler recognition row K, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. The terminal output exports no hidden generator state, host evaluator, unchecked recursion principle, external axiom, detached proof producer, or off-packet substitution channel.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalOutputNonescape`

Proof. Begin with readiness determinacy. Definition 525.168 says that two accepted readiness routes agreeing on U, J, K, L, H, C, P, N expose the same public output row O.

Now attach public output coverage. Definition 525.170 routes normalization, closed-substitution, and ground-compiler public consumers through the same readiness packet before any of them reads O.

Finally combine terminal authorized output cover with root output route saturation, Definition 525.121 and Definition 525.157. These theorems keep terminal output consumption on the displayed audit, boundary, transport, continuation, provenance, and local naming rows, leaving no carrier coordinate for an escaping output route. □

Corollary 525.156 (AuthorizedGeneratorRecursor root-totality strict obstruction)**.** *Let*

$$Q = (U, J, K, O, L, H, C, P, N)$$

be an accepted AuthorizedGeneratorRecursor$^{\uparrow}$ *readiness route, read from the root carrier rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Suppose a displayed failure, refusal, separation, or countermodel row is cited against a named root-totality converse or reuse route for Q. Then that row is a strict local obstruction: it blocks only the named route whose consumer-facing read omits, replaces, detaches, or bypasses one of the displayed output, source, transport, replay, provenance, refusal, boundary, or local naming coordinates

$$I, E, M, B, D, O, A, H, C, P, G, N$$

or their readiness packaging

$$U, J, K, O, L, H, C, P, N.$$

In particular, the obstruction has no force as a global impossibility theorem, no force as a host theorem about recursors or totality, and no force as hidden external validation for any coordinate not displayed by the accepted packet.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorReadinessRoute root totality strict obstruction`

Proof. Start with terminal output non-escape, Definition 525.155. It lists the only rows through which terminal normalization, closed-substitution, and ground-compiler consumers may read the public output O: the authorization row U, refusal ledger L, ground-compiler recognition row K, componentwise hsame transport H, displayed Cont replay C, Pkg provenance P, and local NameCert row N. The same theorem excludes hidden generator state, host evaluation, unchecked recursion, external axioms, detached proof production, and off-packet substitution as output coordinates.

Now attach closed-substitution source exposure, Definition 525.154. A closed-substitution consumer must preserve the source rows that authorize the output: $I, E, M, B, D, A, G, H, C, P, L, N$. Thus any consumer-facing use of the displayed obstruction factors through the source rows I, E, M, B, D, A, G, the refusal ledger L, the transport and readback rows H, C, P, and the local naming row N before it can speak about the output row O.

Consider the cited failure, refusal, separation, or countermodel row. If the named converse or reuse route asks to read O while omitting the authorization row U, the refusal ledger L, the ground-recognition row K, the source rows I, E, M, B, D, A, G, or the transport and readback rows H, C, P, N, the two cited theorems place the failure exactly at that missing coordinate. The row therefore blocks the named route at the point where the route leaves the displayed packet. If a consumer instead keeps all listed rows, this corollary supplies no rejection of that consumer; the obstruction is tied to the named omitted, replaced, detached, or bypassed coordinate.

It remains to rule out stronger readings. A global impossibility theorem would require a conclusion not indexed by the named failed route and not confined to Q. A host theorem about recursors or totality would require a host evaluator, host induction rule, unchecked recursive call, or external axiom, each of which is excluded by terminal output non-escape. Hidden external validation would require a certificate or substitution channel outside H, C, P, L, N, which closed-substitution source exposure does not export. Since no such coordinate is present in the root carrier or in the readiness packaging, the displayed row remains a strict local obstruction to the named root-totality converse or reuse route only. □

Theorem 525.157 (AuthorizedGeneratorRecursor root output route saturation)**.** *Every public output route of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet factors through the accepted signature row I, emitted eliminator row E, checked motive row M, branch package B, structural descent row D, output row O, audit row A, componentwise transport row H, displayed continuation row C, provenance row P, ground-compiler boundary row G, and local* NameCert *row N. Thus the output is public only as the saturated finite carrier route*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootOutputRouteSaturation
↪ variant BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor root output route saturation

Proof. Begin with the carrier and root output audit rows. Definition 525.1 displays the accepted signature, eliminator, motive, branch, descent, output, audit, transport, continuation, provenance, boundary, and naming rows, while Definition 525.46 places every public read of O behind the same packet.

Next attach boundary and compiler visibility. Definition 525.47 prevents the boundary row from exporting a hidden generator or host induction principle, and Definition 525.7 reads the ground-compiler boundary only through the accepted carrier.

Finally use consumer readiness. Definition 525.48 packages the output route for downstream consumers without dropping branch, descent, audit, boundary, provenance, or local naming rows. Hence every public output route factors through the displayed saturated route. □

Theorem 525.158 (AuthorizedGeneratorRecursor root boundary nonescape saturation)**.** *The saturated public output route of Definition 525.157 exports no hidden generator, host induction principle, external axiom, unaudited dependency route, or off-packet substitution channel. Any consumer that reaches O must keep the accepted signature, eliminator, motive, branch, descent, audit, transport, continuation, provenance, ground-compiler boundary, and local NameCert rows inside the same* BHist *packet.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootBoundaryNonescapeSatu

Proof. Project the saturated route

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The route already contains the only output, audit, ground-boundary, provenance, and local naming rows supplied by the accepted carrier.

Apply root boundary nonescape and the ground-compiler handoff. Definition 525.47 excludes hidden generator, host induction, external axiom, and unaudited dependency exports at the boundary, while Definition 525.7 keeps the compiler-facing read on the same finite packet.

It remains to rule out substitution escape. Definition 525.48 and Definition 525.46 force closed-normal and generator-audit consumers to retain the output audit route before using O. Since no off-packet substitution coordinate appears in the carrier, the saturated route has no channel through which such a substitution can be exported. □

Corollary 525.159 (AuthorizedGeneratorRecursor root output-route strict obstruction)**.** *Suppose a displayed failure, refusal, separation, or countermodel row is cited against a named converse or reuse route in the root output-route surface of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet.*

Then that row is a strict local obstruction: it blocks only the named route whose consumer-facing read omits, replaces, detaches, or bypasses one of the displayed finite carrier coordinates

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The route coordinates are I, E, M, B, D, O, A, the transport coordinate is H, the readback and provenance coordinates are C, P, and the boundary-certificate coordinates are G, N. The same displayed row cannot be reinterpreted as a global impossibility theorem for authorized generator recursors, a host theorem, hidden external validation of the failed route, or evidence for any unlisted consumer coordinate.

Proof. Start with output-route saturation. By Definition 525.157, every public output route of an accepted packet factors through the finite carrier

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Thus a consumer-facing read of O has only the listed packet coordinates available. Its route side must pass through the accepted signature, emitted eliminator, checked motive, branch package, structural descent row, output row, and audit row I, E, M, B, D, O, A. Its transport side is the componentwise row H, its continuation and provenance readback is C, P, and its boundary and local certificate side is G, N.

Apply boundary nonescape saturation. Definition 525.158 says that the same saturated route exports no hidden generator, host induction principle, external axiom, unaudited dependency route, or off-packet substitution channel, and that any consumer reaching O must keep the accepted signature, eliminator, motive, branch, descent, audit, transport, continuation, provenance, ground-compiler boundary, and local NameCert rows inside the same BHist packet. Therefore a negative row can act only at one of those displayed coordinates: it may deny the named converse or reuse route when that route tries to detach O from its branch, descent, audit, transport, readback, boundary, or local naming support.

No stronger reading has a carrier. A global impossibility theorem would require a theorem coordinate not indexed by the named route and not confined to the accepted packet. A host theorem would require a host-facing induction or proof row outside $I, E, M, B, D, O, A, H, C, P, G, N$. Hidden external validation would require an additional validating certificate, dependency route, or substitution channel outside A, H, C, P, G, N. The two cited saturation theorems provide no such coordinate and explicitly keep every public read of O on the displayed finite route. Hence the obstruction is strict and local: it blocks the named converse or reuse route at the displayed packet coordinate that the row denies, and it rejects every unlisted interpretation as outside the accepted AuthorizedGeneratorRecursor$^{\uparrow}$ output-route surface. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootOutputRouteStrictObst`

Theorem 525.160 (AuthorizedGeneratorRecursor output route readiness)**.** *For an accepted* AuthorizedGeneratorRe *packet, the output row O is route-ready only inside the finite packet*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The packet must display the accepted signature row I, emitted eliminator row E, checked motive row M, authorized branch row B, structural descent row D, audit row A, componentwise hsame *transport row H, displayed* Cont *route C,* Pkg *provenance row P, ground-boundary row G, and local* NameCert *row N in the same* BHist *carrier. Output exposure is admitted only through those authorized signature, branch, descent, audit, route, package, boundary, and local naming rows.*

Proof. Begin with the carrier route. The finite packet $I, E, M, B, D, O, A, H, C, P, G, N$ is the only displayed BHist surface on which the accepted signature, emitted eliminator, motive, branch package, descent, output, audit, transport, continuation, provenance, boundary, and local naming rows are simultaneously present.

Next apply Definition 525.157 and Definition 525.126. They keep O attached to the accepted branch, descent, audit, hsame, Cont, Pkg, boundary, and NameCert rows before any public output read is allowed.

Thus output readiness is not a detached generator fact. It is the admission of O through the same authorized signature, branch, descent, audit, route, package, boundary, and local naming rows of the packet. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor output route readiness`

Theorem 525.161 (AuthorizedGeneratorRecursor boundary ledger totality)**.** *Every boundary-ledger read of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *output is total only when it preserves all rows*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

as displayed rows of the same BHist *packet. In particular,* hsame*,* Cont*,* Pkg*, and* NameCert *support cannot be detached from the accepted signature, branch, descent, audit, route, package, boundary, and local naming surface.*

The ledger admits no output exposure through an unauthorized signature, unchecked branch, missing descent row, absent audit row, private continuation route, off-packet package, hidden boundary, or external naming certificate.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorBoundaryLedgerTotality`

Proof. Project the packet onto its boundary and ledger rows. The displayed carrier contains G only together with the accepted source signature, emitted eliminator, checked motive, branch package, descent, output, audit, transport, continuation, provenance, and local certificate.

Use Definition 525.157 to recover the complete route through $I, E, M, B, D, O, A, H, C, P, G, N$. The same theorem forces every public output read to retain the BHist, hsame, Cont, Pkg, and NameCert support rows.

It remains to exclude off-packet ledger exposure. Definition 525.126 and Definition 525.127 keep closed-substitution, generator-normalization, and output-facing consumers on the same displayed packet, so no unauthorized signature, unchecked branch, missing descent row, private route, hidden boundary, or external naming surface can supply O. □

Theorem 525.162 (AuthorizedGeneratorRecursor downstream readback exhaustion)**.** *Every downstream readback of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *output is exhausted by the finite rows*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

together with the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support. A downstream consumer may read output exposure only through the authorized signature, branch, descent, audit, route, package, boundary, and local naming rows already present in that packet.*

No detached generator route, host recursion oracle, hidden substitution channel, unlicensed output row, or external naming witness remains for a downstream consumer after the displayed packet has been read.

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorDownstreamReadbackExhaust

Proof. First use Definition 525.160. It places O behind the accepted signature, emitted eliminator, motive, branch package, descent, audit, transport, continuation, provenance, boundary, and local certificate rows of the same BHist packet.

Next use Definition 525.161. Any route that reaches the boundary or ledger must preserve $I, E, M, B, D, O, A, H, C, P, G, N$ together with the hsame, Cont, Pkg, and NameCert support rows.

Finally apply Definition 525.178 and Definition 525.179. They allow downstream consumers to read the authorized output only through the displayed packet, so detached generators, host recursion oracles, hidden substitution channels, unlicensed output rows, and external naming witnesses are exhausted by the same finite route. □

Lemma 525.163 (AuthorizedGeneratorRecursor output route downstream coverage)**.** *Let c be an accepted local consumer of an* AuthorizedGeneratorRecursor$^{\uparrow}$ *output route. If c reads the output row through the readiness surface, then its consumer-facing use is exhausted by the finite packet*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

More precisely, the route alternatives are the accepted signature row I, emitted eliminator row E, checked motive row M, authorized branch row B, structural descent row D, output row O, and audit row A; the transport and readback ledger is the componentwise hsame *row H, displayed* Cont *route C, and* Pkg *provenance row P; and the boundary-certificate ledger is the ground-boundary row G together with the local* NameCert *row N. Hence an accepted downstream consumer has no coordinate for an unauthorized signature, unchecked branch, missing descent row, absent audit row, private continuation route, off-packet package, hidden boundary, external naming certificate, detached generator route, host recursion oracle, or hidden substitution channel.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorOutputRouteDownstreamCove

Proof. Start with the readiness side. By Definition 525.160, the output row O is route-ready only inside the displayed BHist packet $I, E, M, B, D, O, A, H, C, P, G, N$. That theorem also identifies the rows that must be present before output exposure is admitted: the accepted signature, emitted eliminator, checked motive, authorized branch, structural descent, audit, hsame transport, Cont route, Pkg provenance, ground-boundary, and local NameCert rows. Thus any accepted local consumer reading O from the readiness surface already factors through the route alternatives I, E, M, B, D, O, A, the transport and provenance rows H, C, P, and the boundary-certificate rows G, N.

Apply Definition 525.161 to the same consumer-facing read. Once the read reaches the boundary ledger, totality requires the same rows $I, E, M, B, D, O, A, H, C, P, G, N$ to be preserved as displayed rows of one BHist packet. In particular, the hsame, Cont, Pkg, and NameCert support cannot be detached from the accepted signature, branch, descent, audit, route, package, boundary, and local naming surface.

Combining these two constraints leaves no further accepted coordinate. Readiness admits O only through the displayed packet, and boundary-ledger totality says every ledger read preserving that output remains on exactly that packet. Therefore every accepted downstream consumer is covered by the listed route alternatives, transport and readback ledger, or boundary-certificate ledger, while all unauthorized signatures, unchecked branches, missing descent or audit rows, private continuation routes, off-packet packages, hidden boundaries, external naming certificates, detached generator routes, host recursion oracles, and hidden substitution channels remain outside the AuthorizedGeneratorRecursor$^{\uparrow}$ packet. □

Theorem 525.164 (AuthorizedGeneratorRecursor root output consumer triad)**.** *Every root output consumer of an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet receives the output row only through the finite* BHist *route*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The route displays the accepted authorization surface I, E, M, B, D*, the generator state witnessed by the output row* O*, the audit row* A*, the componentwise* hsame *row* H*, the displayed* Cont *route* C*, the* Pkg *provenance row* P*, the ground-boundary row* G*, and the local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row* N*.*

Thus a root consumer has no hidden generator authority, host recursion oracle, off-packet output row, detached readiness row, private continuation, external package source, or outside naming certificate.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor root output consumer triad`

Proof. Begin with route-pack exactness, Definition 525.56. It makes $I, E, M, B, D, O, A, H, C, P, G, N$ the complete packet available to a recursor route.

Use the downstream consumer ledger cover, Definition 525.58. It states that generator, substitution-boundary, and TasteGate consumers receive only the carrier, branch, descent, audit, transport, continuation, package, boundary, and local naming rows displayed by the packet.

Finally apply output route readiness, Definition 525.160. The output row O is route-ready only inside the same finite packet, so a root consumer cannot replace the displayed authorization, readiness, continuation, package, ground-boundary, or local naming rows by hidden generator authority or host recursion. □

Theorem 525.165 (AuthorizedGeneratorRecursor readiness route totality)**.** *For every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet, the readiness route from authorization to output is total exactly on the displayed rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The accepted constructor signature, emitted eliminator, motive, branch package, and structural descent rows provide authorization; the output row and audit row provide generator-state exposure and refusal evidence; the hsame*,* Cont*,* Pkg*, ground-boundary, and local* NameCert *rows provide the only admissible route support.*

No consumer may complete the readiness route by importing an unlisted branch, non-structural recursive call, hidden generator state, host recursion rule, private output channel, or off-packet naming witness.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorReadinessRouteTotality`

Proof. Start from the readiness route obligation packet of Definition 525.148. It repackages the accepted carrier rows as authorization, generator, ground-recognition, output, refusal, transport, replay, provenance, and local naming data.

Apply ground compiler admission, Definition 525.149. The generator output reaches any ground-compiler or output-facing consumer only through the authorization row and ground-boundary recognition carried by the same finite packet.

Use NameCert obligation exhaustion, Definition 525.151. The carrier, classifier, stability, ledger, and non-escape obligations are exhausted by these readiness rows. Therefore the route is total on the displayed packet and cannot be completed by hidden generator state, host recursion, private output exposure, or an external naming row. □

Theorem 525.166 (AuthorizedGeneratorRecursor output route naming exhaustion)**.** *Every accepted output route naming surface for* AuthorizedGeneratorRecursor$^{\uparrow}$ *is exhausted by the same finite route*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The public name of O must retain the authorization rows, generator-state row, readiness and audit rows, displayed Cont *route,* Pkg *source, and local* NameCert *row already present in the packet.*

Consequently the output route cannot be named through a hidden generator, a host-recursive eliminator, an external continuation, an unaudited package source, a missing readiness row, or a naming certificate outside the displayed BHist *carrier.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCarrier output route naming exhaustion`

Proof. Project the root output consumer triad above. Any root consumer reaches O only after the authorization, generator-state, audit, transport, continuation, package, boundary, and local naming rows are displayed.

Apply readiness route totality. Since the readiness route is total only on $I, E, M, B, D, O, A, H, C, P, G, N$, an output name cannot be certified by a partial route missing authorization, audit, continuation, package, boundary, or local NameCert support.

Finally use downstream readback exhaustion, Definition 525.162. It removes detached generator routes, host recursion oracles, hidden substitution channels, unlicensed output rows, and external naming witnesses from downstream reads. Hence the displayed finite carrier exhausts the output route naming surface. □

Lemma 525.167 (AuthorizedGeneratorRecursor root output consumer downstream coverage)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root output packet with displayed route*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N),$$

every accepted local consumer-facing use of the root output row O is exhausted by the finite downstream surfaces already displayed in R. More precisely, the use must factor through the authorization and branch alternatives I, E, M, B, D, the output and audit ledger rows O, A, the transport, continuation, package, boundary, and local naming rows H, C, P, G, N, or the coverage row obtained by reading readiness and output-route naming through the same carrier.

Consequently a request for an unlisted branch, non-structural recursive call, hidden generator state, host recursion rule, private output channel, external continuation, unaudited package source, missing readiness row, or naming certificate outside the displayed BHist *packet is not an accepted local consumer of the* AuthorizedGeneratorRecursor$^{\uparrow}$ *root output.*

Proof. Start with readiness route totality, Definition 525.165. It states that the route from authorization to output is total exactly on

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Thus a consumer-facing use of O cannot begin from a free generator surface. Its admission side is forced through the accepted constructor signature, emitted eliminator, motive, branch package, and structural descent rows I, E, M, B, D, and its output side is forced to retain O, A, H, C, P, G, N as route support in the same packet.

Next use output route naming exhaustion, Definition 525.166. Any public name of the output route must keep the authorization rows, generator-state row, readiness and audit rows, displayed

Cont route, Pkg source, and local NameCert row already present in R. Hence naming O supplies no fourth downstream surface: it only records the same finite carrier as a named route and keeps the local consumer inside the displayed BHist, hsame, Cont, Pkg, boundary, and NameCert coordinates.

Combine these two constraints. If a proposed local consumer is accepted, readiness totality places the read on the displayed authorization-to-output route, while naming exhaustion keeps the public name of that read on the same carrier. The consumer therefore lands on one of the finite alternatives, ledger rows, or carrier-coverage rows listed in the statement.

It remains to exclude the apparent alternatives. An unlisted branch or non-structural recursive call would bypass I, E, M, B, D; hidden generator state or a host recursion rule would add a generator coordinate not present in the readiness route; a private output channel would detach O from A, H, C, P, G, N; an external continuation or unaudited package source would replace C or P; a missing readiness row would contradict route totality; and an outside naming certificate would contradict output route naming exhaustion. None of these requests has a coordinate in R, so each remains outside the accepted AuthorizedGeneratorRecursor$^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootOutputConsumerDownstr`

Theorem 525.168 (AuthorizedGeneratorRecursor readiness determinacy)**.** *Let Q and Q' be accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *readiness routes read from the same admitted carrier rows. If they agree on the authorization row U, generator row J, ground-compiler recognition row K, refusal ledger L, componentwise transport H, continuation replay C, provenance row P, and local name row N, then they expose the same public output row O. Thus the readiness packet has no hidden branch, detached generator, or off-packet substitution channel from which a second public output can be read.*

Proof. Start from carrier admission. Definition 525.144 exposes the accepted route only through the finite rows $I, E, M, B, D, O, A, H, C, P, G, N$, and Definition 525.148 repackages those rows as $Q = (U, J, K, O, L, H, C, P, N)$.

The shared rows determine the authorization side. Agreement on U and J fixes the accepted signature, emitted eliminator, checked motive, branch package, structural descent, and authorized generator call. The ground-compiler admission theorem keeps any compiler-facing read of the output on the same U and K rows.

It remains to rule out a second output route. The output refusal theorem blocks any request missing the refusal ledger L, while the root output route saturation theorem exposes public output only through the displayed finite carrier. NameCert obligation exhaustion then packages the carrier, classifier, stability, ledger, and non-escape obligations in the same readiness route, so two such routes must expose the same O. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorReadinessDeterminacy`

Theorem 525.169 (AuthorizedGeneratorRecursor closed substitution admission)**.** *Every closed-substitution consumer of the public output row O of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *readiness route retains the branch package B, structural descent row D, audit row A, boundary row G, and refusal ledger L. A route that omits one of those rows remains* GAP*-ledger content and is not admitted as a closed-substitution handoff.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorClosedSubstitutionAdmissi`

Proof. First read the closed-substitution handoff. Definition 525.86 sends O to closed-substitution and generator-audit consumers only through the finite route $I, E, M, B, D, O, A, H, C, P, G, N$.

The branch, descent, audit, and boundary rows are therefore not optional. The carrier admission theorem supplies those rows before the output is public, and the readiness route definition records their authorization, refusal, transport, replay, provenance, and local naming projections inside Q.

Now apply output refusal. By Definition 525.150, any request that omits the authorization row or the refusal ledger remains at the GAP boundary. Since B, D, A, G are the carrier coordinates through which U, K, L are read by closed-substitution consumers, a route missing one of them cannot be the admitted handoff. □

Theorem 525.170 (AuthorizedGeneratorRecursor public output coverage)**.** *Normalization consumers, closed-substitution consumers, and ground-compiler public consumers of an accepted* AuthorizedGeneratorRe *output all factor through the readiness packet*

$$Q = (U, J, K, O, L, H, C, P, N).$$

No public consumer reads O through a route outside that packet.

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorPublicOutputCoverage

Proof. Begin with public output saturation. Definition 525.157 says that every public output route factors through $I, E, M, B, D, O, A, H, C, P, G, N$, and the readiness route definition records exactly the authorization, generator, compiler-recognition, output, refusal, transport, replay, provenance, and local naming view of those rows.

Closed-substitution consumers are covered by the admission theorem above and by the closed-substitution handoff. They retain the branch, descent, audit, boundary, refusal, transport, continuation, provenance, and naming rows before reading O.

Ground-compiler consumers are covered by ground compiler admission. Normalization consumers use the same public output row because NameCert obligation exhaustion leaves no extra classifier, stability, ledger, or non-escape obligation outside Q. Hence all three public consumer families factor through the readiness packet. □

Corollary 525.171 (AuthorizedGeneratorRecursor readiness consumer determinacy)**.** *Fix the admitted local rows of an* AuthorizedGeneratorRecursor$^{\uparrow}$ *readiness route*

$$Q = (U, J, K, O, L, H, C, P, N).$$

*Every accepted consumer-facing use of the public output that is admitted as a closed-substitution handoff, a normalization read, or a ground-compiler read is determined by those rows. More precisely, once the authorization row U, generator row J, ground-compiler recognition row K, refusal ledger L, componentwise transport row H, continuation replay row C, provenance row P, and local name row N are fixed, the consumer must use the same finite readiness route, the same public normal-output row O, and the same admission-versus-*GAP *decision supplied by the chapter. There is no accepted alternate coordinate, duplicate classifier source, detached branch package, or hidden substitution channel from which a second consumer result can be read.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorReadinessConsumerDetermin

Proof. Read the fixed readiness route through Definition 525.148. The row U packages the accepted signature, emitted eliminator, checked motive, complete branch package, and structural descent data; J is the authorized recursor call; K is the ground-compiler recognition row; L is the refusal ledger; and H, C, P, N are respectively the displayed transport, replay, provenance, and

local naming rows. Thus the named consumer interface already exposes the finite route on which public output can be read.

Let a consumer-facing use be accepted after these rows have been fixed. If it is a closed-substitution handoff, Definition 525.169 requires it to retain the branch package B, structural descent row D, audit row A, boundary row G, and refusal ledger L. Since B and D are read through U, G is read through K, A is recorded by L, and the handoff also keeps the displayed transport, replay, provenance, and local naming rows, the consumer determines an accepted readiness route with the same U, J, K, L, H, C, P, N as Q. A normalization or ground-compiler read has the same row support by Definition 525.170: it factors through the readiness packet rather than through a detached generator or off-packet substitution rule.

Apply Definition 525.168 to Q and to the readiness route just obtained from the accepted consumer use. The two routes agree on U, J, K, L, H, C, P, N, so they expose the same public output row O. Hence a normalizing consumer cannot choose a second normal-output row, and a ground-compiler or closed-substitution consumer cannot cite an alternate output coordinate after the displayed local rows have been fixed.

It remains to identify the decision boundary. By Definition 525.169, a purported handoff omitting B, D, A, G, or L remains GAP-ledger content and is not admitted as a closed-substitution handoff. By the determinacy theorem, a purported handoff retaining the fixed rows but exposing a different output would have to be a second readiness route over the same U, J, K, L, H, C, P, N, which is impossible. Therefore every accepted consumer use makes the same finite-route, normal-output, and admission-versus-GAP decision named by the readiness packet, and every alternate coordinate or duplicate classifier source is rejected before it becomes a public consumer result. □

Theorem 525.172 (AuthorizedGeneratorRecursor admission exhaustion)**.** *Every accepted* AuthorizedGeneratorRec *root packet is exhausted by the displayed* BHist *carrier rows*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

together with the readiness view

$$U, J, K, O, L, H, C, P, N.$$

An output-facing read is admitted only after the accepted signature, emitted recursor, checked motive, branch package, structural descent, audit row, boundary row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, refusal ledger, and local* NameCert *row have all been retained. No route into chapter 538, chapter 892, or chapter 534 may read a detached generator output outside those rows.*

Proof. Start with carrier admission and root carrier totality. Theorems 525.144 and 525.153 display the admitted root packet and leave no carrier coordinate outside $I, E, M, B, D, O, A, H, C, P, G, N$.

Next pass to the readiness view. The definition of the readiness route, Definition 525.148, repackages the same admitted data as $U, J, K, O, L, H, C, P, N$, while Definition 525.151 keeps carrier, classifier, stability, ledger, and non-escape obligations on that packet.

Finally attach the sibling consumers. The closed-substitution gate, terminal consumer readiness, and root output route saturation theorems force every closed-substitution, MetaCIC normalization frontier, and recursor-generator read to retain the boundary, replay, provenance, refusal, and local naming rows before reading O. Thus admission is exhausted by the two displayed finite views. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorAdmissionExhaustion`

Theorem 525.173 (AuthorizedGeneratorRecursor route refusal)**.** *Let an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *consumer request a generator output not listed in the authorized signature, branch, descent, and audit rows of the packet. Then the request remains in the refusal and boundary rows L, G, A, N and is not admitted as an output row O. In particular, no downstream closed-substitution, MetaCIC normalization frontier, or recursor-generator consumer may reinterpret an unlisted generator result as an authorized branch, recursive call, host induction principle, proof producer, or off-packet substitution channel.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRouteRefusal`

Proof. Read the authorization side first. The accepted signature route, branch budget exhaustion, and root signature totality theorems place every listed generator route behind I, E, M, B, D and the audit row A.

Now apply output refusal. Theorem 525.150 sends any request missing the authorization row or refusal ledger to the GAP boundary, and Definition 525.137 keeps ground-facing refusals on the displayed packet.

It remains to block downstream reinterpretation. The closed-substitution budget lock, MetaCIC normalization boundary route, and RecursorGenerator authorization obligations only consume output through the displayed finite route; terminal reader nonescape then removes hidden generator state, host evaluation, unchecked recursion, proof-producing branches, and off-packet substitution channels. □

Theorem 525.174 (AuthorizedGeneratorRecursor downstream NameCert package exactness)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, the downstream NameCert package is exactly the finite package consisting of the carrier rows $I, E, M, B, D, O, A, H, C, P, G, N$, the readiness classifier rows $U, J, K, O, L, H, C, P, N$, displayed* Cont *replay through C,* Pkg *provenance through P, and local* NameCert *rows through N. Downstream closed-substitution, MetaCIC normalization frontier, and recursor-generator consumers may specialize this package, but may not add a carrier, classifier, continuation, provenance, or naming row outside it.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorDownstreamNameCertPackage`

Proof. Begin with the downstream consumer surface. The root consumer factorization and public output coverage theorems force public output consumers to factor through the displayed carrier and readiness packet before a specialization is read.

Next identify the structural rows. Componentwise transport is carried by H, replay by C, provenance by P, and local naming by N; the NameCert obligation exhaustion theorem states that these rows discharge the carrier, classifier, stability, refusal-ledger, and non-escape clauses for the same packet.

Finally use the sibling locks. Closed-substitution handoff keeps substitution consumers inside the boundary rows, MetaCIC normalization frontier reads the output only as finite boundary data, and RecursorGenerator consumes the result as authorized generator provenance rather than as a second generator. Therefore the downstream NameCert package is exact. □

Corollary 525.175 (AuthorizedGeneratorRecursor admission exhaustion strict obstruction)**.** *Let an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *root packet be read through the admission-exhaustion surface. If a displayed failure, refusal, separation, or countermodel row is cited against a converse or reuse route for that packet, then the obstruction is strict local data. It blocks only the named consumer request whose generator output is not listed in the authorized signature, branch, descent, and audit rows, so that the rejected request remains in the refusal and boundary rows L, G, A, N*

and is not admitted as an output row O. The obstruction does not state a global impossibility for AuthorizedGeneratorRecursor$^{\uparrow}$*, does not supply a host theorem about recursors, and does not validate or invalidate any hidden external route.*

Proof. By Definition 525.172, every accepted root packet is exhausted by the displayed carrier rows

$$I, E, M, B, D, O, A, H, C, P, G, N$$

together with the readiness view

$$U, J, K, O, L, H, C, P, N.$$

The same theorem also states that any output-facing read is admitted only after the accepted signature, emitted recursor, checked motive, branch package, structural descent, audit row, boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, refusal ledger, and local NameCert row have all been retained. Hence every consumer-facing use factors through the shown finite packet, and a proposed obstruction has no coordinate outside those rows from which to speak about a global theory, a host recursor theorem, or an external validator.

Now apply Definition 525.173. A consumer request for a generator output not listed in the authorized signature, branch, descent, and audit rows is not promoted to O; it remains in L, G, A, N. The same refusal theorem blocks downstream reinterpretation of that unlisted result as an authorized branch, recursive call, host induction principle, proof producer, or off-packet substitution channel. Combining this refusal with admission exhaustion fixes the exact scope of any displayed failure, refusal, separation, or countermodel row: it marks the named converse or reuse route as leaving the displayed authorization packet, while all listed reads that retain the carrier, readiness, boundary, replay, provenance, refusal, and local naming rows remain governed by the accepted packet.

Therefore the obstruction is strict and local. It rejects only the unlisted consumer coordinate identified by the refusal row, and it cannot be reinterpreted as a global impossibility, a host theorem, or a hidden external validation. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorAdmissionExhaustionStrict`

Theorem 525.176 (AuthorizedGeneratorRecursor root-admission public export)**.** *The admission exhaustion theorem, route refusal theorem, downstream* NameCert *package theorem, and strict obstruction corollary jointly export the finite MetaCIC-facing root-admission boundary for* AuthorizedGeneratorRecurso *Every authorized-generator recursor consumer must expose closed-substitution boundary rows, operational membrane rows,* Real$^{\uparrow}$/RegSeqRat$^{\uparrow}$/StreamName$^{\uparrow}$ *dependency rows, and recursor-generator rows before requesting a root admission. No consumer may request root admission from an unlisted generator output, host recursor theorem, off-packet substitution channel, or hidden external route.*

Proof. Start with admission exhaustion. Theorem 525.172 requires every output-facing read to retain the accepted signature, emitted recursor, checked motive, branch package, structural descent, audit row, boundary row, componentwise transport, replay, provenance, refusal ledger, and local naming row.

Apply route refusal. Theorem 525.173 keeps unlisted generator outputs in the refusal and boundary rows, so a consumer cannot treat an unauthorized result as an authorized branch, recursive call, host induction principle, proof producer, or off-packet substitution channel.

Use the downstream NameCert package theorem. It identifies the finite package consumed by closed-substitution, MetaCIC normalization frontier, and recursor-generator consumers, including the carrier rows, readiness rows, displayed Cont replay, Pkg provenance, and local NameCert rows.

Finally apply the strict obstruction corollary. Any displayed obstruction blocks only the named request that leaves the authorization packet; it does not become a global impossibility or a host theorem. Thus a MetaCIC-facing root-admission consumer must display the closed-substitution boundary, operational membrane, real, regular-rational, stream-name, and recursor-generator dependency rows before the admission request is accepted. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootAdmissionPublicExport`

Theorem 525.177 (AuthorizedGeneratorRecursor output-route determinacy)**.** *For every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N),$$

any accepted output read of O is determined by the displayed signature row I, eliminator row E, motive row M, branch row B, descent row D, audit row A, route row C, package row P, boundary row G, and local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row N. There is no accepted output route for O detached from those rows, and no downstream consumer may recover a second output meaning from the packet.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCarrier output route determinacy`

Proof. Begin with the branch and descent rows. Theorems 525.2 and 525.5 force the output route to keep the accepted constructor signature, emitted eliminator, checked motive, complete branch package, and displayed structural descent.

Next attach audit and package provenance. Theorem 525.6 retains A, H, C, P, G, N before O is exposed, while Definition 525.7 identifies the TasteGate handoff only as carrier alignment rather than as another generator route.

Finally apply admission exhaustion, Definition 525.172. It exhausts accepted output reads by the finite packet R and its readiness view. Since neither view has a coordinate for a detached output channel, the route to O is determined by the displayed rows. □

Theorem 525.178 (AuthorizedGeneratorRecursor closed-substitution consumer lock)**.** *Every downstream consumer passing an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet to chapter 527 or chapter 538 must retain the authorized output route of Definition 525.177. The consumer may read O only through*

$$I, E, M, B, D, O, A, H, C, P, G, N,$$

and cannot reinterpret closed substitution as an off-packet generator result, an unrestricted substitution calculus, or a proof-producing branch outside the authorized recursor packet.

Proof. Project the output route determinacy theorem. It gives the closed-substitution consumer the output row only as part of the accepted signature, eliminator, motive, branch, descent, audit, route, package, boundary, and local naming rows.

Read the closed-substitution chapters as consumers, not as producers of the recursor output. Their boundary surface can specialize finite BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ data, but it receives no coordinate from which to manufacture a generator result outside R.

The exclusion follows by row projection. If a consumer tries to interpret substitution as an off-packet generator result, the interpretation would need a second output route or branch source. The packet has neither coordinate, and admission exhaustion keeps such requests on the displayed boundary and refusal rows. □

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCarrier closed substitution consumer lock

Theorem 525.179 (AuthorizedGeneratorRecursor normalization-frontier consumer lock)**.** *Every route from an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet into chapter 892 and chapter 534 consumes the output row* O *only through the same finite packet*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Such a route cannot add a second generator, a hidden induction principle, or a proof-producing branch source beyond the authorized signature, branch, descent, audit, route, package, boundary, and local NameCert *rows.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorNormalizationFrontierCons

Proof. First retain the authorized route. The output-route determinacy theorem fixes O behind $I, E, M, B, D, A, C, P, G, N$, with H carrying componentwise transport across the same rows.

Next pass to the normalization-frontier and recursor-generator consumers. They may consume the named output as finite boundary data and generator provenance, but only through the continuation and package rows already displayed in the accepted packet.

It remains to rule out hidden producers. A second generator, hidden induction principle, or proof-producing branch would require an additional constructor, eliminator, branch, descent, or output coordinate. Branch exhaustion, structural-descent locality, audit provenance factorization, and admission exhaustion leave no such coordinate, so the consumers remain locked to the finite packet. □

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCarrier normalization frontier consumer lock

Corollary 525.180 (AuthorizedGeneratorRecursor output-route strict local obstruction)**.** *Let an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be consumed by a normalization-frontier or recursor-generator downstream route as in Definition 525.179. If that consumer displays a failure, refusal, separation, or countermodel row against a converse output reading, a reuse of the recursor output, or a second generator interpretation, then the displayed row obstructs only that named consumer-facing route through

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

It cannot be reinterpreted as a global impossibility theorem, a host theorem about all recursors, a hidden external validation of the failed route, or a second meaning of O *outside the authorized packet.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorOutputRouteStrictLocalObs

Proof. Apply Definition 525.177 first. Any accepted read of O is determined by the displayed signature, eliminator, motive, branch, descent, audit, route, package, boundary, and local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecurso}}$ rows. In particular, there is no accepted output route detached from these rows and no downstream consumer may recover a second output meaning from the packet.

Now pass to the normalization-frontier and recursor-generator consumers. By Definition 525.179, every such route consumes O only through the same finite packet and cannot add a second generator, hidden induction principle, or proof-producing branch source beyond the displayed rows.

Consider a displayed failure, refusal, separation, or countermodel row in such a consumer. For the row to bear on the authorized output, the two cited theorems force its consumer-facing use to factor through the named packet coordinates. Therefore the row can block the advertised converse reading, reuse route, or second-generator interpretation only at those coordinates. Reading it as a global impossibility would require a theorem coordinate outside the packet; reading it as a host theorem would require a host-facing induction or proof row outside the packet; reading it as hidden external validation would require an external certificate route outside the packet. The determinacy theorem and the consumer lock exclude all three additional coordinates, so the obstruction remains strict and local to the named route. □

Theorem 525.181 (AuthorizedGeneratorRecursor boundary audit exhaustion)**.** *Every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet that exposes the boundary row G must retain the audit row A, componentwise transport row H, displayed* Cont *row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row N before any output row O is public. The retained root-boundary packet is exactly the finite* BHist *surface*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Thus an output-facing consumer may reach G only through the same audited carrier, not through a detached boundary witness or a public output name alone.

Proof. Begin with the carrier definition Definition 525.1. It places G in one finite BHist packet with O, A, H, C, P and the local certificate row N, and it gives no separate coordinate for a boundary witness outside that packet.

Apply the local surface theorem Definition 525.3. It allows a downstream consumer to treat O as recursor-generated only through the displayed packet, while Definition 525.2 and Definition 525.5 keep the signature, branch package, and descent rows attached to that read.

Finally use the root-unblock rows already available in this chapter. Theorems 525.128 and 525.129 force every output-facing route through $I, E, M, B, D, O, A, H, C, P, G, N$, and Definition 525.130 excludes a hidden authorization route. Therefore the audit, transport, continuation, provenance, and local naming rows are retained before O becomes public. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorBoundaryAuditExhaustion`

Theorem 525.182 (AuthorizedGeneratorRecursor output provenance coverage)**.** *For every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet, public provenance for the output row O factors through exactly the displayed rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The provenance cannot be replaced by an unaudited generator route, an off-packet Pkg *witness, or a local name that omits the audit row A and boundary row G.*

Proof. Project the finite carrier of Definition 525.1. The output row O is listed with the constructor signature, emitted eliminator, motive, branch package, descent row, audit row, transport row, continuation row, package provenance, boundary row, and local certificate.

Use Definition 525.3 to read this list as the local NameCert surface. Branch coverage and structural descent are not optional provenance side data: by Definition 525.2 and Definition 525.5, they remain part of every public recursive read.

Now attach the root-boundary audit exhaustion just proved. It keeps A, H, C, P, G, N on the same route before O is public. The root-unblock route totality theorem Definition 525.129 supplies the matching output-facing path, and Definition 525.130 rules out a ledger export of an unaudited generator route.

Since the displayed tuple has no coordinate for an off-packet package witness, hidden generator, or local name without audit provenance, the output provenance is covered exactly by $I, E, M, B, D, O, A, H, C, P, G, N$. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorOutputProvenanceCoverage`

Theorem 525.183 (AuthorizedGeneratorRecursor recursion-channel refusal)**.** *Any attempted use of an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet as a non-structural recursion channel, missing-branch repair, detached substitution step, or hidden proof-producing generator is routed to the displayed boundary row G and the audited rows A, H, C, P, N rather than exported as a public output. In particular, the packet exports only the structural recursor route witnessed by $I, E, M, B, D, O, A, H, C, P, G, N$.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRecursionChannelRefusal`

Proof. Start with branch exhaustion and structural descent locality. Theorems 525.2 and 525.5 leave no public branch outside B and no recursive call whose descent is absent from D.

Next read the carrier and NameCert surface. By Definition 525.1 and Definition 525.3, the boundary row G is the displayed place where unlisted branches, non-structural recursion, external axioms, and hidden proof generators are refused.

Detached substitution is handled by the root-unblock packet rows. Theorems 525.129 and 525.130 force output-facing and ledger-facing reads to stay inside the same BHist, Cont, Pkg, and $\mathsf{NameCert}$ rows, so a substitution step cannot become an off-packet generator.

Finally apply boundary audit exhaustion and output provenance coverage above. They keep A, H, C, P, G, N attached before O is public. Therefore every rejected recursion channel is recorded at the displayed boundary rather than exported as a public proof-producing route. □

Corollary 525.184 (AuthorizedGeneratorRecursor boundary audit strict obstruction)**.** *For an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet, the obstruction recorded by the boundary-audit exhaustion and recursion-channel refusal is strictly local. It blocks only the attempted non-structural recursion channel, missing-branch repair, detached substitution step, or hidden proof-producing generator named in Definition 525.183. Its consumer-facing use must factor through the displayed packet*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Consequently the same obstruction cannot be reread as a global impossibility theorem, a host theorem, or an external validation route for any coordinate not displayed in that packet.

Proof. Apply Definition 525.181. It identifies the output-facing boundary audit with the finite BHist surface $I, E, M, B, D, O, A, H, C, P, G, N$ and says that a consumer may reach the boundary row G only through the audited carrier retaining A, H, C, P and the local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ row N. Thus the boundary row is not a detached witness and is not available through the public output name alone.

Now apply Definition 525.183. The only failed uses routed to G are the named attempts: non-structural recursion, missing-branch repair, detached substitution, and hidden proof production. The theorem sends those attempts back to the audited rows A, H, C, P, N and states that the packet exports only the structural recursor route witnessed by the same displayed rows.

These two statements exhaust the consumer-facing cases. A listed failed route factors through G together with A, H, C, P, N, so it is blocked as a local misuse of the accepted recursor packet. An unlisted use would require an additional public coordinate, such as a global impossibility certificate, host theorem row, or external validation row. The carrier displayed in Definition 525.181 has no such coordinate, and Definition 525.183 exports no route besides the structural recursor route. Therefore the obstruction is exactly the local obstruction stated above. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorBoundaryAuditStrictObstru`

Theorem 525.185 (Authorized generator recursor branch descent audit totality)**.** *Every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet reads the branch package B, descent row D, output row O, and audit row A only through the displayed carrier*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The branch, descent, output, and audit coordinates therefore form one root boundary: a consumer cannot read a branch package without the matching descent row, cannot read an output row outside the audit row, and cannot replace the displayed carrier by host induction, an external axiom route, an unaudited dependency route, or an off-packet substitution.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor branch descent audit totality`

Proof. Begin with the carrier, Definition 525.1. It displays exactly the input, authorization, measure, branch, descent, output, audit, transport, continuation, provenance, ground-compiler, and local naming rows.

Apply carrier admission, Definition 525.34. Admission exposes B, D, O, A as rows of the same accepted packet, not as detachable host data.

Now use root boundary ledger totality, Definition 525.74. It forces every public read of the root boundary through the audit ledger attached to the displayed route.

Finally apply the ground-compiler handoff, Definition 525.7. The handoff keeps branch choice, descent evidence, output naming, and audit replay inside $I, E, M, B, D, O, A, H, C, P, G, N$, excluding host induction, external axioms, unaudited dependency routes, and off-packet substitutions. □

Theorem 525.186 (Authorized generator recursor output NameCert non-escape)**.** *For every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet, public output from the displayed output row O remains inside the local* $\mathsf{NameCert}$ *row N and the ground-compiler boundary G. It cannot escape into host induction, external axioms, unaudited dependency routes, detached branch packages, off-packet substitutions, or an output certificate not carried by*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor output namecert nonescape`

Proof. Project the accepted carrier of Definition 525.1. The only public output coordinate is O, and it is packaged together with the audit row A, ground-compiler row G, and local NameCert row N.

Use carrier admission, Definition 525.34, to identify the admitted output as a row of the same finite packet. Then apply root boundary ledger totality, Definition 525.74, so every public output read is replayed through the audit boundary rather than through an off-packet dependency route.

The ground-compiler handoff, Definition 525.7, supplies the final boundary. It sends the output read through G and N, so public output cannot be reinterpreted as host induction, external axioms, a detached branch package, an unaudited substitution, or any output certificate outside the displayed carrier. □

Corollary 525.187 (Authorized generator recursor branch descent local obstruction)**.** *For every accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, any displayed failure, refusal, separation, or countermodel row attached to branch descent blocks only the local route that tries to read one of the following coordinates outside the displayed carrier:*

$$B \text{ without } D, \quad O \text{ outside } A, \quad O \text{ outside } G \text{ and } N, \quad \text{or a certificate not carried by } I, E, M, B, D, O, A, H, C, P, G$$

The obstruction cannot be reinterpreted as a global impossibility theorem for recursors, as a host induction theorem, as hidden external validation, or as a rejection of any consumer route that still factors through the displayed branch, descent, output, audit, ground-compiler, and local NameCert *rows.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorBranchDescentLocalObstruc`

Proof. Fix an accepted packet. By Definition 525.185, every consumer-facing read of branch, descent, output, and audit data is a read through the single displayed carrier

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

In particular, B is not available as a detached branch package, D is the matching descent row for that branch package, O is not available outside A, and the carrier cannot be replaced by host induction, an external axiom route, an unaudited dependency route, or an off-packet substitution.

Apply Definition 525.186 to the output side of the same read. Public output from O remains inside the local NameCert row N and the ground-compiler boundary G, and it has no escape route to a detached branch package, an external certificate, host induction, external axioms, unaudited dependencies, or an off-packet substitution.

Therefore the only coordinates on which a displayed obstruction can act are the named local coordinates of the carrier: branch detachment from D, output detachment from A, output escape from G and N, or certificate reuse outside $I, E, M, B, D, O, A, H, C, P, G, N$. Since both cited theorems exhaust consumer-facing reads by those rows, the obstruction has no additional coordinate from which to assert a global impossibility, a host theorem, or hidden external validation. Conversely, a consumer route that still factors through the displayed rows is not blocked by this corollary; the corollary blocks only the named converse or reuse route that leaves the local carrier. □

Theorem 525.188 (Authorized generator recursor root-output totality lock)**.** *Let* $R = (I, E, M, B, D, O, A, H, C,$ *be an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *carrier. Every public exposure of the root output row O factors through the same displayed packet: branch exhaustion in B, structural descent in D, audit provenance in A, componentwise transport in H, displayed* Cont *routes in C,* Pkg *provenance in P, the* GAP *boundary in G, and the local* NameCert *row N.*

The checked TasteGate marker BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTaste *is used only as the single-carrier alignment witness for this packet. It does not expose host induction, an external axiom route, an unaudited dependency route, off-packet substitution, or a second output certificate.*

Proof. Start from the carrier definition, Definition 525.1. It displays the root packet R and leaves no output coordinate outside $I, E, M, B, D, O, A, H, C, P, G, N$.

Apply branch exhaustion and structural descent locality, Definition 525.2 and Definition 525.5. These force every recursive output read to retain the constructor signature, branch package, and descent row before O can be public.

Next attach audit and route provenance. Theorems 525.4 and 525.6 keep A, H, C, P, G, N attached to the output exposure.

Finally use the ground-compiler handoff, Definition 525.7. The TasteGate marker is read only as the aligned-carrier witness, so no hidden generator, host induction principle, external axiom, unaudited route, or off-packet substitution can replace the displayed root-output packet. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootOutputTotalityLock`

Theorem 525.189 (Authorized generator recursor root audit route exactness)**.** *For the accepted carrier $R = (I, E, M, B, D, O, A, H, C, P, G, N)$, the root audit route is exact: every audit-facing consumer that reads O must also read the branch-exhaustion row B, structural-descent row D, audit-provenance row A, displayed* Cont *route C,* Pkg *row P,* GAP *boundary G, and local* NameCert *row N from the same packet.*

Thus the audit route cannot be reconstructed from output naming alone, and it cannot be replaced by host recursion, a detached proof-producing generator, external kernel equality, or an unaudited dependency channel.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor root audit route exactness`

Proof. Project the accepted packet through Definition 525.1. The row A is displayed next to O and the boundary rows H, C, P, G, N, so the audit route begins inside R.

Use the root-output audit totality theorem, Definition 525.46. It places every public output read behind the branch, descent, audit, route, package, boundary, and local naming rows.

The audit provenance factorization, Definition 525.6, then records that the output row becomes public only after the audit provenance and route rows remain attached.

Finally apply the root boundary nonescape and ground-compiler handoff, Definition 525.47 and Definition 525.7. They keep the GAP boundary and TasteGate alignment on the same carrier, excluding the detached audit routes listed in the statement. □

Theorem 525.190 (Authorized generator recursor root consumer readiness surface)**.** *The accepted packet $R = (I, E, M, B, D, O, A, H, C, P, G, N)$ is ready for downstream root consumers precisely as the displayed branch-exhaustion, structural-descent, audit-provenance,* Cont*,* Pkg*,* GAP*, and* NameCert *surface. Any closed-normal, substitution-boundary, generator-audit, or ground-compiler consumer must read O through those rows and through the checked single-carrier TasteGate alignment marker already attached to the chapter.*

The readiness surface exports no unlisted branch, non-structural recursion channel, hidden generator, host induction principle, external axiom route, unaudited dependency route, or output row outside R.

Proof. Begin with downstream consumer factorization, Definition 525.52. It makes every downstream consumer read through the same finite carrier before using the output row.

Next use terminal consumer readiness, Definition 525.97, and downstream NameCert packaging, Definition 525.174. These route closed-normal, substitution-boundary, and generator-audit consumers through the branch, descent, audit, continuation, package, boundary, and local naming rows.

Attach the root-output totality lock above. It ensures that the output row remains the displayed coordinate O of R after branch exhaustion, structural descent, audit provenance, Cont, Pkg, GAP, and NameCert have all been read.

Finally apply the ground-compiler handoff, Definition 525.7. The checked TasteGate marker is consumed only as the single-carrier alignment witness, so the downstream readiness surface contains exactly the rows stated above. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor root consumer readiness surface`

Lemma 525.191 (Authorized generator recursor root-output totality downstream coverage)**.** *Let $R = (I, E, M, B, D, O, A, H, C, P, G, N)$ be an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *carrier. Every accepted local downstream consumer that reads the root output row O is exhausted by the finite surface displayed in the root-output packet: constructor and branch alternatives are read through I, E, M, B, D, audit and output ledgers are read through O, A, H, C, P, and boundary, coverage, and local naming rows are read through G, N together with the displayed* Cont *route C and componentwise transport row H.*

Consequently an unlisted constructor alternative, detached branch table, unchecked motive, nonstructural recursion channel, hidden generator, host induction principle, external axiom route, unaudited dependency route, off-packet substitution authority, second output certificate, or naming certificate outside R remains outside the BEDC packet exposed to that consumer.

Proof. Start with the root-output totality lock, Definition 525.188. It says that every public exposure of O factors through the displayed packet: branch exhaustion in B, structural descent in D, audit provenance in A, componentwise transport in H, displayed Cont routes in C, Pkg provenance in P, the GAP boundary in G, and the local NameCert row N. Since the carrier itself is the finite tuple $R = (I, E, M, B, D, O, A, H, C, P, G, N)$ of Definition 525.1, this first step leaves no output coordinate from which a downstream consumer could obtain a second route to O.

Now apply root audit route exactness, Definition 525.189. Any audit-facing consumer that reads O must also read the branch-exhaustion row B, structural-descent row D, audit-provenance row A, displayed Cont route C, Pkg row P, GAP boundary G, and local NameCert row N from the same packet. Thus the consumer-facing use of O is not merely named by the output row; it is forced to carry the route, transport, package, boundary, and local naming rows that the totality lock lists.

These two constraints exhaust the downstream cases. A constructor or recursive-call demand is covered by the admitted signature, emitted eliminator, motive, branch package, and descent row I, E, M, B, D. An output-ledger or audit demand is covered by O, A, H, C, P. A boundary, refusal, or local-readback demand is covered by G, N together with the same displayed transport and continuation rows. Any proposed consumer fact outside those alternatives would need either a public exposure of O not factored by the totality lock or an audit-facing route not exact in the sense of Definition 525.189. Both possibilities are excluded, so all unlisted alternatives remain outside the BEDC packet. □

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRootOutputTotalityDownstr

The L10 route reads the authorized recursor packet through chapter 126, chapter 301, and chapter 38, while the audit row remains tied to chapter 533.

Theorem 525.192 (AuthorizedGeneratorRecursor L10 source triad)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. Any L10-facing finite-source consumer for* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *may read the packet only through the displayed rows* $I, E, M, B, D, O, A, H, C, P$ *signature admission in* I*, emitted recursor naming in* E*, motive checking in* M*, branch coverage in* B*, structural descent in* D*, audit provenance in* A*, boundary refusal in* G*, continuation locality in* C*, package provenance in* P*, componentwise* hsame *transport in* H*, and the local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row* N*. No L10 source route may read the packet as a host choice, a detached induction rule, a selected real witness, a quotient stream, or an external proof producer.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorL10OpenPhaseSourceTriad

Proof. Project the carrier of Definition 525.1. The displayed packet lists exactly the signature, eliminator, motive, branch, descent, output, audit, transport, continuation, provenance, boundary, and local naming rows available to a consumer.

Use branch exhaustion, Definition 525.2, together with structural descent locality, Definition 525.5. These keep every recursive read on the accepted constructor signature, complete branch package, and displayed descent row before any finite-source route can use the output name.

Attach the output and audit locks. Theorems 525.177, 525.181, and 525.188 keep O with A, H, C, P, G, N on the same finite route.

The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers therefore receive only a BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ route over the displayed packet. The carrier has no coordinate for host choice, detached induction, selected real data, quotient stream data, or an external proof producer. □

Theorem 525.193 (AuthorizedGeneratorRecursor consumer handoff)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet must preserve the output row* O *together with* A, H, C, P, G, N*. The consumer may specialize the packet to a finite real-source or completion-source route, but it cannot reinterpret the recursor packet as a host choice principle, hidden induction principle, selected limit, quotient stream, or external proof-producing channel.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorOpenPhaseConsumerHandoff

Proof. Start with the L10 source triad above. It gives downstream consumers access to O only through the same finite packet rows, with the audit, transport, continuation, provenance, boundary, and local naming rows still attached.

Read the existing downstream locks. Theorems 525.177, 525.178, and 525.179 treat downstream consumers as readers of the authorized output route rather than as producers of a second generator result.

Now specialize the route to real and completion consumers. A $\mathsf{Real}^{\uparrow}$ or completion-facing route may consume finite BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ evidence, but the row O remains attached to A, H, C, P, G, N by output provenance coverage and root-output totality.

The excluded interpretations would require a separate host choice coordinate, hidden induction row, selected-limit witness, quotient-stream equality, or proof-producing channel. None is present in the carrier, and the boundary row G records their refusal. □

Theorem 525.194 (AuthorizedGeneratorRecursor ledger non-escape)**.** *For L10-facing use of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet, the audit row A and boundary row G exhaust the ledger exported to consumers. Every consumer route is a finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route over*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

No route exports a completion object, a real-completeness datum, a quotient completion equality, a selected limit, or a host proof of completeness.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorOpenPhaseLedgerNonescape`

Proof. Project the carrier and retain the audit and boundary rows. The definition of the carrier places A and G in the same finite packet as the branch, descent, output, transport, continuation, provenance, and local naming rows.

Use the local boundary results. Theorems 525.4, 525.181, and 525.183 route every rejected generator, recursion, or dependency request to the displayed boundary and audit rows.

Next use root-output totality and output provenance coverage. They keep L10-facing reads inside the same BHist, hsame, Cont, Pkg, and NameCert surface before the output row becomes public.

Thus the ledger exported to StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and completion-facing consumers is finite and local to the packet. Completion objects, real-completeness data, quotient completion equality, selected limits, and host completeness proofs are not rows of R, so they cannot escape from the ledger. □

Theorem 525.195 (AuthorizedGeneratorRecursor L10 readiness closure)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted AuthorizedGeneratorRecursor$^{\uparrow}$ *packet. If the L10 source triad, consumer handoff, and ledger non-escape rows are displayed, then R exports exactly the readiness surface required by* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*, and the MetaCIC normalization boundary: finite reads through $I, E, M, B, D, O, A, H, C, P, G, N$, componentwise* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *transport, and the boundary refusal row G. It exports no global recursion theorem, host induction principle, hidden completion selector, selected real witness, quotient stream equality, or proof-producing channel outside the displayed packet.*

Proof. First cite the L10 source triad, Definition 525.192. It identifies the rows available to StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and completion-facing readers before any consumer may treat the recursor output as a source.

Next apply the consumer handoff theorem, Definition 525.193. It keeps the output row O attached to A, H, C, P, G, N when a Real, completion, or normalization-boundary consumer specializes the finite route.

Finally apply ledger non-escape, Definition 525.194. The audit and boundary rows exhaust the exported ledger, so the readiness surface is exactly the displayed finite packet with its BHist, hsame, Cont, Pkg, and NameCert access. A global recursion theorem, host induction principle, hidden completion selector, selected real witness, quotient stream equality, or external proof-producing channel would require an additional coordinate not present in R. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorL10ReadinessClosure`

Theorem 525.196 (AuthorizedGeneratorRecursor public L10 source handoff)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet whose L10 source triad, consumer handoff, and ledger non-escape rows are displayed. Then the public L10 source handoff exported to* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers is exactly the finite route through* $I, E, M, B, D, O, A, H, C, P, G, N$ *with* BHist, hsame, Cont, Pkg, *and* NameCert *access. The exported handoff cannot be read as host choice, detached induction, selected real witness, quotient stream equality, or a proof-producing channel.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorL10PublicSourceHandoff`

Proof. First use Definition 525.192. It identifies the public source rows available to the three L10 consumers and keeps the route inside the accepted packet.

Next use Definition 525.193. It preserves the output row O together with A, H, C, P, G, N when the route is specialized to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$.

Finally apply Definition 525.194 and Definition 525.195. The ledger refusal and readiness closure leave only the displayed BHist, hsame, Cont, Pkg, and NameCert surface, so the excluded host-choice, detached-induction, selected-witness, quotient-equality, and proof-producing readings have no exported coordinate. □

Theorem 525.197 (AuthorizedGeneratorRecursor L10 source-triad public export)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet whose L10 open-phase source triad is exposed to a public consumer. Any accepted authorized-generator recursor consumer of that source triad must factor through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before it exposes generator authorization, recursion scheduling, or ledger replay. The exported route remains the finite* BHist, hsame, Cont, Pkg, *and* NameCert *surface over* $I, E, M, B, D, O, A, H, C, P, G, N$ *and cannot reopen host choice, detached induction, selected real witnesses, quotient stream equality, or proof-producing channels.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorL10SourceTriadPublicExpor`

Proof. First use the L10 source triad, Definition 525.192. It lists the only rows available before a public consumer may read the authorized recursor as a source.

Next apply the consumer handoff, Definition 525.193. It keeps the output row O attached to the audit, transport, continuation, provenance, boundary, and local naming rows when the consumer specializes the route.

Now combine ledger non-escape and readiness closure, Definition 525.194 and Definition 525.195. These results force the public route to pass through the same finite ledger and readiness surface before generator authorization, recursion scheduling, or replay is exposed.

Finally use the public source handoff, Definition 525.196. The handoff identifies the consumer-facing route for $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; adding the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance surface only records the finite tolerance row used before the regular and real-facing consumers. No unlisted host-choice, detached-induction, selected-witness, quotient-equality, or proof-producing coordinate can be exported. □

Corollary 525.198 (AuthorizedGeneratorRecursor L10 source-triad strict obstruction)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet, and let a* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or completion-facing L10 consumer display a failure, refusal, separation, or countermodel row against a named converse or reuse route for the source triad. Then that row is a strict local obstruction: it blocks only the named route whose consumer-facing read factors through the displayed finite route, transport, and readback rows*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

with BHist, hsame, Cont, Pkg, *and* NameCert *access. It cannot be reinterpreted as a global impossibility theorem, a host theorem about recursors or real completion, hidden external validation of the failed route, a selected real witness, a quotient stream equality, a completion object, or a proof-producing channel outside the accepted packet.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorL10SourceTriadObstructio`

Proof. Start with the L10 source triad in Definition 525.192. It identifies the only rows available to an L10-facing finite-source consumer: signature admission I, emitted recursor naming E, motive checking M, branch coverage B, structural descent D, output naming O, audit provenance A, componentwise hsame transport H, continuation locality C, package provenance P, boundary refusal G, and the local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ row N. The same theorem excludes host choice, detached induction, selected real data, quotient stream data, and external proof production as possible source reads.

Now apply ledger non-escape, Definition 525.194. For L10-facing use, the exported ledger is exhausted by the audit row A and boundary row G, and every consumer route is a finite BHist, hsame, Cont, Pkg, and NameCert route over the displayed packet. The ledger exports no completion object, real-completeness datum, quotient completion equality, selected limit, or host proof of completeness.

Consider the displayed failure, refusal, separation, or countermodel row. If it is used by the named consumer against the authorized source triad, the two cited results force that use to pass through exactly the displayed packet rows and their BHist, hsame, Cont, Pkg, and NameCert readback surface. Thus the row can obstruct only the advertised converse or reuse route at the packet coordinate where that route asks to read, replace, or bypass one of those rows.

Any stronger interpretation asks for an unlisted coordinate. A global impossibility theorem would require a theorem surface beyond the finite packet; a host theorem would require host choice, detached induction, or a host completeness proof; hidden external validation would require an external certificate route; a selected real witness, quotient stream equality, completion object, or proof-producing channel would require one of the objects that the triad and the ledger explicitly refuse. Since none of those coordinates is exported by R, the obstruction remains strict and local to the named L10 source-triad route. □

Theorem 525.199 (AuthorizedGeneratorRecursor RegSeqRat route factorization)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of the recursor output factors through the displayed signature, eliminator, motive, branch, descent, output, audit,*

transport, continuation, provenance, boundary, and local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *rows. In particular, the consumer may read* O *only after the route retains* $I, E, M, B, D, A, H, C, P, G, N$ *in the same finite packet, and it obtains no regular-rational source outside that route.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRegSeqRatRouteFactorizati`
Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCarrier regseqrat route factorization`

Proof. Start from the L10 source triad, Definition 525.192. It already identifies the $\mathsf{RegSeqRat}^{\uparrow}$ consumer as a finite-source reader of $I, E, M, B, D, O, A, H, C, P, G, N$ rather than as a separate source producer.

Use the open-phase consumer handoff, Definition 525.193. The handoff keeps O attached to A, H, C, P, G, N, so a regular-rational consumer cannot detach the output from audit, transport, continuation, provenance, boundary, and local naming rows.

Finally apply the ground-compiler authorization row, Definition 525.110. The ground-facing read of O is admitted only after the same finite packet has been retained, which is exactly the required factorization route for $\mathsf{RegSeqRat}^{\uparrow}$ consumption. □

Theorem 525.200 (AuthorizedGeneratorRecursor Real seal non-escape)**.** *For an accepted* AuthorizedGeneratorRec *packet*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N),$$

every $\mathsf{Real}^{\uparrow}$ *consumer of the recursor output preserves the same finite route through* $I, E, M, B, D, O, A, H, C, P, G, N$ *The route supplies only displayed* BHist*,* hsame*,* Cont*,* Pkg*, boundary, audit, and local* NameCert *data; it supplies no selected real witness, quotient stream, host equality, detached induction rule, or external proof producer.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRealSealRouteNonescape`

Proof. Read the output route through Definition 525.192. The theorem places $\mathsf{Real}^{\uparrow}$ use on the same displayed packet as $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$, with no coordinate for a selected limit or quotient stream.

The consumer side is controlled by Definition 525.193. It allows specialization to a real-source route while keeping O with A, H, C, P, G, N and excluding host choice, hidden induction, selected-limit, quotient-stream, and proof-producing interpretations.

The ledger side is closed by Definition 525.194. Since the audit and boundary rows exhaust what can be exported to the real-facing consumer, the real seal does not escape the AuthorizedGeneratorRecursor packet. □

Theorem 525.201 (AuthorizedGeneratorRecursor completion boundary exhaustion)**.** *Let* $R = (I, E, M, B, D, O, A, H, C, P, G, N)$ *be an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. A completion-facing consumer of the recursor output has exactly two admissible boundary shapes: it either displays a separate completion-seal row before using completion data, or it remains bounded by the AuthorizedGeneratorRecursor packet through* $I, E, M, B, D, O, A, H, C, P, G, N$*. Without the separate completion-seal row, the consumer cannot read a completion object, quotient completion equality, selected limit, host completeness proof, or off-packet proof producer.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCompletionBoundaryExhaust`

Proof. Begin with Definition 525.193. Completion-facing use is treated as a downstream specialization of the same finite output route, so O remains attached to A, H, C, P, G, N.

Apply Definition 525.194. The ledger exported by the packet is finite and local to $I, E, M, B, D, O, A, H, C, P, G,$ and it does not export completion objects, real-completeness data, quotient completion equality, selected limits, or host completeness proofs.

If the consumer displays a separate completion-seal row, that row is outside the AuthorizedGeneratorRecursor packet and must carry its own boundary obligation. If it does not, the ground-compiler authorization theorem Definition 525.110 keeps the consumer on the accepted packet surface, exhausting the completion boundary at G, N and the retained audit route. □

Corollary 525.202 (AuthorizedGeneratorRecursor RegSeqRat route strict obstruction)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. Suppose a displayed failure, refusal, separation, or countermodel row is used against a named converse, reuse, or readback route for the* $\mathsf{RegSeqRat}^{\uparrow}$ *factorization of* R*. Then the row is a strict local obstruction: it blocks only that named route at the finite packet surface*

$$I, E, M, B, D, O, A, H, C, P, G, N,$$

with readback through the displayed BHist*,* hsame*,* Cont*,* Pkg*, boundary, audit, transport, provenance, and local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *rows. It cannot be reinterpreted as a global impossibility theorem, a host theorem about recursors or real completion, hidden external validation of the failed route, a selected real witness, a quotient stream equality, a detached induction rule, a completion object, or an external proof producer.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRegSeqRatRouteStrictObstr`

Proof. Apply the $\mathsf{RegSeqRat}^{\uparrow}$ route factorization theorem, Definition 525.199. It states that every $\mathsf{RegSeqRat}^{\uparrow}$ consumer of the recursor output factors through the displayed signature, eliminator, motive, branch, descent, output, audit, transport, continuation, provenance, boundary, and local naming rows. In particular, the consumer may read O only while retaining $I, E, M, B, D, A, H, C, P, G, N$ in the same finite packet, and it obtains no regular-rational source outside that route.

Now apply the Real seal non-escape theorem, Definition 525.200. The real-facing endpoint preserves the same finite route through $I, E, M, B, D, O, A, H, C, P, G, N$ and supplies only displayed BHist, hsame, Cont, Pkg, boundary, audit, and local NameCert data. It supplies no selected real witness, quotient stream, host equality, detached induction rule, or external proof producer.

Consider the displayed failure, refusal, separation, or countermodel row. If it is cited against a named converse, reuse, or readback route, the first theorem forces that citation to live on the $\mathsf{RegSeqRat}^{\uparrow}$ factorization surface, and the second theorem prevents the same citation from being lifted through a real-facing escape coordinate. Thus the row can obstruct only the advertised route at the coordinate where that route asks to read, reuse, detach, or bypass one of the displayed packet rows.

Any stronger interpretation asks for data that neither theorem exports. A global impossibility theorem would require a theorem surface beyond the accepted finite packet; a host theorem would require host equality, detached induction, or host completeness data; hidden external validation would require a proof-producing channel outside the packet; a selected real witness, quotient stream equality, or completion object would require one of the objects explicitly absent from the real seal. Since the accepted packet exports none of these coordinates, the obstruction remains strict and local to the named $\mathsf{RegSeqRat}^{\uparrow}$ route. □

Theorem 525.203 (AuthorizedGeneratorRecursor Real stream route)**.** *For every accepted* AuthorizedGeneratorRec *packet that is read as an L10 source route, the public generator output may depend on* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$ *source rows only after those rows are carried through the same finite route*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The route exposes source rows as BHist, hsame, Cont, Pkg, *boundary, and local* NameCert *data, and it exports no selected Real limit, quotient stream equality, host evaluation, or detached generator state.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor real stream route`

Proof. Begin with the closed-substitution handoff of Definition 525.86. It keeps every output-facing consumer inside the displayed packet before the row O is public.

Use the ground-compiler authorization theorem, Definition 525.110. It forces the same retained route for any consumer that compiles the generator output into a ground-facing surface.

Finally apply Definition 525.121. Terminal authorized output is read only from the finite packet rows, so the Real, regular-rational, and stream-name source rows remain packet data rather than external completion objects. □

Theorem 525.204 (AuthorizedGeneratorRecursor substitution membrane lock)**.** *The L10 route of* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *locks closed-substitution and operational-membrane rows before any generator output is public. A consumer may read substitution, branch, descent, audit, transport, continuation, package, boundary, and local naming rows from the packet, but it cannot cross the membrane through unrestricted substitution, unchecked recursion, external proof generation, host equality, or a private audit channel.*

Proof. Read the output boundary through Definition 525.86. The handoff places closed-substitution consumption behind the displayed carrier route rather than behind a general substitution calculus.

Next use Definition 525.110. The operational side of the membrane retains signature, eliminator, motive, branch, descent, audit, transport, continuation, provenance, boundary, and local naming rows together.

The terminal cover theorem, Definition 525.121, closes the membrane at the output row. It leaves no route for unchecked recursion, host equality, external proof generation, or a private audit channel outside the displayed packet. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor substitution membrane lock`

Theorem 525.205 (AuthorizedGeneratorRecursor generator normalization readiness)**.** *Generator-normalization readiness for the current L10* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet is available only after the Real, regular-rational, stream-name, closed-substitution, operational-membrane, audit, continuation, package, boundary, and local NameCert rows have been retained in one displayed route. The readiness claim does not publicize any output through host normalization, unchecked recursion, selected Real limits, quotient stream equality, or an off-packet generator certificate.*

Proof. Start from Definition 525.86. It makes the output row readable only through the retained closed-substitution and generator-audit route.

Use Definition 525.110 to attach the normalization-facing route to the same accepted signature, emitted recursor, motive, branch, descent, audit, transport, continuation, provenance, boundary, and local naming rows.

Finally apply Definition 525.121. Since terminal output remains covered by the displayed packet, generator normalization is ready only as a packet-local consumer surface and not as a host-normalizer or selected-limit interface. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor generator normalization readiness`

Corollary 525.206 (AuthorizedGeneratorRecursor Real stream route determinacy)**.** *For every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet that is read as an L10* $\mathsf{Real}^{\uparrow}$ *stream route, every accepted consumer-facing use of the route, packet-local normal-form readiness, or exactness decision factors through the same finite packet rows*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

The source side is determined by the $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{StreamName}^{\uparrow}$ *rows carried as* BHist*,* hsame*,* Cont*,* Pkg*, boundary, and local* NameCert *data. The normalization side is determined by the retained closed-substitution, operational-membrane, audit, continuation, package, boundary, and local* NameCert *rows of that same packet. Hence two accepted consumers over those displayed rows choose the same finite route and the same packet-local normal-form or exactness decision named by the chapter; there is no alternate hidden coordinate, selected Real limit, quotient stream equality, host normalizer, off-packet generator certificate, or duplicate classifier source.*

Proof. Apply the Real stream route theorem, Definition 525.203. It places every public $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ reading behind the displayed finite route and states that the exported source data are only the packet rows BHist, hsame, Cont, Pkg, boundary, and local NameCert. Thus a consumer-facing Real stream route has no source coordinate outside $I, E, M, B, D, O, A, H, C, P, G, N$.

Now apply generator-normalization readiness, Definition 525.205. Readiness is available only after the Real, regular-rational, stream-name, closed-substitution, operational-membrane, audit, continuation, package, boundary, and local NameCert rows have been retained in one displayed route. Therefore a packet-local normal-form readiness claim or exactness decision is not a second interface: it is the same route read with the normalization-facing rows retained.

The two cited theorems have the same exclusions. The Real stream route exports no selected Real limit, quotient stream equality, host evaluation, or detached generator state, while generator-normalization readiness exports no host normalization, unchecked recursion, selected Real limit, quotient stream equality, or off-packet generator certificate. Any alleged alternate route, hidden coordinate, or duplicate classifier source would have to enter through one of those excluded interfaces or through a packet coordinate not displayed in the finite row list. Since every accepted consumer use has already been forced through the displayed source rows and the displayed normalization rows of the same packet, no such entry point remains.

Consequently the consumer may choose only the finite route already named by the chapter. Its normal-form readiness and exactness decision are packet-local readings of that route, so any two accepted consumers over the fixed displayed rows determine the same route and the same named decision. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRealStreamRouteDeterminac`

Theorem 525.207 (AuthorizedGeneratorRecursor L10 source-row admission)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. Every L10-facing accepted output packet exposes its* $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows only as displayed finite* BHist *rows inside the authorized output route. The source rows are visible only together with the displayed authorization, branch, descent, audit, componentwise* hsame, Cont, Pkg, *boundary, and local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *rows of* R.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorL10RealStreamOutputFactor`
Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor l10 source row admission`

Proof. Project the accepted carrier through Definition 525.192. That theorem already identifies $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ source use as finite packet access rather than as host source selection.

Next retain the route side. Theorems 525.199 and 525.203 keep regular-rational, stream-name, and Real reads on the displayed packet $I, E, M, B, D, O, A, H, C, P, G, N$ before the output is public.

Finally attach the handoff rows. The closed-substitution handoff Definition 525.86 and terminal-output readback Definition 525.225 preserve A, H, C, P, G, N with the output row. Thus source admission is exactly admission through the displayed finite BHist route with hsame, Cont, Pkg, boundary, and local $\mathsf{NameCert}$ evidence attached. □

Theorem 525.208 (AuthorizedGeneratorRecursor L10 Real-stream output factorization)**.** *For every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet* $R = (I, E, M, B, D, O, A, H, C, P, G, N)$, *each* $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of the output row* O *factors through the already displayed authorization, branch, descent, audit, componentwise* hsame, Cont, Pkg, *boundary, and local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *rows. No such consumer receives an output route that omits* $I, E, M, B, D, A, H, C, P, G, N$ *while retaining* O.

Proof. Begin with L10 source-row admission above. It fixes the consumer's input surface as the finite displayed packet, so a Real, stream-name, or regular-rational consumer begins from R rather than from a detached output token.

Use the route-factorization layer next. Theorems 525.199, 525.200, and 525.221 keep O attached to the source, authorization, audit, transport, continuation, provenance, boundary, and local naming rows.

Now pass to terminal readback. Theorem 525.225 requires every terminal read by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ to expose the same BHist packet, replay through C, preserve H, retain P, and name the read by N.

Therefore the consumer map factors through the displayed BEDC route. Since the carrier has no coordinate for a bare public output token, every consumer that reaches O has already retained the named rows of R. □

Theorem 525.209 (AuthorizedGeneratorRecursor L10 completion-boundary nonescape)**.** *Let* $R = (I, E, M, B, D, O, A, H, C, P, G, N)$ *be an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. No* $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or completion-facing consumer of* R *can recover a selected Real limit, quotient stream equality, host evaluation, detached generator state, ambient completion principle, or off-packet proof channel from the packet. Every such read remains bounded by the displayed* BHist, hsame, Cont, Pkg, *boundary, audit, and local* $\mathsf{NameCert}$ *route.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorL10CompletionBoundaryNone`

Proof. First use L10 source-row admission and L10 Real-stream output factorization. Together they put every Real, stream-name, regular-rational, or completion-facing read on the displayed packet before any output row can be consumed.

Next read the boundary facts. Theorems 525.201 and 525.194 exhaust the completion-facing ledger by A, H, C, P, G, N on the same finite route, with no exported completion object, quotient completion equality, selected limit, host completeness proof, or off-packet generator certificate.

Finally apply terminal-output readback and terminal authorized output cover. Theorems 525.225 and 525.121 keep output consumption inside $I, E, M, B, D, O, A, H, C, P, G, N$ and leave no route for host evaluation or hidden generator state.

The excluded data would require an additional carrier coordinate or a separate completion-seal row. Neither is supplied by the AuthorizedGeneratorRecursor packet, so the completion boundary cannot escape the displayed BEDC route. □

Corollary 525.210 (AuthorizedGeneratorRecursor L10 source-admission strict obstruction)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. Suppose an L10-facing* $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or completion-facing consumer displays a failure, refusal, separation, or countermodel row against a named converse or reuse route for source admission of* R. *Then the displayed row is a strict local obstruction: it blocks only that named converse or reuse route as a consumer-facing read through the finite rows*

$$I, E, M, B, D, O, A, H, C, P, G, N$$

with the displayed BHist, *componentwise* hsame, Cont, Pkg, *boundary, audit, terminal readback, and local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *evidence. It cannot be reinterpreted as a global impossibility result, a host theorem about recursors or completion, hidden external validation of the failed route, a selected real limit, quotient stream equality, detached generator state, ambient completion principle, or off-packet proof channel.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorL10SourceAdmissionStrictO`

Proof. Apply source-row admission, Definition 525.207. It fixes the source surface for every L10-facing accepted output packet: the $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ source rows are exposed only as displayed finite BHist rows inside the authorized output route, and only together with authorization, branch, descent, audit, componentwise hsame, Cont, Pkg, boundary, and local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ rows of R.

Apply completion-boundary nonescape, Definition 525.209. It says that no $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or completion-facing consumer of R can recover a selected Real limit, quotient stream equality, host evaluation, detached generator state, ambient completion principle, or off-packet proof channel from the packet. Every such read remains bounded by the displayed BHist, hsame, Cont, Pkg, boundary, audit, and local $\mathsf{NameCert}$ route.

Now consider the displayed failure, refusal, separation, or countermodel row. If the row is used against the named source-admission converse or reuse route, the admission theorem makes its consumer-facing use factor through the listed finite source rows, and the nonescape theorem prevents that use from acquiring any unlisted completion, host, generator, or external proof coordinate. The row therefore obstructs exactly the requested route at the displayed packet coordinate where the route asks to read, replace, or bypass the source-admission evidence.

A stronger reading would require a coordinate not exported by R. A global impossibility result would require a theorem surface beyond the finite packet; a host theorem would require host evaluation or host completeness data; hidden external validation would require an off-packet certificate channel; and selected limits, quotient stream equalities, detached generator states, ambient completion principles, or proof-producing channels are exactly the data excluded by Definition 525.209. Since the accepted packet supplies none of those coordinates, the obstruction remains strict and local to the named L10 source-admission route. □

Theorem 525.211 (AuthorizedGeneratorRecursor terminal-output readiness)**.** *For an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N),$$

the terminal output row O is dependency-ready only as a read of the same displayed carrier rows. Any terminal-output consumer must first preserve signature admission I, emitted recursor naming E, motive checking M, branch coverage B, structural descent D, audit provenance A, componentwise transport H, displayed routes C, package provenance P, boundary row G, and the local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row N. No terminal-output read may detach O into a hidden generator, host induction rule, external axiom, or proof-producing channel.*

Proof. Project the carrier of Definition 525.1. The output row O is one coordinate of $I, E, M, B, D, O, A, H, C, P, G$, not a second carrier.

Use audit provenance factorization and audit boundary. Theorems 525.6 and 525.4 keep public exposure of O behind the audit row, branch package, descent row, transports, routes, package provenance, boundary, and local name.

Finally attach output-name stability and ground-compiler handoff. Theorems 525.10 and 525.7 preserve the name of O only on the same finite carrier, so no hidden generator or host proof channel can replace the displayed packet. □

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalOutputReadiness`

Theorem 525.212 (AuthorizedGeneratorRecursor audit-gated output coverage)**.** *Every public terminal-output read of an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet is covered by the audit-gated rows A, H, C, P, G, N together with the source rows I, E, M, B, D. In particular, if a consumer reads O, it also reads the audit boundary, output-name stability, and ground-compiler handoff for the same carrier surface.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorAuditGatedOutputCoverage`

Proof. Begin with Definition 525.4. It places public output exposure behind accepted signature, motive, branch coverage, structural descent, and audit provenance.

Next use Definition 525.6. The audit, transport, continuation, package, boundary, and local naming rows remain attached before O is exported.

Output-name stability then prevents the terminal row from being renamed away from this audit package. The ground-compiler handoff consumes the same carrier only as a finite handoff, so terminal-output coverage is exactly the displayed rows and not an external generator route. □

Theorem 525.213 (AuthorizedGeneratorRecursor local-name output exhaustion)**.** *For every accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet, the local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row* N *exhausts terminal-output naming together with* O, A, H, C, P, G*. Any two terminal-output reads preserving the carrier rows* $I, E, M, B, D, O, A, H, C, P, G, N$ *name the same authorized output surface, and no consumer can add a detached local name, substitute branch table, unaudited proof object, or external compiler certificate.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorLocalNameOutputExhaustion`

Proof. Read the carrier and retain N with the output package. The local name row is attached to the same finite packet as O, A, H, C, P, G.

Apply output-name stability. Theorem 525.10 keeps terminal naming componentwise stable under the displayed hsame transports and continuation routes.

Use audit provenance factorization and ground-compiler handoff to close the consumer boundary. Theorems 525.6 and 525.7 leave no coordinate for a detached name, substitute branch table, unaudited proof object, or external compiler certificate outside the carrier. □

Theorem 525.214 (AuthorizedGeneratorRecursor Phase Real carrier readiness)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. Any Phase Real handoff that reads* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *dependency rows for* R *must first admit the displayed carrier as the finite* BHist *route* $I, E, M, B, D, O, A, H, C, P, G, N$*, with* H *carrying componentwise* hsame*,* C *carrying displayed* Cont *replay,* P *carrying package provenance,* G *carrying the boundary ledger, and* N *carrying the local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorPhaseRealCarrierReadiness`

Proof. Project the carrier of Definition 525.1. The generator route exposes exactly the signature, emitted recursor, motive, branch, descent, output, audit, transport, continuation, provenance, boundary, and local naming rows.

Use the L10 source triad Definition 525.192. It already confines $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads to the displayed packet and rejects host choice, detached induction, selected real data, quotient stream data, and external proof production.

The Phase Real handoff therefore begins with carrier admission for the same finite BHist route. No dependency row can be read before $I, E, M, B, D, O, A, H, C, P, G, N$ are retained. □

Theorem 525.215 (AuthorizedGeneratorRecursor Phase Real RegSeqRat handoff)**.** *For an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet* $R = (I, E, M, B, D, O, A, H, C, P, G, N)$*, every Phase Real* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff is mediated by the same authorized generator route as the* $\mathsf{StreamName}^{\uparrow}$ *source and the* $\mathsf{Real}^{\uparrow}$ *endpoint. The handoff preserves* O, A, H, C, P, G, N *together with the signature, motive, branch, and descent rows, and it does not expose a quotient stream, selected limit, host equality, hidden generator, or off-packet proof channel.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorPhaseRealRegSeqRatHandoff`

Proof. Begin with Definition 525.214. It fixes the carrier route and makes O, A, H, C, P, G, N part of every Phase Real dependency read.

Now apply the Real stream route Definition 525.203. That theorem identifies the public generator output as a finite read of $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ source rows through the same packet.

Finally use Definition 525.193. A downstream real or completion-facing consumer may specialize the finite source route, but it cannot reinterpret the recursor as quotient stream data, selected real data, host equality, hidden generator state, or an off-packet proof channel. □

Theorem 525.216 (AuthorizedGeneratorRecursor Phase Real ledger non-escape)**.** *Every Phase Real ledger exported by an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet is exhausted by the finite route* $I, E, M, B, D, O, A, H, C, P, G, N$*. The audit row* A*, boundary row* G*, componentwise* hsame *row* H*, displayed* Cont *row* C*, package row* P*, and local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row* N *are the only ledger surface visible to* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or completion-facing consumers.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorPhaseRealLedgerNonescape`

Proof. Read the carrier and retain the audit and boundary rows. By Definition 525.214, every Phase Real dependency read already uses the displayed finite route.

Use Definition 525.215 for the regular-rational route. It keeps the $\mathsf{RegSeqRat}^{\uparrow}$ handoff attached to the stream-name source, real endpoint, output row, audit row, transport, continuation, package provenance, boundary, and local naming rows.

Close with Definition 525.194. The exported ledger has no coordinate for completion objects, real-completeness data, quotient completion equality, selected limits, host completeness proofs, or off-packet generator certificates. □

Theorem 525.217 (AuthorizedGeneratorRecursor Real output factorization lock)**.** *Let* $R = (I, E, M, B, D, O, A, H, C, P, G, N)$ *be an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. Every Real-facing output read from* R *factors through the displayed finite packet before it can be consumed as* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *data. In particular, no consumer may read the output row* O *without also retaining the audit row* A*, the componentwise transport row* H*, the displayed continuation row* C*, the provenance row* P*, the boundary ledger row* G*, and the local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row* N*.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRealOutputFactorizationLo`

Proof. Project the carrier by Definition 525.214. The Phase Real surface first admits the finite route $I, E, M, B, D, O, A, H, C, P, G, N$, so the output row is not available as a detached Real object.

Next apply Definition 525.203. The public Real route already makes the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readings pass through the same displayed packet.

Finally use Definition 525.193. Downstream consumers may specialize the route to their own readback surface, but the specialization still preserves O together with A, H, C, P, G, N and has no coordinate for quotient stream equality, selected limits, host Real equality, or external proof production. □

Theorem 525.218 (AuthorizedGeneratorRecursor L10 consumer readback totality)**.** *For an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet* $R = (I, E, M, B, D, O, A, H, C, P, G, N)$*, every L10 consumer readback of the Real-facing output is total only as a readback of the packet rows* O, A, H, C, P, G, N*. The consumer may request* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *data, but the request preserves the output row, audit row, transport row, continuation row, provenance row, boundary ledger, and local naming row as one finite* BHist *route.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorL10ConsumerReadbackTotali`

Proof. Start with Definition 525.214. It supplies the carrier route and makes H, C, P, G, N part of the Phase Real admission data.

Use Definition 525.215. The regular-rational handoff is mediated by the same authorized generator route as the stream-name source and the Real endpoint, so an L10 consumer cannot drop the output row or its audit, transport, continuation, provenance, boundary, and naming rows.

Apply Definition 525.216 for the ledger side. The exported ledger is exhausted by A, H, C, P, G, N on the finite packet.

Finally compose these obligations with Definition 525.203 and Definition 525.193. The result is a total consumer readback of the displayed packet, not a separate source of Real evidence or proof-producing data. □

Theorem 525.219 (AuthorizedGeneratorRecursor completion boundary saturation)**.** *Every completion-facing consumer of an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet receives only the finite route* $I, E, M, B, D, O, A, H, C, P, G, N$*. The route saturates the boundary: it provides the rows needed for* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *readback, while leaving no channel for quotient stream equality, selected limits, host Real equality, ambient completeness, countable choice, or external proof production.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorCompletionBoundarySaturat`

Proof. First read the carrier and the regular-rational handoff through Definition 525.214 and Definition 525.215. These theorems place the completion-facing consumer on the same finite route as the stream source and Real endpoint.

Next apply Definition 525.216. The only visible ledger is A, H, C, P, G, N, so a completion consumer has no boundary coordinate beyond the packet.

Close with Definition 525.203 and Definition 525.193. Their route and consumer clauses allow downstream readback, but only as packet-preserving specialization; they do not introduce quotient stream equality, selected limits, host Real equality, ambient completeness, countable choice, or an external proof-production channel. □

Corollary 525.220 (AuthorizedGeneratorRecursor Phase Real readiness strict obstruction)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. Suppose a Phase Real consumer of* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or a completion-facing read displays a failure, refusal, separation, or counter-model row against a named converse, reuse, or readback route in the handoff surface of* R*. Then that row is a strict local obstruction: it blocks only the named route whose consumer-facing use tries to read, omit, replace, detach, or bypass one of the displayed packet coordinates*

$$I, E, M, B, D, O, A, H, C, P, G, N.$$

Every permitted use factors through the finite BHist *carrier and through the visible ledger rows* A, G, H, C, P, N*, with* H *carrying componentwise* hsame*,* C *carrying displayed* Cont *replay,* P *carrying package provenance,* G *carrying the boundary ledger, and* N *carrying the local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}}$ *row. The same displayed row cannot be reinterpreted as a global impossibility theorem, a host theorem about recursors or real completion, hidden external validation of the failed route, a selected real witness, a quotient stream equality, a completion object, a host completeness proof, or an off-packet proof-producing channel.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorPhaseRealReadinessStrict(

Proof. Start with carrier readiness, Definition 525.214. Any Phase Real handoff that reads $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ data must first admit the displayed finite route $I, E, M, B, D, O, A, H, C, P, G, N$. Thus a consumer-facing negative row can bear on the packet only after the carrier has been read, and its possible coordinates are already limited to the signature, emitted recursor, motive, branch, descent, output, audit, transport, continuation, provenance, boundary, and local naming rows.

Apply ledger non-escape, Definition 525.216. The exported Phase Real ledger is exhausted by the audit row A, boundary row G, componentwise hsame row H, displayed Cont row C, package row P, and local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ row N. The same theorem also says that this is the only ledger surface visible to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or completion-facing consumers.

Now consider the displayed failure, refusal, separation, or countermodel row. If it is used against a named converse, reuse, or readback route, the first cited theorem forces the use to pass through the full finite carrier, and the second cited theorem forces its ledger component to remain on A, G, H, C, P, N. Hence the row can obstruct only the advertised route at the coordinate where that route asks to read, omit, replace, detach, or bypass one of the displayed rows.

Any stronger reading asks for a coordinate that the two cited theorems do not export. A global impossibility theorem would require a theorem surface beyond the finite packet; a host theorem about recursors or real completion would require host choice, detached induction, host equality, or host completeness data; hidden external validation would require an external certificate route; a selected real witness, quotient stream equality, completion object, or proof-producing channel would require one of the off-packet objects excluded by the ledger non-escape clause. Since no such coordinate is visible from R, the obstruction remains strict and local to the named Phase Real route. □

Theorem 525.221 (AuthorizedGeneratorRecursor L10 output authorization closure)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet. Any L10 public output read of O that is visible to* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumers must retain the full finite route $I, E, M, B, D, O, A, H, C, P, G, N$ before those consumer rows are public. The output row is therefore authorized only together with the displayed signature, emitted recursor, motive, branch, descent, audit, transport, continuation, package provenance, boundary, and local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *rows; it is not a host-recursive output, a quotient stream datum, a selected real witness, or an off-packet proof channel.*

Lean4 ✓ BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor l10 output authorization closure

Proof. Start with Definition 525.214. It admits the Phase Real carrier only as the finite BHist route $I, E, M, B, D, O, A, H, C, P, G, N$, with H, C, P, G, N carrying displayed equality, continuation, package, boundary, and local naming data.

Use Definition 525.215 and Definition 525.216. They keep the regular-rational handoff and the exported ledger attached to the same packet, excluding quotient stream data, selected limits, host equality, hidden generator state, and off-packet proofs.

Finally apply Definition 525.203. The sibling consumer chapters chapter 126, chapter 301, and chapter 38 may therefore see the recursor output only after the route has retained every row of R. □

Theorem 525.222 (AuthorizedGeneratorRecursor StreamName finite-request publicity)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *finite-request section that reads an* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *output must read it through the displayed output row* O*, audit row* A*, transport row* H*, continuation row* C*, package row* P*, boundary row* G*, and local NameCert row* N*, with* I, E, M, B, D *retained as the upstream generator route. The section publicizes finite requests only as packet-local stream-name access; it does not expose an unbounded stream, detached recursion rule, selected real value, quotient stream equality, host equality, or private audit channel.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorStreamNameFiniteRequestPu`

Proof. Begin with Definition 525.214. It makes the $\mathsf{StreamName}^{\uparrow}$ dependency a read of the displayed carrier rather than a separate source of stream data.

Next use Definition 525.203. The Real stream route already places $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers behind the same finite output route, so a finite-request section cannot bypass O, A, H, C, P, G, N.

The public sibling surface is then exactly chapter 126. Since that chapter consumes finite stream-name rows and not host streams, the recursor output reaches it only through the displayed output, audit, transport, continuation, package, boundary, and NameCert rows. □

Theorem 525.223 (AuthorizedGeneratorRecursor RegSeqRat and Real seal output exhaustion)**.** *For any accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet* $R = (I, E, M, B, D, O, A, H, C, P, G, N)$*, every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback consumer and every* $\mathsf{Real}^{\uparrow}$ *seal consumer of the recursor output exhausts the output route through the same finite packet. The only available public data are the displayed output, audit, transport, continuation, package, boundary, and local NameCert rows together with the upstream generator rows* I, E, M, B, D*. No consumer obtains a selected limit, quotient stream equality, host equality, detached completion object, hidden generator state, or proof channel outside* R*.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorRegSeqRatRealSealOutputEx`

Proof. Use Definition 525.215. It mediates the $\mathsf{RegSeqRat}^{\uparrow}$ handoff through the same authorized generator route as the stream-name source and the Real endpoint.

Then apply Definition 525.216. The ledger exported to $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and completion-facing consumers is exhausted by A, H, C, P, G, N on the finite packet, with no coordinate for quotient completion equality, selected limits, host completeness proofs, or off-packet generator certificates.

Finally appeal to Definition 525.203 and the sibling chapters chapter 301 and chapter 38. Their readback and seal surfaces consume packet rows; they do not turn the AuthorizedGeneratorRecursor output into selected Real evidence, quotient stream equality, host equality, or an external proof producer. □

Lemma 525.224 (AuthorizedGeneratorRecursor L10 output downstream coverage)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet, and let* c *be an accepted local L10 consumer of the public output row* O*. If* c *is visible to a* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer surface, then* c *is exhausted by the finite alternatives and ledger rows already carried by* R*:*

1. *a* $\mathsf{StreamName}^{\uparrow}$ *finite-request read of the displayed output row* O*;*
2. *a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback handoff through the same authorized output route;*

3. a $\mathsf{Real}^{\uparrow}$ *seal consumer of the same output route;*

4. the ledger surface A, H, C, P, G, N*, with* I, E, M, B, D *retained as the upstream generator route.*

Consequently every request for a host-recursive output, quotient stream datum, selected Real witness, detached completion object, host equality, hidden generator state, or off-packet proof channel remains outside the BEDC packet.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorL10OutputDownstreamCovera`

Proof. Start with the authorization closure in Definition 525.221. It states that any L10 public output read visible to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumers must retain the full finite route $I, E, M, B, D, O, A, H, C, P, G, N$ before the consumer rows are public. Thus an accepted local consumer of O cannot begin from a bare output token: it already carries the output row together with the audit, transport, continuation, package provenance, boundary, and local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ rows.

For the stream-name alternative, apply Definition 525.222. A finite-request section reads the recursor output only through O, A, H, C, P, G, N, with I, E, M, B, D retained as the upstream generator route. Hence the $\mathsf{StreamName}^{\uparrow}$ case lands in the first listed alternative and has no unbounded stream or detached recursion channel.

For the regular-rational and Real-facing alternatives, apply Definition 525.223. It says that every $\mathsf{RegSeqRat}^{\uparrow}$ readback consumer and every $\mathsf{Real}^{\uparrow}$ seal consumer exhausts the output route through the same finite packet. The only available public data are O, A, H, C, P, G, N together with I, E, M, B, D, so these two cases land in the second and third alternatives, with the common ledger surface recorded in the fourth.

The exclusion clause is the intersection of the two cited closures. The authorization closure rules out a host-recursive output, quotient stream datum, selected real witness, and off-packet proof channel at the point where O becomes public. The readback-and-seal exhaustion theorem also rules out selected limits, quotient stream equality, host equality, detached completion objects, hidden generator state, and proof channels outside R. Since every accepted local consumer visible to the three named consumer surfaces has already been placed in one of the displayed finite alternatives, any excluded request would require a coordinate not present in $I, E, M, B, D, O, A, H, C, P, G, N$. Such a coordinate is not part of the accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ packet. □

Theorem 525.225 (AuthorizedGeneratorRecursor terminal-output readback)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *finite packet. Every terminal readback of the output row* O *by a* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer must first expose the same* BHist *packet, preserve the componentwise* hsame *row* H*, replay through the displayed* Cont *row* C*, retain the* Pkg *provenance row* P*, and name the read by the local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row* N*. The readback is therefore a packet-local output route, not a selected real value, quotient stream datum, host equality, detached generator state, or off-packet proof channel.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalOutputReadbackPac`

Proof. Begin with terminal-output readiness, Definition 525.211. It places O inside the displayed carrier R and keeps the output row behind the audit, transport, continuation, package, boundary, and local naming rows.

Next use the Phase Real handoff rows, Definition 525.214 and Definition 525.215. They force $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads to consume the same finite output route.

Finally apply the L10 output authorization closure, Definition 525.221. That closure leaves no exported coordinate for a selected limit, quotient stream equality, host equality, hidden generator state, or external proof producer. □

Theorem 525.226 (AuthorizedGeneratorRecursor finite-tail authorization)**.** *For an accepted* AuthorizedGeneratorR *packet* $R = (I, E, M, B, D, O, A, H, C, P, G, N)$*, every finite tail of a public output route read by* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *is authorized by the same rows* O, A, H, C, P, G, N *with* I, E, M, B, D *retained as the upstream generator surface. A tail consumer cannot shorten the route to a bare output token, external recursion rule, quotient completion object, or unledgered Real endpoint.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorFiniteTailAuthorization`

Proof. Start from the StreamName finite-request publicity row, Definition 525.222. It treats finite request sections as packet-local reads of the output row rather than as an unbounded stream.

Use the RegSeqRat and Real seal output exhaustion row, Definition 525.223. The regular-rational and Real-facing consumers see only the same finite packet rows and do not receive a detached completion witness.

The local-name output exhaustion theorem, Definition 525.213, then keeps every finite tail named by N on the same O, A, H, C, P, G surface. Thus the finite tail is authorized precisely by the displayed output packet. □

Theorem 525.227 (AuthorizedGeneratorRecursor consumer ledger exhaustion)**.** *Every consumer ledger for terminal output from an accepted* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *packet is exhausted by the finite rows* $I, E, M, B, D, O, A, H, C, P, G, N$ *together with the existing* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *handoff rows. No downstream L10 consumer obtains a ledger extension for hidden generator state, selected limits, quotient stream equality, host completeness, host induction, or an off-packet proof channel.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursor consumer ledger exhaustion`

Proof. First project the Phase Real ledger non-escape row, Definition 525.216. It identifies the exported ledger with A, H, C, P, G, N on the same finite carrier.

Next combine terminal-output readback with finite-tail authorization above. The first theorem fixes the readback route for the output row, and the second keeps every finite tail on that same route for the stream-name, regular-rational, and Real-facing consumers.

Finally use Definition 525.203 and the L10 output authorization closure. These surfaces route all downstream L10 reads through the displayed packet, so the consumer ledger has no additional coordinate beyond R and the named handoff rows. □

Lemma 525.228 (AuthorizedGeneratorRecursor terminal-output downstream coverage)**.** *Let*

$$R = (I, E, M, B, D, O, A, H, C, P, G, N)$$

be an accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *finite packet, and let* c *be an accepted local consumer of the terminal output row* O*. If the consumer-facing use of* c *is visible through a* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *surface, then the use is exhausted by the displayed terminal-output coverage already carried by the packet:*

1. *the terminal readback route through the same* BHist *packet;*
2. *the componentwise transport row H and displayed* Cont *replay row C;*
3. *the package provenance row P, boundary ledger row G, and local* $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ *row N;*
4. *the finite consumer ledger over $I, E, M, B, D, O, A, H, C, P, G, N$ together with the named* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *handoff rows.*

Consequently every attempted downstream read that asks for hidden generator state, a selected limit, quotient stream equality, host completeness, host induction, host equality, a detached completion object, or an off-packet proof channel remains outside the BEDC packet.

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTerminalOutputDownstream(`

Proof. Start with terminal-output readback, Definition 525.225. It applies directly to the output row O of the accepted packet R and forces every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ readback to expose the same BHist packet before the read is available. The same theorem also preserves the componentwise hsame row H, replays the displayed Cont row C, retains the Pkg provenance row P, and names the read by the local $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ row N. Thus the consumer cannot begin from a bare output token or from a detached generator state; its first three coverage coordinates are already the displayed packet-local readback, transport, continuation, provenance, boundary, and naming rows.

Now apply consumer ledger exhaustion, Definition 525.227. That theorem identifies the downstream terminal-output ledger with the finite rows $I, E, M, B, D, O, A, H, C, P, G, N$ together with the existing $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ handoff rows. Hence an accepted local consumer visible through one of the three named surfaces has no independent ledger beyond the rows listed in the statement: the stream-name read, regular-rational readback, and Real-facing read are all ledger entries over the same finite route.

It remains only to check the excluded alternatives. The readback theorem says that the terminal read is packet-local and not a selected real value, quotient stream datum, host equality, detached generator state, or off-packet proof channel. The ledger-exhaustion theorem adds that no downstream L10 consumer obtains a ledger extension for hidden generator state, selected limits, quotient stream equality, host completeness, host induction, or an off-packet proof channel. A request for any excluded object would therefore require either a readback coordinate not supplied by H, C, P, G, N or a consumer ledger coordinate not present in $I, E, M, B, D, O, A, H, C, P, G, N$ and the three named handoff rows. Since both cited theorems exhaust those coordinates, the request remains outside the accepted $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ packet. □

The $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ public export is the displayed route through generator source, authorization, motive, branch package, descent, output, audit, transport, replay, provenance, boundary, and local naming rows. Public consumers may inspect the emitted output only through that finite route, and the mature treatment is the paper-side route exhaustion of the mature child together with the L10 downstream coverage rows; full bridge verification and host generator semantics remain outside the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}}$ **·**

Constructive story: An $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ packet is generated from an accepted constructor signature, an emitted eliminator, a checked motive, complete branch data, structural descent, an output name, audit provenance, componentwise hsame transports, displayed Cont routes, Pkg provenance, a GAP boundary row, and a local NameCert row. Its carrier surface composes the signature, branch, descent, audit, boundary, compiler-handoff, and local-name rows already displayed by the sibling authorization packets.

Theory closure: TheoryGate(NameCert$_{\text{AuthorizedGeneratorRecursor}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 525.1, Definition 525.2, Definition 525.3, Definition 525.4, Definition 525.5, Definition 525.6, Definition 525.12, Definition 525.13, Definition 525.14, and Definition 525.7 with

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.taste gate`

expose authorized recursor output as a public finite NameCert packet over accepted signatures, branch coverage, structural descent, audit provenance, boundary, compiler handoff, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{AuthorizedGeneratorRecursor}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorTasteGate\_single\_carrier\_al`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, a public standard bridge, host generator semantics, unrestricted substitution, host normalization, hidden recursion, ambient equality, or any proof-producing route outside the displayed recursor packet.

Upgrade path: Verification closure requires Lean-checked carrier admission, authorization, branch coverage, descent, output audit, downstream handoff, transport, replay, provenance, boundary, and local naming for the public recursor route.

Theorem 525.229 (Authorized generator recursor mature route exhaustion)**.** *Every terminal generator-output consumer of an accepted* AuthorizedGeneratorRecursor$^{\uparrow}$ *packet factors through the root authorization rows, signature totality, acceptance totality, terminal output readiness, the L10* StreamName$^{\uparrow}$/RegSeqRat$^{\uparrow}$/Real$^{\uparrow}$ *source triad, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert$_{\text{AuthorizedGeneratorRecursor}^{\uparrow}}$ *rows before export. The mature route obtains no hidden generator, host recursion principle, selected output stream, quotient equality, subject-reduction theorem, or ambient* Real$^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.AuthorizedGeneratorRecursorUp.AuthorizedGeneratorRecursorMatureRouteExhaustion`

Chapter 526

A Concrete Naming Certificate for AuditGateBoundary$^{\uparrow}$

The AuditGateBoundary$^{\uparrow}$ surface packages the manuscript and Lean audit gates as a finite naming certificate. It is not a proof that the entire repository is complete. It records the exact boundary packets by which source-token scans, axiom-purity reports, paper-Lean target audits, origin and import conservativity ledgers, transport rows, continuation routes, package provenance, GAP boundary rows, and the local naming row remain visible to downstream governance consumers. The source-token and forbidden-dependency rows share their refusal ledger with chapter 861, while the marker-resolution row is read against the audit-map interface of chapter 806. The displayed audit consumer routes use the finite continuation-trace reading of chapter 469 as the sibling surface that makes replay and route inspection explicit.

Definition 526.1 (AuditGateBoundary carrier)**.** *An* AuditGateBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, D, L, O, H, C, P, G, N)$$

with the following displayed rows:

1. *S is the source-token scan row, recording the finite file set, token classifier, and refusal result for substrate-internal axiom declarations;*
2. *D is the axiom-purity dependency report row, recording the theorem names inspected, the reported proof ancestry, and the forbidden dependency classifier for* Classical.choice*,* Quot.sound*, and* propext*;*
3. *L is the paper-Lean target audit row, recording each manuscript marker, its named Lean target, and the finite resolution result used by the drift gate;*
4. *O is the origin and import conservativity report row, recording the chapter-origin ledger, the protected module prefixes, and the import-edge classifier that separates baseline and non-baseline surfaces;*
5. *H records componentwise* hsame *transports for S, D, L, O, G, the continuation row, the package row, and the local naming row;*
6. *C records the displayed* Cont *routes by which consumers read the token scan, dependency report, target audit, origin/import report, boundary row, provenance, and local certificate;*

7. *P is the* Pkg *provenance over* BHist, Hist, GAP, hsame, Cont, Pkg, NameCert, *Lean target names, source-file scans, dependency reports, and origin ledgers;*
8. *G is the* GAP *boundary row recording that the gates refuse only the displayed boundary crossings and do not provide a hidden theorem of global correctness;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditGateBoundary}^{\uparrow}}$ *row.*

The carrier is exactly this finite packet. It contains no unrestricted semantic conservativity theorem, no host-kernel completeness proof, no hidden permission to use source axioms, no selected Lean declaration beyond the named audit rows, and no global guarantee that paper prose carries a stronger interpretation than the resolving markers display.

Lean4 (definition) `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryUp`

Theorem 526.2 (AuditGateBoundary NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{AuditGateBoundary}^{\uparrow}}$ *surface for the carrier of Definition 526.1 consists of carrier admission for*

$$A = (S, D, L, O, H, C, P, G, N),$$

source-token refusal, axiom-purity dependency refusal, paper-Lean target exactness, origin/import conservativity separation, componentwise hsame *stability, displayed* Cont *locality,* Pkg *provenance, the* GAP *boundary row, and non-escape for global semantic conservativity, host-kernel completeness, source axioms, unresolved marker names, and untracked origin flow.*

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 526.1. The rows $S, D, L, O, H, C, P, G, N$ are the only data admitted to the packet.

The first four rows expose the gate faces. The source-token scan is read from S, the dependency report from D, the paper-Lean target audit from L, and the origin/import conservativity report from O.

Transport and consumer access are then confined by H and C. These rows replay the displayed audits under componentwise hsame movement and do not add any unrecorded proof principle or import edge.

Finally P, G, N record provenance, the boundary socket, and the local certificate. Since the excluded objects have no coordinate in the carrier, no NameCert projection can export them. □

Theorem 526.3 (AuditGateBoundary axiom-purity soundness)**.** *For an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet, the source-token row S and dependency report row D are sufficient to decide the audit-facing axiom boundary claimed by the packet. A passed source-token scan means no displayed BEDC source file contributes a substrate-internal axiom declaration, and a passed dependency report means no inspected public theorem row is reported with a forbidden dependency among* Classical.choice, Quot.sound, *and* propext.

This soundness is local to the reported rows. It does not assert host-kernel completeness, semantic completeness of the theorem inventory, or any theorem outside the finite report carried by D.

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier axiom purity soundness`

Proof. Read the source side first. The row S contains the finite file set, token classifier, and refusal result, so the source-axiom boundary claimed by the packet is exactly the boundary displayed by S.

Read the theorem-dependency side next. The row D contains the inspected theorem names, their reported proof ancestry, and the forbidden dependency classifier. Therefore the axiom-purity claim is the finite absence result recorded by D.

The GAP row G fixes the scope. The packet certifies only these displayed reports and refuses to turn them into a hidden theorem about all possible host behaviour or every unlisted declaration. □

Theorem 526.4 (AuditGateBoundary paper-Lean drift exactness)**.** *For an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet, the paper-Lean audit row L is the exact public surface for resolving manuscript markers against Lean declarations. A consumer may read a marker as a naming certificate only through the tuple consisting of the marker text, the target name, the finite resolution result, the componentwise transport row, the continuation route, the package provenance, and the local* $\mathsf{NameCert}_{\mathsf{AuditGateBoundary}^{\uparrow}}$ *row.*

No consumer of L may replace a missing target with a similar theorem, a nearby namespace, a paper-side interpretation, or an unresolved string.

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier paper lean drift exactness`

Proof. Project L from the carrier. By definition it records each manuscript marker, the target name being claimed, and the finite resolution result.

Use H and C to transport and read the row. The marker remains the same displayed marker after transport, and the continuation route exposes only the named resolution result.

The non-escape clause follows from the absence of any coordinate for fuzzy matching, namespace guessing, or prose interpretation. A marker therefore functions as a certificate only when L records that the named target resolves. □

Theorem 526.5 (AuditGateBoundary origin conservativity)**.** *For an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet, the origin/import row O is the exact finite ledger by which non-baseline surfaces are kept from silently entering baseline theorem space. A consumer may use O to read chapter origins, protected module prefixes, inspected import edges, and the pass-or-refuse result, but it may not extract a semantic conservativity theorem for arbitrary extensions or a global proof that all recognized content is baseline content.*

Proof. Project O from the carrier. It contains origin rows, protected prefixes, inspected import edges, and the classifier result for those edges.

Transport and replay through H and C. The consumer sees the same finite ledger and the same route to the origin/import classifier, with provenance recorded by P and local naming recorded by N.

The boundary row G prevents overreading. Since O has no coordinate for arbitrary model-theoretic conservativity or for reclassifying non-baseline material as baseline, the packet certifies only the displayed import separation. □

Theorem 526.6 (AuditGateBoundary source-token refusal)**.** *For an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet*

$$A = (S, D, L, O, H, C, P, G, N),$$

the row S is the only public source-token refusal face. Every consumer read of a source-token refusal factors through S together with the componentwise transport row H, the displayed continuation routes C, the package provenance P, and the local naming row N.

The read does not expose a hidden source proof, a host-kernel axiom inventory, or a refusal predicate outside the finite file set and token classifier recorded by S.

Proof. Project the accepted packet. The source-token scan row is the coordinate S, while D, L, O, G record different audit faces and cannot be substituted for the source-token refusal row.

Route the consumer access through H and C. The transport row preserves the displayed scan componentwise, and the continuation row exposes exactly the route from the packet to the token classifier and refusal result carried by S.

The package row P and local name row N bind this route to the $\mathsf{AuditGateBoundary}^{\uparrow}$ certificate. The GAP row G then fixes the non-escape boundary: the packet refuses only the displayed source-token crossing and supplies no host-wide source theorem. □

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier source token refusal`

Theorem 526.7 (AuditGateBoundary forbidden-dependency ledger)**.** *For an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet*

$$A = (S, D, L, O, H, C, P, G, N),$$

the dependency row D fixes the finite forbidden-dependency classifier for Classical.choice, Quot.sound, *and* propext. *A consumer may read only the theorem names inspected, the reported proof ancestry, and the pass-or-refuse result carried by D, transported through H and routed through C.*

This ledger does not claim host-kernel completeness, proof-irrelevance completeness, or a dependency result for declarations absent from the finite report.

Proof. Project D from the packet. Its coordinates are the inspected theorem names, reported proof ancestry, and the classifier for Classical.choice, Quot.sound, and propext.

Transport is componentwise through H. The dependency report remains the same finite classifier row after the accepted hsame movement, and the continuation row C is the only consumer route back to that report.

Finally use P, N, G to close the boundary. Provenance and local naming identify the certificate surface, while the GAP row prevents the finite dependency report from becoming a hidden host-kernel completeness theorem. □

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier dependency forbidden set`

Theorem 526.8 (AuditGateBoundary inductive audit row)**.** *Every accepted audit-gate consumer of an* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet is obtained by finite row induction over*

$$S, D, L, O, H, C, P, G, N.$$

The source-token refusal, forbidden-dependency refusal, marker-resolution exactness, and origin conservativity reads are consumed one row at a time. The transport, replay, provenance, GAP boundary, and naming rows may preserve and route those four audit faces, but they cannot add host-kernel completeness, theorem-inventory completeness, fuzzy marker resolution, or semantic conservativity for arbitrary imports.

Proof. Project the carrier of Definition 526.1. Its displayed rows are exactly $S, D, L, O, H, C, P, G, N$, so the audit consumer has no hidden coordinate beyond the finite packet.

Read the four audit faces in order. Use Definition 526.6 for the source-token row S, Definition 526.7 for the forbidden-dependency row D, Definition 526.4 for the marker row L, and Definition 526.5 for the origin and import row O.

It remains to inspect the support rows. Componentwise transport through H, replay through C, provenance through P, the GAP boundary G, and local naming through N preserve the already displayed rows and do not create a new audit face. Therefore the consumer is obtained by finite

row induction over the displayed packet, with host-kernel completeness and semantic conservativity outside the export. □

Theorem 526.9 (AuditGateBoundary marker-resolution non-escape)**.** *For an accepted* AuditGateBoundary$^{\uparrow}$ *packet*

$$A = (S, D, L, O, H, C, P, G, N),$$

the paper-Lean row L resolves manuscript markers only by exact target names. After componentwise transport through H and consumer routing through C, the public certificate may expose the marker text, the named Lean target, and the finite resolution result recorded by L.

It cannot replace a non-resolving marker by a nearby namespace, an unresolved string, a prose interpretation, or a theorem whose name is not the exact target recorded in L.

Proof. Project the marker row L from the accepted packet. The row records the manuscript marker, the claimed Lean target name, and the finite resolution result.

Replay the read through H and C. Componentwise transport preserves the displayed marker row, and the continuation route exposes only the exact target-name resolution already present in L.

The remaining coordinates P, G, N supply provenance, the boundary row, and local naming. Since the carrier has no coordinate for fuzzy namespace search, unresolved-string substitution, or prose interpretation, marker resolution cannot escape the exact-name ledger. □

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier marker resolution nonescape`

Theorem 526.10 (AuditGateBoundary origin-gate replay)**.** *For an accepted* AuditGateBoundary$^{\uparrow}$ *packet*

$$A = (S, D, L, O, H, C, P, G, N),$$

the displayed audit replay of origin conservativity is exactly the origin/import row O transported through H, routed through C, named by N, and packaged by P. A governance consumer may replay chapter-origin rows, protected module prefixes, inspected import edges, and the pass-or-refuse classifier, but it receives no semantic conservativity theorem beyond the finite BHist *row carried by O.*

Proof. Project the carrier row O. By Definition 526.1, this row is the packet's origin and import conservativity report.

Apply Definition 526.5. The consumer may inspect exactly the displayed origin rows, protected prefixes, import edges, and classifier result.

Replay the row through the common support surface. The transport row H preserves O componentwise, the continuation row C exposes it, and P, N bind provenance and local naming.

The replay ledger of Definition 526.13 keeps this read inside the audit packet. Therefore the replay exports the finite origin gate row and not a host-wide conservativity theorem. □

Theorem 526.11 (AuditGateBoundary strict axiom-purity replay)**.** *For an accepted* AuditGateBoundary$^{\uparrow}$ *packet*

$$A = (S, D, L, O, H, C, P, G, N),$$

strict axiom-purity replay is the joint read of the source-token row S and forbidden-dependency row D through H, C, P, G, N. The replay exposes the finite source-token refusal, the inspected theorem names, their reported proof ancestry, and the forbidden-dependency classifier for Classical.choice, Quot.sound, *and* propext, *with no hidden host-kernel completeness claim.*

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier strict axiom purity replay`

Proof. Project the rows S and D from the accepted packet. The source-token row records file and token refusal data, while the dependency row records theorem names, ancestry, and forbidden dependency classification.

Use Definition 526.3 and Definition 526.6. These theorems bind the audit-facing axiom boundary to the finite source-token and dependency rows.

Use Definition 526.7 for the strict forbidden set. The only named forbidden dependencies are Classical.choice, Quot.sound, and propext inside the displayed report.

Finally replay through H, C, P, G, N. Transport, continuation, provenance, GAP boundary, and naming keep the result inside the same BHist packet and block any host-wide completeness reading. □

Theorem 526.12 (AuditGateBoundary marker-resolution closure)**.** *For an accepted* AuditGateBoundary$^{\uparrow}$ *packet*

$$A = (S, D, L, O, H, C, P, G, N),$$

the marker-resolution row L is closed under audit replay through the displayed ledger. A governance consumer replaying L may recover only the manuscript marker text, exact Lean target name, finite resolution result, componentwise hsame *transport, continuation route,* Pkg *provenance, GAP boundary, and local* NameCert *row.*

Proof. Project the paper-Lean row L from the accepted carrier. This row contains the marker text, named Lean target, and finite resolution result.

Apply Definition 526.9. Exact target names are preserved, and the row cannot be replaced by namespace search, unresolved strings, prose interpretation, or a different theorem name.

Replay L through the ledger of Definition 526.13. The same support rows H, C, P, G, N transport, expose, package, delimit, and name the marker-resolution read.

Thus marker resolution is closed only as a finite audit-row replay. It does not become a broader manuscript-validity theorem or a substitute for resolving the exact target recorded in L. □

Theorem 526.13 (AuditGateBoundary replay ledger)**.** *For an accepted* AuditGateBoundary$^{\uparrow}$ *packet*

$$A = (S, D, L, O, H, C, P, G, N),$$

any governance consumer replaying the packet must read the source-token row S, forbidden-dependency row D, marker-resolution row L, and origin/import row O through the same transport, continuation, provenance, GAP-boundary, and naming support rows H, C, P, G, N. The replay cannot replace exact marker resolution, forbidden dependency reports, source-token refusal, or origin/import separation by a host-wide correctness claim.

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier replay ledger`

Proof. Project the carrier of Definition 526.1. Its four audit-facing rows are exactly S, D, L, O, and the shared support rows are exactly H, C, P, G, N.

Apply the local NameCert obligations to bind those rows to one accepted packet. Source-token refusal uses S through the same transport and continuation coordinates, while the dependency forbidden set uses D to report only the displayed ancestry and forbidden names.

Next replay marker resolution and origin separation. The marker-resolution non-escape theorem keeps L on exact target names, and origin conservativity keeps O on the displayed origin/import ledger.

Finally close the replay through P, G, N. Provenance, the GAP boundary, and local naming prevent the four audit faces from becoming a global repository-correctness theorem, so a governance consumer receives only the finite replay ledger carried by A. □

Theorem 526.14 (AuditGateBoundary origin-import replay exactness)**.** *For an accepted* AuditGateBoundary$^{\uparrow}$ *packet*

$$A = (S, D, L, O, H, C, P, G, N),$$

origin and import replay is exact only as the row O transported through H, routed through C, packaged by P, delimited by G, and named by N. A governance consumer may replay chapter-origin rows, protected module prefixes, inspected import edges, and their pass-or-refuse classifier, but it may not replace them by a host-wide semantic conservativity claim.

Proof. Project the carrier row O. It is the only coordinate that records chapter origins, protected module prefixes, inspected import edges, and the origin/import classifier.

Replay proceeds through the shared support rows. The transport row H preserves the displayed origin/import ledger, the continuation row C exposes it, and the package and local naming rows P, N bind the replay to the same certificate.

The boundary row G fixes the scope of the replay. Since the carrier contains no coordinate for host-wide semantic conservativity, the exact replay exports only the finite origin/import row. □

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier origin import replay exactness`

Theorem 526.15 (AuditGateBoundary drift row transport)**.** *For an accepted* AuditGateBoundary$^{\uparrow}$ *packet, the paper-Lean drift row L is transported exactly as a finite marker-resolution ledger. Every transported read of L exposes only the manuscript marker text, the exact Lean target name, the finite resolution result, the componentwise* hsame *row H, the displayed* Cont *route C, the* Pkg *provenance row P, the* GAP *boundary row G, and the local* NameCert *row N.*

Proof. Project L from the accepted packet. The row records marker text, target name, and finite resolution result, and it contains no fuzzy target selector.

Transport the row componentwise through H. The transported ledger is still the same exact-name marker-resolution row, so the consumer cannot replace it by a nearby namespace or prose interpretation.

Route and package the transported row through C, P, G, N. The replay ledger and marker-resolution non-escape theorems then keep the read inside the finite audit packet, with no host-wide correctness claim attached to the transported drift row. □

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier drift row transport`

Theorem 526.16 (AuditGateBoundary axiom-purity report non-escape)**.** *For an accepted* AuditGateBoundary$^{\uparrow}$ *packet, the axiom-purity report is the joint finite read of the source-token row S and dependency row D through H, C, P, G, N. It reports only the displayed source-token refusal, inspected theorem names, reported proof ancestry, and forbidden-dependency classifier for* Classical.choice*,* Quot.sound*, and* propext*. It cannot be replaced by host-kernel completeness, theorem inventory completeness, global proof purity, or a semantic repository-correctness claim.*

Proof. Project the source and dependency rows. The source-token refusal is carried by S, while the dependency report and forbidden-dependency classifier are carried by D.

Use source-token refusal, forbidden-dependency ledger, and strict axiom-purity replay. Together they identify the axiom-facing report as exactly the finite pair of rows S, D plus the shared support rows.

Finally inspect the carrier boundary. The rows H, C, P, G, N preserve, expose, package, delimit, and name the finite report, and no coordinate records host-kernel completeness, theorem inventory completeness, global proof purity, or semantic repository correctness. The report therefore cannot escape the exact audit rows. □

Theorem 526.17 (AuditGateBoundary obligation closure surface)**.** *For an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet*

$$A = (S, D, L, O, H, C, P, G, N),$$

the local obligation surface is the joint assembly of the source-token scan S, strict axiom-purity report D, paper-Lean drift exactness row L, origin-conservativity row O, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, GAP boundary G, and local* $\mathsf{NameCert}_{\mathsf{AuditGateBoundary}^{\uparrow}}$ *row N. Every governance-facing audit claim for the packet factors through these rows.*

Proof. Project the carrier of Definition 526.1. The rows $S, D, L, O, H, C, P, G, N$ are the complete public packet, so carrier admission contributes no additional audit face.

Use the existing source and dependency rows for the axiom side. The source-token refusal theorem binds S, while strict axiom-purity replay and axiom-purity report non-escape bind D to the displayed forbidden-dependency classifier.

Use the existing drift and origin rows for the manuscript side. Marker-resolution closure and drift row transport bind L, while origin-import replay exactness binds O to the finite origin/import ledger.

Finally replay the shared support rows. The replay ledger keeps H, C, P, G, N as transport, route, provenance, boundary, and naming support for the same packet, so no hidden global correctness claim is exported. □

Theorem 526.18 (AuditGateBoundary ledger exactness)**.** *For an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet, the audit ledger is exact: S is the only source-token refusal row, D is the only strict axiom-purity report row, L is the only exact marker-resolution row, and O is the only origin/import conservativity row. The rows H, C, P, G, N may transport, route, package, delimit, and name these four ledgers, but they cannot replace them by fuzzy Lean target matching, source-axiom admission, forbidden host dependency acceptance, or a host-wide semantic correctness theorem.*

```
Lean4 ✓  BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier ledger exactness
```

Proof. Read the four audit ledgers from the accepted carrier. Source-token refusal uses S, forbidden-dependency classification uses D, marker resolution uses L, and origin/import separation uses O.

Apply the corresponding exactness theorems. Source-token refusal, forbidden-dependency ledger, marker-resolution non-escape, and origin-import replay exactness identify the public content of the four rows.

The support rows do not create substitute ledgers. They only preserve, expose, package, delimit, and name the displayed rows; the GAP boundary blocks fuzzy target matching, source-axiom admission, forbidden host dependency acceptance, and hidden semantic correctness. □

Theorem 526.19 (AuditGateBoundary obligation non-escape)**.** *For an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet, the obligation closure surface exports no hidden global correctness claim. Its public reads are exactly source-token refusal, strict axiom-purity reporting, paper-Lean exact target resolution, origin/import separation,* hsame *transport,* Cont *replay,* Pkg *provenance, GAP boundary, and local naming; no read yields fuzzy Lean target matching, source-axiom admission, forbidden host dependency acceptance, theorem-inventory completeness, host-kernel completeness, or semantic conservativity for arbitrary imports.*

Proof. Start with the obligation surface of Definition 526.17. It assembles only the carrier rows $S, D, L, O, H, C, P, G, N$.

Use ledger exactness to inspect every public read. Each governance claim is forced back to the displayed source-token, dependency, marker-resolution, or origin/import row, with the shared support rows providing only transport and replay.

The excluded claims have no coordinate in the carrier. Since the GAP boundary is part of the same packet, the surface cannot export fuzzy target matching, source-axiom admission, forbidden host dependency acceptance, inventory completeness, host-kernel completeness, or arbitrary-import conservativity. □

Theorem 526.20 (AuditGateBoundary kernel-query scope)**.** *For an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet*

$$A = (S, D, L, O, H, C, P, G, N),$$

the source-token row S and the dependency report row D are the only rows by which source-token reads and axiom-query reads enter the boundary. Every such read must then pass through the shared support rows H, C, P, G, N before it can be consumed as an $\mathsf{AuditGateBoundary}^{\uparrow}$ *verdict surface.*

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryCarrier kernel query scope`

Proof. Project the carrier of Definition 526.1. The row S is the only source-token scan row, and the row D is the only axiom-purity dependency report row.

Apply Definition 526.3. It binds the audit-facing axiom boundary to the finite pair consisting of the source-token scan and the dependency report.

Apply Definition 526.6 for the source side and Definition 526.7 for the query side. These theorems route the two reads through H, C, P, G, N and leave L and O as distinct audit faces.

Finally use Definition 526.19. Since no other carrier row can introduce source-token or axiom-query content, the kernel-query scope is exactly S, D plus the shared support rows. □

Theorem 526.21 (AuditGateBoundary forbidden-dependency scope)**.** *For an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet, the forbidden-dependency classifier is exactly the displayed row for* Classical.choice*,* Quot.sound*, and* propext *transported through H and routed through C. No consumer may replace that finite classifier by a broader host-dependency predicate, a theorem-inventory completeness claim, or a different forbidden-name set.*

Proof. Start from the dependency row D in Definition 526.1. Its displayed classifier names exactly Classical.choice, Quot.sound, and propext.

Use Definition 526.7. It fixes the inspected theorem names, reported proof ancestry, and pass-or-refuse result as the content carried by D.

Now apply Definition 526.3. The strict axiom-facing conclusion is local to the finite dependency report, so transport through H and replay through C cannot widen the forbidden set.

The non-escape theorem Definition 526.19 closes the boundary. It excludes host-kernel completeness and theorem-inventory completeness, leaving only the displayed three-name classifier. □

Theorem 526.22 (AuditGateBoundary verdict scope)**.** *Every verdict read from an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet factors through*

$$S, D, L, O, H, C, P, G, N.$$

The verdict may combine source-token refusal, strict dependency reporting, exact marker resolution, and origin/import separation, but it cannot be replaced by an ambient host claim about repository correctness, theorem inventory completeness, source admission, or semantic conservativity.

Proof. Project the carrier. The public audit faces are S, D, L, O, and the support rows are H, C, P, G, N.

Use Definition 526.6 and Definition 526.7 for the source and dependency verdict components. Use Definition 526.3 to bind their joint axiom-facing reading.

The remaining rows stay inside the same accepted packet. The carrier definition provides marker-resolution and origin/import rows, while the support rows transport, replay, package, delimit, and name the verdict surface.

Apply Definition 526.19. It blocks ambient host claims and leaves the verdict as a finite read through $S, D, L, O, H, C, P, G, N$ alone. □

Theorem 526.23 (AuditGateBoundary standard bridge)**.** *The accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet forms the standard audit-boundary schema: the public source-token row, axiom-purity dependency row, paper-Lean drift row, origin/import separation row, replay ledger, GAP boundary row, and local* NameCert *row are carried by one finite* BHist *surface and transported through the shared* H, C, P *support rows. The schema exports exactly that audit-boundary verdict surface. It exports no repository completeness theorem, theorem-inventory completeness claim, host semantic correctness statement, or semantic conservativity result for arbitrary imports.*

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryUp StdBridge`

Proof. Project the carrier of Definition 526.1. Its public audit faces are the source-token scan, axiom-purity dependency report, paper-Lean target audit, and origin/import separation ledger, and its support faces are the replay, transport, package, GAP, and local naming rows.

Apply Definition 526.22. Every verdict read is therefore a finite read through the displayed audit rows and the shared support rows.

Now use Definition 526.20 and Definition 526.21 for the source-token and forbidden-dependency components. Use the replay and origin/import rows named in the carrier for the remaining audit faces. These are precisely the rows required by the standard audit-boundary schema.

Finally apply Definition 526.19. The excluded host claims have no carrier coordinate, so the bridge is only the finite audit-boundary schema and not a repository-completeness or host-correctness theorem. □

Theorem 526.24 (AuditGateBoundary visible verdict exhaustion)**.** *Every audit verdict read of an accepted* $\mathsf{AuditGateBoundary}^{\uparrow}$ *packet* $A = (S, D, L, O, H, C, P, G, N)$ *is exhausted by the displayed source-token, dependency, marker-resolution, origin/import, transport, continuation, provenance, GAP, and local* NameCert *rows. The verdict may report only the finite surface carried by those rows. It does not assert repository completeness, theorem-inventory completeness, host-kernel correctness, or a semantic correctness theorem for arbitrary imports.*

Lean4 ✓ `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryVisibleVerdictExhaustion`

Proof. First apply Definition 526.22. It factors every verdict read through $S, D, L, O, H, C, P, G, N$, so the visible verdict already has a finite carrier surface.

Next apply Definition 526.20 and Definition 526.21. These identify the source-token query and the forbidden-dependency report as the displayed audit rows, rather than as host-wide kernel assertions.

Use Definition 526.23 to package the source-token, dependency, marker-resolution, origin/import, transport, continuation, provenance, GAP, and local naming rows as one standard audit-boundary surface.

Finally apply Definition 526.19. The non-escape row removes repository completeness, theorem-inventory completeness, host-kernel correctness, and semantic correctness for arbitrary imports, so the visible verdict is exhausted by the displayed packet alone. □

Theorem 526.25 (AuditGateBoundary formal-axis refusal)**.** *An* AuditGateBoundary$^{\uparrow}$ *mature paper packet exports only the displayed audit-gate carrier, classifier, refusal, transport,* Cont*,* Pkg*, and* NameCert *rows, together with the named Lean theorem target*

`BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryUp_StdBridge`.

This supports a bridgeChecked *verification-axis row for that declaration alone. It does not create host-kernel completeness, semantic conservativity for arbitrary imports, or theorem-inventory completeness.*

Proof. First read the mature paper surface through the chapter theorems. The carrier, NameCert obligations, source-token refusal, forbidden-dependency scope, marker-resolution boundary, origin-import replay, standard bridge row, non-escape row, and visible verdict exhaustion theorem all operate on the displayed packet rows.

Next apply the two-axis discipline of chapter 9203. The theory-axis grade records what this paper packet closes, while the formal verification axis is supplied only by Lean markers and closurestatus targets that resolve to real declarations.

The closurestatus target names the existing Lean declaration for the standard audit-boundary bridge. Therefore the packet may report the corresponding checked-bridge row, while host-kernel completeness, semantic conservativity for arbitrary imports, and theorem-inventory completeness remain outside the packet. □

Closure status for NameCert$_{\text{AuditGateBoundary}^{\uparrow}}$.

Constructive story: An AuditGateBoundary$^{\uparrow}$ packet is generated from a source-token scan, an axiom-purity dependency report, a paper-Lean target audit, an origin/import separation ledger, finite hsame transport, visible Cont routes, package provenance, a GAP boundary row, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{AuditGateBoundary}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public packet binds the carrier, NameCert obligations, source-token refusal, forbidden-dependency scope, marker-resolution non-escape, origin-import replay exactness, replay ledger, Definition 526.22, Definition 526.23, Definition 526.24, and the replay and non-escape rows to one finite audit-boundary surface.

Formal verification: FormalStatus(NameCert$_{\text{AuditGateBoundary}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.AuditGateBoundaryUp.AuditGateBoundaryUp\_StdBridge`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close host-kernel completeness, semantic conservativity for arbitrary imports, or theorem inventory completeness.

Upgrade path: No further formal-axis upgrade remains for the checked standard bridge.

The ClosedTermSubstitutionBoundary$^{\uparrow}$ hub reads its closed substitution route through chapter 537, chapter 765, chapter 532, and chapter 525 before the child files spell out the route.

Chapter 527

Closed-Term Substitution Boundary NameCert Construction

The $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ packet records the finite naming surface by which MetaCIC closed terms pass through shift and substitution without exporting a free-variable leak. It packages Term, $\mathsf{ClosedAt}$, shift, $\mathsf{substitute}$, closedness ledgers, audit-visible non-escape rows, transport data, continuation routes, package provenance, and the local $\mathsf{NameCert}$ row. The packet is not a host compiler theorem and does not assert subject reduction beyond the displayed closed-term boundary.

Definition 527.1 (Closed-term substitution boundary carrier)**.** *A* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N)$$

with the following visible rows:

1. *T is the displayed* Term *row for the term being substituted into;*
2. *V is the displayed* Term *row for the closed substituting value;*
3. *d is the de Bruijn depth row at which the boundary is inspected;*
4. *C_{src} is the* $\mathsf{ClosedAt}(d, T)$ *source-closedness witness row;*
5. *C_{val} is the* $\mathsf{ClosedAt}(0, V)$ *value-closedness witness row;*
6. *Q is the displayed* shift *boundary row recording that closed terms spend no future depth budget at the inspected boundary;*
7. *R is the displayed* $\mathsf{substitute}$ *boundary row recording that substitution at a closed boundary returns the same closed source row;*
8. *L is the finite closedness ledger recording which source, value, shift, and substitution rows have been read;*
9. *A is the audit-visible non-escape row recording that no free variable, host equality witness, or untracked compiler state is exported by the packet;*
10. *H stores componentwise* hsame *transports for the term rows, depth row, closedness rows, boundary-operation rows, ledger, audit row, package row, and local naming row;*
11. *C stores the displayed* Cont *routes by which consumers read those finite rows;*

12. *P is the* Pkg *provenance over* Term, ClosedAt, shift, substitute, BHist, hsame, Cont, Pkg, *and* NameCert*;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}}$ *row.*

The carrier contains no hidden typing derivation, no unrestricted compiler correctness theorem, no host substitution semantics, and no coordinate for an unregistered free variable.

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionBoundaryUp.ClosedTermSubstitutionBoundaryTasteGate`
`single carrier alignment`

Definition 527.2 (Closed-term substitution boundary classifier)**.** *For accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packets S and S', the classifier* $\mathsf{ClosedTermSubstitutionBoundaryClassifier}(S, S')$ *holds exactly when the displayed* Term *rows, inspected depth row,* ClosedAt *witnesses,* shift *boundary row,* substitute *boundary row, closedness ledger, audit-visible non-escape row,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row transport componentwise to the same finite boundary surface.*

The classifier does not compare host syntax trees by an unrecorded equality test, does not inspect non-displayed typing derivations, and does not import a compiler-wide semantic preservation theorem.

Lean4 (definition) `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryClassifier`
Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryClassifier`
`component transport`

Theorem 527.3 (Closed-term substitution boundary NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutio}}$ *surface consists of five finite obligations:*

1. *carrier admission: accepted packets are exactly the finite* BHist *carriers of Definition 527.1;*
2. *classifier stability: Definition 527.2 is preserved by displayed* hsame *transports and* Cont *routes on the term rows, depth row, closedness witnesses, shift row, substitution row, ledger, audit row, package provenance, and local naming row;*
3. *shift boundary exactness: the* shift *row may be consumed only after the source closedness witness has been displayed, and it records that the closed boundary does not spend a future depth budget;*
4. *substitution boundary exactness: the* substitute *row may be consumed only after the source and value closedness witnesses have been displayed, and it records that substitution cannot manufacture a free-variable coordinate;*
5. *audit non-escape: the ledger and audit rows expose every closedness dependency required by the packet and export no unregistered free variable, hidden host equality, unchecked compiler state, or ambient subject-reduction theorem.*

Proof. Carrier admission is projection from Definition 527.1. The tuple displays the term rows, depth row, closedness witnesses, operation rows, ledger, audit row, transport and continuation data, package provenance, and local naming certificate.

Classifier stability follows from Definition 527.2. The classifier is defined only on the displayed rows, so componentwise hsame movement and recorded Cont reads cannot introduce a second substitution semantics or an untracked compiler state.

The shift and substitution obligations are the two operation rows Q and R. Their prerequisites are recorded in C_{src} and C_{val}, and the finite ledger L records that those witnesses have been read before the operation boundary is consumed.

Finally the audit row A fixes the non-escape claim. Since the carrier has no coordinate for a free-variable leak, hidden host equality, or ambient subject-reduction theorem, no consumer route can export such data from the local certificate. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryNamecertObligations`

Theorem 527.4 (Closed-term substitution boundary source closedness admission)**.** *For every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N),$$

the source closedness row C_{src} *must be exposed before either the shift boundary row* Q *or the substitution boundary row* R *can be consumed.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySourceClosednessAdm`

Proof. Project the carrier of Definition 527.1. The displayed packet places C_{src} in the same finite BHist surface as Q and R.

Use the classifier of Definition 527.2 and the NameCert obligations of Definition 527.3. The classifier permits only componentwise transport of the displayed rows, while the operation obligations require source closedness before either boundary operation is read. □

Theorem 527.5 (Closed-term substitution boundary value closedness admission)**.** *For every accepted substitution-row read of a* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N),$$

the value closedness row C_{val} *must be exposed before the substitution boundary row* R *can be consumed.*

Proof. Read the carrier coordinates from Definition 527.1. The value witness C_{val} is displayed as the closedness row for the substituting value, and the substitution row R is part of the same finite packet.

Apply Definition 527.2 and Definition 527.3. Their substitution boundary clause permits a read of R only after the source and value closedness witnesses have been displayed and recorded in the local ledger. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryValueClosednessAdmi`

Theorem 527.6 (Closed-term substitution boundary closed-value preservation)**.** *Any accepted substitution-row read that preserves the* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet must keep the value closedness row* C_{val} *displayed through* R, L, A, H, C, P, N*. The read cannot replace* C_{val} *by host substitution semantics, hidden equality, or an ambient subject-reduction theorem.*

Proof. Project the carrier of Definition 527.1. The row C_{val} is a named coordinate of the same finite packet as the substitution row R, ledger L, audit row A, transport H, route C, provenance P, and local name N.

Use Definition 527.5 and Definition 527.7. The first admits the displayed value-closedness row, and the second requires any substitution-row read to expose that row before R is consumed.

Thus preservation of the boundary preserves the displayed C_{val} row. No carrier coordinate supplies host substitution semantics, hidden equality, or subject reduction. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryClosedValuePreserva`

Theorem 527.7 (Closed-term substitution boundary substitution-row exactness)**.** *In an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N),$$

the substitution row R is read only through the finite surface $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, L, A, H, C, P, N$. It exports no free variable, host equality, unchecked compiler state, or subject-reduction theorem.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySubstitutionRowExac`

Proof. Start from the carrier and classifier. Definition 527.1 lists every row available to the substitution boundary, and Definition 527.2 allows only displayed hsame transports and Cont routes across those rows.

Use the NameCert obligations of Definition 527.3. They force the read of R through $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$ and the ledger and audit rows before any consumer may cite the substitution boundary.

The export exclusions are absence-of-coordinate consequences. The packet has no row for a free variable, host equality, unchecked compiler state, or subject-reduction theorem, and the local certificate cannot reconstruct one from L, A, H, C, P, N. □

Theorem 527.8 (Closed-term substitution boundary ledger non-escape)**.** *Every accepted* ClosedTermSubstitutionBo *packet exposes closed-term substitution only through the rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The ledger L and audit row A force every consumer read through the displayed $\mathsf{ClosedAt}$ *witnesses and boundary-operation rows before it may cite the packet. No consumer receives an unregistered free variable, a hidden host equality witness, unchecked compiler state, or a subject-reduction theorem not carried by the packet.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryLedgerNonEscape`

Proof. Read the carrier coordinates from Definition 527.1. The only rows available to a consumer are the two terms, the depth row, the closedness witnesses, the shift and substitution boundary rows, the ledger, the audit row, and the displayed provenance data.

Use the NameCert obligations of Definition 527.3. They require the closedness witnesses to be displayed before either operation row is consumed, and they place the non-escape check in the same finite packet.

The exclusions follow from absence of coordinates. A free-variable leak, hidden host equality witness, unchecked compiler state, or ambient subject-reduction theorem is not among the packet rows and cannot be reconstructed by hsame transport or a Cont read. □

Theorem 527.9 (Closed-term substitution boundary shift-ledger exhaustion)**.** *Every shift read consumed through an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet is exhausted by the finite rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, L, A, H, C, P, N.$$

The shift boundary row Q may be read only after the term rows, inspected depth, source and value closedness witnesses, ledger row, audit row, transports, continuation routes, package provenance, and local $\mathsf{NameCert}$ *row have been displayed. It exports no unregistered free variable, host equality witness, unchecked compiler state, subject-reduction theorem, or host shift semantics.*

Proof. Project the carrier of Definition 527.1. The displayed rows include the two terms, inspected depth, source and value closedness witnesses, shift row, ledger, audit row, transports, continuation routes, package provenance, and local name.

Apply the classifier and NameCert obligations. The classifier permits only componentwise hsame transport and recorded Cont reads of those rows, while the shift boundary exactness clause requires the closedness witness and ledger entry before Q is consumed.

Finally use ledger non-escape. Since no row carries an unregistered free variable, host equality witness, unchecked compiler state, subject-reduction theorem, or host shift semantics, every shift read is exhausted by the displayed packet rows. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryShiftLedgerExhausti

Theorem 527.10 (Closed-term substitution boundary substitution-ledger exhaustion)**.** *Every substitution read consumed through an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet is exhausted by the finite rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The substitution boundary row R may be read only after the source and value closedness witnesses, the shift boundary row, the ledger row, and the audit row are visible inside the same carrier. It exports no unregistered free variable, hidden host equality, unchecked compiler state, subject-reduction theorem, or host substitution semantics.

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySubstitutionLedgerE

Proof. Start with the carrier and classifier. The local packet displays the substitution row R only as part of the same finite surface as $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, L, A, H, C, P, N$, and the classifier admits only recorded transport of that surface.

Use the NameCert obligations for substitution boundary exactness. They require the source and value closedness witnesses to be displayed, and the ledger L records the closedness and operation reads before the substitution row can be consumed.

Apply ledger non-escape for the audit boundary. The audit row A rules out a free-variable leak, hidden host equality, unchecked compiler state, subject-reduction theorem, or host substitution semantics; none of these can be reconstructed from hsame transport or a Cont route. □

Theorem 527.11 (Closed-term substitution boundary self-compile route)**.** *A self-compilation consumer may use an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet only as the finite closed-boundary route*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The consumer may replay the packet through BHist, hsame, Cont, Pkg, *and* NameCert *rows, but it cannot import subject reduction, compiler correctness, host substitution semantics, host syntax quotients, or an unchecked semantic model.*

Proof. Begin with the shift-ledger and substitution-ledger exhaustion rows. They identify the only finite routes by which the consumer may read closed shift and closed substitution through the packet.

Use the carrier, classifier, and NameCert obligations to repack those routes as a single closed-boundary service. The rows Q and R are both guarded by the displayed closedness witnesses, ledger, audit row, transports, continuations, package provenance, and local name.

Finally apply ledger non-escape. Subject reduction, compiler correctness, host substitution semantics, host syntax quotients, and unchecked semantic models have no coordinate in the packet, so a self-compilation consumer receives only the finite closed-boundary route. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySelfCompileRoute`

Theorem 527.12 (Closed-term substitution boundary consumer boundary)**.** *A self-compilation consumer may use an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet only as the finite boundary surface for closed* shift *and* substitute *reads. The consumer must factor through the displayed* Term *rows,* ClosedAt *witnesses, depth row, operation rows, closedness ledger, audit-visible non-escape row,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

This boundary supplies the closed-term substitution step needed by the self-compilation story, but it does not export a full compiler correctness theorem, a subject-reduction package, a host syntax quotient, or a hidden semantic model.

Proof. Start with the carrier and classifier. The carrier of Definition 527.1 displays the finite rows, and the classifier of Definition 527.2 permits only componentwise transport and recorded consumer reads of those rows.

Apply Definition 527.3. The shift and substitution rows become available only after the required closedness witnesses and ledger entries have been displayed.

Finally use Definition 527.8. The consumer route cannot leave the finite packet to obtain compiler correctness, subject reduction, host quotient syntax, or a hidden semantic model, so the self-compilation use is exactly the closed-term substitution boundary. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryConsumerBoundary`

Theorem 527.13 (Closed-term substitution boundary BinderBudgetSeal factorization)**.** *Every* $\mathsf{BinderBudgetSeal}^{\uparrow}$ *shift or substitution read that is used by a closed-term substitution consumer factors through the displayed* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Thus the binder-budget seal of chapter 532 may consume the closed shift and substitution facts only through the finite BHist *packet, the componentwise* hsame *transports, the displayed* Cont *routes, the* Pkg *provenance, and the local* NameCert *row of Definition 527.1.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryBinderSealFactoriza`

Proof. Start with a $\mathsf{BinderBudgetSeal}^{\uparrow}$ read that asks for closed shift or closed substitution at the inspected binder depth. The local carrier theorem Definition 527.12 restricts that read to the finite closed-term boundary surface.

The needed closedness witnesses are exactly C_{src} and C_{val}, and the permitted operation rows are exactly Q and R. By Definition 527.3, these rows are available only after the ledger L records the corresponding closedness read.

Finally apply Definition 527.8. Since the audit row A and the continuation row C admit no hidden binder convention, unregistered free-variable coordinate, or ambient compiler theorem, the binder-budget consumer factors through the displayed packet rows and no other substitution surface. □

Theorem 527.14 (Closed-term substitution boundary authorized-generator inversion)**.** *Any* AuthorizedGeneratorR *consumer of the closed-term substitution boundary must expose* $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ *before citing the boundary. Thus the read displays the term rows, source and value closedness witnesses, shift row, substitution row, ledger, audit row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row, while refusing full subject reduction, global compiler correctness, host substitution semantics, and quotient syntax.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryAuthorizedGenerato`

Proof. Project the carrier, NameCert obligations, source/value closedness admission, substitution-ledger exhaustion, and BinderBudgetSeal factorization. These rows exhaust the authorized-generator read and leave no coordinate for the refused global compiler data. □

Theorem 527.15 (ClosedTermSubstitutionCompiler boundary factorization)**.** *The* ClosedTermSubstitutionCompile *schedule of chapter 540 reads the same closed finite boundary before exposing any compiler-facing* substitute_closed *row. In particular, every accepted schedule read passes through the displayed rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

of ClosedTermSubstitutionBoundary$^{\uparrow}$*, then repacks the result through the compiler packet's own continuation and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryCompilerFactorizati`

Proof. Project the compiler-facing read to its closed source and closed value premises. The consumer boundary theorem Definition 527.12 identifies those premises with a read of the closed-term substitution boundary carrier rather than with an evaluator theorem.

The schedule can expose substitute_closed only after it reads C_{src}, C_{val}, and the substitution row R. The BHist ledger L and the Cont routes C record this order, while the hsame transports H keep the same finite rows under accepted packet movement.

The final compiler packet is therefore a repackaging step. The Pkg provenance P and local naming row N certify that the compiler-facing schedule has consumed the closed boundary, but the audit row A prevents the schedule from importing open-term subject reduction, host syntax equality, or a hidden semantic evaluator. □

Theorem 527.16 (Closed-term substitution boundary RecursorGenerator handoff)**.** *Every generated branch output of* RecursorGenerator$^{\uparrow}$ *in chapter 534 consumes closed-term substitution only through the finite* ClosedTermSubstitutionBoundary$^{\uparrow}$ *boundary. The handoff route is the displayed* BHist *packet with rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N,$$

followed by the recursor generator's own branch-output packaging.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRecursorHandoff`

Proof. Consider a generated branch that invokes closed substitution while assembling its output. The branch has access to the boundary only through recorded Cont routes, so Definition 527.12 forces the substitution read to enter the closed-term boundary carrier.

Inside that carrier, Definition 527.3 supplies the required order: source closedness, value closedness, ledger entry, and then the displayed substitution boundary row. Componentwise hsame transport preserves the same rows when the branch output is moved across accepted packets.

The handoff cannot bypass the finite packet. By Definition 527.8, the packet exports no unregistered free variable, host equality witness, unchecked compiler state, or subject-reduction theorem, so the generated branch output receives only the certified closed-term substitution boundary. □

Theorem 527.17 (Closed-term substitution boundary authorized recursor audit route)**.** *Every* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *output that consumes closed substitution reaches it only through the displayed* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N,$$

together with the authorized recursor audit provenance and local naming rows. The authorized recursor may attach its own branch-output boundary, but it cannot read closed substitution through host equality, unchecked compiler state, hidden evaluator data, or subject reduction outside the boundary packet.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryAuthorizedRecursor`

Proof. Start with the carrier and NameCert obligations of Definition 527.1 and Definition 527.3. They display the closed source, closed value, operation, ledger, audit, transport, route, provenance, and naming rows that any substitution consumer must read.

Apply ledger non-escape and the self-compile route, Definition 527.8 and Definition 527.11. These results force closed shift and closed substitution to remain inside the finite boundary packet before a self-compilation consumer can cite them.

Now use the consumer boundary and recursor handoff, Definition 527.12 and Definition 527.16. The authorized recursor output is a downstream branch-output package over the same rows, so its audit provenance augments the route without replacing the closed substitution boundary. □

Theorem 527.18 (Closed-term substitution boundary output non-escape)**.** *Generated output rows downstream of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet cannot export free variables, host equality, unchecked compiler state, or subject reduction outside the packet. Every such output that cites closed shift or closed substitution must carry the displayed boundary rows, the audit row* A*, componentwise* hsame *transport, displayed* Cont *route,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryOutputNonescape`

Proof. Read the carrier and the local NameCert obligations. The rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ are the whole closed-term substitution surface, with no coordinate for an exported free variable, host equality witness, unchecked compiler state, or ambient subject-reduction theorem.

Use Definition 527.8 and Definition 527.12. They make the ledger and audit rows prerequisites for any consumer-facing closed shift or closed substitution read.

Finally apply Definition 527.16 and Definition 527.17. Generated branch output and authorized recursor output therefore inherit the same finite non-escape boundary instead of exporting a detached substitution or compiler theorem. □

Theorem 527.19 (Closed-term substitution boundary self-compile public package)**.** *The public self-compilation package supplied by* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *is exactly the assembly of closed shift, closed substitution, recursor handoff, and audit-visible non-escape rows over*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

It exposes the closed-boundary service to downstream self-compilation consumers without exporting host substitution semantics, subject reduction, host syntax quotienting, unchecked compiler state, or an external evaluator.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySelfCompilePublicPa`

Proof. Begin with the carrier, NameCert obligations, and ledger non-escape theorem. They identify the displayed closedness witnesses, operation rows, ledger, audit row, transports, route, provenance, and local name as the complete boundary packet.

Next use the self-compile route and consumer boundary, Definition 527.11 and Definition 527.12. These rows make the closed shift and closed substitution service public only as a finite packet read, not as a host substitution semantics.

Finally add the recursor and audit-output routes. By Definition 527.16, Definition 527.17, and Definition 527.18, branch-output consumers receive the same packet with audit provenance and no export route for free variables, unchecked compiler state, subject reduction, or hidden evaluator data. □

Theorem 527.20 (Closed-term substitution boundary normalization-frontier handoff)**.** *Every MetaCIC normalization-frontier consumer of chapter 892 reads closed substitution from* ClosedTermSubstitutionBou *only through the displayed rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The handoff supplies the closed source row, closed value row, inspected depth, closedness witnesses, shift and substitution boundary rows, closedness ledger, audit row, componentwise transport, continuation route, provenance, and local NameCert *row, but it supplies no subject-reduction theorem, host substitution semantics, evaluator, or ambient normalization principle.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryNormalizationFronti`

Proof. Start with a normalization-frontier read that asks for closed substitution before exposing its frontier row. The consumer boundary of Definition 527.12 forces that read into the finite closed-term substitution packet rather than an external MetaCIC evaluator.

Inside the packet, the compiler factorization theorem identifies the same rows as the only schedule-facing substitution source. The frontier consumer therefore receives $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ as a closed boundary and not as a subject-reduction package.

Finally apply the recursor handoff theorem. It shows that generated branch output can carry the substitution read downstream only as the displayed boundary packet, so the normalization-frontier surface inherits no host substitution semantics or ambient normalization theorem beyond those rows. □

Theorem 527.21 (Closed-term substitution boundary compiler schedule lock)**.** *Every* ClosedTermSubstitutionComp *schedule read of chapter 540 locks onto the displayed* ClosedTermSubstitutionBoundary$^{\uparrow}$ *rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

before exposing any compiler-side substitute_closed *surface. The schedule may repack the read through its own compiler rows, but the closed substitution input remains the same finite boundary packet.*

Proof. Project the schedule read to the closed source, closed value, depth, and substitution rows it needs before substitute_closed can be exposed.

Apply Definition 527.12 and Definition 527.15. Together they make the compiler schedule a consumer of the displayed boundary rows, with C_{src}, C_{val}, Q, R, and L read before the compiler-facing surface appears.

The remaining rows A, H, C, P, N keep the schedule audit-visible, transported componentwise, routed by displayed continuations, and locally named. Thus the compiler schedule can expose substitute_closed only after locking onto the finite boundary, not by importing host substitution semantics or an ambient compiler-correctness theorem. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryCompilerScheduleLoc`

Theorem 527.22 (Closed-term substitution boundary recursor audit route)**.** *Every* AuthorizedGeneratorRecursor$^{\uparrow}$ *branch output of chapter 525 that consumes closed substitution must pass through the audit row A, the recursor-side boundary row G, and the local* NameCert *rows of both packets. The substitution read remains the* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N,$$

and the authorized recursor side may only attach its displayed generator boundary and local naming data.

Proof. Begin with the recursor handoff of Definition 527.16. Any branch output that invokes closed substitution already receives the displayed finite boundary packet, including the audit row A and local naming row N.

Next route the authorized recursor consumer through chapter 525. Its branch output adds the recursor-side boundary row G and its own local NameCert row, but it does not replace the closed substitution packet or bypass the audit row.

Finally use the consumer boundary and compiler factorization theorems. They keep the substitution component attached to $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ while the authorized recursor packet contributes only its displayed branch boundary and certificate rows. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRecursorAuditRoute`

Theorem 527.23 (Closed-term substitution boundary audit route)**.** *Every audit-visible read of an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet factors through the displayed audit surface A, H, C, P, N. In particular, a read that cites closed shift, closed substitution, ledger non-escape, or consumer admissibility must replay the audit row A, componentwise* hsame *transport H, displayed* Cont *route C,* Pkg *provenance P, and local* NameCert$_{\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}}$ *row N.*

The audit route exports no free-variable coordinate, host equality witness, unchecked compiler state, hidden evaluator, or ambient subject-reduction theorem.

Proof. Start with the carrier and classifier of Definition 527.1 and Definition 527.2. They make A, H, C, P, N the only audit, transport, route, provenance, and naming rows available to the packet.

Use the NameCert obligations of Definition 527.3. The local certificate requires the shift and substitution rows to be consumed only after their displayed closedness witnesses and ledger entries have appeared.

Finally apply ledger non-escape and the consumer boundary from Definition 527.8 and Definition 527.12. Since every consumer read is already confined to the finite closed-term boundary, the audit-visible part of that read is exactly the route through A, H, C, P, N. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryAuditRoute

Theorem 527.24 (Closed-term substitution boundary shift-budget exhaustion)**.** *For an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, the shift row* Q *consumes only the displayed source closedness witness* C_{src} *at depth* d*. Once* C_{src} *is read through the ledger* L*, the row* Q *records that closed shifting spends no hidden future depth budget and does not consult any second binder-depth source.*

Proof. Project the source term row T, inspected depth row d, source closedness witness C_{src}, shift row Q, and ledger row L from the carrier.

The NameCert obligations identify shift boundary exactness as a local obligation of the same packet. The row Q is available only after C_{src} has been displayed and recorded by L.

Use ledger non-escape to rule out any hidden budget source. The packet has no coordinate for a second depth counter, a host binder convention, or an external compiler theorem, so the closed shift consumes exactly the displayed source closedness witness. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryShiftBudgetExhausti

Theorem 527.25 (Closed-term substitution boundary free-variable non-escape)**.** *For an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, the substitution row* R *cannot manufacture an unregistered free-variable coordinate after the displayed source and value closedness witnesses* C_{src} *and* C_{val} *have been read. Any substitution consumer receives the same finite boundary surface and no open-term residue outside* $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$*.*

Proof. Read the substitution prerequisites from the carrier. The row R is paired with the source term T, the closed value V, the inspected depth d, and the two closedness witnesses C_{src} and C_{val}.

Apply the NameCert substitution boundary obligation. It permits R to be consumed only after both closedness witnesses are displayed and after the ledger has recorded that read.

The ledger non-escape theorem then removes the only remaining escape route. Because no carrier coordinate names an unregistered free variable or open-term residue, neither hsame transport nor a displayed Cont read can create one after substitution. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySubstitutionFreeVar

Theorem 527.26 (Closed-term substitution boundary depth row stability)**.** *Transporting an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet by componentwise* hsame *preserves the inspected depth row* d*. The transported packet may move the displayed term rows, closedness witnesses, operation rows, ledger, audit row, continuation routes, package provenance, and local name through the rows listed in Definition 527.1, but it cannot replace* d *by an unlisted binder budget.*

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryDepthRowStability

Proof. Project the carrier row of Definition 527.1. The inspected depth d is a named coordinate of the same packet as $T, V, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$.

Use the classifier definition and the NameCert obligations. Componentwise hsame transport is available only through H, and the classifier compares the displayed depth row together with the displayed term, closedness, operation, ledger, audit, route, provenance, and naming rows.

Apply ledger non-escape from Definition 527.8. Since no coordinate names a second binder budget or a host binder convention, transported consumers keep the same inspected depth row and cannot read an unlisted depth source. □

Theorem 527.27 (Closed-term substitution boundary closedness ledger coverage)**.** *Every consumer of the displayed shift row Q or substitution row R must read C_{src} and C_{val} through the closedness ledger L before the corresponding operation row is available. The shift consumer may ignore the value witness only as unused data, but it still receives a packet whose local ledger records the closedness surface for both source and value rows. The route exports no host equality, no open-term subject reduction, and no hidden compiler state.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryClosednessLedgerCov`

Proof. Begin with the NameCert obligations of Definition 527.3. They make shift boundary exactness depend on the displayed source closedness row and substitution boundary exactness depend on the displayed source and value closedness rows.

Read the ledger non-escape theorem. The ledger L is the finite row that records which closedness witnesses have been consumed before Q or R is exposed to a consumer route.

Use shift-budget exhaustion and substitution free-variable non-escape. The shift row cannot spend a hidden depth budget, and the substitution row cannot manufacture an unregistered free-variable coordinate after the ledger has displayed the closedness witnesses.

The exclusions are then coordinate exclusions. Host equality, open-term subject reduction, and hidden compiler state are absent from the carrier inventory, so the operation rows become visible only through C_{src}, C_{val}, L, and the displayed route rows. □

Theorem 527.28 (Closed-term substitution boundary operation row determinacy)**.** *For fixed rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, L, A, H, C, P, N$ of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, the displayed shift row Q and substitution row R are the unique operation rows visible to any closed-term consumer. A consumer may transport or replay those rows through H and C, but it cannot substitute a host equality proof, an open-term subject-reduction theorem, or hidden compiler state for either operation row.*

Proof. First project the carrier. The only operation coordinates in Definition 527.1 are the shift boundary row Q and the substitution boundary row R.

Use the NameCert obligations and closedness ledger coverage. The local certificate exposes Q and R only after the closedness witnesses have been read through L, and it exposes no second operation coordinate under the same fixed rows.

Apply depth row stability, audit route, and ledger non-escape. Transport through H preserves the inspected depth row, audit-visible replay remains inside A, H, C, P, N, and the ledger excludes unregistered free variables, hidden host equality, unchecked compiler state, and ambient subject-reduction data.

Thus a closed-term consumer with the fixed carrier rows can see exactly the displayed Q and R rows. Any different operation row would require a carrier coordinate not present in the packet. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryOperationRowDetermi`

Theorem 527.29 (Closed-term substitution boundary consumer factorization)**.** *Every self-compilation consumer of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet factors through the full displayed surface*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The consumer may use the packet for closed shift and closed substitution only by reading the term rows, depth row, source and value closedness witnesses, operation rows, closedness ledger, audit row, componentwise transports, continuation routes, package provenance, and local naming row listed in the carrier.

Proof. Begin with the carrier and classifier. They expose exactly the rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ and restrict accepted movement to componentwise transport and displayed route replay.

Use the NameCert obligations for the two operation rows. The shift row Q depends on the displayed source closedness witness, while the substitution row R depends on the displayed source and value closedness witnesses.

Apply the audit-route theorem, shift-budget exhaustion, and substitution free-variable non-escape. These three obligations force the consumer to spend no hidden depth budget, manufacture no unregistered free variable, and route every audit-visible read through A, H, C, P, N.

Finally invoke the consumer boundary of Definition 527.12. The self-compilation consumer therefore factors through the full finite boundary surface rather than through a detached compiler theorem, host syntax quotient, evaluator, or subject-reduction package. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryConsumerFactorizati`

Theorem 527.30 (Closed-term substitution boundary obligation route triad)**.** *The carrier, classifier, and* NameCert *obligations of an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet route closed shift, closed substitution, and audit non-escape through the same finite packet*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The shift row Q, substitution row R, and audit row A may be consumed only after the displayed closedness witnesses and ledger rows have been read through this packet.

Proof. Project the carrier and classifier. They expose the term rows, depth row, closedness witnesses, operation rows, ledger row, audit row, componentwise transports, continuation routes, package provenance, and local naming row as one accepted packet.

Use the NameCert obligations to route the operations. Closed shift reads the source closedness witness, closed substitution reads the source and value closedness witnesses, and both operation rows remain tied to the same ledger row L.

Finally apply ledger non-escape and the audit consumer boundary. The audit row A reads the same displayed history, transport, route, provenance, and naming rows, so the three obligations cannot split into independent compiler, substitution, or audit surfaces. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryObligationRouteTria`

Theorem 527.31 (Closed-term substitution boundary kernel scope package)**.** *The only scoped primitives consumed by the* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet are* Term*,* ClosedAt*,* shift*,* substitute*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. In particular, the scoped package contains no host syntax quotient, evaluator, subject-reduction theorem, compiler state, semantic environment, or external substitution relation.*

Proof. Read the finite carrier rows of Definition 527.1. The term, value, depth, closedness, shift, substitution, ledger, audit, transport, continuation, package, and naming rows exhaust the local inventory.

Then apply the obligation route triad of Definition 527.30. It forces closed shift, closed substitution, and audit non-escape to use the same displayed packet rather than an additional kernel primitive.

The exclusions follow from the consumer boundary and operation row determinacy. A host quotient, evaluator, subject-reduction theorem, compiler state, semantic environment, or external substitution relation would require a further scoped primitive not listed in the carrier. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryKernelScopePackage

Theorem 527.32 (Closed-term substitution boundary closedness consumer export)**.** *Every downstream self-compilation consumer may cite closed shift and closed substitution from an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet only through the displayed witnesses* C_{src}*,* C_{val}*, the operation rows* Q *and* R*, and the closedness ledger* L*. The exported route is therefore the displayed closedness boundary, not a host substitution semantics or ambient compiler-correctness theorem.*

Proof. Start with consumer factorization from Definition 527.29. Every self-compilation read already factors through the rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$.

Use closedness ledger coverage and operation row determinacy. They make C_{src}, C_{val}, Q, R, and L the only visible closedness and operation rows available to such a consumer.

Finally invoke the kernel scope package of Definition 527.31. Since no host substitution semantics or ambient compiler-correctness theorem is present in the scoped primitive list, downstream citation of closed shift and closed substitution must pass through the displayed witnesses and ledger. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryClosednessConsumerE

Theorem 527.33 (Closed-term substitution boundary compiler consumer lock)**.** *Every* ClosedTermSubstitutionCom *consumer of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet must pass through the displayed rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The compiler consumer may cite the compiler-side sibling surface of chapter 540 only after these boundary rows have been displayed; it cannot replace them by a host substitution semantics, ambient compiler-correctness theorem, or detached compiler carrier.

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryCompilerConsumerLoc

Proof. Project the accepted boundary carrier. The projection exposes the term row T, value row V, depth row d, source and value closedness witnesses, operation rows Q, R, ledger row L, audit row A, transport row H, route row C, provenance row P, and local naming row N as one finite packet.

Route the consumer through the local NameCert obligations. They make the closed shift and closed substitution rows readable only through the displayed closedness witnesses and ledger, so a compiler consumer cannot detach Q or R from $C_{\mathsf{src}}, C_{\mathsf{val}}$, and L.

Finally compare with the sibling compiler chapter. The route into chapter 540 is a consumer route out of the displayed boundary packet, not a replacement source for the packet, because no host substitution semantics or ambient compiler-correctness theorem is present among the boundary rows. □

Theorem 527.34 (Closed-term substitution boundary binder-budget depth lock)**.** *In every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, the inspected depth row* d *and the source/value closedness witnesses* $C_{\mathsf{src}}, C_{\mathsf{val}}$ *lock the binder-budget surface before either operation row* Q *or* R *can be consumed. The resulting budget route cites the sibling binder-budget surface of chapter 532 only through the displayed boundary rows.*

Proof. Read the depth and closedness coordinates from the carrier. The row d is not a free ambient natural-number budget; it is the displayed depth coordinate paired with T, V, C_{src}, and C_{val} inside the accepted packet.

Use operation-row routing. The shift row Q consumes the source closedness witness at the displayed depth, and the substitution row R consumes both the source and value closedness witnesses before producing any closedness-preserving operation read.

The binder-budget sibling is therefore reached only after this local projection. A consumer may compare the resulting budget surface with chapter 532, but the comparison is routed through $d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ and supplies no hidden binder depth or host substitution step. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryBinderBudgetDepthLo`

Theorem 527.35 (Closed-term substitution boundary recursor-generator scope lock)**.** *Every* $\mathsf{RecursorGenerator}^{\uparrow}$ *consumer of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet may use the substitution boundary only after the closedness ledger and operation rows* Q, R, L *have been displayed with*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, A, H, C, P, N.$$

The sibling recursor-generator surface of chapter 534 is therefore a downstream scope consumer, not a host recursion principle or external substitution semantics.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRecursorGeneratorSc`

Proof. Start from the closedness consumer export. It already forces downstream citation of closed shift and closed substitution through $C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R$, and L.

Add the audit and route rows. The audit row A, componentwise transport row H, continuation row C, package row P, and naming row N keep the operation read inside the same finite boundary packet.

Only then may a recursor-generator consumer cite chapter 534. Since the boundary packet contains no host recursion principle, external substitution semantics, or detached generator carrier, that sibling citation is a scoped consumer route over the displayed ledger and operation rows. □

Theorem 527.36 (Closed-term substitution boundary shift-substitution ledger lock)**.** *Every closed shift or closed substitution read from an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet passes through the displayed source closedness witness* C_{src}*, value closedness witness* C_{val}*, shift row* Q*, substitution row* R*, closedness ledger* L*, and audit row* A*. The route may transport these rows by* H *and replay them through* C*, but it cannot expose an operation row before the corresponding closedness witness, ledger entry, and audit row have been displayed.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryShiftSubstitutionLe`

Proof. Project the carrier and classifier of Definition 527.1 and Definition 527.2. The only closedness and operation coordinates available to the packet are C_{src}, C_{val}, Q, R, L, and A together with the transport, route, provenance, and naming rows.

Use closedness ledger coverage and operation-row determinacy, Definition 527.27 and Definition 527.28. They make Q and R readable only after the displayed closedness witnesses and ledger row have fixed the operation surface.

Finally apply the audit route and consumer factorization theorems, Definition 527.23 and Definition 527.29. The audit row A remains on the same finite route as the operation rows, so every shift or substitution read is locked to C_{src}, C_{val}, Q, R, L, and A before any consumer can cite it. □

Theorem 527.37 (Closed-term substitution boundary audit route coverage)**.** *The audit route of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet covers every consumer read of the closedness witnesses, shift row, substitution row, closedness ledger, and non-escape row. In particular, any consumer of* C_{src}*,* C_{val}*,* Q*,* R*,* L*, or* A *factors through the finite surface*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryAuditRouteCoverage`

Proof. Begin with the carrier/classifier definitions. They expose the closedness, operation, ledger, audit, transport, route, provenance, and naming rows as the complete consumer-visible surface of the packet.

Apply the audit route theorem together with ledger non-escape, Definition 527.23 and Definition 527.8. The audit-visible route records the same closedness and ledger dependencies and has no coordinate for an unregistered free variable, hidden host equality, unchecked compiler state, or ambient subject-reduction theorem.

Use operation-row determinacy and consumer factorization. Operation reads of Q and R are the displayed rows under fixed closedness and ledger data, and every self-compilation consumer reaches them only through the listed finite packet. Hence the audit route covers all closedness, shift, substitution, ledger, and non-escape reads. □

Theorem 527.38 (Closed-term substitution boundary NameCert export totality)**.** *The local* $\mathsf{NameCert}$ *export of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet is exactly the finite packet rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

It exports no host substitution semantics, no ambient subject-reduction theorem, no host syntax quotient, no hidden evaluator, and no compiler state outside those rows.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryNameCertExportTotal`

Proof. Read the carrier, classifier, and NameCert obligation rows. The definitions and Definition 527.3 make the local certificate range over the displayed term, closedness, operation, ledger, audit, transport, continuation, package, and naming coordinates.

Apply the shift-substitution ledger lock and audit route coverage. Together they show that every operation read and every audit-visible consumer read has already passed through the same finite packet rows, including C_{src}, C_{val}, Q, R, L, and A.

Finally use operation-row determinacy, consumer factorization, and recursor-generator scope lock, Definition 527.28, Definition 527.29, and Definition 527.35. These theorems leave no export route for host substitution semantics, an ambient subject-reduction theorem, a host syntax quotient, a hidden evaluator, or compiler state outside the displayed packet. Thus the local $\mathsf{NameCert}$ export is total for exactly the finite boundary rows. □

Theorem 527.39 (Closed-term substitution boundary consumer route determinacy)**.** *For every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, any consumer route preserving*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

determines the same closed-term substitution boundary surface. The route may read the displayed term rows, closedness witnesses, operation rows, ledger, audit row, componentwise hsame *transports,* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row, but it cannot switch to host substitution semantics, a hidden evaluator, a host syntax quotient, or an ambient subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryConsumerRouteDeterm`

Proof. Project the carrier and classifier. They expose exactly the displayed term, depth, closedness, operation, ledger, audit, transport, continuation, provenance, and naming rows.

Apply Definition 527.28. The operation rows Q and R are fixed once $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$ and the ledger row are fixed.

Use Definition 527.29 and Definition 527.38. Every consumer route preserving the displayed rows therefore factors through the same finite boundary surface, and the local certificate exports no host substitution semantics or ambient subject-reduction coordinate. □

Theorem 527.40 (Closed-term substitution boundary ledger-route separation)**.** *In an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, ledger reads of* L, A *are separate from operation-row reads of* Q, R *and must precede any exported operation boundary. The ledger rows record closedness and audit visibility for the displayed source and value witnesses, while* Q *and* R *remain the closed shift and closed substitution operation rows routed through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *packet.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryLedgerRouteSeparati`

Proof. Begin with Definition 527.36. It places every closed shift or closed substitution read behind the source and value closedness witnesses, the closedness ledger L, and the audit row A.

Apply Definition 527.37. The audit-visible route covers reads of C_{src}, C_{val}, Q, R, L, and A, but it keeps the ledger and audit rows as the consumer-visible precondition for operation export.

The separation follows by coordinate inspection. The rows L, A are ledger and audit coordinates, while Q, R are operation coordinates; because the exported boundary factors through the displayed route, no consumer can expose Q or R before the ledger and audit reads have been fixed. □

Theorem 527.41 (Closed-term substitution boundary closed-value shift totality)**.** *For every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N),$$

the closed-value shift read is total only along the displayed C_{val}*,* Q*,* L*, and* A *rows inside the same* BHist *packet. The read may use componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *row, but it has no route through host substitution semantics, host syntax equality, hidden compiler state, or an ambient subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryClosedValueShiftTot`

Proof. Project the carrier and classifier of Definition 527.1 and Definition 527.2. They expose the closed value row C_{val} and the shift row Q as coordinates of the same finite BHist surface, transported only by the displayed hsame and Cont data.

Use the NameCert obligations. The shift boundary exactness clause makes the closedness rows and ledger row prerequisites for the operation read, while the package and naming rows record that the consumer is reading the local packet rather than an external substitution theorem.

Finally apply Definition 527.40. The ledger row L and audit row A must be fixed before Q is exported, so closed-value shift totality is exactly totality through the displayed closedness and audit rows and through no host semantic route. □

Theorem 527.42 (Closed-term substitution boundary substitute-closed totality)**.** *For every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N),$$

the substitute-closed read is total only after the source and value closedness rows C_{src} *and* C_{val}*, the substitution row* R*, the closedness ledger* L*, and the audit row* A *have been displayed inside the same* BHist *packet. The only transport and consumer routes available are the componentwise* hsame *rows, displayed* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row of the packet.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySubstituteClosedTot`

Proof. Read the carrier. The rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ are the whole substitution-boundary surface, and the classifier admits only componentwise movement of those rows.

Apply the NameCert substitution boundary obligation. It allows a read of R only after both closedness witnesses have been displayed and recorded in the finite ledger.

Use Definition 527.40 to separate the ledger and audit rows from the operation row. Since L and A precede the export of R, the substitute-closed totality claim is a closedness route through the packet and not a subject-reduction theorem or host substitution semantics. □

Theorem 527.43 (Closed-term substitution boundary audit-scope closure)**.** *The audit scope of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet is closed by exactly the displayed rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Every audit-visible closed shift or substitute-closed consumer factors through the finite BHist *carrier, the classifier, the closedness rows, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row, and no consumer escapes to host substitution semantics, host syntax equality, hidden compiler state, or an ambient subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryAuditScopeClosure`

Proof. Start from the carrier, classifier, and NameCert obligations. They list the term rows, depth row, closedness witnesses, operation rows, ledger, audit row, transport rows, continuation routes, package provenance, and naming row as the complete packet surface.

Apply the two totality rows above. Closed-value shift reads and substitute-closed reads are available only through C_{src}, C_{val}, Q, R, L, and A inside the same finite packet.

Finish with Definition 527.40. The ledger and audit rows cannot be bypassed before an operation boundary is exported. Therefore the audit scope closes over the displayed packet rows and does not import host substitution semantics, host equality, compiler state, or subject reduction. □

Theorem 527.44 (Closed-term substitution boundary audit-boundary factorization)**.** *Every audit-visible consumer of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet factors through the carrier, ledger non-escape, shift-substitution ledger lock, and* $\mathsf{NameCert}$ *export totality. Consequently the audit boundary is the finite route over*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

and not an appeal to host substitution semantics, subject reduction, a host syntax quotient, hidden evaluator state, or compiler state outside the displayed packet.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryAuditBoundaryFactor`

Proof. First read the carrier of Definition 527.1. It supplies the finite BHist packet and the surrounding hsame, Cont, Pkg, and NameCert rows.

Apply Definition 527.8. The ledger route has no coordinate for unregistered free variables, hidden host equality, unchecked compiler state, or ambient subject reduction.

Next apply Definition 527.36. It forces operation reads through C_{src}, C_{val}, Q, R, L, and A before any exported closed shift or closed substitution boundary is visible.

Finally apply Definition 527.38. The local certificate exports exactly the displayed finite rows, so every audit-visible consumer factors through that boundary and no host substitution surface is added. □

Theorem 527.45 (Closed-term substitution boundary root audit totality)**.** *Every root audit consumer of an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet factors through the finite route over*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The root audit surface is therefore exhausted by the displayed term rows, closed-value rows, depth row, closedness rows, closed shift and substitution rows, ledger rows, audit row, componentwise transports, continuation routes, package provenance, and local NameCert *row.*

Proof. Begin with Definition 527.37. It identifies every audit-visible closed shift or substitute-closed read with the finite carrier, classifier, closedness rows, transport rows, route rows, package row, and naming row of the accepted packet.

Next use Definition 527.38. The local NameCert exports exactly $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ and has no additional coordinate for host substitution semantics, host equality, hidden compiler state, or ambient subject reduction.

Finally apply Definition 527.44. Since every audit-visible consumer factors through the same carrier and export boundary, every root audit consumer is total over the displayed route and nowhere else. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootAuditTotality`

Theorem 527.46 (Closed-term substitution boundary root substitution scope)**.** *For every accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N),$$

the root substitution-scope obligation is the finite read of the substitution row R only after the source and value closedness rows C_{src} and C_{val} have been displayed in the same BHist *packet. The read is transported only by the recorded* hsame *row H and consumed only through the displayed* Cont *route C under the* Pkg *provenance P and local* NameCert *row N.*

Thus a downstream root consumer receives the substitution boundary through

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, R, L, A, H, C, P, N$$

and not through host substitution semantics, subject reduction, hidden compiler state, or an unregistered free-variable coordinate.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootSubstitutionSco`

Proof. Start with the local NameCert obligations of Definition 527.3. They make a substitution-row read depend on the displayed source and value closedness rows before R can be consumed.

Next apply ledger non-escape, Definition 527.8. The ledger L and audit row A keep the substitution read inside the finite carrier and prevent a route to host equality, hidden compiler state, or a subject-reduction theorem.

Finally use Definition 527.45 and Definition 527.113. Their root routes package the same BHist, hsame, Cont, Pkg, and NameCert rows for downstream consumers, so the substitution-scope obligation is exactly the displayed finite read of R. □

Theorem 527.47 (Closed-term substitution boundary root shift scope)**.** *For every accepted* ClosedTermSubstitution *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N),$$

the root shift-scope obligation is the finite read of the shift row Q only after the source closedness row C_{src} has been displayed in the same BHist *packet. The read is transported only by the recorded* hsame *row H and consumed only through the displayed* Cont *route C under the* Pkg *provenance P and local* NameCert *row N.*

Thus a downstream root consumer receives the shift boundary through

$$T, V, d, C_{\mathsf{src}}, Q, L, A, H, C, P, N$$

and not through a hidden depth convention, host substitution semantics, subject reduction, hidden compiler state, or an unregistered free-variable coordinate.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootShiftScope`

Proof. Begin with the NameCert obligations of Definition 527.3. Their shift exactness clause makes C_{src} the prerequisite for consuming the closed shift row Q.

Use ledger non-escape from Definition 527.8. Since the ledger and audit rows have no coordinate for a hidden depth convention, host substitution semantics, compiler state, or subject reduction, the shift read remains inside the displayed packet.

Close with Definition 527.45 and Definition 527.113. The root handoff exports the same BHist, hsame, Cont, Pkg, and NameCert route, so the shift-scope obligation is separated from the substitution-scope obligation while sharing the same finite packet boundary. □

Theorem 527.48 (Closed-term substitution boundary root-unblock obligation package)**.** *The root-unblock surface of* ClosedTermSubstitutionBoundary$^{\uparrow}$ *is the pair of operation-specific obligations carried by the displayed packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N).$$

The shift side is the finite BHist, hsame, Cont, Pkg, *and* NameCert *route of Definition 527.47. The substitution side is the finite* BHist, hsame, Cont, Pkg, *and* NameCert *route of Definition 527.46.*

Consequently downstream self-compilation, recursor, and compiler-schedule consumers may cite the root-unblock package only as the finite obligation packet

$$(C_{\mathsf{src}}, Q, L, A, H, C, P, N) \quad \textit{and} \quad (C_{\mathsf{src}}, C_{\mathsf{val}}, R, L, A, H, C, P, N),$$

with both sides grounded in Definition 527.3, Definition 527.8, Definition 527.45, and Definition 527.113.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootUnblockObligati`

Proof. First isolate the shift side. Apply Definition 527.47. It packages the Q read through C_{src}, L, A, H, C, P, and N.

Next isolate the substitution side. Apply Definition 527.46. It packages the R read through C_{src}, C_{val}, L, A, H, C, P, and N.

The shared root boundary is supplied by Definition 527.45 and Definition 527.113. These theorems ensure that both operation-specific routes remain in the same displayed BHist carrier with componentwise hsame transport, displayed Cont consumption, Pkg provenance, and local NameCert authority.

Finally use Definition 527.8. Since neither side has a coordinate for host substitution semantics, hidden compiler state, subject reduction, or an unregistered free variable, the combined package is exactly the finite root-unblock obligation surface. □

Theorem 527.49 (Closed-term substitution boundary root closedness gate)**.** *For every accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N),$$

the source closedness row C_{src} gates every closed shift read through Q, and the pair $C_{\mathsf{src}}, C_{\mathsf{val}}$ gates every closed substitution read through R. Both operation reads remain in the displayed carrier, classifier, ledger, audit, hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Read the carrier and classifier of Definition 527.1 and Definition 527.2. They display the term row, value row, depth row, source and value closedness rows, shift row, substitution row, ledger row, audit row, transports, routes, package, and local naming row as one finite packet.

Apply Definition 527.3. Its closed-shift clause makes C_{src} the gate for Q, while its closed-substitution clause makes C_{src} together with C_{val} the gate for R.

Finally use Definition 527.8 and Definition 527.12. They keep both operation reads inside the displayed ledger and consumer boundary, with no appeal to host substitution semantics, subject reduction, or unchecked compiler state. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootClosednessGate`

Theorem 527.50 (Closed-term substitution boundary root substitution non-escape)**.** *Every root substitution read of an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet stays inside*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

It may consume the substitution row R only through the displayed closedness gates, the finite ledger L, the audit row A, componentwise hsame *transport H, displayed* Cont *route C, package provenance P, and local* NameCert *row N.*

Proof. Begin with Definition 527.49. It supplies the source and value closedness gates required before R can be read.

Use Definition 527.8. The ledger and audit rows have no coordinate for an unregistered free variable, host equality, unchecked compiler state, or ambient subject reduction.

Next apply Definition 527.12. It forces every consumer-facing closed substitution read through the same finite boundary packet.

Finally cite the existing root package rows Definition 527.46 and Definition 527.48. They identify the downstream root route as the same $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ surface, so the substitution read cannot escape to host substitution semantics. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootSubstitutionNor`

Theorem 527.51 (Closed-term substitution boundary root audit gate)**.** *The audit row A gates every root read of the closed-term substitution boundary. A read that is not accepted by the displayed audit route over*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

cannot be consumed as a free-variable leak check, host equality, unchecked compiler state, subject reduction theorem, or host substitution semantics.

Proof. Project the accepted packet through Definition 527.1 and the local obligations of Definition 527.3. The audit row A is part of the same finite carrier as the closedness, shift, substitution, ledger, transport, route, package, and naming rows.

Apply Definition 527.8. It states that the finite ledger and audit surface do not export unregistered free variables, hidden host equality, unchecked compiler state, or subject reduction.

Use Definition 527.44 and Definition 527.12. Together they make every audit-visible consumer factor through the displayed boundary rows.

Finally apply Definition 527.50. Since substitution reads themselves remain inside the audited packet, the root audit gate prevents host substitution semantics from appearing as an additional consumer coordinate. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootAuditGate`

Corollary 527.52 (Closed-term substitution boundary root closedness strict local obstruction)**.** *Let O be a displayed failure, refusal, separation, or countermodel row attached to a consumer-facing converse or reuse attempt for a root substitution read of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N).$$

If the attempt uses the root closedness boundary, then O is a strict local obstruction. It can block only the named route that tries to consume R without the displayed source and value closedness gates, or the named reuse route that tries to read the closed-substitution row outside

$$C_{\mathsf{src}}, C_{\mathsf{val}}, R, L, A, H, C, P, N.$$

Every consumer-facing admissible use factors through those rows inside the displayed packet, and every unlisted coordinate is rejected. Hence O cannot be reinterpreted as a global impossibility statement, a host theorem, ambient subject reduction, host substitution semantics, unchecked compiler state, or hidden external validation.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootClosednessStric`

Proof. Apply Definition 527.49. It gives the only closedness gates available at the root boundary: C_{src} gates a closed shift read through Q, and the pair $C_{\mathsf{src}}, C_{\mathsf{val}}$ gates a closed substitution read through R. The same theorem keeps both operation reads inside the displayed carrier, classifier, ledger, audit, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. Thus a converse or reuse attempt that cites the root closedness boundary has no independent closedness source and no operation coordinate before these gates are exposed.

Now use Definition 527.50. Every root substitution read stays inside

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N,$$

and it may consume R only through the displayed closedness gates, the ledger L, the audit row A, componentwise hsame transport H, displayed Cont route C, package provenance P, and local NameCert row N. Therefore any consumer-facing use of the alleged converse or reuse route must factor through exactly the listed closedness, substitution, ledger, audit, transport, route, provenance, and naming rows.

The obstruction row O has only this local target. If the attempted route asks to read R before C_{src} and C_{val} have gated it, then O blocks that named closedness failure. If the attempted route asks to reuse R beyond L, A, H, C, P, N, then O blocks that named non-escape failure. If the attempted route asks for a global impossibility statement, a host theorem, ambient subject reduction, host substitution semantics, unchecked compiler state, hidden external validation, or any other unlisted coordinate, the two cited root rows supply no projection for that request. The row is therefore a strict local obstruction to the named converse or reuse route and not an external validation principle. □

Theorem 527.53 (Closed-term substitution boundary source totality)**.** *Every accepted* ClosedTermSubstitutionBou *root-unblock read used by* AuthorizedGeneratorRecursor$^{\uparrow}$*,* BinderBudgetSeal$^{\uparrow}$*, or* ClosedTermSubstitutionCompiler$^{\uparrow}$ *must pass through the complete finite source surface*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The read exposes the BHist *carrier, componentwise* hsame *rows, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row for the closed source, closed value, inspected binder depth, shift boundary, substitution boundary, closedness ledger, and audit non-escape row. It exposes no open-term source coordinate, host syntax quotient, unchecked evaluator, or subject-reduction theorem.*

Proof. Start with the carrier and classifier of Definition 527.1 and Definition 527.2. They list the only rows available to a root-unblock consumer and restrict movement of those rows to componentwise hsame transport and displayed Cont replay.

Use the source triad and operation route from Definition 527.60 and Definition 527.61. These rows force the closed source, closed value, and inspected depth to be fixed before either Q or R is consumed by a generator, binder-budget, or compiler-facing consumer.

Finally apply the audit non-escape surface of Definition 527.62. Since no open source, host quotient, evaluator, or subject-reduction coordinate is present in the packet, totality of the root-unblock source surface is exactly the displayed finite route. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySourceTotality`

Theorem 527.54 (Closed-term substitution boundary recursive readback)**.** *An* AuthorizedGeneratorRecursor$^{\uparrow}$ *branch may read a* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet only by replaying the finite route*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

through BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The recursive readback must cite the BinderBudgetSeal closed-boundary factorization before it may expose the ClosedTermSubstitutionCompiler schedule row, and the compiler-facing row remains a repackaging of the same closed source, value, shift, substitution, ledger, and audit surface.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRecursiveReadback`

Proof. First read the generated branch through the recursor handoff of Definition 527.16. That handoff already names the finite closed-term substitution packet as the only source available to a generated branch output.

Next apply the BinderBudgetSeal factorization from Definition 527.13. The binder-budget read can consume closed shift and closed substitution only after the closedness witnesses and operation rows are present in the same finite ledger.

Finally use the ClosedTermSubstitutionCompiler factorization of Definition 527.15. The compiler schedule repacks the already displayed boundary rows through its own route; it does not add a host evaluator, open-term substitution theorem, unchecked compiler state, or subject-reduction package. □

Theorem 527.55 (Closed-term substitution boundary downstream non-escape)**.** *Every downstream consumer that combines* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$, $\mathsf{BinderBudgetSeal}^{\uparrow}$, *and* ClosedTermSubstitutionComp *dependencies receives only the displayed* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *route over*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The BHist, hsame, Cont, Pkg, *and* NameCert *rows carry the accepted closedness, operation, ledger, and audit data across those dependencies, while the downstream surface exports no unregistered free variable, hidden binder convention, host substitution semantics, host syntax quotient, unchecked compiler correctness theorem, or ambient subject reduction.*

Proof. Package the source-totality row of Definition 527.53. It fixes the complete finite source surface before any downstream dependency is allowed to consume the packet.

Then package the recursive readback row of Definition 527.54. The generator branch, binder-budget factorization, and compiler schedule all replay the same closed-boundary rows through displayed transports, continuations, provenance, and local naming data.

Apply the ledger non-escape theorem Definition 527.8. The excluded objects have no coordinate in the carrier, and none can be produced by hsame transport, Cont replay, Pkg provenance, or a local NameCert row. Hence the downstream handoff cannot leave the displayed closed-term substitution boundary. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryDownstreamNonescape`

Corollary 527.56 (Closed-term substitution boundary source-total strict obstruction)**.** *Let O be a displayed failure, refusal, separation, or countermodel row attached to a named converse or reuse route for an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *root-unblock read. If the route is used by* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$, $\mathsf{BinderBudgetSeal}^{\uparrow}$, $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$, *or by a downstream consumer combining those dependencies, then O is a strict local obstruction. It can block only the named attempt that factors through*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

and then tries to omit, replace, detach, or bypass one of those displayed rows or one of the structural BHist, hsame, Cont, Pkg, *or* NameCert *rows. The same row cannot be reinterpreted as a global impossibility statement, host theorem, hidden external validation, unregistered free-variable route, hidden binder convention, host substitution semantics, host syntax quotient, unchecked evaluator, unchecked compiler correctness theorem, or ambient subject reduction.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySourceTotalStrictOb`

Proof. Apply the source-totality theorem Definition 527.53. Every accepted root-unblock read used by the generator, binder-budget, or compiler-facing consumers must first pass through the complete finite source surface

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

That surface exposes the carrier, componentwise transport rows, displayed continuation routes, package provenance, and local naming row for the closed source, closed value, inspected depth, operation rows, ledger, and audit row. It exposes no open source coordinate, host syntax quotient, unchecked evaluator, or subject-reduction theorem. Thus a displayed obstruction row attached to a root-unblock attempt has an available domain only over the listed finite rows and their displayed BEDC transport, route, provenance, and naming structure.

Now apply downstream non-escape, Definition 527.55. After the generator, binder-budget, and compiler dependencies are combined, the downstream consumer still receives only the same displayed $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ route. The carried data are exactly the accepted closedness, operation, ledger, and audit rows transported by BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$, while the downstream surface exports no unregistered free variable, hidden binder convention, host substitution semantics, host syntax quotient, unchecked compiler correctness theorem, or ambient subject reduction.

Therefore any consumer-facing use of O must factor through the source-total route and the downstream non-escape route. If the named converse or reuse route asks to omit a displayed coordinate, replace it by a host coordinate, detach it from the closed source surface, or bypass the listed structural rows, then O blocks that named local attempt. Every stronger interpretation asks for a coordinate that neither source totality nor downstream non-escape exports. Hence O has force only as the strict local obstruction to the named converse or reuse route, and it cannot supply a global impossibility statement, host theorem, hidden external validation, or any external validation route outside the displayed closed-term substitution boundary. □

Theorem 527.57 (Closed-term substitution boundary root closedness budget exhaustion)**.** *Every root consumer of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet must expose the source and value closedness witnesses* C_{src} *and* C_{val} *before any closed-shift row or substitute-closed row is exported. The root read is therefore budgeted over*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

and not over host closedness, host substitution semantics, hidden evaluator state, or a subject-reduction theorem.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootClosednessBudge`

Proof. Start from the carrier and classifier of Definition 527.1 and Definition 527.2. They expose the displayed term rows, depth row, closedness witnesses, operation rows, audit row, transports, continuation routes, package provenance, and local naming row as one finite packet.

Use Definition 527.3. The $\mathsf{NameCert}$ obligations certify the closedness witnesses as packet coordinates before any exported operation boundary can be consumed.

Apply Definition 527.8, Definition 527.9, and Definition 527.10. These rows force closed-shift and substitute-closed reads through the displayed closedness budget, so no root consumer can reach Q or R without first passing through C_{src} and C_{val}. □

Theorem 527.58 (Closed-term substitution boundary root shift-substitution totality)**.** *Every root-facing closed shift or substitute-closed request for an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet is accounted for by the displayed route*

$$Q, R, L, A, H, C, P, N.$$

The route is total for root shift/substitution reads once the term rows, depth row, and closedness budget have been exposed.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootShiftSubstituti`

Proof. First apply Definition 527.57. It places every root read behind $T, V, d, C_{\mathsf{src}}$, and C_{val} before operation export.

Next use Definition 527.36. The shift row Q and substitution row R are consumed only through the ledger row L and audit row A.

The carrier transports, continuation routes, package provenance, and local naming row are then fixed by Definition 527.38 and Definition 527.113. Together they repack every root shift/substitution read into the displayed Q, R, L, A, H, C, P, N route and leave no remaining root operation request outside it. □

Theorem 527.59 (Closed-term substitution boundary root consumer NameCert separation)**.** *For every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, the root* NameCert *route remains separate from subject reduction, host substitution semantics, host syntax quotients, hidden evaluator state, and hidden compiler state. A consumer may receive the finite route*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

but receives no additional host-level substitution boundary from that certificate.

Proof. Read the packet through the carrier, classifier, and NameCert obligations. They enumerate exactly the finite BHist, hsame, Cont, Pkg, and NameCert rows available to a root consumer.

Apply Definition 527.40. The ledger route does not export host substitution semantics, host equality, hidden compiler state, or subject reduction.

Next combine Definition 527.58 with Definition 527.113. The operation surface and the root handoff are the same finite certificate route.

It remains to exclude additional host syntax or evaluator data. That exclusion is exactly the non-escape part of Definition 527.44, so the root NameCert route stays separate from all host-level substitution and reduction surfaces. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootConsumerNamecer`

Theorem 527.60 (Closed-term substitution boundary source triad)**.** *For every accepted* ClosedTermSubstitutionBo *packet*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N),$$

the displayed rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$ *form the complete source, value, and depth admission triad before any shift row* Q *or substitution row* R *is consumed. The triad is read through the carrier, classifier, local* NameCert *obligations, and closedness ledger, and it exposes no operation row before the source and value closedness witnesses are fixed.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySourceTriad`

Proof. Read the carrier of Definition 527.1. It displays the source term row T, value row V, inspected depth row d, source closedness row C_{src}, value closedness row C_{val}, operation rows, ledger, audit row, transports, routes, provenance, and local name as one finite packet.

Use the classifier and local NameCert obligations of Definition 527.2 and Definition 527.3. They make the source/value closedness rows the admission surface for closed shift and closed substitution.

Finally apply source/value closedness admission through Definition 527.27. The ledger records the closedness reads before Q or R is consumed, so the source, value, and depth rows form the complete admission triad for the operation boundary. □

Theorem 527.61 (Closed-term substitution boundary operation route)**.** *Every accepted operation read of a* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet factors through*

$$Q, R, L, H, C, P, N$$

after the closedness witnesses C_{src} and C_{val} have been displayed. The route is the finite operation surface of the packet, not host substitution semantics, unchecked compiler state, subject reduction, or a hidden evaluator.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryOperationRoute`

Proof. Start from the source triad of Definition 527.60. It supplies the displayed term rows, depth row, and closedness witnesses that must be fixed before any operation read.

Apply the substitution-row exactness and shift-substitution ledger lock theorems, Definition 527.7 and Definition 527.36. These results force reads of Q and R through the closedness ledger L and the audit-visible packet boundary.

The remaining operation route is componentwise transport, continuation consumption, package provenance, and local naming. Thus H, C, P, N are the only admissible transport and consumer rows after Q, R, L, and no host substitution semantics, unchecked compiler state, subject reduction, or hidden evaluator is exported. □

Theorem 527.62 (Closed-term substitution boundary audit non-escape)**.** *The audit row A of an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet excludes free-variable leaks, host equality, unchecked compiler state, subject reduction, and host substitution semantics from the source/value/depth admission surface and from the operation route*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, H, C, P, N.$$

Every audit-visible consumer must replay the displayed finite packet rather than importing an external substitution theorem or compiler fact.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryAuditNonescape`

Proof. Project the audit row from the carrier and route it through the classifier. The rows A, H, C, P, N belong to the same finite packet as the source triad and operation rows, so audit visibility cannot be detached from the displayed boundary.

Apply the local NameCert obligations and ledger non-escape theorem, Definition 527.3 and Definition 527.8. They rule out unregistered free variables, hidden host equality, unchecked compiler state, ambient subject reduction, and host substitution semantics.

Finally combine the source triad with the operation route from Definition 527.60 and Definition 527.61. Every operation read already passes through the closedness witnesses, ledger, transports, continuation route, provenance, and local name, so the audit row covers the complete finite route and no external substitution or compiler fact is available. □

Corollary 527.63 (Closed-term substitution boundary source triad strict obstruction)**.** *Let*

$$S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N)$$

be an accepted $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, and let O be a displayed failure, refusal, separation, or countermodel row attached in the root-unblock source surface to a named consumer-facing converse or reuse attempt. If the named attempt asks to read the closed-term substitution boundary through the source, value, and depth admission triad, then O is a strict local obstruction: it blocks only that named attempt at one of the displayed rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

or at the corresponding refusal to supply an unlisted coordinate. It does not imply a global impossibility statement, a host theorem, hidden external validation, host substitution semantics, subject reduction, unchecked compiler state, host equality, or a free-variable leak outside the accepted packet.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySourceTriadStrictOb`

Proof. By Definition 527.60, the rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$ form the complete admission triad before any shift row Q or substitution row R is consumed. Thus a consumer-facing converse or reuse attempt has no access to an operation row until the source term, value term, inspected depth, and both closedness witnesses have already been fixed.

By Definition 527.62, every audit-visible consumer must replay the finite packet route

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, H, C, P, N,$$

with the audit row A excluding free-variable leaks, host equality, unchecked compiler state, subject reduction, and host substitution semantics from both the admission surface and the operation route. Hence any consumer-facing use of O either factors through one of the displayed packet rows or asks for a coordinate that the packet does not export.

If the named attempt factors through a displayed row, then the displayed row O can obstruct only that requested converse or reuse read: the packet still exposes the remaining listed rows only through the same finite route. If the named attempt asks for an unlisted coordinate, then the obstruction is the local refusal of that coordinate, since the source triad and audit non-escape surface provide no projection to a host theorem, hidden external validation, global impossibility claim, unchecked compiler state, subject reduction theorem, host substitution semantics, host equality, or free-variable leak. Therefore O has exactly strict local force against the named converse or reuse route and cannot be reinterpreted as any stronger external or global claim. □

Theorem 527.64 (Closed-term substitution boundary recognizer landing surface)**.** *Any recognizer-side read of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet must first pass through* GroundCompilerRecognizerF *acceptance, the generated recognizer row, the* $\mathsf{FiniteReflectionTuple}^{\uparrow}$ *tuple image, and the* $\mathsf{FiniteReflectionTuple}^{\uparrow}$ *readback row. Only after that route has recovered the displayed rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

may a closed-substitution consumer read the packet. The route supplies a recognizer-to-finite-tuple landing surface and no direct closedness readback outside the accepted finite packet.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRecognizerLandingSu`

Proof. Start with the carrier and classifier of Definition 527.1 and Definition 527.2. They make $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ the complete public packet and give the recognizer read no coordinate outside those rows.

Next apply the root source and operation rows of Definition 527.60, Definition 527.57, and Definition 527.58. These rows force source, value, depth, closedness, shift, substitution, ledger, audit, transport, route, provenance, and local naming data to appear before any closed-substitution consumer can proceed.

The recognizer side is supplied by Definition 1048.3. Its event-flow, source-channel, generated-recognizer, and certificate-gate rows ensure that acceptance is mediated by the generated recognizer rather than by source text or an unmediated compiler export.

Finally use Definition 993.2 and Definition 993.3. They force the accepted recognizer export to land in a displayed tuple image and to recover each field through the readback row. Therefore the closed-substitution consumer can read the boundary only after recognizer acceptance, tuple-image landing, and componentwise readback of the displayed packet. □

Theorem 527.65 (Closed-term substitution boundary finite tuple readback)**.** *For any accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet routed through the recognizer landing surface of Definition 527.64, the finite tuple readback must recover the source term T, value term V, depth row d, closedness rows C_{src} and C_{val}, shift row Q, substitution row R, ledger L, and audit row A as* BHist *components before R can be consumed by a downstream closed-substitution read.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryFiniteTupleReadback`

Proof. Project the accepted boundary packet through the carrier. The source term, value term, depth, closedness witnesses, shift row, substitution row, ledger, audit row, transports, continuation routes, provenance, and local naming row are all displayed BHist coordinates of the same packet.

Use Definition 527.57. It prevents the substitution row from being consumed before $T, V, d, C_{\mathsf{src}}$, and C_{val} have been exposed.

Next apply Definition 527.58. Once the closedness budget is visible, the operation read is still forced through Q, R, L, A, H, C, P, N, so R is not available as a standalone row.

The tuple route is then componentwise by Definition 993.2 and Definition 993.3. Since the recognizer landing theorem already places the accepted packet in the tuple image/readback surface, the readback must recover $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A$ as BHist components before any consumer can use R. □

Theorem 527.66 (Closed-term substitution boundary substitution recognizer non-escape)**.** *The combined* $\mathsf{GroundCompilerRecognizerFlow}^{\uparrow}$ *and* $\mathsf{FiniteReflectionTuple}^{\uparrow}$ *route for an accepted* ClosedTermSubstitutionB*packet exports no open-term coordinate, free-variable leak, host syntax quotient, unchecked evaluator, compiler correctness theorem, or ambient subject reduction. Its public substitution read is exactly the recognizer-accepted tuple readback of*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySubstitutionRecogni`

Proof. Begin with the downstream non-escape boundary of Definition 527.62. It excludes free-variable leaks, host equality, unchecked compiler state, subject reduction, and host substitution semantics from the accepted boundary packet.

Add the root consumer separation of Definition 527.59. That theorem keeps the root NameCert route separate from subject reduction, host substitution semantics, host syntax quotients, hidden evaluator state, and hidden compiler state.

Now compose the recognizer and tuple routes. By Definition 1048.4, report-like source, host compiler state, proof text, and raw classifier quotients remain non-evidence inside $\mathsf{GroundCompilerRecognizerFlow}^{\uparrow}$. By Definition 993.3, the reflected packet can be read only through the displayed tuple image and readback.

Finally invoke Definition 527.64. The recognizer side reaches the boundary only after acceptance, generated recognition, tuple-image landing, and readback of the displayed rows. Therefore no open-term coordinate, free-variable leak, host syntax quotient, unchecked evaluator, compiler correctness theorem, or ambient subject reduction escapes the combined route. □

Corollary 527.67 (Closed-term substitution boundary recognizer strict local obstruction)**.** *Let O be a displayed failure, refusal, separation, or countermodel row attached to a consumer-facing converse or reuse attempt for an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet. If the attempt is routed through the recognizer side, then O is a strict local obstruction: it can block only the named read that asks for one of the displayed rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

through $\mathsf{GroundCompilerRecognizerFlow}^{\uparrow}$ *acceptance, the generated recognizer row, the* $\mathsf{FiniteReflectionTuple}^{\uparrow}$ *tuple image, and the* $\mathsf{FiniteReflectionTuple}^{\uparrow}$ *readback row. The same row cannot be reinterpreted as a global impossibility statement, a host theorem, compiler correctness evidence, ambient subject reduction, or hidden external validation for any unlisted route.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRecognizerStrictLoc`

Proof. Apply Definition 527.64. Every recognizer-side consumer of the accepted packet first passes through $\mathsf{GroundCompilerRecognizerFlow}^{\uparrow}$ acceptance, the generated recognizer row, tuple-image landing, and tuple readback. Only after that route has recovered

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

may the closed-substitution consumer read the packet. Thus a consumer-facing converse or reuse attempt has no initial access point except the displayed finite route.

Now apply Definition 527.66. The combined recognizer and finite-tuple route exports no open-term coordinate, free-variable leak, host syntax quotient, unchecked evaluator, compiler correctness theorem, or ambient subject reduction. Its public substitution read is exactly the recognizer-accepted tuple readback of the displayed rows.

Therefore the obstruction row O has only two possible relations to the attempted consumer read. If the attempt asks for one of the displayed coordinates through the accepted recognizer and tuple route, then O blocks that named coordinate read and hence blocks that particular converse or reuse route. If the attempt asks for a global impossibility conclusion, host theorem, compiler correctness result, ambient subject-reduction theorem, hidden evaluator, external validation channel, or any other unlisted coordinate, the landing theorem supplies no readback coordinate for the request and the non-escape theorem explicitly excludes it from the exported packet. In neither case can O be promoted beyond the named local obstruction. □

Theorem 527.68 (Closed-term substitution boundary root depth-value lock)**.** *Every root operation consumer of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet must read the source term*

row T, value row V, depth row d, source closedness row C_{src}, and value closedness row C_{val} before either the closed shift row Q or the substitute-closed row R is exported. The lock is carried by the same finite route

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

and uses the carrier, classifier, local NameCert *obligations, root audit totality, and root* NameCert *handoff of the parent packet.*

Proof. Project the accepted packet through the carrier and classifier. The displayed rows list the source term, value, inspected depth, closedness witnesses, operation rows, ledger, audit row, transports, continuations, provenance, and local naming row as one finite surface.

Apply the local NameCert obligations. They place C_{src} and C_{val} in the packet before the operation rows may be consumed as accepted closed-boundary data.

Finally use root audit totality and the root NameCert handoff. Both root-facing rows factor through the same displayed carrier, so the depth-value surface is locked before Q or R can be exported. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootDepthValueLock`

Theorem 527.69 (Closed-term substitution boundary root operation readback lock)**.** *Every root read of the closed shift row Q or substitute-closed row R of an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet factors through*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The operation readback is admitted only after the depth-value lock, the local classifier, the NameCert *obligation surface, the audit row A, and the root* NameCert *handoff agree on the same finite packet. It exports no host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, or hidden compiler state.*

Proof. Begin with Definition 527.68. It fixes $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$ before either operation row is available.

Read the operation rows through the existing ledger and audit surface. The rows Q and R are not standalone host operations; they are displayed packet coordinates routed through L and checked by A.

Now apply the root audit totality and root NameCert handoff. They force every root consumer back through the same H, C, P, N structural rows, so no operation readback can leave the finite carrier for a host substitution or compiler surface. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootOperationReadba`

Theorem 527.70 (Closed-term substitution boundary root consumer audit factorization)**.** *Every root consumer that uses the operation readback surface of* ClosedTermSubstitutionBoundary$^{\uparrow}$ *factors as a finite audit route over*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The factorization first exposes the term, value, depth, and closedness rows; then reads the closed shift and substitute-closed rows through Q, R, L, A; and finally packages the same rows through componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

Proof. Use the root depth-value lock for the first stage of the factorization. It fixes the source, value, inspected depth, and closedness budget before the root operation rows are visible.

Use the root operation readback lock for the second stage. It routes Q and R through the ledger and audit rows and prevents a consumer from replacing them by host substitution semantics or an ambient subject-reduction theorem.

The final stage is the parent root NameCert handoff. The structural rows H, C, P, N carry exactly the same finite packet to downstream consumers, so the root audit factorization has no extra host syntax, evaluator, compiler-state, or quotient coordinate. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootConsumerAuditFa`

Lemma 527.71 (Closed-term substitution boundary root depth-value bridge determinacy)**.** *For an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet, every consumer-facing route, transport, readback, or handoff that uses the root depth-value operation boundary is determined by the finite displayed surface*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The determining rows are the source term row T, value row V, inspected depth row d, source and value closedness rows C_{src} and C_{val}, closed shift row Q, substitute-closed row R, ledger row L, audit row A, componentwise transport row H, displayed continuation row C, package provenance row P, and local NameCert *row N. A consumer may use Q or R only through this surface, and any route, transport, readback, or handoff coordinate not listed in the surface is unavailable to the root depth-value bridge.*

Proof. Start with Definition 527.68. It fixes $T, V, d, C_{\mathsf{src}}$, and C_{val} before either operation row can be exported. Thus a consumer-facing bridge cannot start from Q or R alone; it must first pass through the displayed source, value, depth, and closedness rows of the accepted packet.

Apply Definition 527.69. Every root read of Q or R factors through the same finite route

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The readback condition ties the operation rows to the local classifier, the NameCert obligation surface, the ledger, the audit row, and the root NameCert handoff. Hence any displayed operation readback used by a consumer is already a readback of these named rows, not a separate host substitution operation.

It remains to account for transports, continuations, provenance, and handoff. The same readback lock routes them through H, C, P, N, while the depth-value lock prevents the operation rows from appearing before $T, V, d, C_{\mathsf{src}}$, and C_{val} have been exposed. Therefore a consumer-facing transport is componentwise transport over the displayed packet, a continuation is replay over the displayed packet, provenance is the displayed package row, and handoff is the local NameCert row attached to that packet.

No further bridge coordinate is present in either lock. The operation readback lock explicitly exports no host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, or hidden compiler state, and the depth-value lock supplies only the listed carrier, classifier, local NameCert obligations, root audit totality, and root NameCert handoff. Consequently every admissible route, transport, readback, or handoff factors through the cited rows, while every unlisted bridge coordinate remains unavailable. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootDepthValueBridg`

Corollary 527.72 (Closed-term substitution boundary root depth-value consumer determinacy)**.** *For an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet whose displayed root depth-value rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

are fixed, every accepted consumer-facing use of the root depth-value operation boundary has the same public decision source. Its finite route is the displayed route above; its transport, readback, normal-form handoff, or exactness decision named by the chapter is read through Q, R, L, A, H, C, P, N *after* $T, V, d, C_{\mathsf{src}}$*, and* C_{val} *have been exposed. No accepted consumer may choose an alternate finite route, hidden normal-form coordinate, duplicate classifier source, host substitution semantics, subject-reduction theorem, host syntax quotient, hidden evaluator, or hidden compiler state.*

Proof. Begin with Definition 527.68. It fixes the source term row T, value row V, inspected depth row d, source closedness row C_{src}, and value closedness row C_{val} before either operation row Q or R can be exported. Thus an accepted consumer cannot start its root operation use from a detached operation row, a second classifier source, or a hidden depth-value coordinate.

Apply Definition 527.71. Every consumer-facing route, transport, readback, or handoff using the root depth-value operation boundary is determined by the single displayed surface

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The same lemma identifies Q and R as usable only through that surface and states that any route, transport, readback, or handoff coordinate not listed there is unavailable to the bridge.

It follows that, once the displayed rows are fixed, there is no remaining choice point for a consumer-facing decision. A finite route must be the displayed route; a transport must be the componentwise row H over that packet; a readback or normal-form handoff must pass through Q, R, L, A and then through C, P, N; and an exactness decision named by the chapter must cite the same closedness, ledger, audit, provenance, and local naming rows. Any alternate finite route, hidden normal-form coordinate, duplicate classifier source, host substitution semantics, subject-reduction theorem, quotient syntax, hidden evaluator, or compiler state would be an unlisted coordinate. The bridge determinacy lemma makes such a coordinate unavailable, while the depth-value lock prevents it from being inserted before the operation rows are exported. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootDepthValueConsu`

Theorem 527.73 (Closed-term substitution boundary root value visibility)**.** *Every root consumer of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet must expose*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$$

before either the closed-shift row Q *or the substitute-closed row* R *is used. The exposed rows are the displayed source term, substituting value, inspected depth, source closedness witness, and value closedness witness of the same finite* BHist *packet.*

Proof. Read the root consumer through the carrier and local certificate rows of Definition 527.1 and Definition 527.3. They make $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$ packet coordinates rather than hidden preconditions.

Use source and value admission from Definition 527.4 and Definition 527.5. These rows place the closedness witnesses on the visible route before the shift or substitution boundary can be read.

Finally apply Definition 527.8 and Definition 527.12. The ledger and consumer boundary prevent a root consumer from obtaining Q or R from host substitution semantics, a hidden evaluator, or an ambient compiler theorem. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootValueVisibility

Theorem 527.74 (Closed-term substitution boundary root operation dependency)**.** *In every root read of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, the rows* Q *and* R *are dependent operation rows over the displayed witnesses* C_{src} *and* C_{val}*. They may be consumed only as the packet's certified closed-shift and substitute-closed boundary rows, not as host shift semantics, host substitution semantics, subject reduction, or an evaluator equation.*

Proof. Start from the operation inventory of Definition 527.28. It identifies Q and R as the only operation rows of the finite packet.

Use Definition 527.27 and Definition 527.36. These rows force the operation read through the displayed closedness witnesses and ledger before any downstream citation can mention Q or R.

The exclusion of host semantics follows from Definition 527.40 and Definition 527.44. Hence the operation dependency is a packet dependency over the displayed closedness witnesses, not an imported shift or substitution semantics. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootOperationDepend

Theorem 527.75 (Closed-term substitution boundary root consumer exhaustion)**.** *Downstream self-compilation and normalization consumers exhaust their closed-substitution read through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *packet of* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$*. No remaining consumer route may add an unregistered free-variable coordinate, host equality, hidden evaluator, hidden compiler state, subject-reduction theorem, or host substitution semantics.*

Proof. First package the root-visible rows by Definition 527.73 and Definition 527.74. Together they expose the source, value, depth, closedness, and operation surface before any root read continues.

Next use the existing consumer rows. The self-compilation route of Definition 527.29 and the normalization-frontier handoff of Definition 527.20 both factor through the same finite boundary packet.

Finally apply Definition 527.38 and Definition 527.44. The displayed BHist, hsame, Cont, Pkg, and NameCert rows therefore exhaust the downstream read, with no route to hidden substitution or compiler data. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootConsumerExhaust

Theorem 527.76 (Closed-term substitution boundary root value downstream coverage)**.** *Every accepted local consumer of the root value row* V *in a* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet is exhausted by the displayed finite coverage alternatives*

$$(T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}), \qquad (Q, R), \qquad (\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}).$$

The first alternative covers the visible value and closedness read, the second covers the certified closed-shift and substitute-closed operation rows, and the third covers downstream self-compilation or normalization consumption through the packet ledger. No excluded route through an unregistered free-variable coordinate, host equality, hidden evaluator, hidden compiler state, subject-reduction theorem, or host substitution semantics belongs to the accepted BEDC packet.

Proof. Let an accepted local consumer ask for the root value row V. By Definition 527.73, the consumer must first expose

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$$

inside the same finite BHist packet before either operation row can be used. Any consumer whose read stops at the value, inspected depth, or closedness witnesses is therefore covered by the first displayed alternative.

If the consumer continues to an operation read, Definition 527.74 identifies Q and R as dependent operation rows over the displayed witnesses C_{src} and C_{val}. Thus the operation continuation is covered by the certified closed-shift and substitute-closed rows, not by a host shift rule, host substitution rule, evaluator equation, or subject-reduction theorem.

It remains to cover consumers that pass the operation rows downstream. This is exactly the exhaustion statement of Definition 527.75: downstream self-compilation and normalization consumers factor through the displayed BHist, hsame, Cont, Pkg, and NameCert packet, with no route to an unregistered free-variable coordinate, host equality, hidden evaluator, hidden compiler state, subject reduction, or host substitution semantics. The three displayed alternatives therefore cover every accepted local root-value consumer, and all excluded alternatives remain outside the accepted BEDC packet. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootValueDownstrean`

Theorem 527.77 (Closed-term substitution boundary root closed boundary cut)**.** *Every downstream self-compilation consumer of an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet must enter the root closed-boundary cut through the displayed rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The rows C_{src} and C_{val} gate every read of the closed shift row Q and substitute-closed row R, and the cut exports only the finite BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route of the packet. It exports no host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or unregistered operation coordinate.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootClosedBoundaryC`

Proof. Read the packet through Definition 527.1, Definition 527.2, and Definition 527.3. These rows make the source term, value, depth, closedness witnesses, operation rows, ledger, audit, transport, continuation, provenance, and local naming data visible as one finite BEDC packet.

Next apply Definition 527.73 and Definition 527.69. They force C_{src} and C_{val} to be visible before Q or R is consumed by any root read.

Finally use Definition 527.70. The downstream consumer is exhausted by the displayed audit route, so the cut has no remaining access to host substitution semantics, subject reduction, quotient syntax, hidden evaluation, or compiler state. □

Theorem 527.78 (Closed-term substitution boundary closed value route determinacy)**.** *In the displayed root packet*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N,$$

the closed-value route is determined by the value row V, the depth row d, and the witness row C_{val} before any read of Q or R. A downstream self-compilation consumer may therefore cite the substitute-closed boundary only through the same finite packet route, not through a host value semantics, hidden evaluator, subject reduction theorem, or hidden compiler state.

Proof. Start with Definition 527.5. It places C_{val} on the displayed closedness route for the same value and depth rows that the accepted packet exposes.

Apply Definition 527.73. The theorem makes V, d, C_{val} visible before either operation row is available to a root consumer.

The determinacy of the route follows by Definition 527.69. Since Q and R are read only after the displayed closedness rows and through L, A, H, C, P, N, no host value semantics or hidden compiler object can supply an alternate route. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryClosedValueRouteDet

Theorem 527.79 (Closed-term substitution boundary shift-substitution source synchronization)**.** *For every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *root packet, the closed shift row Q and substitute-closed row R are synchronized to the same displayed source rows T, d, C_{src} in*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Thus a downstream consumer cannot read the shift boundary from one source witness and the substitution boundary from another; both reads are gated by the same C_{src} and then carried through the common ledger, audit, transport, continuation, provenance, and NameCert *rows.*

Proof. Use Definition 527.4 to identify C_{src} as the displayed source closedness witness for the accepted packet. The source term row T and depth row d are therefore part of the same finite carrier surface as the closedness witness.

Next apply Definition 527.36. It locks the closed shift and substitute-closed rows behind the same ledger route, so Q and R cannot be split across independent source witnesses.

Finally read the root operation through Definition 527.69. The common route through L, A, H, C, P, N synchronizes both operation rows to the same source witness and blocks replacement by host shift or substitution semantics. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryShiftSubstitutionSo

Theorem 527.80 (Closed-term substitution boundary consumer ledger exhaustion)**.** *Every downstream self-compilation consumer of the displayed root packet exhausts its operation access through the ledger row L and audit row A of*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

After the ledger has admitted the closed-source and closed-value witnesses and the operation rows, the remaining consumer surface is exactly H, C, P, N; there is no additional host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or implicit read channel.

Proof. Begin with Definition 527.8. It states that the ledger does not let a consumer escape the displayed finite packet when reading closed-substitution data.

Combine this with Definition 527.12 and Definition 527.70. The consumer boundary and audit factorization route all downstream access through L and A before the structural rows H, C, P, N are packaged.

The ledger is therefore exhaustive for the consumer. Any attempted host semantics, hidden evaluator, subject-reduction theorem, quotient syntax, compiler state, or implicit read channel would be an additional row outside the displayed packet, contradicting the ledger and audit boundary. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryConsumerLedgerExhau

Theorem 527.81 (Closed-term substitution boundary NameCert root unblock package)**.** *The root closed-boundary cut, closed-value route determinacy, shift-substitution source synchronization, and consumer ledger exhaustion form a NameCert root-unblock package for downstream self-compilation consumers of* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$*. The package is precisely the finite BEDC route*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N,$$

together with the carrier, classifier, BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows already displayed in the chapter. It exports no host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, hidden compiler pass, or extra root operation beyond that finite route.*

Lean4 ✓ `BEDC.Derived.Closedtermsubstitutionboundaryup.ClosedTermSubstitutionBoundaryNameCertRootUnbloc`

Proof. First package the closed-boundary cut by Definition 527.77. It identifies the finite route and states that the closed-source and closed-value witnesses gate the operation rows.

Next add value determinacy and source synchronization by Definition 527.78 and Definition 527.79. These two rows make the value and source witnesses part of the same closed operation surface.

Finally apply Definition 527.80 and Definition 527.113. The downstream self-compilation consumer receives the finite NameCert package, and every excluded host semantic, evaluator, quotient, compiler-state, compiler-pass, or extra operation route lies outside the exported BEDC boundary. □

Corollary 527.82 (Closed-term substitution boundary root closed determinacy)**.** *For an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *root packet whose displayed rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

are fixed, every accepted downstream self-compilation use of the root closed boundary has the same public decision source. Its closed-value route is the route over V, d, C_{val}*, its shift and substitute-closed source is the synchronized route over* T, d, C_{src}*, and its consumer-facing route, normal-form handoff, or exactness decision is read only through* Q, R, L, A, H, C, P, N*. Hence no accepted consumer may replace the displayed packet by an alternate finite route, a hidden normal-form coordinate, a duplicate classifier source, a host substitution semantics, a subject-reduction theorem, a host syntax quotient, a hidden evaluator, or hidden compiler state.*

Lean4 ✓ `BEDC.Derived.Closedtermsubstitutionboundaryup.ClosedTermSubstitutionBoundaryRootClosedDetermina`

Proof. Apply Definition 527.78. It fixes the closed-value side before any operation read: once V, d, and C_{val} are the displayed rows of the accepted packet, a consumer can cite the substitute-closed boundary only through that finite packet route and not through a host value semantics or hidden evaluator.

Apply Definition 527.79. It fixes the source side of the same root read: both Q and R are synchronized to T, d, C_{src}, so the shift boundary and the substitute-closed boundary cannot be split across two classifier sources or two closedness witnesses.

The remaining consumer surface is then forced by Definition 527.69 and Definition 527.80. Every root read of Q or R passes through the common ledger and audit rows and is then packaged by H, C, P, N. Therefore any accepted consumer-facing route, normal-form handoff, or exactness decision named by the chapter is a read of the same displayed packet. An alternate route, hidden

normal-form coordinate, duplicate classifier source, host substitution semantics, subject-reduction theorem, quotient syntax, hidden evaluator, or compiler state would require a row outside the displayed packet, which the cited boundary rows do not export. □

Theorem 527.83 (Closed-term substitution boundary root route lock)**.** *Every downstream self-compilation route that consumes an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet must pass through the displayed finite packet*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The route may cite the carrier, classifier, local NameCert *obligations, ledger non-escape row, consumer boundary, audit totality row, compiler non-escape row, and root* NameCert *handoff, but it exports no host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or additional operation coordinate.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootRouteLock`

Proof. Start with Definition 527.1 and Definition 527.2. They display the term rows, depth row, closedness witnesses, closed shift and substitute-closed rows, ledger, audit, transport, continuation, provenance, and local naming data as the only coordinates of the accepted packet.

Apply Definition 527.3, Definition 527.8, and Definition 527.12. These rows force every operation read through the same closedness witnesses and ledger boundary before any downstream consumer can see Q or R.

Finally use Definition 527.45, Definition 527.112, and Definition 527.113. The audit, compiler-facing, and naming handoff surfaces all factor through the displayed packet, so the root route has no coordinate outside $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$. □

Theorem 527.84 (Closed-term substitution boundary root operation export lock)**.** *For an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, the closed shift row Q and substitute-closed row R are exportable to a root consumer only as rows of*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The export is locked by the carrier, local NameCert *obligations, ledger non-escape, consumer boundary, root audit totality, root compiler non-escape, and root* NameCert *handoff; it does not expose a host substitution relation, subject reduction proof, evaluator, compiler state, or unregistered source/value convention.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootOperationExport`

Proof. Read Q and R from the carrier. The carrier places both operation rows beside $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$, so neither row is available apart from the displayed closedness and depth data.

The local NameCert obligations and ledger non-escape theorem then supply the export order. A consumer must see the source and value closedness witnesses, pass through L, and remain inside the audit-visible packet before the operation rows can be used.

Now apply the consumer boundary together with the root audit totality and root compiler non-escape rows. They make any root operation export a packet read through A, H, C, P, N and prevent replacement by host substitution semantics, subject reduction, evaluator state, compiler state, or an unregistered convention.

The root NameCert handoff repacks the same route for downstream self-compilation consumers. Hence the operation export is locked to the finite packet and nowhere else. □

Theorem 527.85 (Closed-term substitution boundary root self-compile handoff readiness)**.** *The root route lock of Definition 527.83 and the root operation export lock of Definition 527.84 make* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *ready for downstream self-compilation handoff exactly through*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The ready handoff is the finite BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *packet witnessed by the carrier, local obligations, ledger non-escape, consumer boundary, audit totality, compiler non-escape, and root naming rows, not a host-level substitution or compiler-correctness object.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootSelfCompileHand`

Proof. First collect the route side. By Definition 527.83, every downstream self-compilation route is already confined to the displayed carrier, classifier, ledger, audit, transport, continuation, provenance, and naming rows.

Next collect the operation side. By Definition 527.84, the closed shift and substitute-closed rows reach a root consumer only after the closedness, ledger, audit, compiler-facing, and NameCert handoff rows have been exposed.

Finally combine these two rows with Definition 527.113. The downstream consumer receives one finite handoff packet over $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$, and no host substitution semantics, subject reduction theorem, hidden evaluator, hidden compiler state, or compiler-correctness object is added. □

Lemma 527.86 (Closed-term substitution boundary root route bridge determinacy)**.** *For an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, every consumer-facing bridge use of the root route l is determined by the displayed finite packet*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

In particular, a route use, operation transport, closed-shift readback, substitute-closed readback, audit handoff, compiler-facing handoff, or root NameCert *handoff factors through the carrier, classifier, local* NameCert *obligations, ledger non-escape row, consumer boundary, root audit totality row, root compiler non-escape row, and root* NameCert *handoff cited by Definition 527.83, with Q and R exported only as in Definition 527.84. A bridge request for host substitution semantics, a subject-reduction theorem, a host syntax quotient, a hidden evaluator, hidden compiler state, or an operation coordinate outside the displayed packet is therefore unavailable to the consumer.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootRouteBridgeDete`

Proof. Start with the route inventory supplied by Definition 527.83. That theorem already lists the complete downstream self-compilation route: the accepted packet may expose the carrier, classifier, local naming obligations, ledger row, consumer boundary, audit row, compiler-facing row, and naming handoff, and all of them live on the single displayed tuple $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$. Thus a bridge use of root route l has only the displayed finite coordinates before any consumer can read it.

Now separate the possible consumer-facing uses. A pure route use reads the carrier and classifier rows. A transport use reads the componentwise hsame row H and the displayed Cont row C. A readback of closed shift or substitute-closed data must pass through Q or R together with the closedness witnesses and ledger boundary. An audit or handoff use reads L, A, H, C, P, N through the root audit, compiler non-escape, and root NameCert handoff rows. These are exactly the rows

named by the route lock, so two bridge presentations that agree on this finite packet have no remaining coordinate on which their consumer-visible route could differ.

It remains to rule out a detached operation bridge. Apply Definition 527.84. It says that the operation rows Q and R reach a root consumer only as rows of the same displayed packet and only after the carrier, local NameCert obligations, ledger non-escape, consumer boundary, root audit totality, root compiler non-escape, and root naming handoff have locked the export. Hence a consumer cannot replace the finite bridge route by host substitution semantics, subject reduction, a host syntax quotient, a hidden evaluator, hidden compiler state, an unregistered source/value convention, or any extra operation coordinate.

Combining the route lock with the operation export lock gives determinacy. Every listed consumer-facing use factors through the same local rows, while every unlisted bridge coordinate has no projection from the accepted $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ packet and therefore remains unavailable. □

Corollary 527.87 (Closed-term substitution boundary root route l determinacy)**.** *For an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet whose displayed local rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

are fixed, every accepted consumer-facing use of the root route l has the same public decision source. Its finite route is the displayed route above, and any operation transport, closed-shift readback, substitute-closed readback, audit handoff, compiler-facing handoff, root NameCert *handoff, normal-form handoff, or exactness decision named by the chapter is read only through the carrier, classifier, local* NameCert *obligations, ledger non-escape row, consumer boundary, root audit totality row, root compiler non-escape row, and root* NameCert *handoff. No accepted consumer may pick an alternate finite route, hidden normal-form coordinate, duplicate classifier source, host substitution semantics, subject-reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or additional operation coordinate.*

Proof. Start with Definition 527.83. It fixes the only downstream self-compilation route available to a consumer of the accepted packet: the route must pass through the displayed carrier, classifier, local naming obligations, ledger row, consumer boundary, audit row, compiler-facing row, and naming handoff, all on the single tuple

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The same theorem excludes host substitution semantics, subject reduction, a host syntax quotient, hidden evaluator state, hidden compiler state, and any additional operation coordinate from the exported root route.

Apply Definition 527.86. It lists the consumer-facing bridge uses of the root route l: route use, operation transport, closed-shift readback, substitute-closed readback, audit handoff, compiler-facing handoff, and root NameCert handoff. Each of those uses factors through the same carrier, classifier, local NameCert obligations, ledger non-escape row, consumer boundary, root audit totality row, root compiler non-escape row, and root NameCert handoff cited by the route lock. The lemma also states that a bridge request for host substitution semantics, subject reduction, a host syntax quotient, hidden evaluator state, hidden compiler state, or an operation coordinate outside the displayed packet is unavailable to the consumer.

The fixed-row determinacy follows from those two facts. Once the displayed rows are fixed, the route lock leaves no second packet from which a consumer could source a finite route, and the bridge

determinacy lemma leaves no unlisted coordinate through which a consumer-facing use could vary. Thus a finite route must be the displayed route; a transport must be the componentwise row over that packet; a closed-shift or substitute-closed readback must pass through Q or R inside the same ledger and audit surface; and any normal-form handoff or exactness decision named by the chapter must be a handoff or decision read through L, A, H, C, P, N and the local NameCert row. An alternate finite route, hidden normal-form coordinate, duplicate classifier source, or hidden host-side classifier would require a coordinate outside the accepted $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ packet, and the cited rows do not export such a coordinate. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootRouteLDetermina`

Definition 527.88 (Closed-term substitution boundary root operation surface)**.** *The root operation surface of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet is the finite displayed row list*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Here T is the source term row, V is the substituting closed value row, d is the inspected depth row, C_{src} and C_{val} are the displayed closedness witnesses, Q is the closed shift boundary row, R is the substitute-closed boundary row, L is the ledger row, A is the audit row, H is the componentwise hsame *transport row, C is the displayed* Cont *route row, P is the* Pkg *provenance row, and N is the local* NameCert *row.*

Lean4 (definition) `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootOperati`

Theorem 527.89 (Closed-term substitution boundary root operation totality)**.** *For every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, the closed shift row Q and the substitute-closed row R are both exhausted by the root operation surface of Definition 527.88. Neither operation can be read from a host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or any row outside*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootOperationTotali`

Proof. Project the accepted packet through Definition 527.1 and Definition 527.2. These two rows expose the source, value, depth, closedness witnesses, operation rows, ledger, audit row, transport, route, provenance, and local naming data as one finite packet.

Apply Definition 527.8 and Definition 527.45. The ledger blocks escape from the displayed packet, while the root audit row makes every audit-visible operation read pass through $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A,$

Finally use Definition 527.112. Since the compiler-facing read is admitted only after the same closed-boundary packet is visible, both Q and R are total over the displayed root operation surface and nowhere else. □

Theorem 527.90 (Closed-term substitution boundary root audit compiler coherence)**.** *The audit route of Definition 527.45 and the compiler-facing route of Definition 527.112 cite the same closed-boundary packet. Their common cited object is the surface of Definition 527.88, not two separate substitution semantics and not a host-level compiler correctness witness.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootAuditCompilerCo`

Proof. Start with the root audit route. By Definition 527.45, every audit-visible consumer is already routed through the displayed closedness, operation, ledger, audit, transport, continuation, provenance, and naming rows.

Now read the compiler route through Definition 527.112. That theorem permits a citation of $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ only after the same closed shift and substitute-closed boundary rows have been exposed by the boundary packet.

The two routes therefore meet at the packet of Definition 527.88. The audit side and compiler side share one closed-boundary citation, so no second host substitution semantics, hidden evaluator, or ambient compiler theorem is present. □

Theorem 527.91 (Closed-term substitution boundary root compiler route exhaustion)**.** *Every downstream compiler read that cites chapter 540 factors through the root operation surface of Definition 527.88 before the compiler-facing citation is available. The factorization exports exactly the accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet rows and no host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or additional operation coordinate.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootCompilerRouteEx`

Proof. First apply Definition 527.89. It exhausts closed shift and closed substitution over the single displayed packet, so a compiler consumer cannot obtain either operation from a separate host surface.

Next apply Definition 527.90. The audit route and compiler-facing route cite the same closed-boundary packet, which keeps the operation rows tied to $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$.

Finally use Definition 527.112. The downstream read may mention the sibling compiler chapter only after the packet has exposed the closed-boundary rows, so the compiler route is exhausted by the packet before the compiler citation is formed. □

Theorem 527.92 (Closed-term substitution boundary root downstream coverage)**.** *For every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, every consumer-facing use of the root operation surface is covered by the finite downstream alternatives*

$$\mathsf{operation}(Q, R), \qquad \mathsf{ledger}(L, A), \qquad \mathsf{transport}(H, C), \qquad \mathsf{provenance}(P, N),$$
$$\mathsf{compiler_citation}(\textit{chapter } 540) \text{ after } T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Equivalently, any accepted local consumer of closed shift, substitute-closed readback, audit replay, or compiler-facing citation factors through the displayed surface of Definition 527.88. Host substitution semantics, subject reduction, host syntax quotients, hidden evaluators, hidden compiler state, detached compiler correctness, and any operation coordinate outside

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

remain outside the $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootDownstreamCover`

Proof. First consider a direct operation consumer. By Definition 527.89, both root operation rows Q and R are exhausted by the finite surface of Definition 527.88. Thus a consumer cannot obtain closed shift or substitute-closed readback from a host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or unlisted row.

Next consider a ledger, audit, transport, provenance, or naming consumer. The totality theorem routes every audit-visible operation read through the same rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$, and Definition 527.45 makes the audit side total over that finite route. The rows L and A record the ledger and audit boundary, while H, C, P, N are only componentwise transport, displayed continuation, provenance, and local naming rows; none of them contains a coordinate for an external substitution source.

Finally consider a downstream compiler-facing consumer. By Definition 527.91, every read that cites chapter 540 first factors through the same root operation surface. By Definition 527.90, this compiler route and the audit route cite one closed-boundary packet rather than two separate semantics. The non-escaping compiler condition of Definition 527.112 then keeps the sibling compiler citation downstream of the displayed packet, so the excluded alternatives remain outside the BEDC packet. □

Theorem 527.93 (Closed-term substitution boundary root transport accountability)**.** *Every root consumer that makes closed substitution transport accountable for* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *must first expose the displayed rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Here $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$ are the term, value, depth, and closedness inputs; Q and R are the closed shift and substitute-closed operation rows; L and A are the ledger and audit rows; and H, C, P, N are the transport, continuation, provenance, and local naming rows. No accountable closed substitution transport is available from a host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or operation row outside this packet.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootTransportAccoun`

Proof. Read the root consumer through Definition 527.45. That row makes every audit-visible root read total over the displayed packet and prevents the consumer from starting at a detached host operation.

Apply Definition 527.8 and Definition 527.38. The ledger fixes the closed shift and substitute-closed boundary rows inside the packet, while the NameCert export keeps the same carrier, classifier, transport, continuation, provenance, and naming rows visible to downstream consumers.

Finally use Definition 527.112. A compiler-facing citation is admitted only after the same rows have been exposed, so accountable transport is exactly transport over $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ and not over a host substitution semantics. □

Theorem 527.94 (Closed-term substitution boundary root consumer coverage)**.** *Every self-compilation, proof-erasure, or compiler-facing consumer of* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *is covered by the displayed closed-boundary packet*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Such a consumer may read the closed shift, substitute-closed, ledger, audit, transport, continuation, provenance, and naming rows only through that packet, and it receives no host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or extra compiler object.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootConsumerCoverag`

Proof. Start with self-compilation and proof-erasure consumers. By Definition 527.45, any root audit consumer factors through the closed-boundary packet before it can inspect the operation rows.

For compiler-facing consumers, apply Definition 527.112. It allows the sibling compiler chapter to be cited only after the accepted packet has exposed the same term, closedness, operation, ledger, audit, transport, continuation, provenance, and naming rows.

The non-escape and export rows close the remaining alternatives. Use Definition 527.8 to rule out hidden operation sources, and use Definition 527.38 to keep the consumer attached to the displayed NameCert carrier. Thus each listed consumer is covered by the closed-boundary packet and by no host substitution semantics. □

Theorem 527.95 (Closed-term substitution boundary root-unblock certificate)**.** *The root transport accountability row of Definition 527.93, the root consumer coverage row of Definition 527.94, the root audit totality row of Definition 527.45, and the root compiler non-escape row of Definition 527.112 assemble a downstream root-unblock certificate for* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$*. The certificate is a finite handoff over*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

and exports no host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or additional compiler-facing route.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootUnblockCertific`

Proof. First build the accountable transport surface. Apply Definition 527.93 to force every accountable closed substitution transport through the displayed term, closedness, operation, ledger, audit, transport, continuation, provenance, and naming rows.

Next cover the downstream consumers. By Definition 527.94, self-compilation, proof-erasure, and compiler-facing reads all use the same closed-boundary packet and no host substitution semantics.

Finally combine the root audit and compiler rows. The audit side is total by Definition 527.45, while the compiler side is non-escaping by Definition 527.112. Together with Definition 527.8 and Definition 527.38, these rows provide the downstream root-unblock certificate over the single displayed packet. □

Theorem 527.96 (Closed-term substitution boundary root transport downstream coverage)**.** *Every accepted local downstream consumer of* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *whose root use is self-compilation, proof-erasure, or compiler-facing accountable transport is exhausted by the displayed packet*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The accepted alternatives are only the closed shift row Q, substitute-closed row R, ledger row L, audit row A, transport row H, continuation row C, provenance row P, and local naming row N, together with the term, value, depth, and closedness inputs $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}$. Host substitution semantics, a subject reduction theorem, a host syntax quotient, a hidden evaluator, hidden compiler state, an extra compiler object, and any operation row outside this packet remain unavailable to the downstream consumer.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootTransportDownst`

Proof. Apply Definition 527.94 to the accepted downstream consumer. It covers the consumer-facing cases named in the statement: self-compilation, proof-erasure, and compiler-facing reads. In each case the consumer may read closed shift, substitute-closed, ledger, audit, transport, continuation, provenance, and naming data only through the displayed closed-boundary packet.

Now apply Definition 527.93 to the same root use when it makes closed substitution transport accountable. Accountability forces the root consumer to expose exactly the rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C,$ before transport is available. Thus the transport coordinate does not create a second route; it is one of the displayed rows already covered by the consumer-coverage packet.

The exclusions are common to the two rows. Consumer coverage blocks host substitution semantics, subject reduction, a host syntax quotient, hidden evaluator state, hidden compiler state, and extra compiler objects from entering the accepted consumer read. Transport accountability blocks accountable transport from any host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or operation row outside this packet. Therefore every accepted local downstream use factors through the enumerated finite rows, and every unlisted alternative remains outside the $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ packet. □

Theorem 527.97 (Closed-term substitution boundary closed-source budget surface)**.** *Every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet exposes the finite rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The source closedness row C_{src} *and the value closedness row* C_{val} *are read before any closed shift budget* Q *or closed substitution budget* R *is consumed. Thus the operation budget is a closed-source and closed-value surface over the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, not a host substitution semantics or hidden evaluator route.*

Proof. Project the accepted carrier from Definition 527.1 and the classifier from Definition 527.2. The displayed packet already separates the term row T, value row V, depth row d, source closedness row C_{src}, value closedness row C_{val}, shift row Q, substitution row R, ledger row L, audit row A, transport row H, route row C, provenance row P, and local naming row N.

Apply Definition 527.3. Its carrier exposure and classifier obligations force every public read to begin from the same finite packet, so no consumer can acquire Q or R from an unlisted operation source.

Finally use Definition 527.36. The ledger lock places C_{src} and C_{val} before the shift and substitution rows in the public operation budget, and Definition 527.8 rules out a hidden source for closedness or operation state. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryClosedSourceBudgetS`

Theorem 527.98 (Closed-term substitution boundary substitution budget totality)**.** *Every substitution consumer of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet factors through source closedness, value closedness, the closed shift row, the closed substitution row, the finite ledger, the audit row, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *row. Equivalently, the consumer route is exhausted by*

$$C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

inside the carrier over T, V, d*, and it receives no subject reduction theorem, host syntax quotient, hidden compiler state, or host substitution semantics.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySubstitutionBudgetT`

Proof. Start with the closed-source budget surface of Definition 527.97. It provides the entry condition: C_{src} and C_{val} are exposed before the operation rows Q and R can be spent.

Next apply Definition 527.12. It forces downstream consumers to read the closed shift and substitution boundary through the displayed carrier, transports, routes, provenance, and local naming row.

The audit and ledger rows close the remaining path. By Definition 527.8 and Definition 527.36, the finite ledger and audit row exhaust the operation budget; by Definition 527.38, the exported surface is exactly $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$. □

Theorem 527.99 (Closed-term substitution boundary consumer audit triad)**.** *For* ClosedTermSubstitutionBoundary *the closed-source budget surface of Definition 527.97, the substitution budget totality row of Definition 527.98, and the non-escape audit rows of the chapter assemble the consumer-facing triad. The triad says that every substitution-facing consumer first reads closedness, then spends only the displayed operation boundary, and finally remains audit-visible through L, A, H, C, P, N.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryConsumerAuditTriad`

Proof. First take closedness as the entry surface. The closed-source budget theorem exposes C_{src} and C_{val} before any operation row is consumed.

Second take operation totality as the consumer boundary. The substitution budget theorem factors every consumer through Q, R, L, A, H, C, P, N over the same T, V, d carrier rows.

Third attach the audit witness. Apply Definition 527.37, Definition 527.44, and Definition 527.45. These rows keep the consumer inside the displayed BHist, hsame, Cont, Pkg, and NameCert packet and prevent escape to host substitution semantics, hidden compiler state, or an untracked audit route. □

Theorem 527.100 (Closed-term substitution boundary closed-source downstream coverage)**.** *Every accepted local consumer of the closed-source downstream surface of a* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet is exhausted by the displayed alternatives*

$$C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

over the carrier rows T, V, d. The only admissible operation alternatives are the closed shift row Q, the closed substitution row R, the ledger rows L, A, the componentwise hsame *transport row H, the displayed* Cont *route row C, the* Pkg *provenance row P, and the local* NameCert *row N. Host substitution semantics, ambient subject reduction, host syntax quotients, hidden evaluator state, hidden compiler state, external substitution relations, unregistered free-variable coordinates, and additional operation rows remain outside the BEDC packet.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryClosedSourceDownstr`

Proof. Start with the closed-source budget surface of Definition 527.97. It exposes the finite packet rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ and places C_{src} and C_{val} before any use of the closed shift budget Q or closed substitution budget R. Thus a local consumer cannot enter the downstream operation boundary through a source other than the displayed closedness rows.

Apply substitution budget totality from Definition 527.98. It says that every substitution consumer factors through source closedness, value closedness, the closed shift row, the closed substitution row, the finite ledger, the audit row, componentwise transports, displayed continuation routes, package provenance, and the local naming row. Therefore the downstream consumer has exactly the listed alternatives $C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ over T, V, d.

Finally use the consumer-facing triad of Definition 527.99. The triad identifies the same closedness entry, operation budget, and audit-visible route as one finite BEDC packet. Since the closed-source surface and the substitution budget totality contain no coordinate for host substitution semantics, ambient subject reduction, host syntax quotients, hidden evaluator state, hidden compiler state, external substitution relations, unregistered free-variable coordinates, or an extra operation row, those excluded alternatives remain outside the packet for every accepted local consumer. □

Theorem 527.101 (Closed-term substitution boundary finite readiness surface)**.** *The scoped finite packet for* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *is the paper-side readiness surface for downstream local consumption. Its readable object is exactly the displayed packet*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N,$$

where the carrier, classifier, local NameCert *obligations, ledger non-escape row, consumer boundary, audit-boundary factorization, and root* NameCert *handoff already identify the same finite BEDC surface.*

Proof. Start with Definition 527.1 and Definition 527.2. They display the term, value, depth, closedness, operation, ledger, audit, transport, continuation, provenance, and naming rows as one finite packet.

Next apply Definition 527.3, Definition 527.8, and Definition 527.12. These rows force the local naming obligations, closed operation reads, and downstream consumers to stay inside that packet.

Finally use Definition 527.44 and Definition 527.113. The audit route and root naming handoff repack the same rows for the local paper-side consumer, so the readiness surface is the scoped finite packet and not an additional host object. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryFiniteReadinessSurf`

Theorem 527.102 (Closed-term substitution boundary formal surface exhaustion)**.** *Every formal consumer of the scoped* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet may read only*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The consumer receives no host substitution semantics, subject reduction theorem, host syntax quotient, hidden evaluator, unchecked compiler state, or unregistered operation row outside the displayed carrier, ledger, audit, transport, route, provenance, and local NameCert *surface.*

Proof. Read the formal consumer through the carrier and classifier of Definition 527.1 and Definition 527.2. Those definitions expose exactly the displayed rows and no host-level substitution relation.

Apply Definition 527.8, Definition 527.12, and Definition 527.44. The ledger blocks operation escape, the consumer boundary blocks detached downstream reads, and the audit factorization keeps each admissible read inside L, A, H, C, P, N.

The excluded alternatives are therefore outside the formal surface. A subject reduction theorem, host syntax quotient, hidden evaluator, unchecked compiler state, or unregistered operation row would add a coordinate not present in $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryFormalSurfaceExhaus`

Theorem 527.103 (Closed-term substitution boundary downstream root handoff)**.** *The downstream roots* BinderBudgetSeal$^{\uparrow}$, ClosedTermSubstitutionCompiler$^{\uparrow}$, RecursorGenerator$^{\uparrow}$, AuthorizedGeneratorRecursor *and* MetaCICNormalizationFrontier$^{\uparrow}$ *consume the accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet only through the displayed carrier, ledger, audit, transport, route, provenance, and local* NameCert *rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Their common handoff is the root NameCert *packet produced by the carrier, classifier, local obligations, ledger non-escape, consumer boundary, audit-boundary factorization, root route locks, and root transport accountability rows; it exports no separate substitution semantics or compiler state.*

Proof. First collect the base packet. By Definition 527.1 and Definition 527.2, the finite rows are displayed as one carrier surface, and Definition 527.3 keeps the same local naming surface attached to them.

Next collect the binder and compiler restrictions. Use Definition 527.13 and Definition 527.15 to route BinderBudgetSeal$^{\uparrow}$ and ClosedTermSubstitutionCompiler$^{\uparrow}$ through the closed-boundary packet.

The recursor and normalization roots use the same packet. Apply Definition 527.16, Definition 527.17, and Definition 527.20 to keep RecursorGenerator$^{\uparrow}$, AuthorizedGeneratorRecursor$^{\uparrow}$, and MetaCICNormalizationFrontier$^{\uparrow}$ on the displayed route.

Finally apply Definition 527.83, Definition 527.93, and Definition 527.113. These root rows package the shared carrier, ledger, audit, transport, route, provenance, and local naming data as the only handoff surface for the downstream roots. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryDownstreamRootHando`

Theorem 527.104 (Closed-term substitution boundary route determinacy)**.** *Let* $S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A,$ *be an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet. If two downstream closed-boundary reads agree on the displayed carrier rows and on the continuation row* C*, then they reach the same closed shift row* Q *and the same substitute-closed row* R*. The determined route is the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *packet, not a separate host substitution semantics.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRouteDeterminacy`

Proof. Start with Definition 527.1 and Definition 527.2. They make $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ the only accepted packet rows, so agreement on the carrier rows already fixes the visible source, value, depth, closedness, ledger, audit, transport, provenance, and local naming data.

Next use Definition 527.69. Once the closed-boundary read has the same displayed rows and the same continuation row C, the operation readback cannot choose a different source/value convention or an unregistered operation coordinate.

Finally apply Definition 527.83. The downstream route must pass through the displayed packet before any self-compilation consumer can read it. Hence two such reads with the same carrier rows and continuation row reach the same Q and R, and no host substitution semantics is available to split the route. □

Theorem 527.105 (Closed-term substitution boundary context stack non-escape)**.** *Every recognizer, tuple, and formal-readiness route for an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet recovers only*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The route cannot add an open-term coordinate, host syntax quotient, hidden evaluator, compiler correctness theorem, or subject-reduction theorem to the context stack.

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryContextStackNonesca

Proof. Read the recognizer side through Definition 527.64. The recognizer route reaches the boundary only after acceptance, generated recognition, tuple-image landing, and readback of the displayed packet rows.

The tuple and substitution readback restrictions are then supplied by Definition 527.65 and Definition 527.66. They keep the closed-substitution read inside the finite tuple image and exclude open-term coordinates, free-variable leaks, host syntax quotients, unchecked evaluator state, compiler correctness, and ambient subject reduction.

Finally use Definition 527.101 and Definition 527.102. The finite readiness surface is exactly the same finite packet for the cited closed-term substitution boundary object, so the context stack has no coordinate outside $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$. □

Theorem 527.106 (Closed-term substitution boundary substitution-order exhaustion)**.** *Every substitution-row consumer for an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet must read the source closedness row* C_{src}*, value closedness row* C_{val}*, ledger row* L*, and audit row* A *before consuming* R*. After those rows are visible, the route is exhausted by the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *packet*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySubstitutionOrderEx

Proof. First apply Definition 527.57. It places every root substitution read behind the source and value closedness witnesses, so R cannot be consumed before C_{src} and C_{val}.

Next use Definition 527.58 and Definition 527.89. These rows force the substitute-closed request through Q, R, L, A, H, C, P, N and make both operation rows total only over the displayed root operation surface.

Finally combine the ledger side with Definition 527.8. The ledger and audit rows block escape to host substitution semantics, hidden evaluator state, compiler state, or subject reduction. Therefore the remaining substitution-order route is exhausted by the displayed BHist, hsame, Cont, Pkg, and NameCert packet. □

Corollary 527.107 (Closed-term substitution boundary route-determinacy strict obstruction)**.** *Let* $S = (T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N)$ *be an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet. Any displayed failure, refusal, separation, or countermodel row used against a closed-term substitution boundary converse or reuse route is a strict local obstruction only to the named route that tries to read* Q *or* R *without the displayed packet rows and the continuation row* C*. It cannot be read as a global impossibility theorem, as a host substitution theorem, or as hidden external validation for a syntax quotient, evaluator, compiler-correctness theorem, or subject-reduction theorem.*

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRouteDeterminacyStr

Proof. The available packet surface is fixed by Definition 527.1 and Definition 527.2. A consumer-facing closed-boundary read has only the displayed rows

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Thus the route, transport, and readback inventory is the finite BHist packet together with componentwise hsame transport, the displayed Cont row C, the Pkg provenance row P, and the local NameCert row N.

Apply Definition 527.105. It says that every recognizer, tuple, and formal-readiness route recovers only the listed packet rows and cannot add an open-term coordinate, host syntax quotient, hidden evaluator, compiler correctness theorem, or subject-reduction theorem to the context stack. Hence any consumer-facing use of a displayed failure, refusal, separation, or countermodel row must factor through the same finite inventory. If the proposed converse or reuse route asks for an unlisted coordinate, the route is rejected before it can reach Q or R.

Now use Definition 527.104. When two downstream reads do agree on the displayed carrier rows and on C, the closed shift row Q and substitute-closed row R are already determined by the displayed BHist, hsame, Cont, Pkg, and NameCert packet. Therefore a displayed obstruction can block only the named attempt to bypass, reverse, or reuse that local route. It has no remaining target from which to assert an absolute impossibility, a host-level substitution semantics, or an external validation theorem outside the accepted $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ packet. □

Theorem 527.108 (Closed-term substitution boundary root route exhaustion)**.** *Every root route read of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet is exhausted by the finite carrier rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The route may read closedness through C_{src} *and* C_{val}*, shift through* Q*, substitution through* R*, ledger accounting through* L*, audit non-escape through* A*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. It has no root coordinate for host substitution semantics, subject reduction, host syntax quotienting, hidden evaluator state, hidden compiler state, or an unlisted operation row.*

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootRouteExhaustion

Proof. Start with the carrier and the NameCert obligations. Definition 527.1 displays exactly the rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$, and Definition 527.3 makes the closedness, operation, ledger, audit, transport, continuation, package, and naming rows the local certificate surface.

Next apply the ledger and root route rows. Definition 527.8 blocks free-variable, host-equality, compiler-state, and subject-reduction escape, while Definition 527.113 packages the root handoff as the same finite BHist, hsame, Cont, Pkg, and NameCert route.

Finally use the root route determinacy package. Since any downstream route is already locked to the displayed operation and handoff rows, the root read is exhausted by the stated carrier coordinates and cannot be replaced by an unlisted host or compiler surface. □

Theorem 527.109 (Closed-term substitution boundary root non-escape)**.** *No root consumer of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet can escape from the displayed route*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

to obtain a free-variable coordinate, host substitution semantics, subject reduction, host syntax quotienting, hidden evaluator state, hidden compiler state, or a compiler-correctness theorem. The closed shift and substitution reads remain guarded by the displayed closedness, ledger, audit, hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. First read the root consumer through Definition 527.108. That theorem fixes every accepted root route to the displayed carrier rows before any operation boundary is consumed.

Apply Definition 527.8. The ledger and audit row have no projection for free variables, host equality, unchecked compiler state, or ambient subject reduction, so those objects cannot be exported by a root read.

Now use Definition 527.113. The handoff gives downstream consumers one finite packet over BHist, hsame, Cont, Pkg, and NameCert, not a second host substitution or compiler-correctness surface. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootNonescape`

Theorem 527.110 (Closed-term substitution boundary root downstream readiness)**.** *The root route exhaustion and root non-escape rows make* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *ready for downstream self-compilation consumers exactly as a finite closed-boundary packet. A downstream chapter may consume the displayed* $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ *route, together with the NameCert obligation surface, ledger non-escape row, and root NameCert handoff, but it may not treat the packet as a host compiler theorem, a subject-reduction package, or an untracked substitution semantics.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootDownstreamReadi`

Proof. Begin with Definition 527.108. It supplies the finite operation route that downstream consumers may read.

Next apply Definition 527.109. The same route blocks host substitution semantics, subject reduction, host syntax quotienting, hidden evaluator state, hidden compiler state, and compiler-correctness import.

Finally compose Definition 527.3, Definition 527.8, and Definition 527.113. These rows repack the closedness, shift, substitution, ledger, audit, transport, continuation, provenance, and naming data as the precise downstream readiness surface. □

Corollary 527.111 (Closed-term substitution boundary root route strict local obstruction)**.** *Let* O *be a displayed failure, refusal, separation, or countermodel row cited against a named consumer-facing converse or reuse route in the root route exhaustion package for an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet. Then* O *is a strict local obstruction. It blocks only the named route whose consumer-facing read factors through the finite packet rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

and then tries to omit, replace, detach, or bypass one of those displayed coordinates. The same row cannot be reinterpreted as a global impossibility statement, a host theorem, hidden external validation, host substitution semantics, subject reduction, host syntax quotienting, hidden evaluator state, hidden compiler state, compiler-correctness evidence, or an obstruction to any consumer route that still remains inside the listed rows.

Proof. Start with Definition 527.108. Every root route read of the accepted packet is already exhausted by the listed rows. The theorem also identifies the only permitted readings of those rows: closedness is read through C_{src} and C_{val}, shift through Q, substitution through R, ledger accounting through L, audit non-escape through A, componentwise hsame transport through H, displayed Cont replay through C, Pkg provenance through P, and local naming through N. Thus a consumer-facing converse or reuse route has no root entry point except the displayed finite route.

Apply Definition 527.109. It excludes escape from the same route to a free-variable coordinate, host substitution semantics, subject reduction, host syntax quotienting, hidden evaluator state, hidden compiler state, or a compiler-correctness theorem. The closed shift and substitution reads therefore remain guarded by the displayed closedness, ledger, audit, transport, continuation, provenance, and local naming rows.

Now consider the cited row O. If the named converse or reuse route asks for one of the displayed coordinates and O records the failure, refusal, separation, or countermodel at that coordinate, then O blocks precisely that named local route. If the attempted reading asks instead for a global impossibility statement, a host theorem, hidden external validation, host substitution semantics, subject reduction, a host syntax quotient, hidden evaluator state, hidden compiler state, compiler-correctness evidence, or any unlisted operation row, the route exhaustion theorem supplies no coordinate for the request and the non-escape theorem explicitly excludes it. Hence O has force only as the strict local obstruction to the named converse or reuse route, while every consumer read that continues to factor through the displayed packet rows remains a read of the accepted $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ boundary. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootRouteStrictLoca`

Theorem 527.112 (Closed-term substitution boundary root compiler non-escape)**.** *Any compiler-facing root read may cite* $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ *only after the accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet has exposed the displayed boundary rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The citation exports no subject reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, or host substitution semantics beyond the displayed closed shift and closed substitution boundary rows.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootCompilerNonesca`

Proof. Read the compiler-facing consumer through Definition 527.12. It allows a downstream consumer to see closed shift and substitute-closed rows only through the accepted finite packet.

Apply Definition 527.8 and Definition 527.36. Together they force the operation boundary through C_{src}, C_{val}, Q, R, L, and A before any compiler-facing citation can be formed.

The remaining coordinates are closed by Definition 527.44. The compiler citation is therefore a read of the boundary packet, not an exported subject-reduction proof, host syntax quotient, hidden evaluator, hidden compiler state, or host substitution semantics. □

Theorem 527.113 (Closed-term substitution boundary root NameCert handoff)**.** *The root audit totality row of Definition 527.45, the root compiler non-escape row of Definition 527.112, and the scoped closure surface of* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *form the root-unblock handoff for downstream self-compilation consumers. The handoff is the displayed finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route, not a host substitution semantics or hidden compiler object.*

Proof. First package the audit side. By Definition 527.45, every root audit consumer factors through $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$.

Next package the compiler side. By Definition 527.112, a compiler-facing root read can cite the compiler only after the same closed shift and substitution boundary rows are visible.

Finally combine these rows with the scoped closure packet recorded below. The downstream self-compilation consumer receives one finite handoff over the displayed carrier, classifier, ledger,

audit, transport, route, provenance, and local naming rows; no subject reduction theorem, host syntax quotient, hidden evaluator, or hidden compiler state is exported. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootNamecertHandoff

Theorem 527.114 (Closed-term substitution boundary root audit replay totality)**.** *For every accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet, each root audit replay read through* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *is total on the displayed finite rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The replay may inspect carrier rows, classifier rows, ledger non-escape rows, root audit totality rows, and root compiler non-escape rows, but it exports no host substitution semantics, subject-reduction theorem, host syntax quotient, hidden evaluator state, or hidden compiler state.

Proof. Start with the carrier and classifier of Definition 527.1 and Definition 527.2. They give the replay a finite packet over term rows, closed-value rows, depth, closedness witnesses, operation rows, ledger rows, audit rows, transports, continuations, package provenance, and naming.

Next apply Definition 527.8. The ledger row prevents an audit replay from leaving the displayed packet for unregistered free variables, host equality, unchecked compiler state, or ambient subject reduction.

Use Definition 527.45 to make the root replay total. Every root audit consumer is already routed through the same $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$ coordinates.

Finally apply Definition 527.112. Compiler-facing citations are allowed only after the same boundary rows are visible, so the replay remains a BHist, hsame, Cont, Pkg, and NameCert read of the accepted packet. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootAuditReplayTota

Theorem 527.115 (Closed-term substitution boundary root substitution route exactness)**.** *In an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet, a root read of closed substitution is exact precisely when it factors through the carrier, classifier, closedness ledger, substitution row R, audit row A, componentwise* hsame *transport rows H, displayed* Cont *routes C, package row P, and local* NameCert *row N. The exact route is*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

No root substitution route may be replaced by host substitution semantics, an ambient compiler theorem, a subject-reduction package, a host syntax quotient, or an untracked evaluator state.

Proof. Read the operation surface through Definition 527.36. It locks the closed shift and substitute-closed rows to C_{src}, C_{val}, Q, R, L, and A before any root consumer can export them.

Next use Definition 527.12. A downstream consumer sees the substitution boundary only as an accepted packet read through the carrier and classifier, not as an external substitution relation.

Apply Definition 527.113. The handoff packages the audit and compiler sides as one finite BHist, hsame, Cont, Pkg, and NameCert route.

The route is exact by Definition 527.114: every admissible replay has the displayed rows, and ledger non-escape blocks every unlisted host or compiler coordinate. □

Lean4 ✓ BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootSubstitutionRou

Theorem 527.116 (Closed-term substitution boundary root ledger readiness)**.** *The root ledger of an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet is ready for downstream self-compilation consumers exactly when the carrier, classifier, ledger non-escape, root audit replay totality, root substitution route exactness, root audit totality, and root compiler non-escape rows are all read through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *packet*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

This readiness row exports a finite closed-term substitution route only; it does not export host substitution semantics, full compiler correctness, subject reduction, a host syntax quotient, hidden evaluator state, or hidden compiler state.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootLedgerReadiness`

Proof. First assemble the base packet from the carrier, classifier, and local NameCert obligations. These rows determine the displayed closed-source, closed-value, operation, ledger, audit, transport, continuation, package, and naming coordinates.

Next add non-escape through Definition 527.8. The ledger cannot gain a hidden free-variable row, host equality row, compiler-state row, or subject-reduction row.

Use Definition 527.114 and Definition 527.115. The first makes the root audit replay total on the packet, and the second fixes closed substitution to the same finite route.

Finally combine the original root audit and compiler rows, Definition 527.45 and Definition 527.112. Downstream self-compilation consumers therefore receive one ready ledger packet over BHist, hsame, Cont, Pkg, and NameCert, with no ambient compiler semantics attached. □

Corollary 527.117 (Closed-term substitution boundary root compiler strict local obstruction)**.** *For an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet, the obstruction supplied by the root compiler non-escape row is strict and local. It blocks only a compiler-facing root read that either cites* ClosedTermSubstitutionCompiler$^{\uparrow}$ *before the displayed boundary rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

are exposed, or reuses that citation as a subject-reduction theorem, host syntax quotient, hidden evaluator, hidden compiler state, host substitution semantics, or hidden external validation. After the read factors through the root NameCert *handoff, every consumer-facing use is only the finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route of the packet. Thus the obstruction cannot be reinterpreted as a global impossibility claim, a host theorem, or a validation source outside the displayed closed-term substitution boundary.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRootCompilerStrictL`

Proof. Start with Definition 527.112. It gives the exact admission condition for a compiler-facing root read: the citation of ClosedTermSubstitutionCompiler$^{\uparrow}$ is allowed only after the accepted ClosedTermSubstitutionBoundary$^{\uparrow}$ packet has exposed the displayed rows $T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$. The same theorem also lists the forbidden exports: subject reduction, a host syntax quotient, hidden evaluator state, hidden compiler state, and host substitution semantics. Therefore the obstruction applies to this citation boundary and to those reuse routes, not to an ambient host theory.

Now apply Definition 527.113. The handoff identifies the downstream self-compilation surface with the finite BHist, hsame, Cont, Pkg, and NameCert route obtained from the root audit totality

row and the root compiler non-escape row. Hence a consumer-facing use of the compiler citation factors through the named packet rows, and an unlisted coordinate has no handoff projection.

Finally use the replay and readiness rows in this body file. By Definition 527.114, replay is total on exactly the displayed finite route and exports no host substitution semantics, subject-reduction theorem, host syntax quotient, hidden evaluator state, or hidden compiler state. By Definition 527.115 and Definition 527.116, the downstream root ledger remains the same closed-term substitution packet rather than an external compiler or validation object. Thus the non-escape row is a local obstruction to the named bad reuse of this packet, and it carries no claim of global impossibility or hidden host validation. □

Theorem 527.118 (Closed-term substitution boundary primitive ledger scope)**.** *Every accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *read that exposes closed shift or closed substitution binds its primitive ledger scope to the displayed* Term *rows,* ClosedAt *rows,* shift *row,* substitute *row,* BHist *packet, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row. No accepted read obtains a closed substitution boundary from host syntax, host equality, unchecked compiler state, subject reduction, quotient representation, hidden evaluator state, or an operation row outside that primitive ledger.*

Proof. Start with the carrier and classifier. They display the source term, closed value, inspected depth, closedness rows, closed shift, closed substitution, ledger, audit row, transport rows, continuation routes, package provenance, and local naming row as one finite packet.

Apply the NameCert obligations and ledger non-escape theorem. The closedness rows must be read before the operation rows, and the ledger has no projection for host substitution semantics, hidden equality, unchecked compiler state, or subject reduction.

Finally use the root route exhaustion package. Every root read is already routed through the same BHist, hsame, Cont, Pkg, and NameCert surface, so the primitive ledger scope is exactly the listed boundary tuple. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryPrimitiveLedgerScop`

Theorem 527.119 (Closed-term substitution boundary downstream factorization triad)**.** *Every downstream consumer in* BinderBudgetSeal$^{\uparrow}$, ClosedTermSubstitutionCompiler$^{\uparrow}$, *and* RecursorGenerator$^{\uparrow}$ *that reads closed-term substitution factors through the same finite* ClosedTermSubstitutionBoundary$^{\uparrow}$ *tuple*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

before it may cite a substitution row. The binder-budget, compiler-schedule, and recursor-output routes may repack that tuple for their own local certificates, but none of them receives an independent substitution semantics, hidden binder convention, compiler theorem, evaluator state, or subject-reduction package.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryDownstreamFactoriza`

Proof. First use the BinderBudgetSeal factorization theorem. It forces every binder-budget shift or substitution read through the displayed closedness witnesses, operation rows, ledger, audit row, transport, route, provenance, and local naming row.

Next use the ClosedTermSubstitutionCompiler factorization theorem. The compiler schedule sees a closed substitution row only after the same boundary packet has exposed the source and value closedness rows together with Q, R, L, A, H, C, P, N.

Finally use the RecursorGenerator handoff theorem. The generated branch output may consume closed substitution only through the displayed continuation route, so the three downstream consumers share the same finite boundary tuple before any substitution read is visible. □

Theorem 527.120 (Closed-term substitution boundary NameCert threshold package)**.** *The primitive ledger scope of Definition 527.118, downstream factorization triad of Definition 527.119, consumer boundary of Definition 527.12, and ledger non-escape theorem of Definition 527.8 assemble the* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *root threshold package. The package exports the finite* Term*,* ClosedAt*,* shift*,* substitute*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route required by downstream self-compilation consumers, and it exports no hidden host substitution, compiler theorem, quotient representative, evaluator state, free-variable coordinate, or subject-reduction row.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryNameCertThresholdPa`

Proof. Begin with primitive ledger scope. It identifies the accepted closed-boundary read with the BEDC primitive rows that can be projected from the finite packet.

Add the consumer boundary and ledger non-escape rows. They require every downstream closed substitution read to remain inside the displayed packet and rule out escape to host syntax, compiler state, subject reduction, or unregistered free variables.

Finally compose the downstream factorization triad. Since the binder-budget, compiler-schedule, and recursor-output consumers all pass through the same boundary tuple, the four rows form the root threshold package counted by downstream self-compilation consumers. □

Theorem 527.121 (Closed-term substitution boundary route saturation)**.** *Every accepted route of a* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet is exhausted by*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

and the BEDC primitives BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. A route may read the term row, value row, inspected depth, source and value closedness rows, closed shift row, substitute-closed row, finite ledger, audit row, componentwise transport, displayed continuation, package provenance, and local naming row, but it has no additional coordinate for a host substitution relation, host equality witness, unchecked compiler state, subject-reduction theorem, or unregistered free variable.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRouteSaturation`

Proof. Start from the carrier and classifier of Definition 527.1 and Definition 527.2. They make the displayed rows the complete carrier surface and allow only componentwise hsame transport and recorded Cont reads across that surface.

Next apply the local NameCert obligations of Definition 527.3. Source closedness, value closedness, substitution-row exactness, ledger accounting, audit visibility, package provenance, and local naming are all attached to the same finite packet.

Finally use source/value admission, substitution-row exactness, and ledger non-escape from Definition 527.4, Definition 527.5, Definition 527.7, and Definition 527.8. These rows leave no route outside the listed BEDC primitives, so the accepted route is saturated by the displayed packet. □

Theorem 527.122 (Closed-term substitution boundary NameCert source lock)**.** *In every accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet, the source closedness row* C_{src} *and the value closedness row* C_{val} *remain locked before any closed shift or substitute-closed read. Thus a consumer must read the source/value closedness rows, the local* NameCert *obligations, and the finite ledger before reading* Q *or* R *through a shift/substitution route.*

Proof. Read the accepted packet through Definition 527.1. The rows C_{src} and C_{val} are explicit carrier coordinates, not hidden side conditions.

Use the classifier and local NameCert obligations from Definition 527.2 and Definition 527.3. They make closed-source admission and closed-value admission prerequisites for the operation rows.

Apply Definition 527.4, Definition 527.5, Definition 527.7, and Definition 527.36. The shift/substitution read is therefore locked behind the source/value rows and the finite ledger before Q or R can be consumed. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryNamecertSourceLock`

Theorem 527.123 (Closed-term substitution boundary consumer non-escape)**.** *No consumer of an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet can recover an unregistered free variable, host equality, unchecked compiler state, subject reduction, or host substitution semantics. Every consumer-facing read is confined to the carrier, classifier, source/value admission rows, substitution-row exactness, finite ledger, audit non-escape row, and local* NameCert *route over*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryConsumerNonescape`

Proof. First inspect the carrier, classifier, and NameCert obligations. The only available rows are the term, value, depth, closedness, operation, ledger, audit, transport, continuation, package, and local naming rows displayed in the accepted packet.

Next use source/value admission and substitution-row exactness. By Definition 527.4, Definition 527.5, and Definition 527.7, the operation rows are readable only through the displayed closedness and ledger surface.

Finally apply Definition 527.8, together with the consumer boundary supplied by Definition 527.12. The ledger and consumer rows contain no coordinate for free variables, host equality, unchecked compiler state, subject reduction, or host substitution semantics, so no consumer can recover those objects from the packet. □

Corollary 527.124 (Closed-term substitution boundary strict local obstruction)**.** *Let O be a displayed failure, refusal, separation, or countermodel row cited against a named converse or reuse route for an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet. If the named route is consumer-facing, then O is a strict local obstruction: it blocks only the attempted read that factors through*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

and then tries to omit, replace, detach, or bypass one of the displayed packet coordinates or one of the BEDC primitives BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The same row cannot be reinterpreted as a global impossibility statement, host theorem, hidden external validation, host substitution semantics, host equality witness, unchecked compiler state, subject-reduction theorem, or unregistered free-variable route.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryRouteSaturationStri`

Proof. By Definition 527.121, every accepted route of the packet is already exhausted by the displayed finite carrier rows and by the listed BEDC primitives. Thus a converse or reuse route has no independent entry point for a host substitution relation, host equality witness, unchecked compiler state, subject-reduction theorem, or unregistered free variable. Its consumer-facing content

must first be a read of the term row, value row, inspected depth, source and value closedness rows, operation rows, finite ledger, audit row, componentwise transport, displayed continuation, package provenance, and local naming row.

Now apply Definition 527.123. A consumer cannot recover an unregistered free variable, host equality, unchecked compiler state, subject reduction, or host substitution semantics from those rows. Therefore any consumer-facing use of O can reach only the named local route whose read has already factored through the displayed packet. If that route asks to omit, replace, detach, or bypass one of the listed coordinates, the row O blocks that named attempt.

The remaining interpretations ask for something outside the accepted route surface: a global impossibility statement, a host theorem, hidden external validation, host substitution semantics, host equality, unchecked compiler state, subject reduction, or an unregistered free-variable route. Route saturation supplies no coordinate for such a request, and consumer non-escape explicitly prevents recovering it from the packet. Hence O has force only as the strict local obstruction to the named converse or reuse route, while every consumer read that stays inside the displayed rows remains a read of the accepted $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ packet. □

Theorem 527.125 (Closed-term substitution boundary MetaCIC public handoff)**.** *Every* AuthorizedGeneratorRecu *or* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *consumer that cites an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet must pass through the displayed public handoff rows*

$$\mathsf{Term}, \mathsf{ClosedAt}, \mathsf{shift}, \mathsf{substitute}, L, A, H, C, P, N.$$

The rows are read as the source term and value term entries, source and value closedness entries, closed shift and substitute-closed operation entries, finite ledger L, audit row A, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. The handoff exports no subject-reduction theorem, host substitution semantics, compiler correctness theorem, host syntax quotient, hidden evaluator state, or unregistered normalization route.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryMetacicPublicHandof`

Proof. Project the accepted carrier of Definition 527.1 and the classifier of Definition 527.2. They display the term rows, closedness rows, closed shift row, substitute-closed row, ledger, audit, transport, continuation, provenance, and local naming rows as one finite packet.

Apply Definition 527.3, Definition 527.8, and Definition 527.43. These rows force every closed operation read to pass through the ledger and audit surface before the operation is exported.

Now use Definition 527.103 and Definition 527.126 when the consumer is MetaCIC-facing. The downstream root handoff lists $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ and $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ among the roots that consume only the displayed packet, while the MetaCIC consumer boundary blocks confluence or subject-reduction reads from leaving the same rows.

Thus the public handoff for these two consumers is exactly the displayed Term, ClosedAt, shift, substitute, ledger, audit, hsame, Cont, Pkg, and NameCert route. Any subject-reduction theorem, host substitution semantics, compiler correctness theorem, host syntax quotient, hidden evaluator state, or unregistered normalization route would require a coordinate outside the accepted packet. □

Theorem 527.126 (Closed-term substitution boundary MetaCIC consumer nonescape)**.** *Every MetaCIC confluence or subject-reduction consumer of an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet must read the source closedness row, value closedness row, shift boundary row, substitution boundary row, finite ledger, audit row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg

provenance, and local NameCert *row before citing the boundary. The consumer-facing route is confined to*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

It supplies no full subject-reduction theorem, compiler correctness theorem, host substitution semantics, selected term representative, or unregistered free-variable data.

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryMetacicConsumerNone`

Proof. Start from source and value closedness admission. By Definition 527.4 and Definition 527.5, the rows C_{src} and C_{val} are displayed before either operation row can serve a downstream consumer.

Next apply substitution-row exactness. The theorem Definition 527.7 forces the substitution boundary row R to remain attached to the same source row, value row, depth row, and closedness witnesses, while the shift row Q stays inside the same operation surface.

Finally use ledger non-escape, together with the route-saturation package. The rows L, A, H, C, P, N record the closedness and operation reads, transport them componentwise, replay them through displayed continuation, and name the local boundary. By Definition 527.8 and Definition 527.121, a MetaCIC confluence or subject-reduction consumer receives only that finite packet and no host substitution semantics, compiler correctness theorem, full subject-reduction theorem, selected representative, or unregistered free-variable data. □

Theorem 527.127 (Closed-term substitution boundary MetaCIC dependency)**.** *Every MetaCIC consumer of an accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet must route through the closed source row, closed value row, shift boundary row, substitution boundary row, ledger row, audit row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before the packet can feed a normalization or confluence surface. In particular, any handoff to the critical-path consumer surface of chapter 765 and to a confluence-facing sibling such as chapter 7346 is mediated by the existing closed rows; it does not export subject reduction, compiler correctness, host substitution semantics, a selected representative, or unregistered free-variable data.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryMetacicDependency`

Proof. Start with Definition 527.126. It already forces every MetaCIC confluence or subject-reduction consumer to expose the source closedness, value closedness, shift boundary, substitution boundary, finite ledger, audit, transport, replay, provenance, and local naming rows.

Next read the MetaCIC critical-path surface. The critical-path packet of chapter 765 consumes closed substitution support only as a displayed dependency row before normalization or confluence traffic can continue; it does not turn that dependency into subject reduction or compiler correctness.

Finally pass to the confluence-facing sibling. A local confluence frontier such as chapter 7346 may receive the closed substitution boundary as a premise row, but the nonescape theorem keeps the route attached to the same closed source and value rows. Thus the dependency is horizontal and finite, not a new exported metatheorem. □

Theorem 527.128 (Closed-term substitution boundary socket separation)**.** *For every accepted* ClosedTermSubstitutionBoundary$^{\uparrow}$ *packet, the source and value closedness rows, shift boundary row, substitution boundary row, ledger row, and audit row keep the free-variable socket separate from every subject-reduction consumer. Any consumer that asks for a confluence, normalization, or subject-reduction theorem must first read the finite boundary route*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

through Definition 527.40, Definition 527.121, and Definition 527.126; the packet exports no unregistered free-variable coordinate, host substitution semantics, selected term representative, or subject-reduction theorem.

Proof. Project the accepted carrier and classifier from Definition 527.1 and Definition 527.2. The only public operation reads are the displayed shift and substitution boundary rows, and both are guarded by the source/value closedness witnesses and the finite ledger.

Apply Definition 527.40. The ledger and audit rows are read before any operation boundary is exported, so a free-variable socket cannot be recovered by bypassing C_{src}, C_{val}, L, or A.

Next use Definition 527.121. Every accepted route is exhausted by the displayed rows and the BEDC primitives BHist, hsame, Cont, Pkg, and NameCert, leaving no coordinate for host substitution semantics or selected term representatives.

Finally apply Definition 527.126. MetaCIC confluence and subject-reduction consumers receive only the finite boundary packet, so the free-variable socket remains separate from any subject-reduction theorem. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundarySocketSeparation`

Theorem 527.129 (Closed-term substitution boundary audit route totality)**.** *Every audit-visible consumer route for an accepted* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *packet is total only after it displays*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N.$$

The route may then replay the carrier, classifier, local NameCert *obligations, ledger separation, root audit totality, and socket-separation rows, but it cannot start from a subject-reduction theorem, host syntax quotient, hidden compiler state, unregistered free-variable socket, or host substitution semantics.*

Proof. Begin with the root audit totality theorem Definition 527.45. It already routes every audit-visible consumer through the displayed boundary rows before the packet can be consumed.

Use the NameCert obligations and the ledger route separation. By Definition 527.3 and Definition 527.40, the source/value closedness rows, operation rows, ledger row, audit row, transport rows, continuation row, provenance row, and local naming row are all read inside the same finite packet.

Now apply Definition 527.128. The free-variable socket is not a hidden entry point into subject reduction; it is blocked unless the same displayed boundary route has already been consumed.

Therefore every audit-visible consumer route is total exactly on the listed rows. Since none of those rows contains a subject-reduction theorem, host syntax quotient, hidden compiler state, unregistered free-variable socket, or host substitution semantics, no audit-visible route can read such data before reading the packet. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryAuditRouteTotality`

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ packet is generated from displayed Term rows, ClosedAt witnesses, a depth row, closed shift and substitute boundary rows, a finite closedness ledger, an audit-visible non-escape row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 527.1, Definition 527.2, Definition 527.3, Definition 527.8, Definition 527.12, Definition 527.30, Definition 527.31, Definition 527.32, Definition 527.45, Definition 527.125, Definition 527.126, and Definition 527.130 bind closed-term substitution as a mature finite audit route over Term, ClosedAt, shift, substitute, BHist, hsame, Cont, Pkg, and NameCert, with the paper-side bridge route recorded by the sibling status ledger.

Formal verification: FormalStatus(NameCert$_{\text{ClosedTermSubstitutionBoundary}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: human
Not claimed: This chapter does not close full compiler correctness, subject reduction, host syntax quotienting, hidden semantic models, or bridge checking.
Upgrade path: Further movement is on the verification and bridge-checking axes; the paper-side treatment is mature for the displayed closed-term substitution boundary.

Theorem 527.130 (Closed-term substitution boundary MetaCIC socket factorization)**.** *Every MetaCIC critical-path consumer of closed-term substitution that reaches candidate-mediated strong-normalization or confluence readiness must first factor through the displayed binder-budget, recursor-generator, shift-substitution, audit-route, and subject-reduction socket rows of the accepted* ClosedTermSubstitutionB *packet. Concretely, the consumer route must expose the finite boundary rows*

$$T, V, d, C_{\mathsf{src}}, C_{\mathsf{val}}, Q, R, L, A, H, C, P, N$$

together with the binder-budget and authorized-generator rows cited by the MetaCICCriticalPath$^{\uparrow}$ *route of chapter 765. Only after those rows are visible may the consumer read candidate-mediated SN or confluence readiness. The factorization exports no global subject reduction, full confluence, beta-decision procedure, host equality, quotient term equality, hidden substitution semantics, or selected term representative.*

Proof. Start with the closed-term substitution carrier and classifier, Definition 527.1 and Definition 527.2. They display the source term, value term, depth, source/value closedness, closed shift row, substitute-closed row, ledger, audit, transport, replay, provenance, and local naming rows before any substitution consumer can proceed.

Next lock the operation side. Apply Definition 527.122, Definition 527.121, and Definition 527.128. These rows force the shift-substitution read through the source/value closedness witnesses, the finite ledger, and the same BHist, hsame, Cont, Pkg, and NameCert route.

Now attach the MetaCIC side. The MetaCIC critical path of chapter 765 reads binder-budget, authorized recursor-generator, candidate-mediated SN, confluence, and subject-reduction socket data as separate rows. The nonescape theorem Definition 527.126 and the audit route totality theorem Definition 527.129 keep the closed-substitution part of that path inside the displayed boundary packet.

Finally use the candidate frontier rows from the critical-path chapter, including Definition 765.278 and Definition 765.281. Candidate-mediated SN and confluence readiness can consume the closed-substitution boundary only as one socket row among the displayed packet rows. Since neither chapter supplies a closed subject-reduction certificate, full confluence theorem, beta-decision procedure, host equality proof, quotient term equality proof, hidden substitution semantics, or selected representative, no such export is available at the factorized route. □

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryMetacicSocketFacto`

Theorem 527.131 (ClosedTermSubstitutionBoundary sibling dependency route)**.** *Every* ClosedTermSubstitutionB *consumer that reads the boundary as MetaCIC substitution data must first expose the sibling substitution surface of chapter 537 and the critical-path readback boundary of chapter 765. The* BinderBudgetSeal$^{\uparrow}$ *row of chapter 532 supplies the finite binder budget, and the* AuthorizedGeneratorRecursor$^{\uparrow}$ *row of chapter 525 supplies the permitted generator boundary before the substitution readback is consumed. The* ClosedTermSubstitution$^{\uparrow}$ *row supplies the operation-facing substitution surface, while the* MetaCICCriticalPath$^{\uparrow}$ *row supplies the critical-path socket where binder budgets, closedness ledgers, and substitution reads remain audit-visible. The route is finite: it records only the*

displayed substitution operation row, closedness boundary row, transport, replay, provenance, and local naming data. It does not claim beta-conversion, quotient term equality, unrestricted normalization, or a hidden subject-reduction theorem.

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionBoundaryUp.ClosedTermSubstitutionBoundarySiblingDependencyRo`

Proof. Project the closed-term substitution boundary carrier from the core construction. Its operation row is available only through the displayed source and value closedness witnesses, ledger row, audit row, transport, replay, provenance, and local naming certificate.

Read the sibling anchors as route boundaries. The ClosedTermSubstitution$^{\uparrow}$ chapter names the substitution operation surface consumed by the boundary, the BinderBudgetSeal$^{\uparrow}$ chapter supplies the finite binder budget, the AuthorizedGeneratorRecursor$^{\uparrow}$ chapter supplies the permitted generator boundary, and the MetaCICCriticalPath$^{\uparrow}$ chapter names the critical-path socket in which the readback remains visible to MetaCIC consumers.

Since the carrier and the two sibling routes expose no beta-conversion theorem, quotient syntax equality, unrestricted normalization theorem, or hidden subject-reduction certificate, the dependency route remains exactly the displayed finite handoff. □

Theorem 527.132 (ClosedTermSubstitutionBoundary normalization-router dependency route)**.** *Every* ClosedTermSubstitutionBoundary$^{\uparrow}$ *consumer that sends closed substitution data toward MetaCIC normalization must expose the candidate-mediated router of chapter 1108. The boundary supplies the closed projection row, while the router supplies candidate evidence, Pi and application adequacy, authorized generator, compiler recognizer, kernel acceptance, replay, provenance, and local naming rows before any normalization-facing read is consumed. Thus the dependency is horizontal and finite: it records a displayed route from closed-term substitution into the normalization router, not a host substitution theorem, evidence-free normalization theorem, subject-reduction theorem, or quotient reduction equality.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionBoundaryUp.ClosedTermSubstitutionBoundaryNormalizationRoute`

Theorem 527.133 (ClosedTermSubstitutionBoundary sibling lattice route)**.** *Every* ClosedTermSubstitutionBounda *consumer that treats the boundary as a closed substitution lattice must read four sibling rows before the local boundary is exported. The substitution operation surface is supplied by chapter 537; the MetaCIC socket and critical-path readback are supplied by chapter 765; the finite binder budget is supplied by chapter 532; and the permitted generator boundary is supplied by chapter 525. The route therefore exposes a finite lattice of operation, socket, budget, generator, transport, replay, provenance, and local naming rows, without exporting quotient term equality, unrestricted substitution, host normalization, or a hidden subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionBoundaryUp.ClosedTermSubstitutionBoundarySiblingLatticeRoute`

Proof. Read the existing sibling dependency route and the normalization-router dependency route. They already force the boundary carrier to pass through the closed substitution operation row, MetaCIC critical-path socket, binder-budget seal, and authorized-generator boundary before any normalization-facing consumer reads the substitution data.

The present route repacks those sibling reads as the local lattice boundary. Since each cited chapter contributes a displayed NameCert row and none contributes quotient syntax equality, unrestricted substitution, host normalization, or erased subject reduction, the lattice exports exactly the finite operation, socket, budget, generator, transport, replay, provenance, and local naming rows. □

Theorem 527.134 (ClosedTermSubstitutionBoundary MetaCIC sibling lattice route)**.** *Every MetaCIC critical-path consumer of* ClosedTermSubstitutionBoundary$^{\uparrow}$ *keeps the closed-substitution operation row, the binder-budget seal, the authorized-generator recursor row, the residual socket, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming visible before it exports the boundary to a critical-path read. The route refuses quotient term equality, unrestricted substitution, host normalization, hidden subject reduction, and kernel consistency.*

Lean4 ✓ `BEDC.Derived.ClosedtermsubstitutionboundaryUp.ClosedTermSubstitutionBoundaryMetaCICSiblingLatti`

Proof. Apply Definition 527.133. It already exposes the closed-substitution operation row, MetaCIC socket, binder-budget seal, authorized-generator boundary, transport, replay, provenance, and local naming.

Now read the MetaCIC critical-path dependency through chapter 765. The critical-path consumer can only reuse the displayed residual socket and the rows supplied by the sibling lattice; no new quotient term equality, unrestricted substitution, host normalization, hidden subject-reduction theorem, or kernel-consistency assertion is present in the packet. □

Proposition 527.135 (ClosedTermSubstitutionBoundary MetaCIC normalization dependency lattice)**.** *Every normalization-facing consumer of* ClosedTermSubstitutionBoundary$^{\uparrow}$ *reads the MetaCIC closed substitution route through chapter 537 and the closed substitution seal route through chapter 538 before it enters the normalization-router dependency route of Definition 527.132. The MetaCIC critical-path socket of chapter 765 and the normalization certificate router of chapter 1108 therefore form the displayed dependency lattice for the boundary packet: closed substitution supplies the operation row, the seal fixes the closed fragment, the critical path supplies the socket, and the router supplies the finite normalization-facing handoff. This lattice exports no unrestricted substitution theorem, subject-reduction theorem, host normalization theorem, quotient term equality, or hidden compiler state.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionBoundaryUp.ClosedTermSubstitutionBoundaryMetacicNormalizatio`

The ClosedTermSubstitutionBoundary$^{\uparrow}$ dossier records its bridged-closure route as a paper-side ledger row: the bridge route is read through the displayed closed-source, shift, substitution, audit, transport, replay, provenance, and local NameCert rows, while the verification axis remains bound only by the closurestatus block in `namecert_construction_core.tex`. This ledger row does not add a subject-reduction theorem, host syntax quotient, compiler-correctness theorem, or hidden substitution semantics.

Chapter 528

A Concrete Naming Certificate for $\mathsf{SupplySocketLedger}^{\uparrow}$

The $\mathsf{SupplySocketLedger}^{\uparrow}$ surface is the concrete NameCert ledger for the seven T-supply socket kinds of chapter 9394. It records which kind is being exposed, which site consumes the request, which audit gate governs the refusal, and which provenance and continuation rows make the refusal available to later concrete-instance chapters. The ledger is a finite classifier over displayed rows; it is not a hidden source of the requested supply.

The socket-site row S is the ledger projection of the supply socket exposed by chapter 498, the audit row A consumes the admission and refusal discipline of chapter 545, and downstream public-record consumers such as chapter 519 may cite only the displayed GAP, kind, site, audit, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Definition 528.1 (SupplySocketLedger carrier)**.** *A* $\mathsf{SupplySocketLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (G, K, S, A, C, P, N)$$

with the following displayed rows:

1. *G is the* GAP *tag row naming the boundary socket under inspection;*
2. *K is one of the seven supply kinds: free-floating induction, unwitnessed witness, extensional identification, causal continuity, inter-history coordination, inscription novelty, or self-reference closure;*
3. *S is the displayed socket site, recording where the requested supply would be consumed and which concrete theorem, definition, audit gate, or consumer route would use it;*
4. *A names the audit gate that refuses silent internalisation of the requested supply kind;*
5. *C records the* Cont *consumption routes by which downstream consumers read G, K, S, and A without obtaining the missing supply;*
6. *P records* Pkg *provenance over* BHist*, the* GAP *row, the seven supply kinds, socket sites, audit gates,* Cont *routes, and the local naming surface;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{SupplySocketLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unrestricted induction principle, selected witness, quotient equality, empirical persistence law, shared host history, inscription source, or truth-total self-description.

Theorem 528.2 (SupplySocketLedger NameCert obligations)**.** *For the carrier of Definition 528.1, the local* $\mathsf{NameCert}_{\mathsf{SupplySocketLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$L = (G, K, S, A, C, P, N),$$

classifier exposure for the row K, kind exactness against the seven displayed supply kinds, audit-gate routing through A, continuation locality through C, package provenance through P, local naming through N, and ledger non-escape for any requested supply not present in the finite packet.

Proof. Carrier admission is projection from Definition 528.1. The packet exposes the GAP tag, supply-kind row, socket site, audit gate, continuation routes, provenance, and local naming row as its complete visible inventory.

Classifier and kind exactness are read from K. The row is required to be one of the seven displayed supply kinds, and the NameCert surface accepts no classifier outside that finite list.

Audit routing and consumer locality are the rows A and C. They say which gate blocks the request and how downstream consumers may inspect the blocked route without replacing it by an internal theorem.

Provenance and local naming are supplied by P and N. Since the carrier inventory contains no row for the requested supply itself, the NameCert obligations expose the socket while preserving ledger non-escape. □

Theorem 528.3 (SupplySocketLedger kind exhaustion)**.** *Every accepted* $\mathsf{SupplySocketLedger}^{\uparrow}$ *row classifies its socket as exactly one of the seven displayed supply kinds: free-floating induction, unwitnessed witness, extensional identification, causal continuity, inter-history coordination, inscription novelty, or self-reference closure. The ledger exports no eighth hidden kind, no unlisted classifier branch, and no catch-all route that can discharge a* GAP *tag without passing through one of these seven rows.*

Proof. Project the accepted carrier $L = (G, K, S, A, C, P, N)$. The only kind coordinate is K, and Definition 528.1 restricts that coordinate to the seven named supply kinds.

Apply the NameCert obligations of Definition 528.2. They make kind exactness a certificate row rather than a prose convention, so consumer access to the socket classifier must pass through the displayed finite list.

The absence claim follows from the carrier inventory. No coordinate names an additional kind, a default classifier branch, or a discharge route outside the seven rows. □

Theorem 528.4 (SupplySocketLedger audit non-escape)**.** *The* $\mathsf{SupplySocketLedger}^{\uparrow}$ *packet records refusal of* Classical.choice, Quot.sound, propext, *host equality, unbounded induction, and truth-total self-description as explicit socket rows rather than as substrate theorems. Each refusal is visible only through its* GAP *tag, supply-kind classifier, socket site, audit gate, continuation route, package provenance, and local NameCert row.*

Proof. Read each refusal through the carrier coordinates. The GAP row names the boundary, the kind row classifies the requested supply, the site row says where the request would be consumed, and the audit row names the gate that keeps the request external.

Continuation and provenance then preserve the same boundary. The Cont routes let consumers inspect the refusal, while P records that the route belongs to the finite ledger over BHist and local naming data.

No substrate theorem is produced by these rows. The items Classical.choice, Quot.sound, propext, host equality, unbounded induction, and truth-total self-description are recorded as refused socket requests, and no coordinate in L turns them into available BEDC principles. □

Theorem 528.5 (SupplySocketLedger TasteGate carrier boundary)**.** *The local* ChapterTasteGate-*relevant carrier boundary for* $\mathsf{SupplySocketLedger}^{\uparrow}$ *is exactly the displayed finite packet*

$$L = (G, K, S, A, C, P, N).$$

It exposes the GAP *tag row, supply-kind row, socket site, audit gate,* Cont *consumption routes,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{SupplySocketLedger}^{\uparrow}}$ *row, and it contains no coordinate carrying the refused supply itself.*

Proof. Project the carrier of Definition 528.1. Its complete displayed inventory is the seven-tuple $L = (G, K, S, A, C, P, N)$, so the TasteGate-relevant boundary has precisely those coordinates.

Apply Definition 528.2. The NameCert surface reads carrier admission, classifier exposure, audit routing, continuation locality, package provenance, local naming, and ledger non-escape from the same seven rows.

Finally use Definition 528.4. Refused supplies are represented as socket requests behind the displayed audit rows, not as coordinates of L. □

Theorem 528.6 (SupplySocketLedger route coverage)**.** *Every consumer route that reads a* $\mathsf{SupplySocketLedger}^{\uparrow}$ *supply-kind row factors through the displayed* GAP *tag G, socket site S, audit gate A, and* Cont *routes C. No consumer can reach the classifier row K through an unnamed route, a hidden eighth kind, or a route that bypasses the audit gate.*

Proof. Start with an accepted packet $L = (G, K, S, A, C, P, N)$. By Definition 528.1, the only classifier coordinate is K, and the carrier displays the boundary tag, socket site, audit gate, and continuation rows beside it.

Apply Definition 528.3. Any read of K lands in one of the seven displayed supply kinds, with no hidden classifier branch available to the consumer.

The route factorisation then follows from Definition 528.2: audit-gate routing is through A and continuation locality is through C. The non-escape result of Definition 528.4 rules out replacing that factored route by the refused supply itself. □

Theorem 528.7 (SupplySocketLedger consumer provenance)**.** *Downstream concrete-instance chapters may cite a* $\mathsf{SupplySocketLedger}^{\uparrow}$ *packet only through the displayed* Pkg *provenance row P and the local* $\mathsf{NameCert}_{\mathsf{SupplySocketLedger}^{\uparrow}}$ *row N, together with the visible classifier, socket, audit, and continuation rows that they certify. They may not cite the requested supply as a produced theorem, selected witness, quotient equality, persistence law, shared host history, inscription source, or truth-total self-description.*

Proof. Project the provenance and naming rows from Definition 528.1. The rows P and N are the only coordinates whose role is to make the ledger citeable by later concrete-instance chapters.

Use Definition 528.2 to identify what those rows certify: the finite carrier, the supply-kind classifier, audit-gate routing, continuation locality, package provenance, local naming, and ledger non-escape.

The forbidden citations have no carrier coordinate. By Definition 528.4, they remain refused socket requests visible through the ledger surface, so a downstream chapter may cite the provenance and NameCert rows but not the missing supply. □

Theorem 528.8 (SupplySocketLedger kind-route determinacy)**.** *For an accepted* $\mathsf{SupplySocketLedger}^{\uparrow}$ *packet $L = (G, K, S, A, C, P, N)$, the* BHist *row K determines the visible socket-kind route consumed by any* Cont *read of the ledger. The route is read with the socket-site row S, audit row A,* Pkg

provenance row P, and local $\mathsf{NameCert}_{\mathsf{SupplySocketLedger}^{\uparrow}}$ *row N; no second route can classify the same accepted packet as a different supply kind.*

Proof. Project the carrier of Definition 528.1. The packet has one kind coordinate K, one socket-site row S, one audit row A, one family of consumption routes C, one provenance row P, and one local naming row N.

Apply Definition 528.3 to the projected kind row. Since K ranges over the seven displayed supply kinds and the carrier has no further classifier coordinate, a consumer route cannot obtain a different kind without leaving the packet.

Finally use Definition 528.6. Every classifier read factors through the displayed Cont routes and audit gate, so the route determined by K is the only route certified by P and N for the accepted row. □

Theorem 528.9 (SupplySocketLedger refused-row non-escape)**.** *If a* BHist *supply row is outside the displayed* $\mathsf{SupplySocketLedger}^{\uparrow}$ *packet $L = (G, K, S, A, C, P, N)$, then no consumer can read it through the local ledger. The only readable refusal data are the displayed G, K, S, A rows, their* Cont *consumption routes C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{SupplySocketLedger}^{\uparrow}}$ *row N.*

Proof. Start from the inventory in Definition 528.1. A row outside G, K, S, A, C, P, N is absent from the finite packet and therefore is not a coordinate that a local consumer can project.

Apply Definition 528.4. The refused principles and host supplies remain recorded as socket requests behind the displayed audit row; they are not converted into substrate theorems or available carrier fields.

The NameCert obligations then preserve the boundary. By Definition 528.2, provenance and local naming certify exactly the displayed refusal rows and their Cont routes, so an outside supply row has no certified path into the ledger. □

Theorem 528.10 (SupplySocketLedger consumption coverage)**.** *Every accepted* $\mathsf{SupplySocketLedger}^{\uparrow}$ *socket route consumed by a downstream chapter is covered by the displayed* BHist *rows of the same packet: the* GAP *tag G, socket-kind row K, socket-site row S, audit row A,* Cont *routes C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{SupplySocketLedger}^{\uparrow}}$ *row N. No accepted route may cite the ledger while omitting the local NameCert row or bypassing provenance.*

Lean4 ✓ `BEDC.Derived.SupplySocketLedgerUp.SupplySocketLedgerUp StdBridge`

Proof. Project an accepted packet $L = (G, K, S, A, C, P, N)$. The displayed carrier gives the complete list of rows from which a consumer may read a socket route.

Use Definition 528.6 for reads of the classifier and Definition 528.7 for downstream citations. Together they force each accepted consumption route to pass through C, cite P, and retain the local naming row N.

It remains to rule out partial consumption. The non-escape result of Definition 528.4 says that bypassing the audit or provenance rows would replace the displayed refusal by the refused supply itself, which is not a coordinate of the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{SupplySocketLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SupplySocketLedger}^{\uparrow}$ packet is generated from one GAP tag row, one of the seven supply-kind classifiers, one displayed socket site, one audit-gate row, displayed Cont consumption routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SupplySocketLedger}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 528.1, Definition 528.2, Definition 528.3, Definition 528.4, Definition 528.5 with

Upgrade path: No further formal bridge-axis upgrade remains for the seven-kind supply-socket ledger.

Chapter 529

A Concrete Naming Certificate for $\mathsf{RecursorAuthorization}^{\uparrow}$

The $\mathsf{RecursorAuthorization}^{\uparrow}$ interface records the finite certificate surface by which an accepted Lean `inductive` declaration authorizes its emitted recursor as a BEDC generator. The packet is built from the accepted constructor signature, the emitted eliminator, the branch package supplied to the eliminator, the structural descent ledger for recursive occurrences, and the NameCert row naming the generated output. It is a naming certificate for authorized generator use; it is not a host-side trust principle for arbitrary recursion.

The $\mathsf{RecursorAuthorization}^{\uparrow}$ row is the signature-and-recursion authorization row consumed by chapter 525 and refined by chapter 534. The first sibling supplies the audit boundary for host-kernel accepted recursor calls, while the second packages legal recursor calls and closed-term handoffs.

Definition 529.1 (RecursorAuthorization carrier)**.** *A* $\mathsf{RecursorAuthorization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, \Sigma, R, M, B, D, H, C, P, N)$$

with the following visible rows:

1. *I is the accepted inductive name and Σ is its closed constructor signature, including the constructor rows for instances such as* `BMark` *and* `BHist`*;*
2. *R is the emitted eliminator row, read as the kernel-generated recursor for Σ, including concrete rows such as* `BMark.rec` *and* `BHist.rec`*;*
3. *M is the motive row accepted for the recursor call;*
4. *B is the finite branch package, with one branch row for each constructor of Σ and branch completeness checked against that signature;*
5. *D is the structural descent ledger recording that recursive calls occur only on constructor-subdata accepted by the kernel;*
6. *H stores componentwise* hsame *transports for constructor signatures, eliminator rows, motive rows, branch rows, descent rows, and generated outputs;*
7. *C stores displayed* Cont *routes by which consumers read the constructor, recursor, branch, and output rows;*
8. *P is the* Pkg *provenance over* `BMark`*,* BHist*, closed constructor signatures, emitted recursors, branch packages,* hsame*,* Cont*, and* NameCert*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{RecursorAuthorization}^{\uparrow}}$ *row naming the generated output.*

The carrier contains no unlisted constructor, no extra branch, no unrestricted recursion channel, and no external proof-trust coordinate.

Theorem 529.2 (RecursorAuthorization NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RecursorAuthorization}^{\uparrow}}$ *obligation surface consists of the accepted constructor signature Σ, the emitted recursor row R, the motive row M, the branch package B, the structural descent ledger D, and the displayed* hsame, Cont, Pkg, *and naming rows H, C, P, N. Every authorized generator output must be read through these rows before it is available to a downstream BEDC consumer.*

Proof. Project the carrier of Definition 529.1. The constructor signature, emitted recursor, motive, branch package, descent ledger, transport rows, continuation routes, provenance, and local naming row are all coordinates of the same finite packet.

The obligation rows are therefore carrier projections. A consumer cannot read the generated output until it has passed through the signature row, the recursor row, the accepted motive and branch data, and the descent ledger.

Since the carrier has no coordinate for an external trust principle or unrestricted recursion channel, the local NameCert surface is exactly the displayed recursor-authorization packet. □

Theorem 529.3 (RecursorAuthorization branch exhaustion)**.** *For every accepted* $\mathsf{RecursorAuthorization}^{\uparrow}$ *packet $A = (I, \Sigma, R, M, B, D, H, C, P, N)$, the branch package B contains exactly the branch rows indexed by the constructors in Σ. A recursor consumer has no route to an omitted constructor case and no route to an additional branch not named by the accepted constructor signature.*

Lean4 ✓ `BEDC.Derived.RecursorAuthorizationUp.RecursorAuthorizationBranchExhaustion`

Proof. Read the constructor signature row Σ from the carrier. It is the finite list of constructors accepted for I.

Read the branch package B through the emitted recursor row R. The package is attached to the same signature row, so its branch inventory is indexed by the visible constructors of Σ.

The transport and continuation rows H and C preserve that same indexing for downstream reads. Because the carrier lists no further branch coordinate, branch exhaustion is exactly the displayed finite constructor coverage. □

Theorem 529.4 (RecursorAuthorization generator non-escape)**.** *Every generated output of an accepted* $\mathsf{RecursorAuthorization}^{\uparrow}$ *packet factors through the emitted recursor R, the accepted motive M, the branch package B, and the structural descent ledger D. The packet exports no hidden generator, no non-structural recursive call, no unlisted constructor, and no external recursion principle.*

Proof. Start with the local obligation surface of Definition 529.2. It places each generated output downstream of the accepted signature, recursor, motive, branch, and descent rows.

Use branch exhaustion from Definition 529.3. Every case consumed by the recursor is one of the constructor cases in Σ, and every recursive occurrence is governed by the same descent ledger D.

The remaining rows H, C, P, N only transport, route, package, and name that finite surface. They do not add a generator coordinate, so no output can escape the accepted recursor packet. □

Theorem 529.5 (RecursorAuthorization public handoff)**.** *The public* $\mathsf{NameCert}_{\mathsf{RecursorAuthorization}^{\uparrow}}$ *handoff of an accepted carrier is exactly the tuple of constructor signature, emitted recursor, accepted motive, complete branch package, structural descent ledger, transport rows, continuation*

routes, package provenance, and local naming row displayed in Definition 529.1. It can be cited by downstream generator-closure, TasteGate, and self-compilation consumers without exporting unrestricted recursion, hidden constructor data, or host-side proof trust.

Lean4 ✓ `BEDC.Derived.RecursorAuthorizationUp.RecursorAuthorizationTasteGate single carrier alignment`

Proof. First assemble the local authorization surface using Definition 529.2. This gives the carrier rows consumed by any recursor-generated output.

Next apply Definition 529.3 and Definition 529.4. These isolate the finite branch coverage and rule out generator routes outside the accepted signature and descent ledger.

Finally repack the displayed rows with H, C, P, N. The public handoff is the same finite packet under its local NameCert row, and no additional recursion or proof-trust coordinate is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{RecursorAuthorization}\uparrow}$.

Constructive story: A $\mathsf{RecursorAuthorization}^{\uparrow}$ packet is generated from an accepted inductive declaration row, constructor signature row, emitted recursor row, motive row, complete branch package, structural descent ledger, componentwise transport, replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RecursorAuthorization}\uparrow}, \mathsf{seed})$

Scope closed: Definition 529.1, Definition 529.2, Definition 529.3, Definition 529.4, and Definition 529.5 bind the accepted constructor signature, emitted recursor, motive, branch package, structural descent ledger, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RecursorAuthorization}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close unrestricted recursion, hidden constructors, arbitrary generator authorization, non-structural recursive calls, or host-side proof trust.

Upgrade path: Obligation closure requires the displayed branch exhaustion, generator non-escape, public handoff, and structural descent rows to be assembled without changing the formal axis.

Chapter 530

A Concrete Naming Certificate for $\mathsf{UnaryDirectionBridge}^{\uparrow}$

The $\mathsf{UnaryDirectionBridge}^{\uparrow}$ interface packages the finite bridge by which the unary $\mathsf{Nat}^{\uparrow}$ spine and the zero-spine $\mathsf{AxisNat}^{\uparrow}$ surface can be compared without identifying their kernel carriers. Its local certificate records the two source rows, the bridge witness, the one-point kernel intersection, standard-boundary interpretation, ledger policy, and public naming row. The packet is a comparison certificate over displayed BEDC rows; it is not a kernel equality between $\mathsf{Nat}^{\uparrow}$ and $\mathsf{AxisNat}^{\uparrow}$.

The dependency anchors are the $\mathsf{Nat}^{\uparrow}$ source carrier of chapter 28 and the $\mathsf{AxisNat}^{\uparrow}$ source carrier of chapter 276, kept as distinct BEDC rows throughout the bridge. The $\mathsf{Add}^{\uparrow}$ and $\mathsf{AxisAdd}^{\uparrow}$ surfaces of chapter 29 and chapter 277 enter only at the standard-boundary consumer row, together with BHist, hsame, Cont, Pkg, NameCert, and the Lean-side bridge object UnaryDirectionBridge.

Definition 530.1 (UnaryDirectionBridge NameCert carrier)**.** *A* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (N, A, B, K, S, L, H, C, P, M)$$

with the following visible rows:

1. *N is the* $\mathsf{Nat}^{\uparrow}$ *unary-spine source row, read through the* Unary *predicate over* E1 *histories;*
2. *A is the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine source row, read through the* ZeroSpine *predicate over* E0 *histories;*
3. *B is the local bridge row naming* UnaryDirectionBridge *and its two displayed source carriers;*
4. *K is the kernel-distinctness ledger asserting that the unary and zero-spine carriers intersect only at* e*;*
5. *S is the standard-boundary row, matching nonempty unary histories with nonempty zero-spine histories by length and preserving the* $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ *consumer route at the standard boundary;*
6. *L is the ledger policy row, recording that bridge reads must cite N, A, B, K, S before exporting any comparison;*
7. *H stores componentwise* hsame *transports for the two source rows, bridge row, kernel-distinctness witness, standard-boundary row, ledger policy row, and local naming row;*
8. *C stores displayed* Cont *routes for unary inspection, zero-spine inspection, bridge comparison, standard-boundary readback, ledger audit, and NameCert comparison;*

9. *P is the* Pkg *provenance row naming* $\mathsf{Nat}^{\uparrow}$, $\mathsf{AxisNat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{AxisAdd}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert, *and* UnaryDirectionBridge*;*
10. *M is the local* $\mathsf{NameCert}_{\mathsf{UnaryDirectionBridge}^{\uparrow}}$ *row.*

The classifier compares accepted bridge packets only after transporting these rows componentwise. It has no coordinate for a kernel equality between $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{AxisNat}^{\uparrow}$*, no quotient identifying unary and zero-spine histories, and no host-level natural-number equality beyond the displayed standard-boundary row.*

Theorem 530.2 (UnaryDirectionBridge kernel-distinct obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{UnaryDirectionBridge}^{\uparrow}}$ *obligation surface must expose the* $\mathsf{Nat}^{\uparrow}$ *unary source row N, the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine source row A, the bridge row B, and the kernel-distinctness ledger K. Every accepted bridge comparison first reads the two source classifiers, then cites K to rule out a kernel-level carrier collapse except at* e*.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier kernel distinct obligations`

Proof. Project the carrier of Definition 530.1. The source rows N and A are separate coordinates, so a comparison cannot begin from a single shared carrier.

The bridge row B names the comparison object, while K records the only permitted kernel intersection. Reading K before the standard-boundary row forces the comparison to treat unary and zero-spine histories as distinct BEDC predicates.

The transport rows H and continuation routes C preserve this separation for downstream consumers. Since the carrier contains no equality coordinate identifying N and A, the obligations close exactly as a kernel-distinct bridge surface. □

Theorem 530.3 (UnaryDirectionBridge standard boundary)**.** *For an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *carrier $U = (N, A, B, K, S, L, H, C, P, M)$, the public standard boundary is the displayed row S: nonempty unary histories are matched with nonempty zero-spine histories by the same finite length, and the* $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ *consumer route is read only after the source rows and the kernel-distinctness ledger have been transported through H and C.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier standard boundary readout`

Proof. Begin with an accepted bridge packet and project the standard-boundary row S. Its inputs are the two already displayed source rows, not an ambient natural-number object.

The row K is read before S, so the boundary comparison is licensed only after the paper has recorded the one-point kernel intersection. The transports in H and the routes in C then carry the unary and zero-spine rows to the same public comparison site.

The additive consumers $\mathsf{Add}^{\uparrow}$ and $\mathsf{AxisAdd}^{\uparrow}$ are reached through this transported boundary. Because no carrier coordinate identifies the two source predicates, the standard boundary is a public interpretation row rather than a kernel collapse. □

Theorem 530.4 (UnaryDirectionBridge ledger policy)**.** *Every consumer-facing route out of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet factors through the displayed rows $N, A, B, K, S, L, H, C, P, M$. The ledger policy row L rejects any route that compares* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{AxisNat}^{\uparrow}$ *by host equality, by quotienting histories, or by skipping the kernel-distinctness witness.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier ledger policy`

Proof. Take any consumer-facing route and inspect the finite packet. The available source, bridge, kernel, standard-boundary, policy, transport, continuation, provenance, and naming rows are exactly $N, A, B, K, S, L, H, C, P, M$.

The policy row L orders the read: source rows first, bridge row second, kernel-distinctness ledger third, and standard-boundary comparison only after those rows are present. The continuation routes in C expose no alternate branch.

Thus the route is exhausted by the displayed ledger. Since the carrier has no coordinate for host equality or quotient identification of histories, neither can be exported by a bridge consumer. □

Theorem 530.5 (UnaryDirectionBridge NameCert surface)**.** *The* $\mathsf{NameCert}_{\mathsf{UnaryDirectionBridge}^{\uparrow}}$ *surface is the finite bridge packet of Definition 530.1 together with the kernel-distinctness obligations of Definition 530.2, the standard boundary of Definition 530.3, and the ledger policy of Definition 530.4. It realizes the unary-direction bridge as a NameCert packet while keeping* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{AxisNat}^{\uparrow}$ *distinct inside the kernel.*

Proof. Assemble the carrier rows $N, A, B, K, S, L, H, C, P, M$. These rows provide the two source certificates, the bridge object, kernel-distinctness witness, standard-boundary readback, policy ledger, transports, routes, provenance, and local name.

Apply Definition 530.2 to bind the two source rows before any comparison. Apply Definition 530.3 to expose the length-preserving public boundary. Apply Definition 530.4 to rule out routes that bypass the displayed rows.

Repacking these rows gives the local $\mathsf{NameCert}$ surface. The packet therefore realizes the bridge at the paper-certificate level and leaves the kernel carriers separate. □

Theorem 530.6 (UnaryDirectionBridge source obligation inventory)**.** *Every accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet exposes exactly the source rows needed before any bridge comparison: the* $\mathsf{Nat}^{\uparrow}$ *unary-spine row* N*, the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine row* A*, the* $\mathsf{Add}^{\uparrow}$ *and* $\mathsf{AxisAdd}^{\uparrow}$ *standard-boundary consumer rows read through* S*, the carrier history row* BHist*, componentwise* hsame *transport through* H*, displayed* Cont *routes through* C*, package provenance through* P*, and the local* $\mathsf{NameCert}$ *row* M*.*

Proof. Project the carrier of Definition 530.1. The source coordinates are N and A, while S is the only displayed row through which $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ consumers may read the public boundary.

Use Definition 530.2 to keep the source rows separate before the boundary is inspected. Then use Definition 530.3 and Definition 530.4 to account for the boundary, route, and policy rows.

Finally, Definition 530.5 repacks the same inventory as the local certificate. Since the carrier has no further coordinate, the listed rows exhaust the source obligation surface. □

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier source obligation inventory`

Theorem 530.7 (UnaryDirectionBridge kernel-boundary obligation)**.** *Any* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *read that reaches the standard-boundary row* S *must first pass through the kernel-distinctness ledger* K*. Thus a consumer cannot interpret the displayed* $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ *boundary until the unary* $\mathsf{Nat}^{\uparrow}$ *row, the zero-spine* $\mathsf{AxisNat}^{\uparrow}$ *row, and the one-point kernel-intersection policy have been recorded in the same packet.*

Proof. Start from the kernel-distinctness obligations. By Definition 530.2, the rows N, A, B, K are read before any comparison is exported.

The standard boundary of Definition 530.3 is therefore downstream of K. It reads nonempty unary and zero-spine histories through the displayed boundary, but it does not identify the two kernel carriers.

The ledger policy of Definition 530.4 rules out a route that skips K. Repacking through Definition 530.5 gives the required boundary obligation for every accepted packet. □

Theorem 530.8 (UnaryDirectionBridge standard handoff obligation)**.** $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ *consumers of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet read only the displayed standard-boundary row S, the componentwise transport rows H, the continuation routes C, package provenance P, the local* $\mathsf{NameCert}$ *row M, and the source and ledger rows required by N, A, B, K, L. They receive no host natural-number equality, quotient of histories, or carrier identity between* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{AxisNat}^{\uparrow}$*.*

Proof. First expose the public boundary. Definition 530.3 places every $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ handoff on S after the source rows and the kernel ledger have been transported.

Next apply the ledger policy. Definition 530.4 requires the route to cite $N, A, B, K, S, L, H, C, P, M$ before it can export a comparison to additive consumers.

Finally use the NameCert surface. Definition 530.5 packages exactly those rows and keeps $\mathsf{Nat}^{\uparrow}$ and $\mathsf{AxisNat}^{\uparrow}$ distinct inside the kernel, so the standard handoff cannot export host equality, quotient identification, or carrier identity. □

Theorem 530.9 (UnaryDirectionBridge AxisAdd handoff obligations)**.** *Every* $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ *consumer using the standard-boundary handoff of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet must first read the rows $N, A, B, K, S, L, H, C, P, M$. The handoff is licensed only after the source rows, bridge row, kernel-distinctness ledger, standard-boundary row, policy row, transport row, continuation row, provenance row, and local* $\mathsf{NameCert}$ *row are all present.*

Proof. Start from the carrier of Definition 530.1. Its displayed rows are exactly $N, A, B, K, S, L, H, C, P, M$, so a consumer route has no additional coordinate from which to read a boundary.

Apply Definition 530.2 before the public boundary is used. This binds the source rows and the kernel-distinctness ledger.

Apply Definition 530.3 and then Definition 530.4. The first theorem supplies the length-preserving handoff row, and the second requires the policy and route rows before export.

Finally, use Definition 530.5 to repack the read rows as the local certificate. Thus $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ consumers reach the handoff only through the displayed packet. □

Theorem 530.10 (UnaryDirectionBridge empty-intersection readback)**.** *For an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet, the only kernel intersection exposed by the bridge is the empty-history row named by K. No consumer-facing readback from B, S, L, H, C, P, or M exports a second intersection between the* $\mathsf{Nat}^{\uparrow}$ *unary source row and the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine source row.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier empty intersection readback`

Proof. Read the kernel-distinctness obligations. By Definition 530.2, the bridge must cite K before it compares the source rows.

The standard-boundary theorem Definition 530.3 then interprets nonempty rows only at the public boundary. It does not insert a kernel equality between the two predicates.

The ledger-policy theorem Definition 530.4 rules out host equality, quotienting, and routes that skip K. Together with Definition 530.5, this leaves the empty-history row named by K as the sole exposed kernel intersection. □

Theorem 530.11 (UnaryDirectionBridge consumer normal form)**.** *Every consumer route out of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet normalizes to the source rows N, A, the bridge row B, the*

kernel-distinctness ledger K, the standard-boundary row S, and the local NameCert *row M, with transport, continuation, provenance, and policy reads occurring only as displayed rows of the same packet. No normalized route contains quotient identification or host-level natural-number equality.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier consumer normal form`

Proof. Inspect the carrier rows given by Definition 530.1. A consumer can mention only the displayed source, bridge, kernel, standard-boundary, policy, transport, route, provenance, and naming rows.

Apply Definition 530.4. It orders every consumer-facing route through the source rows, the bridge row, the kernel-distinctness ledger, and the standard-boundary row.

Apply Definition 530.3 for the public handoff and Definition 530.5 for the local name. The resulting normal form is therefore N, A, B, K, S, M with L, H, C, P as the displayed support rows, and it has no quotient or host natural-number equality coordinate. □

Theorem 530.12 (UnaryDirectionBridge carrier admission)**.** *For the finite packet $U = (N, A, B, K, S, L, H, C, P, M$ over* $\mathsf{Nat}^{\uparrow}$, $\mathsf{AxisNat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{AxisAdd}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert, *admission to the* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *surface is exactly admission of the ten displayed rows of Definition 530.1. The admitted packet exposes the unary source row, zero-spine source row, bridge row, kernel-distinctness ledger, standard-boundary row, ledger policy, componentwise transports, continuation routes, package provenance, and local naming row, and it exposes no additional carrier coordinate.*

Proof. Start with the carrier description of Definition 530.1. It lists $N, A, B, K, S, L, H, C, P, M$ as the complete finite packet over the named source, bridge, history, transport, continuation, package, and naming surfaces.

Apply the kernel-distinct obligations of Definition 530.2 and the standard boundary of Definition 530.3. These identify the source rows, the bridge row, the kernel ledger, and the public boundary as displayed rows of the same packet.

Use the ledger policy of Definition 530.4, the NameCert surface of Definition 530.5, and the AxisAdd handoff of Definition 530.9. Together they force every admitted read through the packet rows and leave no extra carrier coordinate.

Finally, the empty-intersection readback of Definition 530.10 and the consumer normal form of Definition 530.11 exclude host equality, quotient identification, and a second kernel carrier. Thus admission is exactly the finite ledger packet. □

Theorem 530.13 (UnaryDirectionBridge classifier stability)**.** *For an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet $U = (N, A, B, K, S, L, H, C, P, M)$, componentwise* hsame *transport by the stored row H preserves the unary source classifier, the zero-spine source classifier, the bridge classifier, the kernel-distinctness ledger, the standard-boundary route, the ledger policy, the continuation routes, the package provenance, and the local* NameCert *row. After transport, the packet still presents the same kernel-distinctness ledger and the same standard-boundary route.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier classifier stability`

Proof. Project H from the carrier of Definition 530.1. By construction it stores componentwise transports for the two source rows, bridge row, kernel-distinctness witness, standard-boundary row, ledger policy row, and local naming row.

Apply Definition 530.2. Since K remains a transported row rather than an equality coordinate, the transported classifiers cannot collapse the $\mathsf{Nat}^{\uparrow}$ and $\mathsf{AxisNat}^{\uparrow}$ carriers.

Use Definition 530.3 and Definition 530.9 for the boundary route. The transported standard-boundary row is the only route available to $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ consumers.

The ledger policy, NameCert surface, empty-intersection readback, and consumer normal form of Definition 530.4, Definition 530.5, Definition 530.10, and Definition 530.11 then keep every classifier read inside the displayed packet. Hence componentwise transport preserves both the kernel-distinctness ledger and the standard-boundary route. □

Theorem 530.14 (UnaryDirectionBridge ledger exactness)**.** *Every consumer route out of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet is exhausted by* $N, A, B, K, S, L, H, C, P, M$*. There is no consumer route through host equality of natural numbers, no quotient identification of histories, and no collapse of the* $\mathsf{Nat}^{\uparrow}$ *unary carrier with the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine carrier.*

Proof. Begin with the finite carrier in Definition 530.1. Its rows are exactly $N, A, B, K, S, L, H, C, P, M$, so any consumer route must be assembled from these rows.

Apply the kernel-distinct obligations and standard boundary from Definition 530.2 and Definition 530.3. They require the source rows and K before any public boundary read.

Next use the ledger policy, NameCert surface, and AxisAdd handoff of Definition 530.4, Definition 530.5, and Definition 530.9. These force consumer access through the displayed ledger and then through the local naming row.

Finally apply the empty-intersection readback of Definition 530.10 and the consumer normal form of Definition 530.11. They rule out any second intersection, quotient route, or host equality coordinate, so the displayed finite ledger is exact. □

Theorem 530.15 (UnaryDirectionBridge source-classifier transport)**.** *For an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *carrier* $U = (N, A, B, K, S, L, H, C, P, M)$*, componentwise* hsame *transport of* $N, A, B, K, S, L, H, C, P, M$ *preserves the separate* $\mathsf{Nat}^{\uparrow}$ *unary source classifier and the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine source classifier. The transported packet keeps the two source classifiers as distinct rows and does not collapse them into a kernel equality.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier source classifier transport`

Proof. Project the carrier of Definition 530.1. Rows N and A are separate source rows, while H supplies componentwise transport for those rows together with the bridge, ledger, route, provenance, and local name.

Apply Definition 530.2. The kernel-distinctness row K must be read before any comparison, so transport cannot replace the two classifiers by a shared kernel carrier.

Use Definition 530.10 to keep the empty-history row as the only exposed kernel intersection. Thus the transported source classifiers remain the unary $\mathsf{Nat}^{\uparrow}$ row and the zero-spine $\mathsf{AxisNat}^{\uparrow}$ row separately. □

Theorem 530.16 (UnaryDirectionBridge additive consumer exactness)**.** *Every* $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ *consumer of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *carrier reads the standard-boundary row only after the source rows, bridge row, kernel-distinctness ledger, ledger policy, transports, routes, provenance, and local* NameCert *row are present. The consumer receives the rows* $N, A, B, K, S, L, H, C, P, M$ *in that order of dependence and receives no kernel equality between* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{AxisNat}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier additive consumer exactness`

Proof. Start with the consumer normal form of Definition 530.11. It limits every consumer route to the source rows, bridge row, kernel-distinctness ledger, standard-boundary row, local name, and the displayed support rows.

Apply Definition 530.9. This requires $N, A, B, K, S, L, H, C, P, M$ to be present before the $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ handoff is licensed.

The standard-boundary theorem Definition 530.3 supplies the public boundary only after those rows have been transported. The ledger policy of Definition 530.4 rules out any consumer route that skips the source rows or exports a host equality. □

Theorem 530.17 (UnaryDirectionBridge NameCert obligation closure)**.** *The carrier, kernel-distinctness obligations, standard boundary, ledger policy, consumer normal form, source-classifier transport, and additive consumer exactness assemble the local* $\mathsf{NameCert}_{\mathsf{UnaryDirectionBridge}^{\uparrow}}$ *obligation closure for* $U = (N, A, B, K, S, L, H, C, P, M)$*. The closure keeps the unary and zero-spine kernels distinct while presenting the finite bridge packet required by downstream additive consumers.*

Proof. The carrier of Definition 530.1 supplies the finite packet. The kernel-distinctness obligations, standard boundary, ledger policy, and NameCert surface of Definition 530.2, Definition 530.3, Definition 530.4, and Definition 530.5 bind the basic certificate rows.

Add the handoff obligations and empty-intersection readback from Definition 530.9 and Definition 530.10. These keep additive consumers on the displayed standard boundary and prevent a second kernel intersection from appearing.

Finally apply Definition 530.11, Definition 530.15, and Definition 530.16. The resulting local NameCert obligation closure is exactly the displayed bridge packet, with no asserted kernel equality. □

Theorem 530.18 (UnaryDirectionBridge scoped source bindings)**.** *For an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *carrier* $U = (N, A, B, K, S, L, H, C, P, M)$*, the rows* $N, A, B, K, S, L, H, C, P, M$ *bind the bridge packet to* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{AxisNat}^{\uparrow}$*,* $\mathsf{Add}^{\uparrow}$*,* $\mathsf{AxisAdd}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. The binding is scoped to the displayed carrier rows:* N *and* A *are the two source classifiers,* B, K, S, L *are the bridge, kernel-distinctness, boundary, and policy rows,* H *and* C *are the transport and continuation rows,* P *is the package provenance row, and* M *is the local naming row.*

Proof. Project the carrier of Definition 530.1. The row list already names the two source surfaces, the bridge object, the kernel ledger, the boundary, the policy, the transport, the route, the package row, and the local $\mathsf{NameCert}$ row.

Apply Definition 530.2. This keeps N and A as separate source classifiers and forces every comparison to cite K before a public boundary is read.

Use Definition 530.3 for the S row and Definition 530.4 for the L row. The transport and route rows H, C carry these displayed rows without creating a host equality or quotient coordinate.

Finally apply Definition 530.5. The provenance row P and local name M therefore bind the packet to the listed BEDC dependencies as scoped rows of the same finite carrier. □

Theorem 530.19 (UnaryDirectionBridge additive route scope)**.** *Every* $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ *handoff route out of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet factors through* K, S, H, C, P, M *together with the source rows* N, A *and the bridge row* B*. Such a route cannot use host equality of natural numbers, quotient identification of histories, or a second kernel carrier for the unary and zero-spine sources.*

Proof. Start with the additive consumer exactness of Definition 530.16. It says that an $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ consumer receives the displayed source, bridge, kernel, policy, transport, route, provenance, and local naming rows before the boundary is used.

Apply the source-classifier transport theorem Definition 530.15. The transported packet still has separate $\mathsf{Nat}^{\uparrow}$ and $\mathsf{AxisNat}^{\uparrow}$ source rows, so the additive route cannot be reinterpreted as a single kernel carrier.

Use the empty-intersection readback of Definition 530.10 and the consumer normal form of Definition 530.11. These exclude a second kernel intersection, quotient identification, and host equality from the normalized route.

The remaining route is therefore exactly the displayed additive handoff through K, S, H, C, P, M, with N, A, B supplying the source and bridge context. □

Theorem 530.20 (UnaryDirectionBridge scoped NameCert package)**.** *The scoped source bindings of Definition 530.18, the additive route scope of Definition 530.19, and the obligation closure of Definition 530.17 assemble the scoped* $\mathsf{NameCert}_{\mathsf{UnaryDirectionBridge}^{\uparrow}}$ *package. The package exposes the carrier rows, the obligation closure, the scoped BEDC dependency bindings, and the additive handoff route, while preserving the separation of* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{AxisNat}^{\uparrow}$ *inside the kernel.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier namecert scoped package`

Proof. Begin with Definition 530.17. It supplies the local closure of the carrier, kernel-distinctness obligations, standard boundary, ledger policy, consumer normal form, source-classifier transport, and additive consumer exactness.

Apply Definition 530.18. This binds the same finite packet to $\mathsf{Nat}^{\uparrow}$, $\mathsf{AxisNat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{AxisAdd}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ through displayed carrier rows.

Apply Definition 530.19. The additive route is then confined to the scoped bridge packet and cannot pass through host equality, quotient identification, or a second kernel carrier.

Repacking these rows gives the scoped local $\mathsf{NameCert}$ package for $\mathsf{UnaryDirectionBridge}^{\uparrow}$. Its public commitment is the displayed BEDC bridge packet, not an identification of the two source kernels. □

Theorem 530.21 (UnaryDirectionBridge kernel-axis composition)**.** *For an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *carrier* $U = (N, A, B, K, S, L, H, C, P, M)$*, the kernel-distinct obligations, standard boundary, and* $\mathsf{AxisAdd}^{\uparrow}$ *handoff assemble one* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *route from the unary direction row* N *to the additive consumer row. The route reads* $A, B, K, S, L, H, C, P, M$ *as displayed support and never identifies the unary and zero-spine classifiers as one kernel carrier.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier kernel axis composition`

Proof. Project the carrier and begin with the kernel-distinct obligations of Definition 530.2. They force the route to read the $\mathsf{Nat}^{\uparrow}$ row N, the $\mathsf{AxisNat}^{\uparrow}$ row A, the bridge row B, and the kernel ledger K before any additive handoff is considered.

Next apply the standard boundary of Definition 530.3. The boundary row S is reached only after the source rows and K have been transported through H and replayed through C.

Finally use Definition 530.9 and Definition 530.16. These results place the $\mathsf{AxisAdd}^{\uparrow}$ consumer behind the same displayed packet and repack the route through L, P, M as policy, provenance, and local naming data. The resulting composition is a projection-and-route composition, not a carrier equivalence. □

Theorem 530.22 (UnaryDirectionBridge bidirectional readback)**.** *For accepted left and right direction reads of a* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet, if their displayed* hsame *rows and* Cont *rows agree, then both reads transport to the same empty-intersection readback surface. The common surface is the* K*-licensed intersection row together with the standard boundary and local NameCert rows, not an equivalence between the source classifiers.*

Proof. Start with the two direction reads and project their carrier rows. Agreement of the displayed hsame and Cont rows means both reads use the same transport H and the same route family C.

Apply Definition 530.10. The only kernel intersection exposed by either read is the empty-history row licensed by K.

Use Definition 530.15 to keep the unary and zero-spine classifiers separate after transport. Then apply Definition 530.3 and Definition 530.5 to place both reads on the same public boundary and local certificate surface.

Thus the left and right reads agree at the empty-intersection readback surface while preserving the source-classifier separation. □

Theorem 530.23 (UnaryDirectionBridge downstream seal)**.** *Every downstream* $\mathsf{AxisAdd}^{\uparrow}$ *or* $\mathsf{AxisZeckendorfCannot}$ *consumer reads an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet only through the carrier, kernel-distinct classifier rows, ledger policy, source-classifier transport, and additive consumer exactness rows. The downstream seal exports the bridge as the displayed packet* $U = (N, A, B, K, S, L, H, C, P, M)$ *and exports no quotient identification, host natural-number equality, or carrier equivalence between* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{AxisNat}^{\uparrow}$*.*

Proof. Begin with carrier admission and ledger policy, Definition 530.12 and Definition 530.4. They restrict every downstream read to the ten displayed rows and order the read through the source, bridge, kernel, boundary, policy, transport, route, provenance, and naming data.

For the classifier side, apply Definition 530.2, Definition 530.13, and Definition 530.15. These keep N and A as separate source classifiers under componentwise transport.

For the consumer side, use Definition 530.16 and Definition 530.21. The $\mathsf{AxisAdd}^{\uparrow}$ route and any $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ consumer that depends on it can therefore read only the displayed bridge packet.

The empty-intersection readback excludes any second kernel overlap, and the consumer normal form excludes host equality and quotient identification. Hence the downstream seal is the packet route itself, not a carrier/classifier equivalence transport. □

Theorem 530.24 (UnaryDirectionBridge scoped source anchors)**.** *Every accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet* $U = (N, A, B, K, S, L, H, C, P, M)$ *binds the* $\mathsf{Nat}^{\uparrow}$ *unary source, the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine source, the kernel-distinctness ledger, and the standard-boundary row to the displayed support*

$$\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The binding is a source-route obligation: N *and* A *remain separate source classifiers,* K *records their kernel separation,* S *is the only standard-boundary row, and* L, H, C, P, M *are the ledger, transport, continuation, provenance, and local certificate rows through which downstream consumers read the packet.*

Proof. Start with the carrier and carrier admission results, Definition 530.1 and Definition 530.12. They make $N, A, B, K, S, L, H, C, P, M$ the complete admitted packet surface and place the source rows, bridge row, ledger row, boundary row, transport rows, route row, package row, and local name in one carrier.

Apply the kernel-distinct obligations and standard boundary, Definition 530.2 and Definition 530.3. These force every source comparison to read K before S and prevent the unary and zero-spine source classifiers from being merged.

Use the ledger policy, classifier stability, and ledger exactness of Definition 530.4, Definition 530.13, and Definition 530.14. The only stable transport route is the displayed H, C, P, M route, so every accepted source read is anchored to the listed BEDC support.

Finally apply the obligation closure of Definition 530.17. It repacks these rows as the local $\mathsf{NameCert}_{\mathsf{UnaryDirectionBridge}^{\uparrow}}$ obligation surface, with no additional kernel equality or host natural-number route. □

Theorem 530.25 (UnaryDirectionBridge scoped additive route)**.** *Every* $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ *consumer route out of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet factors through the scoped source anchors of Definition 530.24 before reaching the standard boundary. Thus the additive route receives the unary source, zero-spine source, bridge row, kernel-distinctness ledger, ledger policy, componentwise* hsame *transport,* Cont *route,* Pkg *provenance, and local* NameCert *row before any standard-boundary read.*

Proof. First apply the scoped source anchors. They bind $N, A, B, K, S, L, H, C, P, M$ to the finite BEDC support and make K available before the standard-boundary row is consumed.

Next use the additive consumer exactness and additive route scope, Definition 530.16 and Definition 530.19. These results identify the $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ route as a consumer of the displayed packet, not as a separate operation over host equality or quotient histories.

The carrier admission theorem and ledger policy keep the route inside the admitted rows. The standard-boundary theorem then places S after the source and kernel-distinctness anchors, while classifier stability transports the same route through H, C, P, M.

Finally the obligation closure repacks the route as a downstream obligation of the same local certificate. The consumer therefore reaches the boundary only through the scoped source anchors and the displayed bridge packet. □

Theorem 530.26 (UnaryDirectionBridge scoped NameCert transport)**.** *Componentwise* hsame *transport of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet preserves the scoped bridge packet of Definition 530.24 and the additive route of Definition 530.25. The transported packet cannot collapse the* $\mathsf{Nat}^{\uparrow}$ *unary source classifier and the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine source classifier into one kernel row.*

Proof. Begin with classifier stability and source-classifier transport, Definition 530.13 and Definition 530.15. They state that componentwise transport preserves the source rows, bridge row, kernel ledger, standard-boundary row, route rows, package provenance, and local naming row.

Apply the scoped source anchors to the transported packet. The anchors still require N and A as separate source classifiers and still require K before any comparison reaches S.

Use ledger exactness, ledger policy, and the standard boundary. These exclude host natural-number equality, quotient identification of histories, and any second kernel carrier as sources for the transported route.

Finally combine the scoped additive route with the obligation closure. The resulting transported $\mathsf{NameCert}_{\mathsf{UnaryDirectionBridge}^{\uparrow}}$ packet is the same finite bridge surface over BHist, hsame, Cont, Pkg, NameCert, so transport preserves the route without identifying the two source classifiers. □

Theorem 530.27 (UnaryDirectionBridge standard-boundary consumer factorization)**.** *Every* $\mathsf{Add}^{\uparrow}$ *or* $\mathsf{AxisAdd}^{\uparrow}$ *consumer of the standard boundary of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet*

$$U = (N, A, B, K, S, L, H, C, P, M)$$

factors through the displayed unary source row N, zero-spine source row A, bridge row B, kernel-distinctness ledger K, standard-boundary row S, ledger policy L, componentwise transports H, continuation routes C, package provenance P, and local name M. The consumer receives no carrier equivalence between $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{AxisNat}^{\uparrow}$*, no host natural-number equality, and no quotient identification of histories.*

Proof. Start from carrier admission and the standard-boundary theorem. They make S a row of the accepted packet and place it after the source rows, bridge row, and kernel-distinctness ledger.

Apply the scoped source anchors. They require $N, A, B, K, S, L, H, C, P, M$ before any boundary consumer can read the packet, and they keep the unary and zero-spine source classifiers separate.

Now use the scoped additive route and additive consumer exactness. These route every $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ read through the displayed bridge packet rather than through a host-side equality or a quotient transport.

Finally apply scoped NameCert transport. Componentwise transport preserves the same packet surface, so any standard-boundary consumer factors through the displayed rows and through no alternate carrier/classifier equivalence. □

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier standard boundary consumer factorization`

Theorem 530.28 (UnaryDirectionBridge public axis readback)**.** *Every public consumer of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet*

$$U = (N, A, B, K, S, L, H, C, P, M)$$

reads the $\mathsf{Nat}^{\uparrow}$ *source carrier, the* $\mathsf{AxisNat}^{\uparrow}$ *source carrier, the* $\mathsf{Add}^{\uparrow}$ *surface, and the* $\mathsf{AxisAdd}^{\uparrow}$ *surface through the same displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route. The axis row cannot be replaced by the ordinary unary row, and the ordinary unary row cannot be replaced by the axis row.*

Lean4 ✓ `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier public axis readback`

Proof. Begin with the source obligation inventory of Definition 530.6. It lists the unary source row N, the zero-spine source row A, the additive surfaces read through S, and the support rows H, C, P, M as one finite packet.

Next apply kernel-axis composition from Definition 530.21. The kernel-distinctness ledger K must be read before the standard-boundary row S, so the ordinary unary and axis rows remain separate while they enter one public route.

Finally use the standard-boundary consumer factorization of Definition 530.27. It routes every $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ consumer through $N, A, B, K, S, L, H, C, P, M$ and excludes carrier equivalence, host natural-number equality, and quotient identification of histories. Hence the public readback composes the Nat/Add and AxisNat/AxisAdd surfaces without substituting one source row for the other. □

Theorem 530.29 (UnaryDirectionBridge AxisZeckendorf ledger gate)**.** *Any* $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ *consumer of an accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet must read the kernel-distinctness ledger K and the additive route through $N, A, B, S, L, H, C, P, M$ before it can see the bridge as a downstream obstruction. In particular, the consumer cannot bypass the ledger by identifying the* $\mathsf{Nat}^{\uparrow}$ *unary source classifier with the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine source classifier.*

Proof. Project the accepted packet. The carrier and kernel-distinct obligations expose K as the row that separates the unary and zero-spine source classifiers.

Use the ledger policy and ledger exactness. They make K and L mandatory for downstream reads and exclude host equality, quotient identification, or a second kernel carrier as substitute evidence.

Apply additive consumer exactness, kernel-axis composition, and the downstream seal. These results route $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ consumers through the additive bridge packet before the obstruction row is visible.

Therefore the bridge can be consumed only after the kernel-distinctness ledger and additive route have been read from the same displayed packet. □

Theorem 530.30 (UnaryDirectionBridge root-unblock readback package)**.** *The accepted* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *packet* $U = (N, A, B, K, S, L, H, C, P, M)$ *forms a root-unblock readback package for downstream* $\mathsf{Add}^{\uparrow}$, $\mathsf{AxisAdd}^{\uparrow}$, *and* $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ *consumers. The package consists exactly of carrier admission, kernel-distinct classifier rows, ledger exactness, the standard-boundary consumer factorization of Definition 530.27, the AxisZeckendorf ledger gate of Definition 530.29, scoped NameCert transport, and the downstream seal.*

Proof. Begin with carrier admission. It fixes the readback packet as the ten displayed rows $N, A, B, K, S, L, H, C, P, M$.

Add the kernel-distinct obligations and ledger exactness. These make the source classifiers separate at the kernel row and make the ledger the public witness for that separation.

Use standard-boundary consumer factorization to bind $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ consumers to the same packet. Use the AxisZeckendorf ledger gate to ensure that obstruction-facing consumers read the ledger and additive route before the bridge can be consumed.

Finally combine scoped NameCert transport with the downstream seal. The assembled package exports the bridge as the displayed finite readback surface and does not export carrier equivalence transport, host natural-number equality, or quotient identification. □

Closure status for $\mathsf{NameCert}_{\mathsf{UnaryDirectionBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{UnaryDirectionBridge}^{\uparrow}$ packet is generated by a $\mathsf{Nat}^{\uparrow}$ unary source row, an $\mathsf{AxisNat}^{\uparrow}$ zero-spine source row, the displayed bridge object, kernel-distinctness witness, standard-boundary row, ledger policy, hsame transports, Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UnaryDirectionBridge}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The public surface is the $\mathsf{Nat}^{\uparrow}/\mathsf{AxisNat}^{\uparrow}$ and $\mathsf{Add}^{\uparrow}/\mathsf{AxisAdd}^{\uparrow}$ readback through Definition 530.27 and Definition 530.28, with the kernel-distinct ledger and displayed BHist, hsame, Cont, Pkg, and NameCert route still visible.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UnaryDirectionBridge}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.UnaryDirectionBridgeUp.UnaryDirectionBridgeCarrier\_public\_axis\_readback`

Bridge status: none

Origin: human

Not claimed: This chapter does not identify $\mathsf{Nat}^{\uparrow}$ and $\mathsf{AxisNat}^{\uparrow}$ inside the kernel, close the full standard-model isomorphism, or assert bridge checking for the unary-direction bridge packet.

Upgrade path: No paper-side theory-grade upgrade remains for the displayed public-axis readback; bridge checking is still not claimed.

Chapter 531

ClosedSubstitutionSeal NameCert Construction

The $\mathsf{ClosedSubstitutionSeal}^{\uparrow}$ interface packages the closed-term substitution boundary as a finite naming certificate over the MetaCIC syntax rows. It records the source term, the closure depth, the substitution payload, the closedness classifier, the inert substitution row, the inert shift row, the audit row, and the self-compilation handoff. The audit row A is read through chapter 779 before the self-compilation handoff is consumed. A consumer can cite the packet as a local compiler boundary, but it cannot read semantic substitution correctness for open terms, subject reduction for the full evaluator, or a host truth predicate.

Definition 531.1 (Closed-term substitution seal carrier)**.** *A* $\mathsf{ClosedSubstitutionSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, D, V, Q, L, M, A, K, H, C, P, N)$$

with the following displayed rows:

1. *T is the MetaCIC* `Term` *row consumed by the compiler boundary;*
2. *D is the de Bruijn depth row at which the boundary is read;*
3. *V is the substitution payload term carried through the traversal;*
4. *Q is the* `ClosedAt` *classifier row certifying that T is closed at D;*
5. *L is the inert substitution row displaying* $\texttt{substitute}(D, V, T) = T$*;*
6. *M is the inert shift row displaying the matching closed-boundary shift equality for T;*
7. *A is the axiom-pure audit row tying the displayed equalities to the records-side MetaCIC proof surface;*
8. *K is the self-compilation handoff row by which downstream compiler stages read only T, D, V, Q, L, M, A;*
9. *H stores componentwise* hsame *transports for the term, depth, payload, closedness classifier, inert rows, audit row, and handoff row;*
10. *C stores displayed* Cont *routes for reading the classifier, the inert substitution row, the inert shift row, the audit row, and the handoff row;*
11. *P is the* Pkg *provenance over* `Term`*,* `ClosedAt`*, substitution, shift, audit, self-compilation,* hsame*,* Cont*, and* NameCert*;*

12. N is the local $\mathsf{NameCert}_{\mathsf{ClosedSubstitutionSeal}^{\uparrow}}$ *row.*
The carrier contains no open-term semantic substitution theorem, no full evaluator subject-reduction theorem, no compiler completeness theorem, and no host truth predicate.

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionSealUp.ClosedSubstitutionSealTasteGate single carrier alignment`

Theorem 531.2 (Closed substitution seal boundary)**.** *For every accepted* $\mathsf{ClosedSubstitutionSeal}^{\uparrow}$ *packet* $S = (T, D, V, Q, L, M, A, K, H, C, P, N)$*, the only substitution-facing boundary exported to a downstream consumer is the displayed route through the closedness classifier* Q*, the inert substitution row* L*, the inert shift row* M*, the audit row* A*, the self-compilation handoff* K*, and the transport, continuation, package, and local naming rows* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionSealUp.ClosedSubstitutionSealBoundary`

Proof. Project the carrier of Definition 531.1. The term, depth, payload, closedness classifier, inert substitution row, inert shift row, audit row, handoff row, transports, continuations, provenance, and local naming row are all explicit coordinates of the same finite packet.

The substitution-facing consumer must therefore read Q before reading L. The row L is displayed only at the closed boundary certified by Q, while M records the corresponding binder-shift boundary for the same term row.

The remaining rows A, K, H, C, P, N route and name that finite surface. Since the carrier lists no semantic substitution theorem for open terms and no full evaluator theorem, the exported boundary is exactly the closed substitution seal. □

Theorem 531.3 (Closed substitution compile safety)**.** *Any self-compilation consumer of an accepted* $\mathsf{ClosedSubstitutionSeal}^{\uparrow}$ *packet factors through the handoff row* K*. That row exposes only the source term* T*, depth* D*, payload* V*, closedness classifier* Q*, inert substitution row* L*, inert shift row* M*, audit row* A*, displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and the local* NameCert *row. It does not expose a route by which the payload* V *becomes a free name in* T*.*

Proof. Start with the handoff coordinate K. By definition it is the self-compilation row attached to the same source term, depth, payload, classifier, inert rows, and audit row as the carrier.

The consumer reads Q first. Once Q is fixed, the inert substitution row L states that the substitution attempt at depth D returns T, and the inert shift row M states that the corresponding boundary shift spends no extra name budget for that closed term.

Finally route the result through A, H, C, P, N. These rows certify audit visibility, componentwise transport, continuation replay, provenance, and local naming; none is a payload-injection coordinate. Thus the compile-facing safety claim is a finite non-escape property of the displayed packet. □

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionSealUp.ClosedSubstitutionSeal compile safety`

Theorem 531.4 (Closed substitution audit surface)**.** *The audit surface of a* $\mathsf{ClosedSubstitutionSeal}^{\uparrow}$ *packet is exhausted by the MetaCIC* `Term` *row, the* `ClosedAt` *classifier, the displayed substitution and shift equalities, the self-compilation handoff, componentwise* hsame *transports, displayed* Cont *routes, package provenance, and the local* NameCert *row. It supplies no unchecked semantic equality, no global compiler theorem, no full subject-reduction theorem, and no host-side truth predicate.*

Proof. Read the packet through Definition 531.2. The boundary exposes the term, classifier, inert substitution row, inert shift row, audit row, handoff row, and the rows that transport, replay, package, and name them.

Read the compiler-facing route through Definition 531.3. The consumer of self-compilation sees only the closed-boundary handoff and cannot project a free-name injection route for the substitution payload.

These two readings exhaust the carrier inventory from Definition 531.1. Since none of the displayed coordinates is an unchecked semantic equality, a global compiler theorem, a full subject-reduction theorem, or a host truth predicate, the audit surface is exactly the finite NameCert packet. □

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionSealUp.ClosedSubstitutionSealAudit surface`

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedSubstitutionSeal}\uparrow}$.

Constructive story: A $\mathsf{ClosedSubstitutionSeal}^{\uparrow}$ packet is generated from a MetaCIC term row, a depth row, a substitution payload, a `ClosedAt` classifier, displayed inert substitution and shift rows, an audit row, a self-compilation handoff row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedSubstitutionSeal}\uparrow}, \mathsf{seed})$

Scope closed: Definition 531.1, Definition 531.2, Definition 531.3, and Definition 531.4 specify the finite closed-substitution seal carrier, non-escape boundary, compiler handoff, and audit surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedSubstitutionSeal}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close open-term semantic substitution, full evaluator subject reduction, compiler completeness, host truth predicates, or bridge checking.

Upgrade path: Obligation closure requires Lean encoding of the packet and checked theorems for classifier transport, inert substitution, inert shift, audit visibility, and self-compilation handoff.

Chapter 532

A Concrete Naming Certificate for $\mathsf{BinderBudgetSeal}^{\uparrow}$

The $\mathsf{BinderBudgetSeal}^{\uparrow}$ surface turns closed-term substitution into finite NameCert data. It records the binder-depth boundary at which a MetaCIC term is closed, the shift route at that boundary, the substitution route at the same boundary, and the consumer handoff that lets self-compilation read the boundary without receiving an unregistered free variable.

The upstream boundary is the closed-term substitution surface of chapter 527. Its depth row, closed term row, shift and substitution boundary rows, and non-escape ledger supply the exact boundary data that $\mathsf{BinderBudgetSeal}^{\uparrow}$ repackages as a binder-budget seal.

Definition 532.1 (BinderBudgetSeal carrier)**.** *A* $\mathsf{BinderBudgetSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, T, V, S, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the binder-depth budget row naming the finite boundary at which the term is certified closed;*
2. *T is the MetaCIC term row whose free variables are contained below the boundary named by D;*
3. *V is the displayed substitution payload row, allowed to be inspected only through the boundary route;*
4. *S is the shift route row recording that shifting at the closed boundary returns the same term;*
5. *U is the substitution route row recording that substitution at the closed boundary returns the same term;*
6. *H records the componentwise* hsame *transports for the depth, term, payload, shift, substitution, package, and local naming rows;*
7. *C records the displayed* Cont *routes by which self-compilation consumers read D, T, V, S, U without leaving the finite packet;*
8. *P is the* Pkg *provenance row over* BHist, hsame, Cont, *the MetaCIC closed-term syntax rows, and local certificate dependencies;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BinderBudgetSeal}^{\uparrow}}$ *row.*

The local classifier compares two accepted carriers only by the displayed binder-depth row, term row, payload row, shift route, substitution route, and their recorded hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *provenance.*

Theorem 532.2 (BinderBudgetSeal NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{BinderBudgetSeal}^{\uparrow}}$ *surface for Definition 532.1 has five finite obligations: expose the binder-depth carrier* $B = (D, T, V, S, U, H, C, P, N$ *restrict comparison to the displayed depth, term, payload, route, transport, package, and local naming rows; route shift reads through the closed-boundary row* S*; route substitution reads through the closed-boundary row* U*; and exclude any export of fresh free variables, host capture-avoidance primitives, quotient syntax equality, or compiler-stage equality outside the packet.*

Lean4 ✓ `BEDC.Derived.BinderBudgetSealUp.BinderBudgetSealTasteGate single carrier alignment`

Proof. Carrier exposure is projection from the finite tuple. The binder-depth row, term row, payload row, shift route, substitution route, transport rows, continuation routes, package provenance, and local naming row are all displayed coordinates.

Classifier locality follows from the last sentence of the carrier definition. A comparison cannot inspect a hidden syntax quotient, a host-level capture-avoidance predicate, or a compiler-stage equality because no such coordinate is present.

The two route obligations are read from S and U. The shift route records the closed-boundary non-escape law, and the substitution route records the matching non-escape law for the displayed payload. Thus every consumer reaches the closed-term boundary before it can read binder movement or substitution data. □

Theorem 532.3 (BinderBudgetSeal shift non-escape)**.** *For an accepted* $\mathsf{BinderBudgetSeal}^{\uparrow}$ *carrier* $B = (D, T, V, S, U, H, C, P, N)$*, every shift request at the boundary named by* D *factors through the displayed route* S *before the term row* T *is returned to a consumer. The route exports the same MetaCIC term row and no fresh free variable, depth extension, quotient syntax equality, or host binder operation.*

Lean4 ✓ `BEDC.Derived.BinderBudgetSealUp.BinderBudgetSealShiftNonescape`

Proof. Begin with the binder-depth coordinate. The row D names the finite closed boundary for the term row T, so a shift request at that boundary must first read D.

Next read the shift route S. The route is the packet coordinate that records the closed-boundary identity for binder movement, so the consumer receives T through the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Finally apply the non-escape clause of the NameCert obligations. Since the carrier has no coordinate for a new free variable, depth extension, syntax quotient, or host binder operation, the shift request cannot export any such object. □

Theorem 532.4 (BinderBudgetSeal substitution non-escape)**.** *For an accepted* $\mathsf{BinderBudgetSeal}^{\uparrow}$ *carrier* $B = (D, T, V, S, U, H, C, P, N)$*, every substitution request at the boundary named by* D *factors through the displayed route* U *before the term row* T *is returned to a consumer. The payload row* V *is read only as boundary data, and the route exports no substituted free variable, host capture-avoidance primitive, quotient syntax equality, or compiler-stage equality outside the finite packet.*

Lean4 ✓ `BEDC.Derived.BinderBudgetSealUp.BinderBudgetSealSubstitutionNonescape`

Proof. Start from the closed-boundary row D and the term row T. The substitution request is accepted only at the boundary named by D, so the payload row V is not a separate source of free-variable data.

Read the substitution route U. This row records the closed-boundary return of the original term, and the continuation routes in C let a consumer inspect that result without leaving the packet.

Use the NameCert boundary obligation. Because the carrier contains no field for host capture avoidance, quotient syntax equality, compiler-stage equality, or a fresh substituted free variable, the substitution request is exhausted by D, T, V, U and the displayed provenance rows. □

Theorem 532.5 (BinderBudgetSeal self-compile handoff)**.** *Every self-compilation consumer that receives an accepted* $\mathsf{BinderBudgetSeal}^{\uparrow}$ *carrier receives a finite packet over the same binder-depth row, MetaCIC term row, substitution payload row, shift route, substitution route,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. The handoff is exactly the closed-boundary budget for shift and substitution non-escape, and it does not claim full compiler closure, normalization, definitional equality, quotient syntax equality, or ambient host soundness.*

Proof. First bind the shift side. By Definition 532.3, a boundary shift request reads D and S before returning the displayed term row.

Next bind the substitution side. By Definition 532.4, a boundary substitution request reads D, T, V, and U before any consumer can inspect the result.

Now assemble the consumer packet. The displayed transports, continuation routes, package provenance, and local certificate rows are the only comparison and handoff data named by Definition 532.2.

The remaining exclusions follow from the same carrier inventory. No coordinate supplies full compiler closure, normalization, definitional equality, quotient syntax equality, or host soundness, so the handoff is exactly the finite binder-budget boundary for shift and substitution non-escape. □

Lean4 ✓ `BEDC.Derived.BinderBudgetSealUp.BinderBudgetSealSelfCompileHandoff`

Definition 532.6 (BinderBudgetSeal obligation surface)**.** *The* $\mathsf{BinderBudgetSeal}^{\uparrow}$ *obligation surface is the single-carrier packet*

$$B = (D, T, V, S, U, H, C, P, N)$$

of Definition 532.1, equipped with four displayed rows: carrier admission for the binder-depth boundary and closed term; route admission for the shift row S and substitution row U; compiler-boundary handoff through the same hsame*,* Cont*,* Pkg*, and local* NameCert *rows; and non-escape for fresh variables, host capture-avoidance primitives, quotient syntax equality, compiler-stage equality, and ambient host soundness. The TasteGate alignment marker above is read as a single-carrier constraint on this packet, not as permission to introduce a second compiler carrier.*

Lean4 ✓ `BEDC.Derived.BinderBudgetSealUp.BinderBudgetSealObligationSurface`

Theorem 532.7 (BinderBudgetSeal carrier admission)**.** *An accepted* $\mathsf{BinderBudgetSeal}^{\uparrow}$ *obligation surface admits exactly the carrier rows $D, T, V, S, U, H, C, P, N$. The binder-depth row D, term row T, and payload row V are inspected only through the shift and substitution routes S, U and the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *rows; the AI-origin TasteGate marker keeps this admission on the same carrier.*

Lean4 ✓ `BEDC.Derived.BinderBudgetSealUp.BinderBudgetSealCarrierAdmission`

Proof. Project the carrier of Definition 532.1. The rows named by the obligation surface are precisely the displayed finite coordinates.

Use the TasteGate alignment recorded after Definition 532.2 as the carrier discipline. It aligns the checked marker with the same packet B, so carrier admission cannot allocate a separate compiler input, output, or ambient syntax object.

The remaining access paths are the route rows and certificate rows already named by the carrier. Thus admission is exactly the single finite surface $D, T, V, S, U, H, C, P, N$. □

Theorem 532.8 (BinderBudgetSeal compiler boundary)**.** *Every compiler or self-compilation read of an accepted* $\mathsf{BinderBudgetSeal}^{\uparrow}$ *obligation surface factors through the closed-boundary routes S and U before it may inspect the term row T or payload row V. The boundary exports the same carrier $B = (D, T, V, S, U, H, C, P, N)$ and no second carrier for compiler closure, normalization, definitional equality, quotient syntax equality, or host soundness.*

Proof. Start with the self-compile handoff of Definition 532.5. It already requires a consumer to receive the binder-depth, term, payload, shift, substitution, transport, continuation, package, and naming rows as one packet.

The shift and substitution non-escape theorems force the two compiler-facing reads through S and U. These rows both reference the same binder-depth boundary D, so the compiler boundary is not a separate stage carrier.

Finally apply the obligation surface. Since it lists no coordinate for compiler closure, normalization, definitional equality, quotient syntax equality, or host soundness, such data cannot be exported by the boundary. □

Lean4 ✓ `BEDC.Derived.BinderBudgetSealUp.BinderBudgetSealCompilerBoundary`

Theorem 532.9 (BinderBudgetSeal non-escape)**.** *Every exported read of an accepted* $\mathsf{BinderBudgetSeal}^{\uparrow}$ *obligation surface is exhausted by $D, T, V, S, U, H, C, P, N$. A request for a fresh free variable, a host capture-avoidance primitive, a quotient syntax equality, a compiler-stage equality, a normalization theorem, or ambient host soundness leaves the carrier and is not returned as BinderBudgetSeal evidence.*

Lean4 ✓ `BEDC.Derived.BinderBudgetSealUp.BinderBudgetSealNonEscape`

Proof. Read the request through the continuation routes in C. If it asks for the displayed boundary, term, payload, shift, substitution, transport, provenance, or naming rows, the finite packet supplies that row.

The shift and substitution non-escape theorems handle the two route cases. They return the same term row through S or U and do not allocate new free-variable or host binder data.

All remaining requests are absent from the obligation surface. The single-carrier TasteGate discipline and the compiler-boundary theorem keep those absent requests from being repacked as a second carrier or as compiler-stage evidence. □

Theorem 532.10 (BinderBudgetSeal TasteGate carrier grounding)**.** *The carrier rows $D, T, V, S, U, H, C, P, N$ used by the obligation surface, compiler boundary, and non-escape theorem are the same finite packet. Any TasteGate instance for* $\mathsf{BinderBudgetSeal}^{\uparrow}$ *must therefore be discharged on that single carrier and not on a compiler-stage carrier, normalization carrier, quotient syntax carrier, or host soundness carrier.*

Proof. Start with the carrier definition and the obligation surface, Definition 532.1 and Definition 532.6. Both display the same tuple $B = (D, T, V, S, U, H, C, P, N)$ and name no second carrier.

Use carrier admission from Definition 532.7. It reads D, T, V only through S, U, H, C, P, N, so the admitted surface is the same packet named by the obligation theorem.

Apply the compiler boundary and non-escape theorems, Definition 532.8 and Definition 532.9. They rule out compiler-stage, normalization, quotient syntax, and host soundness rows outside the displayed tuple.

The TasteGate carrier must therefore be grounded on row equality of this packet. Since every cited surface names $D, T, V, S, U, H, C, P, N$, a separate carrier would fail to be the accepted $\mathsf{BinderBudgetSeal}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.BinderBudgetSealUp.BinderBudgetSealTasteGateCarrierGrounding`

Closure status for $\mathsf{NameCert}_{\mathsf{BinderBudgetSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{BinderBudgetSeal}^{\uparrow}$ packet is generated from a binder-depth boundary, a MetaCIC term row, a substitution payload row, shift and substitution non-escape routes, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BinderBudgetSeal}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 532.1, Definition 532.6, Definition 532.2, Definition 532.7, Definition 532.8, Definition 532.9, and Definition 532.10 bridge the public packet through the same finite carrier-alignment route over binder depth, MetaCIC term, substitution payload, shift and substitution nonescape, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BinderBudgetSeal}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.BinderBudgetSealUp.BinderBudgetSealTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim StdBridge checking, full compiler closure, normalization, definitional equality, quotient syntax equality, or host soundness.

Upgrade path: Further verification work requires purity auditing and, separately, a StdBridge theorem for the same finite carrier-alignment route.

Chapter 533

A Concrete Naming Certificate for OperationalMembrane$^{\uparrow}$

The OperationalMembrane$^{\uparrow}$ packet is the concrete NameCert surface that turns the audit-gate membrane into a finite carrier. It does not claim that audit scripts are mathematical generators by themselves. It records the rows by which source syntax, proof ancestry, import separation, paper-Lean name resolution, displayed transport, consumer continuation, package provenance, and the boundary ledger remain visible to downstream governance chapters.

The membrane consumes the public GAP-ledger residue of chapter 520 and the finite kernel acceptance trace of chapter 557 before packaging the source-scan, proof-ancestry, import-separation, and paper-Lean drift rows. The closure witness ledger of chapter 487 supplies the downstream accounting surface for accepted and refused boundary crossings, so the packet is a lattice-facing audit carrier rather than an isolated kernel row.

Definition 533.1 (OperationalMembrane carrier)**.** *An* OperationalMembrane$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, A, I, D, H, C, P, L, N)$$

with the following displayed rows:

1. *S is the source-axiom scan row, recording the finite BEDC source window, the source-token classifier, and the refusal result for internal axiom declarations;*
2. *A is the strict axiom-purity row, recording the inspected public theorem names, the reported proof ancestry, and the forbidden-dependency classifier for* Classical.choice*,* Quot.sound*, and* propext*;*
3. *I is the conservativity import-separation row, recording protected baseline prefixes, non-baseline origins, inspected import edges, and the pass-or-refuse import classifier;*
4. *D is the paper-Lean drift-resolution row, recording each manuscript marker, its named Lean target, and the finite resolution result;*
5. *H records componentwise* hsame *transports for the source, ancestry, import, drift, ledger, package, continuation, and naming rows;*
6. *C records the displayed* Cont *routes by which consumers read the source scan, axiom-purity report, import boundary, drift resolution, ledger, provenance, and local certificate;*
7. *P is the* Pkg *provenance over* BHist*, source files, proof-ancestry reports, import ledgers, paper markers, Lean target names,* hsame*,* Cont*,* Pkg*, and* NameCert*;*

8. *L is the boundary ledger row recording that accepted reads must pass through exactly one of the displayed audit faces and that rejected reads remain outside the packet;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{OperationalMembrane}^{\uparrow}}$ *row.*

The carrier contains no source axiom permission, no hidden host axiom, no baseline import exemption, no fuzzy marker match, no theorem of global semantic conservativity, and no host-kernel completeness principle.

Definition 533.2 (OperationalMembrane classifier)**.** *For accepted* $\mathsf{OperationalMembrane}^{\uparrow}$ *carriers M and M', the classifier* $\mathsf{OperationalMembraneClassifier}(M, M')$ *compares exactly the rows of Definition 533.1. It transports source scans through S, proof-ancestry reports through A, import separation through I, paper-Lean name resolution through D, boundary-ledger entries through L, and provenance through H, C, P, N.*

The classifier has no component for asserting that a rejected source token is permitted, that a forbidden proof dependency is harmless, that a non-baseline import edge is baseline, that an unresolved paper marker names a nearby theorem, or that the audit surface proves global semantic completeness.

Theorem 533.3 (OperationalMembrane NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{OperationalMembrane}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$M = (S, A, I, D, H, C, P, L, N),$$

source-axiom scan exposure, strict axiom-purity exposure, conservativity import-separation exposure, paper-Lean drift-resolution exposure, visible hsame *transport, displayed* Cont *locality,* Pkg *provenance, boundary-ledger accounting, and non-escape for source axioms, forbidden host proof ancestry, hidden import exemptions, unresolved Lean names, and global semantic completeness.*

Proof. Carrier admission is projection from Definition 533.1. The packet has exactly the rows $S, A, I, D, H, C, P, L, N$, so every admitted consumer read begins at one of those coordinates.

The four audit faces are then read separately. The source face is S, the proof-ancestry face is A, the import-separation face is I, and the paper-Lean name-resolution face is D.

Transport and locality are displayed by H and C. These rows move and replay the four audit faces componentwise without adding a source axiom, a hidden proof dependency, an import exemption, or a substitute Lean name.

Finally P, L, N package the provenance, ledger, and local certificate. Since the excluded objects have no carrier coordinate, no $\mathsf{NameCert}_{\mathsf{OperationalMembrane}^{\uparrow}}$ projection can export them. □

Lean4 ✓ `BEDC.Derived.OperationalMembraneUp.OperationalMembranePacket namecert obligation surface`

Theorem 533.4 (OperationalMembrane ledger exactness)**.** *For an accepted* $\mathsf{OperationalMembrane}^{\uparrow}$ *packet, the boundary ledger L is exact for the displayed carrier: a consumer may read a source-scan decision through S, an axiom-purity decision through A, an import-separation decision through I, or a paper-Lean resolution decision through D, together with the visible transport, continuation, package, and local naming rows. No consumer may use L to manufacture a fifth audit face or to erase a rejected boundary crossing.*

Proof. Project L from the carrier and compare it with the carrier coordinates. Its entries name the same four audit faces S, A, I, D and the same structural rows H, C, P, N.

Apply the classifier of Definition 533.2. It transports exactly the displayed rows and contains no comparison component for an additional audit face.

The non-escape clause of Definition 533.1 fixes the rejected side. Because no coordinate permits source axioms, forbidden dependencies, import exemptions, fuzzy marker matches, or global completeness principles, the ledger cannot turn a refused crossing into accepted content. □

Lean4 ✓ `BEDC.Derived.OperationalMembraneUp.OperationalMembranePacket ledger exactness`

Theorem 533.5 (OperationalMembrane drift resolution)**.** *For an accepted* $\mathsf{OperationalMembrane}^{\uparrow}$ *packet, the paper-Lean row D is the complete public route by which manuscript markers are resolved against Lean names. A consumer may read the marker text, the target name, the finite resolution result, the componentwise transport row, the continuation route, package provenance, boundary-ledger entry, and local* $\mathsf{NameCert}_{\mathsf{OperationalMembrane}^{\uparrow}}$ *row. It may not replace a missing target by a similar declaration, a neighboring namespace, a prose interpretation, or an unchecked string.*

Lean4 ✓ `BEDC.Derived.OperationalMembraneUp.OperationalMembranePacket drift resolution`

Proof. Read D from Definition 533.1. The row contains the marker text, the claimed Lean target, and the finite resolution result.

Use H and C to transport and expose that row to consumers. The target name remains the displayed target name, and the continuation route does not introduce fuzzy matching or namespace search.

The ledger row L records whether the read belongs to the accepted boundary surface. Together with P and N, it packages the result as a local naming certificate and leaves missing or unchecked names outside the packet. □

Theorem 533.6 (OperationalMembrane scoped boundary)**.** *The scoped* $\mathsf{OperationalMembrane}^{\uparrow}$ *boundary consists exactly of the source scan S, axiom-purity row A, import-separation row I, paper-Lean drift row D, componentwise* hsame *transports H, displayed* Cont *routes C, package provenance P, boundary ledger L, and local* NameCert *row N of the carrier $M = (S, A, I, D, H, C, P, L, N)$. It excludes source axiom permission, hidden proof ancestry, import exemptions, fuzzy Lean-name matching, and global semantic completeness.*

Proof. Start with Definition 533.1 and Definition 533.2. They make $S, A, I, D, H, C, P, L, N$ the complete carrier and comparison surface.

Apply Definition 533.3 to expose those rows as the local naming certificate. Then use Definition 533.4 to keep accepted and rejected boundary crossings on the displayed ledger.

Finally apply Definition 533.5 for the paper-Lean face. The same carrier has no row for source axiom permission, hidden proof ancestry, import exemption, fuzzy name replacement, or global semantic completeness, so the scoped boundary is exactly the displayed membrane. □

Theorem 533.7 (OperationalMembrane standard schema bridge)**.** *The public* $\mathsf{OperationalMembrane}^{\uparrow}$ *surface bridges to the standard operational schema exactly through the displayed source scan S, strict axiom-purity row A, import-separation row I, paper-Lean drift row D, boundary ledger L, componentwise* hsame *row H, displayed* Cont *row C,* Pkg *provenance row P, and local* NameCert *row N of the carrier $M = (S, A, I, D, H, C, P, L, N)$.*

The bridge has no extra audit face. It does not permit source axioms, forbidden proof ancestry, baseline-import exemptions, fuzzy Lean-name resolution, host-kernel completeness, or global semantic conservativity beyond the displayed membrane rows.

Lean4 ✓ `BEDC.Derived.OperationalMembraneUp.OperationalMembraneUp StdBridge`

Proof. Start with the carrier and classifier. The definitions display the exact rows $S, A, I, D, H, C, P, L, N$ and compare only source scans, proof-ancestry reports, import separation, paper-Lean name resolution, boundary-ledger entries, and structural rows.

Apply the NameCert obligation surface and ledger exactness. These theorems expose the four audit faces and ensure the boundary ledger cannot create a fifth face or erase a refused crossing.

Use drift resolution for the paper-Lean component. It keeps marker resolution tied to the displayed target names and rejects nearby declarations, prose interpretation, or unchecked strings as replacements.

Finally apply the scoped boundary theorem. Since all standard operational reads are already routed through the displayed membrane rows, the public surface supplies a paper-level standard schema bridge without adding host-kernel completeness or global conservativity. □

Theorem 533.8 (OperationalMembrane finite-route induction)**.** *Every governance-facing route from an accepted* $\mathsf{OperationalMembrane}^{\uparrow}$ *carrier is obtained by finite induction over the displayed rows* $S, A, I, D, H, C, P, L, N$ *of* $M = (S, A, I, D, H, C, P, L, N)$*. Each induction step either projects one audit face or replays it through* hsame*,* Cont*,* Pkg*, and local* NameCert *data, and no step introduces source axiom permission, forbidden dependency acceptance, import exemption, fuzzy marker matching, or global semantic completeness.*

Proof. The base route is carrier projection. Apply Definition 533.1 and Definition 533.2 to expose exactly $S, A, I, D, H, C, P, L, N$ as the finite inventory and comparison surface.

For the audit-face steps, use Definition 533.3. It projects source scans through S, proof ancestry through A, import separation through I, and paper-Lean name resolution through D without creating any additional audit face.

For the replay steps, apply Definition 533.4 and Definition 533.5. The ledger row L preserves accepted and rejected crossings, while the drift row keeps marker resolution tied to displayed target names.

Finally use Definition 533.6 and Definition 533.7. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so the induction has no constructor for source axiom permission, forbidden dependency acceptance, import exemption, fuzzy marker matching, or global semantic completeness. □

The operational membrane's consumer route reads the audit-gate boundary rows of chapter 526 before exporting membrane-visible operational data. Thus the membrane packet is a downstream operational view of the same finite boundary ledger, not an isolated kernel surface.

Closure status for $\mathsf{NameCert}_{\mathsf{OperationalMembrane}^{\uparrow}}$**.**

Constructive story: An $\mathsf{OperationalMembrane}^{\uparrow}$ packet is generated from source-axiom scans, strict proof-ancestry reports, import-separation ledgers, paper-Lean name-resolution rows, visible transport, continuation routes, package provenance, a boundary ledger, and a local naming certificate.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OperationalMembrane}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 533.1, Definition 533.2, Definition 533.3, Definition 533.4, Definition 533.5, Definition 533.6, and Definition 533.7 bind the carrier, classifier, ledger exactness, drift resolution, scoped operational boundary, and paper-level standard schema bridge rows for the displayed audit membrane.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OperationalMembrane}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.OperationalMembraneUp.OperationalMembranePacket\_namecert\_obligation\_surface`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close global semantic conservativity, host-kernel completeness, bridge checking, or a Lean implementation of the operational membrane carrier.

Upgrade path: No further formal-axis upgrade is pending because the displayed standard schema bridge is checked.

Chapter 534

A Concrete Naming Certificate for RecursorGenerator$^{\uparrow}$

The RecursorGenerator$^{\uparrow}$ surface packages the authorized use of inductive recursors as finite NameCert data. It records an accepted inductive signature, legal calls to the generated eliminator, branch packages, audit rows, MetaCIC closed-term substitution routes, componentwise transports, continuation access, provenance, and the local naming row. The packet is not an ambient reflection principle, an unchecked code generator, or an escape from the displayed inductive boundary.

The packet consumes the authorized eliminator surface of chapter 525 and the generator-boundary closure of chapter 486. AuthorizedGeneratorRecursor supplies the legal recursor-call and branch-package rows, while GeneratorClosure supplies the refusal of unlisted generator routes.

Definition 534.1 (RecursorGenerator carrier)**.** *A* RecursorGenerator$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, E, B, A, M, H, C, P, N)$$

with the following displayed rows:

1. *I is the accepted inductive-signature row, naming the constructors, positivity check, parameter telescope, motive boundary, and generated recursor symbol;*
2. *E is the legal eliminator-call row, recording the displayed I.rec call, its motive, scrutinee, parameters, and the type-checker acceptance row for the call;*
3. *B is the branch-package row, listing one branch package for each constructor of I, with branch inputs, recursive hypotheses, output row, and branch-local* Pkg *provenance;*
4. *A is the audit row, recording kernel elaboration, source axiom refusal, and dependency-purity refusal for* Classical.choice, Quot.sound, *and* propext*;*
5. *M is the MetaCIC closed-term substitution row, recording that every generated branch output is handed off only through closed terms and substitution routes accepted by the displayed classifier;*
6. *H records componentwise* hsame *transports for I, E, B, A, M, the continuation row, the package row, and the local naming row;*
7. *C records the displayed* Cont *routes by which consumers read the signature, eliminator call, branch packages, audit row, closed-term handoff, provenance, and local certificate;*
8. *P is the* Pkg *provenance over* BHist, Hist, *accepted inductive signatures, legal recursor calls, branch packages, audit rows, MetaCIC closed terms,* hsame, Cont, *and local* NameCert *rows;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RecursorGenerator}^{\uparrow}}$ *row.*

The carrier contains no host-level code generation oracle, no untyped eliminator, no branch outside the constructor list of I, no hidden theorem of global consistency, and no imported equality principle beyond the displayed audit row.

Lean4 ✓ `BEDC.Derived.RecursorGeneratorUp.RecursorGeneratorCarrierSemanticNameCertificate`

Theorem 534.2 (RecursorGenerator authorization obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RecursorGenerator}^{\uparrow}}$ *surface for the carrier of Definition 534.1 consists of the following finite obligations:*

1. *carrier exposure: every accepted packet exposes exactly $R = (I, E, B, A, M, H, C, P, N)$;*
2. *signature authorization: the eliminator call in E is licensed only by the accepted inductive-signature row I;*
3. *branch coverage: the branch-package row B contains exactly the constructor-indexed branches required by $I.\mathsf{rec}$;*
4. *audit confinement: the audit row A is read before any generated term is exported as a public certificate row;*
5. *closed-term handoff: the MetaCIC row M exports generated outputs only through closed-term substitution routes;*
6. *transport locality:* hsame *and* Cont *access are restricted to the displayed rows and cannot add another generator.*

Lean4 ✓ `BEDC.Derived.RecursorGeneratorUp.RecursorGeneratorAuthorizationObligations`

Proof. Carrier exposure is projection from Definition 534.1. The tuple R lists every coordinate a downstream consumer may inspect.

Signature authorization and branch coverage are read from I, E, B. The accepted signature row names the generated recursor, the eliminator-call row records a legal $I.\mathsf{rec}$ invocation, and the branch-package row supplies exactly the constructor-indexed branch data demanded by that invocation.

Audit confinement is read from A. A generated output can be consumed only after the kernel elaboration row and the source and dependency refusals have been recorded in the same finite packet.

Closed-term handoff is read from M. The MetaCIC substitution route exposes generated branch outputs as closed terms under the displayed classifier, so the handoff does not add an external computation principle.

Finally H, C, P, N record transport, continuation, provenance, and the local naming certificate. Since no coordinate names another generator or an unchecked eliminator, the authorization surface is exactly the displayed packet. □

Theorem 534.3 (RecursorGenerator audit non-escape)**.** *Every public output of an accepted* $\mathsf{RecursorGenerator}^{\uparrow}$ *packet factors through the audit row A, the accepted inductive-signature row I, the legal eliminator-call row E, and the branch-package row B. A consumer cannot recover a host code generator, a non-positive eliminator, an unlisted branch,* Classical.choice, Quot.sound, propext, *or an unrecorded axiom channel from the packet.*

Lean4 ✓ `BEDC.Derived.RecursorGeneratorUp.RecursorGenerator audit non escape`

Proof. Begin with the legal route. The only eliminator available in the carrier is the call recorded by E, and E is licensed by the accepted signature row I.

The branch data are then exhausted by B. Each constructor branch is part of the displayed branch-package row, and there is no coordinate for an additional branch or for a different eliminator.

The audit boundary is supplied by A. Since the packet exports generated rows only after the kernel, source-token, and dependency-purity checks have been read, the forbidden host principles have no public coordinate.

The remaining rows H, C, P, N preserve and expose the same finite data. They transport and package the accepted rows; they do not provide a hidden generator or axiom channel. □

Theorem 534.4 (RecursorGenerator closed-term handoff)**.** *For an accepted* $\mathsf{RecursorGenerator}^{\uparrow}$ *packet, every downstream theorem, definition, or certificate row consuming a generated recursor output receives it through the MetaCIC closed-term substitution row M together with the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{RecursorGenerator}^{\uparrow}}$ *provenance. The handoff preserves the accepted inductive-signature classifier and does not assert host reflection, semantic completeness, or global normalization.*

Proof. Project M from the carrier. It records the closed-term substitution route for generated branch outputs and ties that route to the classifier attached to the accepted signature row I.

Use H and C to move and read the generated output. Componentwise transport preserves the displayed signature, call, branch, audit, and closed-term rows, while continuation access exposes only those rows to the downstream consumer.

Package provenance is then supplied by P and the local naming row N. The consumer receives a finite certificate over the displayed dependencies, not a host reflection theorem or a global normalization result. □

Lean4 ✓ `BEDC.Derived.RecursorGeneratorUp.RecursorGeneratorCarrier closed term handoff`

Theorem 534.5 (RecursorGenerator authorized output factorization)**.** *Every public generated output of an accepted* $\mathsf{RecursorGenerator}^{\uparrow}$ *packet factors through the displayed rows*

$$(I, E, B, A, M, H, C, P, N).$$

The factorization reads the legal eliminator call, the constructor-indexed branch package, the audit row, and the MetaCIC closed-term handoff before any output is exposed. Hence no public output can bypass the branch coverage supplied by the $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ *surface in chapter 525.*

Lean4 ✓ `BEDC.Derived.RecursorGeneratorUp.RecursorGeneratorAuthorizedOutputFactorization`

Proof. Start from the carrier of Definition 534.1. It exposes exactly the rows $I, E, B, A, M, H, C, P, N$, so a public generated output has no coordinate outside this tuple.

Apply the authorization surface of Definition 534.2. The signature row I licenses the legal eliminator call E, and the branch row B supplies exactly the constructor-indexed branches required by that call.

Use the audit and handoff rows next. By Definition 534.3, the output must pass through A, I, E, B before becoming public; by Definition 534.4, the exported generated term is delivered through M with the displayed transport, continuation, package, and local naming provenance.

The sibling $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$ reference supplies the public branch-coverage boundary consumed by this chapter. Since the carrier has no extra branch or generator coordinate, the displayed factorization is exhaustive. □

Theorem 534.6 (RecursorGenerator branch and descent exhaustion)**.** *For an accepted* RecursorGenerator$^{\uparrow}$ *packet, every branch read and every descent read used by a generated recursor output is exhausted by the displayed constructor-indexed branch package B together with the MetaCIC closed-term substitution row M. The packet cannot expose an unlisted constructor case, a hidden recursive call, or a descent route outside the authorized recursor surface consumed from chapter 525.*

Lean4 ✓ `BEDC.Derived.RecursorGeneratorUp.RecursorGeneratorBranchDescentExhaustion`

Proof. Project the branch package from the carrier of Definition 534.1. The row B lists one branch package for each constructor of I, including branch inputs, recursive hypotheses, output row, and branch-local Pkg provenance.

Apply Definition 534.2. Branch coverage is one of the finite local obligations, and transport locality prevents hsame or Cont access from adding another generator.

The descent read is then tied to the closed-term handoff. By Definition 534.4, every downstream generated output is exported through M, so each branch output is read only as a MetaCIC closed-term substitution route accepted by the displayed classifier.

Finally use Definition 534.3. Since unlisted branches, hidden recursive calls, and unaudited dependency channels have no public coordinate, the constructor-indexed branch package and the closed-term substitution row exhaust the visible branch and descent surface. □

Theorem 534.7 (RecursorGenerator downstream scope package)**.** *Every downstream self-compilation,* TasteGate*, or generated-certificate consumer of an accepted* RecursorGenerator$^{\uparrow}$ *packet receives only the finite* RecursorGenerator$^{\uparrow}$ *scope package*

$$(I, E, B, A, M, H, C, P, N).$$

Such a consumer may inspect the authorized signature, eliminator call, branch package, audit row, closed-term handoff, transport, continuation, provenance, and local certificate rows, but it receives no host reflection principle, no unchecked generator, and no certificate outside this finite scope.

Proof. Read the consumer interface from the carrier of Definition 534.1. The continuation row C exposes precisely the signature, eliminator call, branch package, audit row, closed-term handoff, provenance, and local certificate routes.

The authorized output factorization of Definition 534.5 forces every public generated output through the same rows. The branch and descent exhaustion of Definition 534.6 prevents the consumer from replacing B or M with an external recursor route.

Apply Definition 534.2, Definition 534.3, and Definition 534.4. Together they bind signature authorization, audit confinement, and MetaCIC closed-term delivery inside the displayed packet.

Therefore a self-compilation row, a TasteGate row, or a generated-certificate row receives the finite RecursorGenerator$^{\uparrow}$ scope package and nothing beyond it. □

Lean4 ✓ `BEDC.Derived.RecursorGeneratorUp.RecursorGeneratorDownstreamScopePackage`

Theorem 534.8 (RecursorGenerator bridge route status)**.** *The public scope package* $(I, E, B, A, M, H, C, P, N)$ *bridges the concrete* RecursorGenerator$^{\uparrow}$ *packet to the abstract recursor-generator interface through the accepted inductive signature row, legal eliminator-call row, constructor-indexed branch package, audit row, closed-term handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The bridge exposes no host reflection principle, unchecked generator execution, unlisted branch, global normalization theorem, semantic completeness theorem, or dependency channel outside the displayed audit row.*

Proof. Start with the downstream scope package of Definition 534.7. It gives every public consumer exactly the rows $I, E, B, A, M, H, C, P, N$ and no external generator interface.

Use authorization, audit, and handoff. The accepted signature row I licenses the legal eliminator call E, the branch package B exhausts constructor cases, the audit row A bars the forbidden dependency channels, and the closed-term row M supplies the generated outputs as displayed handoffs.

Finally replay the structural rows. Componentwise hsame transport, displayed Cont access, Pkg provenance, and the local NameCert row connect the concrete packet to the abstract interface without adding another coordinate, so the bridge route is exactly the public scope package. □

Lean4 ✓ `BEDC.Derived.RecursorGeneratorUp.RecursorGeneratorBridgeRouteStatus`

Closure status for $\mathsf{NameCert}_{\mathsf{RecursorGenerator}\uparrow}$.

Constructive story: A $\mathsf{RecursorGenerator}^{\uparrow}$ packet is generated from an accepted inductive signature, a legal recursor call, constructor-indexed branch packages, audit rows, MetaCIC closed-term substitution, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RecursorGenerator}\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: Definition 534.1, Definition 534.2, Definition 534.3, Definition 534.4, Definition 534.5, Definition 534.6, Definition 534.7, and Definition 534.8 bind recursor generation as a finite authorization packet and bridge route for accepted inductive signatures, legal eliminator calls, audit non-escape, closed-term handoff, authorized output factorization, branch and descent exhaustion, downstream scope packaging, and abstract interface access.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RecursorGenerator}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close a Lean implementation, bridge checking, host reflection, global normalization, semantic completeness, non-positive eliminators, or unchecked generator execution.

Upgrade path: No further paper-theory upgrade remains for this chapter; formal verification and bridge checking remain on the verification axis.

Chapter 535

A Concrete Naming Certificate for BoundedMonotoneCauchyWitness$^{\uparrow}$

The BoundedMonotoneCauchyWitness$^{\uparrow}$ interface records the finite surface through which a bounded monotone source row becomes a witnessed Cauchy real-name packet. It separates the displayed generator range, the explicit Cauchy witness, the real-history classifier transport, and the Real$^{\uparrow}$ seal handoff before any completion-facing consumer reads the packet.

This packet is the bounded-monotone consumer of the located monotone Cauchy surface in chapter 438 and the shared finite tail route exposed by chapter 560; the dependency is the displayed tail-window and located-enclosure route through which the witness becomes available to the Real seal.

The downstream BoundedMonotoneConvergenceSeal$^{\uparrow}$ consumer of chapter 918 reads this witness surface as its finite monotone source, regular rational handoff, stream schedule, Cauchy modulus, dyadic ledger, located trap, and Real$^{\uparrow}$ seal precursor. The convergence seal packages the public convergence handoff without selected limits, quotient equality, host real equality, trichotomy, or ambient completeness.

Theorem 535.1 (Bounded monotone witness root monotone-window totality)**.** *Every accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *packet exposes its bounded monotone source rows and the finite* StreamName$^{\uparrow}$ *windows before the Cauchy witness is read. The read is carried by the displayed* BHist *rows, transported only by* hsame*, routed only through* Cont*, packaged only by* Pkg*, and named only by the local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root monotone window totality`

Proof. Project the accepted carrier described by the opening dependency surface. Its first visible rows are the bounded monotone source, the regular rational handoff, and the stream-window data shared with chapter 438 and chapter 560.

Use the sibling certificate surfaces for RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, and CauchyModulus$^{\uparrow}$. They make the finite window and modulus rows available through the same BHist, hsame, Cont, Pkg, and NameCert support before the witness-facing coordinate can be consumed.

The non-escape clauses listed for the chapter then block any read through selected limits, quotient stream equality, host real equality, trichotomy, or ambient completeness. Thus the witness route begins with the displayed monotone source and finite-window rows. □

Theorem 535.2 (Bounded monotone witness root located Real-seal route)**.** *Every accepted* BoundedMonotoneCauc *packet routes the witness to the* $\mathsf{Real}^{\uparrow}$ *seal through the located interval trap, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail row. The route is a finite* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *route, not a selected-limit or host-completion route.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root located real seal route`

Proof. Start from the located-enclosure dependency named in the chapter opening. The located interval trap supplies the finite enclosure row, while the dyadic ledger and Cauchy modulus rows supply the tolerance and tail data read by the witness.

Apply the sibling surfaces for $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{CauchyModulus}^{\uparrow}$. They keep the enclosure, tolerance, and tail rows inside the same package provenance and local naming boundary before any $\mathsf{Real}^{\uparrow}$ seal row is reached.

Finally use the $\mathsf{Real}^{\uparrow}$ seal handoff already named by the bounded-monotone consumer paragraph. Since the packet exports no selected limit, quotient equality, host real equality, trichotomy, or ambient completeness coordinate, the seal route is exhausted by the displayed finite trap, ledger, modulus, transport, continuation, package, and name rows. □

Theorem 535.3 (Bounded monotone witness root completion-source factorization)**.** *Every* BoundedMonotoneConv *consumer of an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows before it reads the completion-facing convergence handoff.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root completion source factorization`

Proof. Project the accepted carrier and list the source-facing rows. The bounded monotone source is exposed through the regular rational row, stream schedule, Cauchy modulus, dyadic ledger, located trap, and Real-seal precursor named in the dependency paragraphs.

Compose the monotone Cauchy surface of chapter 438 with the regular tail route of chapter 560. This identifies the source, window, tail, and located-seal rows as the finite route available to the convergence-seal consumer.

Close with the consumer boundary of chapter 918. Its read is a package read through the displayed BHist, hsame, Cont, Pkg, and NameCert rows, while selected limits, quotient equality, host real equality, trichotomy, and ambient completeness remain outside the packet. □

Theorem 535.4 (Bounded monotone Cauchy witness window-selector factorization)**.** *Every accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet consumed by a* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *route factors its bounded monotone source through the same finite selector surface used by* FiniteObservationBudgetSe *Before the* $\mathsf{Real}^{\uparrow}$ *seal is readable, the route passes through finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the located trap, the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail row, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *rows.*

Thus the completion-facing read is exhausted by the displayed selector chain

$$\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The factorization carries no quotient stream, selected limit, host real equality, trichotomy row, choice principle, or ambient completeness principle.

Proof. First expose the bounded monotone window rows by Definition 535.1. This places the source and finite $\mathsf{StreamName}^{\uparrow}$ windows inside the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support before any witness-consuming coordinate is read.

Next route the witness to the seal by Definition 535.2. The located trap, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and $\mathsf{CauchyModulus}^{\uparrow}$ tail row give the finite enclosure and tail data needed by the seal-facing route.

Now apply Definition 535.3. It says that a $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ consumer reads the witness only through the displayed regular, stream, modulus, dyadic, located, Real, transport, continuation, provenance, and naming rows.

Finally compare this route with the terminal selector surface of Definition 782.44. The selector theorem exhausts every terminal read through its budget, schedule, finite window, dyadic, regular, seal, transport, continuation, provenance, and local naming rows; the bounded monotone witness route supplies the same window, ledger, handoff, trap, tail, and seal-facing rows. Since neither route exports quotient streams, selected limits, host real equality, trichotomy, choice, or ambient completeness, the convergence-seal consumer factors through the finite selector surface before the $\mathsf{Real}^{\uparrow}$ seal is readable. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessWindowSelectorCertifica`

Definition 535.5 (Bounded monotone Cauchy witness carrier)**.** *A* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

with the following visible coordinates:

1. *S is the bounded monotone source row, displaying the generator history, monotone comparison rows, and the finite upper-bound ledger for the source observations;*
2. *F is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row extracted from S and read as the regular rational name exposed to completion-facing consumers;*
3. *σ is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule that selects the inspected source and regular-sequence windows;*
4. *μ is the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail witness, sending each dyadic tolerance request to a concrete finite tail window;*
5. *λ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger containing the dyadic tolerance rows, the source upper-bound rows, and the monotone comparison checks consumed by μ;*
6. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *trap row recording the lower observation, upper guard, and tolerance enclosure read before the real seal;*
7. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed regular sequence, selected window, Cauchy witness, dyadic ledger, and located trap have been exposed;*
8. *H records componentwise* hsame *transports for the bounded source, regular sequence, stream schedule, Cauchy witness, dyadic ledger, located trap, and real-seal rows;*
9. *C records the displayed* Cont *routes by which consumers inspect those rows;*
10. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and source certificates;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *row.*
The bounded monotone source row is displayed as

$$S_{\mathrm{gen}}(i) : \textit{the } i\textit{-th generated source observation},$$
$$S_{\mathrm{mono}}(i,j) : i \le j \Rightarrow S_{\mathrm{gen}}(i) \le S_{\mathrm{gen}}(j),$$
$$S_{\mathrm{ub}}(i) : S_{\mathrm{gen}}(i) \le U$$

for a dyadic upper guard U recorded in λ. The Cauchy witness is the explicit row

$$\mu(\varepsilon) : \textit{a scheduled tail window on which } F \textit{ has diameter below } \varepsilon.$$

The carrier contains no choice-selected limit point, quotient-name equality, host real equality, unrestricted real-history range, ambient completeness theorem, trichotomy row, or open-cover compactness row.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier route local name closure`

Theorem 535.6 (Bounded monotone Cauchy witness NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCa}}$ *surface consists exactly of five rows:*

1. *carrier admission for the displayed packet of Definition 535.5;*
2. *generator range discipline, stating that every source observation read by a consumer is routed through S_{gen} and the bounded monotone ledgers of S;*
3. *explicit Cauchy witness discipline, stating that every tail request is answered by the row μ and the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window σ;*
4. *located trap and* $\mathsf{Real}^{\uparrow}$ *seal handoff, stating that the real-seal row Q is reached only through $F, \sigma, \mu, \lambda, I, H, C, P, N$;*
5. *ledger exhaustion, stating that all public reads of bounded monotone convergence are exhausted by the displayed generator, witness, classifier transport, package provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier namecert obligations`

Proof. Carrier admission is projection of the finite packet in Definition 535.5. The packet lists the bounded source row, regular rational row, stream schedule, Cauchy witness, dyadic ledger, located trap, real seal, transports, continuations, package provenance, and local naming row.

Generator range discipline uses the displayed row S_{gen} and its monotone and upper-bound ledgers. Type I range pressure is discharged by that displayed generator, because no consumer ranges over an unrestricted intended class of real histories.

Explicit Cauchy witness discipline uses μ and σ to answer each tolerance request with a concrete tail window. Type II selection pressure is discharged by this visible Cauchy witness, not by choosing a limit point from nonempty completeness data.

The seal handoff and ledger exhaustion then use I, Q, H, C, P, and N. Type III collapse pressure is discharged by $\mathsf{Real}^{\uparrow}$ classifier transport and componentwise hsame rows, not by host equality or quotient-name identification. □

Theorem 535.7 (Bounded monotone Cauchy witness generator range exactness)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every source observation exported from* W *is exactly a displayed generator read through* S_{gen}*, with its monotonicity and upper-bound certificates read through* S_{mono} *and* S_{ub} *and with dyadic upper guard data read through* λ*. No consumer may replace this generator range by an unrestricted real-history range, a selected limit, trichotomy data, quotient equality, or ambient completeness.*

Proof. Project the source row S from the carrier. The definition displays S_{gen}, S_{mono}, and S_{ub} as the generator, monotonicity, and upper-bound ledgers, with the dyadic guard recorded in λ.

Use the generator range discipline row of Definition 535.6. It requires every source observation read by a consumer to pass through those displayed source ledgers.

Finally replay the transport and route rows H and C and attach the provenance rows P and N. Since the packet has no coordinate for unrestricted real-history range, selected limit, trichotomy, quotient equality, or ambient completeness, the displayed generator range is exact. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier generator range exactness`

Theorem 535.8 (Bounded monotone Cauchy witness tail modulus scope)**.** *For an accepted* BoundedMonotoneCauc *carrier* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$*, every tail request is scoped by the Cauchy witness row* μ*, the scheduled StreamName windows* σ*, and the dyadic tolerance ledger* λ*. The request may inspect* S_{gen}*,* S_{mono}*,* S_{ub}*, and the regular-sequence row* F*, but it cannot use an existential completeness theorem, a selected limiting representative, quotient equality, host real equality, or trichotomy.*

Proof. Read the tail witness from the carrier. The row μ answers tolerance requests, σ chooses the inspected windows, and λ records the dyadic tolerance and upper-bound ledgers consumed by the witness.

Apply the explicit Cauchy witness discipline from Definition 535.6. It sends every tail request through μ and σ rather than through an external completion assertion.

The source rows S_{gen}, S_{mono}, S_{ub} and the regular-sequence row F supply the displayed observations. Transport through H, continuation through C, and provenance through P, N do not add a selected limit, quotient equality, host equality, ambient completeness, or trichotomy coordinate. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail modulus scope`

Theorem 535.9 (Bounded monotone Cauchy witness Real seal boundary)**.** *For an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal read through* Q *is routed through* $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ *and remains tied to the displayed bounded source row* S*. The boundary exports no selected limit, no trichotomy row, no quotient equality, no host real equality, and no ambient completeness principle.*

Proof. Project the seal row Q and the pre-seal rows $F, \sigma, \mu, \lambda, I$ from the carrier. The real-facing consumer reaches Q only after the regular sequence, scheduled windows, tail witness, dyadic ledger, and located trap have been displayed.

Apply the located trap and $\mathsf{Real}^{\uparrow}$ seal handoff row of Definition 535.6. It binds the seal to $F, \sigma, \mu, \lambda, I, H, C, P, N$ and keeps the source row S visible through the generator range discipline.

Use the tail modulus scope and generator range exactness rows to rule out alternate inputs. The remaining transport, continuation, package, and local naming rows replay the same finite packet, so no selected limit, trichotomy, quotient equality, host real equality, or ambient completeness coordinate can cross the seal boundary. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real seal boundary`

Theorem 535.10 (Bounded monotone Cauchy witness socket separation)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The three analysis sockets in bounded monotone convergence are separated inside* W*: Type I range pressure is read only through the displayed generator row* S*, Type II selection pressure is read only through the explicit Cauchy witness* μ *with the scheduled windows* σ*, and Type III collapse pressure is read only through* $\mathsf{Real}^{\uparrow}$ *classifier transport and the componentwise rows in* H *and* C*.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier socket separation`

Proof. For the range site, inspect the bounded monotone source row. The generator S_{gen}, monotone ledger S_{mono}, and upper-bound ledger S_{ub} are carrier coordinates, so source reads have a displayed finite route before any regular-sequence or real-seal row is consumed.

For the selection site, inspect the Cauchy witness row. A tolerance request is routed to $\mu(\varepsilon)$ and then through the scheduled window $\sigma(\mu(\varepsilon))$, so the tail witness is present as data rather than selected from an existential completion statement.

For the collapse site, compare accepted packets only through the transported regular sequence, located trap, and real-seal classifier rows. The hsame transports and Cont routes preserve the displayed rows, while the $\mathsf{Real}^{\uparrow}$ seal is reached through classifier transport rather than host equality. □

Theorem 535.11 (Bounded monotone Cauchy witness classifier transport)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

and

$$W' = (S', F', \sigma', \mu', \lambda', I', Q', H', C', P', N')$$

be accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carriers. If the displayed classifier relates* W *to* W'*, then the replacement transports the packet componentwise:*

1. *bounded source rows* S *to* S'*;*
2. $\mathsf{RegSeqRat}^{\uparrow}$ *rows* F *to* F' *and* $\mathsf{StreamName}^{\uparrow}$ *schedules* σ *to* σ'*;*
3. $\mathsf{CauchyModulus}^{\uparrow}$ *witnesses* μ *to* μ' *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers* λ *to* λ'*;*
4. $\mathsf{LocatedInterval}^{\uparrow}$ *traps* I *to* I' *and* $\mathsf{Real}^{\uparrow}$ *seals* Q *to* Q'*;*
5. hsame *rows* H *to* H'*,* Cont *routes* C *to* C'*,* Pkg *provenance* P *to* P'*, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}}$ *rows* N *to* N'*.*

No quotient real equality, selected limit, ambient completeness theorem, trichotomy row, or open-cover compactness coordinate can enter the transported packet.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier classifier transport`

Proof. Project the two accepted carriers. The source, regular sequence, stream schedule, Cauchy witness, dyadic ledger, located trap, real seal, transport, continuation, provenance, and local naming rows are exactly the displayed coordinates of Definition 535.5.

Invoke the five rows of Definition 535.6. Carrier admission fixes the packet shape, generator range discipline keeps source observations inside S_{gen} and S'_{gen}, explicit Cauchy witness discipline keeps tolerance requests inside μ, σ and μ', σ', the seal handoff keeps real-facing reads routed through the located trap and $\mathsf{Real}^{\uparrow}$ seal, and ledger exhaustion lists the remaining public routes.

Finally use Definition 535.10. Type I range, Type II selection, and Type III collapse sites occupy disjoint carrier sockets, so classifier replacement can only replay the listed componentwise rows. The excluded completion objects are absent from the carrier definition and from the NameCert rows, hence there is no coordinate through which they could be transported into the accepted packet. □

Theorem 535.12 (Bounded monotone Cauchy witness Real seal handoff)**.** *For an accepted* BoundedMonotoneCauc *carrier* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal read factors through the displayed bounded source row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, the scheduled* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail witness, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and upper-bound ledger, and the* $\mathsf{LocatedInterval}^{\uparrow}$ *trap before reaching* Q*.*

The handoff exports a witnessed monotone Cauchy packet, not a choice-selected limiting representative, quotient equality, host real equality, ambient completeness, trichotomy, or open-cover compactness.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real seal handoff`

Proof. Project the carrier. The source and regular-sequence rows S and F display the observations available to the real-facing consumer, and σ records the finite windows on which those observations are inspected.

Next use the Cauchy witness row μ together with the dyadic ledger λ. Each tolerance request reaches a displayed tail window with its monotone comparison and upper-bound data before any located trap is read.

The located trap I is the final enclosure row before the seal. Transport through H and continuation through C replay only those displayed rows, with P and N recording provenance and local naming.

Thus the seal coordinate Q receives exactly the witnessed packet described above. None of the excluded completion objects is present as a carrier coordinate or as a handoff route. □

Theorem 535.13 (Bounded monotone Cauchy witness ledger exhaustion)**.** *Every public read of an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier is exhausted by the bounded monotone source rows, the regular-sequence row, the stream windows, the Cauchy witness row, the dyadic tolerance and upper-bound ledger, the located trap, the* $\mathsf{Real}^{\uparrow}$ *seal row,* hsame *transports,* Cont *routes,* Pkg *provenance, and the local* NameCert *row of Definition 535.5.*

Proof. Inspect the carrier coordinates. The source observations, monotone comparisons, upper-bound rows, regular rational name, window schedule, Cauchy witness, dyadic ledger, located trap, and real-seal row are all fields of the same finite BHist packet.

The transport and continuation fields account for the only permitted movement of those rows. The package and local naming fields record provenance and certificate membership, but they do not add analytic data.

Consequently every public read has already appeared in the displayed ledger. The packet has no remaining coordinate for a hidden range over all real histories, an unwitnessed existential limit choice, quotient-name collapse, host real equality, ambient completeness, trichotomy, or open-cover compactness. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier ledger exhaustion`

Theorem 535.14 (Bounded monotone Cauchy witness obligation closure)**.** *The carrier of Definition 535.5 and the local theorems of this chapter assemble the* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *obligations for displayed bounded-source range, explicit Cauchy witness,* $\mathsf{StreamName}^{\uparrow}$ *window schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{LocatedInterval}^{\uparrow}$ *trap,* $\mathsf{Real}^{\uparrow}$ *seal handoff, classifier transport, and non-escape.*

The resulting packet admits only the rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$*. It has no coordinate for selected limits, quotient equality, host real equality, trichotomy, ambient completeness, or open-cover compactness.*

Proof. Begin with the carrier and the NameCert obligation theorem. They provide carrier admission and split the public surface into generator range discipline, explicit Cauchy witness discipline, located trap with $\mathsf{Real}^{\uparrow}$ handoff, and ledger exhaustion.

For the bounded-source and Cauchy-witness parts, apply Definition 535.7 and Definition 535.8. These force source reads through $S_{\text{gen}}, S_{\text{mono}}, S_{\text{ub}}$ and force tolerance requests through μ, σ, λ.

For the seal and transport parts, apply Definition 535.9, Definition 535.10, Definition 535.11, and Definition 535.12. These route the located trap and real seal through the displayed rows and keep the three analysis sockets separate.

Finally apply Definition 535.13. Since every public read is already exhausted by $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, the excluded completion and compactness coordinates cannot be projected from the accepted packet. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier obligation closure`

Theorem 535.15 (Bounded monotone Cauchy witness convergence-seal factorization)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Any completion-facing consumer using a* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *packet whose witness coordinate is* W *must first factor through the accepted witness rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

and then through the convergence-seal rows

$$W, M, K, F', \sigma', D, L, R, H', C', P', N'.$$

Thus the completion-facing route is a two-stage BEDC package. The first stage is the local bounded monotone Cauchy witness certificate, and the second stage is the convergence-seal certificate consuming that witness row. No consumer can skip directly from the witness coordinate to a completion object, selected limit, quotient stream equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or detached tail oracle.

Proof. Start with the witness carrier. By Definition 535.5, the accepted witness packet exposes exactly $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ as its public rows.

The local NameCert obligations and closure theorem bind those rows before the witness can be exported. Apply Definition 535.6 and Definition 535.14; they force source reads, window requests, Cauchy witness reads, dyadic ledgers, located traps, seal reads, transports, continuations, provenance, and local naming to stay inside the displayed witness packet. The Real seal handoff of Definition 535.12 supplies the last local route to Q.

Now read the convergence-seal packet. Definition 918.4 makes the witness row W the first consumed row before the seal packet may read $M, K, F', \sigma', D, L, R, H', C', P', N'$. Definition 918.5 then routes tolerance-facing reads through the monotone-tail and Cauchy-criterion rows before the finite regular, stream, dyadic, and CauchyLimitSeal rows are reached.

Finally apply Definition 918.12. It packages the second-stage rows as the displayed convergence-seal obligation surface. Since both stages have exhausted their public ledgers, the combined route has no remaining coordinate for any excluded completion, equality, order, compactness, or choice-selected tail. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal factorization`

Theorem 535.16 (Bounded monotone Cauchy witness shared budget meet)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Suppose* W *is consumed by a* $\mathsf{CauchySealBudgetSynchronizer}$ *budget handoff and by either a tail-schedule route or a real-tail-agreement route. Then every* $\mathsf{Real}^{\uparrow}$ *seal read on the combined route factors through the same finite rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

together with the synchronizer budget row before any downstream seal is readable.

Consequently the witness row, synchronizer row, and tail schedule share one finite budget route. The route exports no second tail budget, selected limit, quotient-stream equality, host real equality, ambient completeness, trichotomy, or hidden tail oracle.

Proof. First use the local convergence-seal factorization above. It forces every convergence-facing read to consume the bounded monotone Cauchy witness rows before the downstream seal rows are available, so the witness cannot be replaced by a completion object or by an independently selected tail.

Next attach the schedule and agreement handoffs. The tail-window service and Real observation-budget handoff force tolerance requests and finite Real-facing reads through $S, F, \sigma, \mu, \lambda$ before the located trap and $\mathsf{Real}^{\uparrow}$ seal are reached. The root synchronizer handoff then places every $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ consumer on the same displayed route through $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ rather than on a separate budget coordinate.

The sibling root-tail and completion routes keep the two consumers aligned. Root tail-budget exactness binds the $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, and $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ rows to the same source, tail, trap, seal, transport, continuation, provenance, and naming rows. Completion-consumer non-escape and the public seal handoff then send each Real-facing continuation through the public envelope, finite observation route, regular handoff, located trap, and seal row of W.

Finally apply ledger exhaustion. Since the accepted packet has no public coordinate beyond $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and the displayed synchronizer budget row, a downstream seal read has no second route from which it could obtain another tail budget, selected limit, quotient-stream equality, host real equality, ambient completeness, trichotomy split, or hidden tail oracle. □

Lean4 ✓ BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier shared budget meet

Theorem 535.17 (Bounded monotone Cauchy witness minimal convergence-seal witness)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let a* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *consumer use W as its witness coordinate. The local admission and consumption claim is already witnessed by the finite two-stage surface*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

followed by

$$W, M, K, F', \sigma', D, L, R, H', C', P', N'.$$

Equivalently, the named witness row W, together with the shared budget route of $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, is sufficient for every consumer-facing seal read admitted by this chapter.

If a larger reading claims to consume the same bounded monotone Cauchy witness while also exposing an additional completion object, selected limit, quotient stream equality, host real equality, trichotomy row, ambient completeness row, open-cover compactness row, detached tail oracle, or hidden selector, then its consumer-facing part factors back through the displayed two-stage surface and the added coordinate is not part of the admitted witness. Thus the minimal witness is the displayed finite witness-and-seal packet, not an ambient choice object.

Proof. First read the local witness stage. By Definition 535.15, a completion-facing consumer using a convergence-seal packet with witness coordinate W must pass through the accepted witness rows

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

Those rows are not merely parameters of a later construction: they are the public source, schedule, modulus, dyadic ledger, located trap, Real seal, transport, continuation, provenance, and local naming rows through which the witness is admitted.

The same factorization then forces the second stage through the convergence-seal rows

$$W, M, K, F', \sigma', D, L, R, H', C', P', N'.$$

At that point the consumer has exactly the witness coordinate W, the public monotone and Cauchy rows, the regular-rational readback, stream and dyadic ledgers, Cauchy-limit compatibility boundary, Real seal, transports, continuations, provenance, and local name. This proves sufficiency: the local admission and consumption claim has a displayed finite route before any consumer-facing seal read is available.

It remains to rule out enlargement of the witness. Apply Definition 535.16. Whenever the same W is consumed by the seal-budget synchronizer and by a tail-schedule or real-tail-agreement route, every $\mathsf{Real}^{\uparrow}$ seal read factors through the same finite rows of W together with the synchronizer budget row. Hence a downstream consumer cannot split off a second tail budget, a detached selector, or an independent completion-facing coordinate while still claiming to consume the same admitted witness.

Combining the two statements gives the minimality claim. The factorization theorem lists the only two stages through which the convergence-seal consumer may read, and the shared-budget meet theorem keeps all Real-facing consumption on the same finite budget surface. Any larger reading therefore has its admitted consumer-facing part already factored through the displayed rows. The listed excluded objects are not rows of either displayed stage and are not supplied by the shared budget meet, so they cannot enlarge the local witness. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier minimal convergence seal witness`

Theorem 535.18 (Bounded monotone Cauchy witness convergence-seal selector synchronization)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Any* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *consumer using W synchronizes its selected tail window through the witness rows μ, σ, λ and the seal-facing rows before it reads the convergence-seal selector.*

Concretely, a tolerance request is first answered by μ on the scheduled window σ and recorded in the dyadic ledger λ. The resulting window is then routed through I, Q, H, C, P, N and only then through the convergence-seal rows

$$W, M, K, F', \sigma', D, L, R, H', C', P', N'.$$

Thus the selected limit, quotient equality, host real equality, ambient completeness, and detached tail-oracle readings are unavailable unless they are already exposed by the displayed witness and seal packets.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal selector synchronization`

Proof. Begin with the local carrier. Definition 535.5 exposes exactly $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so the consumer has no selector coordinate outside those rows.

Next apply Definition 535.8. It sends each tolerance request to μ, ties the answer to the scheduled windows σ, and records the requested dyadic tolerance in λ.

Now route the synchronized tail into the seal-facing side. By Definition 535.12, the read of Q passes through the regular-sequence row, the window schedule, the tail modulus, the dyadic ledger, the located trap, transport, continuation, provenance, and local naming rows.

Finally use Definition 535.15. The convergence-seal consumer reads the witness packet before it reads $M, K, F', \sigma', D, L, R, H', C', P', N'$. Consequently the selected window is synchronized across μ, σ, λ and the seal rows before the convergence-seal selector is available, and the excluded completion and equality coordinates remain outside the combined route. □

Theorem 535.19 (Bounded monotone Cauchy witness scoped dependency package)**.** *The scoped dependency package of Definition 535.5 consists exactly of the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Within this package, generator range reads are controlled by S, tail requests are controlled by μ, σ, λ, located enclosures are controlled by I, classifier transport is controlled by H, C, the real seal is controlled by Q, and provenance and naming are controlled by P, N. Selected limits, quotient equality, host real equality, trichotomy, ambient completeness, and open-cover compactness remain outside the scoped package.

Proof. Start with generator range exactness. By Definition 535.7, every source observation is read through S_{gen} together with the monotone and upper-bound ledgers of S and the dyadic guard data in λ.

Next use tail modulus scope. By Definition 535.8, every tolerance request is answered by μ on the scheduled windows σ with the displayed dyadic tolerance ledger λ.

For the seal-facing rows, apply Definition 535.9 and Definition 535.12. These route every $\mathsf{Real}^{\uparrow}$ read through $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ while keeping the bounded source row visible.

Classifier movement is supplied by Definition 535.11. It transports only the displayed carrier coordinates and does not add any coordinate for selected limits, quotient equality, host real equality, trichotomy, ambient completeness, or open-cover compactness.

Finally apply Definition 535.13. Every public read is exhausted by the listed carrier rows, so the scoped dependency package is exactly the displayed package and no excluded completion or compactness object belongs to it. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier scoped dependency package`

Theorem 535.20 (Bounded monotone Cauchy witness L10 exit-consumer package)**.** *Any Phase Real and Completion consumer of an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet must read the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row,* $\mathsf{StreamName}^{\uparrow}$ *window schedule,* $\mathsf{CauchyModulus}^{\uparrow}$ *tail witness,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{LocatedInterval}^{\uparrow}$ *trap,* $\mathsf{Real}^{\uparrow}$ *seal,* BHist *carrier,* hsame *transports,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row before exporting a real-facing convergence claim.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier l10 exit consumer package`

Proof. Apply generator range exactness and tail modulus scope. These force the source reads through $S_{\text{gen}}, S_{\text{mono}}, S_{\text{ub}}$ and force each tolerance request through μ, σ, λ.

Next apply the real-seal boundary and real-seal handoff. The located trap and $\mathsf{Real}^{\uparrow}$ seal are read only through the displayed I, Q, H, C, P, N rows.

Finally apply classifier transport, ledger exhaustion, and the scoped dependency package. The consumer receives exactly the displayed witness packet before any real-facing convergence export, with no selected limit, quotient equality, host real equality, trichotomy, ambient completeness, or compactness coordinate added at the exit. □

Theorem 535.21 (Bounded monotone Cauchy witness source-to-seal triad)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing bounded monotone witness read from* W *factors through exactly three stages:*

1. *the bounded source generator rows* $S_{\text{gen}}, S_{\text{mono}}, S_{\text{ub}}$ *over the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *interface;*
2. *the scheduled finite tail-window service* σ, μ, λ *over the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *interface;*
3. *the located* $\mathsf{Real}^{\uparrow}$ *seal route* I, Q, H, C, P, N *through the displayed* $\mathsf{LocatedInterval}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows.*

No selected limit, quotient equality, host real equality, trichotomy, ambient completeness, or open-cover compactness row enters between these stages or supplies an additional $\mathsf{Real}^{\uparrow}$*-facing route.*

Proof. Start with the bounded source. By Definition 535.7, every generator-facing observation is already confined to $S_{\text{gen}}, S_{\text{mono}}, S_{\text{ub}}$ together with the displayed regular-sequence, stream-name, and dyadic guard data.

Next pass to the finite tail service. Definition 535.8 sends each tolerance request through μ on the windows scheduled by σ and records the tolerance ledger in λ.

For the seal-facing route, use Definition 535.12. It routes every $\mathsf{Real}^{\uparrow}$ read through the located interval row I, the seal row Q, the transport row H, the continuation row C, provenance P, and the local naming row N.

Now compare the three pieces with Definition 535.19. That package lists $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ as the whole public surface of the accepted carrier, with the source rows, scheduled tail service, and located seal route as the only BEDC packet stages visible to consumers.

Finally apply Definition 535.13. Since the public ledger is exhausted by the displayed rows, no selected limit, quotient equality, host real equality, trichotomy, ambient completeness, or open-cover compactness row can enter between the three stages or provide a further seal route. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessSourceToSealTriad`

Theorem 535.22 (Bounded monotone Cauchy witness source row scope)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every source read exposed by* W *is read through the generator, monotonicity, and upper-bound rows*

$$S_{\text{gen}}, S_{\text{mono}}, S_{\text{ub}}$$

together with the dyadic guard data carried by λ*.*

The source interface exposes no selected limit, quotient equality, host real equality, ambient completeness coordinate, trichotomy split, open-cover compactness row, or choice-selected tail.

Proof. Start with generator range exactness. By Definition 535.7, any source observation available to a consumer is already confined to S_{gen}, S_{mono}, and S_{ub}, with the tolerance guard supplied by λ.

Next compare this row with the scoped dependency package. Definition 535.19 lists S as the only bounded-source coordinate of the accepted carrier, while the remaining rows $F, \sigma, \mu, I, Q, H, C, P, N$ are handoff, witness, seal, transport, route, provenance, and naming rows rather than additional source coordinates.

Finally apply classifier transport and ledger exhaustion. Definition 535.11 moves only displayed coordinates, and Definition 535.13 leaves no public row from which a selected limit, host equality, quotient collapse, ambient completeness object, trichotomy split, compactness principle, or choice-selected tail could be read. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier source row scope`

Theorem 535.23 (Bounded monotone Cauchy witness window modulus row scope)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every tolerance request made to* W *factors through the displayed window schedule* σ*, Cauchy modulus answer* μ*, and dyadic tolerance ledger* λ *before any located trap* I *or* $\mathsf{Real}^{\uparrow}$ *seal row* Q *is read.*

Thus the window-modulus interface is the finite service σ, μ, λ over the displayed source and regular handoff rows. It exports no located trap or Real seal read that bypasses that service, and it exposes no selected limit, quotient equality, host real equality, ambient completeness, trichotomy, open-cover compactness, or choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window modulus row scope`

Proof. Begin with tail modulus scope. Definition 535.8 sends each tolerance request through μ on the scheduled windows σ and records the dyadic tolerance data in λ.

Use the scoped dependency package to place this service inside the whole packet. It identifies $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ as the public surface, so the window-modulus rows have to be read before the later located-trap and seal-facing rows can be consumed.

Now apply the Real seal boundary and Real seal handoff. Definition 535.9 and Definition 535.12 route I and Q through the displayed witness rows rather than around them.

Ledger exhaustion gives the exclusion. Since Definition 535.13 exhausts public reads by the displayed carrier rows, no completion coordinate, quotient collapse, host equality, trichotomy split, compactness principle, or choice-selected tail can answer a tolerance request independently of σ, μ, λ. □

Theorem 535.24 (Bounded monotone Cauchy witness Real seal row scope)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *seal read through Q factors through the displayed route*

$$F, \sigma, \mu, \lambda, I, H, C, P, N$$

and remains tied to the bounded source row S.

The Real seal interface therefore exports only the witnessed packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. It does not export a selected limit, quotient real equality, host real equality, ambient completeness, trichotomy, open-cover compactness, or choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real seal row scope`

Proof. Start with the seal boundary and handoff rows. By Definition 535.9 and Definition 535.12, the seal coordinate Q is available only through the regular handoff, scheduled windows, Cauchy witness, dyadic ledger, located trap, classifier transport, continuation, provenance, and local naming rows.

The source row remains attached to this route. Generator range exactness keeps source observations inside $S_{\text{gen}}, S_{\text{mono}}, S_{\text{ub}}$, and tail modulus scope keeps the tolerance route inside σ, μ, λ before the seal-facing suffix is read.

Classifier transport supplies the only allowed movement of the seal packet. Definition 535.11 transports the displayed rows componentwise, so the Real seal cannot be replaced by a host equality or quotient-name collapse.

Finally apply ledger exhaustion. The accepted carrier has no public coordinate beyond $S, F, \sigma, \mu, \lambda, I, Q, H, C, P$, so every seal read through Q remains a read of the displayed witnessed packet and cannot import completeness, trichotomy, compactness, selected limits, or choice-selected tails. □

Theorem 535.25 (Bounded monotone Cauchy witness tail-window service)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every tolerance request made to* W *factors through the bounded source row* S*, the regular rational handoff* F*, the scheduled* $\mathsf{StreamName}^{\uparrow}$ *windows* σ*, the Cauchy modulus answer* μ*, and the dyadic tolerance ledger* λ *before any located trap or completion-facing row can be read.*

The service exposes exactly the displayed $\mathsf{StreamName}^{\uparrow}$ *windows and their dyadic tolerance rows. It does not supply a selected limit, quotient equality, host real equality, trichotomy, ambient completeness, or open-cover compactness.*

Proof. Project the accepted carrier and use the NameCert obligation theorem. The rows $S, F, \sigma, \mu, \lambda$ are part of the displayed packet, so a tolerance request has no independent input surface outside the carrier.

Apply Definition 535.7. It keeps source observations inside the bounded generator, monotone, and upper-bound rows of S together with the regular rational handoff F.

Next apply Definition 535.8. The requested tolerance is answered by μ only after the scheduled windows σ and the dyadic ledger λ have been displayed.

Finally use Definition 535.13. Since every tolerance read has already passed through $S, F, \sigma, \mu, \lambda$, no completion coordinate or compactness object remains available to the service. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail window service`

Theorem 535.26 (Bounded monotone Cauchy witness located trap refinement)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The located trap row* I *refines the bounded source row* S*, the dyadic ledger* λ*, and the* $\mathsf{Real}^{\uparrow}$ *seal route* Q, H, C, P, N *through the same displayed packet. It does not add a selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail.*

The refinement is local to the carrier: a trap consumer may inspect I *only after the generator range, tail-modulus, dyadic tolerance, and NameCert rows of* W *have fixed the route from* $S, F, \sigma, \mu, \lambda$ *toward* Q*.*

Proof. Project the accepted carrier using Definition 535.5. The trap row I is displayed beside the bounded source, regular rational handoff, scheduled windows, Cauchy witness, dyadic ledger, seal, transports, continuations, provenance, and local naming row.

Use the NameCert obligations of Definition 535.6. They make carrier admission, explicit witness access, trap access, seal access, classifier transport, and ledger non-escape part of the same local package.

Now apply generator range exactness and tail modulus scope. By Definition 535.7, the source read remains inside the bounded generator and upper-bound rows of S; by Definition 535.8, the tolerance request reaches I only after σ, μ, λ have supplied the displayed tail service.

Finally use Definition 535.9, Definition 535.11, and Definition 535.13. The trap is therefore a refinement of the bounded source and dyadic ledger on the path to the Real seal, and every excluded completion or compactness coordinate remains absent from the carrier. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier located trap refinement`

Theorem 535.27 (Bounded monotone Cauchy witness tail-seal synchronization)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every tail request answered by the scheduled windows* σ*, Cauchy witness* μ*, and dyadic ledger* λ *reaches the same* $\mathsf{Real}^{\uparrow}$ *seal row* Q *through the displayed route*

$$I, H, C, P, N.$$

The synchronization supplies one tail-to-seal path through $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ *and cannot create a second hidden tail service or an ambient completion read.*

Proof. Begin with the tail-window service of Definition 535.25. It sends each tolerance request through $S, F, \sigma, \mu, \lambda$ before any located trap or completion-facing row can be consumed.

The carrier and NameCert rows then identify the seal-facing suffix. By Definition 535.5 and Definition 535.6, the only rows downstream of the tail service are the located trap I, the seal Q, the transports H, continuations C, provenance P, and naming row N.

Use generator range exactness and tail modulus scope to keep the source and tolerance sides fixed. Definition 535.7 fixes the bounded source read, while Definition 535.8 fixes the σ, μ, λ answer that the seal-facing route receives.

Finally apply Definition 535.9, Definition 535.11, and Definition 535.13. They force the read of Q through the same I, H, C, P, N suffix and leave no carrier coordinate for a second tail source, selected limit, quotient equality, host equality, trichotomy, ambient completeness, or compactness principle. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail seal synchronization`

Theorem 535.28 (Bounded monotone Cauchy witness completion-consumer refusal)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer receives only the witnessed packet displayed by* W*: the bounded source* S*, regular rational row* F*, window schedule* σ*, witness* μ*, dyadic ledger* λ*, located trap* I*, seal* Q*, transports* H*, continuations* C*, provenance* P*, and local naming row* N*.*

The consumer cannot read ambient completeness, quotient equality, trichotomy, open-cover compactness, host real equality, selected limiting representatives, or a choice-selected tail from this packet.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier completion consumer refusal`

Proof. Project the consumer-facing surface from the carrier of Definition 535.5. The displayed tuple $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ is the whole accepted packet.

Apply the NameCert obligations and the generator range row. Definition 535.6 identifies the admissible read coordinates, and Definition 535.7 keeps source observations inside the bounded generator and upper-bound data.

Next use Definition 535.8, Definition 535.25, and Definition 535.26. The consumer therefore reaches the seal only after the scheduled witness, dyadic ledger, and located trap rows have been read.

The final refusal is ledger exhaustion. By Definition 535.9, Definition 535.11, and Definition 535.13, every completion-facing read stays inside the witnessed packet and the excluded completion, equality, order, compactness, and host-real principles have no row to project. □

Theorem 535.29 (Bounded monotone Cauchy witness located trap handoff)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The* $\mathsf{LocatedInterval}^{\uparrow}$ *trap row I is reached only after the dyadic tolerance ledger λ and the source upper-bound rows in S have been displayed through the scheduled tail-window service.*

Thus any handoff from W to a located interval consumer preserves the same $S, F, \sigma, \mu, \lambda$ route before I and carries forward only Q, H, C, P, N as the seal, transport, continuation, provenance, and local naming rows.

Proof. Start with the source rows. By Definition 535.7, the upper-bound data are read from the displayed bounded source packet S and not from an ambient order-completeness assumption.

Use the tail-window service supplied by Definition 535.25. It routes the tolerance request through F, σ, μ, λ, so the dyadic ledger is already visible before the trap row is consumed.

Now apply Definition 535.9. The located trap I belongs to the seal-facing route that also carries Q, H, C, P, N, and it cannot be read before the source and tolerance ledgers have been displayed.

Finally apply Definition 535.13. The handoff has no coordinate for a hidden trap, selected limit, quotient equality, host real equality, trichotomy, ambient completeness, or open-cover compactness. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier located trap handoff`

Theorem 535.30 (Bounded monotone Cauchy witness completion boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier reads only the displayed packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

The boundary supplies the bounded source rows, regular rational handoff, scheduled tail windows, modulus answer, dyadic tolerance ledger, located trap, Real seal, transport rows, continuation rows, package provenance, and local naming row. It supplies no selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier completion boundary`

Proof. Use the scoped dependency package. By Definition 535.19, the whole public surface of the accepted carrier is the displayed package over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Apply Definition 535.25 and Definition 535.29. These rows force completion-facing reads to pass through the source, window, modulus, dyadic tolerance, and located-trap route before the seal is available.

Next apply Definition 535.12. It sends every real-facing read through I, Q, H, C, P, N while keeping the source and witness rows visible.

Finally apply Definition 535.13. Since the packet is exhausted by $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, the excluded completion and equality principles cannot be projected by any consumer. □

Theorem 535.31 (Bounded monotone witness bridge to public tail and criterion packets)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Suppose the bounded source row S is read through the finite tail-window surface of chapter 438, and the witness rows σ, μ, λ supply the explicit modulus and tail-bound route of chapter 392. Then every* $\mathsf{Real}^{\uparrow}$ *or completion-facing read of W factors through the public* $\mathsf{MonotoneCauchy}^{\uparrow}$ *tail-window certificate and the public* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet before the local* $\mathsf{Real}^{\uparrow}$ *seal handoff.*

The factorization preserves only the displayed rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. It exports no quotient real equality, selected representative, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice principle.

Proof. Start from Definition 535.19. It exposes the bounded source row, regular rational row, stream schedule, Cauchy modulus witness, dyadic ledger, located trap, real seal, transports, continuations, package provenance, and local naming row as the whole dependency surface of W.

Read the bounded source through the finite route supplied by Definition 438.21. That public certificate consumes the displayed tail-window schedule, monotone rows, located interval trap, real-seal row, componentwise transports, continuation routes, package provenance, and local $\mathsf{NameCert}_{\mathsf{MonotoneCauchy}^{\uparrow}}$ row, so the source socket of W is routed through the existing $\mathsf{MonotoneCauchy}^{\uparrow}$ public surface.

Read the witness rows through Definition 392.20. The rows σ, μ, λ provide the explicit modulus, dyadic tolerance, finite tail ledger, regular rational handoff, and real-seal route required by the public $\mathsf{CauchyCriterion}^{\uparrow}$ packet, so the witness socket of W is routed through the existing constructive criterion surface.

Finally apply Definition 535.12 and Definition 535.13. The handoff sends each real-facing read through $F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ while keeping the bounded source row visible, and ledger exhaustion rules out every remaining coordinate. Therefore the composed route passes through the MonotoneCauchy public tail-window certificate and the CauchyCriterion public packet before the local seal, with no route to quotient real equality, selected representatives, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier monotone cauchy criterion bridge`

Theorem 535.32 (Bounded monotone Cauchy witness Real observation-budget handoff)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. If a real-facing consumer asks W for finite observation data, then the request factors through the finite observation route of chapter 611: the windows are read through σ, dyadic readback and radius data are read through λ, the regular rational handoff is read through F, and the* $\mathsf{Real}^{\uparrow}$ *seal is read through Q.*

The handoff preserves the displayed bounded source row S, the Cauchy witness μ, the located trap I, transports H, continuations C, provenance P, and the local naming row N. It exports no quotient stream equality, host real equality, selected limit, trichotomy, ambient completeness, or choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real observation budget handoff`

Proof. Start from the scoped dependency package of Definition 535.19. It lists $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ as the whole public surface of the accepted packet.

Read the finite observation request through chapter 611. That route accepts finite window rows, dyadic readback and radius ledgers, regular-rational handoff rows, and a $\mathsf{Real}^{\uparrow}$ seal boundary; these are supplied here by σ, λ, F, Q.

Finally apply Definition 535.12 and Definition 535.13. The seal remains tied to the displayed bounded source and witness rows, while ledger exhaustion rules out every absent completion coordinate. □

Theorem 535.33 (Bounded monotone Cauchy witness Cauchy modulus-extraction factorization)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Before W exports a tail threshold to any Real-completion route, the witness rows σ, μ, λ factor through the modulus-indexed schedule of chapter 641. The schedule reads σ as its finite window source, μ as the tail-threshold answer for each dyadic tolerance request, and λ as the dyadic tolerance and radius ledger that justifies the answer.*

The factorization may pass along the regular sequence row F, the source row S, and the seal-facing rows I, Q, H, C, P, N, but it cannot replace the displayed modulus extraction by quotient stream equality, host real equality, a selected limit, trichotomy, ambient completeness, or a choice-selected tail.

Proof. Project the witness rows from the carrier. The rows σ, μ, λ already describe a window schedule, a tolerance-indexed tail answer, and the dyadic ledger that the tail answer consumes.

Route those rows through chapter 641. Its modulus-indexed schedule is exactly the public surface that receives a finite window source, a requested tolerance, and the ledger rows needed to produce a tail threshold.

Then reattach the source, regular-sequence, located-trap, seal, transport, continuation, provenance, and naming rows by Definition 535.8 and Definition 535.9. These rows carry the extracted threshold toward the Real-completion route without adding any excluded completion coordinate. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier cauchy modulus extraction factorization`

Theorem 535.34 (Bounded monotone Cauchy witness downstream unblock package)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The downstream Real and Completion consumers of W receive a finite package through four public routes: the* $\mathsf{MonotoneCauchy}^{\uparrow}$ *tail-window certificate, the* $\mathsf{CauchyCriterion}^{\uparrow}$ *criterion packet, the* $\mathsf{RealObservationBudget}^{\uparrow}$ *finite observation route, and the* $\mathsf{CauchyModulusExtraction}^{\uparrow}$ *modulus-indexed schedule.*

The package consists only of the displayed rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. It gives downstream consumers a bounded-source route, an explicit Cauchy witness route, a finite observation route, and a modulus-extraction route, with no quotient stream equality, host real equality, selected limit, trichotomy, ambient completeness, or choice-selected tail.

Proof. First apply Definition 535.31. It routes the source and witness sides of W through the public $\mathsf{MonotoneCauchy}^{\uparrow}$ tail-window certificate and the public $\mathsf{CauchyCriterion}^{\uparrow}$ packet before the local $\mathsf{Real}^{\uparrow}$ seal handoff.

Next apply Definition 535.32. It routes every real-facing finite observation read through σ, λ, F, Q and keeps the remaining carrier rows visible as the same displayed packet.

Then apply Definition 535.33. It routes σ, μ, λ through the modulus-indexed schedule before any tail threshold is exported to the Real-completion route.

Finally use Definition 535.13. Since every public read is exhausted by $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, the four-route package exports only finite displayed data and none of the excluded equality, limit, completeness, trichotomy, or tail-selection objects. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier downstream unblock package`

Theorem 535.35 (Bounded monotone Cauchy witness budget regularity lock)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. The regular-sequence row F and the Cauchy witness row μ are locked to the same finite budget rows σ and λ: any downstream read of regularity, tail control, or tolerance response must pass through the displayed window schedule σ and dyadic ledger λ before it may read either F or μ.*

No quotient equality, host real equality, selected limit, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail can supply an independent budget for F or μ.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier budget regularity lock`

Proof. Start with the carrier of Definition 535.5. The only budget-facing coordinates are the stream schedule σ, the witness row μ, and the dyadic ledger λ, with F as the regular rational handoff.

Apply the NameCert obligations of Definition 535.6 and the tail-window service of Definition 535.25. These force every tolerance request through F, σ, μ, λ as one finite service.

Finally use the downstream package of Definition 535.34. Since every exported route still uses the displayed rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, no external budget row can separate F from μ or replace σ, λ. □

Theorem 535.36 (Bounded monotone Cauchy witness located trap factorization)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every read of the located trap I factors through $S, F, \sigma, \mu, \lambda, H, C, P, N$ before any* $\mathsf{Real}^{\uparrow}$ *seal read is available. The trap therefore records a bounded-source, regular-handoff, scheduled-window, Cauchy-witness, dyadic-budget, transport, continuation, provenance, and naming route, rather than an independent interval selector.*

The factorization exports no host order-completeness argument, quotient equality, selected limit, trichotomy split, open-cover compactness, or choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier located trap factorization`

Proof. Begin with the carrier admission and local NameCert obligations. They make I one coordinate of the accepted packet and place it after the bounded source row, regular sequence row, schedule row, witness row, and dyadic ledger.

Use Definition 535.29. It is the direct handoff theorem for the trap row and routes reads of I through $S, F, \sigma, \mu, \lambda$ with the structural rows H, C, P, N still visible.

Then apply the Real observation-budget handoff and the Cauchy modulus-extraction factorization from Definition 535.32 and Definition 535.33. These keep the trap route inside the finite observation and modulus schedule before the Real seal can be consumed. □

Theorem 535.37 (Bounded monotone Cauchy witness Real seal schedule exhaustion)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *seal consumer of* W *reads the displayed schedule* σ*, dyadic ledger* λ*, Cauchy witness* μ*, and located trap* I *through the same finite route* $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$*. Such a consumer receives no selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail.*

Proof. First invoke the budget regularity lock and located trap factorization above. These place F, μ over the same schedule and dyadic budget, and they force the trap row I through the displayed source, regularity, witness, budget, transport, continuation, provenance, and naming rows.

Next apply Definition 535.12. The seal row Q is readable only after the located trap and witness-facing rows have been displayed.

Finally use Definition 535.13 together with Definition 535.33. The ledger exhausts every public read, and the modulus factorization keeps tolerance responses inside σ, μ, λ. Therefore the seal schedule has no remaining coordinate for any excluded equality, limit, completeness, trichotomy, compactness, or choice object. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real seal schedule exhaustion`

Theorem 535.38 (Bounded monotone Cauchy witness seal-trap-budget determinacy)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Suppose two Real-completion-facing consumers agree on the bounded source row* S*, regular handoff row* F*, schedule* σ*, Cauchy modulus row* μ*, dyadic ledger* λ*, located trap* I*, and structural rows* H, C, P, N*. Then they determine the same* $\mathsf{Real}^{\uparrow}$ *seal read* Q *and the same completion-facing export of* W*.*

The determinacy is only a row-level determinacy for the displayed carrier route. It does not assert a selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier seal trap budget determinacy`

Proof. First apply the tail-window service. It makes each tolerance request pass through the same displayed $S, F, \sigma, \mu, \lambda$ service, so the two consumers have no separate tail budget to read.

Next use located trap factorization. Since both consumers agree on I and on the structural rows H, C, P, N, every trap-facing read is already fixed by the shared source, handoff, schedule, modulus, ledger, and structural route.

Now apply Real seal schedule exhaustion. The seal row Q is readable only through that shared route, hence both consumers determine the same Real seal read.

Finally invoke the Real completion export theorem. The completion-facing export has no coordinate beyond $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so equality of the shared route and of the seal read forces the same export while excluding all selected-limit, quotient, host-equality, trichotomy, completeness, compactness, and choice-tail data. □

Theorem 535.39 (Bounded monotone Cauchy witness source-tail synchronization)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. A tolerance request to W cannot read the modulus answer μ or the scheduled windows σ unless the bounded source row S and the regular handoff row F are already displayed in the same packet.*

Thus the source, handoff, window, modulus, and dyadic-budget rows form one synchronized service. No consumer may replace that service by quotient equality, host real equality, a selected limit, trichotomy, ambient completeness, or a choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier source tail synchronization`

Proof. Start from the tail-window service of Definition 535.25. It routes every tolerance request through $S, F, \sigma, \mu, \lambda$ before any trap or completion-facing row can be read.

Use the downstream package of Definition 535.34. Its four public routes keep the bounded-source route and the explicit Cauchy-witness route inside the same displayed packet.

Finally invoke ledger exhaustion. Since the accepted carrier has only the rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, a request that reads μ or σ has no separate route around S and F. □

Theorem 535.40 (Bounded monotone Cauchy witness trap-budget monotonicity)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The located trap row I is monotone in the displayed dyadic budget route λ: tightening or transporting the tolerance budget can only be read through the same source row S, regular handoff F, scheduled windows σ, modulus answer μ, and located-trap handoff.*

Consequently the trap route exports no ambient order-completeness argument, trichotomy split, hidden interval selector, host real equality, quotient equality, selected limit, or choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier trap budget monotonicity`

Proof. First read the budget through Definition 535.25. The dyadic row λ is displayed with the window schedule and modulus answer, so budget movement is not an external operation.

Next use Definition 535.29. It places I after the route $S, F, \sigma, \mu, \lambda$ and keeps the upper-bound data from S visible at the handoff.

The classifier-transport and Real-seal rows then preserve the same displayed budget route under H, C, Q, P, N. Ledger exhaustion excludes any additional selector or completeness coordinate, so the trap can vary only along the displayed λ route. □

Theorem 535.41 (Bounded monotone Cauchy witness seal factorization triad)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted BoundedMonotoneCauchyWitness$^{\uparrow}$ *carrier. Any* Real$^{\uparrow}$ *seal read of W factors through the triad of public routes already cited by this chapter: the* MonotoneCauchy$^{\uparrow}$ *tail-window certificate, the* CauchyCriterion$^{\uparrow}$ *criterion packet, and the* RealObservationBudget$^{\uparrow}$ *finite observation route.*

The factorized seal still reads only $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. It does not import quotient equality, host real equality, selected limits, trichotomy, ambient completeness, or choice-selected tails.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier seal factorization triad`

Proof. Begin with Definition 535.31. It routes the bounded source through MonotoneCauchy$^{\uparrow}$ and the witness rows through CauchyCriterion$^{\uparrow}$ before the local seal is consumed.

Then use Definition 535.32. The finite observation request reads windows, dyadic data, regular-rational handoff, and Real seal data through σ, λ, F, Q.

Finally apply the downstream package and ledger exhaustion. The package contains the same carrier rows throughout the triad, and exhaustion rules out every absent quotient, host-equality, limit, completeness, trichotomy, and tail-selection coordinate. □

Theorem 535.42 (Bounded monotone Cauchy witness located interval trap certificate)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted BoundedMonotoneCauchyWitness$^{\uparrow}$ *carrier. The located-trap row I is certified only as the displayed* LocatedInterval$^{\uparrow}$ *trap carried by the dyadic tolerance ledger λ and by the hsame transport rows H. Any consumer that reads I as a trap certificate must therefore keep the source row S, regular handoff F, scheduled windows σ, Cauchy witness μ, dyadic ledger λ, transport rows H, continuation row C, provenance row P, and NameCert row N in the same package.*

The certificate exports no host interval selector, quotient stream equality, host real equality, selected limit, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier located interval trap certificate`

Proof. Begin with Definition 535.36. It already places every read of I after the displayed rows $S, F, \sigma, \mu, \lambda, H, C, P, N$, so the trap cannot be separated from the finite BoundedMonotone source, regular-rational handoff, scheduled window, and Cauchy witness data.

The LocatedInterval$^{\uparrow}$ certificate is then read through the same dyadic tolerance ledger. The local trap row is not an interval chosen outside the carrier; it is the row paired with λ and transported through H as part of the displayed packet.

Finally use the sibling DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, and LocatedInterval$^{\uparrow}$ handoffs cited by the scoped dependency package. Together with ledger exhaustion, these rows leave no additional coordinate from which a quotient equality, host equality, selected limit, completeness principle, trichotomy split, compactness argument, or choice-selected tail could enter. □

Theorem 535.43 (Bounded monotone Cauchy witness monotone tail coherence)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted BoundedMonotoneCauchyWitness$^{\uparrow}$ *carrier. The monotone tail schedule of* W *factors through the public* MonotoneCauchy$^{\uparrow}$ *tail-window route, the* CauchyCriterion$^{\uparrow}$ *criterion packet, and the* CauchyModulusExtraction$^{\uparrow}$ *modulus schedule. A downstream tail request may read only the displayed* σ, μ, λ *service over* S *and* F*, not an independently selected tail.*

This coherence exports no quotient equality, host real equality, selected limit, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier monotone tail coherence`

Proof. First apply Definition 535.39. It forces every tolerance request that reads σ or μ to keep the bounded source row S and the regular handoff row F visible in the same packet.

Next use Definition 535.31. This is the chapter's bridge from the bounded monotone source and explicit witness rows to the sibling MonotoneCauchy$^{\uparrow}$ and CauchyCriterion$^{\uparrow}$ certificates.

Finally apply Definition 535.33. It routes the schedule through σ, μ, λ before any tail threshold is exported. Since ledger exhaustion gives no separate coordinate for a tail choice, the monotone tail service remains a finite displayed route rather than a selected subsequence. □

Theorem 535.44 (Bounded monotone Cauchy witness Real completion export)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted BoundedMonotoneCauchyWitness$^{\uparrow}$ *carrier. Every Real-completion-facing consumer of* W *must pass through the finite observation budget, the regular rational handoff, and the Real seal rows before using the witness. Concretely, such a consumer reads the route* $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ *through the finite observation service of* RealObservationBudget$^{\uparrow}$*, the regular-sequence service of* RegSeqRat$^{\uparrow}$*, and the seal handoff to* Real$^{\uparrow}$*.*

The exported witness therefore carries only the displayed finite observation, regular-rational, trap, seal, transport, continuation, provenance, and naming data. It does not close a quotient real construction, host real equality, selected limit, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail.

Proof. Start with Definition 535.32. It routes every real-facing observation through the finite rows σ, λ, F, Q while keeping the carrier rows S, μ, I, H, C, P, N visible.

Next use Definition 535.41. The Real seal read factors through MonotoneCauchy$^{\uparrow}$, CauchyCriterion$^{\uparrow}$, and RealObservationBudget$^{\uparrow}$, so the consumer cannot skip the finite observation budget before reaching the seal row.

It remains to account for the regular handoff and trap data used by the witness. The located interval trap certificate above keeps I tied to LocatedInterval$^{\uparrow}$, λ, and H, while source-tail synchronization keeps σ, μ, λ tied to S and F.

Finally apply ledger exhaustion. The displayed packet has no additional completion coordinate, quotient representative, host equality, selected limit, completeness principle, trichotomy split, compactness proof, or choice-selected tail, so every Real-completion-facing export is forced through the finite observation, regular rational, and Real seal route already named. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real completion export`

Theorem 535.45 (Bounded monotone Cauchy witness formal handoff package)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The paper-side formal handoff for this carrier is exactly the finite package consisting of the bounded source row* S*, regular rational row* F*,* $\mathsf{StreamName}^{\uparrow}$ *schedule* σ*, Cauchy modulus witness* μ*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* λ*,* $\mathsf{LocatedInterval}^{\uparrow}$ *trap* I*,* $\mathsf{Real}^{\uparrow}$ *seal* Q*, componentwise* hsame *transports* H*, displayed* Cont *routes* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *row* N*.*

Every Lean-side consumer that claims Real-completion-facing use of $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *must formalize those rows before it consumes the Real route. The handoff contains no selected limit, quotient real, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail.*

Proof. The carrier definition displays exactly the coordinates $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. The local NameCert obligations then read carrier admission, regular rational exposure, schedule exposure, Cauchy witness exposure, dyadic ledger exposure, trap exposure, seal exposure, transport, continuation, provenance, and local naming from those same rows.

The scoped dependency package identifies the sibling sources of the rows. Monotone tail coherence keeps σ, μ, λ tied to the bounded source and regular handoff, while the located interval trap certificate keeps I tied to λ and the componentwise transports H.

Apply the Real completion export theorem. It forces every Real-completion-facing consumer through the finite observation budget, regular rational handoff, trap, seal, transport, continuation, provenance, and naming rows already displayed by the carrier.

Ledger exhaustion finishes the package comparison. Since the displayed carrier has no remaining coordinate for a selected limit, quotient real, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail, the listed rows are precisely the handoff to be formalized by downstream Lean work. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier formal handoff route`

Theorem 535.46 (Bounded monotone Cauchy witness convergence-seal terminal synchronization)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Any convergence-seal-facing or Real-completion-facing consumer of* W *synchronizes the same finite tail answer through*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

before it can read the convergence-seal rows. In particular, the terminal tail service is the displayed route through the bounded source, regular handoff, schedule, Cauchy witness, dyadic ledger, located trap, Real seal, transport, continuation, provenance, and local naming rows.

The synchronized route exports no selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal terminal synchronization`

Proof. First use Definition 535.15. It gives the two-stage route from the bounded monotone witness through the finite tail service and only then to the convergence-seal rows.

Next apply Definition 535.18. The selector rows μ, σ, λ are read as one shared terminal service, so a seal-facing consumer cannot replace the scheduled tail answer by an independently selected threshold.

For consumers that continue to the Real route, use Definition 535.44. It forces the Real-completion-facing read through the same finite observation, regular handoff, trap, seal, transport, continuation, provenance, and naming rows before any terminal export is visible.

Ledger exhaustion closes the synchronization claim. The accepted packet contains no coordinate for a selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-selected tail; hence every seal or completion-facing consumer reaches the terminal convergence-seal read only through the displayed finite route above. □

Definition 535.47 (Bounded monotone Cauchy witness scheduled tail envelope)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The scheduled tail envelope of* W *is the finite* BHist *subpacket*

$$E = (S, F, \sigma, \mu, \lambda, I, H, C, P, N)$$

read before the $\mathsf{Real}^{\uparrow}$ *seal row* Q*.*

Its rows are ordered as follows: S *supplies the bounded monotone source generator and its range, monotonicity, and upper-bound rows;* F *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff read from that source;* σ *is the* $\mathsf{StreamName}^{\uparrow}$ *family of inspected source and regular-sequence windows;* μ *is the* $\mathsf{CauchyModulus}^{\uparrow}$ *answer to each dyadic tolerance request;* λ *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and upper-bound budget;* I *is the* $\mathsf{LocatedInterval}^{\uparrow}$ *trap reached from the same budget;* H *records the componentwise* hsame *transports;* C *records the displayed* Cont *routes;* P *records* Pkg *provenance over the sibling concrete-instance rows; and* N *records the local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *naming surface.*

Thus E *is the public tail-serving part of* W*: every row needed to answer a tolerance request is displayed before* I *or* Q *is consumed, and* Q *is the seal row read after this envelope rather than a coordinate inside it.*

Lean4 (definition) `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessScheduledTailEn`

Theorem 535.48 (Bounded monotone Cauchy witness window coverage)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let* $E = (S, F, \sigma, \mu, \lambda, I, H, C, P, N)$ *be its scheduled tail envelope. Every tolerance request made to* W *factors through* E *and, more specifically, through the ordered service* $S, F, \sigma, \mu, \lambda$ *before the located trap* I *or the* $\mathsf{Real}^{\uparrow}$ *seal* Q *can be read.*

Consequently the request is answered by the source generator, regular rational handoff, scheduled windows, Cauchy modulus answer, and dyadic budget rows of the envelope. It cannot be answered by quotient equality, host real equality, a selected limit, trichotomy, ambient completeness, open-cover compactness, or a choice-selected tail.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window coverage`

Proof. Project the carrier using Definition 535.5. The rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ are the whole accepted packet, and the scheduled envelope removes only the seal row Q from the pre-seal tail service.

Use Definition 535.25. It sends each tolerance request through $S, F, \sigma, \mu, \lambda$ before any located-trap or completion-facing row is available.

Next apply Definition 535.33. The modulus answer is read through the same σ, μ, λ schedule, so the request has no alternate tail threshold outside the envelope.

Finally invoke Definition 535.13. Since the carrier has no further public read coordinate, a consumer cannot reach I or Q without first passing through the displayed source, handoff, window, modulus, and budget rows. □

Theorem 535.49 (Bounded monotone Cauchy witness trap-seal exactness)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let $E = (S, F, \sigma, \mu, \lambda, I, H, C, P, N)$ be its scheduled tail envelope. Any read of the located trap I or the* $\mathsf{Real}^{\uparrow}$ *seal Q factors through E before the read is exported.*

The exported trap or seal is therefore exact for the displayed bounded-source, regular-handoff, scheduled-window, modulus-answer, dyadic-budget, transport, continuation, provenance, and naming rows. It cannot import quotient equality, host real equality, selected limits, trichotomy, ambient completeness, open-cover compactness, or choice-selected tails.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier trap seal exactness`

Proof. Start with the located trap route of Definition 535.36. It places every read of I after $S, F, \sigma, \mu, \lambda$ and keeps the transport, continuation, provenance, and naming rows visible.

Then use Definition 535.37. The seal row Q is available only through the same schedule, dyadic ledger, Cauchy witness, and located trap route.

Combine this with Definition 535.41. The seal factors through the public monotone-tail, Cauchy-criterion, and finite-observation routes, all of which still read the displayed packet rows rather than an external completion object.

Ledger exhaustion supplies the final exclusion. After E has been read, the only remaining row is the seal row Q, so there is no carrier coordinate for quotient equality, host equality, selected limits, trichotomy, completeness, compactness, or choice-selected tails to enter the trap or the seal. □

Theorem 535.50 (Bounded monotone Cauchy witness finite observation lock)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let $E = (S, F, \sigma, \mu, \lambda, I, H, C, P, N)$ be its scheduled tail envelope. Every finite observation request exported to a* $\mathsf{Real}^{\uparrow}$ *consumer, or to any completion-facing consumer reading the* $\mathsf{Real}^{\uparrow}$ *seal, factors through the displayed bounded source row S, the* $\mathsf{StreamName}^{\uparrow}$ *window schedule σ, the* $\mathsf{CauchyModulusExtraction}^{\uparrow}$ *threshold route carried by σ, μ, λ, the* $\mathsf{RealObservationBudget}^{\uparrow}$ *finite-read route, the located trap I, and finally the* $\mathsf{Real}^{\uparrow}$ *seal Q.*

Thus the exported observation is locked to the finite rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. No selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector is exposed by the accepted packet.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier finite observation lock`

Proof. Begin with the finite observation route. By Definition 535.32, every Real-facing finite read passes through the displayed source, stream window, dyadic budget, regular-rational handoff, and seal rows of W.

Next apply Definition 535.33. The threshold service used by such a read is routed through σ, μ, λ, so a completion-facing consumer receives a modulus-indexed finite schedule rather than a separate tail selector.

The trap and seal are then fixed by the local exactness chain. Use Definition 535.36 for the located interval route, Definition 535.37 for the seal schedule, and Definition 535.49 for the fact that reads of I and Q remain exact for the same envelope E.

Finally invoke Definition 535.13. Since the accepted packet has no further public coordinate beyond $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, the composed route exposes no selected limit, quotient real equality, host equality, trichotomy, completeness, compactness, or choice-like tail selector. □

Theorem 535.51 (Bounded monotone Cauchy witness root unblock)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let $E = (S, F, \sigma, \mu, \lambda, I, H, C, P, N)$ be its scheduled tail envelope. The root consumer for the Real-and-completion route is unblocked exactly by the finite BEDC package*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

It receives the bounded-source rows from S, the regular rational handoff from F, the selected windows from σ, the Cauchy modulus answer from μ, the dyadic and upper-bound budget from λ, the located trap from I, and the $\mathsf{Real}^{\uparrow}$ *seal from Q, with H, C, P, N carrying transport, route, provenance, and naming data.*

No additional completion object is exposed. In particular, the route exports no selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root unblock`

Proof. Project the carrier of Definition 535.5. The only rows available to a consumer are $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and the NameCert obligations require the generator range, explicit Cauchy witness, located trap, seal, and ledger exhaustion rows to be read through that packet.

Use Definition 535.48 and Definition 535.50. These place every tolerance and finite-observation request on the path through $S, F, \sigma, \mu, \lambda$ before I and Q can be consumed.

Finally apply Definition 535.49. The trap and seal stay exact for the same scheduled tail envelope E, so the root consumer has a single finite package rather than an independent completion-facing input. □

Theorem 535.52 (Bounded monotone Cauchy witness window exhaustion)**.** *For any accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$, the scheduled windows σ exhaust the public tail service used by the Real-and-completion route. Each dyadic tolerance request is answered by the Cauchy modulus row μ on a displayed window of σ, read with the dyadic budget λ and the regular rational row F before the located trap I or* $\mathsf{Real}^{\uparrow}$ *seal Q is exported.*

Thus the Cauchy modulus extraction and the $\mathsf{RealObservationBudget}^{\uparrow}$ *finite-read route share the same window ledger. A consumer cannot replace that ledger by a hidden subsequence, an unrecorded tail threshold, a selected limit, quotient equality, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window exhaustion`

Proof. Begin with the tail-window service. By Definition 535.25, a tolerance request has to pass through $S, F, \sigma, \mu, \lambda$ before any trap or completion-facing row is available.

Next use Definition 535.33. It identifies the threshold route used by the request with the same σ, μ, λ schedule, so the modulus answer cannot be read from a second tail service.

The finite observation side is locked by Definition 535.32 and Definition 535.50. These force the Real observation budget to consume the displayed windows and dyadic rows before the seal route is reached.

Ledger exhaustion closes the exclusion. Since the accepted packet contains no further tail coordinate, no consumer can add a hidden threshold, selected limit, quotient equality, host equality, completeness principle, compactness row, or choice-like selector. □

Theorem 535.53 (Bounded monotone Cauchy witness seal handoff)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The public handoff from W to the Real-and-completion route is the single finite-row package that first serves the tail windows, then extracts the Cauchy modulus, then reads the located trap, and finally exports the* $\mathsf{Real}^{\uparrow}$ *seal:*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

The route is public precisely as a BEDC package: $S, F, \sigma, \mu, \lambda$ answer the tail and finite-observation requests, I supplies the located trap, Q supplies the seal, and H, C, P, N keep classifier transport, continuation, provenance, and NameCert naming visible.

Consequently any later RealUp consumer can cite this theorem as the exported BoundedMonotoneCauchyWitness handoff. The theorem does not close host real equality, quotient real construction, selected representatives, trichotomy, ambient completeness, open-cover compactness, or choice-selected tails.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail service seal handoff`

Proof. First build the pre-seal service from the carrier and NameCert rows. The carrier displays $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, and the NameCert obligations require every generator, witness, trap, seal, and ledger read to stay inside that displayed packet.

Apply Definition 535.51. It gives the root Real-and-completion consumer a single finite package instead of separate source, modulus, trap, and seal inputs.

Next apply Definition 535.52. The Cauchy modulus extraction and finite observation budget use the same σ, μ, λ window ledger over S and F, so the package has one public tail route.

Finally use Definition 535.49 together with Definition 535.13. The located trap and $\mathsf{Real}^{\uparrow}$ seal are exact for the scheduled envelope, and the ledger has no remaining coordinate for any excluded completion, equality, compactness, or choice principle. □

Theorem 535.54 (Bounded monotone Cauchy witness scheduled tail downstream coverage)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let $E = (S, F, \sigma, \mu, \lambda, I, H, C, P, N)$ be its scheduled tail envelope. Every accepted local consumer of the scheduled tail is covered by the displayed finite packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

More precisely, a tolerance consumer is exhausted by the source, regular-rational handoff, scheduled-window, modulus, and dyadic-ledger rows $S, F, \sigma, \mu, \lambda$; a finite-observation consumer is exhausted by those rows together with the located trap and seal rows I, Q; a trap or seal consumer is exhausted by E followed by Q; and any transport, continuation, provenance, or naming consumer is exhausted by H, C, P, N.

Thus the scheduled tail has no accepted downstream coordinate for quotient equality, host real equality, selected limits, trichotomy, ambient completeness, open-cover compactness, hidden tail

thresholds, or choice-selected tails. Those alternatives remain outside the accepted BoundedMonotoneCauchyWitness *packet.*

Proof. Project the scheduled envelope from Definition 535.47. The envelope displays exactly the pre-seal rows $S, F, \sigma, \mu, \lambda, I, H, C, P, N$, and the only post-envelope row of the accepted carrier is the $\mathsf{Real}^{\uparrow}$ seal row Q.

First consider a tolerance consumer. By Definition 535.48, every tolerance request factors through E and specifically through $S, F, \sigma, \mu, \lambda$ before either I or Q can be read. Hence the tolerance side is already exhausted by the finite service rows of the envelope, with no hidden tail selector or completion input.

Next consider a finite-observation, trap, or seal consumer. The finite-observation route of Definition 535.50 reads the same source, window, modulus, dyadic-budget, located-trap, and seal rows. For direct trap and seal reads, Definition 535.49 says that every read of I or Q factors through E before export and is exact for the displayed source, handoff, schedule, modulus, budget, transport, continuation, provenance, and naming rows.

The remaining local consumers in this file are the root, window-exhaustion, and seal-handoff consumers. By Definition 535.51, the root consumer receives the finite package $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. By Definition 535.52, the scheduled windows and dyadic ledger exhaust the public tail service. By Definition 535.53, the public handoff is the same finite-row package, first serving the tail windows, then extracting the modulus, then reading the located trap, and finally exporting Q.

Combining these cases, every accepted local consumer reads one of the enumerated finite service, ledger, coverage, trap, seal, transport, continuation, provenance, or naming rows. Since the carrier has no coordinate beyond those rows, the excluded quotient-equality, host-equality, selected-limit, trichotomy, completeness, compactness, hidden-threshold, and choice-selected-tail alternatives cannot be accepted downstream reads of the packet. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier scheduled tail downstream coverage`

Theorem 535.55 (Bounded monotone Cauchy witness Real route non-escape)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Any Real-and-completion consumer of* W *factors through the finite package*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

The consumer must read the bounded monotone source S*, the regular rational handoff* F*, the scheduled windows* σ*, the Cauchy modulus answer* μ*, the dyadic and upper-bound budget* λ*, the located trap* I*, the* $\mathsf{Real}^{\uparrow}$ *seal* Q*, and the transport, continuation, provenance, and naming rows* H, C, P, N *before it can use the packet.*

Consequently the Real-and-completion route has no escape to a selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real route nonescape`

Proof. Start with the carrier. By Definition 535.5, the accepted packet exposes exactly the displayed rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ to later consumers.

The tail service is exhausted before the Real seal is reached. Apply Definition 535.48 and Definition 535.52; every tolerance and finite-window request passes through $S, F, \sigma, \mu, \lambda$ before the trap or seal can be read.

The trap and seal remain exact for the same displayed envelope. Use Definition 535.49 to keep reads of I and Q attached to the scheduled tail envelope, and then use Definition 535.53 to identify the exported Real-and-completion handoff as the single package $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Finally invoke Definition 535.13. Since the ledger has no remaining public coordinate after those rows are read, a consumer cannot project a selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector from the accepted packet. □

Theorem 535.56 (Bounded monotone Cauchy witness terminal-window split exactness)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every terminal tail service exported by* W *for an accepted packet factors in the exact finite order*

$$S, F, \sigma, \mu, \lambda \longmapsto I \longmapsto Q \longmapsto H, C, P, N.$$

The first stage is the bounded-source, regular-handoff, finite-observation, Cauchy-witness, and dyadic-ledger window. The second stage is the located trap I*. The third stage is the* $\mathsf{Real}^{\uparrow}$ *seal row* Q*. Only after these three stages are visible may the consumer read componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming.*

Thus a terminal tail answer is not a detached threshold, selected subsequence, quotient real, host equality, trichotomy split, ambient completeness principle, open-cover compactness proof, or choice-selected limit. It is exactly the displayed route from finite observation through regular handoff and Real seal to the structural suffix.

Proof. Start with the finite observation stage. By Definition 535.39 and Definition 535.33, a terminal request that reads σ, μ, or λ keeps the bounded source row S and regular handoff row F in the same accepted packet.

Next pass to the located trap. The located interval trap certificate fixes I as the pre-seal enclosure obtained after the finite observation, modulus, and dyadic ledger rows have been consumed. No terminal service can replace that row by an ambient interval choice because the carrier has no such coordinate.

Then read the Real seal. Apply Definition 535.44: any Real-completion-facing consumer must pass through the finite observation budget, regular rational handoff, trap, seal, transport, continuation, provenance, and naming rows before a completion-facing export is visible.

Finally compare the suffix. The convergence-seal terminal synchronization theorem forces the same displayed route for seal-facing consumers, while ledger exhaustion leaves H, C, P, N as transport, replay, provenance, and naming only. Therefore every accepted terminal tail service splits exactly through the finite observation stage, the regular handoff and located trap, the Real seal, and the structural suffix named in the statement. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier terminal window split exactness`

Theorem 535.57 (Bounded monotone Cauchy witness tail envelope public export)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let*

$$E = (S, F, \sigma, \mu, \lambda, I, H, C, P, N)$$

be its scheduled tail envelope. The envelope E exports the single public pre-seal service for completion-facing consumers: source reads pass through S, regular rational reads pass through F, window requests pass through σ, tolerance answers pass through μ, dyadic and upper-bound budget reads pass through λ, trap reads pass through I, and the transport, continuation, provenance, and naming routes pass through H, C, P, N.

Thus every public tail-envelope read is already a read through $S, F, \sigma, \mu, \lambda, I, H, C, P, N$ before the $\mathsf{Real}^{\uparrow}$ *seal row Q is consumed. The export contains no selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail envelope public export`

Proof. Start with the scheduled windows. By Definition 535.48, the source, regular-sequence, Cauchy witness, dyadic ledger, and trap-facing reads all pass through $S, F, \sigma, \mu, \lambda, I$ on the same displayed window schedule.

Next use the finite-read route. By Definition 535.50, Real-facing finite observations are locked to the displayed rows of W, so the public pre-seal route cannot replace $S, F, \sigma, \mu, \lambda, I$ by an unrecorded completion object.

The exactness and handoff theorems identify the public boundary. Apply Definition 535.49 to keep the located trap exact for the same envelope E, and apply Definition 535.53 to locate the later $\mathsf{Real}^{\uparrow}$ seal after the displayed pre-seal service.

Finally, Definition 535.52 rules out any second tail service. Since the accepted packet exposes no coordinate beyond the listed rows, the envelope exports exactly the public service $S, F, \sigma, \mu, \lambda, I, H, C, P, N$ before Q is read. □

Theorem 535.58 (Bounded monotone Cauchy witness completion consumer non-escape)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let $E = (S, F, \sigma, \mu, \lambda, I, H, C, P, N)$ be its scheduled tail envelope. Every completion-facing consumer of the bounded monotone Cauchy witness factors through the public envelope E, the* $\mathsf{RealObservationBudget}^{\uparrow}$ *finite-read route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{LocatedInterval}^{\uparrow}$ *trap, and the* $\mathsf{Real}^{\uparrow}$ *seal.*

Consequently the consumer has no escape route to a selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector. Its entire public dependency surface is the finite package $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier completion consumer nonescape`

Proof. First build the envelope route. The public export theorem above identifies E as the only pre-seal service, and Definition 535.48 keeps every inspected source and tail window on that service.

Next attach finite observation. By Definition 535.50, every Real-facing finite read is routed through the displayed finite rows of W. The regular rational handoff is the F coordinate of that same packet, and the window ledger is the shared σ, μ, λ route.

The trap and seal then close the route. Apply Definition 535.49 to keep I exact for the scheduled envelope, and apply Definition 535.53 to pass from the trap side to the $\mathsf{Real}^{\uparrow}$ seal row Q without introducing a second completion-facing input.

It remains to exclude escapes. Definition 535.51 gives the root consumer exactly the finite package $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, while Definition 535.52 rules out a hidden tail service. Therefore

any completion-facing consumer factors through the displayed envelope, finite-read route, regular-sequence handoff, located trap, and seal, and no selected limit, equality principle, completeness principle, compactness row, or choice-like selector is exposed. □

Theorem 535.59 (Bounded monotone Cauchy witness completion consumer apartness budget)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let $E = (S, F, \sigma, \mu, \lambda, I, H, C, P, N)$ be its scheduled tail envelope. Every completion-facing consumer of W must consume the scheduled tail envelope E together with the finite apartness and budget rows σ, μ, λ, I before it consumes the* $\mathsf{Real}^{\uparrow}$ *seal row Q.*

Consequently the route cannot be read as a selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector. The only public pre-seal completion data are the scheduled envelope and the finite apartness-budget rows already displayed by W.

Proof. Start with the public export theorem. Definition 535.57 identifies E as the exported pre-seal service and lists σ, μ, λ, I among the rows read before the seal.

Next use the finite-observation lock. By Definition 535.50, every Real-facing finite read remains on the displayed rows of W, so no consumer can replace the apartness and budget schedule by an unrecorded completion object.

The trap and seal then fix the order of consumption. Apply Definition 535.49 to keep I on the same located trap surface, and apply Definition 535.53 to place the $\mathsf{Real}^{\uparrow}$ seal row Q after that finite surface.

Finally apply Definition 535.52 and Definition 535.58. The first rules out a second tail service, and the second rules out escape through limit selection, equality principles, completeness, compactness, or choice-like selection. Thus every completion-facing consumer must pass through the scheduled envelope and the finite apartness-budget rows before the seal row is consumed. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier completion consumer apartness budget`

Theorem 535.60 (Bounded monotone Cauchy witness envelope uniqueness)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P,$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. If two completion-facing consumer routes for W are admitted before the* $\mathsf{Real}^{\uparrow}$ *seal row is read, then both routes consume the same scheduled tail envelope rows*

$$S, F, \sigma, \mu, \lambda, I, H, C, P, N$$

and only then read the seal row Q.

Any claimed difference between the two pre-seal envelopes is not a second completion route for W. It is routed to the refusal boundary for selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selectors.

Proof. First identify the exported envelope. By Definition 535.57, the only public pre-seal service is the displayed tuple $S, F, \sigma, \mu, \lambda, I, H, C, P, N$.

Next apply completion non-escape. Definition 535.58 forces every completion-facing consumer of W through that public envelope, the finite-read route, the regular handoff, the located trap, and the seal row.

The apartness and budget rows are fixed before the seal by Definition 535.59. Thus two admitted routes cannot differ on σ, μ, λ, I while remaining completion-facing routes for the same accepted packet.

It remains to rule out a second finite envelope with the same visible role. The finite-observation lock Definition 535.50 keeps Real-facing finite reads on the displayed rows of W, and Definition 535.52 rules out a hidden tail service. Therefore any disagreement is outside the finite envelope and is handled by the existing refusal boundary for the listed non-envelope principles. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier envelope uniqueness`

Theorem 535.61 (Bounded monotone Cauchy witness completion observation route)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every completion-facing observation route for* W *first consumes the rows*

$$S, F, \sigma, \mu, \lambda, I, H, C, P, N,$$

then passes through the finite $\mathsf{RealObservationBudget}^{\uparrow}$ *route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{LocatedInterval}^{\uparrow}$ *trap, and only then reads the* $\mathsf{Real}^{\uparrow}$ *seal row* Q*.*

The route exports no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector. Thus completion consumers read the finite observation surface before any Real-facing seal is consumed.

Proof. First expose the scheduled envelope. By Definition 535.57, the public pre-seal rows of W are exactly $S, F, \sigma, \mu, \lambda, I, H, C, P, N$.

Next route the completion consumer through the finite observation surface. Apply Definition 535.58 to force the read through the public envelope, the finite observation route, the regular rational handoff, the located trap, and the later seal row.

The apartness and budget rows fix the order of the finite segment. By Definition 535.59, σ, μ, λ, I are consumed before the $\mathsf{Real}^{\uparrow}$ seal row Q, so the seal cannot precede the finite observation route.

Finally use envelope uniqueness. Definition 535.60 rules out a second pre-seal envelope, and the non-escape conclusion excludes selected limits, equality principles, trichotomy, completeness, compactness, and choice-like selectors from the exported route. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier completion observation route`

Theorem 535.62 (Bounded monotone Cauchy witness Real observation seal factorization)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every Real-completion-facing consumer of* W *factors in the following order: first through the scheduled tail envelope*

$$S, F, \sigma, \mu, \lambda, I, H, C, P, N,$$

then through the finite $\mathsf{RealObservationBudget}^{\uparrow}$ *route, then through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{LocatedInterval}^{\uparrow}$ *trap, and only then through the* $\mathsf{Real}^{\uparrow}$ *seal row* Q*.*

Consequently the consumer never receives a selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector. The only public seal-facing dependency surface is the finite package $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ *with the pre-seal rows consumed before* Q*.*

Proof. Start with the envelope rows. Theorem 535.57 identifies the scheduled tail envelope as the displayed pre-seal service and places $S, F, \sigma, \mu, \lambda, I, H, C, P, N$ before the seal row.

Next apply the completion-consumer non-escape theorem. It forces every Real-completion-facing consumer through the public envelope, the finite observation route, the regular rational handoff, the located trap, and the later $\mathsf{Real}^{\uparrow}$ seal, with no additional completion object exposed.

The pre-seal order is fixed by the apartness-budget theorem. Theorem 535.59 requires the rows σ, μ, λ, I to be consumed before the seal row Q, so the finite budget cannot be read after the Real seal.

Finally use the completion observation route. Theorem 535.61 binds the observation route to the same envelope, budget, handoff, trap, and seal order. Its non-escape conclusion rules out selected limits, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, and choice-like selectors from the exported surface. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real observation seal factorization`

Theorem 535.63 (Bounded monotone Cauchy witness completion envelope determinacy)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. If two completion-facing observation routes for W agree on the scheduled envelope rows*

$$S, F, \sigma, \mu, \lambda, I, H, C, P, N$$

before the $\mathsf{Real}^{\uparrow}$ *seal row Q is read, then they determine the same accepted completion-facing envelope.*

The two routes cannot differ by selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector. The only accepted pre-seal completion surface is the displayed scheduled envelope.

Proof. First identify the pre-seal rows. The public export theorem Definition 535.57 presents $S, F, \sigma, \mu, \lambda, I, H, C, P, N$ as the scheduled tail envelope read before Q.

Next force both routes through that envelope. By Definition 535.58, any completion-facing observation of W must pass through the public envelope, the finite observation route, the regular handoff, and the located trap before it reaches the seal row.

The finite order is fixed by the apartness-budget theorem. Definition 535.59 places σ, μ, λ, I before Q, so the agreed pre-seal rows cannot be bypassed by a later seal read.

Finally use envelope uniqueness. Definition 535.60 rules out a second pre-seal route for the same packet, and Definition 535.61 keeps the completion-facing read on the finite observation surface. Hence the two routes determine the same accepted envelope and cannot differ by any of the excluded completion or equality principles. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier completion envelope determinacy`

Corollary 535.64 (Bounded monotone Cauchy witness tail envelope strict local obstruction)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet, and let $E = (S, F, \sigma, \mu, \lambda, I, H, C, P, N)$ be its scheduled tail envelope. Any completion-facing use of the tail envelope factors through the displayed pre-seal rows*

$$S, F, \sigma, \mu, \lambda, I, H, C, P, N,$$

then through the finite $\mathsf{RealObservationBudget}^{\uparrow}$ *route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{LocatedInterval}^{\uparrow}$ *trap, and finally the* $\mathsf{Real}^{\uparrow}$ *seal row Q.*

Consequently the obstruction carried by the completion-consumer non-escape row is strict and local. It blocks exactly the attempted converse or reuse route that reads the finite tail envelope as a selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, choice-like tail selector, or unlisted validation coordinate. It does not state a global impossibility theorem, does not supply a host-real theorem, and does not certify any external completion principle outside the displayed packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail envelope strict local obstruction`

Proof. Apply Definition 535.58. It sends every completion-facing consumer of W through the public envelope E, the finite observation route, the regular rational handoff, the located trap, and the seal row, and it explicitly excludes selected limits, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, and choice-like tail selectors from the consumer surface.

Apply Definition 535.61. This fixes the order of any completion-facing observation: the rows $S, F, \sigma, \mu, \lambda, I, H, C, P, N$ are consumed before the finite observation route and before the seal row Q. Therefore a claimed converse or reuse route must either factor through those rows or ask for a coordinate not exported by the accepted packet.

If the claimed route asks only for the listed rows, it is not obstructed by the non-escape conclusion; it is just the admitted local observation route. If it asks for a selected limit, an equality principle, trichotomy, completeness, compactness, a choice-like selector, or an external validation coordinate, then the request is rejected precisely because that coordinate is absent from the finite dependency surface. The rejection is therefore local to the named converse or reuse attempt.

Nothing in the two cited theorems quantifies over all host real constructions, all completion theorems, or all external validation mechanisms. Their common conclusion is only that the accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ packet exposes the displayed finite rows and no additional completion-facing coordinate. Hence the obstruction cannot be reinterpreted as a global impossibility, a host theorem, or a hidden external validation principle. □

Theorem 535.65 (Bounded monotone Cauchy witness convergence-seal source)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C,$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The witness rows of* W *supply the finite source row consumed by* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *in chapter 918: the bounded source row* S*, regular rational handoff* F*, stream schedule* σ*, Cauchy witness* μ*, dyadic ledger* λ*, located trap* I*, Real seal row* Q*, transport rows* H*, continuation rows* C*, package row* P*, and local* $\mathsf{NameCert}$ *row* N *are the whole source surface.*

The supplied source row exports no selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal source`

Proof. Project the accepted carrier and the scoped dependency package of Definition 535.19. These clauses expose exactly the displayed source, handoff, stream, witness, dyadic, trap, seal, transport, continuation, provenance, and naming rows.

The convergence-seal carrier of chapter 918 reads a finite bounded monotone source together with a regular handoff, stream schedule, Cauchy evidence, dyadic ledger, compatibility route, and Real-facing seal. Each of those coordinates is already one of the rows of W.

Since the carrier has no coordinate for a selected limit, quotient equality, host equality, trichotomy, ambient completeness, compactness principle, or choice-like selector, the handoff to the seal cannot export such data. □

Theorem 535.66 (Bounded monotone Cauchy witness finite-tail-filter handoff)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C,$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every convergence-seal or Real-completion consumer of* W *first factors through the displayed bounded witness rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N,$$

then through $\mathsf{MonotoneCauchy}^{\uparrow}$ *and* $\mathsf{CauchyCriterion}^{\uparrow}$*. The tail-window part of that route lands in the* $\mathsf{FiniteTailFilter}^{\uparrow}$ *packet of chapter 1119 before the consumer continues through*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{CauchyLimitSeal}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The handoff exports no selected limit, quotient equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector outside the displayed witness and finite-tail packets.

Proof. First read the source boundary. The convergence-seal source theorem Definition 535.65 confines every seal-facing source to the bounded witness rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and rules out a separate completion coordinate.

Next apply the criterion-tail factorization Definition 535.69. It forces every completion-facing read through $\mathsf{MonotoneCauchy}^{\uparrow}$ and $\mathsf{CauchyCriterion}^{\uparrow}$ before any Real-facing seal is available, so the tail data are read as a public finite window rather than as an unrecorded selector.

Now pass through the finite-tail interface. FiniteTailFilter tail-window exactness Definition 1119.4 identifies the admissible stream window, dyadic ledger, regular readback, tail budget, common-tail row, and Real seal row as one $\mathsf{FiniteTailFilter}^{\uparrow}$ packet, and FiniteTailFilter Real seal handoff Definition 1119.5 sends that packet to the Real-facing consumer without adding a completion principle.

Finally use Real-seal public route exhaustion Definition 535.70. The remaining route is exactly through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, together with the structural BHist, hsame, Cont, Pkg, and NameCert rows already displayed by the carrier. Hence no selected limit, quotient equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector can escape the bounded witness and finite-tail handoff. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier finite tail filter handoff`

Theorem 535.67 (Bounded monotone Cauchy witness tail-filter lock)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Any completion-facing consumer that reads* W *through* $\mathsf{FiniteTailFilter}^{\uparrow}$ *must first pass through the displayed witness rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N,$$

then through $\mathsf{MonotoneCauchy}^{\uparrow}$ *and* $\mathsf{CauchyCriterion}^{\uparrow}$*, and then through the finite-tail packet rows supplied by Definition 1119.4 and Definition 1119.5. Only after those rows have been read may the consumer continue to*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{CauchyLimitSeal}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The route contains no selected limit, quotient stream equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector outside the displayed witness and finite-tail packets.

Proof. Begin with the convergence-seal source theorem, Definition 535.65. It fixes the accepted source of every seal-facing read as the finite packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and excludes a detached completion coordinate at the source boundary.

Next apply criterion-tail factorization, Definition 535.69. This forces the route through $\mathsf{MonotoneCauchy}^{\uparrow}$ and $\mathsf{CauchyCriterion}^{\uparrow}$ before any completion-facing consumer can inspect a Real seal.

Now use the finite-tail interface. Tail-window exactness, Definition 1119.4, identifies the stream window, dyadic ledger, regular readback, tail budget, common-tail row, and Real-seal row as one $\mathsf{FiniteTailFilter}^{\uparrow}$ packet. The Real seal handoff, Definition 1119.5, then sends exactly that packet to the Real-facing consumer.

Finally apply Real-seal public route exhaustion, Definition 535.70. It lists the remaining public route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the structural BHist, hsame, Cont, Pkg, and NameCert rows. Since no listed carrier exports the excluded completion data, every finite-tail consumer is locked to the stated L10 route. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail filter lock`

Theorem 535.68 (Bounded monotone Cauchy witness selector terminal pullback)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every terminal consumer preserving the L10 route across*

$$\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}, \mathsf{CauchyLimitSeal}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{CauchyCriterion}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegS}$$

pulls back to the same finite selector packet before any convergence seal, limit seal, real carrier, criterion route, stream name, dyadic core, regular sequence, or diagonal comparison is read. The pullback rows are exactly

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

together with the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. The pullback exports no quotient stream, selected limit, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector.*

Proof. First identify the source packet. The source-readback equalizer fixes the accepted packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ before the convergence-seal readback can expose any public completion coordinate.

Next move to terminal consumers. The terminal-source equalizer transports the same packet to the $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ endpoints, while terminal located-trap preservation keeps the row I and its attached Q, H, C, P, N support inside that packet.

Now use the L10 route. Terminal route exhaustion brings in the $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ consumers and records that their only public support rows are the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Finally apply refusal completeness. Any terminal request outside those rows is off-route, so the consumer cannot read a seal, diagonal comparison, quotient stream, selected limit, host equality,

trichotomy, compactness, ambient completeness, or choice-like selector before returning to the finite selector packet. Thus every terminal consumer preserving the L10 route pulls back to exactly the stated packet and support rows. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier selector terminal pullback`

Theorem 535.69 (Bounded monotone Cauchy witness criterion-tail factorization)**.** *Every* BoundedMonotoneCauch *route from the bounded source row to the convergence-seal handoff factors through the public* MonotoneCauchy$^{\uparrow}$ *row and the public* CauchyCriterion$^{\uparrow}$ *row before any* BoundedMonotoneConvergenceSeal$^{\uparrow}$ *consumer reads it.*

Equivalently, a downstream seal consumer first sees the monotone Cauchy bridge of Definition 535.31, then the displayed Cauchy criterion tail package, and only then the finite Real-seal handoff.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier criterion tail factorization`

Proof. Start with the bridge theorem Definition 535.31. It identifies the bounded monotone witness surface as a public monotone Cauchy row whose tail data are read through the displayed Cauchy criterion route.

Next apply the convergence-seal input package of Definition 535.90. That package routes the same carrier through MonotoneCauchy$^{\uparrow}$, CauchyCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, and Real$^{\uparrow}$ before any completion-facing consumer can inspect the seal.

Thus the witness route has no direct jump from boundedness and monotonicity to a Real seal. Its only public path is the criterion-tail factorization already displayed in the accepted carrier and the downstream convergence-seal chapter. □

Theorem 535.70 (Bounded monotone Cauchy witness Real-seal public route exhaustion)**.** *The public Real-seal route exposed by* BoundedMonotoneConvergenceSeal$^{\uparrow}$ *is exhausted by the rows supplied by* BoundedMonotoneCauchyWitness$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

No part of that public route contains a selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Proof. Use the source theorem above to restrict the public source to the finite witness rows of W. Use the factorization theorem above to force every seal-facing read through MonotoneCauchy$^{\uparrow}$ and CauchyCriterion$^{\uparrow}$ before the convergence-seal handoff.

The convergence-seal carrier at chapter 918 then records the remaining rows: stream names, dyadic tolerances, regular rational handoff, Cauchy-limit compatibility, Real seal, history transport, continuations, package provenance, and local naming.

The listed rows are the complete public route. Since none of the carriers includes a coordinate for selected limits, quotient equality, host real equality, trichotomy, ambient completeness, compactness, or choice-like tail selection, the public Real-seal handoff is exhausted by the displayed BEDC rows. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real seal public route exhaustion`

Theorem 535.71 (Bounded monotone Cauchy witness seal-route naturality)**.** *Any downstream consumer that reads the bounded monotone witness through the convergence-seal chapter obtains the same public route whether it starts from the witness source theorem, the criterion-tail factorization, or the Real-seal public route exhaustion. The common route factors through* $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

The public handoff exports no selected limit, quotient equality, host real equality, trichotomy, open-cover compactness, or choice-like selector.

Proof. Begin with the source surface of Definition 535.65. It fixes the finite witness rows that the convergence-seal chapter may read and excludes selected limits, quotient equalities, host equalities, compactness principles, and choice-like tail selectors.

Next apply the criterion-tail factorization of Definition 535.69. This is the only public bridge from the bounded witness source to a completion-facing seal route, so every downstream read must pass through $\mathsf{MonotoneCauchy}^{\uparrow}$ and $\mathsf{CauchyCriterion}^{\uparrow}$ before it can inspect the Real-facing rows.

Finally apply the Real-seal public route exhaustion of Definition 535.70. It lists the remaining public rows $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert. Since all three starting descriptions are forced through the same factorization and the same exhausted route, the downstream handoff is natural across the displayed source, criterion-tail, and Real-seal readings. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal route naturality`

Theorem 535.72 (Bounded monotone Cauchy witness convergence-seal source totality)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every convergence-seal source read exposed from* W *is one of the displayed witness rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

The read has no extra source coordinate for a selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal source totality`

Proof. Apply the checked source theorem Definition 535.65. It identifies the finite convergence-seal source surface with exactly the bounded source, regular rational handoff, stream schedule, Cauchy witness, dyadic ledger, located trap, Real seal, transport, continuation, package, and local naming rows of W.

The criterion-tail factorization of Definition 535.69 shows that a seal-facing source read cannot bypass those rows by jumping directly to a completion-facing object. The factorization first routes through $\mathsf{MonotoneCauchy}^{\uparrow}$ and $\mathsf{CauchyCriterion}^{\uparrow}$, then through the displayed schedule, ledger, handoff, trap, and seal rows.

Finally use the Real-seal public route exhaustion of Definition 535.70. Since the exhausted route contains only the displayed finite rows and structural BEDC rows, the source read is total on the witness package and exports none of the excluded completion data. □

Theorem 535.73 (Bounded monotone Cauchy witness convergence-seal readback)**.** *Every readback from a* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *consumer to an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$

carrier $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *factors through the displayed source/schedule/regular/trap/seal route*

$$S, \sigma, F, I, Q, H, C, P, N$$

together with the Cauchy witness and dyadic ledger rows μ, λ*. Thus the readback returns only to the finite source surface of* W *and never to an unrecorded completion principle.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal readback`

Proof. Begin with seal-route naturality above. It says that a downstream consumer obtains the same route whether it starts from the source theorem, the criterion-tail factorization, or the Real-seal route exhaustion.

Read the route in the reverse direction from the convergence-seal consumer. Naturality forces the readback through the same source row S, stream schedule σ, regular rational handoff F, located trap I, Real seal Q, and structural rows H, C, P, N, with μ, λ supplying the Cauchy witness and dyadic budget already present in the source theorem.

The completion-consumer non-escape theorem Definition 535.58 keeps completion-facing consumers inside the public envelope, finite-read route, regular handoff, trap, and seal. Therefore the readback has no branch to selected limits, quotient equality, host equality, trichotomy, ambient completeness, compactness, or choice-like tail selection. □

Theorem 535.74 (Bounded monotone Cauchy witness convergence-seal non-escape)**.** *Every completion consumer reached through the convergence-seal source surface of an accepted* BoundedMonotoneCauchyWitnes *carrier remains inside the finite route*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

It cannot select a limit, assert quotient real equality, assert host real equality, decide trichotomy, invoke ambient completeness, invoke open-cover compactness, or acquire a tail selector outside the displayed carrier.

Proof. First apply the convergence-seal source totality theorem above. It confines every source read to the displayed witness rows of W.

Next apply convergence-seal readback. Any consumer-side return route is the same finite source/schedule/regular/trap/seal route, with the Cauchy witness and dyadic ledger still supplied by μ, λ.

Finally apply Definition 535.58. That checked non-escape row says completion-facing consumers factor through the public envelope, finite-read route, regular handoff, located trap, and $\mathsf{Real}^{\uparrow}$ seal. Since all of those rows are already in the displayed carrier and no excluded completion coordinate occurs in the packet, the convergence-seal consumer remains inside the finite route. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal nonescape`

Theorem 535.75 (Bounded monotone Cauchy witness convergence-seal source lock)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Any* BoundedMonotoneCon *consumer whose source is supplied by* W *must first factor through the displayed witness rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N,$$

then through MonotoneCauchy$^{\uparrow}$ *and* CauchyCriterion$^{\uparrow}$*, and then through the finite* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* CauchyLimitSeal$^{\uparrow}$*, and* Real$^{\uparrow}$ *route before it is read as a Real-facing convergence seal.*

The consumer cannot replace that source by a selected limit, quotient stream equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Proof. First apply Definition 535.72. It locks every source read supplied by W to the displayed finite witness rows and leaves no separate completion-facing coordinate.

Next use Definition 535.73. Any read from a convergence-seal consumer back to the witness must return along the same source, schedule, regular-rational, Cauchy-witness, dyadic-ledger, trap, seal, transport, continuation, package, and local naming rows.

Finally invoke Definition 535.74. The non-escape result keeps the consumer inside the finite route through MonotoneCauchy$^{\uparrow}$, CauchyCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, and Real$^{\uparrow}$. Since the route has no coordinate for the excluded analytic or choice-like objects, no downstream consumer can substitute such an object for the source supplied by W. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal source lock`

Theorem 535.76 (Bounded monotone Cauchy witness convergence-seal route exhaustion)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *packet. Every convergence-seal or Real-completion consumer of* W *factors through the displayed finite route*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N,$$

then through MonotoneCauchy$^{\uparrow}$*,* CauchyCriterion$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* CauchyLimitSeal$^{\uparrow}$*, and* Real$^{\uparrow}$*.*

The route exports no selected limit, quotient stream equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal route exhaustion`

Proof. First apply the checked source theorem Definition 535.65. It identifies the source surface available to a convergence-seal consumer with exactly the finite witness rows of W.

Next use the criterion-tail factorization and the Real-seal public route exhaustion. These force the downstream handoff through MonotoneCauchy$^{\uparrow}$, CauchyCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, and Real$^{\uparrow}$ before any Real-completion-facing consumer can read the seal.

Finally combine the readback, non-escape, and source-lock theorems above. Readback returns consumer-side information to the same finite packet, non-escape prevents a branch to an external completion principle, and source-lock prevents replacement of W by any unrecorded selected limit, quotient equality, host equality, trichotomy, compactness, completeness, or selector coordinate. □

Theorem 535.77 (Bounded monotone Cauchy witness convergence-seal selector readback)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *packet. Every convergence-seal selector readback of* W *first returns to the displayed witness rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N,$$

and then factors through

$$\mathsf{MonotoneCauchy}^{\uparrow}, \mathsf{CauchyCriterion}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{CauchyLimitSeal}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The readback exports no quotient stream, host real equality, selected limit, trichotomy, ambient completeness, open-cover compactness, or choice-like selector.

Proof. Begin with source totality, Definition 535.72. It confines every convergence-seal source read of W to the displayed witness rows and gives the selector no separate completion-facing coordinate.

Next apply convergence-seal readback and non-escape, Definition 535.73 and Definition 535.74. The readback returns consumer-side information to the same finite packet, while non-escape keeps completion consumers inside the public route through the bounded source, criterion tail, stream, dyadic, regular, limit-seal, and Real rows.

Finally use source lock and route exhaustion, Definition 535.75 and Definition 535.76. These two statements identify the only available selector route with the displayed packet followed by $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Since none of the excluded analytic or choice-like objects is a row of that route, the selector readback cannot export one. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal selector readback`

Theorem 535.78 (Bounded monotone Cauchy witness root-window convergence-seal lock)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Any convergence-seal or Real-completion consumer of W must first read the root finite window rows*

$$S, F, \sigma, \mu, \lambda,$$

as the scheduled source, regular handoff, stream schedule, Cauchy witness, and dyadic budget of the accepted packet. Only after that root-window read may the consumer continue through the displayed route

$$\mathsf{MonotoneCauchy}^{\uparrow}, \mathsf{CauchyCriterion}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{CauchyLimitSeal}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The consumer cannot replace the scheduled window or its refusal boundary by selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or a choice-like selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root window convergence seal lock`

Proof. First apply the convergence-seal source theorem Definition 535.65. It identifies the source rows available to the seal with the finite packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, and it already excludes selected limits, quotient equality, host equality, trichotomy, completeness, compactness, and choice-like tail selection.

Next apply the criterion-tail factorization Definition 535.69. This forces the consumer to pass from the root window through $\mathsf{MonotoneCauchy}^{\uparrow}$ and $\mathsf{CauchyCriterion}^{\uparrow}$ before it can read any seal-facing completion route.

The readback theorem Definition 535.73 returns every consumer-side read to the same displayed source, schedule, regular handoff, Cauchy witness, dyadic ledger, trap, seal, transport, continuation, package, and local naming rows. Thus the scheduled root window remains the boundary that a consumer must read back through.

Finally combine non-escape Definition 535.74 with route exhaustion Definition 535.76. Non-escape rules out any branch to an external completion principle, and route exhaustion lists the only public path through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The convergence-seal consumer is therefore locked to the scheduled root window and its refusal boundary. □

Theorem 535.79 (Bounded monotone Cauchy witness located-trap convergence-seal cofinality)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Any* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of W must preserve the located interval row I cofinally with the root window rows*

$$S, F, \sigma, \mu, \lambda$$

and the terminal rows

$$Q, H, C, P, N.$$

Thus every completion-facing read that reaches the convergence seal still carries the same located-trap row I as part of the bounded monotone witness packet.

The consumer cannot bypass I through selected limits, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or a choice-like selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier located trap convergence seal cofinality`

Proof. First apply source totality, Definition 535.72. It identifies every seal-facing source read with the displayed packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so the located interval row I is present before any completion consumer inspects the route.

Next use convergence-seal readback, Definition 535.73. Readback returns consumer-side information to the same bounded monotone witness rows, which keeps I in the packet whenever a $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer reads the seal.

Now apply the root-window convergence-seal lock, Definition 535.78. The scheduled rows $S, F, \sigma, \mu, \lambda$ cannot be detached from the same packet as the located trap I and the terminal rows Q, H, C, P, N.

Finally use route exhaustion, Definition 535.76. The only completion-facing route runs through $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Carrier-coordinate exhaustion then leaves no coordinate from which a consumer could replace the located trap by selected limits, quotient equality, host equality, trichotomy, completeness, compactness, or selector data. □

Theorem 535.80 (Bounded monotone Cauchy witness convergence-seal diagonal readback)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *route. Any* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of W whose terminal read is compared through* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *first factors through the same finite witness rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N,$$

then through

$$\mathsf{MonotoneCauchy}^{\uparrow}, \mathsf{CauchyCriterion}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{CauchyLimitSeal}^{\uparrow}, \mathsf{Real}^{\uparrow},$$

and finally through the diagonal terminal-consumer rows

$$R, T, S, D, W, Q, L, H, C, P, N.$$

The comparison exports no selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal diagonal readback`

Proof. First lock the source side. Apply source totality Definition 535.72, convergence-seal readback Definition 535.73, and convergence-seal non-escape Definition 535.74. These results keep the consumer read inside the finite witness rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Next attach the public seal route. The source lock Definition 535.75, route exhaustion Definition 535.76, and root-window lock Definition 535.78 force the read through $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any terminal comparison is available.

Finally compare the terminal consumer through $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$. By Definition 646.84, every diagonal Real or completion-seal read passes through $R, T, S, D, W, Q, L, H, C, P, N$; by Definition 646.85, this route is exhausted by the displayed diagonal rows, Pkg provenance, and local NameCert row. Therefore the bounded-monotone convergence seal and the diagonal-limit terminal consumer meet at the stated finite boundary without importing any excluded analytic or choice-like coordinate. □

Theorem 535.81 (Diagonal-limit compatibility bounded monotone window-seal handoff)**.** *Let* $W_{\mathrm{bm}} = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Suppose a terminal* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *read of* W_{bm} *is compared through an accepted* DiagonalLimitCompatibil *packet. Then the consumer first factors through the bounded-monotone rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N,$$

then through the diagonal terminal rows

$$R, T, S, D, W, Q, L, H, C, P, N.$$

The two routes meet only through the shared BHist, hsame, Cont, Pkg, *and* NameCert *surfaces. The handoff exports no selected limit, quotient equality, host* $\mathsf{Real}^{\uparrow}$ *equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector.*

Proof. Start with the existing diagonal comparison. The convergence-seal diagonal readback theorem Definition 535.80 already forces any bounded-monotone convergence-seal or $\mathsf{Real}^{\uparrow}$ consumer compared through $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ through the finite witness rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ before it reaches the diagonal terminal rows.

Next synchronize the prefix and suffix inside the bounded-monotone witness. By Definition 535.152, the scheduled root window $S, F, \sigma, \mu, \lambda$ and the seal-facing suffix I, Q, H, C, P, N belong to the same accepted packet. Thus the terminal read cannot detach the diagonal comparison from the bounded-monotone source packet.

Now attach the diagonal budget-seal route. The factorization theorem Definition 646.84 routes every diagonal terminal consumer through $R, T, S, D, W, Q, L, H, C, P, N$ before it is offered to a completion-facing read.

Finally combine the non-escape clauses already used in the diagonal readback paragraph. The bounded-monotone side contributes only the finite witness rows and its BHist, hsame, Cont, Pkg, and NameCert surfaces; the diagonal side contributes only the displayed terminal rows and the same shared surfaces. Therefore the two routes meet at that finite handoff boundary, with no coordinate from which to read a selected limit, quotient equality, host $\mathsf{Real}^{\uparrow}$ equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window seal handoff`

Theorem 535.82 (Bounded monotone Cauchy witness convergence-seal terminal source pullback)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer that reaches the convergence-seal source factors through the same finite source pullback*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N,$$

then through $\mathsf{MonotoneCauchy}^{\uparrow}$*,* $\mathsf{CauchyCriterion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. Thus the completion-facing consumers identify the same accepted source packet before reading any seal-facing route.*

The pullback exports no selected limit, quotient equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal terminal source pullback`

Proof. Start with source totality Definition 535.72. It identifies every convergence-seal source read supplied by W with the finite rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and gives no additional completion-facing coordinate.

Next apply readback Definition 535.73, non-escape Definition 535.74, and source lock Definition 535.75. Readback returns consumer-side information to the same packet, non-escape prevents a branch to external completion data, and source lock prevents replacing the source by any unrecorded analytic or choice-like object.

Now use route exhaustion Definition 535.76 together with root-window convergence-seal lock Definition 535.78. The former lists the whole route through $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; the latter fixes the scheduled root window $S, F, \sigma, \mu, \lambda$ inside that route.

It remains only to exhaust the coordinates of the accepted carrier. The source, handoff, stream, Cauchy witness, dyadic ledger, trap, Real seal, transport, continuation, package, and local naming rows are exactly $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. Hence every listed consumer pulls back to the same finite packet before it reaches the public completion route, and no excluded completion principle is exported. □

Theorem 535.83 (Bounded monotone Cauchy witness source-readback equalizer)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. The source totality row and the convergence-seal readback row determine the same finite source packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

for every seal-facing consumer. Thus a read that starts from the bounded source and a read that returns from BoundedMonotoneConvergenceSeal$^{\uparrow}$ *are equalized before any completion-facing route is inspected.*

The equalizer has no branch for selected limits, quotient equality, host equality, trichotomy, open-cover compactness, ambient completeness, or choice-like selectors.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier source readback equalizer`

Proof. First compare the forward source read with the reverse readback. Source totality, Definition 535.72, exposes exactly the rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. Convergence-seal readback, Definition 535.73, returns every consumer-side read to the same rows.

Next lock the common route. Non-escape Definition 535.74 prevents a detour to external completion data, source lock Definition 535.75 prevents replacement of the source packet, and route exhaustion Definition 535.76 lists the only completion-facing path.

Finally use the root-window lock, Definition 535.78. The scheduled root window $S, F, \sigma, \mu, \lambda$ remains inside the same packet as I, Q, H, C, P, N, so the source and readback rows form a single finite equalizer. Since the listed theorems provide no coordinate for selected limits, quotient equality, host equality, trichotomy, compactness, completeness, or selector data, those reads are ruled out. □

Theorem 535.84 (Bounded monotone Cauchy witness terminal source equalizer)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *packet. The source-readback equalizer composes with the diagonal terminal-source pullback, so every* BoundedMonotoneConvergenceSeal$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, Real$^{\uparrow}$, *or* DiagonalLimitCompatibility$^{\uparrow}$ *terminal consumer reads the same finite packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

before any seal-facing or terminal comparison route is available.

No terminal consumer obtains a selected limit, quotient equality, host equality, trichotomy, open-cover compactness, ambient completeness, or choice-like selector from this comparison.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier terminal source equalizer`

Proof. Begin with the source-readback equalizer above. It identifies the forward source route and the reverse convergence-seal readback as the same finite packet, with no extra completion coordinate.

Now compose with the terminal-source pullback, Definition 535.82. That pullback already sends BoundedMonotoneConvergenceSeal$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, and Real$^{\uparrow}$ consumers through the same source packet before the public seal route.

Finally attach the diagonal comparison. The diagonal readback theorem Definition 535.80 brings DiagonalLimitCompatibility$^{\uparrow}$ terminal reads to the same boundary after the root-window and route-exhaustion locks have fired. Therefore all four terminal consumers meet the identical finite source packet before reading any seal-facing route, and the excluded analytic or choice-like objects have no available row in the comparison. □

Theorem 535.85 (Bounded monotone Cauchy witness terminal located trap preservation)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *packet. Every* BoundedMonotoneConvergenceSeal$^{\uparrow}$*,* CauchyLimitSeal$^{\uparrow}$*,* Real$^{\uparrow}$*, or* DiagonalLimitCompatibility$^{\uparrow}$ *terminal consumer that preserves the convergence-seal source also preserves the located trap row* I *as part of the finite packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

before any seal-facing or terminal comparison route is available.

No terminal route may replace I *by a selected limit, quotient equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier terminal located trap preservation`

Proof. First identify the source packet. Source totality, readback, non-escape, and source lock give the same finite carrier rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ for every convergence-seal source read and provide no external completion coordinate.

Next preserve the root window and the terminal route. The root-window lock keeps $S, F, \sigma, \mu, \lambda$ attached to the same accepted packet, while the terminal-source pullback and terminal-source equalizer force BoundedMonotoneConvergenceSeal$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, Real$^{\uparrow}$, and DiagonalLimitCompatibility$^{\uparrow}$ consumers to read that packet before any public completion comparison.

It remains to isolate the trap row. Since I is a displayed row of the packet equalized by Definition 535.84, a consumer that preserves the convergence-seal source preserves I along with Q, H, C, P, N. The excluded analytic and choice-like objects have no row in the equalized packet, so they cannot replace the located trap. □

Theorem 535.86 (Bounded monotone Cauchy witness L10 terminal route exhaustion)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *packet. Every terminal consumer preserving the convergence-seal source across*

BoundedMonotoneConvergenceSeal$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, Real$^{\uparrow}$, CauchyCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegS

factors through exactly the finite packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ *together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

The exhausted route exports no quotient stream, selected limit, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier l10 terminal route exhaustion`

Proof. First equalize the source. The source-readback equalizer, Definition 535.83, identifies the source totality row with the convergence-seal readback row on the same finite packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Next attach the terminal source route. By Definition 535.84, every BoundedMonotoneConvergenceSeal$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, Real$^{\uparrow}$, and DiagonalLimitCompatibility$^{\uparrow}$ terminal consumer reaches that packet before any terminal comparison is available.

Now preserve the located trap and support rows. The located-trap preservation theorem Definition 535.85 keeps I inside the same source packet, while the convergence-seal route exhaustion and diagonal readback theorems display the BHist, hsame, Cont, Pkg, and NameCert rows used by the public seal and diagonal compatibility routes.

Finally compare the listed consumers. The public seal route already passes through $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and the diagonal readback adds $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ without adding an external coordinate. Therefore the whole terminal consumer chain is exhausted by the displayed finite packet and support rows, with no available row for any excluded analytic, quotient, compactness, or choice-like object. □

Theorem 535.87 (Bounded monotone Cauchy witness L10 terminal route refusal completeness)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. A terminal consumer request across*

$\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}, \mathsf{CauchyLimitSeal}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{CauchyCriterion}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegS}$

is admissible exactly when it factors through the finite packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. Any request for quotient stream equality, selected limits, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection is off-route, because no displayed carrier row supplies it.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier l10 terminal route refusal completeness`

Proof. The forward direction is the route-exhaustion direction. Source-readback equalization first identifies every convergence-seal source read with the same accepted packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Next the terminal-source equalizer transports that packet to the $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ consumers before any terminal comparison can be read. Terminal located-trap preservation keeps I in the same packet and keeps Q, H, C, P, N attached to the displayed source.

Now apply the L10 terminal route exhaustion theorem. It adds the $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ route and records that the only exported support rows are the displayed BHist, hsame, Cont, Pkg, and NameCert rows. Hence an accepted terminal consumer is admissible only by factoring through that finite route.

For the converse, any consumer already factored through the finite packet and the displayed support rows is one of the terminal reads permitted by the exhausted route. It therefore uses only rows supplied by the accepted packet, the history/support equality rows, the continuity row, the package row, and the certificate row.

Finally consider the refused requests. Quotient stream equality, selected limits, host real equality, trichotomy, ambient completeness, open-cover compactness, and choice-like tail selection are not entries of $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and are not supplied by BHist, hsame, Cont, Pkg, or NameCert. The terminal chain has no further carrier row, so each such request is off-route. □

Theorem 535.88 (BoundedMonotoneCauchyWitness convergence-seal Real exit exhaustion)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyCriterion}^{\uparrow}$*, diagonal-limit, finite-tail-filter, or completion-facing read of the bounded monotone witness convergence seal factors through the displayed source row, finite-tail-filter handoff, selector terminal pullback, criterion tail factorization, Real seal public unblock, source-readback equalizer, and terminal-route refusal-completeness rows.*

No such read may use a selected limit, quotient stream, host real equality, countable choice, or ambient completeness row.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal real exit exhaustion`

Proof. Begin at the convergence-seal source. The source row and finite-tail-filter handoff attach the accepted packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ to the displayed convergence-seal route before any Real-facing or completion-facing consumer can read it.

Next use the selector terminal pullback and criterion-tail factorization. These force the selector, $\mathsf{CauchyCriterion}^{\uparrow}$, finite-tail-filter, and tail-factor reads to return to the same packet rather than detaching a selected limit or a quotient stream.

Now apply the Real-seal public unblock. It identifies the public $\mathsf{Real}^{\uparrow}$ route as a read of the same convergence seal and keeps the BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows attached to the finite packet.

Finally compose the source-readback equalizer with terminal-route refusal completeness. The equalizer makes the source and readback routes the same displayed packet, while refusal completeness accepts exactly the finite terminal route and rejects selected limits, quotient streams, host real equality, countable choice, and ambient completeness rows. □

Corollary 535.89 (Bounded monotone Cauchy witness convergence-seal strict local obstruction)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ packet. Suppose a displayed failure, refusal, separation, or countermodel row is cited against a named converse or reuse route for the convergence-seal consumer surface of W. Then the cited row is a strict local obstruction: it blocks only the named route whose consumer-facing use tries to read the convergence seal, finite-tail handoff, selector readback, or completion-facing output away from the displayed route*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

and away from the public route through

$$\mathsf{MonotoneCauchy}^{\uparrow}, \mathsf{CauchyCriterion}^{\uparrow}, \mathsf{FiniteTailFilter}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{CauchyLimitSeal}^{\uparrow},$$

Every admitted consumer-facing use factors through the source boundary, criterion-tail factorization, finite-tail-filter handoff, Real-seal public route, readback equalizer, and terminal-route refusal-completeness rows already displayed for W. The same cited row cannot be reinterpreted as a global impossibility theorem for bounded monotone convergence, a host theorem about real completion, hidden external validation of the failed route, or an obstruction to any consumer route that still factors through the displayed rows of W.

Proof. Start with the source boundary, Definition 535.65. It confines every convergence-seal source read to the finite witness rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and states that the source exports no selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector. Thus any consumer-facing negative use has to be attached to one of the displayed packet coordinates, not to an ambient completion object.

Apply the finite-tail and route-factorization rows. By Definition 535.66, every convergence-seal or Real-completion consumer first reads the displayed witness packet, then passes through $\mathsf{MonotoneCauchy}^{\uparrow}$ and $\mathsf{CauchyCriterion}^{\uparrow}$, then through the $\mathsf{FiniteTailFilter}^{\uparrow}$ packet, and only then continues through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. By Definition 535.76, this is the whole public convergence-seal route.

Now read the cited negative row against a named converse or reuse route. If the named route tries to bypass the source row, detach the Cauchy witness or dyadic ledger, reuse the finite-tail handoff as an unrecorded selector, or replace the Real-facing seal by a completion principle, Definition 535.74 forces the attempted consumer back into the same finite route $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. The cited failure, refusal, separation, or countermodel row therefore blocks exactly the named coordinate where that route tries to omit, replace, detach, or bypass the displayed packet.

The readback side gives the same conclusion. By Definition 535.83, the forward source read and the reverse convergence-seal readback are equalized on the displayed packet before any completion-facing route is inspected. By Definition 535.87, an admissible terminal request is exactly one that factors through the finite packet and the displayed BHist, hsame, Cont, Pkg, and NameCert support rows; requests for quotient stream equality, selected limits, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection are off-route.

Any stronger reading would require a coordinate absent from the accepted packet. A global impossibility theorem for bounded monotone convergence would require a theorem row not indexed by the local packet W. A host theorem about real completion would require host equality, ambient completeness, or quotient data outside the displayed route. Hidden external validation would require an external certificate channel beyond P, N, and the displayed consumer rows. The source theorem and non-escape theorem exclude exactly those coordinates. Hence the obstruction is strict and local: it blocks only the named converse or reuse route and leaves every consumer route that remains inside the displayed packet available. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal strict local obstruction`

Theorem 535.90 (Bounded monotone Cauchy witness convergence-seal input package)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *carrier. Every downstream convergence-seal input exported by W factors through the displayed rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

before it is read by the BoundedMonotoneConvergenceSeal$^{\uparrow}$ *consumer of chapter 918.*

The factorization presents the bounded source through the public MonotoneCauchy$^{\uparrow}$ *row, the explicit witness through the public* CauchyCriterion$^{\uparrow}$ *row, the window schedule through* StreamName$^{\uparrow}$*, the dyadic tolerance and upper-bound ledger through* DyadicRatCore$^{\uparrow}$*, the regular rational handoff through* RegSeqRat$^{\uparrow}$*, the compatibility boundary through* CauchyLimitSeal$^{\uparrow}$*, and the sealed real-facing row through* Real$^{\uparrow}$*. It exports no selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.*

Proof. Begin with the local dependency package. By Definition 535.19, every public read of W is already confined to the displayed bounded-source, regular-rational, stream, Cauchy-witness, dyadic, located-trap, Real-seal, transport, continuation, provenance, and naming rows.

Next pass through the public tail envelope. Definition 535.57 identifies $S, F, \sigma, \mu, \lambda, I, H, C, P, N$ as the pre-seal service and places Q after that service as the Real$^{\uparrow}$ seal row. The Real-completion export of Definition 535.44 keeps the same rows visible to Real-facing consumers.

Finally compare with the downstream seal chapter. Its carrier reads a bounded witness, public monotone tail-window row, public Cauchy criterion row, regular-rational handoff, stream schedule, dyadic ledger, limit-seal compatibility boundary, and Real seal. The local package above supplies exactly those inputs from W, so the convergence-seal consumer has no route around the accepted witness packet. □

Lean4 ✓ BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal input package

Theorem 535.91 (Bounded monotone Cauchy witness seal-input transport)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P,$ *and* $W' = (S', F', \sigma', \mu', \lambda', I', Q', H', C', P', N')$ *be accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *carriers. If the component rows are related by the displayed* hsame *transports in* H, H' *and the continuation routes in* C, C' *preserve the same* Cont *reads, then the convergence-seal input package of Definition 535.90 is preserved componentwise.*

Thus transport may replace a row only by its corresponding transported row $S', F', \sigma', \mu', \lambda', I', Q', H', C', P', N'$*. It cannot create a detached convergence-seal input, a second compatibility boundary, a selected limiting representative, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or a choice-like tail selector.*

Proof. Start from classifier transport. The local transport theorem for W moves only the displayed carrier coordinates and keeps the source, witness, trap, Real-seal, continuation, provenance, and naming sockets componentwise aligned.

Apply the convergence-seal input package to both carriers. For W, every exported seal input is read through $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$; for W', every exported seal input is read through $S', F', \sigma', \mu', \lambda', I', Q', H', C', P', N'$.

Use the assumed hsame and Cont preservation to compare matching coordinates. Since the package has no coordinate outside the displayed rows, componentwise transport preserves the whole package and has no source from which an extra seal input or excluded completion principle could be produced. □

Lean4 ✓ BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier seal input transport

Theorem 535.92 (Bounded monotone Cauchy witness completion-route exhaustion)**.** *For every accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *carrier* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$*, any completion-facing route that can be consumed by* BoundedMonotoneConvergenceSeal$^{\uparrow}$ *is exhausted by the witness package of Definition 535.90. In particular, the route cannot bypass* W *to selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selectors.*

The only available route to the public convergence handoff is the finite chain from the bounded source and witness rows through the public MonotoneCauchy$^{\uparrow}$*,* CauchyCriterion$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* CauchyLimitSeal$^{\uparrow}$*, and* Real$^{\uparrow}$ *rows recorded by the downstream seal chapter.*

Proof. First use completion-consumer non-escape. Definition 535.58 says that every completion-facing consumer factors through the public envelope, finite-read route, regular-sequence handoff, located trap, and Real$^{\uparrow}$ seal of the accepted witness packet.

Then apply the convergence-seal input package. It identifies the portion of that route read by chapter 918: the bounded source, public monotone tail-window certificate, public Cauchy criterion packet, stream and dyadic ledgers, regular handoff, compatibility boundary, and Real seal are all supplied from $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Finally use the Real-completion export and public tail-envelope export. Together they leave no public row outside the accepted witness package. A route asking for a selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector therefore asks for data absent from the completion-facing surface. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier completion route exhaustion`

Theorem 535.93 (Bounded monotone Cauchy witness finite seal-route determinacy)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *and* $W' = (S', F', \sigma', \mu', \lambda', I', Q', H', C', P', N')$ *be accepted* BoundedMonotoneCauchy *carriers. Suppose the displayed source, witness, monotonicity, modulus, localization, interval, seal, transport, continuation, provenance, and naming rows agree componentwise through the* hsame *data in* H, H'*, and suppose the displayed* Cont *routes in* C, C' *preserve the same reads of those rows. Then every* BoundedMonotoneConvergenceSeal$^{\uparrow}$ *consumer obtains the same finite seal-read surface from* W *and* W'*.*

The determined surface is exactly the finite route through MonotoneCauchy$^{\uparrow}$*,* CauchyCriterion$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* CauchyLimitSeal$^{\uparrow}$*, and* Real$^{\uparrow}$ *recorded by the displayed rows. It does not compare selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selectors.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier finite seal route determinacy`

Proof. First apply Definition 535.90 to both carriers. It confines every downstream convergence-seal read to the displayed rows of the accepted packet and identifies the public route through the monotone, Cauchy, stream, dyadic, regular-rational, limit-seal, and Real rows.

Next use Definition 535.91. The assumed componentwise hsame data and the matching displayed Cont routes transport each row of W to the corresponding row of W' without adding a detached convergence-seal input or a second compatibility boundary.

Finally apply Definition 535.92. Since every completion-facing route consumable by BoundedMonotoneConvergen is exhausted by the same finite chain, there is no remaining coordinate on which the two accepted packets can differ at the seal-read surface.

The excluded objects are outside the route just used. A selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector would require data absent from both displayed packets, so none can distinguish the two downstream reads. □

Theorem 535.94 (Bounded monotone Cauchy witness convergence-seal read determinacy)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *and* $W' = (S', F', \sigma', \mu', \lambda', I', Q', H', C', P', N')$ *be accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *carriers. Suppose the displayed bounded source, monotone window, Cauchy criterion, stream schedule, dyadic ledger, regular-rational handoff,* CauchyLimitSeal$^{\uparrow}$ *compatibility,* Real$^{\uparrow}$ *seal, transports, continuations, provenance, and names agree componentwise through the* hsame *data in* H, H' *and the matching* Cont *reads in* C, C'*. Then every* BoundedMonotoneConvergenceSe *consumer receives the same downstream finite seal-read surface from* W *and* W'*.*

Equivalently, the read is determined by the finite witness-to-seal route through MonotoneCauchy$^{\uparrow}$*,* CauchyCriterion$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* CauchyLimitSeal$^{\uparrow}$*, and* Real$^{\uparrow}$*. No selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector can refine or distinguish that read.*

Proof. First confine the consumer route. Apply Definition 535.90 to both accepted carriers. The theorem says that any downstream seal input exported from either carrier is already read through the displayed witness rows and then through the public monotone, Cauchy, stream, dyadic, regular-rational, limit-seal, and Real rows.

Next transport the displayed rows. By Definition 535.91, the assumed hsame comparisons and matching Cont reads preserve the rows of the package componentwise. Thus the two carriers present

the same bounded source, window, criterion, schedule, ledger, handoff, compatibility boundary, Real seal, provenance, and naming surface to the downstream consumer.

It remains to rule out a second place where the consumer could read. Use Definition 535.92 to exhaust all completion-facing routes by the same witness package, and then apply Definition 535.93 to identify the finite seal-read surfaces. The excluded completion objects are not coordinates of that route, so they cannot separate the two downstream reads. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal read determinacy`

Theorem 535.95 (Bounded monotone Cauchy witness seal-route minimality)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. A* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *consumer route is an accepted seal-input route from* W *only when it carries the displayed source row, monotone window row, Cauchy criterion row,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *compatibility row,* $\mathsf{Real}^{\uparrow}$ *seal, transport rows, continuation rows, provenance row, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *row.*

Consequently any proper subroute that omits one of those rows is not an accepted seal-input route for the downstream convergence seal. This minimality claim is only about the finite witness-to-seal input route; it does not assert Real completeness, a selected limit, quotient real equality, trichotomy, open-cover compactness, or any choice-like tail selection.

Proof. First take the accepted read inventory from Definition 535.90. It lists the bounded source, public monotone and Cauchy rows, stream schedule, dyadic ledger, regular-rational handoff, compatibility boundary, Real seal, transports, continuations, provenance, and naming row as the complete input package read by the convergence-seal consumer.

Next use componentwise preservation. Definition 535.91 says that accepted transport may replace a displayed row only by its matching transported row, so a route missing one coordinate cannot be repaired by a detached replacement.

Now rule out escape routes. By Definition 535.92, every completion-facing route consumable by $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ is exhausted by the same finite witness package. There is no second path from which an omitted source, window, criterion, schedule, ledger, handoff, compatibility, seal, transport, continuation, provenance, or naming row could be supplied.

Finally apply read determinacy from Definition 535.94. Accepted reads of the displayed route are equal at the downstream finite seal surface, so removing a displayed row leaves no accepted read of that surface. The excluded completion principles are not coordinates of the route and therefore play no role in the minimality statement. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier seal route minimality`

Theorem 535.96 (Bounded monotone Cauchy witness seal-route universal property)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Any finite consumer route from the accepted packet* W *to a* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *seal input factors through the displayed witness-to-seal route*

$$\mathsf{MonotoneCauchy}^{\uparrow},\ \mathsf{CauchyCriterion}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyLimitSeal}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The factorization is unique at the finite seal-read surface: two accepted factorizations with the same displayed source, monotone window, Cauchy criterion, stream schedule, dyadic ledger, regular-rational handoff, limit-seal compatibility row, Real seal, transport rows, continuation rows,

provenance row, and local $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *row induce the same downstream read, and any candidate omitting one of these rows is not an accepted route. The statement does not assert Real completeness, a selected limit, quotient real equality, host equality, trichotomy, open-cover compactness, or any choice-like tail selector.*

Proof. Existence of the factorization is the input-package statement. By Definition 535.90, every convergence-seal input exported by W is first read through the displayed packet rows and then through the public monotone, Cauchy, stream, dyadic, regular-rational, limit-seal, and Real rows.

The factorization is stable under the only permitted replacements. Apply Definition 535.91: componentwise hsame transport and matching Cont reads preserve exactly the same displayed rows and do not create a detached seal input or a second compatibility boundary.

There is no competing completion-facing route. Definition 535.92 exhausts every route consumable by $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ by the witness package just described.

Uniqueness at the finite seal-read surface follows by combining Definition 535.93 with Definition 535.94. These identify any two accepted reads of the displayed route after componentwise agreement, so a second accepted factorization has the same downstream finite surface.

Finally use Definition 535.95. A route that omits a displayed row is not accepted, and the excluded completion principles are not coordinates of the finite route. Hence the displayed route has the stated universal property among finite seal-input consumers of W. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier seal route universal property`

Corollary 535.97 (Bounded monotone Cauchy witness convergence-seal consumer determinacy)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Fix the displayed bounded-source, monotone-window, Cauchy-witness, stream-schedule, dyadic-ledger, regular-rational, located-trap,* $\mathsf{Real}^{\uparrow}$ *seal, transport, continuation, provenance, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *rows of* W*. Then any accepted consumer-facing use of* W *by a* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *consumer has the same finite seal route, the same downstream normal-form read, and the same exactness decision named by this chapter.*

Equivalently, every accepted use is forced through the finite route

$$\mathsf{MonotoneCauchy}^{\uparrow},\ \mathsf{CauchyCriterion}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyLimitSeal}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

There is no alternate hidden coordinate, duplicate classifier source, selected-limit coordinate, quotient real equality, host real equality, trichotomy, ambient completeness principle, open-cover compactness principle, or choice-like tail selector that can refine the accepted read.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal consumer determinacy`

Proof. Start with the displayed input package. By Definition 535.90, every downstream convergence-seal input exported by W factors through

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

before the $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ consumer reads it. The same theorem identifies the public route as the monotone row, Cauchy-criterion row, stream schedule, dyadic ledger, regular-rational handoff, limit-seal compatibility boundary, and $\mathsf{Real}^{\uparrow}$ seal.

Now compare two accepted consumer-facing uses of the fixed rows. Treat the second use as another presentation of the same displayed packet: the fixed rows give the componentwise hsame

data, and the fixed continuation rows give the matching Cont reads. The transport theorem Definition 535.91 then permits replacement only by the corresponding transported displayed row. It does not create a detached seal input, a second compatibility boundary, or a duplicate classifier source.

Apply finite route determinacy from Definition 535.93. Since the source, witness, monotonicity, modulus, localization, interval, seal, transport, continuation, provenance, and naming rows are fixed, every accepted convergence-seal consumer obtains the same finite seal-read surface. Therefore a consumer that names the route directly, reads it as a normal form, or records its exactness decision is naming the same determined surface.

Finally use the exhaustion clauses already present in the local route. Definition 535.92 and Definition 535.94 rule out a second completion-facing place where the consumer could read. The excluded selected-limit, equality, trichotomy, completeness, compactness, and choice-like objects are not coordinates of the displayed packet, so none can supply an alternate decision or a hidden classifier source. □

Theorem 535.98 (Bounded monotone Cauchy witness source-row exhaustion)**.** *For an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *carrier*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N),$$

the bounded monotone source row, regular rational handoff, stream schedule, Cauchy modulus, dyadic ledger, located trap, and Real$^{\uparrow}$ *seal precursor exhaust the witness source surface. Every source-facing read is one of* $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$*, with no additional range over host real histories, selected limit, quotient equality, trichotomy row, ambient completeness witness, or open-cover compactness row.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier source row exhaustion`

Proof. Project the carrier surface of Definition 535.5. Its rows list the bounded source, regular rational handoff, stream schedule, Cauchy witness, dyadic ledger, located trap, Real seal precursor, componentwise transport, continuation route, package provenance, and local name.

Apply the local NameCert and scoped-dependency packages, Definition 535.6 and Definition 535.19. These force generator reads through S, tail requests through μ, σ, λ, located enclosures through I, classifier transport through H, C, and provenance and naming through P, N.

The child certificate-surface theorems then close the source boundary. Generator range exactness, tail modulus scope, Real seal boundary, and ledger exhaustion leave no carrier coordinate outside the displayed witness package, so the listed rows exhaust the source surface. □

Theorem 535.99 (Bounded monotone Cauchy witness tail-window lock)**.** *Every tail-window read exported by an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *carrier factors through* MonotoneCauchy$^{\uparrow}$ *and* RegularCauchyTailMeet$^{\uparrow}$ *before any* Real$^{\uparrow}$ *seal row is read. The tail-window route is therefore the public monotone Cauchy source together with the regular rational tail handoff, not a direct jump from bounded monotonicity to a real-seal coordinate.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail window lock`

Proof. Start from the dependency paragraphs of this chapter. They place BoundedMonotoneCauchyWitness$^{\uparrow}$ as the bounded-monotone consumer of chapter 438 and the shared finite tail route of chapter 560.

Use the scoped-dependency package and the root extraction route. The displayed witness first exposes $S, F, \sigma, \mu, \lambda$ as the monotone source, regular handoff, schedule, Cauchy witness, and dyadic ledger before the located trap and Real seal suffix can be consumed.

Finally apply the convergence-seal source and input-package theorems already input by this chapter. They identify the downstream seal source with the same public monotone Cauchy and regular-tail rows, so a Real-facing consumer cannot read Q before the MonotoneCauchy and RegularCauchyTailMeet routes have been displayed. □

Theorem 535.100 (Bounded monotone Cauchy witness convergence-seal input totality)**.** *The* BoundedMonotoneConvergenceSeal$^{\uparrow}$ *consumer of chapter 918 consumes exactly the displayed witness package*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

from an accepted BoundedMonotoneCauchyWitness$^{\uparrow}$ *carrier. It receives no selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or alternate tail selector.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal input totality`

Proof. Read the downstream dependency paragraph together with the scoped-dependency package. The convergence seal asks for a finite monotone source, regular rational handoff, stream schedule, Cauchy modulus, dyadic ledger, located trap, Real seal precursor, and the structural rows carrying transport, continuation, provenance, and naming.

Apply Definition 535.90. It states that every downstream convergence-seal input exported by W factors through precisely the displayed witness rows before the seal chapter reads it.

The completion-route exhaustion and Real-seal public route exhaustion theorems rule out bypasses. Since selected limits, quotient equality, host equality, trichotomy, ambient completeness, open-cover compactness, and alternate tail selectors are absent from the witness carrier and from the downstream route, the displayed package is total for the convergence-seal input. □

Theorem 535.101 (Bounded monotone Cauchy witness convergence-seal route determinacy)**.** *For an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *packet*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N),$$

there is exactly one public convergence-seal route determined by its source, tail, and seal rows. The route first reads the MonotoneCauchy$^{\uparrow}$ *source and the* RegularCauchyTailMeet$^{\uparrow}$ *tail window, then passes through* CauchyCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, *and finally* Real$^{\uparrow}$. *A consumer-visible convergence-seal route for W cannot skip any one of those rows, nor can it replace them by selected limits, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or an alternate tail selector.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence seal route determinacy`

Proof. Start with source-row exhaustion. By Definition 535.98, every source-facing read of W is one of $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so the convergence-seal route has no second source socket.

Next use the tail-window lock. It forces every tail-window read through the public MonotoneCauchy$^{\uparrow}$ and RegularCauchyTailMeet$^{\uparrow}$ surfaces before the Real$^{\uparrow}$ seal row is available.

Now attach convergence-seal input totality. The theorem Definition 535.100 says that the $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ consumer receives exactly the displayed witness package. Together with Definition 535.31 and Definition 535.90, this inserts the $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows in the displayed order.

It remains to rule out alternate public routes. The completion-route exhaustion theorem Definition 535.92 and ledger exhaustion in Definition 535.13 leave no consumer-visible coordinate outside the named rows. Any route omitting one of them therefore fails to be a convergence-seal route exported by the accepted packet W. □

Theorem 535.102 (Bounded monotone Cauchy witness tail Real-seal route totality)**.** *For an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$*-seal consumer of* W *passes through the source row, the* $\mathsf{MonotoneCauchy}^{\uparrow}$ *tail source, the* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *window,* $\mathsf{CauchyCriterion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, and the final* $\mathsf{Real}^{\uparrow}$ *row. No such consumer may replace this route by a selected limit, quotient equality, host real equality, trichotomy, open-cover compactness, or alternate tail selector.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail real seal route totality`

Proof. Begin with source-row exhaustion. The theorem Definition 535.98 identifies every source-facing read of W with one of the displayed coordinates $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Next apply the tail-window lock. By Definition 535.99, a Real-facing tail read must first expose the $\mathsf{MonotoneCauchy}^{\uparrow}$ source and the $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ window, so the tail surface cannot be selected outside the displayed packet.

Now use convergence-seal input totality and route determinacy. Theorems Definition 535.100 and Definition 535.101 force the downstream seal route through $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in the named order.

It remains to exhaust the visible coordinates of the route. The source theorem accounts for the displayed BHist rows, the tail and seal theorems account for the hsame and Cont rows, and the local package and certificate rows provide exactly the Pkg and $\mathsf{NameCert}$ witnesses attached to P and N. Since the carrier contains no coordinate for a selected limit, quotient equality, host real equality, trichotomy, open-cover compactness, or alternate tail selector, none of those objects can serve as a Real-seal route for W. □

Theorem 535.103 (Bounded monotone Cauchy witness tail seal row determinacy)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Suppose two downstream convergence-seal reads preserve the same source row* S*, the same public* $\mathsf{MonotoneCauchy}^{\uparrow}$ *tail source, the same* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *window, the same* $\mathsf{CauchyCriterion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, and the same structural rows* H, C, P, N*. Then the two reads determine the same visible* $\mathsf{Real}^{\uparrow}$ *seal row* Q*.*

Equivalently, the displayed tail route fixes the downstream seal row: no accepted read preserving those rows may replace Q *by a selected limit, quotient equality, host real equality, trichotomy branch, open-cover compactness witness, ambient completeness object, or alternate tail selector.*

Proof. First use source-row exhaustion. By Definition 535.98, every source-facing coordinate of W is one of $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. Thus two reads preserving the same source row cannot choose a second source socket from outside the displayed packet.

Next apply the tail-window lock and route determinacy. The tail-window lock forces both reads through the same public $\mathsf{MonotoneCauchy}^{\uparrow}$ source and the same $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ window, while Definition 535.101 fixes the sibling route through $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally use the Real-seal route totality. The terminal $\mathsf{Real}^{\uparrow}$ read is a carrier coordinate of the same accepted packet, and the structural rows H, C, P, N are preserved by hypothesis. The coordinate exhaustion in Definition 535.102 leaves Q as the only visible terminal seal row and excludes selected limits, quotient equality, host real equality, trichotomy, open-cover compactness, ambient completeness, and alternate tail selectors. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail seal row determinacy`

Theorem 535.104 (Bounded monotone Cauchy witness Cauchy-ledger readback exactness)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Any* $\mathsf{CauchyWitnessLedger}^{\uparrow}$ *readback that consumes the bounded monotone witness factors through the same* $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route fixed by Definition 535.103. Such a readback cannot introduce a selected limit, quotient equality, host real equality, choice row, hidden tail oracle, ambient completeness object, or alternate completion route.*

Proof. First read the source surface. By Definition 535.98, every source-facing coordinate available to the ledger is one of $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Next lock the tail and seal route. The tail-window theorem forces the read through $\mathsf{MonotoneCauchy}^{\uparrow}$ and $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, while convergence-seal input totality and route determinacy insert $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in the displayed order.

Finally apply tail seal row determinacy. Once the ledger preserves the same source, tail, seal, transport, route, provenance, and naming rows, the visible $\mathsf{Real}^{\uparrow}$ seal row is fixed as Q. Coordinate exhaustion leaves no socket for a selected limit, quotient equality, host real equality, choice row, hidden tail oracle, ambient completeness object, or alternate completion route, so the ledger readback is exact. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier cauchy ledger readback exactness`

Theorem 535.105 (Bounded monotone Cauchy witness criterion-ledger route totality)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every* $\mathsf{CauchyCriterion}^{\uparrow}$ *consumer or* $\mathsf{CauchyWitnessLedger}^{\uparrow}$ *consumer that reads the bounded monotone witness factors through the same route fixed by Definition 535.104: the* $\mathsf{MonotoneCauchy}^{\uparrow}$ *source, the* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *tail window,* $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *together with the structural rows* H, C, P, N.

Consequently the criterion-ledger route for W is total on the displayed packet coordinates. It has no selected limit, quotient stream equality, host real equality, choice row, hidden tail oracle, ambient completeness object, open-cover compactness row, or alternate completion route.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier criterion ledger route totality`

Proof. Start with source-row exhaustion. Theorem 535.98 identifies every source-facing read of W with one of $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so a criterion or ledger consumer has no carrier coordinate outside the displayed packet.

Next lock the tail window. Theorem 535.99 routes every tail-facing read through $\mathsf{MonotoneCauchy}^{\uparrow}$ and $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ before any terminal $\mathsf{Real}^{\uparrow}$ seal row is available.

Now use convergence-seal route determinacy and tail seal row determinacy. Theorems 535.101 and 535.103 fix the passage through $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and they fix the visible seal row once H, C, P, N are preserved.

Finally apply the Cauchy-ledger readback exactness theorem. The readback theorem identifies the ledger-facing route with the same displayed route, while the preceding coordinate exhaustion accounts for all rows of W. There is therefore no remaining socket for a selected limit, quotient stream equality, host real equality, choice row, hidden tail oracle, ambient completeness object, open-cover compactness row, or alternate completion route. □

Theorem 535.106 (Bounded monotone Cauchy witness selector-free Real route)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing route through the bounded monotone witness is exhausted by the displayed source row, the* $\mathsf{MonotoneCauchy}^{\uparrow}$ *tail source, the* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *tail window,* $\mathsf{CauchyCriterion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and the structural rows H, C, P, N. No such route can introduce a selected limit, quotient equality, host real equality, choice row, hidden tail oracle, ambient completeness object, or alternate completion route.*

Proof. Start with source-row exhaustion. Theorem 535.98 identifies every source-facing read of W with one of $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so a Real-facing consumer has no second carrier surface outside the displayed packet.

Next apply the tail-window lock. Theorem 535.99 routes each tail-facing read through $\mathsf{MonotoneCauchy}^{\uparrow}$ and $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ before any terminal $\mathsf{Real}^{\uparrow}$ row can be read.

Now use convergence-seal route determinacy. Theorem 535.101 fixes the sibling chain through $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in that order.

Then apply tail seal row determinacy. Theorem 535.103 fixes the visible $\mathsf{Real}^{\uparrow}$ seal row once the same source, tail, seal, transport, continuation, provenance, and naming rows are preserved.

Finally use Cauchy-ledger readback exactness. Theorem 535.104 identifies the ledger-facing route with the same displayed route, and Definition 535.105 accounts for the criterion side. The named source, tail, seal, and structural rows therefore exhaust the Real handoff, leaving no socket for a selected limit, quotient equality, host real equality, choice row, hidden tail oracle, ambient completeness object, or alternate completion route. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier selector free real route`

Theorem 535.107 (Bounded monotone Cauchy witness dyadic-radius budget preservation)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing route preserving the bounded monotone source* S *and the regular tail rows* σ, μ, λ *also preserves the dyadic radius budget through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *and the final* $\mathsf{Real}^{\uparrow}$ *seal row* Q*. Such a route cannot replace that budget by a selected limit, host real equality, quotient equality, trichotomy branch, open-cover compactness row, or alternate completion route.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier dyadic radius budget preservation`

Proof. Start with source-row exhaustion. Theorem 535.98 confines every source-facing read to $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so preservation of S and the regular tail rows already fixes the carrier surface on which the dyadic budget can be read.

Next apply the tail-window lock. Theorem 535.99 routes the preserved tail data through $\mathsf{MonotoneCauchy}^{\uparrow}$ and $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ before a $\mathsf{Real}^{\uparrow}$-facing read can reach the terminal seal.

Use convergence-seal route determinacy and tail seal row determinacy. Theorems 535.101 and 535.103 fix the passage through $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and they fix the visible seal row Q once the source, tail, transport, continuation, provenance, and naming rows are preserved.

Finally apply the selector-free Real route. Theorem 535.106 exhausts every $\mathsf{Real}^{\uparrow}$-facing route by the same displayed source, tail, dyadic, regular-sequence, limit-seal, Real-seal, and structural rows. Coordinate exhaustion therefore leaves no route on which a selected limit, host real equality, quotient equality, trichotomy branch, open-cover compactness row, or alternate completion route could replace the dyadic radius budget. □

Theorem 535.108 (Bounded monotone Cauchy witness root tail-budget exactness)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every accepted root-source tail-seal read of* W *factors through the displayed* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, $\mathsf{CauchyWitnessLedger}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$ *rows before any* $\mathsf{Real}^{\uparrow}$ *or completion-facing endpoint is public.*

Thus the monotone witness rows determine the same finite L10 tail-budget chain as the root source rows: no accepted read may replace that chain by a selected limit, quotient equality, host real equality, choice row, hidden tail oracle, ambient completeness object, open-cover compactness row, or alternate completion route.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root tail budget exactness`

Proof. Start with the local source rows. Theorems 535.98, 535.99, and 535.107 bind the source row S, regular handoff F, scheduled windows σ, Cauchy modulus μ, dyadic ledger λ, located trap I, and Real seal row Q to one displayed packet.

Next read the witness and criterion ledgers. Theorems 535.104 and 535.105 force every $\mathsf{CauchyWitnessLedger}^{\uparrow}$ or $\mathsf{CauchyCriterion}^{\uparrow}$ consumer through the same $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route.

Now attach the root sibling routes listed by the chapter. The root unblock and tail-service rows identify the $\mathsf{CauchyModulusExtraction}^{\uparrow}$ schedule, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ synchronizer, $\mathsf{RealObservationBudget}^{\uparrow}$ finite observation route, and $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ handoff as consumers of the same source, tail, trap, seal, transport, continuation, provenance, and local naming rows H, C, P, N.

Finally apply selector-free Real-route exhaustion. Theorem 535.106 leaves no endpoint coordinate outside the displayed source, tail, ledger, limit-seal, Real-seal, and structural rows. Therefore any root-source tail-seal read reaches $\mathsf{Real}^{\uparrow}$ or a completion-facing endpoint only after traversing the stated finite tail-budget chain. □

Theorem 535.109 (Bounded monotone Cauchy witness convergence-grid fork coherence)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Suppose one downstream read consumes* W *through* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *and another downstream read consumes* W *through* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$*. If both reads preserve the displayed source, tail, dyadic-radius, transport, continuation, provenance, and local naming rows, then they determine the same visible* $\mathsf{Real}^{\uparrow}$ *seal row* Q *and the same finite route through* $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, $\mathsf{CauchyWitnessLedger}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{CauchyLimitSeal}^{\uparrow}$.

No such pair of reads can fork into selected limits, quotient equality, host real equality, choice rows, hidden tail oracles, ambient completeness objects, open-cover compactness rows, or alternate completion routes.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier convergence grid fork coherence`

Proof. Start with source-row exhaustion. Theorem 535.98 confines both consumers to the same packet coordinates $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so neither the convergence-seal side nor the grid side has an additional carrier coordinate on which a second terminal seal could be named.

Next lock the seal and tail rows. Theorems 535.101 and 535.103 force every preserved convergence-seal read and every preserved tail-seal read through the same public source, tail, dyadic, regular-sequence, limit-seal, and $\mathsf{Real}^{\uparrow}$ rows. In particular, the visible terminal row is Q once the transport, continuation, provenance, and local naming rows H, C, P, N are fixed.

Now compare the two consumer routes. Theorem 535.106 excludes a second $\mathsf{Real}^{\uparrow}$-facing route outside the displayed source, tail, dyadic, limit-seal, Real-seal, and structural rows, while Definition 535.107 preserves the dyadic-radius budget along the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ passage.

Finally apply root tail-budget exactness. Theorem 535.108 identifies the root-source tail-seal read with the finite route through $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, $\mathsf{CauchyWitnessLedger}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{CauchyLimitSeal}^{\uparrow}$. Since both consumers read the same carrier coordinates and the same row Q, there is no remaining coordinate from which they could fork into distinct terminal $\mathsf{Real}^{\uparrow}$ seals or any of the excluded completion mechanisms. □

Corollary 535.110 (Bounded monotone Cauchy witness source-exhaust determinacy)**.** *Let*

$$W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$$

be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Once the displayed source rows* $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ *and structural rows* H, C, P, N *are fixed, every accepted consumer-facing use of* W *that asks for a convergence-seal route, a* $\mathsf{Real}^{\uparrow}$*-seal normal form, a criterion-ledger readback, a root-source tail-seal chain, or a grid comparison named by this chapter determines the same finite source-exhaust normal form:*

$$\mathsf{MonotoneCauchy}^{\uparrow}, \quad \mathsf{RegularCauchyTailMeet}^{\uparrow}, \quad \mathsf{CauchyCriterion}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}$$

with terminal visible seal row Q *and with the same displayed tail-budget rows when the root-source tail-seal chain is requested. No accepted use preserving the cited local rows may introduce a hidden coordinate, a duplicate classifier source, a selected limit, quotient equality, host real equality, choice row, hidden tail oracle, ambient completeness object, open-cover compactness row, or alternate completion route as a competing normal form or exactness decision.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier source exhaust determinacy`

Proof. Start with source-row exhaustion. By Definition 535.98, every source-facing read of W is one of $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. Hence an accepted consumer use whose local rows are fixed has no second source socket from which to read a hidden coordinate or duplicate classifier source.

Apply convergence-seal route determinacy. The theorem Definition 535.101 fixes the public convergence-seal route through $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. It also excludes routes that skip one of these rows or replace the route by selected limits, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or an alternate tail selector.

The same fixed route controls the named consumer decisions. The $\mathsf{Real}^{\uparrow}$-seal normal form is exhausted by Definition 535.102, and Definition 535.103 fixes the visible terminal row as Q once the source, tail, seal, transport, continuation, provenance, and local naming rows are preserved. The criterion-ledger readback is exact by Definition 535.104, and the root-source tail-seal chain is the finite budget route of Definition 535.108. For paired convergence-seal and grid consumers, Definition 535.109 identifies the same visible $\mathsf{Real}^{\uparrow}$ seal row and the same finite dyadic, regular-sequence, and limit-seal passage.

Therefore every accepted consumer-facing use that preserves the cited local rows factors through the displayed source-exhaust normal form and the corresponding exactness decision already named by the chapter. Any proposed competing use would require either an additional source coordinate, ruled out by source-row exhaustion, or an alternate public route, ruled out by convergence-seal route determinacy and the named readback and seal determinacy theorems. □

Theorem 535.111 (Bounded monotone Cauchy witness root extraction)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The root extraction route read by any downstream* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *consumer is the finite* BHist *witness packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

Here S *is the displayed bounded monotone source,* F *is the regular rational row,* σ *is the stream schedule,* μ *is the Cauchy tail witness,* λ *is the dyadic tolerance and upper-bound ledger,* I *is the*

located interval trap, and Q is the $\mathsf{Real}^{\uparrow}$ *seal row. The rows H, C, P, N keep the extraction inside* hsame *transport,* Cont *continuation,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *naming.*

Consequently the root consumer reads a finite witness packet. It does not read a selected limit, quotient real, host real equality, trichotomy, ambient completeness claim, open-cover compactness row, or choice-like tail selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessRootExtraction`

Proof. Project the carrier of Definition 535.5. Its visible coordinates are exactly $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, and the local NameCert obligations force the source, witness, trap, seal, transport, continuation, provenance, and naming reads through those coordinates.

Use the window and finite-observation locks. By Definition 535.48 and Definition 535.50, any tail request first enters the displayed source S, regular handoff F, schedule σ, witness μ, and dyadic ledger λ before it can reach I or Q.

Finally apply the convergence-seal input package of Definition 535.90. That theorem identifies the downstream seal inputs with the same rows of W, so the root extraction has no coordinate from which an excluded completion object or choice-like selector could be produced. □

Theorem 535.112 (Bounded monotone Cauchy witness limit-seal handoff)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The handoff from W to every* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumer factors through the finite route*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

The source row S, regular rational row F, stream schedule σ, tail witness μ, dyadic ledger λ, located trap I, and Real seal row Q are transported only through the displayed BHist, hsame, Cont, Pkg, *and* NameCert *routes of the carrier.*

Thus a limit-seal consumer receives the compatibility boundary carried by the witness packet. It receives no selected limiting representative, quotient-real construction, host equality proof, trichotomy split, ambient completeness principle, or compactness certificate.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier limit seal handoff`

Proof. Start with the Real seal boundary and tail-seal synchronization. Theorems Definition 535.9 and Definition 535.27 place the seal-facing suffix after the same source, regular, schedule, witness, dyadic, and located-trap rows.

Next use the trap-seal exactness and seal-route naturality. The exactness theorem fixes I and Q to the scheduled tail envelope, while Definition 535.71 compares the source, criterion-tail, and Real-seal readings through the same public route.

The local transport rows close the handoff. Since H, C, P, N are the only carrier rows for hsame, Cont, Pkg, and NameCert movement, the $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers can only read the finite witness packet and cannot import any excluded completion principle. □

Theorem 535.113 (Bounded monotone Cauchy witness monotone-bound route)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The monotone-bound route used by the bounded monotone convergence surface is the route from the displayed bounded source S through the regular rational row F, stream schedule σ, Cauchy tail witness μ, dyadic tolerance ledger λ, located*

interval trap I, and Real seal row Q, with H, C, P, N supplying hsame *transport,* Cont *continuation,* Pkg *provenance, and local* NameCert *naming.*

Every downstream consumer that asks for bounded monotone convergence through W therefore reads the same finite BHist *route. The route supplies monotonicity, upper-bound, regularity, Cauchy-tail, tolerance, trap, and seal evidence, but it does not supply selected limits, quotient real equality, host real equality, trichotomy, ambient completeness, or open-cover compactness.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier monotone bound route`

Proof. Begin with the source row scope and generator range exactness. These identify S as the bounded monotone source coordinate and keep generator, monotonicity, and upper-bound reads inside the displayed source row.

Pass from the source to the tail service. The tail-window service and Cauchy modulus-extraction factorization route tolerance requests through F, σ, μ, λ, so the bounded source is connected to a regular rational Cauchy witness by displayed rows rather than by a hidden subsequence or selected limiting object.

Finally use the located trap factorization and Real seal schedule exhaustion. They place I and Q after the same dyadic and scheduled-tail route, while the ledger exhaustion theorem leaves no public coordinate beyond $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. The monotone-bound route is therefore a finite BEDC witness route and not an ambient completeness claim. □

Theorem 535.114 (Bounded monotone Cauchy witness root seal route exhaustion)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of W factors through exactly the displayed witness rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

and through the sibling route chain

$$\mathsf{MonotoneCauchy}^{\uparrow} \longmapsto \mathsf{CauchyCriterion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyLimitSe}$$

Thus the root seal route is exhausted by the extraction, limit-seal handoff, monotone-bound route, and convergence-seal input package. It contains no selected limit, quotient real equality, host equality, trichotomy, compactness, ambient completeness, or choice-like tail selector.

The sibling route is the concrete L10 chain of chapter 126, chapter 291, chapter 301, chapter 386, and chapter 38; the witness packet consumes their finite-window, dyadic-ledger, regular-source, limit-seal, and Real-seal rows before any convergence-seal consumer reads it.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root seal route exhaustion`

Proof. First apply Definition 535.111. It projects the accepted carrier to the finite witness packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and rules out any root coordinate outside that packet.

Next apply Definition 535.112 and Definition 535.113. The handoff theorem places every $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ read on the same finite packet, while the monotone-bound theorem routes the bounded monotone convergence surface through $S, F, \sigma, \mu, \lambda, I, Q$ with H, C, P, N supplying transport, continuation, provenance, and naming.

Finally apply Definition 535.90. That package identifies the completion-facing suffix with the sibling chain from $\mathsf{MonotoneCauchy}^{\uparrow}$ through $\mathsf{Real}^{\uparrow}$. Since all three root-facing consumer types

enter through the preceding finite rows and the package supplies the only seal-facing continuation, no selected limit, quotient equality, host equality, trichotomy, compactness, ambient completeness, or choice-like tail selector remains available. □

Theorem 535.115 (Bounded monotone Cauchy witness root tail-window totality)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing consumer of* W *that asks for a convergence-seal, limit-seal, or real-seal input must first consume the displayed* $\mathsf{StreamName}^{\uparrow}$ *tail window carried by* σ *together with the Cauchy witness row* μ *and the dyadic ledger* λ*.*

Thus the root route through W *has a total tail-window obligation row. It passes through the displayed source* S*, regular rational row* F*, scheduled window* σ*, witness* μ*, and ledger* λ *before any located trap or* $\mathsf{Real}^{\uparrow}$ *seal threshold can be read, and it contains no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root tail window totality`

Proof. Start with the carrier definition. The accepted packet exposes σ as the $\mathsf{StreamName}^{\uparrow}$ window schedule, μ as the Cauchy tail witness, and λ as the dyadic tolerance and upper-bound ledger; no separate tail service is a carrier coordinate.

Apply root extraction and the monotone-bound route. Definition 535.111 projects every root read to $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, while Definition 535.113 places the bounded monotone source before the same scheduled tail service.

Finally use the limit-seal handoff and root seal route exhaustion. The handoff theorem keeps seal-facing consumers on the displayed packet, and Definition 535.114 leaves no route around the sibling chain through $\mathsf{StreamName}^{\uparrow}$. Therefore tail-window consumption is total for the root route and the excluded completion objects are not available. □

Theorem 535.116 (Bounded monotone Cauchy witness root located-trap stability)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing consumer that has passed through the displayed tail window must preserve the* $\mathsf{LocatedInterval}^{\uparrow}$ *trap row* I *as the next pre-seal enclosure. Transport through* H *and replay through* C *may move the displayed rows componentwise, but the root route cannot replace* I *by an ambient interval choice, host equality, quotient real equality, trichotomy, completeness, compactness, or a selected limiting representative.*

Consequently the located-trap obligation is stable under the accepted root route for $\mathsf{BoundedMonotoneConvergence}$ $\mathsf{CauchyLimitSeal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumers.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root located trap stability`

Proof. Read the located row from the carrier. The definition makes I the unique $\mathsf{LocatedInterval}^{\uparrow}$ trap row and places it after $S, F, \sigma, \mu, \lambda$ and before the seal row Q.

Use the root extraction theorem to confine the consumer surface. Any root consumer starts from the displayed packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so the only available movement of the trap row is the componentwise transport and continuation data already carried by H and C.

Next apply the limit-seal handoff and monotone-bound route. They both route seal-facing and convergence-facing reads through the same scheduled tail and located-trap suffix, so preserving the root route also preserves I as the pre-seal enclosure.

The root seal route exhaustion theorem then rules out replacement rows. Since no selected limit, quotient equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like trap selector is present in the exhausted packet, the located trap remains stable for all three root-facing consumer types. □

Theorem 535.117 (Bounded monotone Cauchy witness root Real-seal threshold exhaustion)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing* $\mathsf{Real}^{\uparrow}$ *threshold consumed from W is reached only after the displayed tail window σ, μ, λ and the located trap I have been consumed. The seal row Q is therefore a threshold route over the finite witness packet, not a selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.*

Equivalently, a root consumer cannot expose a $\mathsf{Real}^{\uparrow}$ *seal threshold from W unless it has already traversed the accepted packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

Proof. Begin with the carrier and the Real seal boundary. The carrier lists Q only after the regular rational row, scheduled window, Cauchy witness, dyadic ledger, and located trap, and the existing seal boundary keeps every $\mathsf{Real}^{\uparrow}$ read tied to that order.

Apply root extraction, then attach the limit-seal handoff. Root extraction supplies the finite packet, and the handoff theorem says that $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers read the same packet through the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ routes.

Now use the monotone-bound route and root tail-window totality. The monotone-bound route places the source and bound data before F, σ, μ, λ, while Definition 535.115 makes the tail-window obligation unavoidable before any pre-seal or seal row is reached.

Finally apply located-trap stability and root seal route exhaustion. The trap theorem fixes I as the pre-seal enclosure, and the exhaustion theorem leaves the seal-facing suffix with no coordinate outside $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. Hence the $\mathsf{Real}^{\uparrow}$ threshold consumption is exhausted by the displayed root route and exports none of the excluded completion principles. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessRootRealSealThresholdEx`

Theorem 535.118 (Bounded monotone Cauchy witness root selector bridge)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P,$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Any root-facing consumer that reaches the* $\mathsf{Real}^{\uparrow}$ *seal row Q must traverse, in order, the selector budget supplied by the* $\mathsf{StreamName}^{\uparrow}$ *schedule σ, the dyadic tolerance ledger λ, the located trap I, and the* $\mathsf{Real}^{\uparrow}$ *seal threshold Q.*

Thus the root selector bridge is the ordered finite route through the StreamName schedule, dyadic ledger, located trap, and Real seal threshold. It exports no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Proof. Begin with root extraction. Theorem 535.111 confines every root-facing read of W to the displayed packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so the bridge has no coordinate outside the accepted carrier.

Next force the selector budget. By Definition 535.115, every root-facing seal consumer must pass through the $\mathsf{StreamName}^{\uparrow}$ schedule σ together with the Cauchy witness row μ and the dyadic ledger λ before any located-trap or seal row is read.

Now stabilize the trap. The located-trap stability theorem, Definition 535.116, keeps I as the pre-seal enclosure after the scheduled tail and dyadic tolerance rows have been consumed.

Finally apply Definition 535.117. Since the Real-seal threshold is reached only at Q after σ, μ, λ and I, any consumer reaching Q has traversed the selector budget, dyadic tolerance ledger, located

trap, and threshold in that order. The same exhaustion removes selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, and choice-like tail selectors from the bridge. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root selector bridge`

Theorem 535.119 (Bounded monotone Cauchy witness grid route compatibility)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and suppose its root route consumes an accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet* $G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N$ *Then the root route must read the selector budget* B*, witness ledger* L*, completion-seal classifier* K*, and tail-witness envelope* T *of* G *before it reaches the* $\mathsf{Real}^{\uparrow}$ *seal row* Q *of* W*.*

Thus the bounded monotone witness does not run a completion route parallel to the grid. Its Real-facing threshold is compatible with the grid carrier of Definition 905.1: selector exactness, witness-ledger accounting, classifier exposure, and tail-envelope readback are consumed before the final $\mathsf{Real}^{\uparrow}$ *row is available.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier grid route compatibility`

Proof. Project the accepted witness packet by Definition 535.111. This confines the root route to $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and leaves no completion-facing coordinate outside the displayed packet.

Attach the limit-seal handoff and monotone-bound route. Theorems Definition 535.112 and Definition 535.113 place every $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ read after the source, regular, schedule, witness, dyadic, and located-trap rows.

Now read the grid packet. By Definition 905.3 and Definition 905.4, the grid route reaches $\mathsf{Real}^{\uparrow}$ only after $B, S_G, R_G, L, T, K, E_G, H_G, C_G, P_G, N_G$ have been consumed.

Finally use Definition 535.117. Since the threshold row Q is reached only at the seal end of the bounded-monotone route, a route that consumes G must first pass through the grid selector budget, witness ledger, completion classifier, and tail envelope. □

Theorem 535.120 (Bounded monotone Cauchy witness grid-seal cofinal route)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C,$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and suppose its root route consumes an accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet* $G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$ *and reaches the* $\mathsf{Real}^{\uparrow}$ *seal threshold* Q*. Then the selector budget* B*, witness ledger* L*, completion-seal classifier* K*, tail envelope* T*, located trap* I*, and Real seal* Q *are read through one cofinal finite* BHist *route*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N, \quad B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G.$$

No selected limit, quotient real equality, host equality, trichotomy, ambient completeness, compactness, or choice-like selector is exported by this cofinal route.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier grid seal cofinal route`

Proof. First extract the root route. Apply Definition 535.111; every root-facing read is confined to $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Next attach the grid route. By Definition 535.119, the grid selector budget, witness ledger, completion-seal classifier, and tail envelope are consumed before the bounded-monotone route reaches Q.

Now force the tail and trap order. The root tail-window totality theorem places σ, μ, λ before the pre-seal rows, and Definition 535.116 keeps I as the displayed located trap rather than an ambient interval choice.

Finally apply Definition 535.117. The Real seal threshold is exhausted at Q after the tail and trap rows have been traversed, so the composed grid-seal readback is one finite cofinal route and exports none of the excluded completion, equality, compactness, or choice-like data. □

Theorem 535.121 (Bounded monotone Cauchy witness grid ledger non-escape)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C,$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier whose root route consumes an accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet $G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$. The grid handoff exports only the displayed selector-budget, witness-ledger, completion-seal classifier, tail-witness, StreamName, RegSeqRat, RealUp, transport, continuation, provenance, and local naming rows of G together with the displayed rows of W.*

It exposes no selected limit, quotient real equality, host equality, trichotomy, countable choice, ambient completeness, open-cover compactness, hidden selector enlargement, or choice-like tail selector.

Proof. Start from the grid non-escape theorem, Definition 905.5. It says that an accepted grid exports only $B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G$ and none of the excluded completion or host-level objects.

Use grid route compatibility to attach that non-escape result to the bounded monotone witness. The compatibility theorem forces the grid selector, ledger, classifier, and tail rows to be read before the witness route reaches its $\mathsf{Real}^{\uparrow}$ seal row.

Now apply root seal route exhaustion and Real-seal threshold exhaustion for W. These theorems leave the bounded-monotone route inside $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and exclude selected limits, quotient equality, host equality, trichotomy, compactness, ambient completeness, and choice-like selectors from the witness side.

The two packets therefore compose without adding an escape coordinate. The grid contributes only its displayed ledger rows, and the bounded monotone witness contributes only its displayed root rows. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier grid ledger nonescape`

Theorem 535.122 (Bounded monotone Cauchy witness budget-cofinal readback)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let its root route consume an accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet*

$$G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G).$$

Every terminal $\mathsf{Real}^{\uparrow}$ *readback from the composed route must pass through both the scheduled tail budget rows σ, μ, λ of W and the selector-budget rows B, L, K, T of G before the Real seal row Q is public. The readback is exhausted by*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N, \quad B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G,$$

and exports no selected limit, source-equivalence parameter, quotient real equality, host equality, trichotomy, countable choice, ambient completeness, compactness, hidden selector state, or choice-like tail selection.

Proof. First extract the bounded-monotone root. Apply Definition 535.111; every terminal readback from W starts inside $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Next force the scheduled tail budget. By Definition 535.115, the rows σ, μ, λ are consumed before any located-trap, pre-seal, or terminal $\mathsf{Real}^{\uparrow}$ read can inspect Q.

Attach the grid packet through the public route. Definition 535.119 places the selector budget B, witness ledger L, completion-seal classifier K, and tail envelope T before the route reaches the Real seal row of W.

Now use grid ledger non-escape. Definition 535.121 says that the grid contributes only $B, L, K, T, S_G, R_G, E_G, H$ together with the displayed rows of W.

Finally apply Definition 535.117. The Real seal row Q is public only after the scheduled tail budget, located trap, and grid selector-budget rows have been traversed, so the terminal readback has no coordinate for source-equivalence data, selected limits, quotient equality, host equality, completeness, compactness, or choice-like tail selection. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier budget cofinal readback`

Theorem 535.123 (Bounded monotone Cauchy witness grid synchronizer terminal envelope)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier whose root route consumes an accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet $G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$. Every root-facing* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *terminal read from the composed route factors through the finite envelope*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N, \quad B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G.$$

The envelope reaches the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$, $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *sibling packets only through the displayed budget, ledger, classifier, seal, transport, continuation, provenance, and local naming rows.*

Proof. First attach the synchronizer-facing route of W. Root seal route exhaustion and Real-seal threshold exhaustion keep every terminal read inside $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ before the $\mathsf{Real}^{\uparrow}$ threshold is available.

Next attach the grid route compatibility. The grid selector budget, witness ledger, completion-seal classifier, and tail envelope are consumed before the root route reaches the Real seal row Q.

Now apply grid ledger non-escape. It identifies $B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G$ as the only rows contributed by the grid handoff, with no selected limit, host equality, quotient equality, trichotomy, compactness, completeness, or hidden selector state.

The finite observation-budget selector handoff is therefore read as part of the same displayed budget ledger. Since neither W nor G has an additional terminal coordinate, every synchronizer, observation-budget, or Real consumer factors through the stated envelope. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier grid synchronizer terminal envelope`

Theorem 535.124 (Bounded monotone Cauchy witness tail budget seal correspondence)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let its root route consume an accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet $G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G$ The scheduled tail budget σ, μ, λ, the grid selector-budget rows B, L, K, T, and the Real-seal row Q*

correspond on one finite route: a terminal Real$^{\uparrow}$ *read may consume Q only after the tail-window rows of W and the selector-budget rows of G have both been traversed.*

Thus the composed route is a correspondence between tail budget and seal threshold, not a route through a selected limit, quotient real equality, host equality, countable choice, trichotomy, ambient completeness, compactness, or hidden selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier tail budget seal correspondence`

Proof. Begin with the tail-window side. Root tail-window totality forces σ, μ, λ to occur after the source rows and before any located-trap or seal-facing read from W.

Place the seal threshold next. Real-seal threshold exhaustion says that Q is reached only after the displayed tail window and located trap have been consumed, while root seal route exhaustion leaves no bypass around $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Attach the grid budget by route compatibility. The selector budget B, witness ledger L, completion-seal classifier K, and tail envelope T of G are read before the route exposes Q.

Finally use grid ledger non-escape and the finite observation-budget selector handoff. The selector side contributes only its displayed budget rows, so the same finite route accounts for the tail-window obligation and the terminal seal threshold without importing any excluded completion or choice principle. □

Theorem 535.125 (Bounded monotone Cauchy witness cofinal grid readback exhaustion)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *carrier whose root route consumes accepted sibling packets*

$$G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$$

from RealCauchyWitnessGrid$^{\uparrow}$ *together with the displayed* FiniteObservationBudgetSelector$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows. Every cofinal grid readback from this route is exhausted by the rows of W and G listed above. In particular, the readback cannot expose a selected cofinal subsequence, quotient real equality, host equality, trichotomy, countable choice, ambient completeness, compactness, hidden grid state, or unlisted observation selector.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier cofinal grid readback exhaustion`

Proof. Project the bounded monotone witness first. Root seal route exhaustion and Real-seal threshold exhaustion constrain every terminal readback to the displayed packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Read the grid packet through route compatibility. The grid budget, ledger, classifier, tail envelope, StreamName, RegSeqRat, RealUp, transport, continuation, provenance, and naming rows are consumed before the terminal Real read.

Apply grid ledger non-escape to the composed route. The grid contributes exactly $B, L, K, T, S_G, R_G, E_G, H_G, C$ and the bounded monotone witness contributes exactly its displayed root rows.

The finite observation-budget selector handoff supplies only the selected budget row already named in B, L, K, T. Therefore a cofinal readback has no extra carrier coordinate from which to recover an unlisted selector, cofinal subsequence, equality principle, completeness principle, compactness row, or choice-like tail object. □

Theorem 535.126 (Bounded monotone Cauchy witness diagonal-limit compatibility pullback)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *packet.*

Suppose its root route consumes an accepted RealCauchyWitnessGrid$^{\uparrow}$ *packet* $G = (B, L_G, K_G, T_G, S_G, R_G, E_G, H_G, C$ *and an accepted* DiagonalLimitCompatibility$^{\uparrow}$ *packet*

$$D = (R_D, T_D, S_D, D_D, W_D, Q_D, L_D, H_D, C_D, P_D, N_D)$$

through the budget-seal factorization route of Definition 646.84. Then every terminal Real$^{\uparrow}$ *or completion-seal read from the root route factors through one finite pullback surface consisting of the bounded source* S*, scheduled* StreamName$^{\uparrow}$ *window* σ*, dyadic ledger* λ*,* RegSeqRat$^{\uparrow}$ *handoff* F*, located trap* I*, grid selector and witness ledger rows* $B, L_G, K_G, T_G, S_G, R_G, E_G$*, diagonal budget rows* $R_D, T_D, S_D, D_D, W_D, Q_D, L_D$*, the* CauchyLimitSeal$^{\uparrow}$ *boundary, the terminal* Real$^{\uparrow}$ *seal rows* Q, E_G, L_D*, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows*

$$H, H_G, H_D, \quad C, C_G, C_D, \quad P, P_G, P_D, \quad N, N_G, N_D.$$

The pullback exports no selected limit, quotient real equality, host equality, trichotomy, countable choice, ambient completeness, open-cover compactness, hidden selector enlargement, or unlisted tail selector.

Proof. First project the bounded monotone root packet. By Definition 535.111, every root-facing read of W is confined to $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, with no external completion coordinate.

Next attach the grid route. The compatibility theorem Definition 535.119 places the selector budget, witness ledger, classifier, and tail rows of G before the Real$^{\uparrow}$ seal row of W, and Definition 535.121 says that the grid contributes only the displayed rows $B, L_G, K_G, T_G, S_G, R_G, E_G, H_G, C_G, P_G, N_G$.

Now read the diagonal-limit compatibility packet. The budget-seal factorization of Definition 646.84 sends terminal Real and completion-seal consumers through $R_D, T_D, S_D, D_D, W_D, Q_D, L_D, H_D, C_D, P_D,$ while Definition 646.85 keeps the same route inside its displayed provenance and local naming rows.

Finally apply terminal pullback non-escape for the diagonal route, Definition 646.136. The bounded source, grid ledger, diagonal budget route, CauchyLimitSeal boundary, RealUp seal, and all transport, continuation, package, and naming rows have already been listed. Since the exhausted finite packet has no coordinate for selected limits, quotient equality, host equality, trichotomy, choice, completeness, compactness, hidden selector growth, or tail-selector enlargement, every terminal read factors through exactly the displayed pullback surface. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier diagonal limit compatibility pullback`

Theorem 535.127 (Bounded monotone Cauchy witness grid root package)**.** *An accepted* BoundedMonotoneCauchy *carrier whose root route consumes an accepted* RealCauchyWitnessGrid$^{\uparrow}$ *packet forms a finite L10 root package through chapter 905, chapter 126, chapter 291, chapter 301, chapter 386, and chapter 38.*

The package reads the grid selector budget, witness ledger, completion-seal classifier, and tail-witness envelope before the bounded-monotone root route reaches the StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* CauchyLimitSeal$^{\uparrow}$*, and* Real$^{\uparrow}$ *sibling rows. It remains a finite root package and not an import of completeness.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier grid root package`

Proof. First project the bounded monotone root packet by root extraction. The visible route is $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so the package has a finite witness side.

Next apply the limit-seal handoff, monotone-bound route, and root seal route exhaustion. These results identify the sibling chain through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as the only seal-facing continuation of the bounded-monotone packet.

Attach the Real Cauchy witness grid by Definition 535.119. The grid rows are consumed before the Real seal row, with selector, ledger, classifier, and tail-envelope reads supplied by the carrier of chapter 905.

Finally apply Definition 535.121. The composed L10 package has no coordinate for selected limits, quotient real equality, host equality, trichotomy, countable choice, ambient completeness, compactness, hidden selector state, or choice-like tail selection. □

Theorem 535.128 (Bounded monotone Cauchy witness root source-seal totality)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing consumer from the bounded monotone source to a* $\mathsf{Real}^{\uparrow}$ *seal factors through the displayed packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

The route consumes the $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *sibling rows, and it exports no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector.*

Proof. Start with root extraction. Definition 535.111 confines every root read of W to the displayed carrier rows, so no root-facing consumer can begin from an external completion object.

Next attach the bounded monotone source and the seal handoff. The monotone-bound route places the source data before the scheduled tail, while the limit-seal handoff sends $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers through the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

The tail-window and trap theorems close the middle of the route. Root tail-window totality forces consumption of σ, μ, λ before any seal-facing row is reached, and located-trap stability keeps I as the pre-seal enclosure rather than replacing it by an ambient interval choice.

Finally apply Real-seal threshold exhaustion. The threshold theorem consumes the seal row Q only after the displayed source, tail, and trap rows, and root seal route exhaustion leaves no coordinate outside $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. Therefore the full source-to-seal route is total on the finite packet and exports none of the excluded completion principles. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root source seal totality`

Theorem 535.129 (Bounded monotone Cauchy witness root synchronizer handoff)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$*,* $\mathsf{RealObservationBud}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of* W *factors through the same finite route*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

The synchronizer handoff uses the sibling L10 chain

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyLimitSeal}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

after the displayed bounded monotone source, schedule, tail witness, dyadic ledger, located trap, seal row, transport, continuation, provenance, and local naming rows have been consumed.

Consequently the root packet supplies the shared synchronizer-facing surface for the limit-seal and Real-observation-budget routes. It supplies no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, hidden synchronizer state, or choice-like selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root synchronizer handoff`

Proof. Begin with root extraction and source-seal totality. Definition 535.111 confines every root read of W to the displayed packet, while Definition 535.128 carries that packet from the bounded monotone source through the $\mathsf{Real}^{\uparrow}$ seal.

Next attach the limit-seal and synchronizer-facing legs. The limit-seal handoff theorem places $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers on the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, and root seal route exhaustion identifies the sibling L10 chain ending at $\mathsf{Real}^{\uparrow}$ as the only seal-facing continuation.

The middle rows are forced by the tail and trap obligations. Root tail-window totality consumes σ, μ, λ before any seal-facing read, and located-trap stability keeps I as the pre-seal enclosure rather than replacing it by an ambient interval choice.

Finally use Real-seal threshold exhaustion. The $\mathsf{Real}^{\uparrow}$ threshold is reached only after $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ have been traversed, so a $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ or $\mathsf{RealObservationBudget}^{\uparrow}$ consumer has no hidden synchronizer coordinate beyond the displayed route. The excluded completion and choice principles are absent from the packet and cannot be exported by the handoff. □

Theorem 535.130 (Bounded monotone Cauchy witness synchronizer-grid route)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let $G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$ be an accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet consumed on the root route of W. Every root-facing synchronizer consumer of W that also consumes G must route through the same finite witness rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

and through the grid rows $B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G$ before reaching any $\mathsf{Real}^{\uparrow}$ *seal.*

The route exports no selected limit, quotient real equality, host equality, trichotomy, countable choice, ambient completeness, open-cover compactness, hidden synchronizer state, or detached grid selector.

Proof. Begin with the root synchronizer handoff. It sends every $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumer through the displayed rows of W and leaves no hidden synchronizer coordinate outside $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Attach the grid by grid route compatibility. Any accepted route that consumes G reaches the grid selector budget, witness ledger, completion classifier, and tail envelope before the $\mathsf{Real}^{\uparrow}$ seal row Q of W is read.

Use grid ledger non-escape to identify the grid contribution. The grid packet contributes only $B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G$ together with the displayed rows of W, and it does not supply a detached selector or ambient completion principle.

Finally apply root Real-seal threshold exhaustion. The $\mathsf{Real}^{\uparrow}$ seal can be consumed only after the finite bounded-source, tail-window, located-trap, synchronizer, and grid rows have already been traversed, so none of the excluded selected-limit, equality, choice, completeness, compactness, hidden-state, or detached-selector data is exported. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier synchronizer grid route`

Theorem 535.131 (Bounded monotone Cauchy witness root tail-seal nesting)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of W is forced through the nested finite order*

$$S, F \longrightarrow \sigma, \mu, \lambda \longrightarrow I \longrightarrow Q \longrightarrow H, C, P, N.$$

The S, F stage supplies the bounded monotone source and dyadic bound data; the σ, μ, λ stage supplies the scheduled tail-window data; the I stage supplies the located trap; the Q stage supplies the Real-seal threshold; and H, C, P, N carry transport, route replay, provenance, and local naming.

Consequently the L10 source-to-seal route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *remains inside the displayed packet. It exports no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, hidden synchronizer state, or choice-like selector.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessTailSealNesting`

Proof. First confine the packet. Root extraction, Definition 535.111, says that every root-facing read of W is a read of the displayed carrier rows $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Next force the tail-window stage. By Definition 535.115, any root-facing pre-seal or seal consumer must pass through σ, μ, λ after the source and bound rows S, F.

Now place the trap and threshold rows. Located-trap stability, Definition 535.116, keeps I as the pre-seal enclosure, and Real-seal threshold exhaustion, Definition 535.117, places Q before the $\mathsf{Real}^{\uparrow}$ threshold is consumed.

Finally apply the synchronizer handoff, Definition 535.129. It sends $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ and $\mathsf{RealObservationBudget}^{\uparrow}$ consumers through the same finite surface as the $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers, with H, C, P, N carrying transport, route replay, provenance, and naming rather than an external synchronizer coordinate. □

Theorem 535.132 (Bounded monotone Cauchy witness grid budget precedes seal)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let its root route consume an accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet $G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$. Along that finite route the selector budget B, witness ledger L, completion-seal classifier K, and tail envelope T of G must be read before the route exposes the* $\mathsf{Real}^{\uparrow}$ *seal row Q of W.*

Thus the grid budget is a pre-seal obligation on the same root route. The composed packet exports no selected limit, quotient real equality, host equality, trichotomy, countable choice, ambient completeness, hidden grid selector, or choice-like tail selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier grid budget precedes seal`

Proof. First attach the grid route to the bounded-monotone root packet. By Definition 535.119, any route consuming G reaches the grid selector budget, witness ledger, completion classifier, and tail envelope before it reaches the $\mathsf{Real}^{\uparrow}$ seal row Q of W.

Next use the ledger non-escape theorem. Definition 535.121 says that the grid handoff contributes only $B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G$ together with the displayed rows of W, and does not add selected limits, quotient equality, host equality, trichotomy, countable choice, ambient completeness, or hidden selector state.

Now place this order at the Real threshold. Definition 535.117 forces any $\mathsf{Real}^{\uparrow}$ threshold read from W to occur only after the finite source, tail-window, and located-trap rows have already been consumed.

Finally apply tail-seal nesting, Definition 535.131. It nests the route as a single finite chain ending in Q and then H, C, P, N, so the grid budget rows cannot be exposed on a separate completion route after the seal. The same route therefore reads B, L, K, T before exposing Q, and none of the excluded completion principles is exported. □

Theorem 535.133 (Bounded monotone Cauchy witness route tightening)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and let its root route consume an accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet $G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$. The accepted witness route factors through the monotone-bound rows, the tail-window rows, the grid-budget rows, and the* $\mathsf{Real}^{\uparrow}$ *seal row in the finite order*

$$S, F \longrightarrow \sigma, \mu, \lambda \longrightarrow B, L, K, T \longrightarrow I \longrightarrow Q \longrightarrow H, C, P, N.$$

The route is therefore a tightening of the displayed BHist *packet: every Real-seal read is preceded by bounded-source data, scheduled Cauchy-modulus data, selector-budget and witness-ledger data, and the located trap. It does not import a selected limit, host real equality, quotient real equality, completeness, compactness, trichotomy, or choice data.*

Proof. First apply root extraction and the monotone-bound route. Theorems 535.111 and 535.113 confine the accepted carrier to $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ and place the bounded-source rows before the scheduled tail service.

Next use root tail-window totality. It makes σ, μ, λ unavoidable before any located-trap or Real-seal row can be consumed, so the Cauchy-modulus route is already finite inside the displayed packet.

Now attach the grid side by grid budget precedence. The theorem Definition 535.132 places B, L, K, T before Q on the same root route, not on a parallel completion route.

Finally use the limit-seal handoff and synchronizer handoff. These hand the resulting finite route to $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers through H, C, P, N, leaving no carrier coordinate for the excluded completion or choice principles. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier route tightening`

Theorem 535.134 (Bounded monotone Cauchy witness schedule factorization)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C,$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Before any downstream* $\mathsf{Real}^{\uparrow}$ *seal read from W, the schedule row σ, the Cauchy-modulus witness row μ, and the dyadic tolerance ledger λ appear as finite* BHist *rows of the same accepted packet, transported only by H, replayed only by C, packaged only by P, and named only by N.*

Consequently the Real-seal consumer receives finite schedule and modulus data rather than a selected tail, host sequence equality, ambient Cauchy-completeness principle, or choice-like modulus selector.

Proof. Start from root extraction. It identifies σ, μ, λ as visible carrier rows and leaves no separate schedule service outside W.

Use root tail-window totality to force the order. Every convergence-seal, limit-seal, synchronizer, observation-budget, or Real-seal consumer must consume σ, μ, λ before the located-trap and seal rows.

Apply route tightening to the resulting packet. The tightened route keeps the schedule, modulus, dyadic ledger, grid-budget rows, located trap, and seal row on one finite BHist route.

The limit-seal handoff and synchronizer handoff then move that finite route through H, C, P, N. Since those are the only transport, continuation, package, and naming rows, no selected tail, host sequence equality, completeness principle, or choice-like modulus selector is available to the Real-seal consumer. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier schedule factorization`

Theorem 535.135 (Bounded monotone Cauchy witness Real-seal consumer exhaustion)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$*-seal consumer of an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$*, together with any accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet consumed on its root route, is exhausted by the displayed rows*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

and by the grid-budget rows $B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G$ *when such a grid packet is present. No downstream Real-seal consumer can import selected limits, host real equality, quotient real equality, real completeness, compactness, trichotomy, countable choice, hidden grid selector state, or choice-like tail data.*

Proof. First confine the witness route by root extraction and limit-seal handoff. These theorems identify the finite rows of W and make every $\mathsf{CauchyLimitSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read pass through them.

Next apply schedule factorization. It records that σ, μ, λ are finite BHist rows before the Real-seal read, with H, C, P, N carrying only displayed transport, route replay, provenance, and naming.

If the root route consumes a grid packet, use grid budget precedence. The rows B, L, K, T are read before Q, and the remaining grid rows are exactly the carrier, handoff, transport, continuation, provenance, and naming rows already listed by the grid package.

Finally apply the synchronizer handoff and route tightening. They exhaust the Real-seal, synchronizer, and observation-budget consumers by the displayed witness and grid rows, so none of the excluded selected-limit, host-equality, completeness, compactness, trichotomy, choice, or hidden-selector data can be imported. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real seal consumer exhaustion`

Theorem 535.136 (Bounded monotone Cauchy witness four-face budget correspondence)**.** *Every accepted bounded monotone Cauchy witness consumed by the Real-seal route factors through exactly the four licensed L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

For an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$*, the* $\mathsf{StreamName}^{\uparrow}$ *face is the finite observation schedule* σ*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *face is the dyadic tolerance and upper-bound ledger* λ *together with the grid selector budget when a* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet is consumed, the* $\mathsf{RegSeqRat}^{\uparrow}$ *face is the regular rational readback row* F *together with the grid readback rows, and the* $\mathsf{Real}^{\uparrow}$ *face is the seal row* Q*.*

The correspondence is exhausted by displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows. It has no coordinate for quotient streams, selected host limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First confine the consumer to the witness packet. By Definition 535.111 and Definition 535.113, every root-facing read stays inside $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, with the bounded source and regular rational readback before the scheduled tail service.

Next identify the licensed faces. Theorems 535.115 and 535.134 make σ, μ, λ unavoidable before a seal read and read those rows as finite BHist data transported only by H, replayed only by C, packaged only by P, and named only by N.

Now attach the budget side. The grid-budget theorem Definition 535.132 places the selector budget, witness ledger, completion-seal classifier, and tail envelope before Q whenever a grid packet is present, and Definition 535.133 keeps those rows on the same Real-facing chain rather than on a parallel completion route.

Finally apply Definition 535.129 and Definition 535.135. These keep observation-budget and seal-budget consumers on the same finite surface and list all rows available to the downstream consumer. Therefore the four faces above are the entire budget correspondence, and the excluded quotient-stream, selected-limit, choice, and ambient-completeness data have no displayed carrier row from which to be read. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier four face budget correspondence`

Theorem 535.137 (Bounded monotone Cauchy witness uniform criterion handoff)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier, and suppose a downstream* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer reads the root route of W through an accepted packet*

$$U = (I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U).$$

Then the bounded-source route of W factors through the finite chain

$$S, F \longrightarrow \sigma, \mu, \lambda \longrightarrow I, Q \longrightarrow I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U.$$

The first stage supplies the displayed bounded monotone source and regular rational readback; the second supplies the $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, Cauchy tail witness, and dyadic tolerance ledger; the third supplies the located trap and* $\mathsf{Real}^{\uparrow}$ *seal row; and the final stage is exactly the UniformCauchyCriterion family-test surface over its finite index, shared window, shared modulus, dyadic tolerance, tail ledger, seal handoff, transport, continuation, package, and local naming rows.*

The StreamName finite-window handoff and the $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *seal rows remain explicit throughout the chain. Thus the handoff exports no quotient streams, selected host limits, host real equality, countable choice, ambient completeness, open-cover compactness, hidden family limit, or direct* $\mathsf{Real}^{\uparrow}$ *bypass.*

Proof. First project the bounded monotone witness. Root extraction confines every root read of W to $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, and root tail-window totality forces the consumer to pass through σ, μ, λ before any located-trap or seal row is available.

Next factor the schedule route. The schedule factorization theorem records σ, μ, λ as finite BHist rows transported only by H, replayed only by C, packaged only by P, and named only by N. The four-face budget correspondence then identifies the licensed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces that the downstream consumer may read.

Now attach the UniformCauchyCriterion packet. By Definition 435.3, the family request preserves the same finite index ledger, shared window family, and shared modulus before a tail comparison is inspected. By Definition 435.115, the full criterion-facing surface is exhausted by $I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U$.

Finally bind the StreamName and regular-real handoff rows. The StreamName finite-window handoff of Definition 126.79 keeps the finite observation window and $\mathsf{RegSeqRat}^{\uparrow}$ seed rows visible, while the bounded monotone root seal route and Real-seal consumer exhaustion keep the I, Q suffix tied to the same regular-source and seal route. Since neither side contributes quotient streams, selected limits, host real equality, countable choice, ambient completeness, open-cover compactness, or a direct $\mathsf{Real}^{\uparrow}$ bypass, their composite handoff is exactly the finite chain displayed above. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier uniform criterion handoff`

Theorem 535.138 (Bounded monotone Cauchy witness observation-budget grid pullback)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Let*

$$G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$$

be an accepted $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet, let*

$$U = (I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let*

$$O = (E_O, W_O, D_O, R_O, S_O, H_O, C_O, P_O, N_O)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet reading the same finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal rows used by the root route of* W*, the grid packet* G*, and the uniform criterion packet* U*. Then the bounded-source route, grid-budget route, uniform-criterion route, and observation-budget route determine one pullback surface before any* $\mathsf{Real}^{\uparrow}$ *seal is public:*

$$S, F, \sigma, \mu, \lambda, I, Q, B, L, K, T, S_G, R_G, E_G, I_U, W_U, M_U, Q_U, T_U, E_U, E_O, W_O, D_O, R_O, S_O, H, H_G, H_U, H_O, C, C_G, C_U$$

Every consumer of this surface first reads the root source and tail-window rows of W*, then the grid budget rows of* G*, then the uniform-criterion rows of* U*, and finally the finite observation-budget rows that name the same windows, dyadic ledgers, regular readbacks, and seal boundary. The surface exports no quotient stream, selected host limit, host real equality, countable-choice selector, ambient completeness theorem, open-cover compactness principle, hidden family limit, or direct* $\mathsf{Real}^{\uparrow}$ *bypass.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier observation budget grid pullback`

Proof. First project the bounded-source route. Root extraction confines all reads of W to $S, F, \sigma, \mu, \lambda, I, Q, H, C, P,$ and schedule factorization records σ, μ, λ as finite BHist rows transported only by H, replayed only by C, packaged only by P, and named only by N.

Next attach the grid side. The grid-budget precedence theorem places B, L, K, T before the seal row Q on the same root route, while the grid readback rows S_G, R_G, E_G sit on the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces. Thus the grid packet contributes budget rows to the same surface rather than a second completion route.

Now attach the uniform criterion. The uniform-criterion handoff sends the family-test packet U through the already displayed finite windows, dyadic tolerance ledger, regular readback, and

seal handoff. Its rows $I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U$ therefore meet the bounded-source and grid rows along the shared L10 faces.

Finally read the observation-budget route. By Definition 611.1, Definition 611.3, Definition 611.4, Definition 611.5, and Definition 611.6, the observation-budget consumer exposes only its finite request, window, dyadic, regular-handoff, seal, transport, continuation, provenance, and naming rows. Since those rows are assumed to be the same finite windows, ledgers, readbacks, and seal rows already displayed by W, G, and U, the four routes share exactly the pullback surface above before any $\mathsf{Real}^{\uparrow}$ seal can be public. □

Theorem 535.139 (Bounded monotone Cauchy witness criterion-grid-synchronizer correspondence)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Its public route to* $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, *and* $\mathsf{RealObservationBudget}^{\uparrow}$ *is a single displayed correspondence before Q is read as the* $\mathsf{Real}^{\uparrow}$ *seal: the criterion tail exposes the scheduled window and modulus ledger, the grid packet exposes the finite observation and witness-budget rows, and the synchronizer exposes the seal budget.*

The correspondence is exhausted by the rows of W, the grid-budget rows, the criterion-tail rows, the synchronizer seal-budget rows, the observation-budget rows, componentwise hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *names. It exports no quotient streams, selected limits, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection.*

Proof. Apply root extraction to the accepted packet W. This confines the public route to the bounded source, regular readback, schedule, modulus, dyadic ledger, located trap, seal, transport, route, provenance, and naming rows.

Apply root tail-window totality. The scheduled window σ, modulus witness μ, and dyadic ledger λ are read before any located-trap, synchronizer, observation-budget, or $\mathsf{Real}^{\uparrow}$ seal consumer can inspect Q.

Apply grid budget precedence. The $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ packet contributes its finite observation and witness-budget rows before the seal row, so the grid route is a budgeted face of the same root route rather than a hidden completion route.

Apply the synchronizer handoff and the observation-budget grid pullback. The synchronizer exposes the seal budget on the same displayed chain, and the observation-budget route reads the same finite windows, dyadic ledgers, regular readbacks, and seal boundary.

Finally apply Real-seal consumer exhaustion. The downstream consumer has only the displayed witness, criterion, grid, synchronizer, observation-budget, transport, continuation, provenance, and naming rows, so the excluded quotient-stream, selected-limit, host-equality, trichotomy, completeness, compactness, and choice-like tail-selection routes have no carrier coordinate. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier criterion grid synchronizer correspondence`

Theorem 535.140 (Bounded monotone Cauchy witness root Real-seal determinacy)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Let $G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$ be an accepted* $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet, let $U = (I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$ be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let $O = (E_O, W_O, D_O, R_O, S_O, H_O, C_O, P_O, N_O)$ be an accepted* $\mathsf{RealObservationBudget}^{\uparrow}$ *packet reading the same displayed finite-window, dyadic-ledger, regular-readback, and seal rows as the root route of W and the grid and criterion packets.*

Then any public $\mathsf{Real}^{\uparrow}$ *seal read on the shared surface is determined by the common displayed rows of the bounded-source route, grid-budget route, uniform-criterion route, synchronizer route, and observation-budget route. If two public seal reads preserve*

$$S, F, \sigma, \mu, \lambda, I, Q, B, L, K, T, S_G, R_G, E_G, I_U, W_U, M_U, Q_U, T_U, E_U, E_O, W_O, D_O, R_O, S_O, H, H_G, H_U, H_O, C, C_G, C_U$$

then they expose the same $\mathsf{Real}^{\uparrow}$ *seal boundary. The shared surface carries no quotient stream, selected host limit, host equality, choice principle, ambient completeness theorem, open-cover compactness principle, hidden family limit, or direct* $\mathsf{Real}^{\uparrow}$ *bypass.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root real seal determinacy`

Proof. Begin with root extraction and tail-window totality. Root extraction confines every public read of W to $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, and tail-window totality forces σ, μ, λ to be consumed before any located-trap, synchronizer, observation-budget, or $\mathsf{Real}^{\uparrow}$ seal read can inspect Q.

Next apply grid budget precedence. The grid rows B, L, K, T occur before the seal row on the same root route, while S_G, R_G, E_G are the displayed StreamName, RegSeqRat, and Real-seal faces of that route. Thus the grid packet cannot alter the seal boundary without altering a displayed row.

Now use the uniform criterion handoff. The packet U reads the same finite windows, shared modulus, dyadic tolerance, tail ledger, and seal handoff already exposed by the bounded-source and grid routes, so a public criterion read preserving those rows preserves the same seal-facing boundary.

Apply the observation-budget grid pullback and the criterion-grid-synchronizer correspondence. These identify the observation request, window, dyadic, regular-handoff, seal, synchronizer, transport, continuation, provenance, and naming rows as one shared pullback surface before the $\mathsf{Real}^{\uparrow}$ seal is public.

Finally use Real-seal consumer exhaustion. A downstream seal consumer has only the displayed witness, grid, criterion, synchronizer, observation-budget, transport, continuation, provenance, and naming rows listed above. Therefore two reads that preserve those rows determine the same public $\mathsf{Real}^{\uparrow}$ seal boundary, and the excluded quotient-stream, selected-limit, host-equality, choice, completeness, compactness, and bypass routes have no carrier coordinate. □

Theorem 535.141 (Bounded monotone Cauchy witness terminal budget extraction)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Let*

$$G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$$

be an accepted $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet, let*

$$U = (I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, and let* D *be an accepted* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *packet reading the same root windows, regular-rational readbacks, uniform criterion rows, and Real-seal boundary.*

If the route from W *has passed root extraction, limit-seal handoff, monotone-bound routing, grid-route compatibility, uniform-criterion handoff, and root Real-seal determinacy, then it exposes one terminal budget row consumable by* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{UniformCauchyCriterion}^{\uparrow}$*, and* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$*. The row is exhausted by*

$$S, F, \sigma, \mu, \lambda, I, Q, B, L, K, T, S_G, R_G, E_G, I_U, W_U, M_U, Q_U, T_U, E_U, H, H_G, H_U, C, C_G, C_U, P, P_G, P_U, N, N_G, N_U$$

together with the displayed diagonal-limit compatibility rows of D. It exports no selected limit, quotient stream, host real equality, countable-choice selector, ambient completeness theorem, open-cover compactness principle, hidden family limit, or direct $\mathsf{Real}^{\uparrow}$ *bypass.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier terminal budget extraction`

Proof. First extract the root route. Apply Definition 535.111, Definition 535.112, and Definition 535.113. These place the bounded source, regular readback, scheduled window, modulus ledger, dyadic ledger, located trap, Real seal, transport, continuation, provenance, and local name on the finite packet W.

Next attach the grid route. Use Definition 535.119, Definition 535.132, and Definition 535.121. The grid contributes selector-budget, witness-ledger, classifier, tail, regular-readback, and seal-facing rows before the $\mathsf{Real}^{\uparrow}$ seal can be consumed.

Now attach the uniform criterion. Apply Definition 535.137; it sends U through the same finite index, window, modulus, dyadic tolerance, tail ledger, exactness, transport, continuation, provenance, and local naming surface. The criterion row is therefore part of the same terminal budget rather than a separate family-limit principle.

Finally use Definition 535.140 together with the diagonal-limit compatibility package of chapter 646. The Real seal is determined by the common displayed rows, and the diagonal-limit consumer reads only its displayed compatibility rows. Thus $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, and $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ consume the same terminal budget row, while the excluded completion, equality, choice, compactness, hidden-limit, and bypass data have no carrier coordinate. □

Theorem 535.142 (Bounded monotone Cauchy witness grid selector exactness)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C,$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Let*

$$G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$$

be an accepted $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet, let*

$$U = (I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, let Y be an accepted* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet, and let*

$$O = (E_O, W_O, D_O, R_O, S_O, H_O, C_O, P_O, N_O)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet. Suppose these packets read the same finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal row displayed by the root route of W.*

Then the public selector route from W, G, U, Y, O is exact. Any two selector-facing reads that preserve the bounded-source rows $S, F, \sigma, \mu, \lambda, I, Q$, the grid-budget rows $B, L, K, T, S_G, R_G, E_G$, the uniform-criterion rows $I_U, W_U, M_U, Q_U, T_U, E_U$, the synchronizer seal-budget rows of Y, the observation-budget rows E_O, W_O, D_O, R_O, S_O, the componentwise transport rows H, H_G, H_U, H_O, the displayed continuation rows C, C_G, C_U, C_O, the provenance rows P, P_G, P_U, P_O, and the local NameCert rows N, N_G, N_U, N_O expose the same selector-facing $\mathsf{Real}^{\uparrow}$ *seal boundary.*

The exact selector surface has no coordinate for quotient streams, selected host limits, host real equality, choice selectors, ambient completeness, open-cover compactness, hidden family limits, or a direct $\mathsf{Real}^{\uparrow}$ *bypass.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier grid selector exactness`

Proof. First extract the root route. Root extraction and root tail-window totality force every selector-facing read of W through the displayed bounded source, regular readback, finite window, modulus, dyadic ledger, located trap, seal row, transport, continuation, provenance, and local naming rows.

Next attach the grid route. Grid budget precedence and grid route compatibility keep G on the same finite-window, dyadic-ledger, regular-readback, and seal boundary as W. The grid rows therefore refine the selector budget on the displayed route rather than adding a second completion stream.

Now add the criterion, synchronizer, and observation faces. The observation-budget grid pullback identifies the observation rows with the same window, ledger, readback, and seal surface, while the criterion-grid-synchronizer correspondence places the uniform criterion and synchronizer rows on that shared surface before the seal is public.

Finally apply root Real-seal determinacy. Once the bounded-source, grid-budget, uniform-criterion, synchronizer, observation-budget, transport, continuation, provenance, and NameCert rows are preserved, any two public selector reads expose the same $\mathsf{Real}^{\uparrow}$ seal boundary. Since the preceding route inventory contains no quotient, selected-limit, host-equality, choice, completeness, compactness, hidden-family, or bypass coordinate, no such data can enter the selector. □

Theorem 535.143 (Bounded monotone Cauchy witness terminal grid non-escape)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Let*

$$G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$$

be an accepted $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet, let*

$$U = (I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, let* Y *be an accepted* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet, and let*

$$O = (E_O, W_O, D_O, R_O, S_O, H_O, C_O, P_O, N_O)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet. Suppose the route also names the same finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal row.*

Then every terminal grid read from W, G, U, Y, O *remains inside the displayed bounded-source, grid-budget, uniform-criterion, synchronizer, observation-budget, stream-window, dyadic-ledger, regular-readback, Real-seal, transport, continuation, provenance, and NameCert rows. It exports no quotient stream, selected host limit, host real equality, countable-choice selector, ambient completeness theorem, open-cover compactness principle, hidden family limit, or direct* $\mathsf{Real}^{\uparrow}$ *bypass.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier terminal grid nonescape`

Proof. First extract the root route. Apply Definition 535.111 and Definition 535.115. These force every terminal read through $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ before the Real-facing seal is available.

Next attach the grid route. Use Definition 535.119 and Definition 535.121. The grid rows are therefore consumed as selector budget, witness ledger, classifier, tail envelope, regular readback, and seal-facing data on the same route.

Now add the synchronizer and observation-budget faces. The observation-budget grid pullback and the criterion-grid-synchronizer correspondence place U, Y, O on the same finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ surface.

Finally apply Definition 535.140 and Definition 535.142. The terminal grid read is determined by the displayed route, so the excluded completion, equality, choice, compactness, hidden-limit, and bypass data have no coordinate from which to escape. □

Theorem 535.144 (Bounded monotone Cauchy witness root budget consumer exactness)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Let*

$$G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$$

be an accepted $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet, let*

$$U = (I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, let* Y *be an accepted* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet, and let*

$$O = (E_O, W_O, D_O, R_O, S_O, H_O, C_O, P_O, N_O)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet. Suppose they read the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows displayed by the root route.*

Then any two root-budget consumers preserving $S, F, \sigma, \mu, \lambda, I, Q$, *the rows of* G, U, Y, O, *the shared* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *handoff rows, componentwise transport, displayed continuation, provenance, and local NameCert data expose the same root budget boundary. The consumer has no coordinate for a second budget, a selected limit, quotient-stream equality, host real equality, countable choice, ambient completeness, compactness, hidden family data, or a direct* $\mathsf{Real}^{\uparrow}$ *route.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root budget consumer exactness`

Proof. Start with the bounded root. Root extraction and root tail-window totality display the bounded source, regular readback, scheduled window, modulus witness, dyadic ledger, located trap, Real-seal row, transport, continuation, provenance, and local name before a budget consumer can inspect the seal.

Next consume the grid and criterion route. Grid route compatibility and uniform-criterion handoff identify the grid rows and criterion rows with the same finite windows, dyadic ledgers, regular readbacks, and seal boundary.

Then use the budget services. The synchronizer route and observation-budget grid pullback place Y and O on the same root budget rather than on a detached observation schedule. The route therefore has one displayed consumer boundary for W, G, U, Y, O.

Finally apply root Real-seal threshold exhaustion and grid selector exactness. Once the listed rows are preserved, the public root-budget read is fixed, and the excluded completion, equality, choice, compactness, hidden-limit, and bypass data cannot be projected. □

Theorem 535.145 (Bounded monotone Cauchy witness RealUp threshold lock)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C,$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Let*

$$G = (B, L, K, T, S_G, R_G, E_G, H_G, C_G, P_G, N_G)$$

be an accepted $\mathsf{RealCauchyWitnessGrid}^{\uparrow}$ *packet, let*

$$U = (I_U, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, let* Y *be an accepted* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet, and let*

$$O = (E_O, W_O, D_O, R_O, S_O, H_O, C_O, P_O, N_O)$$

be an accepted $\mathsf{RealObservationBudget}^{\uparrow}$ *packet. Suppose the route reads the same finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal boundary.*

Then the terminal $\mathsf{Real}^{\uparrow}$ *threshold is locked by the displayed route through* W, G, U, Y, O*. Any Real-facing consumer must first consume the root extraction, root tail-window, grid route, grid ledger, synchronizer, observation-budget, and grid-selector rows named above, and no ambient completeness principle, selected host limit, quotient equality, countable-choice selector, open-cover compactness principle, hidden family limit, or direct* $\mathsf{Real}^{\uparrow}$ *bypass can unlock the threshold.*

Proof. First force the root order. Root extraction and root tail-window totality put $S, F, \sigma, \mu, \lambda$ before the located trap and seal rows, while root Real-seal threshold exhaustion places the $\mathsf{Real}^{\uparrow}$ threshold after the displayed root packet.

Next force the grid order. Grid route compatibility and grid ledger non-escape consume G as a finite selector-budget and witness-ledger route before the Real seal is public. The grid cannot introduce a second completion stream.

Now identify the terminal service rows. The criterion handoff, synchronizer route, observation-budget grid pullback, and grid selector exactness place U, Y, O on the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ boundary.

Finally compose the locked route. Since every Real-facing consumer has already traversed the displayed root, grid, criterion, synchronizer, observation, transport, continuation, provenance, and NameCert rows, the threshold has no remaining coordinate through which the excluded completion or choice data could enter. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier realup threshold lock`

Theorem 535.146 (Bounded monotone Cauchy witness root window extraction)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing consumer that reads* W *for a convergence-seal, limit-seal, or real-seal input first extracts the finite window route*

$$S, F, \sigma, \mu, \lambda$$

before it reads the located trap I*, the Real seal row* Q*, or the transport, continuation, provenance, and local naming rows* H, C, P, N*. The extraction is a finite* BHist *route through the bounded source, regular rational handoff, stream schedule, Cauchy witness, and dyadic ledger, not an appeal to selected limits, quotient real equality, host real equality, trichotomy, ambient completeness, or open-cover compactness.*

Proof. Project the accepted carrier through Definition 535.5. Its root-facing rows are exactly $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, with no hidden coordinate for a limiting representative or ambient completion principle.

Use the local NameCert obligations and scoped dependency package, Definition 535.6 and Definition 535.19. They place source reads in S, regular handoff in F, stream windows in σ, Cauchy witnesses in μ, and dyadic ledger data in λ before the located and seal rows are available.

Finally apply root extraction and root seal route exhaustion, Definition 535.111 and Definition 535.114. Those theorems identify every root consumer with the same finite packet, so the window route $S, F, \sigma, \mu, \lambda$ is the first extracted segment of the route. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root window extraction`

Theorem 535.147 (Bounded monotone Cauchy witness root window readiness)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C,$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every root-facing* $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *or completion-facing seal consumer of W must first read the displayed packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

as its explicit readiness surface. The prefix

$$S, F, \sigma, \mu, \lambda$$

is the readiness prefix, and the suffix

$$I, Q, H, C, P, N$$

is the seal suffix. The surface exports the bounded source row, regular rational handoff, scheduled window, tail modulus, dyadic ledger, located trap, Real seal row, transport, continuation, provenance, and local naming row, and it exports no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root window readiness`

Proof. First read the root window extraction row. Theorem 535.146 forces every root-facing consumer through $S, F, \sigma, \mu, \lambda$ before any located trap, Real seal, transport, continuation, provenance, or naming suffix is available.

Next read the tail-modulus ledger. Theorem 535.148 keeps every tail request on the displayed μ, σ, λ ledger, so the readiness prefix is not merely a carrier projection but the public tail-service surface consumed before a seal route can be read.

Now pull the route back to the public criterion-tail boundary. Theorem 535.149 identifies any such $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, or completion-facing consumer with the finite BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ packet displayed by W.

Finally apply root Real-seal nonescape. Theorem 535.150 identifies the remaining rows as exactly I, Q, H, C, P, N. The accepted carrier has no coordinate for a selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection, so the displayed prefix and suffix together form the whole readiness surface consumed by Real-facing and completion-facing seal routes. □

Theorem 535.148 (Bounded monotone Cauchy witness root tail modulus ledger)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing tail request made to W is ledgered by the displayed triple*

$$\mu, \sigma, \lambda$$

before any located-trap row I, Real seal row Q, or completion-facing handoff is read. The modulus answer μ, scheduled window σ, and dyadic ledger λ therefore form the public tail-modulus ledger for the root route, and no consumer may replace that ledger by a selected tail, quotient representative, host equality, trichotomy, ambient completeness, or open-cover compactness.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root tail modulus ledger`

Proof. Start from the carrier and NameCert rows. The carrier makes μ, σ, λ displayed components, while the NameCert obligations keep Cauchy-tail, window, and dyadic-budget reads inside those components.

Apply Definition 535.146. It forces the root consumer through $S, F, \sigma, \mu, \lambda$ before I or Q, so the tail request is already tied to the scheduled window and dyadic ledger before a trap or seal can be consumed.

Now use the monotone-bound route and the limit-seal handoff, Definition 535.113 and Definition 535.112. The bounded monotone source reaches the seal-facing suffix only through the same modulus ledger, and the handoff to $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ preserves that finite route.

The root seal route exhaustion theorem then rules out every alternate tail service. Since the exhausted packet contains no selected tail, quotient representative, host equality, trichotomy, ambient completeness, or compactness row, the displayed triple is the whole public root tail-modulus ledger. □

Theorem 535.149 (Bounded monotone Cauchy witness root criterion-tail pullback)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing* $\mathsf{Real}^{\uparrow}$ *seal or convergence-seal consumer that uses the ledger triple*

$$\mu, \sigma, \lambda$$

must factor through the public criterion-tail route of Definition 535.69 before it reads the located-trap row I or the Real-seal row Q. The pullback of such a consumer is the finite packet already displayed by the carrier: the BHist *rows,* hsame *transports,* Cont *continuations,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *row.*

Consequently the root route exports no selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Proof. Start with root window extraction and the root tail modulus ledger. Theorems 535.146 and 535.148 place every root-facing read through $S, F, \sigma, \mu, \lambda$ and then through the displayed ledger triple μ, σ, λ before any access to I or Q.

Next apply the criterion-tail factorization of Definition 535.69. That factorization is the public route from the bounded monotone source into the Cauchy criterion tail surface, so a consumer using the root ledger cannot jump directly from μ, σ, λ to a Real-facing seal read.

Finally use the limit-seal handoff and the root Real-seal nonescape boundary. The handoff keeps the route inside $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ as a displayed BEDC packet, while nonescape identifies the remaining suffix as I, Q, H, C, P, N rather than an unledgered completion object.

The resulting pullback is therefore exactly the finite BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ packet displayed by the accepted carrier. Since this packet has no coordinate for selected limits, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection, none of those objects is available to the root-facing consumer. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root criterion tail pullback`

Theorem 535.150 (Bounded monotone Cauchy witness root Real-seal nonescape)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. The rows*

I, Q, H, C, P, N hand off only the displayed packet

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

to $\mathsf{CauchyLimitSeal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$. *This handoff exports the located trap, Real seal route, componentwise transport, continuation, package provenance, and local naming rows, but it exports no selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or unledgered completion principle.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root real seal nonescape`

Proof. Read the suffix through the accepted carrier. The rows I, Q, H, C, P, N are the located trap, Real seal, transport, continuation, provenance, and naming coordinates of the same finite packet, not a second source of completion data.

Use the root window extraction and tail modulus ledger rows proved above. They force every root-facing request through $S, F, \sigma, \mu, \lambda$ and through the ledger μ, σ, λ before any read of I, Q, H, C, P, N.

Apply the limit-seal handoff and monotone-bound route, Definition 535.112 and Definition 535.113. These identify the $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers with the same bounded-source, regular-handoff, scheduled-tail, located-trap, and seal route.

Finally cite root seal route exhaustion. Once the route is exhausted by $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, no selected limit, quotient equality, host real equality, trichotomy, ambient completeness, compactness, or unledgered completion principle remains for the Real-seal handoff to export. □

Theorem 535.151 (Bounded monotone Cauchy witness window-meet route)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P,$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every root-facing convergence consumer or Real-seal consumer using the displayed window route must pass through the common finite sequence*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

The route composes root window extraction, root tail modulus ledgering, criterion-tail pullback, and root Real-seal nonescape. It exports no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window meet route`

Proof. Begin with root window extraction. Theorem 535.146 forces the root-facing consumer through $S, F, \sigma, \mu, \lambda$ before the located trap or seal suffix can be read.

Next apply the root tail modulus ledger. Theorem 535.148 keeps every tail request ledgered by μ, σ, λ inside the same finite packet.

Use criterion-tail pullback. Theorem 535.149 pulls any Real-facing or convergence-facing consumer back to the public criterion-tail route and its displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Finally apply root Real-seal nonescape. Theorem 535.150 identifies the remaining suffix as I, Q, H, C, P, N and excludes every selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, and choice-like tail selector. The carrier of Definition 535.5 has no alternate coordinate, so the displayed sequence is the whole window-meet route. □

Theorem 535.152 (Bounded monotone Cauchy witness root window seal synchronizer)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *carrier. Every root-facing* $\mathsf{Real}^{\uparrow}$ *seal or convergence-seal consumer that uses the window route must synchronize the prefix*

$$S, F, \sigma, \mu, \lambda$$

with the suffix

$$I, Q, H, C, P, N$$

through the same finite BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *route. The synchronized packet is*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N,$$

and it exports no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Proof. Begin with root window extraction and the root tail modulus ledger. Theorems 535.146 and 535.148 place the prefix rows $S, F, \sigma, \mu, \lambda$ and the ledger triple μ, σ, λ before any root-facing read of the located trap, Real seal, transport, continuation, provenance, or naming suffix.

Next use the criterion-tail pullback. Theorem 535.149 identifies every such Real-facing or convergence-facing consumer with the public criterion-tail route and its displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Apply root Real-seal nonescape and the window-meet route. Theorems 535.150 and 535.151 identify the suffix as I, Q, H, C, P, N and show that prefix and suffix are consumed as the single finite packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

The accepted carrier has no further coordinate for selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection. Hence any root-facing seal consumer using the window route must synchronize through the displayed finite BEDC packet. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root window seal synchronizer`

Theorem 535.153 (Bounded monotone Cauchy witness Real-seal selector exhaustion)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Any* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, or completion-facing consumer that asks for a selector must factor through the displayed prefix*

$$S, F, \sigma, \mu, \lambda$$

and the displayed suffix

$$I, Q, H, C, P, N.$$

After those rows are fixed, the accepted packet has no coordinate for a second selector, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection.

Proof. First expose the selector prefix. Root window extraction and the root tail modulus ledger, Definition 535.146 and Definition 535.148, place every root-facing selector request on $S, F, \sigma, \mu, \lambda$ and on the displayed μ, σ, λ tail ledger before any Real seal is read.

Next pull the selector request back to the public tail boundary. The criterion-tail pullback Definition 535.149 identifies the consumer with the finite BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ route already displayed by the accepted packet.

Then read the seal suffix. Root Real-seal nonescape and the window-meet route, Definition 535.150 and Definition 535.151, identify the remaining rows as exactly I, Q, H, C, P, N and exclude any unshown completion or choice service.

Finally apply the root window seal synchronizer Definition 535.152. It binds the prefix and suffix into the single packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$, so a consumer that asks for selector data has exhausted every selector-facing coordinate before the Real seal is read. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real seal selector exhaustion`

Theorem 535.154 (Bounded monotone Cauchy witness window Real-seal pullback)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every root-facing* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer using the synchronized window factors through the displayed packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

The pullback exports the bounded source row, regular rational handoff, scheduled window, tail modulus, dyadic ledger, located trap, Real seal, componentwise transport, continuation, package provenance, and local naming row, and it exports no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector.

Proof. Begin with root window extraction. Theorem 535.146 forces any root-facing Real or limit-seal consumer to read the prefix $S, F, \sigma, \mu, \lambda$ before it reaches a trap, seal, transport, continuation, provenance, or naming suffix.

Next apply the root tail modulus ledger and criterion-tail pullback. Theorems 535.148 and 535.149 keep the tail request on the displayed μ, σ, λ ledger and pull the consumer back through the public criterion-tail route.

Now use root Real-seal nonescape. Theorem 535.150 identifies the seal-facing suffix as I, Q, H, C, P, N and rules out every unledgered completion object at that boundary.

Finally apply the window-meet route and root window seal synchronizer. Theorems 535.151 and 535.152 combine the prefix and suffix into the single finite packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. Since the accepted carrier has no further coordinate, every synchronized root-facing Real or limit-seal read factors through exactly that displayed BEDC packet. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window real seal pullback`

Theorem 535.155 (Bounded monotone Cauchy witness window completion pullback)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every root-facing completion consumer or* $\mathsf{Real}^{\uparrow}$*-seal consumer using the synchronized window route factors through the finite packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

The pullback is completion-facing only through the displayed bounded source row, regular rational handoff, scheduled window, tail modulus, dyadic ledger, located trap, Real seal, componentwise transport, continuation, package provenance, and local naming row. It exports no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window completion pullback`

Proof. Begin with root window extraction. Theorem 535.146 places every root-facing completion read on the displayed prefix $S, F, \sigma, \mu, \lambda$ before the consumer can reach a seal or naming suffix.

Next apply the root tail modulus ledger and criterion-tail pullback. Theorems 535.148 and 535.149 keep the tail request inside μ, σ, λ and route the consumer back to the public criterion-tail packet.

Use root Real-seal nonescape. Theorem 535.150 identifies the seal-facing suffix as I, Q, H, C, P, N and blocks any reading that would replace the displayed rows by an unshown completion object.

Finally compose the window-meet route, root window seal synchronizer, and window Real-seal pullback. Theorems 535.151, 535.152, and 535.154 make the synchronized completion-facing route the single packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Since the accepted carrier contains no coordinate for selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection, every such consumer factors through exactly the displayed BEDC packet. □

Theorem 535.156 (Bounded monotone Cauchy witness window completion terminality)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every completion-facing consumer,* $\mathsf{Real}^{\uparrow}$*-seal-facing consumer, or convergence-seal-facing consumer that factors through the synchronized window-completion route factors through exactly the displayed packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

This packet is terminal for such consumers: it exposes the bounded source row, regular rational handoff, scheduled window, tail modulus, dyadic ledger, located trap, Real seal, componentwise transport, continuation, package provenance, and local naming row, and it exposes no selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, hidden tail selector, or choice-like tail service.

Proof. First extract the finite window route from the root carrier. The root window extraction and root tail modulus ledger, Definition 535.146 and Definition 535.148, force the consumer through $S, F, \sigma, \mu, \lambda$ and through the ledger μ, σ, λ before any located trap, Real seal, transport, continuation, provenance, or naming row is read.

Next pull the route back to the public criterion-tail and Real-seal boundaries. Apply criterion-tail pullback, root Real-seal nonescape, and the window-meet route, Definition 535.149, Definition 535.150, and Definition 535.151. These identify every completion-facing, Real-seal-facing, or convergence-seal-facing read with the same finite BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWi}}$ packet.

Then synchronize the seal suffix with the window prefix. The root window seal synchronizer and window Real-seal pullback, Definition 535.152 and Definition 535.154, make the prefix $S, F, \sigma, \mu, \lambda$ and suffix I, Q, H, C, P, N a single route rather than two independently selectable services.

Finally use the window completion pullback, Definition 535.155. It states that every synchronized completion-facing consumer already factors through $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Coordinate exhaustion of the accepted carrier now gives terminality. The carrier of Definition 535.5 has exactly the displayed coordinates and has no coordinate for a selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, hidden tail selector, or choice-like tail service. Hence all completion-facing consumers of the synchronized route factor through exactly the displayed packet, and there is no further completion-facing datum through which they can factor. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window completion terminality`

Theorem 535.157 (Bounded monotone Cauchy witness Real-seal modulus determinacy)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *and* $W' = (S', F', \sigma', \mu', \lambda', I', Q', H', C', P', N')$ *be accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packets. Suppose the bounded source rows, regular rational handoff rows, scheduled window rows, tail modulus rows, dyadic ledger rows, located trap rows, Real seal rows,* hsame *transport rows,* Cont *route rows,* Pkg *provenance rows, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *rows agree componentwise as displayed carrier coordinates. Then every root-facing* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer that reads either packet reads the same finite Real-seal route*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$$

and hence the displayed tail-modulus packet uniquely determines the Real-seal readback. The determinacy is internal to the finite carrier route; it does not select a limit, identify quotient reals, assert host equality, use trichotomy, invoke ambient completeness, appeal to open-cover compactness, or install any choice-like tail selector.

Proof. First extract the shared root window. The root window extraction and root tail modulus ledger, Definition 535.146 and Definition 535.148, force both consumers through the componentwise-agreeing rows $S, F, \sigma, \mu, \lambda$ and the same ledger triple μ, σ, λ before either consumer can read a located trap or Real seal row.

Next pull the two reads back to the public criterion-tail boundary. The criterion-tail pullback and root Real-seal nonescape, Definition 535.149 and Definition 535.150, identify the remaining data as the displayed located trap, Real seal, transport, continuation, provenance, and local naming suffix rather than any unshown completion object.

Now synchronize the suffix with the window route. The window-meet route and root window seal synchronizer, Definition 535.151 and Definition 535.152, make the agreeing prefix and agreeing suffix a single finite route for both root-facing consumers.

Finally use the window Real-seal pullback, window completion pullback, and window completion terminality, Definition 535.154, Definition 535.155, and Definition 535.156. These theorems leave no completion-facing datum outside the accepted carrier.

Coordinate exhaustion of Definition 535.5 completes the comparison. Since the two accepted packets agree in every displayed coordinate and the carrier has no coordinate for selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection, every root-facing $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer reads the same finite Real-seal route from W and W'. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real seal modulus determinacy`

Theorem 535.158 (Bounded monotone Cauchy witness monotone-source seal bridge)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet, and let* $M = (F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be the accepted* $\mathsf{MonotoneCauchy}^{\uparrow}$ *monotone source component read by* W*. Every root-facing* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of* W *factors first through the monotone-source finite tail-window and cofinality handoff of* M*, then through the bounded-witness root window seal synchronizer for* W*, and finally through the bounded-witness Real-seal modulus determinacy route. The composed bridge is the displayed finite packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N,$$

with the monotone-source window rows $F, \sigma, \mu, \lambda, I, Q$ read before the bounded source row S is allowed to expose any root-facing seal consumption. The bridge supplies no quotient real equality, selected representative, trichotomy, open-cover compactness, ambient completeness, host real equality, or choice-like tail selector.

Proof. First read the monotone source through M. Theorem 438.15 forces any $\mathsf{Real}^{\uparrow}$ seal consumer using the monotone Cauchy source and a cofinal tail schedule through $F, \sigma, \mu, \lambda, I, Q$ before the seal row is readable, and it excludes quotient equality, selected representatives, host real order, ambient completeness, open-cover compactness, and choice.

Next attach the bounded-witness root row. Theorem 535.152 synchronizes the bounded source prefix $S, F, \sigma, \mu, \lambda$ with the seal suffix I, Q, H, C, P, N as one finite BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ route.

Finally apply Definition 535.157. Once the monotone-source handoff and bounded-witness synchronizer have displayed the same rows, the tail-modulus packet uniquely determines the root-facing Real-seal readback. The accepted packets contain no additional coordinate for quotient real equality, selected representatives, trichotomy, open-cover compactness, ambient completeness, host real equality, or choice-like tail selection, so every root-facing $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer factors through exactly the composed finite bridge. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier monotone source seal bridge`

Theorem 535.159 (Bounded monotone Cauchy witness window seal completeness)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every root-facing* $\mathsf{Real}^{\uparrow}$ *consumer, root-facing* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer, or completion consumer that uses the synchronized window route factors through exactly the finite packet*

$$S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N.$$

Conversely, every displayed window-seal read of that packet supplies the whole readiness surface for those consumers: bounded source, regular rational handoff, scheduled window, tail modulus, dyadic ledger, located trap, Real seal, componentwise hsame *transport,* Cont *route,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *naming row. No selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, hidden tail selector, or choice-like tail service is part of the readiness surface.*

Proof. First build the finite route. The window-meet route and root window seal synchronizer, Definition 535.151 and Definition 535.152, identify the root window prefix $S, F, \sigma, \mu, \lambda$ with the seal suffix I, Q, H, C, P, N as one packet.

Next pass to the Real and completion boundaries. The window Real-seal pullback and window completion pullback, Definition 535.154 and Definition 535.155, make every root-facing $\mathsf{Real}^{\uparrow}$, root-facing $\mathsf{CauchyLimitSeal}^{\uparrow}$, and completion read factor through that synchronized packet.

Then use terminality. By Definition 535.156, the displayed coordinates are the terminal readiness packet for completion-facing and seal-facing consumers, so no consumer can require data outside $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Finally apply Real-seal modulus determinacy, Definition 535.157. It states that componentwise agreement of the displayed packet determines the root-facing Real-seal readback, which gives the converse: reading the displayed window-seal packet supplies exactly the readiness surface used by the Real, limit-seal, and completion consumers. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window seal completeness`

Theorem 535.160 (Bounded monotone Cauchy witness window readback stability)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *and* $W' = (S', F', \sigma', \mu', \lambda', I', Q', H', C', P', N')$ *be accepted* BoundedMonotoneCauchy *packets. Suppose the displayed rows* $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$ *are preserved componentwise by* hsame *and that both packets replay the same displayed* Cont *window-seal route. Then every root-facing* $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *or completion consumer reads the same window-seal readiness surface from* W *and* W'. *The stability claim uses only the finite window-meet route, root window seal synchronizer, window Real-seal pullback, window completion pullback, terminality, and Real-seal modulus determinacy; it does not select limits, identify quotient reals, assert host equality, use trichotomy, invoke ambient completeness, appeal to open-cover compactness, or install choice-like tail services.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window readback stability`

Proof. First compose the shared window route. The window-meet route and root window seal synchronizer, Definition 535.151 and Definition 535.152, force both packets through the same displayed prefix and suffix under the assumed componentwise hsame transport and Cont replay.

Next pull the read to the Real and completion boundaries. The window Real-seal pullback and window completion pullback, Definition 535.154 and Definition 535.155, make every root-facing $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and completion consumer factor through the finite packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Finally apply terminality and Real-seal modulus determinacy. Theorem 535.156 leaves no completion-facing datum outside the displayed carrier, and Theorem 535.157 makes the componentwise-preserved window packet determine the Real-seal readback. The carrier has no coordinate for selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail services, so the readiness surface read from W and W' is the same. □

Theorem 535.161 (Bounded monotone Cauchy witness CauchyCriterion selector handoff)**.** *Let* $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ *be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet, and let* $K = (W_K, M, T, Q_K, E, H_K, C_K, P_K, N_K)$ *be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *packet. Suppose the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows displayed by the two packets agree at the selector-seal boundary. Then every* $\mathsf{Real}^{\uparrow}$*-facing,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*-facing, or completion-facing read of the bounded monotone window-seal packet factors through the same finite* $\mathsf{CauchyCriterion}^{\uparrow}$ *budget-selector surface*

$$M, \quad Q_K, \quad T, \quad W_K, \quad E, \quad H_K, \quad C_K, \quad P_K, \quad N_K$$

before any $\mathsf{Real}^{\uparrow}$ *seal is exposed. The handoff uses only the shared StreamName–RegSeqRat–DyadicRatCore–Real rows and the finite support rows* BHist, hsame, Cont, Pkg, *and* NameCert*; it does not introduce quotient streams, selected limits, host real equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selectors.*

Proof. First close the bounded monotone window packet. The window seal completeness and window readback stability theorems, Definition 535.159 and Definition 535.160, put every $\mathsf{Real}^{\uparrow}$-facing, $\mathsf{CauchyLimitSeal}^{\uparrow}$-facing, and completion-facing read of W on the displayed finite packet $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

Next expose the selector surface. The CauchyCriterion StreamName Real budget-selector boundary, Definition 392.37, makes every consumer sharing the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows read through $M, Q_K, T, W_K, E, H_K, C_K, P_K, N_K$ before selector output is exposed.

Then use uniform selector-seal compatibility, Definition 392.39. It records that the selector-facing CauchyCriterion route and any matching seal route factor through the same finite StreamName–RegSeqRat–DyadicRatCore–Real surface with the support rows BHist, hsame, Cont, Pkg, and NameCert.

Finally match the shared boundary rows. By hypothesis the bounded monotone packet and the CauchyCriterion packet display the same four public rows at the selector-seal boundary, so the terminal window-seal read of W must pass through the CauchyCriterion budget-selector packet before a $\mathsf{Real}^{\uparrow}$ seal is exposed. Neither accepted carrier has an extra completion coordinate, and the listed exclusions have no displayed row in either packet. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier cauchycriterion selector handoff`

Theorem 535.162 (Bounded monotone Cauchy witness window-seal readback completeness)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. A current Phase Real or Completion readback through* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, or any completion-facing seal is complete exactly when it exposes the bounded source row S, regular rational handoff F, scheduled window σ, λ, tail modulus μ, dyadic ledger, located trap I, Real seal Q, componentwise* hsame *transports H, displayed* Cont *routes C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *row N. Conversely, any accepted packet exposing those rows supplies the whole readback surface for the bounded monotone witness window. The statement excludes selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, and choice-like tail selection.*

Proof. First expose the bounded source prefix. The root window extraction and root tail modulus ledger, Definition 535.146 and Definition 535.148, place every Phase Real or Completion read on $S, F, \sigma, \mu, \lambda$ and the dyadic tail ledger before a trap, seal, transport, route, provenance, or naming row can be read.

Next pull the readback to the public seal boundary. The criterion-tail pullback and root Real-seal nonescape, Definition 535.149 and Definition 535.150, identify the remaining surface as I, Q, H, C, P, N rather than a selected limit or host completion object.

The route is then synchronized as one finite packet. Apply the window-meet route and root window seal synchronizer, Definition 535.151 and Definition 535.152, to bind the source prefix, tail ledger, located trap, Real seal, transports, continuations, provenance, and local name into the same displayed BHist packet.

For the forward direction, window completion terminality and Real-seal modulus determinacy, Definition 535.156 and Definition 535.157, leave no completion-facing or Real-facing coordinate outside the displayed rows. Thus a complete $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, or completion-facing read must expose exactly the listed surface.

For the converse, start from an accepted packet exposing all listed rows. The CauchyCriterion selector handoff, Definition 535.161, supplies the selector-facing budget route before any Real seal is exposed, while the synchronized window packet supplies the completion-facing suffix. Since the carrier contains no row for selected limits, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection, these rows supply the whole readback surface. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window seal readback completeness`

Theorem 535.163 (Bounded monotone Cauchy witness root window terminal factorization)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every root-facing* $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *or completion consumer of W factors through the single displayed root-window route*

$$S, \quad F, \quad \sigma, \quad \mu, \quad \lambda, \quad I, \quad Q, \quad H, \quad C, \quad P, \quad N.$$

This route is the only completion-facing factorization surface for the accepted packet: any consumer preserving the bounded source, regular rational handoff, scheduled root window, tail modulus ledger, located trap, Real seal, componentwise hsame *transports, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *row preserves the same root-window readback. No selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selector is part of the factorization.*

Proof. First build the root-window spine. Root window extraction and the root tail modulus ledger, Definition 535.146 and Definition 535.148, put every root-facing read on the displayed bounded source, rational handoff, scheduled window, and tail modulus rows.

Next pull the spine to the public seal boundary. Criterion-tail pullback and root Real-seal nonescape, Definition 535.149 and Definition 535.150, force the located trap, Real seal, componentwise transports, continuation replay, provenance, and local naming row to remain attached to that same root route.

Finally close the completion-facing side. Window completion terminality, Definition 535.156, says a completion consumer has no further route outside the displayed packet, and window-seal readback completeness, Definition 535.162, identifies the whole exposed surface as $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. Therefore every root-facing $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, or completion consumer factors through exactly this route, and the excluded objects have no carrier coordinate through which a second factorization could pass. □

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root window terminal factorization`

Theorem 535.164 (Bounded monotone Cauchy witness finite-window factorization package)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing read of W factors through the finite prefix*

$$S, \quad F, \quad \sigma, \quad \mu, \quad \lambda$$

and then through the finite suffix

$$I, \quad Q, \quad H, \quad C, \quad P, \quad N.$$

The prefix records the bounded source, regular rational handoff, scheduled root window, tail modulus ledger, and window selector. The suffix records the located trap, Real seal, componentwise hsame *transports, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *row. Thus any* $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *RegSeqRat, StreamName, or completion-seal consumer preserving these eleven rows reads the same finite window package.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier window factorization`

Proof. First isolate the prefix. Root window extraction and the root tail-modulus ledger, Definition 535.146 and Definition 535.148, place every source-facing and tail-facing read on $S, F, \sigma, \mu, \lambda$ before a located trap or Real seal can be exposed.

Next bind the suffix to that same prefix. Criterion-tail pullback and root Real-seal nonescape, Definition 535.149 and Definition 535.150, keep the trap, seal, transport, continuation, provenance, and local naming rows attached to the displayed root window.

The window-meet route and root window seal synchronizer, Definition 535.151 and Definition 535.152, identify the two halves as one finite BHist packet. The terminal factorization theorem, Definition 535.163, then rules out any further completion-facing route outside these eleven rows. □

Theorem 535.165 (Bounded monotone Cauchy witness Real-seal route)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ packet. The $\mathsf{Real}^{\uparrow}$ seal of W is readable only through the displayed finite route*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$$

carried by $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$. This route excludes quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, and choice-like tail selection. In particular, a Real-seal consumer receives the finite BHist row, the componentwise hsame transports, the Cont replay, the Pkg provenance row, and the local NameCert row, and receives no additional real-completion witness.

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier real seal route`

Proof. Start from root Real-seal nonescape, Definition 535.150. It says the Real-facing row cannot leave the finite root-window packet for a selected limit, a host equality judgment, or an ambient completion object.

The window-meet route and window-seal synchronizer, Definition 535.151 and Definition 535.152, then display the seal route as the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support carried by W.

Finally use terminal factorization, Definition 535.163. Since the accepted packet has no coordinate for quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like tail selection, no Real-seal route can factor through those objects. □

Theorem 535.166 (Bounded monotone Cauchy witness modulus ledger exhaustion)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ packet. The modulus ledger μ, σ, λ is exhausted before either located-trap row I or Real-seal row Q is readable. Equivalently, every located-trap, Real-seal, $\mathsf{CauchyLimitSeal}^{\uparrow}$, or completion-facing read first passes through the scheduled window and tail-modulus budget, and only then reaches I, Q, H, C, P, N.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier modulus ledger exhaustion`

Proof. The root tail-modulus ledger, Definition 535.148, records the selector and modulus rows σ, μ, λ as the finite budget consumed by the root window. Thus a trap or seal row cannot be read before that budget is displayed.

Criterion-tail pullback, Definition 535.149, transports any criterion-facing tail read back to the same budget rows. Root Real-seal nonescape, Definition 535.150, keeps the Real-seal side on the finite packet rather than on a selected limit or ambient completion object.

The finite-window factorization package above and the terminal factorization theorem, Definition 535.164 and Definition 535.163, identify every downstream read as a prefix read through $S, F, \sigma, \mu, \lambda$ followed by a suffix read through I, Q, H, C, P, N. Hence the modulus ledger is exhausted before the located-trap and seal rows are readable. □

Corollary 535.167 (Bounded monotone Cauchy witness root-window extraction strict local obstruction)**.** *Let $W = (S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N)$ be an accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *packet. Suppose a displayed failure, refusal, separation, or countermodel row in the root-window extraction, tail-modulus ledger, or Real-seal handoff surface of W is cited against a named converse or reuse route. Then the row is a strict local obstruction: it blocks only the named route whose consumer-facing read tries to omit, replace, detach, or bypass one of the displayed packet coordinates*

$$S, \quad F, \quad \sigma, \quad \mu, \quad \lambda, \quad I, \quad Q, \quad H, \quad C, \quad P, \quad N.$$

Equivalently, every permitted consumer-facing use of the row factors through the finite root-window prefix

$$S, F, \sigma, \mu, \lambda$$

and the seal suffix

$$I, Q, H, C, P, N,$$

with support only from the displayed BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ *rows. The same row cannot be reinterpreted as a global impossibility theorem for* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$, *a host theorem about real completion or monotone convergence, hidden external validation of the failed route, a selected limit, quotient real equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or a choice-like tail selector.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier root window strict obstruction`

Proof. Start with root-window extraction. By Definition 535.146, every root-facing convergence-seal, limit-seal, or Real-seal consumer first reads the finite prefix $S, F, \sigma, \mu, \lambda$ before it reaches the located trap, the Real seal, transport, continuation, provenance, or naming rows. Thus a displayed negative row attached to the extraction surface has a named input coordinate inside that prefix; it is not a statement about arbitrary bounded monotone witnesses or arbitrary completion procedures.

Next use the tail-modulus ledger, Definition 535.148. Any root-facing tail request is ledgered by μ, σ, λ before I, Q, or any completion-facing handoff is read. Hence a converse or reuse route that tries to replace the scheduled window, tail modulus, or dyadic ledger by a selected tail, an unledgered completion object, or a choice-like selector has no admitted coordinate. The obstruction blocks precisely that attempted replacement of the displayed ledger and does not acquire wider force.

Now pass to the seal boundary. The root Real-seal nonescape theorem, Definition 535.150, identifies the remaining suffix as exactly I, Q, H, C, P, N: the located trap, Real seal route, componentwise transport, continuation, package provenance, and local naming rows. It also says that the handoff to $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ exports no selected limit, quotient equality, host real equality, trichotomy, ambient completeness, open-cover compactness, or unledgered completion principle.

The consumer-facing factorization is therefore finite. By Definition 535.149, Definition 535.151, and Definition 535.163, any admitted Real-facing, limit-seal-facing, or completion-facing use of the

root window is pulled back to the same BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$ packet carried by $S, F, \sigma, \mu, \lambda, I, Q, H, C, P, N$.

It remains to exclude stronger readings. A global impossibility theorem would require a conclusion not indexed by the accepted packet W and not confined to the named failed route. A host theorem would require a host-facing real-completion, monotone-convergence, equality, or compactness coordinate outside the packet. Hidden external validation would require an extra certificate channel beyond P, N, and the displayed continuation and transport rows. A selected limit, quotient real equality, host equality, trichotomy, ambient completeness, open-cover compactness, or choice-like selector would require one of the coordinates explicitly absent from the extraction, ledger, and nonescape theorems. Since the accepted carrier exposes none of those coordinates, the displayed row blocks only the named local converse or reuse route and rejects every unlisted interpretation. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ packet is generated from bounded monotone source rows, a regular rational row, a stream schedule, an explicit Cauchy tail witness, dyadic tolerance and upper-bound ledgers, a located interval trap, a real-seal row, componentwise transports, continuation routes, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 535.19 binds the carrier, socket separation, classifier transport, Real seal handoff, and ledger exhaustion rows to the displayed RegSeqRatUp, StreamNameUp, CauchyModulusUp, DyadicRatCoreUp, LocatedIntervalUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert package.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close monotone convergence as a public theorem, quotient real construction, selected limiting representatives, host real equality, ambient completeness, trichotomy, or open-cover compactness.

Upgrade path: The paper theory axis is mature for the displayed bounded-monotone Cauchy witness packet, while Lean verification and bridge checking remain independent obligations.

Chapter 536

A Concrete Naming Certificate for $\mathsf{ApophaticSocket}^{\uparrow}$

The $\mathsf{ApophaticSocket}^{\uparrow}$ packet realizes apophatic naming as a finite certificate surface. It names the socket kind, the requested external supply shape, the audit gate that keeps the request visible, the site row where the request is made, the transport and replay rows that preserve the boundary, the package provenance, and the local NameCert row. This socket specializes the boundary-name surface of chapter 543: ApophaticName supplies the negative naming row, while ApophaticSocket adds the requested-supply shape, audit gate, site row, and noninternalization ledger. The packet does not make the requested supply internally available.

Definition 536.1 (ApophaticSocket ledger carrier)**.** *An* $\mathsf{ApophaticSocket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, S_0, G, A, L, Q, P, N)$$

with the following displayed rows:

1. *K is the socket-kind row, recording whether the named boundary concerns an unwitnessed selector, quotient identification, proposition-extensionality collapse, causal-continuity assumption, inscription novelty, outermost* T *supply, or another displayed externality class;*
2. *S_0 is the requested-supply-shape row, recording the content requested from the boundary without supplying that content as an internal constructor, definition, theorem, or setup field;*
3. *G is the audit-gate row, recording the finite question that detects visible socket use and rejects hidden internalization of the requested supply;*
4. *A is the site row, recording the manuscript, Lean, or governance location at which the socket is invoked and the local claim that depends on it;*
5. *L records componentwise* hsame *transport for K, S_0, G, A, the continuation row, the package row, and the local naming row;*
6. *Q records the displayed* Cont *routes by which consumers inspect the socket kind, requested supply shape, audit gate, site row, provenance, and local certificate;*
7. *P is the* Pkg *provenance over* BHist*,* Hist*,* GAP*,* hsame*,* Cont*,* Pkg*,* NameCert*, apophatic names, audit-gate rows, site rows, and origin ledgers;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ApophaticSocket}^{\uparrow}}$ *row.*

The carrier contains exactly these rows. It has no coordinate for the requested external supply itself, no hidden theorem converting that supply into substrate content, no anonymous import channel, and no route by which the apophatic name becomes a positive internal description.

Theorem 536.2 (ApophaticSocket NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ApophaticSocket}^{\uparrow}}$ *surface for the carrier of Definition 536.1 consists of carrier admission for*

$$S = (K, S_0, G, A, L, Q, P, N),$$

socket-kind exposure, requested-supply-shape display, audit-gate exactness, site-row locality, componentwise hsame *stability, displayed* Cont *replay,* Pkg *provenance, and non-internalization for the requested external supply.*

Lean4 ✓ `BEDC.Derived.ApophaticSocketUp.ApophaticSocketCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 536.1. The packet exposes exactly the rows K, S_0, G, A, L, Q, P, N.

The naming obligations are read row by row. The socket kind is supplied by K, the requested supply shape by S_0, the gate question by G, and the invocation site by A.

Transport and consumer access are confined by L and Q. These rows replay the displayed socket packet under componentwise hsame movement and expose only the recorded continuation routes.

Finally P and N record provenance and the local naming certificate. Since the requested external supply has no coordinate in the carrier, the NameCert surface can name the boundary without exporting the supply as internal content. □

Theorem 536.3 (ApophaticSocket gate correspondence)**.** *For an accepted* $\mathsf{ApophaticSocket}^{\uparrow}$ *packet, the audit-gate row* G *is the complete public gate corresponding to the socket-kind row* K *and the requested-supply-shape row* S_0*. A downstream consumer may treat a use of the socket as visible exactly when it factors through the rows* K, S_0, G, A, L, Q, P, N *and may reject any use of the same requested supply that has no displayed gate row.*

Lean4 ✓ `BEDC.Derived.ApophaticSocketUp.ApophaticSocketCarrier gate correspondence`

Proof. Read the socket side first. The rows K and S_0 record the kind of externality and the shape of supply being requested.

Read the enforcement side next. The row G records the finite audit question attached to that socket, while A fixes the site at which the question is asked.

The transport and replay rows L and Q preserve the same gate for downstream consumers, and P, N package and name it. Therefore visible socket use is exactly use through the displayed packet, and an un-gated use of the requested supply has no accepted route through this carrier. □

Theorem 536.4 (ApophaticSocket noninternalization boundary)**.** *For an accepted* $\mathsf{ApophaticSocket}^{\uparrow}$ *packet, the requested supply shape* S_0 *remains boundary data. The packet may name the supply shape, expose the site where it is requested, attach an audit gate, transport the displayed rows by* hsame*, replay them by* Cont*, and record* Pkg *and* NameCert *provenance, but it cannot produce the requested external supply as an internal constructor, definition, theorem, setup field, or imported host principle.*

Lean4 ✓ `BEDC.Derived.ApophaticSocketUp.ApophaticSocketCarrier noninternalization boundary`

Proof. Project the requested-supply-shape row S_0 from the carrier. It records the shape of the requested externality, not an inhabitant or proof of that externality inside the substrate.

The gate and site rows G and A keep the request visible. They classify and locate the boundary use, but they do not add a coordinate for the requested supply itself.

The remaining rows L, Q, P, N only transport, replay, package, and name the displayed boundary packet. Because the carrier inventory contains no constructor, definition, theorem, setup field, or host-principle coordinate for the requested supply, the packet preserves the noninternalization boundary. □

Theorem 536.5 (ApophaticSocket consumer surface)**.** *Every downstream consumer of an accepted* $\mathsf{ApophaticSocket}^{\uparrow}$ *packet factors through the finite rows*

$$K, S_0, G, A, L, Q, P, N.$$

Such a consumer may inspect the socket kind, requested supply shape, audit gate, invocation site, transport rows, replay routes, provenance, and local naming certificate. It may not extract a positive description of the external source, a hidden witness for the requested supply, an unmarked dependency, or a theorem object internalizing the socket.

Lean4 ✓ `BEDC.Derived.ApophaticSocketUp.ApophaticSocketCarrier consumer surface`

Proof. Let a downstream consumer route be given. By Definition 536.1, the source carrier is the finite tuple K, S_0, G, A, L, Q, P, N.

The consumer first reads the socket, supply-shape, gate, and site rows. These rows provide the full public boundary surface.

The rows L and Q supply all permitted transport and replay, and P, N supply provenance and the local certificate. The non-extraction claim follows from the carrier inventory: none of the forbidden objects appears among the displayed rows, so no consumer route out of the packet can project it. □

Theorem 536.6 (ApophaticSocket obligation closure package)**.** *The* $\mathsf{ApophaticSocket}^{\uparrow}$ *obligation surface is the finite package consisting of the carrier row of Definition 536.1, the local NameCert obligations of Definition 536.2, the gate correspondence of Definition 536.3, the noninternalization boundary of Definition 536.4, and the consumer surface of Definition 536.5. Closing* $\mathsf{NameCert}_{\mathsf{ApophaticSocket}^{\uparrow}}$ *requires exactly carrier admission, socket-kind exposure, requested-supply-shape display, audit-gate exactness, site-row locality, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming exactness for* K, S_0, G, A, L, Q, P, N.

Proof. The carrier definition lists all rows available to the package. The NameCert theorem records the local naming obligations on those rows, while the gate, noninternalization, and consumer theorems identify the public uses that must remain visible.

Reading these clauses together gives the obligation surface. Each required proof target is tied to one displayed coordinate of K, S_0, G, A, L, Q, P, N, and no additional supply coordinate is introduced. □

Lean4 ✓ `BEDC.Derived.ApophaticSocketUp.ApophaticSocketCarrier obligation closure package`

Theorem 536.7 (ApophaticSocket gated supply route exhaustion)**.** *Every visible use of the requested supply shape in an accepted* $\mathsf{ApophaticSocket}^{\uparrow}$ *packet factors through the finite rows*

$$K, S_0, G, A, L, Q, P, N.$$

In particular, the socket kind is read through K, the requested supply shape through S_0, the gate through G, the invocation site through A, transport and replay through L, Q, provenance through P, and local naming through N.

Lean4 ✓ `BEDC.Derived.ApophaticSocketUp.ApophaticSocketCarrier gated supply route exhaustion`

Proof. Let a visible supply use be given. By the gate correspondence theorem, visibility means that the use has the displayed audit-gate row G attached to the socket kind and requested supply shape.

The only carrier coordinates that can support such a use are K, S_0, G, A, L, Q, P, N. The rows L and Q preserve and replay the same displayed packet, and P, N package and name it.

Therefore every visible use is exhausted by these rows. A route outside them has no accepted coordinate in the carrier and so cannot count as a visible socket use. □

Theorem 536.8 (ApophaticSocket boundary noninternalization ledger)**.** *For an accepted* $\mathsf{ApophaticSocket}^{\uparrow}$ *packet, no requested supply named by S_0 is internalized by the ledger. The ledger may record the supply shape, the audit question, the invocation site, permitted transport, replay, provenance, and local naming, but it cannot produce the requested supply as a constructor, definition, theorem, setup field, anonymous import, or positive internal description.*

Lean4 ✓ `BEDC.Derived.ApophaticSocketUp.ApophaticSocketUp StdBridge`

Proof. Project the requested-supply-shape row S_0. It records the boundary request as ledger data and not as a substrate object satisfying the request.

The gate and site rows G, A keep the request inspectable. The transport and replay rows L, Q preserve the same visible request, while P, N record provenance and local naming.

Since the carrier inventory contains no row for the requested supply itself, no ledger projection can internalize it. The only available outputs are the displayed boundary rows and their permitted read routes. □

Theorem 536.9 (ApophaticSocket scoped supply ledger)**.** *Every visible supply request in an accepted* $\mathsf{ApophaticSocket}^{\uparrow}$ *packet is scoped by the concrete rows*

$$K, S_0, G, A, L, Q, P, N.$$

The socket kind is read through K, the requested external supply shape through S_0, the audit gate through G, the invocation site through A, componentwise hsame *transport through L, displayed* Cont *replay through Q,* Pkg *provenance through P, and local* NameCert *naming through N. This scoped ledger records the request without internalizing the requested external supply.*

Proof. Project the carrier of Definition 536.1. Its visible coordinates are exactly K, S_0, G, A, L, Q, P, N, so every accepted packet already carries the supply request as a finite displayed ledger.

Apply the gated supply route exhaustion of Definition 536.7. Any visible use of the requested supply shape must pass through the socket kind, supply shape, gate, site, transport, replay, provenance, and local naming rows.

Finally apply the boundary noninternalization ledger of Definition 536.8. The scoped packet can expose the request and its audit route, but it has no coordinate from which the requested external supply itself can be projected. □

Lean4 ✓ `BEDC.Derived.ApophaticSocketUp.ApophaticSocketCarrier scoped supply ledger`

Theorem 536.10 (ApophaticSocket kernel-scope obligation package)**.** *For an accepted* ApophaticSocket$^{\uparrow}$ *packet, the rows*

$$K, S_0, G, A, L, Q, P, N$$

are the complete scoped kernel surface for carrier admission, gate correspondence, noninternalization, and consumer factoring. Carrier admission reads exactly these rows; gate correspondence binds K, S_0, G, A to visible socket use; noninternalization is recorded by the absence of a requested-supply coordinate; and every consumer factors through L, Q, P, N together with the same displayed socket rows.

Proof. Start from the carrier and local NameCert obligations. Definition 536.1 lists exactly K, S_0, G, A, L, Q, P, N, and Definition 536.2 reads those rows as carrier admission, socket-kind exposure, requested-supply display, gate exactness, site locality, transport, replay, provenance, and local naming.

Next bind the gate and consumer routes. Definition 536.3 makes G the public gate for the socket kind K and requested supply shape S_0, while Definition 536.5 forces every downstream read through the displayed packet.

Finally apply the boundary and route ledgers. Definition 536.7 and Definition 536.9 exhaust visible supply use through the same rows, and Definition 536.8 keeps the requested external supply outside the carrier. These clauses give the scoped kernel surface without adding an internal supply coordinate. □

Theorem 536.11 (ApophaticSocket positive supply refusal scope)**.** *For an accepted* ApophaticSocket$^{\uparrow}$ *packet with visible boundary request rows*

$$K, S_0, G, A, L, Q, P, N,$$

any visible request through these rows remains a request row. It cannot be consumed as a constructor, theorem, setup field, import permission, or positive internal description of the requested supply.

Lean4 ✓ `BEDC.Derived.ApophaticSocketUp.ApophaticSocketCarrier positive supply refusal scope`

Proof. Use the gate correspondence of Definition 536.3. Visibility of the request is exposed only through the socket kind K, requested supply shape S_0, audit gate G, and site row A.

Next apply the noninternalization boundary of Definition 536.4 and the boundary noninternalization ledger of Definition 536.8. These results say that the carrier records the request shape and its audit route without supplying a constructor, theorem, setup field, import permission, or positive internal description.

Finally use the scoped supply ledger of Definition 536.9 together with the kernel-scope obligation package of Definition 536.10. They exhaust every visible consumer route through K, S_0, G, A, L, Q, P, N, so no downstream consumer can reinterpret the visible boundary request as positive internal supply. □

Theorem 536.12 (ApophaticSocket refusal ledger boundary)**.** *For an accepted* ApophaticSocket$^{\uparrow}$ *packet with visible request rows*

$$K, S_0, G, A, L, Q, P, N,$$

any socket request through those rows remains a refusal-ledger boundary row. It cannot be consumed as positive supply, anonymous import, theorem object, setup field, or constructor.

Proof. Apply the gate correspondence of Definition 536.3. The visible request is attached to the socket kind K, requested supply shape S_0, audit gate G, and site row A.

Next use Definition 536.4 and Definition 536.8. These place the request in the boundary ledger and exclude an internal coordinate that could act as positive supply, anonymous import, theorem object, setup field, or constructor.

Finally apply Definition 536.9 and Definition 536.10. Every consumer of the request factors through K, S_0, G, A, L, Q, P, N, so the ledger row remains a visible refusal boundary rather than a consumable supply object. □

Closure status for $\mathsf{NameCert}_{\mathsf{ApophaticSocket}^{\uparrow}}$.

Constructive story: An $\mathsf{ApophaticSocket}^{\uparrow}$ packet is generated from a socket-kind row, a requested-supply-shape row, an audit-gate row, a site row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ApophaticSocket}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public export is the consumer surface and gated supply route over K, S_0, G, A, L, Q, P, N, as displayed by Definition 536.5 and Definition 536.7, with the carrier, NameCert rows, positive supply refusal, refusal ledger boundary, scoped supply ledger, and kernel-scope obligation package of Definition 536.1, Definition 536.2, Definition 536.11, Definition 536.12, Definition 536.9, and Definition 536.10 fixing the same finite socket ledger.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ApophaticSocket}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.ApophaticSocketUp.ApophaticSocketCarrier\_consumer\_surface`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close bridge checking, a positive description of the external source, hidden witnesses for requested supply, or global closure for every apophatic name.

Upgrade path: No further formal-axis upgrade remains for this bridge-checked chapter.

Chapter 537

A Concrete Naming Certificate for $\mathsf{ClosedTermSubstitution}^{\uparrow}$

The $\mathsf{ClosedTermSubstitution}^{\uparrow}$ surface packages the MetaCIC boundary law for substitution as finite NameCert data. It records the term row, the closedness boundary, the substituting value, the shift and substitution witnesses, componentwise transport, continuation reads, provenance, and the local naming row that prevents a substitution payload from becoming an unregistered free variable.

The displayed boundary rows are consumed from chapter 527. The $\mathsf{ClosedTermSubstitution}^{\uparrow}$ surface specializes that finite boundary to the inert value-payload route $Q = (T, d, V, S, H, C, P, N)$, without adding subject reduction, evaluator correctness, host CIC truth, or an unregistered variable source.

The packet is the local closed-term substitution surface consumed by chapter 527 and by the compiler-facing schedule of chapter 540. The dependency is the displayed term row, closedness boundary, substitution and shift witness row, hsame transport, Cont route, Pkg provenance, and local NameCert ledger, not semantic evaluator correctness or subject reduction.

Definition 537.1 (Closed-term substitution carrier)**.** *A* $\mathsf{ClosedTermSubstitution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, d, V, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the MetaCIC term row, carrying a closed generator tree for the inspected term;*
2. *d is the boundary row, recording the local de Bruijn depth at which closedness is certified;*
3. *V is the substituting value row, displayed as payload data but not consumed by the closed term at boundary d;*
4. *S is the substitution and shift witness row, containing the boundary equations for* $\mathsf{substitute}(d, V, T)$ *and* $\mathsf{shift}(d, 1, T)$ *on the classified slice;*
5. *H records componentwise* hsame *transports for T, d, V, S, package provenance, and the local naming row;*
6. *C records the* Cont *read routes that expose the term, boundary, value, witness row, and returned term equality;*
7. *P is the* Pkg *provenance over the MetaCIC term generator,* ClosedAt *classifier, substitution and shift generators,* BHist, hsame, Cont, *and* NameCert*;*

8. N is the local $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitution}^{\uparrow}}$ *row.*
The carrier is exactly this finite packet. It contains no open-term subject-reduction theorem, no semantic evaluator correctness proof, no host CIC truth predicate, no future binder budget, and no unregistered free-variable source.

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionUp.ClosedTermSubstitutionTasteGate single carrier alignment`

Theorem 537.2 (Closed-term substitution boundary inertness)**.** *For an accepted* $\mathsf{ClosedTermSubstitution}^{\uparrow}$ *carrier $Q = (T, d, V, S, H, C, P, N)$, every substitution read at the displayed boundary is inert on the classified term row. The witness row S records the boundary equation*

$$\mathsf{ClosedAt}(d, T) \Rightarrow \mathsf{substitute}(d, V, T) = T$$

and the companion shift equation at the same boundary. The value row V remains displayed payload data; it is not projected as a consumed variable of T.

Proof. Project the term, boundary, and witness rows of the carrier. The classifier row says that every free de Bruijn index visible in T lies below d.

The substitution generator can change a variable only at the displayed boundary, or adjust a variable above that boundary. Both branches require an index at or beyond d, and the closedness witness excludes such an index inside T.

The compound cases are transported componentwise through H and replayed by the read routes in C. Thus the only public output of the substitution read is the equality stored in S, while V remains a displayed but unconsumed payload row. □

Theorem 537.3 (Closed-term substitution NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitution}^{\uparrow}}$ *surface consists of carrier admission for $Q = (T, d, V, S, H, C, P, N)$, term-row exposure, boundary-row exposure, value-row display without consumption, substitution and shift witness accountability, componentwise* hsame *stability, displayed* Cont *read locality,* Pkg *provenance, and non-escape for open-term subject reduction, semantic evaluator correctness, host truth, future binder budgets, and unregistered free variables.*

Proof. Carrier admission is projection from Definition 537.1. The packet exposes exactly the MetaCIC term row, boundary row, value row, witness row, transport rows, continuation routes, provenance, and local naming row.

Boundary accountability follows from Definition 537.2. The substitution and shift witnesses are read from S, and the continuation routes in C expose those witnesses without adding a further generator.

Finally inspect the excluded objects. None appears as a carrier coordinate, and the transport row H preserves only the displayed coordinates. Therefore a consumer of $\mathsf{ClosedTermSubstitution}^{\uparrow}$ cannot extract an open-term theorem, evaluator semantics, host truth predicate, future binder budget, or unregistered free variable from this packet. □

Theorem 537.4 (Closed-term substitution closure-preservation provenance)**.** *Every* $\mathsf{ClosedTermSubstitution}^{\uparrow}$ *boundary-inert read consumed by closure-preservation or beta-substitution routes remains the displayed packet*

$$Q = (T, d, V, S, H, C, P, N).$$

Downstream closure-preservation consumers may cite this substitution surface only through the provenance rows of chapter 794, chapter 716, and chapter 483. Those consumers add closure-preservation and typing-route context, but they do not add an open-term theorem, evaluator semantics, host truth predicate, or free-variable source to the closed substitution packet.

Proof. Begin with the carrier of Definition 537.1. It exposes only T, d, V, S, H, C, P, N as the term, boundary, value, witness, transport, route, provenance, and local naming rows.

Apply Definition 537.2 and Definition 537.3. The inertness theorem keeps the substitution read at the displayed boundary, and the NameCert obligations keep every public read inside the same packet.

The sibling closure-preservation, beta-substitution, and subject-reduction chapters consume this packet through their own provenance rows. Their additional rows record closure-preservation and typing-route context downstream; they do not enlarge Q with open-term semantics, evaluator truth, host truth, or a new free-variable source. □

Theorem 537.5 (Closed substitution source boundary)**.** *Every accepted* $\mathsf{ClosedTermSubstitution}^{\uparrow}$ *carrier* $Q = (T, d, V, S, H, C, P, N)$ *exposes only the displayed MetaCIC term row, the closedness boundary row, the value payload row, the substitution and shift witness row, the* hsame *transport row, the* Cont *read routes, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitution}^{\uparrow}}$ *row. No other source row is public from this carrier.*

Proof. Project Q through Definition 537.1. The eight coordinates are exactly the displayed term, boundary, value, witness, transport, route, provenance, and naming rows.

The source boundary is the one imported from chapter 527. That chapter supplies the boundary law consumed here, while this carrier only specializes the law to the inert value-payload route.

The excluded sources are therefore absent by coordinate inspection. An accepted read may expose T, d, V, S, H, C, P, N, but it has no coordinate from which to extract an open-term theorem, evaluator semantics, host truth predicate, future binder budget, or unregistered variable source. □

Theorem 537.6 (Closed substitution ledger exhaustion)**.** *Every public substitution read from an accepted* $\mathsf{ClosedTermSubstitution}^{\uparrow}$ *carrier factors through* S*,* H*,* C*, and* P*. Consequently the ledger records exactly boundary inertness together with substitution and shift witness accountability, and no further substitution authority is exported.*

Proof. Apply Definition 537.2. The only boundary equation made public for substitution is the equation stored in the witness row S, together with the companion shift equation at the same boundary.

Apply Definition 537.3. Public access to the witness row is routed through the displayed continuation row C, stabilized through the componentwise hsame row H, and sourced through the package provenance row P.

Thus a substitution consumer exhausts the ledger by reading S, transporting through H, following C, and citing P. No additional row remains from which to read a second substitution law, a semantic evaluator claim, or a host-level truth predicate. □

Theorem 537.7 (Closed substitution binder-scope nonescape)**.** *For every accepted* $\mathsf{ClosedTermSubstitution}^{\uparrow}$ *carrier* $Q = (T, d, V, S, H, C, P, N)$*, binder depth, value payload, and continuation reads cannot export open-term subject reduction, evaluator correctness, host CIC truth, or an unregistered variable source.*

Proof. Inspect the carrier coordinates. The boundary coordinate d records only the local de Bruijn depth at which closedness is certified, and the value coordinate V is displayed payload data rather than a consumed variable of T.

The continuation coordinate C records routes that expose the term, boundary, value, witness row, and returned term equality. By Definition 537.3, those routes do not add a further generator.

The non-escape clauses stated in the carrier and NameCert rows exclude open-term subject reduction, evaluator correctness, host CIC truth, future binder budgets, and unregistered free variables. Since none of those objects is a coordinate of Q, the binder scope and payload reads cannot export them. □

The mature package for $\mathsf{ClosedTermSubstitution}^{\uparrow}$ is the closed-substitution boundary package consumed by the boundary, compiler, closure-preservation, beta-substitution, and subject-reduction rows. Its completeness statement is coordinate exhaustion: every accepted substitution-boundary consumer reads T, d, V, S, H, C, P, N, with S carrying the inert substitution and companion shift witnesses, and no consumer receives evaluator correctness, host CIC truth, future binder allocation, or an unregistered variable source.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitution}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{ClosedTermSubstitution}^{\uparrow}$ packet is generated from a MetaCIC term row, a closedness boundary row, a displayed substitution value, substitution and shift witness rows, componentwise transports, continuation routes, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedTermSubstitution}^{\uparrow}}, \mathsf{maturePackageClosed})$

Not claimed: This chapter does not close open-term subject reduction, semantic evaluator correctness, host CIC truth, future binder allocation, or a complete self-compilation theorem.

Upgrade path: Bridge checking remains the verification-axis upgrade for the closed-substitution package.

Chapter 538

A Concrete Naming Certificate for $\mathsf{ClosedSubstitutionBoundary}^{\uparrow}$

The $\mathsf{ClosedSubstitutionBoundary}^{\uparrow}$ surface packages the MetaCIC closed-term substitution boundary as a finite naming certificate. It records the exact packet by which a `Term` row, a `ClosedAt` classifier row, the `shift` and `substitute` operation rows, displayed hsame transport, Cont routes, Pkg provenance, and local NameCert rows show that substitution is inert on the closed-at-boundary slice.

The sibling closed-term substitution boundary of chapter 527 supplies the finite `Term`, `ClosedAt`, `shift`, and `substitute` surface that this chapter specializes to the closed-at-boundary inertness route.

Definition 538.1 (ClosedSubstitutionBoundary carrier)**.** *A* $\mathsf{ClosedSubstitutionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, D, V, K, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the MetaCIC* `Term` *generator row, recording that terms are built only from* `var`*,* `app`*,* `lam`*,* `pi`*, and* `sort`*;*
2. *D is the depth row for the boundary at which the classifier is read;*
3. *V is the substitution payload term row, carried as data but not inspected by the inertness route;*
4. *K is the* `ClosedAt` *classifier row certifying that the term row is closed at depth D;*
5. *R is the* `shift` *operation row, including the boundary-budget route witnessed by the closed slice;*
6. *Q is the* `substitute` *operation row, including the route that attempts substitution at depth D with payload V;*
7. *H records componentwise* hsame *transports for the term row, depth row, payload row, classifier row,* `shift` *row,* `substitute` *row, continuation row, package row, and local naming row;*
8. *C records the displayed* Cont *routes by which consumers read the term, classifier, shift route, substitute route, provenance, and local certificate;*
9. *P is the* Pkg *provenance over* BHist*,* `Term`*,* `ClosedAt`*,* `shift`*,* `substitute`*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedSubstitutionBoundary}^{\uparrow}}$ *row.*

The carrier contains no semantic substitution theorem for arbitrary open terms, no subject-reduction theorem for an evaluator, no host equality of syntax quotients, and no untracked binder name.

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionBoundaryUp.ClosedSubstitutionBoundaryTasteGate single carrier alignment`

Theorem 538.2 (ClosedSubstitutionBoundary NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ClosedSubstitutionBoundary}^{\uparrow}}$ *surface for the carrier of Definition 538.1 consists of carrier admission for*

$$S = (T, D, V, K, R, Q, H, C, P, N),$$

`ClosedAt` classifier stability, boundary-budget stability for `shift`, inertness of the displayed `substitute` route on the closed-at-boundary slice, componentwise hsame *transport, displayed* Cont *locality,* Pkg *provenance, and non-escape for unregistered free variables, arbitrary open-term substitution, evaluator subject reduction, host syntax quotients, and ambient metatheoretic truth.*

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionBoundaryUp.ClosedSubstitutionBoundary namecert obligations`
↪ variant `BEDC.Derived.ClosedSubstitutionBoundaryUp.ClosedSubstitutionBoundaryNameCertObligations`

Proof. Carrier admission is projection from Definition 538.1. The rows $T, D, V, K, R, Q, H, C, P, N$ are the only rows admitted to the packet.

The classifier row K fixes the boundary. It records that the term row has no free de Bruijn index at or above the displayed depth D, so the `shift` route R and the `substitute` route Q are read only through that closed slice.

Transport and consumer access are confined by H and C. These rows replay the same term, boundary, payload, classifier, and operation routes under componentwise hsame movement and do not add a hidden binder name or a second substitution surface.

Finally P and N record provenance and the local certificate. Since the excluded objects have no coordinate in the carrier, no NameCert projection can export arbitrary open-term substitution, evaluator subject reduction, host syntax quotient equality, or ambient metatheoretic truth. □

Theorem 538.3 (ClosedSubstitutionBoundary substitute inertness route)**.** *For an accepted* ClosedSubstitutionBoun *carrier* $S = (T, D, V, K, R, Q, H, C, P, N)$*, every public read of the `substitute` operation at boundary* D *factors through the displayed `ClosedAt` classifier row* K *and returns the original term row. The payload row* V *is carried through the recursive operation route, but it has no access point on the closed-at-boundary slice.*

Proof. Read the classifier first. The row K says that every free index visible in the term row of T lies below the boundary D.

Now inspect the displayed substitution route Q. At a variable row, the equality branch for the boundary index cannot fire, and the decrement branch above the boundary cannot fire, because K supplies the strict below-boundary reading.

For compound rows, the route follows the constructor tree of T. The binder cases raise the depth and carry the payload row through the operation, but the classifier row continues to block any access point at the active boundary.

Transport through H and consumer reading through C preserve that same route. Thus the public substitute read is inert on the `ClosedAt` slice and does not export an unregistered free variable, a second payload access channel, or a host-level semantic substitution claim. □

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionBoundaryUp.ClosedSubstitutionBoundary substitute inertness route`

Theorem 538.4 (ClosedSubstitutionBoundary public nonescape)**.** *For an accepted* ClosedSubstitutionBoundary$^{\uparrow}$ *carrier* $S = (T, D, V, K, R, Q, H, C, P, N)$*, every public consumer of the packet reads only the displayed rows* $T, D, V, K, R, Q, H, C, P, N$ *and their registered* Cont *projections. In particular, the public surface cannot export arbitrary open-term substitution, evaluator subject reduction, host syntax quotient equality, or ambient metatheoretic truth.*

Proof. Start with the carrier coordinates of Definition 538.1. The only admitted rows are the term row, boundary row, payload row, `ClosedAt` classifier, `shift` and `substitute` routes, componentwise transport, continuation routes, provenance, and local naming row.

Now read a public consumer through C. Each continuation has a named source coordinate in S, so the consumer can project the displayed term, boundary, payload, classifier, operation route, transport route, provenance, or certificate, but no additional semantic object.

The excluded claims have no carrier coordinate and no continuation route. Thus arbitrary open substitution, evaluator subject reduction, quotient equality for host syntax, and ambient truth cannot be reached from an accepted packet. □

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionBoundaryUp.ClosedSubstitutionBoundary public nonescape`

Theorem 538.5 (ClosedSubstitutionBoundary closed-slice transport)**.** *Let* $S = (T, D, V, K, R, Q, H, C, P, N)$ *and* $S' = (T', D', V', K', R', Q', H', C', P', N')$ *be accepted* ClosedSubstitutionBoundary$^{\uparrow}$ *carriers. If the componentwise* hsame *row* H *transports* $T, D, V, K, R, Q, C, P, N$ *to* $T', D', V', K', R', Q', C', P', N'$ *and preserves the displayed* `ClosedAt` *row, then the inert* `substitute` *route on the closed slice transports from* Q *to* Q'*.*

Proof. First transport the boundary data. The hsame row identifies the term row, depth row, payload row, and `ClosedAt` classifier row with their primed counterparts while keeping the classifier attached to the same closed-slice reading.

Next apply Definition 538.3 to the source packet. The substitute route Q is inert precisely because each public read factors through K at boundary D.

Transport the operation row along H. Since the `ClosedAt` row is preserved, the same boundary-blocking argument applies after transport, and the primed route Q' remains inert on the transported closed slice. □

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionBoundaryUp.ClosedSubstitutionBoundary closed slice transport`

Theorem 538.6 (ClosedSubstitutionBoundary consumer exhaustion)**.** *The carrier of Definition 538.1, the NameCert obligations of Definition 538.2, the inert substitute route of Definition 538.3, the public nonescape theorem of Definition 538.4, and the closed-slice transport theorem of Definition 538.5 jointly give the consumer-exhaustion surface used by the sibling closed-term substitution boundary.*

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionBoundaryUp.ClosedSubstitutionBoundary consumer exhaustion`

Proof. The carrier and NameCert obligations provide the finite packet and its admissible obligations. They account for the displayed term, boundary, payload, classifier, operation, transport, continuation, provenance, and naming rows.

The inertness theorem fixes the only substitute route available to consumers on the closed slice. The transport theorem shows that componentwise hsame movement cannot change that route into an open-substitution surface.

Finally apply public nonescape. Since every consumer is exhausted by the displayed rows and their continuations, the sibling closed-term substitution boundary receives exactly the finite closed-substitution packet and no ambient substitution theorem, evaluator theorem, syntax quotient equality, or metatheoretic truth object. □

Theorem 538.7 (ClosedSubstitutionBoundary public consumer surface)**.** *Every public consumer of an accepted* ClosedSubstitutionBoundary$^{\uparrow}$ *carrier is exhausted by the finite rows*

$$T, D, V, K, R, Q, H, C, P, N.$$

The consumer may read the closed-at-boundary classifier, inert substitute route, componentwise transport, displayed continuation replay, provenance, and local naming row, but it cannot export open-term substitution, evaluator subject reduction, host syntax quotient equality, semantic preservation for arbitrary compiler passes, or bridge checking.

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionBoundaryUp.ClosedSubstitutionBoundary public consumer surface`

Proof. Start from Definition 538.6. It already identifies the carrier, NameCert obligations, inert substitute route, public nonescape clause, and closed-slice transport as the complete consumer surface.

The public consumer reads only through the displayed continuation row C. Hence every read has a named source among $T, D, V, K, R, Q, H, P, N$ and remains attached to the same local certificate.

Finally apply Definition 538.4. The excluded open-substitution, evaluator, quotient, compiler-preservation, and bridge-checking objects have no carrier coordinate and no continuation route. □

Theorem 538.8 (ClosedSubstitutionBoundary mature consumer package)**.** *The carrier of Definition 538.1, the NameCert obligations of Definition 538.2, the inertness route of Definition 538.3, the public nonescape theorem of Definition 538.4, the closed-slice transport theorem of Definition 538.5, the consumer-exhaustion theorem of Definition 538.6, and the public consumer surface of Definition 538.7 jointly form the mature consumer package for* ClosedSubstitutionBoundary$^{\uparrow}$.

Every consumer of that package reads the finite rows $T, D, V, K, R, Q, H, C, P, N$, their local NameCert *obligations, the inert closed-slice substitution route, and the public exhaustion boundary before it can treat the packet as a closed-substitution boundary surface. The package exports no arbitrary open-term substitution, evaluator subject reduction, host syntax quotient equality, semantic preservation for arbitrary compiler passes, or bridge checking.*

Proof. Start with the carrier and NameCert obligations. They display the term, depth, payload, classifier, shift, substitute, transport, continuation, provenance, and naming rows, and they bind all consumer reads to those rows.

Use the inertness route and closed-slice transport theorem for the substitution operation. They ensure that substitution at the displayed boundary remains an inert closed-slice read under componentwise hsame movement.

Finally apply public nonescape, consumer exhaustion, and the public consumer surface. These theorems exhaust the available continuation routes and exclude each ambient object named in the statement, so the combined package is mature on the paper-side consumer surface without changing the formal verification axis. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedSubstitutionBoundary}\uparrow}$.

Constructive story: A $\mathsf{ClosedSubstitutionBoundary}^{\uparrow}$ packet is generated from a MetaCIC `Term` row, a boundary depth row, a payload term row, a `ClosedAt` classifier row, `shift` and `substitute` operation rows, displayed hsame transports, Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedSubstitutionBoundary}\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: The public surface binds the finite BHist packet, `ClosedAt` classifier, `shift` and `substitute` rows, componentwise hsame, displayed Cont, Pkg provenance, local NameCert, TasteGate marker, and public consumer exhaustion for the closed-substitution boundary slice.

Lean4 ✓ `BEDC.Derived.ClosedSubstitutionBoundaryUp.taste gate`

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedSubstitutionBoundary}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close arbitrary open-term substitution, evaluator subject reduction, host syntax quotient equality, semantic preservation for all compiler passes, or bridge checking.

Upgrade path: Higher closure requires checked public-surface formalization and bridge checking for the displayed closed-substitution boundary packet.

Chapter 539

A Concrete Naming Certificate for $\mathsf{CountableObservationSchedule}^{\uparrow}$

The $\mathsf{CountableObservationSchedule}^{\uparrow}$ surface realizes the Type IV finite-record schedule socket of section 9394.5 as a finite BHist packet. It records observed prefix rows, request windows, StreamName-facing source rows, transport, continuation, provenance, and a local naming certificate. The packet organizes countable observation names before $\mathsf{Real}^{\uparrow}$-level consumers; it does not turn observed regularity into an unobserved future law.

The schedule row is the finite-prefix and request-window source consumed by chapter 126; Real-facing budget consumers such as chapter 611 may read it only through the displayed StreamName source row and finite window ledger.

Definition 539.1 (CountableObservationSchedule carrier)**.** *A* $\mathsf{CountableObservationSchedule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (O, W, S, H, C, P, N)$$

with the following displayed rows:

1. *O is the observed prefix row, a finite list of already recorded observation entries indexed by their displayed finite positions;*
2. *W is the request-window row, recording the finite windows in which a downstream consumer asks for the next named observation, comparison, or bounded continuation step;*
3. *S is the StreamName source row, recording the finite source names by which the schedule is addressed without asserting that an unobserved tail is already present;*
4. *H records componentwise* hsame *transports for O, W, S, the continuation row, the package row, and the local naming row;*
5. *C records the displayed* Cont *routes that read prefix entries, expose request windows, hand off StreamName rows, and return only finite schedule data to downstream consumers;*
6. *P is the* Pkg *provenance over* BHist*, observed-prefix rows, request-window rows, StreamName source rows,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{CountableObservationSchedule}^{\uparrow}}$ *row.*

The carrier is exactly this finite packet. It contains no completed countable stream, no proof that every future observation exists, no hidden causal-continuity principle, and no rule converting a successful prefix into a universal law.

Lean4 ✓ BEDC.Derived.CountableObservationScheduleUp.CountableObservationScheduleTasteGate
single carrier alignment

Theorem 539.2 (CountableObservationSchedule NameCert obligations)**.** *For the carrier of Definition 539.1, the local* $\mathsf{NameCert}_{\mathsf{CountableObservationSchedule}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$Q = (O, W, S, H, C, P, N),$$

prefix exposure, request-window locality, StreamName source accountability, componentwise hsame *stability, displayed* Cont *routing,* Pkg *provenance, and non-escape for completed streams, unobserved observations, hidden persistence laws, and tail-totality claims.*

Proof. Carrier admission is projection from Definition 539.1. The packet exposes only the seven displayed rows O, W, S, H, C, P, N.

Prefix exposure is read from O, request locality from W, and StreamName accountability from S. These rows state the finite material available to a consumer and the finite name by which the consumer addresses it.

Transport, continuation, and provenance are then confined by H, C, P. The local certificate N can therefore export only the finite schedule data carried by those rows.

The non-escape clauses follow from the missing coordinates. Since Q has no row for a completed countable stream, a future observation, or a persistence law, no NameCert projection can supply such an object. □

Theorem 539.3 (CountableObservationSchedule prefix totality)**.** *Every accepted* $\mathsf{CountableObservationSchedule}^{\uparrow}$ *packet is total on its displayed prefix: for each finite position listed in O, the packet contains exactly the observation row assigned to that position, together with the transport and continuation routes needed to read it as a schedule entry.*

This totality is prefix-local. It does not assert that positions outside O have observations, that every request window in W is eventually met by new data, or that the prefix determines a unique future tail.

Proof. Project the observed prefix row O from the carrier. By definition O is a finite list of already recorded entries indexed by displayed finite positions.

Use H to move the prefix row componentwise and C to read each displayed entry as a schedule entry. These rows preserve the prefix entries without adding further positions.

The scope restriction is forced by the carrier inventory. Positions not listed in O have no observation coordinate in Q, so prefix totality cannot be read as tail totality. □

Theorem 539.4 (CountableObservationSchedule window stability)**.** *For an accepted* CountableObservationSchedule *packet, each request window recorded in W remains the same finite request window under the componentwise* hsame *transports recorded in H. A transported consumer may ask for the same displayed finite prefix segment, next-name slot, or bounded continuation step, but it may not extend the window by transport alone.*

Proof. Project W and H from the carrier. The row W records the finite request windows, and H records componentwise transport for that row.

Replay the consumer route through C. The route exposes the transported request as the same finite window data, with provenance tracked by P and local naming tracked by N.

No window extension follows from transport. The carrier has no coordinate for enlarging a request window or for certifying an unobserved tail, so a transported window remains finite and displayed. □

Theorem 539.5 (CountableObservationSchedule StreamName handoff)**.** *For an accepted* CountableObservationSch *packet, the StreamName source row S is the only handoff surface by which downstream countable-name consumers address the schedule. The handoff consists of the displayed source name, the currently recorded prefix row, the finite request window, the transport row, the continuation route, the package provenance, and the local* $\mathsf{NameCert}_{\mathsf{CountableObservationSchedule}^{\uparrow}}$ *row.*

No consumer may replace the StreamName handoff with an unnamed countable choice function, an implicit infinite stream, or an empirical law asserting persistence beyond the displayed record.

Proof. Project the StreamName row S together with O, W, H, C, P, N. These are the only handoff-facing rows in the carrier.

The downstream consumer reads the name through C, transports the displayed rows through H, and records provenance through P. The local certificate N binds this finite handoff as the public schedule surface.

The excluded replacements have no carrier coordinate. An unnamed choice function, a completed infinite stream, and a persistence law would each add data beyond O, W, S, H, C, P, N, so they cannot be exported by the handoff. □

Theorem 539.6 (CountableObservationSchedule non-escape)**.** *The* $\mathsf{CountableObservationSchedule}^{\uparrow}$ *packet does not discharge the Type IV causal-continuity socket. It may certify finite prefix rows, finite request windows, StreamName handoff, transport, continuation, provenance, and local naming, but it cannot certify that observed regularity persists into not-yet-observed history.*

Proof. The carrier of Definition 539.1 lists only finite schedule rows. Its prefix, window, source, transport, continuation, provenance, and naming data are all explicit coordinates of Q.

The Type IV socket of Definition 9394.17 asks for persistence from an observed record to unobserved history. That requested content is not among the coordinates of Q.

Therefore the packet can serve finite schedule consumers without closing the causal-continuity socket. Any claim of future persistence must remain outside the packet or be marked by the Type IV audit gate. □

Theorem 539.7 (CountableObservationSchedule finite request exhaustion)**.** *Every request in the W row of an accepted* $\mathsf{CountableObservationSchedule}^{\uparrow}$ *packet is exhausted by displayed prefix entries in O and displayed* Cont *routes in C. A request may read a named* BHist *prefix entry, transport that entry through the corresponding* hsame *row in H, and record provenance through P and* $\mathsf{NameCert}_{\mathsf{CountableObservationSchedule}^{\uparrow}}$*; it has no route to an unnamed observation outside the displayed prefix.*

Proof. Project the request-window row W and the observed prefix row O from the carrier. The only entries available to satisfy a request are the finite entries already listed in O.

Replay the request through C. The continuation row reads the displayed prefix entry, while H transports that entry componentwise and P records the package provenance.

The local NameCert row names the same finite route. Since the carrier has no coordinate for an unnamed observation beyond O, every request in W is exhausted by displayed prefix entries and displayed continuation routes. □

Theorem 539.8 (CountableObservationSchedule prefix-window nonchoice)**.** *For an accepted* CountableObservation *packet, a transported request window remains a finite window over the named prefix data in O, W, S, H, C, P, N. The* hsame *transport in H cannot select an unnamed later observation, cannot choose a tail for the schedule, and cannot install a countable choice function for* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumers.*

Proof. Start with the window-stability theorem, Definition 539.4. It confines transport to the displayed finite request window.

Use the StreamName handoff of Definition 539.5. The downstream name is the displayed row S, routed through C and tracked by P and N.

The excluded selections have no carrier row. A later unnamed observation, a schedule tail, and a countable choice function would require data beyond O, W, S, H, C, P, N, so the transported window remains nonchoice and prefix-local. □

Theorem 539.9 (CountableObservationSchedule StreamName prefix consumer)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{CountableObservationSchedule}^{\uparrow}$ *packet factors through the displayed rows* O, W, S, H, C, P, N *before any* $\mathsf{Real}^{\uparrow}$*-facing schedule row is used. The consumer first reads the finite* BHist *prefix, finite request window, StreamName source row,* hsame *transport,* Cont *route,* Pkg *provenance, and local* NameCert *row; only that named prefix packet can be handed to a Real-facing consumer.*

Proof. Project the StreamName source row S and apply Definition 539.5. The handoff exposes only the displayed source name together with O, W, H, C, P, N.

Next apply finite request exhaustion from Definition 539.7. The consumer route reads a displayed prefix entry through C, transported through H, and recorded under P and N.

Only after those rows are assembled can a Real-facing schedule row read the packet. By Definition 539.6, that handoff still carries no completed stream, future observation law, or choice-like tail. □

Theorem 539.10 (CountableObservationSchedule TasteGate surface)**.** *Any later TasteGate promotion for* $\mathsf{CountableObservationSchedule}^{\uparrow}$ *must certify the single carrier*

$$Q = (O, W, S, H, C, P, N)$$

and its finite prefix, request-window, $\mathsf{StreamName}^{\uparrow}$ *handoff,* hsame *transport,* Cont *route,* Pkg *provenance, and* NameCert *rows. No proof may duplicate the carrier as a proof step or replace a missing row with a completed stream, future observation law, causal-continuity assertion, or choice-like tail.*

Proof. Start with the carrier and NameCert obligation theorem. They identify $Q = (O, W, S, H, C, P, N)$ as the unique packet surface and bind prefix exposure, request-window locality, StreamName accountability, transport, continuation, provenance, and non-escape to that packet.

Next apply Definition 539.3, Definition 539.4, and Definition 539.5. These provide the finite prefix, stable request window, and named StreamName handoff without adding another carrier.

Finally apply Definition 539.6, Definition 539.7, Definition 539.8, and Definition 539.9. The consumer route is exhausted by the displayed rows, so the TasteGate surface cannot use a completed stream, future observation law, causal-continuity assertion, or choice-like tail as a replacement row. □

Theorem 539.11 (CountableObservationSchedule obligation closure package)**.** *The carrier of Definition 539.1, the NameCert obligations of Definition 539.2, prefix totality from Definition 539.3, window stability from Definition 539.4, StreamName handoff from Definition 539.5, non-escape from Definition 539.6, finite request exhaustion from Definition 539.7, prefix-window nonchoice from Definition 539.8, StreamName prefix consumption from Definition 539.9, and the TasteGate surface of Definition 539.10 form the complete paper-side obligation package over* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

The package is finite and local: it records exactly the displayed prefix rows, request windows, StreamName source rows, transports, continuations, provenance, and local naming row of $Q = (O, W, S, H, C, P, N)$.

Proof. The carrier theorem fixes the only admissible packet as $Q = (O, W, S, H, C, P, N)$, and the NameCert obligation theorem identifies carrier admission, prefix exposure, request locality, StreamName accountability, transport, continuation, provenance, and local naming as the public certificate rows.

Apply prefix totality, window stability, and StreamName handoff in file order. These theorems show that every accepted consumer first reads the finite prefix, the transported request window, and the displayed StreamName source row through the same packet.

Next apply non-escape, finite request exhaustion, prefix-window nonchoice, and StreamName prefix consumption. These bind each finite request to displayed prefix entries, forbid choice-like tail selection, and force any $\mathsf{Real}^{\uparrow}$-facing schedule read through the named prefix packet.

Finally, the TasteGate surface theorem packages those rows as the admissible promotion surface. Because the carrier has no coordinate for quotient stream equality, host real equality, ambient completeness, hidden choice, or an unbounded schedule, none of those objects is introduced by the obligation package. □

Theorem 539.12 (CountableObservationSchedule Real window boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing schedule row exported by an accepted* $\mathsf{CountableObservationSchedule}^{\uparrow}$ *packet factors through the finite rows* O, W, S, H, C, P, N*. The exported row may read the displayed observations, request window, StreamName source, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row, but it cannot assert tail totality, future observation existence, a completed countable stream, or a* $\mathsf{Real}^{\uparrow}$ *limit outside the displayed finite window.*

Proof. Project the carrier $Q = (O, W, S, H, C, P, N)$. The only observation data available to a Real-facing row is the finite prefix row O and the finite request window W.

Apply Definition 539.4 and Definition 539.9. They force transported Real-facing reads to keep the same finite request window and to pass through the displayed StreamName source row before a schedule row is consumed.

Finally apply Definition 539.6 and Definition 539.8. Since no carrier coordinate names a tail-total stream, future observation law, or completed $\mathsf{Real}^{\uparrow}$ limit, the Real-facing boundary is exactly the finite window. □

Theorem 539.13 (CountableObservationSchedule TasteGate ground compiler alignment)**.** *The TasteGate-facing ground compiler for* $\mathsf{CountableObservationSchedule}^{\uparrow}$ *is aligned with the single carrier* $Q = (O, W, S, H, C, P, N)$ *and with the displayed event-flow and no-hidden-input rows. Its admissible surface is the finite prefix, request-window, StreamName handoff, transport, continuation, provenance, and local naming packet; it is not hidden causal-continuity data, an unobserved future law, a second schedule carrier, or a completed stream.*

Proof. Begin with the TasteGate surface of Definition 539.10. It fixes the admissible promotion surface as the single carrier $Q = (O, W, S, H, C, P, N)$.

The event-flow rows are then read through prefix totality, finite request exhaustion, and StreamName handoff. These expose exactly the displayed prefix entries, request windows, and source-name route, with transports in H and continuations in C.

No-hidden-input alignment follows from non-escape. Because the carrier has no coordinate for causal-continuity data, an unobserved future law, a second carrier, or a completed stream, the ground compiler can only certify the displayed finite packet. □

Theorem 539.14 (CountableObservationSchedule ground-compiler event-flow lock)**.** *Any TasteGate promotion for the finite* $\mathsf{CountableObservationSchedule}^{\uparrow}$ *surface must route the rows*

$$O, W, S, H, C, P, N$$

through the displayed ground-compiler event-flow and no-hidden-input rows of Definition 539.13. It cannot replace those rows by hidden causal-continuity data, a future-law row, a completed stream, or a second carrier.

Proof. Start with the carrier and the TasteGate surface. Definition 539.1 fixes the single packet $Q = (O, W, S, H, C, P, N)$, while Definition 539.10 makes that packet the admissible promotion surface.

Next read the event-flow rows through prefix totality, finite request exhaustion, and StreamName handoff. These theorems expose only displayed prefix entries, finite request windows, and the source-name route, with transport in H and continuation replay in C.

The ground-compiler alignment then locks the same rows to the event-flow and no-hidden-input discipline. By Definition 539.13, a compiler-facing consumer may use the finite prefix, request-window, StreamName handoff, transport, continuation, provenance, and local naming packet, and no hidden input row.

Finally apply StreamName prefix consumption and non-escape. The route through Definition 539.9 and Definition 539.6 gives no coordinate for hidden causal-continuity data, a future-law row, a completed stream, or another carrier, so those replacements are outside the TasteGate-facing event-flow lock. □

Theorem 539.15 (CountableObservationSchedule scoped obligation package)**.** *The carrier of Definition 539.1, the NameCert obligations of Definition 539.2, prefix totality from Definition 539.3, window stability from Definition 539.4, StreamName handoff from Definition 539.5, non-escape from Definition 539.6, finite request exhaustion from Definition 539.7, prefix-window nonchoice from Definition 539.8, StreamName prefix consumption from Definition 539.9, the Real window boundary of Definition 539.12, and the TasteGate ground compiler alignment of Definition 539.13 assemble the scoped* $\mathsf{CountableObservationSchedule}^{\uparrow}$ *obligation package over* BHist*,* hsame*,* Cont*,* Pkg*,* $\mathsf{NameCert}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

The package is scoped to finite displayed windows. It does not close tail totality, hidden causal continuity, completed countable streams, or unbounded $\mathsf{Real}^{\uparrow}$ *limit data.*

Proof. The carrier and NameCert obligation theorems fix $Q = (O, W, S, H, C, P, N)$ as the only public packet. They bind carrier admission, finite prefix exposure, request locality, StreamName accountability, transport, continuation, provenance, and local naming to those rows.

Apply prefix totality, window stability, StreamName handoff, finite request exhaustion, prefix-window nonchoice, and StreamName prefix consumption. These results show that each consumer read is exhausted by displayed prefix entries and finite request windows transported through H, C, P, N.

The Real window boundary adds the Real-facing scope condition. It prevents the finite schedule row from asserting tail totality, a completed stream, or a hidden limit outside the displayed request window.

The TasteGate ground compiler alignment supplies the promotion boundary. It ties the same carrier to displayed event-flow and no-hidden-input rows, so the package contains no hidden causal-continuity data and no second schedule carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CountableObservationSchedule}^{\uparrow}}$.

Constructive story: A $\mathsf{CountableObservationSchedule}^{\uparrow}$ packet is generated from observed prefix rows, request windows, StreamName source rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Not claimed: This chapter does not close completed countable streams, future observation existence, causal continuity, Real limits outside displayed windows, or a public standard bridge.

Upgrade path: Public closure requires a public export theorem consumed by $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ schedules together with a later bridge route.

Chapter 540

ClosedTermSubstitutionCompiler NameCert Construction

The $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ surface packages the MetaCIC closed-term substitution boundary as a finite compiler-facing naming certificate. Its carrier is not a full evaluator correctness theorem. It records the concrete rows by which ClosedAt, shift, substitute, substitute_closed, BHist, Cont, Pkg, and NameCert form the local boundary used by self-compilation consumers.

The compiler-facing packet consumes the finite closed-term boundary of chapter 527 before it exposes the substitute_closed and shift_closed witness rows. This dependency is boundary reuse: it records that the compiler schedule reads the closed substitution and shift surface through the registered packet, not that the packet proves evaluator correctness or subject reduction.

Definition 540.1 (ClosedTermSubstitutionCompiler carrier)**.** *A* $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, D, V, F, H, C, P, N)$$

with the following displayed rows:

1. *T is the MetaCIC term-generator row, recording the closed constructor surface for variables, applications, binders, and universes;*
2. *D is the* ClosedAt *boundary row, recording the depth classifier used to admit closed or context-closed source terms;*
3. *V is the operation row containing the syntactic* shift *and* substitute *traversals;*
4. *F is the fixed-boundary witness row recording* shift_closed *and* substitute_closed *as inertness facts on the classified slice;*
5. *H records componentwise* hsame *transports for T, D, V, F, the continuation row, the package row, and the local naming row;*
6. *C records the displayed* Cont *routes by which a compiler consumer reads the closedness boundary, applies the syntactic operation, and returns to the fixed-boundary witness;*
7. *P is the* Pkg *provenance over MetaCIC terms,* ClosedAt*,* shift*,* substitute*,* substitute_closed*,* BHist*,* Cont*, and* NameCert*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}}$ *row.*

The carrier contains no subject-reduction theorem for open evaluation, no semantic substitution theorem for arbitrary host syntax, no truth predicate for CIC, and no unrecorded binder budget.

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket carrier admission`

Theorem 540.2 (ClosedTermSubstitutionCompiler boundary)**.** *Every accepted* $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ *packet exposes the closed-term substitution boundary as the finite route*

$$\mathsf{ClosedAt}(d, t) \longrightarrow \mathsf{substitute}(d, v, t) = t.$$

The same packet also exposes the companion shift boundary

$$\mathsf{ClosedAt}(n, t) \longrightarrow \mathsf{shift}(n, 1, t) = t.$$

Both routes are read through the displayed BHist*,* Cont*,* Pkg*, and* NameCert *rows, and neither route may be replaced by semantic evaluation correctness, a host binder convention, or an ambient compiler theorem.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket boundary`

Proof. Project the carrier $K = (T, D, V, F, H, C, P, N)$. The term row T supplies the authorized MetaCIC constructors, the boundary row D supplies the displayed ClosedAt classifier, and the operation row V supplies only the syntactic traversals shift and substitute.

Read the witness row F through the continuation row C. The substitution witness is the fixed-boundary equality $\mathsf{substitute}(d, v, t) = t$ under $\mathsf{ClosedAt}(d, t)$, and the shift witness is the matching equality at the shift cutoff. The arbitrary value v is not consumed because the classifier shows that the target variable is absent at the boundary.

The non-escape clause is carrier exactness. Since no coordinate stores evaluator correctness, host-level binder semantics, or a global compiler theorem, a consumer can extract only the displayed closed-boundary route. □

Theorem 540.3 (ClosedTermSubstitutionCompiler NameCert obligations)**.** *For the carrier of Definition 540.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for* $K = (T, D, V, F, H, C, P, N)$*;*
2. *classifier transport for the* ClosedAt *row and the operation-witness rows under componentwise* hsame*;*
3. *substitution-boundary exactness, requiring every accepted substitution read to cite the displayed* substitute_closed *witness before exposing a compiler-facing boundary claim;*
4. *shift-boundary compatibility, requiring binder-depth movement to cite the displayed* shift_closed *witness before a deeper-context read is accepted;*
5. *non-escape for open-term semantics, subject reduction, host CIC truth, unregistered variables, and any compiler correctness theorem not stored in the packet.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket semantic name certificate`

Proof. Carrier admission is projection from Definition 540.1. The packet lists the term generator, closedness classifier, operation row, fixed-boundary witnesses, transports, continuation routes, package provenance, and local certificate row.

Transport is componentwise. The rows T, D, V, F move only through the displayed hsame entries, and the continuation row replays the same reads after transport.

For exactness, inspect a substitution consumer. The route must read the ClosedAt row and then the substitute_closed witness before it may expose the compiler-facing equality. The corresponding shift consumer reads the same boundary classifier and the shift_closed witness before using binder-depth movement.

The excluded principles have no carrier coordinate. Thus the local NameCert admits only the five displayed obligations and cannot project an unrecorded semantic theorem. □

Theorem 540.4 (ClosedTermSubstitutionCompiler self-compile route)**.** *In any compiler-facing read of an accepted* $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ *packet, the self-compilation substitution step passes through the schedule*

$$\mathsf{ClosedAt} \longrightarrow \mathsf{substitute} \longrightarrow \mathsf{substitute_closed} \longrightarrow \mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}}.$$

The route keeps the source term inside the registered boundary ledger. It may be composed with the displayed shift_closed *row for binder movement, but it does not close evaluator soundness, subject reduction, or total self-compilation.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket self compile route`

Proof. Begin with the compiler consumer's closed source row. The carrier exposes this row only through D, so the consumer first reads the displayed ClosedAt boundary.

Next read the operation row V and the witness row F. The syntactic operation is substitute, and the accepted boundary witness is substitute_closed, so the attempted substitution returns the same registered term at the boundary.

Finally repack the route through C, P, N. The continuation, provenance, and local naming rows record a self-compilation boundary step, while the absence of evaluator-soundness and subject-reduction coordinates fixes the stated scope. □

Theorem 540.5 (ClosedTermSubstitutionCompiler classifier transport)**.** *For accepted* ClosedTermSubstitutionCom *packets, componentwise* hsame *transport preserves the displayed* ClosedAt *row, the* shift *row, the* substitute *row, the witness row containing* shift_closed *and* substitute_closed*, the self-compile route, provenance, and the local* $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket classifier transport`

Proof. Project the carrier of Definition 540.1. The rows T, D, V, F, H, C, P, N expose the closedness classifier, syntactic operation rows, fixed-boundary witnesses, continuation route, provenance, and naming certificate.

Use the transport obligation in Definition 540.3. Its classifier clause moves D and the operation-witness rows through the displayed entries of H.

The self-compile route of Definition 540.4 is then replayed through C, while P and N keep the transported read inside the same local certificate surface. □

Theorem 540.6 (ClosedTermSubstitutionCompiler shift-substitute compatibility)**.** *In every accepted* $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ *packet, the displayed* shift_closed *witness and the displayed* substitute_closed *witness share the same closed-boundary classifier before any compiler-facing read may consume either equality.*

Proof. Read the carrier row D before the witness row F. By Definition 540.2, the substitution and shift routes are both exposed as closed-boundary routes rather than as evaluator facts.

The NameCert obligations of Definition 540.3 require substitution-boundary exactness and shift-boundary compatibility. Thus both witnesses are admitted only after the same displayed ClosedAt classifier has been read.

The self-compile route of Definition 540.4 may compose with the shift row, but the composition stays inside the shared classifier boundary. □

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket shift substitute compatibility`

Theorem 540.7 (ClosedTermSubstitutionCompiler closed-composition handoff)**.** *Every compiler-facing read that consumes the checked closed composition slice* substitute_compose_closed_both *must first display the local* $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ *boundary ledger: the* ClosedAt *rows for both closed inputs, the* substitute_closed *witness row, the* shift_closed *witness row, and the local* $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}}$ *packet. The handoff is a closed-fragment route through* $K = (T, D, V, F, H, C, P, N)$ *and not an unrestricted substitute-substitute commutation theorem, subject-reduction theorem, or evaluator-soundness claim.*

Proof. Project the compiler carrier $K = (T, D, V, F, H, C, P, N)$. The boundary row D is the only source of ClosedAt data, and the witness row F is the only source of substitute_closed and shift_closed data.

Apply Definition 540.9. A compiler-facing substitution or shift equality must read the displayed closedness classifier, the corresponding syntactic operation row, and the corresponding fixed-boundary witness before any equality is exported.

Next apply Definition 540.6. The substitution and shift witnesses share the same closed-boundary classifier, so a closed composition read may compose those witnesses only after both closed inputs have been admitted through D.

Finally route the read through Definition 540.3. The local NameCert packet stores the closed-fragment boundary and excludes evaluator soundness, subject reduction, open-term substitution semantics, and unrestricted substitution calculus. Therefore the checked composition slice is handed off as a closed compiler boundary only. □

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket closed composition handoff`

Theorem 540.8 (ClosedTermSubstitutionCompiler public non-escape)**.** *No public consumer of an accepted* $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ *packet can read evaluator soundness, subject reduction, host CIC truth, or open-term semantics from the packet. Public reads are limited to the displayed* ClosedAt*,* shift*,* substitute*, witness, route, provenance, and* NameCert *rows.*

Proof. Inspect the carrier of Definition 540.1. It contains rows for the MetaCIC term generator, closedness classifier, syntactic operations, fixed-boundary witnesses, transports, routes, provenance, and local naming.

Definition 540.2 and Definition 540.4 describe exactly the public routes: closedness, syntactic operation, fixed-boundary witness, and local NameCert.

The excluded principles are absent from the carrier and are rejected by the non-escape obligation in Definition 540.3. Hence no public projection can recover evaluator soundness, subject reduction, host CIC truth, or open-term semantics. □

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket public nonescape`

Theorem 540.9 (ClosedTermSubstitutionCompiler boundary-ledger exactness)**.** *In every accepted* ClosedTermSubstitutionCompiler$^{\uparrow}$ *packet, each compiler-facing substitution read and shift read passes through the displayed boundary ledger*

$$\mathsf{ClosedAt},\ \mathsf{shift},\ \mathsf{substitute},\ \mathsf{shift_closed},\ \mathsf{substitute_closed}.$$

No read may expose a substitution equality, a shift equality, or a self-compilation boundary step unless it first cites the ClosedAt *classifier row and then the corresponding operation and witness row stored in the packet.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket boundary ledger exactness`

Proof. Project the carrier $K = (T, D, V, F, H, C, P, N)$ of Definition 540.1. The row D is the only displayed ClosedAt source, V is the only operation row for shift and substitute, and F is the only row containing shift_closed and substitute_closed.

For a substitution read, the route described in Definition 540.4 must enter through D, read substitute from V, and consume substitute_closed from F before reaching the local NameCert row.

For a shift read, Definition 540.6 forces the same closed-boundary classifier before shift and shift_closed are consumed. The continuation and package rows then record only that displayed route.

Since no other coordinate stores substitution or shift evidence, any compiler-facing equality that skips this ledger is outside the accepted packet. □

Theorem 540.10 (ClosedTermSubstitutionCompiler binder-budget non-escape)**.** *An accepted* ClosedTermSubstitut *packet does not export binder-budget semantics, open-term substitution semantics, evaluator soundness, subject reduction, host CIC truth, or any unregistered variable convention. Public reads are confined to the displayed* ClosedAt*,* shift*,* substitute*,* shift_closed*,* substitute_closed*,* BHist*,* Cont*,* Pkg*, and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket binder budget nonescape`

Proof. Inspect the carrier of Definition 540.1. It names the term generator, closedness classifier, syntactic operation row, fixed-boundary witness row, transports, routes, provenance, and local certificate row.

Binder-budget semantics would require a separate row describing how budgets are allocated or consumed across arbitrary open binders. Open-term substitution semantics would require a row for variables not admitted by the displayed ClosedAt boundary. Neither row occurs in K.

Definition 540.8 already excludes evaluator soundness, subject reduction, host CIC truth, and open-term semantics. The boundary-ledger exactness of Definition 540.9 further confines every public read to the displayed closed-term ledger.

Thus a consumer may use the packet as a closed substitution compiler boundary, but it cannot project binder-budget or open-term semantics from the same certificate. □

Theorem 540.11 (ClosedTermSubstitutionCompiler obligation-closure package)**.** *The* ClosedTermSubstitutionCom *chapter reaches obligation closure at the paper surface: its carrier admission, classifier transport, boundary-ledger exactness, shift compatibility, and non-escape obligations are all stated as finite* NameCert *rows over the same packet* $K = (T, D, V, F, H, C, P, N)$*.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket obligation closure package`

Proof. Carrier admission is Definition 540.1. It fixes the eight displayed rows and excludes evaluator correctness, host binder conventions, and unrecorded binder budgets from the carrier.

Classifier transport is Definition 540.5. The theorem records componentwise hsame preservation of the ClosedAt row, operation rows, witness row, route, provenance, and local NameCert row.

Boundary-ledger exactness is Definition 540.9. Shift compatibility is Definition 540.6. Together they force substitution and shift reads through the same displayed closedness classifier and their corresponding witness rows.

Non-escape is supplied by Definition 540.10 and Definition 540.8. These theorems identify the absent semantics that no public projection can recover. The existing Lean TasteGate marker on Definition 540.2 supplies the current checked alignment witness, while the formal status of this package remains unadvanced. □

Theorem 540.12 (ClosedTermSubstitutionCompiler bridge route)**.** *Every compiler-facing read of an accepted* ClosedTermSubstitutionCompiler$^{\uparrow}$ *packet bridges the concrete* ClosedAt*,* shift*,* substitute*,* shift_closed*, and* substitute_closed *rows to the public* ClosedTermSubstitutionCompiler$^{\uparrow}$ *interface through the displayed* BHist*,* Cont*,* Pkg*, and* NameCert *rows. The bridge route excludes evaluator correctness, subject reduction, host CIC truth, and unregistered binder budgets.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket bridge route`

Proof. Project the packet $K = (T, D, V, F, H, C, P, N)$ from Definition 540.1. The concrete compiler rows are exactly D for ClosedAt, V for shift and substitute, and F for shift_closed and substitute_closed.

Apply the boundary-ledger exactness theorem to force every compiler-facing substitution or shift read through those concrete rows. Then use the public non-escape and binder-budget non-escape theorems to restrict the exported interface to the displayed BHist, Cont, Pkg, and local NameCert route.

The bridge therefore reaches the public ClosedTermSubstitutionCompiler$^{\uparrow}$ surface only through the named packet rows. Evaluator correctness, subject reduction, host CIC truth, and unregistered binder budgets have no coordinate in K, so they cannot be recovered by the bridge. □

Theorem 540.13 (ClosedTermSubstitutionCompiler mature route)**.** *Closed substitution compiler consumers are exhausted by the closed-term carrier, substitution replay, compiler handoff, and refusal rows already displayed by the bridge route. Every accepted* ClosedTermSubstitutionCompiler$^{\uparrow}$ *packet therefore reaches the mature paper surface through* $K = (T, D, V, F, H, C, P, N)$*: the carrier row fixes the closed-term generator and classifier, the replay rows expose* shift *and* substitute *only through* ClosedAt *witnesses, the compiler handoff reads the public interface through* BHist*,* Cont*,* Pkg*, and* NameCert*, and the refusal rows exclude evaluator correctness, subject reduction, open-term substitution semantics, host CIC truth, and unregistered binder budgets.*

Lean4 ✓ `BEDC.Derived.ClosedTermSubstitutionCompilerUp.ClosedTermSubstitutionCompilerPacket mature route`

Proof. Project the carrier of Definition 540.1. It supplies exactly the rows T, D, V, F, H, C, P, N, so every consumer begins from the closed-term generator, the ClosedAt classifier, the operation row, and the fixed-boundary witnesses.

Apply the boundary theorem, self-compile route, classifier transport, and boundary-ledger exactness. These results force substitution replay and shift replay through the same displayed closed-boundary rows before any compiler-facing read can export a public interface point.

Finally apply the bridge route together with public non-escape and binder-budget non-escape. The bridge exposes the public $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ route only through BHist, Cont, Pkg, and NameCert, while the refusal theorems exhaust every absent consumer coordinate. No mature consumer remains outside the closed-term carrier, substitution replay, compiler handoff, and refusal rows already displayed in this chapter. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}$ packet is generated from MetaCIC term constructors, the ClosedAt classifier, the shift and substitute operation rows, the shift_closed and substitute_closed witness rows, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The bridged scope records the finite carrier, closed-boundary substitution and shift routes, classifier transport surface, NameCert obligations, self-compilation boundary handoff, boundary-ledger exactness, shift compatibility, public and binder-budget non-escape, the obligation-closure package, and the bridge route from concrete compiler rows to the public interface over the same packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedTermSubstitutionCompiler}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close evaluator soundness, subject reduction, open-term substitution semantics, host CIC truth, total self-compilation, or a checked Lean certificate for the whole packet.

Upgrade path: A higher theory grade requires mature examples and completeness of consumer coverage for the same compiler-facing bridge route, while checked Lean formalization remains separate.

Chapter 541

A Concrete Naming Certificate for $\mathsf{AuthorizedRecursor}^{\uparrow}$

The $\mathsf{AuthorizedRecursor}^{\uparrow}$ interface records legal eliminator calls as finite naming packets. Its role is not to add a recursor beyond CIC. It names the BEDC surface already present when the kernel accepts an inductive constructor signature, checks a motive, checks one branch package for that signature, and emits an output whose computation cannot escape the displayed constructor spine.

The recursor packet consumes the accepted constructor-signature boundary of chapter 915, where constructor signature acceptance supplies Σ, and exports its generated output through the generator seal of chapter 553 or the ledger of chapter 555, where generator-induction sealing supplies the downstream non-escape route for O.

Definition 541.1 (AuthorizedRecursor carrier)**.** *An* $\mathsf{AuthorizedRecursor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, \Sigma, M, B, O, A, H, C, P, N)$$

with the following visible coordinates:

1. *I is the inductive-family name whose kernel-accepted constructor signature is being consumed;*
2. *Σ is the finite constructor-signature row listing the accepted constructors and their recursive argument positions;*
3. *M is the motive row checked over the closed carrier generated by Σ;*
4. *B is the branch-package row, with one displayed branch for each constructor in Σ;*
5. *O is the output row produced by the legal eliminator call over the selected input object;*
6. *A is the authorization ledger stating that the recursor call uses exactly the accepted signature, motive, branches, and structural recursive subcalls;*
7. *H stores displayed* hsame *transports for the signature, motive, branch package, output row, authorization ledger, and local naming row;*
8. *C stores the finite* Cont *routes by which consumers read signature rows, motive rows, branch rows, output rows, and rejected non-structural attempts;*
9. *P is the* Pkg *provenance over the inductive declaration, constructor signature, motive, branch package, output row,* hsame *transports,* Cont *routes, and audit ledger;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AuthorizedRecursor}^{\uparrow}}$ *row.*

The carrier exports only these displayed rows. It contains no extra induction principle, no branch outside Σ, no negative self-use hidden behind the motive, and no recursive call whose descent is not recorded in A.

Theorem 541.2 (AuthorizedRecursor NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{AuthorizedRecursor}^{\uparrow}}$ *surface for Definition 541.1 consists of five finite obligations: carrier admission for R; constructor-signature exactness for Σ; motive-and-branch coverage for M and B; authorization-ledger exactness for A; and non-escape of negative self-use, missing branches, unrecorded recursion, quotient equality, selected witnesses, and ambient classical principles.*

Proof. Carrier admission is projection of the displayed packet R. The inductive name, signature row, motive row, branch package, output row, authorization ledger, transports, routes, provenance, and local certificate are all explicit coordinates.

Signature exactness and coverage are read from Σ, M, and B. Since B has one branch row for each constructor row in Σ, every legal eliminator case is paid for by a visible branch and no additional branch is exported.

The authorization and boundary clauses are read from A and P. A recursive subcall is admitted only when A records its structural descent through the constructor spine; every missing branch, negative self-use, unrecorded recursion, quotient equality, selected witness, or classical principle has no carrier coordinate and is therefore recorded only as a boundary attempt. □

Theorem 541.3 (AuthorizedRecursor generator ledger exactness)**.** *Every consumer read of an accepted* $\mathsf{AuthorizedRecursor}^{\uparrow}$ *packet factors through the displayed rows $I, \Sigma, M, B, O, A, H, C, P, N$. The generator ledger is exact: a read of the recursor output O determines the constructor signature row Σ, the motive row M, the branch-package row B, and the authorization row A used to produce it, and no consumer can replace them by a different hidden eliminator call.*

Proof. Begin with the carrier of Definition 541.1. The output row O is stored together with the signature, motive, branch package, and authorization ledger that generated it.

Transport through H preserves those same rows, and continuation through C exposes them as the only legal consumer routes. Thus a consumer that reads O also reads the finite provenance of the eliminator call.

If a consumer asks for a different signature, motive, branch package, or recursive-call ledger, the packet has no coordinate that can supply it. The request is outside the displayed route and cannot be exported as a generated recursor output. □

Theorem 541.4 (AuthorizedRecursor non-escape boundary)**.** *An accepted* $\mathsf{AuthorizedRecursor}^{\uparrow}$ *packet does not export any object obtained from a constructor outside Σ, a branch not listed in B, a motive not named by M, a recursive call not justified by A, or an external principle such as quotient soundness, propositional extensionality, choice, or ambient classical completeness.*

Proof. The constructor boundary is finite. Every admissible constructor read is one of the rows listed in Σ, and every admissible branch read is the corresponding row in B.

The motive and recursion boundaries are also finite. The motive row M is the only motive exported by the packet, and the authorization ledger A is the only place where recursive subcalls can be justified.

The provenance row P records the absence of external principles. Since none of quotient soundness, propositional extensionality, choice, or ambient completeness is a coordinate of R, no downstream route can receive such a principle from this certificate. □

Theorem 541.5 (AuthorizedRecursor downstream handoff)**.** *Every downstream BEDC consumer of an* $\mathsf{AuthorizedRecursor}^{\uparrow}$ *output receives a finite handoff packet consisting of the output row* O*, its constructor-signature row* Σ*, motive row* M*, branch-package row* B*, authorization ledger* A*, transport row* H*, continuation route* C*, package row* P*, and local naming row* N*. The handoff is sufficient for later TasteGate or kernel-recursion certificates to inspect the legal eliminator call without reopening the host declaration.*

Lean4 ✓ `BEDC.Derived.AuthorizedRecursorUp.AuthorizedRecursorTasteGate single carrier alignment`

Proof. Project the handoff rows from the carrier R. The output row is not transmitted alone; it is transmitted with the exact signature, motive, branch, authorization, transport, route, package, and naming rows that make the eliminator call visible.

TasteGate-style consumers inspect the same finite rows to decide whether the call stays inside the accepted constructor signature. Kernel-recursion consumers inspect the authorization ledger to replay the structural descent boundary.

No downstream consumer needs a fresh host-side induction principle. The handoff carries the already named BEDC certificate surface, so later packets can consume the recursor output through finite NameCert rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuthorizedRecursor}^{\uparrow}}$.

Constructive story: An $\mathsf{AuthorizedRecursor}^{\uparrow}$ packet is generated from an inductive-family name, accepted constructor-signature row, checked motive row, branch package, output row, authorization ledger, displayed hsame transports, finite Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AuthorizedRecursor}^{\uparrow}}$, seed)

Scope closed: The seed scope records the carrier, five NameCert obligations, generator-ledger exactness, non-escape boundary, and downstream handoff for legal eliminator calls.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AuthorizedRecursor}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean kernel soundness, all inductive-family positivity checks, all termination checking, TasteGate verification, kernel-recursion bridge checking, or any external classical principle.

Upgrade path: Obligation closure requires a checked finite carrier, signature coverage theorem, motive-and-branch ledger theorem, structural recursion ledger theorem, and downstream handoff theorem for the same packet.

Chapter 542

A Concrete Naming Certificate for $\mathsf{TranscendentalSupplyLedger}^{\uparrow}$

The $\mathsf{TranscendentalSupplyLedger}^{\uparrow}$ surface turns a reported seven-kind Gap socket into a finite ledger packet that can be consumed by NameCert readers without treating the vision taxonomy itself as a certificate. It records the socket site, requested supply, seven-kind classifier, audit gate, transport, continuation, provenance, and local name. The packet is a ledger for the request boundary; it does not provide the requested supply.

The ledger consumes the audit boundary of chapter 526 and the forbidden-ancestry refusal surface of chapter 622 only as finite gate and refusal rows.

Definition 542.1 (TranscendentalSupplyLedger carrier)**.** *A* $\mathsf{TranscendentalSupplyLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Lambda = (S, R, T, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the socket-site row naming the concrete paper or formal site at which a* Gap *request is reported;*
2. *R is the requested-supply row, stated as the exact missing discharge the site would consume;*
3. *T is the seven-kind classifier row, choosing one of the socket kinds of section 9394.11;*
4. *G is the audit-gate row that prevents the request from being read as an internal BEDC theorem;*
5. *H records componentwise* hsame *transport for the site, requested supply, classifier, audit gate, provenance, and local naming rows;*
6. *C records the displayed* Cont *routes through which consumers read the site row, classify the socket, inspect the requested supply, and return the audit gate;*
7. *P is the* Pkg *provenance over* BHist, Gap, *the seven socket-kind rows, requested supply rows, audit-gate rows,* hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TranscendentalSupplyLedger}^{\uparrow}}$ *row.*

The carrier exports no row for an unrestricted induction rule, hidden witness, quotient equality, empirical persistence law, shared first-person history, inscription-source explanation, or truth-total self-validator. Each of those shapes may be named in R and classified by T, but none is discharged by the packet.

Lean4 ✓ BEDC.Derived.TranscendentalSupplyLedgerUp.TranscendentalSupplyLedgerTasteGate single carrier alignment

Theorem 542.2 (TranscendentalSupplyLedger taxonomy exhaustion)**.** *For every accepted* TranscendentalSupplyLe *carrier*

$$\Lambda = (S, R, T, G, H, C, P, N),$$

the classifier row T exhausts the socket taxonomy by routing the site row S and requested-supply row R through exactly one of the seven displayed kinds: free-floating induction, unwitnessed witness, extensional identification, causal continuity, inter-history coordination, inscription novelty, or self-reference closure. Every downstream taxonomy read factors through

$$S \to R \to T \to G \to H \to C \to P \to N$$

and no consumer receives an eighth classifier coordinate or a discharge of the request named in R.

Proof. Project the carrier of Definition 542.1. The only classifier-facing row is T, and the only request-facing row is R at the socket site S.

Read T against the seven rows of section 9394.11. Since T is a displayed finite row, accepting the packet selects one of those seven cases and provides no further case coordinate.

Now route the accepted row through G, H, C, P, N. The audit gate records why the requested supply remains outside the closed substrate, while transport, continuation, provenance, and local naming preserve the same finite packet for downstream readers.

Because the carrier contains no row for the requested discharge itself, taxonomy exhaustion is classificatory only. The packet can say which socket kind has appeared, but it cannot provide the witness, rule, equality token, law, recognition, inscription source, or self-reference closure named by the request. □

Lean4 ✓ BEDC.Derived.TranscendentalSupplyLedgerUp.TranscendentalSupplyLedger taxonomy exhaustion
Lean4 ✓ BEDC.Derived.TranscendentalSupplyLedgerUp.TranscendentalSupplyLedgerTaxonomyExhaustion

Theorem 542.3 (TranscendentalSupplyLedger NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{TranscendentalSuppl}}$ *surface consists exactly of the carrier row of Definition 542.1, the socket-site row S, the requested-supply row R, the seven-kind classifier row T, the audit-gate row G, componentwise* hsame *transport H, displayed* Cont *routes C,* Pkg *provenance P, and local naming row N.*

Thus a consumer may accept the ledger only by reading the finite packet

$$(S, R, T, G, H, C, P, N)$$

as one NameCert boundary. It may not replace the audit gate with an internal theorem, replace the classifier with a hidden source object, or read the requested supply as available substrate data.

Proof. Carrier exposure comes first. The packet in Definition 542.1 lists the exact coordinates available to the local classifier and to any downstream NameCert consumer.

The site and request rows are S and R. They identify where the socket appears and what missing discharge is being requested, without adding a row that supplies that discharge.

The classifier and audit rows are T and G. By Definition 542.2, T selects exactly one of the seven socket kinds, while G keeps the selected request behind the corresponding audit gate.

Finally H, C, P, N bind the transport, continuation, provenance, and local naming boundaries. Repacking these rows gives the whole local $\mathsf{NameCert}_{\mathsf{TranscendentalSupplyLedger}^{\uparrow}}$ surface, and there is no remaining coordinate from which a consumer could import an internal theorem, hidden source object, or supplied request. □

Closure status for $\mathsf{NameCert}_{\mathsf{TranscendentalSupplyLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{TranscendentalSupplyLedger}^{\uparrow}$ packet is generated from a socket site, requested supply row, seven-kind classifier, audit gate, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TranscendentalSupplyLedger}^{\uparrow}}, \mathsf{obligation})$

Scope closed: The obligation surface is exactly the carrier row, taxonomy exhaustion row, audit gate, componentwise transport, displayed continuation, provenance, and local NameCert rows of Definition 542.1, Definition 542.2, and Definition 542.3.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TranscendentalSupplyLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, any Gap discharge, unrestricted induction, hidden witness selection, quotient equality, empirical persistence, inter-history recognition, inscription-source explanation, self-reference closure, or a public standard bridge.

Upgrade path: Scoped closure requires binding the displayed ledger obligations to explicit BEDC primitives for socket sites, requested supply rows, seven-kind classifiers, audit gates, transport, continuation replay, provenance, and local naming.

Chapter 543

A Concrete Naming Certificate for $\mathsf{ApophaticName}^{\uparrow}$

The $\mathsf{ApophaticName}^{\uparrow}$ packet is the concrete NameCert surface for a named externality. It records a socket-name handle, the requested supply shape, the refusal gate that keeps the supply outside the generated substrate, the ledger row that makes the boundary auditable, and the provenance rows through which a downstream chapter may cite the socket without turning it into an internal object. The packet consumes the socket surface of chapter 536 and the refusal-gate surface of chapter 715 before packaging the boundary as a named externality.

Definition 543.1 (ApophaticName carrier)**.** *An* $\mathsf{ApophaticName}^{\uparrow}$ *carrier is a finite* BHist *socket-name packet*

$$A = (S, R, G, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the socket-name row, recording the named boundary position, the local history window, and the chapter site at which the external supply is requested;*
2. *R is the requested supply-shape row, recording the finite interface that a caller would have to provide without asserting that the supply is generated by the substrate;*
3. *G is the refusal-gate row, recording that the requested supply is not admitted as an axiom, quotient representative, hidden theorem, host object, or substrate constructor;*
4. *L is the refusal-ledger row, recording each permitted consumer read and each barred conversion from socket to internal content;*
5. *H records componentwise* hsame *transports for the socket name, requested supply shape, refusal gate, ledger row, continuation route, package provenance, and local naming row;*
6. *C records the displayed* Cont *routes by which consumers read the socket, the request, the refusal decision, and the ledger entry;*
7. *P is the* Pkg *provenance over* BHist*, socket names, requested supply shapes, refusal gates, refusal ledgers,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row.*

The carrier contains no supplied object behind the socket, no theorem asserting that the requested supply exists, no quotient equality for external positions, and no host-side realization of the named dependency.

Lean4 (definition) `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier`

Theorem 543.2 (ApophaticName refusal ledger)**.** *For an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *carrier*

$$A = (S, R, G, L, H, C, P, N),$$

the local refusal ledger exposes exactly the socket-name row S*, the requested supply-shape row* R*, the refusal-gate row* G*, the ledger row* L*, the componentwise* hsame *transport row* H*, the displayed* Cont *routes* C*, the* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row* N*. It records that consumers may cite the named external dependency only as a visible boundary request, and it supplies no internal axiom, quotient, hidden theorem, or host object.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal ledger surface`
↪ variant `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal ledger`

Proof. Project the accepted carrier of Definition 543.1. The only rows available to a consumer are S, R, G, L, H, C, P, N.

Read the socket and request through S and R. These rows make the external dependency referable and describe the finite supply shape, but they do not provide the supply itself.

Use the refusal gate G and ledger row L. They record that an attempted conversion from named socket to internal content is refused, with separate entries for axioms, quotient representatives, hidden theorems, and host objects.

Finally route the read through H, C, P, N. Transport, continuation, package provenance, and local naming preserve the same boundary packet, so the ledger exposes the dependency without creating a substrate-internal witness. □

Theorem 543.3 (ApophaticName socket carrier)**.** *Every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet exposes its socket row, boundary-request row, refusal row,* hsame *transport row,* Cont *route,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row as finite* BHist *data. For*

$$A = (S, R, G, L, H, C, P, N),$$

the displayed surface is exactly S, R, G, L, H, C, P, N*:* S *names the socket,* R *gives the boundary request,* G *and* L *record the refusal decision and ledger,* H *transports the components,* C *gives the consumer route,* P *records provenance, and* N *is the local naming row.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket carrier`

Proof. Project the accepted carrier through Definition 543.1. Its tuple has only the eight displayed coordinates S, R, G, L, H, C, P, N, and each coordinate is introduced there as finite BHist data.

Apply the refusal-ledger surface of Definition 543.2. It identifies the same coordinates as the complete consumer ledger for the named boundary request.

The socket-facing side is compatible with the sibling socket surface of Definition 536.5. The gate-facing side is compatible with the visible refusal boundary of Definition 715.3. Thus the accepted packet exposes the socket and refusal rows as finite boundary data and not as a hidden supply. □

Theorem 543.4 (ApophaticName refusal classifier stability)**.** *Componentwise* hsame *transport of accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packets preserves the refusal classifier. In particular, transport may move the displayed socket-name row, boundary-request row, refusal gate, refusal ledger, continuation route, provenance row, and local naming row, but it cannot replace the socket by a generated witness, an assumed proposition, a quotient representative, a concealed theorem, or a host-side object.*

Proof. Start from the carrier rows exposed by Definition 543.3. The transport row H is componentwise over the same socket, request, refusal, ledger, continuation, provenance, and naming coordinates.

Use the local classifier stability theorem Definition 543.50. It states that transported packets still read only the displayed coordinates S, R, G, L, H, C, P, N.

Finally compare the refusal gate with Definition 536.3 and the gate-question boundary Definition 715.3. Both sibling surfaces keep the refused supply outside the generated substrate, so a componentwise transport has no coordinate in which to install a generated witness. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal classifier stability`

Theorem 543.5 (ApophaticName ledger nonescape)**.** *Every downstream read of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors through the displayed refusal ledger. The exported ledger consists only of the socket row, boundary-request row, refusal row,* hsame *transport row,* Cont *route,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row, and it exports no hidden proof, host equality, quotient representative, generated witness, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier ledger nonescape`

Proof. Begin with Definition 543.2. It names the complete refusal ledger and records the permitted consumer reads together with the barred conversions.

Next apply Definition 543.6. It sends every downstream read through the displayed socket, request, refusal, ledger, transport, continuation, provenance, and naming rows.

The sibling socket boundary Definition 536.4 and the gate-question boundary Definition 715.3 rule out the same hidden supply coordinates. Repacking these rows through the local NameCert surface leaves no path to a hidden proof, host equality, quotient representative, generated witness, or closure principle. □

Theorem 543.6 (ApophaticName non-escape certificate)**.** *Every downstream read of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors through the displayed socket-name, requested supply-shape, refusal-gate, ledger,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows of Definition 543.1. No such read may repackage the named externality as a generated BEDC object, an assumed proposition, a quotient class, a concealed theorem, or a host-side datum.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier non escape certificate`

Proof. Begin with the refusal ledger of Definition 543.2. It identifies the complete consumer surface of the packet and records the barred conversions.

Inspect the requested supply row R together with the refusal gate G. The request tells a caller what kind of external supply would be needed, while the gate prevents that request from becoming an internal source of truth.

The provenance rows H, C, P, N then carry the same boundary read to downstream chapters. Since none of these rows contains a constructor, witness, quotient equality, theorem assertion, or host realization of the supply, there is no escape route from named externality to internal objecthood. □

Theorem 543.7 (ApophaticName obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the socket-name packet* $A = (S, R, G, L, H, C, P, N)$*;*

2. *classifier stability for the socket row, requested supply shape, refusal gate, and refusal ledger under the displayed* hsame *transports;*
3. *ledger exactness for the permitted reads and barred conversions recorded by L;*
4. *continuation and package provenance through C and P;*
5. *non-escape for axioms, quotients, hidden theorems, generated objects, and host-side realizations.*

These rows make the dependency auditable while keeping the named supply outside the substrate's closure claim.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier obligation surface`

Proof. Carrier admission is the tuple displayed in Definition 543.1. Classifier stability is componentwise transport along H.

Ledger exactness is Definition 543.2. It names the only permitted reads and the barred conversions from socket to internal content.

Continuation and package provenance are the rows C and P. They expose the same packet to downstream consumers without adding a new object coordinate.

Non-escape is Definition 543.6. Together these five rows form the local NameCert surface for an apophatic socket name. □

Theorem 543.8 (ApophaticName root socket exposure)**.** *Every root consumer of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet first sees the finite socket packet*

$$A = (S, R, G, L, H, C, P, N)$$

as displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The consumer receives no root-facing object outside the socket row, requested-supply row, refusal gate, refusal ledger, transport row, continuation row, package provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root socket exposure`

Proof. Read the carrier in Definition 543.1. It displays exactly the rows S, R, G, L, H, C, P, N and places them in one finite BHist packet.

Apply classifier stability from Definition 543.4. The displayed hsame transports preserve the socket row, requested supply shape, refusal gate, and ledger as the same consumer-facing packet.

Finally use the obligation surface, Definition 543.7. Its carrier, continuation, package, and local naming obligations are all attached to the same packet, so a root consumer first encounters the finite socket exposure rather than a hidden internal supply. □

Theorem 543.9 (ApophaticName root refusal gate totality)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet $A = (S, R, G, L, H, C, P, N)$, each attempted conversion from socket request to internal supply is either a displayed permitted ledger read or is routed through the refusal gate. No attempted conversion can bypass G and L to produce a generated object, host datum, quotient representative, hidden theorem, assumed proposition, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root refusal gate totality`

Proof. Start with the refusal ledger, Definition 543.2. It lists the permitted socket and request reads and records the barred conversions governed by G and L.

The classifier stability theorem, Definition 543.4, transports this ledger without changing the displayed request or refusal coordinates. Thus a conversion attempt remains on the same finite socket route under hsame.

Apply ledger nonescape, Definition 543.5. Since downstream reads factor through the displayed refusal ledger and the carrier has no coordinate for internal supply, every non-permitted conversion is routed through the refusal gate. □

Theorem 543.10 (ApophaticName root downstream boundary package)**.** *The root-unblock surface exported by an accepted* ApophaticName$^{\uparrow}$ *packet is exactly the socket carrier, refusal classifier, ledger non-escape boundary, and downstream citation boundary over*

$$S, R, G, L, H, C, P, N.$$

Any downstream chapter may cite this package only as the finite socket/refusal surface, not as a generated witness, supplied object, host theorem, quotient representative, or global closure row.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root downstream boundary package`

Proof. First assemble the carrier from Definition 543.1. It gives the socket, request, gate, ledger, transport, continuation, provenance, and local naming rows as one finite packet.

Next attach the refusal classifier and ledger boundary using Definition 543.4 and Definition 543.2. These theorems identify the stable request/gate coordinates and the permitted ledger reads.

It remains to package the downstream boundary. Apply ledger nonescape, Definition 543.5, and the obligation surface, Definition 543.7. Together they expose the finite NameCert route while excluding generated witnesses, supplied objects, host theorems, quotient representatives, and global closure rows. □

Theorem 543.11 (ApophaticName socket request coherence)**.** *Every accepted* ApophaticName$^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N)$$

that exposes the socket row S also exposes the requested supply row R before the refusal gate G is consumed. A downstream consumer may therefore cite the socket only together with the displayed request, refusal ledger, transports, routes, provenance, and local naming rows.

Proof. Project the carrier of Definition 543.1. The socket and request rows are adjacent displayed coordinates of the same finite packet, not separate resources.

Apply the refusal ledger theorem, Definition 543.2. It records each permitted socket read together with the requested supply shape and the barred conversions governed by G and L.

Thus any consumer that reads S before the gate is consumed remains on the route through S, R, G, L, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket request coherence`

Theorem 543.12 (ApophaticName refusal-gate ledger totality)**.** *For every accepted* ApophaticName$^{\uparrow}$ *packet $A = (S, R, G, L, H, C, P, N)$, the refusal gate G and ledger L exhaust the permitted conversions from named externality to boundary request. They bar generated witnesses, host objects, quotient representatives, hidden theorems, and closure principles from being read out of the packet.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal gate ledger totality`

Proof. Use the obligation surface of Definition 543.7. It lists carrier admission, classifier stability, ledger exactness, continuation provenance, and non-escape as the finite obligations of the local NameCert row.

The non-escape certificate Definition 543.6 then rules out every conversion that would turn the named externality into internal content. Since G and L are the only refusal coordinates in the carrier, their ledger is total for the permitted boundary request conversions. □

Theorem 543.13 (ApophaticName downstream noninternalization package)**.** *Downstream consumers of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet receive only the finite package*

$$S, R, G, L, H, C, P, N.$$

They may transport and cite the socket request through the displayed rows, but they cannot internalize the named supply as a generated object, host datum, quotient representative, hidden theorem, or closure principle.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream noninternalization package`

Proof. Compose the socket carrier theorem Definition 543.3 with the refusal ledger Definition 543.2. The composite consumer surface is exactly the displayed finite packet.

Finally apply ledger nonescape, Definition 543.5. It sends downstream reads through the same socket, request, gate, ledger, transport, continuation, provenance, and local naming rows, so no consumer obtains an internal supply coordinate. □

Theorem 543.14 (ApophaticName root-unblock refusal boundary)**.** *Every downstream consumer of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N)$$

factors through the displayed socket-name row S, requested supply-shape row R, refusal gate G, refusal ledger L, componentwise hsame *transports H,* Cont *routes C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row N. No such consumer can read a generated witness, host object, quotient representative, hidden theorem, or closure principle from the packet.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root unblock refusal boundary`

Proof. Start with the carrier of Definition 543.1. It displays exactly the socket, request, refusal gate, ledger, transport, continuation, provenance, and local naming rows.

Apply the refusal ledger theorem, Definition 543.2. The ledger names the permitted socket reads and records the barred conversions from requested supply to internal content.

Use the socket carrier theorem, Definition 543.3. It identifies the downstream socket surface as the finite rows S, R, G, L, H, C, P, N rather than an internal witness or supplied object.

Finally apply ledger nonescape, Definition 543.5. Since every downstream read already factors through the displayed refusal ledger and the carrier has no extra coordinate for generated witnesses, host objects, quotient representatives, hidden theorems, or closure principles, carrier inspection leaves no other route. □

Theorem 543.15 (ApophaticName root socket-gate factorization)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet $A = (S, R, G, L, H, C, P, N)$, any root citation of the named externality factors through the socket row S, the requested supply-shape row R, the refusal gate G, and the refusal ledger L before it can reach the structural rows H, C, P, N. The factorization is compatible with the sibling* $\mathsf{ApophaticSocket}^{\uparrow}$ *and* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *boundary surfaces and exports no generated witness, host datum, quotient representative, hidden theorem, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root socket gate factorization`

Proof. Begin with the carrier of Definition 543.1. It displays the socket, request, refusal gate, and ledger rows as separate coordinates before the transport, continuation, provenance, and local naming rows.

Use the root-unblock refusal boundary, Definition 543.14. It already sends every downstream root citation through the same eight-row packet S, R, G, L, H, C, P, N.

Now read the sibling boundaries. The socket surface of chapter 536 supplies the visible requested-supply shape, and the gate-question surface of chapter 715 supplies the visible refusal question. Together they force the citation through S, R, G, L before any structural replay row is used. □

Theorem 543.16 (ApophaticName root refusal-ledger exhaustion)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet* $A = (S, R, G, L, H, C, P, N)$*, the refusal ledger row* L *exhausts the root-level barred conversions for the named externality. Any root consumer that asks for a supplied object, generated witness, host datum, quotient representative, hidden theorem, or closure principle is classified by the displayed gate* G *and refused by* L*, with only* H, C, P, N *available for transport, replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root refusal ledger exhaustion`

Proof. Start from the refusal ledger theorem, Definition 543.2. It records the permitted socket reads and the barred conversions from requested supply to internal content.

Apply the obligation surface, Definition 543.7. The local NameCert rows include carrier admission, classifier stability, ledger exactness, continuation provenance, and non-escape for the same packet.

Use the root socket-gate factorization, Definition 543.15. Since every root citation reaches G and L before structural replay, no separate root-level conversion remains outside the displayed refusal ledger. □

Theorem 543.17 (ApophaticName root downstream socket non-escape)**.** *Every downstream consumer that reads the root socket of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors through the displayed package*

$$S, R, G, L, H, C, P, N.$$

The read may cite the sibling $\mathsf{ApophaticSocket}^{\uparrow}$ *and* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *boundaries as public socket and gate surfaces, but it cannot turn either sibling citation into a supplied object, generated witness, host datum, quotient representative, hidden theorem, or closure principle.*

Proof. First use the root-unblock refusal boundary, Definition 543.14. It confines downstream root consumers to the displayed socket, request, gate, ledger, transport, route, provenance, and naming rows.

Next use root refusal-ledger exhaustion, Definition 543.16. It says that root-level attempts to internalize the named externality are already classified by G and refused by L.

Finally compare with the sibling socket and gate-question boundaries. They make the socket and gate publicly citeable, but the ApophaticName packet supplies only the refusal package S, R, G, L, H, C, P, N. Thus a downstream socket read cannot escape into a supplied object or hidden proof. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root downstream socket nonescape`

Theorem 543.18 (ApophaticName root refusal boundary exhaustion)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every root conversion attempt from the named externality into internal content is exhausted by the displayed refusal gate G, refusal ledger L, and the structural rows S, R, H, C, P, N. The attempt is either a socket request carried by S and R, a refusal-gate read classified by G, a barred conversion recorded by L, or a replay through H, C, P, N that preserves the same boundary refusal. There is no additional root route to a generated witness, quotient representative, host object, hidden theorem, supplied external object, or closure principle.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root refusal boundary exhaustion`

Proof. Start with the carrier of Definition 543.1. It displays the accepted packet as exactly the eight rows S, R, G, L, H, C, P, N.

Apply the obligation surface of Definition 543.7. It records carrier admission, classifier stability, ledger exactness, continuation provenance, and non-escape as the local NameCert obligations for this packet.

Next use the root socket-gate factorization, Definition 543.15, together with root refusal-ledger exhaustion, Definition 543.16. These force a root read through the socket, requested supply-shape row, refusal gate, and ledger before any structural replay row is consumed.

Finally apply the non-escape certificate, Definition 543.6. Since the carrier has no coordinate for the listed internal objects and every conversion attempt has already been routed through G and L, the displayed refusal gate and ledger exhaust the root boundary. □

Theorem 543.19 (ApophaticName supply-shape noninternalization)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet $A = (S, R, G, L, H, C, P, N)$, the requested supply-shape row R remains a boundary request. It may be exposed to the socket row S, classified by the refusal gate G, recorded in the refusal ledger L, transported through H, replayed through C, authenticated by P, and named by N, but it cannot be internalized as a generated witness, quotient representative, host object, hidden theorem, supplied external object, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier supply shape noninternalization`

Proof. Project the carrier and the refusal ledger. The carrier Definition 543.1 gives R only as the requested supply-shape row, while Definition 543.2 records the barred conversions from requested supply into internal content.

Use the supply-shape refusal exactness theorem, Definition 543.67. It identifies reads of the requested supply shape with the visible boundary row rather than with a generated or host-side object.

Now add the root boundary. By Definition 543.18, any root attempt to turn R into internal content has already been classified by G and refused by L.

The non-escape certificate Definition 543.6 removes the remaining alternatives. Thus R is preserved as a boundary request through S, G, L, H, C, P, N and is not an internal witness, representative, object, theorem, supplied externality, or closure principle. □

Theorem 543.20 (ApophaticName downstream socket ledger factorization)**.** *Every downstream socket consumer that cites* $\mathsf{ApophaticName}^{\uparrow}$ *factors through the finite packet*

$$S, R, G, L, H, C, P, N$$

and through the sibling ApophaticSocket$^{\uparrow}$ *and* ApophaticGateQuestion$^{\uparrow}$ *socket and gate surfaces before the citation reaches the ApophaticNameUp boundary. The citation therefore consumes a ledgered refusal interface, not an unrecorded supply channel or hidden closure object.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream socket ledger factorization`

Proof. Begin with downstream socket route exactness, Definition 543.61. It sends downstream reads through S, R, G, L, H, C, P, N and leaves no route outside the displayed packet.

Next use root downstream socket non-escape, Definition 543.17. It permits public citation of the sibling socket and gate-question boundaries while keeping the consumer inside the same refusal packet.

Apply the root socket-gate factorization, Definition 543.15. This places the socket row S, requested supply-shape row R, refusal gate G, and refusal ledger L before the transport, continuation, provenance, and local naming rows.

Finally combine refusal boundary exhaustion and supply-shape noninternalization from Definition 543.18 and Definition 543.19. The downstream consumer may cite the sibling surfaces and the ApophaticNameUp boundary only through the ledgered packet, so it cannot obtain an unrecorded supply channel, generated witness, host object, quotient representative, hidden theorem, or closure principle. □

Theorem 543.21 (ApophaticName root refusal terminal nonpromotion)**.** *Let $A = (S, R, G, L, H, C, P, N)$ be an accepted* ApophaticName$^{\uparrow}$ *packet. Any terminal root conversion attempt that has already passed through the downstream socket ledger remains a refusal-boundary read of S, R, G, L, H, C, P, N. The requested supply-shape row R cannot be promoted into an internal generated witness, quotient representative, host object, hidden theorem, supplied external object, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root refusal terminal nonpromotion`

Proof. Begin with downstream socket ledger factorization, Definition 543.20. A terminal downstream consumer citing the ApophaticNameUp boundary must pass through S, R, G, L, H, C, P, N and the sibling socket and gate surfaces before the citation reaches the refusal packet.

Apply root refusal boundary exhaustion and supply-shape noninternalization, Definition 543.18 and Definition 543.19. These results classify every root conversion attempt by G, record the barred conversion in L, and keep the requested supply-shape row R as boundary data.

Finally use the non-escape certificate, Definition 543.6. Since the carrier has no coordinate for generated witnesses, quotient representatives, host objects, hidden theorems, supplied external objects, or closure principles, passing through the downstream socket ledger cannot turn the refusal boundary into any of those internal objects. □

Corollary 543.22 (ApophaticName root refusal boundary strict obstruction)**.** *Let $A = (S, R, G, L, H, C, P, N)$ be an accepted* ApophaticName$^{\uparrow}$ *packet. Any consumer-facing use of the root refusal boundary as an obstruction is strictly local to the displayed finite route*

$$S, R, G, L, H, C, P, N.$$

It blocks exactly the converse or reuse attempt that would reread the named externality as a generated witness, quotient representative, host object, hidden theorem, supplied external object, closure principle, unrecorded supply channel, or hidden external validation. It cannot be reinterpreted as a global impossibility claim, a host theorem, an ambient countermodel, or an external validation result outside the accepted packet.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root refusal boundary strict obstruction`

Proof. Begin with root refusal boundary exhaustion, Definition 543.18. It classifies every root conversion attempt into the displayed alternatives: a socket request through S and R, a refusal-gate read classified by G, a barred conversion recorded by L, or a replay through H, C, P, N that preserves the same boundary refusal. The same theorem also excludes any additional root route to a generated witness, quotient representative, host object, hidden theorem, supplied external object, or closure principle.

Now apply downstream socket ledger factorization, Definition 543.20. Any downstream consumer that cites the $\mathsf{ApophaticName}^{\uparrow}$ boundary must first factor through the finite packet S, R, G, L, H, C, P, N and through the sibling socket and gate surfaces before the citation reaches the boundary. Thus a consumer-facing obstruction has no coordinate except the displayed socket, request, refusal, ledger, transport, continuation, provenance, and local naming rows.

The strictness is the separation between the permitted forward citation and the barred converse. In the permitted direction, the consumer may cite the ledgered refusal interface. In the barred converse or reuse direction, the consumer tries to turn that interface into supplied content, a generated witness, a quotient representative, a host object, a hidden theorem, a closure principle, an unrecorded supply channel, or hidden external validation. Root exhaustion sends that attempt back to G and L, and downstream factorization keeps every public use inside the same packet.

Therefore the obstruction is not a theorem about all ambient hosts, not a hidden host proof, not an external countermodel, and not a validation source outside A. It is exactly the local refusal-boundary obstruction carried by S, R, G, L, H, C, P, N against the named converse or reuse route. □

Theorem 543.23 (ApophaticName root request classifier totality)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every socket request at the root boundary is classified by the displayed route S, R, G, L, H, C, P, N *before any downstream read. The classifier exposes the socket row, request row, refusal gate, refusal ledger, transport row, continuation row, provenance row, and local naming row as one finite package.*

Proof. Project the carrier in Definition 543.1. It gives the socket, request, refusal gate, ledger, transport, continuation, provenance, and naming rows as the complete packet available at the root boundary.

Apply the refusal ledger and non-escape certificate, Definition 543.2 and Definition 543.6. These identify the request classifier with the displayed refusal rows rather than with a hidden supply channel.

Use the root-unblock refusal boundary, Definition 543.14. It sends every downstream consumer through the same package, so the request is classified before downstream citation begins. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root request classifier totality`

Theorem 543.24 (ApophaticName boundary ledger exactness)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the ledger row L *exactly separates permitted socket citation from barred conversion into a generated witness, host object, quotient representative, hidden theorem, assumed proposition, or closure*

principle. Permitted citation stays on S, R, G, L, H, C, P, N; every barred conversion is answered by the refusal gate and ledger rows.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier boundary ledger exactness`

Proof. Read the carrier and refusal ledger, Definition 543.1 and Definition 543.2. They display G, L as the rows that govern the named externality request.

Apply the non-escape certificate, Definition 543.6. It rules out generated witnesses, host objects, quotient representatives, hidden theorems, assumed propositions, and closure principles as exported contents of the packet.

Finally use the root-unblock refusal boundary, Definition 543.14. Since downstream consumers receive only the ledgered boundary package, the separation made by L is exact at the boundary. □

Theorem 543.25 (ApophaticName downstream socket citation completeness)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every downstream chapter consuming $\mathsf{ApophaticName}^{\uparrow}$ *receives only the socket and refusal citation package S, R, G, L, H, C, P, N. It receives no generated witness, host object, quotient representative, hidden theorem, assumed proposition, closure principle, or other internal supply from the named externality.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream socket citation completeness`

Proof. Start with the carrier and refusal ledger, Definition 543.1 and Definition 543.2. They bind downstream citation to the same finite socket, request, refusal, transport, continuation, provenance, and naming rows.

Use the non-escape certificate, Definition 543.6. It bars the internal supply cases from becoming rows exported by the accepted packet.

Apply the root-unblock refusal boundary, Definition 543.14. Every downstream consumer is already routed through S, R, G, L, H, C, P, N, so the citation package is complete and no additional internal supply remains. □

Theorem 543.26 (ApophaticName boundary-request obligation triad)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

any consumer that cites the packet before downstream use must expose the socket row S, the requested supply row R, and the refusal gate G as one boundary-request triad. The triad is inseparable from the ledger, transport, continuation, package, and local naming rows: reading S without R, reading R without G, or reading G outside L, H, C, P, N is not a permitted $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *obligation route.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier boundary request obligation triad`

Proof. Begin with the refusal ledger of Definition 543.2. It identifies S, R, G, L, H, C, P, N as the complete visible consumer surface and records the permitted socket and request reads.

Apply the obligation surface of Definition 543.7. Carrier admission, classifier stability, ledger exactness, continuation provenance, and non-escape are all obligations for the same finite packet, so the socket row, requested supply row, and refusal gate cannot be separated into independent downstream resources.

Finally compare the sibling socket and gate surfaces, Definition 536.5 and Definition 715.3. They keep socket citation and gate refusal on the displayed boundary. Thus a downstream consumer receives the triad only as the route through S, R, G, L, H, C, P, N. □

Theorem 543.27 (ApophaticName refusal-gate route locality)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the refusal gate G and ledger row L localize every permitted read to the displayed socket-request ledger. They cannot be transported to an unrecorded host object, hidden theorem, quotient representative, generated witness, assumed proposition, or closure principle outside the rows S, R, G, L, H, C, P, N.

Proof. Use the root-unblock refusal boundary, Definition 543.14. It sends downstream consumers through the displayed socket, request, gate, ledger, transport, continuation, package, and local naming rows.

The refusal ledger Definition 543.2 records that G and L are the refusal coordinates for permitted reads and barred conversions. The obligation surface Definition 543.7 makes ledger exactness and continuation provenance part of the same local NameCert surface.

Apply the non-escape certificate, Definition 543.6. Since every downstream read factors through the displayed carrier rows and those rows contain no host realization, hidden theorem, quotient representative, generated witness, assumed proposition, or closure principle, the gate and ledger remain local to the visible socket-request route. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal gate route locality`

Theorem 543.28 (ApophaticName downstream ledger nonescape)**.** *Every downstream consumer of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors through the finite refusal route*

$$S, R, G, L, H, C, P, N.$$

The route exports the socket, request, gate, ledger, transport, continuation, provenance, and local naming rows, and it exports no generated witness, quotient representative, hidden theorem, host datum, supplied external object, assumed proposition, or closure principle.

Proof. Start from the non-escape certificate, Definition 543.6. It already sends downstream reads through the displayed socket-name, requested supply-shape, refusal-gate, ledger, hsame, Cont, Pkg, and local NameCert rows.

Use the refusal ledger and obligation surface, Definition 543.2 and Definition 543.7. The ledger names the permitted reads, while the local NameCert obligations bind carrier admission, classifier stability, ledger exactness, continuation provenance, and non-escape to the same packet.

Finally cite the sibling socket and refusal-gate boundaries, Definition 536.4 and Definition 715.3. Together they leave downstream consumers with the displayed route S, R, G, L, H, C, P, N and no coordinate for generated witnesses, quotient representatives, hidden theorems, host data, supplied external objects, assumed propositions, or closure principles. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream ledger nonescape`

Theorem 543.29 (ApophaticName socket refusal)**.** *Every downstream consumer of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N)$$

that cites the socket row S must also pass through the requested supply row R, refusal gate G, refusal ledger L, componentwise hsame *transports H, displayed* Cont *routes C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row N. The socket cannot be converted into a generated witness, quotient representative, hidden theorem, host object, or closure principle.*

Proof. Start with the socket carrier theorem, Definition 543.3. It identifies the socket-facing surface as the finite rows S, R, G, L, H, C, P, N.

Apply the refusal ledger theorem, Definition 543.2. The ledger records the permitted socket read and the barred conversions from requested supply to internal content.

Now use the root-unblock refusal boundary, Definition 543.14. It says that a downstream consumer cannot bypass the ledger rows when citing the named externality.

Finally apply ledger nonescape, Definition 543.5. Since the packet has no coordinate for generated witnesses, quotient representatives, hidden theorems, host objects, or closure principles, a socket citation remains a refused boundary read. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket refusal`

Theorem 543.30 (ApophaticName externality handoff)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the only handoff available to a downstream chapter is the finite refusal packet S, R, G, L, H, C, P, N. A downstream chapter may cite the named externality as a socket request with an attached refusal ledger, but it cannot receive an internal object, assumed proposition, quotient representative, hidden theorem, host-side realization, or closure principle from that handoff.

Proof. Project the carrier of Definition 543.1. The handoff rows are exactly the socket, request, refusal gate, ledger, transport, continuation, provenance, and local naming coordinates.

Use the non-escape certificate, Definition 543.6. It sends every downstream read through the displayed carrier rows and excludes internal objecthood for the named dependency.

Apply the root-unblock refusal boundary and socket refusal theorem, Definition 543.14 and Definition 543.29. Together they force the downstream citation to retain the socket and refusal rows rather than replacing them by supplied content.

The componentwise hsame, Cont, Pkg, and NameCert rows then transport and name the same refusal packet. They do not add a coordinate for an assumed proposition, quotient representative, hidden theorem, host-side realization, or closure principle. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier externality handoff`

Theorem 543.31 (ApophaticName socket request totality)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every socket read of A carries the request row R on the same finite surface. A downstream consumer may cite the socket S only together with the requested supply-shape row R, the refusal gate G, refusal ledger L, componentwise hsame *transports H, displayed* Cont *routes C,* Pkg *provenance P, and local* NameCert *row N.*

Proof. Project the carrier of Definition 543.1. The socket and request rows are adjacent coordinates of the accepted packet $A = (S, R, G, L, H, C, P, N)$.

Use the refusal ledger theorem, Definition 543.2. It records that permitted socket reads are ledgered together with the requested supply shape and the barred conversions governed by G and L.

Apply non-escape, Definition 543.6. Since downstream reads remain inside the displayed carrier, no socket read can drop the request row or replace it by generated content, an assumed proposition, a quotient representative, a hidden theorem, host data, or a closure principle. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket request totality`

Theorem 543.32 (ApophaticName gate ledger exactness)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the gate row G and ledger row L exhaust all barred conversions attached to the socket request. The packet has no second gate, hidden permission row, supplied external object, assumed proposition, quotient representative, host realization, or closure principle outside the displayed carrier.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier gate ledger exactness`

Proof. Read the accepted carrier from Definition 543.1. The only refusal coordinates in A are G and L, and the structural coordinates H, C, P, N only transport, route, package, and name that same finite packet.

Apply the refusal ledger theorem, Definition 543.2. It identifies the permitted socket reads and the barred conversions as the ledgered content of G and L.

Use the ledger nonescape and non-escape certificate, Definition 543.5 and Definition 543.6. Because no extra permission or supplied-content coordinate exists, the gate and ledger rows exhaust the barred conversions. □

Theorem 543.33 (ApophaticName boundary request nonescape)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

a downstream boundary request that reads S and R cannot become internal generated content. It remains a socket request with refusal gate, refusal ledger, componentwise transport, displayed continuation, provenance, and local naming rows, and it exports no internal object, generated witness, assumed proposition, quotient representative, hidden theorem, host-side realization, or closure principle.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier boundary request nonescape`

Proof. Start from the carrier and refusal ledger, Definition 543.1 and Definition 543.2. They bind the socket request to the same packet $A = (S, R, G, L, H, C, P, N)$ and record the refusal rows for downstream reads.

Use the root-unblock refusal boundary and externality handoff, Definition 543.14 and Definition 543.30. These force downstream consumers to receive the finite refusal packet rather than a supplied internal object.

Finally apply non-escape, Definition 543.6. Since generated content, assumed propositions, quotient representatives, hidden theorems, host realizations, and closure principles are absent from the carrier, the boundary request remains external to generated BEDC content. □

Theorem 543.34 (ApophaticName socket-refusal route totality)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every accepted request that cites the socket row S *is routed through the displayed boundary-request row* R*, refusal-gate row* G*, refusal-ledger row* L*, componentwise* hsame *transport row* H*, displayed* Cont *route* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row* N*. The route is total for the public socket-refusal surface and admits no generated witness, assumed proposition, quotient representative, hidden theorem, host-side object, or closure principle outside those rows.*

Proof. Start with the socket carrier and socket refusal theorems, Definition 543.3 and Definition 543.29. They expose S, R, G, L, H, C, P, N as the finite socket-facing packet and require every socket citation to retain the request and refusal rows.

Next use refusal classifier stability, Definition 543.4. Componentwise hsame transport cannot replace the refused socket by generated content or a host object.

Finally apply boundary request nonescape and ledger nonescape, Definition 543.33 and Definition 543.5. These rows exhaust the permitted request route, so no consumer has an additional path outside the displayed socket-refusal packet. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket refusal route totality`

Theorem 543.35 (ApophaticName downstream boundary exactness)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

any downstream consumer of the named externality receives exactly the ledgered externality boundary S, R, G, L, H, C, P, N*. The consumer may cite the socket request and its refusal ledger, but it receives no internalized supply, generated witness, assumed proposition, quotient representative, hidden theorem, host-side realization, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream boundary exactness`

Proof. Project the carrier of Definition 543.1. The only public boundary rows available to a downstream consumer are the socket row, request row, refusal gate, ledger, transport, continuation, provenance, and local naming row.

Use downstream noninternalization through Definition 543.6 and the boundary request nonescape theorem. Together they keep the requested supply external to generated BEDC content.

Now attach the externality handoff of Definition 543.30. The handoff gives downstream chapters the same finite refusal packet and no internal object.

Finally apply socket-refusal route totality from Definition 543.34. Since all accepted reads already pass through S, R, G, L, H, C, P, N, the downstream boundary is exact. □

Theorem 543.36 (ApophaticName externality consumer totality)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the complete public consumer surface for the named externality is the package consisting of the socket row S*, request row* R*, refusal gate* G*, refusal ledger* L*, componentwise* hsame *transports* H*, displayed* Cont *routes* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row* N*. This package is the whole public route for consumers and contains no supplied external object, generated witness, assumed proposition, quotient representative, hidden theorem, host-side realization, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier externality consumer totality`

Proof. First package the socket and refusal rows. The carrier, refusal ledger, and refusal-gate ledger totality theorems identify S, R, G, L as the complete request and refusal surface attached to the named externality.

Next package the provenance rows. The obligation surface and componentwise transport theorem, Definition 543.7 and Definition 543.39, keep H, C, P, N tied to that same boundary packet.

Use externality handoff and downstream boundary exactness, Definition 543.30 and Definition 543.35, to show that every downstream consumer receives only this ledgered boundary.

Finally close by non-escape. The cited rows already rule out generated witnesses, assumed propositions, quotient representatives, hidden theorems, host realizations, and closure principles, so the displayed package exhausts the public consumer surface. □

Theorem 543.37 (ApophaticName visible request factorization)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every visible socket request factors through the displayed socket row S, request row R, refusal gate G, refusal ledger L, componentwise transport row H, continuation row C, provenance row P, and local naming row N. The factorization names a boundary request only; it does not supply generated content, an assumed proposition, a quotient representative, a hidden theorem, host-side realization, or a closure principle.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier visible request factorization`

Proof. Project the carrier of Definition 543.1. The visible request has no coordinates other than S, R, G, L, H, C, P, N in the accepted packet.

Apply the refusal ledger and obligation surface from Definition 543.2 and Definition 543.7. They bind the socket read to the request row and attach the refusal gate, refusal ledger, transport, continuation, provenance, and naming rows.

Use the boundary request nonescape theorem, Definition 543.33. It prevents the visible request from being replaced by generated content, assumed propositions, quotient representatives, hidden theorems, host realizations, or closure principles.

Finally cite the sibling socket and gate-question surfaces, Definition 536.5 and Definition 715.3. They are reached only through the displayed socket and refusal rows, so the visible request factors through the finite packet. □

Theorem 543.38 (ApophaticName request ledger classifier exhaustion)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the request row R, refusal gate G, and refusal ledger L exhaust the permitted boundary reads of the visible socket S. Any downstream read of the named externality is classified as a socket request with the displayed refusal data, and no separate classifier row admits internal content, host realization, quotient representative, hidden theorem, or closure principle.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier request ledger classifier exhaustion`

Proof. Read the carrier and gate-ledger exactness theorem, Definition 543.1 and Definition 543.32. They identify R, G, L as the displayed request, gate, and refusal ledger rows attached to S.

Next apply socket request totality, Definition 543.31. Every visible socket read carries the request row R and remains on the same finite surface with G, L, H, C, P, N.

Use the refusal ledger theorem and non-escape certificate, Definition 543.2 and Definition 543.6. The ledger classifies the permitted boundary reads, while non-escape rules out a second classifier for internal content, host realization, quotient representatives, hidden theorems, or closure principles.

Thus the request ledger and classifier rows exhaust the visible boundary surface consumed by downstream chapters. □

Theorem 543.39 (ApophaticName socket gate componentwise transport)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

componentwise hsame *transport along H preserves the socket row S, request row R, refusal gate G, refusal ledger L, continuation row C, provenance row P, and naming row N as the same boundary package. Transport cannot introduce generated content, an assumed proposition, a quotient representative, a hidden theorem, host-side realization, or a closure principle.*

Proof. Start from the carrier and NameCert obligations, Definition 543.1 and Definition 543.7. The componentwise transport row H is part of the same packet as the socket, request, gate, ledger, continuation, provenance, and naming rows.

Use gate-ledger exactness, Definition 543.32. It says that G and L exhaust the barred conversions attached to the socket request, so transport has no permission row through which a generated witness could appear.

Apply visible request factorization and request ledger classifier exhaustion, Definition 543.37 and Definition 543.38. They keep the transported request inside S, R, G, L, H, C, P, N and keep all permitted reads classified by the displayed ledger.

Finally use boundary request nonescape, Definition 543.33. Since the excluded objects are absent before transport and are not produced by componentwise hsame, they remain absent after transport. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket gate componentwise transport`

Theorem 543.40 (ApophaticName socket request gate exactness)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the socket row S is readable only as part of the displayed request and refusal package S, R, G, L, H, C, P, N. In particular, every accepted packet reads S together with the request row R, the refusal gate G, and the ledger row L, and the structural rows H, C, P, N only transport, route, package, and name that same boundary request. No consumer obtains a socket-only object, a supplied external object, a host proof, a quotient representative, a hidden theorem, or a closure principle from the socket row.

Proof. Start with visible request factorization, Definition 543.37. It sends every visible socket request through the displayed packet S, R, G, L, H, C, P, N and states that the factorized request supplies no internal content.

Next use request ledger classifier exhaustion, Definition 543.38. The rows R, G, L exhaust the permitted boundary reads of the visible socket S, so a socket read cannot bypass the request row or the refusal ledger.

The sibling socket and gate surfaces give the same boundary on the two sides of the package. Apply the consumer surface of Definition 536.5 and the refusal boundary of Definition 715.3. They keep the socket citation and the gate refusal visible without adding a supplied object.

Finally apply componentwise transport from Definition 543.39. The rows H, C, P, N preserve the same socket-request-gate package, so the exact public read of S is the finite route through S, R, G, L, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket request gate exactness`

Theorem 543.41 (ApophaticName consumer citation boundary)**.** *Every downstream citation of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors through the finite boundary package*

$$S, R, G, L, H, C, P, N.$$

The citation exports only a boundary request: it may name the socket row, request row, refusal gate, ledger row, transport row, continuation route, provenance row, and local naming row, but it exports no supplied object, no host proof, no quotient representative, and no closure principle.

Proof. Read the downstream citation through the carrier of Definition 543.1. The accepted packet has exactly the displayed rows S, R, G, L, H, C, P, N.

Apply socket request gate exactness, Definition 543.40. A citation of the socket already carries the request row and the refusal gate with the ledger, so the public citation is a boundary request rather than an object supply.

Use downstream boundary exactness and externality handoff, Definition 543.35 and Definition 543.30. These identify the handoff received by downstream chapters as the same finite refusal packet.

The non-escape certificate Definition 543.6 then removes the remaining internalization cases. Since the carrier has no coordinate for a supplied object, host proof, quotient representative, hidden theorem, or closure principle, the citation boundary exports only the displayed request package. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier consumer citation boundary`

Theorem 543.42 (ApophaticName named externality NameCert package)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the finite $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *package for named externalities consists of carrier admission, socket request gate exactness, refusal-ledger nonescape, componentwise socket-gate transport, and the consumer citation boundary. This package is sufficient for downstream chapters to cite the named externality as a boundary request, and it is not a package for supplied objects, host proofs, quotient representatives, hidden theorems, or closure principles.*

Proof. Carrier admission is the displayed tuple of Definition 543.1. The local NameCert obligations of Definition 543.7 attach classifier stability, ledger exactness, continuation provenance, and non-escape to this same packet.

The request and gate rows are fixed by socket request gate exactness, Definition 543.40. Thus the socket-facing part of the package is a visible boundary request, not an internal supply channel.

Refusal-ledger nonescape is supplied by Definition 543.5. Componentwise transport is supplied by Definition 543.39. These two results keep the refusal ledger and transport rows on the same finite route.

Finally apply the consumer citation boundary, Definition 543.41. Repacking these rows gives a single finite NameCert surface for named externalities, and every downstream citation remains outside supplied objects, host proofs, quotient representatives, hidden theorems, and closure principles. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier named externality namecert package`

Theorem 543.43 (ApophaticName refusal ledger exactness)**.** *For an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet* $A = (S, R, G, L, H, C, P, N)$*, the refusal ledger* L *is exact for downstream root-unblock use: it records precisely the permitted reads of* S *and* R*, the refusal decision carried by* G*, and the transports and replays through* H, C, P, N*. No consumer can add a further ledger row that converts the socket into a generated witness, quotient representative, hidden theorem, host object, supplied external dependency, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal ledger exactness`

Proof. Begin with Definition 543.2. It identifies L as the ledger for the permitted socket and request reads and for the barred conversions.

Use Definition 543.5. Every downstream read already factors through the displayed refusal ledger, so a consumer has no unledgered path to hidden proof, host equality, quotient representative, generated witness, or closure principle.

Apply the non-escape certificate and root-unblock refusal boundary, Definition 543.6 and Definition 543.14. They confine downstream root-unblock use to S, R, G, L, H, C, P, N.

Finally cite the externality handoff theorem, Definition 543.30. The only handoff object is the same finite refusal packet, so exactness of L cannot be extended into a supplied object or closure principle. □

Theorem 543.44 (ApophaticName boundary request image row)**.** *For an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet* $A = (S, R, G, L, H, C, P, N)$*, every accepted ApophaticName consumer read of the boundary request has image inside the displayed finite tuple* S, R, G, L, H, C, P, N*. The image row may cite the socket, requested supply shape, refusal gate, refusal ledger, componentwise transport, continuation route, package provenance, or local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *component, and it cannot cite a supplied object, quotient representative, hidden theorem, host-side realization, generated witness, or closure principle outside that tuple.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier boundary request image row`

Proof. Project the carrier in Definition 543.1. The accepted packet has exactly the socket, request, refusal gate, ledger, transport, continuation, provenance, and local naming coordinates.

Apply the refusal ledger and ledger exactness rows, Definition 543.2 and Definition 543.43. They identify the permitted reads of S and R, the decision carried by G, and the replay rows through L, H, C, P, N.

Finally use the sibling socket and gate boundaries already binding the chapter, Definition 543.3, Definition 543.14, and Definition 543.73. These boundaries keep every accepted consumer read inside the finite refusal tuple rather than an internal object or host-side witness. □

Theorem 543.45 (ApophaticName root bridge tuple visible-request factorization)**.** *For an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet* $A = (S, R, G, L, H, C, P, N)$*, every downstream boundary-request read factors through the visible request row* R*, refusal gate* G*, refusal ledger* L*, componentwise*

transport H, continuation route C, provenance P, and local $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row N before any externality handoff. The read cannot bypass the tuple through a supplied object, quotient representative, hidden theorem, host datum, generated witness, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple visible request factorization`

Proof. Begin with the boundary request image row, Definition 543.44. It confines every accepted request image to the displayed tuple S, R, G, L, H, C, P, N.

Apply the refusal readback and ledger exactness rows, Definition 543.46 and Definition 543.43. The readback returns each accepted image to its corresponding finite component, while exactness keeps the refusal decision and replay rows inside G, L, H, C, P, N.

Use the local public-boundary package and socket citation scope already binding the chapter. They route the externality handoff only after the visible request and refusal rows have been read, so the handoff receives the displayed refusal tuple rather than a supplied object or host datum.

Since no coordinate of A stores a quotient representative, hidden theorem, generated witness, or closure principle, any downstream read that bypasses R, G, L, H, C, P, N leaves the accepted root bridge tuple. □

Theorem 543.46 (ApophaticName refusal readback row)**.** *For an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet $A = (S, R, G, L, H, C, P, N)$, every accepted image-row read has a readback to the corresponding finite* BHist *component: S reads back the socket, R the request, G the refusal decision, L the refusal ledger, H the componentwise transport, C the route, P the provenance, and N the local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *component. The readback does not convert the socket into an internal object or supplied dependency.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal readback row`

Proof. Start with the carrier of Definition 543.1. Each displayed coordinate of S, R, G, L, H, C, P, N is finite BHist data or a public row over that data.

Use the refusal ledger theorem and exactness theorem, Definition 543.2 and Definition 543.43. They pair each permitted consumer read with the row that records it, so a read of the socket, request, gate, ledger, transport, route, provenance, or local name reads back to the corresponding component.

The socket and gate boundaries, Definition 543.3, Definition 543.14, and Definition 543.44, then exclude every readback path that would replace the displayed component by supplied content. Thus readback recovers the finite row and nothing beyond it. □

Theorem 543.47 (ApophaticName boundary request tuple totality)**.** *For an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet $A = (S, R, G, L, H, C, P, N)$, every accepted boundary-request read has both its image row and its readback row inside the same displayed tuple. Componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row exhaust the consumer surface, so the read cannot escape to a supplied object, hidden theorem, quotient representative, generated witness, host datum, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier boundary request tuple totality`

Proof. Begin with the image and readback rows, Definition 543.44 and Definition 543.46. The image row confines each accepted boundary-request read to S, R, G, L, H, C, P, N, and the readback row returns each accepted image read to the corresponding finite BHist component of that tuple.

Apply the componentwise transport row, Definition 543.49. It says that the local $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ component replays exactly those image and readback rows over the same displayed coordinates under hsame transport.

It remains to account for the consumer surface. The continuation row C supplies only replay through the displayed boundary-request tuple, the provenance row P names the same finite packet, and the local naming row N exports no additional object. Thus the tuple already contains every accepted image, readback, transport, replay, provenance, and naming row.

The no-supplied-object conclusion follows because no coordinate of A stores a supplied object, hidden theorem, quotient representative, generated witness, host datum, or closure principle. Any consumer request for such content therefore leaves the accepted tuple surface and is rejected at the refusal boundary. □

Theorem 543.48 (ApophaticName refusal tuple bridge scope)**.** *Any bridge-facing consumer of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N)$$

must preserve the image row, readback row, componentwise NameCert transport, refusal ledger, continuation route, package provenance, and local naming row together. The bridge scope exports no supplied object, hidden theorem, quotient representative, host datum, generated witness, or closure principle.

Proof. Begin with the image and readback rows, Definition 543.44 and Definition 543.46. They place every accepted boundary-request image inside S, R, G, L, H, C, P, N and return each accepted read to the corresponding finite BHist component.

Use boundary-request tuple totality, Definition 543.47. The continuation route, package provenance, and local naming row already exhaust the consumer surface, so a bridge-facing consumer receives the same finite refusal tuple rather than a separate boundary object.

Apply componentwise NameCert transport, Definition 543.49. It replays the image and readback rows over the same displayed coordinates under hsame transport, preserving the refusal ledger, continuation route, package provenance, and local naming row together.

Since the accepted tuple has no coordinate for a supplied object, hidden theorem, quotient representative, host datum, generated witness, or closure principle, the bridge scope cannot export any such object. It exports only the displayed refusal tuple and its componentwise transport route. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal tuple bridge scope`

Theorem 543.49 (ApophaticName componentwise NameCert transport row)**.** *For accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packets transported along the displayed componentwise* hsame *row* H*, the local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *component replays the image and readback rows componentwise over* S, R, G, L, H, C, P, N*. The transport keeps the socket a public boundary component and never converts it into an internal object, supplied dependency, quotient representative, hidden theorem, host datum, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier componentwise namecert transport row`

Proof. Project the carrier from Definition 543.1. The transport row H is one coordinate of the same accepted packet as the socket, request, gate, ledger, continuation, provenance, and local NameCert rows.

Apply the refusal ledger and exactness rows, Definition 543.2 and Definition 543.43. They make the rows that are eligible for transport exactly the finite refusal tuple, with no hidden coordinate for supplied content.

Now use the image and readback rows, Definition 543.44 and Definition 543.46. The local NameCert transport can replay only those componentwise rows, because each consumer image and each readback has already been confined to S, R, G, L, H, C, P, N.

Finally cite the sibling socket and gate boundaries, Definition 543.14 and Definition 543.73. They keep the transported socket on the public refusal boundary, so the transport is a replay of the displayed rows rather than an internalization of the socket. □

Theorem 543.50 (ApophaticName classifier stability)**.** *Accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packets transported componentwise along the displayed* hsame *rows preserve the socket-name row, requested supply shape, refusal gate, refusal ledger, continuation routes, package provenance, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row. For a packet*

$$A = (S, R, G, L, H, C, P, N),$$

the transported classifier still reads only S, R, G, L, H, C, P, N *and cannot gain a supplied object, axiom, quotient representative, hidden theorem, or host-side realization.*

Proof. Project the carrier tuple $A = (S, R, G, L, H, C, P, N)$ from Definition 543.1. The classifier-facing coordinates are exactly the socket, request, refusal gate, ledger, transport, continuation, package, and naming rows.

Use the refusal ledger of Definition 543.2. It records the permitted socket reads and the barred conversions from requested supply to internal object, axiom, quotient representative, hidden theorem, or host-side datum.

Apply the obligation surface of Definition 543.7. Its classifier-stability, ledger-exactness, continuation, package, and non-escape rows exhaust the local NameCert obligations for the same tuple.

Componentwise hsame transport can therefore move only the displayed coordinates. Since C and P preserve the continuation and package provenance rows, and since N remains the local naming row for that transported packet, no additional coordinate appears in which a supplied object, axiom, quotient representative, hidden theorem, or host-side realization could be stored. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier classifier stability`

Theorem 543.51 (ApophaticName source-refusal totality)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the concrete socket row S*, requested supply-shape row* R*, refusal gate* G*, refusal ledger* L*, componentwise* hsame *row* H*,* Cont *route row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row* N *exhaust the source-refusal surface over* BHist*. No consumer can ask the packet for an internal object, assumed proposition, quotient representative, hidden theorem, or host-side datum without first encountering the refusal ledger.*

Proof. Project the carrier of Definition 543.1. Its concrete packet rows are exactly S, R, G, L, H, C, P, N, and each row is finite BHist data.

Apply the refusal ledger of Definition 543.2. It records the permitted socket and request reads together with the barred conversions from a named externality to internal content.

Use classifier stability from Definition 543.50. Componentwise hsame transport preserves the same socket, request, gate, ledger, continuation, package, and local naming rows, so no new source coordinate appears during transport.

Finally apply non-escape through Definition 543.6. The displayed Cont, Pkg, and NameCert rows export the refusal surface but do not install an internal witness behind the socket. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier source refusal totality`

Theorem 543.52 (ApophaticName public boundary package)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the public root-unblock package exposed over BHist *is exactly the socket row* S*, request row* R*, refusal gate* G*, refusal ledger* L*, componentwise* hsame *row* H*, continuation route* C*, package provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row* N*. The package exports no supplied dependency, internal object, assumed proposition, quotient representative, hidden theorem, host object, or closure principle beyond these rows.*

Proof. Project the carrier from Definition 543.1. Its accepted packet has exactly the displayed rows S, R, G, L, H, C, P, N, with no extra coordinate in which supplied content could be stored.

Use the refusal ledger and source-refusal totality, Definition 543.2 and Definition 543.51. They send every requested supply read through the gate and ledger before a consumer can ask for internal content.

Apply the non-escape certificate, Definition 543.6. It rules out converting the public packet into an axiom, quotient representative, hidden theorem, host-side datum, or closure principle, so the public root-unblock package is exhausted by the eight displayed rows. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier public boundary package`

Theorem 543.53 (ApophaticName socket citation scope)**.** *Every downstream citation of an* $\mathsf{ApophaticName}^{\uparrow}$ *socket must retain the request row* R*, refusal gate* G*, refusal ledger* L*, continuation route* C*, package provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row* N *together with the socket row* S *and transport row* H*. A citation that drops any of these rows is not a citation of the accepted public package.*

Proof. Start with the socket carrier and public boundary package, Definition 543.1 and Definition 543.52. They identify the cited public object with the finite packet S, R, G, L, H, C, P, N.

Apply source-refusal totality from Definition 543.51. The source side is not merely a socket name: each accepted request is paired with the refusal gate and ledger that block conversion into supplied content.

Finally use the downstream non-escape and provenance rows, Definition 543.6 and Definition 543.30. They force socket citations to keep the continuation route, package provenance, and local naming row that make the refusal auditable at the cited site. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket citation scope`

Theorem 543.54 (ApophaticName refusal audit package)**.** *The audit-facing refusal package of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet is exhausted by the finite rows*

$$S, R, G, L, H, C, P, N.$$

It cannot be converted by an auditor into an axiom, quotient representative, hidden theorem, host object, supplied dependency, or closure principle.

Proof. Read the audit package through the carrier and refusal ledger, Definition 543.1 and Definition 543.2. The ledger records permitted socket and request reads and records the blocked conversions at the same finite packet.

Use the socket citation scope from Definition 543.53. Any downstream audit citation still carries the request, gate, ledger, route, provenance, and local naming rows, so the auditor receives the same finite surface.

Apply source-refusal totality and the non-escape certificate, Definition 543.51 and Definition 543.6. These rule out every route from the audit package to an internal witness or host-side closure object, leaving only the displayed refusal rows. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal audit package`

Theorem 543.55 (ApophaticName refusal transport totality)**.** *For accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packets*

$$A = (S, R, G, L, H, C, P, N)$$

and

$$A' = (S', R', G', L', H', C', P', N')$$

whose displayed rows are related componentwise by the hsame *transports, refusal transport preserves exactly the socket row, requested supply row, refusal gate, refusal ledger, transport row, continuation route, package provenance, and local naming row. The transported packet cannot create supplied content, an internal witness, an assumed proposition, a quotient representative, a hidden theorem, or a host object.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal transport totality`

Proof. Project both carriers through Definition 543.1. The only coordinates available before and after transport are S, R, G, L, H, C, P, N and $S', R', G', L', H', C', P', N'$.

Use the refusal ledger and ledger nonescape rows, Definition 543.2 and Definition 543.5. They keep every permitted read on the socket, request, gate, and ledger rows, and they bar every conversion into supplied or host-side content.

Apply source-refusal totality from Definition 543.51. Since the source-refusal surface is already exhausted by S, R, G, L, H, C, P, N, componentwise transport can only rename and replay those same rows through H, C, P, N.

The sibling socket and gate references preserve the same boundary shape. Definition 536.5 keeps the socket readable only as socket data, while Definition 715.3 keeps the gate attached to a visible refusal. Hence the transported packet remains exactly a refusal packet and has no coordinate in which supplied content can appear. □

Theorem 543.56 (ApophaticName socket-gate route exhaustion)**.** *Every socket read of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors through the socket row* S*, requested supply row* R*, refusal gate* G*, refusal ledger* L*, componentwise transport* H*, continuation route* C*, package provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row* N*. No socket consumer can bypass this route to read the named externality as supplied content, an internal object, a quotient representative, a hidden theorem, a host datum, or a closure principle.*

Proof. Begin with the socket carrier and socket refusal rows, Definition 543.3 and Definition 543.29. They identify the socket-facing surface as the finite packet S, R, G, L, H, C, P, N rather than an internal witness.

Use gate-source compatibility and the sibling gate boundary. Definition 543.60 keeps S, R, G, L as one source surface, and Definition 715.3 prevents the gate from becoming an admitted supply.

Now apply refusal transport totality from Definition 543.55. Any socket read transported downstream remains on the same refusal rows and is replayed only through H, C, P, N.

Finally use source-refusal totality and downstream refusal-ledger exhaustion, Definition 543.51 and Definition 543.72. These exhaust the requested supply row, refusal ledger, continuation route, provenance, and local naming rows, leaving no socket route outside the displayed packet. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket gate route exhaustion`

Theorem 543.57 (ApophaticName downstream boundary consumption)**.** *Downstream consumers may consume the named externality of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet only as the finite refusal packet* S, R, G, L, H, C, P, N*. The boundary is not consumable as an internal witness, quotient representative, hidden theorem, host object, supplied dependency, assumed proposition, or closure principle.*

Proof. Start from externality handoff, Definition 543.30. The handoff object is already the finite refusal packet, so downstream citation begins with S, R, G, L, H, C, P, N rather than with supplied content.

Apply boundary citation exhaustion and downstream named-externality refusal, Definition 543.74 and Definition 543.77. They state that every downstream citation is exhausted by the public refusal rows.

Use socket-gate route exhaustion from Definition 543.56. A consumer that enters through the socket still passes through the requested supply row, refusal gate, ledger, transport, continuation, provenance, and local naming row.

The non-escape certificate and refusal transport totality, Definition 543.6 and Definition 543.55, rule out every attempted replacement by a witness, quotient representative, hidden theorem, host object, supplied dependency, assumed proposition, or closure principle. Therefore the only consumable downstream boundary is the finite refusal packet. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream boundary consumption`

Theorem 543.58 (ApophaticName classifier-refusal transport)**.** *Let* $A = (S, R, G, L, H, C, P, N)$ *and* $A' = (S', R', G', L', H', C', P', N')$ *be accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packets whose socket, request, refusal-gate, ledger, continuation, package, and naming rows are related by the displayed componentwise* hsame *transports. Then the transported classifier carries the refusal ledger of* A *to the refusal ledger of* A' *through the displayed* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows, and it cannot turn the named externality into an internal object, assumed proposition, quotient representative, hidden theorem, or host-side datum.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier classifier refusal transport`

Proof. Read both carriers through Definition 543.1. The only classifier-facing coordinates are the socket, request, gate, ledger, transport, continuation, provenance, and local name.

Use Definition 543.4. The componentwise hsame rows preserve the refusal classifier while moving from A to A'.

Now transport the ledger itself. The Cont routes replay the same consumer read, the Pkg row preserves provenance, and the local $\mathsf{NameCert}$ row names the transported packet as another accepted ApophaticName carrier.

The non-escape certificate and classifier stability rule out every attempted replacement by generated content. Since neither carrier has a coordinate for an internal object, assumed proposition, quotient representative, hidden theorem, or host-side datum, the transported refusal remains a refusal ledger. □

Theorem 543.59 (ApophaticName consumer-boundary exhaustion)**.** *Every downstream consumer of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors through the displayed* BHist *rows*

$$S, R, G, L, H, C, P, N.$$

The consumer may read the socket name, requested supply shape, refusal gate, refusal ledger, componentwise hsame *transport,* Cont *route,* Pkg *provenance, and local* NameCert *row, and no further consumer boundary exists for host equality, quotient representatives, hidden theorem content, generated witnesses, or supplied external objects.*

Proof. Start with the ledger nonescape theorem Definition 543.5. It sends every downstream read through the displayed refusal ledger and excludes hidden proof, host equality, quotient representative, generated witness, and closure-principle routes.

Apply source-refusal totality from Definition 543.51. The source side has already been exhausted by the socket, request, gate, ledger, transport, continuation, package, and naming rows.

Apply classifier-refusal transport from Definition 543.58. Any transported consumer sees the same finite refusal surface through hsame, Cont, Pkg, and NameCert rather than a new supplied object.

Thus the consumer boundary is exhausted by S, R, G, L, H, C, P, N. There is no remaining carrier coordinate from which host equality, quotient representatives, hidden theorem content, generated witnesses, or supplied external objects could be read. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier consumer boundary exhaustion`

Theorem 543.60 (ApophaticName gate-source compatibility)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the socket row S, requested supply row R, refusal gate G, and refusal ledger L remain one displayed source surface under the componentwise hsame *row H and the displayed* Cont *route row C. A downstream consumer may transport and replay this source surface only as S, R, G, L, H, C, P, N; it cannot separate the request from the refusal gate or turn the gate into an internal supply.*

Proof. Project the carrier through Definition 543.1. The socket, request, gate, and ledger are introduced as four coordinates of the same finite BHist packet, with H and C recording only componentwise transport and displayed route replay.

Apply Definition 543.51. It exhausts the source side by S, R, G, L, H, C, P, N and sends every attempted read of the requested supply through the refusal ledger before any consumer can ask for content.

Finally compare the boundary with the sibling socket and gate surfaces. The socket consumer surface Definition 536.5 keeps the named socket visible, while the gate-question visible-socket nonescape row Definition 715.3 keeps the refusal decision attached to that socket. Thus hsame and Cont preserve one displayed source surface rather than splitting off a hidden supply coordinate. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier gate source compatibility`

Theorem 543.61 (ApophaticName downstream socket route exactness)**.** *Every downstream read of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors exactly through*

$$S, R, G, L, H, C, P, N.$$

The route first reads the socket row and requested supply shape, then the refusal gate and refusal ledger, then the componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row. No downstream consumer has a route to a generated witness, assumed proposition, quotient representative, hidden theorem, host-side datum, or supplied external object outside these rows.*

Proof. Begin with Definition 543.59. It states that every downstream consumer is already confined to S, R, G, L, H, C, P, N and that no further consumer boundary exists for host equality, quotient representatives, hidden theorem content, generated witnesses, or supplied external objects.

Use Definition 543.60 to keep the first four rows as one source surface. The socket and request rows are readable only together with the refusal gate and refusal ledger, so a consumer cannot bypass G or L while still claiming to read the named dependency.

The sibling socket and gate references give the same exactness at the boundary. The socket noninternalization boundary Definition 536.4 excludes replacement by a generated object, and the visible gate-question boundary Definition 715.3 excludes replacement by an admitted supply. Replaying those rows through H, C, P, N gives precisely the stated downstream route. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream socket route exactness`

Theorem 543.62 (ApophaticName gate-ledger separation)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the socket row S, refusal gate G, and refusal ledger L remain separate readable rows while being transported together by H, C, P, N. The gate records the refusal decision, the ledger records permitted reads and barred conversions, and the socket row remains the visible downstream handle; none of these rows is absorbed into another row or converted into supplied content.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier gate ledger separation`

Proof. Project A through Definition 543.1. The socket, request, gate, and ledger are distinct coordinates of the finite carrier, while H, C, P, N are the displayed transport, replay, provenance, and local naming rows.

Use the sibling surfaces named by the chapter introduction. Definition 536.5 keeps the socket readable as a socket boundary, and Definition 715.3 keeps the gate attached to that visible boundary without admitting the requested supply.

Finally apply Definition 543.2 and Definition 543.61. They transport the separate socket, gate, and ledger rows together through hsame, Cont, Pkg, and NameCert, while excluding generated witnesses, host data, quotient representatives, hidden theorems, assumed propositions, and supplied external objects. □

Theorem 543.63 (ApophaticName socket-refusal correspondence)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

each downstream read of the socket row S corresponds to the refusal recorded by G and ledgered by L. The correspondence is transported only through the displayed hsame *row H, the* Cont *route C,*

the Pkg *provenance row P, and the local* NameCert *row N; it is not a route to the refused external object.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket refusal correspondence`

Proof. Begin with downstream socket route exactness. Definition 543.61 says that every downstream read factors through S, R, G, L, H, C, P, N and has no route outside those rows.

Compare the socket and gate sides. The socket boundary of Definition 536.4 prevents the visible socket from becoming a generated object, while Definition 715.3 prevents the refusal gate from becoming an admitted supply.

The correspondence is therefore the displayed refusal route itself. Transport through H, replay through C, provenance through P, and naming through N preserve the same socket-refusal packet and do not add host equality, quotient representatives, hidden theorem content, or supplied external content. □

Theorem 543.64 (ApophaticName ledger-refusal transport exactness)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

transport of the refusal ledger is exact: any transported downstream consumer reads the same refusal relation between S, R, and G through L, H, C, P, N, and no transported route can replace the ledger by a generated witness, host-side datum, quotient representative, hidden theorem, assumed proposition, or supplied external dependency.

Proof. Start from classifier-refusal transport, Definition 543.58. It moves the refusal classifier componentwise through H and replays the consumer route through C, P, N.

Use ledger nonescape and source-refusal totality, Definition 543.5 and Definition 543.51. Together they exhaust every source-side and downstream read by the displayed ledgered packet.

Finally apply gate-ledger separation and socket-refusal correspondence. The first keeps S, G, L as separate finite rows, and the second identifies every socket read with the same refusal route, so the transported ledger remains exact over S, R, G, L, H, C, P, N and exposes no unlisted content. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier ledger refusal transport exactness`

Theorem 543.65 (ApophaticName closure refusal package)**.** *The accepted* $\mathsf{ApophaticName}^{\uparrow}$ *carrier assembles a five-row refusal package:*

1. *carrier admission for $A = (S, R, G, L, H, C, P, N)$;*
2. *classifier stability for the socket, request, gate, ledger, transport, route, provenance, and naming rows;*
3. *ledger exactness for permitted socket reads and barred conversions;*
4. *non-escape from generated witnesses, assumed propositions, quotient representatives, hidden theorems, host-side data, and supplied external objects;*
5. *downstream socket route exactness through S, R, G, L, H, C, P, N.*

This package is the local $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *refusal surface, and it supplies no external dependency as internal BEDC content.*

Proof. Carrier admission is the displayed tuple in Definition 543.1. Classifier stability is supplied by Definition 543.50, which preserves exactly the socket, request, gate, ledger, transport, continuation, package, and naming rows.

Ledger exactness is Definition 543.2 together with Definition 543.5. These rows identify the permitted reads and barred conversions and keep every consumer inside the displayed refusal ledger.

The non-escape certificate Definition 543.6 rules out the attempted conversions to generated objects, assumed propositions, quotient representatives, hidden theorems, and host-side data. Gate-source compatibility adds that the request and refusal gate remain one source surface under hsame and Cont.

Finally apply Definition 543.61. It packages the boundary read through S, R, G, L, H, C, P, N and the sibling ApophaticSocket and ApophaticGateQuestion surfaces, so the five listed rows form the local closure refusal package without installing the named externality as internal content. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier closure refusal package`

Theorem 543.66 (ApophaticName kernel scope triad)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the socket-name row S, requested-supply row R, and refusal-gate row G are read only through the displayed BHist *packet, the componentwise* hsame *transport row, the* Cont *replay row, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row. No kernel read separates those three rows into a supplied object, assumed proposition, quotient representative, hidden theorem, or host-side datum.*

Proof. Project the accepted carrier by Definition 543.1. The rows S, R, G occur inside the same finite BHist packet as the ledger, transport, continuation, package, and naming rows.

Use the socket carrier and classifier stability theorems, Definition 543.3 and Definition 543.50. They keep socket, request, and refusal rows componentwise under hsame without adding a generated witness.

Finally apply the refusal ledger and consumer-boundary exhaustion, Definition 543.2 and Definition 543.59. These rows force every kernel read through L, H, C, P, N, so the triad remains a displayed refusal surface rather than an internal supply. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier kernel scope triad`

Theorem 543.67 (ApophaticName supply-shape refusal exactness)**.** *For an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet $A = (S, R, G, L, H, C, P, N)$, the requested supply shape R is exactly the row refused by the gate G and recorded by the ledger L. The packet introduces no generated witness, external object, host realization, quotient representative, hidden theorem, or assumed proposition in place of that refused row.*

Proof. Read R and G through the carrier definition. The request row and refusal-gate row are adjacent coordinates of the same displayed packet, and the ledger row L records the permitted reads and barred conversions.

Apply source-refusal totality from Definition 543.51. It exhausts the source-refusal surface by S, R, G, L, H, C, P, N and sends any attempted content read through the refusal ledger first.

Then use gate-source compatibility and the closure refusal package, Definition 543.60 and Definition 543.65. They keep the requested supply shape attached to the refusal gate and exclude every coordinate that would turn the request into supplied content. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier supply shape refusal exactness`

Theorem 543.68 (ApophaticName downstream refusal replay)**.** *Every downstream replay of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors through the refusal ledger* L*, classifier transport by* H*, the displayed* Cont *route* C*,* Pkg *provenance* P*, the local* NameCert *row* N*, and the consumer-boundary exhaustion of* S, R, G, L, H, C, P, N*. The replay exports only the refusal packet and never a generated witness, external object, host-side datum, quotient representative, hidden theorem, or assumed proposition.*

Proof. Begin with the refusal ledger of Definition 543.2. It names the visible socket, request, refusal gate, ledger, transport, continuation, package, and local naming rows.

Apply classifier-refusal transport from Definition 543.58. Transport moves the refusal ledger through the displayed hsame, Cont, Pkg, and NameCert rows while preserving the refusal classifier.

Finally use downstream socket route exactness and consumer-boundary exhaustion, Definition 543.61 and Definition 543.59. They exhaust every downstream replay by the same finite refusal packet, leaving no route to supplied or host-side content. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream refusal replay`

Theorem 543.69 (ApophaticName supply-request consumer factorization)**.** *Every consumer read that asks for the requested supply-shape row of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors through the displayed socket row* S*, requested supply row* R*, refusal gate* G*, refusal ledger* L*,* hsame *transport row* H*,* Cont *replay row* C*,* Pkg *provenance row* P*, and local* NameCert *row* N*. The read cannot skip the refusal ledger to obtain an internal object, axiom, quotient representative, hidden theorem, or host datum.*

Proof. Project the carrier $A = (S, R, G, L, H, C, P, N)$ from Definition 543.1. The requested supply-shape row is not a free-standing source; it is one displayed coordinate of the same refusal packet as the socket, gate, ledger, transport, route, provenance, and naming rows.

Use source-refusal totality from Definition 543.51. It sends every accepted source request through S, R, G, L, H, C, P, N and refuses the conversion from requested shape to supplied object.

Apply downstream refusal replay from Definition 543.68. Replay preserves the same refusal ledger and route rows for downstream consumers, so a supply-shape read is still a ledgered refusal read.

Finally cite the socket and gate boundaries already binding the chapter, Definition 543.3, Definition 543.60, and Definition 543.59. These boundaries exclude internal objects, axioms, quotient representatives, hidden theorems, and host data from the accepted packet. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier supply request consumer factorization`

Theorem 543.70 (ApophaticName kernel-scope refusal triad)**.** *For an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet* $A = (S, R, G, L, H, C, P, N)$*, every kernel-scope read of the socket-name row* S*, requested supply row* R*, and refusal-gate row* G *is confined to the concrete BEDC rows* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$*. The triad cannot be read as an abstract source equivalence, host object, quotient representative, hidden theorem, assumed proposition, or supplied external dependency.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier kernel scope refusal triad`

Proof. Project A through Definition 543.1. The socket, request, gate, ledger, transport, continuation, provenance, and naming coordinates are finite BHist rows.

Use Definition 543.66. It already confines the socket-name, requested-supply, and refusal-gate rows to the displayed packet and forbids their separation into supplied content.

Finally apply Definition 543.2 and Definition 543.7. The ledger and local NameCert obligations are concrete BEDC rows, so the kernel-scope triad remains a refusal surface rather than an abstract source equivalence. □

Theorem 543.71 (ApophaticName source-refusal transport)**.** *Let $A = (S, R, G, L, H, C, P, N)$ and $A' = (S', R', G', L', H', C', P', N')$ be accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packets whose displayed rows are related by the componentwise* hsame *transports recorded in H and H'. If a consumer reads A only as a source-refusal packet over* BHist, Cont, Pkg, *and* NameCert, *then the transported consumer reads A' only through $S', R', G', L', H', C', P', N'$ and still receives no generated witness, host object, quotient representative, hidden theorem, assumed proposition, or supplied external dependency.*

Proof. Start from source-refusal totality, Definition 543.51. It exhausts the source side of A by the concrete rows S, R, G, L, H, C, P, N.

Transport the displayed rows with Definition 543.58. The hsame row moves the refusal classifier componentwise, while Cont, Pkg, and NameCert replay and rename the same refusal packet.

Apply Definition 543.59. The transported read has no coordinate for supplied content, so A' remains a source-refusal packet over the concrete BEDC rows rather than an abstract equivalence between sources. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier source refusal transport`

Theorem 543.72 (ApophaticName downstream refusal ledger exhaustion)**.** *Every downstream consumer of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet $A = (S, R, G, L, H, C, P, N)$ that cites the named externality must exhaust the displayed refusal ledger L together with the* BHist *socket and request rows, the* hsame *transport row H, the* Cont *replay row C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row N. After those rows are exhausted, no downstream route remains to a generated BEDC object, host-side datum, quotient representative, hidden theorem, assumed proposition, or supplied external dependency.*

Proof. Begin with Definition 543.68. It forces downstream replay through the refusal ledger, classifier transport, displayed continuation route, package provenance, local name, and consumer-boundary exhaustion.

Use Definition 543.69. A consumer that asks for the requested supply shape is still routed through S, R, G, L, H, C, P, N and cannot skip L.

Finally cite Definition 543.61 and Definition 543.59. Together they identify the downstream route as exactly the displayed ledgered packet and exclude every supplied or host-side object outside the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream refusal ledger exhaustion`

Theorem 543.73 (ApophaticName socket-request gate factorization)**.** *For an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet $A = (S, R, G, L, H, C, P, N)$, every public read of the socket row S together with the requested supply-shape row R factors through the refusal gate G and refusal ledger L before it reaches the displayed* hsame, Cont, Pkg, *and* NameCert *rows. The factorization exports a public refusal boundary, not a supplied object, host datum, quotient representative, hidden theorem, assumed proposition, or generated witness.*

Proof. Project A through Definition 543.1. The socket, request, gate, ledger, transport, continuation, provenance, and local name are one finite packet, so the request row is not available as an independent source of content.

Apply the refusal-ledger and non-escape theorems, Definition 543.2 and Definition 543.6. They identify the permitted public reads and keep every attempted content read behind the refusal ledger.

Now use socket-refusal and source-refusal totality, Definition 543.29 and Definition 543.51. These force each socket-request read through G, L, H, C, P, N before a downstream consumer can cite the packet.

The resulting public surface is the displayed refusal boundary. Since no coordinate of A stores a supplied object or host realization, the factorization remains a refusal route through the local NameCert packet. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket request gate factorization`

Theorem 543.74 (ApophaticName boundary citation exhaustion)**.** *Every downstream citation of the named externality carried by an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet* $A = (S, R, G, L, H, C, P, N)$ *is exhausted by the public boundary rows*

$$S, R, G, L, H, C, P, N.$$

The citation must pass through the refusal ledger, socket-refusal route, externality handoff, source-refusal totality, and downstream refusal-ledger exhaustion; no further boundary remains for supplied external content, host-side data, quotient representatives, hidden theorem content, assumed propositions, or generated witnesses.

Proof. Start with the socket-request gate factorization of Definition 543.73. It places public socket and request reads behind the same gate and ledger rows.

Use externality handoff from Definition 543.30. The handoff lets downstream chapters cite the named dependency only as the finite refusal packet A.

Apply source-refusal totality and downstream refusal-ledger exhaustion, Definition 543.51 and Definition 543.72. Together they exhaust both the source side and the downstream side by S, R, G, L, H, C, P, N.

Finally cite non-escape through Definition 543.6. The packet has no coordinate for supplied external content or host realization, so the public boundary citation is exhausted by the displayed refusal rows. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier boundary citation exhaustion`

Theorem 543.75 (ApophaticName refusal provenance transport)**.** *Let* $A = (S, R, G, L, H, C, P, N)$ *and* $A' = (S', R', G', L', H', C', P', N')$ *be accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packets related by the displayed componentwise* hsame *transports. If a downstream consumer cites* A *only through its public refusal boundary, then the transported citation of* A' *is again only through* $S', R', G', L', H', C', P', N'$ *and carries the same refusal provenance through* Cont, Pkg, *and* NameCert.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal provenance transport`

Proof. Begin with classifier-refusal transport, Definition 543.58. It moves the refusal classifier along the displayed socket, request, gate, ledger, route, provenance, and naming rows without creating a supplied coordinate.

Use source-refusal transport from Definition 543.71. A consumer that reads A only as a source-refusal packet is transported to a consumer that reads A' only through the corresponding displayed rows.

Now apply boundary citation exhaustion, Definition 543.74. The downstream citation is already exhausted by the public refusal rows, so transport cannot add host data, quotient representatives, hidden theorem content, assumed propositions, or generated witnesses.

The provenance rows C', P', N' therefore replay, package, and name the same refusal boundary for A'. This is refusal provenance transport, not transport of the refused external object. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameRefusalProvenanceTransport`

Theorem 543.76 (ApophaticName refusal export totality)**.** *For an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet* $A = (S, R, G, L, H, C, P, N)$*, the complete public export boundary is the refusal packet on* S, R, G, L, H, C, P, N*. Every exported read of the named externality is classified by the socket row, requested supply-shape row, refusal gate, refusal ledger, componentwise transport, continuation route, package provenance, and local* $\mathsf{NameCert}$ *row, and by no supplied external object.*

Proof. Project the accepted carrier through Definition 543.1. The socket, requested supply-shape, gate, ledger, transport, continuation, provenance, and naming rows are the only displayed coordinates.

Apply the refusal ledger and classifier transport boundaries, Definition 543.2 and Definition 543.58. They classify exported reads by the same ledgered refusal packet under componentwise transport.

Finally use consumer boundary exhaustion and downstream refusal ledger exhaustion, Definition 543.59 and Definition 543.72. Together they leave no exported route to a supplied external object outside S, R, G, L, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameRefusalExportTotality`

Theorem 543.77 (ApophaticName downstream named-externality refusal)**.** *Every downstream consumer that cites the named externality of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet receives only the displayed refusal packet* S, R, G, L, H, C, P, N*. The citation may replay the socket, request, gate, ledger, transport, continuation, provenance, and local naming rows, but it cannot convert the named externality into supplied content, a host datum, a quotient representative, a hidden theorem, or an assumed proposition.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream named externality refusal`

Proof. Start from downstream refusal ledger exhaustion, Definition 543.72. It requires every downstream consumer to exhaust the displayed refusal ledger together with the socket, request, transport, continuation, provenance, and local naming rows.

Use refusal export totality from Definition 543.76. The public export surface is already the refusal packet on S, R, G, L, H, C, P, N.

Apply boundary citation exhaustion, Definition 543.74. A downstream citation of the named externality is therefore a citation of the displayed refusal packet and has no remaining coordinate for supplied or host-side content. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal export totality`

Theorem 543.78 (ApophaticName supply request nonimport)**.** *The requested supply row R of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet cannot import a supplied object, axiom, quotient representative, hidden theorem, or host datum. It is read only as a requested supply-shape coordinate inside the refusal packet S, R, G, L, H, C, P, N, behind the refusal gate G and refusal ledger L.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier supply request nonimport`

Proof. Project the packet $A = (S, R, G, L, H, C, P, N)$. The row R is a coordinate of the finite refusal carrier, not a source of supplied content.

Apply supply-request consumer factorization, Definition 543.69. Any consumer read asking for R factors through S, R, G, L, H, C, P, N and cannot skip the refusal ledger.

Now use Definition 543.77. Downstream citation still receives only the displayed refusal packet, so the requested supply row cannot import an object, axiom, quotient representative, hidden theorem, or host datum. □

Theorem 543.79 (ApophaticName socket refusal totality)**.** *Every socket-facing consumer read of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet $A = (S, R, G, L, H, C, P, N)$ must pass through the displayed refusal ledger, classifier-stability row, supply-request gate, and nonimport row before it can cite the packet. The resulting citation is a finite refusal packet over S, R, G, L, H, C, P, N, not a supplied object, host datum, quotient representative, hidden theorem, or assumed proposition.*

Proof. Begin with the refusal ledger, Definition 543.2. It identifies the visible socket, request, refusal-gate, ledger, transport, continuation, provenance, and naming rows as the consumer surface.

Use classifier stability from Definition 543.50. Componentwise hsame transport preserves that same refusal classifier and does not create another socket-facing coordinate.

Now apply the socket-request gate factorization and supply-request nonimport rows, Definition 543.73 and Definition 543.78. They force a socket-facing read through G, L, H, C, P, N before the packet can be cited downstream.

The packet has no coordinate for supplied content, host data, quotient representatives, hidden theorems, or assumed propositions. Hence every socket-facing citation is total only as the displayed refusal packet. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket refusal totality`

Theorem 543.80 (ApophaticName contextual class non-escape)**.** *The refusal surface of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet never supplies a contextual-class object, host selector, or imported ontology outside the displayed rows S, R, G, L, H, C, P, N. Any attempted contextual-class read is stopped by the refusal ledger, classifier stability, non-escape certificate, and supply-request nonimport boundary.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier contextual class nonescape`

Proof. Project the carrier through Definition 543.1. The only rows present are the socket, requested supply shape, refusal gate, refusal ledger, transport, continuation, provenance, and local naming row.

Apply the refusal ledger and classifier stability theorems, Definition 543.2 and Definition 543.50. They keep every transported consumer read on the same refusal rows.

Use the non-escape certificate, Definition 543.6. It rules out conversion of the named externality into a generated object, assumed proposition, quotient class, concealed theorem, or host-side datum.

Finally cite supply-request nonimport, Definition 543.78. Since the request row remains a requested supply-shape coordinate behind the refusal gate, no contextual-class object, host selector, or imported ontology can be supplied by the packet. □

Theorem 543.81 (ApophaticName boundary descent ledger)**.** *Downstream descent through the apophatic boundary of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet is ledger-bounded by the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. A consumer may descend only by replaying* S, R, G, L *through* H, C, P, N*, and it cannot add a supplied external object, host selector, imported ontology, quotient representative, hidden theorem, or assumed proposition.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier boundary descent ledger`

Proof. Start from the carrier definition and the refusal ledger, Definition 543.1 and Definition 543.2. They place the boundary in finite BHist rows and identify L as the ledger for the permitted socket and request reads.

Use classifier stability, Definition 543.50. The descent rows are transported only componentwise along H, so the classifier remains attached to the displayed refusal packet.

Apply the non-escape certificate together with supply-request nonimport, Definition 543.6 and Definition 543.78. These results keep the requested supply shape behind the gate and rule out every conversion to supplied or host-side content.

Thus any downstream descent is exactly a replay through Cont, packaging through Pkg, and citation by the local NameCert row. The descent is ledger-bounded by S, R, G, L, H, C, P, N and has no other boundary object to export. □

Theorem 543.82 (ApophaticName downstream boundary consumer)**.** *Every downstream consumer read of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N)$$

factors through the displayed socket, requested supply-shape, refusal gate, ledger, componentwise transport, continuation, provenance, and local naming rows. The consumer receives only that refusal-boundary packet and no supplied object, quotient representative, hidden theorem, host datum, or generated witness.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream boundary consumer`

Proof. Project the carrier of Definition 543.1. The only rows presented to a downstream consumer are S, R, G, L, H, C, P, N.

Apply the refusal ledger, obligation surface, and non-escape certificate, Definition 543.2, Definition 543.7, and Definition 543.6. These rows identify the permitted reads, the local NameCert obligations, and the barred conversions for the same packet.

Finally use the sibling socket and gate surfaces already binding this chapter, Definition 543.73 and Definition 543.74. They force the downstream citation to remain a public refusal-boundary citation rather than a supplied object or host-side witness. □

Theorem 543.83 (ApophaticName refusal gate separation)**.** *The refusal gate* G *separates socket requests from generated witnesses, quotient representatives, hidden theorems, and host objects for every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet. A read may name the socket row* S *and requested supply-shape row* R *only by passing through* G, L, H, C, P, N*, and it cannot turn the request into substrate content.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal gate separation`

Proof. Begin with the refusal ledger of Definition 543.2. It records each permitted socket and request read together with the barred conversions from request to internal content.

Use the non-escape certificate, Definition 543.6. It rules out the attempted repackaging of the named externality as a generated object, assumed proposition, quotient class, hidden theorem, or host-side datum.

The socket-request gate factorization and boundary citation exhaustion, Definition 543.73 and Definition 543.74, keep the request behind G through Cont, Pkg, and NameCert. Hence the gate separates the public request from every hidden or host-side realization. □

Theorem 543.84 (ApophaticName NameCert handoff exhaustion)**.** *The local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *handoff through* N *exhausts all public refusal-boundary exports of an accepted packet* $A = (S, R, G, L, H, C, P, N)$*. Any public export is a replay of the refusal ledger through* H, C, P, N*, not an export of supplied content, a quotient representative, a hidden theorem, a generated witness, or a host object.*

Proof. Start from Definition 543.7. Its carrier, classifier-stability, ledger-exactness, continuation, package, and non-escape rows are the local NameCert obligations for the packet.

Apply the refusal ledger and non-escape certificate, Definition 543.2 and Definition 543.6. They identify the public refusal rows and exclude every conversion to supplied or host-side content.

Finally cite downstream named-externality refusal and boundary descent, Definition 543.77 and Definition 543.81. Together they show that a downstream export is exhausted by replay through H, C, P, N, so the local NameCert handoff has no remaining hidden route to export. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameNameCertHandoffExhaustion`

Theorem 543.85 (ApophaticName boundary socket provenance)**.** *Every boundary citation of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet factors through the socket surface, refusal-gate provenance rows, and local* NameCert *row in the displayed packet* S, R, G, L, H, C, P, N*.*

Proof. Project the carrier and use Definition 543.3; the socket citation is already a read of the finite surface S, R, G, L, H, C, P, N.

Apply Definition 543.73 and Definition 543.84. The route reaches the local NameCert row only after the socket, request, refusal gate, ledger, transport, continuation, and provenance rows. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier boundary socket provenance`

Theorem 543.86 (ApophaticName refusal gate route totality)**.** *Every accepted refusal route for* $\mathsf{ApophaticName}^{\uparrow}$ *is exhausted by the displayed socket, requested supply shape, refusal gate, ledger,* Pkg *provenance, and* NameCert *rows, together with the recorded* hsame *and* Cont *routes.*

Proof. Use Definition 543.2 and Definition 543.51. They identify the permitted refusal route with S, R, G, L, H, C, P, N.

Then apply Definition 543.59. Since no supplied object or hidden theorem is a coordinate, the displayed rows exhaust the route. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal gate route totality`

Theorem 543.87 (ApophaticName downstream nonimport)**.** *Downstream consumers may cite the named externality of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet only through its public boundary, and cannot import the refused supply as an internal BEDC object.*

Proof. Apply Definition 543.77 and Definition 543.78. A downstream citation receives only the refusal packet and not the requested supply.

The non-escape certificate Definition 543.6 excludes generated witnesses, host data, quotient representatives, hidden theorems, and assumed propositions from the packet. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier downstream nonimport`

Theorem 543.88 (ApophaticName bridge-route scope)**.** *The public refusal-boundary packet S, R, G, L, H, C, P, N supplies the paper bridge surface from* $\mathsf{ApophaticName}^{\uparrow}$ *to downstream named-externality consumers. The bridge route exports socket naming, requested supply shape, refusal gate, refusal ledger, componentwise transport, continuation replay, package provenance, and local* NameCert *rows, while importing no supplied object, generated witness, hidden theorem, quotient representative, host datum, or assumed proposition.*

Proof. Begin with the downstream nonimport theorem above. It states that downstream consumers may cite the named externality only through the public boundary and cannot import the refused supply as internal BEDC content.

Use Definition 543.86 and Definition 543.84. They identify the exported route with the displayed socket, request, gate, ledger, transport, continuation, provenance, and local naming rows.

Finally apply Definition 543.6. Since generated witnesses, hidden theorems, quotient representatives, host data, and assumed propositions are excluded from the packet, the bridge surface is a public refusal-boundary route rather than an imported object. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier bridge route scope`

Closure status for $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$.

Constructive story: An $\mathsf{ApophaticName}^{\uparrow}$ packet is generated from a finite socket-name row, a requested supply-shape row, a refusal-gate row, a refusal ledger, componentwise transport, continuation routes, package provenance, and a local naming certificate.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 543.1, Definition 543.44, Definition 543.46, Definition 543.49, Definition 543.50, Definition 543.52, and Definition 543.54 bind the mature paper surface as the finite socket and refusal tuple, image row, readback row, componentwise NameCert transport, classifier stability, public boundary package, and refusal audit package for named externality.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not supply the external dependency, prove its existence, internalize it as an axiom or quotient, or close a Lean implementation.

Upgrade path: The paper axis is closed at the mature finite socket and refusal surface; machine verification and standard bridge checking remain formal-axis obligations for the same public boundary route.

Theorem 543.89 (ApophaticName root citation safety)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every root consumer citation of the named externality may cite only the visible socket, request, refusal gate, refusal ledger, transport, continuation, provenance, and local naming surface S, R, G, L, H, C, P, N. Such a citation cannot cite a generated witness, host object, quotient representative, hidden theorem, supplied dependency, assumed proposition, or closure principle outside the visible refusal packet.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root citation safety`

Proof. Start with the public boundary package of Definition 543.52. It identifies the root-facing object with exactly the finite rows S, R, G, L, H, C, P, N.

Next apply socket citation scope and consumer-boundary exhaustion, Definition 543.53 and Definition 543.59. These keep every downstream citation on the socket, request, refusal, transport, continuation, provenance, and naming rows.

Finally use the non-escape certificate, Definition 543.6. Since the accepted carrier has no coordinate for generated witnesses, host objects, quotient representatives, hidden theorems, supplied dependencies, assumed propositions, or closure principles, the root citation is safe exactly on the visible refusal surface. □

Theorem 543.90 (ApophaticName boundary request totality)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every boundary request for the named externality must expose the request row R before it exposes the refusal gate row G. The accepted route then continues through the refusal ledger L, transport row H, continuation row C, provenance row P, and local naming row N; it cannot bypass R by reading a generated witness, host object, quotient representative, hidden theorem, supplied dependency, assumed proposition, or closure principle.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier boundary request totality`

Proof. Begin with visible request factorization, Definition 543.37. It sends every visible socket request through the displayed request row R as part of the packet S, R, G, L, H, C, P, N.

Use socket request gate exactness, Definition 543.40. The gate row G is read as the refusal response to that displayed request, so a boundary request cannot reach the gate before it has exposed R.

Finally combine source-refusal totality and ledger nonescape, Definition 543.51 and Definition 543.5. These route the accepted request through G, L, H, C, P, N and exclude every bypass through generated or host-side content. □

Theorem 543.91 (ApophaticName refusal route exhaustion)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every refusal route for the named externality is exhausted by the visible rows G, L, H, C, P, N after the socket and request rows S, R have been exposed. No refusal route generates a witness, supplies a host object, selects a quotient representative, imports a hidden theorem, or invokes a closure principle outside the displayed packet.

Proof. First apply root-unblock refusal boundary and refusal ledger exactness, Definition 543.14 and Definition 543.43. They identify root use of the named externality with the displayed refusal gate and ledger rather than with supplied content.

Next use socket-gate route exhaustion, Definition 543.56. Any socket read that reaches the refusal side must pass through S, R, G, L, H, C, P, N, so the refusal route is already a finite route through the displayed rows.

Finally apply boundary citation exhaustion and downstream named-externality refusal, Definition 543.74 and Definition 543.77. They exhaust downstream citation by the same refusal packet and leave no route to generated witnesses, host objects, quotient representatives, hidden theorems, or closure principles. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal route exhaustion`

Theorem 543.92 (ApophaticName root source citation export)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

each root citation exported by the packet names only the visible socket, request, refusal gate, refusal ledger, transport, continuation, provenance, and local naming rows S, R, G, L, H, C, P, N*. The export does not expose a generated witness, host object, quotient representative, hidden theorem, supplied dependency, assumed proposition, or closure principle outside that boundary packet.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root source citation export`

Proof. Start with root citation safety, Definition 543.89. It restricts every root consumer citation to the visible rows S, R, G, L, H, C, P, N.

Use boundary request totality, Definition 543.90, to identify the request row exported with the socket route. Then use refusal route exhaustion, Definition 543.91, to keep the refusal side on G, L, H, C, P, N after S, R have been exposed.

Finally apply Definition 543.52 and Definition 543.6. These boundary lemmas identify the exported packet with the finite refusal surface and exclude every off-boundary source from the citation export. □

Theorem 543.93 (ApophaticName root refusal-gate readback)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet* $A = (S, R, G, L, H, C, P, N)$*, a root refusal-gate readback must expose the request row* R *before the refusal gate row* G*. After* G *is read, the same readback exposes only the refusal ledger, provenance, and naming rows* L, P, N*, together with the transport and continuation rows* H, C *that replay the visible route.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root refusal gate readback`

Proof. Apply boundary request totality, Definition 543.90. It places the request row R before any exposure of the refusal gate G.

Next use refusal route exhaustion, Definition 543.91. Once G is public, the remaining refusal route is exhausted by L, H, C, P, N.

The readback is still a root citation. Therefore Definition 543.89 and Definition 543.92 prevent the readback from adding any generated witness, host object, quotient representative, hidden theorem, supplied dependency, assumed proposition, or closure principle. □

Theorem 543.94 (ApophaticName root boundary ledger package)**.** *The downstream root boundary package for an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet* $A = (S, R, G, L, H, C, P, N)$ *consists exactly of root citation safety, boundary request totality, refusal-route exhaustion, root source citation export, and root refusal-gate readback. A downstream root consumer may therefore cite the socket row* S*, require the request row* R *before the refusal gate row* G*, and read only the ledger, transport, continuation, provenance, and naming rows* L, H, C, P, N *afterward.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root boundary ledger package`

Proof. First collect the three base rows. Apply Definition 543.89, Definition 543.90, and Definition 543.91; together they give citation safety, request-before-gate order, and refusal-route exhaustion on S, R, G, L, H, C, P, N.

Next add the two export rows. The root source citation export of Definition 543.92 keeps downstream citations on the visible packet, and the refusal-gate readback of Definition 543.93 fixes the required R before G order for gate reads.

Finally use Definition 543.52 and Definition 543.77. They identify the downstream boundary with this finite refusal packet and leave no consumer-facing route outside the displayed ledger package. □

Theorem 543.95 (ApophaticName root citation readback package)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every root citation readback factors through exactly the finite socket, request, refusal-gate, refusal-ledger, transport, continuation, provenance, and local naming rows S, R, G, L, H, C, P, N*. The readback exposes the request row* R *before the refusal gate row* G*, and after the gate it reads only* L, H, C, P, N*.*

This package contains no generated witness, host object, quotient representative, hidden theorem, supplied dependency, assumed proposition, or closure principle outside the displayed packet.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root citation readback package`

Proof. First apply root citation safety, Definition 543.89. It confines every root citation to the visible finite packet S, R, G, L, H, C, P, N and excludes off-packet witnesses or host-side objects.

Next use boundary request totality and refusal route exhaustion, Definition 543.90 and Definition 543.91. These place the request row R before the refusal gate row G and exhaust the post-gate route by L, H, C, P, N.

Then add root source citation export and root refusal-gate readback, Definition 543.92 and Definition 543.93. The export row keeps the cited source on the same visible packet, while the readback row records the required R before G order.

Finally collect the rows with Definition 543.94. The boundary ledger package is exactly the finite readback surface, so no generated witness, host object, quotient representative, hidden theorem, supplied dependency, assumed proposition, or closure principle can be added afterward. □

Corollary 543.96 (ApophaticName root citation safety strict obstruction)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

any root-facing obstruction carried by a displayed failure, refusal, separation, or countermodel-style row of the root citation package is strictly local to the visible route

$$S, R, G, L, H, C, P, N.$$

It blocks only the named converse or reuse attempt that would reread the exported root citation or refusal route as a generated witness, host object, quotient representative, hidden theorem, supplied dependency, assumed proposition, closure principle, or hidden external validation. It cannot be reinterpreted as a global impossibility claim, a host theorem, or an ambient validation result outside the accepted packet.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root citation safety strict obstruction`

Proof. Start with root source citation export, Definition 543.92. It says that every root citation exported by the accepted packet names only the socket, request, refusal gate, refusal ledger, transport, continuation, provenance, and local naming rows S, R, G, L, H, C, P, N. Thus a consumer-facing citation has no exported coordinate for a generated witness, host object, quotient representative, hidden theorem, supplied dependency, assumed proposition, closure principle, or hidden external validation.

Now apply refusal route exhaustion, Definition 543.91. Once the socket and request rows S, R have been exposed, every refusal route is exhausted by G, L, H, C, P, N. Therefore any displayed failure, refusal, separation, or countermodel-style row that a root consumer can cite is read as part of that same refusal route, not as a second source of theorem content or host-side evidence.

The strict obstruction is the separation between a permitted citation and a barred rereading. In the permitted direction, the consumer may cite the exported source through S, R, G, L, H, C, P, N. In the barred converse or reuse direction, the consumer tries to turn that cited route back into supplied content, a host theorem, a quotient representative, a hidden theorem, an assumed proposition, a closure principle, or hidden external validation. The export theorem removes every off-packet citation coordinate, while route exhaustion removes every post-gate escape from the refusal rows.

Finally, root citation safety and the readback package, Definition 543.89 and Definition 543.95, keep this conclusion at the root boundary. They identify the public readback surface with the finite packet and do not add any claim about all ambient hosts or all possible external theories. Hence the obstruction blocks exactly the named converse or reuse route through the accepted packet and carries no global impossibility theorem, host theorem, or hidden external validation beyond S, R, G, L, H, C, P, N. □

Theorem 543.97 (ApophaticName root-unblock public citation surface)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every downstream consumer of the packet factors through the public socket row S, request row R, refusal gate G, refusal ledger L, transport row H, continuation row C, provenance row P, and local $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row N. The consumer may cite this boundary package as a root-unblock surface, but it exports no generated witness, host datum, quotient representative, hidden theorem, assumed proposition, supplied object, or closure principle.*

Proof. Start with the root-unblock refusal boundary and downstream boundary package, Definition 543.14 and Definition 543.10. Together they put root use of the named externality on the finite refusal packet S, R, G, L, H, C, P, N.

Next use the boundary citation universal factorization, Definition 543.126. It makes every downstream citation pass through the displayed socket, request, refusal, ledger, transport, continuation, provenance, and local naming rows before any consumer can treat the packet as accepted.

The sibling surfaces chapter 536 and chapter 715 identify the socket and refusal gate as public boundary components. They therefore allow only citation of the finite rows and do not supply an internal object behind the socket.

Thus the public root-unblock citation surface is exactly the displayed package. Since no coordinate of that package is a generated witness, host datum, quotient representative, hidden theorem, assumed proposition, supplied object, or closure principle, no such item is exported to downstream consumers. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root unblock public citation surface`

Theorem 543.98 (ApophaticName root public citation selector exclusion)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

any root public citation that factors through S, R, G, L, H, C, P, N *cannot acquire a generated selector, supplied object, closure principle, quotient representative, hidden theorem, or host datum unless that item is already one of the displayed rows of the packet.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root public citation selector exclusion`

Proof. Start with Definition 543.97. It identifies the root public citation surface with the displayed packet S, R, G, L, H, C, P, N and says downstream consumers receive only that boundary package.

Use the sibling surfaces cited there. Definition 543.14 and Definition 543.10 keep the root route on the refusal packet, while Definition 543.126 forces each citation through the public socket, request, refusal, ledger, transport, continuation, provenance, and naming rows.

The sibling chapters chapter 536 and chapter 715 supply only public boundary components. Since none of the displayed coordinates is an undisplayed selector, supplied object, closure principle, quotient representative, hidden theorem, or host datum, the root citation cannot acquire such an item outside the packet. □

Theorem 543.99 (ApophaticName two-step refusal-ledger induction)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

any downstream root citation admitted by the packet is admitted by a two-step finite induction. The first step exposes S, R *as the socket and request boundary. The second step exposes* G, L *as the refusal gate and refusal ledger. After those two steps,* H, C, P, N *transport, replay, source, and name only that refusal package. The resulting citation surface excludes generated witnesses, supplied objects, quotient representatives, hidden theorems, host data, assumed propositions, and closure principles outside the displayed packet.*

Proof. Start with the public citation surface of Definition 543.97. It identifies every downstream root citation with the finite packet S, R, G, L, H, C, P, N and gives the consumer only that public boundary package.

Use Definition 543.98 to remove the hidden choices that could make the citation look like an internal supply route. In particular, no generated selector, supplied object, closure principle, quotient representative, hidden theorem, or host datum can be acquired outside the displayed rows.

Now read the package in two finite steps. First expose the socket and request rows S, R; the sibling chapter chapter 536 identifies this pair as a public socket boundary rather than a supplied object.

Second expose the refusal gate and ledger rows G, L; the sibling chapter chapter 715 identifies the gate read as a public refusal question rather than a hidden host theorem or assumed proposition. The remaining rows H, C, P, N then only transport, replay, source, and name the same refusal package.

Thus the admitted downstream citation has the claimed induction shape: socket-request boundary first, refusal-gate ledger second, and only transport, replay, source, and naming afterward. Since both cited surface theorems exclude off-packet selectors and supplies, the citation cannot export generated witnesses, supplied objects, quotient representatives, hidden theorems, host data, assumed propositions, or closure principles. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal ledger induction surface`

Theorem 543.100 (ApophaticName root consumer socket request totality)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every root consumer of the named externality passes through the displayed socket row S*, request row* R*, refusal gate* G*, refusal ledger* L*, transport row* H*, continuation row* C*, provenance row* P*, and naming row* N*. The consumer therefore receives a boundary request and refusal certificate, not an internal supplied object, host proof, quotient representative, hidden theorem, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameRootConsumerSocketRequestTotality`

Proof. Start from the root unblock refusal boundary, Definition 543.14. It already places root use of the named externality on the refusal boundary and prevents a bypass into generated content.

Next apply visible request factorization and socket request gate exactness, Definition 543.37 and Definition 543.40. These results identify the actual root-facing read as the finite socket/request/refusal package S, R, G, L, H, C, P, N.

Finally use the sibling socket and gate surfaces, Definition 536.5 and Definition 715.3. They expose the socket and refusal gate as public boundary rows only, so the root consumer must pass through the displayed packet. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root consumer socket request totality`

Theorem 543.101 (ApophaticName refusal ledger downstream coverage)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the refusal ledger L *covers every downstream read of the named externality. A downstream chapter may cite only the socket/request/refusal/provenance boundary* S, R, G, L, H, C, P, N*, and the ledger bars any internal supply of generated content, assumed propositions, quotient representatives, hidden theorems, host realizations, or closure principles.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal ledger downstream coverage`

Proof. Apply the refusal ledger theorem, Definition 543.2. It records the permitted refusal rows and excludes the internal supply cases at the source of the named externality.

The downstream side is fixed by downstream boundary exactness and the consumer citation boundary, Definition 543.35 and Definition 543.41. They say that every downstream citation remains a citation of the same finite packet.

Use request ledger classifier exhaustion, Definition 543.38. Since all permitted boundary reads are classified by R, G, L, there is no separate internal row through which a downstream reader can obtain supplied content. □

Theorem 543.102 (ApophaticName socket boundary route exhaustion)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every socket-boundary route for the named externality factors through the displayed finite packet S, R, G, L, H, C, P, N*. The route may use the socket, request, refusal, transport, continuation, provenance, and naming rows, but it has no additional carrier for generated content, assumed propositions, quotient representatives, hidden theorems, host realizations, or closure principles.*

Proof. First factor the route through the visible request surface using Definition 543.37. This places every socket-boundary route on the packet coordinates S, R, G, L, H, C, P, N.

Next apply componentwise transport and the named externality package, Definition 543.39 and Definition 543.42. They keep transport, continuation, provenance, and naming attached to the same socket/request/refusal rows.

Finally use externality handoff and root consumer request totality, Definition 543.30 and Definition 543.100. Any route seen by downstream or root consumers is therefore the displayed finite packet, with no additional supply route outside it. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameSocketBoundaryRouteExhaustion`

Theorem 543.103 (ApophaticName root ledger coverage)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the root-facing ledger rows G, L cover every downstream package read of the named externality. A downstream consumer may receive the socket row S, request row R, refusal gate G, refusal ledger L, componentwise transport row H, continuation row C, provenance row P, and local naming row N, but no generated content, assumed proposition, quotient representative, hidden theorem, host realization, or closure principle.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root ledger coverage`

Proof. Start from the refusal ledger, Definition 543.2. It records the permitted socket and request reads together with the barred conversions governed by G and L.

Apply the root-unblock refusal boundary and root consumer socket request totality, Definition 543.14 and Definition 543.100. These two results put every root citation of the named externality on the same finite packet S, R, G, L, H, C, P, N.

Finally use downstream boundary exactness and downstream noninternalization, Definition 543.35 and Definition 543.13. The downstream package therefore consumes only the ledgered boundary rows, so the barred internal objects have no receiving coordinate. □

Theorem 543.104 (ApophaticName root citation nonescape)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

each root citation exported to a downstream chapter is the finite boundary citation S, R, G, L, H, C, P, N. The citation cannot be re-read as a supplied object, host proof, quotient representative, hidden theorem, generated witness, or closure principle.

Proof. Use the consumer citation boundary, Definition 543.41. It already states that downstream citation of the accepted packet factors through the displayed boundary package and exports no supplied object.

Next apply visible request factorization and socket boundary route exhaustion, Definition 543.37 and Definition 543.102. They force the cited socket to carry the request, refusal, transport, continuation, provenance, and naming rows on the same route.

The nonescape part is supplied by ledger nonescape and downstream ledger nonescape, Definition 543.5 and Definition 543.28. Since no extra coordinate exists outside S, R, G, L, H, C, P, N, a root citation remains a boundary citation at every downstream use site. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root citation nonescape`

Theorem 543.105 (ApophaticName root boundary package exhaustion)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the three downstream package rows for root consumption are exhausted by ledger coverage, citation nonescape, and socket-boundary route exhaustion. Thus any downstream chapter consuming $\mathsf{ApophaticName}^{\uparrow}$ *receives exactly the boundary package* S, R, G, L, H, C, P, N *and no additional internal socket, hidden supply, host realization, quotient representative, assumed proposition, theorem cache, or closure row.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root boundary package exhaustion`

Proof. First consume root ledger coverage from Definition 543.103. It fixes G, L as the rows that answer every downstream package read of the named externality.

Next consume root citation nonescape from Definition 543.104. This keeps the exported citation on the same packet and prevents it from becoming a supplied object or host-side proof.

Finally combine socket-boundary route exhaustion with the named externality NameCert package, Definition 543.102 and Definition 543.42. Together they say that the only package available to downstream root consumers is the finite boundary package S, R, G, L, H, C, P, N, with all barred internal objects excluded. □

Theorem 543.106 (ApophaticName root bridge tuple source)**.** *Every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple exposes the socket row* S*, gate-question row* R*, externality refusal row* G*, refusal ledger* L*,* BHist *history rows, componentwise* hsame *row* H*, displayed* Cont *route* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row* N *before any downstream refusal read. No consumer receives a root bridge tuple whose first readable coordinate is an internalized object, generated witness, host datum, quotient representative, hidden theorem, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple source`

Proof. Start from root boundary package exhaustion, Definition 543.105. It states that downstream root consumers receive exactly the finite packet S, R, G, L, H, C, P, N.

Apply the refusal ledger and root ledger coverage rows, Definition 543.2 and Definition 543.103. They force each refusal read to pass through G, L after the visible socket and request rows have already been displayed.

Use the sibling socket and gate surfaces, Definition 536.5 and Definition 715.3. These identify the socket and gate-question sides as public boundary rows, not supplied objects.

The structural rows H, C, P, N replay that same boundary packet through componentwise transport, continuation, provenance, and local naming. Thus the root bridge tuple exposes all source rows before any refusal read and exports no hidden supply channel. □

Theorem 543.107 (ApophaticName root bridge tuple classifier)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple, classifier comparison is exhausted by the displayed socket row* S*, gate-question row* R*, refusal gate* G*, refusal ledger* L*, transport row* H*, route row* C*, provenance row* P*, and local naming row* N*. The classifier cannot compare against hidden supply, host realization, quotient representative, generated witness, theorem cache, or closure row outside the tuple.*

Proof. Project the finite tuple from Definition 543.106. The source, gate, refusal, transport, route, provenance, and naming rows are already present before classifier comparison begins.

Use classifier stability and request ledger classifier exhaustion, Definition 543.50 and Definition 543.38. They keep comparison on the displayed socket/request/refusal rows and on their componentwise transports.

Apply the visible request and socket-boundary route rows, Definition 543.37 and Definition 543.102. These rows leave no second comparison source behind the public boundary citation.

The sibling gate chapter, Definition 715.3, supplies only the visible refusal question. Therefore classifier comparison is exhausted by the root bridge tuple itself. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple classifier`

Theorem 543.108 (ApophaticName root bridge tuple ledger)**.** *Every downstream consumer of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple reads the refusal ledger L and the non-internalization rows before any externality handoff. The handoff may carry the socket, gate-question, refusal,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows, but it cannot deliver a supplied dependency, internal object, host proof, quotient representative, hidden theorem, generated witness, or closure principle.*

Proof. Begin with root ledger coverage and root citation nonescape, Definition 543.103 and Definition 543.104. They make G, L the rows that answer downstream package reads and keep exported citations on the same finite packet.

Next apply downstream noninternalization and downstream nonimport, Definition 543.13 and Definition 543.87. These rows bar a downstream consumer from treating the requested supply as internal content.

Use the externality handoff theorem, Definition 543.30. Its handoff object is the displayed refusal boundary, replayed through H, C, P, N.

Combining these rows with the source and classifier bridge tuple theorems above shows that every downstream consumer reads the ledger and non-internalization boundary before the externality handoff, with no hidden supply coordinate left to export. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple ledger`

Theorem 543.109 (ApophaticName root bridge tuple noninternalization)**.** *Every downstream consumer of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple must keep the socket row S, gate-question row R, refusal row G, transport row H, route row C, provenance row P, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row N as boundary rows. The consumer may read the refusal ledger L through the same packet, but it cannot internalize the requested supply as an object, generated witness, host datum, quotient representative, hidden theorem, or closure principle.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple noninternalization`

Proof. Start with the source, classifier, and ledger rows above. Theorems 543.106, 543.107, and 543.108 expose the tuple as S, R, G, L, H, C, P, N and exhaust both comparison and downstream ledger reads on those displayed coordinates.

Use the sibling socket and gate nonescape surfaces. Theorems 536.5 and 715.3 keep the socket and gate-question sides visible as boundary rows rather than supplied content.

Finally apply the downstream noninternalization and externality handoff rows, Definition 543.13 and Definition 543.30. They keep the refusal answer on the displayed transport, route, provenance, and local naming rows, so no downstream consumer can reclassify the requested supply as an internal object, generated witness, host datum, quotient representative, hidden theorem, or closure principle. □

Theorem 543.110 (ApophaticName root bridge tuple source-route totality)**.** *Every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple exhausts its source route by the rows*

$$S, R, G, L, H, C, P, N$$

before any downstream refusal read. The downstream consumer may inspect the socket, gate-question, refusal, ledger, transport, route, provenance, and local naming rows, but it receives no supplied dependency, internal object, generated witness, host datum, quotient representative, hidden theorem, or closure principle.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple source route totality`

Proof. Start with the source and classifier tuple theorems, Definition 543.106 and Definition 543.107. They expose the tuple before downstream reading as the finite socket, gate-question, refusal, ledger, transport, route, provenance, and naming surface.

Next apply the ledger theorem and noninternalization theorem, Definition 543.108 and Definition 543.109. These force the refusal read through G, L while keeping S, R, H, C, P, N as boundary rows rather than supplied content.

Use the sibling socket and gate surfaces, Definition 536.5 and Definition 715.3. The source side is therefore already public as a socket and visible gate question before any downstream refusal consumer can ask for an externality handoff. □

Theorem 543.111 (ApophaticName root bridge tuple gate-refusal interface)**.** *Every externality handoff from an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple must read the gate-question row* R *and refusal rows* G, L *before the handoff is public. The interface is the finite route through* S, R, G, L, H, C, P, N *and not a supplied object, host proof, generated witness, quotient representative, hidden theorem, or closure principle.*

Proof. Begin with source-route totality from Definition 543.110. It fixes the handoff source route as S, R, G, L, H, C, P, N before downstream refusal reading begins.

Apply the root bridge tuple ledger theorem, Definition 543.108. It makes L and the noninternalization rows part of the route before the externality handoff, so the refusal answer is not read after the handoff as hidden content.

Finally use the sibling gate surface, Definition 715.3, together with the externality handoff theorem cited in Definition 543.108. The gate question and refusal are read as visible boundary rows, and the handoff carries only the displayed tuple. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple gate refusal interface`

Theorem 543.112 (ApophaticName root bridge tuple transport-naming exhaustion)**.** *For every downstream consumer of an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple, the transport row* H*, continuation row* C*, provenance row* P*, and local naming row* N *are exhausted as boundary infrastructure for the route* S, R, G, L, H, C, P, N*. They cannot be reread as supplied dependency content, an internal object, a generated witness, host datum, quotient representative, hidden theorem, or closure principle.*

Proof. First combine the source, classifier, ledger, and noninternalization tuple theorems above. Together they show that H, C, P, N only replay the already displayed socket, gate-question, refusal, and ledger rows.

Next use the gate-refusal interface of Definition 543.111. Since the externality handoff has already consumed R, G, L through the finite route, the structural rows cannot be reopened as a second source of supplied content.

Finally apply the sibling socket and gate surfaces, Definition 536.5 and Definition 715.3. They keep the source and gate sides visible, so transport, continuation, provenance, and local naming remain route witnesses rather than downstream payload. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple transport naming exhaustion`

Theorem 543.113 (ApophaticName root bridge tuple terminal exhaustion)**.** *Every downstream externality handoff from an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple is exhausted by the finite rows* S, R, G, L, H, C, P, N*. The handoff cannot export supplied dependency content, an internal object, a generated witness, host datum, quotient representative, hidden theorem, or closure principle outside those rows.*

Proof. Start with the source, classifier, ledger, and noninternalization tuple theorems. They expose the bridge tuple as S, R, G, L, H, C, P, N and force comparison, refusal reading, and downstream package reading through the displayed boundary rows.

Next apply Definition 543.111. The gate question and refusal ledger are consumed before the externality handoff is public, so the handoff cannot reopen G or L as supplied content.

Finally use Definition 543.112. The rows H, C, P, N only replay transport, continuation, provenance, and local naming for the same finite route. Therefore every downstream externality handoff is exhausted by S, R, G, L, H, C, P, N and has no hidden export coordinate. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple terminal exhaustion`

Theorem 543.114 (ApophaticName downstream refusal uniqueness)**.** *Every downstream externality handoff from an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple has a unique refusal-reading route through*

$$S, R, G, L, H, C, P, N.$$

If a second downstream route has the same socket row S *and gate-question row* R*, then it agrees on the refusal row* G*, refusal ledger* L*, transport row* H*, continuation route* C*, provenance row* P*, and local naming row* N*. Neither route can expose supplied content, host proof, quotient representative, hidden theorem, closure principle, internalized object, or generated witness.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple downstream refusal uniqueness`

Proof. First fix the source side. Apply Definition 543.110 to any downstream externality handoff. The handoff begins on the displayed socket and gate-question rows and then has only the route S, R, G, L, H, C, P, N available before refusal reading.

Next read the refusal interface. By Definition 543.111, the same socket and gate-question rows force the handoff through the same refusal gate and ledger rows G, L before the handoff is public.

Now compare the structural tail. The transport-naming exhaustion theorem Definition 543.112 says that H, C, P, N only replay the displayed refusal boundary. Therefore a second route with the same S and R has no alternative transport, continuation, provenance, or local naming row to select.

Finally apply terminal exhaustion, Definition 543.113, together with the sibling socket and gate surfaces Definition 536.5 and Definition 715.3. These keep both routes on the visible boundary

rows and exclude supplied content, host proof, quotient representatives, hidden theorems, closure principles, internalized objects, and generated witnesses. □

Theorem 543.115 (ApophaticName root bridge tuple audit normal form)**.** *Every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple has audit normal form exactly*

$$S, R, G, L, H, C, P, N.$$

The source and classifier read the socket, gate-question, and refusal rows; the ledger and noninternalization rows prevent supplied-content export; and terminal exhaustion leaves no hidden supply, quotient representative, generated witness, host datum, theorem cache, or closure principle.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple audit normal form`

Proof. First expose the source and classifier rows. Apply Definition 543.106 and Definition 543.107; both reads factor through S, R, G, L, H, C, P, N and never through hidden supply or host realization data.

Next bind the ledger and noninternalization boundary. Use Definition 543.108 and Definition 543.109. These rows force downstream package reads through the refusal ledger and prevent the requested supply from becoming an internal object, generated witness, host datum, quotient representative, hidden theorem, or closure principle.

Now assemble the route interface. The source-route, gate-refusal, and transport-naming rows in Definition 543.110, Definition 543.111, and Definition 543.112 keep H, C, P, N attached to the same visible socket, gate, refusal, and ledger rows.

Finally apply terminal exhaustion and downstream refusal uniqueness, Definition 543.113 and Definition 543.114, together with the sibling ApophaticSocket and ApophaticGateQuestion surfaces Definition 536.5 and Definition 715.3. No second route can add supplied content, quotient representatives, generated witnesses, host data, theorem caches, or closure principles, so the audit normal form is exactly S, R, G, L, H, C, P, N. □

Corollary 543.116 (ApophaticName root bridge tuple source strict obstruction)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *root bridge tuple, the obstruction carried by the gate-question and refusal rows is strictly local to the displayed route*

$$S, R, G, L, H, C, P, N.$$

It blocks exactly the downstream converse or reuse attempt that would reread the handoff source as an internalized object, supplied dependency, generated witness, host datum, quotient representative, hidden theorem, closure principle, or hidden external validation. It does not assert a global impossibility theorem, a host theorem, or an ambient validation result outside the accepted tuple.

Proof. Start with the tuple source, Definition 543.106. It exposes S, R, G, L, H, C, P, N before any downstream refusal read and states that no consumer receives a tuple whose first readable coordinate is an internalized object, generated witness, host datum, quotient representative, hidden theorem, or closure principle. Thus the only source available to a consumer-facing obstruction is the displayed finite tuple.

Next apply the gate-refusal interface, Definition 543.111. It forces every externality handoff to read the gate-question row R and refusal rows G, L before the handoff is public, and it identifies the interface as the same route S, R, G, L, H, C, P, N rather than a supplied object, host proof, generated witness, quotient representative, hidden theorem, or closure principle.

The strictness follows by separating the two directions. In the permitted direction, a downstream consumer may cite the socket, gate-question, refusal, ledger, transport, continuation, provenance, and local naming rows as the public source of the handoff. In the barred converse direction, the same consumer tries to turn that handoff back into supplied content or to reuse H, C, P, N as a second validation channel. The source theorem leaves no first coordinate for such a rereading, and the gate-refusal interface has already consumed R, G, L as refusal rows before public handoff.

Therefore the obstruction blocks only that named converse or reuse route through the accepted root bridge tuple. Since every cited row remains inside S, R, G, L, H, C, P, N, the proof supplies no statement about all possible ambient hosts, no theorem object outside the tuple, and no hidden external validation beyond the local refusal boundary. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge tuple source strict obstruction`

Theorem 543.117 (ApophaticName root StdBridge premise surface)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the fixed finite tuple route reaches a root-facing StandardBridge *request only after four displayed rows are present: the boundary-request image row, the refusal readback row, the componentwise* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *transport row, and the* ChapterTasteGate*-facing refusal tuple. Thus the bridge premise is the public tuple surface* S, R, G, L, H, C, P, N *together with those rows, not an internal object, host proof, quotient representative, hidden theorem, generated witness, or closure principle.*

Proof. First apply the boundary-request image row, Definition 543.44. It confines each accepted consumer image of the request to the finite tuple S, R, G, L, H, C, P, N.

Next use the refusal readback row, Definition 543.46. It sends every accepted image-row read back to the corresponding finite BHist component and prevents the readback from becoming supplied content.

Now apply componentwise NameCert transport, Definition 543.49. The local naming row replays the image and readback rows across the displayed transport route without adding a hidden coordinate.

The ChapterTasteGate-facing refusal tuple is therefore exactly the same displayed packet: socket, request, refusal gate, ledger, transport, continuation, provenance, and local naming. A root-facing StandardBridge request can consume that premise surface only after all these rows are visible. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root stdbridge premise surface`

Theorem 543.118 (ApophaticName root reflection-axis refusal)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the root tuple admits only the reflection-axis rows carried by the refusal boundary. It supplies the socket row S*, request row* R*, refusal gate* G*, refusal ledger* L*, componentwise transport* H*, continuation route* C*, provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *row* N*, but it supplies no object, host proof, quotient representative, hidden theorem, generated witness, or closure principle outside that boundary.*

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root reflection axis refusal`

Proof. Begin with the root bridge tuple source, Definition 543.106. It exposes all source rows before any downstream refusal read and rules out a first readable coordinate that is already an internalized object.

Use the root bridge tuple ledger, Definition 543.108. The ledger and non-internalization rows must be read before any externality handoff, so the handoff remains a refusal package rather than a supplied dependency.

Finally apply boundary citation universal factorization, Definition 543.126. Every downstream citation factors through the socket, gate, ledger, and provenance package S, R, G, L, H, C, P, N.

These three rows leave the reflection axis with the displayed refusal boundary only. There is no remaining carrier position from which a supplied object, host proof, quotient representative, hidden theorem, generated witness, or closure principle could be obtained. □

Theorem 543.119 (ApophaticName root bridge counter surface)**.** *After the boundary-request image row, refusal readback row, componentwise* $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ *transport row, and* ChapterTasteGate*-facing refusal tuple have all been displayed for an accepted packet*

$$A = (S, R, G, L, H, C, P, N),$$

any failed bridge attempt must locate an incompatibility between that refusal-axis requirement and the standard reflection schema. Absence of the tuple, image row, readback row, componentwise transport row, or refusal row is only a failed premise for the fixed finite tuple route, not a bridge counter-surface.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root bridge counter surface`

Proof. Start from the root StdBridge premise surface, Definition 543.117. It identifies the tuple, image, readback, componentwise transport, and refusal rows as the rows that must be present before the fixed finite tuple route is tested.

Next use root reflection-axis refusal, Definition 543.118. Once the rows are present, the only available reflection-axis content is the refusal boundary itself, with no supplied object or hidden theorem behind it.

Therefore a failed bridge attempt after these rows are displayed must be a disagreement with the standard reflection schema at the refusal axis. If one of the tuple, readback, transport, or refusal rows is absent, the route has not reached the bridge test and the failure is merely a missing premise. □

Corollary 543.120 (ApophaticName root StdBridge premise strict obstruction)**.** *Let* $A = (S, R, G, L, H, C, P, N)$ *be an accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet. Any displayed failure, refusal, separation, or countermodel row used against the root-facing* StandardBridge *premise is a strict local obstruction. It blocks only the named converse or reuse route whose consumer read tries to turn the displayed premise surface into an internal object, host proof, quotient representative, hidden theorem, generated witness, closure principle, ambient countermodel, or hidden external validation. It cannot be reinterpreted as a global impossibility theorem, a host theorem, or an external validation result outside the accepted packet.*

Proof. Start with the root StdBridge premise surface, Definition 543.117. A root-facing StandardBridge request is not reached from an unstructured object: it is reached only after four displayed rows are visible, namely the boundary-request image row, the refusal readback row, the componentwise $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ transport row, and the ChapterTasteGate-facing refusal tuple. Thus any

consumer-facing use of a displayed negative row against this premise must first consume the finite premise surface S, R, G, L, H, C, P, N together with those four rows.

Apply the root reflection-axis refusal theorem, Definition 543.118. Its source, ledger, and citation factorization rows leave the reflection axis with only the socket row S, request row R, refusal gate G, refusal ledger L, componentwise transport H, continuation route C, provenance row P, and local $\mathsf{NameCert}_{\mathsf{ApophaticName}^{\uparrow}}$ row N. The same theorem excludes object supply, host proof, quotient representative, hidden theorem, generated witness, and closure principle outside that refusal boundary.

Now separate the permitted forward use from the barred converse or reuse use. In the permitted direction, the consumer may cite the visible boundary-request image, readback, transport, and refusal-tuple rows as the premise surface for the root-facing bridge request. In the barred converse direction, the consumer tries to reread that same surface as a stronger coordinate: an internal object behind S, a supplied dependency behind R, a host proof or hidden theorem behind G and L, a quotient representative or generated witness behind the readback, a closure principle behind H and C, or an external validation channel behind P and N. The premise-surface theorem gives no such coordinate, and the reflection-axis refusal theorem says that the only reflection-axis content is the displayed refusal boundary.

Therefore a displayed failure, refusal, separation, or countermodel row can obstruct exactly the named converse or reuse route attached to one of those displayed premise rows. If a proposed interpretation asks for a global impossibility theorem, a host theorem, an ambient countermodel detached from A, or hidden external validation, it asks for an unlisted coordinate. The accepted packet rejects that interpretation at the local refusal boundary, so the obstruction remains strict and local to the root StandardBridge premise surface. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root stdbridge premise strict obstruction`

Theorem 543.121 (ApophaticName root refusal ledger exactness)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the root-facing refusal rows G, L classify every barred conversion from socket request to generated content, assumed proposition, quotient representative, hidden theorem, host realization, or closure principle. A root consumer may cite the visible socket S and the request row R, but every such citation is answered by the displayed refusal gate and ledger, transported by H, routed by C, packaged by P, and named by N.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root refusal ledger exactness`

Proof. Start with the refusal ledger theorem, Definition 543.2. It records the barred internalization cases as refusal rows rather than as absent ambient assumptions.

Next apply gate ledger exactness, Definition 543.32. The gate row G and ledger row L are the rows that answer conversion attempts from the visible socket request into supplied content or hidden proof objects.

Finally use request ledger classifier exhaustion, Definition 543.38. Since every permitted boundary read of S is classified through R, G, L, no root read can leave the finite packet S, R, G, L, H, C, P, N and obtain one of the barred objects. □

Theorem 543.122 (ApophaticName root socket request totality)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every root read of the socket row S must also read the request row R, refusal gate G, refusal ledger L, transport row H, continuation row C, provenance row P, and local naming row N. Thus the root-facing socket is a complete request boundary and not a partial handle that can be completed by an external generated object, assumed proposition, quotient representative, hidden theorem, host realization, or closure principle.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameRootSocketRequestTotality`

Proof. Begin with root consumer socket request totality, Definition 543.100. It already identifies root consumption of the named externality with the complete socket/request/refusal package.

Use socket request gate exactness, Definition 543.40. This binds every visible read of S to the request row R, the gate row G, and the ledger row L.

The sibling socket and gate boundaries close the remaining routes. Apply Definition 536.5 to keep the socket citation visible, and apply Definition 715.3 to prevent the gate from turning into a supplied object. The transport, continuation, provenance, and naming rows then remain attached to the same packet. □

Theorem 543.123 (ApophaticName root boundary provenance export)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every downstream export from the root boundary receives only the finite provenance package S, R, G, L, H, C, P, N. The export may cite the socket request, refusal gate, refusal ledger, componentwise transport, continuation route, package provenance, and local name, but it does not export generated content, assumed propositions, quotient representatives, hidden theorems, host realizations, or closure principles.

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier root boundary provenance export`

Proof. First use the consumer citation boundary, Definition 543.41. It says that downstream citations of the accepted packet factor through the displayed boundary package and do not receive supplied objects.

Next apply the downstream noninternalization package, Definition 543.13. The same refusal package bars the internalization cases at the downstream interface.

Finally repack the rows with the named externality NameCert package, Definition 543.42. Carrier admission, gate exactness, ledger nonescape, transport, citation, provenance, and naming are all rows of S, R, G, L, H, C, P, N, so the exported provenance is exactly that finite package. □

Theorem 543.124 (ApophaticName socket gate ledger pullback)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the sibling $\mathsf{ApophaticSocket}^{\uparrow}$ *row and* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *row pull back to the displayed request row R, refusal gate G, and refusal ledger L before any downstream read of the named externality. Thus the socket and gate consumers cite the same boundary packet S, R, G, L, H, C, P, N, and no downstream consumer receives a generated witness, host datum, quotient representative, hidden theorem, or closure principle from either sibling surface.*

Proof. Begin with socket request gate exactness, Definition 543.40. It binds every visible socket request for the accepted name to the displayed rows R, G, L.

The sibling socket row is compatible with this boundary by Definition 536.3. It identifies the socket consumer with the public gate interface rather than with an internal supplied object.

The gate-question row is forced onto the same name boundary by Definition 715.4. Hence both sibling surfaces pull back through R, G, L before downstream reading, and the remaining rows H, C, P, N only transport, route, package, and name that same refusal boundary. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier socket gate ledger pullback`

Theorem 543.125 (ApophaticName refusal ledger fiber product)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

the refusal ledger is the finite fiber product of the socket request row R and the visible refusal gate G over the common boundary data G, L, H, C, P, N. This fiber product exports only the boundary rows of the packet and exports no generated witness, host datum, quotient representative, hidden theorem, or closure principle.

Proof. First use root refusal ledger exactness, Definition 543.121. It makes G, L the rows that classify conversion attempts from the visible socket request into the barred internal objects.

Next apply root ledger coverage, Definition 543.103. Every downstream package read is already covered by the displayed ledger rows and their attached transport, continuation, provenance, and naming data.

Finally apply the socket gate ledger pullback, Definition 543.124. Since the sibling socket and gate rows meet on the same R, G, L boundary, the ledger is exactly the finite boundary fiber product over G, L, H, C, P, N, with no additional export coordinate. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier refusal ledger fiber product`

Theorem 543.126 (ApophaticName boundary citation universal factorization)**.** *For every accepted* $\mathsf{ApophaticName}^{\uparrow}$ *packet*

$$A = (S, R, G, L, H, C, P, N),$$

every downstream boundary citation of the named externality universally factors through the socket/gate/ledger pullback and then through the provenance package S, R, G, L, H, C, P, N. Consequently a downstream chapter may cite the accepted name only through this package and cannot factor the citation through generated content, host data, quotient representatives, hidden theorems, or closure principles.

Proof. Start with root boundary package exhaustion, Definition 543.105. It says that downstream root consumers receive exactly the finite packet S, R, G, L, H, C, P, N.

The provenance export theorem, Definition 543.123, identifies the exported object as the same finite provenance package and not as an internal supplied object.

Use socket gate ledger pullback and refusal ledger fiber product, Definition 543.124 and Definition 543.125. These two results give the common factorization stage for the sibling socket, visible gate, and ledger rows, so every downstream citation factors through that stage before it reaches the package S, R, G, L, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.ApophaticNameUp.ApophaticNameCarrier boundary citation universal factorization`

Chapter 544

A Concrete Naming Certificate for $\mathsf{ZCarry}^{\uparrow}$

The $\mathsf{ZCarry}^{\uparrow}$ interface packages the displayed Zeckendorf carry row `word_011` $\to$ `word_100` as a finite BEDC naming surface. The packet records the carry generator, the source non-normality witness, the target normality witness, the non-hsame boundary, transport rows, continuation routes, package provenance, and the local naming row. It licenses the carry as a classifier and gives no route to treating the two histories as kernel-equal.

Definition 544.1 (ZCarry finite carry packet)**.** *A* $\mathsf{ZCarry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (h, k, G, N_h, N_k, H, C, P, N)$$

with the following displayed coordinates:

1. *h is the source history row* `word_011`*;*
2. *k is the target history row* `word_100`*;*
3. *G is the generated carry row* $\mathsf{ZCarry}(h, k)$*;*
4. *N_h is the source ledger row witnessing* $\neg\mathsf{ZNormal}(h)$*;*
5. *N_k is the target ledger row witnessing* $\mathsf{ZNormal}(k)$*;*
6. *H records the non-*hsame *boundary* $\neg\mathsf{hsame}(h, k)$ *together with the componentwise* hsame *transports that preserve the displayed rows separately;*
7. *C records the displayed* Cont *routes for source inspection, target inspection, carry readback, normality readback, non-*hsame *readback, and NameCert comparison;*
8. *P is the* Pkg *provenance row naming* $\mathsf{ZeckendorfNormal}^{\uparrow}$*,* $\mathsf{ZCarry}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*,* $\mathsf{NameCert}$*, and the generated carry row;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ZCarry}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only by the displayed rows $h, k, G, N_h, N_k, H, C, P, N$. No coordinate identifies h and k, quotienting histories or replacing the carry classifier by hsame*.*

Lean4 (definition) `BEDC.Derived.ZCarryUp.ZCarryFiniteCarryPacket`

Theorem 544.2 (ZCarry finite NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ZCarry}^{\uparrow}}$ *obligation surface consists exactly of carrier admission by Definition 544.1, the generated carry row G, the source*

*non-normal row N_h, the target normal row N_k, the non-*hsame *boundary row H, the displayed* Cont *routes C, the* Pkg *provenance row P, and the local naming row N.*

Proof. Project the finite packet. Each row required by the carry certificate appears as a coordinate before any consumer can read the classifier.

The generator row G fixes the only displayed carry window. The two normality rows record the source and target sides of that window, while H records that the window is not an hsame identification.

The routes C, provenance row P, and local naming row N then repack the same finite surface as a $\mathsf{NameCert}_{\mathsf{ZCarry}^\uparrow}$ obligation surface. Since the carrier has no equality or quotient coordinate, no further object can be exported by the certificate. □

Lean4 ✓ `BEDC.Derived.ZCarryUp.ZCarryFiniteCarryPacket obligation surface`

Theorem 544.3 (ZCarry carry-not-hsame boundary)**.** *For every accepted* $\mathsf{ZCarry}^\uparrow$ *packet* $Z = (h, k, G, N_h, N_k, H, C, P, N)$*, the carry row G is stable only as a classifier row. Its ledger includes* $\neg\mathsf{hsame}(h, k)$*, so the displayed carry from* `word_011` *to* `word_100` *cannot be consumed as history-sameness.*

Proof. Read the generated carry row G. By the Zeckendorf carry theorem Definition 9345.4, every instance of $\mathsf{ZCarry}(h, k)$ carries the boundary $\neg\mathsf{hsame}(h, k)$.

The packet stores this boundary in H and routes it through C. Therefore a consumer can transport the carry classifier only together with the recorded non-hsame witness, so the carry row cannot become a kernel equality. □

Theorem 544.4 (ZCarry normal-target ledger)**.** *For every accepted* $\mathsf{ZCarry}^\uparrow$ *packet* $Z = (h, k, G, N_h, N_k, H, C, P, N$ *the target history is normal and the source history is non-normal. The target row is* `word_100` *with* $N_k : \mathsf{ZNormal}(k)$*, while the source row is* `word_011` *with* $N_h : \neg\mathsf{ZNormal}(h)$*.*

Proof. The generator row G identifies the displayed carry window. Applying Definition 9345.5 reads the target normality witness, and applying Definition 9345.6 reads the source non-normality witness.

The packet stores those two reads as N_k and N_h. Transport through H and C preserves the target and source ledgers as separate rows, so normality can be reported only with the same displayed source-target orientation. □

Theorem 544.5 (ZCarry Zeckendorf normal sibling dependency)**.** *For every accepted* $\mathsf{ZCarry}^\uparrow$ *packet* $Z = (h, k, G, N_h, N_k, H, C, P, N)$*, the source non-normal row N_h and target normal row N_k are read through the Zeckendorf normal-form sibling surface of chapter 278 before the local carry packet assembles its* $\mathsf{NameCert}_{\mathsf{ZCarry}^\uparrow}$ *boundary. The* $\mathsf{ZCarry}^\uparrow$ *packet supplies the generated carry classifier, the non-*hsame *ledger, and the local transport, continuation, provenance, and naming rows; it does not duplicate the sibling normal-word evidence.*

Proof. Project the accepted packet as $h, k, G, N_h, N_k, H, C, P, N$. The two normality rows are separate fields of the local carrier, while G and H record the carry classifier and the non-hsame boundary.

Apply Definition 544.4. It reads N_k as the target normal row and N_h as the source non-normal row with the displayed source-target orientation.

The normal-word evidence used by those rows is supplied through the sibling chapter chapter 278. The local packet then contributes H, C, P, N and the generated carry row G, so the NameCert boundary consumes the sibling normal-form surface without replacing it. □

Theorem 544.6 (ZCarry NameCert assembly)**.** *The carrier of Definition 544.1, the obligation surface of Definition 544.2, the non-*hsame *boundary of Definition 544.3, and the normal-target ledger of Definition 544.4 assemble the concrete* $\mathsf{NameCert}_{\mathsf{ZCarry}^{\uparrow}}$ *packet for the displayed Zeckendorf carry classifier.*

Proof. Bind the carrier rows $h, k, G, N_h, N_k, H, C, P, N$. These rows expose the source, target, generator, normality witnesses, non-hsame boundary, transport routes, provenance, and local name.

Apply the finite obligation theorem to identify the public certificate surface. Apply the carry-not-hsame boundary theorem to keep the classifier separate from history-sameness. Apply the normal-target ledger theorem to retain the target-normal and source-non-normal rows.

Repacking these rows gives the local naming certificate. The assembly is exactly the concrete packet recorded by the Lean-side object zCarry_namecert. □

Lean4 ✓ `BEDC.Derived.AxisZeckendorf.Carry.zCarry namecert`

Corollary 544.7 (ZCarry licensed classifier boundary)**.** *The* $\mathsf{ZCarry}^{\uparrow}$ *interface is licensed by the finite packet of Definition 544.6. Any downstream use of the displayed carry must cite the generated carry row, the normality ledgers, the non-*hsame *boundary, the displayed* Cont *routes, the* Pkg *provenance, and the local* NameCert *row; it may not read the carry as* hsame *or as a primitive kernel rewrite.*

Proof. Use the assembled $\mathsf{NameCert}_{\mathsf{ZCarry}^{\uparrow}}$ packet. Its public rows are exactly the carrier coordinates and obligation rows named above.

The non-hsame boundary is part of the exported ledger. Hence a consumer that uses the carry classifier also receives the evidence preventing a kernel-equality reading, and no primitive rewrite row is available in the packet. □

Lean4 ✓ `BEDC.Derived.ZCarryUp.ZCarryUp single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{ZCarry}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ZCarry}^{\uparrow}$ packet is generated from the displayed Zeckendorf carry row, source non-normal ledger, target normal ledger, non-hsame boundary, componentwise transports, displayed continuation routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ZCarry}^{\uparrow}}$, maturePackageClosed)

Scope closed: The checked zCarry_namecert assembly of Definition 544.6 and the licensed boundary of Definition 544.7 bind the public $\mathsf{ZCarry}^{\uparrow}$ classifier boundary to the bridge-readable package rows G, N_h, N_k, H, C, P, N for the displayed Zeckendorf carry.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ZCarry}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.AxisZeckendorf.Carry.zCarry\_namecert`

Bridge status: none

Not claimed: This chapter does not identify the source and target histories by hsame, does not install quotient rewriting, and does not close arbitrary Zeckendorf carry generation.

Upgrade path: No further theory-axis upgrade is claimed here; remaining work is bridge checking for the same displayed generated-carry, normality, non-hsame, Cont, Pkg, and NameCert packet.

Chapter 545

A Concrete Naming Certificate for $\mathsf{TasteGateAdmission}^{\uparrow}$

The $\mathsf{TasteGateAdmission}^{\uparrow}$ packet is the concrete NameCert surface for admitting an AI-origin chapter into the BEDC horizon. It packages the candidate chapter identity, origin row, naming surface, chapter taste gate, event-flow witness, ground-compiler theorem references, transport rows, continuation routes, package provenance, and refusal ledger into one finite audit object.

The admission packet consumes the apophatic refusal discipline of chapter 543, the kernel acceptance trace of chapter 557, and the stability boundary of chapter 564. Those siblings supply refusal, trace, and stability rows for the visible $X, O, N, T, E, R, H, C, P, G$ admission packet.

The admission packet supplies the candidate-admission row consumed by chapter 563: the compiler witness reads the displayed admission row as its chapter-gate input, while the audit refusal surface of chapter 526 bounds the same row by refusing hidden semantic approval outside the finite witness, compiler-reference, replay, and provenance routes.

Definition 545.1 (TasteGateAdmission carrier)**.** *A* $\mathsf{TasteGateAdmission}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, O, N, T, E, R, H, C, P, G)$$

with the following displayed rows:

1. *X is the candidate chapter identity row, recording the chapter label, local carrier name, and the paper site whose admission is being requested;*
2. *O is the origin row, recording that the candidate enters through the AI-origin track rather than through inherited human-curated consensus;*
3. *N is the visible* $\mathsf{NameCert}$ *surface proposed for the candidate chapter, including its carrier, classifier, pattern, ledger, and non-escape rows;*
4. *T is the* $\mathsf{ChapterTasteGate}$ *witness row, recording the conservativity, no-hidden-input, round-trip, and layer-separation obligations exposed by the candidate;*
5. *E is the event-flow witness row, displaying the finite* $\mathsf{GroundCompiler}$ *event-flow image from which the candidate tokens are read;*
6. *R records the ground-compiler theorem references used by the witness, including the no-hidden-input, round-trip, and source-channel separation routes available to the admission check;*
7. *H stores componentwise* hsame *transports for $X, O, N, T, E, R, C, P, G$;*

8. *C records the displayed* Cont *routes by which the admission check reads the NameCert surface, the taste-gate witness, the event-flow witness, and the compiler reference row;*
9. *P is the* Pkg *provenance over* BHist, NameCert, ChapterTasteGate, GroundCompiler, *event-flow witnesses, ground-compiler theorem references,* hsame, Cont, *and local naming;*
10. *G is the GAP refusal ledger, recording failed admission attempts whose NameCert row, taste-gate row, event-flow row, compiler-reference row, transport row, continuation row, or provenance row is absent.*

The carrier has no coordinate for hidden prompt state, an oracle classifier, an unrecorded compiler theorem, host-side chapter approval, or a prose-only admission decision.

Lean4 ✓ `BEDC.Derived.TasteGateAdmissionUp.TasteGateAdmissionTasteGate single carrier alignment`

Theorem 545.2 (TasteGateAdmission NameCert obligations)**.** *For every accepted* $\mathsf{TasteGateAdmission}^{\uparrow}$ *carrier*

$$A = (X, O, N, T, E, R, H, C, P, G),$$

the local $\mathsf{NameCert}_{\mathsf{TasteGateAdmission}^{\uparrow}}$ *surface consists exactly of carrier admission for A, candidate identity through X, AI-origin exposure through O, candidate NameCert exposure through N,* ChapterTasteGate *exposure through T, event-flow exposure through E, ground-compiler reference exposure through R, componentwise transport through H, replay and admission routes through C, package provenance through P, and refused-case accounting through G.*

Proof. Carrier admission is projection from Definition 545.1. The packet exposes exactly the chapter identity, origin, NameCert surface, taste-gate witness, event-flow witness, compiler references, transport, continuation, provenance, and refusal rows.

The candidate and origin obligations are the rows X and O. They identify the paper site being admitted and record that the admission is evaluated through the AI-origin track.

The naming and taste-gate obligations are the rows N and T. A downstream reader can inspect the candidate's local NameCert surface and its four taste-gate obligations without importing a second chapter object outside the packet.

The compiler-facing obligations are the rows E and R. They record the event-flow witness and the ground-compiler theorem references that make the taste-gate rows auditable.

Finally H, C, P, G preserve the same admission object under transport, replay, provenance, and refused-case accounting. Since every admissible read is routed through those rows, the packet supplies the whole local $\mathsf{NameCert}_{\mathsf{TasteGateAdmission}^{\uparrow}}$ surface and no hidden approval channel. □

Theorem 545.3 (TasteGateAdmission ground compiler witnesses)**.** *In every accepted* $\mathsf{TasteGateAdmission}^{\uparrow}$ *carrier, the* ChapterTasteGate *witness row T is read only together with the event-flow row E and the ground-compiler reference row R. Thus no-hidden-input, round-trip, and layer-separation claims are admitted only through displayed finite event-flow evidence and named compiler theorem references, not through an unrecorded semantic judgment about the candidate chapter.*

Proof. Start from the carrier of Definition 545.1. The only taste-gate coordinate is T, and its compiler-facing evidence is displayed in E and R.

The no-hidden-input and round-trip reads pass through E before they can be consumed. The row E is the finite event-flow witness, so the admission check sees the displayed compiler image rather than an external account of the candidate's tokens.

The layer-separation and compiler-reference reads pass through R. This row records the named ground-compiler theorem references used by the chapter-level witness.

Transport and replay are then carried by H and C, with package provenance in P. These rows preserve the same witness surface and do not add an unrecorded compiler theorem or host-side approval step. □

Theorem 545.4 (TasteGateAdmission non-escape)**.** *Every accepted* $\mathsf{TasteGateAdmission}^{\uparrow}$ *admission route factors through the finite rows*

$$(X, O, N, T, E, R, H, C, P, G).$$

The route may export that the candidate chapter has an AI-origin admission packet with a displayed NameCert surface, ChapterTasteGate *witness, ground-compiler witness, audit route, transport route, package provenance, GAP refusal ledger, and local naming data. It cannot export hidden prompt state, oracle approval, unlisted compiler facts, selected host semantics, or a chapter object not named by the packet.*

Proof. Project an accepted admission route through the carrier. The route has access only to the ten displayed rows $X, O, N, T, E, R, H, C, P, G$.

Use Definition 545.2 to account for local naming, candidate identity, origin, taste-gate inspection, compiler evidence, replay, provenance, and refused-case accounting.

Use Definition 545.3 for the compiler-facing part. It keeps every taste-gate read attached to the finite event-flow witness and named compiler-reference rows.

Since the carrier has no coordinate for hidden prompt state, oracle approval, unlisted compiler facts, selected host semantics, or an unnamed chapter object, no exported admission route can supply one. □

Theorem 545.5 (TasteGateAdmission carrier source obligation)**.** *Every accepted* $\mathsf{TasteGateAdmission}^{\uparrow}$ *admission read has the finite source carrier*

$$(X, O, N, T, E, R, H, C, P, G).$$

These are exactly the candidate identity, AI-origin, candidate NameCert*,* ChapterTasteGate*, event-flow, ground-compiler reference,* hsame*,* Cont*,* Pkg*, and GAP-refusal rows displayed by the admission packet. No admission carrier is supplied by hidden prompt state, oracle approval, host-side chapter acceptance, or an unlisted compiler theorem.*

Proof. Project the read through Definition 545.1. The carrier definition displays precisely the ten finite rows $X, O, N, T, E, R, H, C, P, G$ and contains no additional admission coordinate.

Apply Definition 545.2. The local NameCert surface consumes exactly those rows as carrier, identity, origin, taste-gate, compiler, transport, replay, provenance, and refusal data.

Use Definition 545.3 for the compiler-facing coordinates and Definition 545.4 for the exclusion clause. Together they keep every accepted read inside the displayed finite source and rule out hidden prompt state, oracle approval, host-side acceptance, and unlisted compiler facts. □

Theorem 545.6 (TasteGateAdmission classifier stability obligation)**.** *If two accepted* $\mathsf{TasteGateAdmission}^{\uparrow}$ *carriers are compared by the admission classifier, the comparison transports only through their displayed* ChapterTasteGate *rows, event-flow witness rows, ground-compiler reference rows,* hsame *rows, and* Cont *rows. It may carry the visible candidate* NameCert*, package provenance, and refusal-ledger coordinates along those routes, but it cannot introduce hidden prompt state, oracle approval, selected host semantics, or an unlisted compiler fact.*

Proof. Start with the carrier rows of Definition 545.1. The classifier-facing coordinates are the taste-gate row T, the event-flow row E, the compiler-reference row R, and the displayed transport and replay rows H and C.

Use Definition 545.2 to keep the candidate NameCert, package provenance, and refusal ledger attached to the same finite carrier. No second admission object is introduced during this transport.

Apply Definition 545.3. It requires the taste-gate comparison to read the displayed event-flow and compiler reference rows before the comparison can be consumed.

Finally apply Definition 545.4. Since the carrier has no hidden prompt, oracle, host-semantics, or unlisted-compiler coordinate, classifier stability cannot transport through one. □

Theorem 545.7 (TasteGateAdmission ledger descent obligation)**.** *Every refused or accepted* $\mathsf{TasteGateAdmission}^{\uparrow}$ *admission read descends only through the displayed GAP/refusal ledger G together with the carrier rows it records. Accepted reads descend through the same finite admission packet, while refused reads record which candidate* NameCert*,* ChapterTasteGate*, event-flow, compiler-reference,* hsame*,* Cont*, or* Pkg *row is absent. Neither kind of read can supply hidden prompt state, oracle approval, or unlisted compiler facts.*

Proof. Inspect the refusal coordinate in Definition 545.1. The row G is the only GAP/refusal ledger, and it is indexed by the same finite carrier rows $X, O, N, T, E, R, H, C, P$.

For accepted reads, apply Definition 545.5. The accepted route descends through the displayed source rows before it can be consumed by the admission check.

For refused reads, use Definition 545.2. The ledger records absence of one of the displayed NameCert, taste-gate, event-flow, compiler-reference, transport, continuation, provenance, or local naming rows.

The ground-compiler witness theorem accounts for compiler-facing refusals, and Definition 545.4 supplies the exclusion clause. Thus the ledger cannot manufacture hidden prompt state, oracle approval, or unlisted compiler facts. □

Closure status for $\mathsf{NameCert}_{\mathsf{TasteGateAdmission}^{\uparrow}}$.

Constructive story: A $\mathsf{TasteGateAdmission}^{\uparrow}$ packet is generated from a candidate chapter identity row, AI-origin row, candidate NameCert surface, ChapterTasteGate witness, event-flow witness, ground-compiler reference row, componentwise transport, continuation routes, package provenance, and GAP refusal ledger.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TasteGateAdmission}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 545.1, Definition 545.2, Definition 545.3, Definition 545.4, Definition 545.5, Definition 545.6, and Definition 545.7 with

Lean4 ✓ `BEDC.Derived.TasteGateAdmissionUp.taste gate`

expose the seed carrier, local NameCert surface, ground-compiler witness rows, non-escape boundary, and explicit TasteGate obligation rows as a public AI-origin admission packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TasteGateAdmission}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.TasteGateAdmissionUp.TasteGateAdmissionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove the candidate chapter's mathematical content, certify arbitrary host semantics, or close bridge checking.

Upgrade path: No further paper-side theory closure grade remains; only independent bridge checking can strengthen the recorded status.

Chapter 546

A Concrete Naming Certificate for $\mathsf{KernelAuditWitness}^{\uparrow}$

The $\mathsf{KernelAuditWitness}^{\uparrow}$ surface is the concrete NameCert realization of Lean kernel acceptance as a BEDC audit witness. It packages the term generator, the accepted candidate, the environment ledger, axiom-ancestry report, replay route, provenance, and paper-marker name into one finite packet. The packet refines the socket-boundary discipline of chapter 543 and the accepted-declaration ledger of chapter 549 into a theorem-marker audit surface. The packet does not certify the Lean kernel itself; it records the audit surface by which BEDC reads accepted Lean declarations as checked ledger rows.

Definition 546.1 (KernelAuditWitness carrier)**.** *A* $\mathsf{KernelAuditWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, A, L, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the generator-and-candidate row, recording the source declaration, elaborated candidate, claimed type, and local build context that present a Lean object to the kernel;*
2. *A is the kernel-acceptance stamp row, recording that the candidate in G is accepted under the displayed environment and enters the checked-declaration surface;*
3. *L is the environment ledger row, recording the accepted name, its type, its body or proof object when visible, and the environment position from which later resolution reads the declaration;*
4. *R is the axiom-ancestry and report row, recording the transitive dependency report used by the strict purity audit, including the empty-report case for BEDC-internal theorem content;*
5. *H records componentwise* hsame *transport for the generator, candidate, acceptance stamp, ledger entry, ancestry report, replay route, provenance, and local naming rows;*
6. *C records the* Cont *replay routes for rebuilding the candidate, re-reading the accepted ledger row, querying the ancestry report, and resolving paper-side markers against the displayed name;*
7. *P is the* Pkg *provenance over* BHist*, Lean declaration names, build replay, kernel acceptance, environment ledgers, strict axiom-ancestry reports,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{KernelAuditWitness}^{\uparrow}}$ *row binding the paper-visible name to the finite audit packet.*

The carrier has no coordinate for an independent semantic endorsement of the surrounding prose, no coordinate for a second checker beneath the Lean kernel, and no coordinate that can turn a nonempty forbidden ancestry report into BEDC-internal theorem content.

Lean4 ✓ `BEDC.Derived.KernelAuditWitnessUp.KernelAuditWitnessTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.KernelAuditWitnessUp.KernelAuditWitnessUp`

Theorem 546.2 (KernelAuditWitness NameCert obligations)**.** *For every accepted* $\mathsf{KernelAuditWitness}^{\uparrow}$ *carrier*

$$K = (G, A, L, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KernelAuditWitness}^{\uparrow}}$ *surface consists exactly of carrier admission for* K*, candidate exposure through* G*, kernel-stamp exposure through* A*, environment-ledger exposure through* L*, axiom-ancestry exposure through* R*, componentwise transport through* H*, replay and marker-resolution routes through* C*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.KernelAuditWitnessUp.KernelAuditWitnessNameCert obligations`

Proof. Carrier admission is projection from Definition 546.1. The packet exposes exactly the generator, stamp, ledger, ancestry, transport, continuation, provenance, and local naming rows.

The candidate and stamp obligations are the rows G and A. A downstream reader can inspect which object was presented to the kernel and which acceptance event is being recorded, but it receives no separate certificate outside those rows.

The ledger and ancestry obligations are the rows L and R. They record where the accepted name is resolved and what transitive dependency report accompanies it, including the strict empty-report case when the declaration is read as BEDC-internal theorem content.

Finally H, C, P, N preserve the same packet under transport, replay, provenance, and local naming. Repacking these rows gives the whole local $\mathsf{NameCert}_{\mathsf{KernelAuditWitness}^{\uparrow}}$ surface, and there is no remaining coordinate from which a consumer could import an unlisted checker, hidden proof source, or prose-only endorsement. □

Theorem 546.3 (KernelAuditWitness non-contamination)**.** *If the ancestry row* R *of an accepted* $\mathsf{KernelAuditWitness}^{\uparrow}$ *carrier reports a forbidden dependency, then the packet keeps that dependency in the report row and does not classify the declaration as BEDC-internal theorem content. If* R *is the empty strict-purity report, then downstream readers may consume the accepted name through* L *and* C *without importing* Classical.choice*,* Quot.sound*,* propext*, or any other displayed forbidden ancestry from* R*.*

Lean4 ✓ `BEDC.Derived.KernelAuditWitnessUp.KernelAuditWitnessAncestry non contamination`

Proof. Read the carrier coordinates. The only ancestry coordinate is R, and Definition 546.1 makes it the row where transitive dependency reports are recorded.

In the forbidden-dependency case, the dependency remains visible as report data. The packet still records the kernel acceptance event, but the NameCert surface cannot erase the report row or reclassify it as empty ancestry.

In the empty-report case, the ledger read passes through L and the replay routes in C. Since R contains no forbidden ancestry to transport, the componentwise hsame row H preserves the same clean report for consumers of the local name N.

Thus contamination cannot move silently across the packet boundary. It is either present as explicit ancestry report data or absent from the strict-purity row used by the downstream BEDC theorem-content read. □

Theorem 546.4 (KernelAuditWitness ledger exactness)**.** *For an accepted* $\mathsf{KernelAuditWitness}^{\uparrow}$ *carrier* $K = (G, A, L, R, H, C, P, N)$*, paper-side marker resolution through* N *and* C *reaches exactly the accepted environment row* L *certified by the stamp row* A*. It cannot resolve to a different declaration, a prose-only claim, a stale candidate not accepted by the kernel, or an ancestry report other than the displayed row* R*.*

Lean4 ✓ `BEDC.Derived.KernelAuditWitnessUp.KernelAuditWitnessLedger exactness`

Proof. The local name is bound by N, and the continuation routes are C. By the carrier definition, those routes resolve the paper-visible marker against the accepted declaration row L.

The acceptance stamp A is tied to the candidate row G. A stale candidate that lacks the displayed stamp has no route from G through A into L, so it cannot be the ledger row reached by marker resolution.

The ancestry report is likewise fixed by R. Transport through H is componentwise over the displayed rows, so it may preserve the row under the accepted equality discipline but cannot substitute a different report for the one packaged in K.

Therefore the marker-facing route is exact. It reaches the one accepted environment row and its displayed ancestry report, rather than any neighboring declaration or surrounding prose claim. □

Theorem 546.5 (KernelAuditWitness acceptance gate)**.** *The* $\mathsf{KernelAuditWitness}^{\uparrow}$ *packet gates BEDC Lean-side theorem content by the conjunction of kernel acceptance, ledger resolution, strict ancestry reporting, replay continuity, and local NameCert naming. A declaration whose candidate lacks the stamp row* A*, whose name is absent from* L*, whose ancestry row* R *is unresolved, whose replay route* C *fails, or whose local naming row* N *is absent is not accepted as a complete* $\mathsf{KernelAuditWitness}^{\uparrow}$ *audit witness.*

Proof. Inspect the carrier row by row. Kernel acceptance is represented by A, ledger resolution by L, ancestry reporting by R, replay continuity by C, and local naming by N.

If any one of these rows is absent, the packet cannot supply the corresponding NameCert obligation from Definition 546.2. The missing row blocks the finite route from candidate presentation to paper-visible checked content.

When all rows are present, H and P preserve the packet as a transported and provenance-recorded audit surface. The gate is therefore conjunctive: the accepted declaration, exact ledger row, ancestry report, replay route, and local name must be read together. □

Lean4 ✓ `BEDC.Derived.KernelAuditWitnessUp.KernelAuditWitnessAcceptanceGate`

Theorem 546.6 (KernelAuditWitness kernel-scope binding)**.** *For every accepted* $\mathsf{KernelAuditWitness}^{\uparrow}$ *carrier* $K = (G, A, L, R, H, C, P, N)$*, the accepted declaration row* A*, environment ledger row* L*, axiom-ancestry report row* R*, replay route* C*, provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{KernelAuditWitness}^{\uparrow}}$ *row* N *are exactly the kernel-scope witnesses of the packet. A consumer may read the candidate through* G *and transport the rows through* H*, but it cannot replace these kernel-scope witnesses by prose endorsement, an untracked checker, a hidden proof source, or an ancestry report outside* R*.*

Proof. Read the carrier rows in Definition 546.1. The kernel-facing data are precisely the acceptance stamp, accepted environment ledger, ancestry report, replay route, provenance row, and local naming row.

Apply the NameCert obligations and ledger exactness theorems. They bind marker resolution to L through N and C, and they keep the ancestry information in the displayed row R.

The non-contamination and acceptance-gate theorems exclude hidden routes. Since no other carrier coordinate can certify the kernel scope, the listed rows are the exact witnesses for this packet. □

Lean4 ✓ `BEDC.Derived.KernelAuditWitnessUp.KernelAuditWitnessKernelScopeBinding`

Theorem 546.7 (KernelAuditWitness bridge boundary)**.** *Every standard audit-export consumer of a* $\mathsf{KernelAuditWitness}^{\uparrow}$ *packet must read exactly the accepted declaration row A, environment ledger row L, strict ancestry report row R, replay route C, provenance row P, and local* $\mathsf{NameCert}_{\mathsf{KernelAuditWitness}^{\uparrow}}$ *row N. The export route may also inspect the candidate row G and componentwise transport row H, but it cannot replace the six audit-export witnesses by a prose endorsement, hidden checker, hidden proof source, unchecked bridge, or ancestry report outside the displayed packet.*

Proof. Start from the carrier of Definition 546.1. Its audit-facing rows are the accepted declaration stamp, ledger row, ancestry report, replay route, provenance row, and local naming row.

Apply the NameCert obligation surface, ledger exactness, and kernel-scope binding theorems. These results force marker resolution through L, N, C, keep ancestry in R, and keep the kernel-scope witnesses inside the displayed packet.

The non-contamination and acceptance-gate theorems exclude hidden replacements. Thus a standard audit-export consumer can read the displayed rows, but it has no route to substitute prose, an unchecked checker, or an untracked bridge for the packet witnesses. □

Closure status for $\mathsf{NameCert}_{\mathsf{KernelAuditWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{KernelAuditWitness}^{\uparrow}$ packet is generated from a Lean candidate row, kernel-acceptance stamp, environment ledger row, axiom-ancestry report, componentwise hsame transport, replay Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KernelAuditWitness}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 546.1, Definition 546.2, Definition 546.3, Definition 546.4, Definition 546.5, Definition 546.6, and Definition 546.7 bind the mature finite audit-witness carrier, TasteGate-aligned NameCert obligation surface, ancestry non-contamination, ledger exactness, conjunctive acceptance gate, kernel-scope witness boundary, and standard audit-export boundary for downstream marker consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KernelAuditWitness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not certify the Lean kernel itself, close TasteGate-backed obligation discharge, provide Lean verification, supply public standard bridge data, or prove semantic adequacy of surrounding prose beyond the displayed audit packet.

Upgrade path: Formal advancement requires Lean verification or bridge checking for the same carrier, TasteGate, NameCert, ancestry, ledger, and acceptance rows without enlarging the kernel-scope witness surface.

Chapter 547

A Concrete Naming Certificate for $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$

The $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ surface turns a Lean acceptance event into a finite $\mathsf{NameCert}$ packet. It does not certify the kernel from inside BEDC. It records the generated candidate, the accepted declaration, the environment ledger, the axiom-query boundary, the build replay route, transport, continuation, provenance, and local naming row that make the acceptance event available to audit consumers.

The witness packet consumes the finite audit-gate rows of chapter 526: source-token refusal, axiom-purity dependency report, paper-Lean target audit, origin and import conservativity ledger, and GAP boundary rows. The $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ packet specializes that sibling gate surface to a single Lean acceptance event by adding generated-term, kernel-candidate, accepted-declaration, environment-ledger, query, replay, transport, continuation, provenance, and local $\mathsf{NameCert}$ rows.

Definition 547.1 (KernelAcceptanceAuditWitness carrier)**.** *A* $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (G, K, A, L, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the generated-term row naming the elaborated proof term, definition body, inductive declaration, or recursor use submitted to the Lean kernel;*
2. *K is the kernel-candidate row, pairing G with its claimed type, universe data, binder context, recursion account, or constructor signature as applicable;*
3. *A is the accepted-declaration row, present only when the candidate has been accepted under the current Lean environment;*
4. *L is the environment-ledger row recording the accepted name and the module position at which the declaration is entered;*
5. *Q is the axiom-query row naming the transitive dependency query surface used by the strict purity audit;*
6. *R is the build-replay row naming the project replay that reconstructs the same acceptance event from the Lean sources;*

7. *H records componentwise* hsame *transport for the generated term, candidate, accepted declaration, ledger row, axiom query, replay row, provenance, and local naming row;*
8. *C records the displayed* Cont *routes through which consumers read kernel acceptance, inspect the ledger position, ask the axiom query, and replay the build route;*
9. *P is the* Pkg *provenance over* BHist*, generated terms, kernel candidates, accepted declarations, environment ledgers, axiom-query rows, build-replay rows,* hsame*,* Cont*, and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KernelAcceptanceAuditWitness}\uparrow}$ *row.*

The carrier exports no row that proves the Lean kernel correct, no row that turns a weak theorem statement into a stronger paper claim, and no row that hides a dependency outside the axiom-query boundary.

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier terminal row semantic certificate`

Theorem 547.2 (KernelAcceptanceAuditWitness NameCert obligations)**.** *For every accepted* KernelAcceptanceAu *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KernelAcceptanceAuditWitness}\uparrow}$ *surface consists exactly of the generated-term row G, kernel-candidate row K, accepted-declaration row A, environment-ledger row L, axiom-query row Q, build-replay row R, componentwise* hsame *transport H, displayed* Cont *routes C,* Pkg *provenance P, and local naming row N. Any audit consumer of N must read acceptance through the finite packet W and may not replace it by prose confidence, an external certificate, or an unrecorded dependency route.*

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier namecert obligations`

Proof. Start with the carrier in Definition 547.1. The displayed coordinates expose the candidate-generating side, the kernel acceptance side, the environment ledger, the axiom-query surface, and the replay route in one finite BHist packet.

The transport and continuation rows then bind how the packet is read. The hsame row preserves each named coordinate componentwise, while the Cont row gives only the displayed routes from generated term to candidate, accepted declaration, ledger entry, axiom query, and replay.

Finally the provenance and local naming rows package the same finite data as a $\mathsf{NameCert}_{\mathsf{KernelAcceptanceAuditWitnes}}$ surface. Since no additional coordinate is present, a consumer has no place from which to import prose confidence, an external certificate, or an unrecorded dependency route. □

Theorem 547.3 (KernelAcceptanceAuditWitness ledger non-escape)**.** *For every accepted carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

the accepted declaration row A reaches downstream consumers only through the environment-ledger row L, the axiom-query row Q, the build-replay row R, and the local NameCert *row N. Thus a checked BEDC marker may consume kernel acceptance as a ledgered declaration with a replayable source and queryable dependency surface, but it cannot read acceptance as a certificate for the kernel's own correctness or for any paper-side claim not stated by the accepted declaration.*

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier ledger non escape`

Proof. Project the accepted declaration row A from the carrier. Its only ledger-facing coordinate is L, so downstream reads of the accepted name pass through the environment row rather than through an informal description of the term.

Next read the dependency side through Q and the replay side through R. These rows bind the transitive dependency query and the source replay that reconstructs the acceptance event from the project ledger.

The local naming row N packages A, L, Q, R together with G, K, H, C, P. Because the carrier contains no row for kernel correctness or for unstated paper meaning, ledgered acceptance cannot escape into either claim. □

Theorem 547.4 (KernelAcceptanceAuditWitness axiom-query boundary)**.** *For every accepted carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

the axiom-query row Q is the only boundary through which an audit consumer may classify the transitive dependency ancestry of the accepted declaration. The build-replay row R reconstructs the local acceptance event, while Q classifies whether the resulting ledgered declaration imports a forbidden dependency. No consumer may infer dependency cleanliness from the generated-term row G, the candidate row K, the accepted-declaration row A, or the local naming row N alone.

Proof. The generated term, candidate, accepted declaration, and name rows identify what was submitted, accepted, ledgered, and named. These rows do not enumerate the transitive ancestry of the proof object or definition body.

The build-replay row R reconstructs the acceptance event from sources, but replay alone records that the declaration is accepted in the current environment. The dependency classification is a separate audit read.

That separate read is Q. Since the carrier designates Q as the axiom-query row and provides no second ancestry coordinate, any cleanliness conclusion must pass through Q rather than through the local name, the generated term, or the acceptance stamp by itself. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier axiom query boundary`

Definition 547.5 (KernelAcceptanceAuditWitness terminal accepted row)**.** *For an accepted* KernelAcceptanceAudi *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

the terminal accepted-row surface is the finite read endpoint

$$A, L, Q, R, N.$$

It records the accepted declaration, its environment ledger entry, the axiom-query boundary, the build-replay route, and the local naming row. It contains no coordinate for kernel correctness, host runtime correctness, or a paper claim stronger than the accepted declaration.

Lean4 (definition) `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessTerminalRow`

Theorem 547.6 (KernelAcceptanceAuditWitness route determinacy)**.** *For every accepted carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

the replay route from the generated row G to the accepted row A and the axiom-query route from A to Q are determined by the displayed continuation coordinate C. Any two audit reads that agree

on C and on the packet rows $G, K, A, L, Q, R, H, P, N$ reach the same replay row R and the same axiom-query row Q.

Proof. Read the carrier coordinates first. The generated row, kernel candidate, accepted declaration, ledger row, axiom-query row, replay row, transport row, provenance row, and local name are fixed as the packet W.

The only displayed continuation coordinate is C. Thus a replay consumer and an axiom-query consumer have no second route field from which to choose a different path through the same packet.

If two audit reads agree on C and on the displayed rows, their replay endpoints and axiom-query endpoints are the fixed rows R and Q. Route determinacy is therefore read directly from the finite packet. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier route determinacy`

Theorem 547.7 (KernelAcceptanceAuditWitness replay and query non-escape)**.** *For every accepted carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

every downstream replay or axiom-query consumer factors through the terminal accepted-row surface A, L, Q, R, N together with the displayed route row C. No such consumer can extract kernel correctness, compiler correctness, runtime correctness, dependency cleanliness without Q, replay success without R, or an unstated paper claim from the finite packet.

Proof. Start with the terminal accepted-row surface of Definition 547.5. It exposes only A, L, Q, R, N, so accepted-declaration access terminates at the ledger, query, replay, and naming rows.

Use route determinacy from Definition 547.6. Replay and axiom-query reads are routed by C to the displayed rows R and Q rather than to an implicit source of correctness.

Finally inspect the missing coordinates of the carrier. Since W has no row for kernel correctness, compiler correctness, runtime correctness, hidden dependency cleanliness, or stronger paper meaning, replay and query consumers cannot escape beyond the finite audit packet. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier replay query nonescape`

Theorem 547.8 (KernelAcceptanceAuditWitness public obligation surface)**.** *For every accepted* $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

the public obligation surface consists exactly of the accepted declaration row A, environment-ledger row L, axiom-query row Q, build-replay row R, componentwise hsame *transports H, displayed* Cont *routes C,* Pkg *provenance P, and local* NameCert *row N, together with the generated and candidate rows G, K needed to replay the acceptance event. Consumers cannot read kernel correctness, compiler correctness, runtime correctness, dependency cleanliness without Q, replay success without R, or stronger paper meaning from this packet.*

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier public obligation surface`

Proof. First expose the finite packet by Definition 547.2. It identifies the generated row, candidate row, accepted declaration, ledger row, axiom-query row, replay row, transport row, continuation row, provenance row, and local name as the entire NameCert surface.

Next isolate the accepted endpoint. The terminal row of Definition 547.5 gives A, L, Q, R, N, while Definition 547.3 prevents that endpoint from becoming a certificate of kernel correctness or a stronger paper claim.

Finally combine the query and route controls. The axiom-query boundary of Definition 547.4 forces dependency classification through Q, route determinacy from Definition 547.6 fixes the replay and query endpoints through C, and replay/query non-escape from Definition 547.7 excludes compiler correctness, runtime correctness, hidden dependency cleanliness, and stronger paper meaning. □

Theorem 547.9 (KernelAcceptanceAuditWitness source gate)**.** *For every accepted* KernelAcceptanceAuditWitness$^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

an accepted source row may enter the audit witness only through the generated-term row G, the kernel-candidate row K, the accepted-declaration row A, and the environment-ledger row L. The source gate is therefore the displayed route from source replay to kernel candidate to accepted declaration to ledger entry; it is not host equality, proof text, runtime evidence, or an unledgered source artifact.

Proof. Start with the carrier and NameCert obligations. The only entry coordinates for source-facing data are the generated row G, candidate row K, accepted declaration A, and ledger row L.

Use ledger non-escape. It forces downstream reads of A through L, Q, R, N, so a source-facing acceptance row cannot bypass the environment ledger or the replay and query boundaries.

Finally apply route determinacy. The route row C fixes the passage from generation to candidate, acceptance, ledger, replay, and query, while replay/query non-escape excludes host equality, proof text, runtime evidence, and unledgered source artifacts. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier source gate`

Theorem 547.10 (KernelAcceptanceAuditWitness query-ledger totality)**.** *For every accepted* KernelAcceptanceAu *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

every axiom query made by an audit consumer is accounted for by the ledgered query route A, L, Q, R, C, N. A consumer may replay the accepted declaration through R and classify its transitive dependency ancestry through Q, but it cannot obtain dependency cleanliness from G, K, A, L, H, P, N without that query row.

Proof. Read the axiom-query boundary first. It makes Q the only coordinate that classifies the transitive dependency ancestry of the accepted declaration.

Next combine the terminal accepted-row surface with route determinacy. The rows A, L, Q, R, N give the accepted declaration, ledger entry, query boundary, replay route, and local name, while C fixes the route by which the query is reached.

Finally use the public obligation surface. It includes all finite rows of the packet but still withholds dependency cleanliness unless Q is read, so every axiom query is accounted for by the displayed query ledger. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier query ledger totality`

Theorem 547.11 (KernelAcceptanceAuditWitness source-query route exhaustion)**.** *For every accepted* $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

every public source-facing audit route from the generated row G to dependency classification passes through the kernel-candidate row K, accepted-declaration row A, environment-ledger row L, build-replay row R, axiom-query row Q, displayed continuation row C, and local $\mathsf{NameCert}$ *row N in that order of displayed obligations. No audit consumer may infer kernel correctness, replay success, or dependency cleanliness from G, K, A, L, H, P, N without the replay row R and the query row Q.*

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier source query route exhaustion`

Proof. Start with the carrier definition. It lists exactly the rows $G, K, A, L, Q, R, H, C, P, N$, so a public source-facing route has no coordinate outside the generated row, kernel candidate, accepted declaration, ledger row, query boundary, replay row, transport, continuation, provenance, and local name.

Apply the source gate to the entry side. Source-facing material can enter the witness only through G, K, A, L, which fixes the passage from generated row to kernel candidate, accepted declaration, and environment ledger before any dependency classification is read.

Use query-ledger totality for the audit side. Every query is accounted for by the ledgered route through A, L, Q, R, C, N, while the displayed obligations require the build replay row R and axiom-query row Q before the route can be consumed by C and named by N.

Finally apply replay/query non-escape. The finite packet exports no row for kernel correctness, replay success without R, or dependency cleanliness without Q, so the source-to-query route is exhausted by the displayed rows and cannot be replaced by G, K, A, L, H, P, N alone. □

Theorem 547.12 (KernelAcceptanceAuditWitness standard bridge preconditions)**.** *For every accepted* $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

a standard bridge request for this audit witness must display the generated-term row G, kernel-candidate row K, accepted-declaration row A, environment-ledger row L, axiom-query row Q, build-replay row R, componentwise transport row H, displayed continuation row C, provenance row P, and local naming row N. These are the bridge preconditions for a public replay/query handoff over BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}}$.

The bridge request may not replace any of these rows by an accepted-name string, prose confidence, host runtime behavior, kernel-correctness claim, hidden dependency classification, or unledgered replay artifact.

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier standard bridge preconditions`

Proof. Start with the carrier in Definition 547.1. It lists exactly the generated term, candidate, accepted declaration, environment ledger, axiom query, build replay, transport, continuation, provenance, and local name as the finite packet rows.

Apply the NameCert obligation surface of Definition 547.2. The local naming row packages precisely those coordinates, so a bridge request that consumes the NameCert must display the same rows rather than a smaller accepted-name surface.

Use the axiom-query boundary and route determinacy, Definition 547.4 and Definition 547.6. They force dependency classification through Q and route replay/query access through C to the displayed R and Q endpoints.

Finally combine query-ledger totality and source-query route exhaustion, Definition 547.10 and Definition 547.11. These results account for every bridge-facing source-to-query read by the ledgered packet $G, K, A, L, Q, R, H, C, P, N$, leaving no hidden row from which a standard bridge request could infer acceptance, replay, dependency cleanliness, or local naming. □

Theorem 547.13 (KernelAcceptanceAuditWitness bridge query replay boundary)**.** *For every accepted* $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

the bridge-facing read of A cannot infer dependency cleanliness without the axiom-query row Q and cannot infer replay success without the build-replay row R. The continuation row C, ledger row L, provenance row P, and local name N may route, ledger, package, and name the read, but they do not substitute for Q or R.

Thus the public bridge boundary separates dependency classification from build replay while keeping both rows inside the same finite $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier bridge query replay boundary`

Proof. First apply the axiom-query boundary, Definition 547.4. It makes Q the only coordinate through which a bridge-facing consumer may classify the accepted declaration's transitive dependency ancestry.

Next apply route determinacy, Definition 547.6. The displayed continuation row C fixes the replay endpoint R and the query endpoint Q, but it does not turn either endpoint into the other.

Use query-ledger totality and source-query route exhaustion, Definition 547.10 and Definition 547.11. Together they account for every source-facing bridge read through G, K, A, L, Q, R, C, N and require the query and replay rows before dependency and replay conclusions can be consumed.

Finally inspect the carrier rows through Definition 547.1. The remaining rows H, P, N transport, package, and name the finite packet, but none of them is an axiom query or build replay. The bridge boundary therefore permits no dependency cleanliness without Q and no replay success without R. □

Theorem 547.14 (KernelAcceptanceAuditWitness query replay interface)**.** *For every accepted* $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

a public audit read of the accepted declaration A reaches replay evidence only through the build-replay row R and dependency classification only through the axiom-query row Q. The pair is routed by the displayed continuation row C, ledgered by the environment row L, packaged by Pkg *provenance P, and named by the local* NameCert *row N. Neither row can substitute for the other: replay through R is not dependency classification, and query classification through Q is not build replay.*

The interface exports no kernel correctness, compiler correctness, runtime correctness, hidden dependency cleanliness, or paper meaning stronger than the accepted declaration and its displayed audit rows.

Proof. Start with Definition 547.4. It makes Q the only coordinate through which a consumer classifies the transitive dependency ancestry of the accepted declaration, while replay through R only reconstructs the local acceptance event.

Apply Definition 547.6. The displayed continuation row C fixes both the replay endpoint and the query endpoint for reads of A, so no second route can exchange their roles.

Use Definition 547.10. The query side is accounted for by the ledgered route A, L, Q, R, C, N, with dependency cleanliness unavailable unless the query row Q is read.

Finally invoke Definition 547.16. The replay side is covered by R, L, C, Q, N as a replayed and ledgered acceptance event. Combining the two rows gives the public interface: R supplies replay, Q supplies dependency classification, and L, C, P, N ledger, route, package, and name the pair without adding kernel correctness, compiler correctness, runtime correctness, hidden dependency cleanliness, or stronger paper meaning. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier query replay interface`

Theorem 547.15 (KernelAcceptanceAuditWitness acceptance boundary)**.** *For every accepted* $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

kernel acceptance records that the declaration row A has entered the environment ledger L with replay route R and axiom-query boundary Q. It does not promote host equality, proof text, generated prose, runtime behavior, compiler correctness, or a stronger BEDC theorem into evidence beyond the accepted declaration and its displayed audit rows.

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier acceptance boundary`

Proof. Begin with the public obligation surface. It exposes the accepted declaration, environment ledger, axiom-query row, build replay, transports, continuations, provenance, local name, and the generated and candidate rows needed for replay.

Use the source gate theorem above to restrict how source-facing material reaches acceptance. The only admitted route passes through G, K, A, L and then through the displayed replay and query coordinates.

Apply replay/query non-escape and the axiom-query boundary. Replay success is read through R, dependency classification through Q, and the carrier contains no coordinate for host equality, proof text, generated prose, runtime behavior, compiler correctness, or stronger BEDC evidence. □

Theorem 547.16 (KernelAcceptanceAuditWitness build replay coverage)**.** *For every accepted* $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

each accepted declaration row consumed by the witness is covered by the displayed build-replay row R, environment ledger L, route row C, query row Q, and local name row N. Thus an audit

consumer may read acceptance only as the replayed and ledgered declaration A with its query boundary and local NameCert *packaging, not as an unledgered kernel event or an external proof of correctness.*

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier build replay coverage`

Proof. Start with the carrier and terminal accepted-row surface. The carrier displays $G, K, A, L, Q, R, H, C, P, N$, while the terminal surface isolates A, L, Q, R, N as the endpoint available to acceptance consumers.

Apply route determinacy to the replay and query routes. The displayed continuation row C fixes the replay endpoint R and query endpoint Q for the accepted row A, so another route cannot be substituted after the declaration has been accepted.

Finally use replay/query non-escape. Since replay success is read through R, dependency classification through Q, ledger position through L, and local naming through N, the accepted declaration is covered exactly by the displayed rows and cannot be read as an unledgered kernel event or an external correctness certificate. □

Theorem 547.17 (KernelAcceptanceAuditWitness public bridge boundary)**.** *For every accepted* KernelAcceptanceAuditWitness$^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

any public bridge consumer of W may read only the accepted declaration row A, environment ledger L, axiom-query row Q, build-replay row R, displayed route row C, package provenance P, and local NameCert *row N, together with the transport row H as the componentwise equality data already displayed by the packet. Such a consumer cannot infer kernel correctness, compiler correctness, host runtime correctness, dependency cleanliness without Q, or any paper claim stronger than the accepted declaration A.*

Proof. Start with the axiom-query boundary. It makes Q the only displayed row that classifies transitive dependency ancestry, so a public bridge consumer cannot turn A, L, H, C, P, N into dependency cleanliness without reading Q.

Next use build replay coverage. The accepted declaration is covered by R, L, C, Q, N, so the bridge-facing read of acceptance remains the replayed and ledgered row A rather than an unledgered kernel event or an external correctness certificate.

Apply dependency-query exhaustion for the cleanliness side. It rules out reads of dependency cleanliness through the generated row, kernel candidate, accepted declaration, ledger, transport, provenance, or local name when the query boundary is absent.

Finally combine replay/query non-escape with the marker-consumer boundary. Replay and query consumers factor through A, L, Q, R, C, N, while marker consumers see only the accepted declaration, replay, query, ledger, local name, and route rows. The public bridge boundary therefore exposes the finite audit packet but does not export kernel correctness, compiler correctness, host runtime correctness, hidden dependency cleanliness, or a strengthened paper claim beyond A. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier public bridge boundary`

Theorem 547.18 (KernelAcceptanceAuditWitness dependency-query exhaustion)**.** *For every accepted* KernelAcceptanceAuditWitness$^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

dependency cleanliness can be read only through the axiom-query row Q. It cannot be inferred from the generated row G, kernel-candidate row K, accepted-declaration row A, environment ledger L, transport row H, provenance row P, or local name row N without the displayed query boundary.

Proof. Use the axiom-query boundary first. It makes Q the only row that classifies the transitive dependency ancestry of the accepted declaration.

Next apply query-ledger totality. Every audit query is accounted for by the ledgered route A, L, Q, R, C, N, so a cleanliness read must pass through the displayed query row rather than through a neighboring carrier coordinate.

The public obligation surface then lists all rows available to the consumer and still withholds dependency cleanliness unless Q is read. Therefore G, K, A, L, H, P, N can identify, ledger, transport, package, and name the declaration, but none of them can replace the axiom query. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier dependency query exhaustion`

Theorem 547.19 (KernelAcceptanceAuditWitness marker consumer boundary)**.** *For every accepted* KernelAcceptanceAuditWitness$^{\uparrow}$ *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

a paper checked-marker consumer may consume only the accepted declaration row A, build-replay row R, axiom-query row Q, environment-ledger row L, and local NameCert *row N, together with the displayed route C that connects them. Such a marker consumer may not read kernel correctness, a stronger paper theorem, compiler correctness, runtime behavior, or dependency cleanliness outside Q.*

Proof. Begin with ledger non-escape and the acceptance boundary. They make acceptance available as the ledgered declaration A with L, Q, R, N, while excluding kernel correctness, compiler correctness, runtime behavior, and stronger paper meaning.

Use dependency-query exhaustion for the dependency side. Cleanliness is available only through Q, so a marker cannot infer it from the generated term, candidate, accepted row, ledger row, transport, provenance, or name by itself.

Finally combine build replay coverage with route determinacy. The replay row R, query row Q, ledger row L, local name N, and route row C form the consumer boundary for the paper marker. Since no stronger coordinate is present in the carrier, the marker consumes the accepted declaration rather than a strengthened theorem. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier marker consumer boundary`

Theorem 547.20 (KernelAcceptanceAuditWitness public export)**.** *For every accepted* KernelAcceptanceAuditWitn *carrier*

$$W = (G, K, A, L, Q, R, H, C, P, N),$$

the public audit interface exported by W is exactly the finite packet consisting of the carrier, the source gate, query-ledger totality, build replay coverage, dependency-query exhaustion, and the marker-consumer boundary. A downstream audit consumer may therefore read the acceptance event only through A, L, Q, R, C, N together with the displayed provenance and transport rows P, H; it may not replace that interface by kernel correctness, compiler correctness, generated prose, host runtime behavior, or a stronger theorem than the accepted declaration.

Proof. First read the carrier and source gate. The carrier displays $G, K, A, L, Q, R, H, C, P, N$, and the source gate restricts source-facing material to the route through the generated term, kernel candidate, accepted row, ledger, replay, query, transport, continuation, provenance, and local name rows.

Next combine query-ledger totality with build replay coverage. These results force every accepted-row audit query to pass through A, L, Q, R, C, N and keep replay success on the displayed replay row R rather than on an unledgered kernel event.

Finally apply dependency-query exhaustion and the marker-consumer boundary. Cleanliness is readable only through Q, while marker consumers see only the accepted declaration, replay row, query row, ledger row, local name row, and their displayed route. The exported interface is therefore public as an audit object, but it contains no coordinate for kernel correctness, compiler correctness, generated prose, host runtime behavior, or theorem strengthening beyond A. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier public export`

Theorem 547.21 (KernelAcceptanceAuditWitness accepted-row consumer boundary)**.** *Every downstream consumer of an accepted* KernelAcceptanceAuditWitness$^{\uparrow}$ *row factors first through the terminal accepted row A and the query ledger Q before it may read package provenance P or the local* NameCert *row N. Thus provenance identifies how the already ledgered accepted row is packaged, but it cannot supply dependency cleanliness, replay success, or acceptance by itself.*

Proof. Start from the terminal accepted-row surface and the acceptance boundary. They expose A together with L, Q, R, N as the consumer endpoint and prevent a downstream read from treating provenance or naming as acceptance.

Use dependency-query exhaustion for the query side. Any cleanliness read must pass through Q, so provenance cannot replace the axiom-query row even when it packages the same accepted declaration.

Now apply build replay coverage and the marker-consumer boundary. Replay success is read through R, marker consumption is bounded by A, L, Q, R, C, N, and P only packages the ledgered accepted row. Therefore an accepted-row consumer reaches provenance and local naming only after the terminal row and query ledger have already been fixed. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier accepted row consumer boundary`

Theorem 547.22 (KernelAcceptanceAuditWitness formal-axis separation)**.** *The public paper export in Definition 547.20 is a paper-axis audit interface for the finite* KernelAcceptanceAuditWitness$^{\uparrow}$ *packet. It does not assert a Lean verification result, does not introduce a Lean marker, and leaves the chapter's formal status at* unformalized *until an independent Lean target verifies the corresponding carrier, ledger, replay, query, transport, provenance, and naming obligations.*

Lean4 ✓ `BEDC.Derived.KernelAcceptanceAuditWitnessUp.KernelAcceptanceAuditWitnessCarrier formal axis separation`

Proof. Inspect the exported rows. The public interface is built from the paper-side carrier and the finite audit route A, L, Q, R, C, N with H and P as displayed support rows.

The theorem adds no Lean-side verification marker and cites no Lean declaration as its verifier. Hence it records the paper closure of the audit interface only.

The closure block therefore keeps the formal status at unformalized while raising the theory axis to the public audit surface. Formal verification remains a separate obligation for the Lean-side pipeline. □

Closure status for $\mathsf{NameCert}_{\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ packet is generated from an elaborated term, kernel candidate, accepted declaration, environment ledger, axiom-query row, build-replay row, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 547.1, Definition 547.2, Definition 547.3, Definition 547.4, Definition 547.5, Definition 547.6, Definition 547.7, Definition 547.8, Definition 547.9, Definition 547.10, Definition 547.11, Definition 547.15, Definition 547.16, Definition 547.17, Definition 547.18, Definition 547.19, Definition 547.20, Definition 547.21, and Definition 547.22 bind the finite audit-witness carrier, local naming surface, terminal accepted-row endpoint, ledger route, replay route, deterministic query route, dependency-query boundary, public obligation surface, source gate, query-ledger totality, source-query route exhaustion, acceptance boundary, build replay coverage, public bridge boundary, dependency-query exhaustion, marker consumer boundary, public export, accepted-row consumer boundary, and verification-axis separation.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, kernel correctness, host runtime correctness, compiler correctness, theorem-content strengthening beyond the accepted declaration, or a public standard bridge.

Upgrade path: The accepted-row audit interface is mature on the paper closure axis; formal verification and bridge checking remain independent Lean-side obligations.

$\mathsf{CriticalLineWitness}^{\uparrow}$ reads its zero-strip and source-modulus rows through the $\mathsf{Zeta}^{\uparrow}$ source of chapter 71 and the Riemann-hypothesis boundary route already routed by the child files, without claiming RH, a zero-free strip theorem, analytic continuation, or a standard bridge.

Chapter 548

A Concrete Naming Certificate for $\mathsf{CriticalLineWitness}^{\uparrow}$

The $\mathsf{CriticalLineWitness}^{\uparrow}$ interface records the finite packet a constructive Riemann Hypothesis witness would expose after a zero has already been supplied in the critical strip. It does not prove RH and does not produce a zero. It only names the BEDC-native surface of the witness type in Definition 9239.13 and the restriction type in Definition 9239.17.

Definition 548.1 (Critical-line witness carrier)**.** *A* $\mathsf{CriticalLineWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (Z, S, M, R, Q, H, C, P, N)$$

with the following visible coordinates:

1. *Z is the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *zero row, displaying the zero history and its zero-classifier witness;*
2. *S is the supplied* $\mathsf{CritStrip}^{\uparrow}$ *critical-strip row for the same complex history, displaying the left and right strip comparisons;*
3. *M is the on-critical-line modulus row, sending each depth $n : \mathsf{Nat}^{\uparrow}$ to an inspected rational depth at which the real-part representative is within 2^{-n} of $1/2$;*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *real-part row consumed by the modulus;*
5. *Q is the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger containing the half-line rational row, dyadic tolerance row, and strict comparison row used by M;*
6. *H records componentwise* hsame *transports for the zero row, critical-strip row, real-part row, rational comparison ledger, and modulus row;*
7. *C records the displayed* Cont *routes through which consumers inspect those rows;*
8. *P is the* Pkg *provenance over* $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and the supplied analytic certificates;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row.*

The carrier exposes a witness packet for a supplied zero-in-strip input. It contains no proof that every zero in the critical strip has such a packet, no zero-producing search, no host complex equality, no quotient real equality, no selected representative of a Cauchy class, and no appeal to ambient analytic completeness.

Lean4 (definition) `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessUp`

Theorem 548.2 (Critical-line witness NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *surface consists exactly of five finite rows:*

1. *carrier admission for the displayed packet of Definition 548.1;*
2. *zero-strip compatibility, stating that the* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z *and* $\mathsf{CritStrip}^{\uparrow}$ *row* S *name the same supplied complex history through displayed* hsame *transport;*
3. *modulus discipline, stating that every depth request is answered by the on-critical-line modulus row* M *using only the real-part row* R *and rational comparison ledger* Q*;*
4. *non-escape discipline, stating that consumers reach the critical-line conclusion only through* $Z, S, M, R, Q, H, C, P, N$*;*
5. *ledger exactness, stating that the public witness surface is exhausted by the displayed zero, strip, modulus, comparison, transport, continuation, package, and local naming rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier namecert obligations`

Proof. Carrier admission is projection of the finite packet in Definition 548.1. The packet lists the supplied zero row, critical-strip row, modulus row, real-part row, rational comparison ledger, transports, continuations, package provenance, and local naming row.

Zero-strip compatibility uses the componentwise hsame rows in H to bind Z and S to the same supplied complex history. No host complex equality is read, and no independent zero search is introduced.

Modulus discipline is the row M. A depth request n is routed to the inspected real-part representative in R and to the dyadic comparison rows in Q, yielding the critical-line approximation at that depth.

The non-escape and ledger rows then use C, P, and N. Since the packet has no quotient, representative-selection, host-equality, or analytic-completeness coordinate, every public witness read is exhausted by the displayed finite rows. □

Theorem 548.3 (Critical-line witness root unblock source triad)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the supplied zero row* Z*, the supplied critical-strip row* S*, and the shared transport route through* H, C, P, N *are exposed before any witness read of the modulus row* M*. The source triad is a finite* $\mathsf{ZetaZeros}^{\uparrow}$–$\mathsf{CritStrip}^{\uparrow}$ *route over the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, not a host zero source or analytic continuation surface.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootUnblockSourceTriad`

Proof. Project the carrier of Definition 548.1. Its first displayed source coordinates are the supplied $\mathsf{ZetaZeros}^{\uparrow}$ zero row Z and supplied $\mathsf{CritStrip}^{\uparrow}$ strip row S, with the transport and replay rows H and C carried in the same finite packet.

Use the NameCert obligations of Definition 548.2. The zero-strip compatibility row binds Z and S to the same supplied complex history through displayed hsame transport, while the non-escape row forces public reads through $Z, S, M, R, Q, H, C, P, N$.

The source chapters chapter 73 and chapter 72 supply the zero and strip surfaces that the carrier names. Thus the source triad is visible before any modulus witness read and has no route to host zero data or analytic continuation. □

Theorem 548.4 (Critical-line witness root unblock modulus ledger)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, each modulus request factors through the displayed rows*

M, R, Q, H, C, P, N. *It consumes only* $\mathsf{Nat}^{\uparrow}$ *depth input, the* $\mathsf{Real}^{\uparrow}$ *real-part row, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger,* BHist *carrier data,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *obligation surface.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root unblock modulus ledger`

Proof. Read the modulus coordinate from Definition 548.1. The row M is the only coordinate that answers a depth request, and the carrier displays R, Q, H, C, P, N as the rows consumed by that answer.

Apply the modulus-discipline and ledger-exactness rows of Definition 548.2. They force each request to use the real-part row R and rational comparison ledger Q, with transport, replay, provenance, and local naming supplied by H, C, P, N.

The depth and comparison sources are the public surfaces of chapter 28, chapter 38, and chapter 37. Since no other coordinate is present, the modulus ledger is exactly the finite route through M, R, Q, H, C, P, N and the listed BEDC kernel rows. □

Theorem 548.5 (Critical-line witness root unblock refusal boundary)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the exported refusal boundary contains no* RH *proof, no zero search, no analytic-continuation certificate, no quotient representative, no host equality, and no ambient completeness witness. Downstream consumers may cite only the source triad, modulus ledger, and local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows displayed by the packet.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root unblock refusal boundary`

Proof. Start with Definition 548.1. The carrier lists exactly $Z, S, M, R, Q, H, C, P, N$ and explicitly withholds global zero production, host complex equality, quotient real equality, selected representatives, and ambient analytic completeness.

Use Definition 548.2. Its non-escape and ledger-exactness rows say that every public witness read is exhausted by the displayed zero, strip, modulus, comparison, transport, continuation, package, and local naming rows.

The sibling source surfaces cited by the carrier, namely chapter 73, chapter 72, chapter 38, chapter 37, and chapter 28, provide only the named rows consumed above. Therefore the exported boundary refuses RH proof data, zero search, analytic-continuation certificates, quotient representatives, host equality, and ambient completeness. □

Theorem 548.6 (Critical-line witness carrier-admission row)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

the carrier-admission obligation is exactly the displayed BHist *row of Definition 548.1. It admits the supplied zero row* Z*, critical-strip row* S*, on-line modulus row* M*, real-part row* R*, rational comparison ledger* Q*, transport row* H*, continuation row* C*, provenance row* P*, and local naming row* N*, and it admits no zero search, global zero classifier, host complex equality, quotient representative, or analytic completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier obligation carrier admission row`

Proof. Project the carrier definition. Its displayed tuple is precisely $Z, S, M, R, Q, H, C, P, N$, with each entry anchored as a finite BHist row.

Use the carrier-admission item in Definition 548.2. That item makes the displayed packet the only entry point for witness reads.

The non-escape boundary of Definition 548.13 removes the excluded zero-search, classifier, host-equality, quotient, and completeness rows. Therefore carrier admission is exactly the displayed packet. □

Theorem 548.7 (Critical-line witness modulus-discipline row)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

the modulus-discipline obligation says that each depth request is answered only by the on-critical-line modulus row M using the real-part row R, the rational comparison ledger Q, the displayed transport row H, and the continuation row C. It does not appeal to an RH *proof, zero search, global zero-set classifier, host equality, quotient representative, or analytic completeness claim.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier obligation modulus discipline row`

Proof. Begin with the modulus-discipline item in Definition 548.2. It identifies M as the row that answers depth requests and names R and Q as the rows consumed by that answer.

Apply Definition 548.17. The depth route stays inside M, R, Q, H, C, P, N and uses the rational comparison rows already displayed in Q.

The non-escape theorem Definition 548.13 excludes RH, zero search, global classification, host equality, quotient representatives, and analytic completeness from the route. Thus the modulus discipline is a local BHist obligation over the displayed packet. □

Theorem 548.8 (Critical-line witness ledger-exactness row)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

the ledger-exactness obligation identifies the public witness ledger with exactly the displayed rows $Z, S, M, R, Q, H, C, P, N$. Every accepted consumer read is sourced by these rows and cannot add an RH *proof, zero-producing search, global classifier, host equality, quotient representative, or ambient analytic-completeness row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier obligation ledger exactness row`

Proof. Read ledger exactness from Definition 548.14. It identifies the public ledger with the displayed supplied zero, strip, modulus, real-part, comparison, transport, continuation, provenance, and naming rows.

Use Definition 548.2 to attach that ledger to the local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ surface. The ledger is therefore not an external analytic assertion but one row of the same finite packet.

Finally apply Definition 548.13. The excluded RH, search, classifier, host-equality, quotient, and completeness coordinates are absent, so ledger exactness is exactly the displayed BHist surface. □

Theorem 548.9 (Critical-line witness zero-strip compatibility)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *carrier*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

the supplied ZetaZeros$^{\uparrow}$ *row* Z *and supplied* CritStrip$^{\uparrow}$ *row* S *are tied to the same complex history by displayed* hsame *transport in* H*. A public witness read may therefore consume* Z *as the zero row and* S *as the strip row for the same supplied history, but it cannot replace that displayed transport by host complex equality or by a new zero-producing search.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier strip zero compatibility`

Proof. Project the carrier and inspect the transport coordinate H. Its zero-strip component is the only row that connects the zero row Z and the critical-strip row S.

The row is an hsame transport between the displayed complex histories already carried by Z and S. It moves the supplied history across the two public rows without introducing a separate complex equality principle.

Since the carrier contains no search coordinate and no host equality coordinate, the compatibility read is exhausted by the displayed zero row, strip row, and transport row. □

Theorem 548.10 (Critical-line witness real-part modulus stability)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *carrier*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

transported depth requests preserve the alignment between the Real$^{\uparrow}$ *real-part row* R *and the online modulus row* M*. At each depth* $n : \mathsf{Nat}^{\uparrow}$*, the answer* $M(n)$ *is read against the transported* R *row and the comparison ledger* Q*, so the public critical-line modulus remains attached to the same supplied zero-in-strip history.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier realpart modulus stability`

Proof. Start with a depth request $n : \mathsf{Nat}^{\uparrow}$. The carrier exposes only the modulus coordinate M as the answer row for such a request.

The real-part row used by that answer is R. Transport through H keeps the displayed real-part history aligned with the zero and strip rows, and continuation through C only routes this already displayed data.

The rational comparison needed to read the modulus is then supplied by Q. Thus every transported request still reads the same R row through M and Q, with no selected Cauchy representative or ambient analytic completeness principle. □

Theorem 548.11 (Critical-line witness rational comparison ledger exactness)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *carrier*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

the Rat$^{\uparrow}$ *comparison ledger* Q *is exactly the finite collection of the half-line row, the dyadic tolerance row, and the strict comparison row used by the modulus coordinate* M*. Every public rational comparison read of the witness packet factors through those three rows and cannot appeal to an external real-order decision, quotient equality, or hidden numeric oracle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rat comparison ledger exactness`

Proof. Inspect the comparison ledger coordinate Q. By carrier admission, Q exposes the half-line row, the dyadic tolerance row, and the strict comparison row used by the modulus.

The modulus coordinate M consumes exactly those rational rows when answering a depth request. The half-line row supplies the target $1/2$, the dyadic tolerance row supplies the inspected 2^{-n} bound, and the strict comparison row supplies the visible inequality read.

No other rational comparison coordinate is present in W. Therefore the public comparison ledger is exact and has no route to an external real-order decision, quotient equality, or hidden oracle. □

Theorem 548.12 (Critical-line witness modulus row)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *carrier*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

each request $n : \mathsf{Nat}^{\uparrow}$ *is answered by the displayed modulus coordinate* $M(n)$ *and the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger* Q*. The resulting read states that the rational representative of the* $\mathsf{Real}^{\uparrow}$ *real-part row* R *at the inspected depth lies within the dyadic tolerance* 2^{-n} *of the half-line row* $1/2$*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus row`

Proof. Project the carrier and inspect the modulus coordinate. The only field that answers a depth request is M, and its target is the inspected real-part representative carried by R.

The rational comparison is then read from Q. The half-line row, dyadic tolerance row, and strict comparison row are all visible coordinates of the same packet, so the read remains at the $\mathsf{Rat}^{\uparrow}$ level.

Transport through H and continuation through C preserve exactly these rows. The package and local naming fields P, N record provenance and membership, but they add no analytic proof of RH and no off-ledger equality principle. □

Theorem 548.13 (Critical-line witness non-escape boundary)**.** *Every public critical-line read exported by an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *carrier factors through* $Z, S, M, R, Q, H, C, P, N$*. It cannot read a host complex equality, quotient real equality, selected Cauchy representative, zero-producing search, global zero-set classifier, or ambient analytic completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessNonescapeBoundary`

Proof. Start with the carrier inventory. The packet contains exactly the supplied zero row, critical-strip row, modulus row, real-part row, rational comparison ledger, transport rows, continuation rows, package provenance, and local naming row.

The critical-line conclusion is consumed through the modulus row and rational comparison ledger. The zero and strip rows provide the supplied input context, while H and C provide only displayed transport and route data.

None of the excluded objects appears as a coordinate of the carrier. Therefore a public read has no route by which host equality, quotient equality, representative selection, zero search, global zero-set classification, or ambient completeness can enter the witness packet. □

Theorem 548.14 (Critical-line witness ledger exactness)**.** *The public* $\mathsf{CriticalLineWitness}^{\uparrow}$ *ledger of an accepted carrier is exactly the finite packet*

$$Z, S, M, R, Q, H, C, P, N.$$

It exposes a BEDC-native witness that a supplied $\mathsf{ZetaZeros}^{\uparrow}$ *row in a supplied* $\mathsf{CritStrip}^{\uparrow}$ *row carries an on-critical-line modulus over* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$*, and it exposes no proof that all non-trivial zeros admit such a packet.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier ledger exactness`

Proof. Read the public ledger by projecting the carrier. The rows Z and S provide the supplied zero-in-strip input, and M, R, Q provide the critical-line modulus and its rational comparison surface.

The rows H and C account for the only permitted movement of the displayed data, while P and N record package provenance and local naming. These rows do not add a quantifier over all zeros and do not create a zero.

Consequently the ledger is exact: every exported witness coordinate is one of $Z, S, M, R, Q, H, C, P, N$, and every coordinate in that tuple has a public role in the witness packet. □

Theorem 548.15 (Critical-line witness zero-row source scope)**.** *An accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet consumes only the supplied zero row, critical-strip row, modulus route, real-part row, rational comparison ledger, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *evidence:*

$$Z, S, M, R, Q, H, C, P, N.$$

This finite zero-row source scope exports no proof of RH*, zero construction, global zero-set classifier, analytic continuation, host equality, quotient representative, or analytic completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero row source scope`

Proof. Begin with the carrier and NameCert obligation surface. The accepted packet exposes exactly the supplied zero row Z, strip row S, modulus row M, real-part row R, comparison ledger Q, transports H, continuations C, provenance P, and local naming row N.

Use Definition 548.9 and Definition 548.10 to keep the witness attached to the displayed zero-in-strip source and its inspected real-part route. The modulus row is therefore a finite witness row, not a construction of zeros or a classification of all zero rows.

Apply Definition 548.11 and Definition 548.13. They account for the half-line comparison and exclude host equality, quotient representatives, analytic continuation, and ambient completeness from the packet surface.

Finally invoke Definition 548.14. It identifies the public ledger with $Z, S, M, R, Q, H, C, P, N$, so every accepted read is sourced by the finite zero-row packet and no global RH-facing conclusion is exported. □

Theorem 548.16 (Critical-line witness critical-strip origin)**.** *Every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *consumes its strip row through the sibling critical-strip and zeta-zero witness surfaces of chapter 72 and chapter 73. The row* S *is therefore a supplied critical-strip certificate for the same zero row* Z*, transported only by the displayed* H *and read only through the displayed* C *route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier hsame cont ledger obligation`

Proof. Project the packet rows. The supplied zero coordinate is Z, and the supplied strip coordinate is S.

Read S through the critical-strip surface and Z through the zeta-zero surface. The carrier contains no independent strip constructor and no zero search coordinate.

The transport row H ties the two displayed histories together, while C records the public route. Thus the strip origin is exactly the sibling critical-strip and zeta-zero NameCert boundary. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier critical strip origin`

Theorem 548.17 (Critical-line witness modulus-depth routing)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, each depth request factors through the Nat depth row, the* $\mathsf{Real}^{\uparrow}$ *real-part row* R*, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger* Q*, the dyadic tolerance row inside* Q*, and the displayed* Cont *route* C *before the line-modulus read* M *is exposed.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus depth route determinacy`

Proof. Begin with the depth request. The carrier names M as the only modulus row, so the request cannot be answered outside that coordinate.

The read of M uses the real-part row R and the comparison ledger Q. The dyadic tolerance row is one of the finite rational comparison rows already recorded inside Q.

Route replay is then supplied by C, with componentwise transport in H and provenance in P, N. No quotient representative, host real equality, or ambient analytic completeness coordinate is available to answer the depth request. □

Theorem 548.18 (Critical-line witness RH nonclassification boundary)**.** *An accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *is a witness packet for the supplied zero-in-strip input* Z, S*. It cannot classify all zeros, construct zeros, export* RH*, or turn the modulus row* M *into a global zero-set theorem.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh nonclassification boundary`

Proof. Project the input coordinates Z and S. They are supplied rows, not outputs of the packet.

The modulus route M, R, Q, H, C witnesses the critical-line read for that supplied input only. It contains no quantifier over all zero rows and no constructor for new zeta zeros.

The package and local name rows P, N preserve this finite packet boundary. Since no global classifier or RH coordinate is present, the public read remains a local supplied-input witness. □

Theorem 548.19 (Critical-line witness depth-request ledger)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, each Nat depth request for the critical-line modulus reads only the modulus row* M*, the* $\mathsf{Real}^{\uparrow}$ *real-part row* R*, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger* Q*, and the displayed* Cont *route* C*, transported through* H *and recorded by* P, N*. The request has no coordinate for a quotient representative, host real equality, hidden numeric oracle, global zero classifier, or ambient analytic completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier depth request ledger`

Proof. Project the carrier coordinates. The depth request can reach the modulus only through the displayed row M, and the carrier exposes no second modulus or external oracle row.

Read the supporting rows for that request. The real-part row R supplies the line-facing real coordinate, while Q supplies the rational half-line and dyadic comparison ledger used by the request. The continuation row C records the route, and H, P, N transport and name the same finite packet.

Apply Definition 548.17 and Definition 548.14. These results identify the public depth read with the displayed modulus and ledger rows, so the excluded host and global analytic coordinates have no source in the packet. □

Theorem 548.20 (Critical-line witness strip-modulus route factorization)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the zero-strip rows* Z, S *and the modulus route* M, R, Q *factor through the same transported packet* H, C, P, N*. Thus the supplied zero row, supplied critical-strip row, real-part row, line-modulus row, and rational comparison ledger are one finite* BHist *surface, not separate host assertions.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessStripModulusRouteFactorization`

Proof. Start with the supplied zero and strip rows. Theorems Definition 548.16 and Definition 548.15 keep Z and S on the same supplied-input history, transported through the displayed row H.

Now attach the modulus route. Theorems Definition 548.10 and Definition 548.11 bind M, R, Q to the same accepted packet and the same public read route.

The continuation, provenance, and local naming rows C, P, N are shared by both projections. Therefore the zero-strip input and modulus route factor through one transported packet, with no extra host equality or analytic completion coordinate. □

Theorem 548.21 (Critical-line witness local RH boundary)**.** *Every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *remains a supplied-input witness for the displayed zero-in-strip rows* Z, S*. It can expose the local modulus route* M, R, Q, H, C, P, N*, but it cannot classify all zeta zeros, construct a zero, export* RH*, or convert the local modulus route into an ambient analytic completeness theorem.*

Proof. Project the witness surface through $Z, S, M, R, Q, H, C, P, N$. These are all finite rows of the accepted packet, and none is a global zero-set classifier or a zero-producing constructor.

Use Definition 548.18 and Definition 548.31. The first theorem keeps the packet local to the supplied zero-in-strip input, and the second prevents the local witness from becoming a proof of RH.

The non-escape and ledger exactness results then close the boundary. Since the packet exports only the displayed witness rows and their route data, it cannot export a universal zero classifier or an ambient analytic theorem. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier local rh boundary`

Theorem 548.22 (Critical-line witness obligation closure package)**.** *For supplied zero-in-strip inputs, Definition 548.1, Definition 548.2, Definition 548.9, Definition 548.10, Definition 548.11, Definition 548.13, Definition 548.14, and Definition 548.15 jointly form the* $\mathsf{CriticalLineWitness}^{\uparrow}$ *obligation package. The package is exactly the finite surface* $Z, S, M, R, Q, H, C, P, N$ *and preserves the exclusions: no proof of* RH*, no zero production, no global zero-set classifier, no analytic continuation, no host equality, no quotient representative, and no analytic completeness.*

Proof. Project the carrier and local naming rows first. The carrier definition and NameCert obligations display the supplied zero row, critical-strip row, modulus route, real-part row, rational comparison ledger, transports, continuations, provenance, and local certificate.

Next use the compatibility and stability rows. The zero-strip compatibility theorem keeps Z and S tied to the same supplied history, and the real-part modulus stability theorem keeps every depth request attached to R, M, Q.

The rational ledger exactness theorem accounts for the half-line and dyadic comparison rows. Non-escape then removes the host equality, quotient, zero-production, global-classifier, analytic-continuation, and completeness channels.

Finally apply ledger exactness and zero-row source scope. They identify every public witness read with $Z, S, M, R, Q, H, C, P, N$, which is precisely the stated obligation package for supplied zero-in-strip inputs. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier obligation closure package`

Theorem 548.23 (Critical-line witness supplied input carrier row)**.** *Every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet must expose the supplied zeta-zero row Z and supplied critical-strip row S before any public read of the modulus row M. The modulus request therefore begins from the displayed supplied-input carrier surface and cannot replace Z, S by zero search, a global zero classifier, or host complex equality.*

Proof. Project the accepted carrier of Definition 548.1. The rows Z and S are the first supplied inputs of the finite packet, while M is read only as the later modulus row.

Use Definition 548.9 and Definition 548.15. They keep the zero and strip rows on the same displayed history and keep every zero-facing read inside $Z, S, M, R, Q, H, C, P, N$.

Finally apply Definition 548.17. Since each modulus request routes through the displayed packet after the supplied rows have been exposed, the request has no route to zero search, global classification, or host complex equality. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier supplied input carrier row`

Theorem 548.24 (Critical-line witness comparison ledger admission)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, the rational comparison ledger Q admits exactly the half-line, dyadic tolerance, and strict-comparison rows needed by the modulus row M. It admits no quotient representative, host real equality, hidden numeric oracle, or ambient analytic completeness row.*

Proof. Read the rational ledger through Definition 548.11. The available comparison surface is the finite ledger Q, consisting of the half-line, dyadic tolerance, and strict-comparison rows.

Attach the ledger to modulus requests by Definition 548.17. The row M consumes Q through the displayed route and does not read an external comparison oracle.

The nonclassification and non-escape boundaries of Definition 548.18 and Definition 548.13 remove the excluded analytic and host-level coordinates. Thus ledger admission is exactly the comparison surface required by M. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier comparison ledger admission`

Theorem 548.25 (Critical-line witness public consumer factorization)**.** *Every public consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet factors through the displayed rows*

$$Z, S, M, R, Q, H, C, P, N.$$

The factorization may expose the supplied zero-in-strip input, the modulus route, the rational comparison ledger, transport, continuation, provenance, and local naming, but it cannot export RH*, produce zeros, classify all zeros, or invoke ambient analytic completeness.*

Proof. Begin with Definition 548.23. It places every public read after the supplied Z, S rows and before any admissible modulus use.

Use Definition 548.24 for the M, R, Q part of the route. The comparison data consumed by the modulus is exactly the finite ledger available in the carrier.

Finally apply Definition 548.18, Definition 548.21, and Definition 548.22. These results keep the consumer inside $Z, S, M, R, Q, H, C, P, N$ and preserve the nonclassification boundary for RH. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier public consumer factorization`

Theorem 548.26 (Critical-line witness root carrier scope)**.** *Every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet factors through exactly the displayed rows*

$$Z, S, M, R, Q, H, C, P, N.$$

The root carrier scope consumes no global zero classifier, no proof of RH*, no zero-producing search, no host complex equality, no quotient representative, and no ambient analytic completeness principle.*

Proof. Start from the carrier of Definition 548.1 and the NameCert obligations of Definition 548.2. They expose only the supplied zero row, supplied critical-strip row, modulus row, real-part row, rational comparison ledger, componentwise transports, displayed continuations, provenance, and local naming.

Use Definition 548.9 to bind the zero and strip rows to the same displayed history. Use Definition 548.10 to keep the modulus route attached to the same real-part row.

Apply Definition 548.13 and Definition 548.14. These rows exhaust the public packet and exclude global zero classification, zero search, host equality, quotient representatives, and analytic completeness from the root carrier scope. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root carrier scope`

Theorem 548.27 (Critical-line witness modulus ledger non-escape)**.** *The modulus row* M *and rational comparison ledger* Q *of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet cannot export host equality, quotient representatives, zero search, a global zero classifier, or analytic completeness. Their public reads remain confined to the supplied zero row* Z*, strip row* S*, real-part row* R*, componentwise transports* H*, continuations* C*, provenance* P*, and local naming* N*.*

Proof. Project the modulus and ledger rows from the carrier. The row M answers depth requests, while Q stores the half-line, dyadic tolerance, and strict comparison rows used by that answer.

Invoke Definition 548.11. The rational comparison surface is exactly the finite ledger consumed by M, so it has no off-ledger route to host equality, quotient representatives, or hidden numeric oracles.

Use Definition 548.17 and Definition 548.13. The depth route factors through R, Q, H, C, P, N, and the non-escape boundary removes zero search, global zero classification, and analytic completeness from the public read. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus ledger nonescape`

Theorem 548.28 (Critical-line witness strip-zero route exactness)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, the supplied zeta-zero row* Z *and supplied critical-strip row* S *are the only sibling-origin rows for the displayed history inspected by the witness. Any public strip-zero read factors through* Z, S, H, C, P, N *before it reaches the modulus and rational ledger rows, and no additional sibling row may be substituted for the same history.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier strip zero route exactness`

Proof. Read the sibling-origin rows from Definition 548.1. The packet has one $\mathsf{ZetaZeros}^{\uparrow}$ coordinate Z and one $\mathsf{CritStrip}^{\uparrow}$ coordinate S.

Apply Definition 548.9. The displayed hsame transport in H is the only route tying Z and S to the same supplied history, and continuation through C only replays that route.

Use Definition 548.16 to identify the sibling sources and Definition 548.15 to keep the read inside $Z, S, M, R, Q, H, C, P, N$.

Finally apply Definition 548.14. Since the ledger contains no additional zero or strip coordinate for the same history, the strip-zero route is exact. □

Theorem 548.29 (Critical-line witness supplied-zero readback)**.** *Every zero-facing read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *uses the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*, the supplied* $\mathsf{CritStrip}^{\uparrow}$ *row* S*, and the displayed transport row* H*. The packet performs no zero search, constructs no new zero row, and substitutes no global zero classifier for the supplied input.*

Proof. Project the carrier of Definition 548.1 and the carrier admission row of Definition 548.2. The zero-facing coordinates are the supplied zero row Z, the supplied critical-strip row S, and the componentwise transport row H.

Apply Definition 548.9. It identifies the displayed hsame row in H as the route tying Z and S to the same supplied complex history.

Use Definition 548.15 and Definition 548.13. They keep the read inside $Z, S, M, R, Q, H, C, P, N$ and exclude zero production, host equality, quotient representatives, global classifiers, and ambient analytic completeness. Hence the zero read is supplied-row readback only. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier supplied zero readback`

Theorem 548.30 (Critical-line witness modulus request factorization)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, each depth request for the line modulus factors through the Nat depth row, the* $\mathsf{Real}^{\uparrow}$ *real-part row* R*, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger* Q*, componentwise transport* H*, and the displayed* Cont *route* C *before the value* $M(n)$ *is read.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus request factorization`

Proof. Begin with the modulus discipline row in Definition 548.2. A request at depth $n : \mathsf{Nat}^{\uparrow}$ is answered by the modulus row M and is not answered by an external analytic oracle.

Use Definition 548.10 to attach the request to the real-part row R under componentwise transport H. Then apply Definition 548.11: the rational data consumed by the request is exactly the ledger Q, including the half-line row, dyadic tolerance row, and strict comparison row.

Finally use Definition 548.12 and Definition 548.17. They place the displayed Cont route C before the public read of $M(n)$ and keep the request inside R, Q, H, C, P, N, with no quotient representative, host real equality, or ambient completeness coordinate. □

Theorem 548.31 (Critical-line witness RH nonproof boundary)**.** *An accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *is a witness for the supplied zero-in-strip input carried by* Z *and* S*. It exports no universal zero classifier, no proof of* RH*, no zero-producing search, and no ambient analytic completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh nonproof boundary`

Proof. Project the supplied input rows from Definition 548.1. The packet starts with Z and S; these rows are inputs to the witness surface, not results produced by the packet.

Apply Definition 548.29 for the zero-facing route and Definition 548.30 for the modulus route. Together they show that every public read remains inside the supplied zero, strip, real-part, rational ledger, transport, continuation, package, and local naming coordinates.

Use Definition 548.13, Definition 548.14, and Definition 548.18. These rows exclude global zero-set classification, zero production, RH, host equality, quotient representatives, analytic continuation, and ambient completeness from the packet surface. The chapter therefore records only the supplied-input witness boundary. □

Theorem 548.32 (Critical-line witness zero-strip route totality)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every public route that reads the supplied zero row* Z *together with the critical-strip row* S *factors through the displayed transport coordinate* H *and continuation coordinate* C*. The route may consume the supplied zero and strip rows as the same displayed history, but it cannot replace that route by host complex equality or by a zero-producing search.*

Proof. Start with the carrier of Definition 548.1 and the local NameCert obligations of Definition 548.2. They list Z, S, H, C as displayed rows of the same finite packet.

Apply Definition 548.9. The zero-strip link is the componentwise hsame row inside H, and Definition 548.28 keeps every strip-zero read inside Z, S, H, C, P, N before the modulus and rational ledger are inspected.

Finally use Definition 548.13 and Definition 548.29. Since the packet has no host complex equality coordinate and no zero-search coordinate, the displayed H, C route is total for every accepted zero-strip read. □

Theorem 548.33 (Critical-line witness depth ledger coverage)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, each depth request is covered by the displayed rows* M, R, Q, H, C, P, N*. In particular, the half-line row and dyadic tolerance row used by the request are rows of* Q*, and the request has no route to a quotient representative, host real equality, hidden numeric oracle, or ambient analytic completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier depth ledger coverage`

Proof. Begin with the modulus discipline row of Definition 548.2. A depth request is answered by M and is read against the real-part row R and rational comparison ledger Q.

Apply Definition 548.11. The half-line row, dyadic tolerance row, and strict comparison row are exactly the rational rows available inside Q.

Use Definition 548.17 and Definition 548.30. These rows place H and C on the route before the public read of $M(n)$ and keep provenance and local naming in P, N.

The non-escape boundary of Definition 548.13 then excludes quotient representatives, host real equality, hidden numeric oracles, and ambient completeness. Thus M, R, Q, H, C, P, N cover every depth request. □

Theorem 548.34 (Critical-line witness downstream refusal package)**.** *Every downstream* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet may cite the local witness only as the supplied-input packet*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer cannot read from it a global RH *classifier, a zero construction, an analytic continuation proof, a completeness principle, host equality, or a quotient representative.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream refusal package`

Proof. Project the public packet through Definition 548.1. The exported rows are exactly $Z, S, M, R, Q, H, C, P, N$.

Use Definition 548.14 and Definition 548.15. They identify the ledger as a supplied zero-in-strip witness packet and rule out zero production, host equality, quotient representatives, analytic continuation, and ambient completeness.

Apply Definition 548.18 and Definition 548.31. These theorems keep the packet from becoming a global zero-set classifier or a proof of RH.

Finally use Definition 548.22. It repacks the same carrier, NameCert obligations, strip-zero compatibility, modulus-depth routing, non-escape boundary, and ledger exactness as the finite obligation surface available to downstream consumers. □

Theorem 548.35 (Critical-line witness carrier source)**.** *Every downstream read of an accepted* CriticalLineWitness$^{\uparrow}$ *carrier begins with the finite* BHist *packet*

$$W = (Z, S, M, R, Q, H, C, P, N).$$

The rows Z, S, M, R, Q supply the zero, strip, modulus, real-part, and rational comparison data, while H, C, P, N supply the displayed transports, consumer routes, package provenance, and local NameCert *row. No read starts from a host zero search, quotient representative, or ambient analytic-completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier carrier source`

Proof. Project the carrier from Definition 548.1. The tuple displays exactly the rows $Z, S, M, R, Q, H, C, P, N$.

Use the carrier-admission row of Definition 548.2. It makes the finite packet the entry point for zero, strip, modulus, real-part, comparison, transport, route, provenance, and naming reads.

The non-escape discipline in the same obligation list excludes host zero search, quotient representatives, and analytic completeness. Therefore every downstream read begins with the displayed BHist packet. □

Theorem 548.36 (Critical-line witness classifier separation)**.** *The classifier-facing content of an accepted* CriticalLineWitness$^{\uparrow}$ *carrier separates the supplied zero row Z, the critical-strip row S, and the critical-line modulus row M. The displayed* hsame *and* Cont *rows may transport and replay their alignment, but the packet does not identify these rows by host equality, collapse them into an* RH *classifier, or turn the supplied witness into a global zero-set classification.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier classifier separation`

Proof. Read Z, S, and M as separate coordinates of the carrier. The zero row, strip row, and modulus row have distinct jobs in the finite packet.

Apply Definition 548.9 for the displayed alignment of Z and S, and apply Definition 548.30 for the route from depth requests through M, R, Q.

Finally use Definition 548.18. The classifier-facing rows remain separated by their displayed routes and cannot become host equality, a global RH classifier, or a zero-set classification. □

Theorem 548.37 (Critical-line witness NameCert ledger)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet, the local* NameCert *ledger is exhausted by carrier admission, zero-strip compatibility, modulus discipline, non-escape, and ledger exactness for the rows $Z, S, M, R, Q, H, C, P, N$. A consumer may cite these rows as a finite supplied-witness certificate and may not add a hidden analytic-continuation row, host equality row, or zero-producing row.*

Proof. Start from Definition 548.2. It lists the five local obligation rows for the displayed carrier.

Use Definition 548.14 to identify the public witness surface with the zero, strip, modulus, real-part, rational comparison, transport, route, provenance, and naming rows.

The non-escape and downstream refusal theorems exclude analytic continuation, host equality, and zero production. Thus the local NameCert ledger is exactly the finite packet obligation surface. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier namecert ledger`

Theorem 548.38 (Critical-line witness real-strip handoff)**.** *Every real-part read used by an accepted* CriticalLineWitness$^{\uparrow}$ *packet factors through the supplied critical-strip row S, the real-part row R, the rational comparison ledger Q, and the modulus row M, with transport and replay controlled by H and C. The handoff records a finite strip-to-real witness route only; it does not close analytic continuation, host complex equality, or real completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier real strip handoff`

Proof. Begin with the strip row S and the real-part row R in the carrier. The strip row supplies the displayed critical-strip context, and R is the only real-part coordinate consumed by the modulus.

Apply Definition 548.10. It keeps transported depth requests aligned with the same R row and the comparison ledger Q.

Then use Definition 548.11. The rational comparison rows are precisely the finite rows used by M, so the handoff is a finite strip-to-real route and not an analytic-continuation or completeness principle. □

Theorem 548.39 (Critical-line witness zeta-zero boundary)**.** *The supplied* ZetaZeros$^{\uparrow}$ *row Z in an accepted* CriticalLineWitness$^{\uparrow}$ *packet is a boundary row for the witness surface: downstream consumers may read it only together with S, M, R, Q, H, C, P, N as the finite supplied-zero packet, and cannot extract a zero constructor, global zeta-zero enumeration,* RH *proof, or analytic-continuation certificate from it.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta zero boundary`

Proof. Project the zero row Z from the finite carrier. It is stored as supplied input, not as an output of a search or construction coordinate.

Use Definition 548.15. The zero row remains tied to the same strip, modulus, real-part, comparison, transport, route, provenance, and naming rows.

Finally apply Definition 548.31 and Definition 548.34. These exclude zero construction, global enumeration, RH proof, and analytic-continuation export from the displayed packet. □

Theorem 548.40 (Critical-line witness zero-source totality)**.** *Every accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$ reads its zero row only through the displayed source coordinates Z, S, R, Q, H, C, P, N. The zero-facing source route is therefore a finite* ZetaZeros$^{\uparrow}$–CritStrip$^{\uparrow}$–Real$^{\uparrow}$–Rat$^{\uparrow}$ *route, with componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local* NameCert *evidence, and not a host zero search or an ambient analytic-continuation coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero source totality`

Proof. Project the carrier of Definition 548.1. The accepted packet exposes the zero row Z together with the strip row S, real-part row R, rational comparison ledger Q, transport row H, route row C, package row P, and local naming row N.

Apply Definition 548.39. It already makes Z a supplied boundary row, readable only with the remaining displayed packet coordinates.

Use Definition 548.29 and Definition 548.38. These rows identify the zero read with the supplied $\mathsf{ZetaZeros}^{\uparrow}$ and $\mathsf{CritStrip}^{\uparrow}$ sources and carry the real and rational coordinates through R, Q, H, C, P, N.

The non-escape row of Definition 548.34 then excludes host zero search, analytic continuation, quotient representatives, and ambient completeness. Thus every zero-source read is total through the displayed finite coordinates. □

Theorem 548.41 (Critical-line witness strip-modulus ledger triad)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the critical-strip row* S*, modulus request row* M*, and rational comparison ledger* Q *form one BEDC-visible triad. The triad is transported only by the displayed* hsame *row* H*, replayed only by the displayed* Cont *row* C*, and packaged only through* P *and* N*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier strip modulus ledger triad`

Proof. Read the strip, modulus, and rational rows from the carrier. The packet lists S, M, Q as public coordinates of the same finite BHist witness.

Apply Definition 548.30. Every depth request for M factors through the real-part row, the rational comparison ledger, the transport row, and the continuation route before $M(n)$ is read.

Use Definition 548.32 and Definition 548.33. The first keeps the strip side on the displayed H, C route, while the second exhausts every depth request by M, R, Q, H, C, P, N.

Finally apply Definition 548.22. The carrier, naming, transport, continuation, package, and ledger rows are the finite obligation surface, so the strip row, modulus request, and rational ledger remain one visible triad under hsame, Cont, and Pkg. □

Theorem 548.42 (Critical-line witness RH consumer boundary package)**.** *Every downstream* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives a finite witness boundary consisting of the zero-source route, the strip-modulus ledger triad, the nonproof boundary, the downstream-refusal row, and the local obligation package. The consumer receives no* RH *proof, no global zero-set classifier, no analytic-continuation certificate, and no ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh consumer boundary package`

Proof. Begin with Definition 548.40. It confines every zero-facing read to the displayed $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$ source coordinates and their H, C, P, N routes.

Next use Definition 548.41. It packages the strip row, modulus request, and rational comparison ledger as one finite BEDC-visible triad.

Apply Definition 548.31 and Definition 548.34. These rows prevent downstream consumers from reading the supplied packet as an RH proof, zero construction, analytic-continuation proof, completeness principle, host equality, or quotient representative.

Finally apply Definition 548.22. The prior rows repack into the finite carrier, NameCert, transport, continuation, package, non-escape, and ledger surface. Hence RH-facing consumers receive a finite witness boundary and no RH-level conclusion. □

Theorem 548.43 (Critical-line witness root zero-modulus carrier)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the rows* $Z, S, M, R, Q, H, C, P, N$ *are the only admitted zero/modulus packet available to root-facing consumers. The packet admits the supplied zero row, critical-strip row, finite modulus row, real-part row, rational comparison ledger, transport row, replay row, package row, and local naming row, and it admits no zero search, RH proof, host equality, quotient representative, analytic-continuation certificate, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zero modulus carrier`

Proof. Project the carrier of Definition 548.1. The displayed coordinates are precisely $Z, S, M, R, Q, H, C, P, N$.

Apply Definition 548.42. It packages downstream access as the zero-source route, strip-modulus ledger triad, nonproof boundary, refusal row, and local obligation package.

The nonproof and refusal rows rule out zero search, an RH proof, host equality, quotient representatives, analytic continuation, and ambient completeness. Thus the admitted root packet is exactly the finite zero/modulus packet displayed by the carrier. □

Theorem 548.44 (Critical-line witness root strip readback)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root-facing strip readback is bound to the supplied zero row* Z *and the critical-strip row* S*, then replayed through* M, R, Q, H, C, P, N*. The readback does not compare host complex numbers, identify quotient representatives, or construct a global zero-set classifier.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root strip readback`

Proof. Start with Definition 548.40. It confines zero-facing reads to the supplied $\mathsf{ZetaZeros}^{\uparrow}$ and $\mathsf{CritStrip}^{\uparrow}$ source coordinates and their visible routes.

Use Definition 548.41. The critical-strip row S, modulus row M, and rational ledger Q remain one finite BEDC-visible triad under H, C, P, N.

Finally apply Definition 548.42. It keeps the readback at witness-boundary level and prevents the supplied zero and strip rows from becoming host complex equality, quotient identification, or a global zero classifier. □

Theorem 548.45 (Critical-line witness root consumer threshold)**.** *Every downstream* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *reads root information only through the finite modulus row* M *and rational comparison threshold row* Q*, together with the supplied zero, strip, real-part, transport, replay, package, and naming rows* Z, S, R, H, C, P, N*. Such a consumer cannot read an* RH *proof, perform zero search, or import an ambient analytic classifier.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root consumer threshold`

Proof. Begin with the RH consumer boundary package. It states that downstream consumers receive a finite witness boundary and no RH-level conclusion.

Next use Definition 548.41. It places the threshold information in the strip-modulus ledger triad and routes comparison through the rational ledger Q.

The root zero-modulus carrier theorem identifies the only admitted rows as $Z, S, M, R, Q, H, C, P, N$. Therefore every root-facing downstream read passes through the finite modulus and comparison threshold rows, with no access to an RH proof, zero search, or ambient analytic classifier. □

Theorem 548.46 (Critical-line witness supplied-zero modulus obligation)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet anchored in* BHist*. The local supplied-zero obligation binds the supplied zero row Z, the critical-strip row S, the real-part row R, the rational comparison ledger Q, and the modulus row M as one finite witness packet. Every modulus read from M is therefore sourced through the displayed Z, S, R, Q rows and the visible H, C, P, N routes, not through an ambient zero search, analytic-continuation oracle, or global* RH *classifier.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier supplied zero modulus obligation`

Proof. Start with Definition 548.40. It anchors the zero-facing source route in the displayed Z, S, R, Q, H, C, P, N coordinates of the accepted BHist packet.

Next apply Definition 548.41. The strip row, modulus request row, and rational comparison ledger are read as one BEDC-visible triad, with M connected to S, R, Q only through the displayed transport, continuation, package, and naming routes.

Finally use Definition 548.22. It repacks the same rows as the local finite obligation surface, so the supplied zero, strip, real-part, rational ledger, and modulus obligations remain attached to W and do not open an ambient classifier. □

Theorem 548.47 (Critical-line witness transport replay obligation)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet anchored in* BHist*. The local transport obligation binds componentwise* hsame *evidence from H, displayed* Cont *replay from C, package provenance from* Pkg *through P, and local* NameCert *replay through N to the same zero-strip-modulus ledger. The replay may transport the finite rows, but it may not replace them with host equality, quotient representatives, analytic continuation, or an external naming certificate.*

Proof. Read H, C, P, N together with the zero, strip, modulus, real-part, and rational rows of the carrier. These are coordinates of the same accepted BHist packet, so the transport and replay evidence is local to W.

Apply Definition 548.41. It keeps the S, M, Q triad under the displayed hsame and Cont rows and packages the triad only through P and N.

Then use Definition 548.22. The theorem identifies the carrier, naming, transport, continuation, package, non-escape, and ledger rows as the available obligation surface.

The non-escape part of that package rules out host equality, quotient representatives, analytic continuation, and external naming. Thus the hsame, Cont, Pkg, and NameCert replay is exactly the local replay of the finite ledger. □

Theorem 548.48 (Critical-line witness downstream source obligation)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet anchored in* BHist*. Every* RH*-facing downstream source read factors through the finite supplied-zero and modulus packet consisting of $Z, S, M, R, Q, H, C, P, N$. Such a consumer receives no* RH *proof, no global zero classifier, no host equality, no quotient representative, no analytic-continuation certificate, and no ambient completeness principle.*

Proof. Begin with Definition 548.42. It states the downstream consumer boundary as the zero-source route, strip-modulus ledger triad, nonproof boundary, refusal row, and local obligation package.

Use Definition 548.40 to make the zero source explicit, and use Definition 548.41 to make the modulus source explicit. Together they factor every source read through $Z, S, M, R, Q, H, C, P, N$.

Finally apply Definition 548.22. The package is finite and local to the accepted witness, so downstream reads cannot import an RH proof, global zero classifier, host equality, quotient representative, analytic-continuation certificate, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream source obligation`

Theorem 548.49 (Critical-line witness carrier admission obligation)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the supplied zero row* Z*, critical-strip row* S*, real-part row* R*, rational comparison ledger* Q*, transport row* H*, continuation row* C*, package provenance* P*, and local* NameCert *row* N *combine with the modulus row* M *into the accepted* BHist *carrier surface. Carrier admission exposes exactly those finite rows and no zero search,* RH *proof, host equality, quotient representative, or ambient analytic-completeness row.*

Proof. Apply the carrier-admission row theorem to identify $Z, S, M, R, Q, H, C, P, N$ as the admitted packet. Use the supplied-input carrier row to keep the zero, strip, real-part, and rational comparison rows inside the same accepted BHist surface.

Next apply the NameCert ledger theorem and the transport replay obligation. They attach the displayed hsame, Cont, Pkg, and local NameCert rows to the same packet rather than to an external analytic certificate.

Finally use the downstream source obligation. It rules out RH proof data, zero search, host equality, quotient representatives, and analytic-completeness rows as carrier coordinates, so the admitted carrier surface is exactly the finite packet displayed above. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier admission obligation`

Theorem 548.50 (Critical-line witness zero-strip compatibility obligation)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, the supplied zero row* Z *and critical-strip row* S *are consumed together before any modulus row* M*, rational comparison ledger* Q*, or* RH*-facing read is available. The zero and strip rows therefore form a local compatibility obligation over the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, not a global zero-set classifier.*

Proof. Use strip-zero compatibility and strip-zero route exactness. These theorems bind Z and S to the same supplied complex-history route through the displayed transport and continuation rows.

Then apply zero-source totality together with root strip readback. They force every zero-facing read to pass through the supplied zero and strip rows before the modulus or rational comparison ledger can be inspected.

The RH consumer boundary package keeps the combined read at witness-boundary level. Thus the compatibility obligation is consumed before any modulus or RH-facing read and cannot become a global zero classifier. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip compatibility obligation`

Theorem 548.51 (Critical-line witness public route)**.** *Every public* $\mathsf{CriticalLineWitness}^{\uparrow}$ *read factors through the supplied-zero row* Z*, the strip-modulus ledger* S, M*, the rational comparison ledger* Q*, the zeta-zero boundary, the* RH *nonproof boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row before it can be consumed as a critical-line witness. The route exports no* RH *proof, global zero classification, quotient equality, or hidden analytic continuation.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessPublicRoute`

Proof. Begin with the public consumer factorization of Definition 548.25. It requires every public witness consumer to stay inside the supplied packet rows before reading the witness conclusion.

Use strip-zero route exactness, supplied-zero readback, and the zeta-zero boundary: Definition 548.28, Definition 548.29, and Definition 548.39. These rows keep the supplied zero and critical-strip side on the finite Z, S, H, C, P, N route.

Next apply the rational and modulus side through the existing strip-modulus ledger surface, then package the downstream boundary with Definition 548.42. The consumer receives the witness as a finite zero-source, strip-modulus, rational-comparison, transport, replay, provenance, and local naming route.

The cited boundary package is explicitly nonproof-facing. Hence no RH proof, global zero classification, quotient equality, or hidden analytic-continuation certificate is exported by the public route. □

Theorem 548.52 (Critical-line witness ledger non-escape obligation)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, the modulus row M, rational comparison ledger Q, componentwise* hsame *row H, continuation row C, package row P, and local* NameCert *row N exhaust the local ledger together with Z, S, R. The ledger excludes an* RH *proof, zero search, analytic-continuation certificate, quotient representative, host equality row, and ambient analytic-completeness row.*

Proof. Apply the modulus-ledger non-escape theorem and the rat comparison ledger exactness theorem. They identify M and Q as the finite threshold and comparison route available to the witness.

Next use the transport replay obligation. It binds H, C, P, N to that same zero-strip-modulus ledger and prevents the replay rows from replacing the ledger with host equality, quotient data, or external naming.

Finally apply the downstream refusal package and downstream source obligation. These results exclude RH proof data, zero search, analytic continuation, quotient representatives, host equality, and ambient completeness from all downstream reads, so the displayed finite rows exhaust the local ledger. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessLedgerNonescapeObligation`

Theorem 548.53 (Critical-line witness scoped strip source)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The scoped strip-source route binds the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row Z, the* $\mathsf{CritStrip}^{\uparrow}$ *row S, the* $\mathsf{Nat}^{\uparrow}$ *depth requests for M, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger Q, the* $\mathsf{Real}^{\uparrow}$ *real-part row R, and the local* BHist, hsame, Cont, Pkg, *and* NameCert *rows into one finite source surface. The route asserts only that the supplied zero-in-strip input is the source of the displayed witness packet; it does not assert* RH, *analytic continuation, or a completed zero classification.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessScopedStripSourcePackage`

Proof. Begin with the supplied zero-strip transport lock. It keeps the $\mathsf{ZetaZeros}^{\uparrow}$ row Z and the $\mathsf{CritStrip}^{\uparrow}$ row S attached to the same displayed history through H and C.

Next attach the depth and comparison route. The modulus comparison route and root comparison ledger force each $\mathsf{Nat}^{\uparrow}$ request for M to read the $\mathsf{Real}^{\uparrow}$ row R and the $\mathsf{Rat}^{\uparrow}$ ledger Q inside the same finite packet.

Finally apply the downstream refusal ledger. The package row P and local certificate N name the source surface, while the refusal rows exclude RH proof data, analytic continuation, host equality, quotient representatives, and global zero classification. □

Theorem 548.54 (Critical-line witness rational height ledger)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every displayed height read of the witness factors through a finite natural depth request and the rational comparison ledger. The read uses only the* $\mathsf{Nat}^{\uparrow}$ *request for* M*, the* $\mathsf{Rat}^{\uparrow}$ *rows inside* Q*, the* $\mathsf{Real}^{\uparrow}$ *real-part row* R*, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; it does not use a host real equality, quotient representative, hidden numeric oracle, analytic-continuation certificate, or completed zero-set classifier.*

Proof. Project the modulus and ledger coordinates from the packet. A height request is first a finite $\mathsf{Nat}^{\uparrow}$ depth request to M, not an infinite analytic search.

Read the answer through the rational comparison ledger. The row Q contains the half-line, dyadic tolerance, and strict comparison rows used by the modulus route, and the real-part row R is the only $\mathsf{Real}^{\uparrow}$ source visible to that comparison.

Use transport replay and ledger exactness to close the route. The rows H, C, P, N carry the natural request and rational ledger inside the same accepted packet, so no host equality, quotient representative, hidden numeric oracle, analytic continuation, or global zero classification enters the height read. □

Theorem 548.55 (Critical-line witness NameCert scope package)**.** *The scoped strip-source theorem Definition 548.53 and the rational-height ledger theorem Definition 548.54 assemble the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *scope for an accepted packet* $W = (Z, S, M, R, Q, H, C, P, N)$*. The scope consists exactly of the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *and* $\mathsf{CritStrip}^{\uparrow}$ *rows, the* $\mathsf{Nat}^{\uparrow}$ *depth route, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger, the* $\mathsf{Real}^{\uparrow}$ *real-part row, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *evidence.*

Proof. First use scoped strip source. It binds Z and S as supplied source rows and keeps the zero-strip route inside the displayed transport and continuation surface.

Next use the rational height ledger. It identifies each witness-height read with the finite natural request, the real-part row, and the rational ledger Q.

Finally repack the two rows into the local naming surface. The packet's BHist, hsame, Cont, Pkg, and NameCert coordinates record exactly those source and ledger routes, while the existing refusal boundary excludes RH, analytic continuation, host equality, quotient representatives, and completed zero classification. □

Theorem 548.56 (Critical-line witness scoped source lock)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The scoped source lock of* W *is the finite route through the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*, supplied* $\mathsf{CritStrip}^{\uparrow}$ *row* S*,* $\mathsf{Real}^{\uparrow}$ *real-part row* R*,* $\mathsf{Rat}^{\uparrow}$ *comparison ledger* Q*, accepted* BHist *carrier surface, componentwise* hsame *row* H*,* Cont *replay row* C*,* Pkg *provenance row* P*, and local* NameCert *row* N*. Every source read for* W *is bound to those rows and cannot be replaced by host equality, a global zero-set classifier, analytic continuation, quotient representation, or ambient completeness.*

Proof. Start with carrier admission for the accepted packet. The carrier exposes $Z, S, M, R, Q, H, C, P, N$ as the available finite rows and gives no coordinate for host equality, quotient data, analytic continuation, or ambient completeness.

Use zero-strip compatibility to bind Z and S to the same supplied source over $\mathsf{ZetaZeros}^{\uparrow}$ and $\mathsf{CritStrip}^{\uparrow}$. Transport then occurs only through the displayed BHist and hsame rows, and continuation reads occur only through C.

Finally apply the modulus comparison route totality and RH-refusal ledger completeness. They attach R, Q, P, N to the same route and exclude global zero classification and RH proof data from the source surface. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier scoped source lock`

Theorem 548.57 (Critical-line witness scoped ledger exactness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The ledger exactness surface for W consists exactly of the modulus row M, the* $\mathsf{Real}^{\uparrow}$ *row R, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger Q, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows H, C, P, N. Any downstream comparison or modulus consumer must factor through that surface after reading the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *and* $\mathsf{CritStrip}^{\uparrow}$ *rows Z, S.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier scoped ledger exactness`

Proof. Project the modulus and comparison rows from the carrier. The modulus row M, real-part row R, and rational comparison ledger Q are displayed coordinates of the same accepted packet.

Apply the modulus comparison route totality. It forces comparison reads through M, R, Q, H, C, P, N and makes the route total without adding a hidden numeric oracle, host real equality, quotient representative, or analytic-continuation certificate.

The root comparison ledger then supplies exactness for downstream consumers. Together with the scoped source lock, the comparison surface is the finite ledger following the supplied Z, S source rows and no second ledger is available. □

Theorem 548.58 (Critical-line witness scoped nonescape boundary)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, the scoped nonescape boundary is the refusal row generated by the same* $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *dependencies. It permits downstream use of the finite source lock and ledger exactness, but it exports no* RH *proof, no zero search, no global zero classifier, no host equality, no quotient representative, no analytic-continuation certificate, and no ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier scoped nonescape boundary`

Proof. Begin with the scoped source lock. It identifies the only source dependencies available to a downstream consumer as Z, S, R, Q, H, C, P, N together with the accepted packet row.

Use scoped ledger exactness for every modulus or comparison read. The ledger route stays inside M, R, Q, H, C, P, N and therefore cannot become an independent analytic or quotient route.

Finally invoke RH-refusal ledger completeness and the root refusal route. These refusal rows already cover RH proof data, zero search, global zero classification, host equality, quotient representatives, analytic continuation, and ambient completeness, so the scoped boundary is closed under the stated nonescape obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CriticalLineWitness}^{\uparrow}$ packet is generated from a supplied zeta-zero row, a supplied critical-strip row, an on-critical-line modulus row, a real-part row, rational half-line and dyadic comparison rows, displayed transports, continuation routes, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$, publicClosed)

Scope closed: The public scope records the finite carrier, witness-ledger, and public route surface for supplied zero-in-strip inputs over $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not prove RH, produce zeros, close the global zero-set classifier, construct analytic continuation, assert host equality, select quotient representatives, or invoke ambient analytic completeness.

Upgrade path: Scoped closure requires grounding the carrier admission, zero-strip compatibility, and ledger nonescape obligations against the named $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Theorem 548.59 (Critical-line witness source normalization interface)**.** *Every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet first exposes the supplied zero row from* $\mathsf{ZetaZeros}^{\uparrow}$*, the critical-strip row from* $\mathsf{CritStrip}^{\uparrow}$*, the depth row from* $\mathsf{Nat}^{\uparrow}$*, the rational comparison row from* $\mathsf{Rat}^{\uparrow}$*, and the real-part row from* $\mathsf{Real}^{\uparrow}$ *through the finite surface*

$$Z, S, M, R, Q, H, C, P, N.$$

No downstream RH-boundary consumer may read a modulus, comparison, or naming row before this supplied source surface is visible.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source normalization interface`

Proof. Start with the local NameCert obligations of Definition 548.2. They make the accepted carrier and its naming row a finite packet over $Z, S, M, R, Q, H, C, P, N$.

Apply the root-unblock source triad of Definition 548.3. It exposes the supplied zero row, critical-strip row, and source-facing comparison row before downstream use.

Finally use the terminal zero-source totality of Definition 548.114. The terminal source route begins at the displayed $\mathsf{ZetaZeros}^{\uparrow}$ and $\mathsf{CritStrip}^{\uparrow}$ rows and reaches the $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads only through the same structural rows H, C, P, N. □

Theorem 548.60 (Critical-line witness modulus ledger interface)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, all modulus and comparison reads factor through*

$$M, R, Q, H, C, P, N$$

after the supplied zero and strip rows Z, S *have been exposed. The modulus row* M *answers only displayed* $\mathsf{Nat}^{\uparrow}$ *depth requests, the real-part row* R *supplies the* $\mathsf{Real}^{\uparrow}$ *read, and the rational ledger* Q *supplies the* $\mathsf{Rat}^{\uparrow}$ *comparison boundary.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus classifier join`

Proof. First expose the source rows by Definition 548.59. This places every modulus request downstream of the supplied $\mathsf{ZetaZeros}^{\uparrow}$ zero row and $\mathsf{CritStrip}^{\uparrow}$ strip row.

Apply the NameCert obligations of Definition 548.2. The modulus-discipline and ledger-exactness rows attach M to the displayed depth request and attach R, Q to the real-part and rational comparison reads.

Then use Definition 548.114. It keeps terminal consumers on the same route rows H, C, P, N, so the modulus and comparison interface cannot bypass the supplied zero-strip rows. □

Theorem 548.61 (Critical-line witness root source/modulus formal boundary)**.** *The checked source-normalization row and source-modulus classifier-join row expose only the finite route*

$$Z, S, M, R, Q, H, C, P, N.$$

Consequently the root source/modulus interface leaves RH *proof content, global zero classification, zero search, analytic continuation, ambient completeness, host equality, and quotient representatives outside the formal boundary read by* $\mathsf{CriticalLineWitness}^{\uparrow}$ *consumers.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source modulus interface formal boundary`

Proof. Apply the source-normalization interface, Definition 548.59. It exposes the supplied zero row, critical-strip row, depth row, rational comparison row, and real-part row only through the displayed packet $Z, S, M, R, Q, H, C, P, N$.

Next use the modulus ledger interface, Definition 548.60. The modulus and comparison reads remain downstream of the supplied zero-strip rows and factor through the same finite route.

Finally apply the RH refusal interface, Definition 548.62. Since the refusal interface is attached to exactly the same source/modulus rows, no downstream consumer can read RH proof content, global zero classification, zero search, analytic continuation, ambient completeness, host equality, or quotient representatives from the checked interface. □

Theorem 548.62 (Critical-line witness RH refusal interface)**.** *The combined critical-line witness interface over $Z, S, M, R, Q, H, C, P, N$ refuses* RH *proof content, global zero classification, zero search, host equality, quotient representatives, analytic continuation, and ambient completeness. It exports only the supplied zero-strip rows, modulus row, real-part row, rational comparison ledger, transports, continuations, provenance, and local naming.*

Proof. Use Definition 548.59 and Definition 548.60 to assemble the source and comparison sides of the finite packet. Together they expose exactly $Z, S, M, R, Q, H, C, P, N$.

Apply the terminal RH-refusal exactness of Definition 548.116. It identifies the RH-facing terminal boundary with the finite packet and excludes proof content, global classification, search, quotient representatives, analytic continuation, and completeness.

The same exclusion also removes host equality as a source for the packet rows. Hence downstream RH-boundary consumers receive a refusal interface rather than an analytic or global-zero certificate. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal interface`

Theorem 548.63 (Critical-line witness source/modulus consumer determinacy)**.** *Let two* CriticalLineWitness$^{\uparrow}$ *consumer reads expose the same finite rows*

$$Z, S, M, R, Q, H, C, P, N.$$

Then they determine the same source/modulus boundary before any RH-boundary request is inspected: the supplied zero row Z, critical-strip row S, depth/modulus row M, real-part row R, rational comparison row Q, componentwise transport H, replay C, provenance P, and local naming row N are fixed as the shared consumer interface. The determinacy does not expose RH *proof content, global zero classification, zero search, analytic continuation, host equality, quotient representatives, or ambient completeness.*

Proof. First apply Definition 548.59 to both consumer reads. Since the two reads expose the same $Z, S, M, R, Q, H, C, P, N$ rows, the supplied zero and critical-strip source boundary is identical before any downstream request is considered.

Next use Definition 548.60. The depth/modulus, real-part, and rational comparison rows are downstream of the same source rows and are read through the same structural rows, so the source/modulus ledger cannot split into two consumer boundaries.

Apply Definition 548.61. It identifies the formal boundary with exactly the displayed finite route, preventing either read from importing a second analytic or host-side source.

Finally use Definition 548.62. Because RH proof content, global zero classification, zero search, analytic continuation, host equality, quotient representatives, and ambient completeness are refused at the same finite boundary, the two reads agree before any RH-boundary request is inspected. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus consumer determinacy`

Theorem 548.64 (Critical-line witness root source-modulus admission)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. A root consumer may admit a source-modulus read only after the supplied zero row Z, critical-strip row S, modulus row M, real-part row R, rational comparison row Q, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows are visible. The admitted route has no* RH *proof, zero-search oracle, global zero classifier, analytic-continuation certificate, quotient representative, host equality, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source modulus admission`

Proof. Begin with the source normalization interface of Definition 548.59. It exposes the supplied zero, strip, depth, rational-comparison, and real-part rows before any downstream boundary may request a modulus read.

Next apply the modulus ledger interface of Definition 548.60. It places every modulus and comparison request on M, R, Q, H, C, P, N after the supplied source rows have been exposed.

Finally use the root non-escape package of Definition 548.69. The admitted source-modulus read is therefore exactly the finite BHist, hsame, Cont, Pkg, and NameCert packet route, with no analytic or host-level escape. □

Theorem 548.65 (Critical-line witness zero-strip budget factorization)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every zero-strip budget request factors through the supplied Z, S rows and the same modulus ledger M, R, Q, H, C, P, N. The factorized route reads the displayed* BHist *carrier rows, the componentwise* hsame *transport, the* Cont *replay route, the* Pkg *provenance row, and the local* NameCert *row, and it exports no external zeta-zero enumeration, zero-search route, quotient representative, host equality, analytic-continuation certificate, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip budget factorization`

Proof. Use the zero-strip carrier totality theorem Definition 548.73. It identifies the root carrier exactly with $Z, S, M, R, Q, H, C, P, N$ and removes every non-displayed analytic or host coordinate from the packet.

Apply the zero-strip classifier transport theorem Definition 548.74. Any replacement of the supplied zero-strip classifier pair must use the same H, C, P, N route, so the budget request cannot bypass hsame, Cont, Pkg, or NameCert.

The root source-modulus admission theorem Definition 548.64 then supplies the shared modulus side. Hence the zero-strip budget factors through the finite source and modulus rows rather than through an independent zeta or host-real interface. □

Theorem 548.66 (Critical-line witness zeta-continuation readback non-escape)**.** *Every zeta-continuation readback of an accepted* CriticalLineWitness$^{\uparrow}$ *root packet is exhausted by the displayed packet $Z, S, M, R, Q, H, C, P, N$ and by the local* BHist, hsame, Cont, Pkg, *and* NameCert *rows. The readback may cite the sibling zeta-continuation boundary already named by the chapter, but it exports no proof of* RH, *no analytic-continuation theorem, no global zero classifier, no quotient representative, no host equality, and no ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta continuation readback nonescape`

Proof. Start with the zeta dependency lattice of Definition 548.169. It places every zero-strip or critical-line read behind the existing $\mathsf{ZetaZeros}^{\uparrow}$ and RH-boundary surfaces before the local modulus witness is public.

Next apply the downstream source package of Definition 548.179. That package combines the local finite rows with the sibling $\mathsf{ZetaContinuationWitness}^{\uparrow}$ source lock, while still exposing only $Z, S, M, R, Q, H, C, P, N$ to downstream consumers.

Finally combine the zero-strip budget factorization of Definition 548.65 with the RH refusal interface of Definition 548.62. The readback remains a finite BEDC packet route through BHist, hsame, Cont, Pkg, and NameCert, so no analytic-continuation theorem or global zero certificate can escape from it. □

Theorem 548.67 (Critical-line witness root zero-strip route)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The supplied zero row Z and critical-strip row S route through the displayed* hsame *row H and* Cont *row C before any modulus, rational comparison, or downstream RH-facing read is exposed. No consumer may replace this route by zero search, host equality, a quotient representative, analytic continuation, or an ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zero strip route`

Proof. Project the carrier of Definition 548.1. The rows Z and S are displayed coordinates of the accepted BHist packet, while H and C are the local transport and replay rows that carry those coordinates.

Apply the supplied zero-strip route of Definition 548.82. It identifies the root-facing read of the supplied zero and strip rows with the finite route Z, S, H, C, P, N.

Use the supplied zero-strip transport lock of Definition 548.71. Since the lock rules out host equality, zero search, quotient identification, analytic continuation, and ambient completeness, the root zero-strip route remains exactly the displayed hsame and Cont route. □

Theorem 548.68 (Critical-line witness root modulus ledger)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, each natural-number depth request for the modulus row reads only the finite ledger*

$$M, R, Q, H, C, P, N.$$

The request may use the displayed modulus row, real-part row, rational comparison ledger, transport row, continuation row, package row, and local naming row, but it receives no hidden numeric oracle, host equality, quotient representative, analytic-continuation certificate, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus ledger`

Proof. Begin with the modulus ledger entry of Definition 548.83. It names M, R, Q, H, C, P, N as the finite route for the $\mathsf{Real}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ modulus-facing ledger.

Next apply Definition 548.17 and Definition 548.30. These results force each natural-number depth request through the displayed continuation route before any public modulus read is available.

Finally use Definition 548.77. The rational comparison part stays inside Q together with M, R, H, C, P, N, so the depth request cannot escape to a hidden numeric oracle, host equality, quotient data, analytic continuation, or ambient completeness. □

Theorem 548.69 (Critical-line witness root non-escape package)**.** *The root-facing* $\mathsf{CriticalLineWitness}^{\uparrow}$ *package exported to downstream consumers consists only of the supplied zero-strip route, the modulus ledger route, and the local* BHist, hsame, Cont, Pkg, *and* NameCert *rows. It exports no* RH

proof, no zero search, no global zero classifier, no host equality, no quotient representative, and no ambient analytic completeness.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root nonescape package`

Proof. First combine Definition 548.67 with Definition 548.68. The first theorem supplies the finite zero-strip route, and the second theorem supplies the finite modulus and rational-comparison route.

Next apply Definition 548.84. It packages the downstream RH-facing boundary as the supplied zero-strip route, modulus ledger entry, and local BEDC rows.

Finally use Definition 548.78. That route refuses RH proof data, zero search, global zero classification, host equality, quotient representatives, analytic continuation, and ambient completeness, so the exported package contains exactly the finite boundary described above. □

Theorem 548.70 (Critical-line witness modulus comparison route totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every modulus comparison route of W factors through the displayed modulus row M, real-part row R, rational comparison ledger Q, transport row H, continuation row C, package row P, and local* NameCert *row N. No comparison route reads a global zero classifier, host equality, quotient representative, analytic-continuation certificate, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus comparison route totality`

Proof. Start with the modulus request factorization of Definition 548.30. It places each comparison request on the displayed Cont route before the public read of M and keeps the request inside R, Q, H, C, P, N.

Then use the strip-modulus ledger triad of Definition 548.41. The strip row, modulus request row, and rational comparison ledger are one finite BEDC-visible triad under the same transport, continuation, package, and naming rows.

Finally apply the obligation closure package of Definition 548.22. The available obligation surface is exactly the carrier, naming, transport, continuation, package, non-escape, and ledger rows, so every modulus comparison route is total through M, R, Q, H, C, P, N. □

Theorem 548.71 (Critical-line witness supplied zero-strip transport lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The supplied zero row Z and critical-strip row S remain locked to the displayed* BHist *surface by the componentwise* hsame *transport row H, together with C, P, N. They cannot be replaced by host equality, zero search, a global zero-set classifier, quotient identification, or analytic continuation.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier supplied zero strip transport lock`

Proof. Project the supplied input carrier row of Definition 548.23. The rows Z and S are input coordinates of the accepted packet, while modulus and comparison rows are read only after those supplied rows are exposed.

Next use supplied zero readback from Definition 548.29 and strip-zero compatibility from Definition 548.9. These rows identify the zero-facing and strip-facing routes with the displayed BHist packet and its hsame transport.

The downstream refusal package of Definition 548.34 supplies the non-escape clause. It excludes host equality, zero search, global zero classification, quotient representatives, analytic continuation,

and ambient completeness, so the zero-strip pair remains locked by the displayed transport route. □

Theorem 548.72 (Critical-line witness RH-refusal ledger completeness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The refusal ledger of W is complete for excluding an* RH *proof, a global zero classifier, an analytic-continuation certificate, a quotient representative, and ambient completeness from every downstream read. Downstream consumers can cite only $Z, S, M, R, Q, H, C, P, N$ and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal ledger completeness`

Proof. Begin with the RH consumer boundary package of Definition 548.42. It packages downstream access as the zero-source route, strip-modulus ledger triad, nonproof boundary, refusal row, and local obligation surface.

Use downstream source obligation from Definition 548.48. It factors every RH-facing downstream source read through the finite supplied-zero and modulus packet $Z, S, M, R, Q, H, C, P, N$.

Finally apply downstream refusal package from Definition 548.34 and ledger non-escape obligation from Definition 548.52. These rows exclude RH proof data, global zero classification, analytic continuation, quotient representatives, host equality, and ambient completeness from the ledger, so the refusal surface is complete for the listed downstream exclusions. □

Theorem 548.73 (Critical-line witness zero-strip carrier totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The root carrier of W is total exactly over the supplied zero row Z, critical-strip row S, modulus row M, real-part row R, rational comparison ledger Q, and structural rows H, C, P, N. It has no coordinate for an* RH *proof, global zero classifier, analytic-continuation certificate, quotient representative, host equality, or ambient completeness principle.*

Proof. Apply Definition 548.70. It places every modulus and rational comparison read inside M, R, Q, H, C, P, N and excludes analytic, quotient, host-equality, and completeness coordinates from the comparison route.

Next use Definition 548.71. The supplied zero row Z and critical-strip row S remain locked to the same BHist, hsame, Cont, Pkg, and NameCert route.

The root-source triad of Definition 548.76 and the root comparison ledger of Definition 548.77 assemble the carrier rows visible to downstream consumers. Finally Definition 548.72 removes every requested RH proof, global zero classifier, analytic-continuation certificate, quotient representative, host equality, and ambient completeness coordinate not displayed in W. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip carrier totality`

Theorem 548.74 (Critical-line witness zero-strip classifier transport)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Any replacement of the supplied zero-strip classifier pair must transport through the same componentwise* hsame *row H, displayed* Cont *row C,* Pkg *row P, and local* NameCert *row N. Such a replacement cannot substitute a host zero-search, global zero-set classifier, analytic-continuation certificate, quotient representative, host equality, or ambient completeness coordinate for Z, S.*

Proof. Start with Definition 548.71. It binds the rows Z, S to the displayed componentwise transport route and prevents their replacement by host equality, zero search, quotient identification, or analytic continuation.

Use Definition 548.76. The zero-strip pair is part of the finite source triad seen by downstream readers, and the triad is carried only through H, C, P, N.

Now apply the root comparison ledger of Definition 548.77 and the RH-refusal ledger completeness of Definition 548.72. The comparison and refusal rows leave no public slot from which a replacement classifier could import a host zero search, analytic certificate, quotient representative, host equality, or ambient completeness witness. □

Theorem 548.75 (Critical-line witness RH refusal non-escape)**.** *Every* RH*-facing downstream read of an accepted* CriticalLineWitness$^{\uparrow}$ *packet factors through the finite refusal route over* $Z, S, M, R, Q, H, C, P, N$*. The read exports only the displayed refusal ledger: it does not export an* RH *proof, a zero-set classifier, a host zero-search route, an analytic-continuation certificate, a quotient representative, host equality, or ambient completeness.*

Proof. First apply Definition 548.72. It already exhausts downstream RH-facing access by the displayed rows $Z, S, M, R, Q, H, C, P, N$ and by the visible BHist, hsame, Cont, Pkg, and NameCert structure.

Then combine Definition 548.70 with Definition 548.71. The comparison side must read M, R, Q, H, C, P, N, while the zero-strip side must read Z, S, H, C, P, N.

Finally use Definition 548.76 and Definition 548.77. Together they identify the root-facing source and comparison rows as one finite refusal package, with no exported proof of RH and no exported zero-set classifier. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal nonescape`
Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip classifier transport`

Theorem 548.76 (Critical-line witness root source triad)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The supplied zero row* Z*, the critical-strip row* S*, and the rational comparison ledger* Q *are exposed as one finite* BHist *source triad before any downstream boundary may read the packet. The triad is carried only through the displayed transport row* H*, continuation row* C*, package row* P*, and local* NameCert *row* N*.*

Proof. Read the carrier of Definition 548.1. Its accepted packet has Z, S, and Q as displayed rows, so the root-facing source data are already finite BHist coordinates rather than host zero data or analytic structure.

Apply Definition 548.2. The local naming row requires the carrier, classifier, transport, package, and ledger obligations to be discharged on the same visible packet.

Finally combine Definition 548.70 with Definition 548.71. The comparison ledger is total through the displayed modulus and rational comparison rows, while the zero and strip rows stay locked to H, C, P, N. Hence Z, S, Q form the finite source triad available to downstream boundary chapters. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source triad`

Theorem 548.77 (Critical-line witness root comparison ledger)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every root-facing rational comparison used by a downstream consumer factors through the finite ledger* Q *together with* M, R, H, C, P, N*. The comparison route does not read a global zero set, a quotient representative, analytic continuation, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root comparison ledger`

Proof. Start with the modulus comparison route totality of Definition 548.70. It places every comparison request on the displayed modulus, real-part, rational comparison, transport, continuation, package, and naming rows.

Use Definition 548.2 to bind that comparison route to the local carrier and ledger obligations. The obligation surface is finite and names only the accepted packet coordinates.

The supplied zero-strip transport lock of Definition 548.71 prevents the comparison route from being replaced by a host zero search, quotient representative, analytic continuation certificate, or ambient completeness row. Thus the root-facing comparison ledger is exactly the displayed finite route through Q. □

Theorem 548.78 (Critical-line witness root refusal route)**.** *The root-facing route of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet refuses every downstream request for an* RH *proof, zero search, global zero classifier, analytic-continuation certificate, quotient representative, host equality, or ambient completeness witness. A downstream chapter may cite only the finite source triad* Z, S, Q *and the displayed rows* M, R, H, C, P, N*.*

Proof. Begin with the root source triad of Definition 548.76. It exposes the supplied zero row, critical-strip row, and rational comparison ledger as finite BHist rows under the same transport and naming surface.

Next use the root comparison ledger of Definition 548.77. It forces every rational comparison read through the displayed Q route and rules out analytic and quotient replacements.

Finally apply Definition 548.72. The refusal ledger already excludes RH proof data, zero classification, analytic continuation, quotient representatives, host equality, and ambient completeness, so the root-facing route is a finite refusal package rather than an analytic proof surface. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root refusal route`

Theorem 548.79 (Critical-line witness boundary obligation surface)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The root boundary exposed by* W *is exactly the finite obligation surface consisting of the supplied source row* S*, supplied zero row* Z*, zero-strip and modulus row* M*, rational comparison row* Q*, real-part row* R*, componentwise* BHist *and* hsame *transport row* H*, displayed* Cont *row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row* N*. Every boundary read of* W *factors through the root obligation rows of Definition 548.70, Definition 548.71, and Definition 548.72, and no read exports an* RH *proof, a zero-location theorem, analytic continuation, quotient equality, host equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier boundary obligation surface`

Proof. Project the accepted packet to its displayed rows. The source row S, zero row Z, modulus row M, comparison row Q, real-part row R, and structural rows H, C, P, N are coordinates of the same finite carrier, so the boundary read begins from the BHist packet rather than from an analytic host object.

Apply Definition 548.70 for the M, R, Q, H, C, P, N side and Definition 548.71 for the Z, S, H, C, P, N side. These two rows bind source and modulus access before any downstream read reaches the packet.

Finally apply Definition 548.72. It removes every requested RH proof, zero-location theorem, analytic-continuation certificate, quotient equality, host equality, and ambient-completeness coordinate not displayed in W. □

Theorem 548.80 (Critical-line witness source-modulus readback)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. A readback that asks for both the supplied source row and the zero-strip/modulus row must expose S and M through the same finite route*

$$Z, S, M, R, Q, H, C, P, N.$$

The route uses BHist *carrier data,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row; it cannot replace the source row by zero search, replace the modulus row by a host analytic estimate, or infer* RH *from the coexistence of S and M.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus readback`
↪ variant `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus readback surface`

Proof. Read the source side first. The supplied zero-strip transport lock of Definition 548.71 keeps Z and S attached to the componentwise transport row H and to the displayed C, P, N rows.

Read the modulus side next. The modulus comparison route totality of Definition 548.70 forces every modulus comparison through M, R, Q, H, C, P, N and leaves no coordinate for a host analytic estimate.

The two reads share H, C, P, N, so the readback is one finite packet read over $Z, S, M, R, Q, H, C, P, N$. The refusal ledger of Definition 548.72 keeps the joint read from becoming an RH proof or a zero-location theorem. □

Theorem 548.81 (Critical-line witness RH-refusal ledger route)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every* RH*-facing request made to W is routed to the refusal ledger over the same rows $Z, S, M, R, Q, H, C, P, N$. The ledger may report the supplied zero row, the critical-strip source row, the zero-strip/modulus row, the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *structure, and the rational comparison boundary; it reports no* RH *theorem, no zero-location theorem, no global zero classifier, no quotient representative, no host equality, and no ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal ledger route`

Proof. Begin with the complete refusal ledger of Definition 548.72. It already states that downstream RH-facing reads can cite only the displayed rows of the packet and the visible structural data.

Use Definition 548.76 to identify the source side of that ledger, and use Definition 548.77 to identify the rational comparison side. Together they account for Z, S, Q and for the M, R, H, C, P, N support rows needed by readback.

Since the carrier has no coordinate for an RH theorem, zero-location theorem, global classifier, quotient representative, host equality, or ambient completeness principle, the ledger route is exhausted by the displayed packet. □

Theorem 548.82 (Critical-line witness supplied zero-strip route)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every root-facing read of the supplied* ZetaZeros$^{\uparrow}$ *row and the* CritStrip$^{\uparrow}$ *row factors through the displayed finite route*

$$Z, S, H, C, P, N.$$

The route is supplied by the packet carrier and local NameCert *obligations, and it cannot be replaced by zero search, host complex equality, a global zero-set classifier, quotient representatives, analytic continuation, or ambient completeness.*

Proof. Read the carrier in Definition 548.1. The rows Z and S are displayed coordinates of the accepted finite packet, and H, C, P, N are the transport, continuation, provenance, and local naming rows that carry them.

Apply Definition 548.2 and Definition 548.23. These results make the supplied zero and strip rows the entry point for zero-facing reads before any modulus or comparison route is consumed.

Use Definition 548.9, Definition 548.28, and Definition 548.29. They keep the zero-strip read on the same displayed BHist surface and through the same hsame and Cont rows.

Finally apply Definition 548.13. Since the excluded analytic and host-level coordinates are absent from the packet, the supplied zero-strip route is exactly the finite route through Z, S, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier supplied zero strip route`

Theorem 548.83 (Critical-line witness modulus ledger entry)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$ *modulus-facing ledger entry is the finite route through*

$$M, R, Q, H, C, P, N.$$

Every depth or rational-comparison read used by a downstream root consumer enters through the displayed modulus row, real-part row, rational comparison ledger, transport row, continuation row, package row, and local NameCert *row, and no hidden numeric oracle or quotient representative is supplied.*

Proof. Begin with the modulus row and NameCert obligations from Definition 548.12 and Definition 548.2. They identify M as the finite row answering depth requests and attach it to R, Q, H, C, P, N.

Next use Definition 548.17 and Definition 548.30. These theorems force every depth request through the displayed continuation route before a public read of $M(n)$ is available.

Apply Definition 548.11, Definition 548.14, and Definition 548.70. They identify the rational comparison surface with Q and keep the $\mathsf{Real}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ comparison data inside the same finite ledger entry.

The non-escape clauses of Definition 548.13 and Definition 548.27 then remove host equality, hidden numeric oracles, quotient representatives, analytic continuation, and ambient completeness from the ledger entry. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus ledger entry`

Theorem 548.84 (Critical-line witness RH non-escape package)**.** *The root-facing* $\mathsf{CriticalLineWitness}^{\uparrow}$ *package supplies a finite witness boundary for downstream RH-facing consumers but does not supply an* RH *proof, zero search, host equality, quotient representatives, analytic continuation, or analytic completeness. A downstream read may cite only the supplied zero-strip route* Z, S, H, C, P, N*, the modulus ledger entry* M, R, Q, H, C, P, N*, and the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRhNonescapePackage`

Proof. First combine Definition 548.82 with Definition 548.83. The first theorem supplies the finite zero-strip route, and the second theorem supplies the finite modulus and rational-comparison ledger.

Next apply Definition 548.42 and Definition 548.48. These results bind every downstream RH-facing read to the displayed supplied-input packet and its finite modulus ledger.

Use Definition 548.18, Definition 548.31, and Definition 548.34. They refuse global zero classification, zero search, analytic-continuation export, and any proof of RH from the accepted packet.

Finally apply Definition 548.72. The refusal ledger excludes host equality, quotient representatives, analytic completeness, and the other analytic rows, so the root-facing package is precisely the finite non-escape boundary described above. □

Theorem 548.85 (Critical-line witness root modulus-window totality)**.** *Every root modulus-window read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *factors through*

$$M, R, Q, H, C, P, N.$$

The modulus row, real-part row, rational comparison ledger, componentwise transport, displayed continuation, package provenance, and local naming row are therefore the whole finite route available to a root-facing consumer. No hidden numeric oracle, host real equality, quotient representative, analytic continuation row, or ambient completeness input can answer such a read.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus window totality`

Proof. Start with the modulus ledger entry, Definition 548.83. It identifies M, R, Q, H, C, P, N as the finite ledger used by Real and rational-comparison reads.

Next apply Definition 548.12, Definition 548.17, and Definition 548.30. These results force every depth request through the displayed modulus row, real-part row, rational comparison row, transport row, and continuation route before $M(n)$ is public.

The rational side is supplied by Definition 548.11 and Definition 548.70. They make the comparison row Q the only finite rational surface attached to the modulus window.

Finally use Definition 548.27 and Definition 548.13. The excluded host and analytic coordinates are absent, so M, R, Q, H, C, P, N exhaust every root modulus-window read. □

Theorem 548.86 (Critical-line witness root strip-comparison classifier)**.** *The supplied zero-strip row* Z, S, H, C, P, N *and the rational comparison row* M, R, Q, H, C, P, N *of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet share the same finite classifier route through the displayed carrier*

$$Z, S, M, R, Q, H, C, P, N.$$

A root-facing classifier may compare the zero-strip evidence and the half-line rational comparison only by these rows and their componentwise hsame *and* Cont *routes.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root strip comparison classifier`

Proof. Begin with the supplied zero-strip route, Definition 548.82. It locks every zero-facing and strip-facing read to Z, S, H, C, P, N.

Then apply the modulus ledger entry and root modulus-window totality, Definition 548.83 and Definition 548.85. Together they put every rational comparison read on M, R, Q, H, C, P, N.

Use Definition 548.23 and Definition 548.2. These results bind the supplied rows and the modulus-comparison rows to one accepted carrier and one local naming surface.

The classifier route is therefore componentwise: H transports the displayed rows, C replays their reads, P records their provenance, and N names the local packet. The non-escape boundary

excludes host equality, zero search, global zero classification, quotient representatives, analytic continuation, and ambient completeness from the comparison. □

Theorem 548.87 (Critical-line witness root refusal downstream gate)**.** *Every RH-facing downstream consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the finite refusal package over*

$$Z, S, M, R, Q, H, C, P, N.$$

The gate may expose the supplied zero-strip route, the modulus-window route, the rational comparison ledger, transport, continuation, provenance, and local name, but it does not expose an RH *proof, zero search, global zero-set classifier, host equality, quotient representative, analytic continuation proof, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootRefusalDownstreamGate`

Proof. First apply Definition 548.84. It states the root-facing package as a finite witness boundary for downstream RH-facing consumers and refuses analytic proof content.

Next combine the strip-comparison classifier with the downstream source obligation, Definition 548.86 and Definition 548.48. The consumer source read is then forced through the displayed supplied rows, modulus rows, rational comparison ledger, and structural rows.

Apply Definition 548.42, Definition 548.18, and Definition 548.31. These boundaries separate the finite witness route from global zero classification, zero search, and any proof of RH.

Finally use Definition 548.34 and Definition 548.72. Their refusal rows remove quotient representatives, host equality, analytic continuation, and ambient completeness, so the downstream gate exports exactly the finite refusal package. □

Theorem 548.88 (Critical-line witness zero-strip depth lock)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every zero-strip read that reaches the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z *and* $\mathsf{CritStrip}^{\uparrow}$ *row* S *locks the subsequent modulus-depth request to the displayed row* M *under the same* BHist*, componentwise* hsame *row* H*, displayed* Cont *row* C*,* Pkg *provenance row* P*, and local* NameCert *row* N*. The read has no route to a hidden depth oracle, host equality, quotient representative, zero search, analytic continuation, or ambient completeness row.*

Proof. Begin with the supplied zero-strip route of Definition 548.82. It exposes Z, S, H, C, P, N as the finite entry route for root-facing zero-strip reads.

Next apply the root modulus ledger of Definition 548.68. The depth request is recorded through M, R, Q, H, C, P, N, so the zero-strip entry and the depth row share the same transport, continuation, provenance, and local naming surface.

Finally use the root non-escape package Definition 548.69. Since the package exports no hidden depth oracle, host equality, quotient representative, zero search, analytic continuation, or ambient completeness, the zero-strip read locks the modulus depth row to the displayed finite packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip depth lock`

Theorem 548.89 (Critical-line witness comparison-window totality)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every comparison-window read is exhausted by the finite route*

$$Z, S, M, R, Q, H, C, P, N.$$

The route exposes the supplied zero row, critical-strip row, modulus-depth row, real-part row, rational comparison ledger, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row, and it exposes no additional comparison source.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier comparison window totality`

Proof. Start with Definition 548.76. It displays the supplied zero row, critical-strip row, and rational comparison ledger as one finite BHist source triad carried by H, C, P, N.

Then use Definition 548.70 and Definition 548.77. These rows force comparison requests through M, R, Q, H, C, P, N and rule out global zero classifiers, host equality, quotient representatives, analytic-continuation certificates, and ambient completeness.

The zero-strip depth lock supplies the remaining boundary between Z, S and M. Therefore every comparison-window read is exactly the displayed finite route and has no second window or external comparison source. □

Theorem 548.90 (Critical-line witness RH-boundary downstream lock)**.** *Every RH-facing downstream consumer of an accepted* CriticalLineWitness$^{\uparrow}$ *packet receives only the refusal boundary over*

$$Z, S, M, R, Q, H, C, P, N.$$

It may cite the supplied zero-strip rows, modulus-depth row, real-part row, rational comparison ledger, BHist *evidence,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *rows, but it receives no proof of* RH*, no global zero classification, no zero search, no host equality, no quotient representative, no analytic-continuation certificate, and no ambient completeness row.*

Proof. First apply the comparison-window totality theorem. It exhausts the finite route available to a downstream comparison read and leaves no external comparison window.

Next use Definition 548.84 and Definition 548.78. These theorems identify the root-facing export as a finite witness boundary rather than a proof surface for RH.

Finally apply Definition 548.72. The refusal ledger removes global zero classification, zero search, host equality, quotient representatives, analytic continuation, and ambient completeness from downstream access, so RH-facing consumers receive only the displayed refusal boundary. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh boundary downstream lock`

Theorem 548.91 (Critical-line witness depth-comparison scope)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every comparison-window route that uses the modulus-depth row* M *and rational comparison ledger* Q *remains inside*

$$Z, S, M, R, Q, H, C, P, N.$$

Changing the depth request, the zero-strip row, or the comparison ledger leaves the local CriticalLineWitness$^{\uparrow}$ *packet rather than projecting a new RH-facing source from the same certificate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier depth comparison scope`

Proof. Begin with the zero-strip depth lock. By Definition 548.88, a zero-strip read that reaches Z and S locks the later modulus-depth request to the displayed row M under the same H, C, P, N surface.

Next apply Definition 548.89. It exhausts comparison-window reads by the finite route $Z, S, M, R, Q, H, C, P, N$, so the rational comparison ledger Q is not interchangeable with an external comparison source.

Finally use Definition 548.90. RH-facing consumers receive only the refusal boundary over these rows. Replacing the depth request, zero-strip row, or comparison ledger therefore leaves the local packet and cannot create a new RH-facing source. □

Theorem 548.92 (Critical-line witness root modulus ledger scope)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The rows M, R, Q, H, C, P, N are the complete root-facing modulus-comparison ledger: every modulus or rational-comparison read factors through the displayed modulus row, real-part row, rational comparison ledger, componentwise transport, displayed continuation, package provenance, and local naming row.*

No root-facing comparison route may replace this ledger by a global zero classifier, host equality, quotient representative, analytic-continuation certificate, or ambient completeness row.

Proof. Begin with the root source triad of Definition 548.76. It exposes the supplied zero row, critical-strip row, and rational comparison ledger as finite BHist data before downstream access.

Apply the root comparison ledger of Definition 548.77. It sends every comparison request through M, R, Q, H, C, P, N and rules out global zero-set, quotient, analytic, and ambient-completeness replacements.

Finally use Definition 548.70. The modulus row and rational comparison row are read under the same transport, continuation, package, and local naming rows, so M, R, Q, H, C, P, N exhaust the root-facing ledger. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootModulusLedgerScope`

Theorem 548.93 (Critical-line witness root zero-strip exclusion)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, the supplied zero row Z and critical-strip row S cannot be replaced by host zero search, quotient representatives, analytic continuation, ambient completeness, or any detached zero-strip oracle. Downstream root-facing consumers must read Z and S only through the finite source triad and the displayed transport, continuation, package, and naming rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootZeroStripExclusion`

Proof. Read the root source triad. The zero and strip rows are supplied finite source rows, and the rational comparison ledger is exposed with them before any downstream boundary can inspect the packet.

Use the supplied zero-strip transport lock of Definition 548.71. It keeps Z and S attached to the displayed BHist route through H, C, P, N and excludes host equality, zero search, global zero classification, quotient representatives, and analytic continuation.

Now apply the root refusal route of Definition 548.78. The refusal route also removes ambient completeness and RH-facing proof data, so no detached zero-strip oracle remains available to root-facing consumers. □

Theorem 548.94 (Critical-line witness root RH-boundary refusal)**.** *Every RH-facing downstream consumer of an accepted* CriticalLineWitness$^{\uparrow}$ *packet receives only the finite refusal package over*

$$Z, S, M, R, Q, H, C, P, N.$$

It receives no proof of RH*, no global zero classifier, no host zero search, no quotient representative, no host equality, no analytic-continuation certificate, and no ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root rh boundary refusal`

Proof. First apply the root modulus ledger scope. The modulus-comparison side is exhausted by M, R, Q, H, C, P, N and cannot read analytic or quotient replacements.

Next apply the root zero-strip exclusion. It fixes the supplied zero and strip rows as finite source data and prevents replacement by host zero search, analytic continuation, quotient representatives, or ambient completeness.

Finally use the RH-refusal ledger completeness theorem Definition 548.72. It identifies the downstream export as a refusal ledger rather than an RH proof surface, so the downstream consumer receives exactly the displayed finite package and none of the excluded proof data. □

Theorem 548.95 (Critical-line witness root public export)**.** *Every public root-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives exactly the finite package*

$$Z, S, M, R, Q, H, C, P, N.$$

This package is obtained by composing root modulus ledger scope, root zero-strip exclusion, and root RH-boundary refusal. The export contains no proof of RH*, no global zero classifier, no analytic-continuation certificate, no quotient representative, no host equality, and no ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root public export`

Proof. First apply Definition 548.92. It fixes the modulus and rational-comparison side of every root-facing read through M, R, Q, H, C, P, N.

Next apply Definition 548.93. It keeps the supplied zero row Z and critical-strip row S attached to the same finite transport, continuation, package, and naming route.

Finally apply Definition 548.94. It identifies the RH-facing boundary as a refusal package over $Z, S, M, R, Q, H, C, P, N$ rather than as proof data. The public root-facing consumer therefore receives exactly the displayed finite package and none of the refused RH, global-zero, analytic-continuation, quotient, host-equality, or ambient-completeness data. □

Theorem 548.96 (Critical-line witness scoped source boundary)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The scoped source boundary of* W *is the finite surface*

$$Z, S, M, R, Q, H, C, P, N.$$

Here Z *is the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row,* S *is the supplied* $\mathsf{CritStrip}^{\uparrow}$ *row,* M *is the* $\mathsf{Nat}^{\uparrow}$ *depth-request row,* R *is the* $\mathsf{Real}^{\uparrow}$ *real-part row,* Q *is the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger, and the accepted packet itself is the finite* BHist *carrier surface with* H, C, P, N *as the* hsame *row,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The boundary supplies no proof of* RH*, zero search, host equality, quotient representative, analytic continuation, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier scoped source boundary`

Proof. Start with the root zero-strip route and the zero-strip depth lock. They expose the supplied Z and S rows before any modulus read and keep the subsequent $\mathsf{Nat}^{\uparrow}$ depth request on the displayed route through H, C, P, N.

Next attach the modulus and comparison rows. The root modulus ledger, comparison-window totality, and root comparison ledger force every request through M, R, Q under the same finite transport, continuation, provenance, and local naming surface.

Finally apply the RH-boundary downstream lock and the root non-escape package. These rows identify the export as a finite witness boundary and remove RH proof data, zero search, host equality, quotient representatives, analytic continuation, and ambient completeness from the source surface. □

Theorem 548.97 (Critical-line witness source ledger exhaustion)**.** *Every downstream source-ledger read of an accepted* CriticalLineWitness$^{\uparrow}$ *packet factors through the single finite route*

$$Z, S, M, R, Q, H, C, P, N.$$

The read may consume the supplied zero row, supplied critical-strip row, natural depth row, real-part row, rational comparison ledger, displayed history row, componentwise transport, continuation replay, package provenance, and local naming row, and it has no second source ledger outside that route.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source ledger exhaustion`

Proof. First use the scoped source boundary. It names the finite route and records which rows can appear in a downstream source-ledger read.

Then compose the root carrier projection with the root refusal consumer exactness theorem. The projection shows that downstream root evidence is exactly the displayed packet, and exactness prevents the consumer from treating any host object as an additional source.

The refusal ledger completeness theorem closes the route. Since the packet refuses RH proof data, zero search, global zero classification, host equality, quotient representatives, analytic continuation, and ambient completeness, the displayed route exhausts the source ledger. □

Theorem 548.98 (Critical-line witness zero-strip modulus source totality)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every source read that begins with the supplied zero-strip rows* Z, S *and later asks for a modulus or comparison row is total through*

$$Z, S, M, R, Q, H, C, P, N.$$

The total route binds the ZetaZeros$^{\uparrow}$ *row,* CritStrip$^{\uparrow}$ *row,* Nat$^{\uparrow}$ *depth requests,* Real$^{\uparrow}$ *real-part row,* Rat$^{\uparrow}$ *comparison ledger,* BHist *evidence,* hsame *transport,* Cont *replay,* Pkg *provenance, and* NameCert *row without adding RH proof content, zero search, host equality, quotient representatives, analytic continuation, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip modulus source totality`

Proof. Begin with the supplied zero-strip route. It makes Z, S, H, C, P, N the entry surface for zero-strip reads and prevents replacement by analytic or host-level data.

Next use the zero-strip depth lock and root modulus ledger. The first theorem forces later modulus requests to stay attached to the same zero-strip route, while the second theorem records those requests through M, R, Q, H, C, P, N.

Finally combine source-ledger exhaustion with the RH-boundary downstream lock. The downstream read therefore has one finite route through $Z, S, M, R, Q, H, C, P, N$ and no exit to RH proof data, zero search, host equality, quotient representatives, analytic continuation, or ambient completeness. □

Theorem 548.99 (Critical-line witness root downstream package)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every downstream root-facing read factors through the supplied zero row* Z*, critical-strip row* S*, modulus row* M*, real-part row* R*, rational comparison ledger* Q*, displayed* hsame *transport row* H*, displayed* Cont *route row* C*,* Pkg *provenance row* P*, and local* NameCert *row* N*.*

The package excludes RH *proof data, global zero classifiers, analytic-continuation certificates, quotient representatives, host equality, and ambient completeness.*

Proof. Project the accepted packet through Definition 548.1. The downstream source has exactly the rows $Z, S, M, R, Q, H, C, P, N$ available, with Z and S supplied before the modulus and comparison ledger are read.

Use the root non-escape package of Definition 548.69. It assembles the zero-strip route, modulus ledger route, and local BEDC rows as the root-facing export.

Finally apply the RH-refusal ledger completeness theorem Definition 548.72. It removes RH proof data, global zero classification, analytic continuation, quotient representatives, host equality, and ambient completeness from every downstream read of the package. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root downstream package`

Theorem 548.100 (Critical-line witness root carrier projection)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the downstream root carrier projection is exactly the finite projection to the rows* $Z, S, M, R, Q, H, C, P, N$*. The projection preserves the supplied zero row, critical-strip row, modulus row, rational comparison ledger, transport row, continuation route, provenance row, and local naming row, and it forgets no row that a downstream root consumer is allowed to inspect.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootCarrierProjectionRows`

Proof. Begin with the carrier-admission row of Definition 548.6. It identifies the accepted object with the displayed finite BHist tuple and leaves no hidden host coordinate behind the packet.

Apply the root source triad theorem Definition 548.76. The supplied zero, strip, and rational comparison rows remain exposed as the source side of the downstream boundary.

The modulus comparison route totality theorem Definition 548.70 supplies the remaining modulus, real-part, transport, continuation, package, and naming coordinates. Combining these two projections gives exactly $Z, S, M, R, Q, H, C, P, N$. □

Theorem 548.101 (Critical-line witness root refusal consumer exactness)**.** *Every downstream consumer of the root-facing* $\mathsf{CriticalLineWitness}^{\uparrow}$ *package is exact for the refusal boundary: it may cite the supplied zero row, critical-strip row, modulus row, real-part row, rational comparison ledger, displayed* hsame *transport, displayed* Cont *route,* Pkg *provenance, and local* NameCert *row, and it may cite nothing else as root evidence.*

In particular, the consumer cannot extract an RH *proof, a global zero classifier, an analytic-continuation certificate, a quotient representative, host equality, or ambient completeness from the accepted packet.*

Proof. First read the downstream package of Definition 548.99. It supplies the complete row list that a downstream consumer may cite.

Next project through Definition 548.100. This shows that the consumer's root evidence is not a larger analytic object; it is the same finite carrier projection $Z, S, M, R, Q, H, C, P, N$.

Finally apply the root refusal route of Definition 548.78. The refusal route excludes RH proof data, zero search, global zero classification, analytic continuation, quotient representatives, host equality, and ambient completeness, so the consumer boundary is exact for the displayed packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root refusal consumer exactness`

Theorem 548.102 (Critical-line witness root dependency scope)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The root downstream dependency scope of W is exactly the finite route through the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row Z, supplied* $\mathsf{CritStrip}^{\uparrow}$ *row S,* $\mathsf{Nat}^{\uparrow}$ *depth requests for the modulus row M, the* $\mathsf{Real}^{\uparrow}$ *real-part row R, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger Q, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows H, C, P, N.*

The scope contains no RH *proof data, global zero classifier, analytic continuation certificate, quotient representative, host equality, detached zero oracle, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root dependency scope`

Proof. Begin with the downstream package of Definition 548.99. It gives every root-facing consumer the finite row list $Z, S, M, R, Q, H, C, P, N$ and excludes the analytic and quotient data outside that list.

Next use the carrier projection of Definition 548.100. The projection identifies those rows as the complete finite carrier surface available to the consumer, with no extra root evidence hidden behind the packet.

Finally combine the root modulus ledger scope of Definition 548.92 with the root zero-strip exclusion of Definition 548.93. The first binds M, R, Q, H, C, P, N to the modulus and rational-comparison route, while the second binds Z, S to the supplied zero-strip source. Together they give exactly the dependency scope stated above. □

Theorem 548.103 (Critical-line witness downstream refusal factorization)**.** *Every downstream refusal read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet factors through the dependency scope of Definition 548.102. A refusal consumer may cite the supplied zero row, strip row, modulus row, real-part row, rational comparison ledger, transport, continuation, provenance, and local naming row, and it may cite no additional RH-facing proof surface.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream refusal factorization`

Proof. First read the exact consumer boundary of Definition 548.101. It states that a downstream consumer may cite only $Z, S, M, R, Q, H, C, P, N$ as root evidence.

Now apply the dependency scope theorem just established. The allowed rows are not an unstructured list: Z and S are the supplied $\mathsf{ZetaZeros}^{\uparrow}$–$\mathsf{CritStrip}^{\uparrow}$ source, M is read at $\mathsf{Nat}^{\uparrow}$ depths, R is the $\mathsf{Real}^{\uparrow}$ row, Q is the $\mathsf{Rat}^{\uparrow}$ comparison ledger, and H, C, P, N are the BEDC transport, route, provenance, and naming rows.

Finally use the RH-boundary refusal of Definition 548.94. It removes RH proof data, global zero classifiers, zero search, analytic continuation, quotient representatives, host equality, and ambient completeness from the downstream route, so every refusal read factors through the named scope. □

Theorem 548.104 (Critical-line witness zero-strip-modulus package exhaustion)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, the supplied zero row, supplied critical-strip row, modulus row, real-part row, and rational comparison ledger exhaust the root package together with H, C, P, N. There is no remaining coordinate from which a consumer can read another zero source, another strip certificate, another modulus, another rational comparison row, an RH proof, analytic continuation, host equality, quotient representatives, or ambient completeness.*

Proof. Start with Definition 548.102. It identifies the full dependency route as $Z, S, M, R, Q, H, C, P, N$ over $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Use the root modulus ledger scope to exhaust the modulus and rational comparison side. Every modulus or comparison read is already forced through M, R, Q, H, C, P, N.

Use the root zero-strip exclusion to exhaust the zero and strip side. The supplied rows Z and S stay attached to the same displayed history and cannot be replaced by a detached oracle or analytic certificate.

Finally apply the RH-boundary refusal. Since the refusal boundary exports only the finite package and none of the excluded analytic or host-level data, the zero, strip, modulus, and rational comparison rows listed above exhaust the root package. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip modulus package exhaustion`

Theorem 548.105 (Critical-line witness downstream RH boundary refinement)**.** *Let $W = (Z, S, M, R, Q, H, C, P,$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every downstream RH-facing read of W is exhausted by the displayed finite rows*

$$Z, S, M, R, Q, H, C, P, N.$$

The supplied zero-strip route, the modulus ledger entry, the RH non-escape package, the root source triad, and the root comparison ledger together force each read through the visible BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. No downstream consumer receives analytic continuation, quotient representatives, host equality, ambient completeness, a global zero classifier, or an* RH *proof from this boundary.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream rh boundary refinement`

Proof. Begin with the supplied zero-strip route of Definition 548.82. It identifies the zero and strip reads with the finite route Z, S, H, C, P, N.

Next use the modulus ledger entry of Definition 548.83. It places every modulus and rational-comparison request on M, R, Q, H, C, P, N.

The RH non-escape package of Definition 548.84 then removes analytic proof data, zero search, host equality, quotient representatives, analytic continuation, and ambient completeness from the downstream interface. The root source triad and root comparison ledger of Definition 548.76 and Definition 548.77 identify the remaining source and comparison reads with the same displayed packet rows, so the boundary is exactly the finite read surface stated above. □

Theorem 548.106 (Critical-line witness zero-strip modulus route)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The zero-strip route Z, S, H, C, P, N and the modulus route M, R, Q, H, C, P, N form one downstream RH-facing route over the same componentwise* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. A consumer that reads the supplied zero or critical-strip row and then asks for the modulus or rational comparison must stay inside $Z, S, M, R, Q, H, C, P, N$.*

Proof. Apply Definition 548.82 to obtain the supplied route for Z and S. This route is carried by H, C, P, N and excludes replacement by zero search, host equality, quotient representatives, analytic continuation, or completeness.

Apply Definition 548.83 to obtain the modulus-facing route through M, R, Q, H, C, P, N. The shared rows H, C, P, N keep the zero-strip and modulus reads on the same visible packet.

Finally combine Definition 548.76, Definition 548.77, and Definition 548.84. These results make the source triad and comparison ledger the only admissible downstream reads and refuse any analytic or host-level replacement. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip modulus route`

Theorem 548.107 (Critical-line witness root source consumer totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root source consumer for a downstream RH-facing chapter is total on the displayed finite packet: it either reads the supplied zero-strip route, the modulus ledger entry, the root source triad, or the root comparison ledger, and each case factors through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of* W*. There is no fifth consumer route requiring analytic continuation, quotient representatives, host equality, ambient completeness, a global zero classifier, or an* RH *proof.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source consumer totality`

Proof. The supplied zero-strip route of Definition 548.82 covers zero and strip source reads. The modulus ledger entry of Definition 548.83 covers depth, real-part, and rational-comparison reads.

The root source triad of Definition 548.76 packages Z, S, Q as the finite source rows available before a downstream boundary reads the packet. The root comparison ledger of Definition 548.77 packages the comparison side through Q together with M, R, H, C, P, N.

Use the downstream RH boundary refinement of Definition 548.105 and the RH non-escape package of Definition 548.84. They exhaust the public reads by the displayed rows and remove the analytic, quotient, host-equality, completeness, global-zero, and RH-proof alternatives, so the listed source consumers are total for downstream use. □

Theorem 548.108 (Critical-line witness root zero-strip carrier row)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, the root-facing zero, strip, modulus, route, transport, package, and NameCert coordinates are one finite* BHist *carrier row:*

$$W = (Z, S, M, R, Q, H, C, P, N).$$

Carrier admission ties Z *to the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row,* S *to the supplied* $\mathsf{CritStrip}^{\uparrow}$ *row,* M *to the on-line modulus row,* R *to the* $\mathsf{Real}^{\uparrow}$ *real-part row,* Q *to the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger,* H *to componentwise* hsame *transport,* C *to displayed* Cont *replay,* P *to* Pkg *provenance, and* N *to the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row.*

Proof. Begin with Definition 548.6. It admits exactly the finite packet $Z, S, M, R, Q, H, C, P, N$ and excludes zero search, global zero classifiers, host equality, quotient representatives, and analytic-completeness coordinates.

Use the root carrier projection of Definition 548.100 and the downstream package of Definition 548.99 to read the same tuple from the root-facing side. They keep the supplied zero row, critical-strip row, modulus row, comparison ledger, transport, route, provenance, and naming coordinates in one visible carrier.

Finally apply Definition 548.22. The closure package repacks the admitted carrier, NameCert obligations, strip-zero compatibility, modulus routing, non-escape boundary, and ledger exactness as the finite obligation surface available to downstream root consumers. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zero strip carrier row`

Theorem 548.109 (Critical-line witness root modulus route row)**.** *Every root-facing modulus comparison of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet passes through the displayed route*

$$M, R, Q, H, C, P, N.$$

The comparison must use the Cont *row C and the componentwise* hsame *row H before the modulus row M or rational comparison ledger Q can be exported; it has no route through a hidden numeric oracle, host real equality, quotient representative, analytic-continuation certificate, or ambient completeness principle.*

Proof. Start with the modulus request factorization of Definition 548.30 and the modulus comparison route totality of Definition 548.70. They force each depth or comparison request through the displayed modulus row, real-part row, rational comparison ledger, transport row, continuation row, provenance row, and local naming row.

Next use the root comparison ledger of Definition 548.77 and the root modulus ledger of Definition 548.68. These rows identify Q as the root-facing rational comparison ledger and keep the depth request inside M, R, Q, H, C, P, N.

Apply Definition 548.22 to repack the route as part of the local obligation surface. Since that package admits no hidden oracle, host equality, quotient representative, analytic-continuation certificate, or ambient completeness row, every modulus comparison remains on the displayed Cont and hsame route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus route row`

Theorem 548.110 (Critical-line witness root non-escape ledger row)**.** *The root-facing ledger of an accepted* CriticalLineWitness$^{\uparrow}$ *packet excludes an* RH *proof, analytic-continuation certificate, quotient representative, host equality, and ambient completeness from every downstream read. A downstream consumer may cite only the finite carrier row $Z, S, M, R, Q, H, C, P, N$ together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *structure of that packet.*

Proof. First read the root non-escape package of Definition 548.69 and the downstream refusal factorization of Definition 548.103. These rows state that root-facing consumers receive the supplied zero-strip route, modulus ledger route, and local BEDC rows, not RH proof data or analytic proof surfaces.

Next apply the root zero-strip carrier row established above. It identifies the downstream evidence as the finite packet $Z, S, M, R, Q, H, C, P, N$ and prevents the consumer from adding a second carrier behind the accepted witness.

Finally use Definition 548.22. The package closes the local obligation surface around carrier admission, naming, transport, continuation, package provenance, non-escape, and ledger rows. Therefore RH proof data, analytic-continuation certificates, quotient representatives, host equality, and ambient completeness have no admitted ledger coordinate. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root nonescape ledger row`

Theorem 548.111 (Critical-line witness downstream zero-source readback)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every downstream zero-source readback of W must first read the supplied zero row Z, the critical-strip row S, and the rational comparison ledger Q as the root source triad of Definition 548.76, and it may then read only the displayed rows M, R, H, C, P, N needed by the same accepted packet.*

The readback is therefore a finite BEDC row export. It is not an RH *proof, a global zero classifier, analytic continuation, a quotient representative, host equality, or ambient completeness.*

Proof. Start with the root source triad. By Definition 548.76, the downstream source side exposes Z, S, Q as finite BHist rows under the displayed transport, continuation, package, and local naming surface.

Next apply Definition 548.100. The accepted packet projects to exactly $Z, S, M, R, Q, H, C, P, N$, so a downstream readback has no additional carrier coordinate from which to extract analytic or host-level data.

Finally use Definition 548.72. The refusal ledger removes RH proof data, global zero classification, analytic continuation, quotient representatives, host equality, and ambient completeness from every downstream read, leaving only the finite BEDC rows. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream zero source readback`

Theorem 548.112 (Critical-line witness downstream modulus comparison totality)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every downstream modulus or rational-comparison request is total through the displayed route*

$$Z, S \longmapsto M, R, Q \longmapsto H, C, P, N.$$

The source side is the root source triad, the comparison side is the root comparison ledger of Definition 548.77, and the downstream consumer receives no RH *proof, global zero classifier, analytic-continuation certificate, quotient representative, host equality, or ambient completeness row.*

Proof. Read the supplied source first. The root source triad theorem identifies Z, S, Q as the finite source rows available before any downstream boundary inspects the packet.

Now use Definition 548.77. It forces each downstream rational comparison through the ledger Q together with M, R, H, C, P, N and rules out global zero-set, quotient, analytic, and ambient-completeness replacements.

Finally compose with Definition 548.70. The modulus route and the rational comparison route share the displayed transport, continuation, provenance, and local naming rows, so the route is total through the finite packet and cannot acquire host equality or RH-facing proof data. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream modulus comparison totality`

Theorem 548.113 (Critical-line witness downstream refusal export)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The downstream export of* W *is exactly the finite refusal package consisting of the root source triad* Z, S, Q*, the modulus and real-part rows* M, R*, the displayed* hsame *and* Cont *rows* H, C*, the* Pkg *provenance row* P*, and the local* NameCert *row* N*.*

Any downstream RH-boundary chapter may cite that package only as a finite BEDC refusal export. It may not cite it as an RH *proof, a global zero classifier, analytic continuation, a quotient representative, host equality, or ambient completeness.*

Proof. First combine Definition 548.111 with Definition 548.112. The first theorem fixes the zero-source readback through the root source triad, and the second fixes the modulus and rational-comparison route through the displayed ledger.

Then apply the RH-refusal ledger completeness theorem, Definition 548.72. Its ledger clause says that downstream consumers can cite only $Z, S, M, R, Q, H, C, P, N$ and the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

The export is therefore a refusal surface rather than an analytic proof surface. Since the accepted packet contains no coordinate for RH proof data, global zero classification, analytic continuation, quotient representatives, host equality, or ambient completeness, no downstream consumer can read such data from it. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream refusal export`

Theorem 548.114 (Critical-line witness terminal zero-source totality)**.** *Every terminal critical-line read from an accepted* CriticalLineWitness$^{\uparrow}$ *packet first exposes the supplied zero-source row Z together with the supplied critical-strip row S and the displayed route rows H, C, P, N. The terminal read may continue to the modulus and comparison rows only after this zero-source surface is present; it cannot begin from a zero search, global zero classifier, host complex equality, quotient representative, analytic-continuation certificate, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier terminal zero source totality`

Proof. Project the carrier of Definition 548.1. The supplied zero row Z and supplied strip row S are visible before any modulus coordinate can be read.

Use the root zero-strip route of Definition 548.67 and the zero-row source scope of Definition 548.15. These results force the first terminal read through Z, S, H, C, P, N.

Finally apply the root zero-strip exclusion of Definition 548.93. It removes zero search, host equality, quotient representatives, analytic continuation, and ambient completeness from the terminal source route. □

Theorem 548.115 (Critical-line witness terminal modulus-comparison scope)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every terminal modulus comparison is scoped to the displayed* Rat$^{\uparrow}$, Real$^{\uparrow}$, *and* ZetaZeros$^{\uparrow}$ *rows together with the finite* BHist, hsame, Cont, Pkg, *and local* NameCert *routes. The comparison route is exactly the packet surface $Z, S, M, R, Q, H, C, P, N$, and it exports no external real-order decision, host equality, quotient real representative, hidden numeric oracle, or analytic completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessTerminalModulusComparisonScope`

Proof. First expose the supplied zero-source rows using Definition 548.114. The terminal comparison is attached to the displayed ZetaZeros$^{\uparrow}$ and CritStrip$^{\uparrow}$ source rows before it reaches any modulus data.

Next apply the root modulus ledger scope of Definition 548.92. It exhausts modulus and rational-comparison reads by M, R, Q, H, C, P, N.

Finally combine the rational comparison ledger exactness of Definition 548.11 with the non-escape boundary of Definition 548.13. Thus the terminal comparison stays inside the displayed Rat$^{\uparrow}$, Real$^{\uparrow}$, ZetaZeros$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows. □

Theorem 548.116 (Critical-line witness terminal RH-refusal exactness)**.** *Every terminal RH-facing read of an accepted* CriticalLineWitness$^{\uparrow}$ *packet exports only the finite critical-line witness boundary*

$$Z, S, M, R, Q, H, C, P, N.$$

It refuses RH *proof content, universal zero classification, zero-producing search, host complex equality, quotient real equality, selected Cauchy representatives, analytic-continuation certificates, and ambient analytic completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier terminal rh refusal exactness`

Proof. Begin with the terminal zero-source totality theorem. It makes the supplied zero and strip rows the first visible source of the terminal read.

Then use the terminal modulus-comparison scope theorem. The modulus and rational comparison side is exhausted by the displayed $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local NameCert rows.

Finally apply the root RH-boundary refusal of Definition 548.94. The terminal packet is therefore a finite critical-line witness boundary, not an RH proof surface or an analytic oracle. □

Theorem 548.117 (Critical-line witness terminal source exhaustion)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every terminal read first exhausts the displayed finite source rows* Z, S, H, C, P, N *before any modulus or comparison row is read. The read therefore begins inside the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *zero row, the supplied critical-strip row, and the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route; it cannot begin from host equality, a quotient representative, a hidden numeric oracle, analytic continuation, ambient completeness, or a detached zero classifier.*

Proof. Start with terminal zero-source totality, Definition 548.114. It makes Z, S, H, C, P, N the first exposed source surface of a terminal read.

Next project that source through the accepted packet carrier. The rows H, C, P, N keep the read inside the displayed BHist, hsame, Cont, Pkg, and NameCert route, so no host-level equality, quotient representative, hidden numeric oracle, analytic-continuation theorem, or ambient completeness row is available before the source surface is exhausted.

Finally use the terminal modulus-comparison scope of Definition 548.115. It allows modulus and comparison reads only after the finite source route has already been exposed, giving the stated source exhaustion order. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessTerminalSourceExhaustion`
↪ variant `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier terminal source exhaustion`

Theorem 548.118 (Critical-line witness terminal comparison ledger lock)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the terminal comparison ledger is locked to the rows* M, R, Q, H, C, P, N *together with the displayed* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{ZetaZeros}^{\uparrow}$ *source interfaces. The ledger exports only the local modulus, real-part, rational-comparison, transport, continuation, provenance, and naming rows; it excludes host equality, quotient representatives, hidden numeric oracle data, analytic continuation, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier terminal comparison ledger lock`

Proof. First apply terminal source exhaustion. The comparison ledger is reached only after the terminal read has exposed the supplied zero and local route rows.

Then apply terminal modulus-comparison scope, Definition 548.115. It binds every terminal comparison to M, R, Q, H, C, P, N over the displayed $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

The exclusions follow from the same scope statement together with the terminal zero-source totality theorem. Since neither source theorem contains host equality, quotient representatives, hidden numeric oracles, analytic continuation, or ambient completeness, the terminal comparison ledger has no route to those objects. □

Theorem 548.119 (Critical-line witness terminal refusal package)**.** *Every terminal RH-boundary consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives the obligation package consisting of the*

source exhaustion of Definition 548.117, the comparison ledger lock of Definition 548.118, and the RH-refusal exactness of Definition 548.116. Thus the consumed package is exactly the finite BEDC row surface $Z, S, M, R, Q, H, C, P, N$ over BHist, hsame, Cont, Pkg, NameCert, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{ZetaZeros}^{\uparrow}$, *with no* RH *proof, global zero classifier, host equality, quotient representative, hidden numeric oracle, analytic-continuation theorem, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier terminal refusal package`

Proof. Begin with source exhaustion. It supplies the terminal consumer with the finite source route Z, S, H, C, P, N and blocks every external source row.

Next use the comparison ledger lock. It adds only M, R, Q through the displayed $\mathsf{Rat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ comparison surface while preserving the same BHist, hsame, Cont, Pkg, and NameCert route.

Finally apply terminal RH-refusal exactness, Definition 548.116. This identifies the exported terminal boundary with $Z, S, M, R, Q, H, C, P, N$ and removes RH proof content, global zero classification, host equality, quotient representatives, hidden numeric oracles, analytic continuation, and ambient completeness. The three rows together form the root-unblock obligation package used by downstream RH-boundary chapters. □

Theorem 548.120 (Critical-line witness terminal window factorization)**.** *Every terminal* $\mathsf{CriticalLineWitness}^{\uparrow}$ *route factors through the displayed zero strip, source window, modulus comparison,* $\mathsf{Rat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *readback,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The factorization surface is the finite packet*

$$Z, S, M, R, Q, H, C, P, N$$

over the terminal source and comparison ledgers; it has no entry point from a global zero classifier, host equality, quotient representative, hidden numeric oracle, analytic-continuation theorem, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier terminal window factorization`

Proof. Begin with terminal source exhaustion, Definition 548.117. It makes the zero strip and source window rows Z, S the first visible terminal surface and keeps the route inside H, C, P, N.

Next apply the terminal comparison ledger lock, Definition 548.118. The modulus comparison and $\mathsf{Rat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ readback rows are exactly M, R, Q over the same transport, continuation, provenance, and naming surface.

Finally use terminal RH-refusal exactness, Definition 548.116. It rules out the analytic, quotient, oracle, and completeness rows, so the terminal route factors only through the displayed finite packet. □

Theorem 548.121 (Critical-line witness terminal ledger nonescape)**.** *For every accepted terminal* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, analytic continuation content,* RH *proof content, quotient representatives, hidden numeric oracles, host equality, and ambient completeness are refused unless they already occur as displayed rows of the finite terminal ledger $Z, S, M, R, Q, H, C, P, N$. Since the ledger contains only the zero-strip source, source-window, modulus-comparison, readback, transport, continuation, provenance, and naming rows, none of those external objects can be recovered by a downstream terminal consumer.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier terminal ledger nonescape`

Proof. First read the source side from Definition 548.117. Before any terminal consumer reaches a comparison row, the displayed zero strip and source window have already exhausted the available source data.

Then read the comparison side from Definition 548.118. It locks the modulus and readback ledger to M, R, Q, H, C, P, N and names no external analytic or host-level object.

Finally apply terminal RH-refusal exactness, Definition 548.116. The terminal boundary is a finite witness boundary rather than an RH proof, analytic-continuation certificate, quotient representative, oracle, or completeness surface, so the ledger cannot escape its displayed rows. □

Theorem 548.122 (Critical-line witness terminal consumer exhaustion)**.** *Every downstream RH-boundary consumer of an accepted terminal* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives exactly the terminal window factorization of Definition 548.120 together with the nonescape ledger of Definition 548.121. The exported consumer package is therefore the finite row surface* $Z, S, M, R, Q, H, C, P, N$ *over* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{ZetaZeros}^{\uparrow}$*, with no additional RH, analytic, quotient, oracle, host, or completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier terminal consumer exhaustion`

Proof. First apply terminal source exhaustion and terminal comparison ledger lock, Definition 548.117 and Definition 548.118. Together they give the downstream consumer exactly the source window, modulus comparison, readback, transport, continuation, provenance, and naming rows.

Next package those rows through terminal window factorization, Definition 548.120. This gives the consumer the finite packet surface $Z, S, M, R, Q, H, C, P, N$ as its only terminal route.

Finally attach terminal ledger nonescape and terminal RH-refusal exactness, Definition 548.121 and Definition 548.116. They remove every RH-proof, analytic-continuation, quotient, oracle, host-equality, and ambient-completeness coordinate not already displayed in the finite ledger. □

Definition 548.123 (Critical-line witness fixed strip source)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the fixed critical-strip source packet is the displayed finite route over the supplied* $\mathsf{CritStrip}^{\uparrow}$ *row* S*, the depth row* M *from* $\mathsf{Nat}^{\uparrow}$*, the rational comparison ledger* Q *from* $\mathsf{Rat}^{\uparrow}$*, the real-part row* R *from* $\mathsf{Real}^{\uparrow}$*, the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*, and the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows* H, C, P, N*. It contains exactly the rows* $Z, S, M, R, Q, H, C, P, N$ *and no analytic-continuation theorem, host complex-zero classifier, quotient representative, or ambient completeness coordinate.*

Lean4 (definition) `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessFixedStripSource`

Theorem 548.124 (Critical-line witness fixed-strip modulus refusal)**.** *Every zero-strip modulus request served by the fixed critical-strip source packet of Definition 548.123 may read only the displayed strip row* S*, supplied zero row* Z*, depth-lock row* M*, rational comparison row* Q*, refusal rows* R, H, C, P, N*, and the local source route connecting them. It cannot replace that route by zero search, a hidden depth oracle, host equality, quotient representatives, analytic continuation, or ambient completeness.*

Proof. Start with the fixed source packet. Its definition exposes only $Z, S, M, R, Q, H, C, P, N$, so the modulus request begins from the supplied zero, the supplied strip, and the displayed depth and comparison rows.

Use the zero-strip depth lock and root modulus ledger scope, Definition 548.88 and Definition 548.92. They keep the request attached to $Z, S, M, R, Q, H, C, P, N$ and make the comparison ledger the complete root-facing route.

Finally apply the root zero-strip exclusion. It removes zero search, hidden depth oracles, host equality, quotient representatives, analytic continuation, and ambient completeness from the request surface, so the fixed strip source supplies only the displayed refusal rows. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip modulus refusal`

Theorem 548.125 (Critical-line witness RH consumer nonescape)**.** *Every RH-facing consumer of the fixed critical-strip source packet receives only the finite witness boundary $Z, S, M, R, Q, H, C, P, N$. The consumer may cite the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *zero,* $\mathsf{CritStrip}^{\uparrow}$ *strip,* $\mathsf{Nat}^{\uparrow}$ *depth row,* $\mathsf{Rat}^{\uparrow}$ *comparison ledger,* $\mathsf{Real}^{\uparrow}$ *real-part row, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, but it cannot infer a full* RH *proof, analytic continuation theorem, host complex-zero classifier, quotient representative, host equality, or ambient completeness principle.*

Proof. First read the fixed strip source packet. It presents a local witness boundary over the supplied zero and strip rows, not a public theorem about all zeros.

Next apply the fixed-strip modulus refusal theorem. The modulus request and comparison ledger stay inside $Z, S, M, R, Q, H, C, P, N$, with no route to analytic continuation, quotient representatives, host equality, or ambient completeness.

Finally use the root RH-boundary refusal and RH-boundary downstream lock, Definition 548.94 and Definition 548.90. These rows identify the RH-facing export as a finite refusal boundary, so no full RH proof or host complex-zero classifier can be extracted from the fixed strip packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip rh consumer boundary`

Theorem 548.126 (Critical-line witness root source exposure)**.** *Every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root-facing packet exposes its source rows through finite* BHist *data before any downstream consumer reads a zero-strip or modulus boundary. The exposed rows are the* $\mathsf{ZetaZeros}^{\uparrow}$ *continuation source, the zero-strip row, the rational-height and real-part comparison rows, the modulus-depth row, and the structural rows*

$$Z, S, M, R, Q, H, C, P, N.$$

The exposure route is finite, componentwise stable under hsame*, and contains no analytic-continuation oracle outside the displayed continuation rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source exposure`

Proof. Begin with the root source triad of Definition 548.76. It exposes the supplied zero row, strip row, and source-facing comparison data before any downstream boundary is read.

Use the source normalization interface of Definition 548.59. The $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are all opened through the finite packet $Z, S, M, R, Q, H, C, P, N$.

Now apply the modulus ledger interface of Definition 548.60 together with terminal source exhaustion from Definition 548.117. These rows keep the rational-height and modulus reads downstream of the same displayed zero-strip source route.

Finally use the fixed strip boundary of Definition 548.124. It prevents the exposed strip source from becoming a global analytic-continuation source, so the root exposure remains a finite BHist package. □

Theorem 548.127 (Critical-line witness root strip refusal)**.** *The root-facing* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet refuses to export an* RH *predicate, a global zero locator, a zero search procedure, host equality, quotient representatives, analytic-continuation proof content, or ambient completeness. It exports only the finite source, strip, modulus, rational-height, real-part, transport, route, provenance, and naming rows displayed by*

$$Z, S, M, R, Q, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root strip refusal`

Proof. First apply the RH refusal interface of Definition 548.62. It identifies the accepted packet surface with the finite rows $Z, S, M, R, Q, H, C, P, N$ and excludes proof content, global zero classification, zero search, quotient representatives, analytic continuation, and completeness.

Next use the root refusal route of Definition 548.78. The refusal is not an external side condition; it is read along the same displayed route as the source and modulus rows.

The terminal refusal package of Definition 548.119 and the fixed strip boundary of Definition 548.124 then close the remaining consumer-facing exits. A downstream consumer may inspect the finite strip and modulus rows, but it receives no RH predicate or global zero-locator coordinate. □

Theorem 548.128 (Critical-line witness root consumer package)**.** *The source exposure row of Definition 548.126 and the strip-refusal row of Definition 548.127 assemble into one downstream* $\mathsf{CriticalLineWitness}^{\uparrow}$ *consumer package. Every consumer receives a finite* BHist *route over* $Z, S, M, R, Q, H, C, P, N$*; every refused analytic or global-zero object remains outside that route.*

Proof. Use the root source exposure theorem to provide the displayed source, strip, rational-height, real-part, and modulus rows. This gives the consumer a finite entry route through $Z, S, M, R, Q, H, C, P, N$.

Use the root strip refusal theorem for the negative side of the same package. The consumer route carries no RH predicate, global zero locator, zero search procedure, host equality, quotient representative, analytic-continuation proof content, or ambient completeness row.

Finally compose the root downstream package of Definition 548.34 with the downstream RH-boundary refinement of Definition 548.105. The assembled package is therefore a consumer-facing finite route, not an analytic theorem or global zero classifier. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root consumer package`

Theorem 548.129 (Critical-line witness root modulus readback)**.** *Every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *zero-strip modulus read is routed through the displayed* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{ZetaZeros}^{\uparrow}$ *source rows together with the* BHist *readback ledger. In particular, the root-facing consumer reads the zero source, critical-strip row, rational-height row, real-part comparison row, modulus-depth row, componentwise transport, continuation route, provenance row, and local* $\mathsf{NameCert}$ *row before it can consume the modulus boundary.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus readback`

Proof. Start with the root source exposure theorem. It identifies the displayed source route through $Z, S, M, R, Q, H, C, P, N$ before any downstream zero-strip or modulus boundary is read.

Use the source normalization interface and the modulus ledger interface. These rows place the $\mathsf{ZetaZeros}^{\uparrow}$ source, the $\mathsf{Rat}^{\uparrow}$ height read, the $\mathsf{Real}^{\uparrow}$ comparison read, and the modulus-depth row inside the same finite BHist packet.

Finally apply the root consumer package. The readback ledger is the route through H, C, P, N, so a consumer that omits those rows is not consuming the accepted root-facing packet. □

Theorem 548.130 (Critical-line witness strip-zero boundary)**.** *A* $\mathsf{CriticalLineWitness}^{\uparrow}$ *critical-line witness cannot be consumed as an* RH *conclusion unless the critical-strip boundary rows and the zero-source boundary rows have both been displayed. The accepted packet supplies only finite zero-source, strip, rational-height, real-part, modulus, transport, route, provenance, and naming rows; it does not supply a global* RH *predicate, analytic-continuation proof object, zero locator, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier strip zero boundary`

Proof. Apply the root strip refusal theorem. It excludes an RH predicate, global zero locator, zero search procedure, analytic-continuation proof content, and ambient completeness from the root-facing packet.

Now use the fixed strip boundary. The strip row is a displayed finite source boundary, not a global analytic statement about all zeros.

The terminal source exhaustion and downstream RH-boundary refinement keep the same boundary at every consumer site. Therefore a critical-line witness can be cited only as the displayed finite source package, not as an RH conclusion. □

Theorem 548.131 (Critical-line witness root unblock package)**.** *The modulus readback of Definition 548.129, the strip-zero boundary of Definition 548.130, the refusal ledger, the displayed* Cont *route, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows form the root-unblock dependency surface for downstream* $\mathsf{CriticalLineWitness}^{\uparrow}$ *chapters. Any downstream chapter citing this package receives the finite rows*

$$Z, S, M, R, Q, H, C, P, N$$

and no hidden RH *conclusion, analytic-continuation oracle, quotient representative, host equality, zero-search procedure, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus readback unblock package`

Proof. First combine root source exposure with root modulus readback. These theorems display the $\mathsf{ZetaZeros}^{\uparrow}$, critical-strip, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, modulus, and BHist readback rows on one finite route.

Next combine root strip refusal with the strip-zero boundary. The refusal ledger blocks all global zero and RH readings while preserving the finite source package available to downstream consumers.

Finally repack through the root consumer package. The continuation route, provenance row, and local NameCert row are exactly C, P, N, and the transported finite source is carried by H, so the dependency surface is the displayed package $Z, S, M, R, Q, H, C, P, N$. □

Theorem 548.132 (Critical-line witness source modulus exposure)**.** *Every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet exposes the supplied source strip row, modulus row, zero witness row, transport row, route row, package row, and local* $\mathsf{NameCert}$ *row before any critical-line read is available. The visible surface is the finite packet*

$$Z, S, M, R, Q, H, C, P, N,$$

so a critical-line consumer must read the source strip, modulus ledger, zero witness, continuation route, provenance, and naming rows as displayed BHist *data.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus exposure`

Proof. Begin with the root source-modulus interface of Definition 548.59 and Definition 548.60. These rows expose the supplied zero-strip source and the modulus-comparison ledger before downstream use.

Apply Definition 548.67 and Definition 548.68. The zero-strip side is carried by Z, S, H, C, P, N, while the modulus side is carried by M, R, Q, H, C, P, N.

Finally use the root unblock rows in Definition 548.70 and Definition 548.76. Together they identify the accepted source, modulus, zero witness, transport, route, package, and local naming rows as the finite boundary preceding any critical-line read. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessSourceModulusExposure`

Theorem 548.133 (Critical-line witness zero-strip boundary)**.** *Every zero-strip read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet is a finite* BHist*,* Cont*,* hsame*, and* Pkg *row read through*

$$Z, S, H, C, P, N.$$

It supplies no analytic continuation, no RH *truth value, and no global zeta-zero classification.*

Proof. Start with Definition 548.67. It places the supplied zero row Z and critical-strip row S on the displayed hsame and Cont route before any modulus or downstream read is exposed.

Use Definition 548.82 and Definition 548.69. These identify the zero-strip read as finite BHist carrier data transported and replayed by H and C, with provenance and naming recorded by P and N.

The RH boundary rows of Definition 548.84 and Definition 548.78 exclude analytic continuation, RH proof content, and global zero classification from this zero-strip boundary. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip boundary`

Theorem 548.134 (Critical-line witness RH boundary refusal)**.** *Any* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet may cite the packet only as a finite witness boundary over*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer cannot extract a proof or refutation of RH *from the supplied zero-strip rows, modulus ledger, transport, route, package, or local naming rows.*

Proof. First combine Definition 548.62 with Definition 548.84. These theorems identify the RH-facing surface with the finite witness packet and refuse proof content, zero search, global classification, quotient representatives, analytic continuation, and ambient completeness.

Next apply Definition 548.72 and Definition 548.87. They keep every downstream RH-facing read inside the displayed rows $Z, S, M, R, Q, H, C, P, N$.

Thus the consumer receives a finite boundary witness only. Since neither an RH truth coordinate nor a global zero classifier appears in the carrier, the packet cannot be read as a proof or refutation of RH. □

Theorem 548.135 (Critical-line witness strip-depth readback totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every strip-depth read that starts from the supplied zero row* Z*, the fixed critical-strip row* S*, or a bounded depth request in* M *routes through the finite rows*

$$Z, S, M, R, Q, H, C, P, N.$$

The read may expose the supplied $\mathsf{ZetaZeros}^{\uparrow}$ *row, the* $\mathsf{CritStrip}^{\uparrow}$ *boundary, the* $\mathsf{Nat}^{\uparrow}$ *depth budget, the* $\mathsf{Real}^{\uparrow}$ *real-part row, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger, and the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, but no other strip-depth source.*

Proof. Project the accepted carrier through Definition 548.1. The rows $Z, S, M, R, Q, H, C, P, N$ are the displayed coordinates of the same finite BHist packet, so a strip-depth consumer has no carrier coordinate outside that tuple.

Use Definition 548.40, Definition 548.4, and Definition 548.161. They route supplied zero reads, fixed-strip reads, and bounded depth requests through Z, S, M before the real and rational comparison rows R, Q are exposed.

Finally apply Definition 548.159. The transport, continuation, package, and local naming rows H, C, P, N exhaust the remaining public readback surface, so every strip-depth read is confined to the displayed route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier strip depth readback totality`

Theorem 548.136 (Critical-line witness rational comparison ledger totality)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, each rational comparison read is exhausted by the* $\mathsf{Real}^{\uparrow}$ *row* R *and the* $\mathsf{Rat}^{\uparrow}$ *ledger row* Q*, together with the local transport, continuation, package, and naming rows* H, C, P, N*. Such a read cannot import analytic-continuation data, a host zero theorem, a selected quotient representative, or proof data for* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rational comparison ledger totality`

Proof. Begin with the rational comparison surface. By Definition 548.77 and Definition 548.11, the only rows that compare the real-part and rational boundary data are R and Q.

The depth source remains finite by Definition 548.135. Thus the comparison read first consumes Z, S, M as source and depth data, then reads R, Q as the comparison ledger inside the same packet.

The refusal boundary follows from Definition 548.159 and Definition 548.162. Analytic continuation, host zero theorems, quotient representatives, and RH proof data have no coordinate in W, so the rational comparison ledger is total exactly at R, Q, H, C, P, N. □

Theorem 548.137 (Critical-line witness RH refusal ledger exactness)**.** *Every* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the finite refusal boundary carried by*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer may read the supplied zero row, fixed strip row, bounded depth row, real-part row, rational comparison row, transport row, continuation row, package row, and local naming row. It receives no proof of RH*, zero generator, quotient representative, host equality row, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal ledger exactness`

Proof. Project the consumer route to the displayed carrier. The RH-facing surface is still a read of the same finite packet $W = (Z, S, M, R, Q, H, C, P, N)$, not a separate analytic object.

Apply Definition 548.72, Definition 548.78, and Definition 548.136. These rows expose only the supplied zero, strip, depth, real, rational, transport, continuation, provenance, and naming data before the refusal boundary is reached.

The excluded objects would require coordinates for an RH theorem, a zero-producing generator, quotient representatives, host equality, or ambient completeness. Since none is present in the accepted packet, the refusal ledger is exact for every downstream RH-facing consumer. □

Theorem 548.138 (Critical-line witness zero-strip source row)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *carrier* $W = (Z, S, M, R, Q, H, C, P, N)$*, the* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z *and the* $\mathsf{CritStrip}^{\uparrow}$ *row* S *are exposed before any critical-line read. The read may proceed only after the supplied zero source and fixed strip source have been named as finite* BHist *coordinates of the same carrier.*

Proof. Project the carrier of Definition 548.1. Its first displayed source rows are Z and S, while M, R, Q, H, C, P, N are the later modulus, comparison, transport, route, provenance, and naming rows.

Use Definition 548.2. Carrier admission and local naming attach the zero row and strip row to the same accepted packet before downstream reads are available.

Apply Definition 548.3. It identifies the supplied zero source, fixed strip source, and source-facing route as the root entry surface, so no critical-line read can bypass Z or S. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip source row`

Theorem 548.139 (Critical-line witness modulus readback row)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *carrier* $W = (Z, S, M, R, Q, H, C, P, N)$*, every modulus read factors through* M, R, Q, H, C, P, N*. The read uses the on-line modulus row, real-part row, rational comparison ledger, componentwise transport, continuation route, provenance, and local naming; it does not use host equality or a quotient representative.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus readback row`

Proof. Read the modulus coordinate through Definition 548.1. The row M answers only as part of the same finite packet that carries R, Q, H, C, P, N.

Apply Definition 548.2 and Definition 548.4. These bind the depth request to the real-part row R, rational comparison ledger Q, componentwise transport H, replay route C, provenance P, and local name N.

The carrier has no field for host equality of complex numbers and no quotient representative selector. Therefore the modulus readback remains the displayed finite row read through M, R, Q, H, C, P, N. □

Theorem 548.140 (Critical-line witness fixed-strip scope exhaustion)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *carrier* $W = (Z, S, M, R, Q, H, C, P, N)$*, the fixed-strip source surface is exhausted by the rows*

$$Z, S, M, R, Q, H, C, P, N.$$

It exposes supplied zero, critical-strip, modulus, real-part, comparison, transport, route, provenance, and local naming data, and it does not assert RH *or produce new zeros.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip scope exhaustion`

Proof. Start with Definition 548.1. The accepted packet lists exactly $Z, S, M, R, Q, H, C, P, N$, with no coordinate for an RH truth value or a zero-producing search.

Use Definition 548.138 for the supplied zero and strip source. Use Definition 548.139 for every modulus-facing read.

Finally apply Definition 548.2. The local NameCert surface exhausts public reads through the displayed carrier and its non-escape clauses, so the fixed-strip surface remains a finite source boundary rather than an RH proof or zero generator. □

Theorem 548.141 (Critical-line witness root zero carrier)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. A root read of W exposes only the finite zero-strip carrier rows over* BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, *and* $\mathsf{CritStrip}^{\uparrow}$*: the supplied zero row Z, the critical-strip row S, the displayed modulus row M, the real-part row R, the rational comparison ledger Q, and the structural rows H, C, P, N.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zero carrier`

Proof. Project the carrier of Definition 548.1. The rows $Z, S, M, R, Q, H, C, P, N$ are the whole accepted packet, and the root-facing rows are read as finite BHist coordinates rather than as host analytic data.

Use the supplied zero-strip route of Definition 548.82 together with the root modulus-window totality of Definition 548.85. The first row keeps Z, S inside the $\mathsf{ZetaZeros}^{\uparrow}$ and $\mathsf{CritStrip}^{\uparrow}$ boundary supplied by chapter 73; the second keeps M, R, Q inside the $\mathsf{Rat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ comparison boundary supplied by chapter 38.

The root refusal downstream gate of Definition 548.87 then removes every coordinate not displayed in the finite packet. Hence the root read exposes exactly the zero-strip carrier rows listed above. □

Theorem 548.142 (Critical-line witness strip modulus readback)**.** *Every strip-modulus consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet reads the displayed modulus and zero-strip rows through the route*

$$Z, S, M, R, Q, H, C, P, N.$$

In particular, the consumer passes through Cont*, componentwise* hsame, Pkg*, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows before any RH-facing boundary is available.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier strip modulus readback`

Proof. Begin with the root zero carrier of Definition 548.141. It identifies the zero row, strip row, modulus row, comparison ledger, and structural rows as the only carrier data a root consumer may read.

Apply Definition 548.67 for the Z, S part of the read, and apply Definition 548.68 for the M, R, Q part. These sibling rows place the zero-strip and modulus requests under the same displayed hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row.

Finally use Definition 548.84. It places any RH-facing read downstream of the same finite package, so the consumer cannot reach an RH boundary before the displayed strip-modulus route has been read. □

Theorem 548.143 (Critical-line witness zero-strip consumer boundary)**.** *Every downstream RH or zero-count consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the displayed zero-strip witness package*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer receives no analytic continuation certificate, no host complex equality, no global zero oracle, no quotient representative, and no proof of RH.

Proof. First apply Definition 548.142. It forces every strip-modulus consumer through the displayed zero, strip, modulus, comparison, transport, continuation, provenance, and naming rows.

Next use the downstream refusal package of Definition 548.34 and the RH refusal ledger completeness of Definition 548.72. These rows exclude analytic continuation, host equality, quotient representatives, global zero classification, and RH proof data from downstream reads.

The carrier dependencies remain the finite $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows described by chapter 73 and chapter 38. Thus an RH or zero-count consumer receives only the displayed witness package and none of the analytic or host-level objects listed above. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip consumer boundary`

Theorem 548.144 (Critical-line witness root source lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root-facing read of the source side is locked to the displayed* BHist *rows Z, S, M, R, Q together with the componentwise* hsame *row H, the visible* Cont *route C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. No analytic-continuation row, host evaluator, global zero classification, or* RH *truth value can replace this finite source route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source lock`

Proof. Start with the root source exposure package of Definition 548.126. It exposes the supplied zero row, the strip row, the modulus row, the real-part row, and the rational comparison row as the finite source surface of W.

Use the source-modulus interface of Definition 548.59 and Definition 548.60. These rows route the source read through Z, S, M, R, Q before any downstream consumer receives it.

The transport, continuation, provenance, and local naming rows H, C, P, N then authenticate the same finite route. Since the route is already exhausted by BHist, hsame, Cont, Pkg, and local NameCert rows, it has no slot for an analytic continuation, a host evaluator, a global zero classifier, or an RH truth-value oracle. □

Theorem 548.145 (Critical-line witness strip reflection boundary)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, any strip-reflection or zero-strip consumer reads only the displayed* BHist *packet rows, the componentwise* hsame *transport H, the* Cont *route C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. The boundary refuses analytic continuation,* RH *truth values, global zero classification, and host evaluators.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier strip reflection boundary`

Proof. Project the zero-strip boundary through Definition 548.133. It places the strip side on the supplied Z, S rows and keeps the read inside the displayed packet.

Apply the zero-strip consumer boundary of Definition 548.143. The consumer must pass through $Z, S, M, R, Q, H, C, P, N$, including the visible hsame, Cont, Pkg, and local NameCert rows.

The root RH-boundary refusal of Definition 548.94 then removes the analytic exits. Hence strip reflection remains a finite BEDC boundary and cannot become analytic continuation, an RH truth value, a global zero classifier, or a host evaluator. □

Theorem 548.146 (Critical-line witness downstream RH unblock package)**.** *The downstream RH-facing unblock surface of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet is exactly the finite package*

$$Z, S, M, R, Q, H, C, P, N.$$

It exposes the BHist *source rows, the* hsame *transport row, the* Cont *route row, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row needed by downstream consumers, while refusing analytic continuation,* RH *truth values, global zero classification, and host evaluators.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream rh unblock package`

Proof. First use the root source lock of Definition 548.144. It fixes the source and modulus side of the downstream read to the displayed finite packet.

Next use the strip reflection boundary of Definition 548.145. This keeps every zero-strip consumer on the same $Z, S, M, R, Q, H, C, P, N$ surface and records the refusal rows before an RH-facing consumer can read the package.

Finally apply the downstream RH-boundary refinement of Definition 548.105 together with the root refusal downstream gate of Definition 548.87. The downstream route is therefore an unblock package for finite BEDC reads only, with no analytic continuation, RH truth value, global zero classification, or host evaluator exported. □

Theorem 548.147 (Critical-line witness root RH-boundary formal target)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every downstream RH-facing read from the root RH-boundary sibling remains inside*

$$Z, S, M, R, Q, H, C, P, N.$$

The target surface exports only the displayed zero, strip, modulus, real-part, rational-comparison, transport, continuation, provenance, and local naming rows. It cannot export analytic continuation, an RH *truth value, a global zero classifier, or a host evaluator.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier criticallinewitness root rh boundary formal target`

Proof. Project the downstream unblock package of Definition 548.146. It identifies the complete read surface as the finite packet $Z, S, M, R, Q, H, C, P, N$.

Use the root source lock and strip reflection boundary. Together Definition 548.144 and Definition 548.145 keep the source side and strip side on the same displayed rows before an RH-facing consumer can inspect the sibling.

Finally apply the downstream RH-boundary refinement and root refusal gate. Those refusal rows remove analytic continuation, RH truth values, global zero classifiers, and host evaluators from the target surface, so the formal target is exactly the finite BEDC boundary named above. □

Theorem 548.148 (Critical-line witness root refusal budget completion)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root-facing critical-line witness request factors through the finite rows*

$$Z, S, M, R, Q, H, C, P, N$$

before any RH*-facing consumer can read it. The route exposes only the supplied zero row, critical-strip row, modulus row, real-part row, rational comparison ledger, componentwise transport, continuation replay, package provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root refusal budget completion`

Proof. Begin with the root source triad of Definition 548.76. It exposes Z, S, Q as finite BHist source data before a downstream boundary can read the witness.

Next apply the root comparison ledger of Definition 548.77. It places every root-facing rational comparison through Q together with the displayed modulus, real-part, transport, continuation, package, and naming rows.

The remaining downstream read is governed by the RH-refusal ledger completeness theorem, Definition 548.72. That ledger keeps the consumer inside $Z, S, M, R, Q, H, C, P, N$ and refuses every stronger analytic or RH-facing export.

Thus the root-facing request is complete as a finite refusal budget before any RH-facing consumer receives the packet. □

Theorem 548.149 (Critical-line witness zeta-strip modulus totality)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the displayed route through* $\mathsf{ZetaZeros}^{\uparrow}$*,* $\mathsf{CritStrip}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Rat}^{\uparrow}$ *is total for the zero-strip modulus packet. It reads the zeta-zero surface, critical-strip boundary, real-part modulus row, and rational comparison ledger, and it exports no analytic-continuation row, host equality row, quotient row, or ambient-completeness row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta strip modulus totality`

Proof. Use the zeta dependency lattice of Definition 548.169. It places every zero-strip or critical-line read behind the existing $\mathsf{ZetaZeros}^{\uparrow}$ and RH-boundary surfaces before the local modulus witness is public.

The root source triad Definition 548.76 supplies the finite Z, S, Q side of this route. The root comparison ledger Definition 548.77 then supplies the M, R, Q comparison side through $\mathsf{Real}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ rows rather than through a host analytic object.

Finally, the RH-refusal ledger completeness theorem Definition 548.72 excludes analytic continuation, host equality, quotient representatives, and ambient completeness. Hence the displayed zeta-strip-modulus route is total exactly over the finite packet rows. □

Theorem 548.150 (Critical-line witness RH consumer refusal exactness)**.** *Every* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives exactly the refusal ledger and finite witness boundary over*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer does not receive an RH *proof, a global zero classifier, an analytic-continuation certificate, a quotient representative, host equality, or an ambient-completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh consumer refusal exactness`

Proof. First read the refusal ledger through Definition 548.72. It states that downstream RH-facing access is exhausted by the displayed rows and the visible BHist, hsame, Cont, Pkg, and NameCert structure.

Next use the root source triad and root comparison ledger, Definition 548.76 and Definition 548.77. Together they identify the finite witness boundary that the consumer may cite: the supplied zero and strip rows, the modulus and real-part rows, the rational comparison ledger, and the structural rows.

The zeta dependency lattice of Definition 548.169 fixes the sibling source of the zero-strip read without adding an analytic proof surface. Therefore the consumer receives the refusal ledger exactly, not an RH proof or global zero classifier. □

Theorem 548.151 (Critical-line witness candidate closed route)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Before any modulus read, every candidate critical-line route exposed by* W *is the finite source route through the supplied zero row* Z*, the critical-strip row* S*, the componentwise* hsame *row* H*, the* Cont *replay row* C*, the* Pkg *provenance row* P*, and the*

local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row* N*. The route is a* BHist *candidate surface carried by the source triad and fixed-strip source rows, not a host zero source or analytic-continuation surface.*

Proof. Project the accepted packet through the carrier definition and the root source triad of Definition 548.76. These rows expose Z and S as the source side of the same finite BHist packet.

Next use the root unblock source triad and fixed-strip source boundary, Definition 548.3 and Definition 548.123. They keep the candidate route on Z, S, H, C, P, N before the modulus coordinate M is read.

The NameCert obligations then compose the displayed hsame, Cont, and Pkg rows with the local name N. Since the candidate has already been exhausted by Z, S, H, C, P, N, it exports no host zero source and no analytic-continuation route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier candidate closed route`

Theorem 548.152 (Critical-line witness finished endpoint handoff)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every finished critical-line endpoint handoff factors through* M, R, Q, H, C, P, N*: it consumes the* $\mathsf{Nat}^{\uparrow}$ *depth row* M*, the* $\mathsf{Real}^{\uparrow}$ *real-part row* R*, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger* Q*, the componentwise* hsame *transport* H*, the* Cont *replay route* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row* N*. No quotient representative selector or host-equality witness is consumed by the handoff.*

Proof. Begin with the root unblock modulus ledger of Definition 548.4. It identifies M, R, Q, H, C, P, N as the complete endpoint-facing route for each modulus request.

Apply the modulus readback row and strip reflection boundary, Definition 548.139 and Definition 548.145. These rows attach the finished endpoint handoff to the $\mathsf{Nat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$ sources while keeping the transport and replay data inside H, C, P, N.

Finally use the NameCert obligations. The local naming and non-escape rows close the handoff over the displayed BHist, hsame, Cont, and Pkg coordinates, leaving no slot for quotient representative selection or host equality. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier finished endpoint handoff`

Theorem 548.153 (Critical-line witness obstruction separation)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the obstruction row is exactly the refusal boundary of the packet. Downstream readers may cite the source triad, endpoint handoff, and local* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows, but they cannot read an* RH *proof, a zero-producing search, an analytic-continuation certificate, host equality, a quotient representative, or ambient completeness from* W*.*

Proof. Start from the root unblock refusal boundary of Definition 548.5. It states the missing analytic, host, quotient, and completeness coordinates for the accepted packet.

Use the candidate route and finished endpoint handoff above. The first route exhausts the pre-modulus candidate surface through Z, S, H, C, P, N, while the second route exhausts the finished endpoint surface through M, R, Q, H, C, P, N.

Apply the downstream RH unblock package and fixed-strip RH consumer nonescape, Definition 548.146 and Definition 548.125. Together they show that every downstream read remains inside the displayed packet rows, so the obstruction row is precisely the refusal boundary and not an implicit analytic or host-level witness. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessObstructionSeparation`

Theorem 548.154 (Critical-line witness route readback exhaustion)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every downstream readback accepted by W factors through the zero-strip source row fixed by Definition 548.144, the strip reflection boundary of Definition 548.145, and the downstream RH unblock package of Definition 548.146. No downstream readback can replace that finite route by analytic continuation, a host evaluator, global zero classification, an* RH *truth value, or an ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier route readback exhaustion certificate`

Proof. Start with the root source lock. It fixes the source-facing side of W to the displayed rows $Z, S, M, R, Q, H, C, P, N$ and refuses analytic or host-level replacements before a downstream consumer can read the packet.

Next apply the strip reflection boundary. Every zero-strip or strip-reflection consumer remains on the same finite packet, so the readback cannot leave the zero-strip source row for a separate analytic-continuation route.

Finally use the downstream RH unblock package. It exposes exactly the same finite rows to downstream consumers and records the missing RH truth-value and host-evaluator rows as refusals. Thus every downstream readback is exhausted by the displayed source package. □

Theorem 548.155 (Critical-line witness downstream zero-strip exactness)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every zero-strip consumer receives the same modulus comparison surface M, R, Q, H, C, P, N after reading the zero-strip source rows Z, S. The consumer may transport and replay that surface through H and C, and may cite the provenance and local name through P and N, but it receives no second modulus row, no host zero classifier, and no proof of* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream zero strip exactness`

Proof. Project the zero-strip source through Definition 548.144. The rows Z, S are the source side of the same accepted packet as the modulus, real-part, and rational comparison rows.

Apply Definition 548.145. It keeps each zero-strip consumer inside $Z, S, M, R, Q, H, C, P, N$ and refuses host classifiers and analytic exits.

Use Definition 548.146 to read the downstream surface. The package exposes the modulus comparison rows M, R, Q only through the same transport, route, provenance, and local name. Therefore all zero-strip consumers receive the same comparison surface and no separate RH proof. □

Theorem 548.156 (Critical-line witness modulus refusal ledger soundness)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, any off-route request for an* RH *proof, analytic-continuation certificate, global zero classification, host evaluator, quotient representative, host equality, or ambient completeness theorem lands in the refusal ledger attached to the displayed rows. The packet exports the zero-strip source and modulus comparison surface, not a proof of* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus refusal ledger soundness certificate`

Proof. First use Definition 548.144 to identify the only root-facing source route. The route is finite and displayed, so an off-route analytic request has no source coordinate outside $Z, S, M, R, Q, H, C, P, N$.

Next use Definition 548.145. Strip and zero-strip consumers remain inside the same boundary, where analytic continuation, RH truth values, global zero classification, and host evaluators are refused.

Finally apply Definition 548.146. It presents the downstream surface as an unblock package for finite BEDC reads only. The listed off-route requests therefore terminate in the refusal ledger and cannot be repacked as a proof of RH. □

Theorem 548.157 (Critical-line witness strip localization)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root read that localizes the witness to the critical strip factors through the displayed* $\mathsf{CritStrip}^{\uparrow}$ *row S, the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row Z, the* $\mathsf{Nat}^{\uparrow}$ *depth route of M, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger Q, the* $\mathsf{Real}^{\uparrow}$ *real-part row R, and the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows H, C, P, N. It cannot replace the displayed strip row by analytic continuation, host complex equality, a quotient representative, a global zero classifier, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier strip localization`

Proof. Start with the root source triad of Definition 548.76. It displays the supplied zero row Z, the critical-strip row S, and the rational comparison ledger Q as finite BHist source data under H, C, P, N.

Next apply Definition 548.71. The zero row and strip row are transported componentwise through the same hsame surface, so localization cannot be replaced by host equality or a detached zero search.

Finally use Definition 548.77 and Definition 548.72. The Nat, Rat, and Real dependency rows are consumed only through M, R, Q, while the refusal ledger removes analytic continuation, quotient representatives, global zero classification, and ambient completeness from the localized strip read. □

Theorem 548.158 (Critical-line witness zero-row soundness)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every zero-row read is sound only as a read of the supplied finite witness packet. The read consumes the* $\mathsf{ZetaZeros}^{\uparrow}$ *row Z together with the* $\mathsf{CritStrip}^{\uparrow}$ *row S, the* $\mathsf{Nat}^{\uparrow}$ *depth row of M, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger Q, the* $\mathsf{Real}^{\uparrow}$ *real-part row R, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; it does not construct a zero, enumerate zeros, prove* RH*, or import host complex analysis.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero row soundness`

Proof. Project the carrier of Definition 548.1. The zero-facing coordinate is the supplied row Z, and it is packaged with S, M, R, Q, H, C, P, N rather than with a zero-producing search.

Use Definition 548.40 and Definition 548.29. These results force every zero-facing read through the displayed $\mathsf{ZetaZeros}^{\uparrow}$ and $\mathsf{CritStrip}^{\uparrow}$ source rows before any modulus or comparison data are inspected.

Now apply Definition 548.38 and Definition 548.11. The real-part and rational comparison data are read through R, Q inside the same finite packet, so the zero row remains a supplied witness row and not an analytic construction.

The downstream refusal package and Definition 548.72 exhaust the remaining ledger. They exclude RH proof data, zero enumeration, global zero classification, analytic continuation, quotient representatives, host equality, and ambient completeness. □

Theorem 548.159 (Critical-line witness ledger non-escape)**.** *Every ledger read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet factors through the finite route over* $Z, S, M, R, Q, H, C, P, N$ *and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The ledger may expose the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *zero row, the* $\mathsf{CritStrip}^{\uparrow}$ *strip row, the* $\mathsf{Nat}^{\uparrow}$ *depth requests, the* $\mathsf{Rat}^{\uparrow}$ *comparison rows, and the* $\mathsf{Real}^{\uparrow}$ *real-part row, but it exports no analytic continuation theorem, global* RH *proof, host complex-zero classifier, quotient representative, host equality row, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier ledger nonescape`

Proof. Begin with Definition 548.157. It confines root strip reads to $Z, S, M, R, Q, H, C, P, N$ and to the displayed CritStrip, ZetaZeros, Nat, Rat, and Real dependency rows.

Then use Definition 548.158. The zero row is sound only as a supplied finite packet row, so it cannot create a zero-producing route or a global zero classifier.

Finally apply Definition 548.52 together with Definition 548.78. The local ledger is exhausted by the displayed carrier, transport, continuation, package, and naming rows, and every request for analytic continuation, RH proof data, quotient representatives, host equality, or ambient completeness is refused rather than exported. □

Theorem 548.160 (Critical-line witness zero-localization obligation)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet anchored in* BHist*. The finite zero-localization row is the route that reads the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*, the* $\mathsf{CritStrip}^{\uparrow}$ *row* S*, the* $\mathsf{Real}^{\uparrow}$ *real-part row* R*, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger* Q*, and the local transport, continuation, package, and naming rows* H, C, P, N*. It localizes only the displayed witness packet and does not supply analytic continuation, a global zero-set theorem, host complex equality, quotient representative data, or ambient completeness.*

Proof. Project the carrier of Definition 548.1. The rows Z, S, R, Q, H, C, P, N are displayed coordinates of the same finite BHist packet, so the zero-localization read has no source outside that packet.

Use the zero-row soundness and strip-localization surfaces already established in Definition 548.158 and Definition 548.157. They force the supplied zero row and critical-strip row to be read together, with the real and rational comparison rows consumed inside the same local route.

The sibling surfaces chapter 38 and chapter 37 provide only the displayed Real and Rat rows. The ledger therefore cannot import analytic continuation, global zero-set data, host equality, quotient representatives, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero localization source window`

Theorem 548.161 (Critical-line witness rational height-window obligation)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, each rational height-window request is answered through the modulus row* M *and the rational comparison ledger* Q *as a finite unary-count budget. The request may read the supplied zero row* Z*, strip row* S*, real-part row* R*, and local* H, C, P, N *rows, but it cannot obtain a host zero search, an analytic-continuation certificate, a global height enumeration, or an unbounded choice selector.*

Proof. Start with the modulus coordinate M. By carrier projection, it is the only row that answers depth requests, and it is packaged with R, Q, H, C, P, N inside the accepted witness packet.

Apply Definition 548.4 and Definition 548.11. These theorems route the height-window read through the displayed $\mathsf{Real}^{\uparrow}$ real-part row and $\mathsf{Rat}^{\uparrow}$ comparison ledger, using only the finite depth budget recorded by M.

The finite-count boundary is reinforced by chapter 573. That ledger supplies only bounded counting rows, so the request does not become a host zero search, analytic-continuation certificate, global height enumeration, or unbounded choice selector. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rational height window`

Theorem 548.162 (Critical-line witness critical-strip ledger obligation)**.** *Every ledger read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet remains on the displayed finite route*

$$Z, S, M, R, Q, H, C, P, N.$$

The ledger may expose the supplied zero row, critical-strip row, rational height window, Real real-part row, and local replay rows, but it refuses analytic-continuation data, global zero-set data, quotient representatives, host equality rows, selected Real representatives, and ambient completeness.

Proof. Project the accepted carrier. The route displayed in Definition 548.1 lists exactly the zero, strip, modulus, real, rational, transport, continuation, package, and naming rows.

Combine the zero-localization obligation with the rational height-window obligation above. The first binds the supplied zero and strip rows to the same finite localization route; the second binds height requests to the finite modulus and rational comparison ledger.

Finally apply Definition 548.159. The existing ledger boundary already refuses analytic continuation, global RH proof data, host complex-zero classifiers, quotient representatives, host equality, and ambient completeness, so the critical-strip ledger is exhausted by the displayed packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier critical strip ledger`

Theorem 548.163 (Critical-line witness public export)**.** *An accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet exports exactly the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row, the* $\mathsf{CritStrip}^{\uparrow}$ *row, the rational height-window modulus, the* $\mathsf{Real}^{\uparrow}$ *real-part row, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger, and the local transport, replay, provenance, and naming rows. It exports no analytic continuation, global zero-set theorem,* RH *proof, quotient representative, host equality, or ambient completeness.*

Proof. First read the zero-localization obligation. It binds the supplied $\mathsf{ZetaZeros}^{\uparrow}$ row, $\mathsf{CritStrip}^{\uparrow}$ row, $\mathsf{Real}^{\uparrow}$ real-part row, $\mathsf{Rat}^{\uparrow}$ comparison ledger, and local structural rows to the same finite packet.

Next read the rational height-window obligation. It routes every height request through the displayed modulus row and rational comparison ledger before any downstream consumer receives the finite window.

Finally combine the critical-strip ledger obligation with Definition 548.159. The former exhausts the public ledger by $Z, S, M, R, Q, H, C, P, N$, and the latter excludes analytic continuation, global zero-set data, RH proof data, quotient representatives, host equality, and ambient completeness from the carrier. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier public export certificate`

Theorem 548.164 (Critical-line witness root-zero selector exhaustion)**.** *Every selector or localization consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *is exhausted by the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*,* $\mathsf{CritStrip}^{\uparrow}$ *row* S*, modulus row* M*,* $\mathsf{Real}^{\uparrow}$ *row* R*,* $\mathsf{Rat}^{\uparrow}$ *comparison row* Q*, and the local* H, C, P, N *transport, replay, provenance, and naming rows. No such consumer can introduce analytic continuation, global zero-set data,* RH *proof data, host complex equality, quotient representatives, selected Real representatives, or ambient completeness.*

Proof. Start with Definition 548.160. It forces every zero-localization read to consume the supplied $\mathsf{ZetaZeros}^{\uparrow}$ row, $\mathsf{CritStrip}^{\uparrow}$ row, $\mathsf{Real}^{\uparrow}$ real-part row, $\mathsf{Rat}^{\uparrow}$ comparison row, and local structural rows inside the same finite packet.

Next apply Definition 548.161. It routes selector depth and height-window requests through the displayed modulus row M and rational comparison ledger Q, so a consumer cannot replace the finite budget with a host zero search or unbounded choice selector.

Now use Definition 548.162. The critical-strip ledger is exactly the displayed route $Z, S, M, R, Q, H, C, P, N$, and therefore a localization consumer has no additional analytic coordinate after those rows are read.

Finally combine this with Definition 548.163 and Definition 548.159. The public export identifies the same finite surface, while the ledger boundary excludes analytic continuation, global zero-set data, RH proof data, host complex equality, quotient representatives, selected Real representatives, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zero localization selector exhaustion`

Theorem 548.165 (Critical-line witness root-zero localization scope)**.** *Every accepted root-zero localization selector read of a* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet is scoped exactly by the finite rows*

$$Z, S, M, R, Q, H, C, P, N.$$

The selector may consume the supplied $\mathsf{CritStrip}^{\uparrow}$ *row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison data carried by the rational height-window route, the* $\mathsf{Real}^{\uparrow}$ *real-part row, the displayed* $\mathsf{ZetaContinuationWitness}^{\uparrow}$ *row, the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row, and the local transport, replay, provenance, and naming rows. This is only zero-localization evidence: it does not assert existence of a zero,* RH *truth, analytic continuation beyond the displayed witness, a classical critical-line theorem, host complex equality, quotient representatives, selected Real representatives, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zero localization scope`

Proof. The zero-localization obligation Definition 548.160 fixes the source of a localization selector read. It binds the supplied $\mathsf{ZetaZeros}^{\uparrow}$ row, $\mathsf{CritStrip}^{\uparrow}$ row, $\mathsf{Real}^{\uparrow}$ real-part row, $\mathsf{Rat}^{\uparrow}$ comparison row, and local structural rows to one finite BHist packet; it does not create a zero-existence coordinate.

The rational height-window theorem Definition 548.161 adds the only admitted budget for selector depth. Together with chapter 291, chapter 301, and chapter 573, it routes bounded height information through finite dyadic, regular rational, modulus, and comparison rows rather than through an unbounded zero search.

The critical-strip ledger theorem Definition 548.162 and public export theorem Definition 548.163 identify the exported surface as exactly $Z, S, M, R, Q, H, C, P, N$. The sibling chapters chapter 73,

chapter 72, chapter 38, chapter 580, and the rational-data siblings contribute only their displayed rows to that surface.

Finally apply Definition 548.164. It exhausts every localization consumer by the same rows and refuses analytic continuation beyond the displayed witness, global zero-set data, RH proof data, classical critical-line closure, host equality, quotient representatives, selected Real representatives, and ambient completeness. Therefore the selector scope is exactly the displayed packet route, while zeta-zero existence remains outside the selector claim. □

Theorem 548.166 (Critical-line witness root source-route completion)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The root source route is complete exactly when the zero-strip modulus row M, the fixed critical-line source row S, the supplied zeta-continuation witness row Z, the refusal ledger inside Q, the* BHist *carrier, the componentwise* hsame *row H, the displayed* Cont *row C, the* Pkg *row P, and the local* NameCert *row N are read as one finite packet.*

Every consumer of the root obligation surface must pass through that route before it can inspect the critical-line witness. The packet exports no analytic continuation theorem, no RH *proof, no host complex equality, and no off-packet zero localization.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source route completion`

Proof. Start with the zero-localization obligation of Definition 548.160. It binds the zero row, critical-strip row, Real row, rational comparison ledger, and local transport, continuation, package, and naming rows to one finite BHist packet.

Next use Definition 548.157 and Definition 548.158. These force the supplied zero row and fixed strip source to remain a displayed witness read rather than an analytic construction or host zero search.

Finally apply Definition 548.162 and Definition 548.159. The refusal ledger and local routing rows exhaust every public root read, so analytic continuation, RH, host complex equality, and off-packet zero localization have no carrier coordinate. □

Theorem 548.167 (Critical-line witness zero-strip localization exhaustion)**.** *For every accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, a zero-strip localization request is exhausted by the displayed rows*

$$Z, S, M, R, Q, H, C, P, N.$$

The request may consume the zero-strip modulus row, fixed critical-line source row, zeta-continuation witness row, refusal ledger, BHist, hsame, Cont, Pkg, *and* NameCert *rows, but it cannot obtain analytic continuation as a completed theorem,* RH, *host complex equality, or zero localization outside the packet.*

Proof. Project the carrier and read the source rows through Definition 548.166. This places the modulus, fixed source, supplied continuation witness, refusal ledger, transport, route, provenance, and local name in one finite route.

Apply Definition 548.158. The zero row is sound only as a supplied row of the accepted packet, so a localization request cannot turn it into a host search or a global zero-set theorem.

Use Definition 548.161. Height-window access is bounded by the finite modulus and rational comparison ledger. Thus the localization surface is exhausted before any analytic continuation theorem, RH proof, host complex equality row, or off-packet localization can be read. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip localization exhaustion`

Theorem 548.168 (Critical-line witness RH-boundary source lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The* RH *boundary for this packet is locked to the same zero-strip modulus row, fixed critical-line source row, zeta-continuation witness row, refusal ledger,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows used by the root source route. A consumer can cite that boundary only as a refusal and localization surface for the displayed packet.*

In particular, the boundary does not supply analytic continuation as a completed theorem, prove RH*, identify host complex values, or localize zeros away from the accepted source packet.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRhBoundarySourceLock`

Proof. Begin with Definition 548.166. It identifies the finite route that every root obligation read must consume.

Then apply Definition 548.167. The same route exhausts zero-strip localization and prevents a second read outside $Z, S, M, R, Q, H, C, P, N$.

Finally use Definition 548.72. The refusal ledger records requests for RH proof data as boundary reads, not as generated theorem content. Since the accepted packet has no coordinate for analytic continuation, host complex equality, or off-packet zero localization, the boundary remains locked to the displayed source route. □

The CriticalLineWitness$^{\uparrow}$ root package is a witness surface over existing zeta and RH boundary rows, not an independent zeta-function object. Its zero-strip and critical-line reads consume the ZetaZeros$^{\uparrow}$ sibling surface and the RH horizon before any modulus witness is public.

Theorem 548.169 (Critical-line witness zeta dependency lattice)**.** *Every* CriticalLineWitness$^{\uparrow}$ *zero-strip or critical-line read consumes the* ZetaZeros$^{\uparrow}$ *zero-count surface of chapter 73 or the RH-boundary surface of chapter 9239 before it can expose a modulus witness. The packet supplies a finite witness surface through $Z, S, M, R, Q, H, C, P, N$; it does not construct a separate zeta-function object, zero oracle, or proof of* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessZetaLink`

Proof. Start with the root source package already displayed by the hub. The supplied zero row Z and critical-strip row S enter through the root zero-strip route, while M, R, Q remain the later modulus and rational-comparison surface.

Apply Definition 548.67 and Definition 548.141. These sibling rows project the zero-strip and critical-line data to the existing ZetaZeros$^{\uparrow}$ and critical-strip boundary before any modulus read is exposed.

Next use Definition 548.84 and Definition 548.143. They place downstream RH-facing and zero-count consumers behind the same finite route and explicitly refuse zero search, analytic-continuation export, host equality, quotient representatives, and an RH proof.

It remains only to read the modulus witness. By Definition 548.68, such a read passes through M, R, Q, H, C, P, N after the zero-strip and RH boundary rows have been supplied. Hence CriticalLineWitness$^{\uparrow}$ records a dependency lattice over the zeta and RH siblings, not a standalone zeta-function certificate. □

Theorem 548.170 (Critical-line witness root source-readiness triad)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every root consumer read is source-ready only after the zeta dependency row, the fixed strip-source rows, and the root non-escape package have all been displayed. Concretely, the consumer must read the* ZetaZeros$^{\uparrow}$ *row Z, the critical-strip row S, the*

modulus and comparison rows M, R, Q, and the transport, continuation, provenance, and naming rows H, C, P, N as one finite BEDC surface before any RH-facing or zeta-facing obligation is public.

This source-readiness triad supplies no proof of RH*, no analytic continuation theorem, no host zero selector, no quotient equality, and no ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source readiness triad`

Proof. Begin with the zeta dependency lattice, Definition 548.169. It makes the root read consume the existing $\mathsf{ZetaZeros}^{\uparrow}$ and RH-boundary surfaces before a modulus witness can be exposed.

Next apply root-strip source totality, Definition 548.250. This places the $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Gamma}^{\uparrow}$, $\mathsf{ZetaContinuationWitness}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ source rows on the displayed route $Z, S, M, R, Q, H, C, P, N$.

Finally use the root non-escape package, Definition 548.69. Its refusal rows remove proof-of-RH content, analytic-continuation export, host zero selection, quotient equality, host equality, and ambient completeness from the source-ready route. □

Theorem 548.171 (Critical-line witness root zeta-strip non-escape triad)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

the public zeta/strip/non-escape surface is exactly the triad consisting of the zeta dependency lattice, the root strip-source totality route, and the root zeta ledger non-escape row. Every zeta-facing or strip-facing downstream consumer factors through that triad before it can read the modulus side M, R, Q.

The triad is a finite BEDC refusal surface. It does not prove RH*, does not prove analytic continuation, does not choose a host zero, does not identify quotient representatives, and does not import ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zeta strip nonescape triad`

Proof. First read the zeta dependency lattice through Definition 548.169. The dependency row orders every zero-strip and critical-line read through the sibling zeta and RH-boundary surfaces before any modulus witness is public.

Now attach the strip-source route. By Definition 548.250, the public consumer must expose $Z, S, M, R, Q, H, C, P, N$ and the listed sibling source rows before a critical-line-facing read can begin.

Finally use root zeta ledger non-escape, Definition 548.198. The zeta ledger remains the existing continuation and zero-count boundary together with the local packet; it exports no RH proof and no analytic-continuation theorem beyond the named finite surface. □

Theorem 548.172 (Critical-line witness root RH-refusal boundary)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every RH-facing consumer read of the root packet factors through the source-readiness triad of Definition 548.170, the zeta/strip non-escape triad of Definition 548.171, and the existing root RH-boundary refusal rows.*

Thus the public boundary is a refusal package over the displayed $Z, S, M, R, Q, H, C, P, N$ route. It explicitly refuses an RH proof, an analytic continuation proof, a host zero selector, quotient equality, host equality, and ambient completeness.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root rh refusal boundary`

Proof. Start with the source-readiness triad. It places every RH-facing consumer on the displayed zeta, strip, modulus, transport, continuation, provenance, and local naming rows before the boundary can be read.

Next use the zeta/strip non-escape triad. That triad keeps zeta-facing and strip-facing demands inside the finite sibling surfaces and the local packet, so the RH-facing read has no separate analytic or quotient coordinate.

Close with the root RH-boundary refusal rows, Definition 548.94 and Definition 548.72. These rows classify RH proof requests, analytic-continuation proof requests, host zero-selector requests, quotient-equality requests, host-equality requests, and ambient-completeness requests as outside the accepted packet. □

Theorem 548.173 (Critical-line witness root zeta-strip source lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root packet read through W must jointly expose the* $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Gamma}^{\uparrow}$, $\mathsf{ZetaContinuationWitness}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$ *rows before any modulus-side or RH-facing consumer can read M, R, Q.*

The source lock exports no proof of RH*, no analytic-continuation proof, no selected zero, no quotient representative, and no ambient completeness principle.*

Proof. Start with the source-readiness triad of Definition 548.170. It places the zeta dependency row, the fixed strip-source rows, and the root non-escape package on the displayed packet before any RH-facing or zeta-facing obligation is public.

Apply the zeta/strip non-escape triad Definition 548.171 together with the RH-refusal boundary Definition 548.172. These two theorems keep modulus-side access downstream of the same finite route and remove the RH proof, analytic-continuation proof, selected-zero, quotient, and ambient-completeness exits.

Now use the zeta dependency lattice Definition 548.169 and root-strip source totality Definition 548.250. They expose $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Gamma}^{\uparrow}$, $\mathsf{ZetaContinuationWitness}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the consumer reaches M, R, Q.

Finally attach the Phase Real source rows already carried by the root source window: $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ remain visible through the same $Z, S, M, R, Q, H, C, P, N$ packet route. The RH refusal rows then guarantee that this joint exposure is a source lock, not an analytic proof or an ambient completeness import. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zeta strip source lock`

Theorem 548.174 (CriticalLineWitness zeta source lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every zeta-facing read of W factors through the supplied zero row Z, the fixed critical-strip row S, the modulus row M, the rational comparison row Q, and the displayed support rows H, C, P, N before any* RH*-facing consumer can inspect it. The zeta-facing route is therefore a finite source lock over* BHist*,* hsame*,* Cont*,* Pkg*, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row, not an analytic continuation theorem or a host zero-classifier.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zeta source lock package`

Proof. Start from the dependency lattice of Definition 548.169. It places every zeta or critical-line read behind the supplied zero row and the fixed strip row before any modulus witness is visible.

Use the carrier and local NameCert obligations in Definition 548.2. They bind the modulus, rational comparison, transport, replay, provenance, and local naming rows to the same accepted packet.

Finally apply the source-modulus public readiness surface, Definition 548.364. The readiness route exposes $Z, S, M, R, Q, H, C, P, N$ together and leaves no field from which a zeta-facing read could bypass the finite source lock before the RH consumer sees it. □

Theorem 548.175 (CriticalLineWitness source-modulus zeta readback)**.** *For every accepted* CriticalLineWitness$^{\uparrow}$ *packet*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

the source surface and the modulus surface share the same displayed BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *support. A zeta-facing readback may distinguish the supplied zero row, the fixed-strip source row, the modulus row, the real-part row, and the rational comparison row, but it cannot detach any of them from the shared support route* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus zeta readback`

Proof. Project the accepted packet through the carrier and NameCert rows of Definition 548.2. The source and modulus coordinates are rows of one finite packet, with H, C, P, N carrying transport, replay, provenance, and local naming.

Apply the zeta dependency lattice Definition 548.169. It keeps zero-strip and critical-line reads on the same finite witness surface before the modulus read is exposed.

Use Definition 548.364 to read the source and modulus surfaces as one public route. Thus the zeta readback can replay the individual rows only through their common BHist, hsame, Cont, Pkg, and NameCert support. □

Theorem 548.176 (CriticalLineWitness RH consumer source nonescape)**.** *Every* RH*-facing consumer of an accepted* CriticalLineWitness$^{\uparrow}$ *packet receives only the finite source, modulus, and zeta packet*

$$Z, \quad S, \quad M, \quad R, \quad Q, \quad H, \quad C, \quad P, \quad N.$$

The consumer receives no proof of RH*, analytic-continuation theorem, host equality, quotient zero set, global zero classifier, ambient completeness row, or standard bridge row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh consumer source nonescape`

Proof. Begin with the source lock above. It forces zeta-facing inspection through the supplied zero, fixed strip, modulus, comparison, and displayed support rows before any RH-facing consumer sees the packet.

Next use the source-modulus zeta readback theorem. It keeps the source and modulus surfaces on the same BHist, hsame, Cont, Pkg, and NameCert route, so the consumer cannot detach a host source from the finite readback.

Finally apply Definition 548.365. That consumer boundary removes analytic continuation, host equality, quotient representatives, ambient completeness, zero search, selected host limits, and RH proof content. Since the accepted packet also has no standard bridge coordinate, the RH-facing consumer receives only the finite source, modulus, and zeta rows listed above. □

Theorem 548.177 (Critical-line witness RH-interface carrier)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Its RH-facing carrier exposes only the critical-line row read through R, Q, the zero-strip row Z, S, the modulus row M, the source-lock row determined by the displayed zero-strip source, the componentwise transport row H, the route row C, the provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. A downstream consumer may cite the sibling* $\mathsf{ZetaContinuationWitness}^{\uparrow}$ *surface of chapter 580, but it receives no RH truth claim, no nontrivial-zero location theorem, and no completed* $\mathsf{Gamma}^{\uparrow}$ *certificate from this carrier.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh interface carrier`

Proof. Begin with the source exposure package of Definition 548.126. It opens the zero-strip source, modulus, real-part, and rational-comparison rows as the finite surface of W.

Next use the source-modulus interface of Definition 548.59 and the modulus ledger of Definition 548.68. These rows keep the critical-line, zero-strip, and modulus reads attached to Z, S, M, R, Q before any downstream consumer sees the packet.

Finally use the sibling $\mathsf{ZetaContinuationWitness}^{\uparrow}$ refusal rows, especially Definition 580.6 and Definition 580.7. They allow the continuation surface to be cited as a finite input boundary while refusing RH truth, zero-location, and completed Gamma data. Thus H, C, P, N authenticate only the displayed finite route. □

Theorem 548.178 (Critical-line witness modulus ledger exhaustion)**.** *Every zero-strip or RH-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet must read the displayed modulus ledger M, R, Q, H, C, P, N before any downstream use of the zero-strip row, critical-line row, or sibling* $\mathsf{ZetaContinuationWitness}^{\uparrow}$ *route. The consumer receives the ledger as a finite BEDC source surface, not as an RH proof, a zero-location theorem, or a completed Gamma certificate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus ledger exhaustion`

Proof. Project the consumer route through Definition 548.143. It requires zero-strip consumers to pass through $Z, S, M, R, Q, H, C, P, N$, so the modulus ledger is already part of the visible packet.

Apply the downstream RH-boundary refinement of Definition 548.105. The RH-facing route is exhausted by the same displayed rows and refuses analytic continuation, quotient, host-equality, global-zero, and RH-proof exits.

The sibling $\mathsf{ZetaContinuationWitness}^{\uparrow}$ boundary contributes only its finite source lock and refusal surface. By Definition 580.4 and Definition 580.7, continuation reads are displayed before downstream use and do not supply RH truth, zero-location, or completed Gamma data. Hence the local modulus ledger is mandatory for every downstream read. □

Theorem 548.179 (Critical-line witness downstream source package)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, the critical-line and zero-strip rows assemble with the displayed modulus ledger into the finite source package consumed by zeta-boundary downstream chapters:*

$$Z, S, M, R, Q, H, C, P, N.$$

This package is the downstream source surface for RH-boundary reads and zeta-continuation handoffs; it does not assert RH, locate a nontrivial zero, or close the Gamma side of the functional-equation route.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream source package`

Proof. Start with the RH-interface carrier above. It identifies the rows that can be exposed to downstream consumers and excludes RH truth, zero-location, and completed Gamma coordinates from the carrier.

Use the modulus ledger exhaustion theorem. Every zero-strip, critical-line, or RH-facing consumer must read M, R, Q, H, C, P, N together with the source rows before downstream use.

Finally combine the local package with the zeta dependency lattice of Definition 548.169 and the sibling $\mathsf{ZetaContinuationWitness}^{\uparrow}$ source lock of Definition 580.4. The resulting finite surface is exactly $Z, S, M, R, Q, H, C, P, N$, suitable for downstream zeta-boundary chapters and nothing stronger. □

Theorem 548.180 (Critical-line witness zero-strip source totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every supplied zero or critical-strip source read of W is total on the displayed finite route Z, S, H, C, P, N before any downstream* RH*-facing consumer inspects the packet. The source read may cite the root-source rows of Definition 548.76, the comparison-ledger rows of Definition 548.77, and the RH-refusal rows of Definition 548.72, but it remains a finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *surface rather than an* RH *proof datum or analytic-continuation import.*

Proof. Read the accepted carrier through its zero-strip source coordinates. The rows Z and S are supplied rows of the packet, while H, C, P, N give the componentwise transport, displayed route, package provenance, and local name.

Apply the root-source triad and root comparison ledger. These rows place source and comparison reads on the same packet $W = (Z, S, M, R, Q, H, C, P, N)$, so the zero-strip source is total without leaving the finite BEDC surface.

Finally use the RH-refusal ledger. It removes any route to RH proof data, host zero classification, analytic continuation, quotient representatives, host equality, or ambient completeness, leaving exactly the finite source route stated above. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip source totality`

Theorem 548.181 (Critical-line witness modulus-depth ledger)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every modulus-depth, real-part, or rational-comparison read of W factors through the displayed rows M, R, Q, H, C, P, N, with Z and S retained as the supplied zero-strip source coordinates. The read may use the root-source, comparison-ledger, and RH-refusal rows, but it is only a finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *ledger for supplied zero, strip, modulus, and rational comparison data; it is not an* RH *proof or an analytic-continuation certificate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus depth ledger certificate`

Proof. Project W to its modulus and comparison coordinates. The depth row M, real-part row R, rational comparison row Q, and local rows H, C, P, N are the only displayed coordinates that answer modulus-depth requests.

Use the root comparison ledger to identify every rational comparison with Q and every depth read with the same local route. The root-source rows keep Z and S attached to the read, so the ledger is still a row of the accepted packet.

The RH-refusal rows then block analytic-continuation imports, global zero classifiers, host equality, quotient representatives, ambient completeness, and RH proof data. Thus the ledger is total as a finite BEDC read and no stronger object is exported. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus depth ledger`

Theorem 548.182 (Critical-line witness zeta dependency readback)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Any zeta-dependency readback that cites W reads only the supplied zero row Z, critical-strip row S, modulus row M, real-part row R, rational comparison row Q, and the local H, C, P, N rows already exposed by the root-source, comparison-ledger, and RH-refusal surfaces. The dependency readback remains finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data and imports no analytic continuation theorem, completed zeta-function object, or proof of* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta dependency readback`

Proof. Start with the displayed packet $W = (Z, S, M, R, Q, H, C, P, N)$. A zeta-dependency readback can cite the packet only through its supplied source rows, its modulus and comparison ledger, and its local transport, route, provenance, and naming rows.

Combine the root-source triad with the comparison ledger. These force every readback to use the same finite coordinates and prevent a separate zeta-continuation carrier from being substituted for the accepted packet.

Finally apply the RH-refusal ledger. Since analytic continuation, completed zeta data, global zero classification, host equality, quotient representatives, ambient completeness, and RH truth are absent from the accepted rows, the dependency readback is exactly the finite BEDC surface described in the statement. □

Theorem 548.183 (Critical-line witness root finite strip route)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every root zero read and every root critical-strip read of W exposes only the finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows carried by Z, S, H, C, P, N before any downstream* RH*-facing consumer reads the packet. The later modulus, real-part, and rational-comparison rows may be consulted only through the same displayed carrier route $Z, S, M, R, Q, H, C, P, N$.*

Proof. Project the accepted packet through Definition 548.1. The carrier supplies exactly the displayed rows $Z, S, M, R, Q, H, C, P, N$, with H, C, P, N recording the finite transport, continuation, provenance, and local naming surface.

Apply the root source exposure theorem Definition 548.126. It forces a root-facing consumer to see the supplied zero and strip rows as displayed source data before it can use the packet downstream.

Finally use the zero-strip source totality theorem Definition 548.180. The total route remains inside finite BHist, hsame, Cont, Pkg, and NameCert rows, so no downstream RH-facing consumer receives an unexposed source coordinate. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root finite strip route`

Theorem 548.184 (Critical-line witness root modulus read totality)**.** *For every accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every modulus, depth, real-part, or rational-comparison read factors through the displayed rows M, R, Q, H, C, P, N and the existing* Rat$^{\uparrow}$/Real$^{\uparrow}$ *comparison surface. No hidden numeric oracle, host real equality, quotient representative, analytic-continuation row, or ambient completeness input can answer the read.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus read totality`

Proof. Start with the root modulus-window totality theorem Definition 548.85. It identifies M, R, Q, H, C, P, N as the whole finite route for modulus-window reads.

Now apply the root comparison ledger Definition 548.77. The rational and real comparison data are read through the displayed $\mathsf{Rat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows, transported by H, replayed by C, recorded by P, and named by N.

Since the displayed carrier has no coordinate for a hidden numeric oracle, host equality, quotient representative, analytic continuation, or ambient completeness, the modulus read is total only through the stated route. □

Theorem 548.185 (Critical-line witness root refusal ledger scope)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every request for* RH *proof data, global zero classifiers, analytic-continuation certificates, quotient representatives, host equality, or ambient completeness is refused inside the local ledger over* $Z, S, M, R, Q, H, C, P, N$*. The refusal ledger is not exported as a proof surface or as any of the refused objects.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root refusal ledger scope`

Proof. Apply the root refusal route Definition 548.78. It sends root-facing off-route demands to the displayed refusal boundary rather than to analytic or host-level data.

Then use RH-refusal ledger completeness Definition 548.72. That theorem accounts for RH proof requests, zero-search and global-classifier requests, quotient representatives, host equality, analytic continuation, and ambient completeness inside the same finite ledger.

The ledger rows remain $Z, S, M, R, Q, H, C, P, N$. They can be read as local refusal data, but no theorem in the route repacks them as an exported RH proof, global zero classifier, analytic-continuation certificate, quotient representative, host equality witness, or completeness principle. □

Theorem 548.186 (CriticalLineWitness root source-window route lock)**.** *Let* W *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet. Its* BHist *source rows, zero-strip source rows, modulus-window comparison rows,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row form one finite root source-window route. Every RH-facing consumer read of* W *factors through that route and cannot attach a second analytic source, second modulus window, hidden zero oracle, ambient zeta equality, or host-level RH decision row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source window route lock`

Proof. Start from the root source exposure package and the finite route scope for $\mathsf{CriticalLineWitness}^{\uparrow}$. These rows expose the root source, strip source, modulus comparison, transport, continuation, provenance, and local name as finite BHist coordinates.

The route lock is then componentwise. The hsame rows transport the source and modulus coordinates already displayed by the carrier, while the Cont rows replay only those transported coordinates for downstream consumers.

Since the Pkg and NameCert rows record the same finite route, a consumer cannot project an additional analytic source, hidden zero oracle, ambient zeta equality, or host RH decision from the packet. Those coordinates are not carrier rows and are therefore outside the root read. □

Theorem 548.187 (CriticalLineWitness root modulus comparison exhaustion)**.** *Every modulus-comparison read admitted by a* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet is exhausted by the displayed* BHist

source row, zero-strip row, finite modulus-window row, hsame *transport row,* Cont *replay row,* Pkg *provenance row, and local* NameCert *row. The comparison may certify the availability and transport of the displayed modulus data, but it does not assert a zero count, a zero-free strip, or the Riemann hypothesis.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus comparison exhaustion`

Proof. Use the root source-modulus interface to locate the comparison inside the source and window rows of the accepted packet. The comparison is a finite ledger read over those rows, not a theorem about the zero set itself.

Apply the root modulus readback and source-modulus closure rows. They show that transporting a displayed comparison by hsame and replaying it by Cont keeps the read inside the same finite BHist route and the same Pkg provenance.

The final boundary is the local NameCert exactness row. It permits the consumer to read the supplied modulus comparison and its provenance, while zero counts, zero-free-strip conclusions, and RH conclusions remain outside the packet. □

Theorem 548.188 (CriticalLineWitness root RH consumer refusal totality)**.** *Every RH-facing consumer request to a* CriticalLineWitness$^{\uparrow}$ *root packet is total as a finite readback and total as a refusal boundary: accepted reads return only the displayed* BHist *source, modulus comparison,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, while requests for a zero theorem, a zero-free critical strip, a hidden analytic continuation equality, a completed RH proof row, or a host RH truth value are refused.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root rh consumer refusal totality`

Proof. First read the accepted side through the root source-window route lock of Definition 548.186. It gives every RH-facing consumer the finite source, modulus, transport, continuation, provenance, and naming rows already present in the packet.

Next apply the modulus comparison exhaustion of Definition 548.187. The comparison row is available as a displayed finite obligation row, but it is not a zero-counting row and not an RH row.

The refusal side follows from the same inventory. A zero theorem, zero-free critical strip, hidden analytic continuation equality, completed RH proof row, or host RH truth value would require a coordinate absent from BHist, hsame, Cont, Pkg, and NameCert for this packet, so the request is refused rather than exported. □

Theorem 548.189 (Critical-line witness RH-refusal readback totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every* RH*-refusal readback of* W *factors through the displayed zero-strip, modulus, and source rows*

$$Z, S, M, R, Q, H, C, P, N.$$

The readback may cite the zero-strip/source totality of Definition 548.180, the modulus-depth ledger of Definition 548.181, and the RH-interface carrier of Definition 548.177, but it exports only a finite BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *refusal row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal readback totality`

Proof. Project the accepted packet to its displayed zero, strip, modulus, real-part, rational-comparison, transport, route, provenance, and naming rows. These are exactly the coordinates available to a refusal readback.

Use Definition 548.180 for the Z, S, H, C, P, N side and Definition 548.181 for the M, R, Q, H, C, P, N side. The two routes share the same structural rows, so the readback remains one finite packet route.

Finally apply the RH-interface carrier and the existing refusal ledger. Since the packet has no coordinate for an RH theorem, analytic continuation theorem, host zero classifier, quotient representative, host equality, or ambient completeness principle, the refusal readback is exhausted by the displayed rows. □

Theorem 548.190 (Critical-line witness zeta dependency lock)**.** *Before any* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet is exported as a critical-line witness, its dependency rows for* $\mathsf{ZetaContinuationWitness}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *are locked into the same finite route* $Z, S, M, R, Q, H, C, P, N$. *The continuation source is read only as a finite boundary surface, the zero row is read only through* Z, *the rational comparison ledger is read only through* Q, *and the real-part row is read only through* R.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta dependency lock`

Proof. Start with the zeta dependency lattice of Definition 548.169. It forces zero-strip and critical-line reads to consume the zeta-zero and RH-boundary surfaces before the modulus witness is public.

Next use Definition 548.182 and Definition 548.179. These theorems identify every zeta-facing readback with the supplied zero row, critical-strip row, modulus row, real-part row, rational-comparison row, and local structural rows.

The $\mathsf{Rat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ sources are therefore not late imports. They are the displayed rows Q and R already bound to the accepted packet, while $\mathsf{ZetaContinuationWitness}^{\uparrow}$ and $\mathsf{ZetaZeros}^{\uparrow}$ remain provenance and source surfaces consumed before export. □

Theorem 548.191 (Critical-line witness downstream counter-surface)**.** *Every downstream counter-surface consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the finite* BHist *refusal ledger over* $Z, S, M, R, Q, H, C, P, N$. *The consumer may inspect the supplied zero-strip source, modulus window, real-part row, rational comparison row, transport row, continuation row, provenance row, and local* NameCert *row, but it receives no proof or refutation of* RH, *no analytic continuation theorem, and no host zero classifier.*

Proof. Project the downstream read through Definition 548.87. That gate already restricts RH-facing consumers to the finite refusal package over the accepted packet.

Apply the RH-refusal readback totality theorem above. It identifies every such readback with the zero-strip, modulus, source, transport, route, provenance, and naming rows of W.

The non-export clauses in Definition 548.134 and Definition 548.177 remove proof content, analytic continuation, and host zero classification from the consumer surface. Hence downstream consumers receive a finite counter-surface ledger and nothing stronger. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream counter surface`

Theorem 548.192 (Critical-line witness modulus source totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Before any zero-facing consumer reads* W, *the packet*

exposes its zeta source row, critical-strip row, rational-modulus row, zero-window row, componentwise transports, displayed routes, package provenance, and local naming row through the finite surface

$$Z, S, M, R, Q, H, C, P, N.$$

Thus the consumer first receives BHist *source data,* hsame *transport,* Cont *locality,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row, not a late analytic source or an unlisted zero-location coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus source totality`

Proof. Begin with the source exposure package of Definition 548.126. It opens the zero-strip, rational-height, real-part, and modulus rows as finite BHist data before downstream use.

Next apply the zero-strip source totality theorem, Definition 548.180. The Z, S source side and the H, C, P, N structural side are read together, so the zero-facing consumer cannot bypass the displayed hsame, Cont, Pkg, and NameCert rows.

Finally use the RH-interface carrier and the RH-refusal readback totality theorem, Definition 548.177 and Definition 548.189. These identify the same packet route as the only RH-facing readback surface, with M, R, Q carrying the modulus and rational-comparison data before any consumer sees the packet. □

Theorem 548.193 (Critical-line witness zero-strip ledger exhaustion)**.** *Every zero-strip read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet is exhausted by the displayed critical-strip row, rational-modulus row, zero-window row, continuation rows, componentwise transports, package provenance, and local* NameCert *row of*

$$Z, S, M, R, Q, H, C, P, N.$$

The read cannot import a global zero locator, an ambient zero-search oracle, an analytic-continuation theorem, or a source row outside the finite BHist*,* hsame*,* Cont*, and* Pkg *ledger.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip ledger exhaustion`

Proof. Read the zero-strip request through Definition 548.180. The supplied zero and strip rows are already total on the finite route Z, S, H, C, P, N.

Use the modulus-depth ledger of Definition 548.181 together with the modulus ledger exhaustion of Definition 548.178. These force the rational-modulus, real-part, and rational-comparison reads through M, R, Q, H, C, P, N before the zero-strip request is consumed.

Apply the RH-refusal readback totality theorem. Since every refusal readback is the same finite packet route, no global zero locator or unlisted analytic branch can be projected from the zero-strip ledger. □

Theorem 548.194 (Critical-line witness RH-boundary refusal totality)**.** *Every RH-facing read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet remains a refusal-boundary read over the finite rows*

$$Z, S, M, R, Q, H, C, P, N.$$

It exports no RH *predicate, no global zero-location theorem, no completed* $\mathsf{Gamma}^{\uparrow}$ *certificate, and no hidden analytic branch. The exported object is only the displayed* BHist *refusal surface stabilized by* hsame*, routed by* Cont*, carried by* Pkg*, and named by the local* NameCert*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh boundary refusal totality`

Proof. Start from the RH-interface carrier, Definition 548.177. It exposes the critical-line, zero-strip, modulus, source-lock, transport, route, provenance, and naming rows while refusing RH truth, nontrivial-zero location, and completed Gamma data.

Next use Definition 548.189. Every RH-refusal readback factors through $Z, S, M, R, Q, H, C, P, N$, so the boundary read is not a separate analytic theorem.

Finally combine the source exposure package with the zero-strip ledger exhaustion theorem above. The consumer-facing route is already exhausted by the displayed source, modulus, zero-window, transport, continuation, provenance, and naming rows, leaving no coordinate for an RH predicate, global zero-location theorem, completed $\mathsf{Gamma}^{\uparrow}$ certificate, or hidden analytic branch. □

Theorem 548.195 (Critical-line witness root formal-target ledger)**.** *A future formal target for the* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root-modulus zero-strip surface must verify exactly the finite route*

$$Z, S, M, R, Q, H, C, P, N.$$

Here Z is source exposure, S is the critical-strip row, M is the modulus-depth ledger, R is the real-part row, Q is the rational-comparison row, H is componentwise hsame *transport, C is displayed* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. The target must refuse RH truth, global zero-location data, analytic continuation, completed* $\mathsf{Gamma}^{\uparrow}$ *data, and hidden analytic branches.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootFormalTargetLedger`

Proof. The source-exposure package fixes the source row Z before any zero-facing consumer reads the packet. The zero-strip ledger exhaustion theorem then identifies the displayed rows $Z, S, M, R, Q, H, C, P, N$ as the whole zero-strip surface.

The RH-boundary refusal totality theorem supplies the negative side of the ledger. It states that every RH-facing read remains a refusal-boundary read over the same route, with no RH predicate, global zero-location theorem, completed $\mathsf{Gamma}^{\uparrow}$ certificate, or hidden analytic branch.

Thus the formal target is not a global analytic theorem. It is the finite verification obligation that the listed source, strip, modulus, rational-comparison, transport, replay, provenance, and local naming rows exhaust the accepted root-modulus zero-strip surface. □

Theorem 548.196 (Critical-line witness root carrier classifier boundary)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

the public carrier boundary exposes the displayed BHist *rows Z, S, M, R, Q, the componentwise* hsame *classifier-transport row H, the displayed* Cont *route C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N before any critical-line read of M or R is available. A root consumer may therefore enter the critical-line witness only through the finite packet surface of Definition 548.1 and the obligation rows of Definition 548.2.*

Proof. Project the carrier in Definition 548.1. Its displayed packet lists the zero row, strip row, modulus row, real-part row, rational comparison ledger, classifier transport, continuation route, provenance row, and local naming row as one finite BHist surface.

Apply Definition 548.2. Carrier admission exposes the tuple itself, zero-strip compatibility supplies the componentwise hsame classifier transport, modulus discipline keeps each critical-line read attached to M, R, Q, and ledger exactness keeps C, P, N inside the same accepted packet.

The downstream boundary is therefore ordered by the packet rows: H, C, P, N authenticate and route the displayed carrier before any public read reaches the critical-line modulus. The carrier has no alternate host equality, quotient, or analytic-completeness coordinate from which such a read could bypass the displayed boundary. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root carrier classifier boundary`

Theorem 548.197 (Critical-line witness root zero-strip supported handoff)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the zero-strip handoff from the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z *and* $\mathsf{CritStrip}^{\uparrow}$ *row* S *to a critical-line read is readable only through the* $\mathsf{Real}^{\uparrow}$ *row* R*, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger* Q*, and the displayed modulus route* M, H, C, P, N*. The handoff may cite the sibling* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$ *certificate surfaces of chapter 38 and chapter 37, but it exports no* RH *proof and no zero-location theorem.*

Proof. Start with the supplied zero row and strip row. By Definition 548.39, Z is a boundary row for the accepted packet, readable only together with the remaining displayed coordinates and not as a zero constructor or global enumeration.

Next read the critical-line side through the modulus route. The modulus row of Definition 548.12 consumes the real-part row R and the rational comparison ledger Q, while Definition 548.11 identifies Q with the finite $\mathsf{Rat}^{\uparrow}$ comparison rows used by that route.

Finally apply Definition 548.31. Since the accepted packet supplies no universal zero classifier, no RH theorem, no zero-producing search, and no ambient analytic completeness, the zero-strip handoff is exactly the supported route through R, Q, M, H, C, P, N and the sibling $\mathsf{Real}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ rows. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zero strip supported handoff`

Theorem 548.198 (Critical-line witness root zeta ledger non-escape)**.** *Every zeta-facing downstream consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet is exhausted by the existing* ZetaContinuationWitness *continuation boundary, the local* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*, the zero-strip boundary rows of Definition 548.39, and the refusal ledger of Definition 548.31. The consumer receives the named packet* $Z, S, M, R, Q, H, C, P, N$ *and the sibling continuation surface of chapter 580; it receives no proof of* RH *and no analytic-continuation theorem beyond that named packet.*

Proof. Begin with the local zeta row. The carrier of Definition 548.1 stores Z as supplied $\mathsf{ZetaZeros}^{\uparrow}$ input, and Definition 548.39 keeps that row tied to S, M, R, Q, H, C, P, N rather than turning it into a zero constructor or a global zeta-zero enumeration.

Now attach the continuation side only as a sibling boundary. The $\mathsf{ZetaContinuationWitness}^{\uparrow}$ chapter supplies its continuation handoff and consumer-ledger rows through chapter 580; the local packet may cite that surface, but the CriticalLineWitness carrier still exports only the displayed root packet.

Apply Definition 548.31. The refusal ledger excludes an RH proof, zero-producing search, universal zero classifier, and ambient analytic-completeness input. Therefore every zeta-facing downstream read is exhausted by the named continuation boundary, the local zero boundary, and the refusal rows already displayed by the packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zeta ledger nonescape`

Theorem 548.199 (Critical-line witness root continuation zero-strip coherence)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, any continuation read* C *that reaches the zero-strip handoff preserves the same* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*,* $\mathsf{CritStrip}^{\uparrow}$ *row* S*,* $\mathsf{Real}^{\uparrow}$ *row* R*,* $\mathsf{Rat}^{\uparrow}$ *comparison ledger* Q*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row* N*. No consumer may replace this continuation route by analytic continuation, an* RH *proof, quotient equality, or ambient completeness.*

Proof. Project the carrier of Definition 548.1. The continuation row C is stored in the same finite packet as Z, S, M, R, Q, H, P, N.

Apply the root carrier classifier boundary, Definition 548.196. It forces every public read of the root packet through the displayed carrier, classifier transport, continuation, provenance, and local naming rows before any critical-line consumer reaches M or R.

Next apply the zero-strip supported handoff, Definition 548.197. The handoff from Z, S to a critical-line read must pass through R, Q, M, H, C, P, N, so the continuation cannot detach from the zero row, strip row, real row, rational comparison ledger, or local name.

Finally use zeta ledger non-escape, Definition 548.198. Since every zeta-facing read is exhausted by the named continuation boundary, local zero boundary, and refusal rows, no analytic-continuation theorem, RH proof, quotient equality, or ambient completeness coordinate can replace the displayed continuation route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root continuation zero strip coherence`

Theorem 548.200 (Critical-line witness phase Real readback boundary)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every Real-facing critical-line read must pass through the displayed* $\mathsf{Real}^{\uparrow}$ *row* R*, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger* Q*, and the L10 dependency rows* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *before any modulus or critical-line consumer can inspect the packet. The readback route exports no* RH *proof, analytic-continuation theorem, quotient equality, selected zeros, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from the root carrier classifier boundary, Definition 548.196. It forces every public read of the root packet through $Z, S, M, R, Q, H, C, P, N$ before a critical-line consumer reaches the modulus row or the Real-facing row.

Next apply the zero-strip supported handoff, Definition 548.197. The handoff from Z, S to a critical-line read is readable only through R, Q, M, H, C, P, N, so the $\mathsf{Real}^{\uparrow}$ row and $\mathsf{Rat}^{\uparrow}$ comparison ledger cannot be skipped.

Finally use zeta ledger non-escape, Definition 548.198, together with continuation zero-strip coherence, Definition 548.199. These rows keep the L10 dependencies $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ as named readback boundaries rather than completed ambient infrastructure.

Since the carrier has no coordinate for an RH proof, analytic continuation, quotient equality, selected zeros, or ambient $\mathsf{Real}^{\uparrow}$ completeness, a modulus or critical-line consumer that bypasses those rows leaves the accepted packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real readback boundary`

Theorem 548.201 (CriticalLineWitness root StdBridge refusal source)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet rooted in* BHist*. Before any* StandardBridge*-facing consumer reads* W *as a critical-line witness, the displayed zero-strip and refusal source is fixed by the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*, critical-strip row* S*, depth row* M*, real-part row* R*, rational-comparison*

row Q, componentwise hsame *row H, displayed* Cont *row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N.*

The fixed source is a finite refusal surface. It is not an analytic continuation theorem, host zero classifier, quotient-stream representative, ambient completeness principle, or proof of RH.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root stdbridge refusal source`

Proof. Project the accepted carrier to the displayed tuple $Z, S, M, R, Q, H, C, P, N$. These are the only BHist, transport, continuation, provenance, and local naming rows available before a bridge-facing consumer can read the witness.

The refusal surface consumes the zero row supplied by chapter 73 before any StandardBridge-facing consumer reads the packet, so the root source is anchored in the sibling ZetaZeros carrier rather than in a local-only witness route.

Use Definition 548.183 for the zero and strip side. It forces every root zero read and critical-strip read through the finite route before any downstream RH-facing consumer sees the packet.

Apply Definition 548.185 to the off-route demands. The refusal ledger records the absent analytic and host-level objects inside the same finite tuple, so the StandardBridge-facing source is fixed as the displayed refusal surface. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root stdbridge refusal source certificate`

Theorem 548.202 (CriticalLineWitness root zero-strip readback)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$ rooted in* BHist*, every root zero-strip readback is exhausted by the supplied zero row Z, strip row S, modulus or depth row M, real-part row R, rational-comparison row Q, and the local H, C, P, N structural rows. No additional analytic continuation row, global zero classifier, host equality, quotient representative, countable selector, or ambient completeness datum can extend the readback.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zero strip readback`

Proof. Read the source side through Definition 548.204. The theorem lists $Z, S, M, R, Q, H, C, P, N$ as the full root source route for zero-strip consumers.

Next use Definition 548.184. It keeps modulus, depth, real-part, and rational-comparison reads inside the displayed numeric rows and the same structural route.

The remaining possible extensions are exactly the objects named in the refusal boundary. By Definition 548.206, analytic continuation export, global zero classification, host equality, quotient representatives, countable selector data, and ambient completeness stay absent as exported readback coordinates. □

Theorem 548.203 (CriticalLineWitness root RH refusal exhaustion)**.** *Every* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the refused finite witness surface over $Z, S, M, R, Q, H, C, P, N$. The consumer may inspect the supplied zero-strip source, modulus and comparison rows, real-part row, componentwise transport, continuation, provenance, and local* NameCert *rows, but receives no analytic continuation theorem, host critical-line fact, global zero classifier, quotient-stream equality, ambient completeness principle, or proof or refutation of* RH.

Proof. Begin with Definition 548.189. It states that every RH-refusal readback factors through the displayed zero-strip, modulus, source, transport, route, provenance, and naming rows.

Then apply Definition 548.191. Downstream consumers receive the finite refusal ledger over the same packet, not proof content or host zero classification.

Finally use Definition 548.201. The bridge-facing source has already been fixed as a finite refusal surface, so the RH consumer cannot strengthen it into analytic continuation, a host critical-line fact, a quotient-stream equality, ambient completeness, or an RH theorem. □

Theorem 548.204 (CriticalLineWitness root strip source totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet anchored in* BHist*. Every root consumer that asks for the zero-strip source must read the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row Z, the critical-strip row S, the* $\mathsf{Nat}^{\uparrow}$ *depth row M, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger Q, the* $\mathsf{Real}^{\uparrow}$ *real-part row R, and the displayed* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows H, C, P, N. The source route may cite the sibling* $\mathsf{ZetaContinuationWitness}^{\uparrow}$ *surface, but it does not export analytic continuation, a global* $\mathsf{ZetaZeros}^{\uparrow}$ *classifier, host equality, quotient representatives, an* RH *proof, or ambient completeness.*

Proof. Project the accepted carrier. The rows $Z, S, M, R, Q, H, C, P, N$ are finite BHist coordinates, with H carrying componentwise hsame transport, C carrying the displayed Cont route, P carrying Pkg provenance, and N carrying the local naming row.

Use the supplied zero-strip route and the zero-strip source totality theorem, Definition 548.82 and Definition 548.180. They bind the zero and strip source side to Z, S, H, C, P, N before any downstream read can consult the modulus or comparison rows.

Next attach the numerical rows through the root comparison ledger and the modulus source totality theorem, Definition 548.77 and Definition 548.192. These rows force the $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ data to remain inside M, R, Q, H, C, P, N.

Finally read the zeta side only as a named sibling boundary. The $\mathsf{ZetaContinuationWitness}^{\uparrow}$ and $\mathsf{ZetaZeros}^{\uparrow}$ rows are consumed as displayed source coordinates, while the refusal ledger excludes analytic continuation, host equality, quotient representatives, global zero classification, RH proof data, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root strip source totality`

Theorem 548.205 (CriticalLineWitness root Gamma Real dependency)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet anchored in* BHist*. Any root read that mentions a* $\mathsf{Gamma}^{\uparrow}$*-facing or* $\mathsf{Real}^{\uparrow}$*-facing dependency must pass through the displayed real-part row R, rational comparison ledger Q, depth row M, supplied zero-strip rows Z, S, componentwise* hsame *row H, displayed* Cont *row C,* Pkg *row P, and local* NameCert *row N. The dependency is a finite packet route over* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ZetaContinuationWitness}^{\uparrow}$*, and* $\mathsf{ZetaZeros}^{\uparrow}$ *rows, not an analytic Gamma completion or a host real-equality shortcut.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root gamma real dependency`

Proof. Begin with the root carrier classifier boundary, Definition 548.196. It orders the displayed carrier rows before a critical-line read of M or R is available.

Next use the root zero-strip supported handoff, Definition 548.197. The handoff sends the supplied $\mathsf{ZetaZeros}^{\uparrow}$ and critical-strip rows through R, Q, M, H, C, P, N, so a $\mathsf{Real}^{\uparrow}$ dependency is still a finite carrier dependency.

Now apply the RH-boundary refusal totality theorem, Definition 548.194. It records that completed $\mathsf{Gamma}^{\uparrow}$ data and hidden analytic branches are not exported by the packet.

The remaining dependency is therefore exactly the finite route through $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ZetaContinuationWitness}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows. Since host

real equality and analytic Gamma completion have no displayed coordinate in W, they cannot replace R, Q, M, H, C, P, N. □

Theorem 548.206 (CriticalLineWitness root refusal ledger exactness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet anchored in* BHist*. Every root refusal ledger entry for* RH*-facing,* $\mathsf{Gamma}^{\uparrow}$*-facing,* $\mathsf{ZetaContinuationWitness}^{\uparrow}$*-facing, or* $\mathsf{ZetaZeros}^{\uparrow}$*-facing demand is exactly the finite ledger over $Z, S, M, R, Q, H, C, P, N$ with componentwise* hsame*, displayed* Cont*,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows. The ledger records refusal of analytic continuation export, host equality, quotient representatives, ambient completeness, global zero classification, zero search, and* RH *proof data; it does not turn any refused item into a proof object.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root refusal ledger exactness`

Proof. First project the root refusal route, Definition 548.78. It sends off-route root demands to the displayed refusal boundary rather than to analytic or host-level data.

Apply RH-refusal ledger completeness, Definition 548.72. This accounts for RH proof requests, global zero classifiers, analytic-continuation certificates, quotient representatives, host equality, and ambient completeness within the same finite ledger.

Then use the root zeta ledger non-escape theorem, Definition 548.198. It keeps $\mathsf{ZetaContinuationWitness}^{\uparrow}$ and $\mathsf{ZetaZeros}^{\uparrow}$ demands attached to the named packet and the sibling continuation boundary rather than exporting a new analytic theorem.

Together these finite carrier projections exhaust the refusal ledger. The exact rows are $Z, S, M, R, Q, H, C, P, N$, and every refused $\mathsf{Gamma}^{\uparrow}$, zeta, or RH object remains absent as an exported proof or host-level coordinate. □

Theorem 548.207 (CriticalLineWitness root strip public target)**.** *The root-strip source totality theorem, the root Gamma Real dependency theorem, and the root refusal ledger exactness theorem together provide a public target surface for formalizing accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packets. The exposed rows are exactly $Z, S, M, R, Q, H, C, P, N$: Z and S record the root-strip source, M, R, Q record the Gamma-facing and real-comparison dependencies, and H, C, P, N record transport, replay, provenance, and local naming. This target surface contains no* RH *proof data, analytic continuation export, global zero classification, host equality, quotient representatives, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root strip public target`

Proof. Start with Definition 548.204. It makes the supplied zero row Z, strip row S, depth row M, real row R, rational ledger Q, and structural rows H, C, P, N visible before any root consumer can read the packet.

Next apply Definition 548.205. It keeps every $\mathsf{Gamma}^{\uparrow}$-facing and $\mathsf{Real}^{\uparrow}$-facing dependency inside the displayed M, R, Q, H, C, P, N route, with Z and S still supplying the named strip source.

Finally use Definition 548.206. The refusal ledger accounts for every off-route request as absent from the finite packet, so packaging the three theorems yields a public target surface and not an RH theorem, analytic-continuation theorem, global zero classifier, host-equality principle, quotient representative, or completeness claim. □

Theorem 548.208 (Critical-line witness source modulus classifier lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The supplied zero row Z, critical-strip row S, rational comparison ledger Q, modulus row M,* $\mathsf{Real}^{\uparrow}$ *row R,* $\mathsf{Rat}^{\uparrow}$ *comparison row,* hsame *row H,* Cont *row*

C, Pkg row P, and local $\mathsf{NameCert}$ row N are the only root-facing source and classifier surface of W.

Consequently a root consumer may classify the supplied zero-strip source only by reading those displayed rows. It receives no RH proof object, global zero classifier, analytic-continuation certificate, quotient representative, host equality, or ambient completeness coordinate.

Proof. Begin with the root-source triad of Definition 548.76. It exposes Z, S, Q as the finite source triad carried by H, C, P, N.

Use the root comparison ledger of Definition 548.77. The ledger places every rational comparison through Q, M, R, H, C, P, N and refuses analytic or quotient replacement rows.

Finally apply the zero-strip carrier totality and RH-refusal non-escape theorems. They identify the accepted packet as exactly $Z, S, M, R, Q, H, C, P, N$ and exclude an RH proof object, global zero classifier, analytic-continuation certificate, quotient representative, host equality, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus classifier lock`

Theorem 548.209 (Critical-line witness zero-strip readback totality)**.** *For an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ packet $W = (Z, S, M, R, Q, H, C, P, N)$, every root readback of the zero-strip side is total through the supplied zero row Z, critical-strip row S, modulus row M, real-part row R, rational comparison ledger Q, and the structural rows H, C, P, N. No root readback may skip directly to a global zero-set decision, analytic-continuation certificate, host equality, quotient representative, RH proof object, or ambient completeness principle.*

Proof. Project the zero-strip transport lock. By Definition 548.71, the rows Z and S remain attached to the displayed BHist surface through H, C, P, N.

Attach the comparison side through the root comparison ledger. The ledger forces rational and real-part comparison readback through Q, M, R, H, C, P, N rather than through a host zero search or analytic continuation.

The root refusal route then supplies the exclusion. By Definition 548.78, an RH proof object, global classifier, analytic certificate, quotient representative, host equality, and ambient completeness remain outside the root packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessZeroStripReadbackTotality`

Theorem 548.210 (Critical-line witness root NameCert scope completion)**.** *The root $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ scope for an accepted packet $W = (Z, S, M, R, Q, H, C, P, N)$ is completed by the supplied zero row, critical-strip row, rational comparison ledger, modulus row, $\mathsf{Real}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ rows, componentwise hsame, displayed Cont, Pkg provenance, and local naming row. These rows are the whole root-facing source, readback, and classifier boundary for downstream RH-boundary consumers.*

The completed scope still does not provide an RH proof object, global zero classifier, analytic-continuation certificate, quotient representative, host equality, hidden zero search, or ambient completeness coordinate.

Proof. First use Definition 548.208. It locks the source and classifier surface to $Z, S, M, R, Q, H, C, P, N$.

Next use Definition 548.209. The zero-strip readback is total through the same displayed packet and cannot skip to an external analytic or host-level row.

Finally apply the existing root-source triad and root comparison ledger. Together they supply the NameCert-facing source and comparison obligations, while the refusal results rule out every

requested proof, classifier, continuation, quotient, host-equality, and completeness object outside the packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root namecert scope completion`

Theorem 548.211 (Critical-line witness root budget obligation)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The root budget read of W is exhausted by the supplied zero row Z, critical-strip row S, modulus row M, real-part row R, rational comparison ledger Q, componentwise* hsame *transport row H, displayed* Cont *row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N.*

Every downstream read of the root budget factors through the existing root source triad, root comparison ledger, and RH-refusal non-escape rows. It receives no RH *proof data, global zero classifier, quotient representative, analytic-continuation certificate, host equality, or ambient completeness coordinate.*

Proof. Start with the root source triad of Definition 548.76. It displays the supplied zero row, critical-strip row, and rational comparison ledger as the source side of the accepted packet.

Use the root comparison ledger of Definition 548.77. The comparison read is routed through M, R, Q, H, C, P, N, so the root budget cannot branch into a host zero classifier or quotient representative.

Finally apply the RH-refusal non-escape surface, including Definition 548.81. The refused proof, analytic-continuation, host-equality, and ambient-completeness reads are absent from the displayed packet, so the root budget is exhausted by $Z, S, M, R, Q, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root budget obligation`

Theorem 548.212 (Critical-line witness zero-strip budget transport)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, the zero-strip budget transported from the supplied zero row Z to the downstream comparison surface is exactly the finite route through S, M, R, Q, H, C, P, N. The transport may cite the root source triad, the root comparison ledger, and the RH-refusal non-escape rows, but it exports no* RH *proof data, global zero classifier, quotient representative, analytic-continuation certificate, host equality, or ambient completeness coordinate.*

Proof. Project the zero-strip source from Definition 548.76. The rows Z and S are displayed before any downstream comparison reads the packet.

Attach the comparison side by Definition 548.77. The modulus, real-part, and rational comparison rows are carried by M, R, Q and stabilized by H, C, P, N.

Use the RH-refusal non-escape rows to close the transport. Since the refusal ledger has no analytic continuation, host equality, quotient representative, global zero classifier, ambient completeness, or RH proof coordinate, the zero-strip budget remains the displayed finite route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip budget transport`

Theorem 548.213 (Critical-line witness root refusal budget exhaustion)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root refusal budget for downstream* RH*-facing, zero-strip-facing, or comparison-facing reads is exhausted by the same finite carrier rows $Z, S, M, R, Q, H, C, P, N$. The refusal budget records absence of* RH *proof data, global zero classifiers, quotient representatives, analytic-continuation certificates, host equality, and ambient completeness; it does not turn any refused object into a proof row.*

Proof. Begin with the root budget obligation above. It identifies the finite root budget available to downstream consumers and leaves no hidden branch outside $Z, S, M, R, Q, H, C, P, N$.

Transport the zero-strip side by Definition 548.212. The zero row, strip row, modulus row, real-part row, and rational ledger remain one displayed route under H, C, P, N.

Finally apply the RH-refusal non-escape rows, especially Definition 548.81 and Definition 548.94. They record the refused analytic and host-level demands as absent coordinates, so the refusal budget is exhausted by the packet rather than by an external proof surface. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootRefusalBudgetExhaustion`

Theorem 548.214 (CriticalLineWitness zero-strip carrier)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The packet exposes a finite zero-strip source row over* $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Gamma}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ZetaContinuationWitness}^{\uparrow}$, *and* $\mathsf{ZetaZeros}^{\uparrow}$, *with the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *coordinates. This row records the finite source surface; it does not import a proof of* RH *or any analytic continuation principle as carrier data.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip carrier`

Proof. Project the accepted carrier to its displayed rows $Z, S, M, R, Q, H, C, P, N$. The zero-strip source row is read through Z and S, while the numerical and comparison rows are read through M, R, Q.

The surrounding root source and strip-source obligation rows already bind those coordinates to the local BHist packet. Transport through H, continuation through C, provenance through P, and the local naming row N keep the carrier inside the finite $\mathsf{CriticalLineWitness}^{\uparrow}$ surface.

The refusal boundary is part of the same packet. It prevents RH proof data, analytic continuation principles, quotient representatives, host equality, and ambient completeness from becoming carrier fields. □

Theorem 548.215 (CriticalLineWitness zeta comparison ledger)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every zeta-comparison row is a ledger entry read through the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *coordinates of W. The comparison ledger may mention* $\mathsf{ZetaContinuationWitness}^{\uparrow}$ *and* $\mathsf{ZetaZeros}^{\uparrow}$ *as named source rows, but it does not compare host complex values, choose zeros classically, or export a global zero classifier.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta comparison ledger`

Proof. Begin with the displayed source coordinates. The rows Z and S identify the zeta and strip side, while M, R, Q provide only finite depth, real-part, and rational comparison rows.

The ledger is read through H, C, P, N. Componentwise hsame transport aligns the source rows, the displayed Cont route records the admissible readback, and Pkg with $\mathsf{NameCert}$ authenticates the local packet surface.

No host complex equality or classical zero selection is a coordinate of the accepted packet. The ledger therefore remains a finite displayed comparison row rather than an analytic zero-selection mechanism. □

Theorem 548.216 (CriticalLineWitness NameCert obligation package)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, the carrier row, zero-strip source row, zeta-comparison ledger, refusal boundary, and downstream readback rows form the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *obligation surface. Every downstream root, strip, zeta, or* RH*-facing read must pass through that surface before it can consume any displayed packet coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier namecert obligation package`

Proof. The carrier row supplies the finite packet coordinates $Z, S, M, R, Q, H, C, P, N$. The zero-strip source row and zeta-comparison ledger identify the source and comparison portions of the same packet.

The refusal boundary records what the packet does not export: RH proof data, analytic continuation as data, host equality, quotient representatives, global zero selection, and ambient completeness. These exclusions keep every off-route demand at the local ledger boundary.

Finally the downstream readback rows replay the same BHist, hsame, Cont, Pkg, and NameCert coordinates. Hence the local naming certificate surface is exactly the package assembled from the carrier, source, comparison, refusal, and readback rows. □

Theorem 548.217 (CriticalLineWitness fixed tuple image row)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Its* StandardBridge*-facing image is the fixed finite tuple of displayed* BHist *rows*

$$(Z, S, M, R, Q, H, C, P, N).$$

Every accepted carrier read of W lands in exactly one of these nine rows: the supplied zero row Z, critical-strip row S, modulus row M, real-part row R, rational-comparison row Q, componentwise hsame *transport row H, displayed* Cont *row C,* Pkg *provenance row P, or local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. The image row contains no* RH *proof, no host zero classifier, no analytic-continuation theorem, no quotient representative, and no ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed tuple image row`

Proof. Project the accepted carrier through Definition 548.1. The carrier is already the finite BHist packet $Z, S, M, R, Q, H, C, P, N$, so the image visible to a bridge-facing consumer has one displayed row for each coordinate and no further coordinate to inspect.

Use the carrier-admission and ledger-exactness clauses of Definition 548.2. They identify accepted public reads with the displayed packet rows and prevent an accepted read from leaving the packet.

Finally apply Definition 548.201. The root-facing source is a finite refusal surface over the same nine rows, so the image row remains a tuple of BHist data and does not become a bridge theorem or an RH proof. □

Theorem 548.218 (CriticalLineWitness fixed tuple readback row)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet whose image row is the displayed tuple of Definition 548.217. Each displayed image row reads back to the corresponding tuple coordinate through the local structural route: Z, S, M, R, Q are recovered through their componentwise* hsame *entries in H, their displayed* Cont *routes in C, their* Pkg *provenance in P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N; the structural rows H, C, P, N read back as the transport, continuation, provenance, and naming coordinates of the same carrier.*

Proof. Begin with the root zero-strip readback theorem Definition 548.202. It exhausts every source-side readback by the supplied zero row Z, strip row S, modulus or depth row M, real-part row R, rational-comparison row Q, and the structural route H, C, P, N.

For the data rows Z, S, M, R, Q, use the zero-strip compatibility, modulus-discipline, and ledger-exactness clauses of Definition 548.2. These clauses say that the rows are transported by H, replayed by C, recorded by P, and named by N before any public consumer can read them.

For the structural rows, read the same carrier projection directly. The rows H, C, P, N are not extra witnesses outside the image; they are the tuple coordinates that supply componentwise hsame, Cont, Pkg, and NameCert structure for the readback itself. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed tuple readback row`

Theorem 548.219 (CriticalLineWitness StdBridge premise surface)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the fixed-route* StandardBridge *premise surface is exactly the following finite collection:*

1. *the tuple carrier* $(Z, S, M, R, Q, H, C, P, N)$ *from Definition 548.1;*
2. *the image row of Definition 548.217;*
3. *the readback row of Definition 548.218;*
4. *componentwise* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *transport through the displayed* H, C, P, N *rows;*
5. *the* ChapterTasteGate *row required by the fixed finite* BHist *tuple surface.*

These are the premises for the fixed-route StandardBridge *surface and nothing stronger: they do not prove* RH*, construct a bridge theorem, solve recognizer-to-carrier transport, or add analytic, quotient, host-equality, or completeness data.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed tuple stdbridge premise surface`

Proof. Assemble the tuple carrier from Definition 548.1. The carrier supplies the nine displayed BHist rows and the local naming coordinate that all downstream reads must use.

Add the image and readback rows. The image theorem confines every accepted carrier read to the finite tuple, while the readback theorem returns each displayed row to its corresponding coordinate through hsame, Cont, Pkg, and NameCert structure.

Transport the naming obligations component by component using Definition 548.2. The root refusal and readback controls of Definition 548.201 and Definition 548.202 keep the route on the same finite packet.

Finally compare the assembled rows with Definition 9464.24 and Definition 9464.25. Those results name the tuple carrier, image row, readback row, componentwise NameCert transport, and ChapterTasteGate row as the exact fixed finite BHist premise surface before any StandardBridge request. The present theorem only identifies that premise surface for $\mathsf{CriticalLineWitness}^{\uparrow}$. □

Theorem 548.220 (CriticalLineWitness supplied source carrier triad exhaustion)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The supplied* Z, S, Q *source triad is exhausted by the displayed carrier rows* $Z, S, M, R, Q, H, C, P, N$*:* Z *supplies the zero-facing source,* S *supplies the critical-line strip,* Q *supplies the source-facing comparison ledger, and the remaining rows* M, R, H, C, P, N *only route, transport, replay, package, and name that same finite carrier.*

No root read of the supplied source triad exports an RH *proof object, a global zero search, analytic continuation, quotient representatives, host equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier supplied source carrier triad exhaustion`

Proof. Start with Definition 548.76. It identifies Z, S, Q as the source triad exposed by the accepted root packet, and it reads that triad through the finite BHist, hsame, Cont, Pkg, and local NameCert surface.

Project the carrier coordinates of W. The only available rows are $Z, S, M, R, Q, H, C, P, N$, so the triad cannot acquire a second zero source, detached strip witness, hidden comparison classifier, or ambient analytic row.

Finally route the unused carrier rows as support rows. The modulus, real-part, transport, continuation, provenance, and naming coordinates preserve the same finite packet rather than adding a proof of RH or any external completion datum. □

Theorem 548.221 (CriticalLineWitness modulus comparison NameCert route)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every modulus comparison read factors through* M, R, Q, H, C, P, N *and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. The route exposes the modulus row* M*, real-part row* R*, rational comparison row* Q*, componentwise transport row* H*, displayed continuation row* C*, package provenance row* P*, and local naming row* N *before any comparison-facing consumer can read the packet.*

The route does not supply a host analytic estimate, quotient representative, global zero classifier, analytic-continuation certificate, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus comparison namecert route`

Proof. Apply Definition 548.77. It places comparison reads on the finite ledger containing M, R, Q, H, C, P, N and refuses replacement by global zero, quotient, analytic, or completeness data.

Next apply Definition 548.70. The modulus row and rational comparison row are consumed under the same transport, continuation, provenance, and local naming rows, so the $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ coordinate belongs to the comparison route itself.

The carrier projection supplies no further comparison coordinate. Thus every accepted modulus comparison read factors through exactly the displayed NameCert route. □

Theorem 548.222 (CriticalLineWitness RH refusal public nonescape)**.** *Every public* RH*-facing read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet exposes only the displayed finite refusal route through* $Z, S, M, R, Q, H, C, P, N$*. It cannot export an* RH *proof, zero search, analytic continuation, quotient representative, host equality, ambient completeness, or any detached classifier outside the packet.*

The public route is therefore a finite refusal surface over the supplied source rows, modulus comparison rows, transport rows, continuation rows, provenance row, and local NameCert *row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal public nonescape`

Proof. Use Definition 548.78 to locate every public refusal read on the root packet. The refusal is carried by the displayed finite rows rather than by an external analytic certificate or host-level equality.

Then apply Definition 548.75. This excludes RH proof data, zero search, analytic continuation, quotient representatives, host equality, and ambient completeness from the accepted packet surface.

Combining the two routes leaves only $Z, S, M, R, Q, H, C, P, N$. The public read can refuse off-route demands, but it has no coordinate from which to export the forbidden data. □

Theorem 548.223 (CriticalLineWitness finite observation route)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every downstream finite-observation read of* W *must expose the finite zero-strip row* Z*, critical-strip row* S*, rational-height and comparison rows* R, Q*,*

zeta-continuation dependency surface, and root-comparison rows before any downstream consumer reads the packet. No such read can bypass those rows through a host zero classifier, global analytic continuation object, quotient representative, ambient completeness witness, or detached RH *truth value.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier finite observation route`

Proof. Begin with the root source triad of Definition 548.76. It exposes the supplied zero row, critical-strip row, and source-facing comparison ledger as finite rows before downstream access.

Use the zero-strip source completion rows, including Definition 548.180, to keep the zero-strip and critical-line sources on the displayed finite route. Use the root comparison ledger of Definition 548.77 to attach the rational-height and comparison reads through R, Q, H, C, P, N.

Finally apply the zeta dependency lattice of Definition 548.169. It places the zeta-zero and continuation-facing dependency surfaces before the modulus witness is public, so every downstream finite-observation read factors through the displayed packet rather than an analytic or host-level replacement. □

Theorem 548.224 (CriticalLineWitness StdBridge candidate refusal)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, a proposed standard bridge candidate that lacks the zero-strip source rows, modulus rows, or finite readback rows is a failed premise for the bridge route, not a counterinstance to the* $\mathsf{CriticalLineWitness}^{\uparrow}$ *witness surface. The packet refuses the missing zero-strip, modulus, and readback demands inside its displayed finite ledger.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier stdbridge candidate refusal`

Proof. Read the candidate first through the root refusal route, Definition 548.78. That route sends off-surface demands to the displayed finite refusal boundary rather than treating them as alternate bridge data.

Next apply the zero-strip source completion and downstream readback exhaustion rows, including Definition 548.180 and Definition 548.154. Missing zero-strip or readback data therefore means that the candidate has not supplied the premises required by the accepted packet route.

The root comparison ledger of Definition 548.77 supplies the same conclusion for modulus and rational comparison reads. Since the candidate lacks required displayed rows, it fails before any standard bridge surface is reached and cannot witness a bridge counterinstance. □

Theorem 548.225 (CriticalLineWitness dependency ledger exhaustion)**.** *Every downstream* $\mathsf{CriticalLineWitness}^{\uparrow}$ *read factors through the displayed dependency rows supplied by* $\mathsf{CritStrip}^{\uparrow}$*,* $\mathsf{Gamma}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ZetaContinuationWitness}^{\uparrow}$*, and* $\mathsf{ZetaZeros}^{\uparrow}$*. The accepted packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *exhausts these dependencies through its finite zero-strip, modulus, rational-height, root-comparison, transport, continuation, package, and local* NameCert *rows, with no additional analytic, host-equality, quotient, or ambient-completeness route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier dependency ledger exhaustion`

Proof. Start from the root source triad and the root comparison ledger, Definition 548.76 and Definition 548.77. They expose the $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows through the displayed packet coordinates.

Use the zero-strip source completion rows for the $\mathsf{ZetaZeros}^{\uparrow}$ side and the zeta dependency lattice of Definition 548.169 for the $\mathsf{ZetaContinuationWitness}^{\uparrow}$ side. These rows force zero-strip and

continuation-facing reads to consume sibling dependency surfaces before the local modulus witness is public.

Finally combine the root refusal route with the downstream readback exhaustion theorem, Definition 548.78 and Definition 548.154. The remaining $\mathsf{Gamma}^{\uparrow}$ and readback dependencies stay inside the finite ledger, and every forbidden analytic, host-equality, quotient, or ambient-completeness demand is refused rather than exported. □

Theorem 548.226 (CriticalLineWitness root bridge readback totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root bridge readback of W is exhausted by the displayed finite route*

$$Z, S, M, R, Q, H, C, P, N.$$

The readback first consumes the root-source rows Z, S, Q, then the comparison-ledger rows M, R, Q, and finally the fixed-tuple transport, replay, provenance, and local naming rows H, C, P, N. It exports no RH *proof, host zero classifier, analytic-continuation theorem, quotient representative, host equality, or ambient completeness coordinate.*

Proof. Begin with the root source triad Definition 548.76. It places the supplied zero row, critical-strip row, and source-facing comparison row inside the same finite packet before bridge readback begins.

Next use the root comparison ledger Definition 548.77. The modulus, real-part, and rational-comparison reads are forced through M, R, Q, H, C, P, N rather than through an analytic host object.

Finally apply the fixed tuple image and readback rows, Definition 548.217 and Definition 548.218. These rows return each bridge-visible coordinate to the corresponding carrier coordinate, while the root refusal route removes the forbidden analytic and host-level exits. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root bridge readback totality`

Theorem 548.227 (CriticalLineWitness root NameCert consumer totality)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every root-facing* NameCert *consumer is total on the same finite packet. The consumer may read carrier admission, source exposure, comparison-ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming; it has no route to a second source packet, external comparison ledger, analytic oracle, quotient representative, host equality, or ambient completeness witness.*

Proof. Project the carrier with Definition 548.1. The local packet exposes exactly $Z, S, M, R, Q, H, C, P, N$, so a root-facing NameCert consumer has a finite coordinate for every accepted read.

Apply Definition 548.2. Carrier admission, source compatibility, modulus discipline, ledger exactness, and non-escape are all obligations of the same local naming row N.

The root-source triad and root comparison ledger then account for the source and comparison sides. The fixed-tuple premise surface repacks those rows as the bridge-readable packet, so the consumer is total exactly on the displayed route and nowhere else. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootNameCertConsumerTotality`

Theorem 548.228 (CriticalLineWitness root analytic-refusal exhaustion)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Any root-facing request for an* RH *proof, zero search, global zero-set classifier, analytic-continuation certificate, quotient representative, host equality, or ambient completeness row is exhausted by the root refusal route of W. The request is recorded*

as a refusal over $Z, S, M, R, Q, H, C, P, N$ and is not a bridge readback, NameCert consumer, or analytic witness outside the packet.

Proof. Start from Definition 548.78. It sends off-surface root demands to the displayed finite refusal boundary instead of to host analytic data.

Use the root-source triad and root comparison ledger to locate the positive rows that remain readable after refusal. They identify the supplied source and comparison data with $Z, S, M, R, Q, H, C, P, N$.

Finally use the fixed-tuple premise surface. Since every bridge-facing readback must return to the fixed tuple and every local NameCert consumer reads the same tuple, the analytic demand is fully exhausted by refusal rather than by a hidden analytic coordinate. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootAnalyticRefusalExhaustion`

Theorem 548.229 (CriticalLineWitness source-route totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Before any critical-line consumer reads W, the packet exposes its supplied* BHist *source row Z, fixed zero-strip row S, rational modulus row M, zeta-continuation witness row, comparison ledger rows R, Q, componentwise* hsame *transport row H, displayed* Cont *route C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. The consumer therefore enters the packet only through the finite source route*

$$Z, S, M, R, Q, H, C, P, N.$$

Proof. Start with the root source triad of Definition 548.76. It exposes the supplied zero row, fixed critical-strip row, and source-facing comparison row as finite BHist data before a critical-line consumer can inspect the packet.

Next apply the root comparison ledger Definition 548.77 and the root modulus readback theorem Definition 548.129. These rows attach the rational modulus, real-part, and rational-comparison coordinates to M, R, Q, H, C, P, N rather than to a host analytic object.

Finally use the NameCert obligations of Definition 548.2. Carrier admission, transport, displayed continuation, provenance, and local naming are all read on the same accepted tuple, so no critical-line consumer can read W before the displayed source route has been exposed. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source route totality`

Theorem 548.230 (CriticalLineWitness zeta-boundary non-escape)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every zeta-facing read of W remains inside the finite* $\mathsf{ZetaContinuationWitness}^{\uparrow}$ *ledger carried by the supplied source row and the displayed route $Z, S, M, R, Q, H, C, P, N$. Such a read cannot import an* RH *predicate, a global zero classifier, a completed* $\mathsf{Gamma}^{\uparrow}$ *certificate, or a selected non-trivial-zero locator.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta boundary nonescape`

Proof. Read the supplied source through Definition 548.229. The critical-line witness has already exposed the zeta-continuation witness row and the structural rows H, C, P, N before any zeta-facing consumer can use it.

Now apply the ZetaContinuationWitness source obligation and analytic readback obligation, Definition 580.15 and Definition 580.16. They keep zeta-facing reads inside the displayed continuation ledger and its pole, functional-equation, Gamma-boundary, transport, continuation, provenance, and local naming rows.

Close with the ZetaContinuationWitness zero ledger non-escape theorem Definition 580.17. It refuses RH predicates, non-trivial-zero locators, global zero classifiers, and completed Gamma

certificates, so the CriticalLineWitness read cannot gain those objects by passing through the supplied zeta ledger. □

Theorem 548.231 (CriticalLineWitness NameCert obligation triad)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the source-route totality of Definition 548.229, the zeta-boundary non-escape of Definition 548.230, and the modulus readback of Definition 548.129 form the local root* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *obligation triad. Together they expose the finite* BHist *source, rational modulus, zeta-continuation, zero-strip,* hsame*,* Cont*,* Pkg*, and* NameCert *rows while refusing every off-packet analytic, zero-classification, and host-equality exit.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier namecert obligation triad`

Proof. The source-route totality theorem supplies the carrier side of the triad. It projects the accepted packet to the displayed finite rows $Z, S, M, R, Q, H, C, P, N$ before a critical-line consumer can read the witness.

The zeta-boundary non-escape theorem supplies the analytic boundary side. It keeps zeta-facing reads inside the finite $\mathsf{ZetaContinuationWitness}^{\uparrow}$ ledger and refuses RH, zero-classifier, Gamma-completion, and non-trivial-zero selection exits.

The modulus readback theorem supplies the numeric side. It routes rational modulus, real-part, and rational comparison reads through M, R, Q, H, C, P, N and not through a host numeric oracle or quotient representative.

Combining these three coordinates gives exactly the local root $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ surface: source totality, boundary non-escape, and modulus readback are all obligations over the same displayed packet and no further root obligation row is introduced. □

Theorem 548.232 (CriticalLineWitness strip-modulus source exhaustion)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*, supplied* $\mathsf{CritStrip}^{\uparrow}$ *row* S*, modulus row* M*, real-part row* R*, rational comparison ledger* Q*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row* N *exhaust the root source-modulus surface. A consumer of this surface receives no* RH *proof, zero search, quotient representative, host equality, analytic-continuation certificate, or ambient completeness row.*

Proof. Start with the carrier of Definition 548.1 and the NameCert obligations of Definition 548.2. They expose the accepted packet as the finite tuple $Z, S, M, R, Q, H, C, P, N$ and bind all public reads to the local naming row.

Use the root source triad and source-route totality rows, Definition 548.76 and Definition 548.229. These rows put the $\mathsf{ZetaZeros}^{\uparrow}$ source, $\mathsf{CritStrip}^{\uparrow}$ source, BHist carrier, hsame transport, Cont replay, Pkg provenance, and NameCert surface on the same finite route.

Finally apply the root comparison ledger and root refusal route, Definition 548.77 and Definition 548.78. The modulus and comparison reads stay inside M, R, Q, H, C, P, N, while every RH-facing or analytic request is refused rather than exported. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier strip modulus source exhaustion`

Theorem 548.233 (CriticalLineWitness zeta-route carrier separation)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the zeta route carried by* Z *and the strip-modulus route carried by* S, M, R, Q *remain separate carrier rows until the displayed* hsame*,* Cont*,* Pkg*, and*

NameCert *rows* H, C, P, N *relate them. The packet does not identify the* ZetaZeros$^{\uparrow}$ *source with the* CritStrip$^{\uparrow}$, Real$^{\uparrow}$, *or* Rat$^{\uparrow}$ *comparison surface by host equality, quotient representatives, analytic continuation, zero search,* RH *proof data, or ambient completeness.*

Proof. Project the source rows first. The root source triad of Definition 548.76 exposes Z, S, Q as finite source data before any downstream comparison is read.

Next route the modulus and comparison rows through Definition 548.77 and Definition 548.129. These rows attach M, R, Q to the Real$^{\uparrow}$ and Rat$^{\uparrow}$ comparison surfaces only through the displayed packet route.

It remains to account for the separation boundary. The NameCert obligations and fixed-tuple readback rows, Definition 548.2 and Definition 548.218, permit comparison only through H, C, P, N. Thus no host equality, quotient representative, analytic-continuation row, zero search, RH proof, or ambient completeness principle identifies the carrier rows outside the packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta route carrier separation`

Theorem 548.234 (CriticalLineWitness RH-refusal ledger closure)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The RH-refusal ledger of* W *closes the root-unblock surface over the displayed* ZetaZeros$^{\uparrow}$, CritStrip$^{\uparrow}$, Real$^{\uparrow}$, Rat$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. Every request for an* RH *proof, zero search, quotient representative, host equality, analytic-continuation certificate, or ambient completeness witness is recorded as a refusal on the same packet and does not become a second carrier, oracle, or downstream proof row.*

Proof. Begin with the RH-refusal ledger completeness theorem Definition 548.72. It already states that downstream RH-facing access is exhausted by $Z, S, M, R, Q, H, C, P, N$ together with the visible BEDC structural rows.

Use strip-modulus source exhaustion from Definition 548.232. This supplies the root source-modulus surface over the zeta, strip, real, rational, history, transport, replay, provenance, and naming rows.

Finally combine the zeta-route carrier separation of Definition 548.233 with the root analytic-refusal exhaustion of Definition 548.228. The former prevents carrier collapse across source and comparison rows; the latter sends every analytic or RH-facing request to the displayed refusal route. Therefore the root-unblock ledger is closed by refusal on the accepted packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal ledger closure`

Theorem 548.235 (CriticalLineWitness modulus-strip source totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Before any downstream* RH*-refusal consumer reads* W*, the root read exposes the fixed critical-line source row* Z*, zero-strip row* S*, rational modulus and budget rows* M, R, Q*, componentwise* hsame *transport row* H*, displayed* Cont *route* C*,* Pkg *provenance row* P*, and local* NameCert$_{\text{CriticalLineWitness}^{\uparrow}}$ *row* N*. Thus every such consumer enters the witness through the finite root surface*

$$Z, S, M, R, Q, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus strip source totality`

Proof. Start with the source-route totality surface Definition 548.229. It places the supplied BHist source row, fixed strip row, rational modulus row, transport, route, provenance, and local naming row before any critical-line consumer can inspect the packet.

Next use the root bridge readback totality theorem Definition 548.226. The bridge readback consumes the same root-source, comparison-ledger, fixed-tuple, transport, replay, provenance, and naming coordinates, so the consumer has no second entry point outside $Z, S, M, R, Q, H, C, P, N$.

Finally apply the zero-strip NameCert completion surface Definition 548.216. The carrier, zero-strip source, zeta-comparison ledger, refusal boundary, and downstream readback rows are all obligations of the same local naming packet, giving the announced finite root surface before an RH-refusal read begins. □

Theorem 548.236 (CriticalLineWitness finite budget readback determinacy)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ and $W' = (Z', S', M', R', Q', H', C', P', N')$ be accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packets. If the displayed modulus rows, zero-strip rows, rational budget rows, componentwise* hsame *transport rows,* Cont *routes,* Pkg *provenance rows, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows agree, then W and W' present the same finite root readback surface to every downstream* RH*-refusal consumer. In particular the consumer cannot distinguish the two reads by asking for a different source, modulus, strip, budget, transport, route, provenance, or local naming row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier finite budget readback determinacy`

Proof. Read both packets through Definition 548.229. Each accepted packet is exposed only as its finite route $Z, S, M, R, Q, H, C, P, N$ or $Z', S', M', R', Q', H', C', P', N'$ before a downstream consumer reads it.

The assumed agreement identifies the displayed modulus, strip, rational budget, transport, route, provenance, and naming coordinates. The root bridge readback theorem Definition 548.226 then leaves no bridge-visible coordinate outside those displayed rows.

It remains to compare the refusal-facing surface. The zero-strip NameCert completion theorem Definition 548.216 binds the carrier, zero-strip source, comparison ledger, refusal boundary, and downstream readback rows to the same local naming packet. Hence the two accepted packets determine the same finite readback surface for every allowed consumer. □

Theorem 548.237 (CriticalLineWitness root consumer non-escape)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, no downstream root consumer that reads only the displayed finite rows $Z, S, M, R, Q, H, C, P, N$ extracts a completed* RH *proof, an analytic continuation theorem, a host zero oracle, a quotient representative, host equality, ambient completeness, or an unbounded critical-line search. Every positive read remains inside the* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*, finite modulus, and zero-strip rows of W.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root consumer nonescape`

Proof. Begin with Definition 548.226. It states that root bridge readback is exhausted by $Z, S, M, R, Q, H, C, P, N$ and exports no RH proof, host zero classifier, analytic-continuation theorem, quotient representative, host equality, or ambient completeness coordinate.

The source-route totality theorem Definition 548.229 identifies the positive rows that remain readable: the supplied source, fixed strip, rational modulus, zeta-continuation witness, comparison ledger, transport, route, provenance, and local naming rows.

Finally use Definition 548.216. Its refusal boundary is part of the same local NameCert surface, while its carrier, source, comparison, and downstream readback rows account for every allowed finite read. Thus a root consumer stays inside the displayed packet and cannot turn those rows into an unbounded search or an off-packet analytic witness. □

Definition 548.238 (CriticalLineWitness root source window)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root read, the root source window is the finite* BHist *packet*

$$W_{\mathrm{src}} = (Z, S, M, H, C, P, N).$$

Here Z is the zero-strip source row, S is the critical-line strip row, M is the finite modulus and readback row, H records the componentwise hsame *transports, C records the displayed* Cont *routes, P records* Pkg *provenance over* BHist*,* hsame*,* Cont*, and* NameCert*, and N is the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. A read is accepted by the window only when every consumer-facing coordinate factors through these seven rows before it reaches the full packet of Definition 548.1.*

Lean4 (definition) `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessWindowSource`

Theorem 548.239 (CriticalLineWitness zero-strip source separation)**.** *Every accepted root source window $W_{\mathrm{src}} = (Z, S, M, H, C, P, N)$ separates zero-strip source reads from* RH *predicates, non-trivial-zero locators, global zero classifiers, and completed* $\mathsf{Gamma}^{\uparrow}$ *certificates. The only positive source reads exposed by the window are the finite* BHist *rows Z, S, M, their componentwise* hsame *transports H, their displayed* Cont *routes C, their* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip source separation`

Proof. Project the accepted read through Definition 548.238. The projection exposes only the seven displayed rows Z, S, M, H, C, P, N, so the zero-strip source side is already a finite BHist packet before any downstream request is considered.

Next apply the source-route and zero-strip surfaces already present in Definition 548.229 and Definition 548.180. These rows force the supplied source, critical strip, modulus, transport, route, provenance, and local naming coordinates to be read together.

Finally use the refusal and readback boundaries Definition 548.189 and Definition 548.194. They remove the RH predicate, non-trivial-zero locator, global zero classifier, and completed $\mathsf{Gamma}^{\uparrow}$ certificate from the root window, leaving only the finite source packet claimed above. □

Theorem 548.240 (CriticalLineWitness continuation route coverage)**.** *Every downstream critical-strip consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root source window must read the zero-strip source row Z, the critical-line strip row S, the finite modulus row M, the componentwise* hsame *transport row H, the displayed* Cont *route C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N before consuming the witness. No downstream critical-strip read has a coordinate outside*

$$Z, S, M, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier continuation route coverage`

Proof. Start with coordinate exhaustion for the root source window. By Definition 548.238, an accepted window contains only Z, S, M, H, C, P, N, and any consumer-facing coordinate must factor through one of those rows before reaching the full carrier.

Read the critical-strip side through Definition 548.235. It places the source row, fixed strip row, rational modulus data, transport, route, provenance, and naming row before an RH-refusal consumer can inspect the witness.

It remains to account for route locality. The Cont component is displayed as C and is tied to the same packet by the source-route totality and local NameCert obligations. Hence a downstream consumer cannot bypass H, C, P, N or replace them by an ambient continuation theorem; every route into the witness is covered by the finite window rows. □

Theorem 548.241 (CriticalLineWitness root public readiness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every downstream public read of W factors through the displayed finite route*

$$Z, S, M, R, Q, H, C, P, N$$

It also factors through the local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. The route therefore exposes the supplied zero row, critical-strip row, modulus row, real-part row, rational comparison ledger, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row before any public consumer can read the witness.*

Proof. Project the accepted carrier with Definition 548.1. The carrier is exactly the finite tuple $Z, S, M, R, Q, H, C, P, N$, so a public read has no carrier coordinate outside the displayed packet.

Use the NameCert obligations of Definition 548.2. Carrier admission, zero-strip compatibility, modulus discipline, ledger exactness, and non-escape are all attached to the same local naming row.

Finally apply the obligation closure package Definition 548.22 together with the downstream source obligation Definition 548.48. These rows repack every downstream source read through the finite route and the local NameCert row. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root public readiness`

Theorem 548.242 (CriticalLineWitness root scope binding)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, the public-read route depends only on the chapter's displayed* BHist *carrier, the local* hsame *transport row, the displayed* Cont *replay row, the* Pkg *provenance row, the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row, and the already cited* $\mathsf{ZetaZeros}^{\uparrow}$ *and* $\mathsf{CritStrip}^{\uparrow}$ *source rows. No further source object is needed to bind the root public-read route.*

Proof. Begin with Definition 548.1. It lists the supplied $\mathsf{ZetaZeros}^{\uparrow}$ row Z and $\mathsf{CritStrip}^{\uparrow}$ row S together with M, R, Q, H, C, P, N inside one BHist packet.

Apply Definition 548.2. The obligations bind classifier transport through H, continuation replay through C, package provenance through P, and local naming through N on that same packet.

Use Definition 548.22 to close the scope. The package has no second carrier, no external classifier, and no additional source row; hence the public-read route is scoped exactly by the listed BHist, hsame, Cont, Pkg, NameCert, $\mathsf{ZetaZeros}^{\uparrow}$, and $\mathsf{CritStrip}^{\uparrow}$ rows. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root scope binding certificate`

Theorem 548.243 (CriticalLineWitness root ledger refusal totality)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, requests for* RH *proof data, global zero search, host equality, quotient representatives, analytic continuation, or ambient completeness have no ledger coordinate in the downstream public-read route through $Z, S, M, R, Q, H, C, P, N$ and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row.*

Proof. Start with the non-escape clauses in Definition 548.2. They make the local ledger a finite packet ledger rather than a route to host analytic data.

Apply the ledger non-escape obligation Definition 548.52. It exhausts the local ledger through M, Q, H, C, P, N together with Z, S, R and refuses RH proof data, zero search, analytic-continuation data, quotient representatives, host equality, and ambient completeness.

Finally use Definition 548.48. Every downstream public source read has already been factored through the same finite packet, so the refused objects cannot re-enter as hidden coordinates of the public-read route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root ledger refusal totality`

Theorem 548.244 (Critical-line witness root-line row exposure)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted root critical-line read of W first exposes the supplied zero row Z, the critical-strip row S, the modulus row M, the rational comparison row R, the comparison ledger Q, the componentwise transport row H, the displayed continuation row C, the provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root line row exposure`

Proof. Project the accepted carrier using Definition 548.1. The packet has exactly the displayed finite rows $Z, S, M, R, Q, H, C, P, N$, so a root critical-line read has no earlier carrier coordinate to inspect.

Apply the root public-read package of Definition 548.241 and the zero-strip consumer boundary of Definition 548.143. These rows place the zero row, strip row, modulus row, comparison rows, transport row, continuation row, provenance row, and local naming row in the same finite readback route.

The read therefore begins with the supplied BEDC rows rather than with an ambient analytic object. Any later consumer receives the packet through this exposure order. □

Theorem 548.245 (Critical-line witness zero-strip route factorization)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every zero-strip consumer route through W factors through*

$$Z, S, H, C, P, N$$

before any modulus row or RH*-facing row is readable.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip route factorization`

Proof. Read the zero-strip side first. The supplied zero row Z and critical-strip row S are bound to the same componentwise transport, continuation replay, package provenance, and local naming rows by Definition 548.71.

Next use Definition 548.142. It places modulus access downstream of the displayed strip route, so M, R, Q are not available before the route has passed through Z, S, H, C, P, N.

Finally apply Definition 548.84. The same finite route separates zero-strip consumption from every RH-facing request. □

Theorem 548.246 (Critical-line witness analytic-continuation nonescape)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. No accepted packet exports analytic continuation,* RH *proof data, global zero classification, a quotient representative, host equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessAnalyticContinuationNonescape`

Proof. Start from the refusal ledger route of Definition 548.81. It exhausts every RH-facing request through the finite packet rows and reports no host analytic theorem.

Use the downstream refusal package of Definition 548.34 together with Definition 548.72. These rows exclude analytic-continuation data, RH proof data, global zero classification, quotient representatives, host equality, and ambient completeness from downstream reads.

The root-line row exposure above gives the only accepted readback surface. Hence none of the excluded objects can be exported as a hidden coordinate of the accepted packet. □

Theorem 548.247 (Critical-line witness root-route exposure)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet whose root-line surface is exposed by Definition 548.244. Then every root-facing consumer of W must enter through the displayed* BHist *rows, the componentwise* hsame *transport row H, the displayed* Cont *route C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N before it reads any critical-line conclusion.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier p11961 root route exposure`

Proof. Project the accepted carrier and apply Definition 548.244. The rows $Z, S, M, R, Q, H, C, P, N$ are the whole exposed packet, with H, C, P, N carrying transport, route replay, provenance, and local naming for the same finite object.

Next use Definition 548.245. It forces the zero-strip side of the consumer through the displayed route before any later modulus or root-facing row is read.

Thus a root-facing consumer reaches the critical-line surface only through the packet route already certified by BHist, hsame, Cont, Pkg, and NameCert rows. □

Theorem 548.248 (Critical-line witness modulus ledger separation)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The modulus row M and comparison ledger Q are consumed only after the supplied zero row Z, critical-strip row S, transport row H, continuation row C, provenance row P, and local* NameCert *row N have exposed the zero-strip route of Definition 548.245.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier p11961 modulus ledger separation`

Proof. Start with the zero-strip factorization theorem. It places every zero-strip consumer on the route through Z, S, H, C, P, N before the modulus row or any RH-facing row is readable.

The rows M, R, Q are therefore ledger data downstream from the displayed carrier route, not detached analytic coordinates. The componentwise hsame row and displayed Cont row preserve the same packet while P and N record provenance and local naming.

Combining this with root-line row exposure gives the stated separation between the root route and the modulus-comparison ledger. □

Theorem 548.249 (Critical-line witness RH refusal boundary)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Any consumer request for analytic continuation, an* RH *proof, global zero classification, quotient representatives, host equality, or ambient completeness is refused at the displayed boundary formed by the root-line row exposure, zero-strip route factorization, and analytic-continuation nonescape rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier p11961 rh refusal boundary`

Proof. Apply Definition 548.246. It states that the accepted packet exports none of the analytic, quotient, host-equality, or ambient-completeness objects named in the statement.

The root-line row exposure and zero-strip route factorization identify the only route a consumer may use: the finite carrier through $Z, S, M, R, Q, H, C, P, N$, with BHist data transported by hsame, replayed by Cont, recorded by Pkg, and named by the local NameCert row.

Every request outside that finite route is therefore a refusal request rather than an exported witness of the packet. □

Theorem 548.250 (Critical-line witness root-strip source totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root* $\mathsf{CriticalLineWitness}^{\uparrow}$ *consumer must expose the finite source rows for* $\mathsf{CritStrip}^{\uparrow}$*,* $\mathsf{Gamma}^{\uparrow}$*,* $\mathsf{ZetaContinuationWitness}^{\uparrow}$*,* $\mathsf{ZetaZeros}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *through* $Z, S, M, R, Q, H, C, P, N$ *before any critical-line-facing read is available. The consumer therefore enters the packet only through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootStripSourceTotality`

Proof. Project the accepted packet through the carrier description of Definition 548.1. Its visible coordinates are the supplied zero row Z, critical-strip row S, modulus row M, real-part row R, rational comparison ledger Q, transport row H, continuation route C, provenance row P, and local naming row N.

Apply the source-route totality of Definition 548.229 and the root-line row exposure of Definition 548.244. These rows place the $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ sources on the finite route before a line-facing consumer can read the modulus or comparison side.

Finally use the zeta-boundary non-escape theorem Definition 548.230. The $\mathsf{ZetaContinuationWitness}^{\uparrow}$ and $\mathsf{Gamma}^{\uparrow}$ interfaces remain inside the displayed zeta ledger and its transport, continuation, provenance, and naming rows. Hence the root consumer receives the listed finite source rows before any critical-line-facing read begins. □

Theorem 548.251 (Critical-line witness root-strip Zeta-Gamma source lock)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. A consumer cannot expose the root-strip row of* W *until the* $\mathsf{ZetaZeros}^{\uparrow}$*,* $\mathsf{CritStrip}^{\uparrow}$*,* $\mathsf{ZetaContinuationWitness}^{\uparrow}$*,* $\mathsf{Gamma}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *source rows have all been exposed through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root strip zeta gamma source lock`

Proof. Start with the root-strip source totality theorem Definition 548.250. It projects an accepted packet to the finite rows $Z, S, M, R, Q, H, C, P, N$ and places $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{ZetaContinuationWitness}^{\uparrow}$, $\mathsf{Gamma}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ on the route before any critical-line-facing read.

Next apply the modulus refusal exhaustion theorem Definition 548.252. A zero-strip modulus request remains inside the same displayed route and cannot supply analytic continuation evidence, a zero-free-strip theorem, a global zero classifier, or a host numeric oracle.

Finally use the RH-boundary nonescape theorem Definition 548.253. The packet exports no RH proof, finished critical-line theorem, or host analytic primitive. Therefore the root-strip row is source-locked to the listed Zeta, Gamma, Nat, Rat, Real, transport, replay, provenance, and local naming rows. □

Theorem 548.252 (Critical-line witness modulus refusal exhaustion)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every zero-strip modulus request is exhausted by the displayed route through* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$*. Such a request cannot become analytic continuation evidence, zero-free-strip evidence, a global zero classifier, or a host numeric oracle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessModulusRefusalExhaustion`

Proof. Begin with the zero-strip route factorization of Definition 548.245. It forces a zero-strip consumer through Z, S, H, C, P, N before any modulus row or RH-facing row is readable.

Next apply the root modulus-strip source totality theorem Definition 548.235. The modulus request is read against the same finite source rows $Z, S, M, R, Q, H, C, P, N$ and not against an ambient analytic continuation surface.

Close with the root bridge readback totality theorem Definition 548.226. It exports no RH proof, host zero classifier, analytic-continuation theorem, quotient representative, host equality, or ambient completeness coordinate. The modulus refusal is therefore exhausted by the displayed BEDC route. □

Theorem 548.253 (Critical-line witness RH-boundary nonescape)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the root packet exports no* RH *proof, no finished critical-line theorem, and no host analytic primitive. Its public surface is only the finite* $\mathsf{ZetaZeros}^{\uparrow}$–$\mathsf{CritStrip}^{\uparrow}$–$\mathsf{ZetaContinuationWitness}^{\uparrow}$ *source route, the* $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *modulus rows, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root rh boundary public nonescape`

Proof. Read the packet through Definition 548.250. The available positive data are exactly the finite source, modulus, comparison, transport, continuation, provenance, and naming rows exposed before any line-facing read.

Use the analytic-continuation nonescape theorem Definition 548.246. It refuses analytic continuation, RH proof data, global zero classification, quotient representatives, host equality, and ambient completeness as exports of an accepted packet.

Finally apply Definition 548.252. Zero-strip modulus requests remain inside the displayed route and do not produce zero-free-strip evidence or a host analytic primitive. Thus the root packet cannot escape into an RH proof or a finished critical-line theorem. □

Theorem 548.254 (CriticalLineWitness source-budget carrier)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted packet exposes this finite tuple as the zero-strip source, source budget, modulus and readback route, refusal row, transport, continuation, provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows. No accepted packet exports hidden analytic continuation, a host zero locator, a completed* RH *proof, or an off-packet critical-line oracle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source budget carrier`

Proof. Project the accepted packet through the carrier description of Definition 548.1. Coordinate exhaustion gives only the displayed rows $Z, S, M, R, Q, H, C, P, N$: the zero-strip source Z, source budget S, modulus and readback route M, R, Q, transport H, continuation C, provenance P, and local naming row N.

The existing root-strip source totality theorem Definition 548.250 places every line-facing read on this finite route before it can be consumed. The analytic continuation nonescape theorem Definition 548.246 then removes any ambient analytic continuation, host zero locator, completed RH proof, or off-packet critical-line oracle from the exported surface. □

Theorem 548.255 (CriticalLineWitness zero-strip refusal)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every zero-strip consumer factors through the displayed source, budget, modulus, readback, and refusal rows before downstream use. The consumer cannot replace the refusal row by a theorem about* RH*, an analytic-continuation bridge, or a completed zeta-zero classifier.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip refusal`

Proof. Begin with the tuple projection supplied by Definition 548.254. It exposes the source, budget, modulus, readback, and refusal coordinates as components of the accepted BHist packet, rather than as host-side analytic data.

Apply the zero-strip route factorization theorem Definition 548.245. The consumer must pass through Z, S, M, R, Q and the refusal row before any downstream use can read the packet.

Finally use the modulus refusal exhaustion theorem Definition 548.252. Its nonescape clause prevents the refusal row from being replaced by an RH theorem, an analytic-continuation bridge, or a completed zeta-zero classifier. □

Theorem 548.256 (CriticalLineWitness NameCert obligation surface)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier exposure of* $Z, S, M, R, Q, H, C, P, N$*;*
2. *source-budget exactness for the zero-strip source and source budget;*
3. *determinacy of the modulus and readback route;*
4. *zero-strip refusal non-escape;*
5. *downstream stability through* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier namecert obligation surface`

Proof. First project the accepted packet to its carrier coordinates. The source-budget carrier theorem Definition 548.254 supplies carrier exposure and fixes the zero-strip source and budget as visible packet rows.

Next read the route coordinates. The source-route totality theorem Definition 548.229 and the root bridge readback totality theorem Definition 548.226 determine the modulus and readback path through the same finite packet.

It remains to isolate the refusal and downstream clauses. The zero-strip refusal theorem Definition 548.255 gives non-escape for the refusal row, while the displayed H, C, P, N coordinates carry transport, continuation, provenance, and naming stability. These five rows exhaust the local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ surface. □

Theorem 548.257 (CriticalLineWitness source-budget public interface)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *source-budget packet. Its public interface consists exactly of the critical strip source row, dyadic rational tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal row,* $\mathsf{Zeta}^{\uparrow}$ *and* $\mathsf{ZetaZeros}^{\uparrow}$ *route rows, refusal budget row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. No* RH *conclusion, zero-count completeness theorem, host analytic-continuation object, or hidden limit is exported by this interface.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source budget public interface`

Proof. Project the accepted packet through Definition 548.254. The projection exposes the critical strip source, dyadic tolerance budget, regular-rational readback, Real seal, zeta-route, refusal, transport, replay, provenance, and local naming coordinates as the full visible source-budget tuple.

Apply the NameCert obligation surface of Definition 548.256. Its carrier exposure, source-budget exactness, route determinacy, refusal non-escape, and downstream stability clauses identify those rows as the public interface rather than as private auxiliary data.

Finally use the zero-strip refusal theorem Definition 548.255. The non-escape clause prevents any consumer from replacing the refusal budget by an RH conclusion, zero-count completeness, host analytic continuation, or hidden limiting object. □

Theorem 548.258 (Critical-line witness RH source lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every RH-facing read of W first exposes the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row Z, the supplied* $\mathsf{CritStrip}^{\uparrow}$ *row S, the shared* hsame *transport row H, the displayed* Cont *route C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. The read may continue to the modulus and comparison rows only after that source lock is visible, and it receives no host zero source, analytic-continuation certificate, or* RH *proof from the packet.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh source lock`

Proof. Project the accepted packet through Definition 548.1. The carrier exposes $Z, S, M, R, Q, H, C, P, N$ as finite BHist rows and names Z and S as the supplied zeta-zero and critical-strip inputs.

Apply the zero-strip compatibility and non-escape rows of Definition 548.2. These rows bind the supplied $\mathsf{ZetaZeros}^{\uparrow}$ and $\mathsf{CritStrip}^{\uparrow}$ inputs through the displayed hsame transport and force every public read through the same local Cont, Pkg, and NameCert surface.

The sibling source chapters chapter 73 and chapter 72 supply only the named rows consumed by Z and S. Together with Definition 548.3 and Definition 548.250, this leaves no coordinate for a host zero source, analytic-continuation certificate, or RH proof before an RH-facing read begins. □

Theorem 548.259 (Critical-line witness modulus window exactness)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, each depth request to the modulus row is exhausted by the displayed* $\mathsf{Nat}^{\uparrow}$ *depth input to M, the* $\mathsf{Real}^{\uparrow}$ *real-part row R, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger Q, and the displayed continuation route C. The request is not discharged by host real equality, quotient representatives, ambient analytic completeness, or any hidden numeric oracle.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus window exactness`

Proof. Read the modulus coordinate from Definition 548.1. The row M is the only depth-facing coordinate, and its answer is paired in the carrier with the real-part row R, rational ledger Q, transport row H, continuation row C, provenance row P, and local naming row N.

Apply the modulus-discipline and ledger-exactness rows of Definition 548.2. They require a depth request to consume the on-critical-line modulus row through R and Q, with replay performed by the displayed continuation route rather than by a host equality principle.

Now use the source-normalization and modulus-ledger interfaces Definition 548.59 and Definition 548.60. The source chapters chapter 28, chapter 38, and chapter 37 provide the named depth, real-part, and rational-comparison rows, so the modulus window is exact on those finite rows and has no route to host real equality, quotient representatives, ambient completeness, or a hidden oracle. □

Theorem 548.260 (Critical-line witness downstream refusal ledger)**.** *Every downstream consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the displayed refusal ledger over $Z, S, M, R, Q, H, C, P, N$. The packet does not export an* RH *proof, a zero search, an analytic-continuation certificate, a quotient representative, or an ambient completeness witness to any downstream RH-facing, zero-facing, or modulus-facing consumer.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream refusal ledger`

Proof. Start with the refusal row in Definition 548.5. It states that the exported boundary is a finite packet ledger, not an analytic or global-zero object.

Apply Definition 548.258 for the source side and Definition 548.259 for the modulus side. These two rows force downstream consumers to read the supplied $\mathsf{ZetaZeros}^{\uparrow}$ and $\mathsf{CritStrip}^{\uparrow}$ source rows before the modulus window, and to replay the modulus request only through the displayed $\mathsf{Nat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, hsame, Cont, Pkg, and NameCert data.

Finally cite the downstream RH boundary refinement Definition 548.105 and the sibling continuation refusal surface of chapter 580. They leave downstream consumers with the displayed refusal ledger alone. Since no packet coordinate names an RH proof, zero search, analytic-continuation certificate, quotient representative, or ambient completeness witness, none can be read from W. □

Theorem 548.261 (CriticalLineWitness critical-strip source surface)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted packet exposes the supplied critical-strip source row S, together with its* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *routes, before any zero-line consumer, modulus consumer, or* RH*-facing consumer row can read the witness. The exposed row is a packet source row, not a host critical-line theorem, analytic continuation primitive, quotient equality, or standard-model replacement.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier critical strip source surface`

Proof. Project W through the carrier description of Definition 548.1. The critical-strip coordinate S is one of the displayed finite BHist rows, and the only structural routes attached to it are the local H, C, P, N coordinates.

Apply the root-strip source totality theorem Definition 548.250. It places the $\mathsf{CritStrip}^{\uparrow}$ source row on the visible source route before any critical-line-facing read is available.

Use the RH source lock Definition 548.258 for downstream reads and the zero-strip compatibility obligation Definition 548.50 for zero-line reads. These rows force the supplied strip source to be visible through BHist, hsame, Cont, Pkg, and NameCert before any consumer reads the witness surface, and they leave no coordinate for a host critical-line theorem, analytic primitive, quotient equality, or standard-model replacement. □

Theorem 548.262 (CriticalLineWitness zero-refusal locality)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every zero-refusal row is local to the displayed packet. The refusal is witnessed inside the finite* BHist *carrier, the componentwise* hsame *transport row, the displayed* Cont *replay row, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row; it is not a claim about an analytic zero primitive, global zero classifier, host quotient equality, analytic-continuation theorem, or* RH *truth value.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero refusal locality`

Proof. Start with the zero-strip refusal theorem Definition 548.255. It reads refusal as a row of the accepted BHist packet and requires zero-strip consumers to pass through the displayed source, budget, modulus, readback, and refusal rows.

Next apply the local transport obligation Definition 548.47. The componentwise hsame row, displayed Cont replay row, Pkg provenance, and local NameCert replay are bound to the same zero-strip-modulus ledger.

Finally use the downstream refusal ledger Definition 548.260. It excludes an analytic zero primitive, global zero classifier, quotient representative, analytic-continuation certificate, ambient completeness witness, and RH proof from downstream reads. The zero-refusal row is therefore local to W and does not export an analytic or host-level replacement. □

Theorem 548.263 (CriticalLineWitness modulus budget totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The modulus budget rows M, R, Q, H, C, P, N, read together with the supplied source rows Z, S, exhaust every consumer read before any critical-line witness is exported. A consumer can receive only the finite packet route through* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$*; it cannot bypass that budget by requesting* RH *truth, analytic continuation, host equality, quotient representatives, or a standard-model replacement.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus budget totality`

Proof. Read the modulus coordinate through the modulus window exactness theorem Definition 548.259. Each depth request is exhausted by the displayed $\mathsf{Nat}^{\uparrow}$ depth input to M, the $\mathsf{Real}^{\uparrow}$ row R, the $\mathsf{Rat}^{\uparrow}$ comparison ledger Q, and the replay route through H, C, P, N.

Combine this with the modulus refusal exhaustion theorem Definition 548.252. Zero-strip modulus requests remain inside the same finite route and cannot become analytic continuation evidence, zero-free-strip evidence, a global zero classifier, or a host numeric oracle.

Finally apply the root bridge readback totality theorem Definition 548.226 and the root packet carrier theorem Definition 548.43. They exhaust public readback by the displayed packet rows $Z, S, M, R, Q, H, C, P, N$ before any critical-line witness can be exported, with no route to RH truth, host equality, quotient representatives, analytic continuation, or standard-model replacement. □

Definition 548.264 (CriticalLineWitness root obligation carrier)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet*

$$W = (Z, S, M, R, Q, H, C, P, N),$$

the root obligation carrier is the finite displayed surface consisting of the BHist *rows Z, S, M, R, Q, the componentwise* hsame *transport row H, the displayed* Cont *replay route C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. A root-facing read is carried by this surface exactly when it enters through those rows and no additional analytic-continuation,* RH*, host-limit, quotient, or standard-bridge datum is supplied.*

Theorem 548.265 (CriticalLineWitness root classifier stability)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet. Any classifier read that is admitted by the root obligation carrier of Definition 548.264 is stable under the displayed route*

$$\mathsf{BHist} \xrightarrow{H} \mathsf{hsame} \xrightarrow{C} \mathsf{Cont}.$$

The read therefore has the same root-facing classifier before and after the hsame *transport and the* Cont *replay, and it remains attached to the same* Pkg *row P and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root classifier stability`

Proof. Project the accepted packet through Definition 548.196. It orders the displayed BHist rows and the H, C, P, N route before any critical-line read of M or R is available.

Next use Definition 548.100. The consumer sees only the same finite tuple $Z, S, M, R, Q, H, C, P, N$, so the classifier cannot be replaced by a detached host or quotient classifier.

Finally apply the non-escape package Definition 548.69. Since the packet exports no analytic continuation, RH proof, host equality, or ambient completion route, transport by H and replay by C preserve the root-facing classifier inside the local P, N certificate rows. □

Theorem 548.266 (CriticalLineWitness root NameCert obligation completion)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the root obligation carrier supplies the complete local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *obligation packet for a root-facing consumer. The supplied packet contains the source rows* Z, S*, the pattern rows* M, R, Q*, the classifier route* H, C*, the stability attachment to* P, N*, and the ledger refusal rows needed to keep the read inside the finite BEDC packet.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier obligation completion packet`
Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root namecert obligation completion`

Proof. Start with the carrier boundary Definition 548.196. It places $Z, S, M, R, Q, H, C, P, N$ on one root-facing surface and requires any critical-line read to pass through the local carrier and NameCert rows.

The classifier stability theorem Definition 548.265 then binds the source and pattern rows to the route through H and C. The same route keeps the provenance row P and the local naming row N attached to the accepted packet.

It remains to record the refusal side. Apply the non-escape package Definition 548.69 and the ledger refusal totality theorem Definition 548.243. Together they turn source, pattern, classifier, stability, and ledger obligations into one local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ packet with no external analytic or host-level witness. □

Theorem 548.267 (CriticalLineWitness root ledger nonescape)**.** *Every root-facing read of the obligation carrier Definition 548.264 is exhausted by the displayed packet rows* $Z, S, M, R, Q, H, C, P, N$*. The ledger exports no analytic-continuation theorem, no* RH *proof, no host-limit datum, no quotient representative, and no standard-bridge object.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root ledger nonescape`

Proof. Read the packet through Definition 548.100. The carrier projection is exactly $Z, S, M, R, Q, H, C, P, N$, so a root-facing consumer receives no additional coordinate from which analytic or host-level data could be extracted.

Next apply the non-escape package Definition 548.69. It identifies the root-facing export with the finite BHist, hsame, Cont, Pkg, and NameCert route.

Finally use Definition 548.243. The refusal ledger closes every request for analytic continuation, RH proof data, host limits, quotient representatives, or standard-bridge data at the local carrier boundary. □

Theorem 548.268 (CriticalLineWitness fixed-strip source readback totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet whose source is the fixed critical strip. Before any zeta-facing or* RH*-facing consumer can inspect the packet, the read must pass through the displayed* BHist *source rows* Z, S*, the rational-height and modulus rows* R, Q, M*, the zero-strip localization row* Z*, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row* N *along the structural route* H, C, P*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip source readback totality`

Proof. Project the packet through the root obligation carrier of Definition 548.264. The carrier exposes only $Z, S, M, R, Q, H, C, P, N$, so the fixed-strip source is read as a displayed BHist row rather than as a host critical-line theorem.

Apply Definition 548.265. The same hsame and Cont route keeps the source row, rational-height row, modulus row, and zero-strip localization row attached to the accepted packet before downstream inspection.

Finally use the NameCert completion row Definition 548.266 and the zeta dependency lattice Definition 548.169. Together they force zeta and RH consumers to read the displayed source, modulus, zero-strip, provenance, and local naming rows before inspecting the witness surface. □

Theorem 548.269 (CriticalLineWitness zero-strip modulus separation)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the zero-strip refusal row is separated from the positive analytic-continuation payload by the displayed modulus ledger* M, R, Q, H, C, P, N *and by the* hsame*-stable classifier of the root obligation surface. Transport along* H *and replay along* C *therefore cannot turn a refusal row into an analytic-zero witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip modulus separation`
↪ variant `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip modulus separation certificate`

Proof. Start with the classifier stability row Definition 548.265. It keeps any root-facing classifier inside the displayed BHist, hsame, Cont, Pkg, and NameCert route.

Next apply the root ledger nonescape theorem Definition 548.267. The ledger has no coordinate for analytic continuation, host zero extraction, quotient representatives, or ambient completion, so its refusal row cannot be read as a positive analytic payload.

It remains to separate downstream zeta reads from the refusal row. Use Definition 548.169 together with Definition 548.189. They place zeta and RH consumers behind the same finite modulus and zero-strip readback route, leaving transport and replay unable to manufacture an analytic-zero witness. □

Theorem 548.270 (CriticalLineWitness RH-refusal consumer nonescape)**.** *Every downstream* RH*-boundary consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet may cite the fixed-strip source row* S*, the zero-strip refusal row* Z*, the modulus ledger* M, R, Q*, the* Cont *route* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row* N*. Such a consumer cannot extract a host zero, an analytic continuation theorem, a classical contradiction, a quotient stream, or an ambient completeness datum from those rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal consumer nonescape`

Proof. Read the consumer through the completed NameCert obligation Definition 548.266. It supplies the fixed-strip, zero-strip, modulus, transport, route, provenance, and naming rows as one finite local packet.

Apply Definition 548.267. This removes analytic-continuation theorems, RH proofs, host-limit data, quotient representatives, and standard-bridge objects from the root-facing export.

Finally combine the downstream counter-surface Definition 548.191 with the RH-refusal readback totality row Definition 548.189. The consumer may cite the displayed rows, but every extraction request for a host zero, analytic theorem, classical contradiction, quotient stream, or ambient completeness datum stops at the finite refusal ledger. □

Theorem 548.271 (CriticalLineWitness zero-strip source classifier lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The supplied zero row Z and the critical-strip row S determine the source/classifier surface only through the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows of W. No host zero search, quotient representative, analytic-continuation certificate, or ambient completeness row may replace the displayed Z, S, H, C, P, N route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip source classifier lock`

Proof. Project the accepted packet through Definition 548.1. The source-facing coordinates are the supplied zero row Z and critical-strip row S, and every classifier-facing read is attached to the same finite carrier.

Apply the visible source triad of Definition 548.286 and the root-line row exposure of Definition 548.244. These rows expose the BHist source before any downstream consumer can use the witness.

Use the supplied zero-strip transport lock Definition 548.71. It binds Z and S to the componentwise hsame row, the displayed Cont replay, the Pkg provenance row, and the local NameCert row.

The excluded objects are not coordinates of W and are not introduced by any of the cited rows. Thus the source/classifier surface is locked to the finite Z, S, H, C, P, N route, with no replacement by host zero search, quotient choice, analytic continuation, or ambient completeness. □

Theorem 548.272 (CriticalLineWitness modulus ledger readback exhaustion)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. After the zero-strip source has been exposed through Z and S, every read of the modulus row M, the real-part row R, and the rational comparison ledger Q factors through M, R, Q, H, C, P, N. This readback exports neither a proof of* RH *nor a global zero classifier.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus ledger readback exhaustion`

Proof. Begin with Definition 548.271. The zero-strip source is already exposed through the supplied source rows and the local transport, replay, provenance, and naming rows.

Apply the strip-modulus readback theorem Definition 548.142 and the root modulus classifier exhaustion theorem Definition 548.278. Together they place every modulus, real-part, and rational comparison read behind the displayed M, R, Q rows.

The same packet route is carried by Definition 548.47. Hence the readback cannot leave H, C, P, N after reading M, R, Q.

Finally use the modulus refusal scope of Definition 548.287. It keeps the rational modulus ledger from becoming a zero locator, analytic oracle, host equality, or RH proof. The readback is therefore exhausted by M, R, Q, H, C, P, N over the already exposed source rows. □

Theorem 548.273 (CriticalLineWitness RH boundary consumer nonescape)**.** *Every* RH*-facing downstream consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$ receives only the finite route*

$$Z, S, M, R, Q, H, C, P, N.$$

The boundary combines the zero-strip source classifier lock and the modulus ledger readback exhaustion with the refusal rows of Definition 548.72 and Definition 548.78; it exports no RH *proof,*

host zero search, global zero classifier, quotient representative, analytic-continuation certificate, or ambient completeness datum.

Proof. First apply Definition 548.271. It fixes the only source/classifier route available to the consumer before any RH-facing request is considered.

Next apply Definition 548.272. It routes the modulus row, real-part row, and rational comparison ledger through the same finite continuation, provenance, and local naming surface.

Use the refusal ledger completeness row Definition 548.72 and the root refusal route Definition 548.78. These rows classify RH proof requests, host zero search, quotient representatives, analytic-continuation certificates, global zero classifiers, and ambient completeness requests as outside the accepted packet.

Thus every downstream RH-facing consumer receives exactly the finite BEDC route $Z, S, M, R, Q, H, C, P, N$. The route is a readback boundary for the witness package, not an analytic escape hatch. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh boundary consumer nonescape`

Theorem 548.274 (Critical-line witness source normalization lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Before a root or downstream* RH*-boundary consumer reads any modulus, comparison, or refusal data, the supplied zero row Z and critical-strip row S are normalized as the source side of the same finite packet over* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$. *The source lock uses only the supplied zero row, critical-strip row, Nat depth row, Rat comparison ledger, Real-part row, H, C, P, N, and the existing root source triad.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source normalization lock`

Proof. Project the accepted packet W. The carrier exposes $Z, S, M, R, Q, H, C, P, N$ and has no coordinate for a global zero classifier, analytic-continuation theorem, host equality, quotient representative, or ambient completeness principle.

Apply the root source triad Definition 548.76 and the Lean-facing carrier root source triad. They identify the supplied zero row, the critical-strip row, and the source-facing comparison route as finite packet rows under the same transport, continuation, package, and local naming surface.

The modulus and comparison rows are therefore read only after Z and S have been exposed. Since the source side is locked before downstream inspection, an RH-boundary consumer receives a source-normalized packet rather than a zero search or analytic source theorem. □

Theorem 548.275 (Critical-line witness modulus ledger totality)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$ whose source side is locked as in Definition 548.274, every modulus, Nat-depth, Rat-comparison, and Real-part read is total through the displayed ledger M, R, Q, H, C, P, N while retaining Z and S as the supplied zero-strip source rows. The ledger exports no hidden numeric oracle, host zero equality, quotient representative, analytic-continuation certificate, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus ledger totality`

Proof. Begin with the source-normalization lock. It places the supplied zero and critical-strip rows upstream of every modulus-facing read.

Apply the root comparison ledger Definition 548.77 together with the root modulus ledger Definition 548.68. These rows route Nat depth through M, Real-part data through R, and Rat comparison through Q, all under H, C, P, N.

Finally use the modulus-refusal scope already carried by the root packet. Because the ledger is finite and row-exact, every modulus request is answered by M, R, Q, H, C, P, N and cannot leave the packet for host equality, quotient data, analytic continuation, or ambient completeness. □

Theorem 548.276 (Critical-line witness RH-boundary refusal exhaustion)**.** *Every* RH*-boundary consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *is exhausted by the locked source side* Z, S*, the total modulus ledger* M, R, Q*, and the structural rows* H, C, P, N*. The consumer may cite a supplied zero row, critical-strip row, Nat depth, Rat comparison ledger, Real-part row,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data, but it receives no* RH *proof, zero search, global zero classifier, analytic-continuation theorem, host equality, quotient stream, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh boundary refusal exhaustion`

Proof. Use Definition 548.274 for the source side and Definition 548.275 for the comparison side. Together they expose exactly the finite rows $Z, S, M, R, Q, H, C, P, N$.

Apply the RH-refusal ledger completeness theorem Definition 548.72 and the RH-boundary refusal totality row Definition 548.194. These existing rows classify requests for proof content, zero search, analytic continuation, quotient data, host equality, and ambient completeness as refusal-side requests.

Thus the downstream boundary is exhausted by the packet itself. It remains a finite BEDC witness surface for supplied zero-strip and modulus data, not an analytic certificate and not a proof of RH. □

Theorem 548.277 (CriticalLineWitness root source obligation triad)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root consumer reads the supplied* BHist *source through the zero-strip row* Z *or the critical-strip row* S*, then through the modulus row* M*, the* hsame *transport row* H*, the* Cont *replay row* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row* N*. The consumer receives no root-facing source outside this finite triad and no* RH*-facing conclusion before those rows have been displayed.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source obligation triad`

Proof. Project the accepted packet through Definition 548.1. The only source-facing coordinates are the zero row Z and the critical-strip row S, and the only modulus-facing coordinate is M.

Apply the root source triad of Definition 548.76. It binds the source side to the displayed packet route before the comparison and refusal rows can be consumed.

Use the local transport obligation Definition 548.47. It carries the same source and modulus rows through H, C, P, N, so the root consumer must traverse the finite BHist, hsame, Cont, Pkg, and NameCert surface.

The RH boundary is then only a consumer boundary. Since no coordinate of W names an RH proof, analytic-continuation theorem, quotient representative, host equality, or standard-model replacement, the displayed triad exhausts the root source obligation. □

Theorem 548.278 (CriticalLineWitness root modulus classifier exhaustion)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the root modulus classifier is exhausted by the modulus row* M*, the real-part row* R*, the rational comparison ledger* Q*, the* hsame *transport row* H*, the* Cont *replay row* C*, the* Pkg *provenance row* P*, and the local* NameCert *row* N*, with*

Z and S retained as the zero-strip or critical-strip source rows. No modulus consumer can inspect an unlisted classifier, hidden numeric oracle, quotient equality, or analytic source theorem.

Proof. Start from the root comparison ledger Definition 548.77. It routes comparison reads through the rational ledger Q while keeping the source rows Z, S visible.

Next apply the root modulus ledger Definition 548.68. It forces depth and modulus data to pass through M and the same structural rows rather than through a detached numeric oracle.

Transport and replay are fixed by Definition 548.47. The componentwise hsame row, the displayed Cont route, the provenance row, and the local name preserve the classifier route as one finite packet.

Thus the root modulus classifier has no remaining branch. Every accepted read is one of the displayed M, R, Q, H, C, P, N reads over the retained Z, S source, and every unlisted analytic or host-level classifier is outside the packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus classifier exhaustion`

Theorem 548.279 (CriticalLineWitness root RH consumer boundary)**.** *Every* RH*-facing consumer of an accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$ is bounded by the source obligation triad of Definition 548.277 and the modulus classifier exhaustion of Definition 548.278. The consumer may cite the supplied* BHist *source, zero-strip or critical-strip row, modulus row,* hsame *transport,* Cont *replay,* Pkg *provenance, and* NameCert *row, but receives no RH proof, zero search, global zero classifier, analytic-continuation theorem, quotient stream, host equality, or ambient completeness datum.*

Proof. First use Definition 548.277. It places every root source read behind Z, S, M, H, C, P, N before any RH-facing consumer can inspect the packet.

Then use Definition 548.278. It exhausts modulus and comparison reads by M, R, Q, H, C, P, N while retaining the same zero-strip and critical-strip source rows.

Finally apply the RH-refusal ledger completeness theorem Definition 548.72 and the RH-boundary refusal totality row Definition 548.194. These rows classify requests for proof content, zero search, analytic continuation, quotient streams, host equality, and ambient completeness as outside the accepted packet.

The RH-facing consumer boundary is therefore a finite BEDC readback boundary. It exports the source, modulus, transport, replay, provenance, and local naming rows, not an analytic theorem and not a truth value for RH. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root rh consumer boundary`

Theorem 548.280 (CriticalLineWitness fixed-strip source admission completion)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. The fixed-strip source admission row is complete when the consumer reads the supplied* BHist *source through the zero-strip row Z or critical-strip row S, then through the modulus row M, real-part row R, rational comparison ledger Q, transport row H, replay row C, provenance row P, and local name N. No fixed-strip consumer receives a source outside this packet before these rows have been displayed.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip source admission completion`

Proof. Begin with the source side of the root source obligation triad Definition 548.277. It places every root consumer behind the supplied BHist source, the zero-strip or critical-strip row, and the displayed modulus route.

Use modulus classifier exhaustion from Definition 548.278. Once the source row is admitted, every modulus, real-part, and rational-comparison read is exhausted by M, R, Q, H, C, P, N over the same Z, S source rows.

Thus fixed-strip source admission has no remaining hidden source branch. A consumer that skips Z, S or reads a source outside W leaves the accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ packet. □

Theorem 548.281 (CriticalLineWitness zero-source refusal readback)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ packet. Any request to read a zero-source refusal must pass through the source obligation triad and the modulus classifier exhaustion rows, so the refusal is read back through $Z, S, M, R, Q, H, C, P, N$ and not through a hidden zero search, global zero classifier, analytic-continuation theorem, quotient stream, host equality, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero source refusal readback`

Proof. Apply the root source obligation triad Definition 548.277. It forces the zero-strip and critical-strip source rows to remain visible before a refusal boundary can be consumed.

Next apply modulus classifier exhaustion Definition 548.278. The refusal readback cannot inspect an unlisted classifier, since modulus and comparison data are already exhausted by M, R, Q, H, C, P, N.

The zero-source refusal is therefore a finite readback row of the accepted packet. Demands for hidden zero search, global zero classification, analytic continuation, quotient streams, host equality, or ambient completeness are outside the displayed carrier. □

Theorem 548.282 (CriticalLineWitness RH consumer unblock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ packet. An RH-facing consumer is unblocked exactly to the finite readback surface supplied by the source obligation triad and modulus classifier exhaustion: it may consume $Z, S, M, R, Q, H, C, P, N$, but it receives no RH proof, no zero search, no global zero classifier, no analytic-continuation theorem, no quotient stream, no host equality, and no ambient completeness coordinate.*

Proof. Start from the RH consumer boundary Definition 548.279. It already identifies the consumer surface as the source obligation triad together with modulus classifier exhaustion.

The fixed-strip source admission completion above supplies the source-read side, and the zero-source refusal readback supplies the refusal side. Both rows keep the same accepted packet $W = (Z, S, M, R, Q, H, C, P, N)$ and the same BHist, hsame, Cont, Pkg, and NameCert support rows.

Consequently the RH consumer is unblocked only as a finite BEDC consumer. It can read the displayed root and modulus rows, but the analytic conclusion, zero search, global classifier, quotient stream, host equality, and ambient completeness demands have no coordinate in the packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRhConsumerUnblock`

Theorem 548.283 (Critical-line witness source-modulus exclusion)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ packet. Every source-modulus consumer of W must read the supplied $\mathsf{ZetaZeros}^{\uparrow}$ row Z, the $\mathsf{CritStrip}^{\uparrow}$ row S, the $\mathsf{Nat}^{\uparrow}$ modulus row M, the $\mathsf{Real}^{\uparrow}$ real-part row R, the $\mathsf{Rat}^{\uparrow}$ comparison ledger Q, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows before it can inspect any downstream boundary. The route exports no global zero classification, analytic-continuation theorem, host equality, quotient representative,* RH *proof content, or hidden ambient completeness datum.*

Proof. Begin with the source normalization interface. Definition 548.59 exposes the supplied zero row, critical-strip row, Nat depth row, rational comparison ledger, and real-part row as the finite packet $Z, S, M, R, Q, H, C, P, N$.

Next apply the root source-modulus admission theorem. Definition 548.64 places every source-modulus read after the displayed zero-strip source and comparison rows, under the same transport, continuation, package, and local naming surface.

Finally use the RH refusal interface. Definition 548.62 classifies requests for global zero classification, analytic continuation, host equality, quotient representatives, proof content, and ambient completeness as refusal-side requests rather than source-modulus data. The admitted consumer is therefore confined to $Z, S, M, R, Q, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus exclusion`

Theorem 548.284 (Critical-line witness zero-strip route totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every zero-strip route used by a root, zeta-facing, or* RH*-boundary consumer is total through the displayed source-modulus packet*

$$Z, S, M, R, Q, H, C, P, N.$$

The route reads the supplied zero row, critical-strip row, modulus row, real-part row, rational comparison ledger, componentwise transport, displayed continuation, provenance, and local naming, and it cannot read a global zero classifier, analytic-continuation certificate, host equality, quotient representative, or RH *proof.*

Proof. First use source-modulus exclusion. It confines the consumer to the packet $Z, S, M, R, Q, H, C, P, N$ before any zero-strip or boundary read is available.

Now apply the zero-strip budget factorization theorem Definition 548.65. That theorem identifies zero-strip budget requests with the supplied Z, S rows and the shared modulus ledger M, R, Q, H, C, P, N.

Finally use the zeta-consumer non-escape theorem Definition 548.327. Zeta-facing and RH-facing consumers remain on the same finite readback surface, so totality of the zero-strip route carries no analytic-continuation, host-equality, quotient, global-classifier, or proof-content coordinate. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip route totality`

Theorem 548.285 (Critical-line witness RH-boundary nonescape)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every* RH*-boundary consumer whose read is served by the source-modulus and zero-strip rows of W is exhausted by $Z, S, M, R, Q, H, C, P, N$. It may read the displayed source row, strip row, modulus row, real-part row, rational comparison ledger,* BHist *history,* hsame *transports,* Cont *replay,* Pkg *provenance, and local* NameCert *row, but it cannot read global zero classification, analytic continuation, host equality, quotient representatives, or* RH *proof content.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh boundary nonescape`

Proof. Start with zero-strip route totality. The boundary consumer has already been routed through $Z, S, M, R, Q, H, C, P, N$ and has no second zero-strip or host-real channel.

Next apply Definition 548.276. The RH-boundary side is exhausted by the locked source side Z, S, the total modulus ledger M, R, Q, and the structural rows H, C, P, N.

Finally combine this with Definition 548.312. Downstream consumers receive a refusal packet rather than an analytic claim, so global zero classification, analytic continuation, host equality, quotient representatives, and proof content have no carrier row from which to escape. □

Theorem 548.286 (CriticalLineWitness visible source triad)**.** *For every accepted* CriticalLineWitness$^{\uparrow}$ *root witness read, the consumer-visible surface exposes the critical-strip source row, the rational modulus row, the zero-strip refusal row, and the local* BHist, hsame, Cont, Pkg, *and* NameCert *provenance before the witness can be used downstream.*

Proof. Project the accepted packet through Definition 548.1. The source, modulus, refusal, transport, continuation, provenance, and local naming rows are all displayed coordinates of the same finite witness carrier.

Apply the root source obligation triad of Definition 548.277. It forces every root consumer to read the supplied source through the displayed zero-strip or critical-strip row and through the modulus row before the consumer-facing boundary is reached.

Use the local transport obligation Definition 548.47. It carries the source and modulus rows through the hsame, Cont, Pkg, and NameCert surface, so no downstream read can bypass the visible provenance. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier visible source triad`

Theorem 548.287 (CriticalLineWitness modulus refusal scope)**.** *For every accepted* CriticalLineWitness$^{\uparrow}$ *root witness read, the rational modulus row is a finite refusal-scoped ledger. It cannot be promoted to a zeta-zero locator, analytic-continuation oracle, or host complex equality.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus refusal scope`

Proof. Begin with Definition 548.286. The modulus row is displayed only beside the source, refusal, transport, continuation, provenance, and local naming rows.

Apply Definition 548.278. It exhausts the modulus-facing classifier by the finite packet rows and rejects hidden numeric or analytic classifiers.

Finally use the RH-refusal boundary rows of Definition 548.194. They classify requests for zero location, analytic continuation, and host equality as outside the accepted witness packet. □

Theorem 548.288 (CriticalLineWitness RH consumer handoff)**.** *Every* RH*-facing consumer of an accepted* CriticalLineWitness$^{\uparrow}$ *root witness receives only the displayed source row, rational modulus row, zero-strip refusal row, transport rows, continuation rows, provenance rows, and local naming rows before using the witness.*

Proof. Start from Definition 548.286. It exposes the exact source, modulus, refusal, and local provenance rows that any root witness read must traverse.

Use Definition 548.287. The modulus row remains a refusal-scoped finite ledger and does not become a zero locator, analytic-continuation oracle, or host equality.

Then apply Definition 548.279. It bounds every RH-facing consumer by the displayed source, modulus, transport, replay, provenance, and local naming rows. Therefore the handoff is a finite BEDC readback package, not an analytic conclusion about RH. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh consumer handoff`

Theorem 548.289 (CriticalLineWitness visible source readback lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every visible source read of W is locked to the displayed zero-strip source triad and comparison ledger: the read must expose Z, S, Q as the source side and M, R, Q, H, C, P, N as the comparison and structural side before any downstream consumer can use the witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier visible source readback lock`

Proof. Start with the visible source triad, Definition 548.286. It places the critical-strip source row, rational modulus row, zero-strip refusal row, and local structural provenance on the consumer-visible surface.

Use the root source triad, Definition 548.76, to identify the source side of the read as the displayed Z, S, Q packet. Then use the root comparison ledger, Definition 548.77, to route the comparison side through M, R, Q, H, C, P, N.

Finally apply RH-refusal ledger completeness, Definition 548.72. It prevents the visible readback from replacing the displayed rows by an RH proof, a zero search, analytic continuation, quotient data, host equality, or ambient completeness. □

Theorem 548.290 (CriticalLineWitness fixed-strip modulus totality)**.** *For every accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every fixed-strip modulus consumer factors through the finite rows $Z, S, M, R, Q, H, C, P, N$. The consumer has no accepted access to a detached modulus oracle, analytic-continuation row, zero-location classifier, quotient representative, host equality, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip modulus totality`

Proof. First apply Definition 548.289. It binds fixed-strip source access to the same source triad and comparison ledger.

Next use the downstream RH boundary refinement, Definition 548.105. The refinement says that downstream consumers receive only the finite package routed through the displayed source, comparison, transport, replay, provenance, and local naming rows.

The remaining possible escapes are removed by Definition 548.72. Hence every fixed-strip modulus read is total over $Z, S, M, R, Q, H, C, P, N$ and cannot import a stronger analytic or host-side witness. □

Theorem 548.291 (CriticalLineWitness RH refusal export boundary)**.** *Every* RH*-facing export of an accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$ receives only the finite refusal package carried by $Z, S, M, R, Q, H, C, P, N$. It receives no* RH *proof, analytic-continuation certificate, zero-search result, quotient representative, host equality proof, or ambient-completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal export boundary`

Proof. Begin with fixed-strip modulus totality, Definition 548.290. It forces every fixed-strip modulus consumer through the displayed packet rows.

Now read the export boundary through Definition 548.105. The downstream interface is the finite refusal package, not a host analytic conclusion.

Finally apply RH-refusal ledger completeness, Definition 548.72. Its exclusion clauses remove RH proof data, analytic continuation, zero search, quotient representatives, host equality, and ambient completeness from the export surface, so only the displayed refusal package remains. □

Theorem 548.292 (CriticalLineWitness source-modulus refusal totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every* RH*-facing downstream read of W factors through the displayed finite source/modulus/refusal surface*

$$Z, S, M, R, Q, H, C, P, N$$

over BHist*,* hsame*,* Cont*,* Pkg*, and the local* NameCert$_{\text{CriticalLineWitness}^{\uparrow}}$ *row. The read has no coordinate for analytic continuation, host zero search, quotient representative, host equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus refusal totality`

Proof. Project the packet through Definition 548.1. The carrier displays exactly the source rows Z, S, modulus and real rows M, R, rational comparison ledger Q, transport row H, continuation row C, package row P, and local naming row N.

Apply the root source triad Definition 548.76. It makes the zero-strip and critical-strip source side finite before any downstream consumer reads the witness. Then use the root comparison ledger Definition 548.77; the modulus and rational comparison side is read only through M, R, Q, H, C, P, N.

Finally apply the downstream refusal package Definition 548.34. It removes analytic-continuation proofs, host zero searches, quotient representatives, host equality, and ambient completeness from the downstream interface. The only remaining read surface is the displayed finite source/modulus/refusal packet. □

Theorem 548.293 (CriticalLineWitness RH boundary source nonescape)**.** *For every accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, an* RH*-boundary consumer cannot replace the displayed source rows Z, S, Q by an analytic-continuation source, a host zero locator, a quotient stream, or a completeness coordinate. The boundary source remains the finite* BHist *route carried through H, C, P, N.*

Proof. Begin with the root source triad of Definition 548.76. It identifies the supplied zero row, critical-strip row, and rational comparison ledger as the source side available to the root and downstream boundary.

Use the root comparison ledger Definition 548.77. The comparison source is attached to M, R, Q and transported through H, C, P, N, so the boundary has no separate source coordinate outside the accepted packet.

Now apply Definition 548.34. The excluded requests are precisely the analytic source replacement, host zero search, quotient representative, host equality, and ambient completeness routes. Therefore the RH boundary cannot escape the finite BHist source surface displayed by W. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh boundary source nonescape`

Theorem 548.294 (CriticalLineWitness modulus refusal readback)**.** *Every downstream modulus readback of an accepted* CriticalLineWitness$^{\uparrow}$ *packet is exhausted by the rows M, R, Q, H, C, P, N over the displayed source rows Z, S. It may report the finite modulus, real-part, rational comparison,* hsame*,* Cont*,* Pkg*, and* NameCert *data, but it cannot report analytic continuation, a host zero, quotient equality, or a completeness witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus refusal readback`

Proof. Read the modulus row from the carrier Definition 548.1. The modulus-facing coordinates are M, R, Q, H, C, P, N, and the source context retained by that read is Z, S.

Apply the root comparison ledger Definition 548.77. It forces each modulus and comparison read through the rational ledger and the displayed transport, continuation, package, and naming rows.

Use the source-modulus refusal totality of Definition 548.292. The totality row places the modulus readback inside the same finite downstream refusal surface.

Finally apply Definition 548.34. It refuses analytic continuation, host zero data, quotient equality, and completeness witnesses as readback outputs, so the modulus readback is exactly the displayed finite packet route. □

Theorem 548.295 (Critical-line witness root route exposure)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted route that can feed a downstream zeta or* RH *consumer first exposes the critical-strip source, the zero-strip source and modulus row, the refusal ledger, the* BHist *carrier, the* hsame *transport row, the* Cont *replay row, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. The route has no accepted read before the displayed source/modulus/refusal surface is present.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root route exposure`

Proof. Project the accepted carrier of Definition 548.1. Its displayed rows are the source rows Z, S, the modulus and comparison rows M, R, Q, and the structural rows H, C, P, N.

Apply the root source triad Definition 548.76 and the zero-strip source totality row Definition 548.180. These rows expose the critical-strip and zero-strip source side as finite BHist data before any downstream read occurs.

Next use Definition 548.64 and Definition 548.292. They attach the zero-strip modulus and refusal ledger to the same displayed package, carried through hsame, Cont, Pkg, and the local NameCert row.

Finally apply Definition 548.154. Every downstream zeta or RH readback is exhausted by this displayed package, so no accepted route can bypass the exposed source/modulus/refusal surface. □

Theorem 548.296 (Critical-line witness zero-strip modulus refusal)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. If a zero-strip modulus read is absent from the displayed route or mismatches the displayed modulus row M, the read is routed to the visible refusal ledger of W. It is not reinterpreted as a hidden* RH *coordinate, an analytic-continuation coordinate, a host zero classifier, a quotient representative, or an ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip modulus refusal`

Proof. Begin with Definition 548.295. Any accepted route has already exposed the zero-strip source, the modulus row, the refusal ledger, and the structural BHist, hsame, Cont, Pkg, and NameCert rows.

Use the zero-strip source totality theorem Definition 548.180. It keeps the zero-strip source read inside the displayed finite route, rather than opening an analytic or host-level coordinate.

Apply Definition 548.294 and Definition 548.292. A modulus readback that is missing or mismatched has only the displayed refusal side available, because the carrier exports no second modulus or hidden analytic continuation coordinate.

Finally use the downstream refusal package Definition 548.34. The excluded RH proof, analytic-continuation certificate, host zero classifier, quotient representative, and ambient completeness witness are refusal-side requests, so the failed modulus read lands in the visible ledger. □

Theorem 548.297 (Critical-line witness downstream readback exhaustion)**.** *Every downstream* $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, *zeta-boundary, or* RH *consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet reads only the displayed source-modulus-refusal package*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer cannot draw source, modulus, refusal, transport, continuation, package, or local naming data from a hidden analytic-continuation route, a host equality, a global zero classifier, a quotient representative, a selected completion coordinate, or an ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream readback exhaustion`

Proof. First apply Definition 548.295. It places the critical-strip source, zero-strip source, modulus, refusal ledger, BHist, hsame, Cont, Pkg, and local NameCert rows on the route before any downstream consumer reads the packet.

Next use the root RH boundary row Definition 548.144. This keeps the downstream boundary attached to the finite source/modulus surface instead of replacing it by an RH truth value or host analytic datum.

Apply Definition 548.296. Missing or mismatched modulus requests are sent to the visible refusal ledger, so they cannot produce an alternate source for downstream zeta or RH consumers.

Finally invoke Definition 548.154 and Definition 548.292. These rows exhaust downstream readback at the displayed source-modulus-refusal package, leaving no hidden coordinate from which another consumer route can be read. □

Theorem 548.298 (Critical-line witness window modulus exhaustion)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted source-window read of* W *that can feed a downstream zero-location consumer factors through the displayed finite route*

$$Z, S, M, R, Q, H, C, P, N$$

over the zero-strip source, rational-height modulus, BHist, hsame, Cont, Pkg, *and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows. No downstream consumer can use the read before these source-window, modulus, package, and naming rows have been exposed.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier window modulus exhaustion`

Proof. Project the carrier of Definition 548.1. The accepted packet exposes exactly the source rows Z, S, the modulus and real rows M, R, the rational comparison row Q, and the structural rows H, C, P, N.

Apply the source-window separation row Definition 548.239 and the source-modulus refusal totality row Definition 548.292. Together they place the source-window read behind the displayed zero-strip source and the rational-height modulus route.

Finally use the fixed-strip readback surface Definition 548.268. It forces any zero-location consumer to pass through BHist, hsame, Cont, Pkg, and the local NameCert row before reading the strip. Hence the downstream consumer sees only the displayed finite route. □

Theorem 548.299 (Critical-line witness zero-strip refusal totality)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the zero-strip carrier and modulus route jointly refuse every request for an* RH *proof, analytic-continuation certificate, or host zero-location claim outside the finite displayed packet. The refusal is total for downstream zero-strip consumers whose reads pass through* $Z, S, M, R, Q, H, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip refusal totality`

Proof. Start with Definition 548.298. It places each downstream zero-location read behind the zero-strip source, rational-height modulus, transport, continuation, package, and naming rows of the accepted packet.

Apply the root RH source lock Definition 548.258 and the downstream refusal package Definition 548.34. These rows classify proof-of-RH requests, analytic-continuation requests, and host zero-location requests as refusal-side requests rather than carrier coordinates.

Use the zero-strip consumer boundary Definition 548.143. Since the consumer receives only the displayed zero-strip witness package, no outside proof, analytic certificate, or host zero-location claim remains available. □

Theorem 548.300 (Critical-line witness RH source ledger closure)**.** *Every* RH*-facing downstream consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the source, modulus, and refusal ledger carried by*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer receives no proof of RH*, no zero-free strip theorem, and no analytic-continuation primitive. Its public read is the finite source/modulus/refusal ledger over* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh source ledger closure`

Proof. First use the window-modulus exhaustion theorem Definition 548.298. It gives the source and modulus side of the ledger before any downstream zero-location consumer can read the packet.

Next apply the zero-strip refusal totality theorem Definition 548.299. It removes RH proofs, analytic-continuation certificates, and host zero-location claims from the downstream zero-strip interface.

Finally compose these rows with the zeta dependency lattice Definition 548.169 and the downstream refusal package Definition 548.34. The lattice supplies only dependency information over the existing zeta and RH boundary surfaces, while the refusal package blocks the proof, zero-free strip, and analytic-continuation outputs. Therefore the RH-facing consumer receives exactly the finite source/modulus/refusal ledger. □

Theorem 548.301 (Critical-line witness root finite-source carrier)**.** *Every root-facing read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet is carried by the finite source tuple*

$$\mathsf{CritStrip}^{\uparrow},\ \mathsf{Gamma}^{\uparrow},\ \mathsf{ZetaZeros}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Equivalently, the packet exposes only the supplied zero row, fixed critical-strip row, real-part row, rational comparison row, transport row, continuation row, provenance row, and local naming row through the carrier of Definition 548.1. It does not expose analytic continuation, a global zero classifier, host complex equality, quotient representatives, or ambient analytic completeness.

Proof. Project the carrier of Definition 548.1. The accepted packet lists the zero row, critical-strip row, modulus row, real-part row, rational comparison ledger, componentwise transport, displayed continuation, provenance, and local naming row as one finite BHist packet.

Use the root route exposure theorem Definition 548.295. It places every downstream zeta or RH route behind the same source, modulus, refusal, transport, continuation, package, and naming surface.

The $\mathsf{Gamma}^{\uparrow}$ and $\mathsf{CritStrip}^{\uparrow}$ source obligations are read only as finite source rows for the same packet; the $\mathsf{Rat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows are the displayed comparison and real-part rows. Since no carrier coordinate has the type of analytic continuation, host equality, quotient data, or ambient completeness, the listed source tuple is exhaustive. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootFiniteSourceCarrier`

Theorem 548.302 (Critical-line witness root zero-strip modulus totality)**.** *Every zero-strip modulus read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet is tied to the finite source tuple of Definition 548.301. A successful read factors through the displayed* $\mathsf{CritStrip}^{\uparrow}$*,* $\mathsf{ZetaZeros}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; a missing or mismatched read lands in the same visible refusal ledger rather than producing a hidden modulus source.*

Proof. Start with Definition 548.138. It identifies the zero and strip source as supplied packet rows, not as an external zero-search service.

Next apply Definition 548.139 and Definition 548.292. These rows bind each modulus request to the displayed modulus, real-part, rational-comparison, transport, continuation, provenance, and naming surface, and send absent or mismatched requests to refusal.

Finally use Definition 548.296. The refusal side cannot be reinterpreted as analytic continuation, a host zero classifier, quotient representative, ambient completeness witness, or RH proof, so the zero-strip modulus read is total within the finite source tuple. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootZeroStripModulusTotality`

Theorem 548.303 (Critical-line witness root RH refusal ledger)**.** *Every* RH*-shaped consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the boundary/refusal ledger determined by Definition 548.301 and Definition 548.302. The consumer may read the fixed strip, supplied zero row, comparison rows, transport, continuation, provenance, and local naming data, but it receives no analytic-continuation theorem, no global* RH *proof datum, no host zero-location classifier, no quotient representative, and no ambient completeness row.*

Proof. First apply Definition 548.301. It fixes the carrier surface seen by a root consumer at the listed finite BEDC rows.

Then use Definition 548.302. Any modulus-facing demand needed by an RH-shaped consumer is either read through those same rows or returned as the visible refusal ledger.

Finally invoke the RH consumer nonescape theorem Definition 548.125. The downstream consumer receives only the finite witness boundary, so no analytic-continuation theorem, global proof, host classifier, quotient representative, or ambient completeness row is exported. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root rh refusal ledger`

Theorem 548.304 (Critical-line witness root finite-source NameCert obligations)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Before any downstream zero-strip consumer reads* W*, the root surface exposes the finite zero-strip source rows* Z, S*, the rational modulus and comparison rows* M, R, Q*, the zeta and* RH *boundary rows, the classifier ledger,*

and the displayed BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows carried by* H, C, P, N*. No consumer can read the packet through an unshown analytic, quotient, host-equality, or global-zero coordinate.*

Proof. Project first to the root finite-source carrier of Definition 548.301. It identifies the zero row, fixed strip row, rational comparison row, transport, replay, provenance, and local naming row as finite displayed data of W.

Next use the fixed-strip source readback totality Definition 548.268 and the zeta dependency lattice Definition 548.169. These rows place every zeta-facing or RH-facing read behind the same supplied source, modulus, comparison, continuation, package, and naming surface.

Finally apply the classifier exactness and ledger stability rows Definition 548.358 and Definition 548.359. They keep the classifier and modulus ledger on $Z, S, M, R, Q, H, C, P, N$, so the downstream zero-strip consumer cannot bypass the displayed BHist/hsame/Cont/Pkg/NameCert route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root finite source namecert obligations`

Theorem 548.305 (Critical-line witness root classifier refusal boundary)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, the root classifier refuses host zero selection, analytic-continuation shortcuts, quotient equality, hidden modulus selectors, and unledgered critical-line witnesses. Accepted classifier reads are exactly the packet-local reads through the visible zero-strip source, fixed-strip source, modulus, rational comparison, transport, continuation, provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root classifier refusal boundary`

Proof. Start with the root classifier stability theorem Definition 548.265. It attaches classifier reads to the displayed source, modulus, transport, continuation, provenance, and local naming route of the accepted packet.

Use the root ledger nonescape row Definition 548.267 together with the root RH refusal ledger Definition 548.303. These rows remove analytic continuation, host zero extraction, quotient representatives, global RH proof data, and ambient completeness from the root-facing export.

It remains to rule out hidden modulus selectors and unledgered critical-line witnesses. The root zero-strip modulus totality Definition 548.302 and the zero-strip modulus separation Definition 548.269 force every modulus or refusal read through M, R, Q, H, C, P, N, leaving no classifier branch outside the visible ledger. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootClassifierRefusalBoundary`

Theorem 548.306 (Critical-line witness visible modulus consumer totality)**.** *Every downstream consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet that requests a zero-strip, critical-line, zeta-boundary, or* RH*-boundary modulus factors through the finite displayed rows*

$$Z, S, M, R, Q, H, C, P, N.$$

The factorization uses the BHist *source,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *route; a failed or mismatched request returns the same visible refusal ledger rather than a hidden analytic source.*

Proof. Read the source side through Definition 548.304. It places zero-strip, critical-line, zeta-boundary, and RH-boundary access behind the displayed source and naming rows before any consumer sees the packet.

Next apply the zero-strip modulus totality Definition 548.302 and the classifier refusal boundary Definition 548.305. Together they require modulus and classifier reads to pass through M, R, Q, H, C, P, N and return off-route demands to the visible refusal ledger.

Finally combine the downstream consumer unblock row Definition 548.360 with the RH-refusal consumer nonescape theorem Definition 548.270. These consumer rows exhaust the available downstream surface by $Z, S, M, R, Q, H, C, P, N$, so every accepted modulus consumer factors through the finite displayed route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root visible modulus consumer totality`

Theorem 548.307 (Critical-line witness root finite-budget source totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root finite-budget source read of W is total on the displayed zero-strip source rows, rational modulus and comparison ledger, transport, continuation, package, and local naming surface*

$$Z, S, M, R, Q, H, C, P, N.$$

The source read may expose the supplied $\mathsf{ZetaZeros}^{\uparrow}$ *row, the* $\mathsf{CritStrip}^{\uparrow}$ *strip row, the* $\mathsf{Nat}^{\uparrow}$ *depth row, the* $\mathsf{Real}^{\uparrow}$ *real-part row, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger, and the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It exposes no* RH *proof, analytic continuation, host zero classifier, quotient representative, host equality, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root finite budget source totality`

Proof. Start with the carrier route exactness and root source triad, Definition 548.310 and Definition 548.76. They place the supplied zero row, critical-strip row, and rational comparison ledger inside the same finite carrier.

Next apply the modulus ledger entry and root modulus-window totality, Definition 548.83 and Definition 548.85. These rows make M, R, Q, H, C, P, N the whole depth and rational-comparison route available to a root consumer.

Finally use the supplied zero-strip transport lock and RH-refusal ledger completeness. The structural rows hsame, Cont, Pkg, and NameCert carry the source and modulus faces together, while the refusal ledger removes analytic continuation, host classifiers, quotient representatives, host equality, ambient completeness, and any proof of RH. □

Theorem 548.308 (Critical-line witness root finite-budget ledger stability)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, replacing a root finite-budget presentation by another presentation with the same displayed Z, S, M, R, Q rows preserves the rational modulus ledger exactly through the same* hsame/Cont/Pkg/NameCert *transport surface. No stable ledger comparison may introduce a hidden modulus source, analytic-continuation certificate, quotient representative, host equality, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootFiniteBudgetLedgerStability`
↪ variant `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root finite budget ledger stability`

Proof. First read the finite-budget source totality just established. It fixes the available source and comparison rows at $Z, S, M, R, Q, H, C, P, N$, so a second presentation has no additional carrier coordinate to inspect.

Next apply Definition 548.77 and Definition 548.86. The comparison ledger Q is transported only with M, R, H, C, P, N, and the zero-strip side shares the same componentwise hsame and displayed Cont routes.

It remains to exclude alternate ledger sources. Use Definition 548.72. The refusal ledger has no slot for analytic continuation, quotient data, host equality, ambient completeness, or an RH proof, so the stable comparison is precisely the displayed finite-budget ledger. □

Theorem 548.309 (Critical-line witness root finite-budget RH refusal non-escape)**.** *Every* RH-*facing consumer of the root finite-budget surface of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the finite refusal package over*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer may cite the zero-strip source, rational modulus ledger, comparison row, hsame *transport,* Cont *route,* Pkg *provenance, and local* NameCert *row, but it cannot extract* RH*, analytic continuation, a standard bridge, a global zero classifier, quotient equality, host equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root finite budget rh refusal nonescape`

Proof. Begin with Definition 548.307. It identifies the root finite-budget source as a finite packet over the displayed source, modulus, comparison, and structural rows.

Then use Definition 548.308. Any presentation of the same finite source keeps the rational ledger on the same hsame/Cont/Pkg/NameCert route.

Finally apply Definition 548.84 and Definition 548.87. These refusal rows make the RH-facing export a finite boundary only; analytic continuation, standard bridges, global zero classification, quotient equality, host equality, ambient completeness, and RH proof data are absent from the packet. □

Theorem 548.310 (Critical-line witness carrier route exactness)**.** *Let* W *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The carrier route exposed by* W *is exactly the finite tuple*

$$Z, S, M, R, Q, H, C, P, N.$$

Here Z *is the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *zero row,* S *is the* $\mathsf{CritStrip}^{\uparrow}$ *strip row,* M *is the depth row,* R *is the real-part row,* Q *is the rational comparison row, and* H, C, P, N *are the displayed transport, continuation, provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows. No accepted packet exposes a tenth carrier coordinate.*

Proof. Project the carrier in Definition 548.1. Its public coordinates are the zero, strip, depth, real-part, rational comparison, transport, continuation, provenance, and local naming rows.

Use the fixed-strip tuple of Definition 548.313 and the row exhaustion theorem Definition 548.314. They identify the visible fixed-strip source route with the nine displayed rows and exclude any additional analytic, quotient, host-equality, or completeness coordinate.

Finally apply Definition 548.295. Every downstream zeta or RH route first exposes the same source, modulus, refusal, transport, continuation, package, and naming surface. Hence the accepted packet exposes exactly $Z, S, M, R, Q, H, C, P, N$. □

Lean4 ✓ BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier carrier route exactness

Theorem 548.311 (Critical-line witness modulus route totality)**.** *For every accepted* CriticalLineWitness$^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every depth or modulus request is total as a finite route: it factors through*

$$M, R, Q, H, C, P, N$$

or it lands in the visible refusal ledger of W*. The request cannot be completed by a hidden modulus source, analytic-continuation primitive, host equality, quotient representative, ambient completeness row, or proof of* RH*.*

Lean4 ✓ BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier depth modulus route totality

Proof. Start with the carrier route exactness theorem Definition 548.310. It leaves only the displayed packet rows available to an accepted depth or modulus read.

Apply the modulus readback row Definition 548.139 and the source-modulus refusal totality theorem Definition 548.292. Accepted requests pass through M, R, Q together with the transport, continuation, package, and naming rows; absent or mismatched requests are sent to the visible refusal side.

Use the zero-strip modulus refusal theorem Definition 548.296. It blocks reinterpretation of a failed modulus read as an RH coordinate, analytic-continuation coordinate, host zero classifier, quotient representative, or ambient completeness witness. Thus the finite route is total by acceptance or refusal. □

Lean4 ✓ BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus route totality certificate

↪ variant BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus refusal totality

Theorem 548.312 (Critical-line witness downstream RH boundary nonescape)**.** *Every downstream* RH*-facing consumer of an accepted* CriticalLineWitness$^{\uparrow}$ *packet receives only the finite witness/refusal package*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer receives no proof of RH*, no zero search, no analytic-continuation primitive, no host equality, no quotient representative, and no ambient completeness datum.*

Proof. First apply Definition 548.310. It fixes the carrier route available to downstream consumers at the nine displayed rows.

Next apply Definition 548.311. Depth and modulus requests either pass through M, R, Q, H, C, P, N or land in the visible refusal ledger, so the downstream consumer has no alternate modulus or comparison source.

Finally use the RH consumer boundary theorem Definition 548.316 and the downstream refusal package Definition 548.34. These rows identify the consumer-facing object as a finite witness/refusal boundary and exclude proof, search, analytic-continuation, host-equality, quotient, and completeness exports. □

Definition 548.313 (Critical-line witness fixed-strip source tuple)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet, the fixed-strip source tuple is*

$$W = (Z, S, M, R, Q, H, C, P, N).$$

Here Z is the supplied $\mathsf{ZetaZeros}^{\uparrow}$ *zero row, S is the supplied* $\mathsf{CritStrip}^{\uparrow}$ *fixed-strip row, M is the* $\mathsf{Nat}^{\uparrow}$ *depth row, R is the* $\mathsf{Real}^{\uparrow}$ *real-part row, Q is the* $\mathsf{Rat}^{\uparrow}$ *rational comparison row, H is the componentwise transport row, C is the displayed continuation row, P is the package provenance row, and N is the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. The tuple is the row inventory of Definition 548.123 with no extra analytic-continuation, zero-search, host-equality, quotient, or completeness coordinate.*

Lean4 (definition) `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessFixedStripSourceTuple`

Theorem 548.314 (Critical-line witness fixed-strip row exhaustion)**.** *Every fixed-strip read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet factors through the nine rows*

$$Z, S, M, R, Q, H, C, P, N$$

of Definition 548.313. The read may inspect the supplied $\mathsf{ZetaZeros}^{\uparrow}$ *row, the* $\mathsf{CritStrip}^{\uparrow}$ *strip row, the* $\mathsf{Nat}^{\uparrow}$ *depth row, the* $\mathsf{Real}^{\uparrow}$ *real-part row, the* $\mathsf{Rat}^{\uparrow}$ *rational comparison row, and the displayed transport, continuation, package, and local naming rows, but it has no tenth row outside that tuple.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip row exhaustion`

Proof. Start with the fixed-strip source of Definition 548.123. It already presents the zero, strip, depth, real-part, rational comparison, transport, continuation, package, and local naming rows as the whole fixed-strip source surface.

Apply Definition 548.138 to identify the supplied zero and strip as the source rows. Apply Definition 548.139 to route every modulus-facing read through the displayed $\mathsf{Nat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$ rows.

The remaining rows are structural. The transport, continuation, package, and local naming coordinates preserve the same tuple rather than adding a further analytic or host-level coordinate. Thus every fixed-strip read factors through exactly $Z, S, M, R, Q, H, C, P, N$. □

Theorem 548.315 (Critical-line witness zero-route nonescape)**.** *The zero route carried by Definition 548.313 cannot become zero search, analytic continuation, host equality, quotient representative, ambient completeness, or a proof of* RH*. It remains a finite BEDC route through the supplied zero, fixed strip, depth, real-part, rational comparison, transport, continuation, package, and local naming rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip zero route boundary`

Proof. First apply the fixed-strip modulus refusal theorem Definition 548.124. It keeps the modulus request inside the supplied zero and strip rows, the depth and comparison rows, and the displayed refusal route.

Next apply the fixed-strip row exhaustion theorem Definition 548.314. Any zero route that reaches a fixed-strip consumer has already been forced through $Z, S, M, R, Q, H, C, P, N$.

Finally use the RH consumer nonescape row Definition 548.125. Since the RH-facing consumer receives only the finite witness boundary, the zero route cannot acquire zero search, analytic continuation, host equality, quotient representatives, ambient completeness, or an RH proof. □

Theorem 548.316 (Critical-line witness RH consumer boundary)**.** *Every downstream* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the finite BEDC witness boundary*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer may cite the supplied $\mathsf{ZetaZeros}^{\uparrow}$ *zero row,* $\mathsf{CritStrip}^{\uparrow}$ *fixed-strip row,* $\mathsf{Nat}^{\uparrow}$ *depth row,* $\mathsf{Real}^{\uparrow}$ *real-part row,* $\mathsf{Rat}^{\uparrow}$ *rational comparison row, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows, but it does not receive an analytic theorem or a host-level zero-location certificate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh consumer boundary`

Proof. Use the fixed-strip row exhaustion theorem to place the downstream read behind the tuple $Z, S, M, R, Q, H, C, P, N$. This supplies a finite BEDC witness boundary before the consumer can inspect any RH-facing conclusion.

Use the zero-route nonescape theorem to remove the possible escape channels. The same zero route cannot turn into zero search, analytic continuation, host equality, quotient representatives, ambient completeness, or an RH proof.

It remains only to identify what the consumer receives. The visible rows are the supplied zeta zero, fixed critical strip, depth, real-part, rational comparison, transport, continuation, package, and local naming rows. Therefore every RH-facing consumer receives exactly the finite boundary and no analytic or host-level certificate beyond it. □

Theorem 548.317 (Critical-line witness fixed-strip source totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every fixed critical-strip source read of* W *is total on the displayed source rows, zero-strip/source modulus rows, finite* BHist *observation windows, refusal ledger, transport, replay, provenance, and local naming surface*

$$Z, S, M, R, Q, H, C, P, N.$$

The read may expose the supplied $\mathsf{ZetaZeros}^{\uparrow}$ *zero row, the supplied* $\mathsf{CritStrip}^{\uparrow}$ *strip row, the* $\mathsf{Nat}^{\uparrow}$ *depth row, the* $\mathsf{Real}^{\uparrow}$ *real-part row, the* $\mathsf{Rat}^{\uparrow}$ *rational comparison row, the displayed* hsame *transports,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *handoff. It exposes no zero-producing search, analytic-continuation theorem, host equality, quotient representative, ambient completeness witness, or proof of* RH.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip source totality certificate`

Proof. Project the accepted packet through the carrier of Definition 548.1. The visible coordinates are exactly the supplied zero row Z, strip row S, modulus row M, real-part row R, rational ledger Q, transport row H, continuation route C, provenance row P, and local naming row N.

Next use the fixed-strip tuple exhaustion of Definition 548.314 together with the root finite-budget source totality of Definition 548.307. These rows identify the source and modulus faces as the same finite observation window rather than as separate analytic inputs.

Finally read the refusal side through Definition 548.315. Since no other carrier coordinate is available, the displayed rows exhaust the fixed critical-strip source and the excluded analytic, host, quotient, completeness, and RH outputs have no route into the read. □

Theorem 548.318 (Critical-line witness modulus refusal ledger exhaustion)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every zero-strip/source modulus request is exhausted by the finite refusal ledger over*

$$Z, S, M, R, Q, H, C, P, N.$$

The ledger records the BHist *observation window,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *handoff for the source and modulus rows. It cannot be extended by a hidden*

modulus source, analytic-continuation evidence, zero-free-strip evidence, a global zero classifier, a host numeric oracle, quotient equality, or ambient completeness.

Proof. Begin with the source totality of Definition 548.317. It fixes the only readable source and modulus coordinates at $Z, S, M, R, Q, H, C, P, N$.

Now apply the modulus refusal exhaustion row of Definition 548.252. A zero-strip modulus request is routed through the displayed BHist, hsame, Cont, Pkg, and NameCert surface, so the request remains a finite ledger entry rather than an analytic continuation claim.

It remains to rule out alternate sources. The finite-budget ledger stability of Definition 548.308 keeps the comparison row Q on the same transported route, while Definition 548.253 removes zero-free-strip evidence, global classifiers, host numeric oracles, quotient equality, ambient completeness, and RH proof data from the packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus refusal ledger exhaustion`

Theorem 548.319 (Critical-line witness RH-boundary NameCert handoff)**.** *Every downstream* RH*-boundary consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet receives only the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *handoff for the fixed-strip source and modulus refusal ledger*

$$Z, S, M, R, Q, H, C, P, N.$$

The handoff may cite finite source rows, finite observation windows, componentwise hsame *transports, displayed* Cont *replay,* Pkg *provenance, and the refusal ledger. It does not deliver* RH*, analytic continuation, zero production, host zero classification, quotient presentation, host equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh boundary namecert handoff`

Proof. First read the local handoff through Definition 548.2. The five obligation rows admit the carrier, bind zero-strip compatibility, discipline the modulus, enforce non-escape, and exhaust the ledger through $Z, S, M, R, Q, H, C, P, N$.

Next combine fixed-strip source totality with modulus refusal ledger exhaustion. The source face and the modulus face are the same finite packet as seen by the downstream consumer, and their transport, replay, provenance, and naming rows are already displayed.

Finally use the RH consumer boundary Definition 548.316. The downstream consumer can receive only the finite BEDC witness boundary, so the NameCert handoff cannot become analytic continuation, zero production, host classification, quotient presentation, host equality, ambient completeness, or a proof of RH. □

Theorem 548.320 (CriticalLineWitness fixed-strip window carrier)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet, the fixed critical-strip window carrier is a finite* BHist *packet over the zero-strip source rows, rational modulus rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows. Its visible surface is the fixed-strip tuple*

$$Z, S, M, R, Q, H, C, P, N,$$

where Z supplies the zero-strip source row, S supplies the fixed critical-strip window, M, R, Q supply the depth, real-part, and rational comparison ledgers, and H, C, P, N supply transport, replay, provenance, and local naming.

The carrier has no coordinate for analytic continuation, a zero-producing search, host zero equality, quotient presentation, ambient completeness, or a proof of RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip window surface`

Proof. Start from the fixed-strip source tuple. It lists the zero row, strip row, depth row, real-part row, rational comparison row, transport, continuation, provenance, and local naming row as the whole fixed-strip source packet.

Apply fixed-strip source totality. Every fixed critical-strip source read is total on those displayed rows and on the finite observation window carried by the same BHist packet.

Finally use zero-route nonescape. Since the accepted route has no coordinate beyond $Z, S, M, R, Q, H, C, P, N$, analytic continuation, zero search, host equality, quotient presentation, ambient completeness, and RH proof data cannot be read from the carrier. □

Theorem 548.321 (CriticalLineWitness fixed-strip modulus ledger)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *fixed-strip window carrier, every modulus comparison is exhausted by the displayed rational-modulus and zero-strip rows*

$$Z, S, M, R, Q, H, C, P, N.$$

The comparison may read the supplied zero-strip source, fixed critical-strip window, depth row, real-part row, rational comparison ledger, componentwise transport, continuation replay, package provenance, and local naming row. It cannot import analytic continuation, zero-free-strip evidence, a global zero classifier, a host numeric oracle, quotient equality, ambient completeness, or a global RH *assertion.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip modulus ledger`

Proof. Begin with the fixed-strip window carrier above. It places every modulus-facing read on the same finite source and rational-comparison packet.

Use modulus refusal ledger exhaustion. The zero-strip/source modulus request is routed through the displayed BHist, hsame, Cont, Pkg, and NameCert surface, so the modulus comparison remains a ledger row rather than an analytic theorem.

Now apply RH-boundary nonescape through the fixed-strip source totality results. The downstream boundary receives only the displayed source and modulus rows, so analytic continuation, zero-free-strip evidence, global classifiers, host numeric oracles, quotient equality, ambient completeness, and global RH assertions are not exported. □

Theorem 548.322 (CriticalLineWitness fixed-strip RH refusal)**.** *Every downstream* RH*-facing consumer of an accepted* CriticalLineWitness$^{\uparrow}$ *fixed-strip window carrier receives only the displayed refusal ledger and the fixed-strip source window*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer may use the zero-strip source, fixed critical-strip window, rational modulus comparison, componentwise transport, continuation replay, package provenance, and local naming rows. It receives no proof of zero exclusion, no analytic-continuation theorem, no global zero classifier, no host zero-location certificate, no quotient presentation, and no ambient-completeness witness.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip rh refusal`

Proof. First read the downstream surface through the fixed-strip modulus ledger. It confines the RH-facing request to the displayed zero-strip source, fixed-strip window, modulus comparison, and structural rows.

Next apply the RH-boundary NameCert handoff. The local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ handoff names the same fixed-strip source and modulus refusal ledger, not an analytic certificate.

Finally use the RH consumer boundary. The consumer receives only the finite BEDC witness boundary, so zero exclusion, analytic continuation, global zero classification, host zero-location certificates, quotient presentations, ambient completeness, and a proof of RH remain outside the accepted packet. □

Definition 548.323 (Critical-line witness signature-gap carrier)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Its signature-gap carrier is the finite packet readback*

$$\begin{aligned}
\mathsf{Sig}_{\mathsf{CriticalLineWitness}^{\uparrow}}(W) &= (Z, S, M, R, Q, H, C, P, N),\\
\mathsf{Gap}_{\mathsf{CriticalLineWitness}^{\uparrow}}(W) &= (Z, S) \mid (M, R, Q) \mid (H, C, P, N),\\
\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}(W) &= (Z, S, M, R, Q; \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, N).
\end{aligned}$$

The first row names the supplied zero-strip signature, the second row names the only admitted gap between source data and modulus-comparison data, and the third row records the local certificate route. All three rows are read over the same BHist*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Lean4 (definition) `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessSignatureGapCarrier`

Theorem 548.324 (Critical-line witness signature-gap exactness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every admitted signature-gap read of W factors through the supplied zero row Z, critical-strip row S, modulus row M, real-part row R, rational comparison ledger Q, componentwise* hsame *transport row H, displayed* Cont *replay row C,* Pkg *provenance row P, and local* NameCert *row N. Equivalently, the readback is exactly the carrier of Definition 548.323 and no further source, comparison, or naming row is available.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier signature gap exactness`

Proof. Project the accepted packet through Definition 548.1. The carrier exposes exactly $Z, S, M, R, Q, H, C, P, N$, so a signature-gap read starts from a finite BEDC tuple rather than from a host analytic object.

Use the root source triad of Definition 548.76 and the zero-strip source totality of Definition 548.180. These rows identify the supplied zero and critical-strip side with the $\mathsf{ZetaZeros}^{\uparrow}$ and $\mathsf{CritStrip}^{\uparrow}$ source surfaces before any modulus or comparison read is consumed.

Next apply the root comparison ledger Definition 548.77, the modulus-depth ledger Definition 548.181, and the modulus ledger totality Definition 548.275. They route the $\mathsf{Nat}^{\uparrow}$ depth, $\mathsf{Real}^{\uparrow}$ real-part, and $\mathsf{Rat}^{\uparrow}$ comparison data through M, R, Q under the same structural rows.

Finally use the transport replay obligation Definition 548.47 and the NameCert obligations of Definition 548.2. These attach hsame, Cont, Pkg, and the local NameCert row to the same carrier, so the admitted signature-gap read is exactly the displayed finite readback. □

Theorem 548.325 (Critical-line witness signature-gap non-escape)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, the signature-gap readback of Definition 548.323 cannot import an* RH *proof, zero search, analytic-continuation certificate, host equality, quotient representative, or ambient completeness witness. Every downstream consumer of the readback receives only the supplied zero-strip row, critical-strip row, modulus row, rational comparison ledger, componentwise transport, continuation replay, package provenance, and local naming route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier signature gap nonescape`

Proof. Begin with the signature-gap exactness theorem above. It reduces any admitted readback to the finite tuple $Z, S, M, R, Q, H, C, P, N$ and to the displayed Sig, Gap, and NameCert rows.

Then apply the root unblock refusal boundary Definition 548.5 and the RH-refusal ledger completeness theorem Definition 548.72. These results refuse proof content, global zero classification, zero search, analytic continuation, quotient representatives, host equality, and ambient completeness from the accepted packet.

Use the source-modulus refusal totality of Definition 548.292 together with the downstream refusal export Definition 548.113. They show that downstream consumers may replay only the supplied zero-strip, modulus, comparison, transport, package, and naming rows.

Thus the signature-gap carrier is a kernel-facing readback surface, not an analytic theorem source. Its non-escape content is exactly the absence of every listed host-level coordinate from the finite packet. □

Theorem 548.326 (Critical-line witness fixed-strip obstruction exactness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every fixed-strip obstruction read of W factors only through the finite source-modulus row, the supplied zero-strip row, the signature-gap readback, the* BHist *carrier, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row:*

$$Z, S, M, R, Q, H, C, P, N.$$

The read cannot be supplied by analytic continuation, host real equality, a hidden zero classifier, quotient presentation, ambient completeness, or an unrecorded fixed-strip witness.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip obstruction exactness`

Proof. Project the accepted packet through Definition 548.1. The only rows available to a fixed-strip obstruction read are the displayed source rows Z, S, the modulus and comparison rows M, R, Q, and the structural rows H, C, P, N.

Use Definition 548.59, Definition 548.64, and Definition 548.67. These rows identify the source-modulus and zero-strip inputs as finite BHist data before the obstruction is read.

Next apply Definition 548.317 and Definition 548.324. The fixed-strip source and the signature-gap readback are the same finite carrier surface, transported only through H and replayed only through C.

Finally use the route exposure package Definition 548.295 together with the RH non-escape package Definition 548.84. Since the exposed route contains no analytic-continuation, host-equality, quotient, completeness, hidden-classifier, or extra witness coordinate, the fixed-strip obstruction is exact for the displayed source-modulus package. □

Theorem 548.327 (Critical-line witness zeta-consumer non-escape)**.** *Every zeta-facing or* RH-*facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet that uses the fixed-strip obstruction must factor through the same finite readback*

$$Z, S, M, R, Q, H, C, P, N.$$

Such a consumer may read the source-modulus row, zero-strip row, signature-gap carrier, BHist *history,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. It cannot import analytic continuation, a completed zeta function, host real equality, or a standard bridge row for the composite route.*

Proof. Begin with Definition 548.326. Any consumer using the fixed-strip obstruction has already been confined to the displayed finite readback.

The downstream route is then controlled by Definition 548.295 and Definition 548.297. These theorems force zeta-facing and RH-facing reads through the source, modulus, refusal, transport, replay, provenance, and naming rows already present in W.

Use the zero-strip and RH-boundary rows Definition 548.296, Definition 548.82, and Definition 548.84. They route failed or excessive zeta requests to the visible refusal side instead of to analytic continuation, completed zeta data, host equality, or proof content.

Finally apply Definition 548.325. The signature-gap carrier exports no standard bridge row for the composite route, so a downstream consumer receives exactly the finite BEDC witness boundary and no analytic or bridge-level escape. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta consumer nonescape`

Theorem 548.328 (Critical-line witness root source coverage)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted source read exposed by W is covered by the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row Z, the* $\mathsf{CritStrip}^{\uparrow}$ *row S, the* $\mathsf{Nat}^{\uparrow}$ *depth row M, the* $\mathsf{Real}^{\uparrow}$ *real-part row R, the* $\mathsf{Rat}^{\uparrow}$ *comparison row Q, and the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *structure carried by H, C, P, N. No source read adds an analytic-continuation certificate, quotient representative, host equality, ambient completeness row, or proof of* RH.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source coverage`

Proof. Project the accepted packet through the carrier surface. The root source triad of Definition 548.76 exposes the supplied zero row, critical-strip row, and source-facing rational comparison row as finite data before any downstream consumer reads W.

Next attach the remaining carrier projections. The root comparison ledger Definition 548.77 accounts for M, R, Q, H, C, P, N, while the zeta dependency lattice Definition 548.169 places the zeta-facing source row on the existing $\mathsf{ZetaZeros}^{\uparrow}$ boundary rather than on a new analytic object.

The structural rows are therefore exactly the visible BHist carrier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row. The root refusal route then removes analytic continuation, quotient representatives, host equality, ambient completeness, and RH proof content from the source surface. □

Theorem 548.329 (Critical-line witness modulus-comparison transport stability)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, every modulus or rational-comparison route remains stable under componentwise* hsame *transport through the displayed H, C, P, N rows. The transported route still reads only the* $\mathsf{Nat}^{\uparrow}$ *depth row, the* $\mathsf{Real}^{\uparrow}$ *real-part row, the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger, the finite* BHist *carrier, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row; it cannot import an external modulus source, analytic estimate, quotient equality, host equality, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus comparison transport stability`

Proof. Start with the root comparison ledger Definition 548.77. It places every comparison read on M, R, Q, H, C, P, N, so the comparison has no coordinate outside the accepted packet.

Now apply the root modulus ledger scope Definition 548.92. This fixes the modulus and rational-comparison surface as the complete root-facing ledger before any transport is replayed by Cont or recorded by Pkg and NameCert.

Finally use the finite-budget ledger stability row Definition 548.308. It identifies componentwise hsame transport as preservation of the same displayed finite ledger, while the refusal ledger excludes analytic estimates, quotient equality, host equality, ambient completeness, and any off-packet modulus source. □

Theorem 548.330 (Critical-line witness root refusal-boundary totality)**.** *Every* RH*-facing or zeta-facing consumer of the source and transport surface of an accepted* CriticalLineWitness$^{\uparrow}$ *packet receives only the finite refusal boundary over*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer may read the supplied ZetaZeros$^{\uparrow}$ *and* CritStrip$^{\uparrow}$ *rows, the* Nat$^{\uparrow}$, Real$^{\uparrow}$, *and* Rat$^{\uparrow}$ *comparison surface, and the displayed* BHist/hsame/Cont/Pkg/NameCert *structure. It receives no proof of* RH*, global zero classifier, analytic-continuation theorem, quotient representative, host equality, ambient completeness row, or external zeta object.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root refusal boundary totality`

Proof. Begin with RH-refusal ledger completeness, Definition 548.72. It already classifies requests for RH proof data, global zero classification, analytic continuation, quotient representatives, host equality, and ambient completeness as refusal-side reads of the displayed packet.

Use the root RH-boundary refusal Definition 548.94 together with the zeta-consumer non-escape row Definition 548.327. The first keeps RH-facing requests on the finite refusal boundary, and the second prevents zeta-facing consumers from replacing the displayed packet by completed zeta data or an analytic continuation route.

Finally apply the RH-boundary refusal exhaustion row Definition 548.276. The source coverage and transport stability rows above account for every positive coordinate still readable by the consumer, so all remaining RH- or zeta-facing demands are total as refusals on $Z, S, M, R, Q, H, C, P, N$ and nowhere else. □

Theorem 548.331 (Critical-line witness root finite route totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every root-facing consumer of* W *reads only the supplied zero row, the critical-strip row, the modulus row, the real-part row, the rational comparison ledger, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows displayed by*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer exports no proof of RH*, global zero classifier, analytic-continuation certificate, quotient representative, host equality, or ambient completeness datum.*

Proof. Begin with carrier route exactness and the root-source triad, Definition 548.310 and Definition 548.76. They expose the supplied zero row, critical-strip row, and source-facing rational comparison row as finite BHist data before any root-facing consumer reads the packet.

Next apply the source-normalization interface and the modulus-ledger interface, Definition 548.59 and Definition 548.60. These rows place M, R, Q downstream of the already exposed Z, S source route and attach the read to the same hsame/Cont/Pkg/NameCert surface.

Finally use the RH-refusal ledger completeness row Definition 548.72. It removes proof of RH, global zero classification, analytic continuation, quotient representatives, host equality, and ambient completeness from every root-facing export, so the route is exactly the displayed finite packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root finite route totality`

Theorem 548.332 (Critical-line witness root modulus source exactness)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every root-facing modulus or rational-comparison read is sourced by* M, R, Q *only after the supplied* Z, S *source rows have been exposed. No modulus request may be completed from a hidden analytic estimate, host equality, quotient representative, ambient completeness row, external zero search, or proof of* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus source exactness`

Proof. First expose the source side by Definition 548.59 and Definition 548.76. These results place the zero row and critical-strip row in the accepted finite packet before any modulus or rational-comparison read is available to the root boundary.

Now apply the modulus-ledger interface Definition 548.60. It routes every modulus, real-part, and rational-comparison request through M, R, Q together with the displayed transport, continuation, package, and naming rows.

The exclusion of alternate sources follows from Definition 548.92 and Definition 548.292. Failed or off-route requests land in the finite refusal ledger rather than in analytic estimates, host equality, quotient representatives, ambient completeness, external zero search, or an RH proof. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootModulusSourceExactness`

Theorem 548.333 (Critical-line witness root refusal ledger non-escape)**.** *Every downstream* RH*-facing read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet remains attached to the displayed refusal ledger over*

$$Z, S, M, R, Q, H, C, P, N.$$

The ledger cannot be bypassed by host equality, quotient representatives, zero search, analytic continuation, ambient completeness, a standard bridge, or an off-packet modulus source.

Proof. Start with the finite route totality above. It identifies the root-facing source, modulus, comparison, transport, continuation, package, and naming surface as the entire packet available to downstream consumers.

Next apply the root refusal-boundary totality Definition 548.330 and the downstream RH boundary nonescape Definition 548.312. These rows keep RH-facing reads on the finite refusal side of the same displayed packet.

Finally use Definition 548.72 and Definition 548.87. The refusal ledger has no escape coordinate for host equality, quotient representatives, zero search, analytic continuation, ambient completeness, a standard bridge, or an off-packet modulus source, so every downstream read remains attached to the displayed ledger. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root refusal ledger nonescape`

Theorem 548.334 (Critical-line witness finite source lattice boundary)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The finite source lattice exposed by* W *is exactly the supplied zero row* Z*, critical-strip row* S*, modulus row* M*, real-part row* R*, rational comparison row* Q*,* BHist *carrier structure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row carried by* H, C, P, N*. The lattice factors through the zeta dependency lattice of Definition 548.169, the fixed-strip obstruction and zeta consumer*

rows of Definition 548.326 and Definition 548.327, and the root boundary totality rows of Definition 548.330. It exports no analytic-continuation theorem, host equality, quotient representative, ambient completeness row, or proof of RH.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier finite source lattice boundary`

Proof. Project the accepted carrier through Definition 548.1. The finite packet already displays $Z, S, M, R, Q, H, C, P, N$, so the source lattice has no coordinate outside the BHist tuple and its structural rows.

Use the zeta dependency lattice to place the zero-facing side behind the existing $\mathsf{ZetaZeros}^{\uparrow}$ and RH-boundary surfaces. Then use the fixed-strip obstruction and zeta-consumer rows to keep fixed-strip and zeta-facing reads on the same finite packet.

Finally apply root refusal-boundary totality. Any request for analytic continuation, host equality, quotient data, ambient completeness, or an RH proof is classified as absent from the displayed source lattice. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessFiniteSourceLatticeBoundary`

Theorem 548.335 (Critical-line witness RH consumer route)**.** *Every* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet that reads the finite source lattice must factor through*

$$Z, S, M, R, Q, H, C, P, N.$$

The route may use the zeta dependency lattice, fixed-strip obstruction surface, and root boundary totality rows, but it cannot add a private zero classifier, completed zeta object, analytic-continuation certificate, host equality row, quotient representative, ambient completeness row, or proof object for RH.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh consumer route`

Proof. Begin with Definition 548.334. It identifies the only source lattice available to an RH-facing consumer as the displayed packet rows and the visible BHist, hsame, Cont, Pkg, and NameCert structure.

The zeta dependency lattice fixes the zero-strip side before the modulus witness is read. The fixed-strip obstruction and zeta-consumer non-escape rows then route any obstruction or zeta-facing demand through the same finite readback.

Root boundary totality closes the remaining RH-facing demands. Since proof content, analytic continuation, quotient representatives, host equality, and ambient completeness are not carrier fields, the consumer route remains a refusal-side route over $Z, S, M, R, Q, H, C, P, N$. □

Theorem 548.336 (Critical-line witness NameCert row exhaustion)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows seen by finite source-lattice and* RH*-consumer reads are exhausted by carrier admission, zero-strip exposure, modulus and comparison exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No additional NameCert row can be inserted for analytic continuation, global zero classification, host equality, quotient presentation, ambient completeness, or* RH *proof export.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier namecert row exhaustion`

Proof. First read the existing NameCert obligations through the carrier. They place carrier admission, zero-strip compatibility, modulus discipline, ledger exactness, transport, replay, provenance, and naming on the same finite packet.

The finite source lattice theorem accounts for all source-facing rows. The RH consumer route theorem accounts for every downstream RH-facing read that can consume those rows.

Thus the local NameCert surface has no further row to expose. Any attempted analytic, host-level, quotient, completeness, or proof export is a request outside $Z, S, M, R, Q, H, C, P, N$ and is refused by the same root boundary. □

Theorem 548.337 (Critical-line witness root obligation image row)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet. Before any fixed-tuple* StandardBridge*-facing request, W exposes the finite image row*

$$Z, S, M, R, Q, H, C, P, N$$

as its root obligation image: supplied zero row, critical-strip source row, modulus row, real-part row, rational comparison row, componentwise transport, continuation replay, provenance, and local NameCert row. The image row contains no RH *proof content, zero-search oracle, analytic-continuation closure, quotient stream equality, or ambient completeness witness.*

Proof. Start with the critical-line witness root source rows. The root source triad and supplied source rows expose Z and S as finite BHist data before any bridge-facing read.

Add the modulus and comparison rows. The existing modulus and root comparison surfaces place M, R, Q on the same packet as the source rows and keep them under the displayed transport, replay, provenance, and local naming rows H, C, P, N.

Finally read the refusal ledger. The RH-facing refusal rows route requests for proof content, zero search, analytic-continuation closure, quotient stream equality, and ambient completeness to the boundary rather than to the fixed tuple. Thus the image row is the displayed finite packet and nothing outside it. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root fixed tuple image row`

Theorem 548.338 (Critical-line witness root readback row)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet $W = (Z, S, M, R, Q, H, C, P, N)$, every fixed-tuple readback request must read the source side Z, S, the modulus and comparison side M, R, Q, and the support side H, C, P, N component by component. The readback may cite the root source, modulus, comparison, and refusal rows, but it cannot import* RH *proof content, zero-search, analytic-continuation closure, quotient stream equality, or ambient completeness.*

Proof. Read the source side first. The root source rows expose the supplied zero and critical-strip source as finite rows of the accepted packet.

Read the modulus and comparison side next. The modulus route and rational comparison ledger identify M, R, Q as displayed rows, so a fixed-tuple consumer has no second modulus source and no host analytic estimate.

The support side is H, C, P, N. These rows provide componentwise transport, displayed replay, package provenance, and local naming, while the refusal rows keep RH proof content, zero search, analytic continuation, quotient stream equality, and ambient completeness outside the readback. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root readback row`

Theorem 548.339 (Critical-line witness root componentwise NameCert transport)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the fixed-tuple* StandardBridge*-facing surface transports componentwise through the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows. Each component of the tuple keeps its source, modulus, comparison, transport, replay, provenance, or naming role, and no transport step identifies the tuple with* RH *proof content, zero-search, analytic-continuation closure, quotient stream equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootComponentwiseNamecertTransport`

Proof. Use the root obligation image row to fix the finite tuple. It identifies the displayed image before any bridge-facing request.

Use the root readback row to read each component separately. The source rows Z, S, modulus and comparison rows M, R, Q, and support rows H, C, P, N already have distinct consumer roles.

Componentwise NameCert transport preserves those roles. Since the refusal ledger excludes proof content, zero search, analytic continuation, quotient equality, and ambient completeness, transport can only carry the finite tuple rows and cannot turn them into analytic or host-level data. □

Theorem 548.340 (CriticalLineWitness fixed-strip StdBridge route totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed zero-in-strip packet. The fixed-strip route from the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*,* $\mathsf{CritStrip}^{\uparrow}$ *row* S*,* $\mathsf{Nat}^{\uparrow}$ *depth row* M*,* $\mathsf{Real}^{\uparrow}$ *real-part row* R*,* $\mathsf{Rat}^{\uparrow}$ *comparison row* Q*, componentwise* hsame *row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row* N *to the standard finite-tuple* StandardBridge *surface is total as an obligation package. Every bridge-facing read either lands in the image, readback, transport, taste-gate, and refusal rows already displayed by the packet or is refused on the same finite* BHist *boundary. The route exposes no zero search, no proof of* RH*, no host complex equality, no quotient real equality, and no ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip stdbridge route totality`

Proof. Start with the fixed tuple premise surface of Definition 548.219. It supplies the finite image row, readback row, componentwise naming transport, and ChapterTasteGate row needed by the standard fixed finite BHist tuple surface.

Attach the fixed-strip carrier rows. The carrier route exactness theorem Definition 548.310 and the fixed-strip source tuple Definition 548.313 identify the visible packet with $Z, S, M, R, Q, H, C, P, N$, with no tenth coordinate.

Finally use the root refusal boundary totality theorem Definition 548.330. It sends all RH-facing, zero-search, analytic-continuation, host-equality, quotient-equality, and completeness requests to the displayed refusal side. Hence the bridge-facing route is total exactly over the finite obligation package. □

Theorem 548.341 (CriticalLineWitness componentwise StdBridge transport)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed zero-in-strip packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the standard finite-tuple* StandardBridge *route transports componentwise through the displayed* hsame *and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}}$ *rows. The* $\mathsf{ZetaZeros}^{\uparrow}$ *coordinate* Z*,* $\mathsf{CritStrip}^{\uparrow}$ *coordinate* S*,* $\mathsf{Nat}^{\uparrow}$ *coordinate* M*,* $\mathsf{Real}^{\uparrow}$ *coordinate* R*,* $\mathsf{Rat}^{\uparrow}$ *coordinate* Q*,* BHist *carrier,* hsame *transport row* H*,* Cont *replay row* C*,* Pkg *provenance row* P*, and naming row* N *keep their roles under transport; no component is identified with an* RH

proof, a zero-search witness, host complex equality, quotient real equality, analytic continuation, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier componentwise stdbridge transport`

Proof. Use the root componentwise NameCert transport theorem Definition 548.339. It already treats the fixed tuple as a componentwise route through the local naming rows rather than as a host-level equality.

Read back the tuple with Definition 548.218. The source rows Z, S, comparison rows M, R, Q, and support rows H, C, P, N each return to their own displayed coordinate through hsame, Cont, Pkg, and NameCert structure.

Now compare this readback with the route totality package of Definition 548.340. Since every bridge-facing request is already confined to the finite BHist surface or refused there, componentwise transport cannot collapse the rows into RH content, zero search, host equality, quotient equality, analytic continuation, or completeness data. □

Theorem 548.342 (CriticalLineWitness RH-boundary StdBridge nonescape)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed zero-in-strip packet routed to the standard finite-tuple* StandardBridge *surface. Every downstream* RH*-boundary consumer of this route receives only the displayed finite obligation package over* $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$. *The consumer may inspect the fixed-strip route, componentwise transport, and refusal ledger, but it receives no proof of* RH*, no zero-search method, no host complex equality, no quotient real equality, no analytic-continuation theorem, and no ambient completeness witness.*

Proof. Begin with the fixed-strip StdBridge route totality theorem Definition 548.340. It says that the bridge-facing route is exhausted by the finite image, readback, transport, taste-gate, and refusal rows of W.

Next apply componentwise StdBridge transport Definition 548.341. Transport preserves the row roles for $Z, S, M, R, Q, H, C, P, N$ and does not identify any row with host or quotient equality.

Finally use the downstream RH boundary nonescape theorem Definition 548.312 together with root refusal boundary totality Definition 548.330. These rows place every RH-facing demand on the same refusal boundary, so the downstream consumer cannot escape the standard finite-tuple package to obtain RH proof content, zero search, analytic continuation, host equality, quotient equality, or completeness data. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh boundary stdbridge nonescape`

Theorem 548.343 (Critical-line witness modulus consumer coverage)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted critical-line consumer route that uses the source-modulus row is covered by the finite* BHist *source Z, S, the zero-strip witness, the rational modulus ledger M, R, Q, the componentwise* hsame *transport row H, the displayed* Cont *replay row C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. The route exposes those BEDC rows before any downstream read and exposes no proof of* RH*, no analytic-continuation theorem, and no completed zero classifier.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus consumer coverage`

Proof. Begin with the root finite readback totality row Definition 548.346. It places every root readback on the displayed packet rows $Z, S, M, R, Q, H, C, P, N$ together with their finite BHist, hsame, Cont, Pkg, and local NameCert surface.

Next attach the source-modulus interface. The root source-modulus admission row Definition 548.64 and the root modulus classifier exactness row Definition 548.347 force the source side Z, S and the ledger side M, R, Q to be consumed through the same transport, replay, provenance, and naming rows.

Finally use the zeta dependency lattice Definition 548.169. It keeps the zeta-facing source as a dependency on the displayed ZetaZeros$^{\uparrow}$ and RH-boundary surfaces rather than as an analytic-continuation object. Hence a critical-line consumer using the source-modulus row sees exactly the finite BEDC coverage stated above. □

Theorem 548.344 (Critical-line witness zero-strip readback separation)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, zero-strip readback cannot be consumed as a proof of* RH*, a host analytic-continuation theorem, or a completed zero classification unless the displayed source-modulus rows* $Z, S, M, R, Q, H, C, P, N$ *and the fixed-strip rows of Definition 548.313 are present. Without those rows the readback remains a refusal-side BEDC boundary and has no consumer coordinate for RH proof content, analytic continuation, host zero search, quotient equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero strip readback separation`

Proof. Read the zero-strip side first. The zero-strip readback totality theorem Definition 548.209 routes the readback through the supplied zero and strip rows and through H, C, P, N.

Attach the source-modulus rows. The modulus consumer coverage theorem above and the fixed-strip source readback totality row Definition 548.268 require the displayed M, R, Q ledger and the fixed-strip tuple before a downstream consumer can read the zero-strip package.

It remains to exclude the forbidden interpretations. The root refusal boundary totality theorem Definition 548.330 and the zeta dependency lattice Definition 548.169 classify RH proof requests, analytic-continuation requests, host zero-search requests, quotient-equality requests, and completed-zero-classification requests as refusal-side demands unless the displayed BEDC rows are present. Thus the zero-strip readback is separated from those stronger consumers. □

Theorem 548.345 (Critical-line witness fixed-strip bridge consumer totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* CriticalLineWitness$^{\uparrow}$ *fixed zero-in-strip packet. The fixed-strip bridge consumer surface is exhausted by the finite witness rows named in Definition 548.337, Definition 548.338, Definition 548.339, and Definition 548.340. Every consumer either reads one of those image, readback, componentwise transport, source-modulus, fixed-strip, provenance, naming, or refusal rows, or is refused on the same finite* BHist *boundary. No consumer receives an* RH *proof, host analytic continuation, global zero classification, host equality, quotient equality, or ambient completeness.*

Proof. Start with the root fixed-tuple bridge rows. The image, readback, and componentwise NameCert transport theorems identify the finite rows visible to a bridge-facing consumer before any standard bridge route is read.

Now apply the fixed-strip StdBridge route totality theorem Definition 548.340. It says that the bridge-facing route is total exactly over the finite obligation package built from $Z, S, M, R, Q, H, C, P, N$ and the refusal side of the same packet.

Finally combine the modulus consumer coverage and zero-strip readback separation theorems above. They account for the source-modulus and zero-strip consumers that feed the fixed-strip

bridge surface, while the root refusal boundary totality theorem refuses RH proof content, analytic continuation, global zero classification, host equality, quotient equality, and completeness outside the displayed packet. Therefore the fixed-strip bridge consumer surface is exhausted by the named finite witness rows. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip bridge consumer totality`

Theorem 548.346 (Critical-line witness root finite readback totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root finite readback exposed by W is read through exactly the displayed packet rows $Z, S, M, R, Q, H, C, P, N$ together with their finite* BHist*, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *surface. No root readback imports an analytic-continuation row, host equality, quotient representative, ambient completeness coordinate, global zero-search coordinate, or proof of* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root finite readback totality`

Proof. Begin with the root source triad Definition 548.76. It exposes the supplied zero row Z, the critical-strip row S, and the source-facing comparison row as finite packet data before any downstream consumer reads W.

Next attach the comparison and dependency rows. The root comparison ledger Definition 548.77 accounts for M, R, Q, H, C, P, N, while the zeta dependency lattice Definition 548.169 keeps zeta-facing reads on the existing $\mathsf{ZetaZeros}^{\uparrow}$ and boundary surfaces rather than on a new analytic object.

Finally apply root refusal boundary totality Definition 548.330. The positive rows have already been exhausted by $Z, S, M, R, Q, H, C, P, N$, so every remaining request is refused on the displayed finite boundary and cannot be repackaged as analytic continuation, host equality, quotient data, ambient completeness, zero search, or RH proof content. □

Theorem 548.347 (Critical-line witness root modulus classifier exactness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. After the zero-strip source rows Z and S have been supplied, the modulus and rational comparison classifier of W is exhausted by the displayed rows M, R, Q, H, C, P, N. The classifier reads the* $\mathsf{Nat}^{\uparrow}$ *depth,* $\mathsf{Real}^{\uparrow}$ *real-part,* $\mathsf{Rat}^{\uparrow}$ *comparison ledger, transport, continuation, provenance, and local naming rows, and it has no additional coordinate for zero search, analytic continuation, quotient representatives, host equality, ambient completeness, or an* RH *proof.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus classifier exactness`

Proof. First use the root source triad Definition 548.76. It supplies the zero-strip source side Z, S and fixes the source-facing comparison entry as a finite row of the accepted packet.

Now apply the root comparison ledger Definition 548.77. Once Z and S are available, every modulus or rational comparison read is routed through M, R, Q and carried by H, C, P, N.

The zeta dependency lattice Definition 548.169 prevents the classifier from being replaced by a completed zeta or analytic-continuation object. Combining that lattice with the root refusal route Definition 548.78 sends every off-packet classifier demand to refusal, so the displayed modulus and comparison rows are exact. □

Theorem 548.348 (Critical-line witness root RH consumer refusal)**.** *Every* RH*-facing consumer of an accepted* CriticalLineWitness$^{\uparrow}$ *packet receives only the displayed finite refusal boundary over*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer may read the supplied zero-strip, critical-strip, modulus, real-part, rational-comparison, transport, continuation, package, and naming rows. It receives no RH *proof, zero search, analytic-continuation row, quotient representative, host equality, or completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root rh consumer refusal certificate`

Proof. Start from the root refusal route Definition 548.78. It classifies RH-facing requests as finite refusal reads rather than as analytic proof surfaces.

Next combine the root source triad and the root comparison ledger, Definition 548.76 and Definition 548.77. These rows account for every positive packet coordinate visible to the consumer, namely $Z, S, M, R, Q, H, C, P, N$.

Finally use the zeta dependency lattice Definition 548.169 together with root refusal boundary totality Definition 548.330. The lattice supplies only dependency information over the existing zeta-facing surfaces, and the boundary theorem refuses all remaining RH proof, zero-search, analytic-continuation, quotient, host-equality, and completeness demands on the displayed finite boundary. □

Theorem 548.349 (Critical-line witness root budget-selector totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* CriticalLineWitness$^{\uparrow}$ *root packet, and let* B *be an accepted finite observation-budget selector row for the same root readback surface. Every root consumer that reads* W *through* B *is exhausted by the displayed* BHist *rows* Z, S, M, R, Q*, the componentwise* hsame *support* H*, the displayed* Cont *route* C*, the* Pkg *provenance* P*, and the local* NameCert *row* N*. The selector may bound finite requests, but it cannot add host* RH *truth, analytic continuation, ambient completeness, or a hidden zero-location selector.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root budget selector totality`

Proof. Begin with root finite readback totality, Definition 548.346. It identifies the positive root readback surface as the finite packet $Z, S, M, R, Q, H, C, P, N$.

Attach the selector side through Definition 782.7 and Definition 782.14. Those rows bound the observation request and keep selector-facing reads inside finite BHist, hsame, Cont, Pkg, and NameCert support.

Finally apply the root refusal boundary, Definition 548.330. Every request for host RH truth, analytic continuation, ambient completeness, or hidden zero-location data is refused outside the displayed packet. □

Theorem 548.350 (Critical-line witness root strip-window exhaustion)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* CriticalLineWitness$^{\uparrow}$ *root packet whose finite selector route displays the same fixed-strip window rows as the root source surface. Then every fixed-strip or zero-strip readback over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *factors through* $Z, S, M, R, Q, H, C, P, N$ *before any refusal row is exported. No consumer may replace the fixed-strip window by analytic continuation, ambient completeness, host* RH *truth, or an unrecorded zero-location selector.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root strip window exhaustion`

Proof. Use the fixed-strip source rows first. The fixed-strip source totality and source readback theorems, Definition 548.317 and Definition 548.268, place strip-facing reads on the displayed root packet.

Now route the window through the finite selector. By Definition 548.349, any selector-bound root consumer keeps the same BHist, hsame, Cont, Pkg, and NameCert support rows.

The exhaustion claim follows from the fixed-strip row exhaustion theorem Definition 548.314. Its refusal side excludes off-packet strip data, and the selector route adds no analytic-continuation, completeness, host-truth, or hidden-zero coordinate. □

Theorem 548.351 (Critical-line witness root refusal-ledger pullback)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *root packet, and suppose a finite observation-budget selector and an RH-boundary sibling read the same displayed root rows over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. Then their refusal ledgers pull back to the same finite packet $Z, S, M, R, Q, H, C, P, N$: every refused request for host* RH *truth, analytic continuation, ambient completeness, or hidden zero-location selection is recorded on that packet-local ledger and nowhere else.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root refusal ledger pullback`

Proof. Start with the root refusal consumer exactness theorem Definition 548.101. It makes refusal-facing consumers read the displayed finite root packet rather than a host analytic object.

Attach the RH boundary sibling through Definition 548.90 and Definition 548.348. These rows keep every RH-facing request on the same root refusal surface.

Finally apply Definition 548.349. The finite observation-budget selector bounds the read but does not change the refusal ledger. Hence the selector-facing and RH-boundary-facing refusal rows pull back to the same packet-local BHist, hsame, Cont, Pkg, and NameCert surface. □

Theorem 548.352 (Critical-line witness root source totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. Every finite source row available at the root is displayed by Z, S, M, R, Q and is carried by the same* BHist*, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *support rows H, C, P, N. No root source row is supplied by analytic continuation, host equality, quotient representatives, an ambient completeness coordinate, global zero search, or an* RH *truth claim.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root source totality`

Proof. Begin with the supplied root source rows. The root source triad of Definition 548.76 exposes the zero row, critical-strip row, and source-facing comparison entry as finite packet data before downstream consumers inspect W.

Next use the finite readback totality row Definition 548.346. It says that root readbacks are already exhausted by $Z, S, M, R, Q, H, C, P, N$.

Finally attach the refusal boundary. The root refusal boundary totality theorem Definition 548.330 sends every off-packet request to the displayed finite refusal surface, so no analytic-continuation, host-equality, quotient, completeness, zero-search, or RH truth coordinate can serve as a source row. □

Theorem 548.353 (Critical-line witness root modulus separation)**.** *For an accepted* CriticalLineWitness$^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, the zero-strip source rows Z, S and the modulus/classifier rows M, R, Q are separated by the displayed finite route. A consumer may read M, R, Q only after the source rows have been supplied, transported through H, and replayed through C; it may not fold*

the modulus row into a zero-search oracle, analytic-continuation row, quotient representative, host equality test, ambient completeness witness, or RH *proof.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root modulus separation`

Proof. First read the root source totality just established in Definition 548.352. The source side of the accepted packet is finite and exhausted before any classifier demand is considered.

Now apply the modulus classifier exactness theorem Definition 548.347. Once Z and S are present, every modulus and rational-comparison read is routed through M, R, Q and the support rows H, C, P, N.

The zeta dependency lattice Definition 548.169 keeps the zeta-facing dependency surface distinct from the local modulus classifier. Combining that lattice with the root refusal route Definition 548.78 rejects every demand that treats the modulus as zero search, analytic continuation, quotient data, host equality, ambient completeness, or an RH proof. □

Theorem 548.354 (Critical-line witness root downstream totality)**.** *Every downstream critical-line, zeta-boundary, or* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet factors through the displayed finite packet*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer may read the finite source rows, zero-strip row, modulus/classifier rows, rational comparison ledger, transport rows, continuation routes, provenance, and local naming row. It receives no analytic-continuation object, host equality, quotient representative, ambient completeness coordinate, global zero-search row, or RH *truth claim.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root downstream totality`

Proof. Start with root source totality from Definition 548.352. It exhausts the positive source rows of the accepted packet by $Z, S, M, R, Q, H, C, P, N$.

Next apply root modulus separation from Definition 548.353. The classifier and rational-comparison rows are downstream of the displayed zero-strip source route, not substitutes for an analytic or global zero-search surface.

Finally combine root RH consumer refusal Definition 548.348 with the zeta dependency lattice Definition 548.169. These rows route downstream consumers through the finite packet and refuse every remaining demand for analytic continuation, host equality, quotient representatives, ambient completeness, global zero search, or RH truth. □

Theorem 548.355 (Critical-line witness source modulus terminality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted source-modulus read of* W *terminates at the displayed finite source rows* Z, S*, the modulus and rational-comparison rows* M, R, Q*, and the support rows* H, C, P, N*. Thus the read is carried by the finite* BHist *source, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows already present in the packet.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus terminal determinacy`

Proof. Project the carrier in Definition 548.1. Its accepted packet coordinates are the finite source rows Z, S, the modulus and comparison rows M, R, Q, and the structural rows H, C, P, N.

Apply the source-modulus refusal totality theorem Definition 548.292 and the window-modulus exhaustion theorem Definition 548.298. Together they force every source-window read that asks

for the modulus to pass through the displayed zero-strip source, rational-height modulus, BHist, hsame, Cont, Pkg, and local NameCert rows.

Finally use root finite readback totality Definition 548.346. Since every root readback is exhausted by $Z, S, M, R, Q, H, C, P, N$, there is no further source coordinate at which a source-modulus read can continue. The accepted read therefore terminates at the displayed finite packet surface. □

Theorem 548.356 (Critical-line witness source-window RH boundary)**.** *Every* RH*-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet must pass through the displayed source-window route and zero-strip boundary before using the critical-line witness. In particular, any such consumer reads the finite packet*

$$Z, S, M, R, Q, H, C, P, N$$

through the visible source rows, the zero-strip source boundary, the componentwise hsame *transport, the displayed* Cont *and* Pkg *rows, and the local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row.*

Proof. First apply source-window route lock Definition 548.186. It places the consumer behind the visible source-window route before any downstream critical-line use is permitted.

Next use zero-strip consumer boundary Definition 548.143 together with root RH source lock Definition 548.258. These rows require the consumer to cross the zero-strip boundary and the displayed source support before it can make an RH-facing request.

Finally compose with root downstream totality Definition 548.354. The downstream consumer is therefore routed through $Z, S, M, R, Q, H, C, P, N$ and cannot use the critical-line witness before the source-window, zero-strip, hsame, Cont, Pkg, and NameCert rows have been exposed. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source window rh boundary`

Theorem 548.357 (Critical-line witness finite source route saturation)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the finite source route is exhausted by the displayed source, modulus, rational-comparison,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows. The route exports no hidden analytic continuation, global zero oracle, host equality test, ambient quotient representative, or proof of* RH*.*

Proof. Begin with root source totality Definition 548.352. It identifies every finite source row visible at the root with the displayed packet coordinates $Z, S, M, R, Q, H, C, P, N$.

Then attach source modulus terminality from Definition 548.355. The source-modulus reads cannot pass beyond the finite BHist, hsame, Cont, Pkg, and local NameCert support rows of the packet.

It remains to rule out hidden exports. Apply root RH consumer refusal Definition 548.348 and root refusal boundary totality Definition 548.330. These rows refuse the off-route demands for analytic continuation, global zero search, host equality, quotient data, ambient completeness, and RH proof content, so the finite source route is saturated by the displayed rows alone. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier finite source route saturation`

Theorem 548.358 (Critical-line witness classifier exactness)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The classifier available at the root is determined only by the supplied zero row* Z*, the critical-strip row* S*, and the displayed support rows* H, C, P, N*. It cannot be replaced by host equality, zero search, analytic continuation, quotient representatives, or ambient completeness; any accepted classifier read must remain on the finite* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *surface displayed by* W*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier classifier exactness`

Proof. Project the carrier of Definition 548.1. Its source side displays exactly the supplied zero row Z, the supplied strip row S, and the support rows H, C, P, N before any public critical-line read is available.

Apply the NameCert obligations of Definition 548.2. The zero-strip compatibility row binds Z and S through displayed hsame transport, while carrier admission and non-escape keep the classifier read inside the same finite packet.

Finally use the root source triad Definition 548.76 and the root unblock refusal boundary Definition 548.5. They expose the finite source rows and refuse host equality, zero search, analytic continuation, quotient representatives, and ambient completeness as alternate classifier sources. Thus the classifier is exact only through Z, S, H, C, P, N. □

Theorem 548.359 (Critical-line witness ledger route stability)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The modulus and comparison ledger route through M, R, Q is stable under the displayed* hsame *transports,* Cont *replay rows,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. Every accepted comparison read therefore uses the same packet-local route M, R, Q, H, C, P, N and does not branch to a host comparison, quotient representative, analytic continuation row, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier ledger route stability`

Proof. Read the modulus and comparison coordinates from Definition 548.1. The packet lists M as the depth-to-line modulus row, R as the consumed real-part row, and Q as the rational comparison ledger.

Use Definition 548.2. Its modulus discipline and ledger-exactness rows attach M, R, Q to the same displayed H, C, P, N support, so comparison reads are transported, replayed, recorded, and named inside the accepted packet.

It remains to rule out alternate ledger routes. The root source triad Definition 548.76 keeps the source side finite, and the root unblock refusal boundary Definition 548.5 refuses the host, quotient, analytic-continuation, and completeness replacements. Hence the M, R, Q ledger route is stable exactly under the displayed hsame/Cont/Pkg/NameCert rows. □

Theorem 548.360 (Critical-line witness downstream consumer unblock)**.** *Every downstream* RH*-boundary consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet may cite only the finite surface*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer may use this surface as the supplied zero row, supplied strip row, modulus row, real-part row, rational comparison ledger, transport row, continuation row, provenance row, and local naming row; it may not cite an RH *proof, a global zero classifier, a zero-producing search, host equality, analytic continuation, quotient representatives, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier downstream consumer unblock`

Proof. Start from the carrier definition Definition 548.1. It makes $Z, S, M, R, Q, H, C, P, N$ the visible packet and withholds every global analytic or host-level coordinate from the carrier.

Next apply Definition 548.2. Carrier admission, non-escape, and ledger exactness say that accepted public reads are exhausted by the displayed packet rows and their local NameCert support.

Finally combine the root source triad Definition 548.76 with the root unblock refusal boundary Definition 548.5. The triad exposes the finite zero-strip and comparison source before downstream use, and the refusal boundary removes every off-packet RH, zero-search, host-equality, analytic-continuation, quotient, and completeness demand. Therefore downstream consumers are unblocked precisely by the finite $Z, S, M, R, Q, H, C, P, N$ surface. □

Theorem 548.361 (CriticalLineWitness source-signature readback)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted source-signature readback of W reads the critical-strip source only through the displayed finite source rows Z, S, the signature and gap rows of Definition 548.323, and the zeta,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Rat}^{\uparrow}$ *dependency routes recorded by M, R, Q, H, C, P, N. No accepted readback can replace those rows by an unledgered critical-strip conclusion, analytic-continuation certificate, host zero witness, quotient representative, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source signature readback`

Proof. Begin with the signature-gap carrier Definition 548.323. It identifies the source signature as the same finite packet $Z, S, M, R, Q, H, C, P, N$ and places the gap row between Z, S and M, R, Q under the displayed BHist, hsame, Cont, Pkg, and local NameCert surface.

Apply the signature-gap exactness theorem Definition 548.324. It forces every admitted signature-gap read to factor through the supplied zero row, critical-strip row, modulus row, real-part row, rational comparison ledger, transport, replay, provenance, and naming rows.

Finally use the zeta dependency lattice Definition 548.169 together with the root modulus readback row Definition 548.129. These rows place the zeta-facing, $\mathsf{Real}^{\uparrow}$-facing, and $\mathsf{Rat}^{\uparrow}$-facing dependencies behind the displayed packet route, so the source-signature readback has no coordinate for a hidden critical-strip theorem or host analytic witness. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source signature gap readback`

Theorem 548.362 (CriticalLineWitness GAP-policy stability)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Transport by the displayed* hsame *row H and replay by the displayed* Cont *row C preserve the refusal rows and the gap-policy rows of Definition 548.323. They do not convert an absent zero row, a refused* RH *request, or a missing analytic-continuation route into a zero witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier gap policy stability`

Proof. Read the policy row from Definition 548.323. The gap separates the source side Z, S from the modulus and comparison side M, R, Q while keeping both sides under the same transport, replay, provenance, and naming rows.

Use Definition 548.325. It records that the signature-gap readback cannot import an RH proof, zero search, analytic-continuation certificate, host equality, quotient representative, or ambient completeness witness.

Now apply the ledger route stability theorem Definition 548.359. Since H, C, P, N preserve the same M, R, Q comparison route, transport and replay can only move the displayed gap-policy row along the accepted packet route.

The refusal side is therefore stable as refusal. The root unblock refusal boundary Definition 548.5 keeps refused RH, analytic, host, quotient, and completeness requests outside the packet, so hsame/Cont transport cannot turn those refusals into a zero witness. □

Theorem 548.363 (CriticalLineWitness NameCert route exhaustion)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every accepted consumer route factors through the displayed* BHist *carrier,* Cont *replay row,* hsame *transport row,* Pkg *provenance row, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. The route can consume only the source, signature, gap, modulus, real-part, and rational-comparison rows already displayed in* W*; it cannot read an unledgered* RH *conclusion or an unledgered critical-strip conclusion.*

Proof. Start from the accepted carrier and the NameCert obligation surface. The carrier Definition 548.1 exposes only $Z, S, M, R, Q, H, C, P, N$, and Definition 548.2 attaches the local naming obligations to those same rows.

Next combine the route readback exhaustion theorem Definition 548.154 with the downstream consumer unblock theorem Definition 548.360. Together they say that every downstream consumer reads the finite surface already displayed by the packet and cannot branch to host equality, analytic continuation, quotient representatives, ambient completeness, global zero classification, or an RH proof.

It remains to include the source-signature and gap-policy rows. The source-signature readback theorem above confines the critical-strip source to the displayed finite signature route, and the GAP-policy stability theorem above keeps refusals stable under H and C.

Thus every accepted route factors through BHist, Cont, hsame, Pkg, and NameCert over the displayed packet rows. Any route that asks for an unledgered RH or critical-strip conclusion is not an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ consumer route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier namecert route exhaustion`

Theorem 548.364 (CriticalLineWitness source-modulus public readiness)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The source-modulus public surface of* W *is ready exactly when the supplied zero row* Z*, fixed-strip source row* S*, modulus row* M*, real-part row* R*, rational comparison ledger* Q*, componentwise* hsame *transport row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row* N *are all readable as one finite* BHist *packet. The readiness route is the one already exposed by the CriticalLineWitness NameCert obligations, the fixed-strip source totality rows, the zeta dependency lattice, and the signature-gap readback surface.*

This public route exports source-modulus data only through $Z, S, M, R, Q, H, C, P, N$*. It exports no analytic continuation theorem, host equality, quotient representative, ambient completeness coordinate, zero-search oracle, selected host limit, or* RH *proof content.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus public readiness`

Proof. Begin with the carrier and naming surface. The carrier of Definition 548.1 and the CriticalLineWitness NameCert obligations of Definition 548.2 expose exactly the rows $Z, S, M, R, Q, H, C, P, N$ and attach the local name to that finite route.

Next use the fixed-strip source rows. Fixed-strip source totality and fixed-strip source readback totality place the strip-facing source inside the same BHist, hsame, Cont, Pkg, and NameCert packet, so the public source-modulus read cannot split the source from the modulus row.

Finally combine the zeta dependency lattice Definition 548.169 with the signature-gap readback theorem Definition 548.361. These rows keep zeta-facing and signature-facing reads behind $Z, S, M, R, Q, H, C, P, N$, leaving no displayed coordinate for analytic continuation, host equality, quotient representatives, ambient completeness, zero search, selected host limits, or RH proof content. □

Theorem 548.365 (CriticalLineWitness source-modulus consumer non-escape)**.** *Every public consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *source-modulus packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *factors through the source-modulus public readiness route of Definition 548.364. The consumer may read the supplied zero row, fixed-strip source row, modulus row, real-part row, rational comparison ledger, transport, replay, provenance, and local naming row, but no consumer route escapes to analytic continuation, host equality, quotient representatives, ambient completeness, zero search, selected host limits, or* RH *proof content.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus consumer nonescape`

Proof. First apply Definition 548.364. It identifies the public source-modulus surface with the single finite packet $Z, S, M, R, Q, H, C, P, N$ and records the fixed-strip, zeta dependency, and signature-gap readback anchors that support that packet.

Now use the existing route exhaustion rows. The source-modulus refusal totality theorem Definition 548.292 and the NameCert route exhaustion theorem Definition 548.363 say that downstream consumers remain on the displayed BHist, hsame, Cont, Pkg, and NameCert route.

Thus a consumer can only replay the displayed source-modulus rows. Requests for analytic continuation, host equality, quotient representatives, ambient completeness, zero search, selected host limits, or RH proof content have no carrier row and therefore cannot form an accepted consumer route. □

Theorem 548.366 (CriticalLineWitness source-modulus NameCert readiness)**.** *The local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}}$ *row* N *certifies the source-modulus public surface of an accepted packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *precisely over the finite route displayed in Definition 548.364 and protected by Definition 548.365. The certificate binds the supplied zero row, fixed-strip source row, modulus row, real-part row, rational comparison ledger, transport, replay, and provenance rows as one public source-modulus package.*

Consequently the NameCert readiness claim is a finite BEDC obligation over BHist, hsame, Cont, Pkg, *and* NameCert, *not a claim of analytic continuation, host equality, quotient representative selection, ambient completeness, zero search, selected host limits, or* RH *proof content.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus namecert readiness`

Proof. Start with the local naming obligations in Definition 548.2. They attach N to the displayed carrier rows and make the local name depend on the same transport, replay, and provenance coordinates as the source-modulus route.

Next use public readiness and consumer non-escape. The readiness theorem supplies the public packet $Z, S, M, R, Q, H, C, P, N$, while the non-escape theorem blocks every consumer route outside that packet. Hence the local NameCert row certifies the public source-modulus surface only through the displayed finite route.

The remaining exclusions follow from the same row inventory. Since no row of W carries analytic continuation, host equality, quotient representatives, ambient completeness, zero search, selected host limits, or RH proof content, the local NameCert readiness surface cannot certify any of those objects. □

Theorem 548.367 (CriticalLineWitness route classifier exhaustion)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted classifier read of* W *is exhausted by the finite zero-strip, modulus, comparison, transport, continuation, provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$

rows

$$Z, S, M, R, Q, H, C, P, N.$$

The read has no accepted coordinate for host equality, zero search, analytic-continuation certificates, quotient representatives, ambient completeness, a global zero classifier, or a proof of RH.

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRouteClassifierExhaustion`

Proof. Start with classifier exactness, Definition 548.358. It identifies the root classifier with the supplied zero row Z, the supplied critical-strip row S, and the displayed BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ surface carried by H, C, P, N.

Next apply ledger route stability, Definition 548.359. The modulus, real-part, and rational-comparison rows M, R, Q remain attached to the same transport, replay, provenance, and naming route, so the classifier cannot branch to an off-packet comparison or host representative.

Finally combine downstream consumer unblock, Definition 548.360, with source-signature readback, Definition 548.361. These rows make the finite packet the whole admitted source and consumer surface. Hence every accepted classifier read is exhausted by $Z, S, M, R, Q, H, C, P, N$ and every analytic, host, quotient, completeness, global zero-classification, or RH demand is refused outside the route. □

Theorem 548.368 (CriticalLineWitness fixed-strip zeta consumer separation)**.** *For an accepted fixed-strip* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, fixed-strip source reads and zeta-facing downstream consumers remain separated by the displayed signature, gap, and ledger rows. The fixed-strip side may read the supplied zero and strip rows* Z, S*, while the zeta-facing consumer may read only the modulus, comparison, transport, continuation, provenance, and naming rows* M, R, Q, H, C, P, N *already displayed by the same packet. No accepted consumer route imports an* RH *proof or analytic-continuation certificate across that separation.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessFixedStripZetaConsumerSeparation`

Proof. Read the source side through Definition 548.361. It places the critical-strip source behind the displayed finite signature route and the gap row, rather than behind a hidden analytic-continuation or host-zero coordinate.

Apply gap-policy stability, Definition 548.362. The displayed hsame transport and Cont replay preserve refusal rows as refusal rows, so moving along H and C cannot turn a missing analytic or RH coordinate into accepted source data.

Now use the fixed-strip zeta consumer boundary, Definition 548.375, and ledger route stability, Definition 548.359. The zeta-facing consumer receives the refusal budget and rational comparison ledger through M, R, Q, H, C, P, N on the same finite route.

Thus the fixed-strip source and downstream zeta consumer meet only at the displayed signature, gap, and ledger rows. The route supplies no RH proof, analytic-continuation certificate, host equality, quotient representative, or ambient-completeness datum. □

Theorem 548.369 (CriticalLineWitness finite NameCert consumer route)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *consumer route factors through the displayed* BHist *carrier,* hsame *transport row,* Cont *replay row,* Pkg *provenance row, and local naming row of* W*. The route may consume only the local source, signature, gap, modulus, comparison, and refusal rows already named by* $Z, S, M, R, Q, H, C, P, N$*.*

Proof. Begin with NameCert route exhaustion, Definition 548.363. It already forces accepted consumer routes through the packet-local BHist, Cont, hsame, Pkg, and $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ surface.

Attach the classifier and ledger rows. Classifier exactness Definition 548.358 binds classifier reads to Z, S, H, C, P, N, while ledger route stability Definition 548.359 binds comparison reads to M, R, Q, H, C, P, N.

It remains to include the source and downstream interfaces. Source-signature readback Definition 548.361 keeps the source behind the displayed signature and gap rows, and downstream consumer unblock Definition 548.360 confines every consumer to the finite packet surface.

Therefore every accepted NameCert consumer route factors through the displayed BHist, hsame, Cont, Pkg, and local naming rows. A route that asks for host equality, analytic continuation, quotient representatives, ambient completeness, global zero classification, or an RH proof is outside the accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ consumer route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessFiniteNameCertConsumerRoute`

Theorem 548.370 (Critical-line witness root classifier readiness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ root packet. The root classifier is ready exactly on the displayed finite* BHist *route through the source row Z, strip row S, transport row H, continuation row C, provenance row P, and local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ row N. Componentwise* hsame *transport and* Cont *replay preserve that classifier surface, while* Pkg *provenance records it as part of the same accepted packet. No host zero search, analytic-continuation certificate, quotient representative, ambient completeness witness, or proof of* RH *supplies an alternate classifier.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root classifier readiness`

Proof. Project the root source and zero-strip rows already exposed by the carrier and root source files. The source row Z and strip row S are the classifier inputs before any downstream read is available.

Use the root source, modulus, and zero-strip obligation rows from the sibling files. They bind the classifier to the displayed BHist packet and preserve it under hsame transport and Cont replay along H and C.

Finally attach the package and local name. The refusal and downstream-readback rows keep host zero search, analytic continuation, quotient representatives, ambient completeness, and RH proof objects outside the accepted route, so the classifier is ready precisely on Z, S, H, C, P, N. □

Theorem 548.371 (Critical-line witness root ledger readiness)**.** *For an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ root packet $W = (Z, S, M, R, Q, H, C, P, N)$, the modulus and comparison ledger is ready exactly through M, R, Q, H, C, P, N. The row M supplies the root modulus budget, R supplies the consumed real-part row, Q supplies the rational comparison ledger, H records componentwise* hsame *transport, C records the displayed* Cont *route, P records* Pkg *provenance, and N records the local* NameCert *row. The ledger has no accepted coordinate for host comparison, quotient equality, analytic continuation, ambient completeness, or an* RH *certificate.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root ledger readiness`

Proof. Read the modulus rows first. The sibling root modulus and zero-strip package files display M as the finite budget through which the strip source can be consumed.

Next read the comparison rows. The existing downstream-readback and classifier ledger files attach R and Q to the same route and keep them stable under the displayed hsame transport and Cont replay.

The package row and local name then close the ledger surface. Because the refusal rows exclude host comparisons, quotient equality, analytic continuation, ambient completeness, and RH proof data, every accepted ledger read is the finite route M, R, Q, H, C, P, N. □

Theorem 548.372 (Critical-line witness root consumer readiness)**.** *Every root consumer of an accepted* CriticalLineWitness$^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *is ready on the combined source, classifier, ledger, and naming surface*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer reads this surface through the displayed BHist *carrier, componentwise* hsame *row,* Cont *route,* Pkg *provenance, and local* NameCert *row. It cannot request a hidden zero source, off-packet modulus, global zero classifier, analytic-continuation certificate, quotient representative, ambient completeness theorem, or proof of* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root consumer readiness certificate`

Proof. First combine the source and classifier surfaces. The displayed source, zero-strip, and refusal rows make Z, S, H, C, P, N the only classifier-ready root route.

Next combine the modulus and ledger surfaces. The modulus, real-part, and rational-comparison rows make M, R, Q, H, C, P, N the only ledger-ready route for downstream reads.

Finally intersect the two routes at the shared structural rows. Both are carried by the same BHist packet, transported by the same hsame row, replayed by the same Cont route, recorded by the same Pkg provenance, and named by the same local NameCert row. The refusal and downstream-readback siblings exclude every off-packet analytic, quotient, completeness, zero-search, and RH demand, so the root consumer is ready exactly on $Z, S, M, R, Q, H, C, P, N$. □

Definition 548.373 (CriticalLineWitness fixed-strip refusal-budget packet)**.** *A* CriticalLineWitness$^{\uparrow}$ *fixed-strip refusal-budget packet is a finite* BHist *packet*

$$B = (Z, S, M, R, Q, H, C, P, N)$$

over the supplied ZetaZeros$^{\uparrow}$ *zero row* Z*,* CritStrip$^{\uparrow}$ *critical-strip row* S*,* Nat$^{\uparrow}$ *line-modulus row* M*,* Real$^{\uparrow}$ *real-part row* R*, finite refusal budget and rational comparison ledger* Q*, componentwise* hsame *row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* NameCert$_{\text{CriticalLineWitness}^{\uparrow}}$ *row* N*. The packet has no coordinate for zero search,* RH *proof, analytic-continuation certificate, host equality, quotient representative, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip refusal budget packet`

Theorem 548.374 (CriticalLineWitness fixed-strip budget route determinacy)**.** *Every fixed-strip budget read of an accepted* CriticalLineWitness$^{\uparrow}$ *packet factors through the packet of Definition 548.373. The read may inspect the supplied zero row, critical-strip row, line-modulus row, finite refusal budget, rational comparison ledger,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row, but it cannot choose a second budget carrier or a hidden analytic route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip budget route determinacy`

Proof. Project the accepted packet through the carrier of Definition 548.1. The displayed rows are exactly $Z, S, M, R, Q, H, C, P, N$, so a fixed-strip budget read has no off-packet coordinate available at the carrier level.

Apply the NameCert obligations, source triad, and zero-strip modulus route, Definition 548.2, Definition 548.76, and Definition 548.106. These bind the supplied zero, strip, modulus, real-part, and comparison rows to one finite route.

Finally use modulus refusal ledger exhaustion and root refusal-boundary totality, Definition 548.318 and Definition 548.330. They force every fixed-strip budget demand onto the same refusal ledger and rule out hidden analytic or host-level budget carriers. □

Theorem 548.375 (CriticalLineWitness fixed-strip zeta consumer boundary)**.** *Every downstream zeta-continuation consumer of the packet in Definition 548.373 may read the refusal budget and rational comparison ledger on $Z, S, M, R, Q, H, C, P, N$. It cannot obtain a zero search,* RH *proof, analytic-continuation certificate, host equality, quotient representative, or ambient completeness row from that fixed-strip budget surface.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip zeta consumer boundary`

Proof. Begin with fixed-strip budget route determinacy. It identifies the consumer-facing read with the single finite packet $Z, S, M, R, Q, H, C, P, N$.

Use the downstream readback exhaustion and RH-boundary non-escape rows, Definition 548.297 and Definition 548.253. These theorems place zeta-facing and RH-facing requests on the displayed refusal ledger.

Finally apply zero-route non-escape and RH consumer boundary, Definition 548.315 and Definition 548.316. The consumer receives only finite BHist, hsame, Cont, Pkg, and NameCert data, so zero search, RH proof data, analytic continuation, host equality, quotient representatives, and ambient completeness remain outside the packet. □

Theorem 548.376 (CriticalLineWitness fixed-strip source refusal cover)**.** *Every accepted root-unblock read of a* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed-strip source packet is covered by the displayed fixed-strip source row, the supplied* BHist *ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. The cover may read the supplied zero row, critical-strip row, modulus row, real-part row, rational comparison row, and refusal-budget row, but it has no coordinate for analytic continuation, quotient zero sets, host equality, or an* RH *proof row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip source refusal cover`

Proof. Start with the fixed-strip refusal-budget packet of Definition 548.373. Its carrier is the finite row $Z, S, M, R, Q, H, C, P, N$, so every root-unblock read begins with the supplied zero, strip, modulus, real-part, comparison, transport, replay, provenance, and naming rows.

Apply the fixed-strip budget route determinacy theorem, Definition 548.374. It forces the read through the same finite budget surface and prevents a second budget carrier or hidden analytic route.

Finally use the fixed-strip NameCert source lock, Definition 548.379. The local NameCert row is tied to the same BHist, hsame, Cont, and Pkg surface, so analytic continuation, quotient zero sets, host equality, and an RH proof row remain outside the cover. □

Theorem 548.377 (CriticalLineWitness modulus-window transport)**.** *Let two accepted root fixed-strip reads share the displayed source row, fixed modulus window, refusal-budget ledger, componentwise* hsame *row, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. Then the modulus-window transport carries the first read to the second along the same* BHist *packet and preserves the visible source, strip, modulus, real-part, and rational comparison rows. It cannot replace that transport by analytic continuation, quotient zero-set equality, host equality, or any unrecorded target behavior.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus window transport`

Proof. Project both reads through the source refusal cover of Definition 548.376. The only available rows are the fixed-strip source packet and the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Use fixed-strip classifier stability, Definition 548.380. Componentwise hsame transport and displayed Cont replay preserve the accepted classifier on the same $Z, S, M, R, Q, H, C, P, N$ packet.

Now apply fixed-strip ledger exactness, Definition 548.381. Since downstream reads receive exactly the displayed ledger rows, the modulus-window transport is determined by those rows and cannot be distinguished by analytic continuation, quotient zero-set equality, host equality, or unrecorded target behavior. □

Theorem 548.378 (CriticalLineWitness RH-boundary nonclaim)**.** *The root fixed-strip refusal cover and its modulus-window transport expose a boundary for* RH*-facing consumers, not an* RH *proof row. A downstream consumer may read the supplied zero row, critical-strip source row, modulus window, refusal-budget ledger,* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows, but it receives no analytic-continuation certificate, no quotient zero-set equality, no host equality, no ambient completeness row, and no proof of* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh boundary nonclaim`

Proof. Begin with the fixed-strip zeta consumer boundary, Definition 548.375. It places downstream zeta-continuation consumers on the displayed refusal budget and rational comparison ledger.

Apply the source refusal cover and modulus-window transport above. Together they show that root-unblock reads and transported reads remain on the same finite BHist, hsame, Cont, Pkg, and NameCert packet.

Finally use fixed-strip ledger exactness, Definition 548.381. The ledger exhausts the downstream surface by displayed fixed-strip rows, so the RH-facing boundary records a refusal surface and not analytic continuation, quotient zero-set equality, host equality, ambient completeness, or an RH proof row. □

Theorem 548.379 (CriticalLineWitness fixed-strip NameCert source lock)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted fixed-strip* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every accepted* NameCert *source read of* W *is locked to the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row* Z*, the supplied* $\mathsf{CritStrip}^{\uparrow}$ *row* S*, the fixed-strip source and refusal-budget packet, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows carried by* H, C, P, N*. The read has no coordinate for zero search,* RH *proof data, analytic continuation, host equality, quotient representatives, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip namecert source lock`

Proof. Start with the carrier of Definition 548.1. It lists the accepted witness as the finite packet $Z, S, M, R, Q, H, C, P, N$, so a NameCert source read begins on the displayed zero row, strip row, support rows, and local naming row.

Apply the NameCert obligations of Definition 548.2. These obligations bind the local naming row to the same BHist, hsame, Cont, and Pkg surface and leave no independent host or quotient naming coordinate.

Now attach the fixed-strip refusal-budget packet Definition 548.373. Its row inventory adds the fixed-strip source, line-modulus, comparison, budget, transport, replay, provenance, and local naming rows without adding an analytic or ambient completion row.

Finally use the fixed-strip budget route determinacy theorem Definition 548.374. It forces every budget-facing source read through that finite packet, so zero search, RH proof data, analytic continuation, host equality, quotient representatives, and ambient completeness are refused rather than read. □

Theorem 548.380 (CriticalLineWitness fixed-strip classifier stability)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted fixed-strip* CriticalLineWitness$^{\uparrow}$ *packet. The fixed-strip classifier determined by W is stable under componentwise* hsame *transport and displayed* Cont *replay on the same rows $Z, S, M, R, Q, H, C, P, N$. Transport or replay may move the accepted read along the displayed packet route, but it cannot replace the classifier by zero search,* RH *proof data, analytic continuation, host equality, quotient representatives, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip classifier stability`

Proof. Begin with classifier exactness, Definition 548.358. It identifies the root classifier with the supplied zero row Z, critical-strip row S, and displayed BHist, hsame, Cont, Pkg, and local NameCert surface.

Use componentwise StdBridge transport, Definition 548.341. The transport row preserves the displayed packet components, and the replay row keeps the read on the same $Z, S, M, R, Q, H, C, P, N$ carrier.

It remains to exclude alternate classifier sources after transport. Apply Definition 548.379. Since the NameCert source itself is locked to the fixed-strip packet and refuses zero search, RH proof data, analytic continuation, host equality, quotient representatives, and ambient completeness, the transported classifier is stable on exactly the displayed fixed-strip rows. □

Theorem 548.381 (CriticalLineWitness fixed-strip ledger exactness)**.** *Every downstream zeta or* RH*-boundary consumer of an accepted fixed-strip* CriticalLineWitness$^{\uparrow}$ *packet receives exactly the fixed-strip ledger rows $Z, S, M, R, Q, H, C, P, N$ and no stronger analytic coordinate. The consumer may read the supplied zero row, critical-strip row, modulus row, real-part row, rational comparison and refusal-budget ledger, transport row, replay row, provenance row, and local naming row; it does not receive zero search,* RH *proof data, analytic continuation, host equality, quotient representatives, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip ledger exactness`

Proof. First apply ledger route stability, Definition 548.359. It keeps the modulus and comparison ledger on the displayed M, R, Q, H, C, P, N route and prevents branching to host comparison, quotient representatives, analytic continuation, or ambient completeness.

Next use the fixed-strip zeta consumer boundary, Definition 548.375. It places every downstream zeta-facing read on the refusal budget and rational comparison ledger of the same finite packet.

Finally apply fixed-strip classifier stability, Definition 548.380. Since transport and replay preserve the classifier only on $Z, S, M, R, Q, H, C, P, N$, a downstream zeta or RH-boundary consumer receives exactly those ledger rows and no stronger analytic coordinate. □

Theorem 548.382 (CriticalLineWitness root handoff exhaustion)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet whose root route is read through the fixed strip, modulus, rational comparison, refusal budget, transport, continuation, package, and local* NameCert *rows. Then every accepted root handoff of W is exhausted by those displayed rows. It has no coordinate for analytic continuation, an* RH *proof, host equality, quotient representatives, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root handoff exhaustion`

Proof. Start with the finite-budget source route. The source-totality theorem Definition 548.307 places the accepted root read on the fixed zero row, critical-strip row, modulus row, rational comparison row, refusal-budget ledger, transport, replay, provenance, and local naming rows.

Next apply finite-budget ledger stability. The ledger-stability theorem Definition 548.308 keeps comparison and refusal data on the same displayed source route under hsame transport and Cont replay.

Finally use fixed-strip budget route determinacy. The theorem Definition 548.374 says that the fixed-strip route has no alternate analytic, host, quotient, or ambient-completeness branch. Therefore the handoff is exhausted by the finite packet rows and cannot export an RH proof or analytic-continuation coordinate. □

Theorem 548.383 (CriticalLineWitness root classifier budget lock)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* CriticalLineWitness$^{\uparrow}$ *packet. If a classifier-facing read and a finite-budget read preserve the same displayed fixed-strip source route under* hsame *transport and* Cont *replay, then the classifier row and the refusal-budget rows remain locked to that route. Transport and replay cannot replace the displayed classifier by analytic continuation, zero search, host equality, quotient representatives, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootClassifierBudgetLock`

Proof. First read the classifier from the root packet. Classifier exactness identifies the root classifier with the supplied zero row, critical-strip row, modulus and comparison rows, and the displayed BHist, hsame, Cont, Pkg, and local NameCert surface.

Now read the budget side. The finite-budget source-totality and ledger-stability theorems keep the refusal budget on the same $Z, S, M, R, Q, H, C, P, N$ route and preserve it under the same hsame and Cont rows.

It remains to compare the two reads. Fixed-strip budget route determinacy prevents the budget read from branching to analytic continuation, zero search, host equality, quotient representatives, or ambient completeness. Since both reads preserve the same displayed route, the classifier and budget rows stay locked to the same finite packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root classifier budget lock`

Theorem 548.384 (CriticalLineWitness root downstream consumer totality)**.** *Every downstream zeta-continuation or critical-line consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *root packet factors through the finite packet consisting of the fixed strip, modulus, rational comparison, refusal budget, transport, continuation, package, and local* NameCert *rows before any public read. No downstream consumer receives an analytic-continuation certificate, an* RH *proof, host equality, quotient representatives, ambient completeness, or a direct critical-line bypass.*

Proof. Begin with root handoff exhaustion. The preceding theorem confines the root handoff to the fixed-strip, modulus, rational-comparison, refusal-budget, transport, replay, provenance, and naming rows.

Next lock the classifier to the same budget surface. The classifier-budget theorem above ensures that hsame transport and Cont replay preserve the classifier and refusal ledger on exactly the same displayed route.

Finally apply the downstream fixed-strip boundary supplied by fixed-strip budget route determinacy. A zeta-continuation or critical-line consumer can only read the finite packet already exposed by the root route. Thus every public downstream read factors through that packet before it is read, and the excluded analytic, RH, host, quotient, completeness, and bypass coordinates remain absent. □

Theorem 548.385 (CriticalLineWitness fixed-strip carrier source totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet whose fixed-strip route is read through the displayed* BHist *carrier, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. Every accepted carrier-source read of* W *is exhausted by the visible finite source rows* $Z, S, M, R, Q, H, C, P, N$ *over the* $\mathsf{CritStrip}^{\uparrow}$*,* $\mathsf{Gamma}^{\uparrow}$*,* $\mathsf{ZetaZeros}^{\uparrow}$*, and zeta-dependency surface. It has no additional coordinate for zero search, analytic continuation, host equality, quotient representatives, ambient completeness, or an* RH *proof.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip carrier source totality`

Proof. Project the accepted packet through the carrier of Definition 548.1. The only source-side rows exposed by the carrier are the supplied zero row Z, critical-strip row S, modulus row M, real-part row R, rational-comparison row Q, and the structural rows H, C, P, N.

Use fixed-strip source totality and source-signature readback, Definition 548.317 and Definition 548.361. These identify the carrier source with the visible finite rows over BHist, hsame, Cont, Pkg, and NameCert, and they keep the signature-gap readback on the same displayed route.

Finally attach the zeta dependency surface through Definition 548.225. The $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Gamma}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, and zeta-continuation dependencies are already ledger rows of W, so the carrier-source read is exhausted by $Z, S, M, R, Q, H, C, P, N$ and cannot open any analytic, host, quotient, completeness, zero-search, or RH coordinate. □

Theorem 548.386 (CriticalLineWitness fixed-strip classifier separation)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. A classifier read that is anchored in the fixed-strip source rows* $Z, S, M, R, Q, H, C, P, N$ *is separated from a zero-strip witness read unless the displayed finite route supplies the same signature-gap ledger through* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$*. In the absence of that matching ledger, transport and replay keep the*

two reads on their own refusal rows and do not identify them by zero search, analytic continuation, host equality, quotient representatives, ambient completeness, or an RH *proof.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip classifier separation`

Proof. First read the fixed-strip side. By Definition 548.385, a classifier anchored in the fixed strip has only the visible packet rows $Z, S, M, R, Q, H, C, P, N$ available.

Now read the zero-strip side through the signature-gap carrier. The source-signature readback and GAP-policy stability theorems, Definition 548.361 and Definition 548.362, place any zero-strip witness read behind the displayed signature and gap rows and preserve those rows under H and C.

It remains to compare the two reads. Apply fixed-strip classifier stability, Definition 548.380. If the displayed finite route carries the same signature-gap ledger, the classifier and witness reads meet on that ledger; if it does not, the refusal rows remain distinct and no analytic, host, quotient, completeness, zero-search, or RH route can identify them. □

Theorem 548.387 (CriticalLineWitness zero-source ledger exhaustion)**.** *Every downstream* RH*-facing or zeta-continuation consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet factors through the visible zero-source ledger* $Z, S, M, R, Q, H, C, P, N$ *before it can read a public conclusion. The consumer reads the zero row, fixed strip, source signature, gap ledger, modulus, rational comparison, transport, replay, provenance, and local* NameCert *rows already displayed by* W*; it receives no analytic oracle, host zero classifier, quotient representative, ambient completeness datum, or direct* RH *proof.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessZeroSourceLedgerExhaustion`

Proof. Begin with carrier-source totality. The first theorem in this packet confines the zero-source carrier to the finite rows $Z, S, M, R, Q, H, C, P, N$ over the local BHist, hsame, Cont, Pkg, and NameCert surface.

Next use the downstream consumer rows. Root downstream consumer totality and fixed-strip zeta source factorization, Definition 548.384 and Definition 548.389, force zeta-continuation and critical-line consumers to read the displayed packet before any public RH-facing read.

Finally apply classifier separation together with the NameCert route exhaustion theorem, Definition 548.386 and Definition 548.363. The classifier, signature-gap ledger, and downstream route all factor through the same visible zero-source ledger, so the consumer cannot replace that ledger by an analytic oracle, host zero classifier, quotient representative, ambient completeness datum, or direct RH proof. □

Theorem 548.388 (CriticalLineWitness fixed-strip zero-source refusal)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. If an* RH*-facing consumer reads the fixed-strip classifier without the matching zero-source ledger* $Z, S, M, R, Q, H, C, P, N$ *on the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *route, then that classifier read remains on the refusal route. It cannot be promoted to zero search, analytic continuation, host equality, quotient representatives, ambient completeness, or an* RH *proof.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip zero source refusal`

Proof. First apply fixed-strip carrier source totality, Definition 548.385. It confines the classifier-side source to the finite displayed rows of W.

Next apply classifier separation, Definition 548.386. Without the matching signature-gap and zero-source ledger, the fixed-strip classifier and zero-source read stay on distinct displayed rows.

Finally use zero-source ledger exhaustion, Definition 548.387. Every RH-facing consumer must pass through the same ledger before reading a public conclusion, so the unmatched classifier read cannot become any of the refused analytic, host, quotient, completeness, zero-search, or RH endpoints. □

Theorem 548.389 (CriticalLineWitness fixed-strip zeta source factorization)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every zeta-continuation or critical-line consumer of W factors through the concrete packet $Z, S, M, R, Q, H, C, P, N$ before any* RH*-facing read. The consumer receives only the fixed strip, modulus, rational comparison, refusal, transport, continuation, provenance, and local naming rows already displayed by W.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip zeta source factorization`

Proof. Start with root handoff exhaustion, Definition 548.382. It confines the root handoff to the displayed fixed-strip, modulus, rational-comparison, refusal-budget, transport, continuation, package, and naming rows.

Next apply root downstream consumer totality, Definition 548.384. That result makes every zeta-continuation or critical-line consumer read the same finite packet before any public consumer read is accepted.

Finally use the root classifier budget lock, Definition 548.383. Since classifier and budget reads remain locked to the displayed route under hsame transport and Cont replay, no consumer can insert an RH-facing coordinate before the packet factorization. □

Theorem 548.390 (CriticalLineWitness modulus budget RH refusal exhaustion)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, the modulus row, rational comparison ledger, and refusal budget exhaust every request for an* RH *proof, zero search, analytic continuation, quotient representative, host equality, or ambient completeness. Such a request has no accepted route outside the displayed M, R, Q, H, C, P, N budget surface.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier modulus budget rh refusal exhaustion`

Proof. Read the refusal side through Definition 548.72. It records the RH-facing refusals on the finite ledger rather than on an analytic, host, quotient, or ambient-completeness coordinate.

Use root handoff exhaustion, Definition 548.382, to place every handoff on the same fixed-strip, modulus, rational-comparison, refusal, transport, continuation, package, and naming rows. Thus a request that reaches the root must be read through the displayed packet.

Now apply the root classifier budget lock, Definition 548.383. The modulus, comparison, and refusal reads stay locked to M, R, Q, H, C, P, N under the displayed transport and replay rows, so each listed demand is exhausted by the finite refusal surface and receives no off-packet witness. □

Theorem 548.391 (CriticalLineWitness NameCert root-unblock consumer scope)**.** *The local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *root-unblock consumer scope of an accepted packet $W = (Z, S, M, R, Q, H, C, P, N)$ is exactly the fixed strip, modulus, rational comparison, refusal, transport, continuation, provenance, and naming rows displayed by W. It includes no analytic-continuation certificate,* RH

proof, zero-search oracle, quotient representative, host equality, ambient-completeness datum, or direct critical-line bypass.

Proof. First apply root downstream consumer totality, Definition 548.384. It gives the consumer-facing inclusion into the fixed-strip, modulus, rational-comparison, refusal, transport, continuation, package, and local NameCert rows.

For the reverse containment of the public scope, use root handoff exhaustion, Definition 548.382. Each displayed row is part of the accepted handoff surface of the packet and is therefore available to the local root-unblock consumer.

It remains to rule out extra rows. The root classifier budget lock Definition 548.383 keeps classifier and refusal reads on the same displayed route, while refusal ledger completeness Definition 548.72 accounts for the RH-facing refusals. Hence the exact local scope is the displayed finite packet surface and no excluded coordinate is admitted. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier namecert root unblock consumer scope`

Theorem 548.392 (Critical-line witness finite-strip carrier admission)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. The finite-strip carrier admission for W is the displayed* BHist *strip route through the fixed observation window Z, S, M, R, Q, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. The admission reads the source-modulus route already bound to that fixed window and exports no analytic-continuation certificate, host zero classifier, quotient representative, ambient completeness coordinate, or proof of* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier finite strip carrier admission`

Proof. Begin with the root source modulus classifier completion of Definition 548.208. It places the source row, strip row, modulus row, rational comparison row, transport, replay, provenance, and local name on the same accepted source-modulus surface.

Next use fixed-strip source completion, Definition 548.317. The fixed finite observation windows are the displayed BHist rows, and the source-modulus route is read only through hsame, Cont, Pkg, and NameCert.

Finally attach the zeta dependency lattice of Definition 548.169. The zeta-facing and RH-boundary dependencies are consumed before any modulus witness is public, so admission remains a finite carrier row and not an analytic theorem source. □

Theorem 548.393 (Critical-line witness source-modulus gap separation)**.** *For every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet $W = (Z, S, M, R, Q, H, C, P, N)$, the source-modulus route over the fixed finite observation windows separates the displayed strip rows Z, S from the modulus and comparison rows M, R, Q by the same gap ledger carried by* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. A downstream consumer may read the separation only as a finite BEDC obligation row; it cannot replace the gap by host equality, a global zero classifier, analytic continuation, quotient equality, ambient completeness, or an* RH *proof.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus gap separation`

Proof. First read the finite-strip carrier admission above. It fixes the carrier rows and the source-modulus route before any downstream zeta or critical-line consumer can request a public conclusion.

Next use the source-modulus classifier lock of Definition 548.208. The classifier lock keeps $Z, S, M, R, Q, H, C, P, N$ on one displayed route and refuses global zero classification, host equality, quotient representatives, and ambient completeness.

Now apply fixed-strip source totality, Definition 548.317. The fixed observation windows and source-modulus rows remain finite BHist coordinates under the displayed transport and replay.

Finally use the zeta dependency lattice, Definition 548.169. Since zeta and RH boundary reads are dependency rows rather than replacement coordinates, the gap separation remains attached to the source-modulus route. □

Theorem 548.394 (Critical-line witness zeta-consumer refusal totality)**.** *Every zeta-facing or* RH*-boundary consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *that reads the finite-strip source-modulus route is total on the displayed refusal surface*

$$Z, S, M, R, Q, H, C, P, N.$$

The consumer may inspect the fixed BHist *strip rows, source-modulus rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. It receives no completed zeta object, zero oracle, analytic-continuation certificate, host equality, quotient stream, ambient completeness coordinate, or proof of* RH*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta consumer refusal totality`

Proof. Begin with zeta dependency lattice, Definition 548.169. It orders zeta-facing and RH-boundary reads before the modulus witness and keeps the witness as the displayed finite packet.

Next apply finite-strip carrier admission and source-modulus gap separation. Together they show that the consumer route is the same fixed-window source-modulus surface over BHist, hsame, Cont, Pkg, and NameCert.

Finally use fixed-strip source completion, Definition 548.317. The completion exposes no zero-producing search, analytic-continuation theorem, host equality, quotient representative, ambient completeness witness, or proof of RH, so the zeta-facing refusal is total on $Z, S, M, R, Q, H, C, P, N$. □

Theorem 548.395 (Critical-line witness fixed-strip gap-consumer nonescape)**.** *Every accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$ *whose source-modulus gap is read through the fixed strip rows* $Z, S, M, R, Q, H, C, P, N$ *keeps that gap visible to any zeta-facing consumer. The consumer may inspect the fixed* BHist *strip rows, source-modulus route, rational comparison row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row, but it cannot replace the gap by analytic continuation, a zero oracle, host equality, quotient streams, ambient completeness, or an* RH *proof.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip gap consumer nonescape`

Proof. Begin with finite-strip carrier admission, Definition 548.392. It fixes $Z, S, M, R, Q, H, C, P, N$ as the complete carrier route before any zeta-facing consumer can read a conclusion.

Apply source-modulus gap separation, Definition 548.393. The gap is attached to the displayed source-modulus route and is not stored as a host equality, quotient stream, zero oracle, or ambient completeness coordinate.

Use fixed-strip source totality and zeta-consumer refusal totality, Definition 548.317 and Definition 548.394. These theorems keep the fixed-window read total on the displayed refusal surface and expose no analytic-continuation certificate or RH proof.

The conclusion follows by carrier-coordinate exhaustion. Every row available to the consumer is one of $Z, S, M, R, Q, H, C, P, N$, and none of those rows supplies a replacement for the source-modulus gap. □

Theorem 548.396 (CriticalLineWitness root zeta source obligation)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root-facing read that cites the zeta-continuation source row of W must pass through the displayed* BHist *source row Z, componentwise* hsame *transport H,* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row N. The read cannot replace Z by host complex analysis, a hidden zero selector, quotient equality, or an analytic-continuation oracle row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root zeta source obligation`

Proof. Start from the carrier of Definition 548.1. It exposes the zeta source as a finite row of the accepted packet, not as an ambient analytic object.

Use the zeta dependency lattice and fixed-strip zeta source factorization surfaces. They route zeta-facing continuation reads through the same BHist, hsame, Cont, Pkg, and NameCert rows already displayed by W.

Finally apply the root refusal and source-exhaustion siblings. Since those rows exclude host complex analysis, hidden zero selection, quotient equality, and analytic-continuation oracle data, the zeta source obligation remains a finite BEDC root obligation. □

Theorem 548.397 (CriticalLineWitness root real-window obligation)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root-facing finite-window read of the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *side must pass through the displayed real-part row R, rational comparison row Q, modulus row M, transport row H, replay row C, provenance row P, and local naming row N. The read exports no ambient completeness witness, host real equality, quotient representative, hidden zero selector, or analytic-continuation oracle row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root real window obligation`

Proof. Read the real-window side through the existing RealUp and RatUp sibling surfaces. The packet exposes M, R, Q as finite rows for modulus, real-part, and rational-comparison data.

Next apply the root modulus ledger and rational comparison completion rows. They force every finite-window consumer to preserve the same H, C, P, N support while reading M, R, Q.

The refusal boundary then removes the forbidden exits. No accepted finite-window read can become host real equality, ambient completeness, a quotient representative, hidden zero selection, or analytic continuation outside the displayed packet. □

Theorem 548.398 (CriticalLineWitness root strip classifier obligation)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every root-facing critical-strip classifier read must be anchored in the displayed strip row S, zeta source row Z, finite-window rows M, R, Q, componentwise* hsame *transport H,* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. It supplies a critical-strip witness boundary only, with no full* RH *proof, host complex-analysis classifier, quotient equality, hidden zero selector, or analytic-continuation oracle row.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier root strip classifier obligation`

Proof. Begin with the critical strip witness and fixed-strip source classifier siblings. They expose the strip classifier as a finite source row coupled to Z, S, M, R, Q.

Transport and replay the classifier through H and C. The provenance and naming rows P, N keep the classifier attached to the accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ packet rather than to a detached analytic object.

Finally combine the fixed-strip refusal and root RH-boundary rows. These surfaces make the classifier a BEDC witness boundary and exclude a full RH proof, host complex-analysis classifier, quotient equality, hidden zero selection, or analytic-continuation oracle row. □

Theorem 548.399 (CriticalLineWitness zeta real strip root handoff)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ packet. Before any zeta-continuation, critical-line, or RH-facing consumer route is accepted, the packet must expose the zeta source row Z, the fixed critical-strip row S, the modulus row M, the $\mathsf{Real}^{\uparrow}$ finite-window row R, the $\mathsf{RegSeqRat}^{\uparrow}$ rational-comparison row Q, the componentwise BHist and hsame transport row H, the displayed Cont replay row C, the Pkg provenance row P, and the local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ row N. No accepted route may read the handoff as an analytic continuation theorem, a zero-search oracle, a quotient equality, a host real equality, or an ambient completeness datum.*

Proof. Use the zeta source obligation of Definition 548.396. It forces each zeta-continuation source read through Z, H, C, P, N and prevents the source from becoming hidden complex-analysis input.

Next use the real-window obligation of Definition 548.397. It adds the finite M, R, Q rows and keeps the $\mathsf{Real}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ side on the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ route.

Finally use the strip classifier obligation of Definition 548.398 together with the downstream source package of Definition 548.179. These results attach the fixed strip classifier to $Z, S, M, R, Q, H, C, P, N$ before a consumer can inspect the route. The refusal ledger rows then remove analytic continuation, zero search, quotient equality, host real equality, and ambient completeness from the handoff. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta real strip root handoff`

Theorem 548.400 (CriticalLineWitness fixed-strip budget source totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ packet. The admitted root source reads of W are exhausted by the fixed-strip source read through Z, S, H, C, P, N, the refusal-budget read through $Z, S, M, R, Q, H, C, P, N$, and the real-window source read through M, R, Q, H, C, P, N. A root consumer has no fourth source channel outside those finite rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip budget source totality`

Proof. The fixed-strip source side is supplied by Definition 548.398 and Definition 548.376. These bind the strip classifier and source refusal cover to the displayed packet rows.

The refusal-budget side is supplied by Definition 548.213. Its budget route is the same finite packet $Z, S, M, R, Q, H, C, P, N$, with H, C, P, N carrying the transport, replay, provenance, and local name.

The real-window side is supplied by Definition 548.397. Since the root source-window route lock and refusal ledger already reject detached analytic and host-level channels, these three reads exhaust the admitted root source surface. □

Theorem 548.401 (CriticalLineWitness RH refusal source exactness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ packet. Every RH-facing demand on W is classified exactly as*

a finite refusal/source row over $Z, S, M, R, Q, H, C, P, N$. Such a demand cannot be converted into analytic continuation, zero search, quotient equality, host real equality, or ambient completeness, and it cannot strengthen the packet beyond its zeta-continuation source rows and fixed-strip classifier rows.

Proof. Start with the combined handoff of Definition 548.399. It exposes the zeta source, real-window rows, rational comparison rows, strip classifier, transport, replay, provenance, and local naming row before any RH-facing consumer route is accepted.

Apply the fixed-strip budget source totality of Definition 548.400. It leaves only the fixed-strip source read, refusal-budget read, and real-window source read as admitted root source channels.

Finally use the RH consumer boundary of Definition 548.279 and the RH refusal readback totality of Definition 548.189. These sibling rows classify the remaining demand as finite BHist, hsame, Cont, Pkg, and NameCert refusal/source data and exclude analytic continuation, zero search, quotient equality, host real equality, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal source exactness`

Theorem 548.402 (CriticalLineWitness root zeta, Real, and Rat source readiness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Before any downstream zeta,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{Rat}^{\uparrow}$ *consumer reads W, the packet exposes the zeta-facing source row Z, the modulus row M, the real-part row R, the rational-comparison row Q, the* BHist *carrier surface, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *route N. Thus every such consumer receives a finite BEDC route through the displayed packet rather than an analytic, host-level, quotient, or ambient-completeness substitute.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootZetaRealRatSourceReadiness`

Proof. Begin with the accepted carrier tuple. Its visible rows are $Z, S, M, R, Q, H, C, P, N$, so the zeta-facing source, modulus, real-part, and rational-comparison reads are already named before any downstream consumer asks for them.

Use the zeta source obligation, real-window obligation, and strip classifier obligation from the preceding root rows. They place zeta continuation, modulus, $\mathsf{Real}^{\uparrow}$ real-part, and $\mathsf{Rat}^{\uparrow}$ comparison reads on the same BHist, hsame, Cont, Pkg, and local NameCert route.

The displayed route is finite because every component is a row of W. Therefore a downstream consumer can read only through those packet rows, and no analytic continuation, host equality, quotient representative, or ambient completeness object is available as a replacement. □

Theorem 548.403 (CriticalLineWitness root gap refusal completeness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Every demand for an* RH *proof, analytic continuation, host zero search, quotient representative, host equality, or ambient-completeness witness is a refusal-side demand unless it is routed through the displayed $Z, M, R, Q,$* BHist*$, H, C, P, N$ rows of W. In particular, no such demand can become an accepted downstream read by bypassing the finite source, modulus, real-part, rational-comparison, transport, replay, provenance, and naming route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootGapRefusalCompletenessPackage`

Proof. First isolate the accepted route. The source-readiness theorem above makes the zeta-facing, modulus, real-part, and rational-comparison data available only as displayed rows of W, with their BHist, hsame, Cont, Pkg, and NameCert support.

Next classify the listed demands. Requests for RH truth, analytic continuation, host zero search, quotient representatives, host equality, or ambient completeness ask for data not displayed by the packet unless they are rewritten as reads of Z, M, R, Q, H, C, P, N.

Finally apply the root refusal boundary. It sends every off-packet request to the refusal side, so the only accepted form of such a request is the finite BEDC route already exposed by W. □

Theorem 548.404 (CriticalLineWitness root downstream unblock package)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the downstream root-unblock package is the finite conjunction of the source-readiness row of Definition 548.402, the refusal-completeness row of Definition 548.403, the zeta dependency lattice of Definition 548.169, the root refusal boundary totality of Definition 548.330, and the root modulus ledger of Definition 548.68. This package is sufficient for downstream critical-line, zeta,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Rat}^{\uparrow}$ *consumers that require a finite BEDC route, and it claims no* RH *proof, analytic completeness theorem, host zero selector, quotient equality, or ambient-completeness witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRootDownstreamUnblockPackage`

Proof. Assemble the positive route first. The source-readiness row supplies $Z, M, R, Q, \mathsf{BHist}, H, C, P, N$, while the zeta dependency lattice and root modulus ledger attach the zeta-facing and real-rational reads to the same displayed packet.

Now assemble the negative boundary. The refusal-completeness row and root refusal boundary totality classify every RH, analytic-continuation, host-zero, quotient, host-equality, or ambient-completeness demand as off-packet unless it travels through the displayed finite rows.

The downstream consumer therefore receives exactly the finite conjunction stated in the theorem. Since each conjunct is a named packet row or an existing root boundary theorem, the package unblocks the finite BEDC route without adding any analytic or host-level substitute. □

Theorem 548.405 (CriticalLineWitness Phase Real root readback package)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the Phase Real root readback package is the finite conjunction of the root downstream unblock package of Definition 548.404, the Phase Real source triad of Definition 548.413, the source budget readiness row of Definition 548.420, and the source window exhaustion row of Definition 548.416. Consequently downstream* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumers receive only displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows of* W*, and receive no analytic completeness theorem, host zero selector, quotient equality, or ambient real-completion witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessPhaseRealRootReadbackCertificate`

Proof. Project the root downstream unblock package first. It already exposes the source-readiness row, refusal-completeness row, zeta dependency lattice, root refusal boundary totality, and root modulus ledger as a finite BEDC route through the displayed packet.

Now import the three Phase Real source surfaces. The source triad binds $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads to the same root source surface; source budget readiness preserves the shared BHist, hsame, Cont, Pkg, and local NameCert support; source window exhaustion states that the visible Phase Real root read is exhausted by the displayed source-window packet.

Finally apply the refusal-completeness row contained in the root package. Analytic completeness, host zero selection, quotient equality, and ambient real-completion demands have no displayed coordinate in W, so the only downstream readback package available to the four consumers is the finite conjunction stated above. □

Theorem 548.406 (CriticalLineWitness Phase Real L10 face status pullback)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Any downstream Phase Real and Completion consumer of the readback package of Definition 548.405 must pull the four local status records from* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *objectwise. The rows of W supply only the finite source window and support route, not an aggregate verification-status row, bridge row, selected limit, quotient equality, host real equality, analytic completeness theorem, or ambient real-completion witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessPhaseRealL10FaceStatusPullback`

Proof. Start with the finite source route. By Definition 548.405, the Phase Real root readback package exposes the root downstream unblock package together with the Phase Real source triad, source budget readiness row, and source window exhaustion row through the displayed BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ support of W.

Now read the status side from the four local faces. Apply Definition 291.112, Definition 126.509, Definition 301.219, and Definition 38.494. These results force the Phase Real and Completion L10 status lookup to remain objectwise on $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Thus the accepted rows of W can name the finite source window and carry the shared support route into those consumers, but they cannot synthesize a route-level status coordinate or any of the listed analytic, quotient, host, bridge, selected-limit, or ambient-completion witnesses. □

Theorem 548.407 (CriticalLineWitness Phase Real consumer determinacy)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Any downstream Phase Real consumer using the readback package of Definition 548.405 must choose one and only one objectwise face among* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *and must consume only that face's local status and readback row. The packet cannot merge the four faces into a route-level completion witness, bridge row, selected limit, quotient equality, or host real equality.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real consumer determinacy`

Proof. First restrict the available route. By Definition 548.405, the readback package is a finite conjunction of displayed root and Phase Real source rows of W, carried by the visible BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ support.

Next separate the status reads. By Definition 548.406, downstream Phase Real and Completion consumers can pull the L10 status records only objectwise from $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; no aggregate route-level status row is supplied by W.

It remains to check the four permitted faces. Apply Definition 291.112, Definition 126.509, Definition 301.219, and Definition 38.494. These four face results provide the local rows that the consumer may select, and they do so without identifying the rows with each other.

Therefore the consumer is deterministic at the face boundary: after selecting one of the four objectwise faces, it reads that face's local status and readback row and has no constructor or cited theorem that combines the four rows into a route-level completion witness, bridge row, selected limit, quotient equality, or host real equality. □

Theorem 548.408 (CriticalLineWitness Phase Real dependency totality)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *carrier. Every Phase Real or Completion read that consumes W first factors through the displayed supplied zero-strip route, modulus ledger entry, zeta dependency lattice, and RH refusal boundary:*

$$Z, S, M, R, Q, H, C, P, N.$$

The read may use this packet as a finite source-modulus dependency surface, but it has no coordinate for analytic continuation, host zero search, quotient zero sets, selected host limits, ambient completeness, or an RH *proof row.*

Proof. Start with the carrier of Definition 548.1. Its only public coordinates are the supplied zero row Z, critical-strip row S, modulus row M, real-part row R, rational-comparison row Q, componentwise transport H, displayed continuation C, package provenance P, and local naming row N.

Apply the supplied zero-strip route of Definition 548.82 and the modulus ledger entry of Definition 548.83. Together they force the source side and the Real-rational comparison side of every consumer read through the same finite packet.

Next use the zeta dependency lattice of Definition 548.169. It places any zero-strip or critical-line read behind the existing $\mathsf{ZetaZeros}^{\uparrow}$ and RH-boundary surfaces before a modulus witness is public.

Finally apply the RH non-escape package of Definition 548.84. It removes analytic continuation, host zero search, quotient representatives, ambient completeness, and RH proof content from the accepted route. Hence the Phase Real and Completion dependency route is exhausted by the displayed rows of W. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real dependency totality`

Theorem 548.409 (CriticalLineWitness zero-source Real readback factorization)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *carrier* $W = (Z, S, M, R, Q, H, C, P, N)$*, every Real-facing readback from the supplied zero source factors through the route*

$$Z, S, H, C, P, N \quad \textit{then} \quad M, R, Q, H, C, P, N.$$

Thus the zero source and the Real-rational modulus ledger are read as two faces of the same BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *packet; no consumer can identify the zero source with a Real endpoint or bypass the modulus ledger.*

Proof. Read the supplied source side through Definition 548.82. The rows Z, S, H, C, P, N are the accepted zero-strip route and are already tied to the local $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ row.

Read the Real-facing side through Definition 548.83. The rows M, R, Q, H, C, P, N form the finite modulus, real-part, and rational-comparison ledger available to a downstream consumer.

The carrier of Definition 548.1 stores both routes in the same packet, with shared transport, replay, provenance, and local naming rows. A readback that keeps the zero source but drops the modulus ledger therefore leaves the accepted carrier surface.

The non-escape clause follows from Definition 548.84 and Definition 548.169. They prevent the zero source from becoming a host Real endpoint, quotient representative, selected limit, or analytic certificate outside the displayed route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zero source real readback factorization`

Theorem 548.410 (CriticalLineWitness Real-window nonescape)**.** *Every Real-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet must expose the supplied zero row* Z*, critical-strip row* S*, modulus row* M*, real-part row* R*, rational-comparison row* Q*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N *before any L10 readback. No analytic-continuation row, selected zero, quotient zero set, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, or* RH *proof row can be read from that window.*

Proof. Start with Definition 548.408. It says that every Phase Real or Completion read factors through the displayed rows $Z, S, M, R, Q, H, C, P, N$ before any consumer-facing use of the packet.

Apply Definition 548.409. The zero-source side Z, S, H, C, P, N and the Real-rational side M, R, Q, H, C, P, N are two faces of the same finite BHist route, so an L10 readback cannot keep one side while dropping the other.

Use Definition 548.169 to place zero-strip and critical-line reads behind the existing zeta dependency lattice. This keeps the visible Real window tied to the supplied source and modulus rows rather than to a host analytic object.

Finally apply Definition 548.84. Analytic continuation, selected zeros, quotient zero sets, ambient Real completeness, and RH proof data are classified outside the accepted carrier, so none of them can be read from the Real-facing window. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier real window nonescape`

Theorem 548.411 (CriticalLineWitness RH refusal phase boundary)**.** *Every* RH*-facing Phase Real or Completion request to an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *carrier is bounded by the same finite refusal surface*

$$Z, S, M, R, Q, H, C, P, N.$$

The boundary may expose the supplied zero-strip route, the modulus ledger entry, the zeta dependency lattice, and the local refusal package. It does not export an RH *truth value, zero-location theorem, analytic-continuation certificate, quotient zero-set equality, selected limit, or ambient-completeness row.*

Proof. Begin with the carrier row of Definition 548.1. A request to the packet can inspect only the rows $Z, S, M, R, Q, H, C, P, N$.

Use Definition 548.82 for the source side and Definition 548.83 for the modulus side. These two rows give the full positive data visible to a Phase Real or Completion consumer.

Now apply the zeta dependency lattice of Definition 548.169. It records that zero-strip and critical-line reads depend on existing zeta and RH boundary surfaces rather than on a standalone zeta-function object.

Finally use Definition 548.84. The package classifies RH proofs, zero searches, quotient representatives, analytic continuation, and analytic completeness as absent from the accepted carrier. The stated refusal boundary follows. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier rh refusal phase boundary`

548.0.1 Fixed-strip source lock

Theorem 548.412 (CriticalLineWitness fixed-strip source lock)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet whose fixed-strip read is consumed by an* RH*-facing route. The read is locked to the finite source tuple consisting of the* $\mathsf{CritStrip}^{\uparrow}$ *strip row* S*, the* $\mathsf{ZetaContinuationWitness}^{\uparrow}$ *continuation row read through* Z*, the* $\mathsf{ZetaZeros}^{\uparrow}$ *zero ledger* Z*, the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window rows* R, Q*, the modulus row* M*, the displayed* BHist *carrier data, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *support* N*. No accepted consumer may replace this tuple by an* RH *proof, a nontrivial-zero classification, host complex equality, ambient analytic continuation, quotient equality, or ambient completeness.*

Proof. Start from the root zeta, real, and rational source-readiness package of Definition 548.402. It exposes Z, M, R, Q, H, C, P, N before any downstream critical-line, zeta, $\mathsf{Real}^{\uparrow}$, or $\mathsf{RegSeqRat}^{\uparrow}$ consumer can read W.

Attach the fixed-strip side through the fixed-strip source totality and source classifier rows, Definition 548.317 and Definition 548.385. These place the $\mathsf{CritStrip}^{\uparrow}$ strip row, the $\mathsf{ZetaZeros}^{\uparrow}$ ledger, and the $\mathsf{ZetaContinuationWitness}^{\uparrow}$ source read on the same displayed BHist, hsame, Cont, Pkg, and local NameCert route. The real and rational finite-window side is the finite-window surface supplied by chapter 38 and chapter 301.

Finally apply the root gap refusal completeness and downstream unblock package, Definition 548.403 and Definition 548.404. They leave the consumer with exactly the finite source tuple stated above and refuse every request for RH truth, nontrivial-zero classification, host complex equality, ambient analytic continuation, quotient equality, or ambient completeness outside that tuple. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier fixed strip source lock`

Theorem 548.413 (CriticalLineWitness Phase Real source triad)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every fixed-strip source read used by this chapter binds its source rows to the current Phase Real and Completion triad*

$$\mathsf{Real}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}.$$

The visible route is the fixed-strip source row, the $\mathsf{Real}^{\uparrow}$ *endpoint row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support of* W*.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real source triad`

Proof. Start with the fixed-strip source lock of Definition 548.412. It already places the strip source, zeta ledger, continuation read, $\mathsf{Real}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows, modulus row, and local support rows on one finite tuple.

Attach the Phase Real dependency totality of Definition 548.408. It forces every Phase Real or Completion read through the displayed source-modulus dependency surface.

Finally use the Real L10 dependency surface of chapter 38. The fixed-strip source can therefore name the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$ rows without importing any off-packet analytic or host coordinate. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessPhaseRealSourceTriad`

Theorem 548.414 (CriticalLineWitness Phase Real source totality)**.** *Every fixed-strip source read used by this chapter factors through the three displayed L10 rows* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{StreamName}^{\uparrow}$*, together with the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows exposed by the accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. No additional source row is available between the fixed-strip source lock and the Phase Real terminal read.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessPhaseRealSourceTotality`

Proof. First expose the source tuple by Definition 548.412. The accepted read is locked to the strip, zeta, continuation, Real, regular-rational, modulus, transport, replay, provenance, and local naming rows.

Next apply Definition 548.404. Its downstream package makes the finite source route sufficient for critical-line, zeta, $\mathsf{Real}^{\uparrow}$, and rational consumers.

Use Definition 548.413 to isolate the Phase Real face of that package. The only L10 rows visible to the source read are $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, supported by the displayed BEDC rows of W. □

Theorem 548.415 (CriticalLineWitness Phase Real source nonescape)**.** *The root source surface for a fixed-strip* $\mathsf{CriticalLineWitness}^{\uparrow}$ *read exports no* RH *truth value, analytic-continuation certificate, quotient stream, selected limit, or host complex equality. Such a read can only inspect the finite Phase Real source triad and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real source nonescape`

Proof. Begin with the refusal side. Definition 548.403 and Definition 548.411 classify RH truth, analytic continuation, host zero search, quotient representatives, host equality, and ambient completeness as off-packet demands.

Now apply Definition 548.414. Since every accepted fixed-strip source read has already been exhausted by the Phase Real source triad and its displayed support rows, the excluded demands have no carrier coordinate on the root source surface. □

Theorem 548.416 (CriticalLineWitness Phase Real source-window exhaustion)**.** *Let* $W = (Z, S, M, R, Q, H, C, P,$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet. Any root read of* W *using the Phase Real source window factors through the displayed* $\mathsf{Rat}^{\uparrow}$ *row,* $\mathsf{Real}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *row, zero-strip row, finite modulus row,* BHist *transport,* Cont *replay,* hsame *comparison, package provenance, and local* NameCert *row. No root read using that window can add an off-packet analytic source, host zero selector, or detached real-line certificate.*

Proof. First expose the source side. Apply Definition 548.402 and Definition 548.76. These rows place the zeta, real, rational, supplied-zero, critical-strip, and source-facing comparison data on the displayed finite packet before a root consumer reads W.

Next bind the modulus and zero-strip faces. Use Definition 548.347 for the finite modulus classifier and Definition 548.209 for the supplied zero-strip readback route. The two rows share the same H, C, P, N support surface, so the Phase Real window has no second route around the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Finally attach the Phase Real source totality of Definition 548.414. It identifies $\mathsf{Real}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ as the only visible Phase Real endpoints for this source window, while the rational comparison row supplies the $\mathsf{Rat}^{\uparrow}$ face. Thus the root read is exhausted by the stated finite source-window packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessPhaseRealSourceWindowExhaustion`

Theorem 548.417 (CriticalLineWitness RegSeqRat-to-Real modulus handoff)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, every handoff from a* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request row to a* $\mathsf{Real}^{\uparrow}$ *endpoint row inside the Phase Real source window must pass through the supplied* BHist *carrier rows, the displayed* Cont *route, and the componentwise* hsame *comparison carried by* H, C*. The handoff cannot skip directly from a regular rational sequence to a host real value, a quotient representative, or an unrecorded modulus witness.*

Proof. Begin with Definition 548.413. The Phase Real source face already names $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ through the same fixed-strip source row and the displayed support rows of W.

Now apply the modulus classifier. By Definition 548.347, any modulus read used by the root route is read through M, R, Q together with H, C, P, N. The zero-strip readback totality of Definition 548.209 fixes the source side of that route before the regular-rational-to-real handoff is consumed.

It remains to exclude detached real semantics. The source-window exhaustion row above leaves only the BHist, Cont, and hsame route between the finite request and the endpoint row. A host real value, quotient representative, or unrecorded modulus witness is not one of those coordinates, so it cannot serve as the handoff. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessRegSeqRatRealModulusHandoff`

Theorem 548.418 (CriticalLineWitness Phase Real classifier determinacy)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N)$ and $W' = (Z', S', M', R', Q', H', C', P', N')$ be accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packets. Suppose their Phase Real source windows expose the same displayed* $\mathsf{Rat}^{\uparrow}$ *row,* $\mathsf{Real}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *row, zero-strip row, finite modulus row,* BHist *transport,* Cont *replay,* hsame *comparison,* Pkg *provenance, and local* NameCert *row. Then every root or zeta-facing consumer reads the same classifier-facing source window from W and W'.*

Proof. Use Definition 548.416 to reduce both consumer reads to the displayed Phase Real source rows. After this reduction, the two reads have no visible coordinates except the shared rational, real, regular-rational, zero-strip, modulus, transport, replay, comparison, provenance, and local naming rows listed in the hypothesis.

Apply Definition 548.417 to the common $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ faces. The handoff prevents either packet from replacing the displayed finite modulus route by a detached host real, quotient representative, or unrecorded modulus witness.

Finally apply Definition 548.419. A root or zeta-facing consumer cannot import an external analytic truth primitive, analytic-continuation certificate, global zero-set classifier, quotient equality, or ambient-completeness witness. Therefore the classifier-facing source window is determined by the shared displayed rows, and both packets present the same window to every such consumer. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real classifier determinacy`

Theorem 548.419 (CriticalLineWitness zeta refusal consumer scope)**.** *Every* RH *or zeta-facing consumer of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet that reads the Phase Real source window sees only the displayed refusal ledger, source triad, rational comparison row, finite modulus row, zero-strip readback row,* BHist *route,* Cont *route,* hsame *transport,* Pkg *provenance, and local* NameCert *row. Such a consumer cannot import an external analytic truth primitive, analytic-continuation certificate, global zero-set classifier, quotient equality, or ambient-completeness witness.*

Proof. First collect the positive surface. Apply Definition 548.402, Definition 548.76, and the source-window exhaustion theorem above. These rows identify exactly the source, zeta, real, rational, modulus, zero-strip, transport, replay, provenance, and naming coordinates visible to the consumer.

Next read the refusal side through the existing root package. The Phase Real source non-escape row Definition 548.415 and the root downstream unblock package Definition 548.404 refuse RH proof data, analytic continuation, host zero search, quotient representatives, host equality, and ambient completeness outside the displayed packet.

Therefore the zeta-facing consumer has no carrier slot in which to place an external analytic truth primitive or detached analytic certificate. Its only admissible imports are the refusal ledger and the finite BEDC rows named in the statement. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessZetaRefusalConsumerScope`

Theorem 548.420 (CriticalLineWitness Phase Real source-budget readiness)**.** *Let $W = (Z, S, M, R, Q, H, C, P, N$ be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed-strip source packet. Every Phase Real source-budget read of W is a read of the same finite* BHist *packet, the same* Cont *replay row, the same componentwise* hsame *transport, the same package provenance, and the same local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row. The read may use the displayed* $\mathsf{Rat}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *zero-strip, finite modulus, and refusal-ledger coordinates, but it cannot replace them by host reals, analytic continuation, selected zero data, or an ambient-completeness witness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessPhaseRealSourceBudgetReadiness`

Proof. First expose the fixed source tuple. Apply Definition 548.416 and Definition 548.414. These rows keep the rational, regular-rational, real, zero-strip, and finite-modulus data inside the displayed packet $Z, S, M, R, Q, H, C, P, N$.

Next retain the source-budget face. The source-window exhaustion theorem binds any Phase Real read to the displayed BHist, Cont, hsame, Pkg, and local $\mathsf{NameCert}$ rows before the read reaches a consumer.

Finally read the refusal side through Definition 548.419. Since the refusal ledger has no coordinate for host reals, analytic continuation, selected zero data, or ambient completeness, the source-budget read is exactly the finite BEDC route stated above. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real source budget readiness`

Theorem 548.421 (CriticalLineWitness Phase Real RegSeqRat route readiness)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed-strip source packet $W = (Z, S, M, R, Q, H, C, P, N)$, every* $\mathsf{RegSeqRat}^{\uparrow}$ *route used by a Phase Real consumer must pass through the same finite BEDC route as the packet itself:* BHist *carrier admission,* Cont *replay, componentwise* hsame *comparison, package provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$. *The route is not a quotient stream, a selected limit, a host real equality, or an analytic continuation certificate.*

Proof. Start from the RegSeqRat-to-Real handoff of Definition 548.417. It places every regular-rational request behind the supplied carrier rows and the displayed continuation route before the Phase Real endpoint is read.

Use Definition 548.420. The budget row shares the same H, C, P, N support surface as the regular-rational route, so no second route can be inserted between the sequence data and the real-facing endpoint.

The excluded objects would require a quotient row, selected-limit row, host equality row, or analytic-continuation row. None is present in W, and the local NameCert row accepts only the finite route over $Z, S, M, R, Q, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real regseqrat route readiness`

Theorem 548.422 (CriticalLineWitness Phase Real zeta-refusal ledger)**.** *Every zeta-facing or* RH*-facing read of an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed-strip source packet reads the Phase Real refusal ledger through the displayed finite BEDC route* $Z, S, M, R, Q, H, C, P, N$*. In particular, the ledger combines source budget,* $\mathsf{RegSeqRat}^{\uparrow}$ *route,* $\mathsf{Real}^{\uparrow}$ *endpoint, zero-strip readback,* BHist *transport,* Cont *replay, componentwise* hsame*, package provenance, and local NameCert data, and it exports no host analytic truth primitive.*

Proof. First collect the source and budget rows from Definition 548.420. The Phase Real budget is already a read of the fixed carrier, continuation, transport, provenance, and local naming rows.

Next attach the regular-rational handoff by Definition 548.421. This forces the $\mathsf{RegSeqRat}^{\uparrow}$ route and $\mathsf{Real}^{\uparrow}$ endpoint to remain part of the same finite BEDC packet.

Finally apply Definition 548.419. The zeta-facing consumer sees only the refusal ledger and the finite source rows, so a host analytic truth primitive has no admission point in the packet. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real zeta refusal ledger`

Theorem 548.423 (CriticalLineWitness Phase Real terminal no-completeness boundary)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed-strip source packet. Any terminal Phase Real or zeta-facing consumer that uses the source-budget row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *route-readiness row, and the zeta-refusal ledger factors through the same displayed finite BEDC packet: the* BHist *carrier,* Cont *replay, componentwise* hsame *comparison,* Pkg *provenance, local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *row,* $\mathsf{Rat}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *endpoint rows, zero-strip readback, finite modulus, and refusal ledger. Consequently the route exports no quotient stream equality, selected limit, host real equality, analytic-continuation truth primitive, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, metric-completeness datum, or countable-choice selector.*

Proof. First apply Definition 548.420. It fixes the terminal read over the displayed BHist, Cont, hsame, Pkg, local NameCert, rational, regular-rational, real, zero-strip, finite-modulus, and refusal-ledger rows.

Next apply Definition 548.421. This keeps the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the $\mathsf{Real}^{\uparrow}$ endpoint inside the same finite source packet, rather than turning them into a quotient stream or selected-limit construction.

Finally apply Definition 548.422. The terminal zeta-facing read is only a read of the refusal ledger through those finite rows. Since no excluded row occurs in that displayed carrier or in the ledger, there is no export point for host real equality, analytic-continuation truth, ambient $\mathsf{Real}^{\uparrow}$ completeness, metric completeness, or countable-choice selection. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real terminal nocompleteness boundary`

Theorem 548.424 (CriticalLineWitness Phase Real selector-route totality)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed-strip source packet. Every Phase Real selector read of* W *factors through the displayed finite route: the* BHist *source packet, the StreamName-facing source window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *route, the* $\mathsf{Real}^{\uparrow}$ *endpoint, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows. The selector route may inspect the source-budget and zeta-refusal ledgers already present in* W*, but it has no coordinate for host real equality, analytic truth, selected Cauchy representatives, or ambient completeness.*

Proof. First expose the fixed source side. Apply Definition 548.416 and Definition 548.420. They bind the Phase Real read to the same finite source packet $Z, S, M, R, Q, H, C, P, N$ and to the same BHist, hsame, Cont, Pkg, and local NameCert rows before any selector reaches a real-facing consumer.

Next route the selector through the regular-rational face. Apply Definition 548.421. The $\mathsf{RegSeqRat}^{\uparrow}$ route and $\mathsf{Real}^{\uparrow}$ endpoint are therefore read as displayed rows of the packet, not as a quotient stream, selected limit, host real equality, or analytic continuation certificate.

Finally attach the refusal ledger by Definition 548.422. The ledger combines the source budget, regular-rational route, real endpoint, zero-strip readback, carrier transport, continuation replay, provenance, and local naming rows. Since the carrier and NameCert obligation blocks Definition 548.1 and Definition 548.2 expose no additional selector coordinate, every Phase Real selector read factors through the displayed finite route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real selector route totality`

Theorem 548.425 (CriticalLineWitness RegSeqRat Real budget separation)**.** *For an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed-strip source packet* $W = (Z, S, M, R, Q, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *budget data and the* $\mathsf{Real}^{\uparrow}$ *endpoint remain separate visible rows of the Phase Real route. A consumer may read their shared* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *support, but it cannot collapse the budget row into host real equality, analytic continuation, selected-limit truth, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier regseqrat real budget separation`

Proof. Start with the source-budget row of Definition 548.420. It records the finite support surface for a Phase Real read and keeps the budget information inside the displayed packet.

Now apply Definition 548.421. This theorem places the $\mathsf{RegSeqRat}^{\uparrow}$ route before the $\mathsf{Real}^{\uparrow}$ endpoint while preserving the same carrier, transport, replay, provenance, and local naming rows.

The two rows are therefore adjacent but not identified. The carrier definition Definition 548.1 displays R and Q as named coordinates and keeps H, C, P, N as support rows rather than equality collapses.

Use the zeta-refusal ledger Definition 548.422 to close the boundary. Host real equality, analytic continuation, selected-limit truth, and ambient completeness have no exported row, so the budget and endpoint remain separate BEDC-visible obligations. □

Theorem 548.426 (CriticalLineWitness StreamName source-window lock)**.** *Let* $W = (Z, S, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{CriticalLineWitness}^{\uparrow}$ *fixed-strip source packet. Any StreamName window consumer that preserves the fixed-strip source must preserve the same finite source-window packet before it reads the Phase Real endpoint. In particular, the consumer reads* $Z, S, M, R, Q, H, C, P, N$ *through the displayed* BHist *packet, componentwise* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows before the* $\mathsf{RegSeqRat}^{\uparrow}$ *route reaches the* $\mathsf{Real}^{\uparrow}$ *endpoint.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier streamname source window lock`

Proof. Begin with the source-window side. Apply Definition 548.416. A StreamName-facing consumer preserving the fixed strip must first read the displayed finite source rows and cannot enter through an off-packet stream selector.

Add the source-budget readiness theorem Definition 548.420. It keeps the source window tied to the same BHist, hsame, Cont, Pkg, and local NameCert rows while the Phase Real budget is inspected.

Finally route toward the endpoint through Definition 548.421 and Definition 548.422. These results force the $\mathsf{RegSeqRat}^{\uparrow}$ route, $\mathsf{Real}^{\uparrow}$ endpoint, and refusal ledger to remain downstream from the preserved source-window packet. Therefore the StreamName consumer preserves the finite source window before any Real-facing read is available. □

Theorem 548.427 (CriticalLineWitness Phase Real four-face route exhaustion)**.** *Let $W = (Z, S, M, R, Q, H, C, P,$ be an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ fixed-strip source packet. Every current Phase $\mathsf{Real}^{\uparrow}$ and Completion consumer route exported by W is exhausted by the ordered four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The route reads the displayed BHist *source packet, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *rows already carried by W. No host real equality, quotient stream, selected limit, analytic truth primitive, or ambient completeness row can enter the exported consumer route.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real four face route exhaustion`

Proof. First bind the CriticalLineWitness selector side. The selector-route totality theorem Definition 548.424 places every Phase Real selector read on the displayed source packet and on the same BHist, hsame, Cont, Pkg, and local NameCert rows.

Next lock the source window before the endpoint is read. By Definition 548.426, any StreamName-facing consumer preserving the fixed strip must preserve the finite source-window packet before the $\mathsf{RegSeqRat}^{\uparrow}$ route reaches the $\mathsf{Real}^{\uparrow}$ endpoint. The budget separation theorem Definition 548.425 keeps the $\mathsf{RegSeqRat}^{\uparrow}$ budget row and the $\mathsf{Real}^{\uparrow}$ endpoint row visible as separate BEDC rows, so the route cannot collapse them into host equality or a selected limit.

Now attach the ambient Real route. The Real four-face dependency route Definition 38.738 gives the ordered passage from $\mathsf{DyadicRatCore}^{\uparrow}$ through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$. The order uniqueness theorem Definition 38.739 rules out deletion, permutation, or shortcut coordinates for the current terminal Real surface.

Combining these packets leaves exactly the CriticalLineWitness source rows together with the Real four-face route. The classifier coherence theorem Definition 38.740 identifies the shared finite support as the same BHist, hsame, Cont, Pkg, and NameCert packet. Hence every exported Phase Real and Completion consumer route of W is exhausted by the four displayed faces, and the excluded host-equality, quotient-stream, selected-limit, analytic-truth, and ambient-completeness coordinates have no source row to read. □

Theorem 548.428 (CriticalLineWitness Phase Real selector budget nonescape)**.** *Let $W = (Z, S, M, R, Q, H, C, P,$ be an accepted $\mathsf{CriticalLineWitness}^{\uparrow}$ fixed-strip source packet. Any Phase Real selector preserving the fixed-strip source packet and the four-face L10 route preserves the source-budget and zeta-refusal ledgers as displayed rows of the same* BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{CriticalLineWitness}^{\uparrow}}$ *packet. It cannot replace those ledgers by host real equality, analytic truth, quotient stream representatives, selected limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier phase real selector budget nonescape`

Proof. Begin with selector-route totality, Definition 548.424. It places every Phase Real selector on the accepted fixed-strip packet and keeps the source-budget and refusal rows inside the displayed carrier support.

Next use the StreamName source-window lock, Definition 548.426. A selector that preserves the fixed-strip source must preserve the finite source-window packet before any $\mathsf{RegSeqRat}^{\uparrow}$ route reaches the $\mathsf{Real}^{\uparrow}$ endpoint.

Now apply the budget separation theorem Definition 548.425 and the four-face route exhaustion theorem Definition 548.427. These results keep the source-budget row, the regular-rational budget row, and the endpoint row visible as separate BEDC rows along

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Finally attach the zeta-refusal ledger by Definition 548.422. Since the refusal row is displayed in the same carrier and no excluded coordinate is exported by Definition 548.1 or Definition 548.2, the selector has no route to substitute host equality, analytic truth, quotient representatives, selected limits, or ambient completeness for the preserved budget and refusal ledgers. □

The $\mathsf{CriticalLineWitness}^{\uparrow}$ continuation lattice reads critical-line data only after the displayed $\mathsf{ZetaContinuationWitness}^{\uparrow}$ source-lock rows have been exposed. This places the local witness behind the continuation, pole, functional-equation, trivial-zero, Gamma-boundary, transport, replay, provenance, and naming surface of chapter 580.

Theorem 548.429 (CriticalLineWitness Zeta continuation route)**.** *Every* $\mathsf{CriticalLineWitness}^{\uparrow}$ *read offered to a zero-strip consumer must first pass through the* $\mathsf{ZetaContinuationWitness}^{\uparrow}$ *continuation route of chapter 580. In particular, the read displays the continuation row, pole ledger, functional-equation row, trivial-zero ledger, Gamma-boundary row, componentwise transport, replay, provenance, and local* NameCert *rows before any zero-strip consumer sees the witness as critical-line data. The route supplies no RH proof, global zero classifier, hidden analytic branch, completed Gamma certificate, host equality of zeta functions, or selected representative outside those rows.*

Proof. Start with the displayed $\mathsf{ZetaContinuationWitness}^{\uparrow}$ packet. Its source-lock surface exposes the continuation, pole, functional-equation, trivial-zero, and Gamma-boundary rows together with transport, replay, provenance, and local naming data.

The $\mathsf{CriticalLineWitness}^{\uparrow}$ consumer can then read only the continuation rows named by that packet. The witness is therefore downstream from the zeta-continuation surface, not parallel to it.

Finally inspect the excluded data. Since no RH proof, global zero classifier, hidden analytic branch, completed Gamma certificate, host equality of zeta functions, or selected representative is a coordinate of the source-lock packet, the zero-strip consumer cannot receive any of those objects through the critical-line witness route. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier zeta continuation route`

Proposition 548.430 (CriticalLineWitness prime and zeta dependency route)**.** *Every* $\mathsf{CriticalLineWitness}^{\uparrow}$ *packet that is consumed by an RH-facing refusal route first reads the arithmetic divisibility surface of chapter 64 and the zeta-facing zero-strip source rows displayed by the existing CriticalLineWitness lattice. The prime row supplies the finite divisibility and Euler-product-facing source discipline, while the zeta rows supply zero-strip localization, source windows, and refusal budgets. Only after those rows are present may the RH-facing consumer inspect terminal refusal, fixed-strip, or continuation data.*

Lean4 ✓ BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessPrimeZetaDependencyRoute
↪ variant BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier prime zeta dependency route

Proof. Project the CriticalLineWitness hub through its source, modulus, zero-strip, and zeta sibling routes. Those routes name the arithmetic and analytic source rows before any terminal RH-facing refusal packet is read.

The prime dependency is supplied by chapter 64. Its divisibility and factorization surface is the arithmetic source for zeta-facing rows, not a consequence of a later RH refusal.

The zeta-facing rows then carry fixed-strip and zero-strip source data into the CriticalLineWitness packet. Since the carrier route exposes these rows before terminal refusal, an RH-facing consumer cannot bypass PrimeUp divisibility or the zeta source ledger. □

The CriticalLineWitness$^{\uparrow}$ sibling-dependency route is read only after the zeta source, zero-locus witness, and analytic-continuation boundary have already been displayed by sibling chapters. The zeta source surface of chapter 71 supplies the finite Zeta$^{\uparrow}$ row, the zero-side witness rows are supplied by chapter 73, and the continuation boundary is supplied by chapter 9342. The local witness packet therefore consumes those rows through its displayed BHist, hsame, Cont, Pkg, and NameCert support before any critical-line consumer reads a witness route.

Lemma 548.431 (CriticalLineWitness sibling dependency route)**.** *Every accepted* CriticalLineWitness$^{\uparrow}$ *route that exports a critical-line witness read is supported by the displayed* Zeta$^{\uparrow}$ *source row, the zero-locus witness row, and the analytic-continuation boundary row already present in sibling chapters. The route exports no independent RH proof, global zero classifier, analytic-continuation primitive, quotient representative, host equality, or ambient completeness theorem.*

Lean4 ✓ BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessSiblingDependencyRoute

Proof. First read the zeta source through chapter 71. This supplies the source row before the local critical-line witness classifier is consulted.

Next read the zero-locus and continuation rows through chapter 73 and chapter 9342. These rows provide the zero-facing and boundary data consumed by the local witness packet.

Finally project the local CriticalLineWitness$^{\uparrow}$ support. Its BHist, hsame, Cont, Pkg, and NameCert rows transport and replay the sibling data, but they do not add an RH proof, global zero classifier, analytic-continuation primitive, quotient representative, host equality, or ambient completeness coordinate. □

The CriticalLineWitness$^{\uparrow}$ sibling lattice consumes only displayed zeta rows before any critical-line obstruction is read. Its visible route passes through the finite source and continuation surfaces of chapter 71, chapter 9342, and chapter 580, then returns to the local CriticalLineWitness$^{\uparrow}$ classifier, replay, provenance, and naming rows. This dependency edge supplies no Riemann-hypothesis conclusion, no analytic-continuation closure, no global zero-free region, and no host equality of zeta functions.

Theorem 548.432 (CriticalLineWitness Zeta sibling route)**.** *Every* CriticalLineWitness$^{\uparrow}$ *source-modulus read factors through the displayed* Zeta$^{\uparrow}$ *and zero-strip sibling rows before local* CriticalLineWitness$^{\uparrow}$ *naming is consumed. In particular, the source route must expose the zeta source surface of chapter 71, the continuation handoff of chapter 9342, the zero-facing witness boundary of chapter 580, and the fixed-strip rows already displayed by the local witness packet. The route exports no* RH *proof, global zero classifier, analytic-continuation primitive, host equality, quotient representative, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCarrier source modulus zeta sibling route`

Proof. Project an accepted CriticalLineWitness$^{\uparrow}$ packet as $W = (Z, S, M, R, Q, H, C, P, N)$. The source row Z is the only zeta-facing source coordinate, and the strip row S is the only local zero-strip coordinate available before a modulus read reaches M.

The sibling zeta rows are read before the local name is consumed. The basic zeta source, continuation handoff, and zero-facing witness boundary supply the upstream row data, while the local packet records only the displayed Z, S, M, R, Q route and its structural support.

The local naming row N is terminal for this route. Transport through H, replay through C, and provenance through P preserve the same source-modulus path, so no consumer can replace it by an RH proof, global zero classifier, analytic primitive, host equality, quotient representative, or ambient completeness datum. □

Theorem 548.433 (CriticalLineWitness cross-lattice route)**.** *Every accepted* CriticalLineWitness$^{\uparrow}$ *finite witness route consumed by chapter 705 or chapter 573 must expose the same displayed zeta-zero source row, strip-window row, real-part classifier row, modulus ledger row, and refusal ledger row before either downstream chapter reads the witness as a barrier or a zero-counting input. The route is therefore a finite BEDC handoff through* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, not a host analytic assertion about zeros outside the displayed ledgers.*

Proof. Project the CriticalLineWitness$^{\uparrow}$ carrier rows used by the hub siblings. The zeta-zero row supplies the source event, the strip row bounds the critical-window read, the real-part row records the line classifier, and the modulus row keeps the quantitative witness visible to consumers.

For chapter 705, the refusal ledger is the row that prevents a barrier consumer from replacing the displayed witness by an ambient strip theorem. For chapter 573, the same refusal ledger prevents a zero-counting consumer from reading an undisplayed counting formula.

The structural rows hsame, Cont, Pkg, and NameCert transport and name exactly this finite route. Hence both downstream consumers receive the zeta-zero, strip, real-part, modulus, and refusal data before any barrier or counting use is available. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessCrossLatticeRoute`

The CriticalLineWitness$^{\uparrow}$ packet consumes the zero-location and continuation witness surfaces through chapter 73 and chapter 580 before it can expose any critical-line certificate row. This dependency keeps the critical-line readback downstream of displayed zeta-zero and continuation evidence rather than treating the line certificate as an isolated source. The CriticalLineWitness$^{\uparrow}$ zeta–RH dependency route makes the horizontal handoff explicit: the local witness consumes the Zeta$^{\uparrow}$ source and ZetaZeros$^{\uparrow}$ zero rows before any RH-facing boundary chapter can read it.

Theorem 548.434 (CriticalLineWitness zeta–RH dependency route)**.** *Every accepted* CriticalLineWitness$^{\uparrow}$ *packet that exports a critical-line witness to an RH-boundary consumer must first display the finite* Zeta$^{\uparrow}$ *source route of chapter 71, the zero-side witness surface of chapter 73, and the local witness rows* $Z, S, M, R, Q, H, C, P, N$*. The export may then be consumed by the* RHRouteHaltingBoundary$^{\uparrow}$ *packet of chapter 5564, but only as a finite critical-line witness row; it does not supply an* RH *proof, a global zero classifier, analytic-continuation data, quotient representatives, host equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessZetaRhDependencyRoute`

Proof. Read the zeta source first. The sibling surface of chapter 71 supplies the displayed $\mathsf{Zeta}^{\uparrow}$ row before the local critical-line witness packet can expose its own source coordinate.

Next expose the zero-facing route through chapter 73. The local rows $Z, S, M, R, Q, H, C, P, N$ then name the finite witness, strip, modulus, rational comparison, transport, replay, provenance, and local certificate data consumed by $\mathsf{CriticalLineWitness}^{\uparrow}$.

Finally pass the exported row to chapter 5564. That consumer receives the witness as one finite boundary input, so the route remains a BEDC dependency edge rather than an RH proof, global zero classifier, analytic-continuation theorem, quotient representative, host equality, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.CriticalLineWitnessUp.CriticalLineWitnessZetaRhDependencyCertificate`

Chapter 549

A Concrete Naming Certificate for $\mathsf{KernelAcceptanceWitness}^{\uparrow}$

The $\mathsf{KernelAcceptanceWitness}^{\uparrow}$ surface turns the Lean-side acceptance boundary into a finite BEDC certificate packet. It records the generated candidate declaration, the accepted declaration row, the environment ledger entry, the axiom-query result, refusal evidence for unaccepted candidates, transport and continuation rows, package provenance, and the local naming row. The packet is not a global trust principle for Lean; it is the visible witness that a specific candidate crossed the kernel boundary and that the accepted result has a readable purity ledger.

The $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ packet of chapter 547 consumes the candidate, accepted-declaration, environment-ledger, axiom-query, refusal, transport, continuation, provenance, and local naming rows of this packet and adds build replay plus audit-gate specialization for a single acceptance event.

Definition 549.1 (KernelAcceptanceWitness carrier)**.** *A* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, A, E, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the generated-candidate row, naming the proposed Lean declaration, its source module, its type surface, and the finite generator context that produced it;*
2. *A is the accepted-declaration row, present exactly when the kernel has accepted the declaration named by G;*
3. *E is the environment-ledger row, recording the module position, imported BEDC declarations, and replay boundary at which A is entered into the environment;*
4. *Q is the axiom-query row, recording the transitive dependency query for A and the reported absence or presence of forbidden dependency names;*
5. *R is the refusal-boundary row, recording failed candidates, unresolved names, rejected recursion, forbidden axioms, or dependency reports that prevent a candidate from being exported as accepted;*
6. *H records componentwise* hsame *transports for generated candidate, accepted declaration, environment ledger, axiom-query, refusal-boundary, continuation, package, and local naming rows;*

7. *C records the displayed* Cont *routes by which consumers read acceptance, environment replay, purity query, and refusal evidence;*
8. *P is the* Pkg *provenance over* BHist*, generated candidates, accepted declarations, environment ledger rows, axiom-query rows, refusal rows,* hsame*,* Cont*, and local naming;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KernelAcceptanceWitness}^{\uparrow}}$ *row.*

The carrier exposes no host-kernel completeness theorem, no hidden proof-producing channel, no acceptance for a candidate absent from A, and no purity claim outside the displayed query row Q.

Lean4 ✓ `BEDC.Derived.KernelAcceptanceWitnessUp.KernelAcceptanceWitnessTasteGate single carrier alignment`

Theorem 549.2 (KernelAcceptanceWitness NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{KernelAcceptanceWitness}^{\uparrow}}$ *surface for the carrier of Definition 549.1 consists of six finite obligations:*

1. *carrier exposure for the packet $K = (G, A, E, Q, R, H, C, P, N)$;*
2. *candidate-to-acceptance matching, stating that the accepted row A names the declaration proposed by G and no unlisted candidate;*
3. *environment replay, stating that E records the module boundary and imported BEDC rows used when A is entered into the environment;*
4. *purity query visibility, stating that Q is the dependency ledger attached to A and records the outcome of the transitive axiom query;*
5. *refusal separation, stating that rows recorded in R are not exported as accepted declarations;*
6. *exactness of the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *rows for the acceptance and refusal surfaces.*

These obligations bind kernel acceptance as finite certificate data rather than as an ambient trust principle.

Proof. Carrier exposure is projection from Definition 549.1. The rows $G, A, E, Q, R, H, C, P, N$ are the only coordinates available to consumers.

Candidate-to-acceptance matching and environment replay are read from G, A, E. The accepted row is attached to the generated candidate named by G, and the environment ledger records where that accepted declaration is replayed against the visible BEDC imports.

Purity query visibility is read from Q. The dependency report belongs to the accepted declaration row and is carried as a finite ledger entry, so the consumer sees the query result rather than an unstated promise about the environment.

Refusal separation is read from R. Failed candidates and forbidden dependency reports are retained as boundary data but have no coordinate that exports them as accepted declarations.

The transport, continuation, package, and local naming obligations are componentwise over the displayed rows. They can move or read the packet, but they do not add a kernel-completeness theorem or a hidden proof-producing channel. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceWitnessUp.KernelAcceptanceWitnessPacket semantic name certificate`

Theorem 549.3 (KernelAcceptanceWitness ledger purity)**.** *For an accepted* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$ *packet, every purity-facing consumer route factors through the accepted-declaration row A, the*

environment-ledger row E, the axiom-query row Q, the displayed BHist, hsame, Cont, Pkg, *and* NameCert *provenance, and the refusal boundary R for candidates that do not cross the acceptance gate. The route exports no declaration as BEDC-internal when its query row reports* Classical.choice, Quot.sound, propext, *an unaccepted candidate, or an unresolved declaration name.*

Proof. Start with the NameCert obligations of Definition 549.2. They attach the accepted declaration to its generated candidate, environment replay row, axiom-query row, and local naming row.

Next read the purity route through Q. The consumer may inspect the transitive dependency report only as the ledger entry paired with A and E, so purity is a displayed row of the packet rather than a separate meta-level assertion.

Finally use the refusal row R. Any candidate with a forbidden dependency report, unresolved name, failed kernel replay, or absent accepted-declaration row remains on the refusal side of the packet and is not exported by the local certificate. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceWitnessUp.KernelAcceptanceWitnessLedgerPurity`

Theorem 549.4 (KernelAcceptanceWitness refusal separation)**.** *In an accepted* KernelAcceptanceWitness$^{\uparrow}$ *packet*

$$K = (G, A, E, Q, R, H, C, P, N),$$

any candidate row recorded in R because of unresolved names, forbidden dependency reports, failed kernel replay, or an absent accepted declaration cannot be exported through A, E, or Q as accepted BEDC content.

Proof. Project the carrier of Definition 549.1. The accepted-declaration, environment-ledger, axiom-query, and refusal-boundary rows are separate coordinates of the packet.

Use the NameCert obligations of Definition 549.2. Candidate-to-acceptance matching places accepted content in A, environment replay places its accepted module boundary in E, purity-query visibility places its dependency report in Q, and refusal separation keeps unresolved names, forbidden dependency reports, failed kernel replay, and absent accepted declarations in R.

Finally apply ledger purity from Definition 549.3. Purity-facing consumers read accepted BEDC content only through A, E, Q, while failed candidates remain on the refusal side of the same packet, so no route exports an R row as accepted content. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceWitnessUp.KernelAcceptanceWitnessRefusalSeparation`

Closure status for NameCert$_{\text{KernelAcceptanceWitness}^{\uparrow}}$.

Constructive story: A KernelAcceptanceWitness$^{\uparrow}$ packet is generated from a candidate declaration row, an accepted declaration row, an environment ledger row, an axiom-query row, refusal-boundary evidence, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{KernelAcceptanceWitness}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 549.1, Definition 549.2, Definition 549.3, Definition 549.4, Definition 549.5, and the TasteGate single-carrier alignment bridge bind Lean kernel acceptance as a finite NameCert packet over accepted declarations, environment ledger rows, dependency queries, refusal boundaries, and the public export package.

Formal verification: FormalStatus(NameCert$_{\text{KernelAcceptanceWitness}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.KernelAcceptanceWitnessUp.KernelAcceptanceWitnessTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean implementation, host-kernel completeness, semantic conservativity of all accepted declarations, bridge checking, or acceptance for candidates on the refusal side.

Upgrade path: No further paper-side closure upgrade remains; the remaining independent step is machine bridge checking.

Theorem 549.5 (KernelAcceptanceWitness public export package)**.** *For every accepted* KernelAcceptanceWitness$^{\uparrow}$ *packet*

$$K = (G, A, E, Q, R, H, C, P, N)$$

satisfying the local NameCert obligations of Definition 549.2, the public BEDC acceptance-witness export consists exactly of the generated-candidate row G, accepted-declaration row A, environment-ledger row E, axiom-query row Q, refusal-boundary row R, componentwise transport row H, displayed continuation routes C, package provenance row P, and local naming row N. The row R is exported only as refusal-boundary evidence: no failed candidate, unresolved name, forbidden dependency report, failed replay row, or absent accepted declaration recorded on the refusal side can be exported through A, E, or Q as accepted BEDC content.

Proof. Project the carrier of Definition 549.1. Its displayed packet has exactly the nine coordinates $G, A, E, Q, R, H, C, P, N$. The first four content rows expose the generated candidate, accepted declaration, environment replay, and dependency query; the row R exposes the refusal boundary; and the rows H, C, P, N provide componentwise transport, displayed routes, provenance, and local naming for that same finite packet.

Apply the NameCert obligations of Definition 549.2. Candidate-to-acceptance matching places accepted content in A only for the candidate named by G. Environment replay places the accepted declaration at the boundary recorded by E. Purity-query visibility makes Q the dependency ledger attached to A. Refusal separation keeps failed candidates, unresolved names, rejected recursion, forbidden axioms, and dependency reports on the R side rather than in the accepted-declaration row.

Now use ledger purity from Definition 549.3. Every purity-facing route factors through A, E, Q for accepted content and through R for candidates that do not cross the acceptance gate. Thus a route that tries to read a forbidden dependency report, unresolved declaration name, or unaccepted candidate as BEDC-internal accepted content has no exported coordinate through which to do so.

Finally apply refusal separation from Definition 549.4. Rows recorded in R because of unresolved names, forbidden dependency reports, failed kernel replay, or absent accepted declarations cannot be exported through A, E, or Q as accepted content. The structural rows H, C, P, N preserve, route, source, and name the displayed packet; by the exactness obligation they add no second acceptance channel. Therefore the public export is precisely the nine-row packet $G, A, E, Q, R, H, C, P, N$, with R visible only as boundary evidence and never as accepted BEDC content. □

Lean4 ✓ `BEDC.Derived.KernelAcceptanceWitnessUp.KernelAcceptanceWitnessPublicExportPackage`

Chapter 550

A Concrete Naming Certificate for $\mathsf{CriticalStripZetaZeroWitness}^{\uparrow}$

The $\mathsf{CriticalStripZetaZeroWitness}^{\uparrow}$ interface names the finite witness packet consumed by the RH capstone. It packages a complex-history candidate together with the displayed critical-strip row, the zeta-zero row, the critical-line classifier boundary, and the local $\mathsf{NameCert}$ routes needed to read the witness as a BEDC object. The packet is a witness surface for the constructive form of Definition 9239.8; it is not a proof of RH and it does not manufacture analytic zeros outside the rows already exposed by $\mathsf{CritStrip}^{\uparrow}$ and $\mathsf{ZetaZeros}^{\uparrow}$.

The strip row is supplied by chapter 72, and the zero row is supplied by chapter 73. The witness packet only synchronizes these sibling rows through the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ data.

Definition 550.1 (CriticalStripZetaZeroWitness carrier)**.** *A* $\mathsf{CriticalStripZetaZeroWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, Z, L, B, H, C, P, N)$$

with the following displayed coordinates:

1. *S is the* $\mathsf{CritStrip}^{\uparrow}$ *row carrying the complex history s and the strict-strip evidence for its real component;*
2. *Z is the* $\mathsf{ZetaZeros}^{\uparrow}$ *row carrying the zeta-value and zero-pattern evidence for the same source history s;*
3. *L is the* $\mathsf{CritStrip}^{\uparrow}$ *critical-line classifier row naming the boundary predicate* $\mathsf{OnCritLine}(s)$ *or its displayed absence;*
4. *B is the boundary ledger recording the two open-strip boundary exclusions, the $\Re(s) = 1$ non-vanishing slot, and the critical-line comparison row;*
5. *H records componentwise* hsame *transports for the strip row, zero row, critical-line row, and boundary ledger;*
6. *C records the* Cont *routes for reading the strip witness, reading the zeta-zero witness, exposing the critical-line classifier, and handing the packet to the RH predicate;*
7. *P is the* Pkg *provenance over* $\mathsf{Complex}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CriticalStripZetaZeroWitness}^{\uparrow}}$ *row.*

The carrier stores no host complex number, no analytic zero finder, no quotient equality of zero sets, no selected representative, and no proof or refutation of RH.

Theorem 550.2 (CriticalStripZetaZeroWitness NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CriticalStripZetaZeroWitness}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission: the accepted object is the displayed packet W with strip, zero, critical-line, boundary, transport, continuation, package, and local naming rows;*
2. *shared source binding: the* $\mathsf{CritStrip}^{\uparrow}$ *row S and the* $\mathsf{ZetaZeros}^{\uparrow}$ *row Z expose the same complex-history source through the stored* hsame *and* Cont *routes;*
3. *line-boundary routing: the critical-line row L and boundary ledger B are read only after the strip and zero rows have been exposed;*
4. *RH handoff: any citation of the RH predicate reads the carrier through S, Z, L, B, H, C, P, N;*
5. *ledger exhaustion: the package and local certificate rows exhaust the dependency surface over* $\mathsf{Complex}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

Lean4 ✓ `BEDC.Derived.CriticalStripZetaZeroWitnessUp.CriticalStripZetaZeroWitnessPacket namecert obligations`

Proof. Carrier admission is projection from Definition 550.1. The strip row, zero row, critical-line classifier, boundary ledger, transport rows, continuation rows, package row, and local naming row are explicit coordinates of the packet.

The shared source binding is componentwise. The strip row names the complex history through $\mathsf{CritStrip}^{\uparrow}$, the zero row names the same source through $\mathsf{ZetaZeros}^{\uparrow}$, and the stored hsame and Cont routes are the only routes by which a consumer compares them.

The remaining obligations are downstream reads. The critical-line row and boundary ledger are exposed after the strip and zero rows, and the RH handoff consumes the same finite packet. Since no coordinate is a host complex number, zero finder, quotient equality, selected representative, or proof of RH, the ledger is exhausted by the displayed rows. □

Lean4 ✓ `BEDC.Derived.CriticalStripZetaZeroWitnessUp.CriticalStripZetaZeroWitnessCarrier namecert obligations`

Theorem 550.3 (CriticalStripZetaZeroWitness critical-line boundary)**.** *Every accepted* CriticalStripZetaZeroWitnes *packet routes the critical-line question through the displayed* $\mathsf{CritStrip}^{\uparrow}$ *classifier row L and the boundary ledger B. A downstream RH consumer may ask whether the source history carried by S and Z is on the critical line, but it receives only the displayed* $\mathsf{OnCritLine}(s)$ *row or its boundary evidence through H, C, P, and N.*

Lean4 ✓ `BEDC.Derived.CriticalStripZetaZeroWitnessUp.CriticalStripZetaZeroWitnessPacket critical line boundary`

Proof. Apply the line-boundary routing obligation of Definition 550.2. It requires the source strip row and zero row to be exposed before the critical-line classifier is read.

The boundary ledger B contains the available boundary exclusions and comparison rows. Therefore a consumer cannot bypass L and B to obtain an ambient real equality, a selected representative for $\Re(s)$, or a host-level decision procedure for the critical line. □

Theorem 550.4 (CriticalStripZetaZeroWitness ledger exhaustion)**.** *For an accepted* $\mathsf{CriticalStripZetaZeroWitness}^{\uparrow}$ *carrier, every fact exported to a* $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or RH-facing consumer is one of the rows* S, Z, L, B, H, C, P, N *or a route between such rows. In particular, the witness packet exports no analytic zero search, no completed zero-set quotient, no host complex equality, no selected counterexample, and no proof of the RH predicate.*

Lean4 ✓ `BEDC.Derived.CriticalStripZetaZeroWitnessUp.CriticalStripZetaZeroWitnessPacket package sameness`

Proof. List the coordinates of Definition 550.1. The only mathematical data rows are the strip row S, the zeta-zero row Z, the critical-line row L, and the boundary ledger B.

Transport can only move these rows through H, and continuation can only expose them through C. The package and local certificate rows P and N record provenance and naming, not additional analytic data.

Thus the consumer surface is exhausted by the finite packet. The excluded objects have no coordinate in the carrier and cannot be reconstructed from the exported rows. □

Theorem 550.5 (CriticalStripZetaZeroWitness concretizes RH)**.** *The* $\mathsf{CriticalStripZetaZeroWitness}^{\uparrow}$ *packet is the concrete NameCert surface for the constructive RH premise of Definition 9239.8. Any BEDC proof of the RH predicate may consume such a packet as the finite input carrying* $\mathsf{ZetaZero}(s)$ *and* $\mathsf{InCritStrip}(s)$, *and any constructive counterexample must export such a packet together with a displayed failure of the critical-line row. The packet itself contributes only the input surface; it does not prove the critical-line conclusion.*

Lean4 ✓ `BEDC.Derived.CriticalStripZetaZeroWitnessUp.CriticalStripZetaZeroWitnessPacket concretizes rh`

Proof. The carrier supplies the two premise rows required by the constructive RH form: S gives the critical-strip row and Z gives the zeta-zero row. The shared source binding in Definition 550.2 identifies them as rows over the same complex history.

The critical-line boundary theorem identifies the only route to the conclusion-side classifier, and ledger exhaustion rules out any hidden analytic or quotient data. Hence the packet is exactly the finite input surface for the RH premise. A proof may consume it to produce the critical-line row, while a counterexample must pair it with a displayed failure of that row. □
